Absolute synchronization with master value reference

The master axis moves at a velocity of 100 mm/s. The following axis is stationary at position 50 mm. Synchronization is performed within 20 mm; this means that for a master axis position of 80 mm, absolute synchronism between the master and following axis occurs.

Relative synchronization with master value reference and offset

The master axis moves at a velocity of 100 mm/s. The following axis is stationary at position 0 mm. Starting with a master axis position of 100 mm, the following axis will be synchronized relative to the master axis within 40 mm. When synchronism is achieved, this results in a following axis position based on the position at the start of synchronization and the offset of 30 mm.

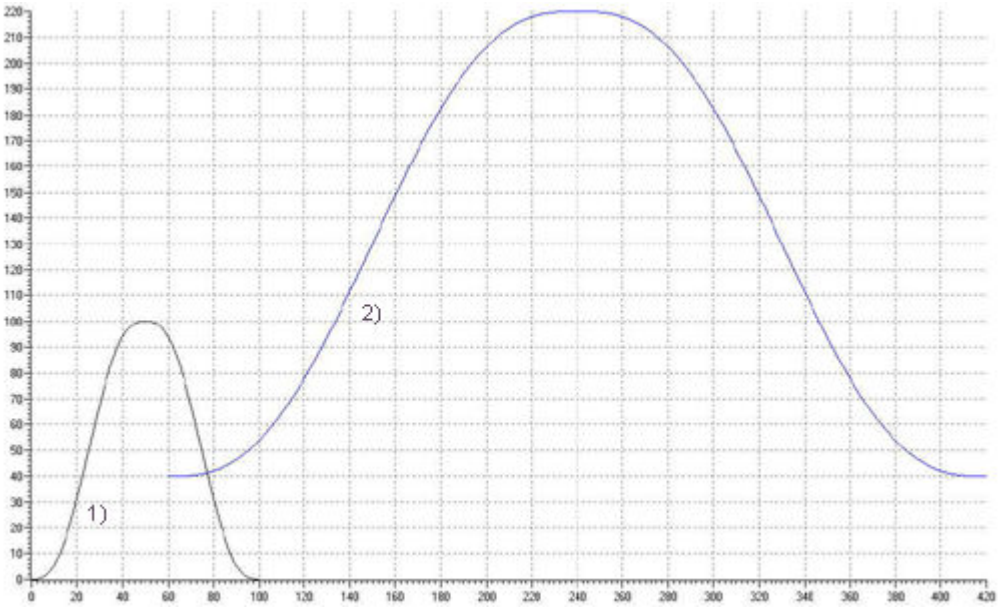
Example of offset and scale on the synchronous object

A leading axis provides position values over a range of 360° and 60° phase offset, i.e. from 60...420°. The following axis should move in the range 40...220°.

Definition range of cam: 0...100
Range of cam: 0...100

The definition and value range of the cam can be adapted to the required representation range for the camming using scaling and offset as follows (See also Figure **Equation for scale and offset on the camming** in Chapter **Camming**):

	Scaling	**Offset**
Master value	360 / 100 = 3,6	60
Slave value	(220 - 40) / 100 = 1,8	40



1) unscaled, non-offset function

2) scaled, offset function

Figure 4-706 Example of the scaling and the offset of a cam

In the following programming example, the offset and scale commands for the synchronous object take effect when camming is next activated:

Table 4-289 ST programming

```
(*scaling of the master value*)
    retval:= _setCammingScale(
    followingObject:= <SYNCHRONOUS_OBJECT>,
    scalingRange:= MASTER_RANGE,
    scaleValue:= 3.6,
    activationMode:= DEFAULT_VALUE
);
(*scaling of the slave value*)
retval:= _setCammingScale(
    followingObject:= <SYNCHRONOUS_OBJECT>,
    scalingRange:= SLAVE_RANGE,
    scaleValue:= 1.8,
    activationMode:= DEFAULT_VALUE
);

Camming (Page 2638)

Example of applying offset as superimposition

The following example shows the two dynamic corrections of the **dynamicReference** parameter in their different effects using an accelerating master value.

Example: Master and following axis for a synchronous operation of 1:1 are absolutely synchronous, accelerate at 100 mm/s². The offset of -50 mm on the master value side is implemented using _setGearingOffset for a programmed correction velocity of 300 mm/s and a correction acceleration of 3,000 mm/s², by means of a non-continuous-acceleration velocity profile.

Table 4-294 ST programming

```
retval := _setGearingOffset (
    followingObject:= <SYNCHRONOUSOBJECT>,
    offsetRange := MASTER_RANGE,
    offsetMode := RELATIVE,
    offsetValue := -50.0,
    velocityType := DIRECT,
    velocity := 300.0,
    positiveAccelType := DIRECT,
    positiveAccel := 3000.0,
    negativeAccelType := DIRECT,
    negativeAccel := 3000.0,
    velocityProfile := TRAPEZOIDAL,
    activationMode := ACTUAL_VALUE,
    dynamicReference := TOTAL_MOVE / OFFSET_MOVE
);
```

Note

When the master value velocity is constant, the dynamic transitions have a generally identical form and differ only as a result of the dynamic response parameters that act differently.

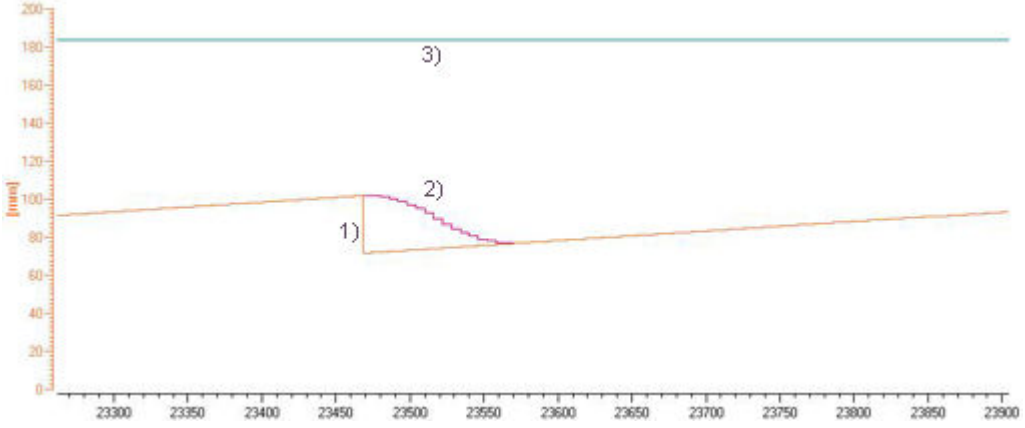
Special actions

Redefining the axis position during active synchronous operation

The following options are available for resetting an axis position, e.g. by means of **_redefinePosition()** or **_homing()**:

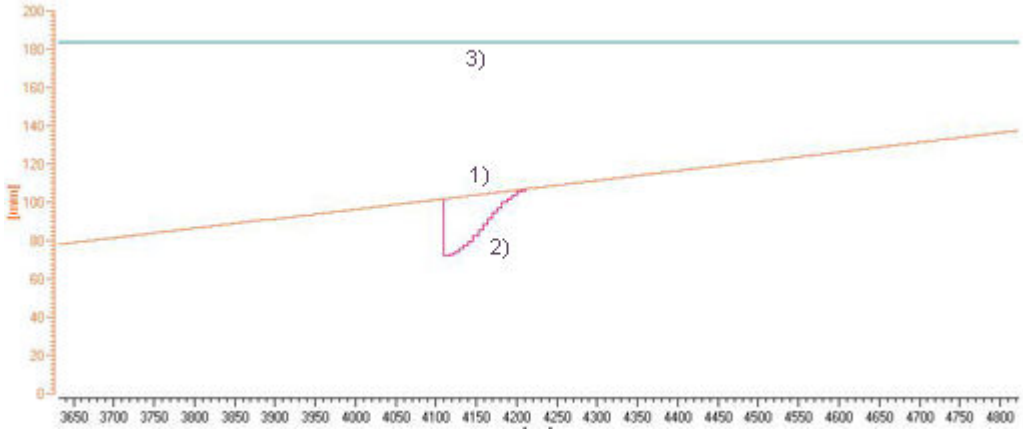
- Redefining the *master axis position* causes a jump in the master value.
  The following axis then performs a compensating movement and finally moves in synchronism again with the master axis. If the position tolerance > the synchronous operation tolerance, the error 40201 "Synchronous operation tolerance on gearing axis exceeded" will be output.
- Redefining the *following axis position* does *not* cause a jump on the master value.
  - For the *absolute synchronous operation*, the slave axis is no longer position-synchronous and so performs a compensating movement.
  - For the *relative synchronous operation*, the following axis does *not* perform a compensation motion, because position synchronization is not necessary.

Examples:



1) Master axis position
2) Following axis position
3) Synchronization status

Figure 4-711 Redefining the leading axis position (absolute or relative gearing) -> The following axis performs a compensation motion



1) Master axis position
2) Following axis position
3) Synchronization status

Figure 4-713 Redefining the following axis position for the relative gearing -> The following axis does not perform a compensation motion

Retaining a synchronous connection for _disableAxis

If the slave axis is no longer able to apply the generated synchronous operation setpoints, e.g. due to the removal of enables or an error response, an active synchronous operation connection is closed. It is possible to retain the synchronous operation connection by using synchronous operation in simulation mode and setting the **DecodingConfig.disableSynchronousOperation=YES** configuration data element on the synchronous object.

See Simulation mode (Page 2690).

The existing synchronous connection remains active except in the following situations:

- Restart of following axis (**_restartAxis()**)
- Invalid actual values on the following axis

When simulation mode is terminated, the current synchronous operation setpoints are applied immediately as axis setpoints.

Remove the axis from the synchronous operation interconnection, and return it

Example:
Opening and closing protective doors

Removing an axis from the synchronized group

1. Stop the leading axis.
2. Switch the synchronous operation to simulation mode.
3. **DecodingConfig.disableSynchronousOperation** on the synchronous object must be set to **YES**. As a result, the synchronous operation connection is not disconnected on **_disableAxis**.
4. If a superimposed motion had been performed (e.g. for correcting):
   - Save the position of the superimposed coordinate system in a user variable.
   - Perform **_redefinePosition** in the coordinate system 2 to absolute position 0.
5. Cancel the controller enables (**_disableAxis()**). This will clear the drives. The axis goes into follow-up mode, "control" on the axes is deleted.

Returning the axis to the synchronized group

1. Reconnect the controller enables (**_enableAxis()**).
2. If necessary, use **_redefinePosition** to pass the saved actual position as absolute position to the coordinate system 2.
3. Switch synchronous operation back from simulation mode.

A compensation motion will be performed if the setpoints for the synchronous object and the setpoints on the axis do not match.

Substitution of velocity gearing with absolute synchronous operation

A synchronous velocity operation cannot be substituted directly with an absolute synchronous operation. Immediately afterwards, only a relative synchronous operation can be executed.

If an attempt is made to execute an absolute synchronous operation immediately after a velocity gearing, the following technological alarm is output:
50110 "Call-up of an absolute synchronous position operation after a synchronous velocity operation not permitted" (as of V3.2)

Procedure:

- Switch a relative position-controlled synchronous operation in between for one IPO cycle. (mergeMode = IMMEDIATELY and then a **waitTime** with Time = 0 sec)

Motion with absolute synchronous operation

Substitution of a position axis by an absolute synchronous operation (as of V4.4)

A position axis traversing in speed-controlled mode (_move(movingMode = SPEED_CONTROLLED)) can be substituted directly by an absolute synchronous operation. As a consequence of this, for example, with a stationary master value, the following axis positions itself at the absolute position of the master value.

Canceling active and pending synchronous operations

If gearing or camming is active and another gearing or camming operation is started, the first **_disableCamming()/_disableGearing()** command ends the synchronous operation to be synchronized, and the second **_disableCamming()/_disableGearing()** command ends the active synchronous operation.

Alternatively, in V4.1 and higher the synchronous operation commands can be canceled using the commandId associated with the command. The **_cancelFollowingObjectCommand()** command can be used to cancel the synchronous operation command by specifying the commandId in the **commandToBeCancelled** parameter. This removes the synchronous operation command from the command buffer. This means that a pending command for synchronization can be canceled (for example, if the application recognizes that resynchronization is not intended to take place).

Adapt the synchronization velocity to the master value velocity

The following axis cannot be synchronous with the master object if the velocity of the following axis for the synchronization process is lower than that of the master value during the synchronization process.

Example: The master axis is, for example, currently travelling at 200 mm/s. A gearing is started for which the synchronization velocity is limited by the default value of 100 mm/s. The following axis cannot overtake the master object.

To adapt the synchronization velocity of the following axis to the master value velocity, proceed as follows:

1. Create a **master axis**.
2. Create a **following axis** (synchronized axis).
   A **Following_Axis_SYNCHRONOUS_OPERATION** object is automatically created below the following axis.
   The project navigator should look like this:

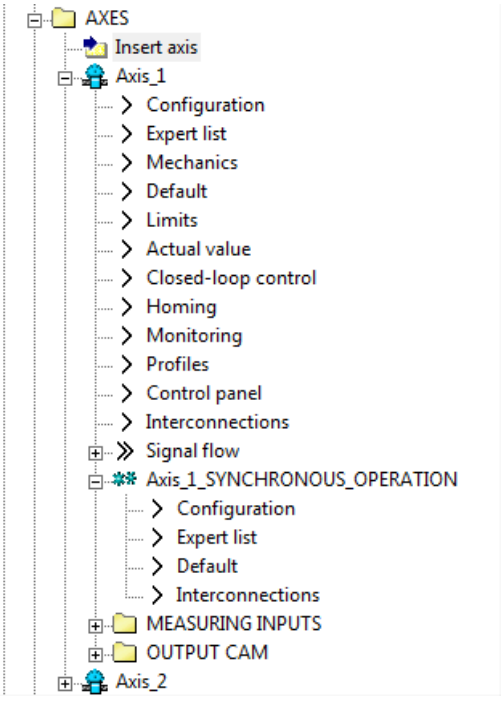

Figure 4-714 Axes for example

3. Make the following settings for **FollowingAxis_SYNCHRONOUSOPERATION -> Settings**:
   – **Overdrive factor for dynamic values**: 150 %

– **Adapting the dynamic values for synchronization**: activated

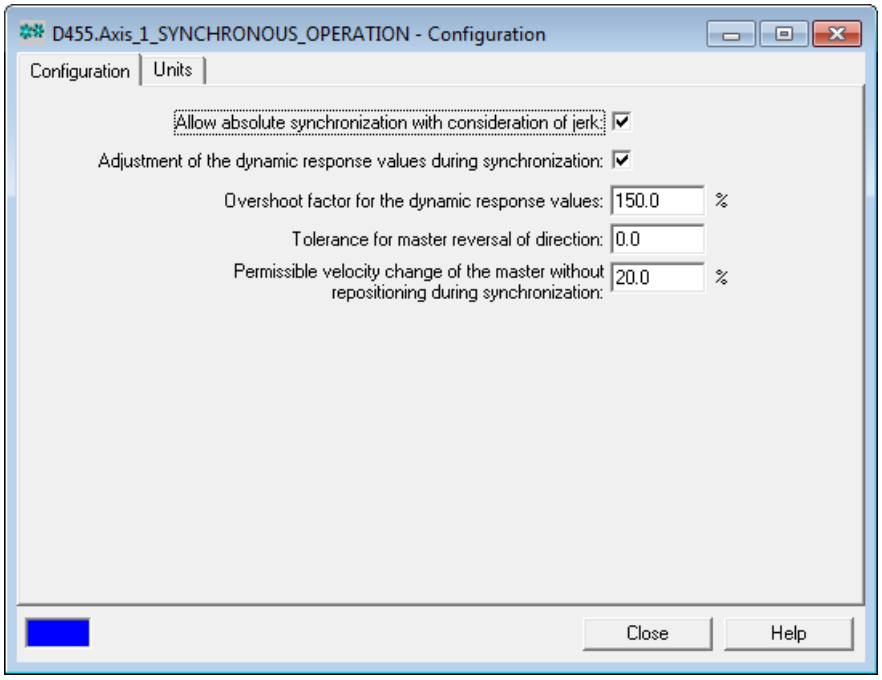

Figure 4-715 Settings for FollowingAxis_SYNCHRONOUSOPERATION

For the synchronization, the following axis uses the dynamic response values of the master axis (increased by the **overdrive factor**) and travels with the maximum velocity of 300 mm/s.

Another application scenario

The master object travels with the constant velocity of 80 mm/s. The dynamic response setting of the following axis allows a synchronization velocity of 100 mm/s. Under these conditions, the following axis can synchronize itself without adaptation of the dynamic response values. If the master object accelerates to 150 mm/s, but the **synchronous** status is not yet attained, the following axis can synchronize itself only with adaptation of the dynamic response values. During the synchronization action, the maximum velocity of the following axis is calculated using the current set velocity of the master object (150% of the current value).

Substitution of synchronous operation through _move, _pos, _stop with reset of an existing acceleration to zero

Description

When a motion is replaced with the **_stop()**, **_pos()** and **_move()** functions and a smooth velocity profile with jerk specification is applied during the axis acceleration phase, the velocity can continue to increase until the acceleration is reduced by means of the jerk that has been set. In extreme cases, the velocity can rise still further until it reaches the configured maximum velocity. The axis is only decelerated once acceleration has been reduced by the jerk.

With the **abortAcceleration** parameter, you can set that a possible acceleration does not exceed the jerk limitation, but is immediately cleared.

The **abortAcceleration** parameter is available for **_stop()** as of V4.2.1 and for **_pos** and **_move** as of V4.4.

You will find more information in the *TO Axis Electric/Hydraulic, External Encoder* Function Manual.

4.7.2.3 Synchronous Operation Configuration

This section shows you how to create and configure axes with **synchronous operation** in SIMOTION SCOUT.

It is assumed that you have already created cams, master axes, or external encoders.

Note

If the actual values/setpoints are required to be equal during a synchronous operation, the same Ti (actual value acquisition) and To (setpoint acceptance) times must be adopted for all drive units used (e.g. SINAMICS Integrated, CU320).

When configuring a synchronous operation, you must follow the steps below:

- Create an axis with synchronous operation functionality (Page 2722).
- Assign master values and cams to the synchronized axis (Page 2723).
- Assign synchronous operation parameters (Page 2725).
- Define the settings for the synchronization procedure (Page 2741).
- Define synchronous operation monitoring (Page 2743).

Creating an axis with synchronous operation

Create a synchronous axis as follows:

1. To create an Axis TO with the Synchronous operation technology in **SCOUT**, double-click **Insert axis** under **AXES** in the project navigator. You can also copy an existing Axis technology object using the clipboard and insert it with another name.
2. Activate for creating the axis the **Synchronous operation** technology. A synchronous object will automatically be created.

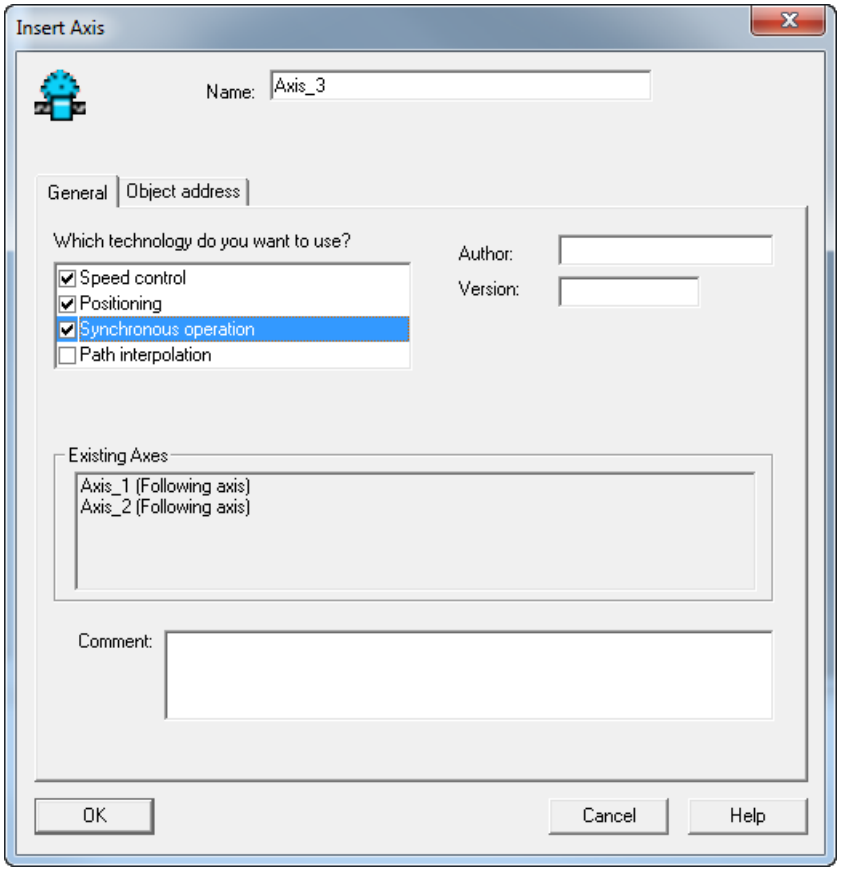

Figure 4-716 Inserting an axis with synchronous operation

Note

If synchronous operation technology is specified for an Axis technology object, the synchronous object will be inserted together with the Axis technology object. The synchronous object is permanently assigned to the Axis technology object. The name of the synchronous object is automatically defined and cannot be changed.

It is *not* possible to subsequently convert a positioning or speed axis to a following axis.

It is *not* possible to add a synchronous object. Only a superimposed synchronous operation can be added to the synchronous axis using expert (see Superimposed synchronous operation (Page 2683)).

Representation in the project navigator

The synchronous object is generated automatically when a synchronous axis is created and is displayed below this synchronous axis in the project navigator. The object is automatically given the name of the axis, followed by _SYNCHRONOUS_OPERATION. There the permitted synchronous operation relationships of the synchronous axis can be defined and the preassignments for the synchronous operation coupling to a leading axis assigned.

The assignment of the master values and cams is indicated in the project navigator using links:

- For the **Synchronous object**:
  Links to the master values (axes, external encoders, addition objects, formula objects, and fixed gears) as well as cams
- For the technology objects used:
  Link to the synchronous object
- Below the **master values** (axes, external encoders, addition objects, formula objects, and fixed gears): Link to the synchronous object

Superimposed synchronous operation

If a superimposed synchronous operation relationship to another master value is also to be established, an additional synchronous object can be placed below the following axis via the shortcut menu for the following axis (**Expert > Insert superimposed synchronous object**) (see Superimposed synchronous operation (Page 2683)).

The standard and superimposed synchronous operation relationships then affect the following axis additively by means of the two master values.

Assigning master values and cams

When an axis with synchronous operation is created, the synchronous operation configuration still has to be specified, i.e., the master values to be used must be selected and, if required, a cam must be assigned.

Note

Synchronous operation is not possible if a master value is not assigned. Camming is not possible if a cam is not assigned.

Defining the synchronous operation configuration

- In the project navigator, double-click on **Interconnections** under the object <Axis name>**_SYNCHRONOUS OPERATION**. The window below opens.

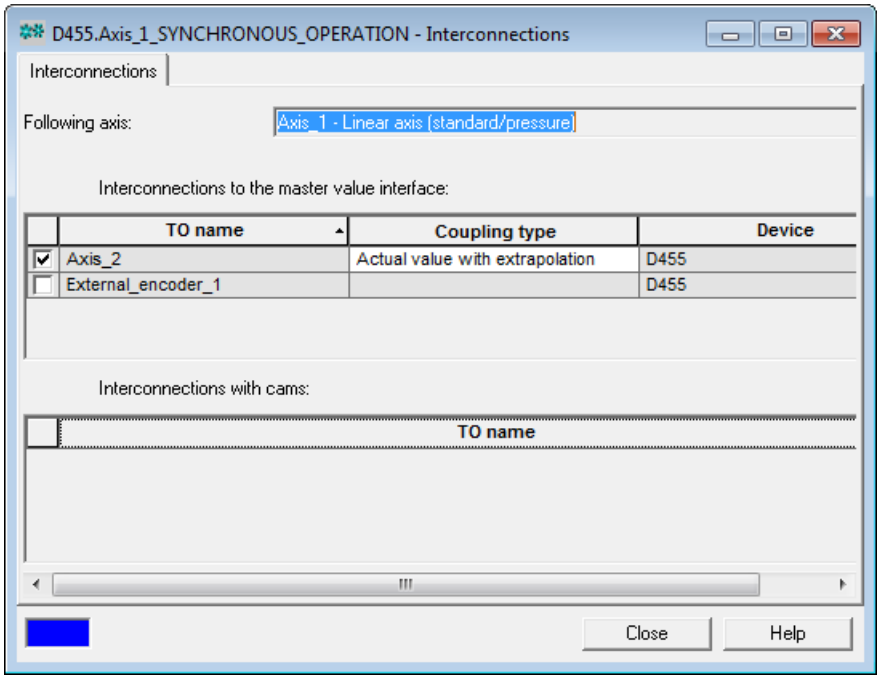

Figure 4-717 Selection of master values and cams

Assign the master values and cams to the following axis in this window.

You can set the following parameters:

Table 4-295 Parameters for configuring synchronous operation

Field/Button	Meaning/Instruction
Following axis	The name of the following axis is displayed here.
Possible master values (leading axis)	The master values available in the project, which you can assign to the following axis, are listed here. The master value can be specified by the following technology objects: • Axis (real or virtual axis) • External encoder • Fixed gear • Addition object • Formula object In accordance with the specified synchronous operation condition (e.g. camming), the slave value is calculated on the basis of the master value and assigned to the following axis as a leading value. When more than one master value is assigned, you must specify which master value is to be used by means of programming in SIMOTION SCOUT (e.g. with MCC).
Possible cams	Cams created in the project are listed here. You can assign cams to the synchronous object for camming. When more than one cam is assigned, you must specify which cam is to be used by means of programming in SIMOTION SCOUT (e.g. with MCC).

1. Assign the desired **master values** to the axis with synchronous operation. You select the current master value to be used in the user program (**_setMaster**).
2. Assign the desired **cams** to the axis with synchronous operation. You select the cam to be used in the user program (**_enableCamming**).
3. For real axes or external encoders, select **setpoint coupling** or **actual value coupling** for axes, or select **actual value coupling** or **actual value coupling with extrapolation** for external encoders.
   See Setpoint/actual value coupling (Page 2647).

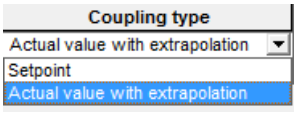

Figure 4-718 Selection of the coupling type

When the window is **closed**, the configuration is accepted and saved automatically.

Assigning parameters/defaults for synchronous operation

In the project navigator, double-click **Default** under the object <Axis name>**_SYNCHRONOUS OPERATION** to change the default settings.

Synchronous operation - Default

In this window, you define the replacement values (default) for calling the synchronous operation functions (**_enableGearing**, **_enableVelocityGearing**, and **_enableCamming** or **_disableGearing**, **_disableVelocityGearing**, and **_disableCamming**).

These replacement values are only evaluated if no special settings are made in the associated function calls for synchronization/desynchronization (ST and LAD or MCC).

You can set parameters for the following functionality:

- Gearing (Page 2727)
- Velocity gearing (Page 2728)
- Camming (Page 2729)
- Gearing synchronization (Page 2731)
- Camming synchronization (Page 2735)
- Dynamic response (Page 2738)
- Master dynamic response (Page 2740)

Note

All tabs are always available for default settings. Only parameters used for the relevant functionality are evaluated.

Further information

- For information about this function, refer to Overview of synchronous operation and Fundamentals of synchronous operation.
- For information about programming, refer to Synchronous operation programming/ references (Page 2744).
- The meaning of the dialog window parameters and their permissible value ranges can be found in the **SIMOTION reference lists**.

Gearing

Gearing is characterized by a constant coupling between the master value source and following axis. This coupling (via the gear ratio) can be specified as the ratio of two decimal numbers (numerator/denominator) or as a floating-point number.

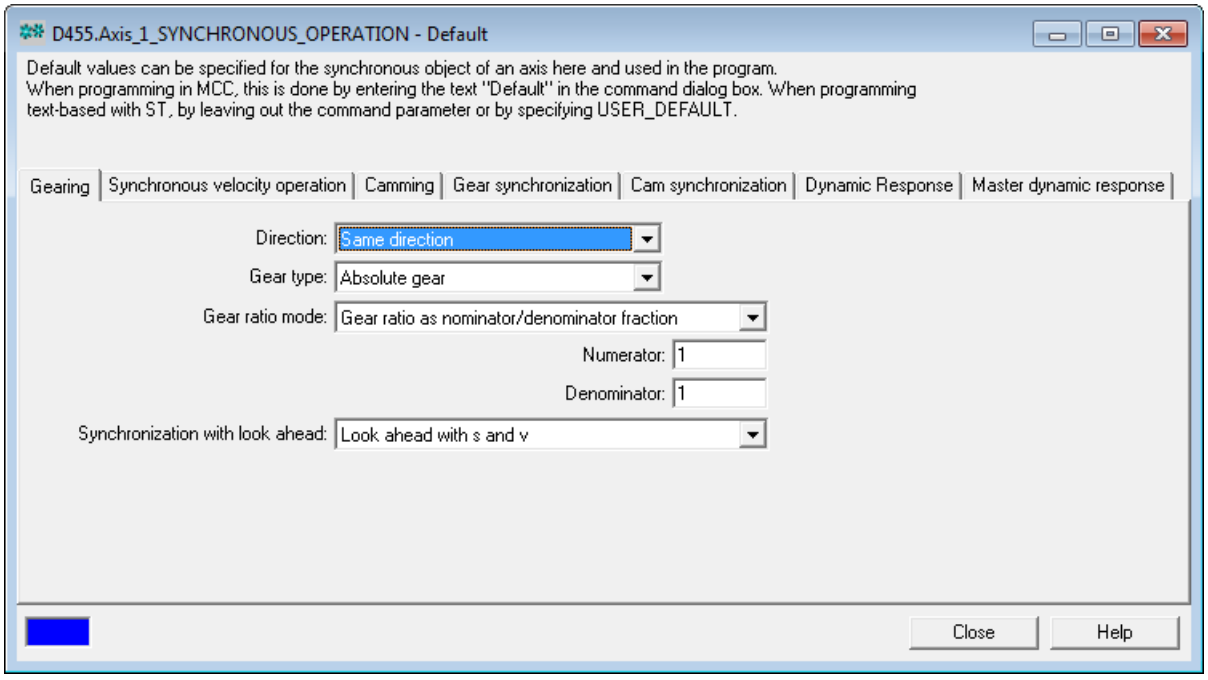

Figure 4-719 Synchronous object: Default setting for gearing

Gearing - default

In the **Gearing** tab, select the **direction**, **absolute** or **relative synchronous operation** and the **gear ratio**. These settings are only relevant when **gearing** mode is used.

You can set the following parameters:

Table 4-296 Parameters for gearing

Field/Button	Meaning/Instruction
Direction	Here, you specify the direction of the gearing.
Gear type	Here, you select the gear type (absolute or relative).
Gear ratio mode	Specify the gear ratio mode here. Further parameters are displayed depending on the selected mode (gear ratio as floating-point number or gear ratio as numerator/denominator ratio).
Gear ratio	You can enter the gear ratio as a floating-point number here.
Counter instructions	Here, you can enter the numerator of the gear ratio in the form of a numerator/denominator ratio.
Denominator	Here, you can enter the denominator of the gear ratio in the form of a numerator/denominator ratio.
Synchronization with look-ahead	You can set here whether a constant acceleration/deceleration of the master value is to be used for the synchronization.

See also

Gearing (Page 2631)

Velocity gearing

In contrast to gearing or camming, which relate to the position of an axis, velocity gearing relates to the velocity of an axis with a constant coupling between the master value source and the following axis. With velocity gearing, a non-position-controlled, i.e. speed-controlled synchronous operation with the velocity of a master axis, is activated on an axis that is set as a position-controlled axis (synchronized axis).

Possible master values are:

- Velocity of a master axis configured as a position-controlled axis
- Velocity of an external encoder

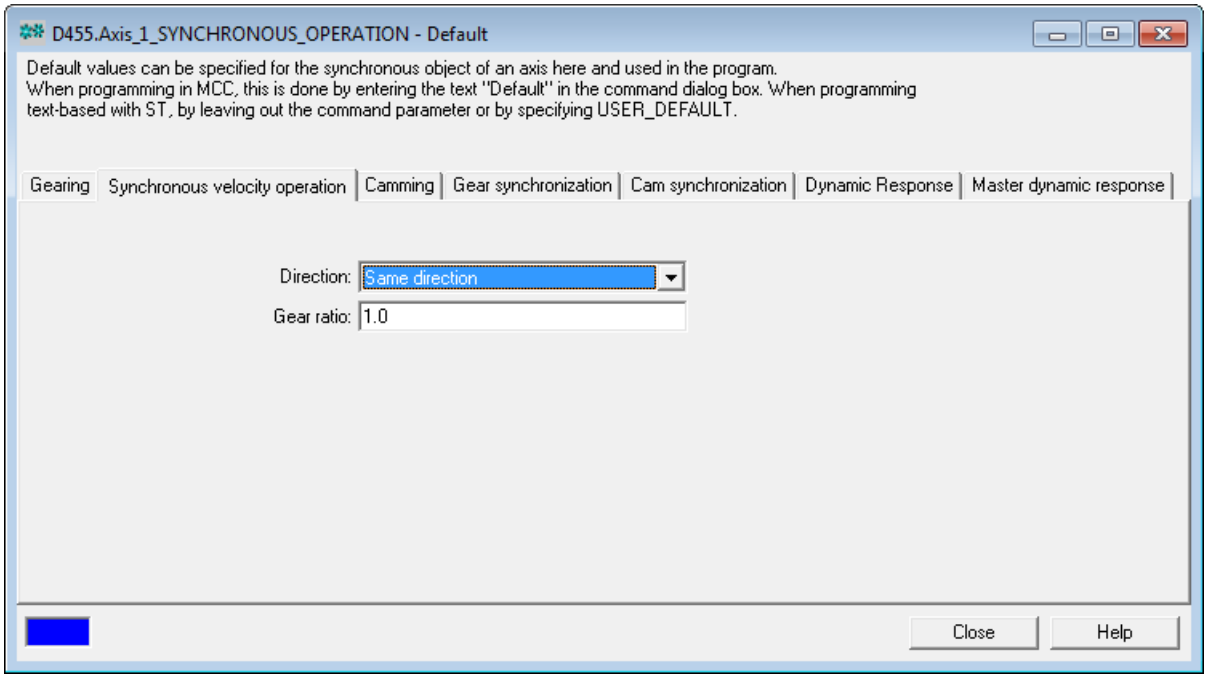

Figure 4-720 Synchronous object: Default setting for synchronous velocity operation

Velocity gearing - default

On the **Velocity gearing** tab, you set the **direction** and the **gear ratio**. These settings are only relevant when **velocity gearing** mode is used.

You can set the following parameters:

Table 4-297 Parameters for velocity gearing

Field/Button	Meaning/Instruction
Direction	Specify the direction of the synchronous velocity operation here.
Gear ratio	Enter here a coupling ratio for the synchronous velocity operation as floating-point number.

See also

Velocity gearing (Page 2637)

Camming

Camming is characterized by variable coupling between the master value source and the following axis. The coupling is described by a cam (transmission function). Camming can be scaled and offset on both the master value source side and on the following axis side. This enables a cam to be custom-adjusted in its definition range and value range.

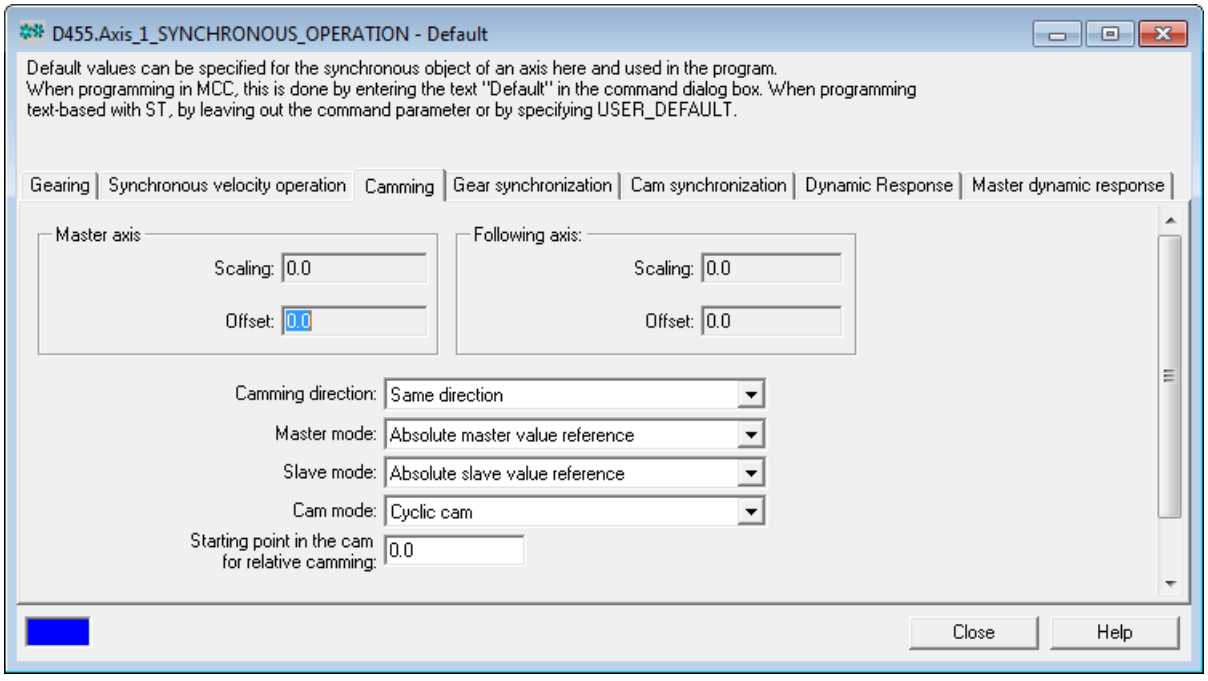

Figure 4-721 Synchronous object: Default setting for camming

Camming - Default

On the **Camming** tab, the **scaling** and **offset** for each master axis and following axis are shown. The **Scaling** and **Offset** setting can be made on the cam or via **_setCammingScale** or **_setCammingOffset**. You select the **direction**, **absolute** or **relative synchronous operation** for the master value and the slave value, as well as the **cam mode**. These settings are only relevant when **camming** mode is used.

You can set the following parameters:

Table 4-298 Parameters for camming

Field/Button	Meaning/Instruction
Leading axis	
Scaling	The scaling of the master value is displayed here.
Offset	The offset of the master value is displayed here.
Following axis	
Scaling	The scaling of the following axis is displayed here.
Offset	The offset of the slave axis is displayed here.
Camming direction	Specify the direction in which the cam is run.
Master mode	Specify the mode in which the master value runs through the cam (absolute or relative).
Slave mode	Specify the mode in which the following axis runs through the cam (absolute or relative).
Cam mode	Specify the execution type for the cam here (cyclic or non-cyclic).
Starting point in the cam for relative camming	Specify here for relative master value reference the reference of the master values by specifying a starting position (camStartPositionMaster) in the cam. The position is always an absolute reference in relation to the definition range of the cam.

Camming (Page 2638)

Gearing synchronization

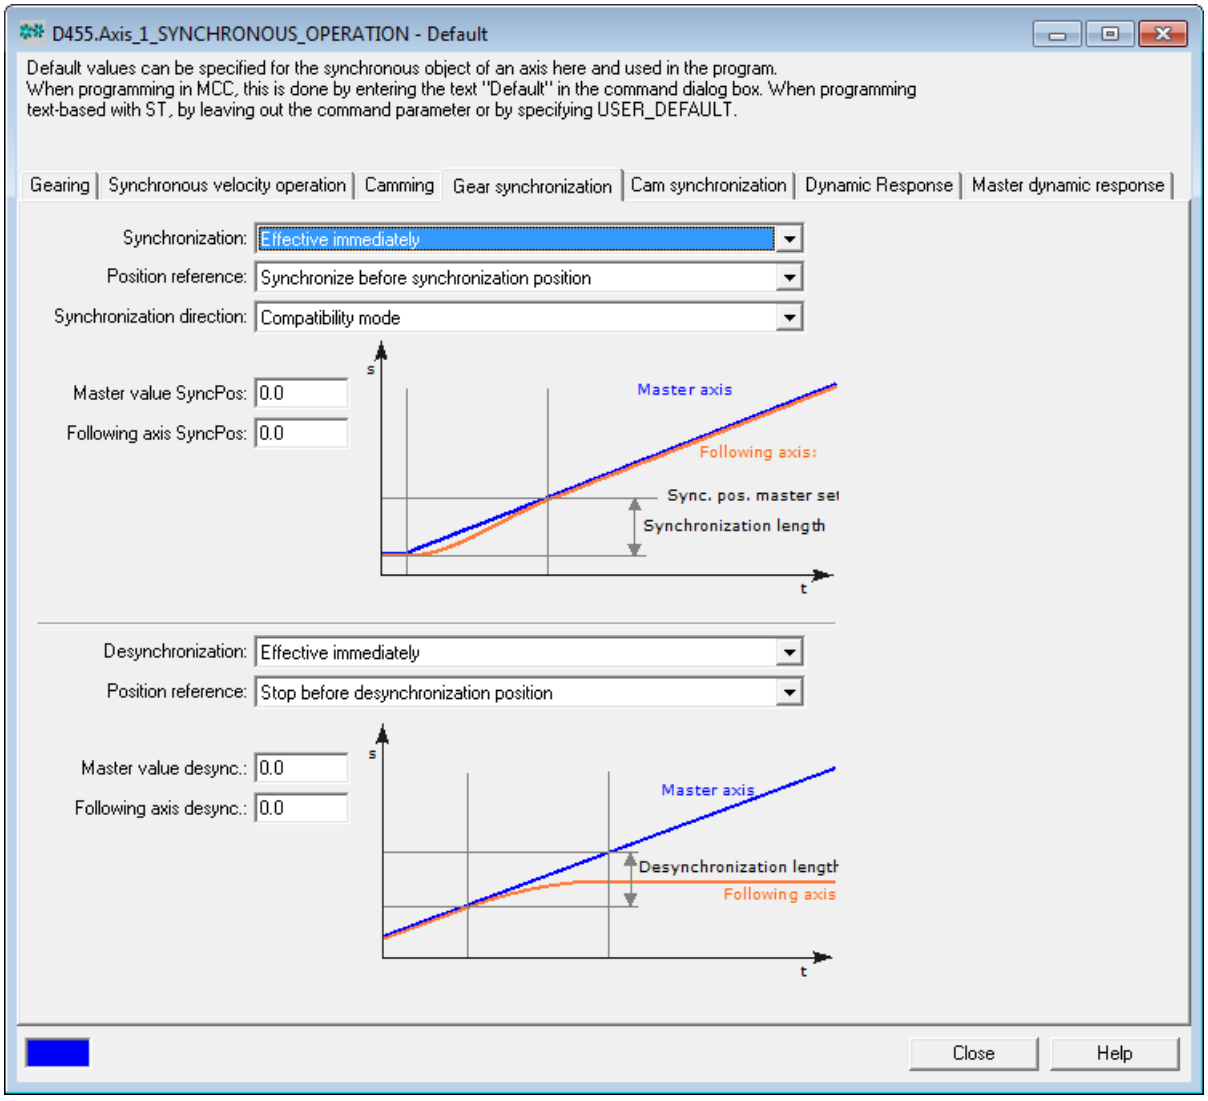

Figure 4-722 Synchronous object: Default setting for gear synchronization

Gear Synchronization - Default

You use the **Gear synchronization** tab to set the parameters for **synchronization and desynchronization**. These settings are only relevant when **gearing** mode is used.

You can set the following parameters:

Table 4-299 Parameters for gear synchronization

Field/Button	Meaning/Instruction
Synchronization	Specify when synchronization of the following axis with the master value is performed. For more information, see Synchronizing the gear (Page 2652)
Position reference	Here, you specify the position of the synchronization profile relative to the position of the synchronization point. For more information, see Position reference during synchronization (Page 2733)
Synchronization direction	Specify the synchronization direction here. See Synchronization direction (Page 2658).
Master value SyncPos	Here, you enter the position of the synchronization point of the master value.
SyncPos slave axis	Here, you enter the position of the synchronization point of the slave axis
Desynchronization	Specify when desynchronization of the following axis with the master value is performed. For more information, see Desynchronizing the gear (Page 2734).
Position reference	Here, you specify the position of the desynchronization profile relative to the position of the desynchronization point For more information, see Position reference during desynchronization (Page 2734).
Desync. Master value	Here, you enter the position of the desynchronization point of the master value.
Desync. Following axis	Here, you enter the position of the desynchronization point for the following axis

Synchronizing the gear

You can set the synchronization condition using the **Synchronization** drop-down list box on the **Gear synchronization** tab:

Table 4-300 Parameters for gear synchronization

Setting	Meaning
Effective immediately	Synchronization takes immediate effect. The start point is derived from the position of the current master value. The settings in **Master value SyncPos** and **Following axis SyncPos** are not evaluated.
Default synchronization position of the leading axis	This setting is only appropriate for an absolute master value coupling. Synchronization depends on the position of the master value. The synchronization position is specified in **Master value SyncPos**. The setting in **Following axis SyncPos** is not evaluated.
Specified by the synchronization position of the following axis	This setting is only appropriate for an absolute following axis. The synchronization criterion depends on the position of the following axis. The synchronization position is specified in **Following axis SyncPos**. The setting in **Master value SyncPos** is not evaluated.

Setting	Meaning
Default synchronization position of the leading axis and following axis	This setting is only appropriate for an absolute master and an absolute following axis. Synchronization depends on the position of the master value. The synchronization position is specified in **Master value SyncPos**. An offset is additionally created on the following axis by the setting in **Following axis SyncPos**. That is, the following axis is not synchronized to the programmed slave position but to the position **Following axis SyncPos** plus absolute position value of the following axis.
Last programmed setting	Setting of the last active command

See also

Synchronization criterion/synchronization position (Page 2654)

Position reference during synchronization

How synchronization is to performed is set via the **Position reference** picklist:

Table 4-301 Position reference parameters for synchronization

Setting	Meaning
Synchronize from synchronization position	Synchronization starts at the synchronization position. The following axis runs synchronously after the synchronization length resulting from the dynamic response data.
Synchronize before synchronization position	The synchronization is performed so that the following axis runs synchronously to the master value at the synchronization position. If the following axis is stopped, it is accelerated before the synchronization position so that it runs synchronously to the master value at the synchronization position. The position at which the axis is accelerated is the synchronization position minus the synchronization length.
Synchronize symmetrically to synchronization position	The synchronization is performed so that the synchronization position is exactly in the middle of the synchronization length. Therefore, a stopped following axis is already accelerated before the synchronization position and only runs synchronously to the master value after half the synchronization length.
Last programmed setting	Setting of the last active command

You will find further information in the section Position of synchronization range relative to synchronization position (Page 2660).

Desynchronizing the gear

You can set the position at which desynchronization is to start using the **Desynchronization** drop-down list box on the **Gear synchronization** tab:

Table 4-302 Parameters for desynchronization

Setting	Meaning
Effective immediately	Desynchronization takes immediate effect.
Specified by the desynchronization position of the leading axis	The desynchronization is performed as of the **Master value desync** value. The setting in **Following axis desync** is not evaluated.
Default desynchronization position of the following axis	The desynchronization is performed as of the **Following axis desync** value of the following axis. The setting in **Master value desync** is not evaluated.
Last programmed setting	Setting of the last active command

See also

Desynchronization criterion/desynchronization position (Page 2676)

Position reference during desynchronization

How desynchronization is to performed is set via the **Position reference** picklist:

Table 4-303 Parameters for the position reference

Setting	Meaning
Stop after desynchronization position	The desynchronization is started at the desynchronization position. The desynchronization is completed after the synchronization length resulting from the dynamic response data.
Stop before desynchronization position	The desynchronization is performed so that the desynchronization is completed at the desynchronization position. The position at which the desynchronization is started is the desynchronization position minus the desynchronization length.
Stop symmetrically to desynchronization position	The desynchronization is performed so that the desynchronization position is exactly in the middle of the desynchronization length.

See also

Position of synchronization range relative to desynchronization position (Page 2677)

Camming synchronization

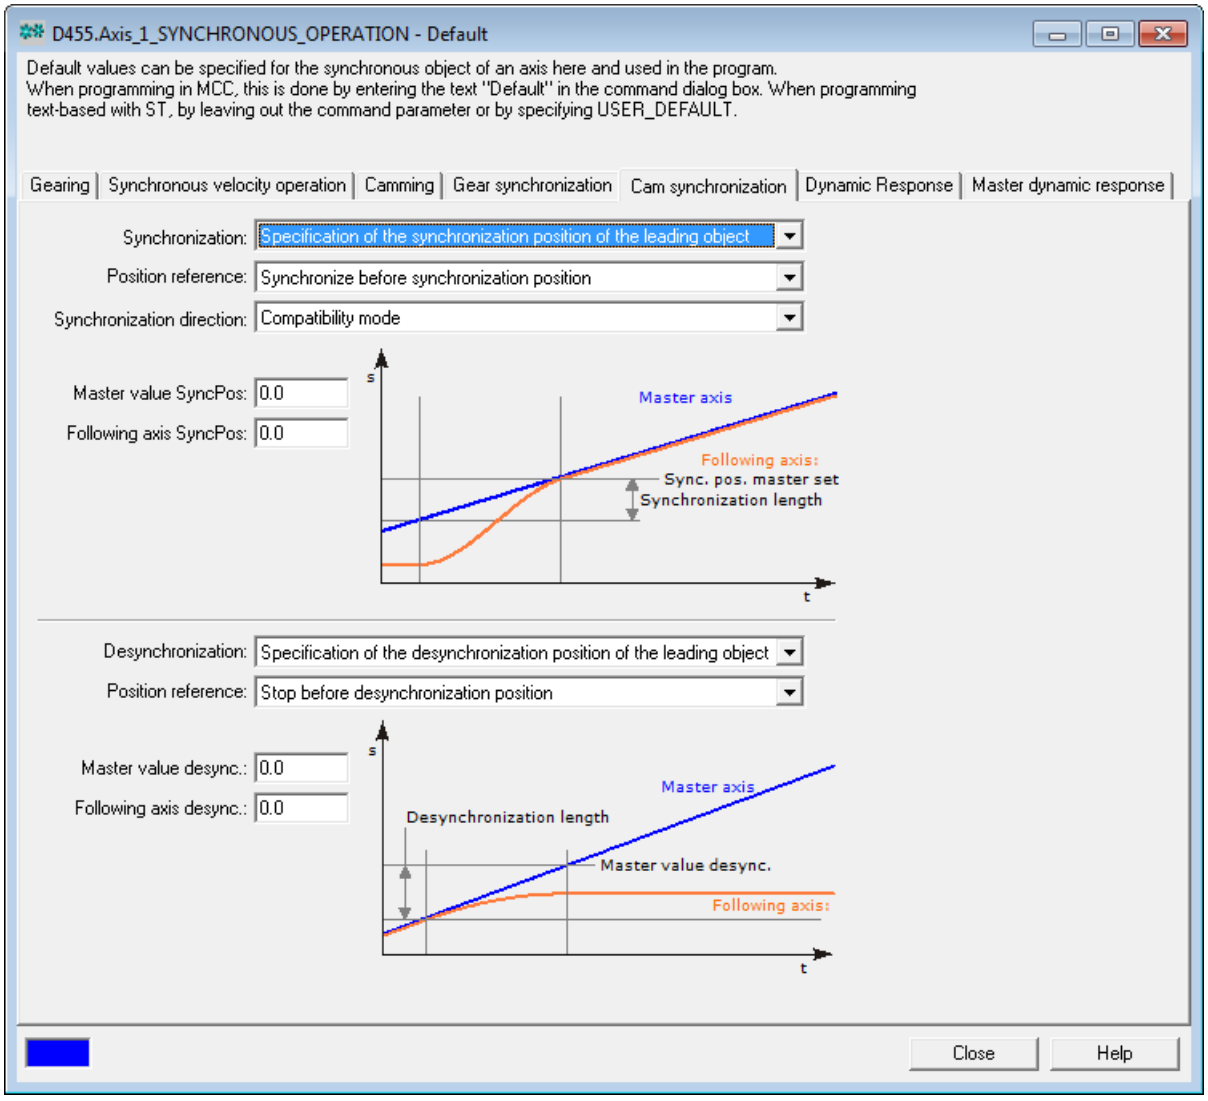

Figure 4-723 Synchronous object: Default setting for cam synchronization

Cam Synchronization - Default

You use the **Cam synchronization** tab to set the parameters for **synchronization and desynchronization**. These settings are only relevant when **camming** mode is used.

You can set the following parameters:

Table 4-304 Parameters for camming synchronization

Field/Button	Meaning/Instruction
Synchronization	Specify when synchronization of the following axis with the master value is performed. For more information, see Synchronizing the curve (Page 2736).
Position reference	Here, you specify the position of the synchronization profile relative to the position of the synchronization point. For more information, see Position reference during synchronization (Page 2733)
Synchronization direction	Specify the synchronization direction (Page 2658) here.
Master value SyncPos	Here, you enter the position of the synchronization point of the master value.
SyncPos slave axis	Here, you enter the position of the synchronization point of the slave axis
Desynchronization	Specify when desynchronization of the following axis with the master value is performed. For more information, see Desynchronizing the curve (Page 2737).
Position reference	Here, you specify the position of the desynchronization profile relative to the position of the desynchronization point For more information, see Position reference during desynchronization (Page 2734).
Desync. Master value	Here, you enter the position of the desynchronization point of the master value.
Desync. Following axis	Here, you enter the position of the desynchronization point for the following axis

Synchronization (Page 2652)

Cam synchronization

You can set the synchronization condition using the **Synchronization** drop-down list box on the **Cam synchronization** tab:

Table 4-305 Parameters for synchronization

Setting	Meaning
Effective immediately	Synchronization takes immediate effect. The start point is derived from the position of the current master value. The settings in **Master value SyncPos** and **Following axis SyncPos** are not evaluated.
Default synchronization position of the leading axis	This setting is only appropriate for an absolute master value coupling. Synchronization depends on the position of the master value. The synchronization position is specified in **Master value SyncPos**. The setting in **Following axis SyncPos** is not evaluated.

Setting	Meaning
Transition at the end of the active cam	This setting is only possible for a relative master value coupling. The synchronization criterion is the master setpoint position at the end of the current cam disk cycle. The setting in **Following axis SyncPos** is not evaluated.
Default synchronization position of the leading axis and following axis	This setting is only appropriate for an absolute master and following axis. Synchronization depends on the position of the master value. The synchronization position is specified in **Master value SyncPos**. An offset is additionally created on the following axis by the setting in **Following axis SyncPos**. That is, the following axis is not synchronized to the programmed (e.g. via cam) slave position but to the position **Following axis SyncPos** plus absolute position value of the following axis in relation to the cam.
Last programmed setting	Setting of the last active command

See also

Synchronization criterion/synchronization position (Page 2654)

Cam desynchronization

You can set the position at which desynchronization is to start using the **Desynchronization** drop-down list box on the **Cam synchronization** tab:

Table 4-306 Parameters for desynchronization

Setting	Meaning
Effective immediately	Desynchronization takes immediate effect.
At position of the leading axis	The desynchronization is performed as of the **Master value desync** value. The setting in **Following axis desync** is not evaluated.
At position of the following axis	The desynchronization is performed as of the **Following axis desync** value of the following axis. The setting in **Master value desync** is not evaluated.
End of cam cycle	The desynchronization is performed at the end of the current cam cycle.
Last programmed setting	Setting of the last active command

Desynchronization criterion/desynchronization position (Page 2676)

Dynamic response

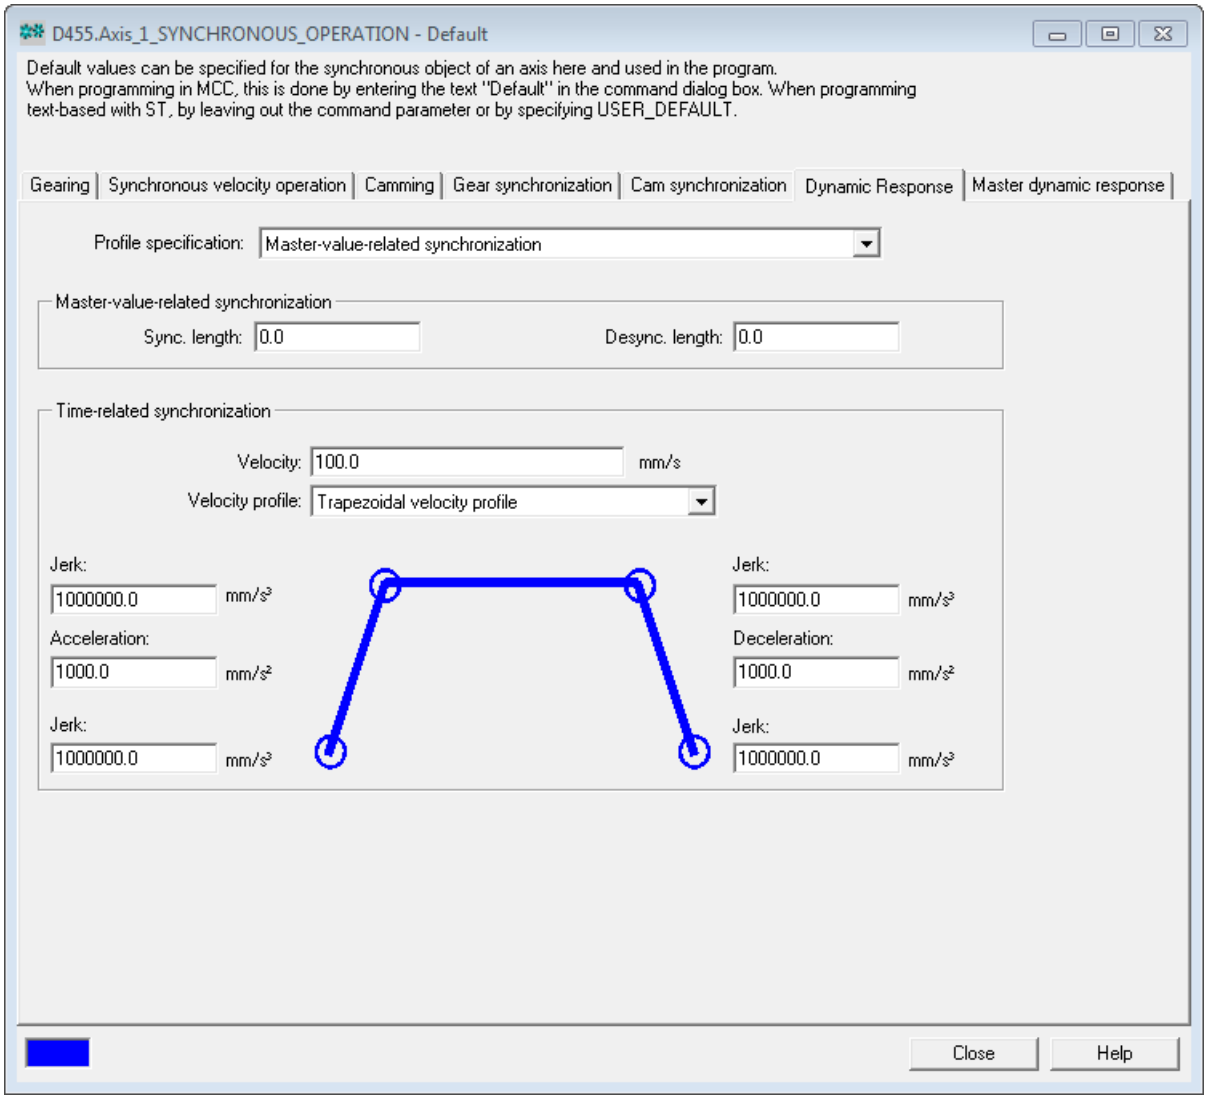

Figure 4-724 Synchronous object: Default setting for dynamic response

Dynamic response - Default

In the **Dynamics** tab, you make the basic settings for synchronization and desynchronization.

You can enter the following profile settings:

- **Length-related synchronization**; see Synchronization via a specifiable master value distance (Page 2692).
- **Time-related synchronization**; see Synchronization profile based on specifiable dynamic response parameters (Page 2694).

Dynamic response parameters are used for:

- Time-related synchronization
- Compensatory motions on the synchronous object

You can set the following parameters:

Table 4-307 Dynamic response parameters

Field/Button	Meaning/Instruction
Profile specification	Specify the reference for the synchronization profile here.
Leading axis-related synchronization	
Sync. Length	Here, you enter the path length for synchronization.
Desync. Length	Here, you enter the path length for desynchronization.
Time-related synchronization	
Velocity profile	Select the velocity profile here.
Velocity	Enter the maximum velocity here.
Acceleration	Enter the maximum acceleration here.
Deceleration	Enter the maximum deceleration here.
Jerk	Enter the maximum jerk here.

The synchronization length and desynchronization length are only evaluated for master-axis-related synchronization profiles. Velocity profile, velocity, acceleration, deceleration and jerk are only evaluated for time-related synchronization profiles.

Synchronization (Page 2652)

Master dynamic response

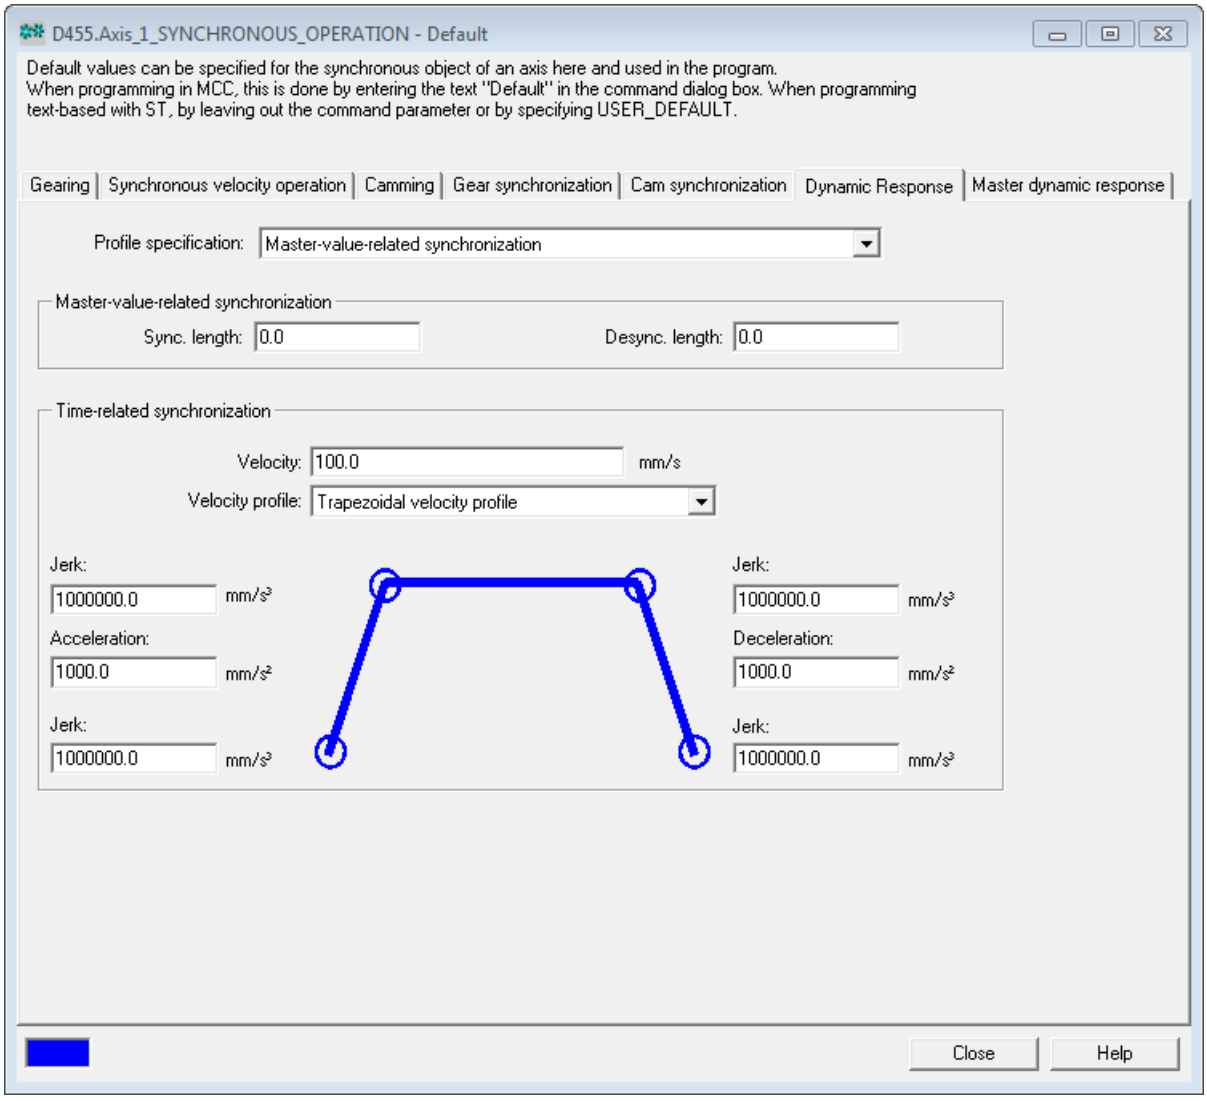

Figure 4-725 Synchronous object: Default setting for master dynamic response

Master dynamic response - default

In the **Master dynamic response** tab, you make the settings for the dynamic response for the master value switchover.

You can set the following parameters:

Table 4-308 Dynamic response parameters - Master

Field/Button	Meaning/Instruction
Master switchover with dynamic response values	
Velocity profile	Select the velocity profile here.
Velocity	Enter the maximum velocity here.

Field/Button	Meaning/Instruction
Acceleration	Enter the maximum acceleration here.
Deceleration	Enter the maximum deceleration here.
Jerk	Enter the maximum jerk here.

Switching over the master value source – Overview (Page 2680)

Set synchronization

Certain settings for synchronization can be defined on the synchronous object.

- In the project navigator, double-click **Settings** under the synchronous object.

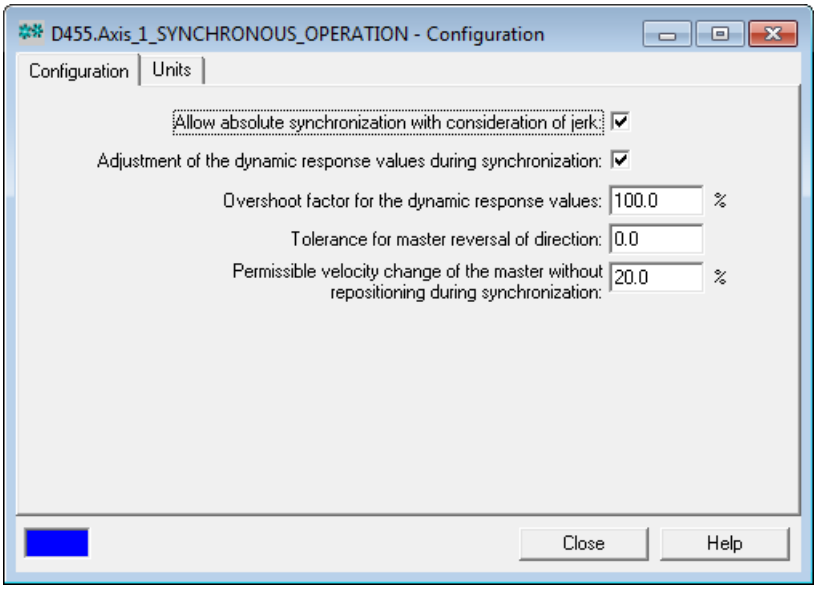

Figure 4-726 Settings on the synchronous object

Synchronous object - Settings

In this window, define the parameters for the synchronization.

Table 4-309 Synchronization parameters

Field/Button	Meaning/Instruction
Permit absolute synchronization with provision for jerk	For absolute synchronization, the "Yes" setting of the jerk is used. If "No" is set, the set jerk will not be used in spite of velocity profile = SMOOTH being selected. Travel follows a trapezoidal path. (syncingMotion.smoothAbsoluteSynchronization) See also section Trailing synchronization with synchronization profile based on dynamic response parameters (Page 2665).
Adapt the dynamic response values for the synchronization	Adaptation to the dynamic response in the synchronous position (syncingMotion.synchronizingAdaption) If "Yes" is set, the following parameter is available: See also section Synchronization profile based on specifiable dynamic response parameters (time reference) (Page 2662).
Magnification factor for the dynamic response values	Overdrive factor for the adapted dynamic response values to compensate for a remaining path difference (syncingMotion.overdriveFactor) Value as percentage (%) Reference to the current master value velocity for the synchronization start. See also section Synchronization profile based on specifiable dynamic response parameters (time reference) (Page 2662) and section Adapt the synchronization velocity to the master value velocity (Page 2718).
Tolerance for master direction reversal	Tolerance window for canceling the synchronization for direction reversal of the master values (syncingMotion.masterReversionTolerance) Position value in the user unit of the master values. See also section Settings for evaluation of the master value behavior during synchronization (Page 2667).
Permitted velocity change of the master without restarting for synchronization	Maximum permitted change of the master value velocity (syncingMotion.maximumOfMasterChange) Refers to the current master value velocity for the synchronization start. Value as percentage (%). See also section Settings for evaluation of the master value behavior during synchronization (Page 2667).

Dynamic response effect on slave values (Page 2678)

Synchronization (Page 2652)

Configuring synchronous operation monitoring

Synchronous operation monitoring between the master value/following object and the following axis can be configured on the synchronized axis.

1. In the project navigator, double-click **Monitoring** under the axis object.
2. Set the required parameters on the **Synchronous operation** tab.

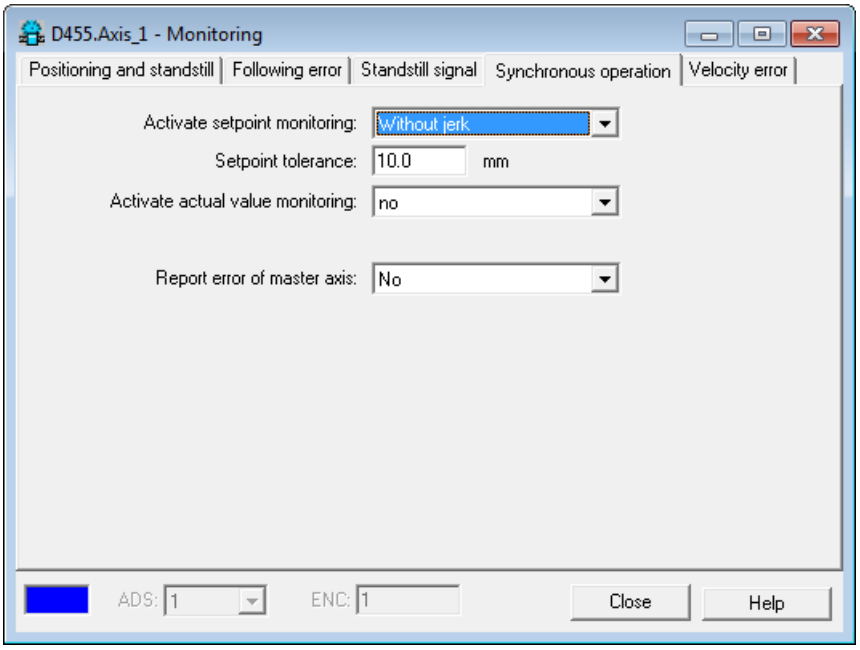

Figure 4-727 Monitoring of a following axis

Here, you specify the synchronous operation monitoring of the axis.

Table 4-310 Monitoring parameters

Field/Button	Meaning/Instruction
Activate setpoint monitoring	Activate the setpoint monitoring of the following axis here. (TypeOfAxis.GearingPosTolerance.enableCommandValue)
Setpoint tolerance	Specify the setpoint tolerance with activated setpoint monitoring. (TypeOfAxis.GearingPosTolerance.commandValueTolerance)
Activate actual value monitoring	Activate the actual value monitoring of the following axis here. (TypeOfAxis.GearingPosTolerance.enableActualValue)
Actual value tolerance	Specify the actual value tolerance with activated actual value monitoring. (TypeOfAxis.GearingPosTolerance.actualValueTolerance)
Signal error of the leading axis	Specify here which tolerance-exceeded messages (actual values / setpoints) are signaled to the leading axis. Take into account that the tolerance-exceeded messages are signaled to all higher-level leading axes (if, for example, the leading axis is also a following axis in a synchronous operation configuration). (TypeOfAxis.GearingPosTolerance.enableErrorReporting)

Error handling (Page 2754)

Menus (Page 2757)

Overview of commands

ST commands

Table 4-311 Commands on the synchronous object

Command type / command	Description
Information and conversion	See Commands for reading out function values (Page 2746).
_getMasterValue	The **_getMasterValue** command supplies the master value at a specified slave value position.
_getSlaveValue	The **_getSlaveValue** command supplies the slave value on a specified master value position.
_setMaster	The **_setMaster** command is used to assign a new master value source to a synchronous object. See Switching of the master value source (Page 2680).
Command tracking	See Commands for command tracking (Page 2747).
_getStateOfFollowingObjectCommand	The **_getStateOfFollowingObjectCommand** command returns the execution state of a synchronous operation command.
_getMotionStateOfFollowingObjectCommand	The **_getMotionStateOfFollowingObjectCommand** command returns a structure with the state of a synchronous operation command. The state of a synchronous operation command must then also be read out.

Command type / command	Description
_bufferFollowingObjectCommandId	The **_bufferFollowingObjectCommandId** command enables the **commandId** and the associated command status to be saved beyond the processing time of the command. The **commandId** parameter is used to define the command for which the respective status is to be saved. The maximum number of command states that can be saved is set in configuration data **decodingConfig.numberOfMaxBufferedCommandId**.
_removeBufferedFollowingObjectCommandId	The **_removeBufferedFollowingObjectCommandId** command discontinues saving of the **commandId** and the associated command status beyond the processing time of the command.
Motion	
_enableGearing	The **_enableGearing** command produces gearing with a constant transfer ratio. See Gearing (Page 2631).
_disableGearing	The **_disableGearing** command terminates gearing with a constant transfer ratio.
_enableVelocityGearing	The **_enableVelocityGearing** command produces velocity gearing with a constant coupling. See Velocity synchronous operation (Page 2637).
_disableVelocityGearing	The **_disableVelocityGearing** command terminates velocity gearing with a constant coupling.
_enableCamming	The **_enableCamming** command produces camming with a variable transfer ratio. See Camming (Page 2638).
_disableCamming	The **_disableCamming** command terminates camming with a variable transmission ratio.
Correction and superimposition	
_setGearingOffset	The **_setGearingOffset** command offsets the gearing with reference to the master value or the slave value (V3.1 and higher). See **Changing the offset** in chapter Gearing (Page 2631)
_setCammingScale	The **_setCammingScale** command scales the camming relative to the master value or the slave value. See **Scaling and offset** in Camming (Page 2638).
_setCammingOffset	The **_setCammingOffset** command offsets the camming with reference to the master values or the slave values. See **Scaling and offset** in Camming (Page 2638).
Object and Alarm Handling	See Commands for resetting of states and errors (Page 2749).
_resetFollowingObject	The **_resetFollowingObject** command resets the synchronous object, i.e. an active synchronous grouping will be cancelled, any pending errors will be cleared.
_resetFollowingObjectError	The **_resetFollowingObjectError** command acknowledges and resets errors on the synchronous object.
_resetFollowingObjectErrorState	The **_resetFollowingObjectErrorState** command acknowledges and resets the error status on the synchronous object.
_getFollowingObjectErrorNumberState	The **_getFollowingObjectErrorNumberState** command is used to fetch the status of a specific error
Simulation	See Simulation mode (Page 2690).

Command type / command	Description
_enableFollowingObjectSimulation	The **_enableFollowingObjectSimulation** command sets a synchronous operation into simulation mode.
_disableFollowingObjectSimulation	The **_disableFollowingObjectSimulation** command disables simulation mode of the synchronous grouping.

PLCopen commands

MultiAxis commands of PLCopen are relevant for synchronous operation. These commands are provided for use in cyclic programs/tasks and enable motion control programming in a view shaped by a PLC. They are used primarily in the LAD/FBD programming language. The commands are certified in accordance with "PLCopen Compliance Procedure for Motion Control Library V1.1".

Table 4-312 PLCopen commands for synchronous operation

Command	Description
_MC_CamIn	Synchronize and engage cam; included implicitly:
_MC_CamOut	Remove cam with desynchronization
_MC_GearIn	Synchronize synchronous operation
_MC_GearOut	Desynchronize synchronous operation
_MC_Phasing	Phase offset

For further information, refer to the **PLCopen Blocks** Function Manual.

MCC commands

MCC commands are available for synchronous operation. For information on this see the Programming and Operating Manual for the **SIMOTION MCC Motion Control Chart**.

Commands for reading out function values

Commands that calculate values and supply them as return values are available for reading out master value positions and slave value positions in pairs:

- The **_getSlaveValue** command supplies the slave value at a specified master value position. If several master values may have the same slave value, an approximate value can be specified for the master value.
  - **slavePositionType:=CURRENT** returns the current value.
  - **slavePositionType:=DIRECT** returns in **slavePosition** the specified approximation value.
- The **_getMasterValue** command supplies the master value at a specified slave value position. If several slave values may have the same master value, an approximate value can be specified for the slave value.
  - **masterPositionType:=CURRENT** returns the current value.
  - **masterPositionType:=DIRECT** returns the approximate value specified in **masterPosition**.

The commands only supply the correct position if a synchronous relationship is active and synchronized.

Commands for command tracking

The following commands are available for command tracking:

- The **_getStateOfFollowingObjectCommand** command returns the execution state of a synchronous operation command:
  - **ACTIVE**: The command is being executed.
  - **NON_EXISTENT**: The command is complete or the commandID is unknown.
  - **WAITING**: The command is decoded, but execution not yet started.
  - **WAITING_FOR_SYNC_START**: The command is waiting for synchronous start.
- The **_getMotionStateOfFollowingObjectCommand** command returns a structure with the execution state of a command.
  - **functionResult** specifies the error code.
  - **motionCommandIdState** returns the current phase of the motion of the queried command.
  - **abortId** specifies the reason for aborting the command.
    The reason for aborting is specified with alarm 30002 "Command aborted (reason: <abortId>, command type: ...)".
- With **_bufferFollowingObjectCommandId**, the command status can be queried after completion or an abort of the command.
- With **_removeBufferedFollowingObjectCommandId**, the command should be explicitly removed from the command management of the technology object after evaluation is complete.

The number of motion commands that the MotionBuffer can accept can be specified using the **followingObjectType.DecodingConfigInfo.numberOfMaxbufferedCommandId** configuration data.

System variables

The sequence of programmed commands can be read out by means of system variables; see Monitoring the synchronization (Page 2671).

System variable syncMonitoring:

The structure elements belonging to **syncMonitoring** indicate the monitoring functions and status information for synchronization.

The variable is used for the monitoring of the synchronous operation relationship to the synchronous operation setpoint, see also Synchronous operation monitoring (Page 2687).

- The **limitCommandValue** variable indicates whether the setpoint differences have exceeded the maximum limit for synchronous operation errors.
- The **differenceCommandValue** variable shows the difference between the setpoint generated at the synchronous object and the executable setpoint at the axis, with dynamic limits taken into account.
- The **limitActualValue** variable indicates whether the actual value differences have exceeded the maximum limit for synchronous operation errors.
- The **differenceActualVelocity** variable shows the pending position lag at the following axis, including the setpoint error, caused by any acting dynamic response of the following axis (**syncMonitoring.differenceCommandValue**). The dynamic response also acts on superimposed motions and can possibly trigger monitoring of the actual value. The position lag for DSC operation refers to the position lag present at the position controller in the drive. For versions prior to V4.2, the difference between the setpoint calculated on the synchronous object and the actual value present in the interpolator is indicated.
- The **syncErrorReported** variable indicates whether an alarm has already been issued to the master axis.
- The **syncState** variable indicates the synchronous operation status of the setpoint; it is syncState:=NO during synchronization and desynchronization. The setpoint synchronous operation error is the error that arises from limiting the setpoint to the maximum slave axis dynamic response values for the synchronous operation component.
  The **followingMotionState** indicates the state of the synchronous operation motions.
  The **differenceCommandVelocity** variable shows the difference, during velocity synchronous operation, between the set velocity calculated on the synchronous object and the set velocity that is executable on the axis taking into account the dynamic limits.

Canceling/deleting a synchronous operation command

The **_cancelFollowingObjectCommand** command can be used to cancel a synchronous operation command by specifying the **commandId** in the **commandToBeCancelled** parameter (as of V4.1). This removes the synchronous operation command from the command buffer and, if necessary, also from the IPO.

The synchronous motion is canceled with the local response **FOLLOWING_OBJECT_DISABLE**; see also **_cancelAxisCommand/_cancelExternalEncoderCommand** for the Axis/External Encoder technology object.

Additional references

You can find detailed information in both the **Motion Control Technology Objects Axis Electric/ Hydraulic, External Encoder** Function Manual and the **SIMOTION reference lists**.

Commands for resetting states and errors

The following commands are available for resetting states and errors:

- The **_resetFollowingObject** command resets the synchronous object, i.e. an active synchronous operation relationship is canceled and any pending errors cleared.
  The command can be executed when an error response (e.g. **DECODE_STOP**) is pending. All active commands and commands pending in the buffer are canceled. Changed default values can be reset using the **userDefaultData:=ACTIVATE_CONFIGURATION_DATA** parameter. Canceling commands by resetting the synchronous operation function does not generate any warnings.
  The **deleteSynchronizingCommandsOnly** parameter (V3.2 and higher) can be used to remove the waiting and active commands directly, without the need to reset the entire technology object.
- The **_resetFollowingObjectError** command acknowledges and resets errors on the synchronous object.
  The command can be executed when an error response (e.g. **DECODE_STOP**) is pending. One particular error or all errors can be ordered to be reset. The error response changes to the response with the highest priority of the still pending errors. It is terminated with a negative acknowledgment for any errors that cannot be acknowledged at this point. If all errors can be reset, the error response changes to **NONE**.
- The **_getFollowingObjectErrorNumberState** command is used to fetch the status of a specific error

Command processing

Command execution

Command advance

A criterion for the command advance is specified in the commands. If the condition for the command advance is satisfied, the next command in the user program is executed.
*****Specifying a command advance condition in a command influences the time at which the next programmed command will be executed.

Possible step enabling conditions on the synchronous object

The step enabling condition is indicated in the command parameter **nextCommand**.

Table 4-313 Step enabling conditions on synchronous object commands

Step enabling condition for next command	Time of advance
IMMEDIATELY	As soon as the command is issued
WHEN_BUFFER_READY	When the command enters the command buffer
AT_MOTION_START	When the command changes over to the interpolator
WHEN_ACCELERATION_DONE	When the acceleration phase is complete
AT_DECELERATION_START	When deceleration starts

Step enabling condition for next command	Time of advance
WHEN_INTERPOLATION_DONE	When setpoint interpolation for this command is complete
WHEN_AXIS_SYNCHRONIZED	When axis is synchronized with the master value
WHEN_MOTION_DONE	When motion generation is complete

Group classification of commands and command buffers

Each synchronous object has two dedicated command buffers for each command, which can be fetched for each IPO cycle. These command buffers are the buffer for synchronous operation commands and the buffer for *parallel effective commands*. The behavior of the buffers corresponds to the behavior of the axis.

Commands are classified in groups as follows:

- **Group 1**: *Synchronous operation commands*
  The following commands belong to this group: **_enableGearing**, **_disableGearing**, **_enableVelocityGearing**, **_disableVelocityGearing**, **_enableCamming**, and **_disableCamming**
  Depending on the transition behavior, new commands to be entered may behave in the following ways if the buffer is full:
  - Return with an error (**nextCommand** = **IMMEDIATELY** and **mergeMode** = **SEQUENTIAL**),
  - Wait for the buffer to become available (**nextCommand** ≠ **IMMEDIATELY** and **mergeMode** = **SEQUENTIAL**) or
  - Supersede the command pending in the buffer (**mergeMode** = **IMMEDIATELY**).
- **Group 2**: *Concurrently active commands*
  Commands that supersede each other in the command buffer. These commands are executed in the IPO. If there are more than one parallel effective command, only the last one is executed, because these commands overwrite each other. In this case, technology alarm 30002 "Command aborted (reason: ..., command type: ...)" is output.
  The following commands belong to this group: **_setGearingOffset**, **_setCammingScale**, **_setCammingOffset**, **_enableFollowingObjectSimulation**, **_disableFollowingObjectSimulation**, and **_setMaster**
- **Group 3**: Directly executed commands without entry in a command buffer
  Commands in this group do not abort each other.
  This group includes:
  _getSlaveValue, _getMasterValue,
  _resetFollowingObjectError,
  _getStateOfFollowingObjectCommand,
  _getMotionStateOfFollowingObjectCommand,
  _bufferFollowingObjectCommandID,
  _removeBufferFollowingObjectCommandId,
  _resetFollowingObject,
  _resetFollowingObjectConfigDataBuffer,
  _getFollowingObjectErrorNumberState

Command execution of sequential commands in the IPO cycle clock

If enabled to this effect, the commands are read out from the command buffer in every interpolation cycle. Within the slave value generation, up to two synchronous operation commands (_enableGearing(), _disableGearing(), _enableVelocityGearing(), _disableVelocityGearing(), _enableCamming(), _disableCamming()) are active at the same time and are executed in the IPO.

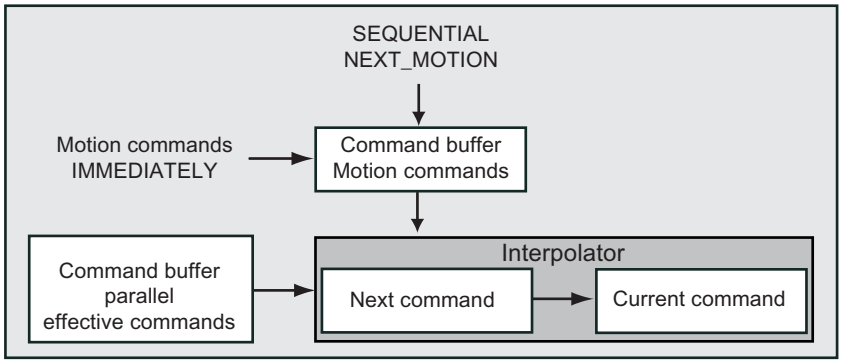

Figure 4-728 Command buffer and execution of sequential commands

Behavior regarding programming of a motion command:

- No motion command is active:
  An **_enable...** command is processed as the current command in the interpolator first as a waiting command, while a **_disable...** command is aborted immediately. If the synchronization criterion is satisfied, the waiting command changes its state to active (synchronizing/synchronous).
- If a motion command is waiting or active, the new motion command is processed as the next command in the interpolator first as a waiting command. A new **_disable...** command is immediately canceled if the current command is not a complementary **_enable...** command. If the next command is active, the current command is canceled. The next command is thereafter processed as the current command.
- If two motion commands are active or waiting and **mergeMode:=SEQUENTIAL** or **mergeMode:= NEXT_MOTION**, the new command is prevented from being read in until at least one command has been aborted or completed. With **mergeMode:= IMMEDIATELY**, the next command up to that point is aborted and replaced with the new command. Exception: If the new command is a complementary **_disable...** command for the next command, the new command is canceled immediately and only the current command is waiting/active.

See Command transition conditions (Page 2752) for further information.

Behavior regarding programming of a parallel effective command:

- **_setCammingScale()/_setCammingOffset()/_setGearingOffset()** act on the current (**_enable...**) command when **activationMode:= ACTUAL_VALUE** or **activationMode:= ACTUAL_AND_DEFAULT_VALUE**.
  If no command is active or the active command does not correspond to the correction being executed, the parallel effective command is canceled.
- In general, commands for simulation mode and resetting of current master value source are active.

Command transition conditions

The transition behavior is set in the **mergeMode** command parameter, on the commands of the synchronous object. The transition behavior affects the execution of the queued commands on the synchronous object. An active command can thus affect the execution of a command of another task.

The **mergeMode** on the synchronous object commands also determines the behavior of the following axis commands.

- A command issued with **mergeMode** = **IMMEDIATELY** clears the command buffer and overwrites the IPO (next command). The current command is executed. The next command is substituted.
- A command issued with **mergeMode** = **NEXT_MOTION** will be executed once the active command is complete and the pending commands have been deleted. It overwrites the command buffer.
- A command issued with **mergeMode** = **SEQUENTIAL** will be executed after the completion of the active command and the motion. The command will be entered in the command buffer when it is empty; if the command buffer is not empty, the command waits.

Influences between axis and synchronous object

Table 4-314 Transition behavior on synchronous object commands

Transition behavior for synchronous motion	Effect
IMMEDIATELY	The active command is aborted. The starting point for the slave value in the synchronous operation is the current axis setpoint. If the synchronous motion is active, the second synchronous function to be programmed or the non-active synchronous function is overwritten. If the synchronous function is already effective, then it remains effective. An active motion function in the following axis is overridden. It is therefore possible for motion, positioning, and synchronous operation to override each other another. If a synchronous operation command is issued with **mergeMode:=IMMEDIATELY**, the command waits in the command buffer until the synchronization criterion is fulfilled. Only then will the command enter the **active** state. A synchronous operation command will only be aborted by another motion command if the motion command is already active. In the same way, motion commands that are already active will only be aborted once a waiting synchronous operation command is activated.
SEQUENTIAL, NEXT_MOTION	If a main motion is active on the following axis, this main motion is first carried out completely. The starting point is the current axis setpoint for the main motion or, in the case of multiple synchronous commands, the internally generated slave value. If a synchronous motion is already active, the synchronous function is set to wait until the active synchronous function is completed or aborted. This requires the **nextCommand=WHEN_BUFFER_READY** setting. When **nextCommand=IMMEDIATELY** is set, the command is not executed and is returned with error information in the return value. The synchronous function is added to an active motion function in the following axis. A synchronous function that is in effect but not yet active can be deleted • With the **_disable...** command with **mergeMode=IMMEDIATELY** and **Synchronization criterion=IMMEDIATELY** or • With the **_resetFollowingObject** command

Table 4-315 Transition behavior on axis commands

Transition behavior for axis motion	Effect on the synchronous object
IMMEDIATELY	All active synchronous motions are aborted. None of the synchronous motions that are not active (i.e. they are neither in the synchronization motion nor in the "synchronous" status, but are instead waiting for the synchronization criterion) are aborted.
SEQUENTIAL, NEXT_MOTION	The synchronous operation commands/synchronous motions are not aborted and the axis motion only becomes active once the synchronous operation is complete.

The following special feature applies when motion commands are pending on the synchronous object and on the axis in the same interpolation cycle clock:

- If **mergeMode**(axis)=**SEQUENTIAL**, the synchronous command is executed
- If **mergeMode**(axis)=**IMMEDIATELY**, the axis command is executed

Error handling

Local alarm reaction on the synchronous object

Local **alarm responses** are specified by means of the system.

The following responses are possible:

- **NONE**
  No response
- **DECODE_STOP**
  Abort of the command preparation, the current synchronous operation function remains **active**.
- **FOLLOWING_OBJECT_DISABLE**
  Abort of the command preparation, abort of the current synchronous operation function.

An error can be reset with **_resetFollowingObject** or **_resetFollowingObjectError**

Note

The stop responses are listed in order of increasing priority. Global alarm responses can be set in the **alarm configuration** in the technology object; these can also be set to require **Power On**. For further information, see the **Motion Control Basic Functions** Function Manual, "Configuring technological alarms".

Local alarm reaction of the following axis and its mutual effects with the synchronous object

The synchronous object and the Axis TO have a reciprocal effect on each other depending on their respective operating modes and which commands are in effect. Thus, errors and alarms in the TO axis have a direct effect on the synchronous object functions. For example, if a technology alarm triggers a stop response in the following axis, the synchronous motion is also stopped. If an error is pending on the synchronous object only, the following axis can still position but can no longer perform synchronous operation.

The following responses by the Axis TO, which can be read in the **errorReaction** system variable, affect the synchronous object:

- **MOTION_STOP**
  Controlled motion stop with programmed ramp values.
- **MOTION_EMERGENCY_STOP**
  Controlled motion stop with maximum ramp values/limits for the axis.
- **MOTION_EMERGENCY_ABORT**
  Controlled motion stop with maximum axis dynamic values (starting from the current setpoint).

- **FEEDBACK_EMERGENCY_STOP**
  Motion stop with preassigned braking ramp.

  Note

  Problems with FEEDBACK_EMERGENCY_STOP on the leading axis

  Switchover to the actual value of the leading axis is performed. An existing setpoint-actual value different results in a step response of the speed or position on the synchronous object and therefore also on the synchronized axis.

  - Configure Motion_Emergency_Abort on the master axis

- **OPEN_POSITION_CONTROL**
  Motion stop with speed setpoint zero and abort.
- **RELEASE_DISABLE**
  Motion disable with controller disable and abort of all commands.

Synchronous operation is aborted for all responses indicated.

Note

Errors on the synchronous object do not have any effect on the enables/error response of the following axis.

Note

If the **disableSynchronousOperation** configuration data item is set to **YES** and simulation is active on the synchronous object, the synchronous operation function is *not* aborted on the stop response or when the **_disableAxis** command is executed.

The synchronous operation function is aborted with alarm "20005 Device type:..., log. address:... failed" if no valid actual value is present, e.g. if the axis is restarted.

Error handling in the user program

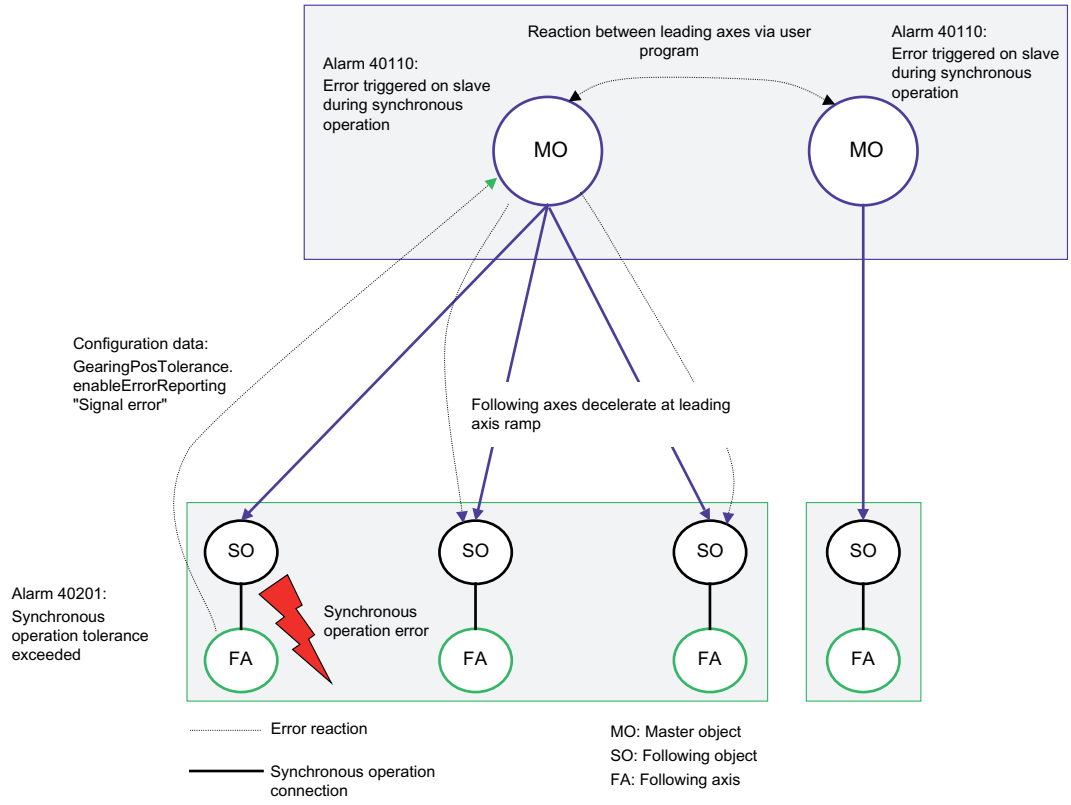

Figure 4-729 Error response in user program in distributed synchronous operation

The starting point is a synchronous operation error in a following axis (synchronous operation tolerance exceeded). Alarm 40201 "Synchronous operation tolerance of the gearing axis exceeded" is issued. The following axis changes to STOP mode.

The leading axis/external encoder responds with an error. The alarm 40110 "Error triggered on slave during synchronous operation (error number: ...) is signaled. The master object enters the STOP state.

- The local following axes also change to STOP mode.
- However, distributed synchronized axes continue to follow the master setpoint if measures are not taken in the user program to initiate an appropriate response to this error response.

Note

With V4.2 and higher, an error message is also output on the master object when the following axis disconnects the synchronous coupling for any reason in the event of an error.

For additional information, see Synchronous operation monitoring (Page 2687).

Menus

Synchronous Operation - Menu

Grayed out functions cannot be selected.

Table 4-316 You can select the following functions:

Function	Meaning/Note
Close	Use this function to close the active window in the working area.
Properties	Properties displays the properties of the synchronous object selected in the project navigator. You can enter the object name plus author and version in this window.
Configuration	This function opens the configuration for the synchronous object selected in the project navigator. Assign the master values and cams to the following axis in this window.
Expert List	This function opens the expert list for the synchronous object selected in the project navigator. The configuration data and system variables can be displayed and changed in this list; see Basic functions - Expert list.
Default setting	This function opens the default settings for the synchronous object selected in the project navigator. In this window, you define the replacement values for calling synchronous operation functions (**_enableGearing**, **_enableVelocityGearing**, and **_enableCamming** or **_disableGearing**, **_disableVelocityGearing**, and **_disableCamming**).
Settings	This function opens the settings for the synchronous object selected in the project navigator. You can define some synchronization settings in this window.
Interconnections	This function opens the interconnections for the synchronous object selected in the project navigator. You can see the inputs of the axis in this window.
Expert	This function opens the submenu for the expert settings.
Configure units	This function opens the Configure units of the object window in the working area. You can configure the units used for the selected object here.

4.7.3 Part II - Distributed Synchronous Operation

4.7.3.1 Overview of distributed synchronous operation

This chapter describes the **Distributed Synchronous Operation** function (V3.0 and higher). It introduces you to the operating principle and provides information about the technological supplementary conditions as well as the operating characteristics of distributed synchronous operation. You are shown how to create and configure a distributed synchronous operation.

Function overview

The **Distributed synchronous operation** functionality allows you to create a master value source and a synchronized axis on different controls. In a project, it is possible to form function groups and thus a machine structured on a modular basis. Synchronized axes no longer need to be present in a single control, but can instead be distributed among several controls.

Isochronous (clock-synchronized) bus coupling

The coupling between the master axis (or the external encoder) and the following axis is performed using an isochronous bus coupling between the controls, via PROFIBUS DP or PROFINET IO with IRT.

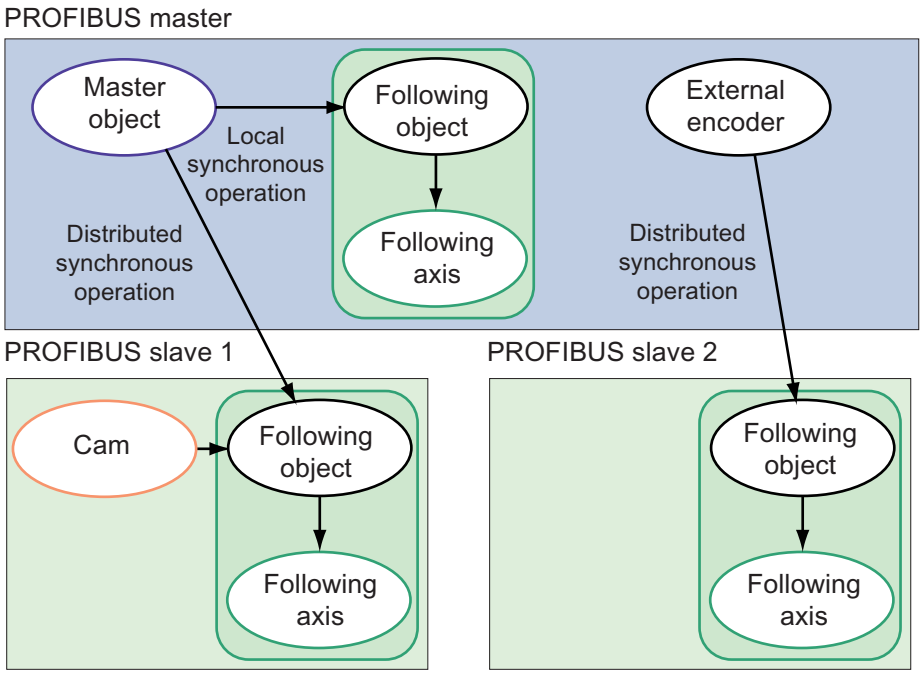

Figure 4-730 Distributed synchronous operation using PROFIBUS DP as an example

Synchronizing the bus interfaces

The DP/PN interfaces must be synchronized with each other for distributed applications using the isochronous PROFIBUS or PROFINET IO with IRT.

Information on this subject is available in the **Motion Control Basic Functions for Modular Machines** Function Manual and the **Communication** Configuration Manual.

Application

You can use distributed synchronous operation to create function groups in your project and set up a machine on a modular basis. Instead of having to use the same control system to control synchronously operating axes, you can now distribute the axes across a number of modules.

Operating principle/Compensation

With distributed synchronous operation, the interpolator cycle clocks of the master object and the following axis may be offset. As a result of the communication required, there is also an offset in the calculation of related signals (master value source and remote following axis).

The cycle clock offset can be compensated using the following measures:

- Compensation on the master value side by means of setpoint output delay
- Compensation on the slave value side by means of master value extrapolation

See Compensations for distributed synchronous operation (Page 2767).

4.7.3.2 Fundamentals of Distributed Synchronous Operation

Boundary Conditions

Rules for the communication/topology for distributed operation using PROFIBUS

The following rules apply for the PROFIBUS topology with distributed synchronous operation:

- Distributed synchronous operation is only possible via equidistant master/slave communication.
- The leading axis or external encoder must be located in the PROFIBUS master, and the distributed following axis must be located in the PROFIBUS slave.
  Further local synchronizations with the master control are possible.
- Distributed synchronous operation can only be created on one PROFIBUS level.
  Consequently, cascaded distributed synchronous operation is not possible.
- Different IPO cycle clocks and position control cycle clocks can be used in the SIMOTION devices involved.
- The same DP cycle clock must be used in the SIMOTION devices taking part in the distributed synchronous operation.

Exception: See **Cycle clock scaling for SIMOTION D** in this chapter

Data transmission for distributed synchronous operation using PROFIBUS

A total of 24 bytes are transmitted and received via the PROFIBUS interface for each synchronous operation connection and cycle clock (bi-directional connection for synchronous operation data). Only a certain amount of data can be transmitted in each DP cycle for each master-slave connection (a maximum of 244 bytes can be sent and received). This also enables a maximum of 10 connections with 24 bytes each. In addition, the amount of data in the PROFIBUS master is limited to 1 Kbyte for inputs and 1 Kbyte for outputs per PROFIBUS interface, irrespective of the number of devices connected; in other words, 40 connections are theoretically possible.

In addition to the transmitted data, the following must be noted:

- Drive connection
- I/O connection
- Application Data

This limits the number of possible connections with distributed synchronous operation.

The system can be optimized. Instead of several distributed connections, for example, a virtual axis on the slave can first be coupled to a (real or virtual) master axis which then serves several following axes.

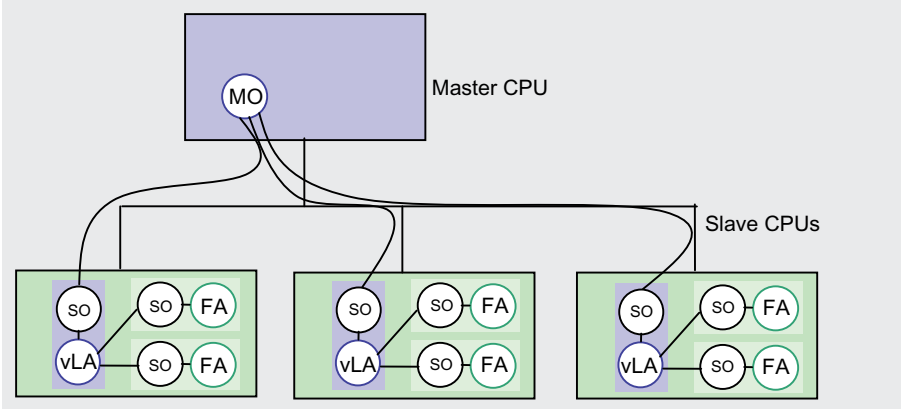

Figure 4-731 Example of optimizing connections using virtual master axes on slave devices

The virtual master axes on each slave allow axis groupings of the individual machine modules to also be operated "independently" (e.g. for the commissioning of individual modules).

Master-slave relationship

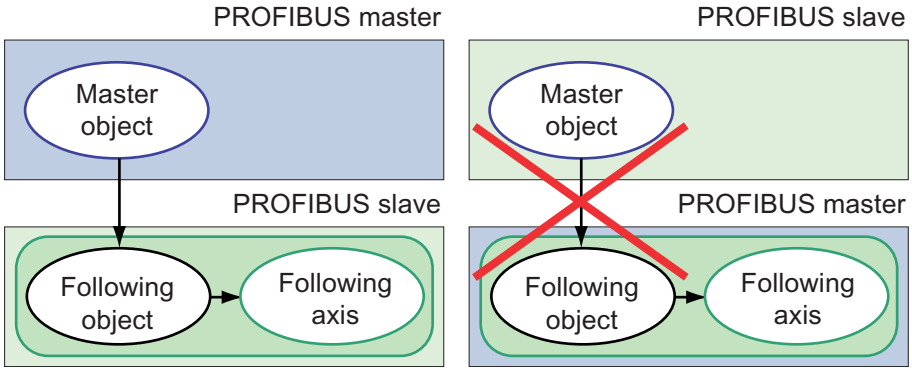

Figure 4-732 Master-slave relationship in distributed synchronous operation

Connection between axis and synchronous object

The synchronous object and, if appropriate, the cam must be located on the slave controller, together with the slave axis. The master value source (axis or external encoder) is always located on the master control.

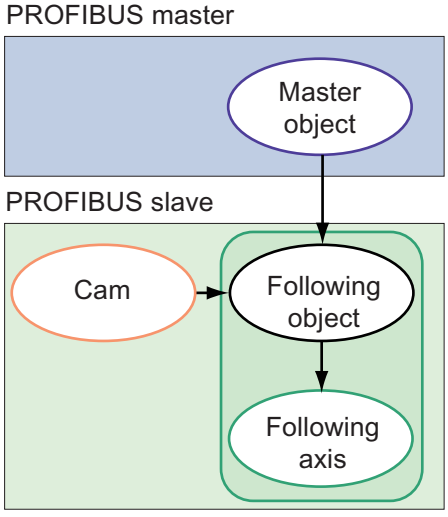

Figure 4-733 Following axis and synchronous object on the same control

Cascading

A distributed synchronous operation can be connected to following local synchronous operation on the slave controller.

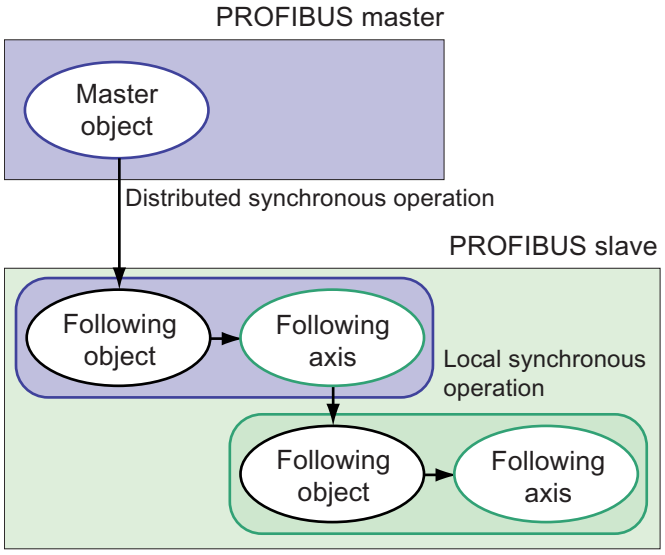

Figure 4-734 Cascading: distributed synchronous operation to following local synchronous operation

However, it is not possible to cascade two distributed synchronous operations one after the other, i.e. the following axis in distributed synchronous operation 1 cannot be used as the master axis in distributed synchronous operation 2. This is also true if the second PROFIBUS interface configured as a master is used.

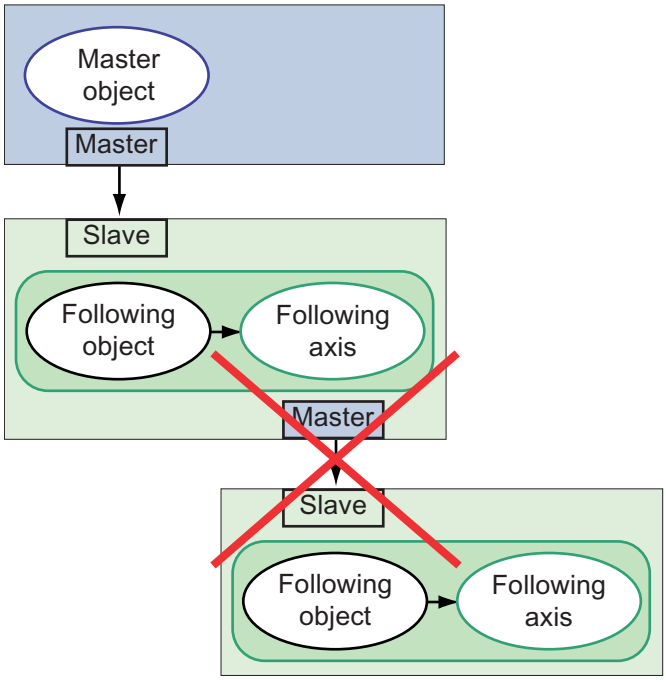

Figure 4-735 Distribution via one PROFIBUS level only

No feedback

It is not permitted to configure distributed synchronous operation from Device1 to Device2 and back again. This is true even if two appropriately configured PROFIBUS interfaces are used.

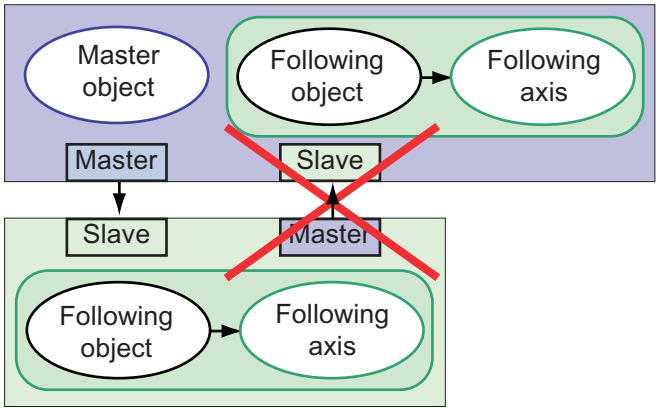

Figure 4-736 No feedback in distributed synchronous operation

Example hierarchy with synchronized isochronous PROFIBUS interfaces

The following is an overview of requirements for distributed synchronized operation:

All PROFIBUS connections:

- Must have the same DP cycle clock settings
  Exception: See **Cycle clock scaling for SIMOTION D** in this chapter
- Must have isochronous cycle clock settings
- Must have master and slave synchronization
  if a master and slave are used on the same device

- Distributed synchronous operation is only possible over one shared bus segment.
- Possible number of slaves: See **Data transmission for distributed synchronous operation using PROFIBUS** in this chapter

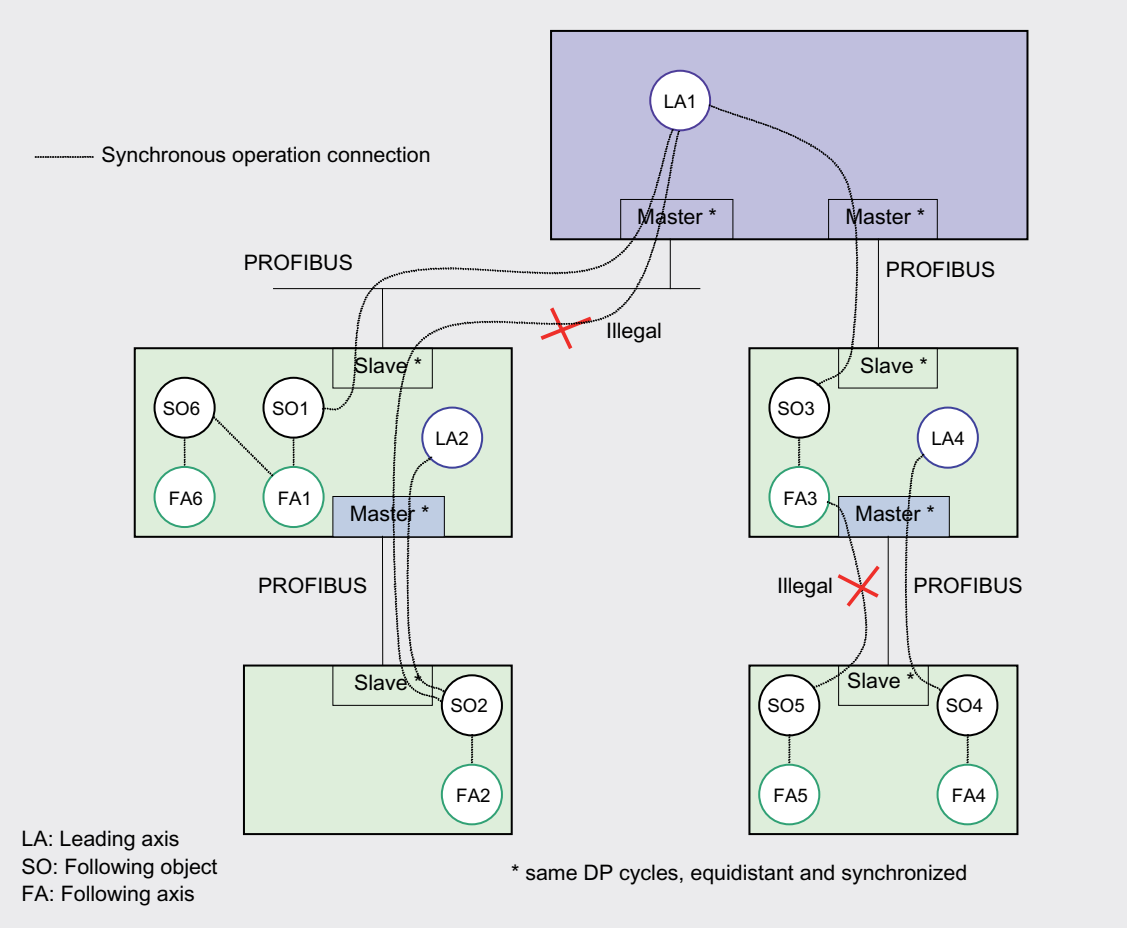

Figure 4-737 PROFIBUS topology: Hierarchy with synchronized isochronous PROFIBUS interfaces

Cycle clock scaling for SIMOTION D

With SIMOTION SCOUT V3.2 SP1 and higher, a distributed synchronous operation with cycle clock scaling between the two external DP interfaces (DP1/DP2) and the internal DP interface for SIMOTION D is possible.

If the master value changes only very slowly or the external DP interface requires a faster cycle time than the internal DP interface, a decoupling of the fast internal DP cycle from the slower external DP cycle is desirable.

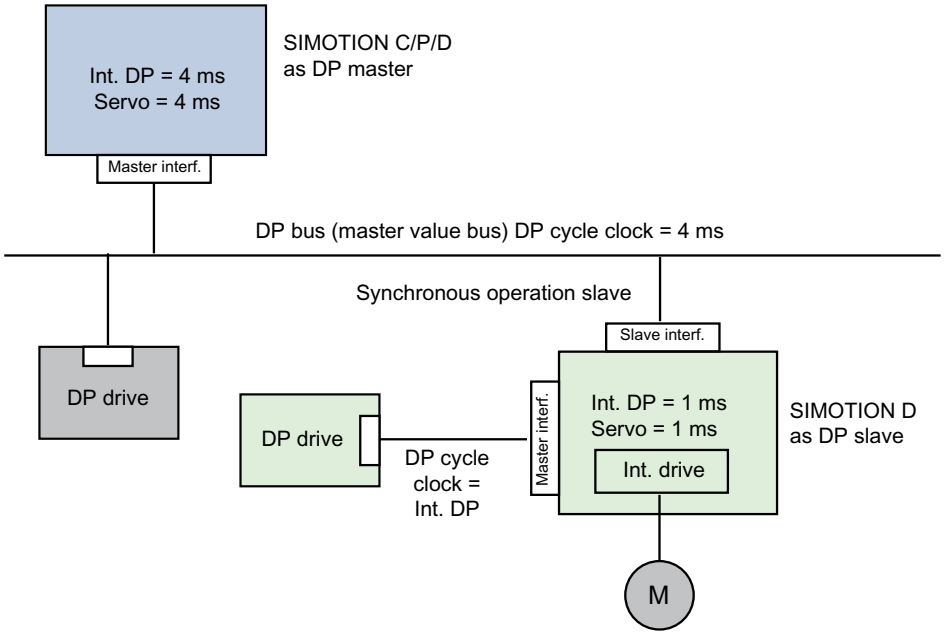

Figure 4-738 Cycle clock scaling for SIMOTION D

This is possible under the following boundary conditions:

- An external DP interface of SIMOTION D is used as an isochronous slave interface. Only in this case can an integer cycle clock scaling of isochronous external DP slave interface to internal interface be specified.
- For SERVO, IPO, and IPO_2, settings can be made for all permissible cycle clocks. The master axis and following axis can run on different IPO levels.
  The IPO cycle clock of the synchronous object, however, must be set equal to the cycle clock of the isochronous external DP slave interface (otherwise the error message "50205 - Offset cannot be determined" will be issued).
- In addition, the second external DP interface can be operated as isochronous master (the first is isochronous slave), for example, to operate external drives. In this case, the cycle clock must be the same as the cycle clock of the internal DP cycle.
- The second external DP interface can also be operated as a "non-isochronous, free-running interface". In this case, there is no effect on the cycle clock settings.
- The reduced cycle clocks of the external DP interfaces must be set in HW Config.
- For D4xx, DP to Servo reduction ratio is possible
- For D4xx-2, a DP to Servo reduction ratio is possible from V4.3 and higher
- A DP to Servo reduction ratio is generally only permissible if no PROFINET IO with IRT has been configured.

Rules for the communication/topology for the distribution using PROFINET IO with IRT (V4.0 or later)

Distributed synchronous operation between SIMOTION devices via PROFINET IO with IRT uses the controller-controller data exchange broadcast for PROFINET IO to exchange the synchronous operation data.

Differences to PROFIBUS

Regarding distributed synchronous operation with PROFIBUS, see **Rules for the communication/topology for distributed operation using PROFIBUS** in this chapter, the following differences exist:

- Master object and following axis / synchronous object can be located on any controllers. (PROFINET IO with IRT does not have any communications master and communications slave as for PROFIBUS.)
- Cascading of distributed synchronous operations is possible over more than one level.
- Recursive interconnection with PROFINET is possible (see Note)
  Note:
  slave value compensation via master value extrapolation is possible.
  Master value compensation by delaying setpoint output is not possible.

Note

For the following Control Units, a second Servo task is optionally available:
- SIMOTION D435-2 DP/PN (V4.3 and higher)
- SIMOTION D445-2 DP/PN (V4.2 and higher)
- SIMOTION D455-2 DP/PN (V4.2 and higher)
For further information, see *D4x5-2 Commissioning and Hardware Installation Manual and Basic Functions Function Manual*.

Compensations for distributed synchronous operation

In a distributed synchronous coupling, calculation of related signals between the master value source and the remote following axis is offset due to the distribution and the associated communication requirements. Compensation of this offset is supported by the system.

The following compensations are available in the system:

- Compensation on the master value side by means of setpoint output delay on the component that provides the master value for the distributed synchronous operation
- Compensation on the slave value side by means of master value extrapolation on the component containing the remote slave objects

Note

For distributed synchronous operation with extrapolation on the following axis, the **setpoint monitoring with jerk** setting is not appropriate.

The compensations are set and displayed via the system variable **distributedMotion**.

- The output delay is displayed on the leading axis.
- The master value delay is displayed on the synchronous object.
- The cycle clock offset is displayed on the synchronous object.

Sign-of-life monitoring is required for the compensation using master value extrapolation.

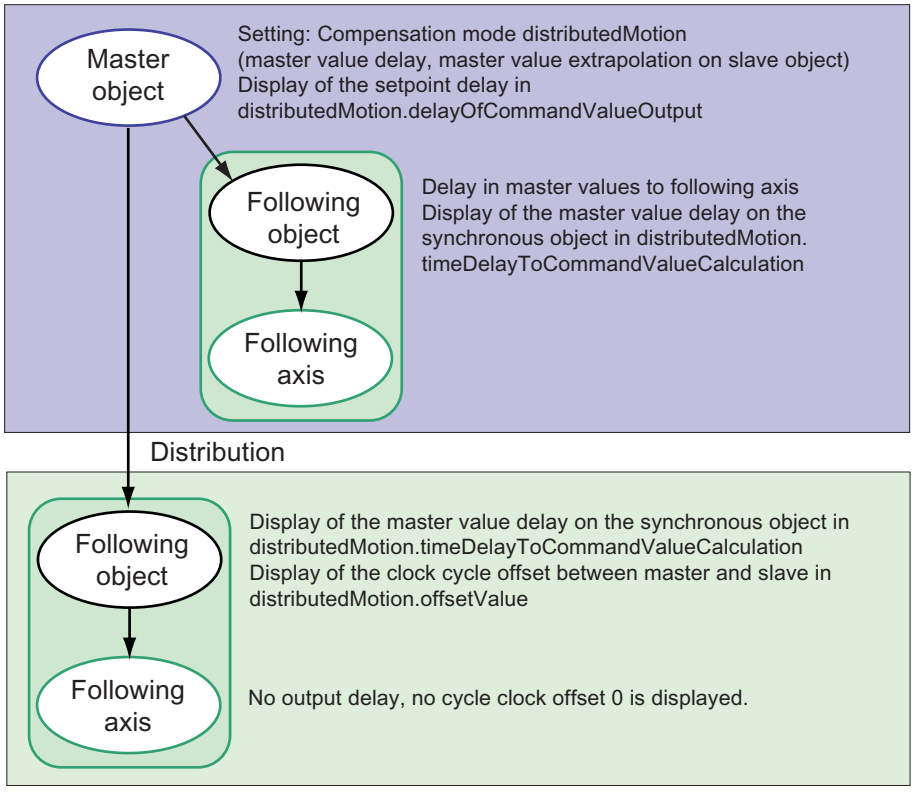

Figure 4-739 Overview: Compensations for distributed synchronous operation

Applications and results

- It is useful to activate a setpoint output delay on the master value side if, for example, synchronism of distributed synchronous operation is of primary importance and a rapid response on the master value side to local events is of lesser importance.
- It is useful to activate compensation on the slave value side by means of master value extrapolation without a setpoint output delay on the master value side if, on the master side, the master values and slave values need to be output without a delay due to a short response time, for example, and if, on the slave side, synchronism or a secondary error resulting from the larger extrapolation range is permissible.

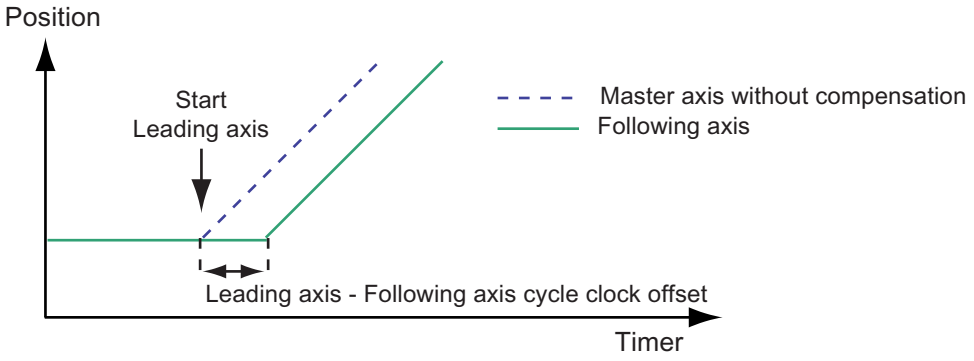

Figure 4-740 Distributed synchronous operation without setpoint output delay on the leading axis side and without compensation on the following axis side

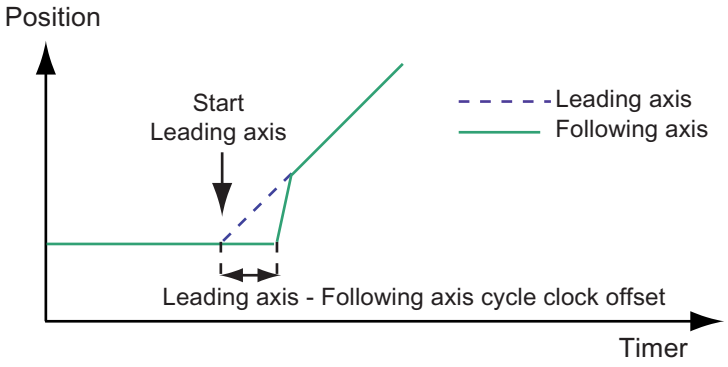

Figure 4-741 Master value extrapolation on the slave value side without setpoint output delay on the master value side

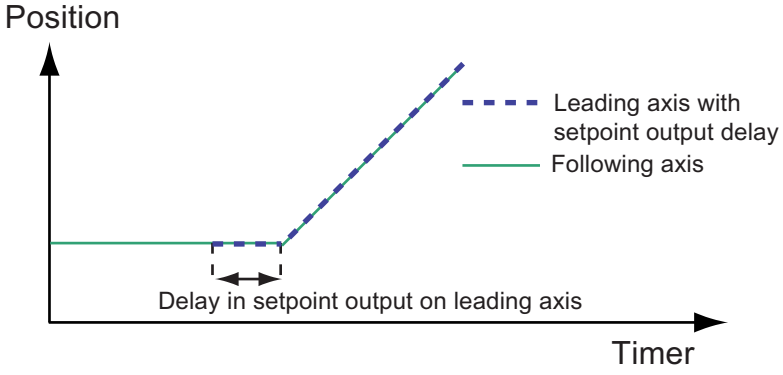

Figure 4-742 Setpoint output delay on the leading axis side

Activating

- When output delay on the master value side is activated, the signal output on the master value side is delayed by the calculated IPO clock cycles and any resulting IPO phase offset is compensated by means of interpolation on the slave value side.
- When master value extrapolation on the slave value side is activated without output delay on the master value side, the total cycle clock offset between the master value calculation and the slave value calculation is compensated for by means of the master value extrapolation on the slave value side.

Scope

- The setpoint output delay on the master value side is applicable to the following:
  - Axis setpoints calculated directly on the leading axis that are delayed on the axis prior to being passed on to the servo
  - Axis setpoints calculated by local synchronous objects; the synchronous object forwards the calculated setpoints to the axis
- Compensation on the slave value side by means of interpolation/extrapolation takes place on the master value of the remotely interconnected synchronous object.

See also

Compensation on master value side by means of setpoint output delay (Page 2770)

Compensation of the slave value side by means of master value extrapolation (Page 2772)

Permissible combinations for cycle clock offset compensation in distributed synchronous operation (Page 2773)

Cycle clock offset calculation using a command (Page 2774)

Compensation on master value side by means of setpoint output delay

Compensation on the master value side by means of setpoint output delay of the distributed synchronous operation will be activated for the master object.

Compensation on the master value side results in the following:

- The output of setpoints calculated for the axis, delayed by "n" IPO cycle clocks, to the servo/ position controller of the axis
- The output of setpoints from a local synchronous object interconnected with the master axis or external encoder, delayed by "n" IPO cycle clocks, to the interconnected synchronized axis

The number of IPO cycle clocks is calculated from the maximum cycle clock offset across all distributed synchronous relationships with the master value source. The number of IPO cycle clocks (integer), which contains the total delay, is calculated.

When compensation on the master value side by means of setpoint output delay is deactivated, setpoints are output to the axis and the master value is forwarded to and evaluated on local synchronous objects without delay.

Activating compensation on the master value side by means of setpoint output delay

Master value compensation by delaying setpoint output is activated using the following configuration data on the master axis and/or an external encoder:

- **(TypeOfAxis.)distributedMotion.enableOffsetCompensation:=YES**: Calculation of offset is activated
- **(TypeOfAxis.)distributedMotion.enableDelayOfCommandValueOutput:= YES**: Compensation on master value side is activated Delay to setpoint output on master value side, simultaneous start and no overshoots. The local following axis also has a delayed start. Disadvantage of "YES": There is less likely to be a response to an event on the master. When activated, a setpoint output delay on the axis is always effective.
- **enableDelayOfCommandValueOutput:= NO** is used to deactivate compensation on the master side. The master immediately outputs the setpoint value.

When activated, a setpoint output delay on the axis is always effective.

Cycle clock offset calculation

The system automatically calculates the maximum cycle clock offset after a transition from **STOP**/ **STOPU** to **RUN**. Cycle clock offset calculation also runs after one of the axes or an external encoder involved has been restarted and after disconnection/reconnection. The status of the cycle clock offset calculation is indicated in the **distributedMotion.stateOfOffsetCalculation** system variable on the master axis and on the remote distributed synchronous object. The cycle clock offset is not yet determined for status **INVALID**, the cycle clock offset cannot be determined. The master axis/external encoder issues the technological alarm "40304 Offset cannot be determined".

Compensation on the master value or slave value side requires that offset calculation be activated in configuration data element **(TypeOfAxis.)distributedMotion.enableOffsetCompensation**, on the master axis or external encoder.

setpoint output delay

The absolute value of the setpoint output delay can be read out by means of the **distributedMotion.delayOfCommandValueOutput** system variable on the master axis.

The time is indicated in the **distributedMotion.timeDelayToCommandValueCalculation** system variable on the synchronous object of the remote following axis.

The status of the setpoint output delay is indicated in the **distributedMotion.stateOfDelayValue** system variable on the master axis or external encoder and on the remote synchronous object.

- If the status is **INVALID**, the setpoint output delay is not activated.
- If the status is **VALID**, the setpoint output delay is active.

The maximum permissible delay for setpoint output is 10 interpolation cycle clocks. If the delay exceeds this, two alarms are output on the master value axis or external encoder: "40124 Offset cannot be compensated" and "40125 Setpoint output delay on the master side is deactivated."

If a local interconnected synchronized axis is acting as the master value for a distributed synchronous operation, the same setting in terms of the effective compensations on the master value side should be made on the first master value and on the local synchronized axis.

Compensation of the slave value side by means of master value extrapolation

When compensation on the master value side by means of setpoint output delay is not activated, the compensation on the slave value side performs a linear extrapolation using the two most recent master values received in order to compensate for the cycle clock offset.

In the event that master values are lost, the two most recent master values received are used for the extrapolation.

Activating compensation on the slave value side using master setpoint extrapolation

Slave value compensation (interpolation/extrapolation) is activated using the following configuration data on the master axis and/or an external encoder:

- **(TypeOfAxis.)distributedMotion.enableOffsetCompensation:=YES**: Calculation of offset is activated.
- **(TypeOfAxis.)distributedMotion.enableDelayOfCommandValueOutput:= NO**: Compensation on master value side is deactivated.

Display of setpoint output time delay on the master value side

The setpoint output delay time on the master value side is indicated in the **distributedMotion.timeDelayToCommandValueCalculation** system variable on the synchronous object. This delay time is generally greater than the offset calculated across all remote synchronous relationships.

The **distributedMotion.timeDelayToCommandValueCalculation** system variable on the remote synchronous object corresponds to the **distributedMotion.delayOfCommandValueOutput** system variable of the associated master value object.

Status of calculation of compensation on the slave value side

The status of the compensation calculation on the slave value side is indicated by means of the **distributedMotion.stateOfOffsetCalculation** system variable on the synchronous object as well as on the master value source/master axis.

Cycle clock offset calculation

The system automatically calculates the maximum cycle clock offset after a transition from **STOP**/ **STOPU** to **RUN**. Cycle clock offset calculation also runs after one of the axes or an external encoder involved has been restarted and after disconnection/reconnection. The status of the cycle clock offset calculation is indicated by means of the **distributedMotion.stateOfDelayValue** system variable on the synchronous object as well as on the master value source.

If a command is transmitted to the synchronous object before completion of the cycle clock offset calculation, a technological alarm is output ("50204 Offset calculation is active"). If the cycle clock offset cannot be calculated, the synchronous object outputs a technology alarm ("50205 Offset cannot be calculated").

Cycle clock offset between master value calculation and slave value calculation

The clock cycle offset between the master value calculation and slave value calculation is indicated on the synchronous object by means of the **distributedMotion.offsetValue** system variable. The cycle clock offset displayed does not depend on the output delay on the master value side.

Comment:

- All system variables on the master value source indicate the status or the respective value across all interconnected following axes.
- All system variables on the synchronous object indicate the status or the respective value for the interconnection with the current master value source.

Permissible combinations for cycle clock offset compensation in distributed synchronous operation

The compensation settings are made on the master value side (on the master control) using configuration data elements **(TypeOfAxis.)-distributedMotion.enableDelayOfCommandValueOutput** and **(TypeOfAxis.)distributedMotion.enableOffsetCompensation**.

The following combinations are possible:

Table 4-318 Permitted settings of compensation on the master value side and slave value side (setting on the leading axis or external encoder)

enableOffset Compensation	enableDelay OfCommand ValueOutput	
NO	**NO**	No compensation activated
NO	**YES**	Not permitted. An output delay on the master value side without interpolation on the remote following axis is not permitted.
YES	**NO**	Linear extrapolation in the following axis on the last two master setpoints using the cycle clock offset
YES	**YES**	Leading setpoint output delay in the local following axis, linear interpolation in the following axis of the master setpoints transmitted using the cycle clock and phase offset

Cycle clock offset calculation using a command

The cycle clock offset calculation can be initiated explicitly (V4.1 and higher), for example, when adding an axis for modular machine concepts.

The cycle clock offset can be calculated on the leading axis with the **_enableDistributedMotionDelayValueCalculation** command. This command acts on the master value and all cascades below it for which this master value applies in its cascade. Active synchronous operation commands are aborted when the offset calculation is started. If there are multiple master values at the top level, the command must be called on each object.

Rules for the communication/topology for the distribution using PROFINET IO with IRT (V4.0 or later) (Page 2766)

Operating axes with distributed synchronous operation

Sign-of-life monitoring

The master axis/external encoder and the remote synchronous object exchange signs of life to provide confirmation that the application is running correctly on the other side. For example, a distributed synchronous operation connection can be adversely affected by a fault on the bus (such as, message frame repetition).

Life-sign monitoring is implemented in the form of one life-sign counter in the master axis/external encoder and the synchronous object for each distributed synchronous operation. The process could be described as a "clock comparison". The sign of life is sent from the synchronous object to the master axis/external encoder and vice versa (bidirectional sign-of-life monitoring).

The life-sign counters are incremented on the source side in each IPO cycle clock, and the current value is transmitted to the relevant partner, where it is compared to an expected value. If the life-sign counter values differ from the expected values, an error will be output. Life-sign monitoring is only active if both SIMOTION devices are in **RUN** mode.

Note

A life-sign failure is not the same as an interrupted connection. The life-sign failure occurs if the life-sign is not received by the communication partner. This is the case with IPO overflow, for example. The connection is interrupted when the two communication partners are physically separated from one another. Further information can be found under "Connection interruption" in this chapter.

Failure limit

A parameter can be assigned to permit the life-sign to fail "n" times before an error response is output. This is set using the **(TypeOfAxis.)DistributedMotion.numberOfLifeSignFailures** configuration data (default: **1**).

The failure limit can be set on the leading axis or external encoder and on the following axes.

Extrapolation in the event of a failure

If a sign of life (and therefore also the master value) is absent and no error response is triggered (n > 0), the last available master setpoint is extrapolated.

Error reaction

An error response is triggered if the number of failures exceeds the parameterized value "n". The life-sign error is indicated on the following axis and the leading axis/external encoder. Consequently, the error reaction is applied to both of the following:

- **Leading axis/external encoder**: **40301** Loss of slave connection to the distributed control in the distributed synchronous operation
- **Following axis**: **50201** Loss of connection on the assigned control to the master in the distributed synchronous operation

Activating/deactivating life-sign monitoring

Life-sign monitoring can be enabled/disabled using the **(TypeOfAxis.)distributedMotion.enableLifeSignMonitoring** configuration data element on the master axis/external encoder and the synchronous object (default: **YES**).

Status signal

Life-sign monitoring must be activated on all participating objects or deactivated on all participating objects. If this is not the case, a technological alarm is issued on the master axis/external encoder or synchronous object to indicate that life-sign monitoring has been deactivated:

- **Leading axis/external encoder**: **40302** Life-sign monitoring for slave deactivated in distributed synchronous operation
- **Following axis**: **50202** Life-sign monitoring for master deactivated in distributed synchronous operation

The **distributedMotion.lifeSignError** system variable on both the leading axis/external encoder and synchronous object can be used to check whether life-signs have failed. When life-sign monitoring is activated, the assigned tolerated life-sign monitoring failures in **(TypeOfAxis.)DistributedMotion.numberOfLifeSignFailures** must be identical.

Connection interruption

If there is no axis error as subsequent error of synchronous operation monitoring, the following steps must be complied with in the event of a connection interruption:

- The connection must be physically restored.
- Wait with the program execution until the offsets have been exchanged and the setpoint output delay has been calculated (see System variables **stateOfOffsetCalculation**, **stateOfDelayValue**).
- The synchronous operation must be enabled again.

Operating states

Please note that in order for distributed synchronous operation to function, the master CPU *and* the slave CPU must both be in **RUN** mode. The connection for distributed synchronous operation does not occur automatically unless both are in **RUN** mode.

Association with life-sign monitoring

If life-sign monitoring is *deactivated* (**(TypeOfAxis.)distributedMotion.enableLifeSignMonitoring** = **No**) and a transition occurs from **RUN** to **STOP**/**STOPU**, the master CPU outputs a technological alarm (life-sign error **50201**) to all connected slave CPUs.

Synchronization status

The following device-related system variables on the slave indicate the status of synchronization:

- **StateOfDpinterfaceSynchonization**: only relevant if DP of PROFIBUS is equidistant
- **StateOfDpSlaveSynchonization**: only relevant if DP of PROFIBUS is not equidistant

Direction reversal of the master value for the synchronization

A maximum master value reversal can be defined in the configuration data **syncingMotion.masterReversionTolerance** on the synchronous object (V4.0 and higher). Specifying a tolerance is particularly useful for a distributed synchronous operation, where master value noise for actual value coupling can cause a master value reversal due to extrapolation.

See Actual value coupling with tolerance window (Page 2651).

Error handling

During distributed synchronous operation, the following axis sends the "Synchronous operation tolerance exceeded" error to the master axis. With V4.2 and higher, an error message is also output on the master object when the following axis disconnects the synchronous coupling for any reason in the event of an error. The error transfer must be configured: By means of the synchronous operation monitoring wizard on the following axis of the slave or by means of the **TypeofAxis.GearingPosTolerance.enableErrorReporting** configuration data.

Other errors (e.g. if the following axis is unable to synchronize) are not communicated to the master object. It is recommended that the 4xxxx errors be sent by the application to the master via the bus.

In HW Config of the I-slave, for example, a byte can be added to the configuration created by the system. This means that the following axis can report every error to the master axis by means of an application.

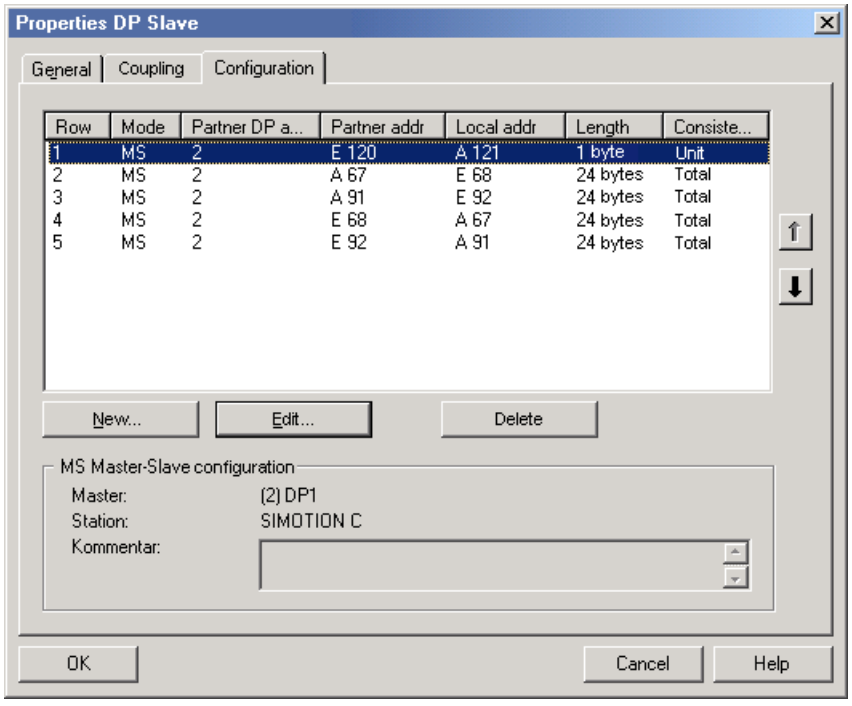

Figure 4-743 Configuration of an error byte for signaling the leading axis

See Error handling (Page 2754).

4.7.3.3 Distributed Synchronous Operation Configuration

This section describes how to create and configure SIMOTION devices and objects with distributed synchronous operation, and how to download them to the target system.

It is assumed that you have already created cams, master axes, or external encoders. A sample project for distributed synchronous operation can be found in the FAQ on the **SIMOTION Utilities & Applications DVD**.

To configure a distributed synchronous operation, you must carry out the following tasks:

- Creating SIMOTION devices with SCOUT (Page 2778)
- Creating connections with HW Config (Page 2778)
- Creating synchronous operation connections with SCOUT (Page 2780)
- Synchronizing the interfaces (Page 2784)
- Generating a synchronous operation configuration (Page 2783)
- Identify Possible error (Page 2783)

Creating SIMOTION devices with SCOUT

Creating a slave and master

In SIMOTION SCOUT, create two SIMOTION devices in your project:

- A SIMOTION device configured as a slave.
- A SIMOTION device configured as a master.
- Both SIMOTION devices must be connected and configured so that the HW Config can be compiled without errors.

Note

The SIMOTION devices must always be created with the same kernel version for the master and all slaves.

For exceptions, see information at Overview of distributed synchronous operation with different RT versions (Page 2822).

Note

Addresses entered by SIMOTION SCOUT for axis communication of distributed synchronous operations in HW Config may not be changed.

Creating connections with HW Config

Requirement

You have created a SIMOTION project containing two SIMOTION devices.

Creating connections using PROFIBUS

1. Set the "Operating mode" property for SIMOTION devices in HW Config. Open the "Properties" window at the relevant interface, e.g. DP/MPI. On the "Operating mode" tab, set one SIMOTION device to **DP Slave** and the second SIMOTION device to **DP Master**.
2. Set PROFIBUS addresses for both SIMOTION devices.
3. Set the DP mode to **DPV1** for both SIMOTION devices.
4. Insert a subnet master system on the PROFIBUS master.
5. Under **Properties**, set the transmission rate.
   For PROFIBUS communication, a transmission rate of **12 Mbit/s** is recommended.
6. Under **Options** in **Properties**, select **Equidistant bus cycle** and set the cycle time.
7. Check that the check box for **Programming, status/control or other PG functions and non-configured communication connection possible** under **Operating mode** in **PROFIBUS properties** for the slave has *not* been selected. Clear it if necessary.
   If the check box is selected, isochronous operation is *not* possible.
8. From the hardware catalog of **PROFIBUS DP**, **already configured stations**, add the **C23x**/**P3xx**/**D4xx ISlave** to the existing master system.

9. The DP slave which has already been configured is offered under Coupling. Use **Connect** to connect the slave to the master.

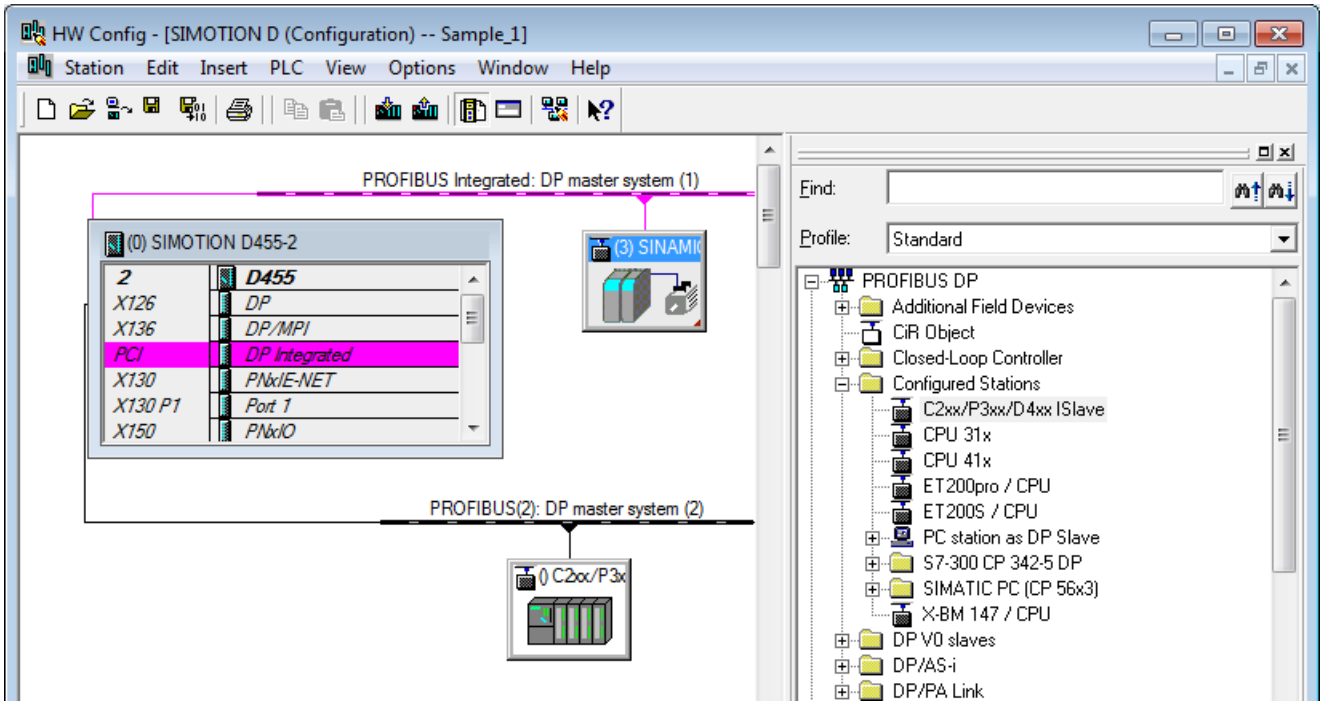

Figure 4-744 Device as PROFIBUS master

10. Establish a connection between the two devices (e.g. one byte for synchronization tasks between user programs on the devices); alternatively, you can ignore compilation errors in HW Config resulting from the absence of configured connections.
The connection is configured only once the axes on various devices in SIMOTION SCOUT have been interconnected.

Detailed information on cross-project distributed synchronous operation illustrated with an example configuration can be found in Section PROFIBUS communication configuration (Page 2788). You will find detailed information on communication configuration in SCOUT TIA in Section Communication between SIMOTION two controllers in the SIMOTION SCOUT TIA Configuration Manual.

Creating connections using PROFINET IO with IRT

The creation of a distributed synchronous operation connection requires that at least two IO controllers are connected with each other using IRT; a complete IRT configuration does not need to have been performed:

1. Set the IP addresses. Recommendation: fixed IP addresses
2. Create the two SIMOTION devices.
3. Configure the IRT operation by setting synchronization type **SyncSlave** for one of the devices and **SyncMaster** for the other device in HW Config.

This creates HW Config for distributed synchronous operation. The configuring of the axes and the interconnection of the axes is the same as for PROFIBUS.

Detailed information on cross-project distributed synchronous operation illustrated with an example configuration can be found in Section Communication configuration via PROFINET IO (Page 2799).

Saving and compiling in SIMOTION SCOUT automatically creates the data to be exchanged between the SIMOTION devices for the distributed synchronous operation.

Creating synchronous operation connections with SCOUT

Master axis/external encoder

1. Create the master axis or the external encoder (in the PROFIBUS master for the distribution using PROFIBUS).
2. Configure the master object (master axis/external encoder) using the wizard.

Following axis

1. Create a following axis (in the PROFIBUS slave if distribution is taking place via PROFIBUS). Make sure that **Synchronous operation** is activated as the technology when creating the following axis.

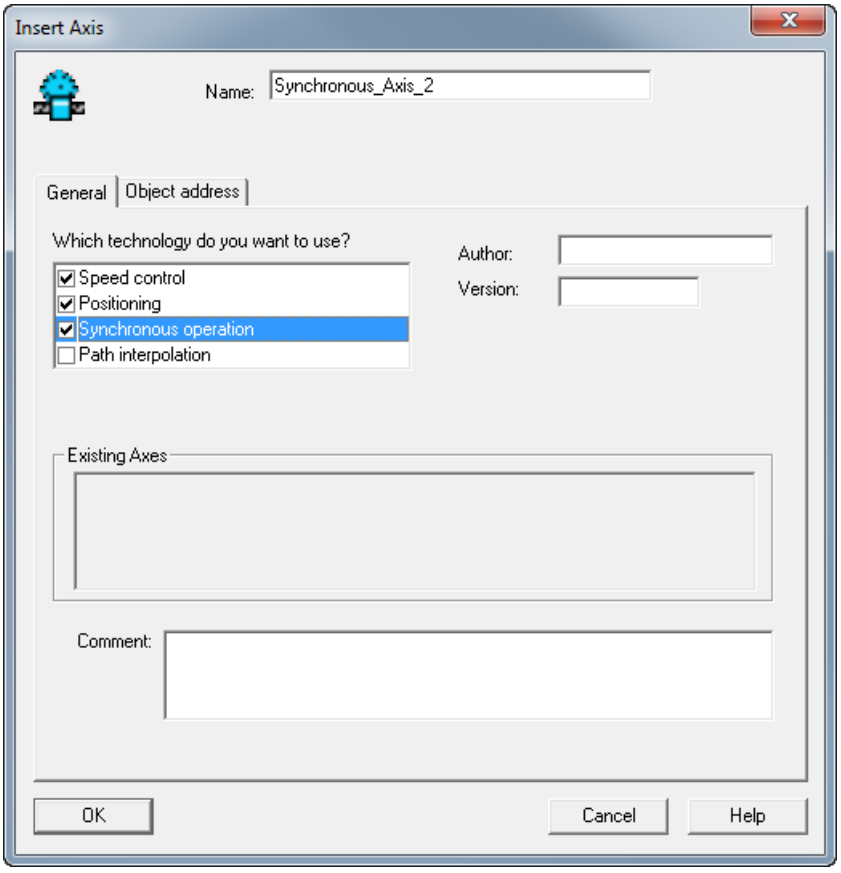

Figure 4-745 Inserting an axis with synchronous operation

2. Configure the following axis using the wizard.
3. Connect the synchronous object for the following axis to the master object (master axis/ external encoder) by selecting the master object under Interconnections.

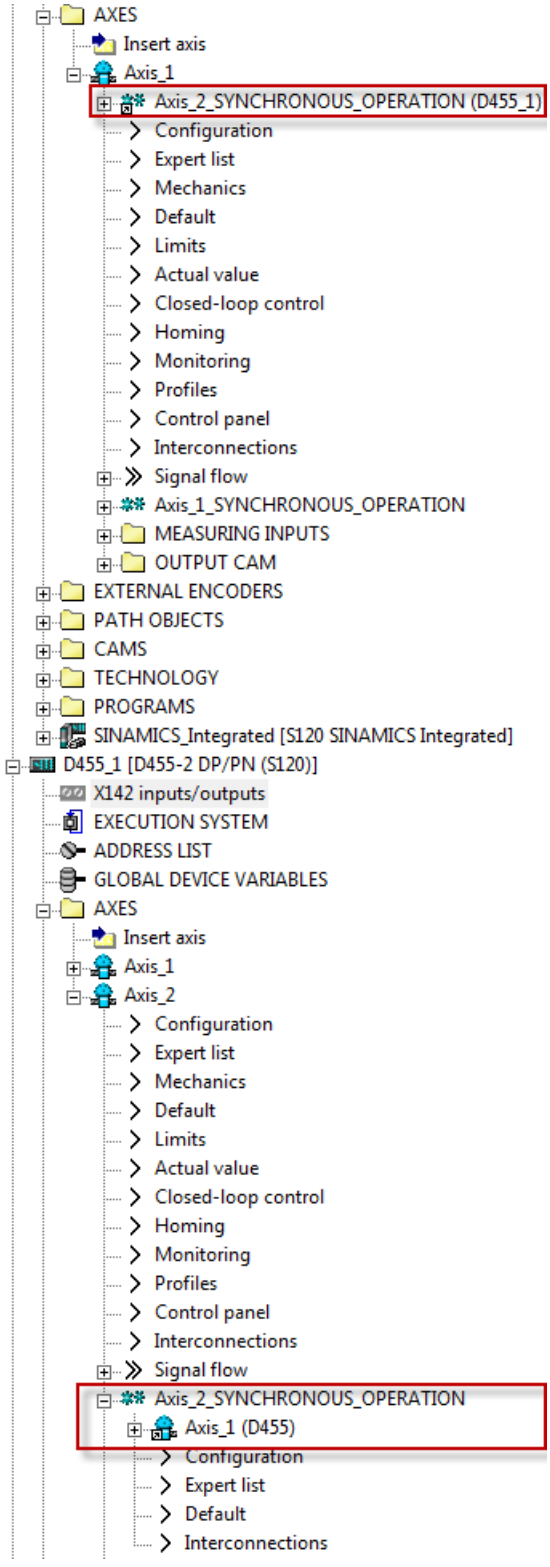

Figure 4-746 Distributed synchronous operation: Connecting a leading axis to a following axis

Generating a synchronous operation configuration

Compiling the project

Save the project via the menu **Project -> Save and compile changes**.

The system automatically generates the PROFIBUS IO configuration data in HW Config for the 24 bytes of send and receive info for the distributed synchronous operation. The configuration is generated and checked for consistency. Both SIMOTION devices must be connected and configured so that the HW Config can be compiled with no errors.

Note

Only at this point can it be determined whether the network resources are sufficient. If they are not, an error message will be generated to this effect. The compilation process must be free of errors; otherwise, it will not be possible to download the project to the target system.

Downloading the project to the target system

Load the project to both SIMOTION devices, so that these are displayed consistently. The configuration for the synchronous operation is also transferred to the SIMOTION devices during loading.

Note

There is no mechanism integrated into the SIMOTION Kernel for checking the consistency of downloaded projects among multiple devices, e.g. during ramp-up. Consistent downloading can only be achieved by means of "Download" in SIMOTION SCOUT.

Possible error

I/O resources unavailable (PROFIBUS)

If the system detects that the required resources (number of bytes) are no longer available in the PROFIBUS I/O data, SCOUT will generate an error message during the compilation process.

Check resources

- Call the PROFIBUS **DP Properties** for the relevant slave in HW Config.

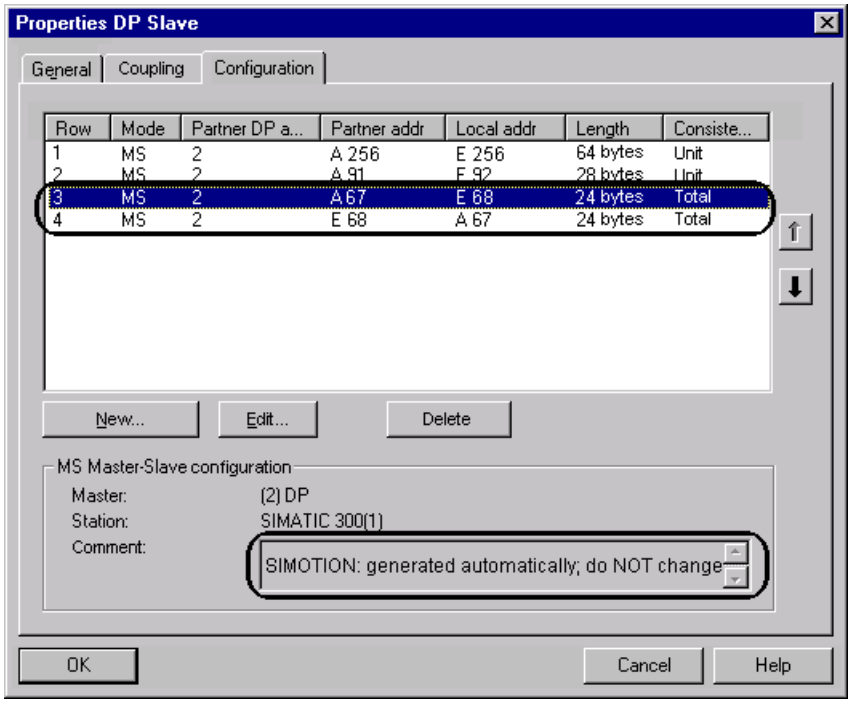

Figure 4-747 View of PROFIBUS resources with automatically generated entries

Note

Do *not* change or delete the entries in the I/O PROFIBUS configuration generated automatically by SIMOTION SCOUT. If you do, the distributed synchronous operation connection can no longer be used.

Faulty/incomplete configuration

If the system detects a fault in the configuration, SIMOTION SCOUT will output an error message during the compilation process.

4.7.3.4 Programming distributed synchronous operation

Synchronizing the interfaces

The interfaces are synchronized in the StartupTask for the slave by means of the **_enableDpInterfaceSynchronizuationMode** function call, either automatically by transferring the **dpInterfaceSyncMode** function parameter with the **AUTOMATIC_INTERFACE_SYNCHRONIZATION** option, or manually by transferring the **MASTER_SLAVE_ALARMMESSAGES_1** option.

If the **_enableDpInterfaceSynchronizationMode** function is called with the **MASTER_SLAVE_ALARMMESSAGES_1** option, the **_synchronizeDpInterface** function must be called at a later point in time to synchronize the interfaces.

If the "automatic" function is used and the connection is interrupted, the interface synchronizes itself automatically once the connection is restored.

If the "automatic" function is not used, the interface must be synchronized manually every time the connection is interrupted.

The **stateOfDpInterfaceSynchronization** = **DP_INTERFACES_SYNCHRONIZED** system variable on the slave indicates whether the two interfaces are synchronized.
Exception for SIMOTION C240:
If drives are connected to a SIMOTION C240 via the analog interface (onboard, e.g. for hydraulic applications), the synchronization is displayed via the **stateOfDpSlaveSynchronization = DP_INTERFACES_SYNCHRONIZED** system variable.
The interfaces must be synchronized to ensure error-free distributed synchronous operation.

Further information is available in the **Motion Control Basic Functions for Modular Machines** Function Manual.

Synchronous commands

If your commands include the object name of the master value source that is located on the other SIMOTION device, you must specify the name of this device as a prefix (e.g. D445.axis_1)

If you require data from technology objects that are located on the other device, you can use the application as a vehicle for this, by expanding synchronous operation communication between the devices.

See also the section titled *Error handling*.

Checking to determine whether the following axis is ready

When the distributed synchronous operation is to be started on the following axis (e.g. through **_enableGearing**), he application must ensure that the synchronized axis is ready.

Compensation on the following value side:

The following conditions must be met on the following axis if the following are activated on the master axis **TypeOfAxis.DistributedMotion.enableOffsetCompensation = YES** and

TypeOfAxis.DistributedMotion.enableDelayOfCommandValueOutput = NO:

- The **stateOfDpInterfaceSynchronization** system variable for the following axis must indicate **DP_INTERFACES_SYNCHRONIZED**.
- The **distributedmotion.stateOfOffsetCalculation** system variable for the synchronous object must indicate **valid**.

Compensation on the master value side:

The following conditions must be satisfied on the following axis if the following are activated on the master axis **TypeOfAxis.DistributedMotion.enableOffsetCompensation = YES** and **TypeOfAxis.DistributedMotion.enableDelayOfCommandValueOutput = YES**:

- The **stateOfDpInterfaceSynchronization** system variable for the following axis must indicate **DP_INTERFACES_SYNCHRONIZED**.
- The **distributedmotion.stateOfOffsetCalculation** system variable for the synchronous object must indicate **valid**.
- The **distributedMotion.stateOfDelayValue** system variable for the synchronous object must indicate **valid**.

No compensation:

When **TypeOfAxis.DistributedMotion.enableOffsetCompensation = NO** and **TypeOfAxis.DistributedMotion.enableDelayOfCommandValueOutput = NO** is activated on the master axis, the function is the same as for compensation on the following value side.

If this is not the case (for example, if **_enableGearing()** is executed on the following axis even though the master axis is not ready), the command is aborted with error "50102 Master is not assigned/configured or is faulty (reason: ..." aborted).

4.7.3.5 Configuring distributed synchronous operation across projects

Overview

As of V4.1, it is possible to configure a distributed synchronous operation across projects; this is carried out using proxy objects. The SIMOTION devices for the master object and the following axis are located in separate SIMOTION projects.

In each case, there is a proxy "External Synchronous Operation" technology object, which is assigned to the master axis, and a proxy "External Master Value" technology object, which is assigned to the slave axis. The external interface of the proxy technology objects is formed by means of coupling via I/O addresses. The network configuration must be set in HW Config. The send and receive data must be interconnected with one another. From the point of view of the runtime system, *distributed synchronous operation* and *cross-project distributed synchronous operation using proxy technology objects* are identical.

With regard to version requirements, see Overview of distributed synchronous operation with different RT versions (Page 2822)

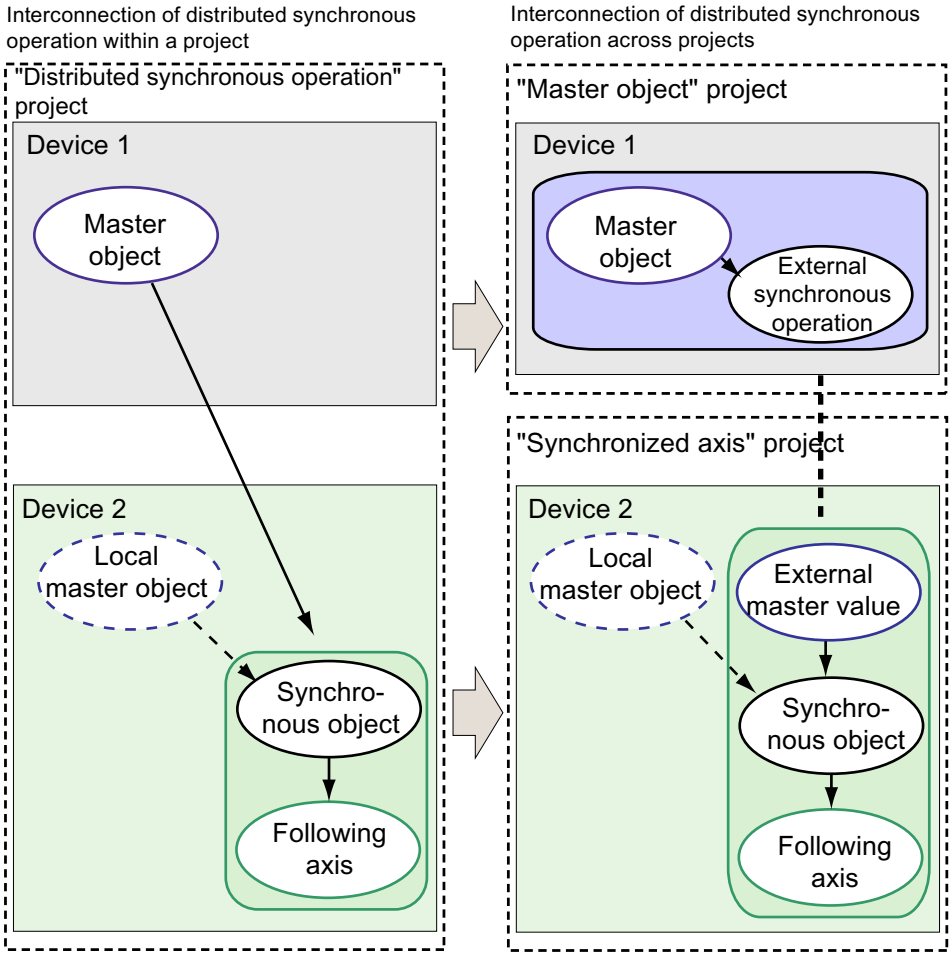

Figure 4-748 Configuration of a cross-project distributed synchronous operation

This figure shows the logical view of a synchronous operation interconnection. If the objects are located in the same project, the master object (master) and the synchronous object (slave) can be directly interconnected (see left-hand side of figure).

If the master object and synchronous object are in different SIMOTION devices that are not located in the same project, they must be interconnected using proxy objects. In each case, these represent the external object (see right-hand side of figure). External synchronous operation reflects the "transmitter master value," whereas the external master value reflects the "receiver master value."

This description uses the following terms:

Table 4-319 Terms used

Master/slave	PROFINET IO	PROFIBUS DP
Master object on	IO controller	DP master
Synchronous object on	I device	I slave

The description below uses an example to explain how communication is configured for cross-project distributed synchronous operation.

Communication configuration for PROFIBUS DP

The following steps need to be carried out for configuration using PROFIBUS DP:

- Create and configure a "synchronized axis" project; see Section Creating and configuring a "synchronized axis" project (Page 2789).
- Create and configure a "master object" project; see Section Creating and configuring a "master object" project (Page 2796).
- Create proxy objects; see Section Creating proxy objects (Page 2814).

Communication configuration for PROFINET

The following steps need to be carried out for configuration using PROFINET:

- Create and configure a "synchronized axis" project; see Section Creating and configuring "Synchronous axis" project on SIMOTION D455-2 (Page 2800).
- Create and configure a "master object" project; see Section Creating and configuring "Master Object" project on SIMOTION D455-2 (Page 2808).
- Create proxy objects; see Section Creating proxy objects (Page 2814).

Proxy objects (Page 2814)

PROFIBUS communication configuration

Communication via PROFIBUS DP

This section uses an example to describe how cross-project distributed synchronous operation is configured using PROFIBUS DP. You can adapt the project properties to suit your system requirements. Please note that you must set the entire PROFIBUS configuration. This example only refers to configuring cross-project distributed synchronous operation.

Introduction

If the SIMOTION devices are connected via PROFIBUS, data exchange takes place between a DP master and a DP slave. The SIMOTION device for the "master object" project is configured as the DP master and the SIMOTION device for the "synchronized axis" project is configured as the DP slave. In the "master object" project, in order to configure data exchange with the DP slave in the "synchronized axis" project the DP slave on the PROFIBUS line must be configured with the "GSD file" of the SIMOTION device.

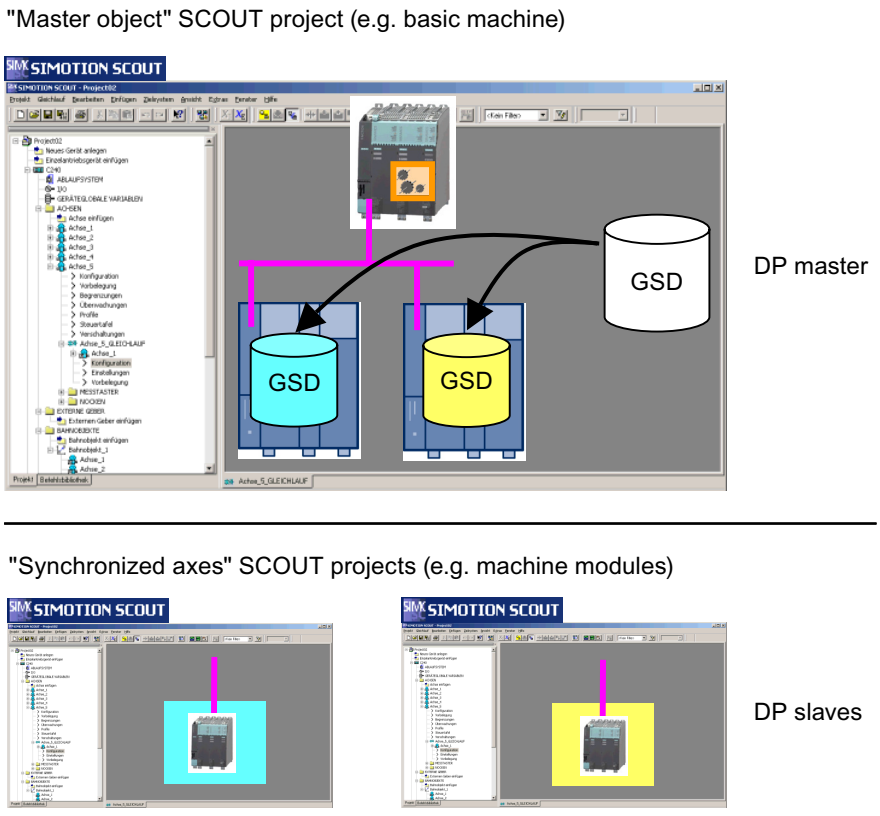

Figure 4-749 PROFIBUS DP: HW configurations of DP slaves via GSD

Creating and configuring a "synchronized axis" project

This description is just an example. You can adapt the project properties to suit your system requirements. In this example, communication takes place via PROFIBUS.

Creating a DP slave (project creation in SIMOTION SCOUT)

1. Open SIMOTION SCOUT and create a new project named "synchronous axis".
2. Double-click on "Add SIMOTION device" and add a SIMOTION D455-2 DP/PN V4.3.
3. Click "OK".
4. In the "Interface Selection - D455-2" window, select the "PROFIBUS DP1 (X126)" interface by clicking "OK" and click "OK" again to confirm.
   HW Config opens.

Configuration of the interface in HW Config

1. In the rack, double-click the "DP" interface.
   The "Properties - DP - (R0/S2.1)" window opens.
2. Click the "Properties..." button on the "General" tab.
   The "Properties - PROFIBUS interface DP - (R0/S2.1)" window opens. Address 2 is displayed as the default PROFIBUS address. Leave this setting unchanged.
3. Click the "New..." button in the "Subnet" area to create a subnet.
   The "Properties - New PROFIBUS subnet" window opens.
4. On the "General" tab, enter the name "Synchronous operation" at "Name".
5. Click the "Network settings" tab and set the recommended value of 12 MBit/s as the transmission rate.
6. Click "OK" to confirm your settings. You will then be in the "Properties - DP1 - (R0/S2.1)" window.

Setting DP slave

1. Click the "Operating Mode" tab and activate "DP Slave."
   Ensure that the option button "Programming, status/control or other PG functions and non-configured communication connection possible" is not activated, deactivate it if necessary. When the option is activated, no isochronous operation is possible.

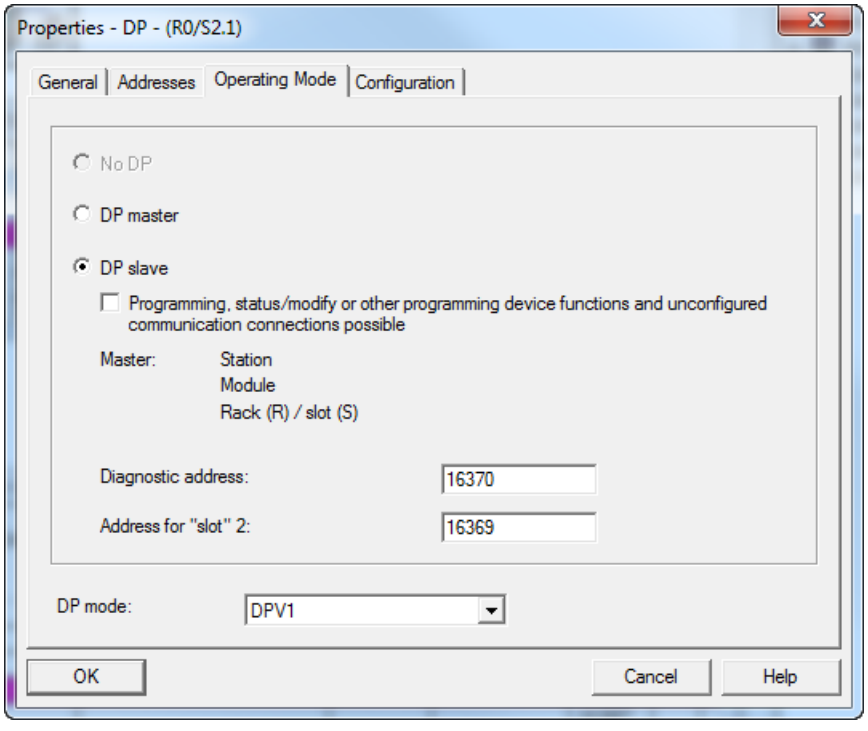

Figure 4-750 Setting the properties for the DP slave

2. Click the "Configuration" tab to create input and output addresses for communication.

3. Click the "New..." button.
   The "Properties - DP - (R0/S2.1) - Configuration - Line 1" window opens.
   Enter the following settings for the input data:
   - Address type: Input
   - Address: 256
   - Length: 12
   - Unit: Word
   - Consistency: Unit
   , and click "OK" to confirm your settings.

Note

In this example, you enter 256 as the first available address. If you have already configured other objects in the project, such as a drive, you will need to enter the first potentially available address.

Please note that you will need the set input and output addresses later when configuring the external master value in SIMOTION SCOUT.

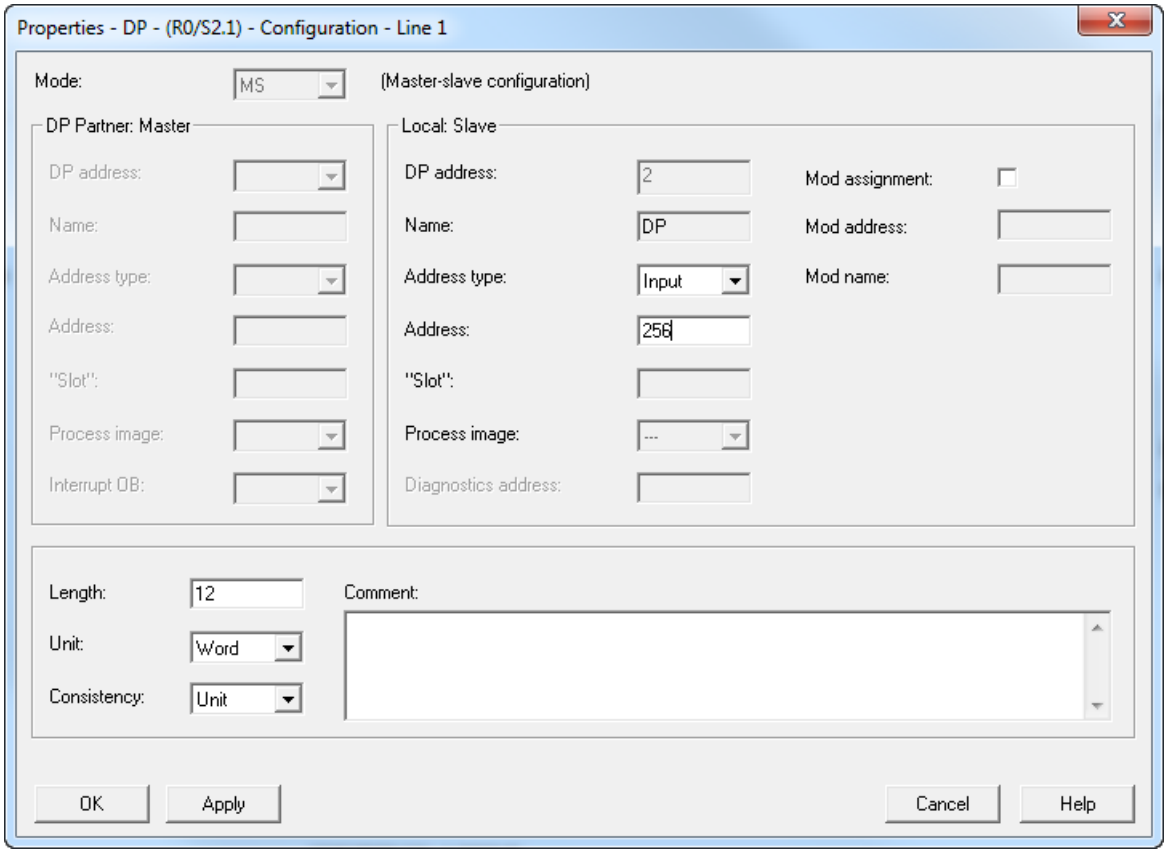

Figure 4-751 Configuring the input address on the slave

4. Click "New...".
   The "Properties - DP1 - (R0/S2.1) - Configuration - Line 2" window opens.
   Enter the following settings for the output data:
   - Address type: Output
   - Address: 256
   - Length: 12
   - Unit: Word
   - Consistency: Unit
   , and click "OK" to confirm your settings.

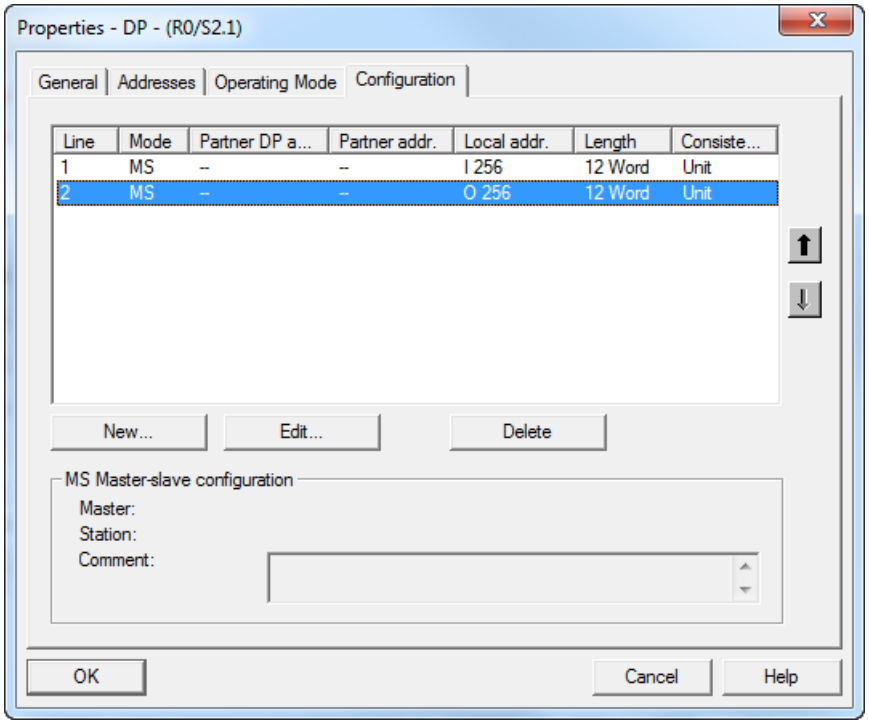

Figure 4-752 Configured input and output addresses on the DP slave

Note

Please also note that, in addition to the data for the synchronous operation, you may also want to transfer user data (communication between master and slave, such as project-specific control and status data for synchronous axes) and will, therefore, need to configure further lines with additional input and output addresses accordingly.

5. Click "OK" to confirm your settings, followed by the "Save" button.

In order to configure an isochronous PROFIBUS line, you must now use HW Config to create and configure a new station ("Dummy master") in the same project. This "dummy master" is only required to act as a proxy and does not have to be physically present.

Configuring the dummy master

It is recommended that you configure an S7 CPU as the master, so that the slave project remains clear and the dummy master is not visible in SIMOTION SCOUT.

1. Open or switch to HW Config of the DP slave.
2. In the HW Config menu bar, click "Station > New...".
   The "New" window opens. Enter "dummy master" as the object name and select the SIMATIC 300 station as the object type.

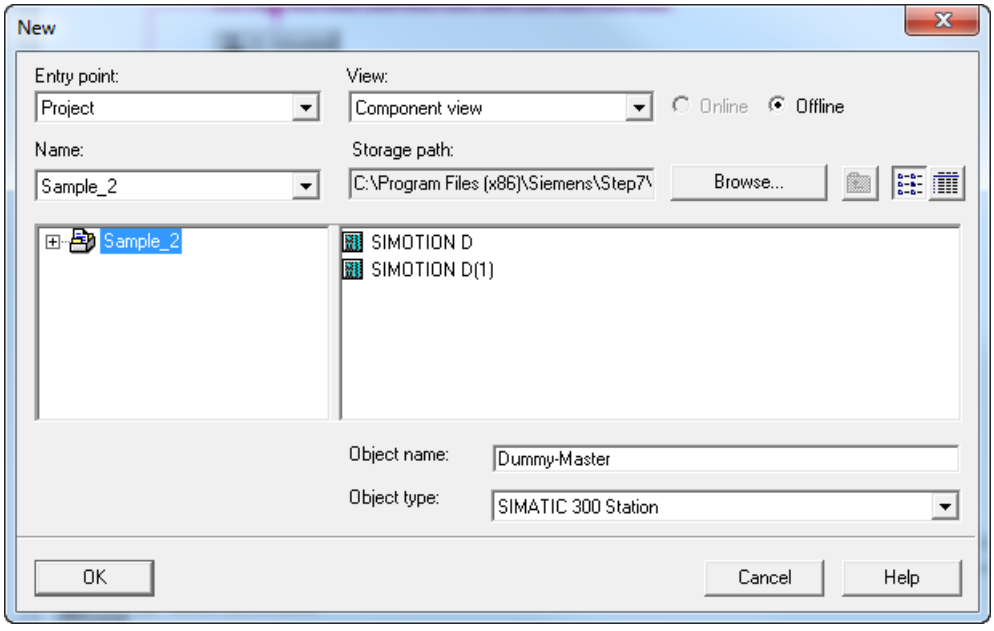

Figure 4-753 Creating a new station ("Dummy master") in HW Config

3. Click "OK" to confirm your settings. The new "Dummy master" station opens

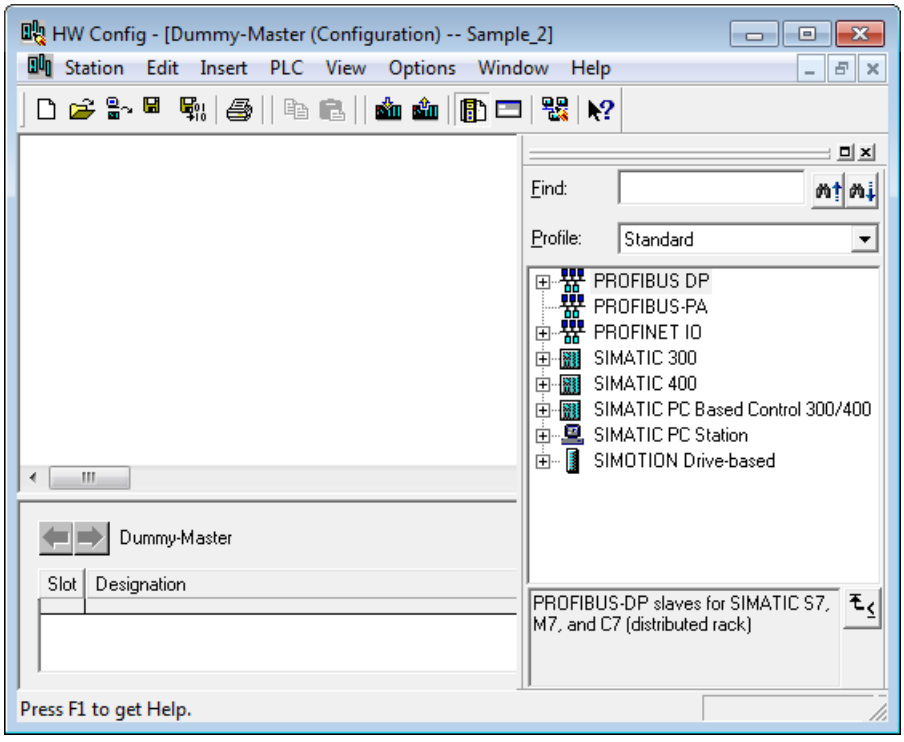

Figure 4-754 New station in HW Config

4. In the hardware catalog, open "SIMATIC 300 > RACK 300". Double-click the "Mounting rail". This is inserted in HW Config.

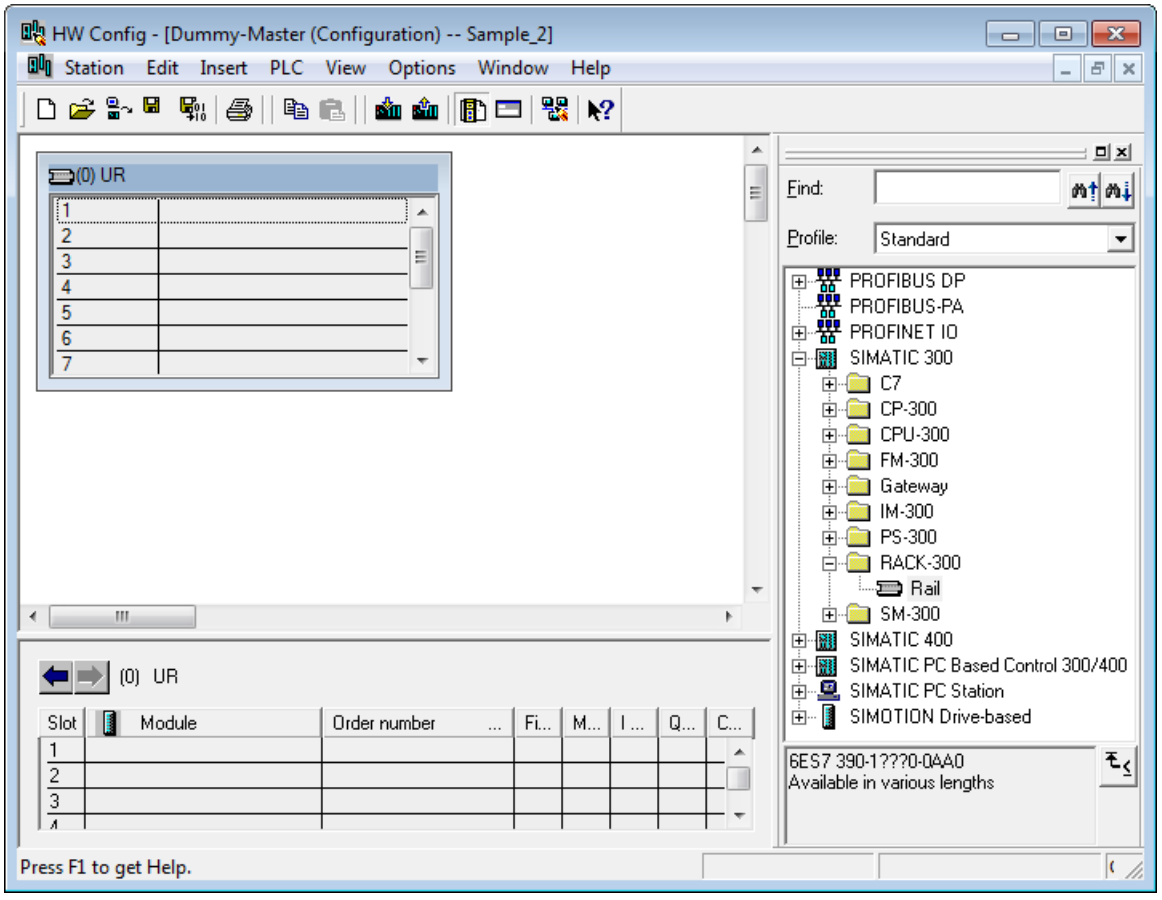

Figure 4-755 Inserting a mounting rail in HW Config

5. In the hardware catalog, open SIMATIC 300 > CPU 300 > CPU 316-2 DP > 6ES7 316-2AG00-0AB0. Select "V1.2" and move the module to its designated slot (highlighted in green) using drag-and-drop.
   The "Properties - PROFIBUS interface DP - (R0/S2.1)" window opens. It is not necessary to set the operating mode for the dummy master.
6. Select PROFIBUS address 3 as the address. The PROFIBUS address of the dummy master must be identical to that of the DP master in the "master object" project. You will create the "master object" project later.
7. Click "New...". The "New" window opens.
8. Click the "Network settings" tab and set the recommended value of 12 MBit/s as the transmission rate.
9. Click the "Options..." button. The "Options" window opens.
10. Activate the "Activate equidistant bus cycle" function and enter 3 ms for the "Equidistant DP cycle." This value must also be set later in the "master object" project.

11. Click "OK" to confirm your settings in the open window, followed by the "Save" button.
12. Switch to SIMOTION SCOUT and save the "synchronous axis" project.
    This concludes configuration of the DP slave communication in HW Config. The next step involves creating the "master object" project in SIMOTION SCOUT, see section Creating and configuring a "master object" project (Page 2796).

Creating and configuring a "master object" project

This description is just an example. You can adapt the project properties to suit your system requirements. In this example, communication takes place via PROFIBUS.

Creating a "Master object" project in SIMOTION SCOUT

1. Open SIMOTION SCOUT and create a new project named "Master Object."
2. Double-click on "Add SIMOTION device" and add a SIMOTION D455-2 DP/PN V4.3.
3. Click "OK".
4. In the "Interface selection - D435" window, select the "PROFIBUS DP1 (X126)" interface by clicking "OK" and click "OK" again to confirm.
   The HW Config opens.

Configuration of the interface in HW Config

1. In the rack, double-click the "DP" interface.
   The "Properties - DP - (R0/S2.1)" window opens.
2. Click the "Properties" button on the "General" tab.
   The "Properties - PROFIBUS interface DP - (R0/S2.1)" window opens.
3. Select the PROFIBUS address by putting 3 in the "Address" field. The address of the DP master must be identical to that of the dummy master in the "synchronous axis" project.
4. Click the "New..." button in the "Subnet" area to create a subnet.
   The "Properties - New PROFIBUS subnet" window opens.
5. On the "General" tab, enter the name "Synchronous operation" at "Name".
6. Click the "Network settings" tab and set the recommended value of 12 Mbit/s as the transmission rate, then click "Options".
   The "Options" window opens.
7. Activate the "Activate equidistant bus cycle" function and enter 3 ms for the "Equidistant DP cycle."
8. Click "OK" to confirm your settings in the open window.

Setting DP Slave

1. In the hardware catalog, open "PROFIBUS DP > Additional field devices > PLC > SIMOTION" and select "SIMOTION D4xx".
2. Using drag-and-drop, move "SIMOTION D4xx" (DP slave) to the "Synchronous operation: DP master system (2)" subnet. The "Properties – PROFIBUS interface SIMOTION D4xx" window opens.
3. Select PROFIBUS address 2 as the address and confirm the settings with "OK". This PROFIBUS address must be identical to that of the DP slave in the "synchronous axis" project.

4. Insert a 12-word module from the hardware catalog for the slave outputs first. Under "SIMOTION D4xx" in the hardware catalog, select the "Master_O Slave_I 12Wo/Unit" module and move it to its designated slot (highlighted in green) using drag-and-drop.

Note

Please note that the the inputs and outputs must always be configured in the opposite direction. An input slot must always go to an output slot (and vice-versa). That means that if the first slot is configured as an input in the "synchronous axis" project, then the first slot in the "master object" project has to be configured as an output. The length of configured inputs and outputs must always be identical.

The addresses for the inputs and outputs must lie above the first 64 bytes of the logic address area. You will need this address again later for configuring the proxy object.

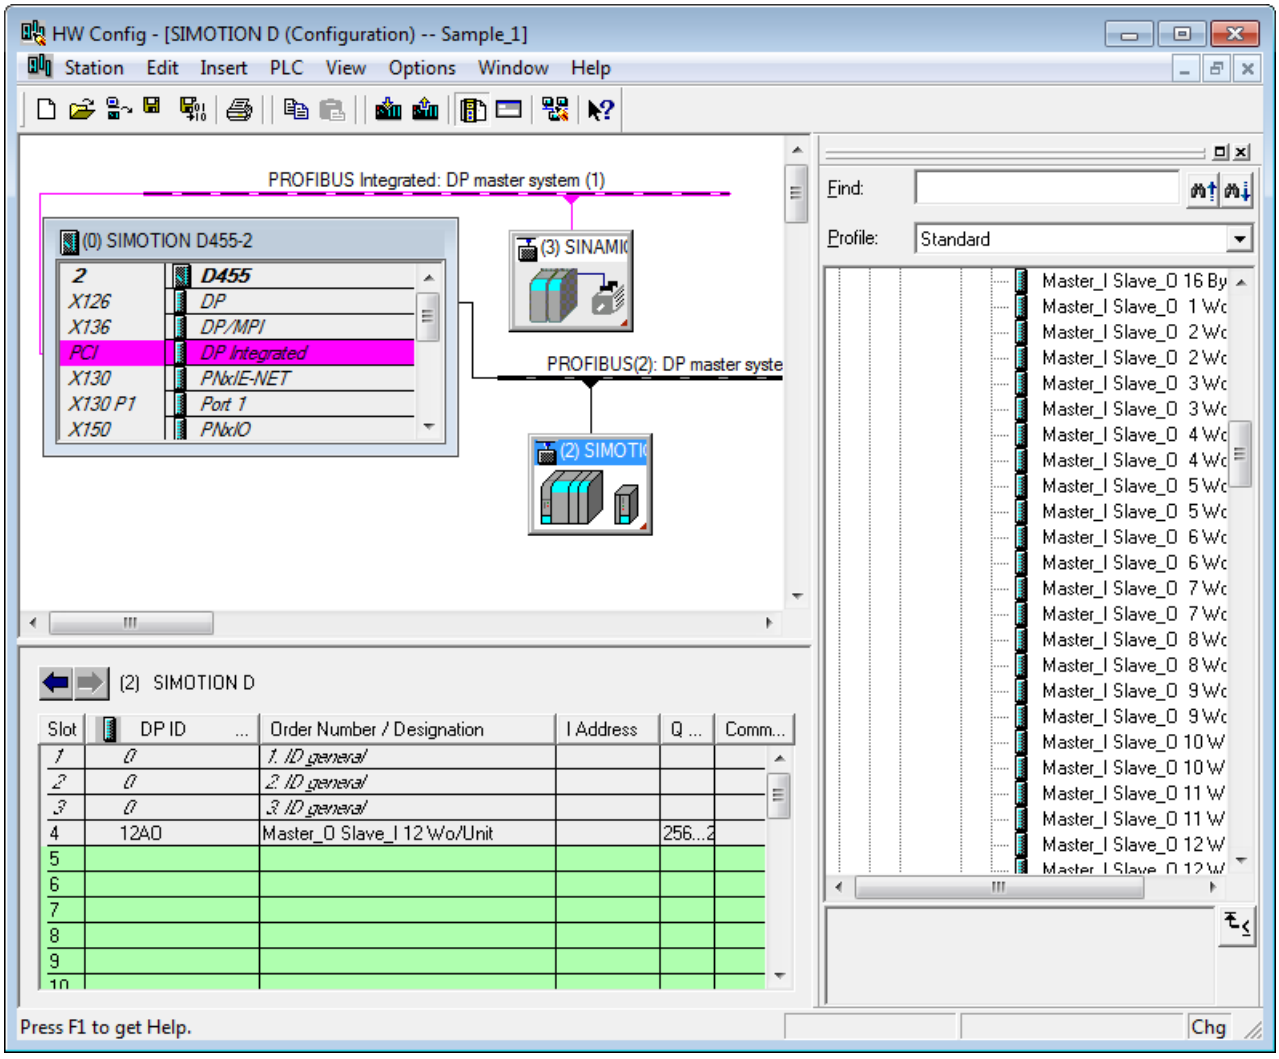

Figure 4-756 Creating an output module on the DP slave in HW Config

5. Under "SIMOTION D4xx" in the hardware catalog, select the "Master_I Slave_O 12Wo/Unit" module and move it to its designated slot (highlighted in green) using drag-and-drop.

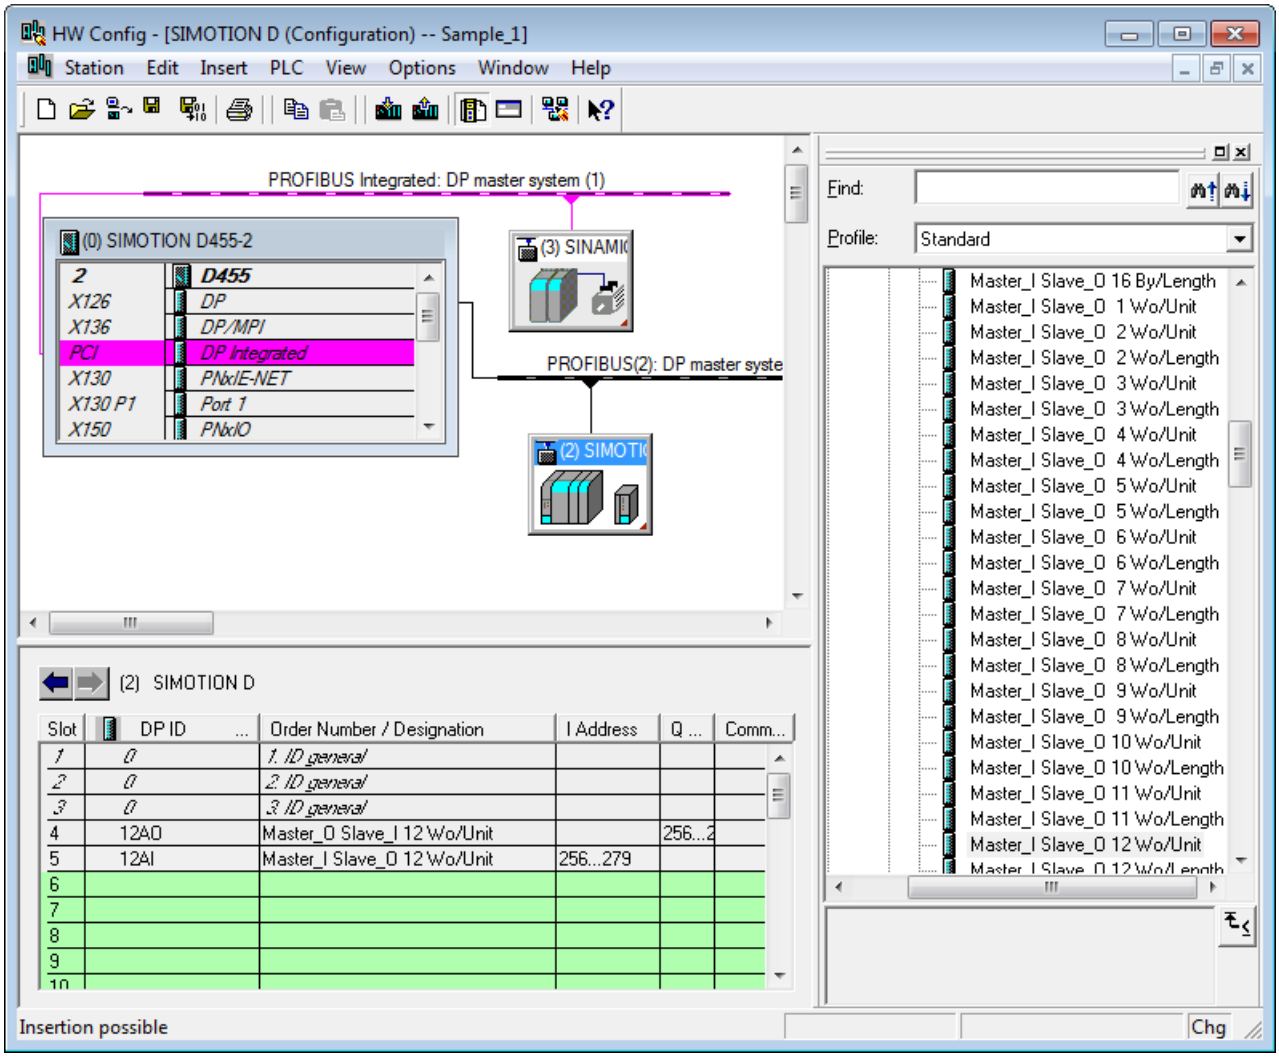

Figure 4-757 Creating an input module on the DP slave in HW Config

6. Click the "Save" button.
7. Switch to SIMOTION SCOUT and save the "master object" project.
   This concludes configuration of the DP master communication in HW Config. The next step involves creating proxy objects in SIMOTION SCOUT, see section Creating proxy objects (Page 2814).

Communication configuration via PROFINET IO

Communication via PROFINET IO

This section uses an example to describe how cross-project distributed synchronous operation is configured using PROFINET IO. You can adapt the project properties to suit your requirements.

Introduction

If the devices are connected via PROFINET, data exchange takes place between an IO controller and an I device. The I device must be taken into account during the configuration of the I/O controller by means of its GSDML file. The GSDML can be generated in HW Config of the I device.

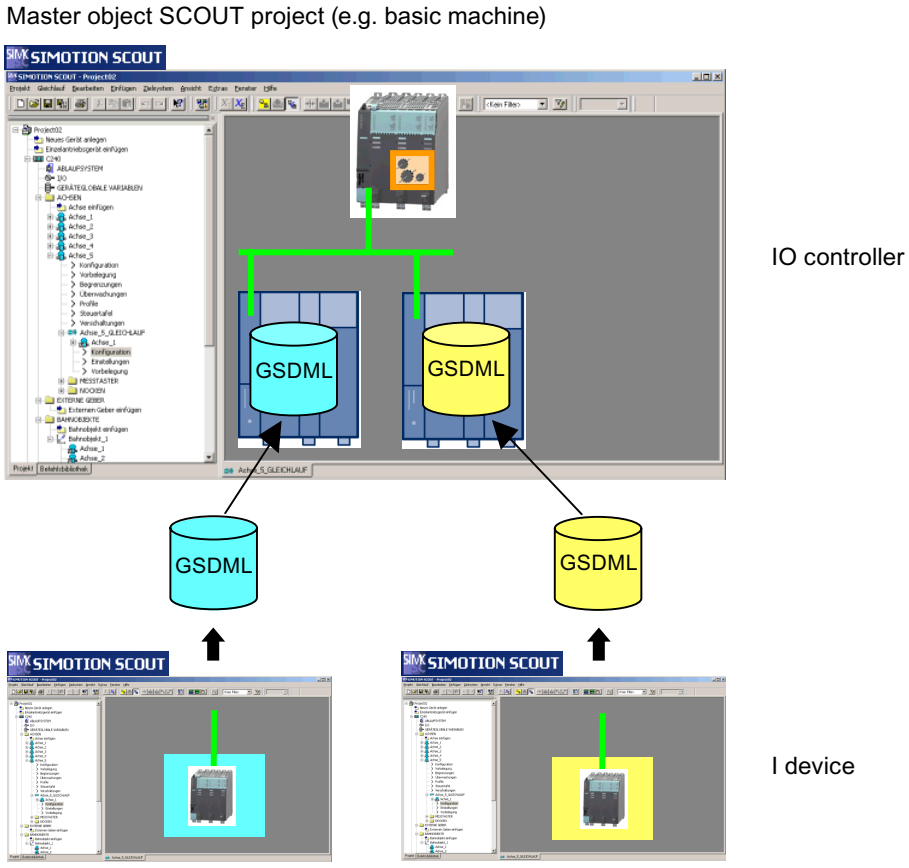

Figure 4-758 PROFINET distribution bus: HW configurations of the basic machine and modules

Note

The I device can be configured in STEP 7 as of V5.4 SP2.

Note

Distributed synchronous operation is also possible via two PN interfaces, see Section *Example configuration for controlled Sync Master* in the *Communication* System Manual.

Creating and configuring "Synchronous axis" project on SIMOTION D455-2

This description is just an example. You can adapt the project properties to suit your system requirements. In this example, configuration using PROFINET V2.2 is described. SIMATIC STEP 7 V5.5 SP1 must be installed for this.

The creation and configuration of a "synchronous axis" project on SIMOTION D455-2 consists of the following steps:

Project creation in SIMOTION SCOUT

1. Open SIMOTION SCOUT and create a new project named "synchronous axis".
2. Double-click on "Add SIMOTION device" and add a SIMOTION D455-2 DP/PN V4.3.
3. Click "OK".
4. Click on "New..." in the "Properties - Ethernet interface PNxIO" window.
5. In the following window, add a new Industrial Ethernet subnet with the name "Synchronous operation".
6. Make the interface selection for PG/PC connection.
7. Click "OK" to confirm your settings. HW Config opens.

Configuration of I device in HW Config

1. In the rack, double-click the PNxIO interface to change the device name for the PROFINET interface of the I device, and enter the device name "pn1a."
   This is necessary because you are working with 2 projects and the default name is the same for both. retaining these same names would result in consistency problems at a later point.
2. In this same window, click the "PROFINET" tab and set the required send cycle clock. In this example, this is set to 2 ms.

Note

You can set the cycle clocks in two ways:

- You can set the send cycle clock so it is equal to the DP cycle clock on the drive.
- You can set the send cycle clock so that it is lower than the DP cycle clock: By opting for this you will be working with cycle clock scaling. The position control cycle clock (master application cycle) and the DP cycle on the drive must then be of an equal length.

3. In this same window, click the "I device" tab.

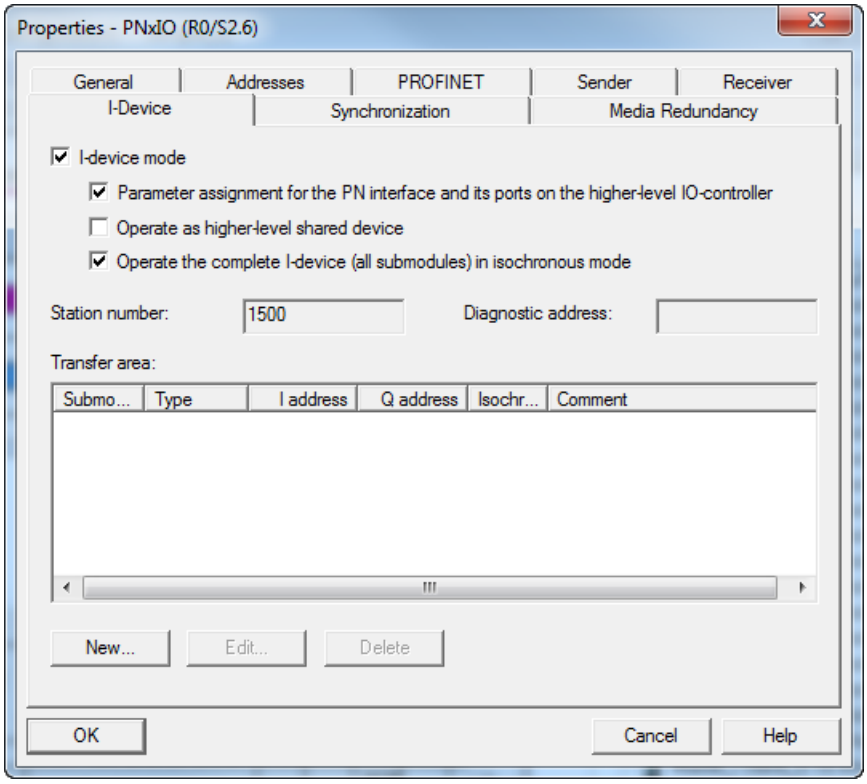

Figure 4-759 Settings on the I device

4. Activate the "I device mode", "Parameterization of the PN interface and its ports on the higher level IO controller" and "Operate complete I device (all submodules) isochronously" functions.
5. In the lower area of this same tab, click "New...".
The "Properties of virtual submodule" window opens.

6. Enter the following properties for the send and receive data:
   - Address type: Input
   - Start: 256
   - Length: 24
     and click "OK" to confirm your settings.

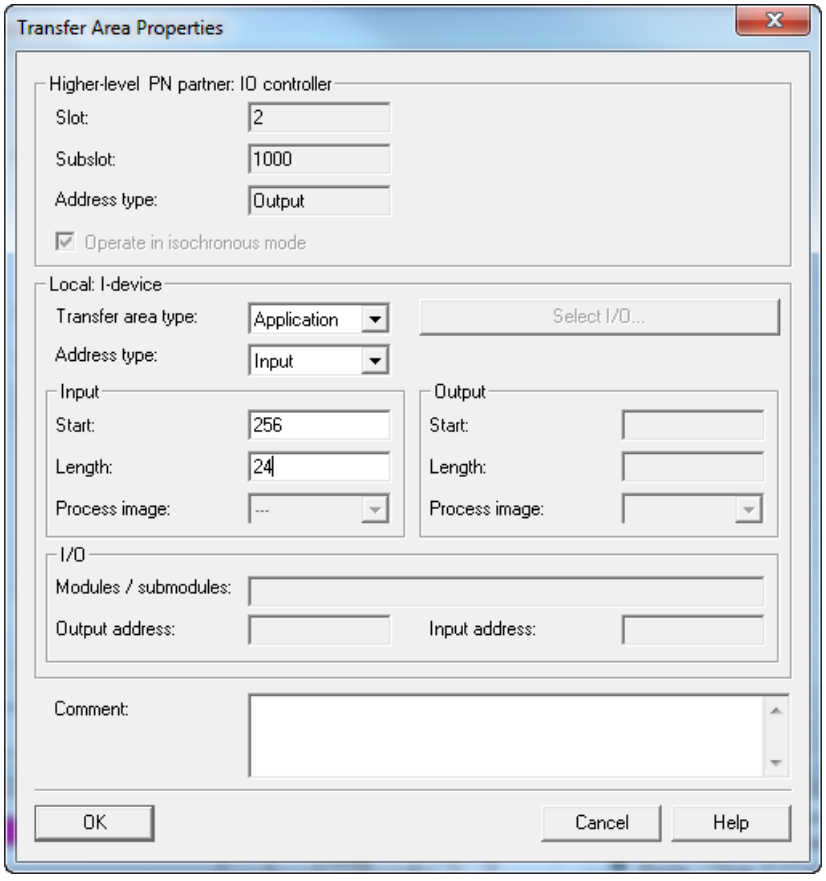

Figure 4-760 Configuring settings on the I device

7. Click the "New..." button again to configure the output address as described below:
   – Address type: Output
   – Start 256

– Length 24
and click "OK" to confirm your settings.
You will need the set input and output addresses later to configure the proxy object in SIMOTION SCOUT.

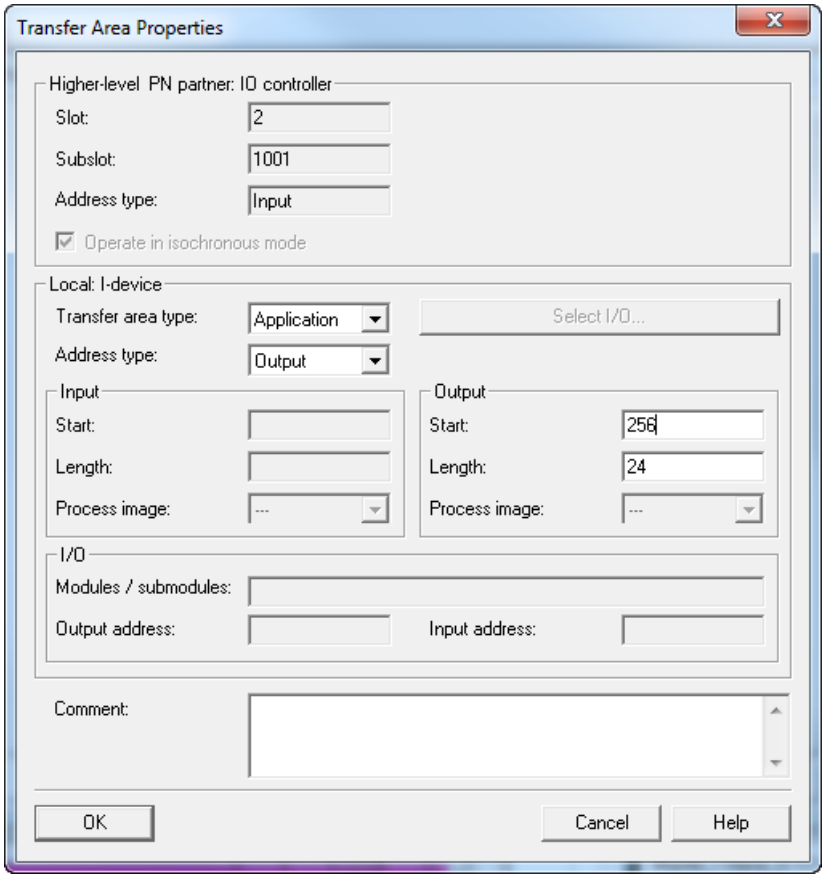

Figure 4-761 Configuring output addresses on the I device

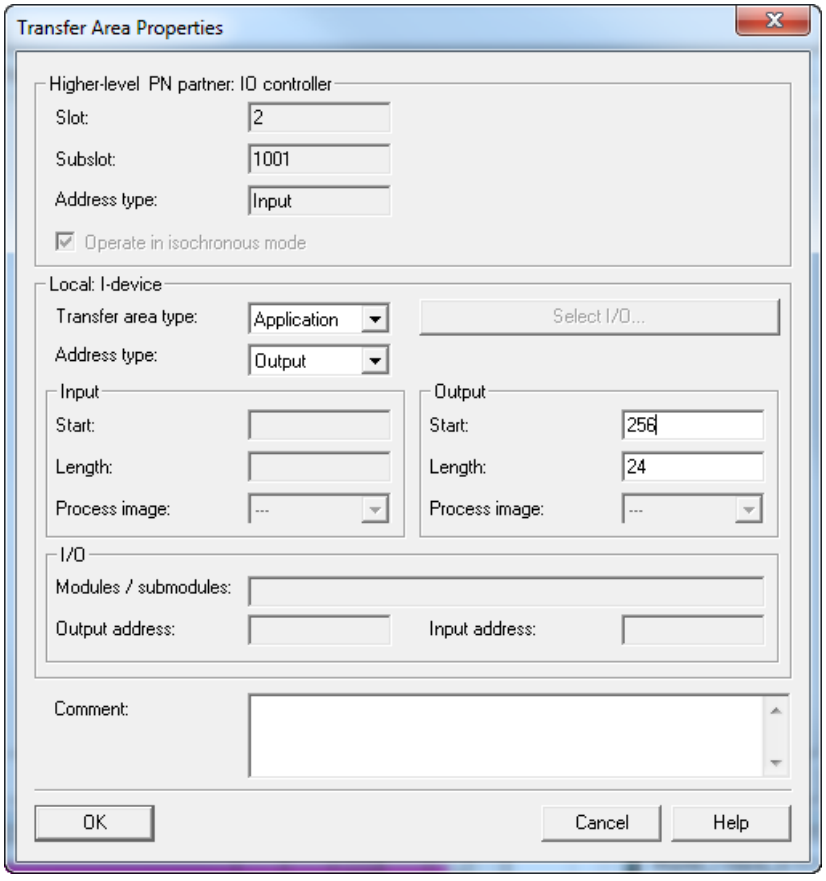

Figure 4-762 Settings on the I device - Addresses

Note

Please note that, in addition to the data for the synchronous operation, you may also want to transfer user data (communication between master and slave, such as project-specific control and status data for synchronous axes) and will, therefore, need to configure additional inputs and outputs accordingly.

8. Confirm your entries with "OK". The I device is created.

Setting DP cycle

1. Double-click on SINAMICS_Integrated.
   The "DP slave properties" window opens.
2. Click the "Isochronous operation" tab and set the "DP cycle" to factor 16. This corresponds to a DP cycle clock of 2 ms.
3. Confirm your entry with "OK".
4. Click the "Save" button.

Creating the GSD file for the I device

1. On the menu bar, select Options > Create GSD for I Device.
   The "Create GSD for I Device" window opens.

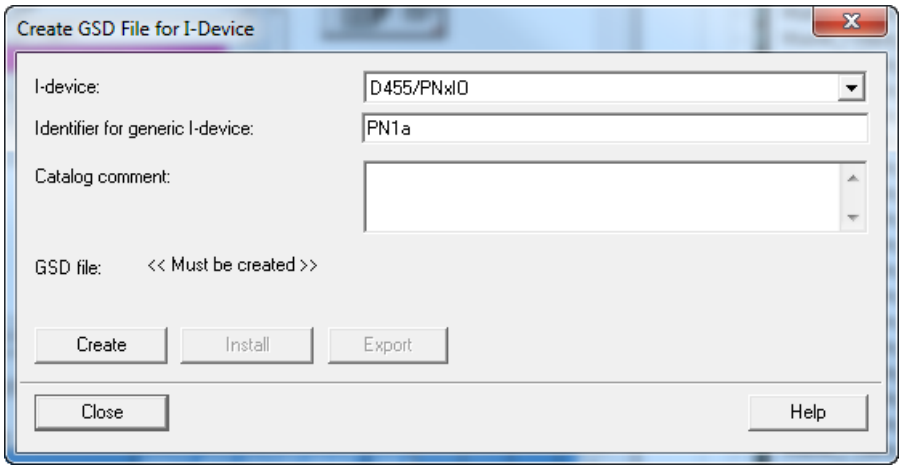

Figure 4-763 Creating the GSDML file

2. Click the "Create" button. This creates a GSDML file for the I device. You will need this file as the proxy for the I device in the "master object" project on the PROFINET IO controller. The name of the GSDML file is shown.
3. Click the "Install" button.

4. Click "OK" to confirm the message that appears, followed by the "Close" button. The GSDML file will now be entered in the HW Config hardware catalog in the PROFINET IO > Preconfigured Stations/D455 structure.

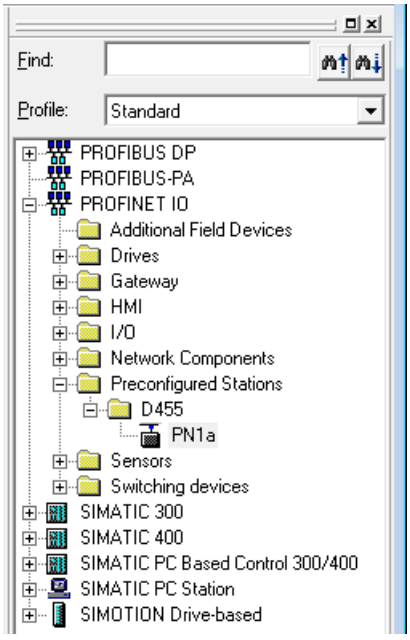

Figure 4-764 View of HW Config after installation of GSDML file

Note

If the project for the PROFINET IO controller is not to be executed with the same engineering system, you must export the GSDML file. The GSDML file must then be imported into HW Config of the other engineering system.

5. Click the "Save" button.
6. Switch to SIMOTION SCOUT and save the "Synchronous axis" project.
This concludes configuration of the I device communication in HW Config. The next step involves creating the "master object" project in SIMOTION SCOUT, see section Creating and configuring "Master Object" project on SIMOTION D455-2 (Page 2808).

Creating and configuring "Master Object" project on SIMOTION D455-2

This description is just an example. You can adapt the project properties to suit your system requirements.

The creation and configuration of a "master object" project for communication via PROFINET IO consists of the following steps:

Project creation in SIMOTION SCOUT

1. Create a new project in SIMOTION SCOUT and call it "Master object".
2. Double-click on "Add SIMOTION device" and add a SIMOTION D455-2 DP/PN V4.3.
3. Click "OK".

4. Click on "New..." in the "Properties - Ethernet interface PNxIO" window.
5. In the following window, add a new Industrial Ethernet subnet with the name "Synchronous operation".
6. Make the interface selection for PG/PC connection.
7. Click "OK" to confirm your settings. HW Config opens.

Setting synchronization type

1. In the rack, double-click on the PNxIO interface.
   The "Properties - PNxIO (R0/S2.10)" window opens.
2. Click the "Synchronization" tab and set Sync-Master as the synchronization type.

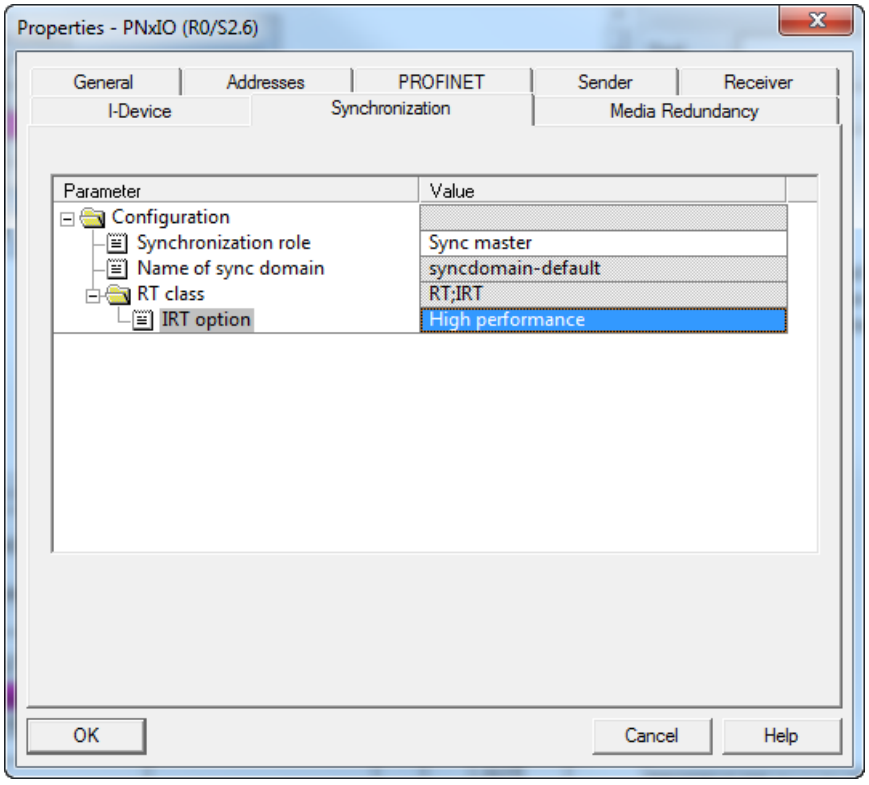

Figure 4-765 Setting Sync-Master on the IO controller

3. Click "OK" to confirm your settings.
4. On the menu bar, select "Edit > PROFINET IO > Domain management..."
   The "Domain management - Synchronous operation" window opens.

5. Set the required send cycle clock: In our example, this is 2 ms.

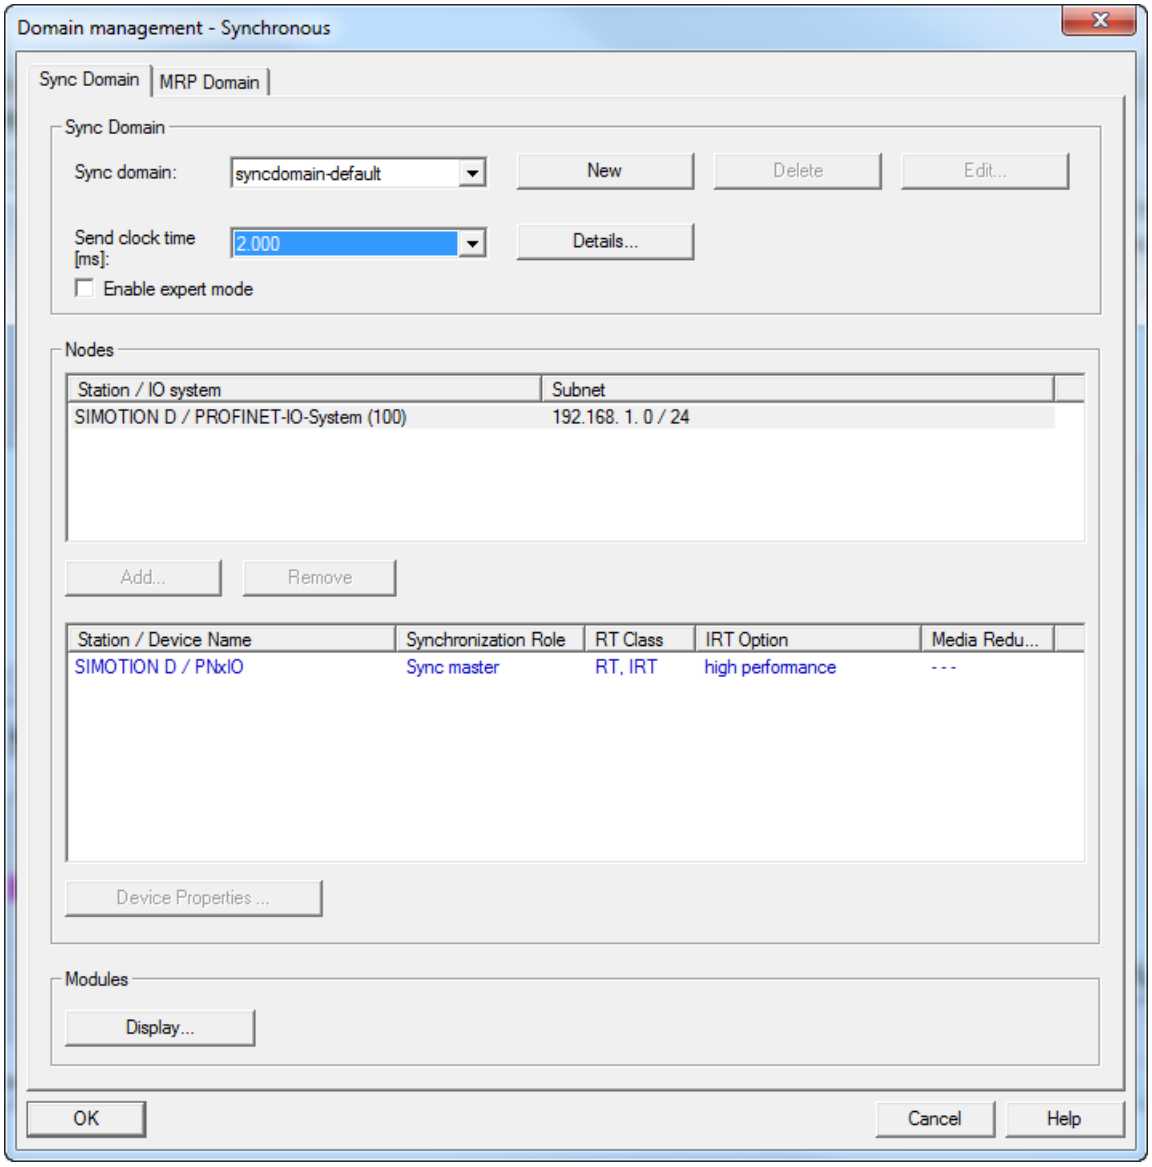

Figure 4-766 Setting the sending cycle on the IO controller

6. Click "OK" to confirm your settings.

Interconnect to PROFINET IO I device

1. Using drag-and-drop, move the I device from the hardware catalog to the "Synchronous operation: PROFINET IO system (100)" subnet. The proxy for the I device is located in the hardware catalog in the PROFINET IO > Preconfigured Stations > D455 structure.

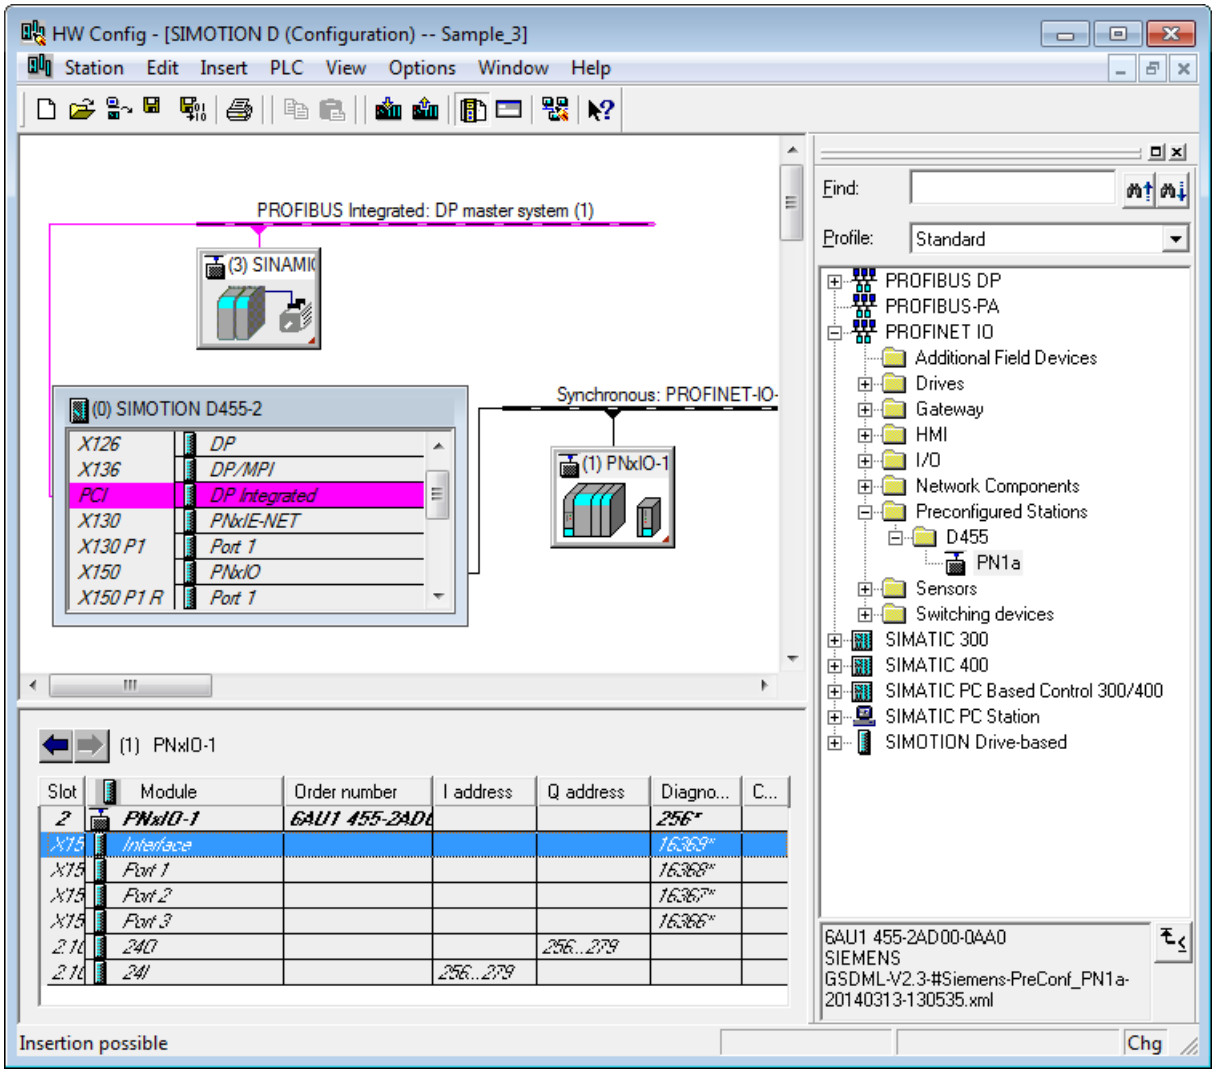

Figure 4-767 View of HW Config after insertion of the I device

Note

When you insert the proxy for the I device, the logic addresses for the cyclic input and output data of HW Config are preassigned. If necessary, correct these addresses before continuing with the configuration of the proxy objects in SIMOTION SCOUT.

2. Select the I device and double-click "Interface" in the detail view.
   The "Properties - Interface (X150)" window opens.
3. Click the "Synchronization" tab and set Sync-Slave as the synchronization type.

4. In this same window, click the "IO Cycle" tab and select the "Servo" entry in the "IO-Device/ assign isochronous application" drop-down list.

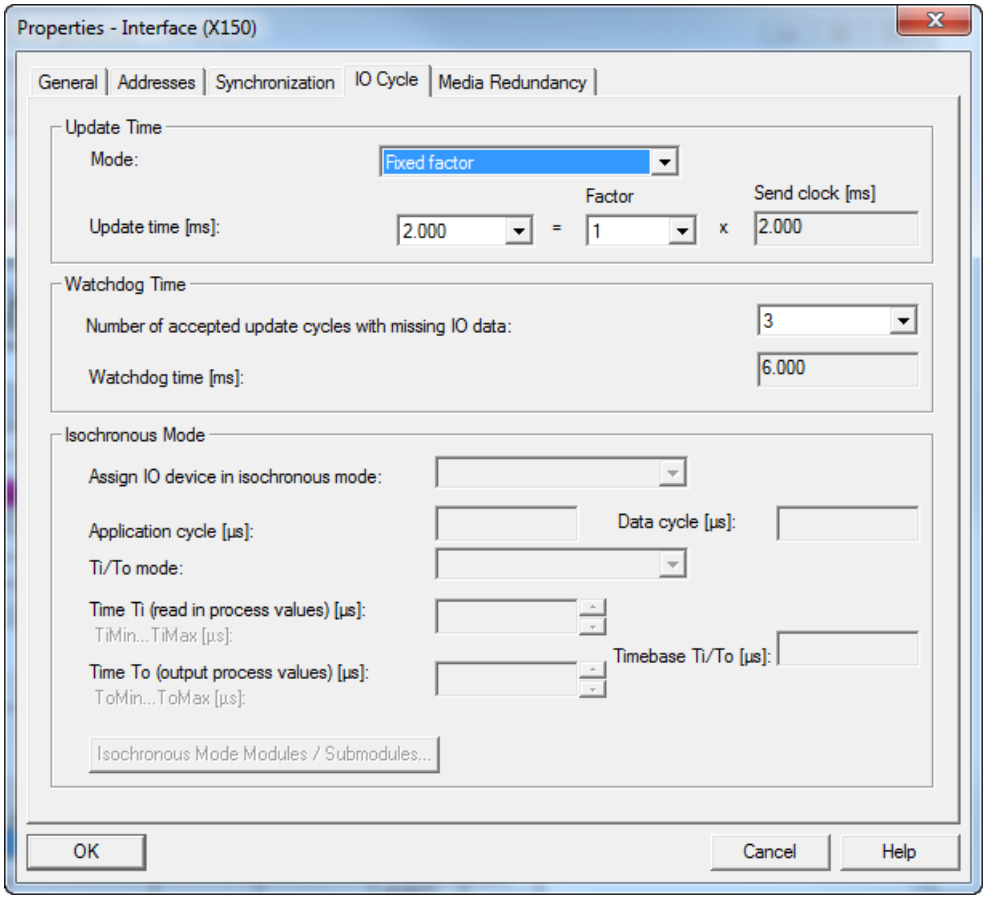

Figure 4-768 Setting isochronous mode

5. Click "OK" to confirm your settings.

Setting DP cycle

1. Double-click the SINAMICS_Integrated.
   The "DP slave properties" window opens.
2. Click the "Isochronous operation" tab and set the "DP cycle" to factor 16. This corresponds to a DP cycle clock of 2 ms.
3. Confirm your entry with "OK".

Interconnecting ports

1. Interconnect the ports by double-clicking on port 1 of the PNxIE net in the rack.
   The "Properties - PN-IO - Port 1 (R0/S2/X1400 P1 R)" window opens.
2. Click the "Topology" tab.

3. At "Partner", select the required port;
   In our example, this is "SIMOTION D\(1)pn1a\Port 1 (X1400 P1)."

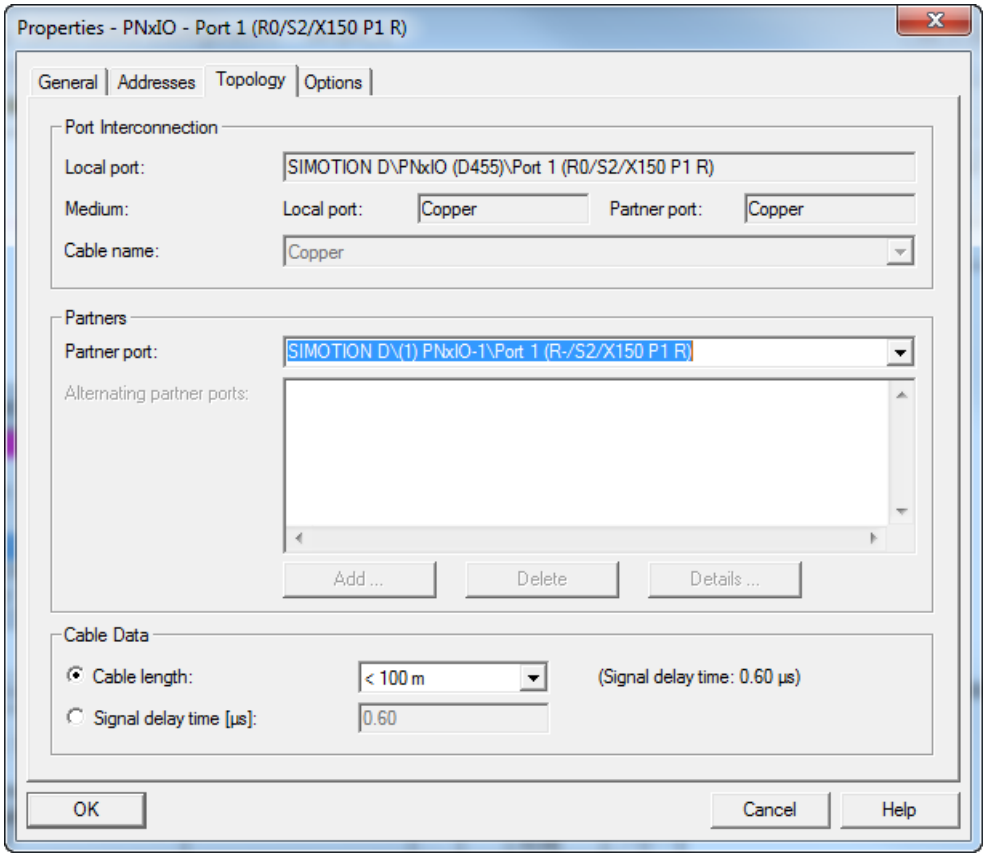

Figure 4-769 Interconnecting ports

4. Confirm your entry with "OK".
5. Click the "Save" button.
6. Switch to SIMOTION SCOUT and save the "master object" project.
   This concludes configuration of the IO controller communication in HW Config. The next step involves creating proxy objects in SIMOTION SCOUT, see section Creating and configuring "Synchronous axis" project on SIMOTION D455-2 (Page 2800).

Proxy objects

Proxy object types

Proxy object types

There are two different types of proxy objects:

- **External master value** (**ExternalMasterType**): Proxy object for an external master value
  A proxy object for an external master value can only be created under a synchronous object, i.e. interconnected with it.
- **External synchronous operation** (**ExternalFollowingObjectType**): Proxy object for an external synchronous operation
  A proxy object for external synchronous operation can be created under the following technology object types, i.e. interconnected with them.
  - External encoder
  - Synchronous axis
  - Positioning axis
  - Path axis

See also

Creating proxy objects (Page 2814)

Configuring proxy objects with SIMOTION scripting (Page 2818)

Creating proxy objects

In SIMOTION SCOUT, you now need to create the proxy objects. This section uses an example to describe the process involved in this.

Creating TOs with a master value for external synchronous operation

1. In the "master object" project, create a virtual position axis using the axis wizard and call it "master_axis_vir".
2. Select the axis in the project navigator, followed by "Expert > Insert external synchronous operation" (in the shortcut menu).
   An object called "Ext_sync_operation" is created below the selected axis and interconnected with the "Master_axis_vir."

3. In the working area, enter the input and output addresses configured in HW Config. 256 is set for the address in this example.

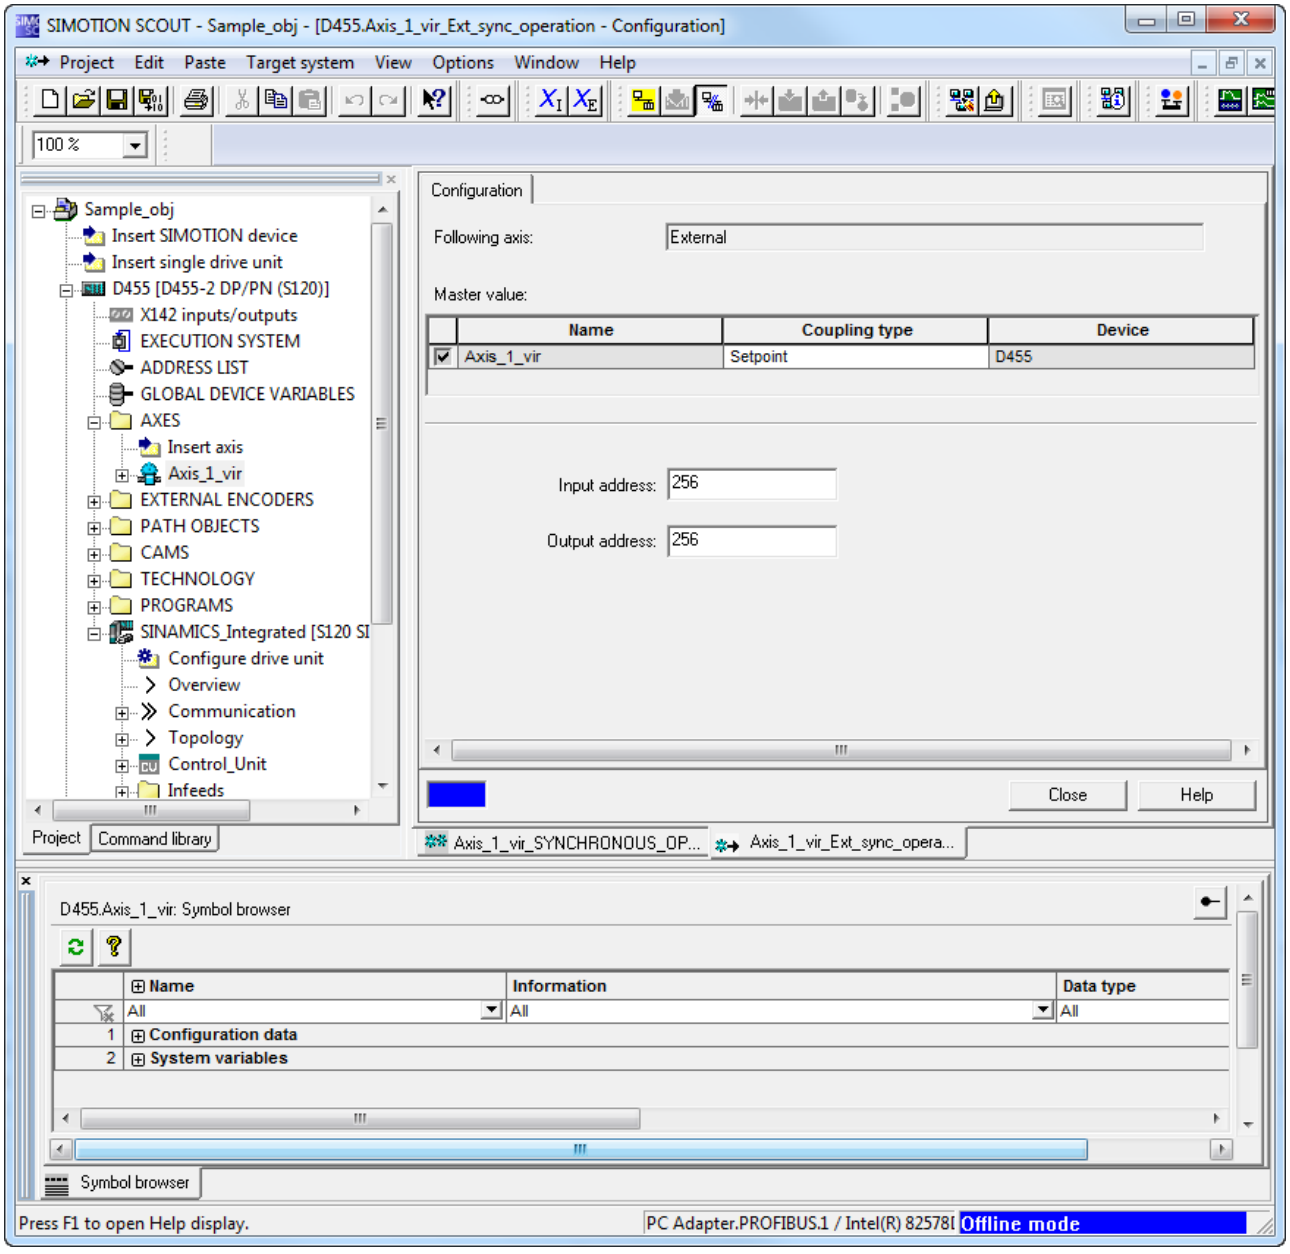

Figure 4-770 Entering input and output addresses

4. Save and close the project.

This concludes configuration of the "Ext_sync_operation" on the master object. The next step involves creating the "Ext_master_value" in the "synchronous axis" project.

Creating the synchronous axis TO with an external master value

1. Open the "synchronous axis" project.
2. Create a synchronous axis and call it "synchronous_axis_slave".

3. An "Ext_master_value" object is created below the selected synchronous object and interconnected with the synchronous object. In the project navigator, select the "synchronous_axis_slave_SYNCHRONOUS_OPERATION" synchronous object below the synchronous axis, followed by "Expert > Insert external master value" (in the shortcut menu). The "Ext_master_value" window opens in the working area.

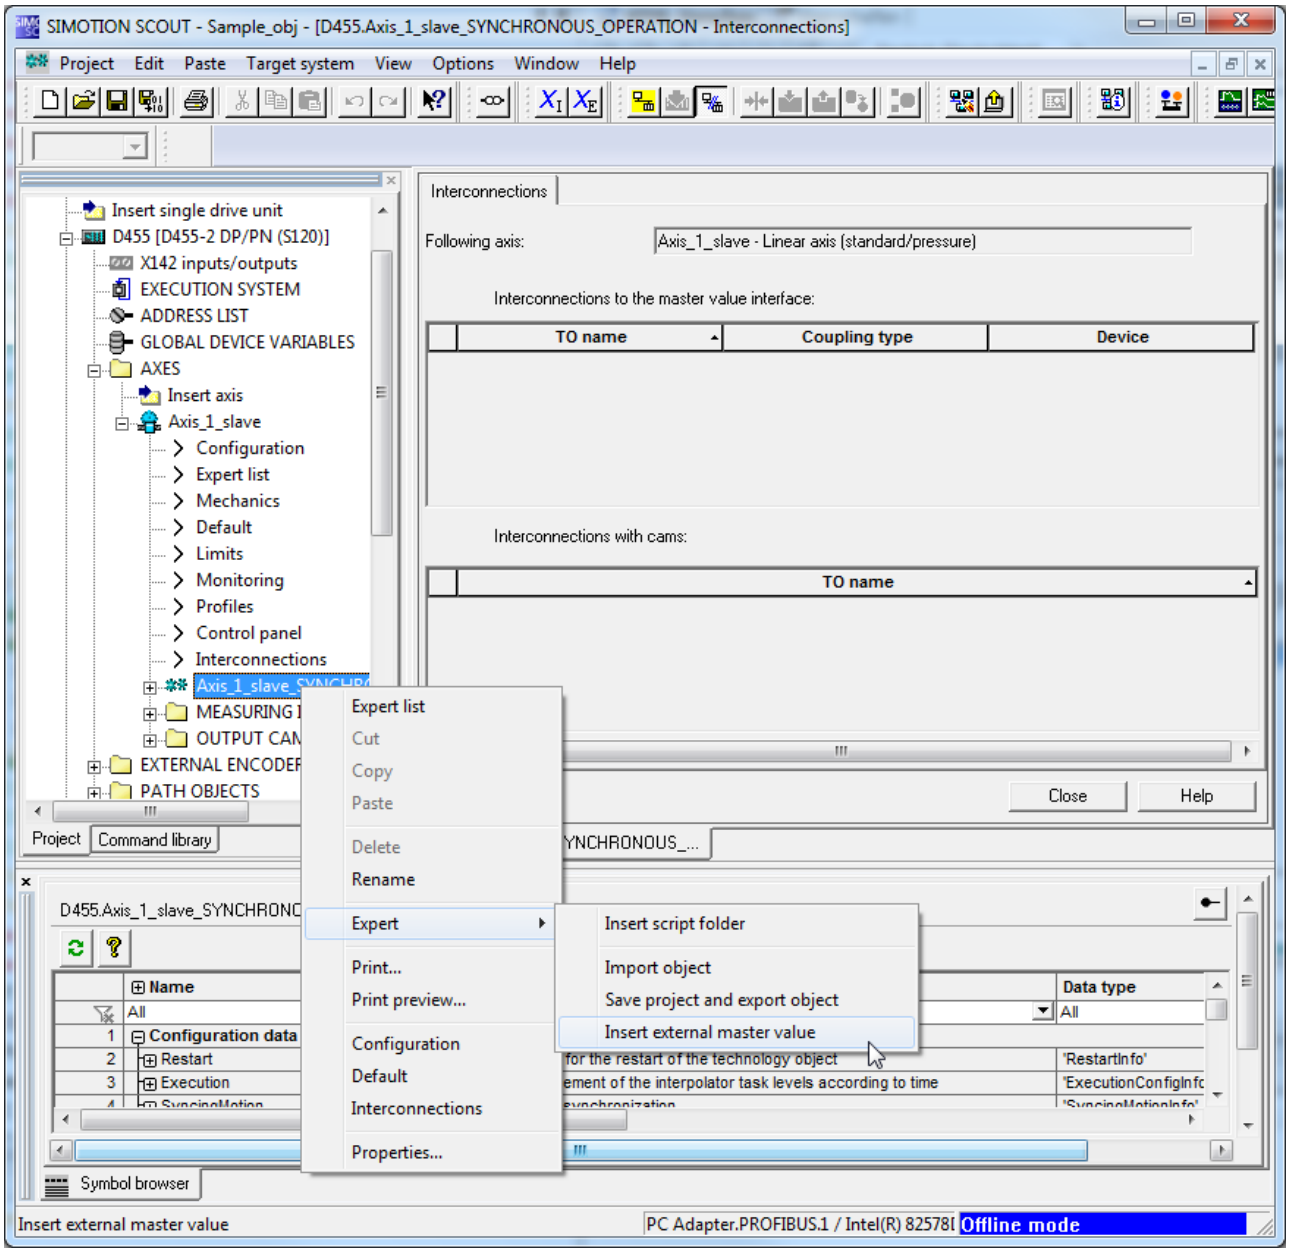

Figure 4-771 Proxy technology object - Setting the external master value

4. In the "Ext_master_value" window within the working area, enter the input and output addresses that you set as input and output addresses in HW Config. 256 is set for the address in this example.

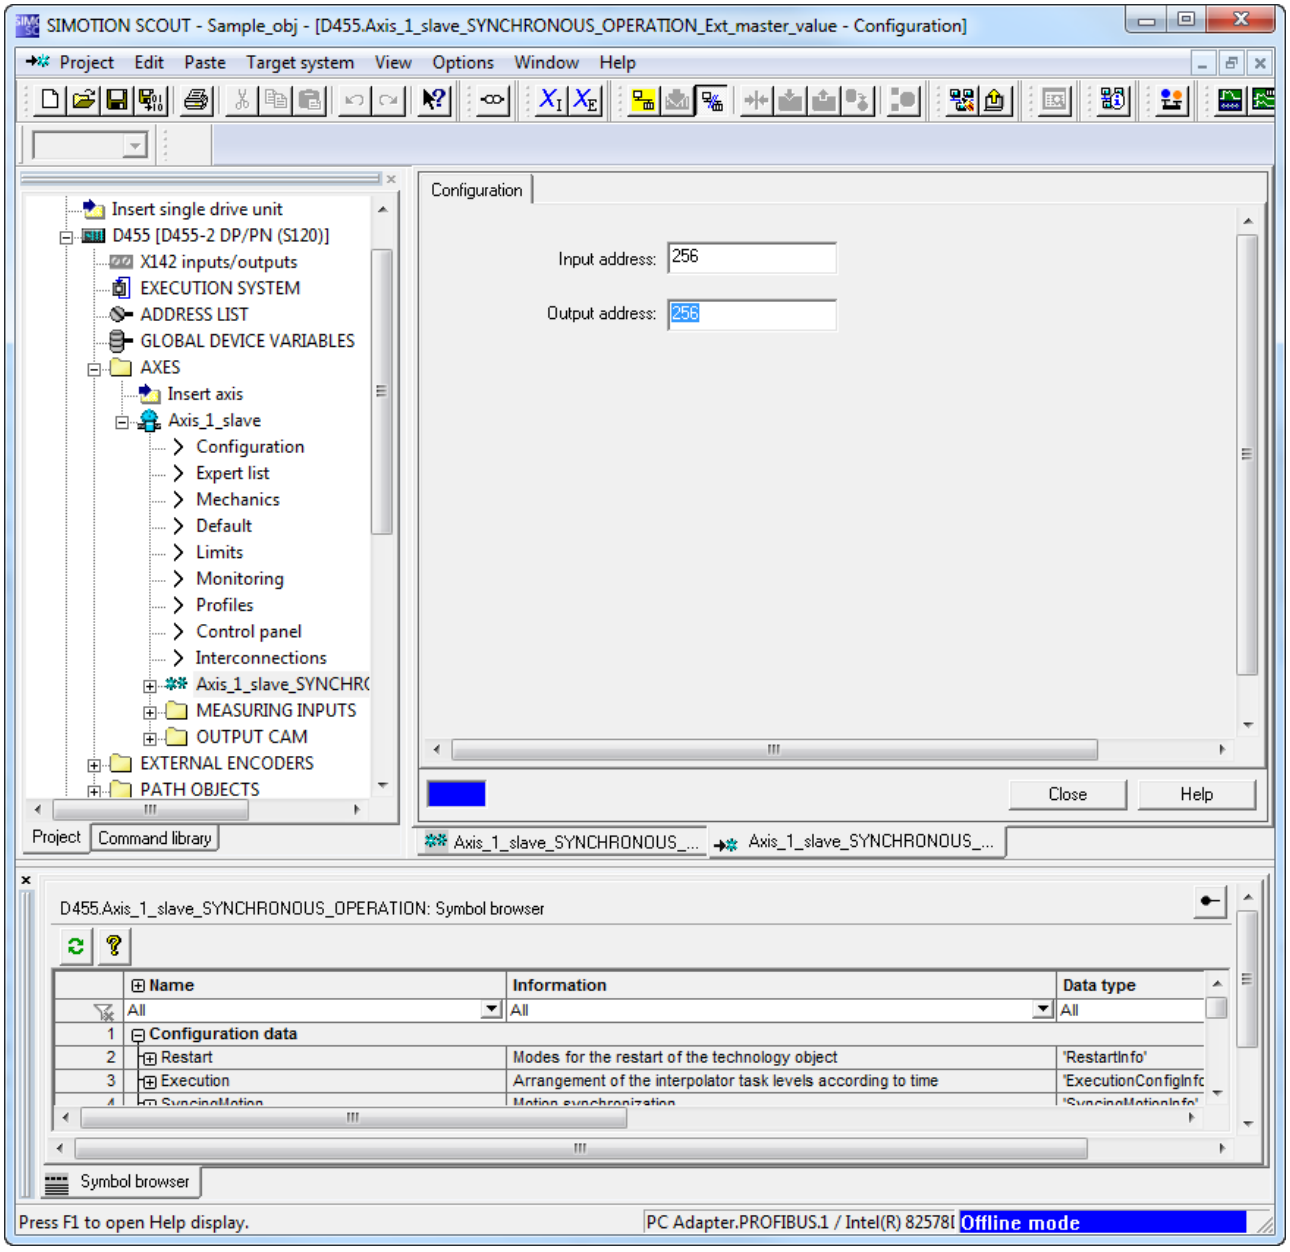

Figure 4-772 Entering input and output addresses on the external master value

This concludes configuration of the communication for cross-project distributed synchronous operation. The steps that follow this are the same as those involved in configuring a distributed synchronous operation, see section Distributed Synchronous Operation Configuration (Page 2777).

Configuring proxy objects with SIMOTION scripting

The logical input and output addresses for the proxy object can be accessed with SIMOTION Scripting. Only the offline data of the object can be accessed. Further information can be found in the online help and on the Utilities & Applications DVD.

Table 4-320 Configuration data for access via scripting

DriverInfo		
	logAddressIn	Base address of the 12-word input data from HW Config
	logAddressOut	Base address of the 12-word output data from HW Config

Changing the logical input and output addresses in the SIMOTION project

An example is described below. The logical input address is changed to address 257 and the output address to address 258.

Note

If the logical input and output addresses are changed with SIMOTION Scripting within the SIMOTION SCOUT project, the project will no longer be consistent, as there is no automatic alignment with HW Config. This means that you must automate the changes to the input and output addresses in HW Config, for example via SIMATIC STEP 7 Scripting.

Proceed as follows to change the logical input and output addresses with SIMOTION Scripting:

1. In SIMOTION SCOUT, create a folder called SCRIPTS below the project. Select the name of the project, open the shortcut menu and click on **Insert script folder**.
2. Create a script.
3. Enter the following text:
   - `PROJ.TOs ("Ext_sync_operation").Symbols("DriverInfo.LogAddressIn") = 257`
   - `PROJ.TOs ("Ext_sync_operation").Symbols("DriverInfo.LogAddressIn") = 258`

4. Save the project.
5. Execute the script by selecting it and clicking on **Accept and execute** in the context menu. The logical input and output addresses are then changed.

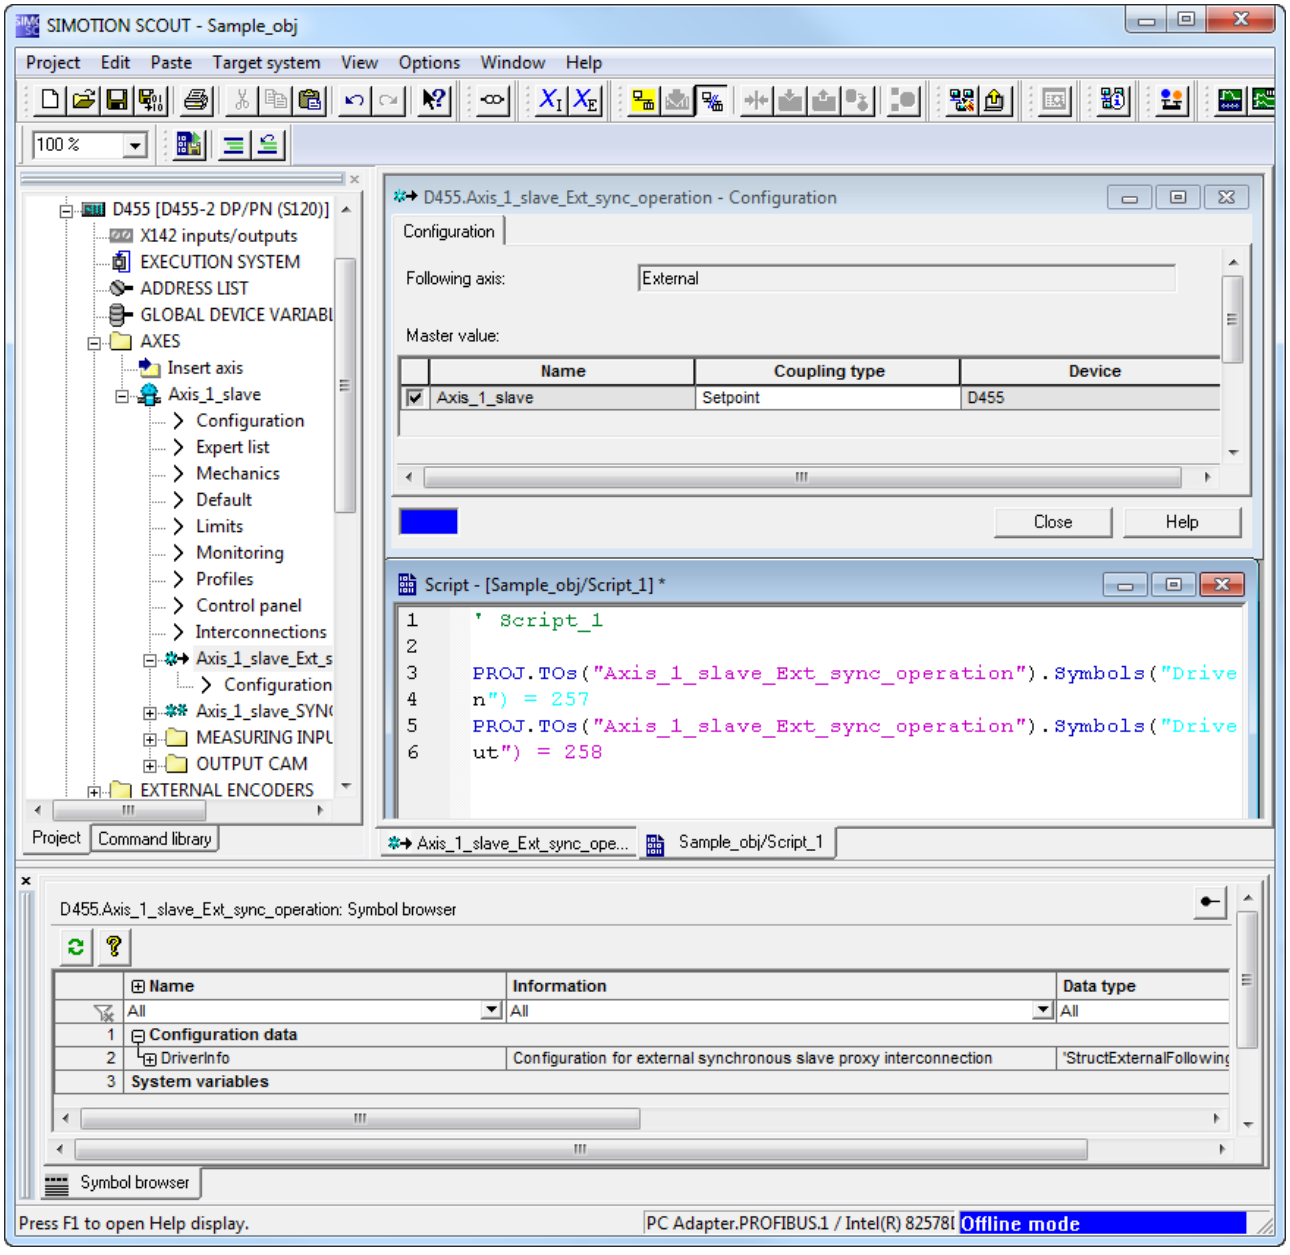

Figure 4-773 SIMOTION Scripting - example

Interconnection possibilities

In general, proxy objects can be interconnected with a maximum of one technology object. The following figure shows the interconnection options.

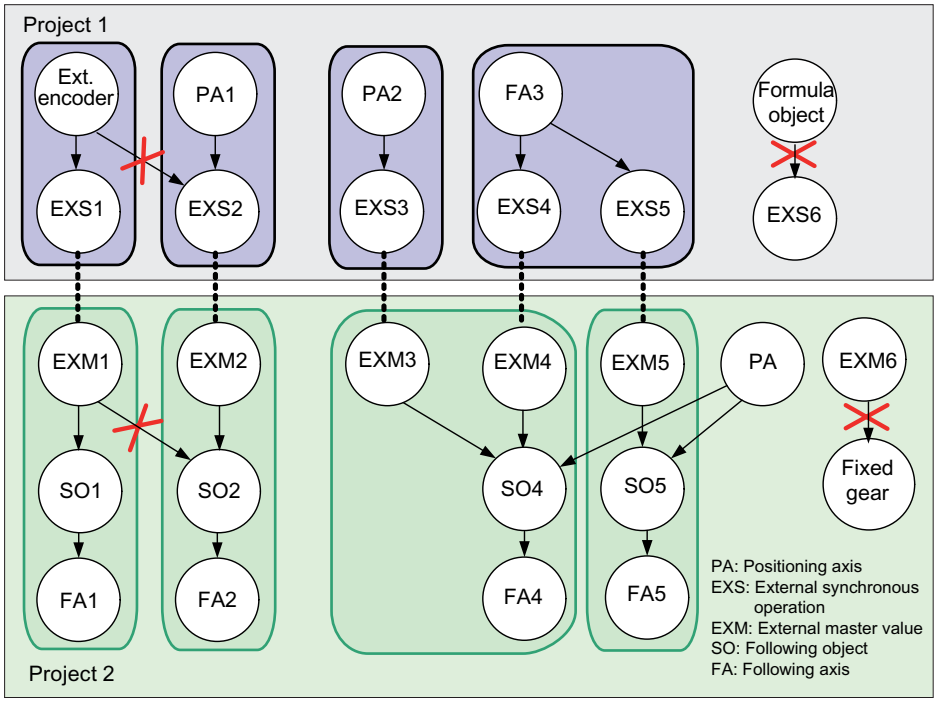

Figure 4-774 Interconnection options for proxy objects

In order to interconnect multiple synchronous objects to one external master value, you must create an additional synchronous operation with a virtual axis, to which the external master value proxy object will be assigned. In this case, the additional virtual axis acts as a master value source for multiple synchronous objects.

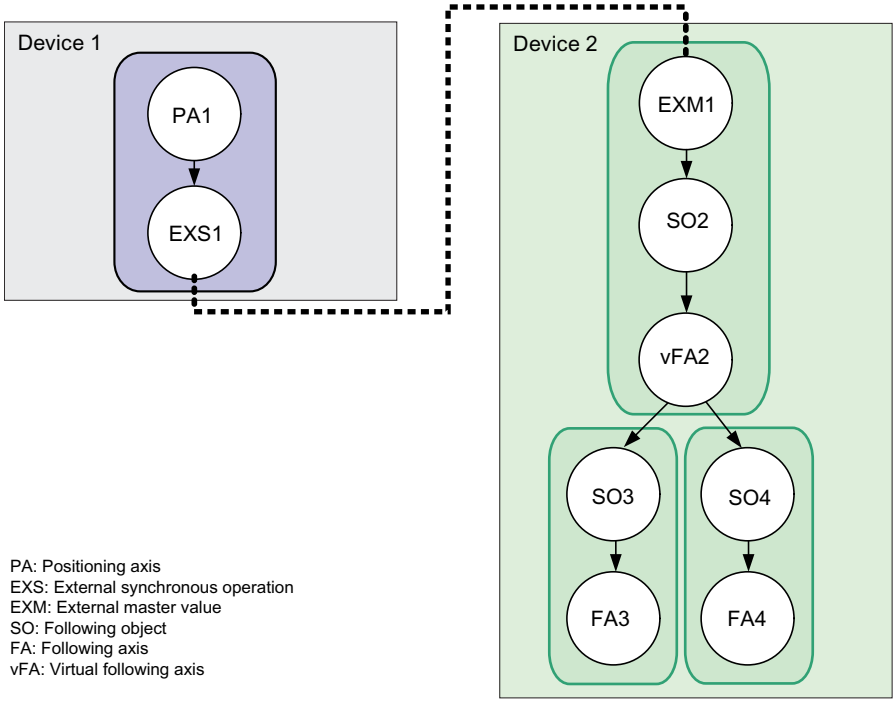

Figure 4-775 Interconnection of multiple synchronous objects to an external master value

The same also applies when different master objects can alternatively be the master value for an external synchronous operation. In this case, an additional synchronous object with a virtual axis must be provided to be interconnected with the master object. The external synchronous operation is assigned to the virtual axis.

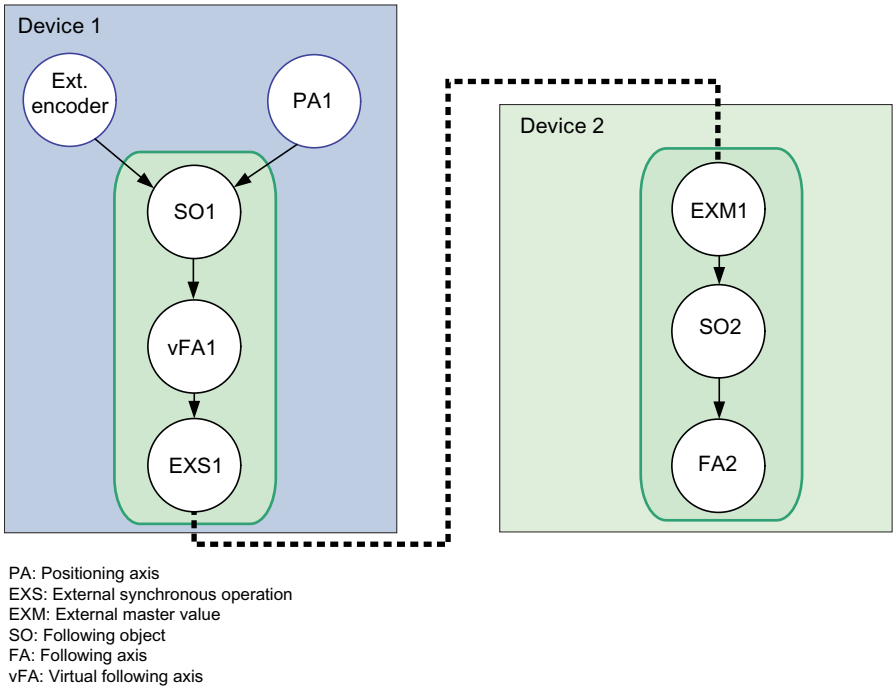

Figure 4-776 Interconnection of multiple master objects to an external synchronous operation

Synchronizing the interface

See Synchronizing the interfaces (Page 2784).

Switching over to an external master value source

If more than one master value is assigned to a synchronized axis, the master value source can be selected and switched over on the synchronous object using the **_setMaster** command (see **Fundamentals of synchronous operation**, "Switching over the master value source"). If you want to switch to an external master value source, you must specify the name of the external master value proxy object in the **_setMaster** command.

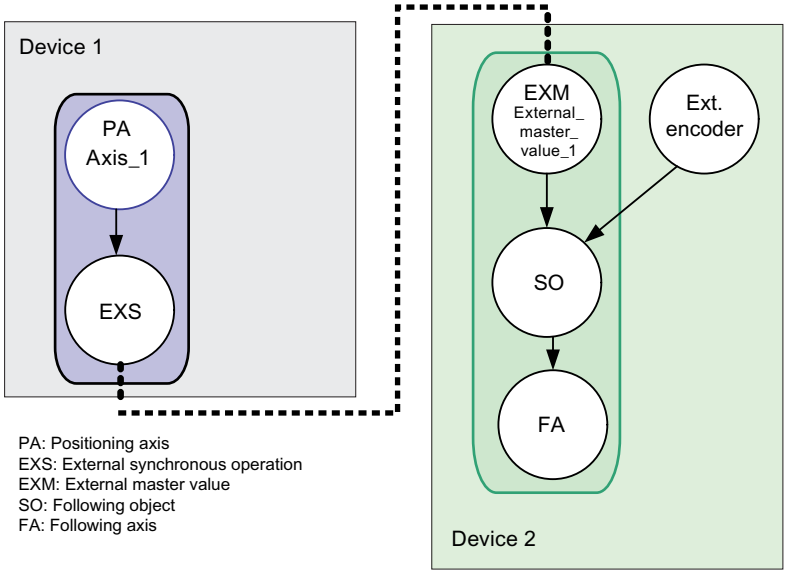

Figure 4-777 Synchronous operation with external and local master value source

This figure shows an example with interconnection to a local and external master value source. In order to switch to the master value of **Axis_1** with the **_setMaster** command, the name of the **Ext_master_value_1** proxy object must be specified in the command.

4.7.3.6 Configuration of distributed synchronous operation with different RT versions

Overview of distributed synchronous operation with different RT versions

It is useful to configure a distributed synchronous operation with different RT versions when existing plants/machines are to be extended partly, or functions are required that are not supported in the currently used RT version. This applies for an extension by one or more controllers and for the upgrade of an individual SIMOTION controller in a machine with several SIMOTION controllers.

Configuration of distributed synchronous operation with different RT versions across projects

This is possible as of RT version V4.3. For further information, see Configuring distributed synchronous operation across projects (Page 2786).

Configuration of distributed synchronous operation with different RT versions in one project

Prerequisite for the configuration is an engineering system version as of SCOUT V5.1 in conjunction with RT versions as of V4.3.

The following scenarios are considered in more detail:

- Extending an existing project by a SIMOTION controller with a different RT version than that used previously in the project.
- Upgrading a single controller to a different RT version in the project.

Project extension by a SIMOTION controller with a different RT version

To configure an additional controller that has a different RT version for a distributed synchronous operation in an existing project, proceed as follows:

1. Create the new controller with the appropriate RT version in a project.
2. Configure the controller as IRT slave (master axis available in the project) or as IRT master (slave axes available in the project) and integrate it in the PROFINET topology. Further information can be found in Section Distributed Synchronous Operation Configuration (Page 2777).
3. Create an external synchronous operation on the master axis. Further information can be found in Section Configuring distributed synchronous operation across projects (Page 2786).
4. Create an external master value on the synchronous object on the slave axis.
5. Create the input and output addresses with 24-byte length in the controller-controller direct data exchange. More detailed information can be found in the Communication System Manual, *in Section Configuring direct data exchange (data exchange broadcast) between IO controllers*.
6. Assign input and output addresses on the external synchronous operation (master) and external master value (slave) from item 5. corresponding to the start address in the controller-controller direct data exchange. Note that changes to the addresses in the controller-controller direct data exchange must also be made in the external synchronous operation / external master value.
7. Optionally: Perform the PROFIsafe configuration on the new controller (F-proxy). Note that when using the controller-controller direct data exchange with IRT, the controllers must not be used on the same interfaces as IRT I device. Only RT I device couplings are possible. Further information on F-proxy configuration can be found in the Communication System Manual.

Upgrading a single controller to a different RT version in the project

To upgrade a single controller to a different RT version in the project, proceed as follows:

1. Upgrade the controller in the existing project that requires functions of a later RT version.
2. Remove the existing distributed synchronous operation configuration on the controller.
3. Use the proxy TOs to implement the distributed synchronous operation. If the master axis is on the upgraded CPU, an external synchronous operation must be created. If the slave axis/ axes are on the CPU, create an external master value. Further information can be found in Section Configuring distributed synchronous operation across projects (Page 2786).

4. Depending on which axis/axes are on the upgraded CPU, the counterpart of the proxy TO (external synchronous operation / external master value) must be created on the other controllers.
5. Create the input and output addresses with 24-byte length in the controller-controller direct data exchange. More detailed information can be found in the Communication System Manual, *in Section Configuring direct data exchange (data exchange broadcast) between IO controllers*.
6. Assign input and output addresses on the external synchronous operation (master) and external master value (slave) from item 5. corresponding to the start address in the controller-controller direct data exchange. Note that changes to the addresses in the controller-controller direct data exchange must also be made in the external synchronous operation / external master value.
7. Adapt the user programming. Change the master values on the synchronous operation commands on the external master value.

4.7.4 Part III - Synchronous operation across multiple cycles

4.7.4.1 Overview of multiple cycle synchronous operation

This part describes the function of **synchronous operation across multiple cycles**. A synchronous operation can be configured such that high-priority axes are calculated in the SERVO or IPO processing cycle clock and low-priority axes in the IPO or IPO_2 processing cycle clock (see under processing cycle clock Real and virtual axes Runtime model and processing). It introduces you to the operating principle and technological boundary conditions of synchronous operation with the master object and following axis in different interpolator cycle clocks (IPO, IPO_2, SERVO). You are shown how to create and configure a synchronous operation in different interpolator cycle clocks.

Function overview

The **synchronous operation across multiple cycles** functionality allows you to operate a master value source and a synchronous axis in different IPO cycle clocks (IPO, IPO_2 and SERVO).

Example:

- Axis_1 is the master axis and is assigned to the IPO task.
- Axis_2 is the following axis and is assigned to the IPO_2 task.

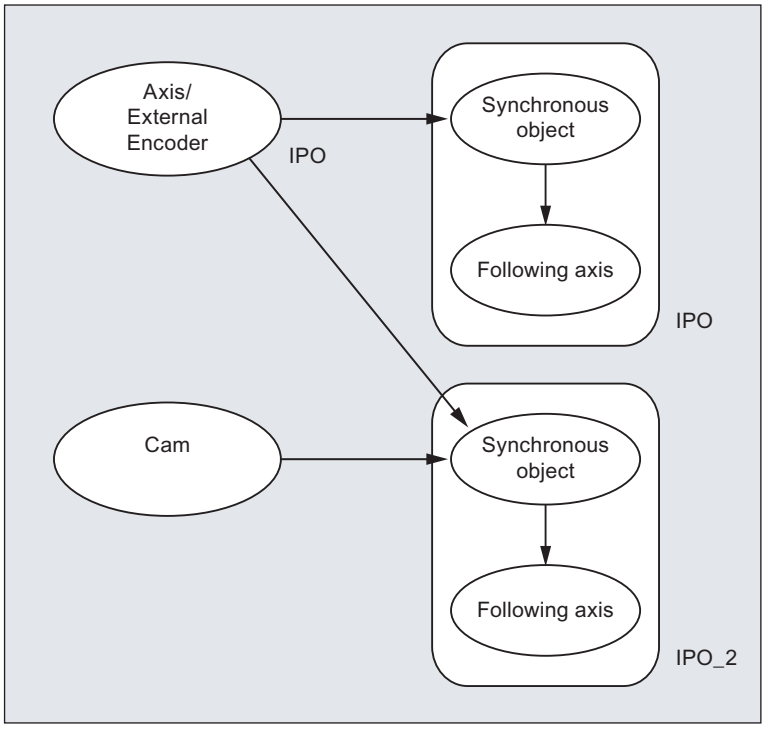

Figure 4-778 Example configuration of synchronous operation between IPO and IPO_2

Application

The **synchronous operation across multiple cycles** function enables the interpolator to be placed in a cyclical system task with a greater cycle time for axes that do not require a high time resolution for calculating the reference value. This reduces the required processor performance.

In this way, it is possible to:

- Operate coupled axes on one device in different IPO cycle clocks
- Operate coupled axes on different devices in different IPO cycle clocks (**synchronous operation across multiple cycles** can be combined with **distributed synchronous operation**).

Operating principle/Compensations

The phase error, which results from processing in a succession of different cycles, can be compensated for in the same way as with distributed synchronous operation:

- Compensation on the master value side by means of setpoint output delay
- Compensation on the slave value side by means of master value extrapolation

For details, see section Running synchronous operation across multiple cycles (Page 2827).

4.7.4.2 Boundary conditions

Objects with synchronous operation across multiple cycles cannot be created arbitrarily, but rather must satisfy the following rules:

- In a synchronous operation interconnection of multiple axes, more than one transition of axes is allowed in different IPO cycle clocks. Several compensations are thus required. These can be set independently at the transitions. The total compensation is determined by the system. The effective delay and offset are indicated at each axis and following object.

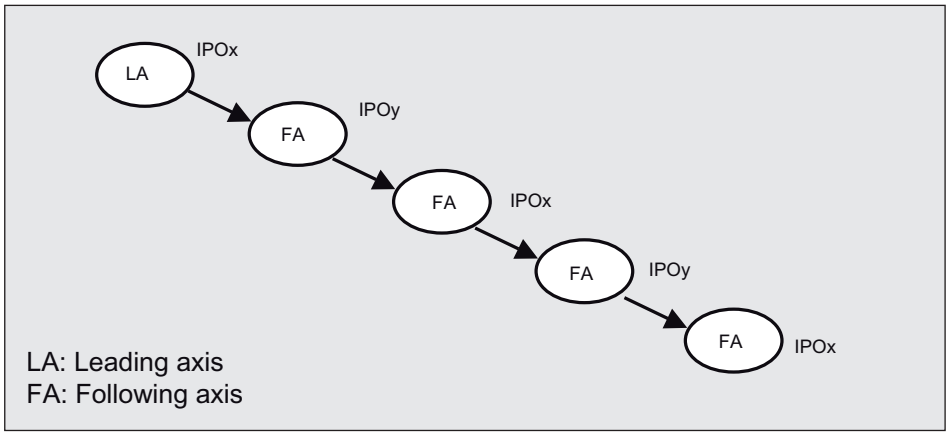

Figure 4-779 Inappropriate configuration with multiple change

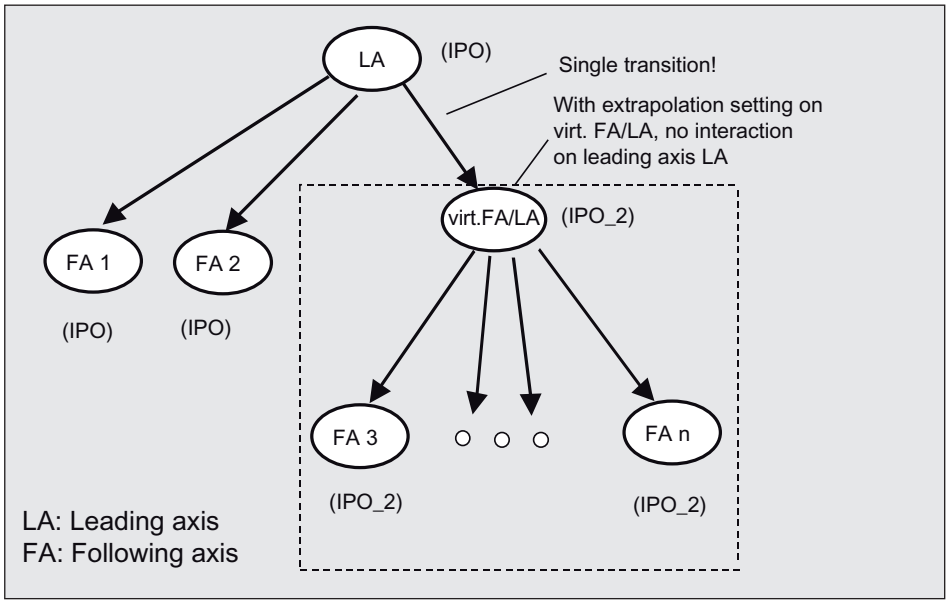

Figure 4-780 Configuration example with axis grouping

Since the calculation of compensation values needs processor resources, it is recommended to keep the number of transitions low and to form axis groups.

- Distributed synchronous operation and synchronous operation across multiple cycles can be combined.
  Synchronous operation across multiple cycles is permitted both in the master system as well as in the slave system.
  For further information, see Rules for the communication/topology for distribution using PROFIBUS. (Page 2760)
- A distributed synchronous operation and an IPOx - IPOy transition is only possible between a leading axis (Axis TO or External Encoder TO) and a synchronous object.
  - A Fixed Gear TO, Addition Object TO, Formula Object TO, Closed-loop controller TO cannot be at a transition, neither on the master value side nor on the slave value side.
  - These TOs may only be located in an effective sequence without transitions between distributed synchronous operation or IPO-IPO 2.
- Recursive interconnections which also contain IPOx - IPOy transitions are not prevented.
  Please note, however, that:
  When switching over during motion, the compensations will lead to a jump or a temporarily constant position setpoint, and a loss in velocity as a result. (Although the monitoring functions will remain active.)
  Therefore, the IPOx- IPOy transitions in the recursive synchronous operation interconnection should be switched *during standstill only*.

4.7.4.3 Running synchronous operation across multiple cycles

With synchronous operation across multiple cycles, an offset between the master value source and following axis results from the calculation of the synchronous operation in different cycles.

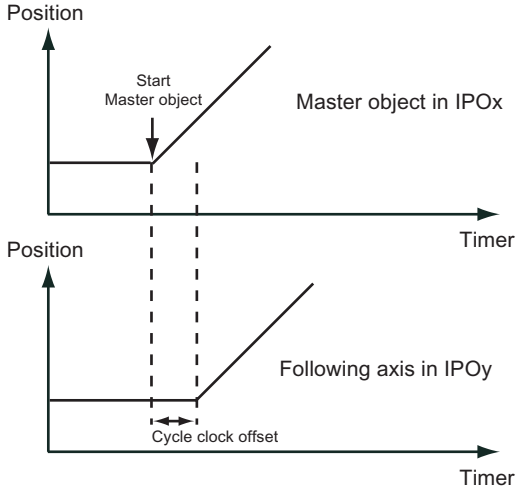

Figure 4-781 Schematic representation of the clock cycle offset due to different interpolator clock cycles

Compensation

The offset can be compensated for in the same way as for distributed synchronous operation:

- Compensation on the master value side by means of setpoint output delay in the IPO cycle clock that provides the master value for the distributed synchronous operation (master CPU).
- Compensation on the slave value side by means of master value extrapolation in the IPO cycle clock containing the slave objects (slave CPU).

The compensations are set and displayed via the system variable **distributedMotion**.

- The output delay is displayed on the leading axis.
- The master value delay is displayed on the synchronous object.
- The cycle clock offset is displayed on the synchronous object.

The details in Compensations for distributed synchronous operation apply accordingly.

Information on compensations

- Compensations can be set differently on different master objects.
- If "Extrapolation" compensation mode is selected, the output delay on the master is zero. In this way, there is no effect on other higher-level master values and their compensation calculation. This allows you to form axis groups.
- It is not possible to specify interpolation on the following axis without master value delay on the leading axis.
- With the "No compensation" setting, the master values are taken over as the exist.
  - Therefore a transition from the slower IPO to the faster IPO is possible but not technically practical.
  - A transition from the faster IPO to the slower IPO is possible, but is associated with a phase offset.

Life-sign monitoring

The life-sign monitoring is also active for synchronous operation across multiple cycles and takes effect, for example, with level overflows.

The details in Operating axes with distributed synchronous operation apply accordingly.

Note

If commands for the master value and the slave value are programmed in the same task, it must be ensured that the commands are effective in the respective processing cycle clock.

If the master value is in a slower execution level than the slave value (e.g. IPO_2 to IPO), it must be noted, for example, that a **_redefinePosition** to the master value for the slave value only becomes effective at the IPO_2 cycle limit. This must be taken into account before issuing an immediately following synchronize command.

4.7.4.4 Creating synchronous operation across multiple cycles in SCOUT

This section describes how to create and configure devices and objects with synchronous operation across multiple cycles.

Master object

1. Insert the leading axis or external encoder and configure it.
2. If required, insert cams and configure these.

Following axis

1. Create one or more following axes.
   Make sure that **Synchronous operation** is activated as the technology on the following axes.
2. Configure the synchronous object.
   Interconnect the synchronous object with the master object.

Processing cycle clock

The processing cycle clock is defined in the **executionConfigInfo.executionLevel** configuration data element of the axis and the synchronous object. The setting can also be made on the axis via the configuration mask.

- Set the desired IPO cycle clock for each object.
  When doing so, select the **IPO** or **IPO2** setting for the **Processing cycle clock**.

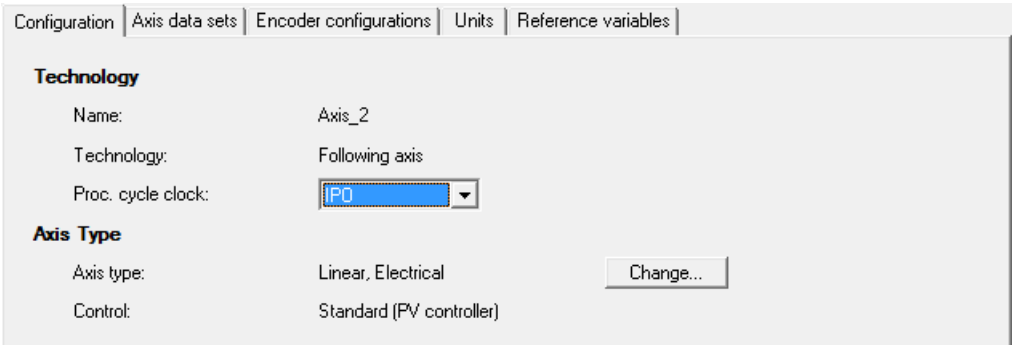

Figure 4-782 Defining the execution cycle in the axis configuration

Configuration

1. In the shortcut menu of the synchronous object, select **Expert > Expert list**; see **Motion Control Basic Functions**, "Expert list."
2. Specify the required configuration (see Operation of synchronous operation across multiple cycles (Page 2827) and Compensations of the distributed synchronous operation (Page 2767)).

4.7.5 Part IV - Cam

4.7.5.1 Overview of cam

This part describes the function of the **Cam** technology object. It introduces you to the creation and definition of cams, as well as providing information on supplementary conditions and the operating characteristics of cams.

Function overview

The **Cam technology object** can be used to define a *transmission function* and apply it with other technology objects. A cam describes the dependency of an output variable on an input variable.

- An *input variable* could be the actual position of a master axis, a virtual master value source, or the time.
- An *output variable* could be used as the set position of a following axis, the setpoint profile, or the pressure/force profile.

The TO cam is a *stand-alone* technology object, which can be interconnected with other technology objects.

Application

At present, a **TO cam** can be utilized with the following objects:

- With a **synchronous object** as a transmission function
- With a **TO axis**, e.g.
  - As a velocity, position, or pressure profile
  - As a valve characteristic curve in the hydraulic axis setting

Definition

A **TO cam** describes a function y = f(x) in sections. The sections can be defined by means of *interpolation points* or *segments* (using polynomials). Cams are *dimensionless*. No physical units are used to define them.

Creation and storage

Cams can be created by means of the SIMOTION parameter assignment tool in the engineering system (**CamEdit**) or using the **CamTool** add-on. Cam objects *cannot* be created by the user program.
In order to define a cam in the **user program**, the object must have been created previously in SIMOTION SCOUT.

Cams are stored *by device* and can be assigned to each applicable object of this device. Multi-device cams are not possible.

Exporting/importing cams

With CamEdit, you can export or import the geometry data of the cam.

Scaling and offset

Cams are scalable either in subranges or overall using commands from the user program, even if you have defined the cam using the parameter assignment system. For further information, see "Scaling and offset".

Interpolation

If a curve is defined using segments, gaps in the definition range can be filled by interpolation. If the cam is defined by interpolation points, the characteristic is interpolated. You can select from a variety of interpolation methods. For additional information, see "Interpolation".

Reset

Resetting a cam causes the contents of the cam to be reset. The reset command deletes previously defined interpolation points or segments. The reset command sets the scaling factor to 1 and the offset to 0. If the cam is interpolated, it must be reset before definitions are made in the user program.

Access protection

Only one write action can be performed on the cam at any one time. Any number of read actions can be performed on the cam at any one time. Several write or read actions cannot be performed at the same time.

4.7.5.2 Fundamentals of Cam

Definition

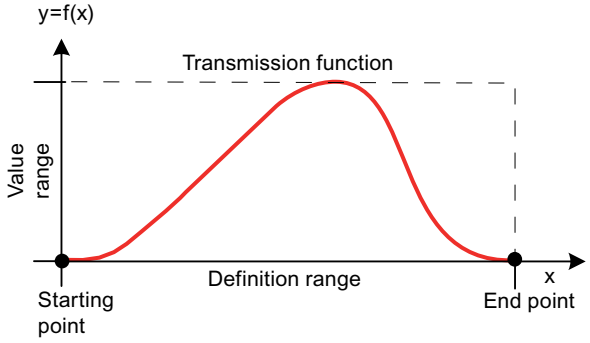

Figure 4-783 Definition of the cam

A cam is defined by the following:

- Definition range
- Starting point and end point of the function in the definition range
- Transmission function
- The value range,
  which is generated from the transmission function

SIMOTION provides the following two options for defining cams. As an option, on the cam in the **interpolatorSettings.dataMode** configuration data element you can set whether only interpolation points, only segments, or both are to be used:

- Definition by means of interpolation points and segments (default).
  Setting **interpolatorSettings.dataMode=SEGMENTS_AND_POINTS**
- Definition by means of segments.
  Setting **interpolatorSettings.dataMode=SEGMENTS_ONLY**
- Definition by means of interpolation points.
  Setting **interpolatorSettings.dataMode=POINTS_ONLY**

A cam can be non-normalized or normalized (with a unit interval of 0.0 ... 1.0) (see Normalization (Page 2833)).

Definition based on interpolation points

Interpolation points are represented in the form **P = P(x, y)** in the interpolation point tables. The order by which the value pairs are entered is irrelevant. They are automatically sorted in the definition range in ascending order. SIMOTION interpolates according to the assigned **interpolation type**.

Definition by means of segments

Individual segments are described in accordance with **VDI 2143**, Motion Laws for Cam Mechanisms. For additional information, see Motion laws in accordance with VDI (Page 2841).

Polynomials with a maximum polynomial degree of 6 and (as an option) a compound trigonometric function are used for this purpose.

Advantages and disadvantages of the definition modes

Table 4-321 Advantages and disadvantages of defining cams by means of interpolation points or segments

	Definition based on interpolation points	Definition by means of segments
advantages	• Simple definition • Any algorithms can be mapped by interpolation points • Curve creation assisted by teach-in • Simple interface to HMI	• Fewer data used for definition • Standard transitions in accordance with VDI ... • Contour is very precise, transitions are continuous
Disadvantages	• Large number of interpolation points required for the exact representation of the contour	• Complex arithmetic required for calculation of coefficients

Definition by means of interpolation points and segments (mixed)

With V4.2 and higher, on the cam in the **interpolatorSettings.dataMode** configuration data element you have the option of setting whether only interpolation points, only segments, or a mixture of both are to be used.

Normalization

When a cam is defined by means of segments, the individual cam segments can be in normal form (normalized to 1), i.e. both the definition range and value range are contained within the interval [0,1].

Alternatively, the segments can also be entered in the real range.

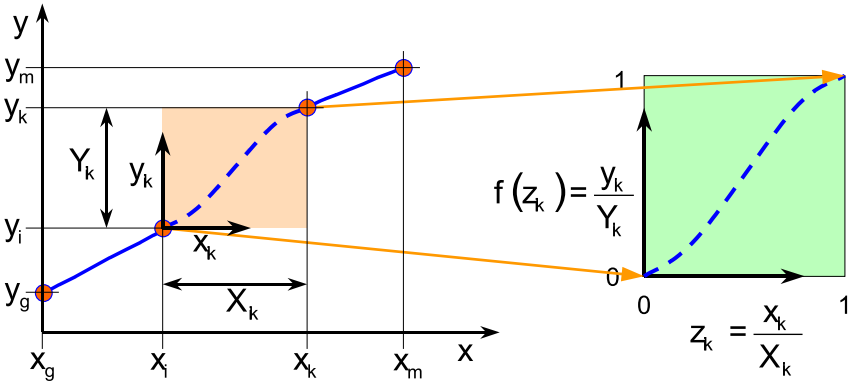

Figure 4-784 Mapping of a real cam segment to the normalized range

A normalization offers the following advantages:

- Motion is clearly defined for similar tasks
- Independent of the real units and value ranges

In addition to the function, the derivatives can also be normalized (normalized transmission function, NTF).

Scaling and offset

The definition range and value range of a cam can be adjusted according to the application, i.e. the function can be offset and stretched/compressed (scaled).

The function value for a scaled and offset cam is generated from the definition using the following formula:

$$y = F_{CAM}\left(\frac{\text{x = Offset of definition range}}{\text{Scaling of definition range}}\right) \bullet \text{Scaling of value range + Offset of value range}$$

Figure 4-785 Formula for scaling and offset of the cam

Scaling

The **_setCamScale** command scales a cam in the value range or definition range. Scaling is applied when the command is successfully issued. Scaling takes place over the complete cam or within a range defined by the starting and end points.

- With *basic scaling*, the entire cam can be scaled and offset.
- With *range scaling*, individual segments of a curve can be scaled and offset.

The zero point of the coordinate axes is used as the scaling point ("pivot point") for basic scaling, whereas the starting point of the specified scaling range is used for range scaling. The starting point of the range scaling can be greater than the end point. In this case, the larger value is the pivot point for scaling (thus the starting point).

The following are possible for the x-axis and y-axis, respectively:

- One complete scaling
- Two range scalings
- One offset

The range scalings can overlap.

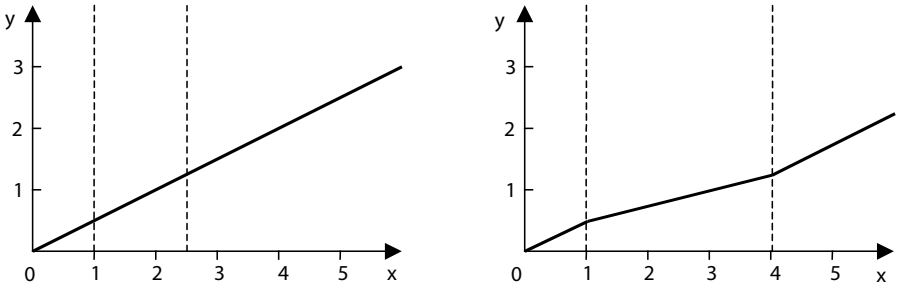

Figure 4-786 Example of scaling of definition range in the range of 1 to 2.5 using a factor of 2

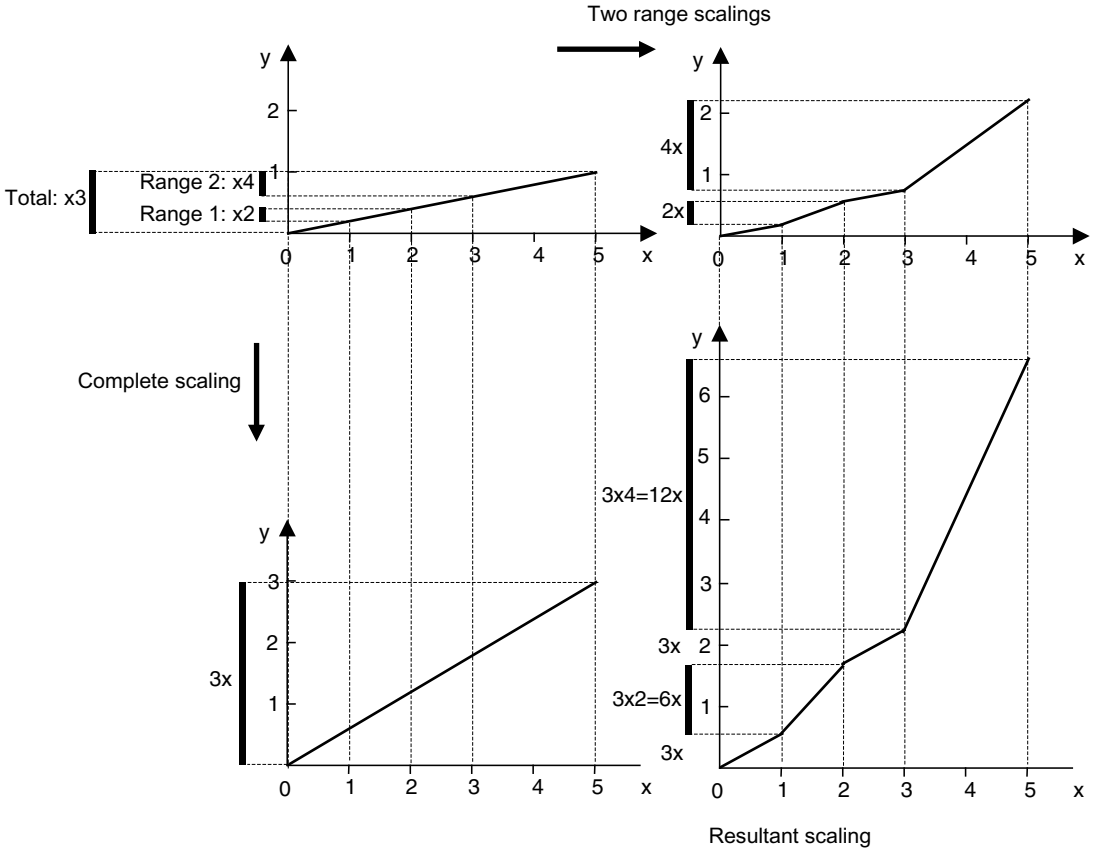

Figure 4-787 Example of two range scalings and a complete scaling in the value range

Scaling can be performed before or after segments and points are inserted or the interpolation is performed. If scaling is performed after interpolation, however, there will be a discontinuity in the first derivative of the cam (even if B-spline or C-spline interpolation is used).

Tip: To prevent this, scaling should begin and end in the dwell ranges.

Offset

The **_setCamOffset** command can be used to separately offset the domain and/or range of a cam.

An offset can be specified as *absolute* or *relative* with respect to the current offset.

- With **ABSOLUTE**, the offset value applies instead of the previous offset value.
- With **RELATIVE**, the offset value is added to the current offset value.

Interpolation

If a curve is defined using segments, gaps in the definition range can be filled by interpolation.

When the cam is defined using **interpolation**, the following checks are performed:

- A plausibility check, i.e., the cam definition is checked (for redundant values within the definition range, for example).
- Missing ranges are added (interpolated).
- Continuity and junction conditions in boundary points are checked.

Note

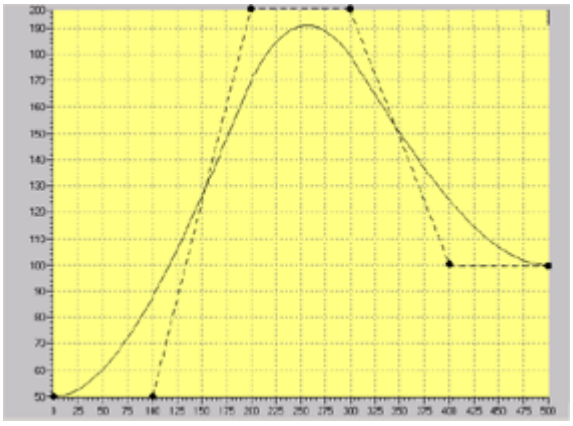
Once interpolation has been performed, new segments or interpolation points can only be inserted after resetting the cam (see Commands for resetting the cam and errors (Page 2850)).

If an attempt is made to insert new segments or interpolation points without first resetting the cam, the attempt is rejected and the return value for the function provides error information. Previously defined interpolation points and segments are deleted when the cam is reset.

Interpolation types

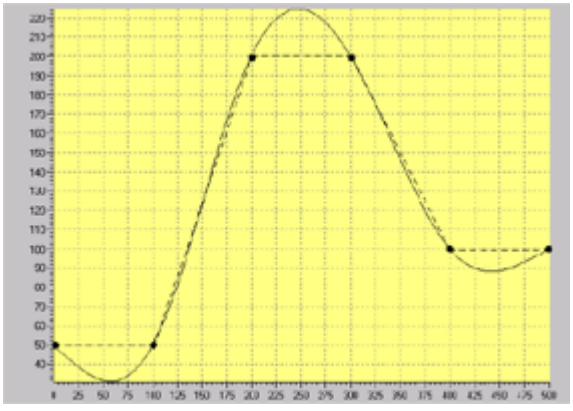
SIMOTION offers the following interpolation types for the **Cam** technology object:

Interpolation	Description	Example
LINEAR	Linear interpolation	
B_SPLINE Approximation using *Bezier splines*, i.e., curve characteristic along the interpolation points



With V4.2 and higher, in the **interpolationSettings.bSplineInterpolation = WITHOUT_APPROXIMATION** configuration data element you have the option of setting whether the 2nd derivation should run continuously.

C_SPLINE Interpolation using *cubic splines*, i.e., curve characteristic through the interpolation points



With V4.2 and higher, in the **interpolationSettings.cSplineInterpolation = ADVANCED** configuration data element you have the option of setting whether the 2nd derivation should run continuously.

Special interpolation settings

- **B spline interpolation**: As an option, you may choose not to set approximation of the B splines in the **interpolationSettings.bSplineInterpolation** configuration data element. This is a good idea if the interpolation points are not at the same distances and at least continuity of the 2nd derivation is required. An accurate display in the ES is not supported in this mode.
- **C spline interpolation**: As an option, you may choose to set a global interpolation in the **interpolationSettings.cSplineInterpolation** configuration data element if problems sometimes arise in the continuity of the 2nd derivation. This results in additional memory and performance requirements.

Continuity check

A function with assigned parameters can be checked for **continuity** in the definition range and value range, and possible points of discontinuity can be corrected. During this process, the points of discontinuity are examined separately for the definition range and value range, and are rated for one of the following corrective actions:

- If the absolute value of the spacing between segments exceeds a maximum value, a correction is made by performing an interpolation between the two segments. This results in insertion of a new segment.

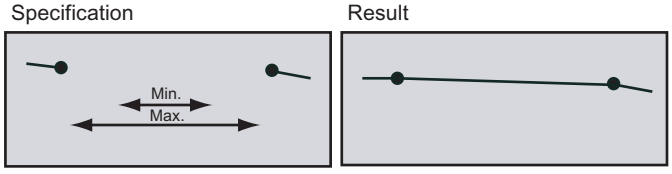


Figure 4-788 Interpolation by insertion a new segment

- If the absolute value of the spacing between segments is greater than the minimum value and less than the maximum value, correction is made by joining the segment end points. The mean value of the spacing of the function is used for the correction. The shape of the segments is affected as a result.

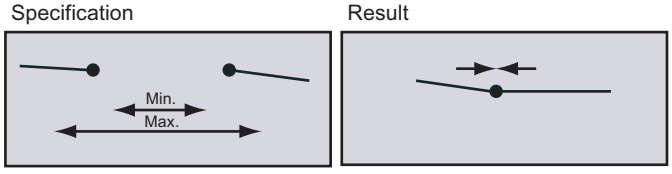

Figure 4-789 Correction by joining segment end points

- If the absolute value of the spacing between segments or interpolation points is less than the minimum value, a correction is not made. The discontinuity point is retained. When this discontinuity point is accessed, the right boundary point is output.

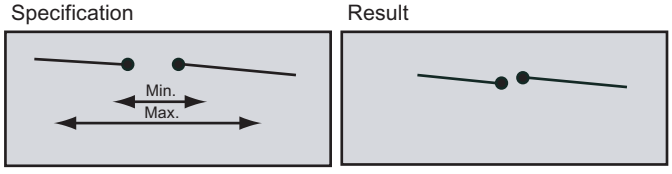

Figure 4-790 Allowing the discontinuity to remain unchanged

The point of discontinuity is corrected according to the evaluation for the definition range and value range.

Table 4-322 Boundary conditions for evaluation in the definition range or value range of the point of discontinuity

Condition	Result
Deviation < minimum	Discontinuity retained
Minimum < deviation < maximum	Join segment end points
Deviation > maximum	Interpolation (new segment)

The correction is controlled (separately for definition range and value range) by specifying the **minimum** and **maximum shape deviation**. This specification can be made on the **_interpolateCam** command for interpolation of the cam.

Depending on the combined evaluation in the definition range and value range, the point of discontinuity is corrected according to the following scheme:

Table 4-323 Combined evaluation for definition range and value range of point of discontinuity

		Correction for definition range		
Discontinuity retained	Join segment end points	Interpolation		
Correction for value range	Retain discontinuity	Retain discontinuity	Join segment end points	New segment
	Join segment end points	Join segment end points	Join segment end points	New segment
	Interpolation	Retain discontinuity	Join segment end points	New segment

- Function continuity can be achieved with **linear interpolation**.
- With **spline interpolation**, continuity is possible in the derivatives.

If the continuity condition cannot be adhered to because of the selected interpolation method or the programmed geometry, a message is provided to that effect.

If an **interpolation boundary point** lies within the programmed geometry, all geometry elements up to the boundary points are rejected. If an interpolation boundary point lies outside the programmed geometry, an end point is extrapolated according to the interpolation method used and taking into account the geometry characteristic.

Continuity at boundary points

When assigning parameters to a cam object, you can make three different settings in the **interpolation** tab.

These settings specify how the runtime system should handle discontinuity at the boundaries of the cam. The appearance of the cam in SIMOTION SCOUT may be different from when it is used later in the runtime system.

- **Non-cyclic**: Not constant at the boundary points
  The runtime system uses the cam as specified, including all discontinuities at the boundaries, even if it is applied cyclically. However, the acceleration limits and moment inertia of the mechanical system / drive are the governing factors.
- **Cyclic absolute**: Position-continuous in the boundary points
  The runtime system converts the cam in such a way that is position-continuous and velocity-continuous at the boundaries during cyclic operation, which can cause changes to occur in the characteristic.
- **Cyclic relative**: Constant velocity in the boundary points
  The runtime system calculates the cam in such a way that is has constant velocity at the boundaries during cyclic operation - within mathematical limits, which can cause changes to occur in the characteristic.

Overlapping segments

In the case of overlapping segments, segment validity can be defined using the options listed below.

- Segments *after* the *segment starting points* are valid
- Segments *up to* the *segment end points* are valid
- Valid segments are determined by the chronological order of insertion.

This behavior is set using the **_resetCam** command.

Inversion

Inverse mapping

For some applications, it is necessary to determine the master value for a defined slave value. The master value can be retrieved using **_getCamLeadingValue**. This inverse mapping is only unique in the case of strictly monotone output functions. In order to supply a master value for output functions that are not strictly monotone, an x-value is specified, and the nearest solution (in both directions) for a y-value is then sought for the specified x-value. If an x-value is not specified, the search will begin from the starting point of the function.

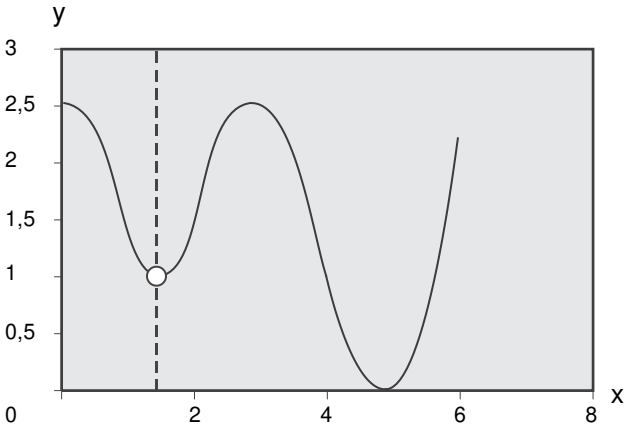

Figure 4-791 Output function

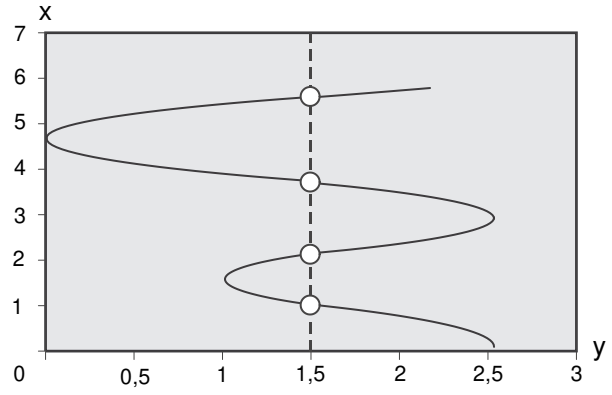

Figure 4-792 Inverse mapping

Inversion during interpolation

The option exists to invert a cam during preparation/interpolation and to store the cam in both the non-inverted and inverted shape (V3.0 and higher). Setting via configuration data **camRepresentation**

Advantage:
Data that has already been inverted can be accessed more quickly when the master value associated with the slave value is read out.

Disadvantage:
More memory is required in the runtime system.

Note

The inverted shape of the cam cannot be represented.

Motion laws in accordance with VDI

The VDI concept of *working ranges and motion transitions* is used to define a cam by means of segments. The **VDI Wizard** can also be used for assistance in the creation of cams.

Motion tasks (Page 2841)

Defining a cam for a motion task using segments (Page 2843)

Motion tasks

The VDI concept differentiates between working ranges and motion transitions.

- *Working ranges* correspond to sequences in a process. The VDI (Association of German Engineers) distinguishes between four different types of working ranges (see below).
- *Motion transitions* are transitions between working ranges, which are not directly relevant to the process but must satisfy certain boundary conditions (such as continuity in velocity and acceleration).

Working ranges in accordance with VDI

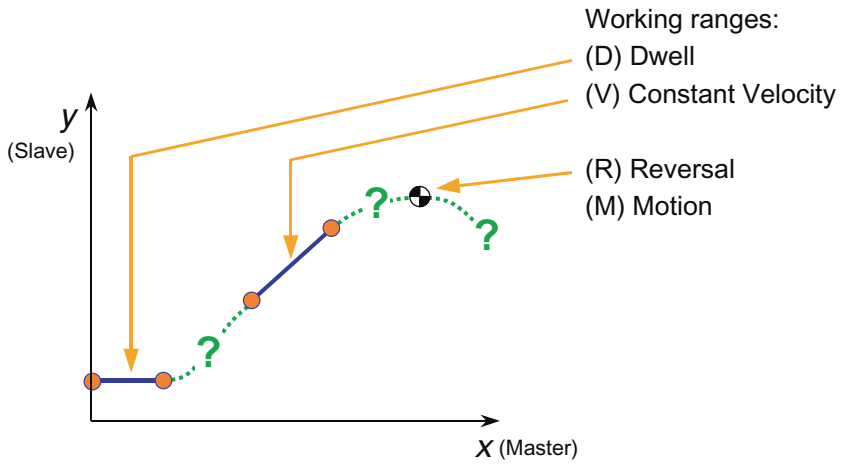

Figure 4-793 Working ranges in accordance with VDI

The VDI concept distinguishes between the following working ranges:

- **R: Dwell** (velocity = 0, acceleration = 0)
- **V: Constant velocity** (velocity <> 0, acceleration = 0)
- **A: Dwell** (velocity = 0, acceleration <> 0)
- **B: Motion** (velocity <> 0, acceleration <> 0)

Example

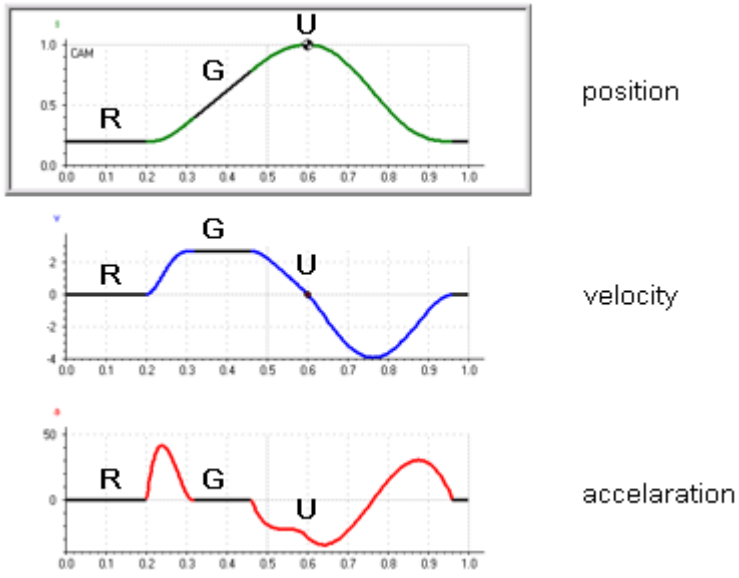

Figure 4-794 Example of a cam with three working ranges

Motion transitions in accordance with VDI

The motion transitions shown in the figure can occur between the individual working ranges.

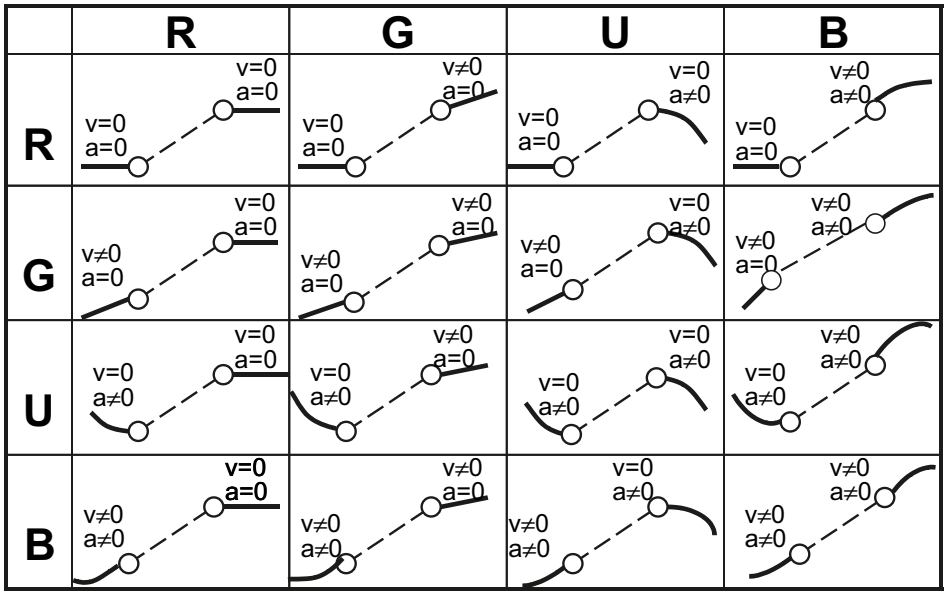

Figure 4-795 Motion transitions in accordance with VDI 2143

Defining a cam for a motion task using segments

Definition of working ranges

The **working ranges** of a motion task are usually specified by the process.

Example:

1. A tool waits on a production line for a piece to pass by (dwell).
2. The tool is synchronized to the work piece and performs an action on the work piece (constant velocity).
3. The tool then returns to the waiting position (reversal).

The process starts over from the beginning.

- In order to implement this sequence, the segments of a cam corresponding to the working ranges must first be created.

Creating a motion transition

Now the "only" things left to define are the **motion transitions** that satisfy certain conditions (e.g., jerk-free motion).

- Start by transforming the motion transition to the normalized range.
  For additional information, see Normalization (Page 2833).
- The **boundary conditions**, i.e., positions, velocities, and accelerations, must then be taken into account at the boundaries between segments.
- In order to apply a polynomial defined in such a way, it must be transformed back into the **real range**.

4.7.5.3 Cam Configuration

Cams can be created with SIMOTION SCOUT or the add-on SIMOTION CamTool add-on. In addition, the curve characteristic can also be defined by a user program during runtime.

You must perform the following tasks when you configure **cams** in SIMOTION SCOUT:

- Create a cam (Page 2844)
- Define the cam. (Page 2845)
- Exporting/importing cams (Page 2845)
- Interconnect the cam.
  Cams are assigned in the respective application. For related information, refer to the descriptions for the corresponding technology objects.

Creating a cam

Follow the steps described below to create a cam:

1. To create a Cam TO in **SCOUT**, double-click **Insert cam** below **CAMS** in the project navigator. You can also copy an existing Cam TO using the clipboard and insert it under another name.
2. Define the cam.

All cams are saved to the **CAMS** folder and are valid for the entire device. The cams can be assigned to all applicable objects of a device (e.g. synchronous objects). This assignment is symbolized in the project navigator, for example, as follows:

- A link to the cam is created below the synchronous object.
- A link to the synchronous object is created below the cam.

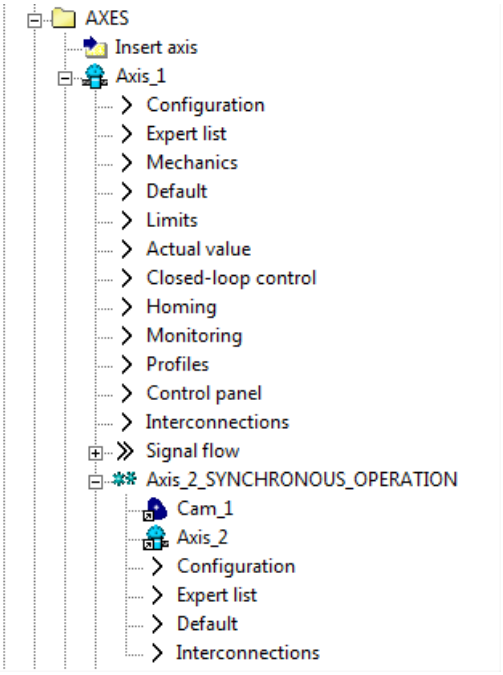

Figure 4-796 Representation of cams in the project navigator

Exporting/importing cams

Description

With CamEdit, you can export or import the geometry data of the cam. For further information, refer to the online help of the "CamEdit cam editor."

Defining and loading cams

Defining with CamEdit

CamEdit can be used to describe cams by means of either interpolation points or segments. These two methods cannot be combined. If the cam is to be created from segments using polynomials, **SIMOTION SCOUT** provides the **VDI Wizard** to assist in creation of the cam.

Defining with CamTool

CamTool is an add-on to the **SIMOTION SCOUT** engineering system providing a graphical option for creation of cams. The add-on is supplied with its own documentation.

Defining by means of program

SIMOTION provides various commands for creation of cams from the application. In ST, cams can be defined by specifying interpolation points, segments, interpolation type, and scaling.

For additional information, see Cam Programming/References (Page 2846).

Loading cams

With V4.2 and higher, an active, meshing cam can be loaded with CamEdit or by pressing the **Download** button.

Engaged cams can, therefore, be modified in the engineering system and replaced online. Neither the active camming motions nor active calculation of the valve characteristics are interrupted.

With versions lower than V4.2, it is not possible to download meshing cams to the device.

A cam is only calculated during runtime in the runtime system.

To facilitate diagnostics, the cam can be uploaded again from the runtime system following download so that any changes due to dynamic response adaptations can be detected.

If the cam is modified during runtime and the original cam is going to be downloaded to the runtime system again, the cam must be recompiled in SIMOTION SCOUT. (Otherwise, no change will be detected and the download will be skipped.)

Commands for definition (Page 2847)

4.7.5.4 Cam Programming/References

Table 4-324 Commands for cam programming

Command	Description
Message functions	Commands for reading out function values (Page 2849)
_getCamFollowingValue **_getCamFollowingDerivative** **_getCamFollowingMinMax**	The **_getCamFollowingValue** command returns the cam value, **_getCamFollowingDerivative**, the nth derivation for a specified value in the definition range. The **_getCamFollowingMinMax** command returns (with V4.2 and higher) the minimums and maximums of the cam or of an area of the cam and the associated nth derivation in a specified section of the definition range.
_getCamLeadingValue	**_getCamLeadingValue** returns the value in the definition range for the specified value in the value range
Command tracking	Commands for command tracking (Page 2851)
_getStateOfCamCommand	The **_getStateOfCamCommand** command returns a structure with the processing state of a command.
_bufferCamCommandId	With **_bufferCamCommandId**, the command status can be queried after completion or an abort of the command.
_removeBufferedCamCommandId	With **_removeBufferedCamCommandId**, the command should be explicitly removed from the command management of the TO after evaluation is completed.

Command	Description
Geometry	Commands for definition (Page 2847)
_addSegmentToCam	The **_addSegmentToCam** command provides you with the option of defining a cam profile in the user program on the basis of polynomial segments f = f(t).
_addPointToCam	The **_addPointToCam** command provides you with the option of defining a cam profile in the user program on the basis of individual interpolation points.
_addPolynomialSegmentToCam	The **_addPolynomialSegmentToCam** command creates a segment f = f(t), consisting of a polynomial with a maximum of 6 degrees.
_interpolateCam	Before a cam is used, it must first be interpolated with the **_interpolateCam** cam.
_setCamScale	The **_setCamScale** command scales a cam in the range or domain. See Scaling and offset (Page 2833).
_setCamOffset	The **_setCamOffset** command can be used to separately offset the domain and/or range of a cam. See Scaling and offset (Page 2833).
Object and Alarm Handling	Commands for resetting the cam and errors (Page 2850)
_getCamErrorNumberState	The **_getCamErrorNumberState** command can be used to fetch the status of an error number.
_resetCam	The **_resetCam** cam resets the cam.
_resetCamError	The **_resetCamError** command provides you with the option of acknowledging a particular error or all pending errors on the cam.

Commands for definition

Interpolation points, segments, or a combination of the two can be used to describe cams.

Commands for the following actions are available for modifying the definition of a cam:

- Adding segments (**_addSegmentToCam**)
- Adding interpolation points (**_addPointToCam**)
- Adding a polynomial segment (**_addPolynomialSegmentToCam**)
- Interpolation (**_interpolateCam**)

Programming a cam

When the cam is created, the order in which the cam is edited plays a role. If the shape of the cam is dependent on parameters and undergoes a change, the cam must be reset before each redefinition using the **_resetCam** command. The cam can also be reset prior to the first calculation without triggering an error message. This command "erases" the cam. This means that the interpolation is cleared and the points and segments are removed. The technology object is retained but is empty.

The interpolation points and/or segments are then placed side by side in the appropriate order. As with CamEdit, the interpolation points can be in any order and will be sorted automatically.

- This is accomplished using the **_addPointToCam** command (addition of an interpolation point), the **_addSegmentToCam** command (addition of a segment) or **_addPolynomialSegmentToCam** (addition of a polynomial segment).
- Use the **_resetCam** command to define cam behavior for overlapping segments/ranges.
- If the shape of the cam is described completely, interpolation is performed using the **_interpolateCam** command.

Subsequent addition of one or more points or segments, or modification of points or segments is not possible. In this case, the cam must be reset and recreated.

Adding segments (_addSegmentToCam)

The **_addSegmentToCam** command provides you with the option of defining a cam profile in the user program on the basis of polynomial segments f = f(t). Individual segments consist of a polynomial with a maximum of 6 degrees and a trigonometric component.

The polynomial parameters, amplitude, period, and phase of a sine function must be entered in standard form. The transformation parameters must be specified in the basic cam representation (without scaling or offset) or in the actual cam representation (with scaling, offset). The definition range values of the cam must always be increasing, i.e. specified in the positive direction.

Adding interpolation points (_addPointToCam)

The **_addPointToCam** command provides you with the option of defining a cam profile in the user program on the basis of individual interpolation points. In so doing, you can choose to specify values either for a scaled and offset range or a range that is not scaled and offset. The definition range values of the cam must always be increasing, i.e. specified in the positive direction.

Adding a polynomial segment (_addPolynomialSegmentToCam)

The **_addPolynomialSegmentToCam** command creates a segment f = f(t), consisting of a polynomial with a maximum of 6 degrees. The polynomial parameters are input in the real range.

Interpolation (_interpolateCam)

Before a cam is used, it must be interpolated. The interpolation defines the connections between points, between segments and between a point and a segment.

For additional information, see Interpolation (Page 2835).

Commands for reading out function values

The following commands can be used to read out individual function values from cam characteristics.

- The **_getCamLeadingValue** command supplies the value in the domain (master value) for the specified value in the range (slave value).
  Since this relationship is not always unique, a reference value can be specified. See Inversion (Page 2840).
- The **_getCamFollowingValue** command supplies the cam with a specified value in the domain (master value).
- The **_getCamFollowingDerivative** command can be used to obtain the n-th derivative of the function for a specified value in the domain (V4.0 and higher).
  The **derivativeOrder** parameter can be used to select the n-th derivative.
  This allows, for example, the application to replace specific cams and so take account of the velocity, acceleration, etc.

The **leadingPositionMode** parameter can be selected for the commands to specify whether the scaling and offset is to be used (**ACTUAL**) or not (**BASIC**).

Reading out the minimums/maximums of a cam

The **_getCamFollowingMinMax** command returns (with V4.2 and higher) the minimums and maximums of the cam or of an area of the cam and the associated nth derivation in a specified section of the definition range.

The minimums/maximums are also available (in the case of V4.2 and higher) via the **followingRange** system variable.

System variables

The sequence of programmed commands can be read out by means of system variables; see Monitoring the synchronization (Page 2671).

The **activeCam** variable indicates the active cam on the synchronous object. The variable is a read-only variable.

The **activeMaster** variable indicates the active master on the synchronous object. The variable is a read-only variable.

Commands for resetting the cam and errors

- The **_resetCam** command has the following effect:
  - The cam is reset to the initial state.
  - Pending errors are deleted.
  - Depending on the command parameters, the geometry and corrections are deleted as applicable (see table below).
  - The system variables are reset according to parameters.
    With versions lower than V4.2, resetting an active cam that is interconnected with a synchronous operation function by means of the **_enableCamming** command always results in an error message that has to be acknowledged. The **_resetCam** command cannot be executed.
  - With V4.2 and higher, the **camModify = WITHOUT_INTERPOLATION_AND_HOLD_ACTIVE_CAM** parameter can even be used to reset an active cam. This makes it easy to modify the cam subsequently.
- The **_resetCamError** command provides you with the option of acknowledging a particular error or all pending errors on the cam.
  The command is terminated with a negative acknowledgment if any errors that must not be acknowledged at this point are present.
- Parameter of the **_resetCam** command (for additional information, see TP system functions reference list)
- **insertMode** parameter (optional). Specifies the sequence interpretation with respect to subsequent entry of overlapping segments.
- **userDefaultData** parameter (optional). This parameter controls whether the user default values are reset to the configured values.
- **activateRestart** parameter (optional). Can be used to perform a technology object restart as well.
- **camData** parameter (optional). Specifies how the cam is to be reset.
- **camModify** parameter (optional, V4.2 and higher). This parameter controls the cam status during and after the **_resetCams** in relation to the geometry data.

Table 4-325 Modes of operation for the parameters associated with the **_resetCam** command for modifying a cam via the user program (UP)

	camModify parameter (V4.2 and higher)		
	WITH_INTERPOLATION	**WITHOUT_INTERPOLATION**	**WITHOUT_INTERPOLATION_AND_HOLD_ACTIVE_CAM**
camData parameter			
CAM_DATA_RESET	Deletes the currently effective cam. The cam can be reprogrammed. *) (Also applies to < V4.2)	Deletes the currently effective cam. The cam can be reprogrammed. *)	The active cam is retained. The cam can be reprogrammed in the background in parallel. *) **_interpolateCam()** activates the cam programmed in the background.

LOAD_CONFIGURED_DATA	The currently effective cam is loaded and interpolated with the configured interpolation with the data specified by the ES. (Also applies to < V4.2)	The currently effective cam is loaded with the data specified by the ES without interpolation and can be modified via UP before interpolation is then performed. *)	The active cam is retained. The cam is reloaded in parallel in the background without interpolation with the data specified by the ES and can be modified via the UP. *) **_interpolateCam()** activates the cam programmed in the background.
MAINTAIN_PROGRAMMED_DATA (V4.2 and higher)	Regardless of whether it is loaded from the ES or programmed via the UP, the currently effective cam is interpolated with the current interpolation settings.	Regardless of whether it is loaded from the ES or programmed via the UP, the currently effective cam is loaded without interpolation. It can then be modified via the UP and subsequently interpolated. *)	The active cam is retained. Regardless of whether it is loaded from the ES or programmed via the UP, the cam is loaded in parallel in the background without interpolation. It can then be modified via the UP. *) **_interpolateCam()** activates the cam programmed in the background.

*) Alteration of geometry definition, e.g. with **_add**...**ToCam()**

Commands for command tracking

- The **_getStateOfCamCommand** command returns a structure with the processing state of a command.
  - **functionResult** specifies the error code.
  - **commandIdState** returns the current state of the cam.
  - **abortId** specifies the command abort reason. The abort reason is specified for the alarm 30002 "Command aborted (reason: <abortId>, command type ...)".
    See also **_getMotionStateOfAxisCommand** for the **Axis technology object**.
- With **_bufferCamCommandId**, the command status can be queried after completion or an abort of the command.
- With **_removeBufferedCamCommandId** , the command should be explicitly removed from the command management of the technology object after evaluation is complete.

The number of motion commands that the MotionBuffer can accept can be specified using the **camType.DecodingConfigInfo.numberOfMaxbufferedCommandId** configuration data.

Further information is available in the SIMOTION reference lists.

Programming and sequence model

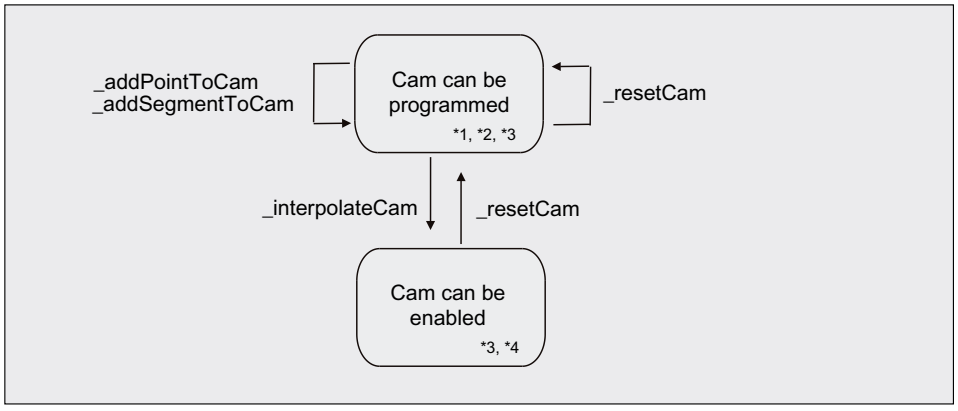

Figure 4-797 Programming and sequence model for a cam technology object

The following commands and functions are active in the particular technology object states:

*1 **_setCamScale**
_setCamOffset

*2 **_addPointToCam**
_addSegmentToCam

*3 **_getCamFollowingValue**, **_getCamFollowingDerivative**
_getCamLeadingValue

*4 **Error**
In general, illegal parameters and commands do not affect the states of the technology object, but they must be acknowledged using **_resetCamError**.

If commands that are not permitted in the technology object state are transmitted to the **Cam** technology object, an error message is triggered, which requires an acknowledgment. The technology object state, such as **programmable** or **cannot be activated**, is retained.

Local alarm response

Local **alarm responses** are set by means of the system.

The following responses are possible:

- **NONE**
  No response
- **DECODE_STOP**
  Command preparation aborted

Following a **_resetCam** or **_resetCamError**, editing of the Cam technology object can be resumed.

4.7.5.5 Graphic output

Reading out cams with CamEdit

Cams can be read out from the controller and displayed graphically using CamEdit.

A cam is only calculated during runtime in the runtime system. If it is read out from the controller, the calculated cam can be displayed graphically in CamEdit. If the cam is modified during runtime and the original cam is going to be downloaded to the runtime system again, the cam must be recompiled in SIMOTION SCOUT. (Otherwise, no change will be detected and the download will be skipped.)

By default, the cam is graphically displayed in the standard form in CamEdit. If scaling and/or offsetting of the cam is required, display in scaled form must be explicitly enabled.

If the command **_resetCam** with the parameter **camModify = WITHOUT_INTERPOLATION_AND_HOLD_ACTIVE_CAM** has been output in the user program, the active cam disk will be retained. On read-out, the data of the cam disk loaded in parallel in the background and modified via user program are fetched.

4.8 TO Axis Electric / Hydraulic, External Encoder

Preface

Content

This document is part of the **System and Function Descriptions** documentation package.

Scope of validity

This manual is valid for SIMOTION SCOUT product version V5.4:

- SIMOTION SCOUT V5.4 (engineering system of the SIMOTION product family)
- SIMOTION Kernel V5.4, V5.3, V5.2, V5.1, V4.5, V4.4, V4.3, V4.2, V4.1, V4.0
- SIMOTION technology packages CAM, CAM_ext and TControl in the version adapted to the respective kernel.

Sections in this manual

The following is a list of sections included in this manual along with a description of the information presented in each section.

Part I Axis

- **Overview**
  This section provides the user with an overview of the Axis technology object.
- **Axis Fundamentals**
  This section explains the basic setting options and functions of the Axis Technology Object.
- **Configuring an Axis**
  This section explains the configuration procedure with reference to various tasks.
- **Support for SINAMICS Safety Integrated Functions**
  This section describes the SIMOTION-side support for safety functions for SINAMICS drives.

Part II Hydraulic Functionality

- **Overview**
  This section provides the user with an overview of the hydraulic functionality of the Axis technology object.
- **Fundamentals of Hydraulic Functionality**
  This section explains the basic setting options and functions concerning the hydraulic functionality of the Axis technology object.

Part III Programming / Reference

- This section explains the commands and functions in greater detail.

Part IV External Encoder

- **Description**
  This section provides the user with an overview of the External Encoder technology object.
- **External Encoder Fundamentals**
  This section explains the basic setting options and functions of the External Encoder technology object.
- **Configuring an External Encoder (online help only)**
  This section explains the configuration procedure with reference to various tasks.
- **Programming External Encoders Reference**
  This section explains the commands and functions in greater detail.

Index

- Keyword index for locating information

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics

- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

4.8.1 Fundamental safety instructions

4.8.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

4.8.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

4.8.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

4.8.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

4.8.2 Part I Axis - Overview

4.8.2.1 General information about axes

Overview of available axis types

The instantiable **Axis technology object (TO)** is downloaded to the SIMOTION device with a technology package, thus providing the function for activating and monitoring an actuator (drive, motor, valve, etc.). As of V3.2, the **Axis technology object (TO)** is included in the Cam, Path, and Cam_ext technology packages.

The functionality is set by configuration and parameter assignment / programming.

The Axis technology object can be applied to an axis with an electric drive (axis) or an axis with a hydraulic final controlling element / valve (hydraulic functionality).

Any number of axes may be generated, based on the CPU processing power.

When programming in SIMOTION SCOUT (e.g. with MCC), an Axis technology object can be accessed via system functions or system variables. For example, to traverse an axis at a specified velocity to a certain position, you specify the velocity and position via system functions. All other functions (e.g. monitoring of limit values) are specified via the configuration data and system variables of the Axis technology object.

The following axis technologies are distinguished during the configuration phase:

- **Speed-controlled axis**
  Motion control is performed using a speed specification without position control.
  Choosing this axis technology provides the minimum functionality for an axis.
  The speed-controlled axis is referred to by the data type **driveAxis** in reference lists and when programming.
- **Positioning axis**
  Motions are position-controlled.
  The position axis is referred to by the data type **posAxis** in reference lists and when programming.

- **Synchronous axis**
  The synchronous axis creates a grouping of the following axis and synchronous object. Functions such as master value coupling, synchronization and desynchronization, and gearing and camming are provided via the synchronous object. The synchronous object can be interconnected with different master values.
  See the Technology Objects Synchronous Operation, Cam manual for information about using the synchronous axis.
  The following axis is referred to by the data type **followingAxis** and the synchronous object by **followingObjectType** in reference lists and when programming.
- **Path axis**
  The path axis type can be interconnected with a path object.
  The path object can be used to calculate and traverse a linear, circular or polynomial path in the 2D/3D coordinate system for at least two path axes and up to three path axes. A synchronous axis can be traversed in parallel to this.
  The Technology Object Path Object manual describes how to use the path axis with the path object.
  The path axis is referred to by the data type **_pathAxis** and the path object by the data type **_pathObjectType** in reference lists and when programming.

All axis types can also be configured as **virtual axes**, i.e. they do not control a real drive but are used as auxiliary axes for calculations, e.g. as a virtual master axis for several slave axes (line shaft).

Axis operation in SIMOTION

- Any necessary settings can be made by means of configuration data on the axis.
- States are indicated, and standard values and settings can be read and entered by means of system variables on the axis.
- Axis motion sequences are specified by means of motion commands on the axis. The user program can be used to check the motion status at any time and to control specific aspects of the motion. Motions can be aborted, overridden, appended, or superimposed.
- Errors and technological alarms are indicated using alarms on the axis.

Advanced functions

Advanced functions on the axis include path interpolation, synchronous operation, measuring inputs, and output cams. For more information refer to the manuals: Technology Object Path Object, Technology Object Synchronous Operation, and Technology Objects for Output Cams and Measuring Inputs.

Functional interface to the drive

The functional interface to the drive is the speed setpoint interface.

The functional interface to a hydraulic valve is the analog flow rate setpoint and, if available, the analog force limiting or pressure limit value.

It is possible to connect both analog drives and digital drives as well as stepper drives.

Standardized protocols are used for setpoint specification for digital drives and for acknowledgments of encoder information.

Note

A SIMOTION axis can only execute functions that are supported by the connected drive. For further information, refer to the relevant product descriptions for the drives.

Automatic configuration as of V4.2 (Use symbolic assignment setting)

The only settings required during configuration are the preferred technology and functionality for the axis and encoder and the drive to be used by the axis. The PROFIdrive telegrams required for communication are determined and set by the system when the online connection is established.

Automatic adaptation uses add relevant drive data to the TO configuration without having to make these settings manually.

This functionality is available as of with SIMOTION V4.2 in conjunction with SINAMICS V2.6.2.

Programming commands / functions for the Axis technology object

The MCC and ST programming languages are available for programming axes.

Axis functions can also be addressed via the PLCopen blocks of the SIMOTION Function Library (up to V3.2) and the SCOUT command library (as of V4.0). This can also be accomplished in the LAD and FBD programming languages.

See the *SIMOTION MCC Motion Control Chart*, *SIMOTION ST Structured Text* and *PLCopen* Programming Manuals.

4.8.3 Axis fundamentals

4.8.3.1 Axis technologies

Overview of axis technologies

The Axis technology object can be configured as a speed-controlled axis, positioning axis, synchronous axis, or path axis. The various axis technologies differ according to the functionality provided on the axis.

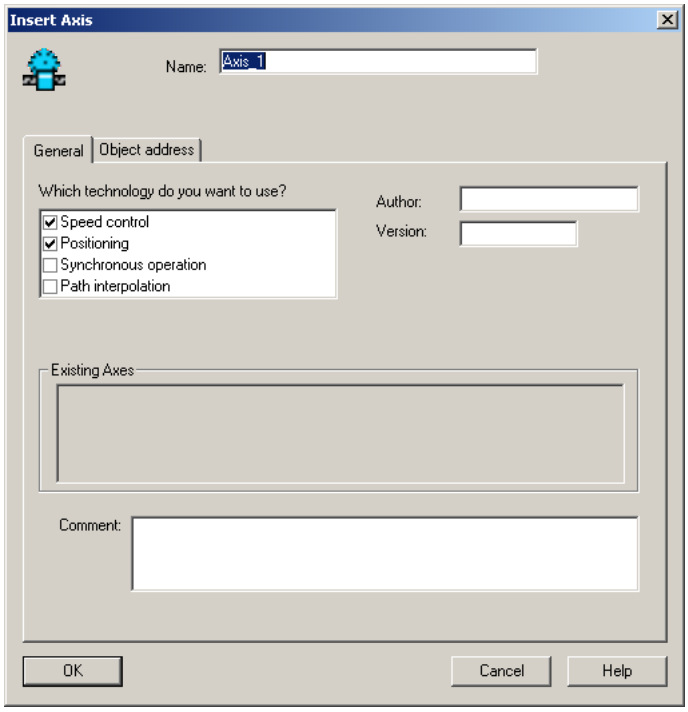

Figure 4-798 Axis technology setting in SIMOTION SCOUT

Possible axis functions in relation to the axis type

Table 4-326 Axis functions - Overview

Function	Speed-controlled axis	Positioning axis	Following axis	Path axis
Speed or velocity specification	X	X	X	X
Travel with torque limitation	X	X	X	X
Traversing according to motion vectors	X	X	X	X
Positioning	-	X	X	X
Travel to fixed stop	-	X	X	X
Homing	-	X	X	X

Function	Speed-controlled axis	Positioning axis	Following axis	Path axis
Advanced functions				
Measuring input	-	X	X	X
Output cam	-	X	X	X
Cam track	-	X	X	X
Gearing	-	-	X	X
Camming	-	-	X	X
Path interpolation	-	-	-	X

Operating modes

- Setpoint operation
  Setpoint mode is the "normal" mode of the axis, in which motion commands are accepted and executed.
- Follow-up mode
  The setpoint is corrected to the actual value in follow-up mode. The actual position value and actual speed value will be updated. The axis can then also be tracked if it is moved by external effects.
  Motion commands are not accepted/executed.
- Simulation mode
  The axis and the position controller are active in simulation mode. Simulation mode is used to test the programmed sequences in the control and the interaction between various axes, for example, on the basis of trace recordings without moving the axis.
  Simulation mode is only useful for real axes.
  Two variants of simulation mode are possible:
  - Program simulation mode
    The setpoints are calculated according to the programming, but are not sent to the position controller. The position controller setpoints remain set at the values they had prior to switching to simulation mode.
    See also Enabling/disabling program simulation (Page 3170).
  - Axis simulation mode
    Unlike program simulation, it is possible to switch a real axis to axis simulation status even if the drive is not connected. The position controller remains active and the drive is simulated.
    See also Setting as a real axis without drive (axis simulation) (Page 2899).

The operating modes are set via commands.

Speed-controlled axis

The speed-controlled axis type is used when the position of the axis is of no importance. Only the speed or velocity of an axis is specified, controlled, and monitored.

The speed is monitored if an encoder is configured on the axis; otherwise, the speed is not monitored.

The position of the speed-controlled axis is not monitored or controlled.

The speed of rotation is indicated as a unit of velocity, such as rpm.

Operating modes

- Speed controlled / speed specification (setpoint mode)
- Simulation
- Follow-up mode

Functions

- Speed or velocity specified via
  - Programmable value setting
  - Free velocity profile (time-related)
- Travel with torque limitation
- Force/pressure control, force/pressure limiting (for hydraulic functions only)

Positioning axis

The positioning axis type specifies, controls, and monitors the position of the axis.

The axis is moved to a programmed target position, which can be specified as a relative or an absolute value. The direction of motion or rotation can be specified for modulo axes.

For position-controlled positioning axes, position control is possible in the CPU or in the drive, provided the drive supports the dynamic servo control (DSC) method.

The positioning axis in SIMOTION does not have a velocity controller. The speed controller for an electric axis is in the drive.

The positioning axis can be interconnected with a path object for path-synchronous motion as a master axis with synchronous axis or as an axis.

Operating modes

As for speed-controlled axis, plus

- Position control

Functions

- Speed or velocity specified via
  - Programmable value setting
  - Free velocity profile (time- or position-related)
- Travel with torque limitation
- Position specified via
  - Programmable value setting
  - Free velocity profile (time-related)
- Travel to fixed stop
- Homing
- Force/pressure control, force/pressure limiting

- Synchronization of encoder values
- Positioning axis with path-synchronous motion (see path interpolation)

Synchronous axis

The synchronous axis type determines the axis setpoint from a master value according to conversion rules.

The synchronous object and following axis are separate objects, but together they form a synchronous axis.

The "Axis" and "Synchronous Operation" technology objects have a reciprocal effect on each other in terms of their operating states and the effectiveness of the commands used.

For example, errors in the "Axis" technology object will directly affect the synchronous operation functionality. When an axis stop response is triggered, the synchronous motion is stopped as well.

Operating modes

As for positioning axis

Functions

In addition to the positioning axis functions, other functions are available via the synchronous object:

- Gearing
- Camming
- Velocity gearing
- Dynamic synchronization/desynchronization

Other functions associated with the Synchronous Axis technology object can be found in the SIMOTION Technology Objects for Synchronous Operation, Cam Manual.

Path axis

The path axis type is used to travel along a path together with at least one additional path axis on the path object.

Via the path object, a path can be generated for at least two and up to three path axes.

The setpoints generated for the axis on the path object are limited on the axis to the maximum dynamic values of the axis.

The "Path Axis" and "Path Object" technology objects have a reciprocal effect on each other in terms of their operating states and the effectiveness of the commands used.

For example, errors in the "Path Axis" technology object will directly affect the generation of motion on the path object. When a stop response is triggered on the axis, the path motion is stopped as well.

Operating modes

As for positioning axis

Functions

In addition to the positioning axis functions, other functions are available via the path object:

- Linear path interpolation
- Circular path interpolation
- Polynomial path interpolation

The path axis contains the functionality of the synchronous axis.

Other functions associated with the Path Interpolation technology object can be found in the *SIMOTION Technology Object Path Object* Manual.

Axis-drive relationship

Technology objects represent the applicable real objects (e.g. an axis) in the controller.
The Axis technology object provides the user with a technological view of the drive and encoder (actuator and sensor), provides technological functions for them and performs the specific hardware connection.

The Axis technology object includes comprehensive functionality, e.g. communication with the drive, actual value conditioning, position control and positioning functions. It executes control and motion commands and indicates statuses and actual values.

The drive contains the speed and current control for the motor.

Technological limiting functions and values for the axis and encoder mechanics (e.g. leadscrew pitch and gear) are set at the axis.
The user can then only work with technological parameters.

The Axis technology object communicates with an actuator (drive or hydraulic valve) via a field bus system (PROFIBUS or PROFINET via PROFIdrive protocol) or via a direct setpoint interface (analog ±10 V or pulse/direction).

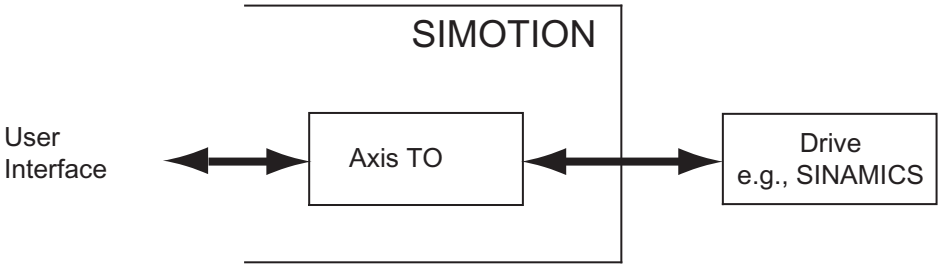

Figure 4-799 Axis-drive relationship

Functional interface to the drive

Various functional interfaces to the drive are available.

Analog drives, hydraulic valves, or stepper drives can be operated at the direct setpoint interface. See also Setting as a real axis with analog drive link (Page 2877), Linking analog drives to SIMOTION (Page 3062).

Setpoint specifications and feedback signals (incl. encoder information) for drives connected to a field bus are provided via standardized protocols (standard telegrams in accordance with the PROFIdrive profile). See also Coupling of digital drives (Page 2895).

4.8.3.2 Axis types

Overview of axis types

There are different axis types that differ according to their axis mechanism. The axis type also determines the units used to calculate axis variables such as position, velocity, etc.

- **Linear axes**
  Linear axes have coordinates that are specified in a unit of length. The position profile is continuous within the traversing range. Motion instructions are specified in units of length, for example in mm.
- **Rotary axes**
  Rotary axes have coordinates that are specified in a unit of rotation. The position profile is continuous within the traversing range. Motion instructions are specified in units of rotation, for example in degrees or rad.
- **Setting a linear axis or rotary axis as a modulo axis**
  Modulo axes have an unlimited traversing range and their position is mapped to a repeating modulo traversing range. The modulo range is defined by the start value and the modulo length.
  If the position value or axis position overshoots the modulo length, the position is reset to the modulo start value. If the position value undershoots the modulo start position, it is reset to the modulo start value plus the modulo length.
  Like rotary axes, linear axes can also be defined as modulo axes (modulo linear axis, modulo rotary axis).

Axis type setting

The following settings are available for the **axis type**:

- **Linear**
- **Rotary**

and

- **Electrical**
- **Hydraulic**
- **Virtual**

The **electrical**, **hydraulic**, or **virtual** setting affects the subsequent menu content.

Real_QFAxis_With_Closed_Loop_Force_Control	x			x			x			x	
		x		x			x			x	
	x			x				x		x	
		x		x				x		x	
Real_QFAxis_With_Open_Loop_Force_Control_only [b]		x		x			x		x		
		x		x				x	x		

a not possible for speed-controlled axis
b speed-controlled axis only
c not possible for speed-controlled axis
d hydraulic functionality only

4.8.3.3 Units and accuracies

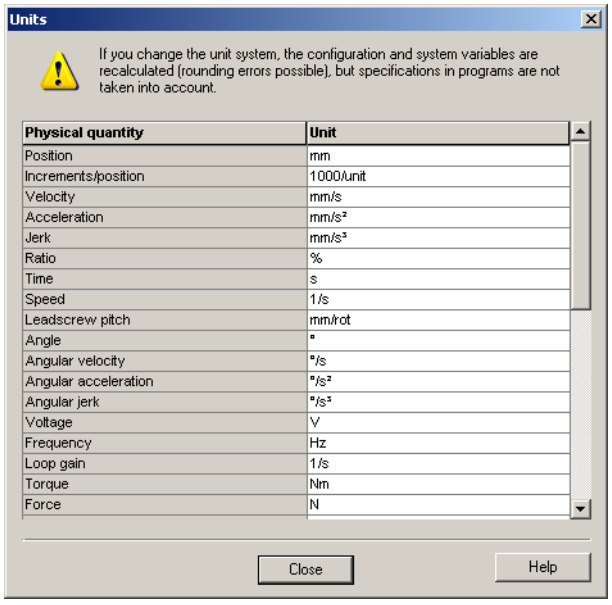

Figure 4-804 Setting the units and resolution in SIMOTION SCOUT

With the SIMOTION technology objects, such as the Axis technology object, physical variables such as position, velocity, acceleration, time, force, and torque are represented in the SI or US system of units (metric or imperial). The unit can be defined for all variables on the relevant technology object during configuration, for example, for:

- Unit of length
  - mm
  - m
  - km
  - inch
- Unit of force
  - N
  - kN
  - tfm
    ton force, metric unit
  - tfs
    ton force (short) or ton force (US), US unit

The defined units represent system variables and configuration data.

Changing the unit settings converts the current values of the system variables and configuration data from the engineering system to the new units.

Note

Values in the command parameters are interpreted in the defined unit on the technology object.

Numerical values in user programs (e.g. in the motion commands) are **not** converted to the new units when the unit settings are changed!

In compound variables, such as controller gains, the units may differ from the units of the individual variables, for example, force in [kN] and force/time in [N]/[sec].

The **internal computational accuracy and internal representation of the position** can also be defined in the unit configuration. It defines, among other things, the accuracy with which specifications in system variables, configuration data, and command parameters are accepted, processed, and displayed by the system.

Note

The positioning accuracy equates to one computational increment (increments/position), i.e. positions can only be defined at integer increment values. Intermediate values arising during interpolation and as a result of closed-loop control may also exist between the integer increments.

The display resolution and the resolution when entering parameter values are independent of the increments.

This definition refers to a specific basic unit of the position, depending on the axis type.

- Linear axis: Increments/mm
- Rotary axis / speed-controlled axis: Increments/degree

The control performs internal calculations in increments with reference to these basic units. Prior to processing, values are converted to the internal representation.

Example 1

The following configuration has been defined:

- Linear axis
- Position unit: m
- Increments/position: 1000/mm

Calculation of setpoint accuracy during positioning:

Position: 1,000/mm corresponds to 0.001 mm = 10^{-6} m

Example 2

The following configuration has been defined:

- Linear axis
- Position unit: mm
- Increments/position: 1000/mm

- Leadscrew pitch: 10.3334 mm
- Modulo length: 20.3335 mm

Determination of the effective leadscrew pitch and modulo length:

Position accuracy: 0.001 mm

- Effective leadscrew pitch on the TO: 10.333 mm
- Effective modulo length: 20.333 mm

If the leadscrew pitch and the modulo length have to be mapped precisely, the positioning accuracy on the TO has to be increased (incr/mm).

Fetch the units setting

The units setting can be fetched using the associated specially defined system variables. The listing of the variables is shown below:

- <speedaxis>.units : StructUnitsSpeedAxis
- <posaxis>.unitsPosAxis : StructUnitsPosAxis
- <externalencoder>.units : StructUnitsExternalEncoder
- <controller>.units : StructUnitsController
- <sensor>.units : StructUnitsSensor
- <synchronousoperations>.units : StructUnitsSynchronousOperations
- <temperaturechannel>.units : StructUnitsTemperatureChannel
- <pathobject>.units : StructUnitsPathObject
- <additionobject>.units : StructUnitsAdditionObject
- <fixedgear>.units : StructUnitsFixedGear
- <measuringinputs>.units : StructUnitsMeasuringInputs
- <outputcam>.units : StructUnitsOutputCam
- <camtrack>.units : StructUnitsCamTrack

Note

Fetching is possible only when the units have valid values, which is the case only in online mode.

For further information, see the *TP System Variables* List Manual.

4.8.3.4 Axis settings / drive assignment

Overview of how to create an axis

New axes are created using an axis wizard in which the axis parameters (configuration data and system variables) are queried or are configured automatically. You can specify other selected parameters via the axis parameter assignment dialog boxes (under Axis Object in the project navigator).

Real and virtual axes

Setting options

In SIMOTION, you can define the axes as:

- **Real axis**
  This axis features motion control, as well as drive and encoder interfaces.
- **Real axis with force/pressure control**
  This axis features motion control, drive and encoder interfaces, and an interface for force/pressure measurement and closed-loop control.
  For force/pressure control, the input for the force/pressure measurement must also be configured.
- **Virtual axis**
  This axis features reference variable generation, but does not have closed-loop control or a drive or encoder interface. The setpoints and actual values are always identical. A virtual axis is generally used as an auxiliary axis, in order to generate the setpoints for several real axes as the master axis, for example.
  The controller-specific enables are set by default.

See also Overview of axis types (Page 2866).

Axes with no drive assignment (as of V4.2)

A drive is assigned to the axis in the drive assignment dialog during axis configuration. It is also possible, however, to leave the drive assignment open. The real axis can be programmed with all functions and the system remains operational after axes with no assigned drive have been downloaded. No consistency error is output.

One advantage of axes with no assigned drive is that you can set up and test the configuration in advance while there is still no drive or if you do not have all the necessary drive know-how. The axis can be connected to a drive later.

Runtime model and processing

The integrated motion control functionality uses a deterministic real-time runtime model for motion control purposes. This includes, in particular:

- Isochronous system levels for
  - Bus task
    PROFIBUS/PROFINET communication for linking digital drives, data exchange with the I/O
  - Servo_fast (optional)
    Position control and monitoring of axes, drive communication, and I/O processing synchronized with a fast PROFINET cycle clock
  - Servo
    Position control and monitoring of axes, drive communication, and I/O processing
  - IPO_fast
    Motion control for the axes is calculated in the fast PROFINET bus system
  - IPO
    Interpolator = reference variable calculation/motion profile calculation of the axes
    The interpolator cycle clock is set during configuration of the execution system of the device. There are two interpolator levels in the system, IPO and IPO2.
- Adjustable transformation ratios between bus task, servo, and IPO for appropriate load distribution and optimum system utilization

The processing cycle clock (axis-specific interpolator cycle clock) of the axis technology object can be set to IPO or IPO2. This makes it possible to place an interpolator for axes that do not require a high time resolution to calculate reference variables in a cyclical system task with a longer cycle time, thereby requiring less processing power.

For fast responses in motion control, in exceptional cases, the processing cycle clock can even be set to servo or servo_fast, see also Motion execution/interpolator (Page 3045).

The processing cycle clock is set in the axis dialog configuration.

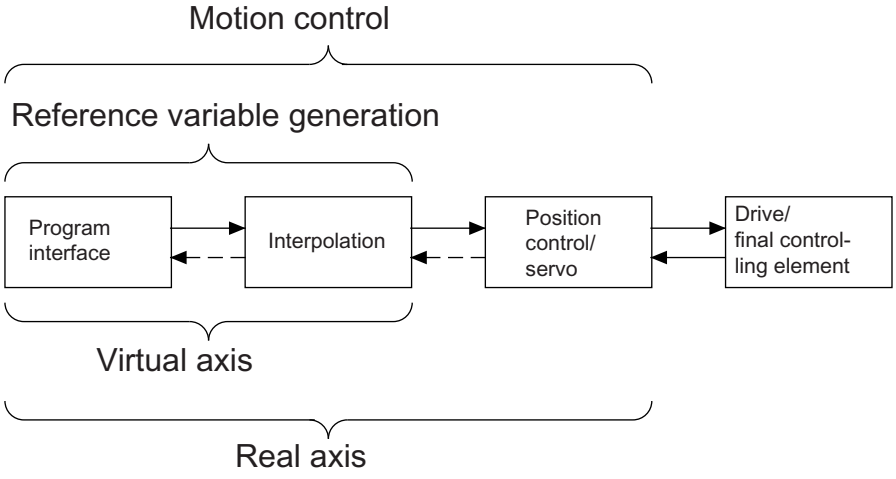

Figure 4-805 Difference between real and virtual axis (position axis example)

For real axes, the interface to the drives/final controlling elements is set.

For the hydraulic functionality, the analog output is set for manipulated variable value Q (flow rate) and, if applicable, for manipulated variable value F (force/pressure limiting). This makes it possible to connect valves with an analog manipulated variable.

If DSC (Dynamic Servo Control) is set for digital drives with a PROFIdrive interface, a position controller is executed in the drive (e.g. in the closed-loop speed control cycle clock).

If **symbolic assignment** is used (default setting as of V4.2), DSC is selected automatically.

Setting as a real axis with analog drive link

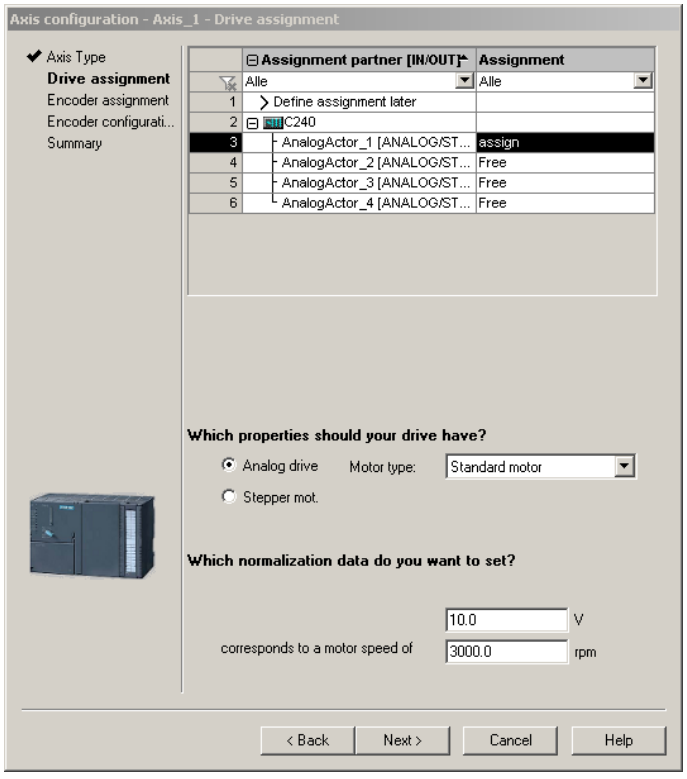

Figure 4-806 Setting for analog drive link to C2xx

For interconnection of the axis-specific inputs/outputs (encoder, analog output, enables), see the C2xx operating instructions.

In addition to the option of operating analog axes on the onboard inputs of the C2xx, the PROFIBUS ADI4 and IM174 modules are available for use in all platforms as interfaces for analog drive links. From the SIMOTION perspective, these modules behave like digital drive links; see Coupling of digital drives (Page 2895).

The enable signal to the drive is activated with **_enableAxis()** (**enableMode**=ALL); the enable is displayed by the system variables **actormonitoring.driveState** = ACTIVE and **actormonitoring.power** = ACTIVE.

See also

Coupling of digital drives (Page 2895)

Setting as a real axis with digital drive coupling

Symbolic assignment and adaptation (as of V4.2)

As of V4.2, SIMOTION supports the automatic adaptation of drive data as well as the configuration of technology objects (TOs) with symbolic assignment.
This makes it easier to configure the technical relationships between the SIMOTION technology objects (TOs) and the SINAMICS drive objects (DOs).

Adaptation and symbolic assignment enable:

- The required axis telegrams, as well as the addresses used, to be automatically specified by the engineering system
- Telegrams to be expanded and interconnections in the drive to be set up automatically dependent upon the selected TO technology (e.g. SINAMICS Safety Integrated)
- Axis configuration and drive configuration to be completed as two separate procedures
- Drive and encoder data, as well as reference variables, maximum variables, torque limits, and the selectivity associated with torque reduction on the SINAMICS S120 to be adapted automatically on system ramp-up

For more information, please refer to the sections of the **Motion Control Basic Functions** manual which deal with *symbolic assignment (as of V4.2)*.

Requirement

The following components support adaptation and symbolic assignment:

- SIMOTION C, P and D devices, with firmware as of SIMOTION V4.2
- SINAMICS S110 drives, firmware V4.x with SINAMICS as of V4.3
- SINAMICS S120 drives, firmware V2.x with SINAMICS as of V2.6.2
- SINAMICS S120 drives, firmware V4.x with SINAMICS as of V4.3

The SINAMICS versions indicated relate to:

- SINAMICS control units connected via PROFIBUS or PROFINET
- SINAMICS Integrated on a SIMOTION D
- Controller extensions CX32/CX32-2

Axis configuration: Drive assignment

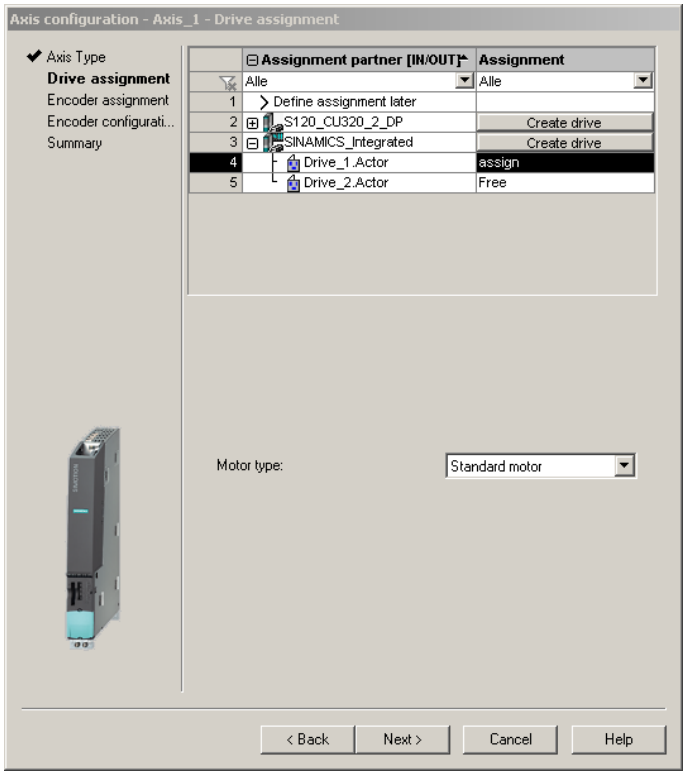

Figure 4-807 Drive assignment dialog

The following settings can be made in the **Drive assignment** dialog for the axis configuration:

- Assign drive
  All of the drives configured in SCOUT or HW Config are displayed as assignment partners. To interconnect a drive, click a drive object in the table in the **Drive assignment** dialog.
  The hardware addresses and telegrams are determined automatically by the system.
- Assign later
  Enables the axes to be configured independently on the SIMOTION side and the drives to be configured independently on the SINAMICS side.
  This means, for example, that:
  - The drives can be configured by a drive expert and tested and optimized using the drive control panel
  - The PLC and Motion Control functions can be configured by a programmer using technology objects (e.g. Axis technology object)
  - The technology objects can then be symbolically assigned to the drive objects at a later point in time via an assignment dialog
- Create drive
  From the Assign dialog, a new drive can be created on an existing drive unit directly (e.g. S120 CU320-2 or SINAMICS Integrated) and the axis assigned. As a result, it is not necessary to configure a drive before creating an axis.

The TO axis, TO external encoder, TO output cam, TO cam track, and TO measuring input support symbolic assignment. Furthermore, the onboard I/O of a SIMOTION D, a SINAMICS S120 control unit, and even selected terminal modules can be interconnected symbolically (e.g. for hardware-limit-switch inputs on the technology object).

The list of addresses in the **All addresses** view provides an overview of the assignments of all the Axis technology object interfaces. It is also possible to change the assignments from this view via the Assign dialog (**...** button).

Note

The previous methods of drive and axis configuration continue to be available. Symbolic assignment must be deactivated in such cases.

Symbolic assignment is used by default for newly created projects.

If projects < V4.2 are converted upwards, symbolic assignment is deactivated by default and must be activated if required.

Symbolic assignment can be activated/deactivated in SIMOTION SCOUT via the **Project > Use symbolic assignment** menu.

Adaptation

In addition to the benefits offered by symbolic assignment, configuration is also made easier as of SIMOTION V4.2 with the addition of automatic adaptation of SINAMICS S120 data.

Drive and encoder data as well as reference variables, maximum values, torque limits and granularity for SINAMICS S120 torque reduction, are taken over automatically for the configuration data of the SIMOTION Axis and External encoder technology objects. These data no longer have to be entered in SIMOTION.

Events and commands after which an adaptation is carried out:

- Switching the controller on (ramp-up)
- Download
- STOP-RUN transition, if no adaptation has been made yet
- Restarting a TO
- **_activateTO()** command
- **_enableAxisInterface()** command if the status "not adapted" is present at the interface with non-exclusive drive assignment
- **_adaptAxisConfigData()** and **_adaptExternalEncoderConfigData()** user commands
- Drive data set changeover (and encoder changeover does not cause adaptation)

The adaptation of relevant drive data is activated automatically as of SIMOTION V4.2 in conjunction with SINAMICS S120 as of V2.6.2. If projects < V4.2 are converted upwards, automatic adaptation is deactivated by default. You can activate automatic adaptation if required via the expert list in the configuration data element **TypeOfAxis.DriveControlConfig.dataAdaption**. You can activate automatic adaptation of encoder data in the configuration data element **TypeOfAxis.NumberOfEncoders.Encoder_n.dataAdaption**.

The configured data initially contains default values for the values to be adapted. Adaptation may result in a difference between the configured values and the adapted values. In the case of a *Copy current data to RAM*, the TO would, therefore, be displayed as inconsistent in the project navigator.

When executing the functions *Copy current data to RAM* and *Copy RAM to ROM*, the difference will be detected and an upload of the adapted data into the SCOUT project will be executed. However, this can be deselected in the dialog box.

Adapted data (SINAMICS S120 as of V2.6.2)

The adapted drive and encoder data is listed in the following.

Adapted drive data (motor and actuator)

Table 4-331 Reference and maximum velocity

Motor type	Parameter	Configuration data element
Round-frame motor	p2000	**driveData.nominalSpeed**
Linear motor	p2000	**linearMotorDriveData.nominalSpeed**
Round-frame motor	p1082	**driveData.maxSpeed**
Linear motor	p1082	**linearMotorDriveData.maxSpeed**

Table 4-332 Resolution of torque reduction

Motor type	Parameter	Configuration data element
Round-frame motor	p1544	**driveData.torqueReductionGranularity**
	p1520	**driveData.maxTorque** (and p1520 = |p1521|)
Linear motor	p1544	**linearMotorDriveData.forceReductionGranularity**
	p1520	**linearMotorDriveData.maxForce** (and p1520 = |p1521|)

Table 4-333 Resolution of the reference and maximum values for B+, B-, M_{add} (technology data block)

Motor type	Parameter	Configuration data element
Round-frame motor	p2003	**driveData.nominalTorque**
Linear motor	p2003	**linearMotorDriveData.nominalForce**

Table 4-334 Adaptation of the parameters for specific DO types and availability in the drive

Parameter	Semantics	DO Servo	DO Vector	DO TM41	DO DCM	DO Encoder
p2000	Reference speed	x	x	x	x	x
p2003	Reference torque	x	x	x	x	-
p1082	Maximum speed	x	x	-	-	-

Parameter	Semantics	DO Servo	DO Vector	DO TM41	DO DCM	DO Encoder
p1520	Maximum torque	x	x	-	-	-
p1544	Torque reduction granularity (only 100 telegrams)	x	-	-	-	-
p0979	Encoder information	x	x	x	x (only telegram 1)	x

The following conditions must be observed:

- When assigning an axis on a SINAMICS drive, the following is set implicitly:
  - **Adaptation**
    driveControlConfig.dataAdaption=YES
  - **speedReference** (speed, velocity) to nominalspeed, ~velocity
    driveDate.speedreference=NOMINAL_VALUE
    linearMotorDriveData.velocityReference=NOMINAL_VALUE
  - **torqueReference**, **forceReference** (torque, force) to nominaltorque, ~force
    driveDate.torqueReference=NOMINAL_VALUE
    linearMotorDriveData.forceReference=NOMINAL_VALUE
- Adaptation is not set generally for an interconnection to a SINAMICS DO, but specifically depending on the DO type.
  This means that the properties of the DO type are known when setting the adaptation.
- Parameter p1544:**driveData.torqueReductionGranularity** or **linearMotorDriveData.forceReductionGranularity** is only adapted when a 1xx telegram is set.
  Otherwise no adaptation, since it is not relevant or with DO vector, DO TM 41 and DO DCM also not available.
- If parameter p1082 (maximum speed) is not available on a DO, then the maximum speed is set equal to the reference speed in SIMOTION (**driveData.maxSpeed** = driveData.nominalSpeed or **linearMotorDriveData.maxSpeed** = linearMotorDriveData.nominalSpeed).
  This is the case, for example, for DO TM41 or TO DCM.
- If parameter p1520 (maximum torque) is not available on a DO (e.g. DO DCM), then the maximum torque/force is set equal to the reference torque/force on the TO (**driveData.maxTorque** = driveData.nominalTorque or **linearMotorDriveData.maxForce** = linearMotorDriveData.nominalForce). The torque values are not adapted when interconnecting to DO TM41.

Adapted encoder data

The encoder type set in the axis configuration, incremental or absolute, is checked during the adaptation.

The measuring system setting, linear or rotary, is adapted.

Table 4-335 Incremental rotary encoder

Encoder characteristic data	Parameter	Configuration data element
Increments/revolution	p0979[2]	**incEncoder.incResolution**
Fine resolution	p0979[3]	**incEncoder.incResolutionMultiplierCyclic**

Table 4-336 Incremental linear encoder

Encoder characteristic data	Parameter	Configuration data element
Grid spacing	p0979[2]	**resolution.distance**
Fine resolution	p0979[3]	**resolution.multiplierCyclic**

Table 4-337 Absolute rotary encoder

Encoder characteristic data	Parameter	Configuration data element
Increments/revolution	p0979[2]	**absEncoder.absResolution**
Fine resolution	p0979[3]	**absEncoder.absResolutionMultiplierCyclic**
Fine resolution for absolute value in Gn_XIST2	p0979[4]	**absEncoder.absResolutionMultiplierAbsolute**
Data width of absolute value without fine resolution	p0979[2] and p0979[5] *)	**absEncoder.absDataLength**

*) The data width of the absolute value (without fine resolution) is a result of the sum of the bits for representing the number of encoder pulses and the bits for representing the maximum number of revolutions that can be registered by the encoder according to the type plate.

Example:
4,096 pulses/rev (= 12 bit) and maximum of 4096 revolutions that can be registered results in a 12 + 12 = 24-bit data width of the absolute value.

Table 4-338 Absolute linear encoder

Encoder characteristic data	Parameter	Configuration data element
Grid spacing	p0979[2]	**resolution.distance** (**resolution.multiplierCyclic** has no significance for a linear absolute encoder)
Fine resolution	p0979[3]	**absEncoder.absResolutionMultiplierCyclic**

Encoder characteristic data	Parameter	Configuration data element
Fine resolution for absolute value in Gn_XIST2	p0979[4]	**absEncoder.absResolutionMultiplierAbsolute**
Data width of absolute value without fine resolution	p0979[2] and p0979[5] *)	**absEncoder.absDataLength**

*) The data width of the absolute value (without fine resolution) is a result of the sum of the bits for representing the number of encoder pulses and the bits for representing the maximum number of revolutions that can be registered by the encoder according to the type plate.

Example:
4,096 pulses/rev (= 12 bit) and maximum of 4096 revolutions that can be registered results in a 12 + 12 = 24-bit data width of the absolute value.

Communication and control word / status word

Communication with the drive via PROFIdrive

The communication with digital drives using PROFIBUS/PROFINET is made in accordance with the PROFIdrive V4 specification and the application classes 1 to 4 (class 4 both with and without DSC).

The ADI4 and IM 174 modules can be used to connect axes with analog interface to the system. The system uses the standard 3 telegram in accordance with the PROFIdrive profiles for the ADI4 and IM174 modules. Consequently, in this case, the axis TO sees a real axis with digital drive coupling.

For axes with digital drive coupling using the PROFIdrive telegram, the maximum velocity is twice the reference velocity.

Control word

Drive enables are set in conformity with PROFIdrive Profile V3.1 via control word STW1.

Control bits in control word STW1

The Axis technology object takes over control of the control word with the **_enableAxis()** and **_disableAxis()** commands.

The system uses **_enableAxis()** or **_disableAxis()** to set the control bits in STW1 bit 0 - STW1 bit 6. Also refer to the following table for the semantics of the STW1 bit 0 – STW1 bit 6 control word bits.

_enableAxis() (**enableMode**=DRIVE) is used to set Bit4 - Bit6 in STW1, while **_enableAxis()** (**enableMode**:=POWER) is used to set Bit0 - Bit3 in STW1.

enableMode=ALL is used to set the DRIVE and POWER bits.

Table 4-339 Meaning of the control word bits STW1 bit 0 – STW1 bit 6

STW1	Bit = 0 meaning	Bit = 1 meaning	Notes
Bit 0	OFF, Brake on ramp-function gen. (OFF 1)	ON	Brake along the ramp generator deceleration ramp followed by pulse suppression
Bit 1	Coast stop (OFF2)	No coast stop (no OFF2)	Pulse suppression
Bit 2	Quick stop (OFF3)	No quick stop (no OFF3)	Brake along the OFF3 deceleration ramp followed by pulse suppression
Bit 3	Disable operation	Enable operation	-
Bit 4	Disable ramp generator	Enable ramp generator	-
Bit 5	Freeze ramp generator	Unfreeze ramp generator	-
Bit 6	Disable setpoint	Enable setpoint	-

You can find a detailed description of the bits in status and control words in the SINAMICS List Manuals.

The control word from the drive protocol is displayed in the system variable **driveData.STW** (STW1 corresponds to STW[0]).

The states are also displayed in the SCOUT at **Drives - Drive_x - Diagnosis - Control/status words**.

Stop modes with PROFIdrive – Profile Drive Technology

- STW1 bit 0 = 0 (OFF1): **Ramp stop**
  - The drive travels to zero velocity with the deceleration that can be defined on the drive.
  - The stopping process can be interrupted and the drive reactivated.
  - After stopping, a pulse suppression is carried out and the status changes to ready to start.
- STW1 bit 1 = 0 (OFF2): **Coast stop**
  - The drive immediately goes to pulse suppression and the status changes to switch-on disable.
    The drive coasts to a standstill.
- STW1 bit 2 = 0 (OFF3): **Quick stop**
  - The drive travels to zero velocity with the torque limit that can be defined on the drive.
  - The stopping process cannot be interrupted.
  - After stopping, a pulse suppression is carried out and the status changes to switch-on disable.

Status word

Status word ZSW1 contains status information of the drive in accordance with PROFIdrive profile V3.1.

Table 4-340 Meaning of the status word bits ZSW1 bit0 – ZSW1 bit 15

ZSW1	Bit = 0 meaning	Bit = 1 meaning	Notes / parameters
Bit 0	Not ready to power up	Ready to start Power supply on, electronics initialized, line contactor released if applicable, pulses inhibited.	BO: r0899.0
Bit 1	Not ready for operation Reason: No ON command present	Ready for operation Voltage at Line Module, i.e. line contactor closed (if used), field is being built up.	BO: r0899.1
Bit 2	Operation inhibited	Operation enabled Enable electronics and pulses, then ramp up to active setpoint	BO: r0899.2
Bit 3	No fault active No active fault in the fault buffer.	Fault active The drive is faulty and, therefore, out of service. The drive switches to "switching on inhibited" once the fault has been acknowledged and the cause has been remedied. The active faults are stored in the fault buffer.	BO: r2139.3
Bit 4	Coasting down active (OFF2) An OFF2 command is active.	No OFF2 active	BO: r0899.4
Bit 5	Quick stop active (OFF3) An OFF3 command is active.	No OFF3 active	BO: r0899.5
Bit 6	No "Power-on inhibit" Switching on is possible	Power-on inhibit A restart is only possible by means of OFF1 and then ON.	BO: r0899.6
Bit 7	No alarm active No active alarm in the alarm buffer.	Alarm active The drive is operational again. No acknowledgment necessary. The active alarms are stored in the alarm buffer.	BO: r2139.7
Bit 8	Setpoint/actual speed monitoring not within tolerance band	Setpoint/actual speed monitoring within tolerance band Actual value within a tolerance band; dynamic overshoot or undershoot for t < t_{max} permissible, e.g. $n = n_{set}\pm$ $f = f_{set}\pm$, etc., t_{max} can be parameterized	BO: r2197.7

ZSW1	Bit = 0 meaning	Bit = 1 meaning	Notes / parameters
Bit 9	Local operation Control only possible on device	Control requested The PLC is requested to assume control. Condition for applications with isochronous mode: Drive synchronized with PLC system.	BO: r0899.9
Bit 10	f or n comparison value not reached.	f or n comparison value reached or exceeded.	BO: r2199.1 **Note:** The message is parameterized as follows: p2141 Threshold value p2142 Hysteresis
Bit 11	I, M or P limit reached or exceeded	I, M or P limit not reached	BO: r1407.7
Bit 12	Holding brake closed	Holding brake opened	BO: r0899.12
Bit 13	Motor overtemperature alarm active	Motor overtemperature alarm not active	BO: r2135.14
Bit 14	Actual speed < 0	Actual speed > = 0	BO: r2197.3
Bit 15	Alarm, converter thermal overload The overtemperature alarm for the converter is active.	No alarm active	BO: r2135.15

The status word from the drive protocol is displayed in the system variable **driveData.ZSW** (ZSW1 corresponds to ZSW[0]).

Alarm reactions (Page 3181)

Specific removal of drive enables in the event of a fault

In the event of a fault (local alarm reaction RELEASE_DISABLE), all drive enables are removed by default.
A setting can also be made to remove drive enables individually.
To access the **Functions - Response to alarm** dialog, select the *Axis - Configuration* menu and click the *Change* ... button under Functions.

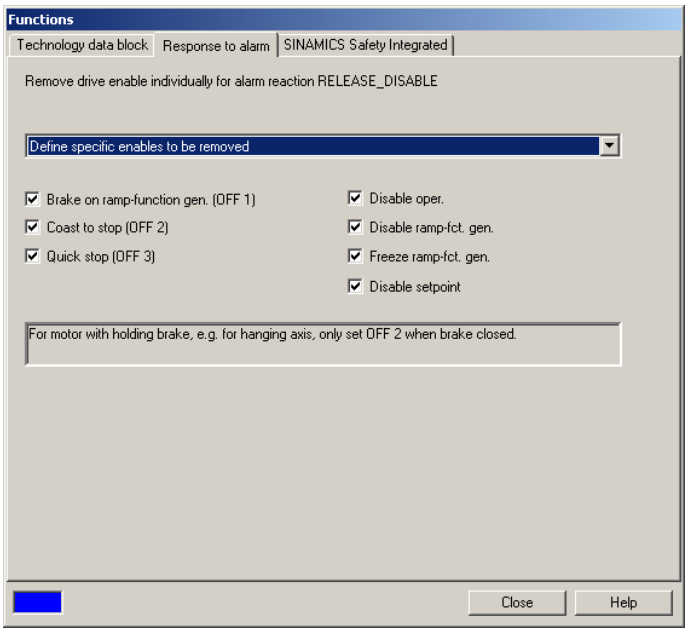

Figure 4-808 Settings for the drive in SCOUT

The bits selected in the screen form will be reset in the control word for the RELEASE_DISABLE local alarm response.

For the local RELEASE_DISABLE alarm response, all enables to the drive will be removed for system setting. Before the enables in STW1 bit 0 - STW1 bit3 are removed, status word ZSW1 bit 10 = 0 (n = 0 in the drive) will be awaited in accordance with the general state diagram in SIMOTION (see figure below).
This system setting can be changed in the **TypeOfAxis.driveControlConfig.releaseDisableMode** configuration data as well as in the dialog box.

Note

At a minimum, the canceling of one enable from bit 0 to bit 6 must be set.

If the value 0 is entered in **releaseDisableMode** in bit 0 to bit 6, all enables are canceled.

See also

Alarm reactions (Page 3181)

Brake control

The brake control is required for operating "hanging axes", for example. The integral brake control of the drives is used for this purpose.
The brake control must be taken into account when enabling the drive and revoking the enable signal.

System support (from SIMOTION V4.4)

The configuration data element **TypeOfAxis.DriveControlConfig.disableModeSpecification** can be used to switch off the drive via AUS3 by default if OFF1_AND_OFF3_MODE is set. OFF2 is therefore only set for the drive when e.g. the brake is closed.
This setting is also the standard setting for newly created axes.

When the enable signals are revoked (via **_disableAxis()** or the RELEASE_DISABLE alarm response), the system behaves as follows if OFF1_AND_OFF3_MODE is set:

1. OFF1 and OFF3 are canceled first when the axis is switched off.
   - The OFF3 ramp is therefore active.
   - STW1 bit0 is already 0 (power-on inhibit canceled)
2. After the drive has transitioned to S1 or S2 as per the PROFIdrive General State Diagram, the remaining enable signals for switching off are canceled.

This functionality is independent of the brake control configuration in the drive and is active even when the enable signals are canceled via the axis control panel.

Directly and exclusively setting OFF2 is always effective.

Extended brake control with SINAMICS

In the case of extended brake control with SINAMICS, the ready signal "Operation enabled" is sent to SIMOTION via status word 1 (system variable **driveData.ZSW[0]** Bit 2) after the brake opening time has expired (p1216). This means the step enabling condition following **_enableAxis()** is not met until the brake opening time has expired.

Please note that when using the extended brake control, the feedback signal "Brake released" is not sent to the ZSW[0] Bit2 (operation enabled), and instead only the brake opening time is taken into account.

When implementing a brake control in the drive, the enable signals must be specifically revoked in the case of **_disableAxis()** and the RELEASE_DISABLE local alarm response (see above), e.g.:

- First, revoke OFF3 (STW1 bit 2)
- When the brake is closed, disconnect the power (revoke STW1 bit 1)

For information on defining the reaction to technological alarms, refer also to Chapter Adjustable response to RELEASE_DISABLE (Page 3185).

Specify control bits via the application (without TO check) [expert]

As of V3.2, it is also possible to specify Bit0 - Bit6 in STW1 specifically via **_enableAxis()** (enableMode:=BY_STW_BIT) and **_disableAxis()** (disableMode:=BY_STW_BIT). Each bit to be set/canceled is then specified in the STWBitSet parameter. For this setting, the axis TO checks also for single bit assignment whether the specifications of the PROFIdrive state machine are observed.

If the axis is switched on from the S1 state, in accordance with PROFIdrive, bit 0 of the initial state 0 for STW1 is required (pulse suppression and ready-to-start status). If STW1 bit 0 in state S1 is not set to 0 (as result of enables being canceled using single-bit assignment or the cancelation of some enables with the RELEASE_DISABLE alarm reaction), STW1 bit 0 must be set to 0 by means of single-bit assignment in the **_disableAxis()** command or **_disableAxis()** with disableMode:=ALL. If this is not the case, a switch on of the axis will be rejected with alarm 20005: Type 1 reason 0x0100h (control signals to the PROFIdrive state machine specified incorrectly).

The status in **actorMonitoring.power** is displayed as specified in STW1 in versions up to and including V3.1. As of V3.2, it is displayed as per Bit0 - Bit2 in ZSW1.

The status indication in **actorMonitoring.driveState** is made in accordance with the specifications in STW1 bit 4 - STW1 bit 6, and will not be derived from the drive status.

The control word and the status word from the drive protocol are indicated in the **drivedata.stw** and **drivedata.zsw** system variables.

n-actual from the drive protocol is indicated in the **actorData.actualspeed** system variable (as of V4.0).

Specify control bits in STW1 via the application (without checking technology object) [expert]

As of V4.1 SP2, the **_disableAxis()** (**disableMode**:=STATE_MACHINE_CONTROL_BY_APPLICATION) setting can be used to directly specify the control bits in STW1 bit 0 - STW1 bit 6 using the **_setAxisSTW()** command without the TO testing correctness in accordance with the PROFIdrive profile state machine.

This makes it possible to switch a drive on and off that does not behave conform to the PROFIdrive profile state machine. A traversing of the drive using the TO or a motion variable generation using the TO for the drive is not possible in this status.

Another possible use is, for example, the stopping of large drives with closed brake in the magnetized state. If the speed controller enable is removed, after the re-setting of the speed controller enable, it is possible to continue motion again without switching the drive on again and so needing to pass through the S1 to S4 states.

The position controller must be switched to 'tracking' (**servoControlMode**=INACTIVE). This setting places the **control** indicator variable to INACTIVE, i.e. no movement commands can be performed. For independent drive transitions, e.g. S4->S5, no 20005 alarm will be generated in this state. The STATE_MACHINE_CONTROL_BY_APPLICATION mode is switched off with the **_enableAxis()** / **_disableAxis()** commands, with another setting of the mode and with **_resetAxis()**.

In the STATE_MACHINE_CONTROL_BY_APPLICATION mode,

- The **actorMonitoring.driveState** and **actorMonitoring.power** system variables indicate INACTIVE.
- The setting/resetting of the STW1 bit 0 - STW1 bit 6 bits is permitted directly using the **_setAxisSTW()** command.
- A fault message for the drive can be reset only using the TO control with **_resetAxisError()**. The control bit STW1 bit 7 (reset fault memory / fault acknowledge) remains in TO administration, a handling of STW1 bit 7 using **_setAxisSTW()** is not possible.
  This means a fault is reset uniformly using the TO, whereby the acknowledgement can be made using SCOUT/HMI or the user program.
- The TO axis no longer performs any monitoring for drive failure / independent disable of the drive. Other monitoring functions remain active, e.g. encoder monitoring, sign-of-life monitoring, drive error 20005: Reason 1 will be signaled and entered in the diagnostic buffer.
- All alarms are performed with RELEASE_DISABLE response as OPEN_POSITION_CONTROL response.

When the STATE_MACHINE_CONTROL_BY_APPLICATION mode is exited and so further handling of the state machine continues using the TO,

- The TO uses the control signals that were transferred last to the drive.
- When the mode is disabled, the current status of the state machine will be assumed. If the axis is activated in state S4, e.g. with **_enableAxis()**, no reactivation of the drive is possible. Consequently, the drive should be in a defined PROFIdrive S1-S4 state with regard to the drive, otherwise the TO will initiate the technological alarm 20005: type 1 reason 0x04 and the enables for the drive removed.

The status is indicated with the **actorMonitoring.stateMachineControl**=APPLICATION system variables.

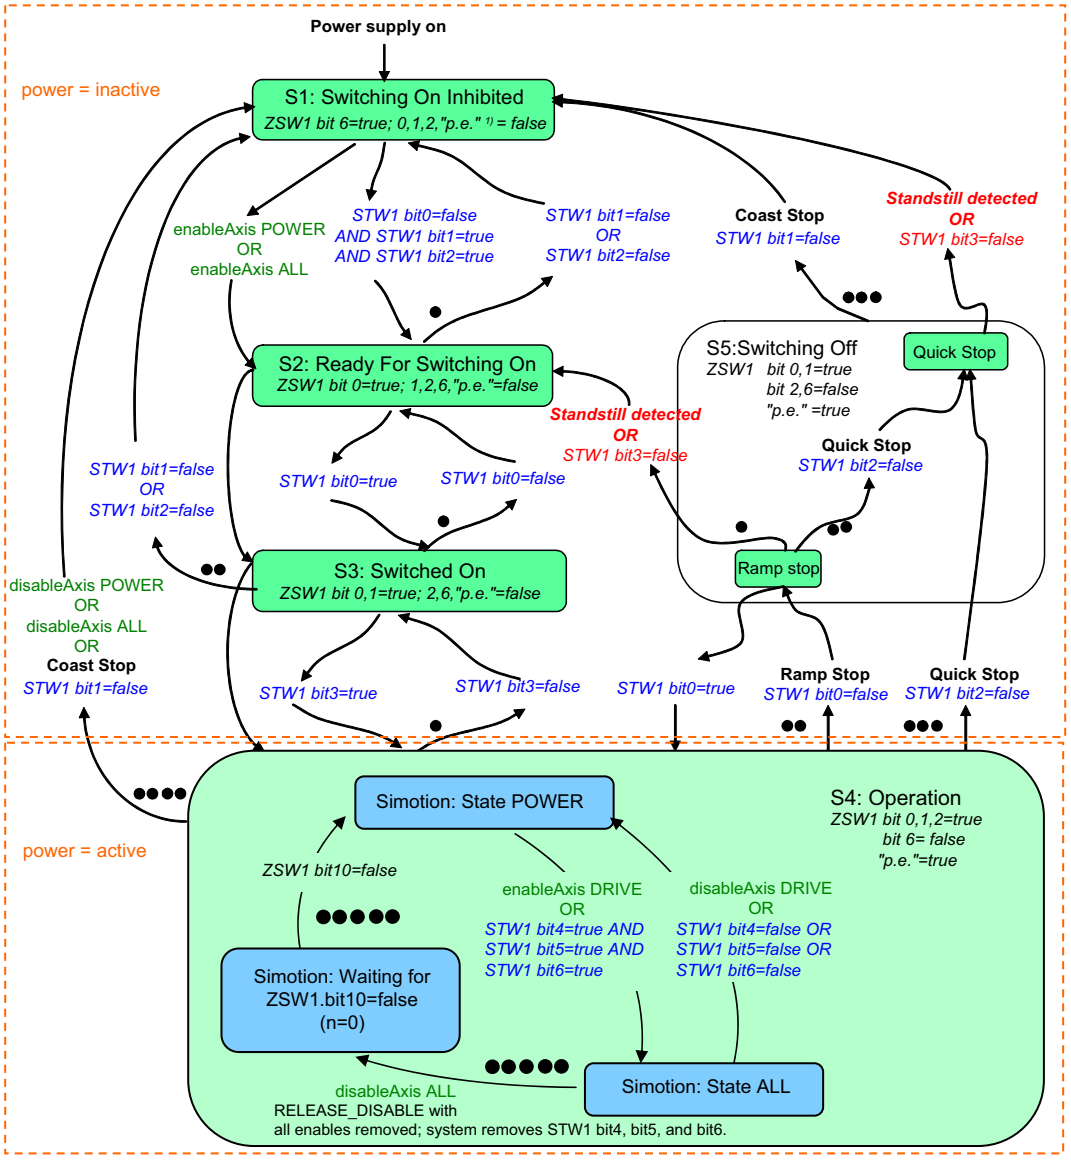
Alarm reactions (Page 3181)

Status diagram - PROFIdrive General State Diagram



STW1 bit x,y = These control word bits must be set by the controller.
ZSW1 bit x,y = These status word bits indicate the current status.
1) Abbreviation: "p.e." = "pulses enabled" optional, not supported by SIMOTION
Standstill detected: an internal result of a Stop operation
●●●…: The number of points at the illustrated transitions determines the priority.
The more points, the higher the priority.
- With SIMOTION V3.2 and higher, two variations are possible for the parameter assignment of the _enableAxis() command:
POWER/DRIVE/ALL: The StateMachine is controlled by the Axis technology object.
BY_STW_BIT: The StateMachine is controlled by the user program.
- The drivestate system variable is active in all states S1-S4 if STW1 bits 4 to 6 are set to true.

Figure 4-809 General state diagram in SIMOTION

SIMOTION system behavior with a drive-autonomous OFF3 ramp

When an OFF3 ramp is triggered (by the SS1 or SS2 safety functions, for example), the behavior with regard to the shutting down of the SINAMICS drives during the OFF3 ramp varies dependent upon certain settings on the Axis technology object:

A) Behavior as of SIMOTION V4.2:

As of SIMOTION V4.2, drive-autonomous motion (triggered by SS1, for example), can be clearly identified even if the *Safety Integrated Extended Functions* have not been set; in other words, even if **TypeOfAxis.TechnologicalData.driveSafetyExtendedFunctionsEnabled**=NO.
This requires that the configuration data item **TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation** is set to YES (system setting when new axes are set up).
This means that drive enables can be canceled during the drive-autonomous state.

If **TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation** is set to COMPATIBILITY_MODE (for axes from projects converted upwards), the behavior from V4.1 applies. If DSDB (Page 3087) is used, this setting is not allowed (**TypeOfAxis.TechnologicalData.numberOfDriveSafetyDataBlock**>0).

B) Behavior in SIMOTION V4.1:

If a drive-autonomous motion is triggered, it is not possible to cancel the drive enables during the autonomous state unless the Extended Safety Functions are set (**TypeOfAxis.TechnologicalData.driveSafetyExtendedFunctionsEnabled**=NO).

A drive-autonomous motion can be triggered by selecting SS1, for example. The drive enables cannot be removed during the drive-autonomous motion - neither through the user command **_disableAxis()** nor through an error on the axis with the local reaction RELEASE_DISABLE.

This is to be taken into account when designing software and hardware limit switches among other things.

If the Extended Functions are set (that is to say if **TypeOfAxis.TechnologicalData.driveSafetyExtendedFunctionsEnabled**=YES and **TypeOfAxis.DriveControlConfig.pulsesEnabled** are correctly configured), it is possible to cancel the drive enables during the autonomous state (e.g. by using the **_disableAxis()** command and the RELEASE_DISABLE error response).

For **TypeOfAxis.DriveControlConfig.pulsesEnabled** configuration, see Pulse enable evaluation (when standard settings are deactivated) (Page 3107).

This needs to be taken into account, for example, in cases where a control has already been configured for a V4.1 CPU and an additional control is then added via PROFIsafe or TM54F to the OFF3 ramp via a terminal or to the Safety Integrated Basic Functions via terminals (mixed operation).

To avoid following error limit 50102 during the OFF3 ramp in this case, the following procedure is recommended:

1. Cyclic evaluation of the system variables
   - driveData.driveSafetyExtendedFunctionsInfoData.state.1=TRUE
   - driveData.driveSafetyExtendedFunctionsInfoData.state.2=TRUE
   - driveData.ZSW[0].5=FALSE
2. If a condition is fulfilled switch to follow-up mode.
   (e.g. with the command **_move()** at velocity = 0 and movingMode=SPEED_CONTROLLED)

Technology data (Page 3018)

Coupling of digital drives

Separation of reference value and maximum value (as of V4.0 through < V4.2)

With V4.2 and higher, the reference/maximum velocity, reference/maximum torque, and reference/maximum force are adapted by the SINAMICS drive during runtime by default. The following is not relevant in this context.

For digital drive coupling, the reference value for sending the speed or velocity to the drive can be configured independently of the maximum value. Alternatively, the maximum speed/velocity can still be used as the reference value. This can be defined accordingly in the **driveData.speedReference** or **linearMotorDriveData.speedReference** configuration data element.

When a new axis is created and coupled with a digital drive, the normalization speed/velocity is pre-selected as the reference value by default in the axis wizard. The maximum speed/velocity can be entered independently.

With SIMODRIVE and MASTERDRIVE, this data must be entered manually. You must make sure that the reference values are the same on the drive and the controller.

In all cases, you still have the option of setting the maximum velocity as the reference velocity.

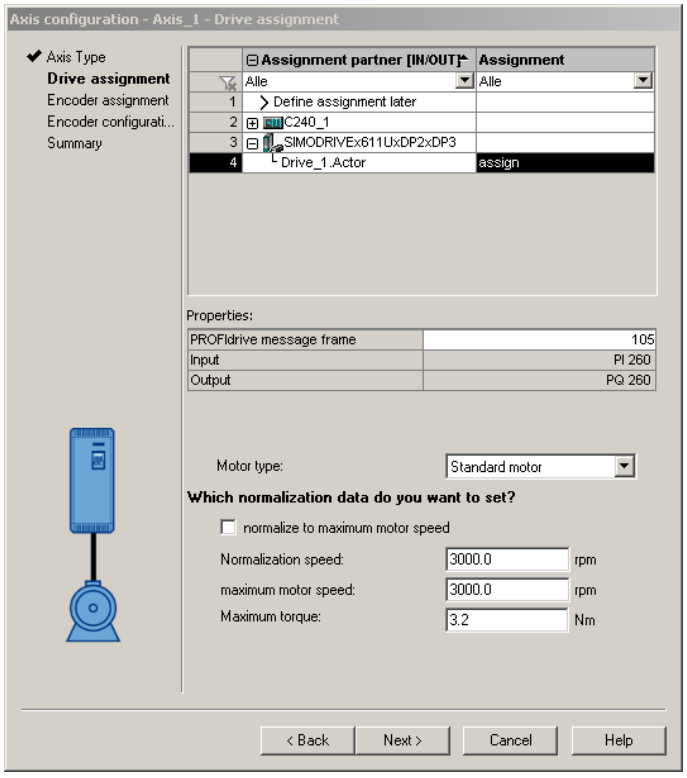

Figure 4-810 Setting the normalization speed and maximum motor speed

In the axis wizard, the drive settings are displayed as default settings.

For a coupling with SINAMICS, you can use the **Data transfer from the drive** button to transfer the **normalization speed**/velocity and the **maximum speed**/velocity from the offline configuration of the drive. If the relevant drive parameters are modified online, they must be uploaded and saved to the project prior to the data transfer.

SINAMICS Safety Integrated Extended Functions

See Overview - Support of SINAMICS Safety Integrated Functions on the Axis technology object (Page 3079).

Drive communication based on DPV1 services

Drive communication based on DPV1 services facilitates acyclic communication with the drive, e.g. making it possible to read and write drive parameters.

For more information, see Drive communication based on DPV1 services (Page 3059).

Time-of-day synchronization SIMOTION - SINAMICS

As of V4.2, SIMOTION features automatic time-of-day synchronization.

The time of day on the SINAMICS drive system is synchronized with the master SIMOTION system and the time ratio between SINAMICS messages and SIMOTION messages is correct.

For firmware versions < V4.2, see Drive communication based on DPV1 services (Page 3059).

The following control units support time synchronization:

- SINAMICS Integrated of the SIMOTION D
- CX32/CX32-2 controller extensions
- SINAMICS S120 CU310, CU310-2, CU320, CU320-2 Control Units connected via PROFIBUS or PROFINET

Requirement: SIMOTION V4.4 and higher

Setting as a real axis with stepper drive C2xx (V3.2 and higher)

Possible drive types for stepper motors:

- Stepper motor with encoder
- Stepper motor without encoder
  In this case, stepper motor is entered as the encoder mode and the encoder side is not used.

When you select stepper motor without encoder on drive 1, encoder input 1 is assigned automatically since this data is traced back to it within the system. Drive 1 cannot be selected if the encoder input is no longer free.

For stepper motors, you can enter the number of steps and the stepping rate. The speed of rotation is then calculated and displayed.

Stepper drives on IM174 and stepper drives with PROFIBUS interface

The IM174 module is available as the interface for stepper drives for all SIMOTION platforms. From the SIMOTION perspective, stepper drives linked via IM174 behave like digital drive links.

Alternatively, stepper drives can be linked with a PROFIBUS interface if they support the PROFIdrive profile.

You can find more information in the *Distributed I/Os IM 174 PROFIBUS Module* Manual.

Coupling of digital drives (Page 2895)

Setting as a real axis with encoder signal simulation (V4.0 and higher)

With this setting, no drive/actuator is connected via the Axis technology object. An angle signal is output directly to a third-party control via the SINAMICS TM41 peripheral module (encoder simulation).

The output angle signal behaves just like the signal from an incremental encoder.

Enable signal

The enable signal to the drive is activated with **_enableAxis()** (**enableMode**=ALL); the enable is displayed by the system variables **actormonitoring.driveState** = ACTIVE and **actormonitoring.power** = ACTIVE.

See also

Encoder signal output (V4.0 or later) (Page 2984)

Setting a non-exclusive drive assignment (as of V4.1 SP1)

The **typeOfAxis.setpointDriverInfo.InterfaceAllocation** setting is used to assign the drive/actuator of the axis to the drive, either exclusively (in versions up to and including V4.0) or non-exclusively (as of V4.1 SP1). For non-exclusive assignment, you must specify whether this drive interface should be activated when the technology object is ramped up.

With non-exclusive drive assignment, you can interconnect several Axis technology objects with one drive.

The **_enableAxisInterface()** and **_disableAxisInterface()** commands or the actor=YES function parameter are used to activate and deactivate the actuator interface during operation.

The Activated/Deactivated drive interface status is displayed in the **actorMonitoring.output** system variable.

See also

Non-exclusive encoder assignment (as of V4.1 SP1) (Page 2917)

Setting as a real axis without drive (axis simulation)

It is possible to switch a real axis to simulation status even if the drive is not connected. The axis simulation status is displayed in the configuration dialog for the axis under drive and encoder assignment.

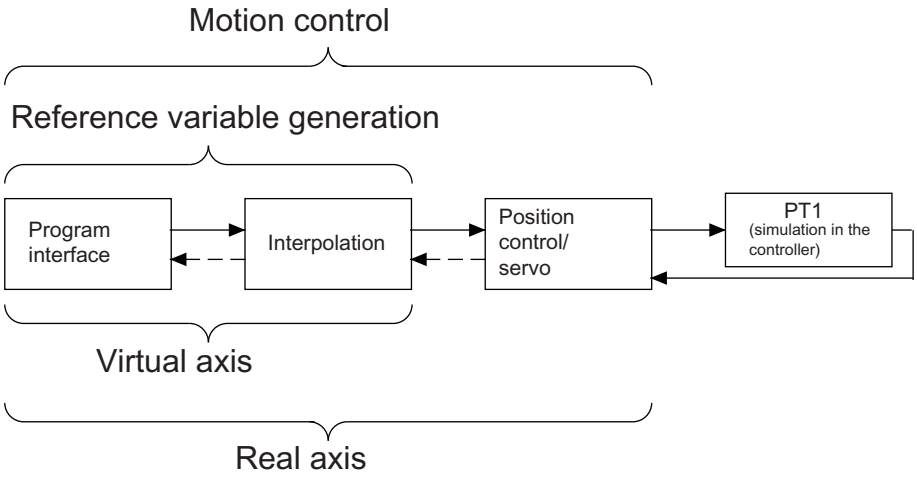

Figure 4-811 Axis simulation functional scheme

The dynamic behavior of the axis is simulated with the total time constant via an internal PT1 element.

The axis is thus available for the user program in the basic functions (e.g. setting of enables, execution of motion commands), but the manipulated variable is not output to the connected or missing drive.

There is no need for precise dynamic modeling of signals.

The simulation of an axis with an "analog output via I/O peripheral" drive assignment is not supported.

The complete axis configuration is kept when setting the simulation status and is still available without any changes after switching back in the expert list to the normal mode status.

Table 4-343 Settings in the configuration data

TypeOfAxis.SetPointDriverInfo.mode	= SIMULATION
TypeOfAxis.SetPointDriverInfo.outputNumberOnDevice	= 0
TypeOfAxis.NumberOfEncoders.Encoder_1.encoderIdentification	= SIMULATION
TypeOfAxis.NumberOfEncoders.Encoder_1.DriverInfo.encoderNumberOnDevice	= 0
TypeOfAxis.NumberOfDataSet.DataSet_x.ProcessModel.T1 (as of V4.0)	Time constant T1
TypeOfAxis.NumberOfDataSet.DataSet_x.ProcessModel.T2 (as of V4.0)	Time constant T2

Comments

- All real axis types can be set to SIMULATION.
- The process response/axis response is simulated from **processModel.T1** and **processModel.T2** via the PT1 element with the total time constant (T1+T2).

- Homing to the encoder zero mark and the external zero mark is not possible in Axis simulation mode.
- Output cam functions are executed.
- Only measuring input via time stamp is possible.
- If an axis with the DSC setting is set to SIMULATION, the position controller is calculated in the position control cycle clock in the control/simulation driver, i.e. it may be necessary to cancel the gain and adjust the following error monitoring.
- Unlike program simulation, the drive does not need to be present and the position controller remains active with simulated drive behavior.
- The simulation mode is provided for actuators and sensors. Technology data (such as Technology Data Block TDB, Safety Information Data Block SIDB, Drive Safety Data Block DSDB, etc.) of an axis cannot be simulated. Deactivate them before the axis is switched to simulation mode.
- The **_setAxisSTW()** command is not active in simulation mode.

As of SIMOTION V4.2

Axes with symbolic drive allocation

If symbolic allocation is set and if an axis allocated to a SINAMICS drive is to be removed from axis simulation, then this axis must be reallocated to the drive again.

Axes without drive assignment

If the axis is not yet assigned (see also Real and virtual axes (Page 2875)), the logical addresses for the actuator and encoder must be converted.
To do this, set the following configuration data in the expert list to a free and valid address: The address must not be equal to 65535 and the same one must be used for all four items of configuration data, e.g. 15000.

Configuration data:

- **TypeOfAxis.SetPointDriverInfo.logAdressIn**
- **TypeOfAxis.SetPointDriverInfo.logAdressOut**
- **TypeOfAxis.NumberOfEncoders.Encoder_n.DriverInfo.logAdressIn**
- **TypeOfAxis.NumberOfEncoders.Encoder_n.DriverInfo.logAdressOut**

When deactivating the simulation, set each of the values for this configuration data back to 65535.

Note

A script is available to switch the axis simulation on and off for axes with and without symbolic drive assignment. This script can be integrated into a project via the ProjectGenerator (accessible from SCOUT). You can find the script in *SIMOTION Utilities & Applications*, which is part of the scope of delivery of SIMOTION SCOUT.

4.8.3.5 Encoders and encoder parameters

Overview of encoders and encoder parameters

Sensing of the actual position value can be performed using:

- Motor measuring system (motor encoder)
- Additional direct measuring systems (external encoders), if necessary

The adaptation of relevant drive data is activated automatically as of SIMOTION V4.2 in conjunction with SINAMICS S120 as of V2.6.2. The encoder parameters are adapted automatically.

A direct measuring system measures the technological parameter directly, i.e. without the interference of influences such as torsion, backlash, slip, etc.
This may facilitate improved smoothing of mechanical influences by means of the closed-loop control.

Up to eight encoders can be generated on the axis. All generated encoders are internally active, and the measured values are updated cyclically. It is possible to switch between the encoders via data sets. Whether an encoder is active for closed-loop control is displayed in the **sensorData[n].control** system variable.

Several data sets can be assigned to one axis. These data sets can contain different encoders. A data set is active.
Encoders can be added and parameterized in the Axis technology object under **Configuration** on the **Encoder configuration** tab.

Via the
typeOfAxis.numberOfEncoders.Encoder_1.sensorControlConfig.tolerateSensorDefect setting (V4.0 and higher), it is possible to tolerate the failure of an encoder which is not selected or which is not involved in the closed-loop control. This setting is defined for individual encoders. It is output via **Alarm 20015**.

For more information on data set switchover and encoder configuration, see Data set switchover / encoder switchover (Page 3037).

Data set overview (Page 3037)

Encoder for position

The controller uses an encoder to detect the axis position.

From a technological standpoint, the following encoder types can be differentiated:

- Incremental encoder
  On the controller side, only the difference between two read encoder values is evaluated. Values are read out in the servo cycle clock at equal intervals. In order to determine the mechanical axis position, the axis must be homed each time the system is switched on. Position zero is displayed after it is switched on.
- Absolute encoder
  This encoder supplies the absolute value or, in the case of an absolute value in the PROFIdrive message frame, the absolute value is read one time after the system is switched on. After this, the actual value is processed in the same way as with the incremental encoder.
  The absolute value supplied by the encoder is assigned to the associated mechanical axis position by means of the absolute encoder adjustment. The absolute encoder adjustment occurs only one time, and the controller remembers the compensation value/absolute encoder offset even after it is powered on/off.
  Certain situations, such as an encoder failure, a restart, etc., can require an absolute encoder re-adjustment. For more information, refer to the chapter titled *Absolute encoder homing/ Absolute encoder adjustment*.
  The following absolute encoder types are differentiated:
  - Absolute encoder with absolute encoder setting
    The measuring range of this encoder is greater than the axis traversing range.
    The axis position results directly from the current encoder value since this can be uniquely mapped.
    An offset may be entered - it is not necessary to hold overflows within the controller.
    There are no overflows of the absolute actual value stored when SIMOTION is switched off. The next time it is switched on, the actual position value is generated from the absolute actual value only.
  - Absolute encoder with cyclic absolute encoder setting
    The axis traversing range is greater than the range of values measured by the encoder, and the encoder returns an absolute value within its measuring range.
    The controller also counts the number of measuring ranges internally in order to hold a unique actual axis position beyond the range of measured values.
    When SIMOTION is switched off, the overflows of the absolute actual value are stored in the retentive memory area of SIMOTION. The next time it is switched on, the stored overflows are taken into account for the calculation of the actual position value.
    The actual position of the axis is passed internally in a 64-bit integer variable.
    Example of a single-turn encoder with 4,096 increments:
    The position of the encoder is mapped in bits 0 to 11, and the number of overflows of the encoder range in bits 12 to 63.
    Example of a multi-turn encoder with 4,096 x 4,096 increments:
    The position of the encoder is mapped in bits 0 to 23, and the number of overflows of the encoder range in bits 24 to 63.
    The overall position of the axis is retained after the controller is switched off. When the controller is switched on again, if the actual encoder value does not match the actual position stored in the controller, it will be corrected to a maximum of ± ½ the encoder measuring range.

Note

If the axis/encoder is moved by more than one half the encoder measuring range with the controller switched off, the actual value in the controller no longer matches the real axis.

See also

Overview of homing (Page 2923)

Encoder for velocity

Encoders for detection and display of the speed/velocity can only be applied to speed-controlled axes.

Options are:

- Incremental encoders/absolute encoders with number of increments or pulses/revolution (for electric axes)
- Interval counters (for hydraulic axes)
- Encoders providing the velocity as a direct value in the I/O area (for hydraulic axes)
- Read-out of the speed from the PROFIdrive message frame and provision for technological functionality, e.g. velocity monitoring

Encoder assignment and terminology

The encoder type is specified with the encoder mode.

Table 4-344 Definable encoder mode depending on the encoder type

Encoder mode	Encoder type		
	Absolute encoder	Cyclic absolute encoder	Incremental encoder
PROFIdrive (with adaptation [1]) (as of V4.2)	x	x	x
Endat (encoder data interface)	x	x	x
SSI (synchronous serial interface)	x	x	-
Sinusoidal	-	-	x
Rectangle	-	-	x
Resolver	-	x [2]	x
Analog encoder (value in the I/O area)	x	-	-

[1] The adaptation setting (set by the system by default with V4.2 or higher and SINAMICS) makes changes based on the encoder set in SINAMICS. The encoder resolution and fine resolution are adopted during runtime.

[2] Possible with single-pole-pair resolver only

When the encoder signals are evaluated in an encoder module or drive, the actual values are transferred to the controller in the normalized format according to the PROFIdrive profile. The type of measured value acquisition is dependent on the drive or encoder module, e.g. Sinus, SSI or Endat. The PROFIdrive encoder mode can therefore be set in the controller (as of V4.2).

As of SIMOTION V4.2, the system makes the settings for communication between SIMOTION and SINAMICS drive (encoder). The project setting **Use symbolic assignment** is activated by default for new projects as of V4.2. Telegrams are set automatically. Encoder characteristics such as fine resolution, grid spacing, and the absolute value for data width are adapted automatically when the system ramps up.

For encoder data, refer to the data sheet or type plate of the encoder. With SINAMICS, encoder data can be transferred from the drive.

The rest of this chapter is only relevant if the project default setting **Use symbolic assignment** is deactivated as of V4.2, or if you are working with a project which uses SIMOTION V4.1.

Encoder pulses per revolution

The encoder pulses per revolution is specified on the encoder type plate as the number of signal periods per revolution (incremental encoder: Pulses/rev; absolute encoder: Pulses/rev; resolver: Number of pole pairs (for SINAMICS and MASTERDRIVES)).

Configuration data:

- **AbsEncoder.absResolution**
- **IncEncoder.incResolution**

Grid line spacing (linear encoder system)

The grid line spacing is specified on the type plate of the encoder as the distance between lines on the linear measuring system (linear scale).

Configuration data:

- **Resolution.distance**

Fine resolution

The fine resolution of the actual value is the interpolation result of a signal period of an encoder pulse.

The fine resolution steps are generated by the measuring electronics from the raw signal of the encoder pulses. Factors as a multiple of 2 are possible.

Example:

- A rectangle signal has a fine resolution of 1
- Two rectangle tracks (TTL signal) offset by 90° have a fine resolution of up to 4
- Depending on the measuring electronics, a sinusoidal signal can have any fine resolution, in principle, e.g. 2,048

Depending on the defined encoder type, the default value 0 is interpreted differently in SIMOTION (see table: *Default settings for fine resolution in SIMOTION*).

In SIMOTION, the multiplication factor is specified, rather than the shift factor/number of bits (x).

The actual value, including the fine resolution, is indicated in the **sensorData.incrementalPosition** system variable.

Configuration data:

- **AbsEncoder.absResolutionMultiplierCyclic**
- **IncEncoder.incResolutionMultiplierCyclic**

Data width of absolute value (without fine resolution) for absolute encoders

The data width of the absolute value (without fine resolution) is a result of the sum of the bits for representing the number of encoder pulses and the bits for representing the maximum number of revolutions that can be registered by the encoder according to the type plate.

Example:

4,096 pulses/rev (= 2^{12}) and a maximum of 4,096 revolutions that can be registered yields a 12 + 12 = 24-bit data width of the absolute value.

Configuration data:

- **AbsEncoder.absDataLength**

Fine resolution of absolute value in Gn_XIST2.

This parameter for the format of the Gn_XIST_2 is only relevant for encoders via PROFIdrive telegram (for more information, see *Encoder interconnection via PROFIdrive telegram*).

Configuration data:

- **AbsEncoder.absResolutionMultiplierAbsolute**

The fine resolution of the absolute value in Gn_XIST2 must be less than or equal to the fine resolution of the absolute value in Gn_XIST1.

Default setting for fine resolution.

Depending on the encoder mode, the default settings are evaluated by the system as described in the table below. The default settings are used if 0 is assigned to the value.

Table 4-345 Default settings for fine resolutions in SIMOTION

Encoder type	Encoder mode	Fine resolution (Gn_XIST1)	Fine resolution on the absolute value (Gn_XIST2)
Onboard C2xx			
Incremental encoder	Rectangle	4	-
	Stepper motor	1	-
Absolute encoder	SSI	1	1
Encoder in PROFIdrive axis telegram (applies to SINAMICS, SIMODRIVE 611U and MASTERDRIVES)			
Incremental encoder	Rectangle	2048	-
	Sinusoidal	2048	-
	Resolver	2048	-
	Endat	2048	-
Absolute encoder	Endat	2048	512
	SSI	1	1
...Cyclic absolute	Resolver (only pole pair number 1 possible)	2048	512
	Endat	2048	512
	SSI	1	1
PROFIBUS absolute encoder in PROFIdrive encoder telegram			
Absolute encoder	SSI	$2^{(32 - \text{Number of data bits})}$	1

These settings are aligned to the default parameter settings of the corresponding Siemens devices. If the behavior is different, alignment with the encoder should be performed by making a corresponding entry in the configuration data of the technology object or in the parameters of

the drive or encoder. Depending on the device it may be necessary to assign the corresponding parameters in the drive or encoder with the value of the exponent (shift factor).

Device-specific features for Masterdrives with Endat encoders:

For Masterdrives with Endat encoders, Endat or SSI can be selected in the encoder mode. However, the fine resolution must always be configured in the axis wizard of the Axis or External Encoder technology object differently from the default settings (see Encoder list (Page 2906)).

Default setting:

- Fine resolution (**~Encoder.~ResolutionMultiplierCyclic**) = 0
- Fine resolution of the absolute encoder in Gn_XIST2 (**AbsEncoder.absResolutionMultiplierAbsolute**) =0
- If encoderMode=PROFIDRIVE, the values are evaluated as available, since the correct values are adapted by the drive. A default setting of 0 is not permitted for this setting.

Encoder interface as a direct value in the I/O area (Page 2911)

Encoder list (Page 2906)

Encoder list

For the most up-to-date list of encoders you can use with SIMOTION in conjunction with SINAMICS, SIMOVERT-MASTERDRIVES, and SIMODRIVE 611U, go to **http://support.automation.siemens.com/WW/view/de/18769911**.

The encoder list is also documented under *FAQs > Drives > Parameters of the connectable encoders* in the *SIMOTION Utilities & Applications* and in the online help (look for encoder parameter assignment in the index). *SIMOTION Utilities & Applications* is part of the scope of delivery of SIMOTION SCOUT.

Onboard encoder interface on SIMOTION C2xx

Incremental encoders with TTL signal and absolute encoders with SSI protocol can be connected directly to C230-2 or C240. (See the C230-2 and C240 operating instructions and Encoder list (Page 2906))

See also

Encoder list (Page 2906)

Encoder interface using the PROFIdrive message frame

As of SIMOTION V4.2, the system sets up communication between SIMOTION and SINAMICS drive (encoder). For SINAMICS drives and encoders with V4.2 and higher, encoder resolution data is transferred directly from the drive during runtime. Telegrams are set automatically.

The rest of this chapter is only relevant if the project default setting **Use symbolic assignment** is deactivated as of V4.2, or if you are working with a project which uses SIMOTION V4.1.

The encoder values are transmitted in the PROFIdrive telegram (see Table *Telegram types* in Section *Setting as a real axis with digital drive coupling*).

Encoder forced values, status values, and actual values are transmitted in the PROFIdrive telegram.

The encoder behavior on SIMOTION is set as represented in the PROFIdrive protocol.

The encoder parameters are defined via the drive wizard during drive configuration (either user-defined or by selecting the encoder).

Encoder parameters that are entered subsequently in the SIMOTION axis wizard must match the encoder parameters in the drive.

Note

For SINAMICS drives with earlier versions than SIMOTION V4.2, it is possible to transfer the encoder parameters from the drive. When assigning encoders in the axis wizard, click **Data transfer from the drive**.

If you are using a DRIVE-CLiQ component with electronic type plate (e.g., SMI motor, DRIVE-CLiQ encoder) you must first upload the parameters from the drive and save them in the project (online commissioning). If the online commissioning is carried out at a later point, you can work with the default settings of the axis wizard in the meantime during offline configuration. Once online commissioning is complete, upload the drive parameters, save them in the project, run the axis wizard again, and perform the **Data transfer from drive** function.

If you change the encoder data in the drive, you must perform an alignment again in the axis wizard.

Further sources of information:

- Encoder list (Page 2906)
- User Manual *SIMODRIVE sensor Absolute encoder with PROFIBUS-DP*
- Operating Instructions *Absolute encoder with PROFINET IO* (Chapter *Operating with SIMOTION*)

Encoder value via PROFIdrive axis telegrams

For further information, refer to the commissioning manuals for the drives.

The first and (if present) second encoder of the PROFIdrive axis telegram can be assigned freely to an External Encoder technology object or to the encoder of an axis.

Encoder value via PROFIdrive encoder telegram 8x

PROFINET/PROFIBUS encoders can be set in accordance with the current specifications of the encoder profile with telegram type 81 and as of V4.2, with telegram type 83. These encoders can be assigned freely. See also **PROFINET/PROFIBUS absolute encoder via PROFIdrive encoder telegram** in the next chapter.

Inconsistent configuration

In the event of errors or inconsistencies between the configuration data in SIMOTION and the parameter settings for the encoder in the drive, a technological alarm is triggered as soon as an online connection is established between the control and the drive/encoder.

As off SIMOTION Runtime V4.4: **Technological alarm 20025** with applicable reason

In SIMOTION Runtime < V4.4: **Technological alarm error 20005: Device type:2, log.address:1234 faulty. (Bit:0, reason: 0x80h)**

For PROFIdrive encoders and encoders on the axes according to PROFIdrive, a comparison of the parameter assignment takes place via the following drive/encoder parameters:

P979 (SensorFormat) according to PROFIdrive, which contains information about the type, resolution, and shift factors.

For drives or encoders that do not support parameter P979, the configuration data is evaluated as valid without alarm message.

Actual value Gn_XIST1

The incremental actual value is transferred cyclically with the defined fine resolution in Gn_XIST1. The incremental actual value in Gn_XIST1 is steadily continued according to the actual value change and reset when the data width of Gn_XIST1 is exceeded. If operating with incremental and absolute encoders, the control evaluates the incremental actual value in Gn_XIST1 according to the settings made for encoder pulses per revolution and fine resolution, or grid line spacing for linear scaling.

When the controller is switched on, the fine resolution value within one encoder signal period is indicated correctly in Gn_XIST1. The initial value for the number of signal periods is set by the drive/encoder, and the actual value can then be steadily continued from this initial value.

In the PROFIdrive profile, the fine resolution is given as "shift factor" (x).

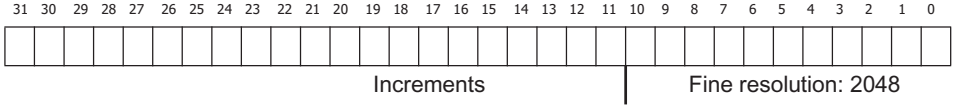

Figure 4-812 Example composition of the 32-bit encoder data of the cyclic actual value Gn_XIST1

Example of for an encoder with number of encoder pulses = 2048 (data width, 11 bits)

The fine resolution in SIMOTION in the **Inc/AbsResolutionMultiplierCyclic** configuration data element is set to the default setting 0 and is thus evaluated as a default fine resolution of 2048 (the default value depends on the encoder mode setting; see Table *Default settings for fine resolution in SIMOTION*).

SIMODRIVE 611U:

Table 4-346 Settings

SIMOTION		611U	
Encoder pulses per revolution [1]	=2048	P1007	=2048
Fine resolution [2]	=0 (≡ 2048)	P1042	=11

[1] Inc/AbsEncoder.Inc/AbsResolution

[2] Inc/AbsEncoder.Inc/AbsResolutionMultiplierCyclic

SINAMICS:

Table 4-347 Settings

SIMOTION		SINAMICS	
Encoder pulses per revolution [1]	=2048	P408	=2048
Fine resolution [2]	=0 (≡ 2048)	P418	=11

[2] Inc/AbsEncoder.Inc/AbsResolutionMultiplierCyclic

Note the information about the SINAMICS alignment.

Actual value Gn_XIST2

If the positions for the measuring input or homing functions are transferred to Gn_XIST_2 (n = 1 or 2, number of encoder), they are transferred with the fine resolution defined for the encoder. When the absolute value is read, the value in Gn_XIST_2 is evaluated based on the settings for the data width of the absolute value (without fine resolution) in **AbsEncoder.absDataLength** and the fine resolution absolute value in Gn_XIST2 is evaluated in **AbsEncoder.absResolutionMultiplierAbsolute**.

The fine resolution of the absolute value in Gn_XIST2 indicates the fine resolution factor included in the absolute value transfer. This can match the fine resolution of the actual value, but it can also be smaller, for example, if the 32-bit data width in Gn_XIST2 is not sufficient for the entire fine resolution factor as a result of the data width of the absolute value (without fine resolution).

Example:

Encoder pulses per revolution = 2048 (11 bits) and multi-turn resolution of 4,096 revolutions (12 bits)

Thus, the data width of the absolute value without fine resolution is 11 bits + 12 bits = 23 bits.

Therefore, 9 bits remain for the fine resolution in Gn_XIST2 (32 bits - 23 bits = 9 bits). The setting 0 for the fine resolution of the absolute value in Gn_XIST2 is thus evaluated by the system as 512 (= 9 bits).

Table 4-348 Setting the encoder data

Encoder pulses per revolution [1]	2048
Data width of absolute value (without fine resolution) [2]	23
Fine resolution of absolute value in Gn_XIST2 [3]	0 (= 512)
Fine resolution [4]	0 (= 2048)

[1] AbsEncoder.AbsResolution

[2] AbsEncoder.absDataLength

[3] AbsEncoder.absResolutionMultiplierAbsolute

[4] AbsEncoder.AbsResolutionMultiplierCyclic

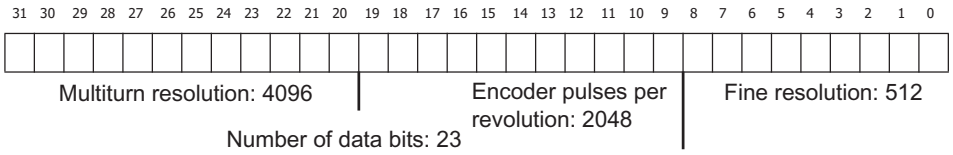

Figure 4-813 Example composition of the 32-bit encoder data of the absolute actual value Gn_XIST2

The number of bits resulting from the data width of the absolute value (without fine resolution) and the number of data bits for the fine resolution of the absolute actual value must not exceed 32. If it is less than 32, leading zeroes are added in Gn_XIST2.

Resolver in PROFIdrive axis telegram

For SINAMICS and MASTERDRIVES, parameters are assigned for the pole pair number of the resolver rather than the encoder pulses per revolution (example: 8-pole resolver = 4 pole pairs → input value = 4).

With SIMODRIVE, parameters are assigned for the encoder pulses per revolution based on parameter P1011.2

As of V4.1 SP1, the resolver with pole pair number 1 is supported as an absolute encoder with the cyclic absolute setting. (encoder pulses per revolution = 1, data width of the absolute value = 0, default value evaluation: fine resolution = 2048, fine resolution Gn_XIST2 = 512)

When a 1-pole resolver is used as Endat encoder, the p418(XIST1) and p419(XIST2) parameters must be set to "11" to prevent information loss of the absolute position. (Settings on the axis: absolute encoder, cyclic absolute, Endat, line count = 1, fine resolution = 2048, fine resolution absolute value = 2048, data width = 0)

See also the Encoder list (Page 2906).

PROFINET/PROFIBUS absolute encoder via PROFIdrive encoder telegram

The data width of the encoder value in the technology object configuration data in SIMOTION must match the parameter settings for the PROFINET/PROFIBUS absolute encoder in HW Config.

See also the Encoder list (Page 2906).

Example:

Parameter settings of a PROFIBUS absolute encoder in HW Config with 24-bit data width of the absolute value.

The 'SIMODRIVE isochronous sensor' PROFIBUS absolute encoder in HW Config is defined according to the default setting for 24-bit data width and encoder pulses per revolution of 4096: measuring steps per revolution = 4096
24-bit data width for the total resolution yields 0x01000000 (32-bit HEX number). This number, represented separately in HighWord and LowWord, equals 0x0100 in the HighWord and 0x0000 in the LowWord. The decimal values of these two parts (0x0100 = 256 decimal) are to be entered as follows:
total resolution (high) = 256
total resolution (low) = 0

This results in the following consistent configuration for the technology object:
the encoder value is transferred left-justified to Gn_XIST1; the unused bits of the fine resolution are set to 0 according to PROFIdrive, but must be specified in the fine resolution of the actual value. This results in a fine resolution of 8 bits (32 bits - 24 bits = 8 bits) (2^8 = 256 as a factor).

According to the setting above, the absolute value in Gn_XIST2 has a right-justified alignment and therefore a fine resolution of the absolute value in Gn_XIST2 of 0 bits ($2^0 = 1$ as a factor).

Encoder via PROFIdrive axis telegram on ADI4 and IM174

At least one electric or hydraulic axis must be configured on ADI4/IM174.

The defined update rate (BaudRate) for SSI encoders must be supported by the encoder.

See also the Encoder list (Page 2906).

For more information about configuration and operation, refer to the *ADI4 - Analog Drive Interface for 4 Axes Manual* and *Distributed I/Os IM 174 PROFIBUS Module Manual*. These documents are provided on the *SIMOTION Documentation* DVD.

Note

An encoder in a PROFIdrive axis telegram can only be used for an external encoder TO or for the encoder of a TO axis in cyclical operation if a TO axis is also created on the PROFIdrive telegram and is not deactivated.

Coupling of digital drives (Page 2895)

Encoder list (Page 2906)

Encoder interface as a direct value in the I/O area

Encoders can be used that

- Provide actual value information directly as absolute value in the input/output area.
- Provide a counter value in the peripheral area (as of V4.0).
- Provide an actual velocity in the peripheral area.

Actual value information directly as absolute value

These encoders must be parameterized and operated as absolute encoders, for example with respect to homing.

The following settings are provided to set the **adaptation to the properties of the measured value**:

- The **justification of the measured value** in the **NumberOfEncoders.Encoder_n.AnalogSensor.DriverInfo.format** configuration data element
  - Signed left-justified (VALUE_LEFT_MARGIN)
  - Signed right-justified (VALUE_RIGHT_MARGIN)
  - Unsigned left-justified (VALUE_LEFT_MARGIN_WITHOUT_SIGN)
  - Unsigned right-justified (VALUE_RIGHT_MARGIN_WITHOUT_SIGN)
- The **data width of the measured value** without the sign bit in the **NumberOfEncoders.Encoder_n.analogSensor.DriverInfo.resolution** configuration data
- The upper limit and lower limit, the **maximum limits of the measured value** in the following configuration data
  - **NumberOfEncoders.Encoder_n.AnalogSensor.DriverInfo.maxValue**
  - **NumberOfEncoders.Encoder_n.AnalogSensor.DriverInfo.maxValue**

Example: Use of an ET 200S, SSI module, or an analog input.

Justification of the measured value

The measured value is mapped to an internal 32-bit wide signed data value of the DINT type in accordance with the justification specification. The mapped value is then tested with actual value limitation against the maximum limits and evaluated using the weighting factor for the **NumberOfEncoders.Encoder_n.AnalogSensor.ConversionData.factor** direct value that specifies the technological resolution or assignment of the LSB.

⚠ WARNING

Weighting factor for analog sensors

The scaling or conversion in the value of the configuration data **ConversionData.factor** for the position of the analog sensor has changed in SIMOTION V4.4.

As of V4.4, the following applies:

The values are entered directly in inches and no longer converted from mm to inches for the configured Inch unit system. This can result in a higher velocity being detected (by a factor of 25) if it is an axis that works in inches.

The following applies for SIMOTION up to V4.4:

The values were entered in mm and then converted to inches (1 inch corresponds to approx. 25 mm). Please check the values entered for **ConversionData.factor** in older projects and correct them when necessary.

Regardless of the sign, the encoder resolution/measured value width is limited to maximum 31-bit, because the configuration data of the maximum limits are signed data values of the DINT type.

For the **Left-justified/Right-justified without sign** setting, the measured value for the setting of the encoder resolution/measured value width is processed as follows:

- At ≤16 bits the measured value left-justified/right-justified is mapped to the least-significant byte 1 and byte 2 of an internal data value of the DINT type. In this process, the missing 16 bits minus the measured value width of the least-significant byte 1 and byte 2 are right/left-padded with zeros and the most-significant byte 3 and byte 4 are filled with zeros.
- > At 16 bits the measured value left-justified/right-justified is mapped to an internal data value of the DINT type. In this process, the missing 32 bits minus the measured value width are right/left-padded with zeros.
  As this mapped measured value is tested against the maximum limits of the data type DINT, the encoder resolution/measured value width is limited to maximum 31 bits. This means the measuring range is limited to maximum 50% of the measured value width.

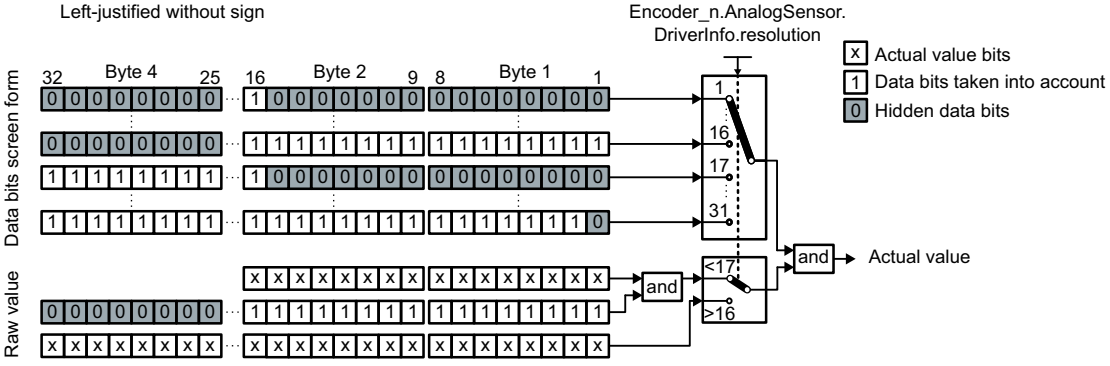

Figure 4-814 Masked reading of the analog IO value left-justified without sign

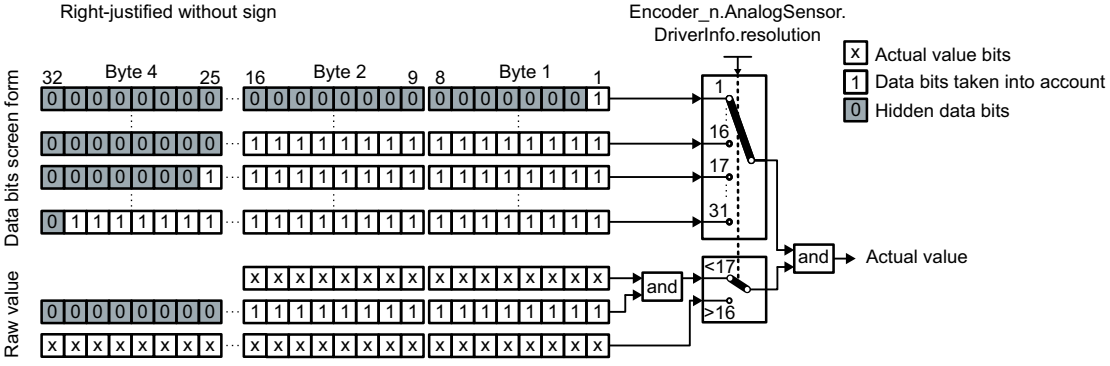

Figure 4-815 Masked reading of the analog IO value right-justified without sign

For the **Left-justified/Right-justified without sign** setting, the measured value for the setting of the encoder resolution/measured value width is processed as follows:

- At <16 bits the measured value left-justified/right-justified is mapped to the least-significant byte 1 and byte 2 of an internal data value of the DINT type. For left-justified, the missing 15 bits minus measured value width of the least-significant byte 1 and byte 2 are right-padded with zeros and the sign bit is extended left to bit 32. For right-justified, the sign bit is padded left to bit 32.
- At ≥16 bits the measured value left-justified/right-justified is mapped to an internal data value of the DINT type. For left-justified, the missing 31 bits minus measured value width are right-padded with zeros. For right-justified, the sign bit is padded left to bit 32.

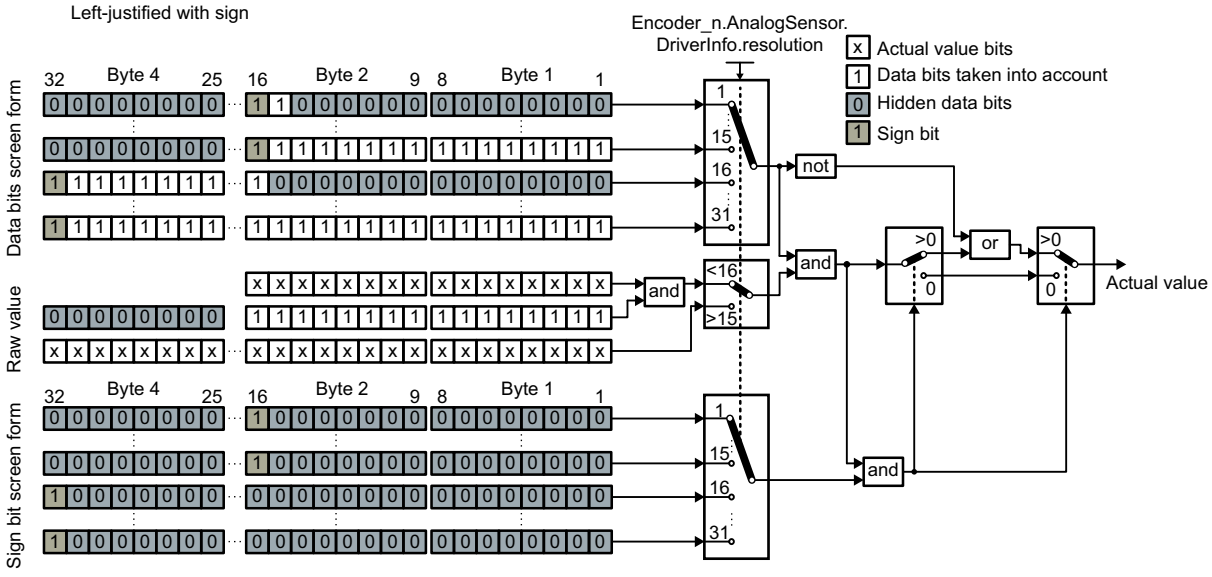

Figure 4-816 Masked reading of the analog IO value left-justified with sign

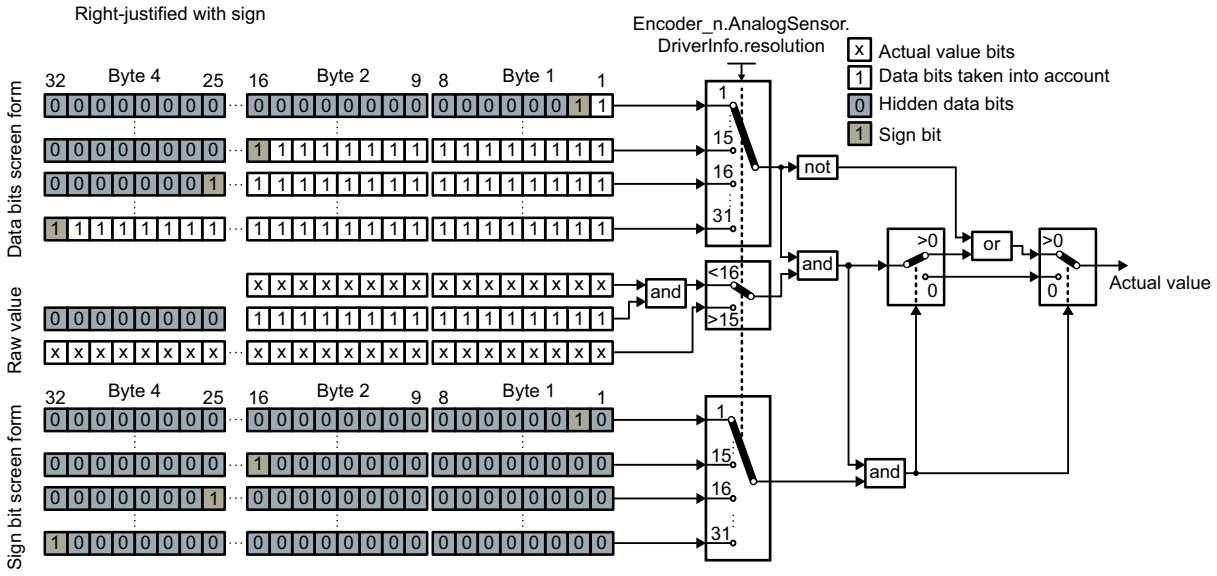

Figure 4-817 Masked reading of the analog IO value right-justified with sign

Counter value (as of V4.0)

The encoder is set as an incremental encoder. 16 bits or 32 bits can be set as counter value width.

Example: Use of an ET 200S, COUNT module

Actual velocity

The actual value information can include the number of pulses between two scans or, alternatively, the time interval between two sequential pulses. This type of encoder is used, for example, to measure actual velocities with the hydraulic axis functionality.

Example: Use of an ET 200S, COUNT module

Direct value as absolute value in I/O area (as of V4.1 SP1)

The following bits can be configured for the direct value as absolute value in the I/O area:

- **Ready bit** via the elements of the **analogSensor.readyStateMonitoring** configuration data element
- **Error bit** via the elements of the **analogSensor.errorStateMonitoring** configuration data element

These can be used for evaluation on the Axis technology object of a *ready identifier* and an *error identifier*, which are available from the peripheral module in addition to the measured value.

In SIMOTION V4.1 SP1, this configuration data is defined directly in the expert list.

If the *not ready* status or an error is displayed in these identifiers during operation, and the **ready bit** or **error bit** is configured, technology alarm 20005 is issued with the *sensor error* identifier.

If the Axis technology object is ready during ramp-up, but the direct value in the I/O area is not yet in ready status, the *WAIT_FOR_VALID Sensor* status is displayed on the encoder. (**sensorData[n].state** system variable)

As of V4.1 SP1, the direct value in the I/O area does not have to be updated in every equidistant communication cycle (for example, if an encoder connected to the peripheral module is not able to supply a new measured value in each cycle during a fast communication cycle clock due to measurement reasons or processing time reasons). In such cases, the actual value is extrapolated by the control.

The control supports the following options:

- The peripheral module displays the new measured value set in an update bit/update counter. The update bit or update counter is defined in the **analogSensor.UpdateCounter** configuration data element.
  UpdateCounter configuration: The update counter can be one (toggle) bit or several (counter) bits in width.
- The refresh cycle of the actual value in the peripheral module is known and is defined directly in the **analogSensor.UpdateCounter.updateCycle** configuration data element.
  Default setting with refresh cycle = 1 (default behavior for updating in every cycle clock)

Encoder value via system variable

A **position or velocity value** can also be defined directly in a system variable (sensorSettings.actualValue) from the user program, for example. With this value, it is possible, for example, to simulate the actual technological value for an axis or to provide the value from any encoder/I/O value (for which there does not exist a TO interface) via the user program and to apply it to the axis as an actual value.

This behavior is defined in
TypeOfAxis.numberOfEncoders.Encoder_x.encoderIdentification=SET_ACTUAL_VALUE.

This encoder type can be defined on the axis and the external encoder.

The update rate for the default setting (**updateCycle**) and the maximum number of servo clocks (**maxFailures**) in which the system variable is not written are specified in the **StructAxisSensorSetActualValueConfig** configuration data structure.

The **sensorSettings.actualValue** system variable must be provided in the cyclical level set in the **typeOfAxis.NumberOfEncoders.Encoder_x.SensorSetActualValue.updateCycle** configuration data. If, for example, in the user program of the IPOsynchronousTask, the actual position is written cyclically to **sensorSettings.actualValue**, **~.updateCycle** = IPO must be set.

The value specified in **sensorSettings.actualValue** is accepted using the set refresh rate (**SensorSetActualValue.updateCycle**) and extrapolated linearly in between.

SensorSetActualValue.maxFailures always refers to the servo clock. The **SensorSetActualValue.updateCycle** setting does not have any affect.

Example:
If the **sensorSettings.actualValue** system variable is updated in the IPO cycle clock and IPO:Servo is set 2:1, **SensorSetActualValue.maxFailures** = 1 must be set.

Non-exclusive encoder assignment (as of V4.1 SP1)

The sensor/encoder of the axis can be defined as exclusive or non-exclusive in **typeOfAxis.NumberOfEncoders.Encoder_x.interfaceAllocation**. If it is defined as non-exclusive, you must also specify whether the encoder interface should be activated when the technology object is ramped up.

The functionality supports the configuring of an encoder on several axes. However, the encoder can only be evaluated on one axis at a time.

The **_enableAxisInterface()** or **_disableAxisInterface()** commands and the sensor=<sensorNumber> function parameter are used to activate and deactivate the encoder interface during operation and the specification of the sensor. Because the sensor function parameter is encoded as bits, it is also possible to activate/deactivate several encoders concurrently. If the bit is not set, the encoder interface status remains unchanged.

The Activated/Deactivated encoder interface status is displayed in the **sensorData.sensorData[i].input** system variable.

Example:

sensor=5 Activation/deactivation of the encoder interface 1 and 3

Also refer to the parameters description in the reference lists.

These commands are not available for enabling/disabling the actuator/sensor interface on the hydraulic axis. For information on the hydraulic functionality, see Access to the same final controlling element from multiple axes (Page 3134).

Setting a non-exclusive drive assignment (as of V4.1 SP1) (Page 2898)

Diagnostic features

The measuring system increments are displayed as 32-bit information in the **sensorData.incrementalPosition** system variable.

It can first be verified whether the change in this variable over one encoder revolution with allowance for the measuring gear corresponds to the increments of the encoder. If this is not the case, the configuration of the axis and the drive must be modified accordingly (e.g. measuring gear, (drive) parameters for setting the resolution: number of increments per revolution, fine resolution, etc.).

In addition, the path (angle) change/revolution (**sensorData.position**) can be checked. If this check reveals problems, the axis configuration must be checked (e.g., leadscrew pitch, gear ratios, etc.).

4.8.3.6 Input limits, technological limiting functions

System-side input limits

All parameters that can be entered have a lower and an upper limit derived either from the variable format range or from limits set by the system for each parameter. See the TP Cam System Variables Reference List.

Internally there are also limits for the position specifications resulting from the accuracy of the data format of the variables. When these limits are violated, an error message is output on the axis: **Internal traversing range limit reached**.

4.8.3.7 Setting for axis and encoder mechanics

Overview of setting options for axis and encoder mechanics

The following options are available on the drive side of a real axis:

- Consideration of load gear
- Consideration of spindle pitch on linear axis
- Inversion of manipulated variable/drive direction

The following options are available on the encoder side of a real axis:

- Setting of encoder mounting method
- Consideration of measuring gear
- Setting of distance per revolution

- Settings for load compensation
- Consideration of the count direction (inversion of actual position value)

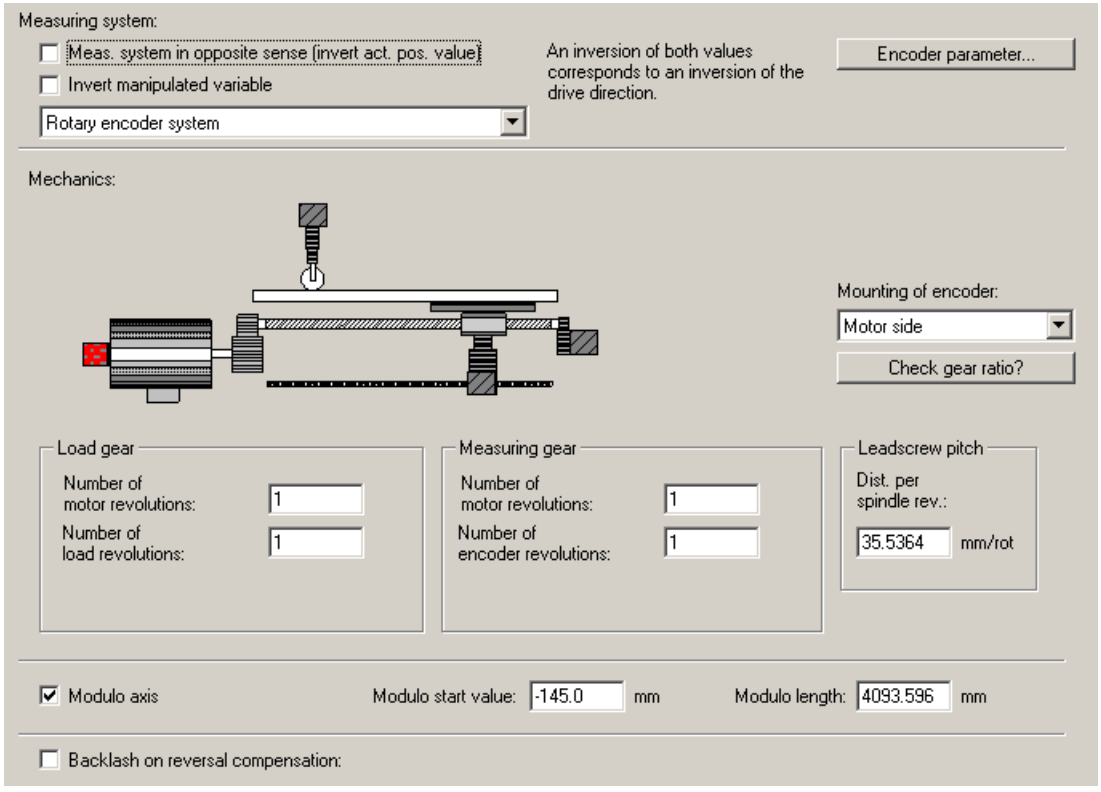

Figure 4-818 Overview of encoder/linear axis mechanics

The following options are available on the final control element side for the hydraulic functionality:

- Consideration of output characteristic
- Inversion of manipulated variables

The available encoders in SIMOTION can be used for the hydraulic functionality. They can be configured on the **Encoder configurations** tab in the **Configuration** dialog or via the expert list. (see SIMOTION SCOUT online help)

Inversion of actual position value

You can invert the count direction of an incremental or absolute encoder by selecting the **Meas. system in opposite sense** check box in the **Encoder/linear axis mechanics** screen form. This changes the count direction to match the technological view.

Once the Invert actual position value setting has been modified, the encoder should be adjusted once again, this time with the new absolute encoder offset which has been set accordingly, just as the home position offset needs to be redefined for an incremental encoder.

Special features of the absolute encoder

With an n-bit encoder (n-bit data length), the incremental position lies between 0 and 2^n-1. The position is then derived independently of the resolution, e.g. from 0 to 100 mm.

If the sign is changed by inverting the actual position value (measuring system is in opposite direction or encoder is mounted backwards), the incremental position lies between 2^n-1 and 0. The position range is inverted accordingly, e.g. from 100 to 0 mm. If the actual position in this case is 15 mm without sign change when the encoder is switched on, then the position with sign change is 85 mm.

Example:
A linear scale with a grid line spacing of 0.005 mm and a measuring range of 30 mm or 6,000 increments is specified. The maximum value for the incremental position can be displayed on a computer as a data value with a width of 13 bits (2^{13} = 8,192).
Therefore, the encoder's maximum position is in theory 40.96 mm (8,192 * 0.005 mm). If the axis is offset in the positive direction, the displayed encoder position increases its value, moving from 0.0 up toward 40.96 mm, and the incremental position increases from 0 up toward 8,191 increments. An incremental position of 1,000 increments, for example, corresponds to an axis position of 5.0 mm. By contrast, changes to the axis position in the positive direction on an encoder where the invert actual position value function has been activated will cause the displayed encoder position to decrease its value, moving from 46.96 down toward 0.0 mm. The inverted encoder position is derived from the difference between the encoder's theoretical maximum position and the encoder position determined by the current incremental position. This means that the encoder incremental position of 1,000 increments given in the example results in a position of 35.96 mm (40.96 mm - 5.0 mm = 35.96 mm).

Boundary conditions for mechanical settings for modulo axes (long-term stability / long-term accuracy)

For modulo axes, SIMOTION checks whether the long-term accuracy can be guaranteed. Testing takes place on initial download, each restart of the CPU and each restart of the technology objects, if relevant data have changed. The long-term accuracy ensures the following:

- That the axis position displayed by the controller always conforms to the real position, i.e. the axis position can be displayed uniquely from the accumulated encoder increments.
- That the calculated position in the controller does not differ from the real position. Without long-term accuracy, differences result, e.g. because of rounding errors or calculations with finite accuracy.

This enables positions to be approached exactly, even after any number of modulo overflows.

Note on non-modulo axes:

Non-modulo axes are “always accurate” because of an endless traversing range, even if the convertibility of gear ratios is not stable over the long term.

If the maximum internal position ($9x10^{12}$ at 1000 increments/unit) is reached and the convertibility of gear ratios is not stable over the long term, an alarm 50011 occurs (range limit of the incremental actual value exceeded) and the axis must be re-homed.

The long-term accuracy/stability of modulo axes is dependent on the following:

- Internal resolution, increments/position [units/mm]
  (can be set at **Configuration > Axis type > Configure units**)
- Encoder resolution: [incr/rev]

- Encoder fine resolution
- Spindle pitch [mm/rev] (for linear modulo axes)
- Measuring gearbox
- Load gearbox

Checking long-term accuracy as of V4.2

The long-term accuracy is only checked during runtime, as a result of the encoder data adaptation.

Long-term accuracy means that the technological position can be determined from the accumulated encoder increments (without rounding error) and is therefore always accurate.

With long-term accuracy, the encoder position is converted to the mechanical position via the numerator/denominator factor of the gear ratio. If there is no long-term accuracy, an LREAL factor is used as substitute for the conversion. Alarm 50024 (long-term stability of the actual values is not guaranteed) is then output. NONE is the default setting for the local response.

When using the LREAL factor to take into account the gear ratio, modulo axes are accurate as long as the total traversing distance of the axes without modular conversion does not exceed the maximum traversing range of the axis (representation range $9x10^{12}$ at 1000 increments/unit).

If the maximum value of the representation range is exceeded, this results in inaccuracy of the technological position. The unavoidable rounding error in the last available position of the LREAL factor applies in this case. However, for the generally used settings, this is only reached after years.

Determining the maximum traversing time of an endlessly traversing axis

The maximum traversing time can be determined based on the following estimate. The maximum position and the traversing velocity are decisive:

Maximum position = $9x10^{12}$mm at an internal resolution (default) of 1000 internal increments/ position unit

Traversing time = maximum position / velocity

Table 4-349 Example of a linear modulo axis

Velocity:	20 m/min = $2x10^4$ mm/min
Maximum position:	$9x10^{12}$mm
Traversing time = $9x10^{12}$ mm / ($2x10^4$ mm/min) = $4.5x10^8$ min = 856.16 years	

At a higher set internal computational accuracy, the traversing time is correspondingly lower.

If the determined traversing time does not meet your requirements, you can use the alternative procedure presented below or identify the required settings for long-term stability in accordance with the section “Checking long-term accuracy < SIMOTION V4.2”.

Alternative procedure

Reset the position by homing if the maximum traversing time does not meet your requirements.

Incremental encoder

Home the incremental encoder again before the position value $9x10^{12}$ is reached.

Absolute encoder (as of SIMOTION V4.3 SP1 HF17)

Perform absolute encoder adjustment with preset current known position via the **_homing()** function using homingMode=SET_OFFSET_OF_ABSOLUTE_ENCODER_BY_POSITION.

This resets the position values to the current measurement range in a cyclic absolute encoder. The reset may be performed via a user program e.g. after a

Power ON.

Checking long-term accuracy < V4.2

The long-term accuracy of a modulo axis is a precondition for operating the axis.

If long-term accuracy cannot be guaranteed as a result of the mechanical settings, then one of the following error messages is output in the engineering system during the consistency check.

- Configured gear ratio cannot be represented
- Configured modulo length cannot be represented

A test of the long-term accuracy is also performed on the target device during runtime. If the long-term stability is not ensured due to the configuration, the following alarm is issued: **Alarm 20006 Configuration error, reason 3041**.

The reason for this error is the unsuitable selection of values in the configuration data. The Excel list available on the Siemens Service & Support (https://support.industry.siemens.com/cs/ww/en/view/40786053) website assists you when checking and calculating gearbox parameters.

4.8.3.8 Defaults

The axis has system variables that can be set to default values for the axis. The most important default values, e.g., for the dynamic response of the axis, are compiled in the Dynamic Response screen form. These default values will be used if you use **Default** or **USER DEFAULT** in your programming.

Table 4-350 Other default values that can be set via the expert list

Default values for	System variable
Clamping values	**userDefaultClamping**
Dynamic values	**userDefaultDynamics**
Switchover to force control	**userDefaultForceControl**
Force/pressure limiting	**userDefaultForceLimiting**
Homing	**userDefaultHoming**

Default values for	System variable
Positioning	**userDefaultPositioning**
Hydraulics	**userDefaultQFaxis**
Torque limiting	**userDefaultTorqueLimiting**

Default settings for dynamic response parameters (Page 2997)

4.8.3.9 Homing

Overview of homing

On the positioning axis, inputs and displays concerning the position refer to the coordinate system of the axis.

The coordinate system of the axis must be aligned with the real, physical position of the axis.

Absolute encoder

For absolute encoders, inclusion of the absolute encoder offset must be activated **once**.

For more information, refer to Section States that require re-adjustment of the absolute encoder (Page 2934).

Incremental encoder

For **incremental encoders**, synchronization is performed by homing when the home position coordinates, or the home position coordinate taking into account the home position offset, are set in active homing to a defined mechanical position of the axis. This defined mechanical position of the axis is signaled to the controller via the encoder zero mark of the measuring system or via the external zero mark.

For incremental encoders, if you want to establish a direct reference to the position, you must synchronize the actual value system of the axis after every activation.

Note

Traversing commands with **relative position specification** can always be executed. The axis configuration can be set to determine whether traversing commands with **absolute position specification** can also be executed on a non-homed axis. Configuration data: **referencingNecessary**.

See also

Homing (Page 3156)

Terminology

Home position

When the axis has been synchronized and the reference point offset has been applied, the axis is at the reference point and has the value specified in the reference point coordinate.

Set the home position or the home position coordinate in the **userDefaultHoming.homePosition** system variable. The setting is axis-specific.

The **homingCommand.state** system variable displays the homing status on the axis.

Synchronization point

In the synchronization point, the actual value of the axis due to an external or internal event is set to the value **home position coordinate minus home position offset**.

Reference point offset

The offset between the home position and the synchronization point is only effective during active homing. It is applied after synchronization of the axis by means of the homing command. In modulo axes, the **home position offset** is always applied with the **Shortest_Way** direction setting. (Exception: As of 4.1 SP1, the direction can be specified with the "Home in one direction only" setting.)

Specify the home position offset in the **TypeOfAxis.NumberOfEncoders.Encoder_1.IncHomingEncoder.proceedShiftPos** configuration data element.

Reference mark

A homing mark is a hardware signal that is used for homing.

- Encoder zero mark
  The encoder zero mark of an incremental encoder is used as a reference mark.
- External zero mark
  An external signal (zero mark substitute) is used as the reference mark.

Homing output cam

The homing output cam outputs an enable signal for the actual reference signal (encoder zero mark or external zero mark). The drive reduces the velocity on the basis of the switching edge returned by the homing output cam and waits for the next incoming homing signal in order to perform the homing operation.

Note

Device-specific properties

The homing output cam is connected to any control input for homing with homing output cam and encoder zero mark.

For more information about the device-specific boundary conditions and additional parameter setting requirements, see the supplementary information for drives and the product manuals.

Homing types

Open-loop control supports the following types of homing:

- **Active homing**
  A special traversing motion is carried out for this type of homing. The following homing modes can be selected via the configuration:
  - Homing with homing output cam and encoder zero mark
  - Homing with external zero mark only
  - Homing with encoder zero mark only.
- **Passive homing/flying homing**
  This type of homing occurs during motion that was not initiated by a homing command. The following homing modes can be selected via the configuration:
  - Homing with homing output cam and encoder zero mark
  - Homing with external zero mark only
  - Homing with encoder zero mark only.
- **Direct homing / Set home position**
  The axis position is set without a traversing motion having taken place.
- **Relative direct homing**
  The actual position value of the axis is shifted by a specified offset without a traversing motion having taken place.
- **Absolute encoder homing/absolute encoder adjustment**
  The zero point of the absolute encoder is adjusted.

Note

As of V4.2, the inputs for homing output cams and for the status of the external zero mark and of the reversing cam can be interconnected to SINAMICS inputs symbolically instead of via the intermediary of a logical address.

Active homing

During active homing, the homing operation is performed according to the specified mode by means of a motion initiated by the homing command.

A home position offset is in effect and is applied after synchronization with the reference mark. Once the home position offset has been applied, the axis position has the value specified in the home position coordinate.

In active homing, the velocity specifications for the homing approach velocity, the homing reduced velocity, and the homing entry velocity are effective.

The axis has **synchronized** or **homed** status once the reference mark is detected.

Note

The direction of approach to the reference cam or reference mark must be specified in the user program. As of V4.1, support is provided for using hardware limit switches as reversing cams.

Active homing with reference cam and encoder zero mark mode

The homing command causes the axis to move toward the reference cam. After the axis has detected and left the reference cam, the axis moves to the next encoder zero mark of the position measuring system. You can specify in a configuration data element whether the encoder zero mark is in the positive or negative traversing direction. The axis is synchronized with the first encoder zero mark detected after the reference cam. Then, the home position offset is traveled at the homing entry velocity. The axis position now has the value defined in the home position coordinate.

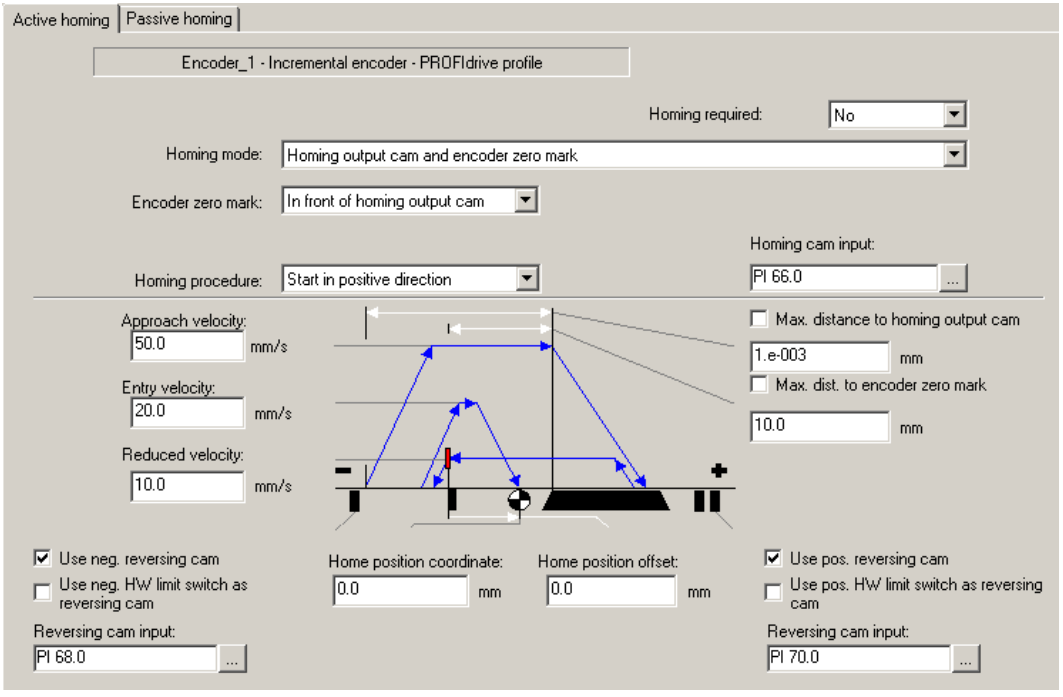

Figure 4-819 Parameters for active homing with reference cam and encoder zero mark

The sequence can be divided into three phases:

- **Phase 1**
  Travel to the reference cam
  The axis moves to the reference cam at the **approach velocity**. The approach direction is parameterized.
- **Phase 2**
  Synchronization with encoder zero mark
  The axis moves to the encoder zero mark of the incremental position encoder at the **reduced velocity**. The position of the encoder zero mark relative to the reference cam can be parameterized. Depending on this position, the movement is either continued in the same direction or reversed. The controller is synchronized to the first detected encoder zero mark which is detected according to the configuration setting. When the encoder zero mark is detected, the axis is considered to be synchronized, and the axis position is set to the value specified in the home position coordinate, minus the home position offset.
- **Phase 3**
  Travel to the home position
  When the encoder zero mark is detected, the axis moves to the home position at the **entry velocity**.

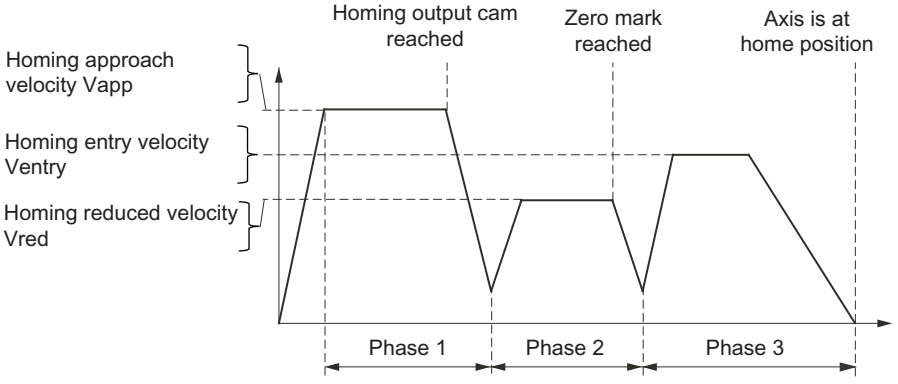

Figure 4-820 Homing with incremental measuring systems

Hardware limit switch as reference cam (as of V4.1 SP1)

The hardware limit switches can also be defined as a reference cam. The axis is homed to the first encoder zero mark after the direction is reversed as a consequence of approaching the hardware limit switch. The axis cannot continue to travel in the direction of the hardware limit switch.

This corresponds to homing with reference cam and encoder zero mark, whereby the encoder zero mark lies in front of the reference cam.

Alternatively, a left and right hardware limit switch can be used (positive or negative approach direction). In this case, the hardware limit switch is deactivated during homing.

Active homing with external zero mark only

Here, the homing command initiates motion toward the external zero mark. Once the axis reaches the configured edge of the external zero mark, the home position offset is applied at the homing entry velocity. The axis position now has the value defined in the home position coordinate.

Note

For homing to the external zero mark of axes with a digital drive link via PROFIdrive, the external zero mark must be configured as a digital input on the drive (configuration of zero mark substitute for SIMODRIVE 611U, SINAMICS). The external zero mark signal must be connected at the same location where the encoder is measured, e.g. on the drive, on the ADI4/IM174, or on the inputs of the C2xx intended for the external zero mark.

SINAMICS

With SINAMICS, a positive direction of motion is synchronized to a positive trigger edge and a negative direction of motion is synchronized to a negative trigger edge, i.e. on the left side of the external zero point signal in each case.

By inverting the signal (setting option on the drive: SINAMICS parameter via P490), synchronization is also possible on the right side of the external zero point signal.

In SINAMICS, the homing to the encoder zero mark or the external zero mark is set in P495.

To be able to detect for drives coupled using PROFIdrive that the drive is positioned at the external zero point, the state of the external zero point on the axis must be made available. Because the corresponding status bit is not provided in the PROFIdrive telegram of the drive DO, an additional input bit containing the status of the external zero mark can be configured on the axis in the **incHomingEncoder.stateDriveExternalZeroMark** configuration data element as of V4.1 SP1. For drives linked with SINAMICS, the corresponding status bit in PZD2 of telegram 390 or 391 of the CU is transferred to the controller.

If symbolic assignment is activated, the status of the external zero mark can be assigned to the corresponding onboard terminal on the control unit directly using the Assign dialog.

Refer to the SINAMICS documentation for the assignment of digital inputs of the drive to the status bits of the PZD2.

The system will detect whether the axis is already positioned at the external zero point. Travel from the external zero point is made opposite to the approach direction. This is followed by normal homing.

SIMODRIVE 611U

With SIMODRIVE 611U, only falling edges are permitted in the positive traversing direction, and only rising edges are permitted in the negative traversing direction, meaning that the same output cam side is always used.

Inverting is not possible with SIMODRIVE 611U. The edges can be inverted by using initiators of the inverted type or via an application (inaccurate).

MASTERDRIVES

With MASTERDRIVES Motion Control, only rising edges are permitted.

OnBoard C2x0

With OnBoard, only rising edges are permitted.

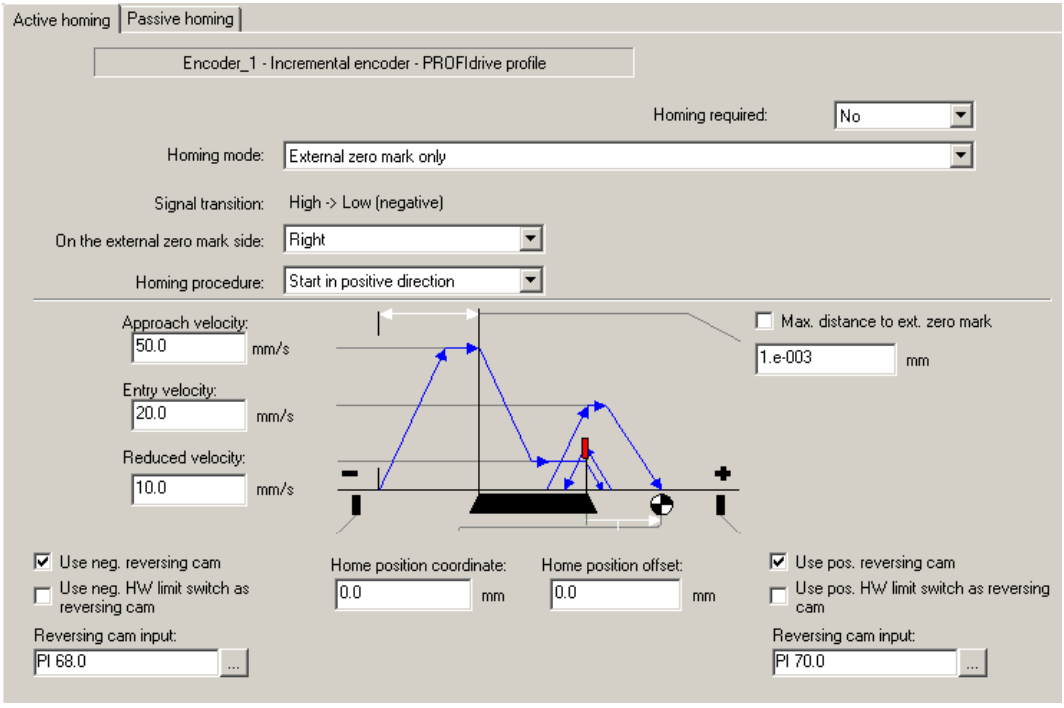

Figure 4-821 Parameters for active homing with external zero mark only

Note

- Only homing with a reference cam and an encoder zero mark should be considered for a resolver with a pole pair number > 1.

- With a digital link to SINAMICS S120, the settings for homing are read out from the drive on request. Changes are not written back to the drive.

Active homing with encoder zero mark only (without reference cam)

Homing without a reference cam is used, for example, in axes for which the encoder has only one encoder zero mark in the entire axis traversing range. This homing command causes the axis to travel to the encoder zero mark. After the encoder zero mark is detected, the axis approaches the shifted reference point at homing velocity. The axis position now has the value defined in the home position coordinate.

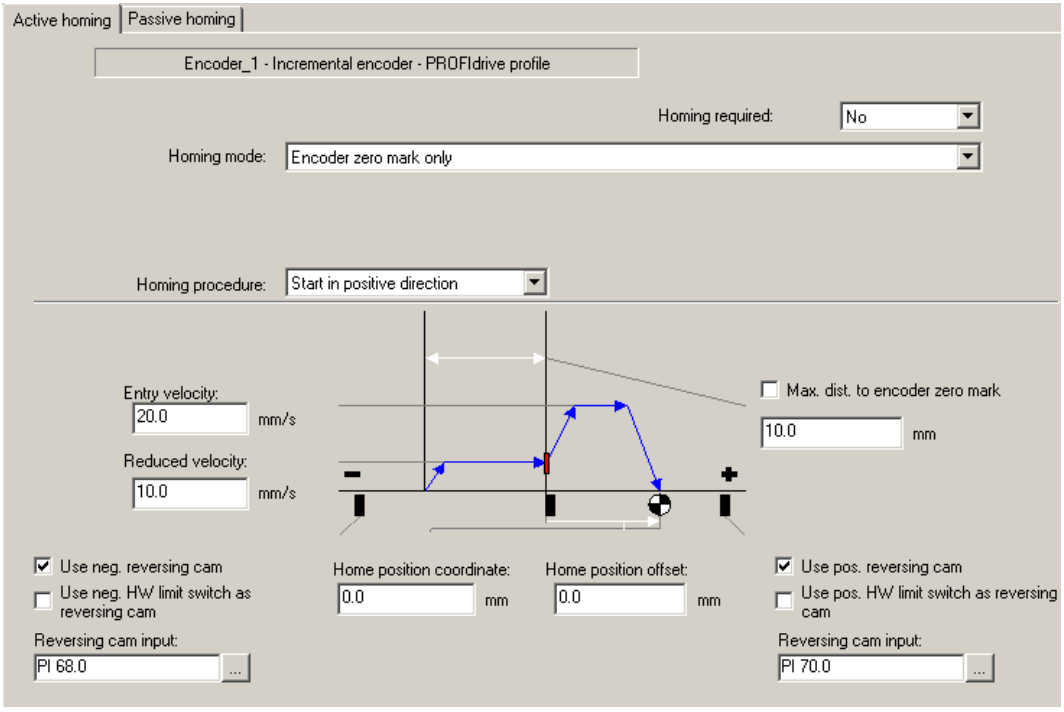

Figure 4-822 Parameters for active homing with encoder zero mark only

Note

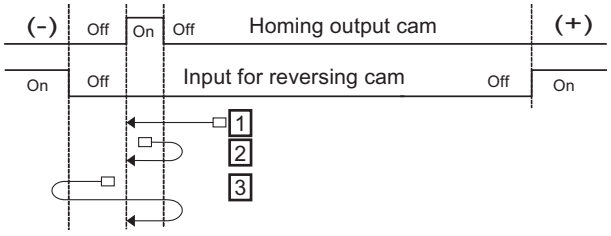
Only homing with a reference cam and an encoder zero mark should be considered for a resolver with a pole pair number > 1.

Reversing cams for homing (as of V4.1 SP1)

Reversing cams, which are effective only during active homing, are used to reverse the direction of the home position travel when approaching a reversing cam.

The reversing cams are configured as two additional input signals. The left reversing cam and the right reversing cam can be configured and activated separately. The reversing cams are defined once on the axis. They cannot be defined specifically for an encoder.

The following figure illustrates homing sequences based on the starting point position with respect to the reference cam.



All examples are programmed with the Left-hand approach direction (negative)

1 Starting point in front of reference cam

2 Axis is on reference cam
This is detected by the system, and the axis travels against the approach direction away from the reference cam. This is followed by normal homing.

3 Axis is behind the reference cam on the left
A normal homing operation with approach direction left is started. The axis reverses direction at the reversing cam and travels against the approach direction until it is over the reference cam. This is followed by normal homing.

Figure 4-823 Reversing cams for homing

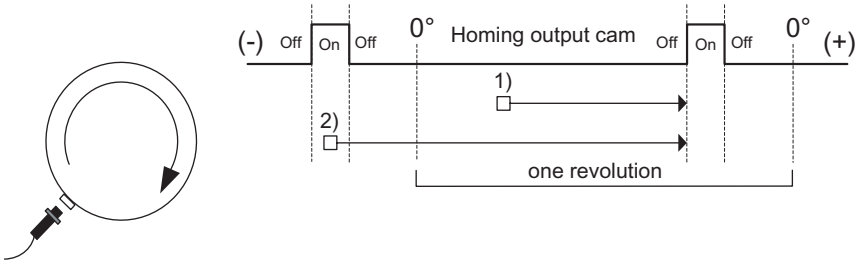
The hardware limit switches can also be defined as reversing cams. In this case, the hardware limit switch is deactivated during homing.

The reversing cams are defined via the configuration data elements **typeOfAxis.homing.reverseCamPositive** and **typeOfAxis.homing.reverseCamNegative**.

Homing in one direction only (as of V4.1 SP1)

As of V4.0, you can specify in the **typeOfAxis.homing.direction** configuration data element that a direction reversal during homing should be suppressed and the specified traversing direction should always be maintained. This setting is effective only during active homing.

The figure below shows an application example featuring a rotary axis that is not permitted to reverse direction.



All examples are programmed with the Right-hand approach direction

1) Starting point in front of reference cam
Reference cam is found in the modulo area.

2) Axis is on reference cam
This is detected by the system. The axis travels in the programmed approach direction to the next reference cam, even if the modulo area is overtraveled.

Figure 4-824 Example of homing in one direction only

Passive homing/on-the-fly homing

In passive homing, the homing is performed according to the mode setting using a motion not initiated by the homing command. Passive homing is possible in position-controlled mode in association with motion commands. A home position offset is not applied. The axis has synchronized or homed status once it has detected the homing mark. Specifications for the homing approach velocity, reduced velocity, and entry velocity are not applied.

Default homing mode (DEFAULT_PASSIVE)

With this setting, the homing mode is defined by the system based on the encoder type:

- With incremental sin/cos encoders, TTL encoders, or resolvers, homing is executed to an encoder zero mark.
- With Endat encoders defined as incremental encoders, homing is executed to an external zero mark.

Passive homing with homing output cam and encoder zero mark mode

Once the homing output cam has been detected, the next encoder zero mark takes effect according to the synchronization specified in the configuration. Synchronization is performed with the first encoder zero mark detected after the homing output cam. When the encoder zero mark is detected, the axis is set to the value specified in the home position coordinate. The axis is then given Synchronized and Homed status.

Passive homing with external zero mark only

Once the external zero mark has been detected, synchronization takes place according to the configuration. When the external zero mark is detected, the axis is set to the value specified in the home position coordinate. The axis is then in synchronized and homed status.

Passive homing with encoder zero mark only

Homing without a homing cam cam is used, for example, in axes for which the encoder has only one homing mark in the entire axis traversing range. When the homing mark is detected, synchronization takes place according to the configuration. Once the homing mark has been detected, the axis is set to the value specified in the home position coordinate and is in synchronized or homed status.

Note

Use the "homing output cam and encoder zero point" setting for homing for measuring systems with more than one encoder zero point in the traversing distance of the axis. This ensures that travel is made to an exact, reproducible homing position.

As an alternative, you can use the "only external zero point" setting. The external signal means, however, that the attainable homing position is less accurate.

Direct homing/setting the home position

The current position of the axis is set to the value specified in the home position coordinate. A home position offset is not applied. A traversing motion is not carried out. When the command is executed, the axis is in synchronized or homed status.

The setting of parameters for axis homing is irrelevant here. The home position coordinate is specified in the command.

Direct homing is not possible if the axis is traversed in speed control. Switch to position control for the homing.

See also

Positioning (Page 3158)

Synchronization/homing with incremental encoders (Page 3205)

Relative direct homing/relative setting of home position (V3.2 and higher)

The current position of the axis is offset by the value specified in the home position coordinate, so in this case the home position coordinate should be regarded as an offset.

This homing method can also be used during operation (while traversing).

The setting of parameters for axis homing is irrelevant here. The home position coordinate is specified in the command.

States that require a new homing procedure for incremental encoders

With incremental encoders, the status is reset to not homed in the following cases:

- Error in the sensor system / encoder failure
- New homing command
- Power off
- Termination of the communication to the drive/encoder
- SCOUT is downloaded with selection of the *Initialization of all retentive data* setting
- Changes requiring a download or restart are made to the axis configuration
- Technology object restart is performed on the Axis technology object
- When active homing is initiated

Absolute encoder homing / absolute encoder adjustment

The current axis position is set to equal the encoder value + absolute encoder offset using the **_homing()** command in ENABLE_OFFSET_OF_ABSOLUTE_ENCODER homing mode.

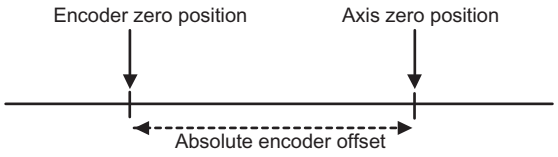


Figure 4-825 The axis zero position is the encoder zero position plus the absolute encoder offset

The axis must be in position-controlled mode while the absolute encoder is adjusted.

The absolute encoder offset (as of V3.2) may be set as an additive or absolute value.

This absolute encoder offset is stored in the NVRAM and remains in effect until the next absolute encoder adjustment. This function must therefore be executed once when the control is commissioned.

The offset value and its calculation are set during **configuration**.

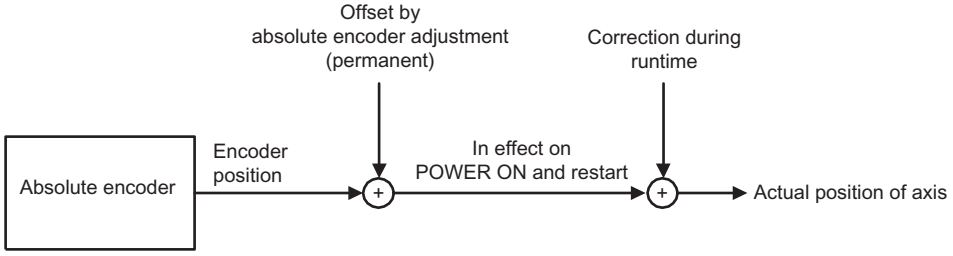

Figure 4-826 Incorporating the absolute encoder offset

A value may be set as a total offset using the **absHomingEncoder.setOffsetOfAbsoluteEncoder** and **absshift** configuration data.

Setting an additive offset

Setting **absHomingEncoder.setOffsetOfAbsoluteEncoder**=RELATIVE (default behavior):

- Actual axis value = actual encoder value + (previous offset already in effect + absshift)
- (new) offset = previous offset + absshift

absHomingEncoder.absshift is added to the existing absolute encoder offset whenever the **_homing()** function is called.

Setting an absolute offset (as of V3.2)

Setting **absHomingEncoder.setOffsetOfAbsoluteEncoder**=ABSOLUTE (as of V3.2):

absHomingEncoder.absshift is set as the absolute encoder offset whenever the **_homing()** function is called.

- Actual axis value = actual encoder value + **absshift**

Example of ABSOLUTE offset where actual encoder position value = 100.000:

absshift = 5.000		
_homing() command called for the first time	⑧	Position = 105.000
_homing() command called for the second time	⑧	Position = 105.000
absshift = 7.000		
_homing() command called for the third time	⑧	Position = 107.000

Setting the axis to a predefined position (as of V4.1 SP1)

When the function
parameter **homingMode**=SET_OFFSET_OF_ABSOLUTE_ENCODER_BY_POSITION is set on the **_homing()** command, the value in the *homePosition* parameter is set as the current position. The resulting absolute encoder offset is calculated with this value, indicated in the **absoluteEncoder[n].totalOffsetValue** system variable, and stored as a retain variable in the system.

The value in the **absHomingEncoder.absshift** configuration data element is not changed.

Displaying the offset

The offset can be read out. (as of V3.1)

The total offset is indicated in the **absoluteEncoder[x].totalOffsetValue** system variable, while the activation status of the total offset is indicated in the **absoluteEncoder[x].activationState** variable.

In addition, the status indicates whether the **_homing()** function where **homingMode**= ENABLE_OFFSET_OF_ABSOLUTE_ENCODER was executed at least once after the project was downloaded.

Absolute encoder adjustment

Perform the following steps to adjust the absolute encoder:

1. Disable the software limit switches, because you cannot adjust the absolute encoder while these are active.
2. Perform the absolute encoder adjustment:
   - **_homing()** where **homingMode**= ENABLE_OFFSET_OF_ABSOLUTE_ENCODER
     The value of the **absHomingEncoder.absshift** configuration data element is included when the command is called once. (**absHomingEncoder.absshift** is a configuration data element that can be modified online, i.e. any changes take effect immediately.)
     or
   - **_homing()** where **homingMode**=SET_OFFSET_OF_ABSOLUTE_ENCODER_BY_POSITION (as of V4.1 SP1)
     Move the axis to the desired reference position and call the command once.
     This sets the value in the *homePosition* parameter as the current position. The resulting absolute encoder offset is calculated using this value, indicated in the **absoluteEncoder[n].totalOffsetValue** system variable, and stored as a retain variable in the system.
     The value in the **absHomingEncoder.absshift** configuration data element is not changed.
3. Enable the software limit switches again (if necessary).

Note that the absolute encoder adjustment only acts as an offset to the absolute encoder value. The offset from the absolute encoder adjustment and the value of the absolute encoder are determining factors for the position after a power off or restart. During operation, the current actual position is also affected by the modulo settings for the axis and by position setting or position correction tasks.

States that require re-adjustment of the absolute encoder

- Once a new project has been downloaded to the control, the stored offset is no longer available.
  If the control already contains a project before the new project is downloaded, and if the technology object name is not changed, the stored offset is retained (as of V4.1 SP1). This behavior also applies for an upgrade, i.e. it is not version-dependent.
- After power is cycled off and on, the offset is deleted unless the project was saved to the ROM.
- After a memory reset.

Encoder for position (Page 2901)

Homing mark monitoring

If the homing mark is not reached within the defined travel path, an alarm is triggered. In homing with homing output cam and homing mark, the path is monitored only after the axis leaves the homing output cam.

If reversing cams are present, monitoring is applied again when the direction reverses as a result of the revering cams.

When homing mark monitoring is enabled, both active and passive homing procedures are monitored.

Homing output monitoring

If the homing output cam is not reached within the defined travel path, an alarm is triggered.

If reversing cams are present, monitoring is applied again when the direction reverses as a result of the revering cams.

When homing output cam monitoring is enabled, both active and passive homing procedures are monitored.

Displaying actual value change during homing (V4.0 and higher)

A change of the actual value during homing is displayed in the **homingCommand.positionDifference** system variable.

Traversing with a non-homed axis

With the **referencingNecessary** configuration data element, you define whether absolute positions can be used with a non-homed axis.

Settings:

- referencingNecessary = NO
  - Relative and absolute motions are possible.
  - The software limit switches are monitored with the setting **swlimit.state** = YES.
- referencingNecessary = YES
  With a non-homed axis:
  - Only relative motion is possible
  - The software limit switches are not monitored even with the setting **swlimit.state** = YES.

Correcting the actual position/set position without homing

Position correction can also be used to manipulate the actual values and setpoints of individual coordinates (basic coordinates, superimposed coordinates).

The homing status of the axis (Homed/Not homed) does not change.

See also

Resetting the set and actual positions (Page 3168)

Differential position measurement (V3.2 and higher)

The axis position is not measured directly; it is determined as the difference between two encoders/actual values. The system adopts this differential position as the actual position and uses it as an absolute value.

The encoders for the individual positions may be either absolute encoders or incremental encoders.

Homing of the differential position is not permitted.

The offset relative to the differential position can be modified online using the **positionDifferenceMeasurement.Offset** configuration data element.

The differential position and the position sensors are used as encoders.

Differential position value =
Position (numberEncoderA) - Position (numberEncoderB)

Proceed as follows to specify the setting via the expert list:

- Configure at least two position sensors on the axis.
- In the expert list, increase the value of **TypeOfAxis.NumberOfEncoders.NumberOfEncoders** by 1.
- Set the other sensor as the "differential position sensor" via the **TypeOfAxis.NumberOfEncoders.Encoder_n.EncoderType** configuration data element with SENSOR_POSITION_DIFFERENCE_MEASUREMENT.
- The sensors whose values are used and the individual factors are set in the elements of the **TypeOfAxis.NumberOfEncoders.Encoder_n.PositionDifferenceMeasurement** structure.

4.8.3.10 Monitoring/limiting functions

Overview of monitoring/limiting functions (block diagram)

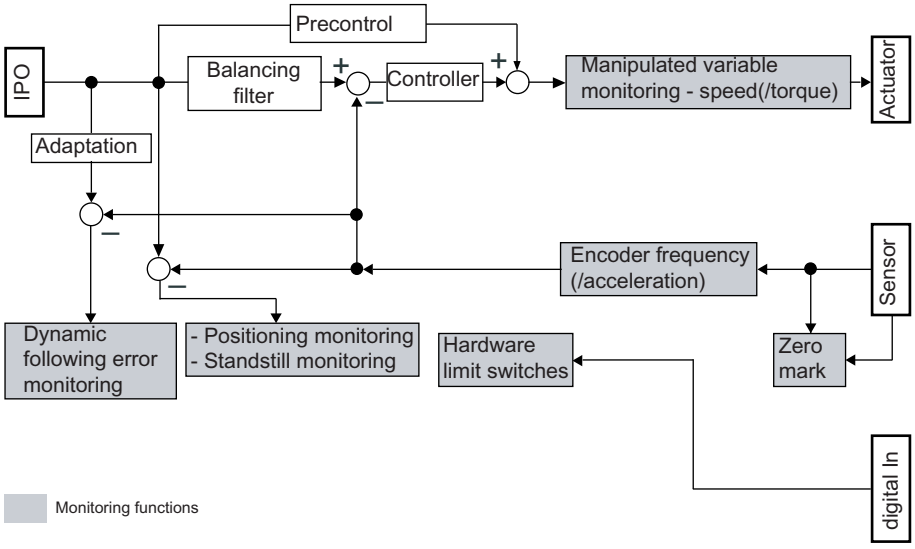

Figure 4-827 Block diagram of positioning axis monitoring functions

Dynamic monitoring of following errors

The following error monitoring on the position-controlled axis is performed on the basis of the velocity-controlled following error limit.

The maximum permissible following error is dependent on the set velocity.

For velocities less than a specified lower velocity, the maximum permissible following error is constant and set in **typeOfAxis.NumberOfDataSets.DataSet_N.DynamicFollowing.minPositionTolerance**. The lower velocity value for the characteristic of the maximum following error is set in **typeOfAxis.NumberOfDataSets.DataSet_N.DynamicFollowing.minVelocity**.

Above this lower velocity, the maximum permissible following error is proportional to the set velocity up to the maximum permissible velocity.

The maximum permissible following error for the maximum velocity of the axis is set in **typeOfAxis.NumberOfDataSets.DataSet_N.DynamicFollowing.maxPositionTolerance**. The gradient factor of the characteristic for the maximum following error is calculated from these settings.

The **dynamicFollowing.warningLimit** configuration data can be used to specify a threshold as percentage value based on the maximum permissible following error of the associated set velocity which, when exceeded, causes the issuance of a warning.

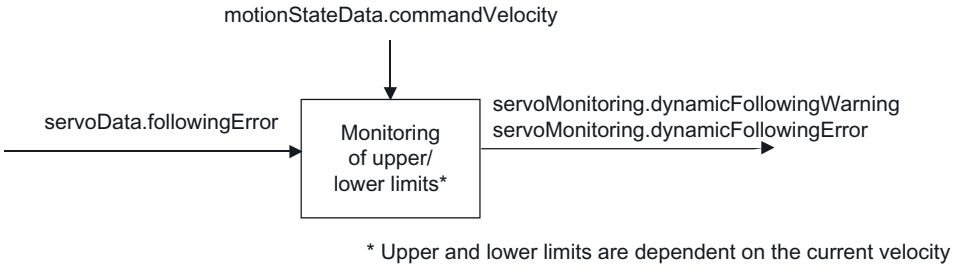

Figure 4-828 Dynamic monitoring of following errors

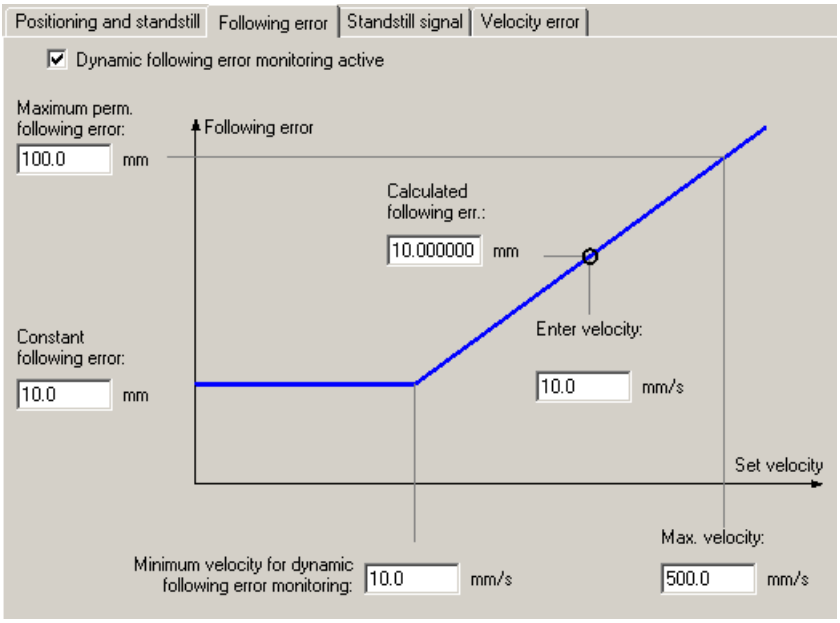

Figure 4-829 Function and parameters for following error monitoring

System variable on the TO with current position lag limit

The **Permissible following error** block is provided to monitor the stability of the axis. This contains the permissible dynamic following error as system variable (**servoData.permissibleFollowingError**).

Following error determination without DSC

The following error is determined from the difference between the non-symmetrical setpoint prior to inclusion of the dynamic response adjustment and the actual value present in the control.

Therefore, the transfer times of the setpoint to the drive and the actual value to the control are included in the following error.

Following error determination with DSC

The following error is determined from the difference between the non-symmetrical setpoint delayed by the transfer times (T_i+T_o+T_{dp}+T_{servo}) + **systemDeadTimeData.additionalTime** prior to inclusion of the dynamic response adjustment and the actual value present in the control.

The transfer times of the setpoint to the drive and the actual value to the control are calculated from the following error in order to refer to the following error present on the position controller in the drive.

Positioning and standstill monitoring

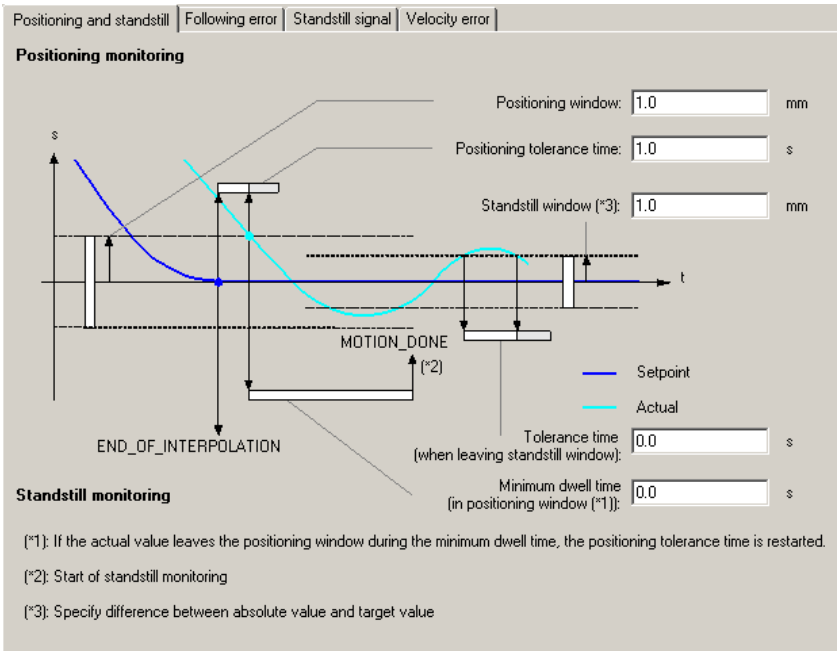

Figure 4-830 Function and parameters for positioning monitoring

Positioning monitoring

The behavior of the actual position at the end of the setpoint interpolation is monitored. (Positioning monitoring)

This positional monitoring does not distinguish whether the setpoint interpolation is ended as a result of reaching the target position from the setpoint side or due to a position-controlled stop during the motion performed by the interpolator (e.g. with a _stop() command). This monitoring is referred to as positioning monitoring, although the position does not have to be the same as the target position. The tolerance window specified for this monitoring is called the positioning window.

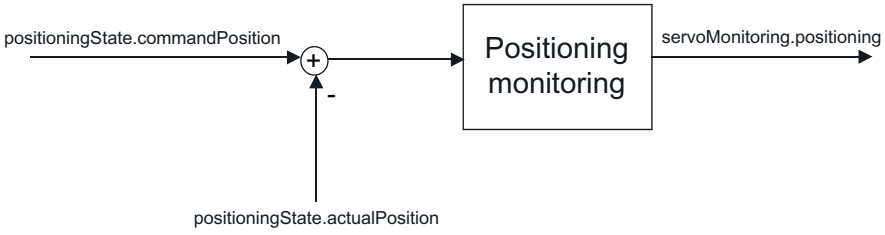

Figure 4-831 Positioning monitoring

Sequence:

- When the setpoint interpolation is complete, the **typeOfAxis.positionMonitoring.posWinTolTime** monitoring time is started.
- If, before this time expires, the actual value reaches a definable window **typeOfAxis.positionMonitoring.tolerance** around the existing position at the end of the setpoint interpolation, monitoring of the minimum delay time **typeOfAxis.positionMonitoring.posWinTolDelayTime** is initiated. This window is indicated as a deviation in **typeOfAxis.standStillMonitoring.stillStandTolerance**, meaning that half of the window width is set.
  If the actual value does not reach the window within the monitoring time **typeOfAxis.positionMonitoring.posWinTolTime**, alarm 50106 (positioning monitoring) is issued.
- If the actual value leaves this window again during the minimum dwell time **typeOfAxis.positionMonitoring.posWinTolDelayTime**, the monitoring time **typeOfAxis.positionMonitoring.posWinTolTime** is restarted; each time it re-enters this window, the minimum delay time **typeOfAxis.positionMonitoring.posWinTolDelayTime** is restarted.
- If the actual value remains in this window for the minimum delay time **typeOfAxis.positionMonitoring.posWinTolDelayTime**, the MOTION_DONE status is set in the system variable **motionStateData.motionCommand** and the standstill monitoring is started.

In addition, the individual monitoring phases are displayed in **servoMonitoring.positioningState** (as of V4.1 SP1):

- ACTUAL_VALUE_OUT_OF_POSITIONING_WINDOW = setpoint interpolation is complete; actual value has not yet reached the positioning window.
- ACTUAL_VALUE_INSIDE_POSITIONING_WINDOW = actual value is inside positioning window; standstill monitoring is not yet started.
  The ACTUAL_VALUE_OUT_OF_POSITIONING_WINDOW is displayed when the actual value has left the positioning window again.
- STANDSTILL_MONITORING_ACTIVE = standstill monitoring is active; positioning to the position reached at the end of the setpoint interpolation has taken place.
- INACTIVE

Note

Positional monitoring (e.g. following error monitoring or positioning monitoring) are disabled when the pressure control is enabled or via the pressure limiting or torque limiting command.

Standstill (zero-speed) monitoring

Standstill monitoring is defined by the standstill window and the tolerance time during which the standstill window may be exited without alarm 50107 (standstill monitoring) being triggered.

Standstill monitoring starts when the minimum dwell time in the positioning window has elapsed.

The standstill window is indicated as a deviation in **typeOfAxis.standStillMonitoring.stillStandTolerance**, meaning that half of the window width is set.

The status of the standstill monitoring is displayed in **servoMonitoring.stillstand**. Standstill monitoring is not available on the speed-controlled axis.

Standstill signal

The standstill signal **motionStateData.stillstandVelocity** is ACTIVE when the current velocity is less than a configured velocity threshold for at least the duration of the delay time.

Note

Below this velocity, the motion is stopped in response to **_stopEmergency()** at zero setpoint without a preconfigured deceleration ramp.

In speed-controlled motion, the criterion for completing the command is standstill monitoring. The completion of commands for position-controlled motions is described in **Positioning and standstill monitoring**.

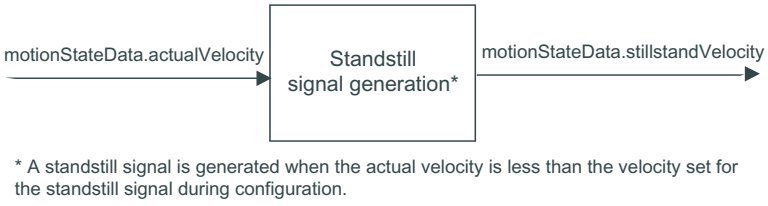

Figure 4-832 Standstill signal generation

The standstill signal is available on the positioning axis and the speed-controlled axis.

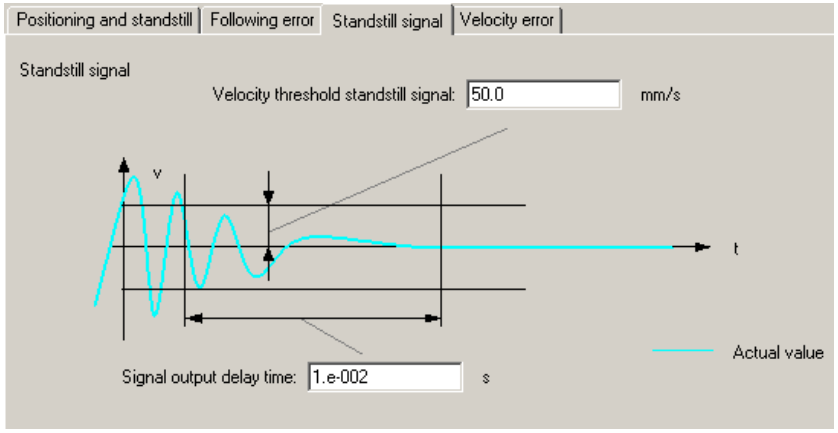

Figure 4-833 Function and adjustable parameters for the standstill signal

Standstill signal monitoring

motionStateData.ActualVelocity shows the actual velocity after the smoothing filter. The axis velocity before the smoothing filter is used for the standstill signal monitoring.

The unfiltered velocity used for the standstill window is not displayed specifically.

Positioning and standstill monitoring (Page 2941)

Manipulated variable monitoring

The maximum manipulated variables are limited for monitoring of the assigned speed limits. If the manipulated variables exceed the maximum value configured in **MaxSpeed**, alarm "50005 speed setpoint monitoring" is triggered.

With the help of increase monitoring of the manipulated variable, the maximum possible acceleration and thus the maximum torque are monitored. If the monitoring function is switched on and the acceleration set in the configuration data **MaxAcceleration** is exceeded, alarm 50003 (limit of speed set acceleration is active) is output, and the parameter **SetPointChangeRate** is set to LIMIT_EXCEEDED.

Manipulated variable limiting (backstop) (V3.1 and higher)

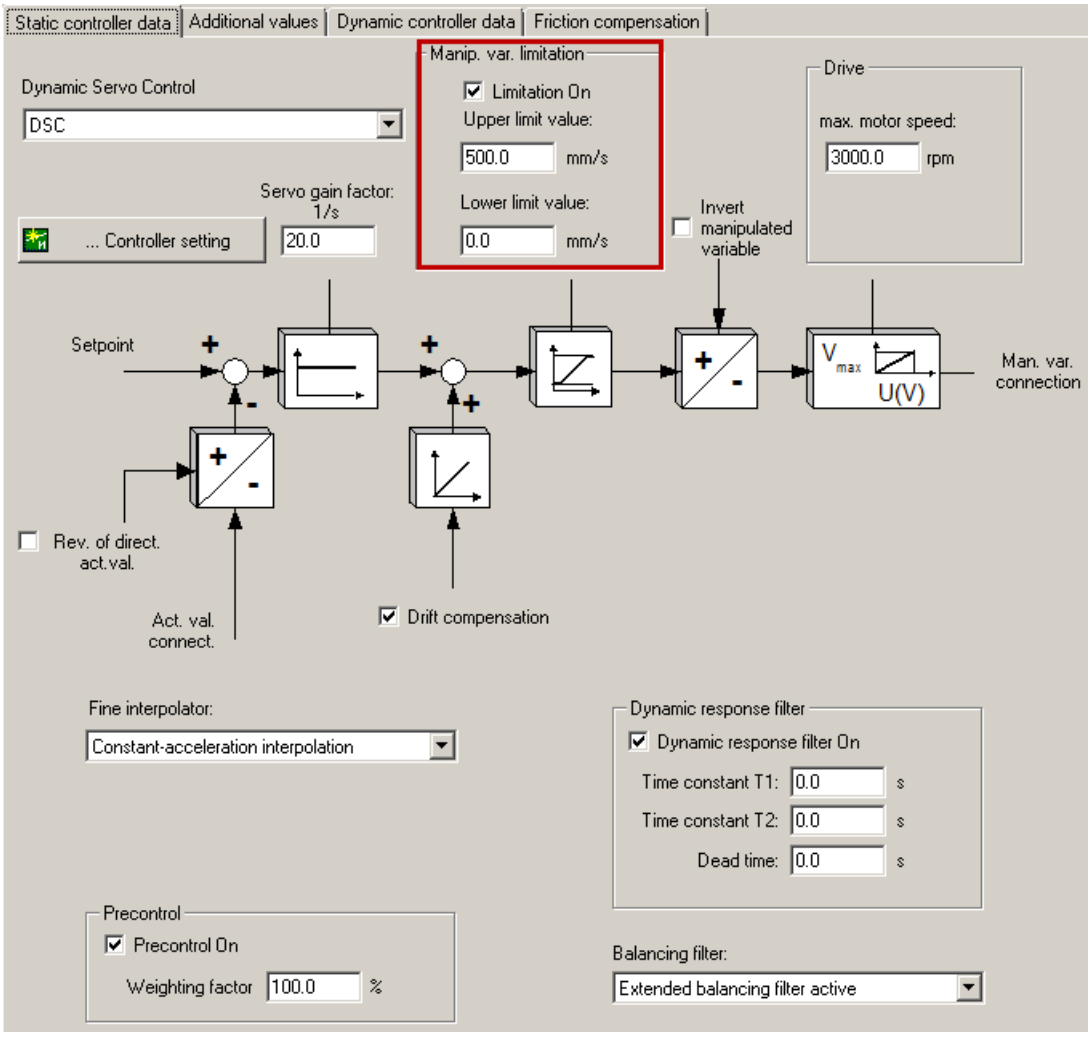

Figure 4-834 Manipulated variable limitation in static controller data

Manipulated variable limitation on an electrical positioning axis in the servo performs absolute limiting of the position value to an upper and a lower limit value.

This limitation is applied prior to inversion.

The values can be modified online (with immediate effect).

If the upper value is positive and the lower value is 0, the axis can, for example, be traversed in the positive direction only.

The manipulated variable limitation can be configured and activated by means of the **speedLimitation** configuration parameter. The zero velocity must lie within the permissible range to enable the axis standstill.

Only the setpoint is limited; reversing of the drive must also be prevented.

Note

When the **Dynamic Servo Control** (position controller in the drive) function is active, backstop (limiting of the manipulated variable for the drive) is only effective for the precontrol.

Therefore, when DSC is active, the backstop must be generated in the drive.

Hardware limit monitoring

Traversing range limits are monitored by means of digital inputs and limit switches. Hardware limit switches are **always normally closed switches** and should **always be active outside** the permissible traversing range.

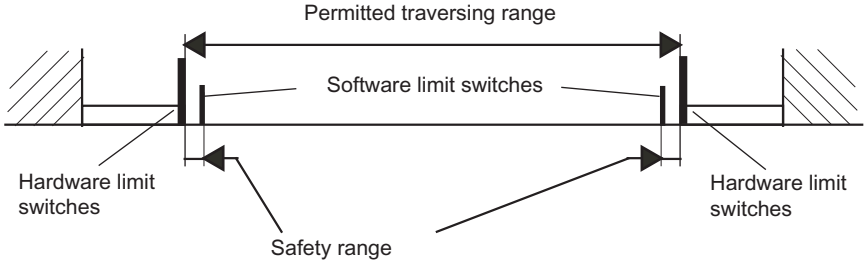

Figure 4-835 Monitoring of the permissible traversing range by limit switches

Approaching the limit switch triggers **technology alarm 50007**.

This state can be remedied in two ways:

- **Manual retraction (without drive)**
  The axis is returned manually to the permissible traversing range. The system variables remain in LIMIT_EXCEEDED state until the axis leaves the limit switch. Only then can the alarm be acknowledged.
- **Retraction with drive**
  The technology alarm must be acknowledged. **Warning 50009: Limit switch overtraveled** is retained. The axis can only travel in the direction of retraction as long as the limit switch is active. Travel in the opposite direction triggers a technology alarm and cancels the enables. When the axis has left the limit switch, the system variables **sensorMonitoring.hwLimitSwitchMinus** and **sensorMonitoring.hwLimitSwitchPlus** assume the **O_K** state, and the **Limit switch overtraveled** warning can now be acknowledged.

When a limit switch is approached, its position is stored. The limit switch is not considered to have been left until the axis moves back from the position.

NOTICE
Switching the controller off after the limit switch has been overtraveled
Once the limit switch has been overtraveled, the controller must not be switched off to avoid a conflict between the polarity monitoring of the limit switches and the overtravel monitoring of the limit switches in the direction of the permissible area.
If the controller is switched off, the information of the limit switch polarity is lost. The axis must then be moved into the permissible range by the user.
When the controller is **switched on**, the axis must be positioned within the permissible traversing range.
If the hardware limit switches are configured as reversing cams or reference cams for homing, these hardware limit switches can be overtraveled during homing, even if they are activated.

If the limit switch is overtraveled and the configuration reloaded, internal states are lost. Reloading without loss of the approach information is only possible within the valid range. Exception: Deactivation of limit monitoring after a polarity reversal error.

A cable break can only be reset with **Power On** or by a one-time deactivation of the function.

The hardware end position interface can be activated and deactivated on the axis using the **_enableAxisInterface()** and **_disableAxisInterface()** commands.

The Activated/Deactivated hardware end position interface status is displayed in the **sensorMonitoring.hwLimitSwitchInput** system variable.

Software limit monitoring

Software limit switches can be specified and monitored as soon as the actual values are valid. Monitoring is enabled/disabled using the **swLimit.state** system variable. The software limit switch positions are defined in the **swLimit** system variable. Software limit switches should be inside of the hardware limit switches.

If an axis motion, synchronous motion, or path motion is canceled by approaching the software limit switch, because continuing the motion would violate the software limit switch, movement to the software limit switch is performed at the braking ramp's maximum dynamic values. Technological alarm 40106, "Approach SW limit switch", is only output when the software limit switch is reached.

If the software limit switches are also to be monitored with non-homed axes, **homing.referencingNecessary** = NO must be set in the configuration data element.

With the setting **Homing required**, active limit monitoring is only effective if the axis is homed. If the setting **Homing required** is not selected, active limit monitoring is always effective.

The software limit position monitoring is effective also for isochronous movement and path movement. For a violation of the software limit position, the isochronous movement or path movement will be terminated and travel made to the software limit switch with maximum deceleration and maximum jerk.

If valid actual values are present for a speed-controlled procedure, these serve as limits for the software end position monitoring.

Monitoring the software limit switch at motion start (V3.2 and higher)

The controller checks for a violation of the limits before the motion starts. If the software limit switch is exceeded, the axis is limited to the software limit switch position and alarm 40105 is triggered.

If alarm 40105 is active, no more movement commands will be accepted and the limit switch will be approached at the programmed dynamic values. The error only needs to be acknowledged when, for example, using an application program, to stop before the limit switch or to travel in the reverse direction.

If, for example, a second motion is superimposed and acts in the opposite direction, it is possible for the software limit monitoring to signal an alarm when the first motion is activated, even though the software limit switch is not reached.

The **monitoringAtMotionStart** configuration data element can be used to enable/disable the check when the motion starts.

Note

The cyclical software limit monitoring check is always performed during the motion.

Passing a software limit switch

If the axis is positioned after the software limit switch due to reconfiguring of the software limit switch, for example, or the axis has passed the software limit switch in speed-controlled mode, alarm 40107 *Software limit switch passed* is output. The axis can be traversed out of the limit switch area in position-controlled mode depending on the local error response set in alarm 40107, e.g. when setting FEEDBACK_EMERGENCY_STOP.

For retraction in speed-controlled mode, a tolerance window with the configuration data **relieveWindow** can be defined. The tolerance window always refers to the current actual value. This means that jittering of the actual value will not cause the software limit switch to respond again during retraction. Traversing within the tolerance window is possible in both directions.

Encoder limit frequency monitoring

The system monitors the limit frequency of the encoders for compliance. The monitoring function triggers an alarm. It has no effect on axis motion.

Velocity error monitoring

An encoder must be connected and configured to monitor the velocity error (setpoint minus actual value) on the axis. The controlled system is simulated using a PT1 model. This model is supplied with the setpoint as the input value, and the difference of the output value is compared with the real actual value curve. The time constant for the PT1 model is set during axis configuration in the **dynamicData.velocityTimeConstant** or **dynamicQFData.velocityTimeConstant** configuration data element. Velocity error monitoring is of relevance for the drive axis and for the position axis in SPEED_CONTROLLED mode.

Measuring system differential/slip monitoring

The system can monitor a measuring system difference / slip between two encoders on the axis to a specified maximum value. The monitoring is activated with **_enableMonitoringOfEncoderDifference()** and deactivated with **_disableMonitoringOfEncoderDifference()**.

The maximum value is specified in the **_enableMonitoringOfEncoderDifference()** command in the *maximalEncoderDifference* function parameter and transferred with the execution of the command in the **sensorMonitoring.maximalSensorDifference** system variable or the existing value in the **sensorMonitoring.maximalSensorDifference** system variable is used optionally by setting the *maximalEncoderDifferenceType* function parameter.

If the maximum measuring system difference specified in **sensorMonitoring.maximalSensorDifference** for activated monitoring is exceeded, the alarm 20009, "the permissible difference between encode (/1/%d) and (/2/%d) has been exceeded" will be generated and signaled with LIMIT_EXCEEDED in the **sensorMonitoring.slippageTolerance** system variable.

Before activating the function (and if applicable while the function is active), check whether the two encoders involved in the measuring system difference are valid. The check can be performed using the system variables **sensormonitoring.cyclicinterface**=ACTIVE and **sensordata.state**=VALID, for example.
The absolute encoder is restarted, for example, on switchover by means of data set changeover and may then supply other values over the course of a small number of cycle clocks, so that in this case measuring system difference monitoring may respond.

4.8.3.11 Positioning axis with position control

Overview of positioning axis with position control

This figure shows the block diagram of the position axis with position control.

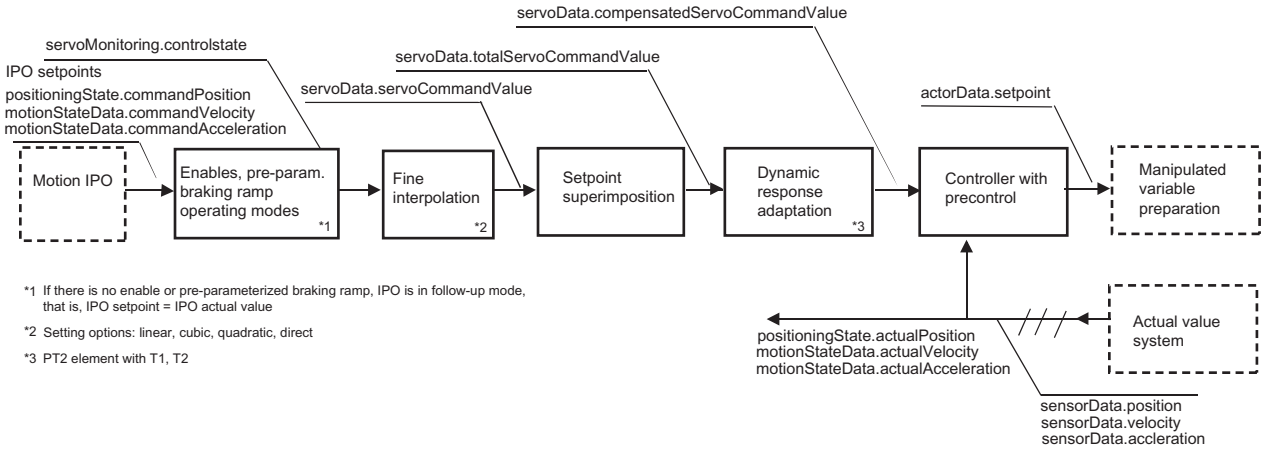

Figure 4-836 Overview of position axis with position control

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

You can call signal flow diagrams under the Axis object in the project navigator. The signal flow diagram illustrates the signal path and enables major items of configuration data and important system variables to be parameterized using the signal flow.

Position control

When position control is **active**, controllers, monitoring, and compensation are active. There are modes in which monitoring mechanisms are deactivated. They include torque limitation and the position-related monitoring functions for pressure limitation, for example.

All compensation functions can be activated/deactivated.

Encoder systems, actual value calculation, and monitoring are active on the actual value side when position control is not activated. Compensation functions are not taken into account.

The **servoMonitoring.controlState** system variable indicates whether the position controller is active.

SIMOTION provides a P-controller with or without precontrol and a PID controller.

Controller with precontrol

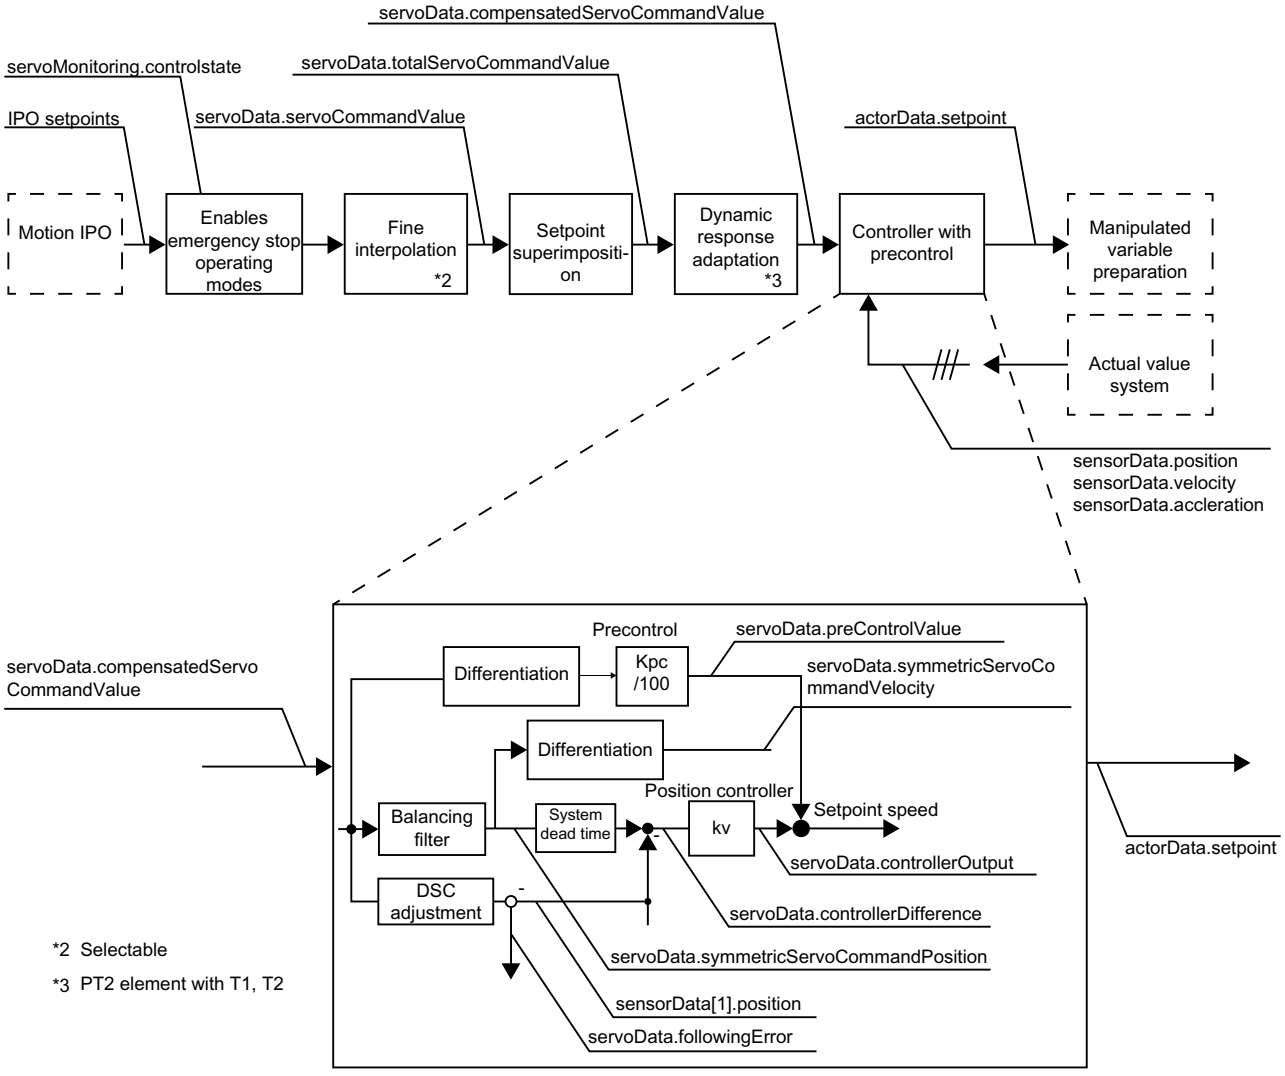

Figure 4-837 Proportional-action controller with precontrol

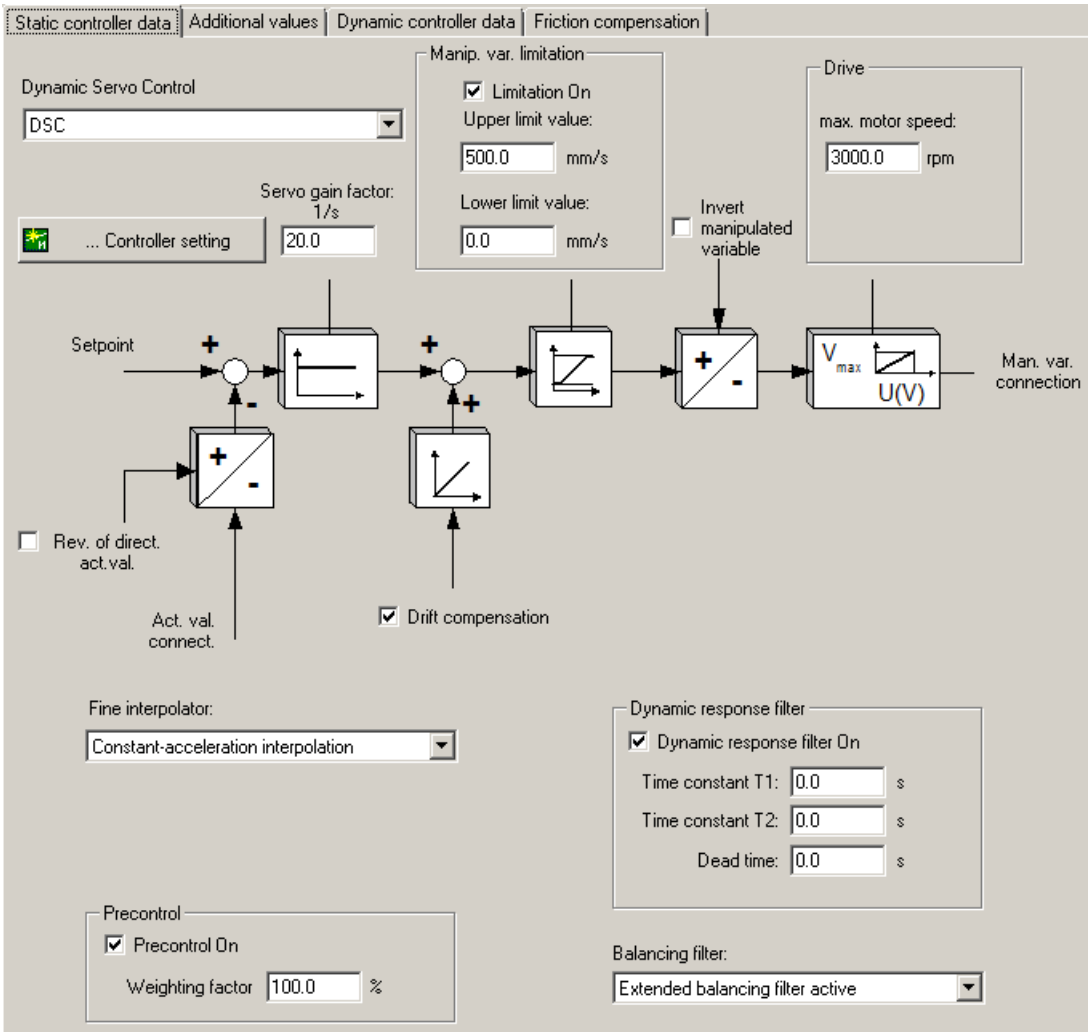

Figure 4-838 Static controller data

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

Axis wizard default settings

- P-action controller with precontrol for the electric axis
- DSC to improve the control quality (higher servo gain values) for digitally coupled drives (only with P controllers with precontrol)
- PID controller for hydraulic axes (allows you to switch the actual value directly to the D component).

See also Position control for setting a positioning axis with hydraulic functionality (Page 3124).

Position loop gain (servo gain factor)

For a P controller with or without precontrol, the gain of the P controller can be specified via the servo gain factor. The manipulated variable/traversing velocity component of the closed-loop control is generated from the control error via the servo gain factor Kv.

The mathematical (proportional) relationship is:
Servo gain factor Kv = (traversing velocity v / control error Δs) [1/s]

The servo gain factor Kv affects the following characteristic values:

- Positioning accuracy and holding control
- Uniformity of motion
- Positioning time

The better the axis design (high degree of stiffness), the higher the achievable servo gain factor Kv, and therefore the better the axis parameters are from a technological perspective (lower following error and higher dynamic response).

Precontrol

The velocity precontrol can be used to limit the velocity-related following error during position control. It can also help to achieve faster positioning.

With precontrol, the velocity setpoint is also switched additively to the position controller output. This additional setpoint can be weighed with a factor.

Balancing filter for feedforward control

The balancing filter is a simplified model of the speed control loop. It is used to prevent the position controller from overriding the manipulated velocity variable during the acceleration and deceleration phases. This is accomplished by delaying the position setpoint of the position controller by the balancing time with reference to the velocity precontrol.

Function of the balancing filter

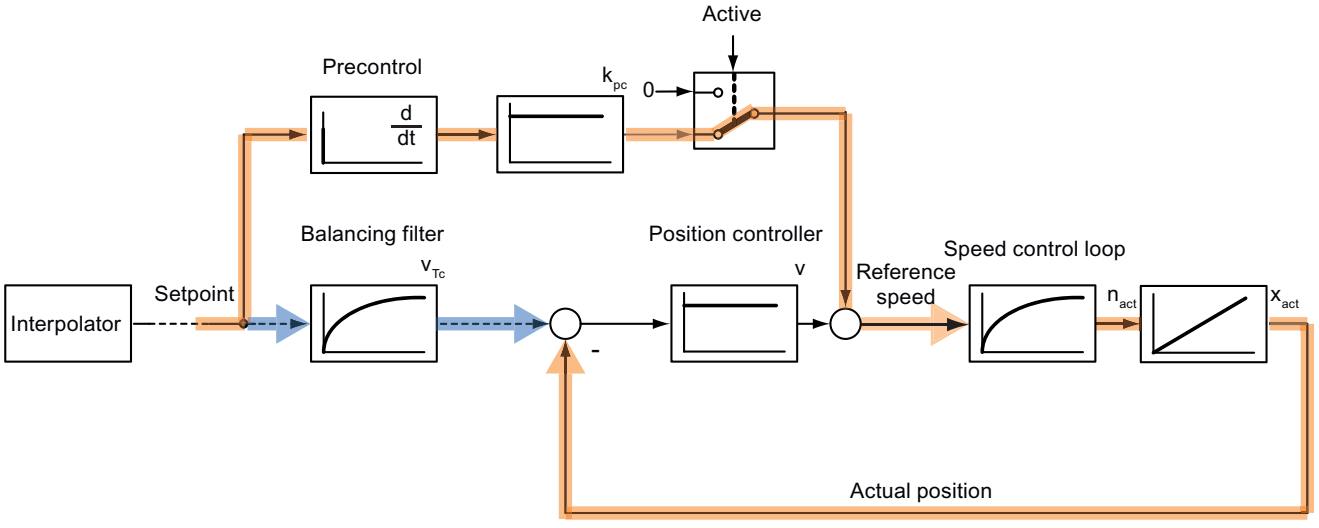

Figure 4-839 Balancing filter - Example of an electric axis without DSC

The speed is precontrolled; to this end, the position setpoint is adopted from the reference variable calculation directly or with differentiation applied, and the set velocity is defined on the speed controller directly. The position controller then simply has to compensate for any position errors which may be present in spite of the precontrol.

The position error, therefore, is generated from the position setpoint, delayed by the speed control loop equivalent time, and the existing actual position value.

Settings and configuration data

The setting can be made using the *Closed-loop control* dialog for *Dynamic controller data* (activate expert mode).

When precontrol is active, allowance can be made in the balancing filter for the response of the speed control loop prior to formation of the system deviation from the position setpoint and actual position.

- With the **balanceFilterMode=OFF** configuration setting, the balancing filter is switched off.
- With the **balanceFilterMode=MODE_1** configuration setting, a PT1 filter is used as the balancing filter.
  - For electric axis without DSC:
    The following must be set as the time constant for the balancing filter in **dynamicData.velocityTimeConstant**: $T_{Balancing\ filter}=T_{Speed\ control\ loop\ equivalent\ time}+T_i+T_o+T_{dp}+T_{servo}$
    The transmission dead times and process response (equivalent time of speed control loop) must be taken into account in the time constant.
    systemDeadTimeData.additionalTime is not included additively by the system in the balancing filter.
  - For electric axis with DSC:
    The following must be set as the time constant for the balancing filter in **dynamicData.velocityTimeConstant**: $T_{Balancing\ filter}=T_{Speed\ control\ loop\ equivalent\ time}$, because the transmission dead times for the position controller in the drive are not present in the position control loop.
    systemDeadTimeData.additionalTime is not included additively by the system in the balancing filter.
  - For the hydraulic axis:
    The following must be set as the time constant for the balancing filter in **dynamicQFData.qOutputvelocityTimeConstant**: $T_{Balancing\ filter}=T_{qOutputEquivalent\ time}$ + Communication times according to the setpoint output/actual value interface.
    ($T_{qOutputEquivalent\ time}$ as equivalent time for the QOutput process response)
- With the **balanceFilterMode=MODE_2** configuration setting (as of V3.1), the equivalent time of the speed control loop, the dead time determined by the system for the drive, and a dead time that can be input in additive increments by the user are taken into account in the balancing filter.
  Maximum time constant = 16 x T_{servo}
  - For electric axis without DSC:
    The following must be set as the time constant for the balancing filter in **dynamicData.velocityTimeConstant**: $T_{Balancing\ filter}=T_{Speed\ control\ loop\ equivalent\ time}$
    $T_i+T_o+T_{dp}+T_{servo}$ is taken into account by the system.
    The value set in **systemDeadTimeData.additionalTime** is included additively by the system in the balancing filter.
  - For electric axis with DSC:
    The following must be set as the time constant for the balancing filter in **dynamicData.velocityTimeConstant**: $T_{Balancing\ filter}=T_{Speed\ control\ loop\ equivalent\ time}$, because the transmission dead times for the position controller in the drive are not present in the position control loop.
    systemDeadTimeData.additionalTime is not included additively by the system in the balancing filter.

– For the hydraulic axis:
The following must be set as the time constant for the balancing filter in **dynamicQFData.qOutputvelocityTimeConstant**: $T_{Balancing\ filter}=T_{qOutputEquivalent\ time}$ + Communication times according to the setpoint output/actual value interface ($T_{qOutputEquivalent\ time}$ as equivalent time for the QOutput process response)

The setting **balanceFilterMode=MODE_2** on the balancing filter is recommended.

An overswing is apparent should the **dynamicData.velocityTimeConstant** value be too small. If the value is too large, the axis has limited dynamic behavior and creeps to the end position.

System deviation

The control deviation is the difference between the balanced setpoint and the actual value and is displayed in the **servoData.ControllerDifference** system variable.

Note

As of runtime version V4.1 SP1, the control deviation present on the position controller in the drive is displayed for DSC. This is calculated in the control using a model (see the Control Structure figure in the next chapter).

With versions prior to V4.1 SP1, the control deviation present in the control is displayed with DSC.

The **servoData.controlDifferenceCommandPosition** system variable (as of V4.4) displays the setpoint present in the drive. With reference to the current actual value, this setpoint is relevant to control deviation generation. The signal runtime and output times are taken into account.

Calculating the servoData.controlDifferenceCommandPosition system variable without balancing filter (configuration setting balanceFilterMode=OFF):

- Without DSC
servoData.controlDifferenceCommandPosition
= **servoData.symmetricServoCommandPosition**
- With DSC
servoData.controlDifferenceCommandPosition
= **servoData.symmetricServoCommandPosition** delayed by $T_i+T_o+T_{dp}+T_{servo}$

Calculating the servoData.controlDifferenceCommandPosition system variable with balancing filter (configuration setting balanceFilterMode<>OFF):

- Without DSC
servoData.controlDifferenceCommandPosition
= **servoData.symmetricServoCommandPosition** delayed by $T_i+T_o+T_{dp}+T_{servo}$
- With DSC or DSC with spline (requirement: position-control in the controller and in the drive is to the same encoder)
servoData.controlDifferenceCommandPosition
= **servoData.symmetricServoCommandPosition** delayed by $T_i+T_o+T_{dp}+T_{servo}+T_{additionalTime}$

Control loop structures

When the mode is changed from speed-controlled to position-controlled mode while the axis is in motion, the equivalent time of the position controller is required to apply the setpoint. The equivalent time is set during configuration in **dynamicData.positionTimeConstant** (for an electric axis) or in **dynamicQFData.positionTimeConstant** (for the hydraulic functionality).

Quantization of the control error for stepper motors or low-resolution encoders

The **commandValueQuantization.enable**=YES configuration data can be used to activate the quantization of the control deviation. A quantization of the control deviation is performed in accordance with the encoder resolution (distance per increment) or stepper motor increment.

This prevents, for example, the motor from oscillating between two increments while at a standstill.

With the setting **commandValueQuantization.mode**=DIRECT, the value for quantizing the control deviation can also be specified directly in **commandValueQuantization.value** (as of V4.1 SP1). This is sensible when for stepper motors, the encoder has a higher resolution than the increment of the stepper motor.

Note

Quantization of the control deviation should be activated for stepper motors.

Axis data sets

Like other items of axis configuration data, controller data can be assigned to multiple data sets. A data set is assigned to every axis when it is created.

Axis data sets are used as a means of activating multiple controller settings simultaneously.

Axis data sets are configured for axes on the **Axis data sets** tab under **Configuration**.

Data sets (Page 3037)

Dynamic Servo Control (DSC)

With the **Dynamic Servo Control (DSC)** function, the position controller in the drive is executed in the cycle clock of the speed control loop. In the drive, intermediate setpoints are generated in the speed controller cycle clock from the position setpoints transferred in the position controller/communication cycle clock via linear fine interpolation.

It is thus possible to set a substantially greater position controller gain factor **K**v. This increases the dynamic response for the reference variable sequence and disturbance variable compensation for highly dynamic drives.

For a position axis with position control and an assigned SINAMICS drive, the system sets DSC by default provided this is available at the drive's DO type (e.g. when a servo drive is assigned).

Advantages of DSC (compared to a position controller in the controller)

- Higher servo gain factor Kv (position controller gain) possible
- Larger bandwidth -> higher dynamic response
- Shorter response times for disturbance characteristic

Detailed information

The position difference (XERR) and the gain factor for the position controller in the drive are transferred in the PROFIdrive telegram, in addition to the speed precontrol value.

To activate the **DSC** function, the position controller must be set as PV controller (P controller with precontrol). In addition, the encoder in **typeOfAxis.NumberOfEncoders.DSCEncoderNumber** on the axis must specify to which increments the position differential (XERR) is normalized during operation. In SINAMICS, this is by default the motor encoder. **typeOfAxis.NumberOfEncoders.DSCEncoderNumber** must be initialized to the first encoder of the axis TO.

DSC is supported by MASTERDRIVES (standard telegrams 5 and 6 according to PROFIdrive), SIMODRIVE 611U and SINAMICS S120 (additional SIEMENS telegrams 105 and 106).

A SCRIPT is available to support you when commissioning MASTERDRIVES.

In SINAMICS, SIMODRIVE 611U, and MASTERDRIVES, the motor measuring system is used for normalizing the position difference in the drive.

The following is to be taken into account for DSC:

- With DSC, XERR (position error) and Kpc (position control loop gain) are also transmitted, i.e., an 8-byte long setpoint telegram is required.
- With DSC, the communication times are taken into account in determining the following error of the setpoint since the actual comparison of setpoint and actual value is generated in the drive in the speed control cycle clock.
- The response time to a change in the actual position value is one speed controller cycle clock.
- With DSC and synchronous operation with actual value coupling, the extrapolation time must be increased by one position control cycle clock.

- If precontrol is deactivated for the DSC, zero is shown for the system variables with reference to the controller output or manipulated variable value.
  System variables:
  - **servodata.controllerOutput**
  - **actorData.setPoint**
  - **actorData.compensatedSetPoint**
  - **actorData.totalSetPoint**

  The axis is moved in accordance with the system deviation (XERR) given to the drive.
- If the direction in the drive is inverted for DSC p0410.0 and p0410.1 must be set the same, i.e. either the actual speed value and the actual position value are not inverted, or they are both inverted.

Overview of commissioning the position controller of positioning axes (Page 2986)

DSC with spline (as of V4.4) [Expert]

With the **Dynamic Servo Control (DSC)** function, the position controller in the drive is executed in the cycle clock of the speed control loop. In the drive, intermediate setpoints are generated in the speed controller cycle clock from the position setpoints transferred in the position controller/communication cycle clock via linear fine interpolation.

With the **DSC with spline** function, the position controller is also executed in the drive in the cycle clock of the speed control loop. The intermediate values in the drive are generated via polynomial functions. Intermediate setpoints are also generated for speed and torque, in addition to position. Using the intermediate setpoints, highly dynamic motions down to the current controller cycle clock are simulated exactly and precontrol is possible right down to the torque.

To use DSC with spline, activate "DSC with spline" in the drive of the function module.

The setpoints are fine-interpolated in the following way:

- Position setpoint - cubic fine interpolation
- Speed setpoint - quadratic fine interpolation
- Acceleration setpoint/torque setpoint - linear fine interpolation

DSC with spline provides the following advantages and functionality:

- Linear fine interpolation and precontrol of the torque
- Extended support for highly dynamic motions
- Process response is determined by the lower current controller equivalent time

DSC with spline can be used or set as follows:

1. **DSC with spline and torque precontrol**
   - The torque is precontrolled.
   - Speed and position are controlled taking into account the equivalent time of the current controller in the balancing filter in the drive.
   - The torque is calculated in the drive from the acceleration and the total moment of inertia.
   - Balancing of the position setpoint and of the speed setpoint using the current controller equivalent time (ttc).

   The total moment of inertia J is used to calculate a torque from the acceleration.
   The following parameters are available in the drive for input:
   - p0341 Motor moment of inertia (in motors on the motor list this parameter is automatically preset)
   - p0342 Moment of inertia ratio Load+motor / motor (should be defined during speed controller optimization, reference model determination)
   - p1498 Load moment of inertia
   - p1497 Moment of inertia scaling factor
2. **DSC with spline and speed precontrol**
   - The speed is precontrolled.
   - The position is controlled taking into account the equivalent time of the speed controller (VTC) in the balancing filter in the drive.
   - The speed controller equivalent time is taken into account in the balancing filter.
3. **DSC with spline without precontrol**
   - Speed and torque are not precontrolled.
   - The position is controlled in the drive.
   - The balancing filter in the drive and in the controller is not included.

Use DSC with spline with torque precontrol for constant load torque and
DSC with spline with speed precontrol for non-constant load torque.

If the torque constant of the feed motor does not remain in the overload range, the function module **Extended torque control** functions can be activated. This improves the accuracy of the torque simulation.

Requirements and settings in SIMOTION

The following requirements must be satisfied for the use of DSC with spline:

- Axis type must be a real electrical axis (REAL_AXIS)
- Telegrams 125 and 126 must be supported by the drive
  (SINAMICS drives as of V4.7 that support telegrams 125 and 126)
- Activation of DSC with spline
  DSC with spline is first activated when the axis is powered up if the axis is at standstill (standstill signal active).
- Consistent setpoints
  Position and velocity setpoints must be consistent with each other, i.e. the setpoint pair must originate from the same cycle clock time of the motion control.
  In the setpoint calculation of the technology object, the position setpoints and the velocity are consistent with each other and are limited to the maximum values.
  If the setpoints are modified using compensation values or limits after the setpoint calculation, the consistency of position and velocity must be ensured by the user.
  If the setpoints are defined by the user, the user must ensure consistency.
  System variable with DSC spline status display: **servoData.dscSpline**
- Fine interpolation type
  Use the default setting (configuration data item **FineInterpolator._type**=CUBIC_MODE)
- High-resolution measuring system
  DSC with spline requires a high setpoint resolution. The setpoint resolution in the system is based on the actual value resolution. If the actual value only has a low resolution, you can increase the setpoint resolution internally.
  (Set p0418, e.g. to 18-bit)
- Recommendation: Set the equivalent time of the speed control loop and the current control loop to at least 3x current control cycle clock
  VTC configuration data item **dynamicData.velocityTimeConstant**
  TTC configuration data item **dynamicData.torqueTimeConstant**
- Switching the setting from DSC with spline to standard DSC and back
  controllerStruct.PV_Controller.enableDSCSpline configuration setting
  Restart required
- Speed control mode
  Performed via Kpc=0.
  The position for the generation of the position difference (XERR) is simulated internally.
- Speed precontrol = 100%
  Precontrol factor is not evaluated for the DSC with spline setting.
- Friction compensation
  This setting can cause irregular splines at the start of motion.
- Backlash compensation
  This setting can cause irregular splines at the direction reversal.

- Setpoint superimposition
  DSC without spline is used by the system, as long as superimposition is active, by activating system variable **servoSettings.additionalCommandValueSwitch**.
- Manipulated variable superimposition
  DSC without spline is used by the system, as long as superimposition is active, by activating system variable **servoSettings.additionalSetPointValueSwitch**.

Restrictions

The following restrictions apply in SIMOTION when using DSC with spline:

- Encoder switchover during operation or during a motion is not supported
- Pressure control is not possible
- Pressure limiting is not possible

Closed-loop control on a direct measuring system

A direct measuring system can be controlled on condition that the control is set to the same encoder system in the controller and in the drive.

The encoder for the position control in the drive is set in p1192.

The transmission factor between the motor measuring system (MMS) (motor encoder) and the direct measuring system (DMS) is set in p1193.

X_ERR is further normalized to the motor measuring system if not converted in the drive.

Encoder switchover during operation or during a motion is not supported.

Note

Position and velocity values must be consistent

Closed-loop control on a direct encoder in the controller in conjunction with closed-loop control on a motor encoder in the drive is not permitted. The position and velocity values would then no longer be consistent in the spline calculation.

The user must ensure the values are consistent with each other if the position setpoints and velocity setpoints change.

Balancing filter

When DSC with spline is activated, the balancing filter is calculated in the drive. The balancing time is transferred to the drive in the telegram. The setpoint to calculate X_ERR is therefore tapped before the balancing filter.

The controller calculates the actual control error in the drive taking into account the balancing filter.

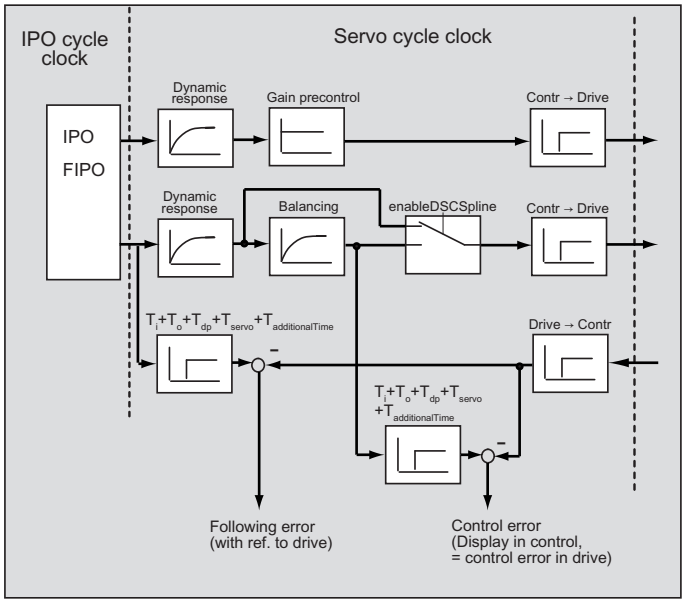

Figure 4-844 Effect with activated DSC with spline

Fine interpolation

The purpose of the fine interpolator (FIPO) is to generate interim setpoints for the position setpoints when the interpolator (IPO) and the controller (servo) have different cycle clock ratios.

Interpolation types

During configuration, the following interpolation types can be set by means of the **FineInterpolator._type** configuration data element:

- **DIRECT_MODE:** when no fine interpolation is required
- **LINEAR_MODE:** linear interpolation (continuous position for positioning axis)
  Use for discontinuous velocity setpoints (no precontrol)
- **QUADRATIC_MODE:** quadratic interpolation (continuous velocity for positioning axis)
  Use for continuous velocity setpoint curves
- **CUBIC_MODE (recommended, default setting):** cubic interpolation
  Use for continuous velocity or continuous acceleration setpoint curves

With the positioning-axis setting, the set position is interpolated.

With the speed-controlled axis setting, the set velocity is interpolated.

Dynamic controller data

The equivalent time of the current control loop is set in the **dynamicData.torqueTimeConstant** configuration data element. The equivalent time of the current control loop is not used at present.

The equivalent time of the speed control loop is set in the **dynamicData.velocityTimeConstant** configuration data element and used in the balancing filter. See also *Balancing filters for precontrol* in Position control (Page 2950).

The setting can be made using the *Closed-loop control* dialog for *Dynamic controller data* (activate expert mode).

The equivalent time of the position control loop is set in the **dynamicData.positionTimeConstant** configuration data element. The equivalent time of the position control loop is set in the following cases:

- Preassigned braking ramp
- Switchover from SPEED_CONTROLLED to POSITION_CONTROLLED
- Switchover from pressure-controlled to position-controlled operation
- A moving axis is enabled with **_enableAxis()**

If the equivalent time of the position control loop has not be set correctly, compensation movements can occur for switching tasks.

With DSC, the equivalent time of the position control loop can be set as follows:

- Without precontrol
  PTC = 1/Kv
- For 100% precontrol of the velocity setpoint:
  The equivalent time of the position control loop can be set as equal to the equivalent time of the speed control loop (PTC = VTC).
  (Control loop optimization for minimal overshoot)

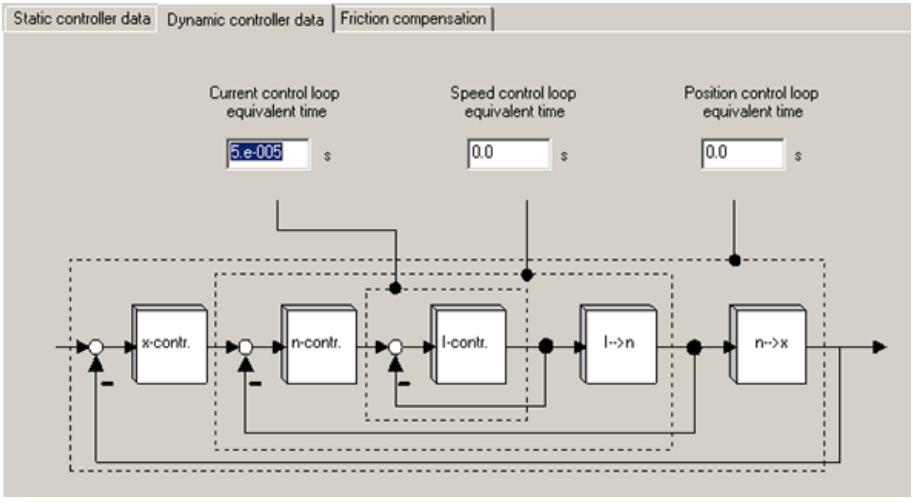

Figure 4-845 Dynamic controller data

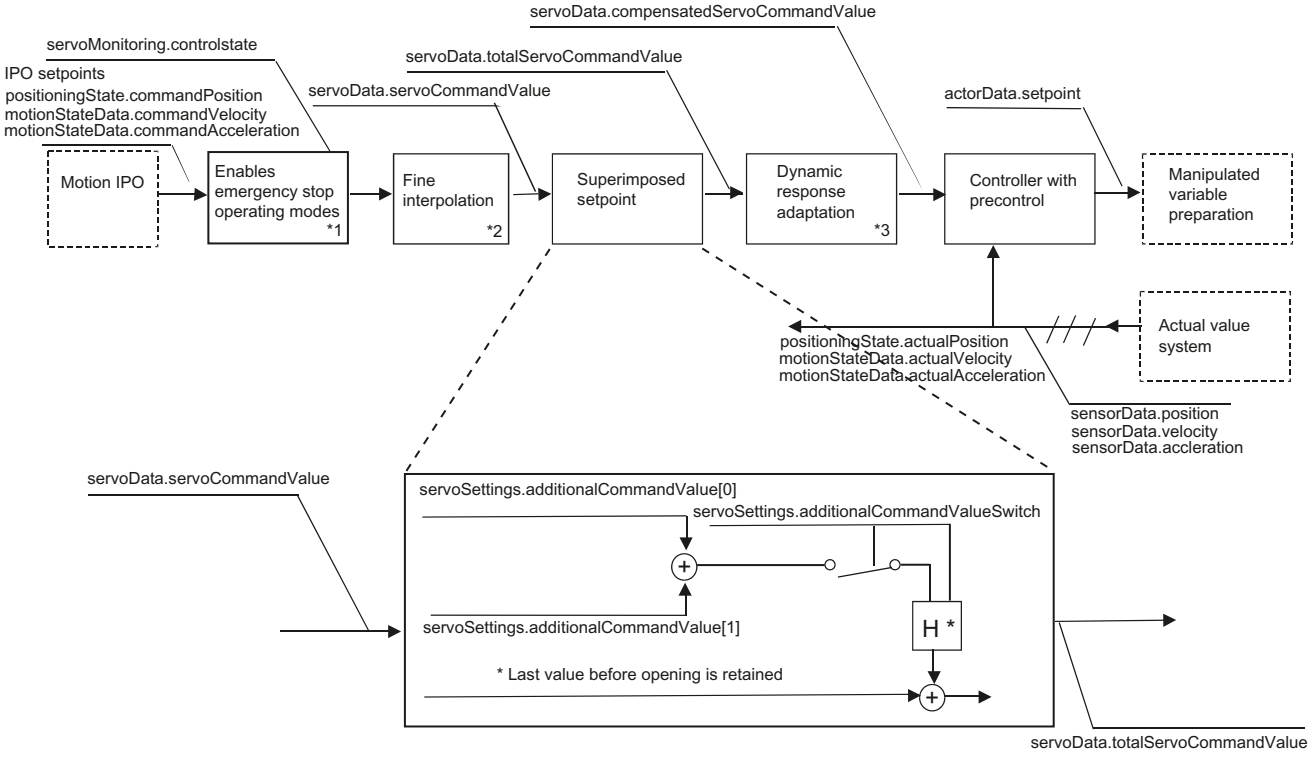
Setpoint superimposition

The setpoint specified by the interpolator can be superimposed in the servo via the cyclically active system variables
(**servoSettings.additionalCommandValue**, **servoSettings.additionalCommandValueSwitch**)



*1 If there is no enable or emergency stop, IPO is in follow-up mode, i.e. IPO setpoint = IPO actual value

*2 Selectable: linear, cubic, quadratic, direct

*3 PT2 element with T1, T2

Figure 4-846 Setpoint superimposition

Superimposition has an effect on the position of the position axis. It is also effective during active position control and interpolator (IPO) in follow-up mode.

No setpoint superimposition occurs for traversing the axis in the SPEED_CONTROLLED mode and for active force/pressure control.

If the setpoint superimposition is disconnected, the last value of the setpoint superimposition is retained. If the value should no longer function, it must be explicitly set to zero.

Note

During execution of the alarm response FEEDBACK_EMERGENCY_STOP and the execution of **_stopEmergency()** with stopMode=STOP_WITH_COMMAND_VALUE_ZERO:

- The actual value (position and velocity) is accepted once and the preassigned deceleration ramp is applied
- The superimposed setpoint is unclamped (as of V4.0)
- The switch for the superimposed setpoint is opened (status displayed in system variable).
- A switch is prevented from closing or the switch is closed via the system variable and triggers Alarm 50021 "ServoSettings system variable (Element /1/%d) cannot be write-accessed due to a stop response".

With the FEEDBACK_EMERGENCY_STOP alarm response, there is no setpoint superimposition.

When a stop ramp is assigned (e.g. **_stopEmergency(**...WITH_COMMAND_VALUE_ZERO) **)**, the superimpositions are deleted and transferred to the setpoint generation. This triggers Alarm 50020 "Servosettings system variable (Element /1/%d) is reset due to a stop response".

For switching to SPEED_CONTROLLED (as of V4.1 SP1) and in pressure control (as of V4.1 SP1), the setpoint superimposition is not active.

Dynamic response adaptation

In order to adapt the dynamic behavior of axes, the setpoint branch contains a programmable PT2 setpoint filter with the time constants T_1, T_2, and T_t. This allows compensation for axes with higher dynamic behavior with the lowest dynamic behavior (axis with the largest equivalent time constant of the T_{LR} position controller).

The dynamic response of the axes is determined by T_{Res}, the resulting total time constant.

$T_{Res} = T_{LR\,1}$ (axis with the smallest dynamic behavior)

$T_{Res} = T_{da} + T_{LR\,2}$ (considered dynamic axis)

The dynamic adaptation, T_{da}, must be selected so that the resulting total time constants are equal for all axes to the adapted.

The dynamic adaptation consists of
$T_{da} = T_1 + T_2 + T_t$

T_1	additive time constant 1 (setting in the configuration data: **NumberOfDataSets.DataSet_1.DynamicComp.T1**)
T_2	additive time constant 2 (setting in the configuration data: **NumberOfDataSets.DataSet_1.DynamicComp.T2**)
T_t (V4.1 SP1 and higher)	Dead time (setting in the configuration data: **NumberOfDataSets.DataSet_1.DynamicComp.deadTime**)

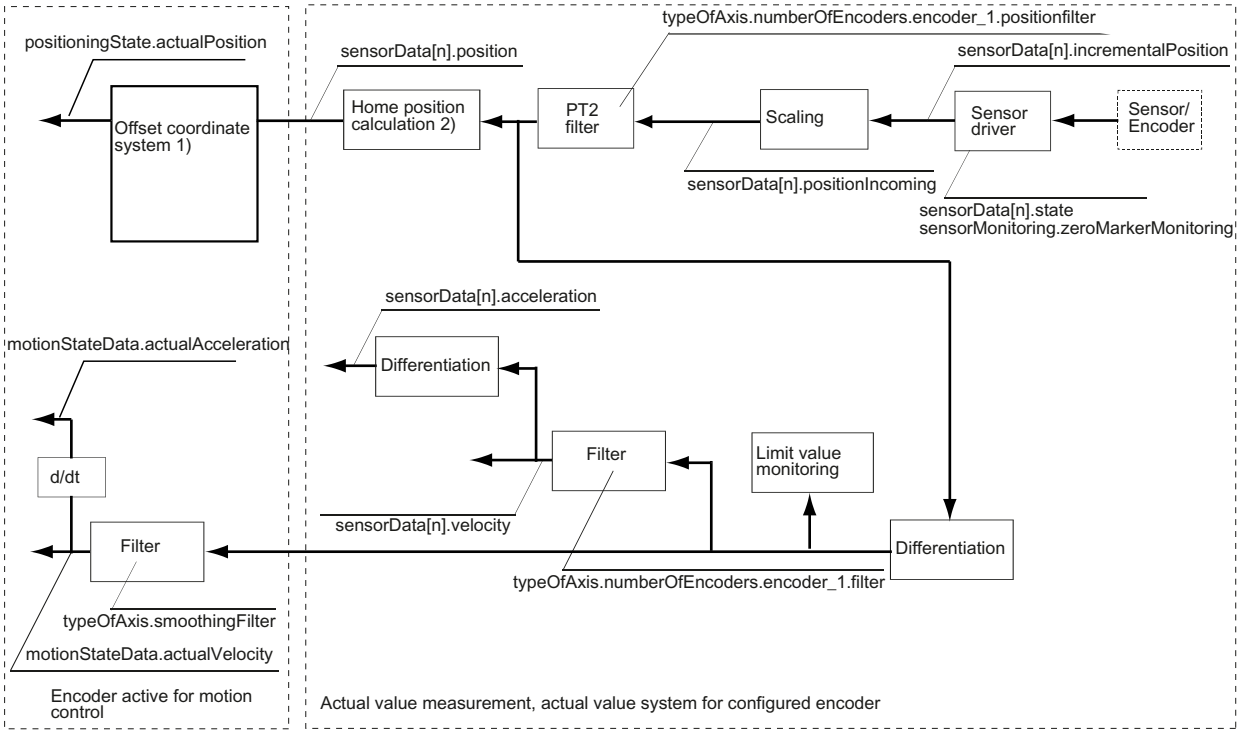
T_{Res}	(Desired) resulting total time constant of the axis
T_{LR}	Equivalent time constant of the closed position control loop of the axis (see **dynamic~Data.positionTimeConstant**)

The function is enabled/disabled via **dynamicComp.enable**.

Note

The used procedure means that a setpoint delay can be implemented exactly by specifying a dead time.

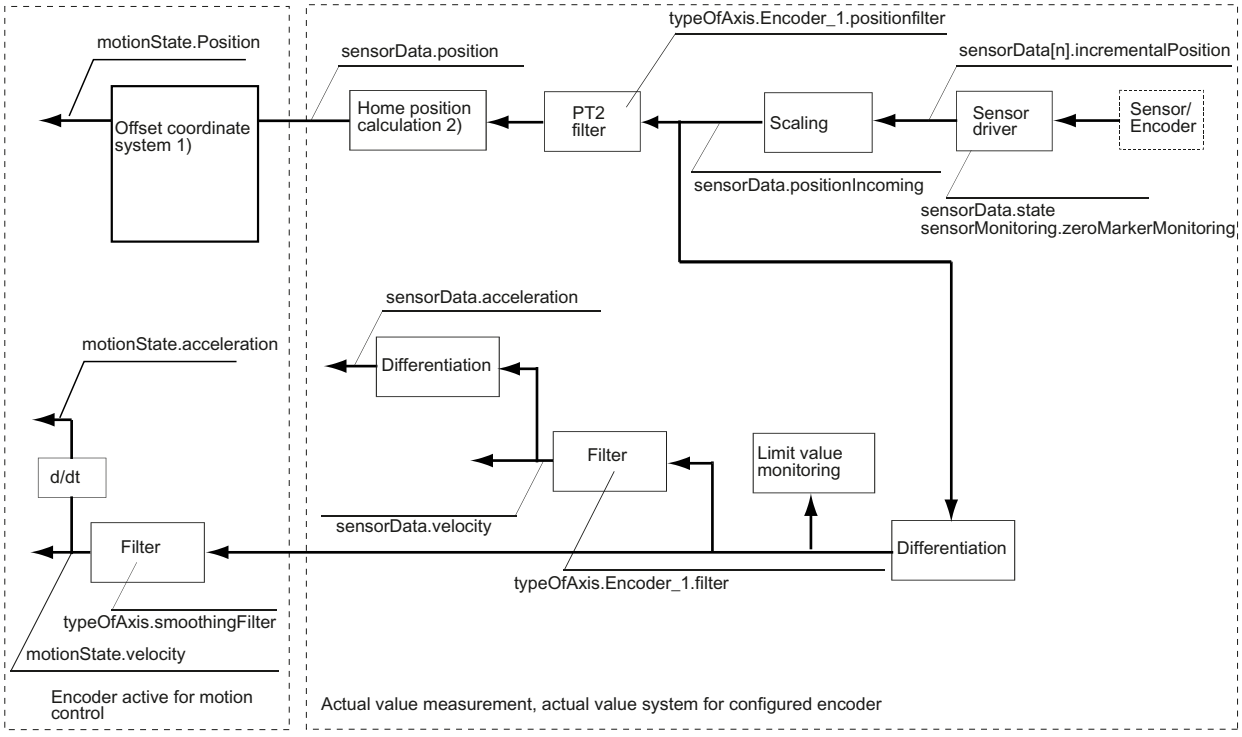
Actual value measurement / actual value system



1) Absolute and incremental encoder: Offset coordinate system e.g. using _redefinePosition() and _homing() with the DIRECT_HOMING setting
Incremental encoder: Home position userDefaultHoming.homePosition, home position offset incHomingEncoder.proceedshiftpos

2) Incremental encoder: Positions are zeroed at zero mark
Absolute encoder: Absolute encoder adjustment in absShift or absoluteEncoder.totalOffsetValue is included

Figure 4-847 Actual value system of technology object axis



1) Offset coordinate system e.g. using _redefineExternalEncoderPosition and _synchronizeExternalEncoder with the DIRECT_HOMING setting

2) Incremental encoder: userDefaultHoming.homePosition
Absolute encoder: absShift

Figure 4-848 Actual value system of technology object external encoder

The monitoring of the **actual velocity** and **actual acceleration** is used to identify errors in the control loop of the drives. If the rise in the actual value exceeds the **encoder limit frequency**, an **alarm** is triggered.

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

Display

The actual data for each sensor/encoder is displayed in the following variables:

- sensorData[n].position
- sensorData[n].velocity
- sensorData[n].acceleration

The system variables for **sensorData** are calculated in the servo cycle clock.

The actual axis value that is active for closed-loop control, the IPO cycle clock, and master value coupling is displayed in the following variables:

- positioningState.actualPosition
- motionStateData.actualVelocity
- motionStateData.actualAcceleration

The system variables for **positioningState** and **motionState** are calculated in the IPO cycle clock.

These actual values comprise the reference for the output cam calculation in the IPO cycle clock, the actual value coupling for external encoders without extrapolation, and the actual value reference in the IPO cycle clock, e.g. for actual-position-related profiles.

Noisy encoder signals lead to high velocity jumps. These can be reduced or compensated by using suitable filter settings.

Filtering of the velocity

The **smoothingFilter** configuration data element refers to the velocity calculated in the IPO cycle clock. Here, you can select whether a PT1 filter is to be applied to the data or whether the data is to be generated from the mean value. The mean value is determined from the ratio of the servo cycle clock to the IPO cycle clock.

The **numberOfEncoders.encoder_1.filter** configuration data element relates to the velocity calculated in the servo cycle clock. A PT1 filter is used.

During synchronous operation with master value reference to the actual axis values, these axis values are derived separately (refer to *Synchronous Operation description of functions, Actual value coupling*).

Actual position filtering (as of V4.1 SP1)

A sensor/encoder-specific actual position value filter is available.

This actual value filter is set in **typeofAxis.numberOfEncoders.encoder_1.positionfilter.T1** and **~.T2** and activated via **~.enable**.

The *positionFilter* has no effect with the velocity encoder setting **encoderValueType**=VELOCITY.

The actual velocity and actual acceleration are derived from the filtered position.

The *positionFilter* is calculated based on the actual values in SIMOTION and so does not act for active DSC for the actual values of the lower-level control loop in the drive.

The *positionFilter* present on the analog sensor input (for raw value filtering) is not dependent on the filter described here.

Extrapolation

For a synchronized group with actual value coupling (e.g. master value is the actual encoder value of an axis or an external encoder), the associated principle means delay times result because of bus communication, system cycle clocks and clock-pulse scaling, fine interpolation, position setpoint filters, and controller settings. These times can be compensated using an extrapolation (**Extrapolation.extrapolationTime**).

Extrapolation means knowing what has gone before and casting a glance at what is to come in the future (extrapolation time). In the case of dynamic changes to the master value, the extrapolation time should be as short as possible. An IPO cycle clock ratio: Servo pulse duty factor of 1:1 is good.

Note

Extreme care must be taken when changing the extrapolation time to the runtime; otherwise knocking could result in the machine.

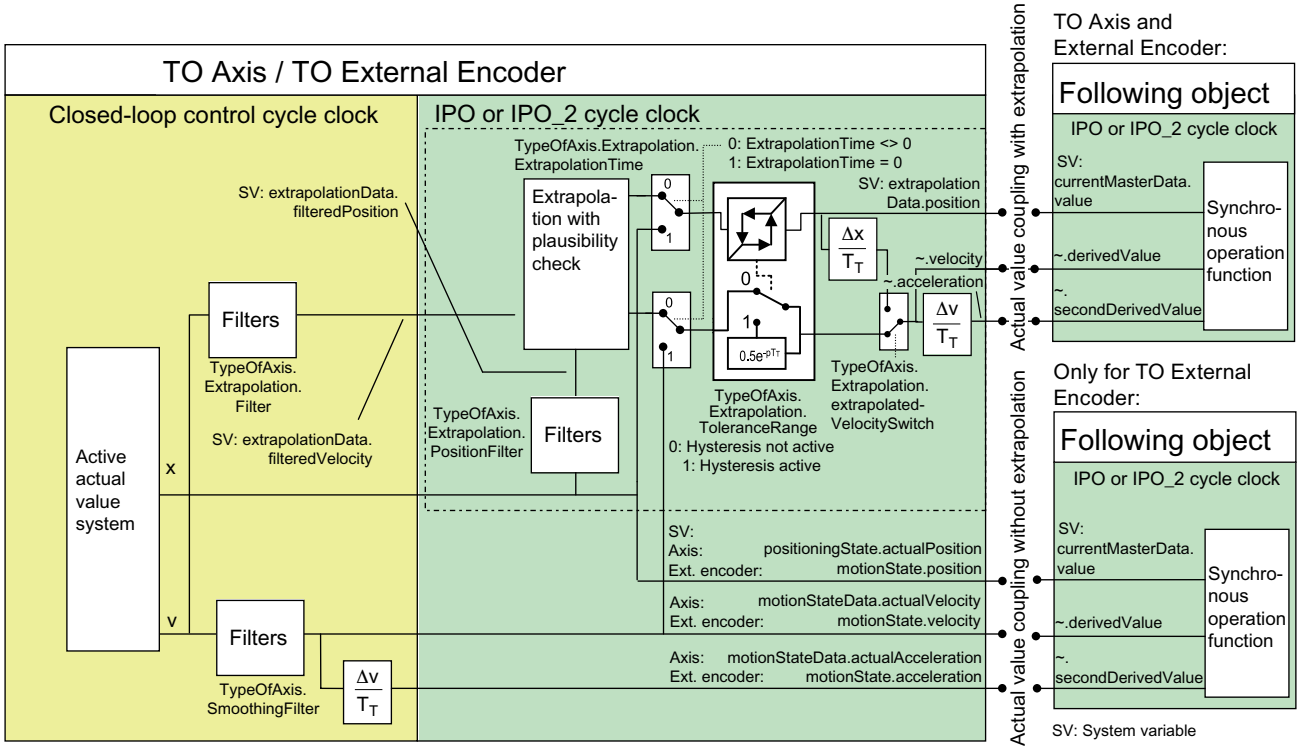


Figure 4-849 Actual value coupling with extrapolation for the Axis technology object or External Encoder technology object

During master value extrapolation, filtering on the actual velocity value is performed separately by means of a PT1 filter/mean value generation that is set with **typeOfAxis.extrapolation.Filter**.

The actual position value for synchronous operation can be filtered separately during extrapolation by means of a PT2 element. (as of V4.1 SP1)

As with extrapolation, there is only one filter for each axis rather than for each sensor/encoder. It is set in **typeOfAxis.extrapolation.positionFilter.T1** and **~.T2**. The filter acts on the actual position for the extrapolation, see also *Technology Objects Synchronous Operation, Cam* function manual, *Actual value coupling with extrapolation* section.

The velocity for the extrapolation is taken over from the actual values of the axis or External Encoder before application of the smoothing filter (**typeOfAxis.smoothingFilter**).

Although the velocity filter (**Extrapolation.Filter**) does not affect the extrapolation time, it is significant in the case of dynamic changes to the master value (due to the values being delayed).

The filter for the velocity during extrapolation is independent of this filter.

We recommend setting the velocity filter (**Extrapolation.Filter**) first; if the result is not sufficient, use the position filter as well. The position filter times are an additional factor to be taken into account in the extrapolation time.

For extrapolation, you can specify in **typeOfAxis.extrapolation.extrapolatedVelocitySwitch** whether the master value velocity should be recalculated from the extrapolated position or whether the velocity derived for the extrapolation should also be used as the master value velocity.

The extrapolated and filtered actual values can be checked in the following system variables:

- Filtered and extrapolated
  - **extrapolationData.position**
  - **extrapolationData.velocity**
  - **extrapolationData.acceleration**
- Filtered and not extrapolated
  - **extrapolationData.filteredposition**
  - **extrapolationData.filteredvelocity**

(This topic is presented in detail in the *Technology Objects Synchronous Operation, Cam* Function Manual under Actual value coupling with extrapolation.)

Note

You can find a tool to help you calculate extrapolation times under *Tools and Documentation > Calculating the extrapolation time for an actual-value-coupled drive* in the *SIMOTION Utilities & Applications*. *SIMOTION Utilities & Applications* is part of the scope of delivery of SIMOTION SCOUT.

Transferring the actual velocity from the drive (as of V4.1 SP1)

With velocity precontrol, sudden changes in velocity directly affect the control behavior (quantization jumps primarily in the case of low-resolution encoders).

With the setting **typeOfAxis.numberOfEncoders.encoder_n.encoderValueType**=POSITION_AND_PROFIDRIVE_NIST_B, you have the option of converting the speed of rotation transferred in PROFIdrive NIST_B to a velocity and applying this value as the actual velocity of the encoder/sensor. In this case, the actual position of the sensor does not need to be differentiated to derive the actual velocity.

With the setting **typeofAxis.numberOfEncoders.encoder_n.encoderValueType**= POSITION_AND_DIRECT_NIST, a speed of rotation transferred in the I/O area and normalized as NIST_B is taken as the actual value and converted to an actual velocity. In this case, 4000H corresponds to 100%. The address is set in **typeofAxis.numberOfEncoders.encoder_n.sensorNist.logAddress**, and the reference value is set in **typeofAxis.numberOfEncoders.encoder_n.sensorNist.referenceValue**.

With encoders with NAct evaluation, the speed determined by the encoder and the resulting velocity can be accepted by the encoder. In this case, the actual position of the sensor does not

need to be differentiated to derive the actual velocity.
Two transmission options are available:

- Transmission in the PROFIdrive telegram
- Transmission in the I/O area

Number of modulo revolutions (as of V3.2)

The number of modulo revolutions is displayed in the **positioningState.commandModuloCycles**, **positioningState.actualModuloCycles** and **sensorData.moduloCycles** system variables with the following constraints:

- The value is not initialized at first.
  The start value must be stored in the user program so that, for example, the number of revolutions since the start can be calculated subsequently.
- The value is reset when the system is switched on and in response to initialization tasks such as set actual value system (**_redefinePosition()**) or homing (**_homing()**).
  The modulo revolution can change via **_redefinePosition()**. For absolute position specifications and stationary axes, the principle of the shortest path is used; for moving axes, corrections are made in the direction of motion. For relative position specifications, the correction is made over the entire position difference.
- There is no special overflow handling for the count value.
  A counter overflow must be taken into account in the user program.

Table 4-351 System variables for determining the modulo revolutions

Variable	State	Meaning
positioningState.commandModuloCycles	See the **StructAxisPositioningState** data type in the System variables parameters manual	Setpoint for modulo revolutions
positioningState.actualModuloCycles	See the **StructAxisPositioningState** data type in the System variables parameters manual	Actual value for modulo revolutions
positioningState.moduloCycles	See the **StructAxisSensorData** data type in the System variables parameters manual	Actual value for modulo revolutions

Preparation of manipulated variables for electric axis

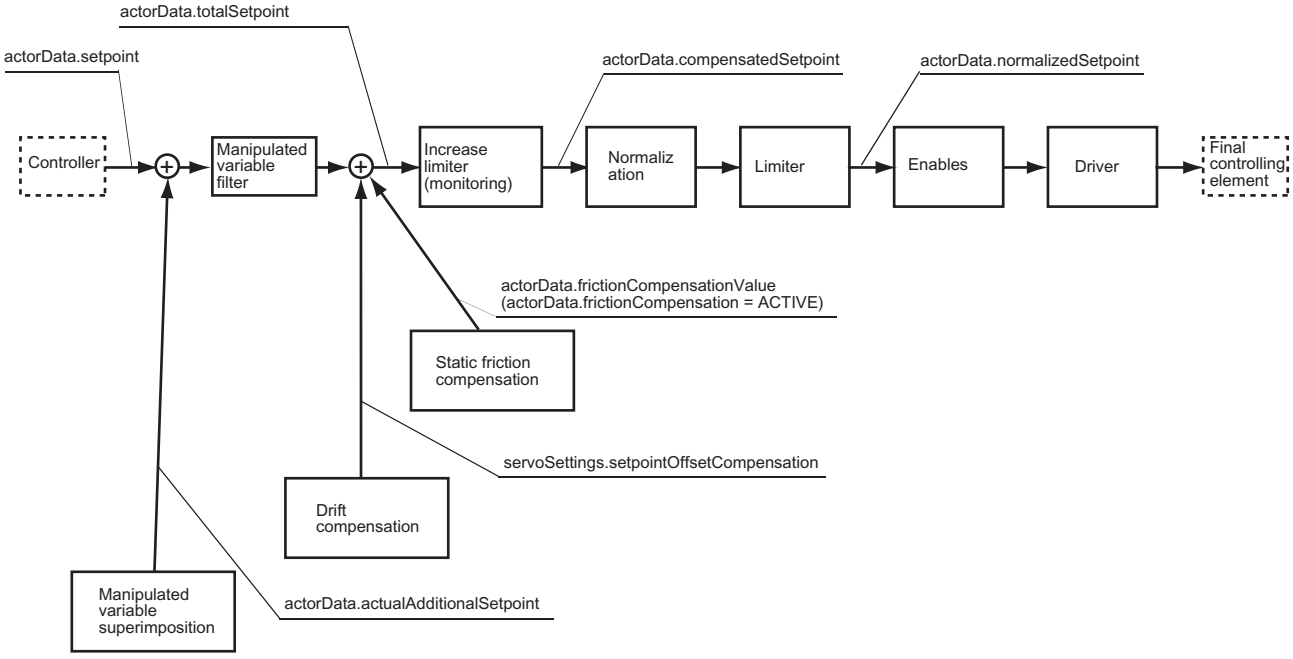

Figure 4-850 Manipulated variable preparation

Manipulated variable superimposition

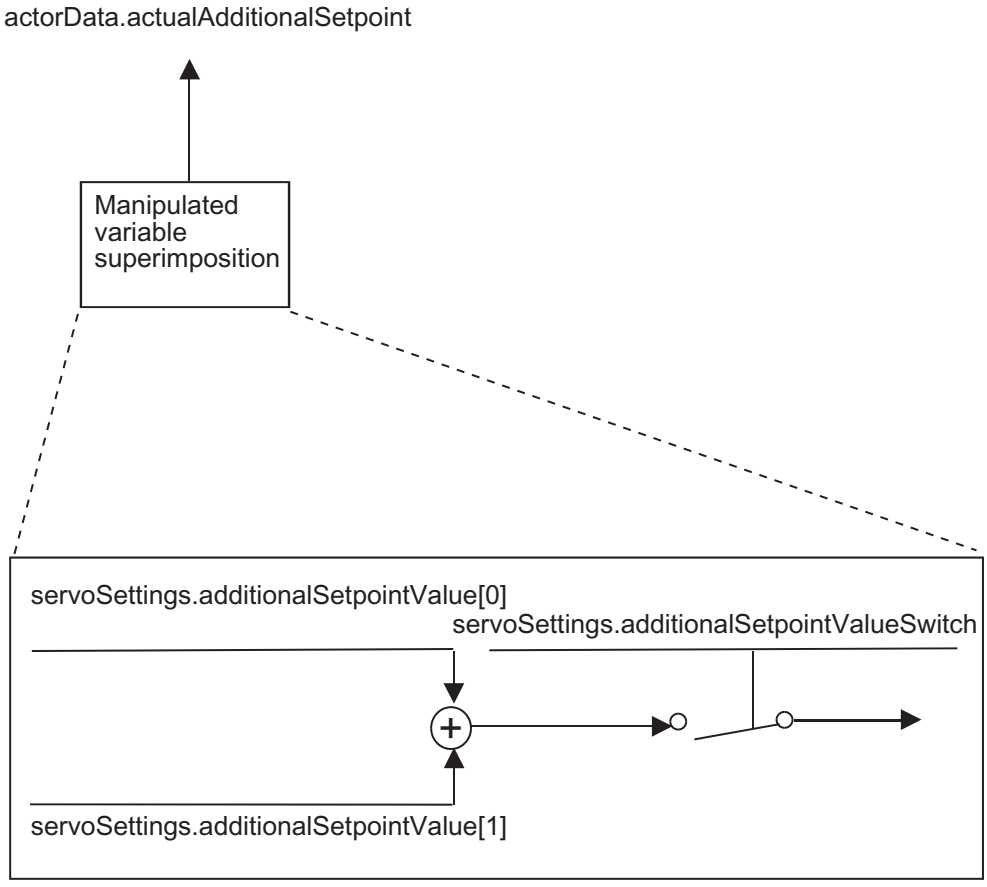

Figure 4-851 Manipulated variable superimposition

Superimposition of manipulated variables is enabled by means of a switch.

Manipulated variable superimpositions remain in effect when the drive is active. The user is responsible for handling the superimpositions.

As of V4.1 SP1, the superimposition of manipulated variables is not active for the FEEDBACK_EMERGENCY_STOP alarm reaction and the **_stopEmergency()** command with stopMode=STOP_WITH_COMMAND_VALUE_ZERO.

Manipulated variable filtering (as of V4.1 SP1)

A man. var. filter can be set as a PT1 filter in the **setpointFilter** configuration data element. This filter acts after the controller and after the precontrol value and the additive manipulated variable value (additionalSetpoint) have been added.

A change in the filter data takes effect immediately.

With the DSC setting, the man. var. filter is only effective for the precontrol.

Drift/offset compensation

The analog output signal of analog-coupled drives can include a **drift**. This can be compensated for by an offset in the axis.

Drift is enabled/disabled using the **DriftEnable** configuration data element. The value is specified in the system variable **servoSettings.setpointOffsetCompensation**.

The value of the system variable **servoSettings.setPointOffsetCompensation** is reset to 0.0 with **_disableAxis()** (or with the alarm response RELEASE_DISABLE). If a value not equal to 0.0 is effective when the axis is switched on, the value needs to be reset before switching on the axis (before issuing **_enableAxis()**).

Static friction compensation

A simple compensation is available for overcoming for the forces of static friction. During startup from a standstill, a DT1 element adds a static friction compensation signal to the manipulated variable.

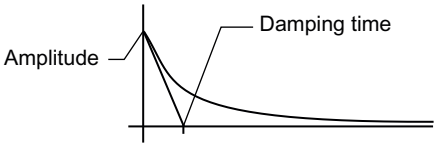

Figure 4-852 Static friction compensation

Static friction is added relative to the velocity setpoint. It only takes effect when processing motion specifications and does not affect force/pressure control.

The standstill identification for static friction compensation can be set separately, as is the case for the amplitude and the decay response. The amplitude and decay response are set in the configuration.

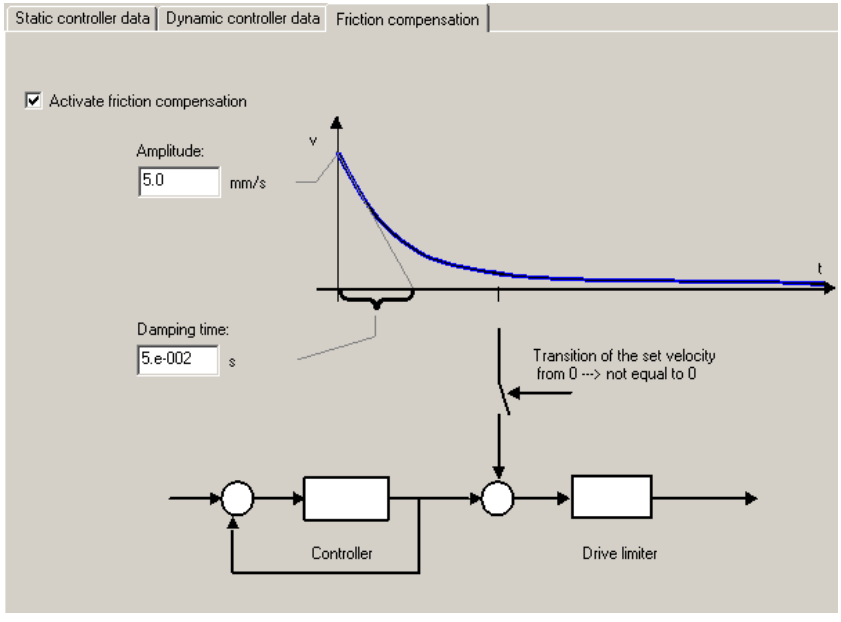

Figure 4-853 Static friction compensation

Backlash on reversal compensation

During the power transmission between a moving machine part and the corresponding drive, a backlash on reversal (play) usually occurs.

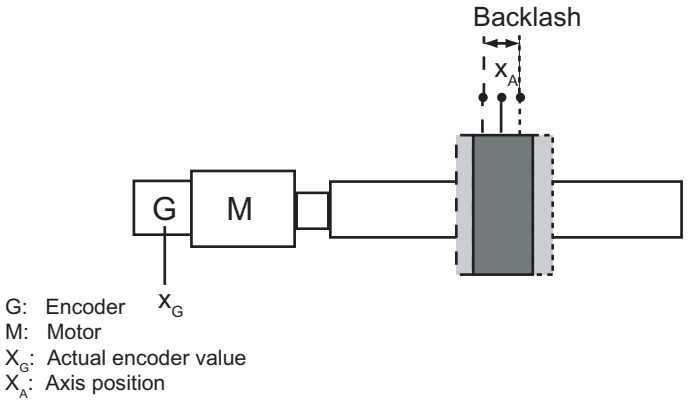

Figure 4-854 Backlash

Despite the backlash on reversal, a clear derivation of the axis position from the encoder position and an exact traversing, positioning and synchronous operation of the axis must be possible. SIMOTION provides the backlash on reversal compensation function for this purpose.

The backlash is specified in **absBacklash.length** or **incBacklash.length**, and the backlash compensation velocity is specified in **absBacklash.velocity** or **incBacklash.velocity**.

Backlash on reversal compensation is effective only for encoders mounted on the motor side and is set specifically for each encoder. A direct measuring system measures the variable directly without any intermediate backlash. Therefore, any existing backlash is compensated with closed-loop control to the direct measuring system.

Backlash type

- Positive backlash
  A positive backlash is set with **absBacklash._type** = POSITIVE or **incBacklash._type** = POSITIVE.
  Setting =POSITIVE means that the mechanical position lags behind the actual encoder value. This is the case, for example, if the ball screw has play and the encoder is attached to the motor (normal condition, default).
  When the direction is reversed, the backlash is applied by the system at the backlash compensation velocity.
  Unless stated otherwise, the POSITIVE setting is assumed in the following.
- Negative backlash
  The setting **incBacklash._type** = NEGATIVE is not supported.
  The setting **absBacklash._type** = NEGATIVE is not supported.

Homing with incremental encoders

In homing, the encoder value is assigned a unique (mechanical) axis position based on the reference signal of a homing mark.

If there is a backlash, the axis must always be traversed from the same side to the synchronization point during homing. The assignment of the actual control position to the mechanical position of the axis is thus unique.

This applies to:

- Homing on encoder zero mark
- Homing on external zero mark
- Homing via actual value setting (setting the actual axis value to a specified value)

Note

The fraction backlash that the axis lags when traversing in the homing direction is irrelevant. Homing yields a unique assignment of the mechanical and displayed axis position relative to the encoder value. When traversing in this direction, the same ratios always result.

Direction reversal and switch-on behavior of incremental encoders

In a direction reversal when **incBacklash._type**=POSITIVE, the motor runs through the backlash range. During this motor motion, the mechanical and thus the displayed actual position of the axis does not change, whereas the encoder value in **sensordata.incrementalPosition** does change. The axis is then traversed by the commanded distance or to the commanded position.

In case of direction reversal, the backlash compensation is independent on the 'homed' status. However, the first motion after the control unit is switched on is run through without backlash compensation.

When the backlash range has been run through completely one time (no matter which direction), the set backlash is then compensated when the direction is reversed - if backlash compensation is enabled. This is independent of the homing status and applies to the relative or, if applicable, absolute traversing of the axis in the non-homed state.

Homing with absolute encoders

The absolute encoder value is assigned a mechanical axis position by defining the absolute encoder offset for homing with absolute encoders or absolute encoder adjustment.

This results in a direction dependency for the absolute encoder, too, since the position of the backlash relative to the encoder value/axis position is relevant when setting the absolute encoder offset or the mechanical axis position.

After the absolute encoder adjustment, backlash on reversal is carried out if the direction is reversed, but not when traversing is continued in the same direction.

If the control unit is switched off/on, the mechanical axis position is assigned/indicated to the actual encoder value via the absolute encoder offset. In the same way as motion restart after absolute encoder adjustment, backlash compensation is not activated after switch-on for motion in the same direction as the absolute encoder adjustment; however, it is activated for motion in the opposite direction.

In the **absBacklash.startupDifference** configuration data element, the direction opposite to the reference direction must be entered for setting the absolute encoder offset. For example, **absBacklash.startupDifference**= NEGATIVE must be set for referencing the absolute encoder offset to a positive direction of motion, since the backlash must be compensated in this case

when immediate travel in the negative direction occurs after switch-on. This is independent of the position of the backlash relative to the actual axis position at the time of switch-on.

Note

Directly after switch-on, the mechanical axis position is displayed correctly only if the position of the backlash at the time of switch-on corresponds to the position of the backlash relative to the mechanical axis position when the absolute encoder offset is set. If this is not the case, the mechanical axis position may deviate from the displayed axis position up to the total amount of the backlash; that is because the control detects the actual encoder value at the time of switch-on but it is not able to establish the position of the backlash without moving the axis.

Direction reversal and switch-on behavior of absolute encoders

With direction reversal and the setting **absBacklash._type**=POSITIVE, the motor runs through the backlash range. During this motor motion, the mechanical axis position and, thus, the displayed actual position of the axis does not change, whereas the encoder value in **sensordata.incrementalPosition** does change (also with the absolute encoder). The axis is then traversed by the commanded distance or to the commanded position.

Backlash compensation for direction reversal is independent of the 'Homed' status (here, the absolute encoder adjustment).

Backlash compensation is not activated for the first motion in both directions once the control has been switched if no absolute encoder adjustment has yet been carried out. When the backlash range has been run through completely one time (no matter which direction), the set backlash is then compensated when the direction is reversed - if backlash compensation is enabled.

Status display

The **sensorMonitoring.passingBacklash** system variable indicates that the backlash is being run through without changing the actual axis value.

Since the travel specification resulting from the specified motion and backlash recovery is superimposed, this indication is not identical to the specification for backlash recovery.

Note

In order not to impair the response times with the backlash, the backlash compensation is started simultaneously with the motion.

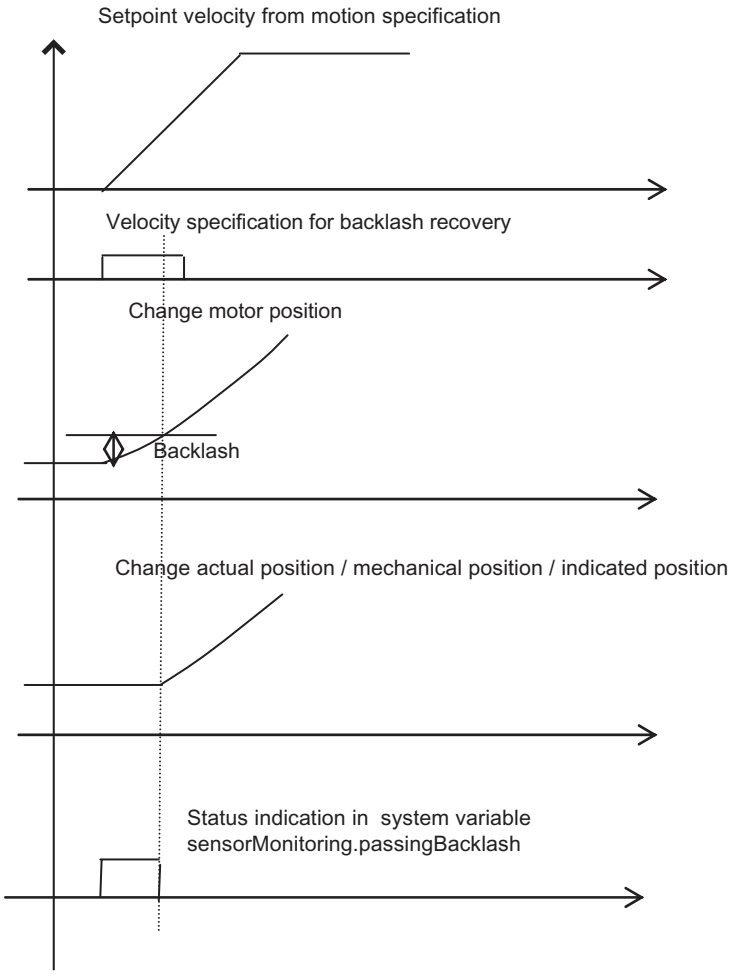

Figure 4-855 Backlash on reversal compensation sequence

Traversing of the positioning axis without position control

The positioning axis can also be traversed without active position control.

Traversing motions with **_move()** or as velocity profiles can be applied on the position axis/ synchronized axis with position control or, alternatively, with a velocity specification only.

Table 4-352 Setting via movingMode parameter in command

Commands	Function
_move()	For traversing with a programmable velocity profile
_runTimeLockedVelocityProfile()	For traversing with a user-definable velocity profile
_runPositionLockedVelocityProfile()	For traversing with a position-related velocity profile

The transition from a position-controlled or open-loop/closed-loop pressure-controlled motion to a motion solely with a velocity/speed specification can take place when the axis is at a standstill or in motion; this is also the case for the transition from a motion with speed specification to a position-controlled motion.

The **decodingConfig.speedModeSetpointZero** configuration data element can be used to specify whether the current velocity is maintained during the switchover from position-controlled or open-loop/closed-loop force-/pressure-controlled operation to operation with velocity/speed specification, or whether the velocity is set to zero at the time of switchover.

The dynamic response parameters and the maximum values for speed specification are derived from the settings for position-controlled axis operation.

The position-related monitoring functions are deactivated. The encoder limit frequency can be exceeded.

It is possible to activate the position-controlled axis with **_enableAxis()** for the velocity specification only.

Stepper drives

The special torque characteristics of a stepper motor and the response to overloading should be considered when assigning the stepper motor axis parameters.

Functionality of stepper motor axes

The Axis technology object can be used to implement the following functions:

- Positioning axis without additional encoders
  - Homing with edge of external zero mark
  - Rotation monitoring with external zero mark
- Position axis with additional incremental or absolute encoder
  - The axis works in the same way as with a servo motor with an analog interface +/-10 V.

Behavior of a stepper motor

From a given speed of rotation of the stepper motor (around 500 rpm), the torque produced by the motor drops logarithmically, and approaches zero at a maximum speed (around 3,000 rpm). The specific data can be found in the data sheet for the motor used.

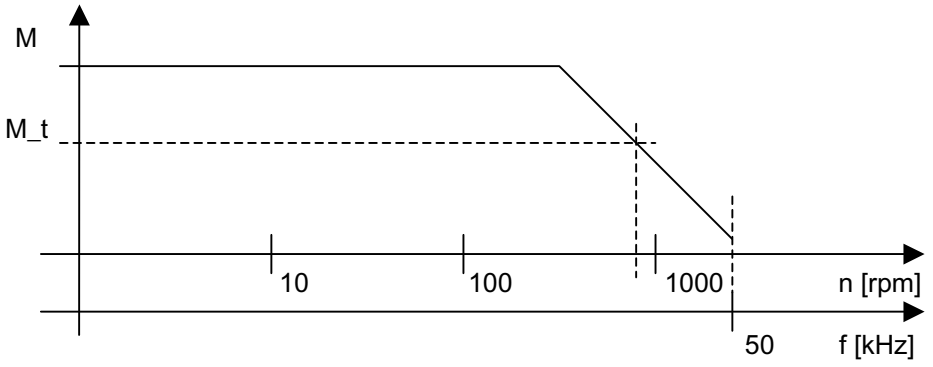

Figure 4-856 Example of a stepper motor torque characteristic

Consequences of operation in the overload range

If the stepper motor is ever unable to produce the requested torque, it loses synchronization with the predefined frequency and its speed drops suddenly. This can lead to standstill.

In this state, motion cannot be resumed unless a setpoint of 0 is entered in the meantime.

For a position axis without additional encoders, the traversing position and, as a result, the synchronization of the axis are lost.

Avoiding operation in the overload range

When the axis is designed, a maximum motor speed should be determined using the torque M_t required by the process. This maximum speed corresponds to the maximum velocity of the axis. The maximum frequency of the stepper motor must not be exceeded.

Encoder signal output (V4.0 or later)

The real axis with the setting **typeOfAxis**=REAL_AXIS_WITH_SIGNAL_OUTPUT can be used to output encoder signals via the SINAMICS TM41 module.

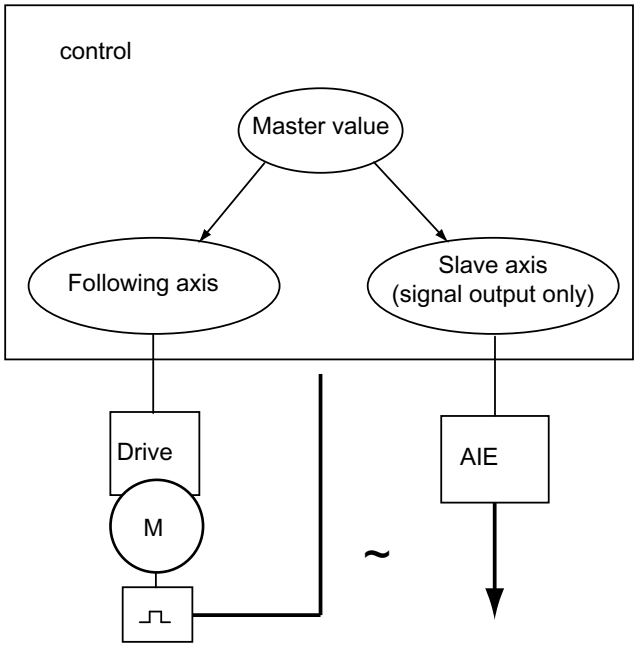

Figure 4-857 Using the axis for encoder signal output

Application

The axis position (a master value) is to be made available to a second control unit as an encoder signal via encoder signal simulation.

The standard message frame 3 is set between control unit and drive. An offset for the zero pulse output can be specified in the application.

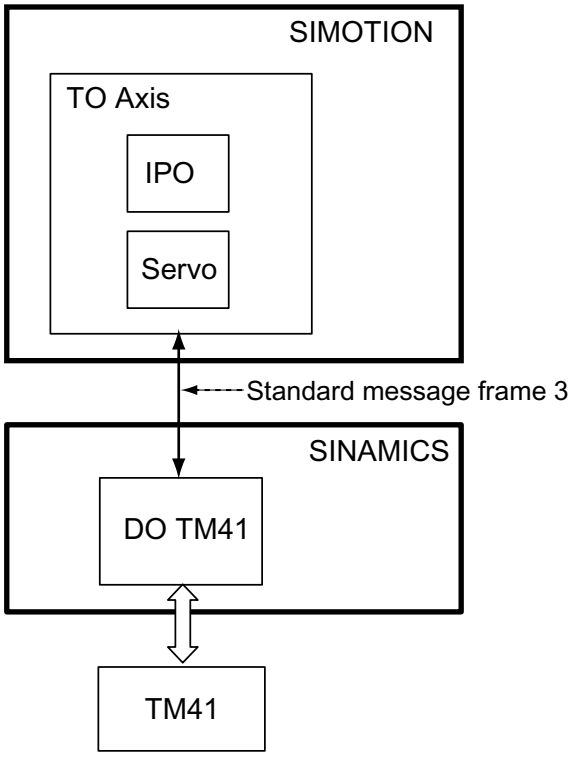

Figure 4-858 Interface of TM41 / DO41 to Axis technology object

In order to rule out lasting position deviations in the output signal, the axis can be provided with a PI controller that is applied to the actual position returned by TM41 / DO41.

Setting as an axis with signal output via the TM41 module only

Setting the axis as an axis with signal output only via the enumerator element **REAL_AXIS_WITH_SIGNAL_OUTPUT in TypeOfAxis**.

The following functions are not practicable or cannot be activated with this setting:

- Active homing is not permitted
- Measurement via digital drive is not permitted
- Compensations are disabled
- Following error monitoring functions are disabled
- Following error monitoring is disabled
- Positioning monitoring is deactivated
- Standstill monitoring is disabled
- Hardware limit monitoring is disabled

Note

You can also find further information under *FAQs* in the *SIMOTION Utilities & Applications* provided with SIMOTION SCOUT.

4.8.3.12 Commissioning the position controller of positioning axes

Overview of commissioning the position controller of positioning axes

Basic procedure

When commissioning the position controller, you should follow a basic procedure, which is outlined below. You can find detailed information in subsequent chapters.

- Enter/check the settings for the controller type, load gear, measuring gear, normalization of the speed setpoint interface, leadscrew pitch, encoders, and valve characteristic (for hydraulic axes)
- Set the speed controller on the drive
- On the SIMOTION control unit, preselect the axis data set (Page 3037) whose controller parameters are to be optimized (and, if necessary, preselect the appropriate data set on the drive)
- Set the controller parameters
  The SIMOTION measuring functions (Page 3073) for manual optimization and the automatic controller setting (Page 3066) are available for this.
- Set the equivalent time constant of the position controller
- Non-volatile storage of parameters on the target device and in the offline project

You can also find a commissioning guide under *FAQs* in the *SIMOTION Utilities & Applications* provided with SIMOTION SCOUT.

Example of commissioning a proportional-action controller with precontrol

The procedure for determining the control parameters of an electric axis manually is outlined below using a P controller with precontrol (PV controller) as an example.

This procedure is the same whether or not the DSC setting is used.

Requirements

- The settings have been made for the controller type (PV controller), velocity precontrol, load gear, measuring gear, normalization of the speed setpoint interface, leadscrew pitch, and encoders.
- The fine interpolator should be set to cubic (continuous acceleration) or quadratic (continuous velocity) interpolation in order for the velocity precontrol to provide continuous values in the acceleration and deceleration phases.

- The axis data set whose control parameters are to be determined is active (if necessary, the relevant data set on the drive must also be selected).
- Monitoring and compensation functions are deactivated
  - Drift and friction compensation
  - Dynamic monitoring of following errors
  - Positioning monitoring

Checking the interface to the drive

Before performing the actual axis optimization, you should check whether the interface between the SIMOTION control and the drive has been configured correctly.

The following check is useful for this purpose:

The axis is traversed at constant velocity, and the control errors are recorded with the SIMOTION trace function in SCOUT. For this check, the servo gain factor Kv should be set to a low value (e.g. default value: Kv = 10/s).

-> Control error: **servoData.controllerDifference**

If the axis is operated with 100-percent velocity precontrol, the control error in the steady-state condition must be zero on average during the constant motion phase.

If velocity precontrol is not in effect, the control error in the steady-state condition is calculated as follows:

Control error = set velocity/Kv

If another control error results, then the configuration of the interface between the SIMOTION control and the drive is faulty.

A common cause for the faulty behavior is a discrepancy in the normalization speed configuration between the SIMOTION control and the drive. Check the following setting:

Scenario 1: **TypeOfAxis.setPointDriverInfo.DriveData.speedReference** = MAX_VALUE

In this case: drive normalization speed =
TypeOfAxis.setPointDriverInfo.DriveData.maxSpeed

Scenario 2: **TypeOfAxis.setPointDriverInfo.DriveData.speedReference** = NOMINAL_VALUE

In this case: drive normalization speed =
TypeOfAxis.setPointDriverInfo.DriveData.nominalSpeed

Note

Drives are typically linked to the SIMOTION control with PROFIdrive (via PROFIBUS/PROFINET). The parameters for setting the normalization speed for the SINAMICS, MASTERDRIVE MC, and SIMODRIVE 611U drive systems are listed below.

For SINAMICS, the normalization speed can be accepted by the drive in the axis wizard; as of V4.2, it is adapted during runtime. See Coupling of digital drives (Page 2895).

Table 4-355 Parameters for setting the normalization speed

Drive system	Parameter
SINAMICS	P2000
MASTERDRIVES MC	P353
SIMODRIVE 611U	P880

Determining the controller parameters

The following controller parameters of the active axis data set should be determined:

Kv P controller gain	**controllerStruct.PV_Controller.kv**
VTC Equivalent time of the lower-level drive (time constant of the balancing filter)	**dynamicData.velocityTimeConstant**
PTC Equivalent time of the position control loop	**dynamicData.positionTimeConstant**

Two main optimization goals can be differentiated:

1. High dynamic response for continuous movements and synchronous operation groups. The axis is allowed a certain amount of overswing.
2. High dynamic response for discontinuous movements, i.e. fast, time-optimized positioning movements without overswings.

As first step, the automatic speed optimization and subsequently the automatic position optimization (if DSC possible) are performed.

This optimization provides very good results even for the above-mentioned strategy.

The optimization of movements without overswing is described next.

Prerequisite:
The speed controller of the drive has already been set as (nearly) overshoot-free. In principle, this can be achieved by using a low-pass filter as the speed setpoint filter or through the use of a system model (reference model) for the I-component of the speed controller. For more information, refer to the relevant drive documentation.

Determining the servo gain Kv of the P-controller

Disable the velocity precontrol and balancing filter in the configuration data of the axis.

controllerStruct.PV_Controller.kpc = 0
dynamicData.velocityTimeConstant = 0

Position the axis cyclically with a high deceleration rate and trapezoidal velocity profile and trace the system variables for the set and actual positions of the axis with SIMOTION trace in SCOUT. Make sure that the axis reaches the constant velocity phase during this operation. You must also select the deceleration such that the current or torque in the drive is not limited.

Set position: **servoData.symmetricCommandPosition**
Actual position: **servoData.actualPosition**

Starting with Kv = 10, continue increasing the servo gain factor in five-percent increments as long as the actual value does not overshoot or undershoot when entering the target position.

Deduct 10 percent from this maximum Kv value and make this setting on the target device.

Setting the balancing filter

When velocity precontrol is used, the entry behavior during positioning and the control errors in the acceleration and deceleration phases can be influenced by the time constant of the balancing filter (VTC).

VTC: **dynamicData.velocityTimeConstant**

The velocity precontrol must be activated to determine the time constant.

controllerStruct.PV_Controller.kpc = 100
controllerStruct.PV_Controller.preCon = YES

Position the axis cyclically with a high deceleration rate and record the control error with SIMOTION trace in SCOUT. Make sure that the axis reaches the constant velocity phase during this operation. You must also select the deceleration such that the current or torque in the drive is not limited.

Control error: **servoData.controllerDifference**

Continue increasing the time constant of the balancing filter (VTC) incrementally until the axis enters the target position without overshooting or undershooting.

If you have to set a very large time constant to avoid overshooting/undershooting, and if the axis "creeps" to its target position, you may be able to achieve a smoother setpoint curve by using the SMOOTH velocity profile. In this case, you must limit the jerk in the motion command for entry in the target position and then repeat the balancing filter optimization.

If this still does not yield the desired result, you should check the drive setting again. It could be that the drive setting has not yet been optimized to be overshoot-free.

You may want to allow a small overshoot/undershoot upon entry in the target position to enable a faster settling behavior.

For axes with different balancing filter settings in a synchronous operation group, a dynamic response adaptation is desirable, see Dynamic response adaptation (Page 2968).

Setting the equivalent time of the position controller

To apply the preassigned axis stop ramp (in the event of an error, for example), the system requires the equivalent time constant of the position controller (PTC).

PTC: **dynamicData.positionTimeConstant**

In this example, this time constant is derived from the time constant of the balancing filter (VTC), due to the use of velocity precontrol (at 100%). The following relation applies:

PTC = VTC

If the velocity precontrol is not activated, the following is true for PTC:

PTC = 1/Kv

Storing the control parameters

If the control parameters have been entered in the corresponding configuration data in the target device, they must now be stored as non-volatile data so that they will still be available the next time the control is powered up. The following online functions are available for this purpose under the target device in SCOUT.

Table 4-356 Online storage functions

Function	Comments
Copy ACTUAL to RAM	Copies the configuration data to the RAM memory on the target device
Copy from RAM to ROM	Non-volatile storage of configuration data on memory card

In order to transfer modified configuration data to the configuration, you must select the **Load configuration data to PG** function under the target device in SCOUT and then save the project.

After you have optimized the position controller, you must reset the compensations and monitoring functions listed under "Requirements", if applicable.

4.8.3.13 Command variable calculation

Velocity profiles

Specifications of velocity changes for axes (approaching, stopping, other velocity changes) are applied via **velocity profiles**.

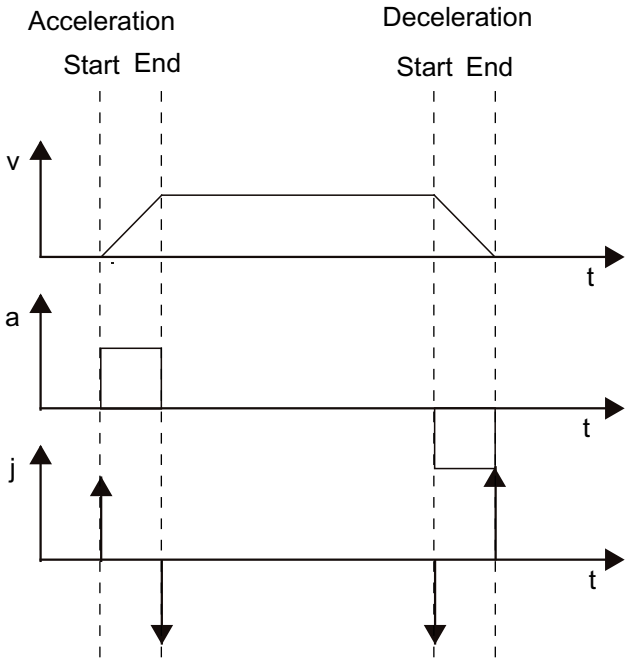
The velocity profile defines the behavior of the axis during startup and when braking, and for velocity changes.

The following velocity profiles are available:

- **Trapezoidal** velocity profile (**TRAPEZOIDAL**)
  The trapezoidal profile is set for constant acceleration and deceleration of motion in a positive and negative direction.
- **Smooth** velocity profile (**SMOOTH**)
  This profile is used for a continuous acceleration and deceleration. The jerk can be set.

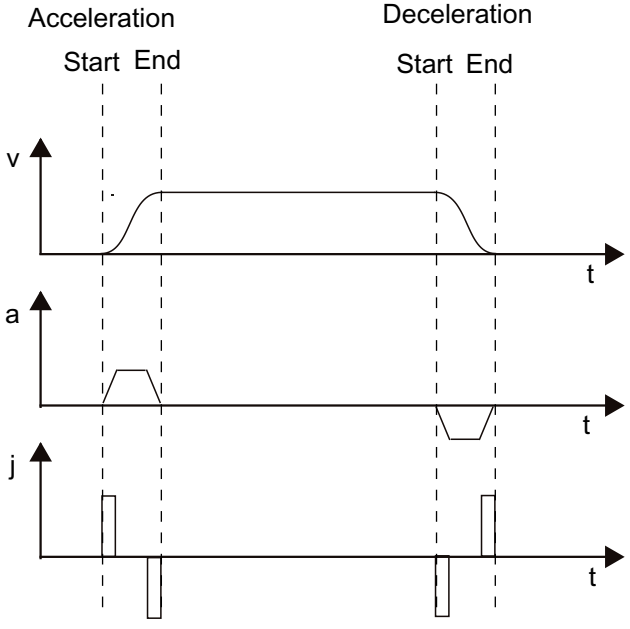
The parameters for profile, velocity, acceleration, and jerk can be assigned in the command, or the **userDefault** value settings are used.

The parameter for the velocity profile is specified via the motion command (velocityProfile) or stored as a default value in the userdefaultdynamics.profile system variable.



v - velocity
a - acceleration
j - jerk
t - time

Figure 4-859 Trapezoidal velocity profile



v - velocity
a - acceleration
j - jerk
t - time

Figure 4-860 Smooth velocity profile

Continuous acceleration curve for smoothing

Prior to SIMOTION V4.4., the following applies to single axis motions and path motions when a continuous acceleration curve is specified: When blending to the motion of the new command on transition, acceleration is zeroed, i.e. the deceleration is canceled via the jerk.

As of SIMOTION V4.4, it is possible to set that the acceleration is not zeroed. See also Positioning with blending (Page 3003).

Continuous acceleration curve for reversing

For single axis movements, for path movements, for the synchronization of synchronization movements and for the specification of a continuous acceleration curve, for any required reversing in the reversal point of the movement direction, the acceleration is made to zero. This means the acceleration/deceleration will be removed using the jerk and re-established after the reversal using the jerk.

This does not apply for motion specification via user-defined profiles or for the procedure based on motion vectors (MotionIn interface).

Setting the acceleration to zero when stopping or substituting a motion

When stopping with the **_stop()** and **_stopEmergency()** commands or substituting a motion with the **_pos()** and **_move()** commands, an existing acceleration or deceleration can be set immediately to zero. The existing acceleration or deceleration is not first reduced via the jerk.

The abortAcceleration function parameter is available for the stop commands as of V4.2.1 and the substitution commands as of V4.4.

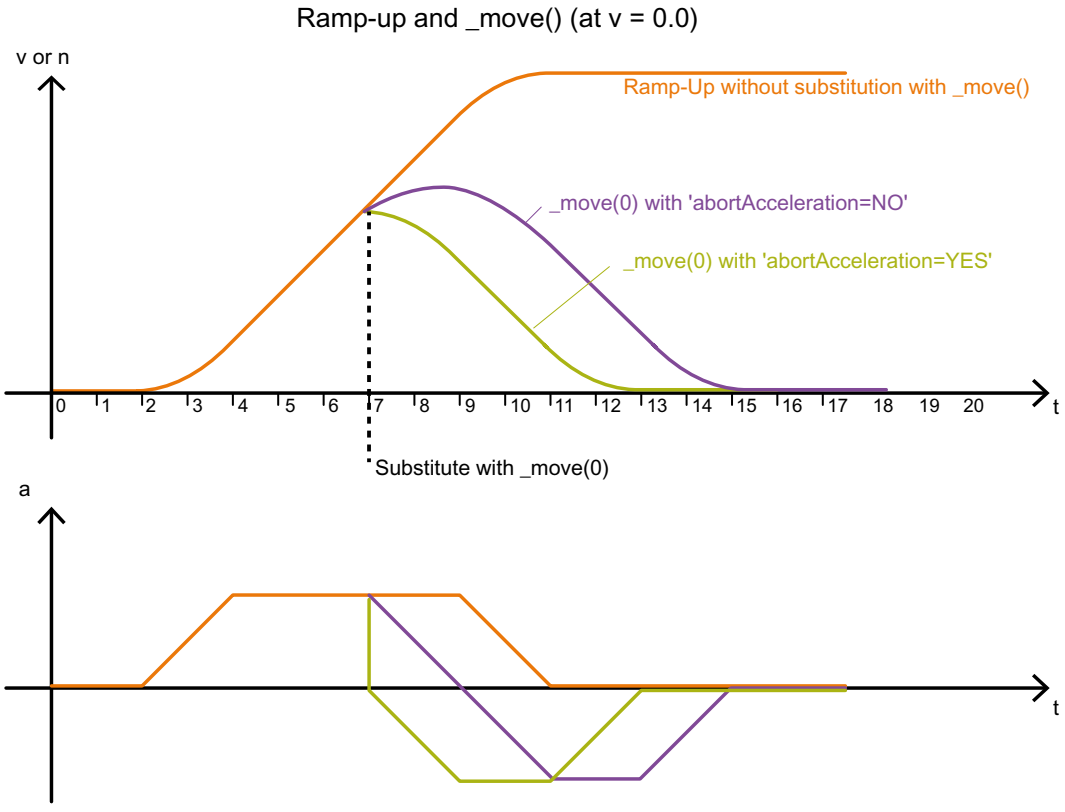


Figure 4-861 Velocity profile on ramp-up with and without abortAcceleration

Defining accelerations and decelerations

The axis acceleration and deceleration parameters can be set to take effect in relation to the direction or state using the **decodingConfig.directionDynamic** configuration data element.

Parameters for direction-related setting

- **positiveAccel:** Acceleration in the positive direction of motion and deceleration in the negative direction of motion
- **negativeAccel:** Acceleration in the negative direction of motion and deceleration in the positive direction of motion

The option to assign parameters for a direction-dependent dynamic response is relevant, for example, for applications such as vertical axes.

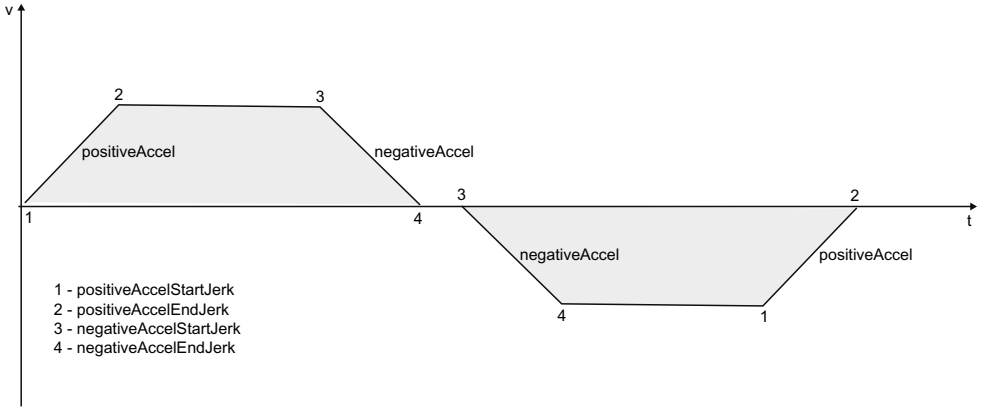

Figure 4-862 Operative points for acceleration and jerk parameters

Parameters for state-dependent setting

- **positiveAccel:** Acceleration of axis motion, irrespective of the direction of motion
- **negativeAccel:** Deceleration of axis motion, irrespective of the direction of motion

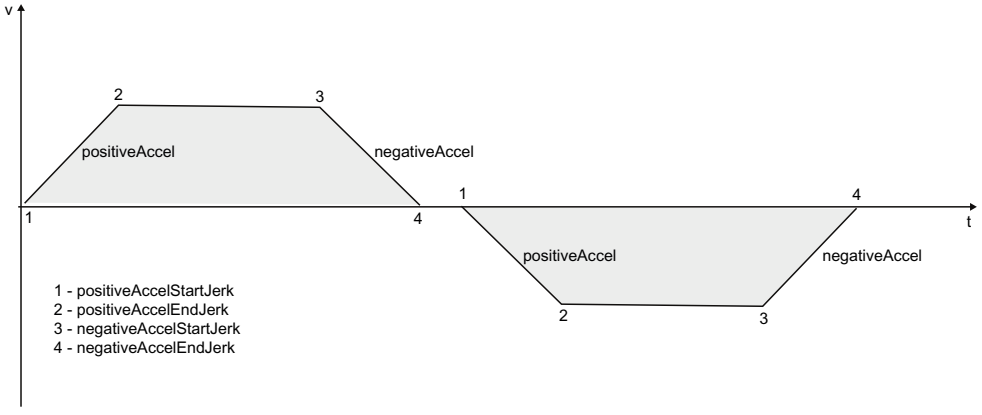

Figure 4-863 Operative points for acceleration and jerk parameters

Values set by the command or set by means of a system variable

- velocity
- positiveAccel
- negativeAccel
- positiveAccelStartJerk
- positiveAccelEndJerk
- negativeAccelStartJerk
- negativeAccelEndJerk

The dynamic response parameters are set with parameters in the motion command or stored as default values in the system variables of the userdefaultdynamics structure.

Override

Factors can be superimposed online on the current traversing velocity or acceleration/ deceleration. The velocity override is applied to the velocity, and the acceleration override is applied to the acceleration and deceleration.

The override values can be set and read via **system variables**.

The override for the **velocity** can be set from **0** to **200%**.

The override for the **acceleration/deceleration** can be set from **1%** to **1000%**.

System variables

- override.velocity
- override.acceleration

Default settings for dynamic response parameters

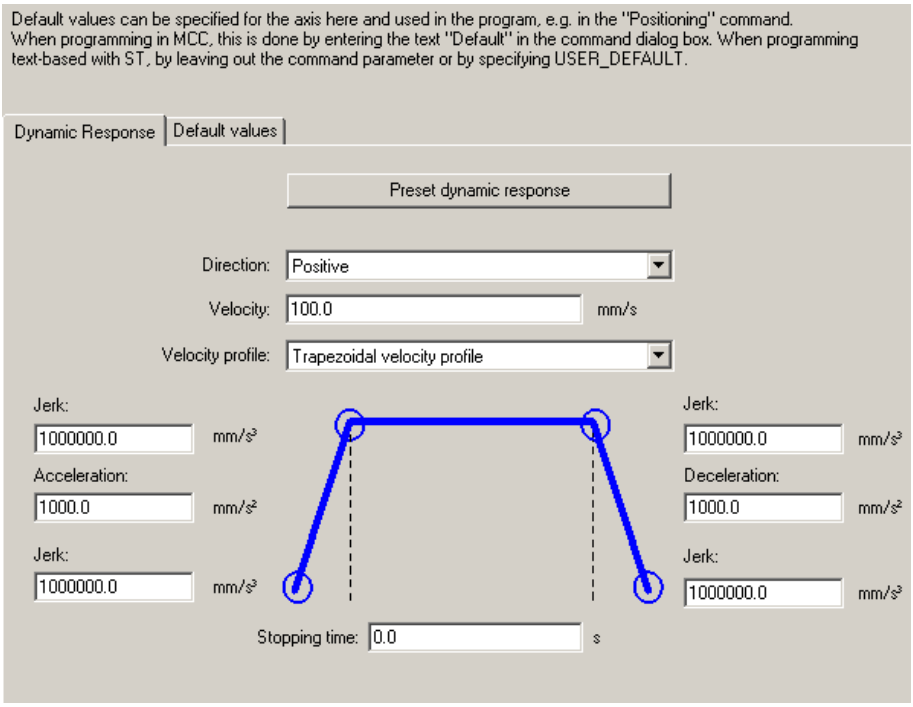

Figure 4-864 Default settings for dynamic response parameters

Stop time

This time becomes active if the default value is used for the time with **_stopEmergency()** and the **stopDriveMode=**STOP_IN_DEFINED_TIME setting.

Dynamic response default setting

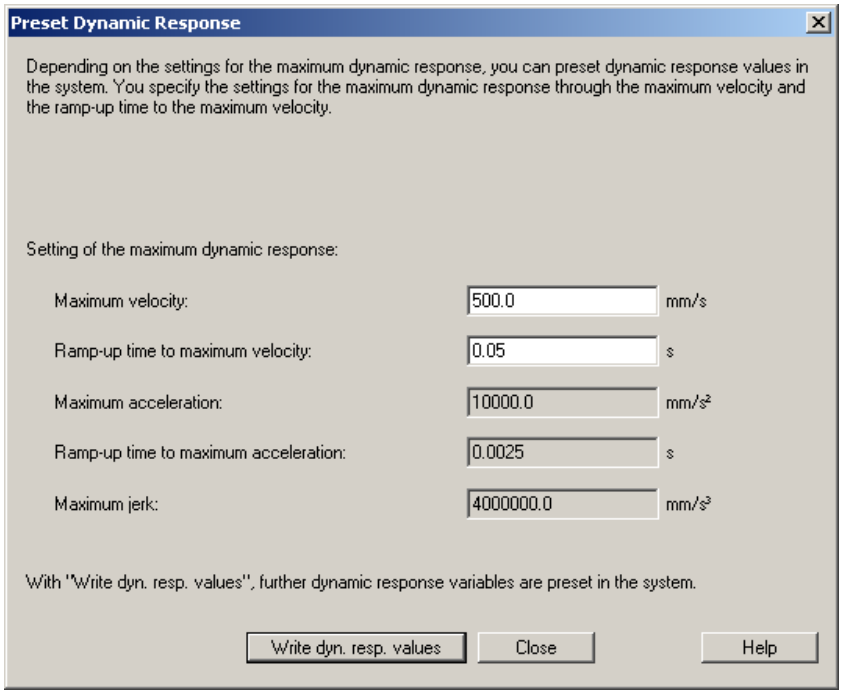

Figure 4-865 Dynamic response default setting

For the selection of the screen form, the **maximum velocity**, **maximum acceleration** and **maximum jerk** fields will be displayed using the setting in the associated configuration date. This provides the **startup time to the maximum velocity** and **startup time to the maximum acceleration**.

If the **maximum velocity** or the **startup time to the maximum velocity** is changed, the dependent values will be recalculated and displayed. The configuration data will be written directly and remain at the changed values also for **close** without **write dynamic values**.

The **startup time to the maximum velocity** will be used as startup time assuming the constant maximum acceleration over this time, i.e. without considering the time for building and removing the acceleration because of the maximum jerk.

Write dyn. resp. values writes corresponding values to the configuration data and adapts system variables, see Dynamic limiting functions (Page 2999).

Velocity profiles (Page 2992)

Defining accelerations and decelerations (Page 2995)

Defaults (Page 2922)

Dynamic limiting functions

Maximum values

The properties of the drive and the mechanical system produce the maximum values for velocity, acceleration and jerk. The values are set in the **maxVelocity**, **maxAcceleration**, and **maxJerk** variables.

Technological maximum values

For programming, additional dynamic limit values are available in the **plusLimitsOfDynamics** and **minusLimitsOfDynamics** system variables. These can be read and written in the program.

The technological maximum values are state-dependent, i.e. are not a direction-dependent setting:

- **plusLimitsOfDynamics.velocity**
  Technological limit value for the velocity of the axis independent of the direction of motion
- **plusLimitsOfDynamics.positiveAccel**
  Technological limit value for the acceleration of the axis independent of the movement direction
- **plusLimitsOfDynamics.negativeAccel**
  Technological limit value for the deceleration of the axis independent of the movement direction
- **plusLimitsOfDynamics.positiveAccelJerk**
  Technological limit value for the jerk for establishing the acceleration and removing the deceleration independent of the movement direction
- **plusLimitsOfDynamics.negativeAccelJerk**
  Technological limit value for the jerk for removing the acceleration and establishing the deceleration independent of the movement direction

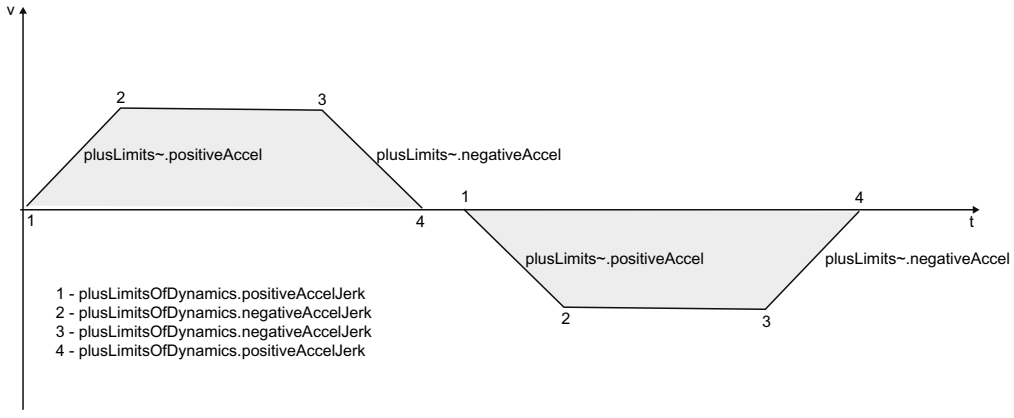

Figure 4-866 Technological maximum values for non-direction-dependent setting

Technological maximum values for direction-dependent setting:

- **plusLimitsOfDynamics.velocity**
  Technological limit value for the velocity of the axis independent of the direction of motion
- **minusLimitsOfDynamics.velocity**
  Technological limit value for the velocity of the axis independent of the direction of motion

- **plusLimitsOfDynamics.positiveAccel**
  Technological limit value for the acceleration of the axis in the positive movement direction
- **plusLimitsOfDynamics.negativeAccel**
  Technological limit value for the deceleration of the axis in the positive movement direction
- **minusLimitsOfDynamics.positiveAccel**
  Technological limit value for the acceleration of the axis in the negative movement direction
- **minusLimitsOfDynamics.negativeAccel**
  Technological limit value for the deceleration of the axis in the negative movement direction
- **plusLimitsOfDynamics.positiveAccelJerk**
  Technological limit for the jerk for establishing the acceleration and removing the deceleration in the positive movement direction
- **plusLimitsOfDynamics.negativeAccelJerk**
  Technological limit for the jerk for removing the acceleration and establishing the deceleration in the positive movement direction
- **minusLimitsOfDynamics.positiveAccelJerk**
  Technological limit for the jerk for establishing the acceleration and removing the deceleration in the negative movement direction
- **minusLimitsOfDynamics.negativeAccelJerk**
  Technological limit for the jerk for removing the acceleration and establishing the deceleration in the negative movement direction

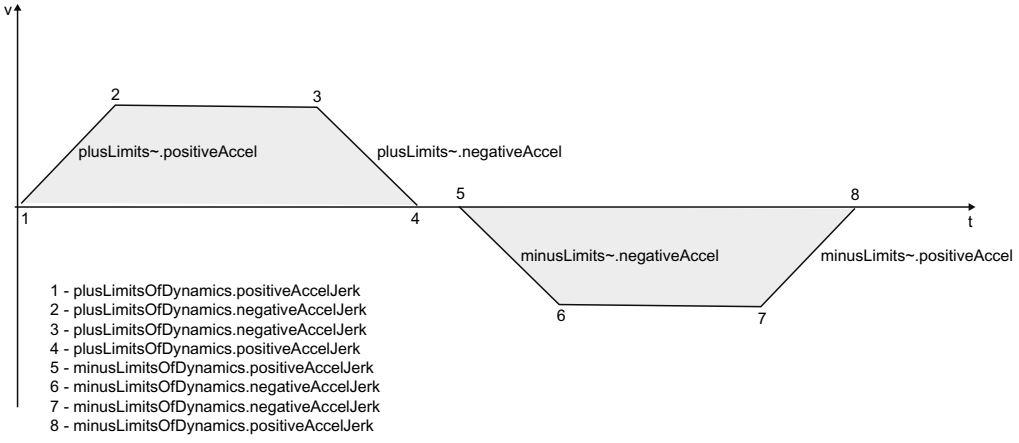

Figure 4-867 Technological maximum values for direction-dependent setting

The minimum from the maximum value of the axis and the set technological maximum value for the associated dynamic response quantity are used.

For system created movements with maximum dynamic response values, e.g. travel to the software limit switch, the minimum from the maximum value and the technological maximum value is used for the corresponding dynamic response quantity.

Active dynamic limitation

- Enter the maximum velocity in **maxVelocity**. This must always be less than or equal to the velocity that is physically possible. The greater the difference between the two, the larger the available control margin.
  Please note that the gear is data-set-dependent. Maximum velocity is calculated per data set. The maximum across all data sets is taken to be the maximum velocity.
- The effective limit is always the minimum of the maximum value and the technological maximum value.
- The **maxJerk** limiting is only monitored for motions in jerk-controlled mode or motions with continuous acceleration.

Dynamic limitation with synchronous operation relationships

If the axis provides a master value for a synchronous operation relationship, the maximum velocity is also limited to less than half the modulo range/IPO cycle clock (maximum possible master value velocity of the axis).

It is the minimum value from the following that applies when calculating the setpoint value for the following axis:

- Maximum velocity (**maxVelocity**) of the following axis
- Maximum technological velocity (**plusLimitsOfDynamics**/**minusLimitsOfDynamics**)
- Maximum master-value velocity of the axis

If a velocity faster than this maximum velocity is specified, the technological alarm 40002 "velocity will be limited" will be generated and the set velocity adapted appropriately.

Dynamic limitation with active ramp calculation in the drive

Please note that when linking with digital drives and with a ramp calculation for the speed active in the drive, additional dynamic limitation may occur, which is not taken account of separately in the motion control and motion monitoring functions performed in the control.

The operating mode is displayed in the drive's PROFIdrive parameter R0930 (PROFIdrive operating mode):

1. Speed-controlled operation with ramp-function generator
2. Position-controlled operation
3. Speed-controlled operation without ramp-function generator

SINAMICS drives:

- Drive object type vector
  Default setting *1. Speed-controlled operation with ramp-function generator*
  The motion dynamic response is, therefore, limited in the drive, if applicable.
- Drive object type servo
  Default setting *3. Speed-controlled operation without ramp-function generator*
  The motion dynamic response is not limited in the drive.

When using vector drives, therefore, you must check that the ramp-up/ramp-down time parameterized for the drive matches the configured axis acceleration/deceleration.

Stopping with preassigned braking ramp

The deceleration set in the **emergencyRampGenerator.maxDeceleration** configuration data element is used to stop an axis with a preconfigured braking ramp.

The current velocity is brought to zero at the assigned deceleration rate.

With position-controlled traversing, the position controller continues to be active during the stopping procedure.

For position-controlled, and thus position-related, traversing, the application point of the actual position value is extrapolated with the current velocity and the equivalent time of the position control loop set in the **dynamicData.positionTimeConstant** configuration data element.

Therefore, the application point can only be calculated correctly if the equivalent time of the position control loop is set correctly.

The preassigned braking ramp is effective in the following cases:

- During stopping with the **_stopEmergency()** command and the **STOP_WITH_COMMAND_VALUE_ZERO** setting
- During the **FEEDBACK_EMERGENCY_STOP** alarm response
- When program simulation is enabled during axis motion using the **_enableAxisSimulation ()** command

Traversing the axis via velocity specifications

The axis can be traversed via velocity specifications. A position axis can be traversed either via a velocity setpoint specification or in position-controlled mode.

The following is specified for the axis motion:

- Direction
- Dynamic response parameters
- Optionally, the duration of the constant motion phase

Parameters

- Direction
  The direction of motion is defined using either the sign of the velocity specification or a specific parameter.
- Velocity

- Duration of constant motion phase
  The duration of the constant motion phase is an optional parameter. If the constant motion phase is not specified, the **_move()** command triggers a continuous motion that must be overridden by a **_stop()** command or another motion command.
- Dynamic response parameters

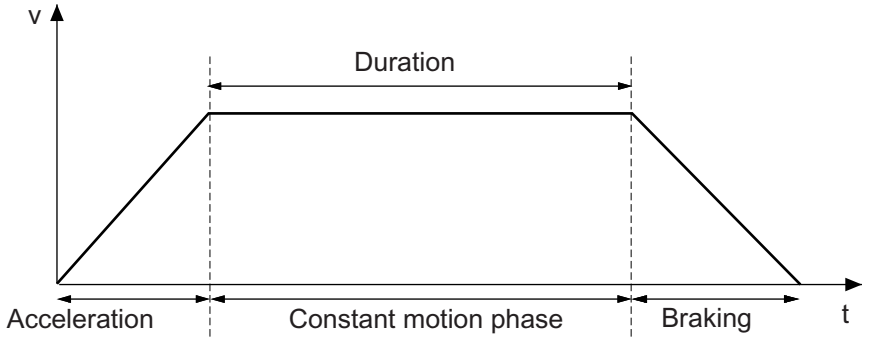

Figure 4-868 Phases for moving with _move()

An acceleration phase or a deceleration phase can be ended with jerk control using the **velocityType=RESULTING** parameter. The resulting velocity is then retained.

See also

Velocity profiles (Page 2992)

Defining accelerations and decelerations (Page 2995)

Positioning

The axis is moved to a target position via a parameterizable velocity profile. The entry in the target position is monitored.

See also

Positioning and standstill monitoring (Page 2941)

Positioning with blending

Blending is a special way of linking the positioning motion programmed in the command to a previous positioning motion. Unlike overriding, the previous motion command is completed up to the target position, where the transition occurs. Blending takes place between two positioning commands. The set velocity specified in the commands for each motion is never violated.

The previous positioning motion is performed at the velocity specified in the command up to the target position. **Exception:** If the velocity of the new positioning motion is less than the set velocity of the previous motion and both motions have the same sign, then the velocity of the previous positioning motion is reduced to the velocity of the new motion by the time the target position is reached.

In versions earlier than SIMOTION V4.4, the dynamic response is planned via two traversing blocks.

As of SIMOTION V4.4, the dynamic response is planned via three traversing blocks (current, next and next but one) for a newly created axis. It is therefore possible to plan a higher velocity if necessary for axis motion in the same direction. The setting is saved in the **DecodingConfig. commandsForAxisDynamics** configuration data element.

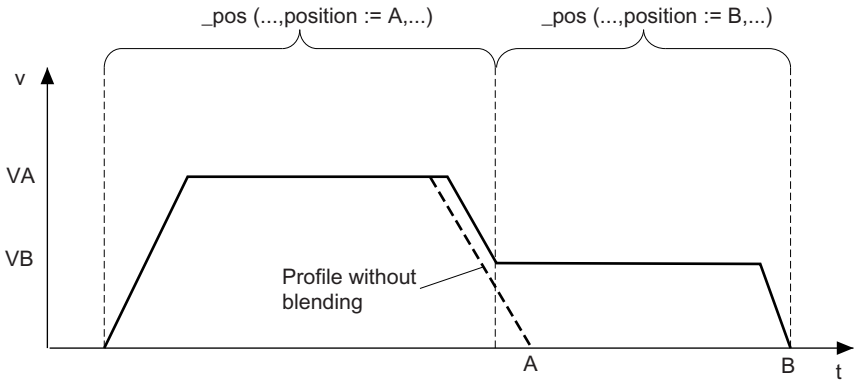

Figure 4-869 Blending when velocity of the subsequent motion is lower

If the direction is reversed, the previous positioning motion is slowed down at the target point, and transition to the new motion takes place immediately.

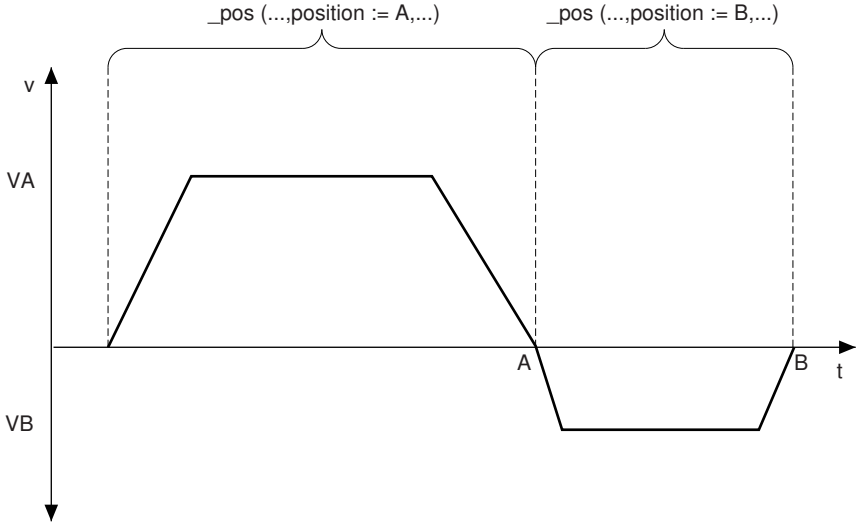

Figure 4-870 Blending when the subsequent motion reverses direction

If the absolute value of the velocity of the new command is greater than the velocity of the current motion, the velocity is increased after the transition to the new command, that is, after the previous target position is reached.

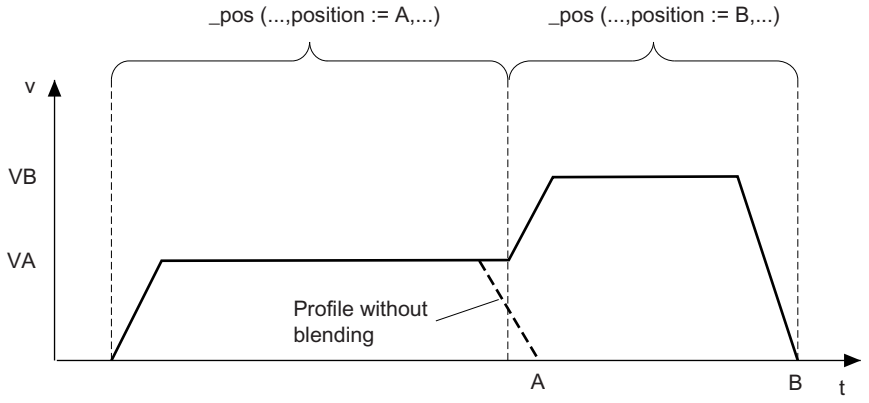

Figure 4-871 Blending when velocity of the subsequent motion is higher

Active blending requires **mergeMode**= NEXT_MOTION or SEQUENTIAL in the command where blending is to take place, plus timely decoding of the command. If the command in which blending is to be carried out is not known to the interpolator at the deceleration starting point of the current motion, the braking ramp is traveled.

The braking distance is always adhered to, even if the path length of the subsequent motion command is shorter than the required braking distance.

Acceleration at the command transitions

Versions before SIMOTION V4.4 are limited by the fact that acceleration is zeroed on blending with programmed, constant acceleration curve (SMOOTH) at the transition to the new command.

As of SIMOTION V4.4, it is possible to use the **DecodingConfig.blendingAcceleration** configuration data element to set that the acceleration at the transition to the new motion command is not zeroed if not necessary for the overall motion. In a newly created axis, WITHOUT_REDUCTION is the default.
When reversing, the acceleration is always zeroed regardless of this setting. Reversing here means that the direction of motion of the axis changes at the blending point.

Superimposed positioning

Superimposed positioning is performed in the superimposed coordinate system of the axis. The target position can be specified as an absolute or relative position in this coordinate system. (For feedback of the target position, see **Superimposed motion**)

The superimposed motion has its own programmable dynamic response parameters. The **userDefault** settings of the dynamic response parameters are identical to the settings of the main motion. Blending conditions for the superimposed motion are ignored.

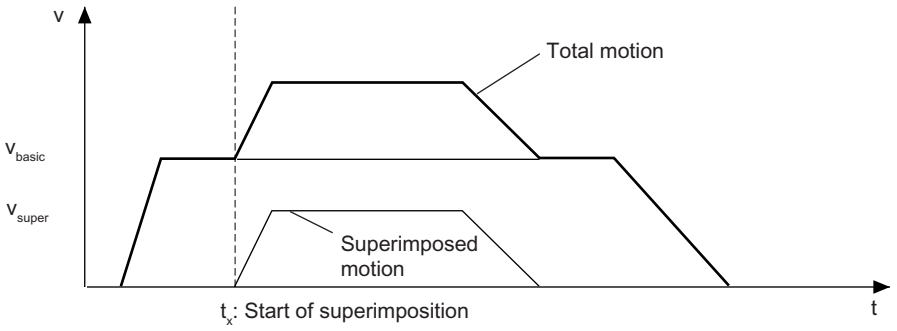

Figure 4-872 Superimposed positioning

See also

Superimposed motion (Page 3008)

Traversing with specific motion profiles

In addition to traversing/positioning via system functions, the axis can also be traversed via user-defined profiles/specific profiles.

See also

Overview of traversing with user-defined motion and force/pressure profiles (Page 3040)

Traversing according to motion vectors (V3.2 and higher)

The axis can be traversed directly in accordance with the specification on the MotionIn interface.

The MotionIn values can be directly picked up by another technology object, e.g., axis, external encoder, adding object, formula object, fixed gear. Alternatively, the MotionIn values can be specified via the default values from the user program.

The **_runPositionBasedMotionIn()** command activates the MotionIn interface with position-reference and **_runVelocityBasedMotionIn()** activates the MotionIn interface with velocity-reference. The MotionIn interface is replaced by motion commands, such as **_move()**, **_pos()**, **_stop()**, and **_stopEmergency()** or it can have an overriding effect itself.

Options for linking drive and position-controlled axes (position axes, following axes) to the motion vector:

- Linking position-controlled axis to motion vector (based on: position)
- Linking position-controlled axis to motion vector (based on: velocity) in position-controlled or velocity-controlled mode
  In this way, a position-controlled axis (position axis) is linked to a drive axis.
- Linking drive axis to motion vector (based on: velocity)
  This links a drive axis to a drive axis.

The MotionIn values can also be directly specified cyclically via the default variables.

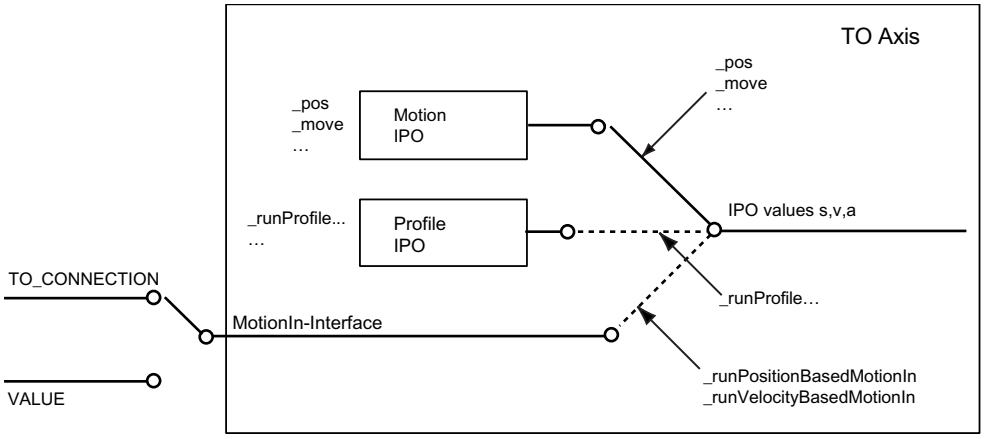

Figure 4-873 How the MotionIn interface works

Property

- Cyclical inclusion of MotionIn interface values
- Superimposition and overriding motion are possible
- Dynamic response parameters can be predefined in the commands for moving to the MotionIn values and for stopping
- The dynamic response can be limited via configuration data
- The MotionIn interface on the axis is multipoint-capable
- The reference TO is specified in the activation command
- It is then possible to switch to the reference TO

Note

Further information is available under Interconnection of technology objects in the Motion Control Basic Functions Function Manual.

Jerk limitation for local stop response (V3.2 or higher)

Local stop responses (stop responses triggered by alarm responses) may optionally be applied with or without rounding and jerk limiting.

The **decodingConfig.StopWithJerk** configuration data element can be used to specify whether the maximum jerk limitation of the Axis technology object is taken into account.

The jerk is only taken into account for IPO stops.

The jerk is determined from the minimum of the **plusLimitsOfDynamics**/ **minusLimitsOfDynamics** system variables and the **maxJerk** configuration data element.

4.8.3.14 Superimposed motion

Superimposed motion is defined with mergeMode=SUPERIMPOSED_MOTION_MERGE.

Superimposed motions are independent motions.

Superimposed motions cancel each other.

Superimposed motions can be stopped and continued separately.

Superimposed motions on a position axis are executed in the superimposed axis coordinate.

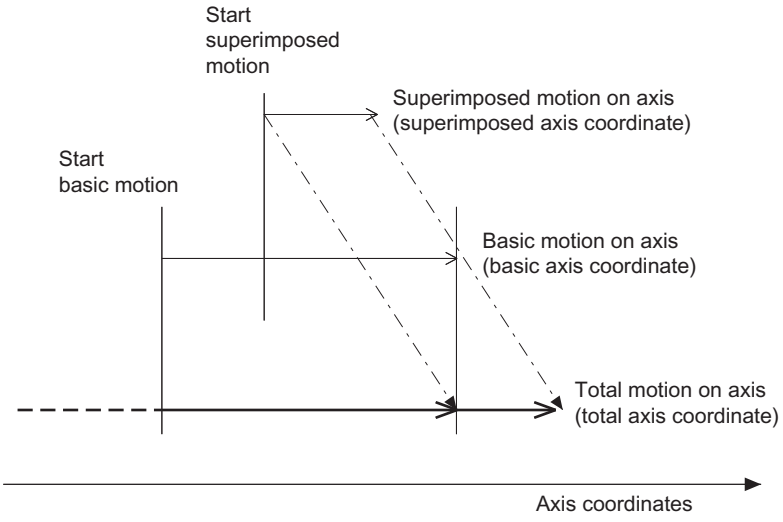

Figure 4-874 Functional diagram for motion transition SUPERIMPOSED_MOTION_MERGE

Commands that allow superimposed motions on the axis include:

_move()
_pos()
_runTimeLockedVelocityProfile()
_runTimeLockedPositionProfile()

Note

Only one superimposed motion can be active on the axis at a given time, e.g. superimposed positioning motion or superimposed synchronous operation.

Note

The dynamic limits always relate to the overall dynamic response. This may result in the superimposed motion having a dynamic response that is not as good as that defined in the specifications.

The superimposed motion is carried out in the superimposed axis coordinate as relative or absolute motion, depending on how it was programmed. Likewise, the basic motion of the axis is executed in the basic axis coordinate as an absolute motion or a relative motion, depending on the programming.

The timing of the feedback of the superimposed axis coordinate to the basic axis coordinate is set in the **decodingConfig.transferSuperimposedPosition** configuration data element; this

setting also specifies when superimposed motions are applied to the basic motion and, thus, when they are overridden. When the criterion becomes effective, the basic motion accepts the superimposed motion component.

Possible settings:

- Only on axis reset with _resetAxis()
- On axis reset and on each overriding command where mergeMode= IMMEDIATELY
- On axis reset, on each overriding command where mergeMode=IMMEDIATELY, and on each axis standstill motionStateData.motionStat=STANDSTILL

In addition, the superimposed axis coordinate/motion is fed back to the basic axis coordinate in the following cases:

- The axis switches into or out of follow-up mode.
- Switchover occurs between speed-controlled, position-controlled, and force-/pressure-controlled operation.
- For force-/pressure-controlled operation

Absolute and/or relative traversing is possible in the basic axis coordinate and in the superimposed coordinate. The total motion of the axis results from adding the position values, velocity values, and acceleration values of the basic motion and the superimposed motion together.

Notes on working with the superimposed axis coordinate

During active homing, a superimposed axis coordinate is always reset.

An active superimposed motion is aborted during active homing.

Display of current axis coordinates

The values/dynamic response vector of the basic axis coordinate and the superimposed coordinate are displayed on the axis.

These coordinates can be read via the following system variables:

- Total axis coordinates:
  positioningState.commandPosition: Set position (total)
  motionStateData.commandVelocity: Set velocity (total)
  motionStateData.commandAcceleration: Set acceleration (total)
- In basicMotion, the values of the basic axis coordinate are displayed on the axis.
  basicMotion.position
  basicMotion.velocity
  basicMotion.acceleration
- In superimposedMotion, the values of the superimposed axis coordinate are displayed on the axis.
  superimposedMotion.position
  superimposedMotion.velocity
  superimposedMotion.acceleration

4.8.3.15 Torque limiting via torque reduction

Overview of torque limiting via torque reduction

On the electric axis, torque limiting is available via a torque reduction. The limit value is specified in the command.

This function can be used with a drive axis, a position axis and a following axis. The accuracy depends on the drive used.

To be able to use the function, the PROFIdrive telegram type 10x (apart from telegram 101) must be set. It also requires the use of a drive that supports the function. As of V4.2, 10x telegrams are used with automatic telegram definition.

When the function is called, the desired torque (for rotary and linear axes) or the desired force (for linear axes only) is specified in the corresponding unit or as percentage relative to a reference value (**userDefaultTorqueLimiting.torqueLimit**). 0% means no torque on the drive and 100% means full torque on the drive.

The torque limiting is transferred to the drive as a torque reduction in the PROFIdrive telegram. If, for example, 80% is specified for the torque limiting, SIMOTION calculates the value 20(%) for the torque reduction for the drive and transfers this value to the drive via the PROFIBUS interface.

The limitation acts as an absolute value and thus has the same effect on both positive and negative torque.

If torque limiting is active, the following error monitoring and positioning monitoring functions are deactivated.

Active motion commands and synchronous operation relationships continue to be executed.

The limiting functions can be activated before a motion or simultaneously with a motion and can be switched by reissuing the command.

The position-related monitoring can remain active even with active torque limiting. For this purpose, there is the **TypeOfAxis.ServoMonitoring.motionMonitoringWhenTorqueLimiting** configuration data as of V5.1. When activated, this ensures that the position monitoring, positioning monitoring and/or following error monitoring that was active before the torque limiting remains active during the limiting.

As a result of torque limiting, for example, a greater difference between actual and target values can build up on the position-controlled axis, which can cause the axis to accelerate (in order to reduce the difference) even if the velocity calculated by the interpolator is now lower.

Please note that if an axis is ready as a result of active torque limits/torque reduction, the control difference to the position reference value is initially canceled and then the **_stop()** command is terminated, despite a position-controlled stop motion. Alternatively, you can enter a speed-controlled **_stop()** command.

If, for example, torque limiting is not required during the acceleration phase, the function must not be activated until after the acceleration phase; otherwise, the acceleration must be reduced.

Value specifications and transferring from the drive

The maximum values **SetpointDriverInfo.DriveData.maxTorque** and **SetpointDriverInfo.LinearMotorDriveData.MaxForce** are the reference values for the transmission of the obtained torque reduction to the drive and must be entered in the drive and in SIMOTION in accordance with the motor values.
With SINAMICS, the parameters are present in P1520, P1521, and P2003:
~.DriveData.maxTorque = P1520 = |P1521|
If the technology data block (Page 3018) is interconnected, the following applies: **~.DriveData.maxTorque** = P2003

As of V4.2

The above still applies for the setting **SetpointDriverInfo.DriveData.TorqueReference** = MAX_VALUE or **SetpointDriverInfo.LinearMotorDriveData.ForceReference** = MAX_VALUE.

For SINAMICS and round-frame motors, and for the setting **SetpointDriverInfo.DriveData.TorqueReference** = NOMINAL_VALUE and **SetpointDriverInfo.DriveData.SpeedReference** = NOMINAL_VALUE, the following applies:

- **~.DriveData.nominalSpeed** = P2000
- **~.DriveData.MaxSpeed** = P1082
- **~.DriveData.nominalTorque** = P2003
- **~.DriveData.MaxTorque** = P1520

For SINAMICS and linear motors, and for the setting **SetpointDriverInfo.LinearMotorDriveData.SpeedReference** = NOMINAL_VALUE and **SetpointDriverInfo.LinearMotorDriveData.ForceReference** = NOMINAL_VALUE, the following applies:

- **~.LinearMotorDriveData.nominalSpeed** = P2000
- **~.LinearMotorDriveData.MaxSpeed** = P1082
- **~.LinearMotorDriveData.nominalForce** = P2003
- **~.LinearMotorDriveData.MaxForce** = P1520.

By default, these settings are transferred by the drive during the assignment of the axis to a SINAMICS drive by the system as of V4.2.

By default, the settings for torque granularity (see below as well) are transferred by the system from the drive:

~.driveData.torqueReductionGranularity = P1544

~.LinearMotorDriveData.ForceReductionGranularity = P1544

Enabling/disabling

The limiting function is disabled by default and must be specifically activated.

The torque limiting is activated using the **_enableTorqueLimiting()** command and has the following effect:

- The reduced maximum torque limit is in effect immediately
- The following error and positioning monitoring are disabled

With the function parameter **torqueLimitType**=USER_DEFAULT (system default), the default torque limit value set in the **userDefaultTorqueLimiting.torqueLimit** system variable is used. This default can be modified by entering a value in the **torqueLimit** parameter. The value of the parameter is interpreted as a percentage.

With the setting **torqueLimitType**=DIRECT, the value is specified as torque or force based on the **torqueLimitUnit** parameter. Depending on the **torqueLimitUnit** parameter, this value refers to the load or the motor side. For more information, see Conversion of torque/force (Page 3014).

The torque reduction is not disabled with **_disableAxis()**; it must be explicitly disabled via a command.

It is disabled/canceled

- With **_disableTorqueLimiting()**
- In the case of **_resetAxis()**, **_restartAxis()**, etc.
- In the case of a transition to STOP

Suppression of the "Speed alignment" fault message of the drive

If torque reduction is enabled and the value is not equal to 0, the fault message of the drive (discrepancy between actual speed and the speed setpoint) is suppressed.

If the fault message is also to be suppressed when the torque reduction is disabled or when the torque reduction is enabled and the value is equal to 0, bit 8 in STW2 can be set for message suppression using the **_setAxisStw()** function.

The setting via the **_setAxisStw()** function has a storing effect, i.e. it is kept during and after the period that a torque reduction is activated.

Special features

- The commands for torque limiting (**_enableTorqueLimiting()**) and travel to fixed endstop (**_enableMovingToEndStop()**) cannot be active simultaneously.
  The transition from _enableTorqueLimiting() to **_enableMovingToEndStop()** is permitted (and has an override effect).
  The transition from **_enableMovingToEndStop()** to **_enableTorqueLimiting()** is not permissible since the setpoint must be clamped when retaining the torque in the fixed endstop.
- The **_stopEmergency()** command:
  If a motion is ended with position control (movingMode = POSITION_CONTROLLED) with the **_stopEmergency()** command, the stop ramp is generated from the current set position in stop modes STOP_IN_DEFINED_TIME, STOP_WITH_DYNAMIC_PARAMETER, and STOP_WITH_MAXIMAL_DECELERATION.
  If a following error has built up at this time due to active torque limiting, it is removed, and as a result, the axis does not come to an immediate standstill.
  For this reason, if you are using torque limiting, you should stop the motion with speed control (movingMode = SPEED_CONTROLLED). Alternatively, you can select the WHEN_COMMAND_VALUE_ZERO stop mode for stopping the motion with position control.
  An active torque reduction (including when moving to a fixed end stop) is retained.
  Exception:
  The **_stopEmergency()** command with stopDriveMode = STOP_WITH_COMMAND_VALUE_ZERO disables the torque reduction, and the travel to fixed endstop command is aborted.
- When torque limiting is active, the following error monitoring is disabled.
  As a result of torque limiting, for example, a greater difference between actual and desired values can build up on the position-controlled axis, which can cause the axis to accelerate (to reduce the difference) even if the velocity calculated by the interpolator is now lower.
  If, for example, torque limiting is not required during the acceleration phase, the function must not be activated until after the acceleration phase; otherwise, the acceleration must be reduced.
- The torque limits B+ / B- and the torque reduction must not be active simultaneously.

Status displays

Table 4-357 Status display variables

Variable	Meaning
TorqueLimitingCommand.State	
	Indicates the torque limiting state. ACTIVE: Torque limiting activated INACTIVE: Torque limiting deactivated
TorqueLimitingCommand.torqueLimitingState	
	Here, it is indicated if the drive is running at the torque limit. **Note:** This state is derived from the PROFIdrive profile status word 'MeldW' (PZD 5), bit 1 (M < Mx) of the drive.

Assignment of the resolution in the drive

Table 4-358 System data

SIMOTION system data	Meaning
userDefaultTorqueLimiting.torqueLimit	
	This data element specifies the user default setting of the torque limit value for the torquelimit function parameter in the _enableTorqueLimiting() command. This value is accessed when the command contains the USERDEFAULT setting. System default: 10.0

Setting the resolution in SIMOTION

The resolution of the torque reduction to the drive can be set, as of V4.0,
in **driveData.torqueReductionGranularity** or
in **linearMotorDriveData.forceReductionGranularity**.
In terms of value transfer, also consult the above section *Value specifications and transferring from the drive*.

Possible settings:

- BASIC (default, 1% resolution)
  64H in PZD (PROFIdrive telegram) is a torque reduction of 100%.
  - SINAMICS
    Setting required: P1544 = 16384.0
  - SIMODRIVE 611U
    Standard setting: P0881 = 16384.0
- STANDARD (~0.006% resolution)
  4000h in PZD (PROFIdrive telegram) is a torque reduction of 100%.
  - SINAMICS
    Standard setting: P1544 = 100.0
  - SIMODRIVE 611U
    Setting required: P0881 = 100.0

Note

Be sure to set the values in the drive consistently.

See also

Enabling and disabling torque limiting (Page 3162)

Conversion of torque/force

Speed-controlled axes and rotary axes

When the **_enableTorqueLimiting()** function is programmed, there is always a torque specified in Nm, kNm or MNm.

If the TORQUE setting is specified when calling the function with the **torqueLimitUnit** function parameter, the specified torque refers to the motor. The gear ratio is not taken into account.

If the DEFAULT_UNIT setting is selected in the function parameter **torqueLimitUnit**, the torque refers to the load side and the gear ratio is taken into account. The following conversion formula applies:

$M_{Load} = M_{Motor}$ x (motor revolution/load revolution)

Linear axes with standard motor

In the **_enableTorqueLimiting()** function, the following can be optionally specified: a torque in Nm, kNm or MNm in relation to the motor, or a force in N, kN or MN in relation to the load side.

If the TORQUE setting is specified when calling the function with the **torqueLimitUnit** function parameter, the programmed value is interpreted as torque in relation to the motor. The gear ratio, leadscrew pitch, and efficiency of the leadscrew are not taken into account.

If the DEFAULT_UNIT setting is selected in the function parameter **torqueLimitUnit**, the programmed value is interpreted as force in relation to the load side. The gear ratio, leadscrew pitch, and efficiency of the leadscrew are taken into account in this setting. The following conversion formula applies, whereby **S** is the leadscrew pitch (adjustable in **leadscrew.pitchval**) and η is the efficiency of the leadscrew (adjustable in **leadscrew.efficiency**):

$F = M_{Motor}$ x 2 x π x ($\eta_{Leadscrew}$ / S) x (motor revolution/load revolution)

Linear axes with linear motor

There is always a force in N, kN or MN specified when programming.

4.8.3.16 Travel to fixed endstop

The **_enableMovingToEndStop( )** function activates the monitoring of **travel to fixed endstop** in parallel with an axis motion activated by a motion command and the retention of a clamping torque once the fixed endstop has been reached. The operation is also referred to as **clamping**.

This function requires that torque reduction be supported by the digital coupled drive.

Positioning with an immediate step enabling condition must take place first (position-controlled traversing).

During configuration, a setting can be made in **clampingMonitoring.recognitionMode** to define which of the following methods is to be used for detecting that the fixed stop has been reached:

- The following error limit is exceeded
- The torque limit is exceeded (evaluation of the **| M | < M**x message bit in the PROFIdrive telegram / status word (message word bit1 for SIEMENS telegram 101, 102, 103, 104, 105, 106, 125 and 126))
  As of V4.2, 10x telegrams are used with automatic telegram definition.

If the criterion is met, the fixed endstop status is regarded as having been reached, the **movingToEndStop.clampingState**= ACTIVE system variable is enabled, and the clamping tolerance is activated. Following error monitoring is switched off as soon as the command

becomes effective. The setpoint at the input of the position controller is maintained. Provided that the position of the fixed endstop does not change, the difference between the setpoint and actual value remains the same.

Note

The position-related monitoring can remain active with TypeOfAxis.ServoMonitoring.motionMonitoringWhenTorqueLimiting even with active torque limiting.

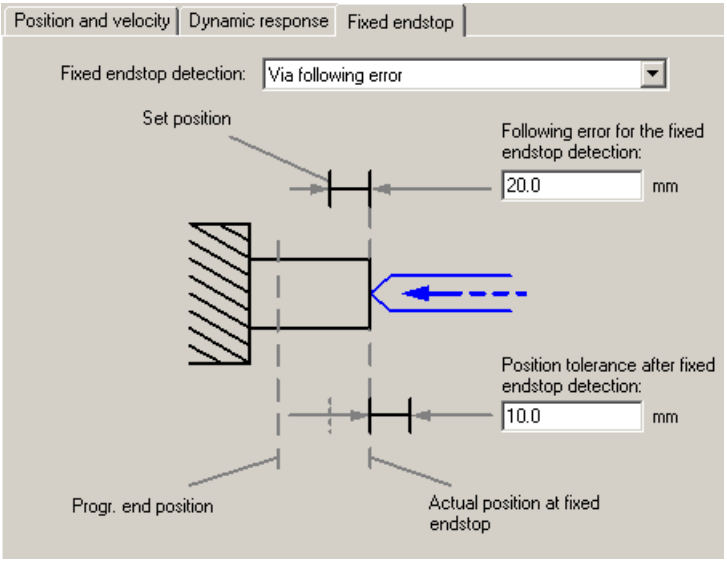

Figure 4-875 Function and parameters for travel to endstop with detection of fixed endstop by means of following error

The motion command is aborted with an error message; closed-loop control remains active. The setpoint at the input of the position controller is clamped. For new motion commands, the clamping set position is used as the start position. Motion commands in the direction of clamping are aborted. Motion commands in the opposite direction to the clamping direction are executed, thereby reducing the torque.

Travel to fixed stop is canceled when the clamping tolerance window is exited.

Issuing the **_enableMovingToEndStop()** command again can cause the torque to switch over, even if clamping is active.

The following commands cancel the function:

- **_resetAxis()**
- **_disableAxis()**
- **_disableMovingToEndStop()**
  - Up to and including V4.1 SP3: Cancel if outside the clamping window
  - As of V4.1 SP3 HF4: Cancel always
- **_cancelAxisCommand()** as of V4.1 SP3 HF4

Non-stepped torque transitions and torque retention over a defined time period can be implemented in the user program, as can specification of torque profiles.

Note

If the clamping torque is increased during clamping (by a new **_enableMovingToEndStop()** command), then this torque might not be achieved. Position control is active, but no more setpoints are generated for a motion in the direction of clamping.

The **_disableMovingToEndStop()** command deactivates the **Travel to fixed endstop** function. The **_disableMovingToEndStop()** command has no effect while clamping is active. The **_disableMovingToEndStop** command can be issued in parallel to position-controlled motion.

If a breakaway of the fixed endstop occurs, the position controller abruptly reduces this difference. This response is used for monitoring purposes. Clamping monitoring saves the current actual value that applies at the time of clamping. The clamping tolerance window then wraps around this value (see the figure above). This is why the clamping tolerance value should be lower than the setpoint/actual value difference at the point when clamping is detected. An error is only detected if the axis leaves the clamping tolerance window during abrupt reduction of the setpoint/actual value difference. In this case, a 50108 alarm is triggered.

If the clamping tolerance window is exited, **alarm 50108: Clamping monitoring error** is triggered and the **travel to fixed stop** is aborted.

In the command, the limiting force for the clamping value is set in [N] for linear axes, while for rotary axes, the limiting torque is set in [Nm].

If the **_enableMovingToEndStop()** command is active and the fixed stop has not been detected, the system behaves the same as with active torque limiting.

The **_enableMovingToEndStop()** and **_enableTorqueLimiting()** commands cannot be active simultaneously.

The transition from "torque limiting" (**_enableTorqueLimiting()**) to "travel to fixed stop" (**_enableMovingToEndStop()**) is permitted (and has an override effect), but the reverse is not permitted.

System variables

Table 4-359 System variables for travel to fixed stop

Variable	State	Meaning
MovingToEndStopCommand.state	ACTIVE / INACTIVE	Command status
MovingToEndStopCommand.clampingState	ACTIVE / INACTIVE	Clamping torque reached status

Note

In the case of travel to fixed stop with fixed stop detection by means of the following error, the entry for the position tolerance applicable to the fixed stop detection should be significantly less than the entry for the following error for the fixed stop detection.

Note

If the "travel to fixed stop" function is to be used in combination with the RecognitionMode=CLAMP_WHEN_TORQUE_LIMIT_REACHED setting, the following setting must also be made on the 611U and in SINAMICS:

- 611U
  Set parameter P1426 ("tolerance band for nset = nact message") to the maximum speed of the drive (P880).
- SINAMICS
  Set parameter P2163 ("Speed 4 threshold value") to the maximum possible value.
- Axis with digital drive link and no setting of a 1xx telegram (i.e. telegram without torque reduction and without actual torque identification)
  The "travel to fixed stop" functionality is only possible by means of the following error criterion.

You will also find further information about travel with torque limiting and travel to fixed stop in the corresponding drive documentation.

Overview of torque limiting via torque reduction (Page 3010)

4.8.3.17 Technology data

Technology data can be specified cyclically from the controller to the drive or read cyclically by activating the technology data block.

The technology values are needed to implement winder functionality with SIMOTION, for example.

The setting of the motor type determines whether the physical quantity is force or torque (round-frame motor: torque, linear motor: force).

For more information, refer to *'LREAL' interconnection interface type* in the **Motion Control Basic Functions** manual.

The **additive data block 1** contains:

- Controller → drive:
  - Additive torque setpoint: 16 bits
    (display of the value in the **additiveTorque.value** system variable)
  - Positive torque limit (B+): 16 bits
    (display the value in the **torqueLimitPositive.value** system variable)
  - Negative torque limit (B-): 16 bits
    (display of the value in the **torqueLimitNegative.value** system variable)
- Drive → controller:
  - Actual torque value: 16 bits
    (display of the value in the **actualTorque.value** system variable)

As of SIMOTION V4.2, the technology data block is set up and connected automatically.

The technology data is appended as INT to the In/Out drive protocol. This is activated in the **technologicalData.enable** configuration data element.

The logical addresses for the technology data are displayed in the **technologicalDataOutInfo** and **technologicalDataInInfo** configuration data elements.

- They are set when the telegram is specified in the axis wizard. (When you set the axis telegram in HW Config, the relevant data must be created via the PZD area.)

The values B+, B- and additive torque setpoint

- Are indicated and entered according to their associated units.
- Are normalized to the specified maximum values (maxTorque, maxForce) before they are transferred to the drive and are sent to the drive as % values.
- Can be sent to the drive as values from 0 to +/- 200%.

The positive and negative torque limits (torqueLimitPositive (B+), torquelimitNegative (B-)) are sent as a weighting, rather than as a reduction.

The values are sent with reference to the 100% value:

- 4000H corresponds to 100%
- 7FFFH corresponds to 200%

Negative values are possible.

Note

The **SetpointDriverInfo.DriveData.maxTorque** or **SetpointDriverInfo.LinearMotorDriveData.MaxForce** configuration data and the P2003 parameter on the drive serve as normalization basis on the axis. The values must be equal.

See also Chapter Overview of torque limiting via torque reduction (Page 3010)
Section *Specification of the values and transfer from the drive*.

Creating technology data block 1 (e.g. with SINAMICS drive):

The drive has already been configured.

Telegram extension (as of V4.2)

As of V4.2, with SINAMICS drives and the **Use symbolic assignment** SCOUT setting (default setting) activated, telegram extension is set automatically by the system.

Telegram extension in HW Config (up to V4.1 SP1)

- Set standard telegram for the drive, then add to the PZD via Details:
  - Input: +1 (PZD)
  - Output: +3 (PZD)
- Save HW Config

Telegram extension in SCOUT (as of V4.1 SP1)

- In the project navigator, select the drive device (e.g. "SINAMICS_Integrated") and open the configuration:
  Project - CPU (e.g. D435) - drive device (e.g. SINAMICS_Integrated) - configuration
- Mark the line of the drive, e.g. "Drive_1"
- Click the "Insert line" button and select "Telegram extension"
- Set one word for the input data and three words for the output data
- Click the "Transfer to HW Config" button and confirm the comparison with HW Config
- Click the "Configure telegram" button
- For "PROFIBUS receive direction" and "PROFIBUS send direction", enter the telegram extension according to the table below at:
  Project - CPU (e.g. D435) - drive device (e.g. SINAMICS_Integrated) - Drives - Drive_x - Communication - PROFIBUS

Table 4-360 BICo interconnections

PROFIdrive telegram - receive direction		
	1st additional PZD (M_Add)	P1511
	2nd additional PZD (B+)	P1522
	3rd additional PZD (B-)	P1523
PROFIdrive telegram - send direction		
	1st additional PZD (M_act)	E.g. R0080 (actual torque value)

The values are normalized in the drive via P2003.

NOTICE
Scaling of additional torque 1 Parameter P1512 "Additional torque 1 scaling" must be interconnected so that additional torque (M_Add) is transferred correctly. Values from 0 to 100% can be set. A scaling factor of 100% corresponds to the transfer of the value configured in M_Add.

Activation in SIMOTION

The technology data block is created when the axis is configured.

The technology data block can only be assigned correctly by the system for active symbolic assignment, manual telegram setting and deactivated automatic telegram extension when the correct BICO interconnection for the technology data block is available on the drive side.

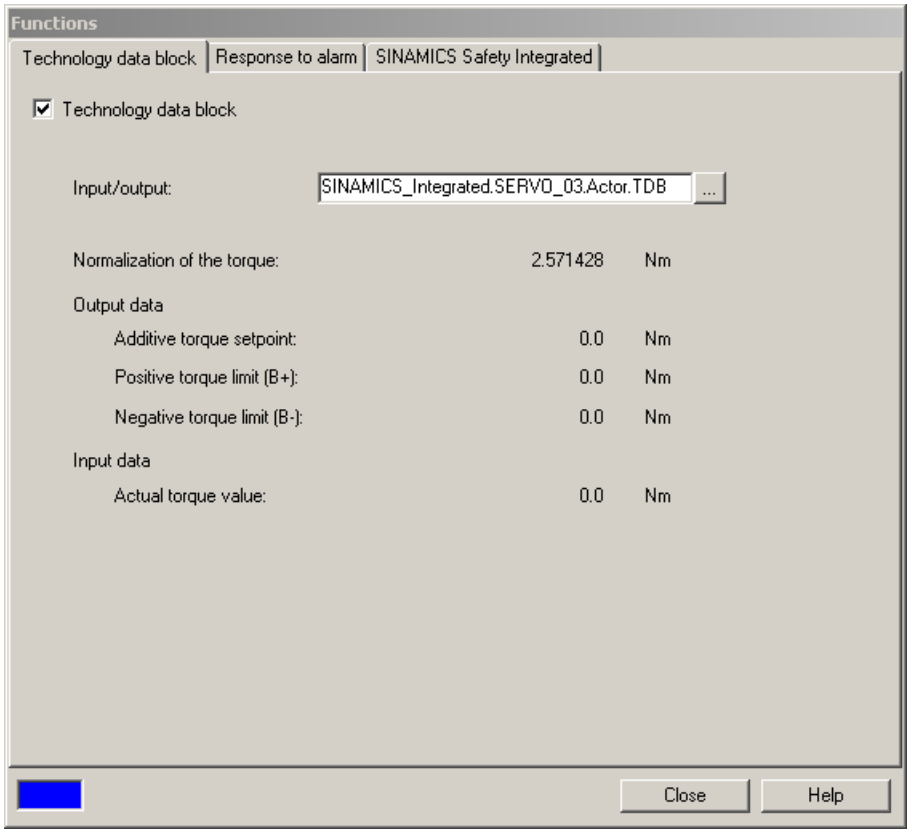

Figure 4-876 Activating a technology data block

Alarms

20005 "Logical address of technology data block driver not found"

The limiting values and additive values are initialized/transferred regardless of the activation and error status of the axis.

4.8.3.18 Torque limiting B+/B- (V3.2 and higher)

The torque limits B+/B- can be cyclically specified on the electric axis downstream of the speed controller using the expanded drive message frame to the drive.

As a prerequisite, the technology data block (Page 3018) must have been activated on the electric axis. The torque limits B+ and B- are set downstream of the speed controller.

By specifying the upper limit B+ and the lower limit B-, it is possible to enter a specific range that does not have to be symmetrical with respect to the zero position.

The limit values can be predefined on the axis directly by means of cyclically effective system variables. These values can be preset.

The limit values can also be defined on the axis by means of interconnection with other technology objects.

The B+ value and the B- value can be interconnected by means of an LREAL interface or an LREAL connector (using a formula object or a controller object, for example).

See also:

- **SIMOTION Supplementary Technology Objects** function description
- **Motion Control Basic Functions** Manual, Sections *Interconnection using general interconnection dialog box* and *'LREAL' interface type*

Note

If the manipulated variable is inverted on the Axis technology object, then B+/B- are also reversed on the Axis technology object. You must take this into account when specifying the torque limits B+/B-.

Units

The unit settings are used.

The physical quantity depends on the type of motor:

- For rotary motors: Torque [Nm]
- For linear motors: Force [N]

Commands and effectiveness

The limiting is deactivated by default and has to be explicitly activated.

The torque limits are activated using the **_enableAxisTorqueLimitPositive()** / **_enableAxisTorqueLimitNegative()** commands.

The command specifies whether the limits relate to the interconnected value, the system variable or a value defined on the command itself. If they relate to the system variable, then this is applied cyclically; in other words, a change in the system variables takes effect immediately.

If torque limitation B+/B- is activated using the above commands, this will deactivate the following monitoring and limiting functions:

- Following error monitoring
- Velocity error monitoring via reference model
- Time-outs for positioning monitoring and standstill monitoring

The torque limits are not disabled with **_disableAxis()**; they must be disabled explicitly using a command.

The torque limits are deactivated or aborted using the following commands:

- **_disableAxisTorqueLimitPositive()** / **_disableAxisTorqueLimitNegative()**
- **_resetAxis()**, **_restartAxis()**, etc.
- In the case of a transition to STOP

If the function is not activated, the maximum torque and maximum force are output via the interface in accordance with **maxTorque** and **maxForce**.

With activated torque limiting B+ / B- (**_enableAxisTorqueLimitPositive()** / **_enableAxisTorqueLimitNegative()**), as of V4.2, with setting **TypeOfAxis.SetPointDriverInfo.DriveData.torqueReference**, the = MAX_VALUE maximum of the set value in **~.DriveData.maxTorque** or **maxForce** is transferred to the drive.

In the versions <V4.2 up to 200% of this value are possible with activated torque limitation.

If the torque limiting function B+ / B- is not activated, the maximum value set in **~.maxTorque** is transferred in V4.2 as well as in versions <V4.2.

When using the technology data block and with the setting **~.torqueReference** = MAX_VALUE in **~.maxTorque** , the 100% reference value for torque transmission to the drive must be set, i.e., for the value corresponding to p2003 (reference torque), a greater maximum torque is possible in the drive, in accordance with the value in p1520 (maximum torque).

The separation of reference and maximum torque has been introduced in the reference variables with V4.2.

In projects with V4.2 or higher, the new configuration data **~.torqueReference** is set to MAX_VALUE. As such, only the reference torque value can be set as maximum torque limitation without changing projects.

Remedy:

If, in the case of activated torque limiting, a value greater than the reference value in p2003 is transferred to the drive**, ~.torqueReference** = NOMINAL_VALUE needs to be set, in **~.nominalTorque** the value corresponding to p2003 and in **~.maxTorque** the value corresponding to p1520 must be entered.

With the deactivated torque limiting function B+ / B, the set value in **maxTorque** is transferred to the drive.

For new TOs created in V4.2, **~.torqueReference** = NOMINAL_VALUE is set, as well as for the default set adaption the reference values for **~.nominalTorque** and **~.maxTorque** for runtime are transferred from the drive.

The position-related monitoring can remain active even with active torque limiting. For this purpose, there is the **TypeOfAxis.ServoMonitoring.motionMonitoringWhenTorqueLimiting** configuration data as of V5.1. When activated, this ensures that the position monitoring, positioning monitoring and/or following error monitoring that was active before the torque limiting remains active during the limiting.

System variables

Table 4-361 System variables for torque limitation

Variable	Meaning
torqueLimitPositiveIn	Value, state and validity of the interconnected positive limitation
torqueLimitPositiveInDefault	Default
torqueLimitNegativeIn	Value, state and validity of the interconnected negative limitation
torqueLimitNegativeInDefault	Default
torqueLimitPositive	Shows the programmed limit value
torqueLimitNegative	

Variable	Meaning
torqueLimitPositiveCommand	Command status / function status
torqueLimitNegativeCommand	
motionMonitoringWhenTorqueLimiting	The position-related monitoring is active during active torque limiting.

Suppression of the "Motor blocked" fault message of the drive

Message: **F07900 (N, A) drive: Motor blocked / speed controller at its endstop**

Cause: The motor has been operating at the torque limit for longer than the time specified in p2177 and below the speed threshold set in p2175.

If the fault message is to be suppressed, the **_setAxisStw()** function can be used once to set bit 8 in ctrl word2 for message suppression.

The setting via the **_setAxisStw()** function has a storing effect, i.e., it is kept during and after the period that a torque reduction is activated.

The p2175 (0.0) parameter to suppress the fault message on the drive.

Coupling of digital drives (Page 2895)

Technology data (Page 3018)

4.8.3.19 Additive set torque (V3.2 and higher)

An additive set torque can be transmitted to the drive on the axis.

This requires that an axis with digital drive link is used and that the technology data block (Page 3018) is activated.

The additive setpoint torque can be set on the axis directly using a cyclically effective system variable (**defaultAdditiveTorque**). This value can be preset.

The additive setpoint torque can also be defined on the axis by means of interconnection with other technology objects.
The additive torque can be interconnected by means of an LREAL interface or an LREAL connector (using a formula object or a controller object, for example).

See also:

- **SIMOTION Supplementary Technology Objects** function description
- **Motion Control Basic Functions** manual, *Interconnection using general interconnection dialog box* and *'LREAL' interface type* chapters

The function is activated via the **_enableAxisAdditiveTorque()** command. Without an activation, the transmitted additive torque is = 0.

The command specifies whether the limits relate to the interconnected value, the system variable or a value defined on the command itself. If they relate to the system variable, then this is applied cyclically; in other words, a change in the system variables takes effect immediately.

The **additiveTorque** configuration data element can be used to determine whether the last valid value or the replacement value is used if an interconnection value is activated but is invalid. After system start-up, the last valid value is 0.

The additive set torque can also be specified directly via the replacement value.

The replacement value can be preset.

This value takes effect immediately after a change if the function is active.

For more information, refer to *'LREAL' interconnection interface type* in the **Motion Control Basic Functions** manual.

Unit

The unit setting is used.

The physical quantity depends on the type of motor:

- For rotary motors: Torque [Nm]
- For linear motors: Force [N]

Commands

_enableAxisAdditiveTorque() enables the additive torque.

The additive set torque is not disabled with **_disableAxis()**; instead it must be explicitly deactivated via a command.

It is disabled/canceled

- with **_disableAxisAdditiveTorque()**
- In the case of **_resetAxis()**, **_restartAxis()**, etc.
- In the case of a transition to STOP

System variables

Table 4-362 System variables for the additive set torque

Variable	Meaning
additiveTorqueIn	Value, state and validity of the additive set torque
defaultAdditiveTorque	Default
additiveTorque	Value that is sent to the drive (before normalization)

Suppression of the "Motor blocked" fault message of the drive

Coupling of digital drives (Page 2895)

4.8.3.20 Force/pressure control

Overview of force/pressure control

Force/pressure control requires at least the **position axis technology**. If a hydraulic axis is used as a hydraulic drive axis, force/pressure control is also possible here.

Pressure control and force control are available on the position axis. The actual pressure or force value is measured using an external sensor. Several force/pressure sensors can be connected to the axis. The actual force/pressure values can be smoothed with a **PT1 filter**. A **PT2 filter** is available at the output of the pressure control.

The manipulated variable on the drive is still the speed or velocity setpoint.

Monitoring for maximum force, control deviation, force/pressure entry (see positioning monitoring) and force/pressure end value is performed on the actual value side. Limiting functions on the setpoint side include speed setpoint limiting (manipulated variable limitation) and anti-windup (I-component) with manipulated variable limitation.

Conditions can be specified in a specific activation command **_enableForceControlByCondition()** for switchover from position-controlled motion to force/pressure controlled status. The force/pressure setpoint or profile is specified using commands.

The commands for force/pressure control can also be programmed on the virtual axis. Commands that cannot be executed, such as activate force/pressure controller, position-related profile, or data set commands generate a technological alarm, **Technological alarm: 030015: Technology not configured**.

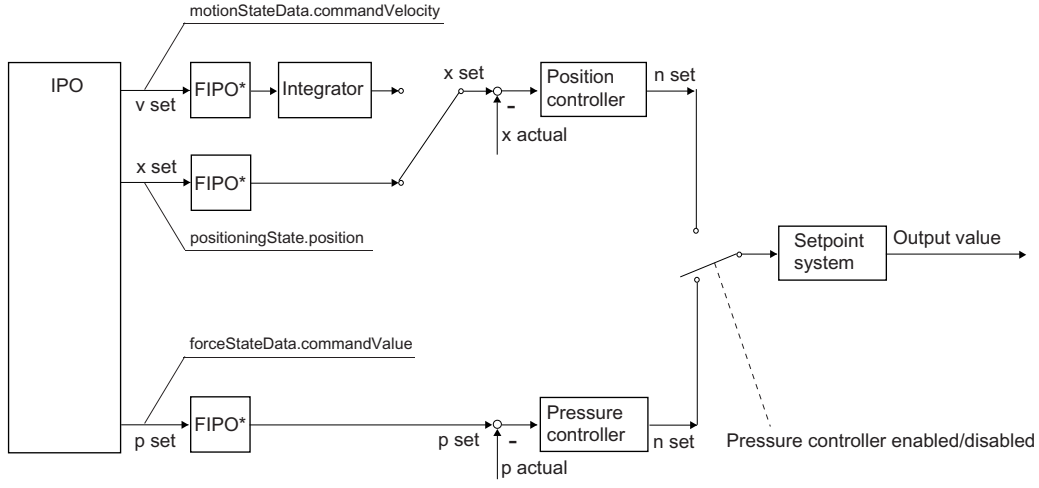

Figure 4-877 Overview of control structure for force/pressure control

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

You can call signal flow diagrams under the Axis object in the project navigator. The signal flow diagram illustrates the signal path and enables major items of configuration data and important system variables to be parameterized using the signal flow.

Possible operating modes with force/pressure control

- **Force/pressure control active, setpoint mode**
  Actual force/pressure value is controlled to force/pressure setpoint.
  Monitoring and limiting functions are active.
- **Force/pressure control active, follow-up mode**
  Force/pressure setpoint is controlled to actual force/pressure value.
  Force/pressure monitoring and limiting functions are not active in follow-up mode.
- **Program simulation**
  (analogous to positioning mode)
  Force/pressure setpoints are calculated but not output.
  Actual force/pressure value is set to force/pressure setpoint.
- **Velocity-limited mode**
  The closed-loop force/pressure control or open-loop force/pressure control is the master. The velocity is limited in parallel.

Remark

While the force/pressure controller is active, the position values of the IPO are corrected.

Switchover between position-controlled motion and force/pressure-controlled motion is performed by the application.

Fine interpolation

The force/pressure values undergo linear fine interpolation (V4.1 SP1 and later).

See also

Force/pressure control with hydraulic speed-controlled axes with Q valve only (Page 3136)

Technology data (Page 3018)

Configuration of the actual force/pressure value sensors

More than one pressure or force sensor can be configured.

The various sensors can be of different types and have different interfaces. The sensor for the transition criterion can be specified in the switchover command.

There can be up to eight (8) sensors for the force/pressure value on the axis and up to eight (8) binary inputs on the axis, for example, for switchover criteria.

Because the sensor can be accessed via the logical address, the same sensor can therefore be used on several axes. The sensor data must be set separately on each axis.

In V4.0 or higher, a calculated value from the user program can also be specified as the actual sensor value via the cyclically effective **forceActualValueSetting.value** system variable. This requires the setting **additionalSensorType**= SET_ACTUAL_VALUE.

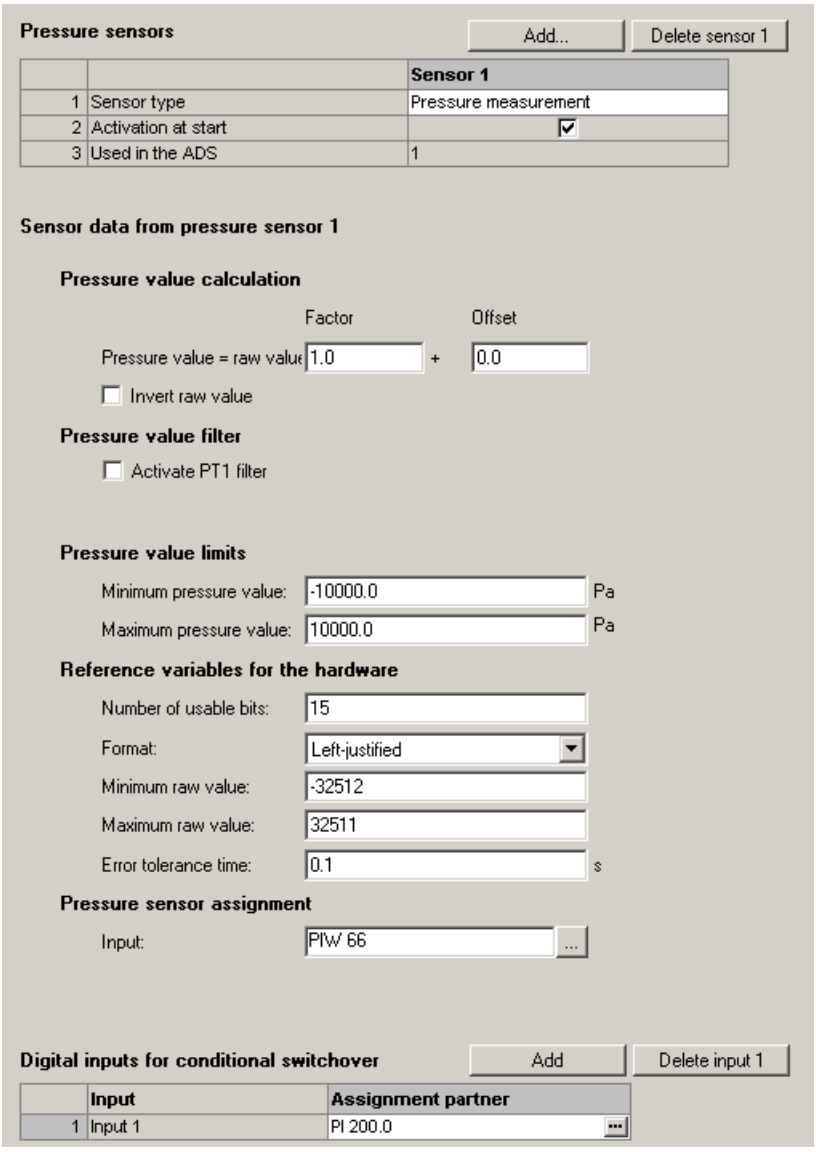

Figure 4-878 Setting the force/pressure sensor

The force/pressure sensor interface can be activated and deactivated on the axis using the **_enableAxisInterface()** and **_disableAxisInterface()** commands.

The Activated/Deactivated force/pressure sensor interface status is displayed in the **additionalSensorData.additionalSensorData[i].input** system variable.

Controller for force/pressure control

The force/pressure control is carried out via an adjustable PID controller.

The controller has the same structure for force/pressure control and for force/pressure limiting. One controller for both tasks is available; the controller parameters for each task can be accessed by switching the data set.

The I component of the controller is implicitly set during enabling. When the data set is changed over, the system sets the I component so that a continuous setpoint curve is obtained.

When pressure limiting is enabled, the most recent position setpoint is maintained during the switchover to pressure control; otherwise, the actual value is applied. The force/pressure setpoint is set the same as the actual force/pressure value at the switchover time.

The initial value of the force/pressure controller can be limited by an upper value (**forceControllerData.outputLimits._max**) and a lower value (**forceControllerData.outputLimits._min**). It is thus possible to react in one direction only, e.g. to maintain pressure, to move in one direction only in the event of overpressure, to not actively build up pressure.

If the interpolator cycle clock is not the same as the position control cycle clock, a linear fine interpolation is carried out for the force/pressure setpoint. The force/pressure setpoints are limited to a maximum value.

If the hydraulic functionality of the axis is used, specific factors can be predefined for the sliding friction and the additive offset for the force/pressure control.

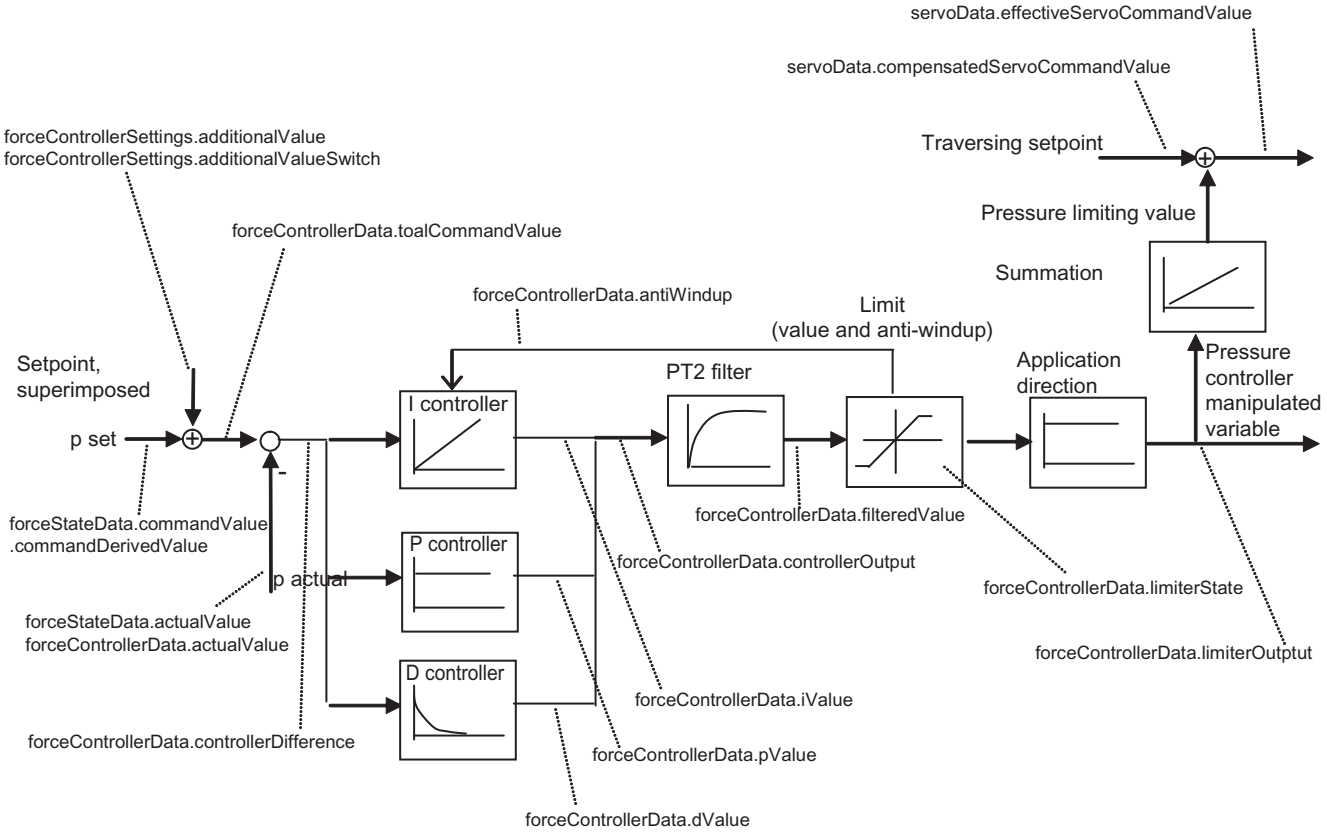

Figure 4-879 Overview of pressure controller/pressure limiting controller

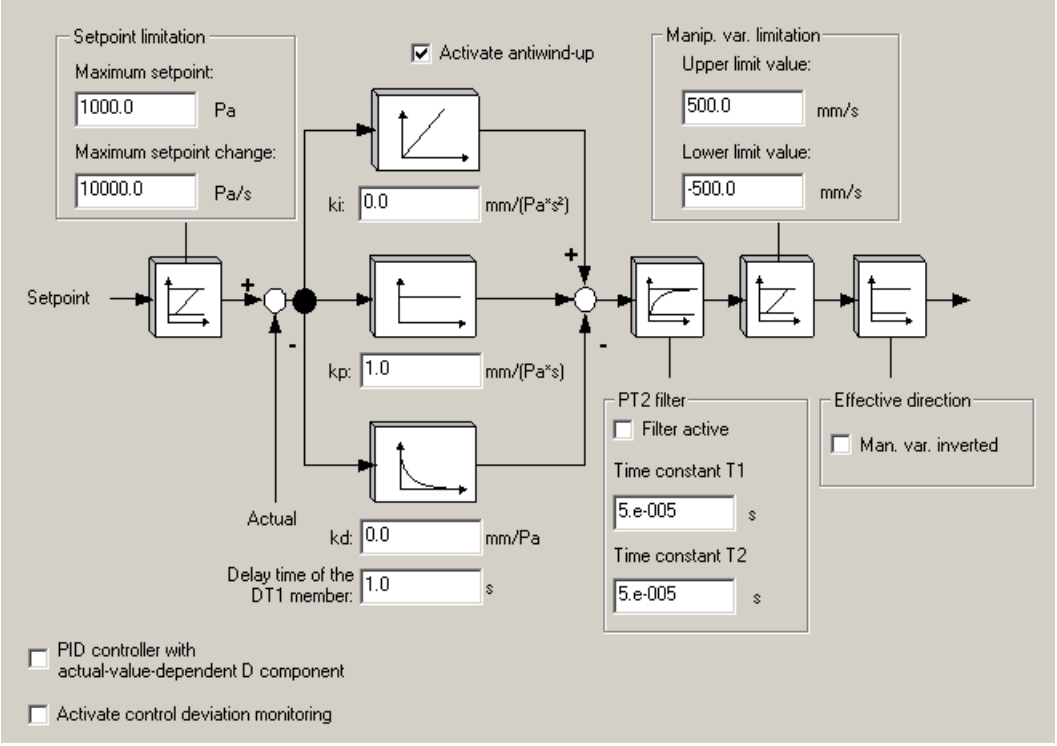

Figure 4-880 Controller setting

Reducing the I component via the user program (as of V4.1 SP1):

It is now possible to reduce the I component of the pressure controller with a PT1 filter (setting in **PID_Controller.iValueFeedbackTimeConstant** configuration data element) using the write-accessible **forceControllerSettings.integratorMode** system variable from the user program.

This enables faster reduction of the I component, for example, following the switchover from pressure limiting to pressure control.

See also

Compensations that are active only on the axis with hydraulic functionality (Page 3129)

Monitoring functions / limiting functions / emergency strategies with active force/pressure control

The actual force/pressure value is monitored for a maximum value or limit value. The control deviation is monitored for a maximum value.

Based on a force/pressure entry window, you can monitor correct termination of a force/pressure profile (force/pressure entry monitoring) – refer to positioning monitoring during positioning.

You can also monitor observance of a constant force/pressure setpoint within a tolerance band (force/pressure end value monitoring) – see standstill monitoring on a position-controlled axis.

Travel to software limit switch:

When traveling to the software limit switch, pressure limitation is deactivated.

You must ensure that the maximum deceleration values are set correctly so that the setpoints of the software limit switches are not overtraveled when the system switches automatically from pressure-limited operation to position-controlled operation.

Limiting functions are available for:

- Force/pressure setpoint
- Force/pressure controlled variable
- Actual force/pressure value

Note

To allow an immediate stop with active force/pressure control, e.g. via the **_stopEmergency()** command (stopDriveMode=WITH_COMMAND_VALUE_ZERO), the control switches to pressure limitation and, with pressure limitation active for the force/pressure setpoint, moves to velocity 0 using the specified velocity profile for active position control.

If the STOP_EMERGENCY alarm response occurs for active pressure control, a switch is made to position control using pressure limitation. The pressure setpoint is active at the switching point. If in this case, the actual pressure value is higher than the pressure setpoint or limit value, the actual pressure value will be removed appropriately.

See also

Dynamic limiting functions (Page 2999)

Activating the force/pressure control

Force/pressure control is activated by commands from the application.

SIMOTION supports different activation modes.

- **Direct activation**
  Direct activation is achieved using the axis-enable command (**_enableAxis()** or **_enableQFAxis()**) (**forceControlMode** parameter = ACTIVE). When enabled, the last actual force/pressure value is taken as the force/pressure setpoint. The position controller must also be enabled.
  The direct activation of the pressure control is possible in the stopped state (**motionStateData.stillStandVelocity** = ACTIVE).
- **Direct deactivation**
  Direct deactivation occurs via the command to reset the axis enable or the command for axis enable without the parameter for force/pressure control.
- **Automatic activation with condition**
  There is a separate command for automatic activation. The conditions are verified and the switchover takes place in the position control cycle clock. The axis is switched over to a pressure-time profile. The conditions (force, pressure, position, time, and input) are specified in the command and can be linked in the command in several stages. The conditions can also be changed before they occur by reissuing the command. The force, pressure, position, and time are stored at the time of switchover. The values are available through system variables.

Switching from position control to force/pressure control:

To obtain a continuous manipulated variable curve for switching from the position control to force/pressure control, the I component of the process controller will be initialized so that the new manipulated variable from the process controller corresponds to the estimated manipulated variable from the position controller.

The estimated manipulated variable is the last manipulated variable of the position controller plus the filtered actual acceleration multiplied with the clock time.

Switching from force/pressure control to position control:

To obtain a continuous manipulated variable curve for switching from force/pressure control to force/pressure control, the setpoint generation and the position controller will be restarted. The current actual value measured by the encoder modified with the estimated following error is used as starting value for the set position.

The estimated following error is calculated from the current manipulated variable multiplied by the replacement time constant of the position control loop PTC (**typeOfAxis.NumberOfDataSets.DataSet_1.DynamicData.positionTimeConstant** configuration data item).

The position controller then outputs in the first cycle clock after the switching the same manipulated variable as the force/pressure controller before the switching.

Note

In certain situations, the reference to the current manipulated variable can cause problems. This is the case, for example, when an offset compensation is active. The PTC for the switching time should then be set to zero. PTC can be switched with the data set.

Force/pressure setpoint specification

Force/pressure setpoints can be specified as follows:

- Directly as a value
- Via a time-related force/pressure profile
- Via a position-related force/pressure profile

The derivation value for the transition to the setpoint, or starting value can be specified in the command. The last force/pressure setpoint is maintained at the end of the profile.

Even with direct setpoint value specification, the command requires different runtimes for its execution on account of the possible transition to the pressure setpoint (pressure entry monitoring). Synchronous and asynchronous command execution can be set.

With direct force/pressure setpoint specification, the setpoint is always active immediately. **mergeMode** can be set in the force/pressure profile commands (sequential execution).

In position-related profiles the absolute position reference of the profile applies at the starting point. During ramp up to the profile and ramp down from the profile, the **additionalSensorData.derivedValue** refers to derivation of the setpoint over time.

An error message is output for starting at a position outside the profile.

Commissioning procedure for force/pressure control

Procedure for commissioning:

1. Commission the drive.
2. Commission the position controller for positioning mode.
3. Set the force/pressure controller. To do this, you can define setpoints for the force/pressure controller via the additive force/pressure setpoint using a function generator.

Force/pressure control with velocity limiting

On the position axis, velocity limiting (flow rate limiting for hydraulic functionality) can be activated in parallel with the force/pressure control. Velocity limitation is effective within pressure control.

It is activated in the same way, for example, as force limiting with limiting value setting or limiting profile enabling. Explicit deactivating is possible by means of a specific command.

If the velocity/flow rate limit is reached, the flow rate is limited, and the I component is stopped in the force/pressure controller.

Like torque limiting, velocity limiting can be activated in parallel with the motion commands.

Velocity limiting is enabled by means of the following commands:

- Activate position-related limiting profile
  _enablePositionLockedVelocityLimitingProfile()
- Activate time-related limiting profile
  _enableTimeLockedVelocityLimitingProfile( )
- Activate limiting value
  _enableVelocityLimitingValue()

Velocity limiting is disabled by means of the following command:

- **_disableVelocityLimitingValue()**

In the event of an error, the velocity limiting remains inactive, the force/pressure control is replaced by the force/pressure limiting and the velocity limiting is disabled.

The velocity limiting direction can be activated by means of the **velocityLimitingDirection** parameter (as of V4.1 SP1).

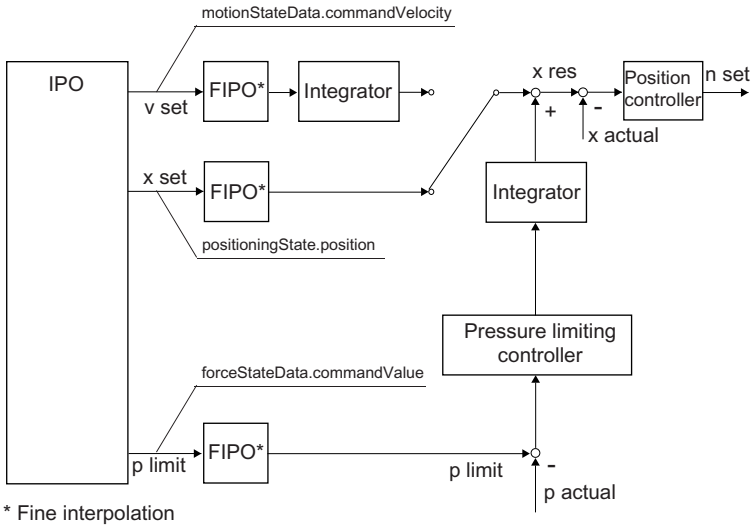
The set direction is indicated in **velocityLimitingCommand.velocityLimitingDirection**.

4.8.3.21 Force/pressure limiting

Overview of force/pressure limiting

The force/pressure limiting functionality requires **position axis technology**. If a hydraulic axis is used as a drive axis, force/pressure limiting is possible here, too.

The position controller is active as a lower-level controller if force/pressure limiting is active.



Overview of control structure for force/pressure limiting

With force/pressure limiting, the force/pressure controller is not activated until the force/pressure limit is exceeded ($\mathbf{p}_{act} > \mathbf{p}_{limit}$). It is limited to positive force/pressure values.

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

The force/pressure limiting is switched on using commands, e.g.:

- **_enableTimeLockedForceLimitingProfile()**
- **_enableMotionInPositionLockedForceLimitingProfile()**
- **_enablePositionLockedForceLimitingProfile()**
- **_enableForceLimitingValue()**
- **_enableForceLimitingByCondition()**

Time-related monitoring is deactivated.

The force/pressure limiting remains active in the event of an error, except for the RELEASE_DISABLE and OPEN_POSITION_CONTROL error reactions.

Position-related monitoring (e.g. following error monitoring or positioning monitoring) are deactivated when pressure control is activated or via the pressure limitation command.

You can configure the monitoring functions to remain active with external pressure/force limiting in the **servoMonitoring.motionMonitoringWhenExternalForceLimiting** configuration data element.

A PT2 filter on the force/pressure limiting controller output (as of V3.2) will prevent abrupt signal changes. The filter time constants can be modified online and take effect immediately.

The pressure limiting value is not subject to fine interpolation if **_enableForceLimitingValue()** or **_enable...LimitingProfile()** with derivativeLimitingMode=WITHOUT_LIMITING is set.

The status of the pressure limiting is displayed via the system variable **forceControllerData.limitingState**. The requirement for updating the status variable is that the pressure controller must be in operation (kp must not be equal to 0).

See also

Force/pressure limiting with hydraulic speed-controlled axes with Q valve only (V4.0 and higher) (Page 3137)

Positioning with active force/pressure limiting (V3.2 and higher)

With position-related motions and active pressure limitation, cyclic continuation of the interpolator position and velocity can be set.

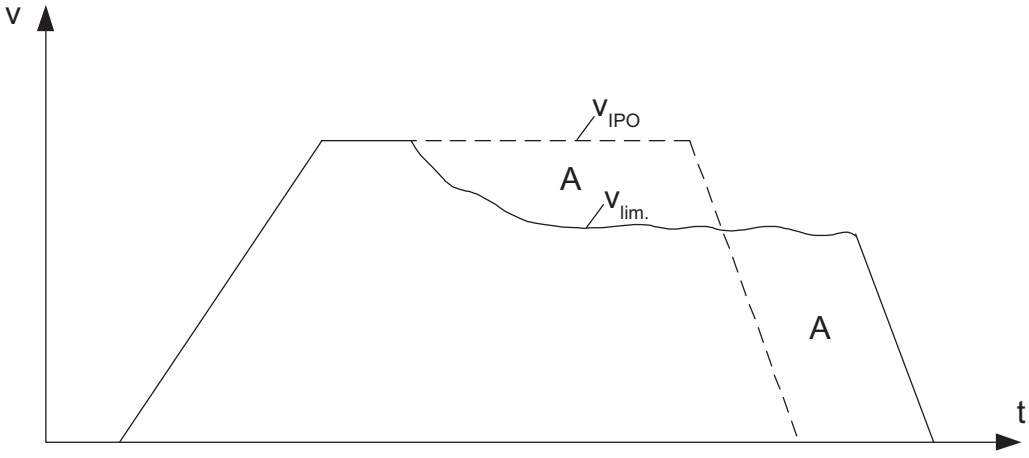


Figure 4-881 Position-related motion with pressure limitation and cyclic continuation

This example shows a v/t profile in which the velocity is reduced by the pressure limitation. Cyclic continuation allows continuous interpolation to the end point, starting from the current position and, optionally, the velocity.

The **decodingConfig.cyclicSetUpInForceLimiting** configuration data element defines how the continuation should take place.

With the setting **decodingConfig.cyclicSetUpInForceLimiting** = POSITION_BASED, cyclic continuation at the current set position and the non-reduced velocity of the interpolator takes place.

With the setting **decodingConfig.cyclicSetUpInForceLimiting** = POSITION_AND_DYNAMIC_BASED, cyclic continuation at the current position and velocity takes place.

Recommended setting: **decodingConfig.cyclicSetUpInForceLimiting** = POSITION_BASED

Braking phase initiated via software limit switch

Cyclic continuation stops from the time at which the braking phase is initiated because the software limit switch is reached. The drive shuts down at maximum deceleration. The pressure limitation remains active.

At standstill, the axis switches from position control to velocity control.

Behavior during positioning/moving to the target position

- Reaching the target position and actual position within the positioning window
  - The target point is reached with respect to the setpoint with cyclic continuation
  - The axis is positioned within the positioning window
  - MOTION_DONE is set and the command is ended as EXECUTED
- Reaching the target position within the positioning window
  - The target point is reached with respect to the setpoint with cyclic continuation
  - The axis is not positioned within the positioning window
  - MOTION_DONE is not set and the positioning monitoring alarm is suppressed due to active pressure limitation
  - Standstill monitoring is activated, and an alarm is triggered if the standstill window is overshot, which cancels the command if necessary
- As a result of pressure limitation, the target position is not reached even through cyclic continuation
  - The target point is not reached with respect to the setpoint even with cyclic continuation
  - No alarm is triggered
  - The command is not ended

Note

Cyclic continuation is not practicable with active torque limitation. In this case, the torque limitation takes place in the drive, and the setpoints limited by the drive are not known to the control.

Increase limiting for pressure profiles and pressure limiting (V3.2 and higher)

Increase limitation can be specified for **_enable...ForceLimiting()** commands.

Determining the output value for the increase limitation

When determining the output value, it is necessary to ascertain whether the pressure limitation is already active when the **_enable...ForceLimiting()** command is activated.

Note

If you prefer to specify the output value directly:

- Use **_enableForceLimitingValue()** to set the output value

- Wait until the value is reached

- Use a new command to ramp up to the target value

A programmed increase limitation can then be used to move to new values.

Initial activation of the pressure limitation

- Output value when pressure sensor not present is FValue=0.0
- If pressure sensor is activated, the output value is the measured actual pressure value
- When pressure control is triggered by means of pressure limitation, the output value is the pressure setpoint in the IPO

New pressure limitation command with pressure limitation already activated

The output value is the limit value in the IPO.

4.8.3.22 Data sets

Data set overview

The configuration data belonging to the axis data set (ADS) can be seen on the **Axis data sets** tab in the Configuration dialog for the axis.
Details of the parameters can be found in the TP Cam Configuration Data Reference List.

ADS contain axis configuration data for the axis, especially that pertaining to the servo (controller data, encoder data, process data, data for axis gearing, and data for force/pressure control, for example).

Data sets must be defined and activated as a group because some data, such as controller data, can only be activated simultaneously in groups to ensure consistency of the controller and function.

Data set switchover / encoder switchover

Data sets can be switched over in the runtime application. This switchover is also possible within one IPO cycle clock (e.g., to activate new controller data or to switch over to a second encoder).

One axis can use several encoders for the position control, but only one encoder at a time.

One data set and one encoder are assigned to each axis when it is set up. If you need additional data sets or encoders, they must be added. Data sets can be added in the Axis technology object under **Configuration** on the **Axis data sets** tab.

In V4.0 and higher, the **smoothingTimeByChangeDifference** configuration data element can be used to configure a switchover smoothing filter. This switchover smoothing filter is active for all status transitions/switchovers in which an offset in the manipulated variable can occur due to the switchover. Gear switchover in the data set is not smoothed.

The data sets must have the same control structure and must not contain any change that requires a restart. For example, if data set 1 has DSC, data set 2 must have DSC too, or if following error monitoring is disabled for data set 1, it must also be disabled for data set 2. Data sets with different structures cannot be set up.

Data sets are specified and selected using their numbers.

You can also define which data record is to be loaded for the technology object during CPU power up.

Figure 4-882 Configuration of axis data sets in SIMOTION SCOUT

The individual data sets appear next to each other on the **Axis data sets** tab.

Configuration data which must be the same for all data sets can only be entered in ADS 1. A change in ADS 1 is only mapped in the other ADS if the configuration data has to be set identically for all ADS.

If parameters for axis data sets undergo changes in the expert list, consistency conditions may be violated (check during download). This may happen with controller settings, for example. In this case, the line and cell are highlighted on the **Axis data sets** tab.

Only variables which are effective immediately can be changed online.

The parameter assignment dialog boxes for the Axis technology object (e.g. Control) display the configuration data for one data set at a time. A function bar at the bottom of the dialogs features

a combo box  with the option to switch over the axis data set. This switches over the data set displayed (not the active data set).

Note

Please also note the tooltips above the parameter fields in the individual screen forms for the axis. These show the name of the variable, from which you can also tell whether the variable is assigned to a specific axis data set.

The number of data sets is specified with the structural elements for the **NumberOfDataSets** configuration data element. Up to 16 data sets are possible.

The data set changeover mode is specified in the **NumberOfDataSets.changeMode** parameter.

Table 4-363 Parameter NumberOfDataSets.changeMode

NEVER	No data set changeover takes place.
IN_STANDSTILL	Data set changeover takes place when the standstill signal is applied.
IMMEDIATELY	Data set changeover takes place immediately.
IN_POSITION	Data set changeover takes place when the positioning window is reached.

Switchover to another encoder via the data set switchover

The data set shows which encoder is used with this data set. You can define up to 8 different encoders. All configured measuring systems (encoders) are internally active, and the measured values are updated cyclically.

The encoder contained in the data set is specified and selected using its number (EncoderNumber).

The basic settings for encoders are made under **Configuration** on the **Encoder configuration** tab.

Note

Please also note the tooltips above the parameter fields in the individual screen forms for the axis. These show the name of the variable, from which you can also tell whether the variable is assigned to a specific encoder.

Activating data sets

Data set commands can be used to read, write, and activate data sets on the axis.

The configuration data of a data set are contained in the structure **TypeOfAxis.NumberOfDataSets.DataSet_n** (n: data set number). The display depends on the technology set on the axis.

Data sets must be defined and activated as a group because some data, such as controller data, can only be activated simultaneously in groups to ensure consistency of the controller and function.

- **_getAxisDataSetParameter()** reads a data set on the axis
- **_setAxisDataSetParameter()** overwrites a data set on the axis
- **_setAxisDataSetActive()** sets the data set specified in the function parameter to active

Note

If the active measuring system is switched via a data set changeover, the **_setAndGetEncoderValue()** system function should be used to synchronize the two measuring systems before the switchover takes place. This will prevent unwanted compensating movements of the position controller if differences in position are identified.

4.8.3.23 Traversing with user-defined motion and force/pressure profiles

Overview of traversing with user-defined motion and force/pressure profiles

In addition to traversing/positioning via system functions, the axis can also be traversed directly via user-defined profiles.

The curve specification of a cam is used as profile function. The cam can be set using the SIMOTION SCOUT engineering system (CamEdit, CamTool) or, alternatively, by means of the application.

A system command is used to assign the appropriate technological variables of the axis to the domain and range.

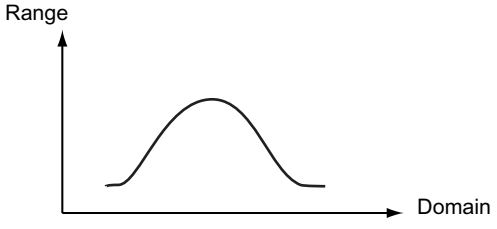

Figure 4-883 Application of cam/technological profiles

A defined start is also possible within a profile.

Application:

Specific adaptation and optimization of traversing specifications.

Additional information about cams can also be found in the SIMOTION CamTool Manual and in the SIMOTION SCOUT online help.

Table 4-364 Possible assignments

Designation	Definition range	Value range	Command
Position-related velocity profile	Position 1) 2)	Velocity specification	_runPositionLockedVelocityProfile()1) _runMotionInPositionLockedVelocityProfile() 2)
Time-related velocity profile	Time	Velocity specification	_runTimeLockedVelocityProfile()
Time-related position profile	Time	Position	_runTimeLockedPositionProfile()
Time-related force/pressure profile	Time	Force/pressure specification	_runTimeLockedForceProfile()
Position-related force/pressure profile	Position 1) 2)	Force/pressure specification	_runPositionLockedForceProfile() 1) _runMotionInPositionLockedForceProfile()2)
Position-related force/pressure limiting profile	Position 1) 2)	Force/pressure limiting	_enablePositionLockedForceLimitingProfile() 1) _enableMotionInPositionLockedForceLimitingProfile() 2)
Time-related force/pressure limiting profile	Time	Force/pressure limiting	_runTimeLockedForceLimitingProfile()
Time-related velocity limiting profile	Time	Velocity limitation	_runTimeLockedVelocityLimitingProfile()
Position-related velocity limiting profile	Position 1) 2)	Velocity limitation	_enablePositionLockedVelocityLimitingProfile() 1) _enableMotionInPositionLockedVelocityLimitingProfile() 2)

1) Actual position of axis – the axis position is assigned to the definition range.

2) Interconnected position – the actual position present at the MotionIn interface is assigned to the definition range.

Profile reference

Time-related profiles

The domain of the cam to be used in the command is interpreted as time in the time unit of the axis. The profile can be executed from start to finish or, alternatively, from a starting point that can be predefined.

Position-related profiles with respect to the axis' own position

The domain of the cam to be used in the command is interpreted as the position in the position unit of the axis.

The profile reference is equivalent to the absolute axis position. The profile is started from the current axis position.

The velocity traversing profiles are related to the resulting position setpoint.

The velocity limiting profiles and the force/pressure profiles are related to the actual position value.

Position-related profiles with respect to interconnected position (V3.2 and higher)

The profile is related to the position interconnected via MotionIn connectors.

Table 4-365 Possible commands for reference to a position interconnected via MotionIn

Command	Description
_runMotionInPositionLockedForceProfile()	Force profile related to an interconnected position (MotionIn)
_runMotionInPositionLockedVelocityProfile()	Velocity profile related to an interconnected position (MotionIn)
_enableMotionInPositionLockedForceLimitingProfile()	Force limiting profile related to an interconnected position (MotionIn)
_enableMotionInPositionLockedVelocityLimitingProfile()	Velocity limiting profile related to an interconnected position (MotionIn)

Separate system variables are available for status queries, e.g.:

- **forceMotionInPositionProfileCommand** for force/pressure profiles
- **velocityMotionInPositionProfileCommand** for velocity profiles

Profile types

Velocity profile/velocity limiting profile

The range of the cam to be used in the command is interpreted as the velocity in the velocity unit of the axis. The motion direction, acceleration, and jerk are calculated accordingly.

A transition profile is generated by the axis for discontinuous transitions. The dynamic response parameters of this profile are specified using the command parameters for acceleration and jerk.

Position profile

The range of the cam to be used in the command is interpreted as the position in the position unit of the axis. The motion direction, position, acceleration, and jerk are calculated from this relationship.

The position reference to the axis can be selected as either absolute or relative.

A transition profile is generated by the axis for discontinuous transitions. The dynamic response parameters of this profile are specified using the command profile parameters for acceleration, jerk, and velocity.

Force/pressure profile and force/pressure limiting profile

The range of the cam to be used in the command is interpreted as the force/pressure in the pressure unit of the axis. The derivation of force/pressure for any necessary transition motions (for entering the profile and exiting the profile, for example), can be programmed in the command. The behavior at the end of the profile is set during axis configuration.

Limitation of the acceleration and braking ramps (V3.2 and higher)

The **DecodingConfig.profileDynamicsLimiting** configuration data element is used to determine whether the permitted acceleration and braking ramps should be limited by the programmed values (**derivedCommandValue**) or the maximum values (configuration data).

- Limiting by programmed values:
  The axis is ramped up to the profile or to the values specified in the motion vector (MotionIn) using the minimum value from the dynamic values defined in the command and the maximum values set in MaxJerk, MaxAcceleration, and MaxVelocity.
  While traversing on the profile, the axis is limited to the lowest value of the programmed values and the set maximum values.
- Limiting by maximum values:
  The axis is ramped up to the profile or to the values specified in the motion vector (MotionIn) using the minimum value from the dynamic values defined in the command and the maximum values set in MaxJerk, MaxAcceleration, and MaxVelocity.
  While traversing on the profile, the axis is only limited to the set maximum values.

Status display during profile processing (V3.2 and higher)

During profile processing, extended states are displayed in the system variables for the profiles, e.g. in **positionTimeProfileCommand.processingState**.

The PROFILE_END status is set if the end of profile has already been reached, but the command is still active.

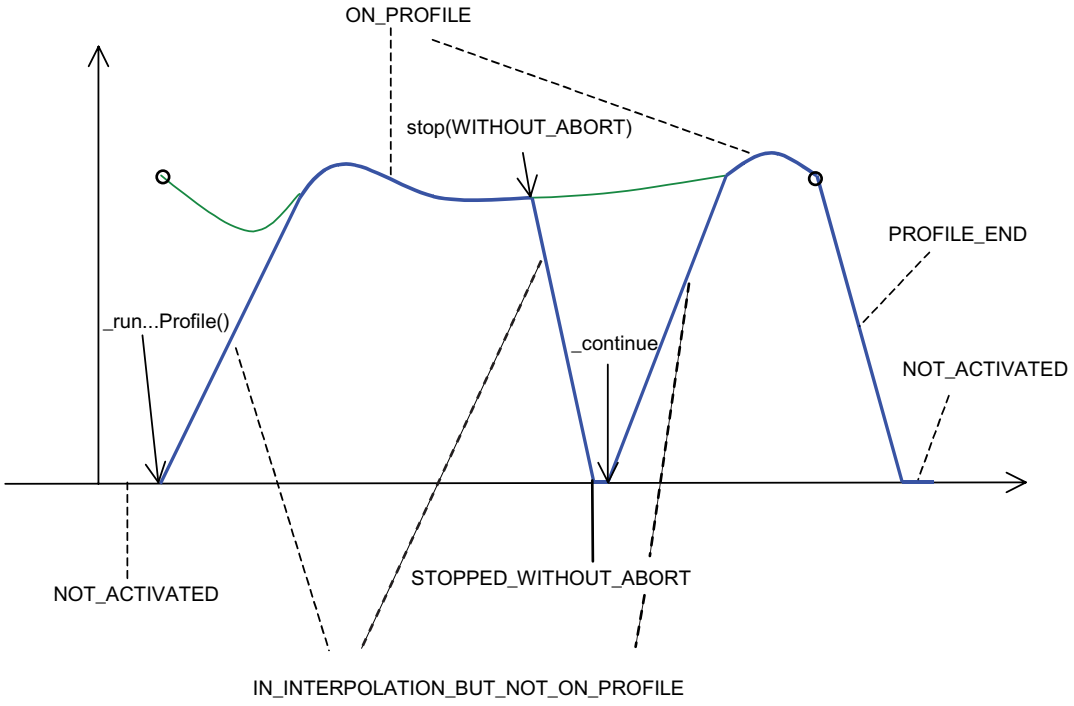

Figure 4-884 Status displays when traveling through a profile (example)

Behavior at the end of the profile (V3.2 and higher)

The **decodingConfig.behaviourAtTheEndOfProfile** configuration data element is used to configure various behaviors.

Table 4-366 Assignable behaviors

Setting	Meaning
MOVE_WITH_CONSTANT_SPEED	Constant continuous motion • Position/velocity: Hold value • Force/pressure: Hold value
STOP_IN_PROFILE_END	Decelerate to target point/velocity 0 • Position/velocity: Velocity 0 at the end of profile (via ramp) • Force/pressure: Value at the profile end point (= Hold value)
STOP_WHEN_PROFILE_END_REACHED	Decelerate after completed traverse • Position/velocity: Velocity 0 when end of profile reached (via ramp) • Force/pressure: Value at the profile end point (= Hold value)

Changes can be made online and take effect immediately.

Note

For position-related profiles with the setting STOP_IN_PROFILE_END, it should be remembered that the velocity calculated by the system can cause vibration.

4.8.3.24 Motion commands

Motion execution/interpolator

Axis motion is executed in the interpolator, in the servo, and in Servo_fast.

The servo for all axes is calculated in the position-control cycle clock.

The reference variables are calculated in the interpolator. The interpolator cycle clock of the device is set during the configuration of the execution system. There are two interpolator levels in the system, **IPO** and **IPO2**.

The processing cycle clock (axis-specific interpolator cycle clock) of the Axis technology object can be set to **IPO** or **IPO2**.
For the possible setting **IPO_fast**, see the chapter titled *Second position control cycle clock (Servo_fast)* in the *Motion Control Basic Functions* manual.

This makes it possible to place an interpolator for axes that do not require a high time resolution to calculate reference variables in a cyclical system task with a longer cycle time, thereby requiring less processing power.

Setting for shorter axis reaction times (e.g. faster start of motion) (as of V4.1 SP1)

The **Execution.executionLevel=SERVO** or **processing clock** = Servo setting in the configuration screen form can be used to execute the IPO system component of the axis in the servo following actual value measurement. After the actual value system in the servo, the IPO system functionality is calculated first, followed by the controller and the setpoint system.

This reduces the response time to the switching of external signals or synchronous operation in the control to one servo cycle clock.

Note

Due to the higher performance requirement, this setting should only be used for selected (i.e. a limited number of) axes.

Temporarily high IPO system components in the servo of the axis can result in a level overflow in the servo, thus causing the CPU to go to STOP mode.

For the possible setting **Servo_fast**, see the chapter titled *Second position control cycle clock (Servo_fast)* in the *Motion Control Basic Functions* manual.

System and user tasks

In addition to the technology object system tasks of ServoTask, IPOTask, and IPOTask_2, there are also synchronous user tasks called ServoSynchronousTask, IPOSynchronousTask, and IPOSynchronousTask_2.

How the system and user tasks interact with each other is demonstrated in the following example for the Axis technology object. At the end of cyclic data transfer, the ServoSynchronousTask and ServoTask are started, followed by the IPOSynchronousTask and IPOTask. Axis data which is active in the servo (e.g. superimposed setpoint or manipulated variable value) can be modified in the ServoSynchronousTask. In the IPOSynchronousTask, issued motion commands are processed directly in the subsequent IPOTask (e.g. switchover to superimposed motion or registration mark).

Because the ServoSynchronousTask is executed before the IPO system component in the servo level even if **execution.executionLevel=SERVO** is set, this enables a very rapid response with motion affected at user level as well.

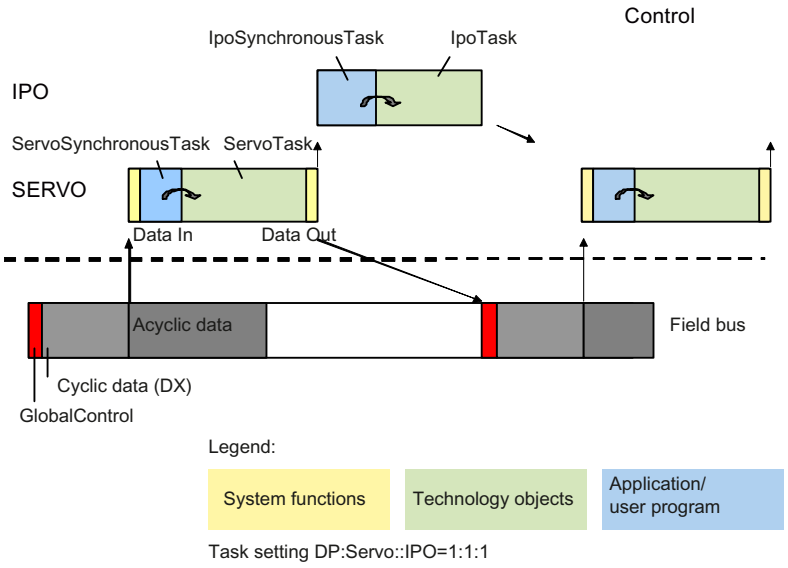

Figure 4-885 Example of cycle clock settings

See also the chapters titled *Execution system/Tasks/System cycle clocks* and *Dynamic response to data processing in the control* in the *Motion Control Basic Functions* Function Manual.

Command groups

Commands on the axis are divided into command groups to enable multiple commands to be active in one **IPO** cycle clock. Commands on the axis are read in and processed in the IPO cycle clock. If the user program issues more than one command for a command group within an interpolator cycle clock and the user program can run, for example, in another task, then a specific behavior is defined for the command group. The commands assigned to a command group are implicitly assigned to the corresponding command buffer.

The overwritten commands trigger technological alarm "030002 Command aborted".

Command buffers and their properties

Every axis has command buffers that can buffer one command each. These buffers are read out in every interpolator cycle clock.

- Buffer[1)] for **_stopEmergency()**, **_stop()**, and **_continue()** commands
  This buffer contains **_stopEmergency()**, **_stop()** without command abort, and **_continue()**. The procedure followed when motions stop depends on the command priorities. Higher priorities are indicated by larger numbers. A command with the same or higher priority displaces a command already in the buffer.
  - **Priority 1: _stop()** without command abort and **_continue()**
  - **Priority 2: _stopEmergency()** with time ramp
  - **Priority 3: _stopEmergency()** with maximum deceleration
  - **Priority 4: _stopEmergency()** with setpoint zero
- Buffer[2)] for **Enable**- and **Disable** commands
  This buffer contains the enable and disable commands. The commands displace each other from the command buffer.
- Buffer[3)] for **superimposed** commands
  Commands that are executed in parallel or superimposed to a main motion are, for example:
  - Motion commands with mergeMode=SUPERIMPOSED_MOTION_MERGE
  - **_redefinePosition()**
  - **_enableAxisAdditiveTorque()**
  - **_homing()** with homingMode=DIRECT_HOMING or PASSIVE_HOMING

  The following applies to SIMOTION < V4.4:
  The buffer has an entry. These commands overwrite each other if they are issued within one IPO cycle clock.
  As of SIMOTION V4.4, the following applies:
  A maximum of 10 command entries are possible in the command buffer for superimposed commands. The number can be set in
  the **DecodingConfig.lenghtOfBufferForSuperimposedCommands** configuration data element. When a new axis is created, five entries are preset by the system.
- Buffer[4)] for **overriding** and **sequential** commands
  Acceptance of all commands, in particular motion commands that have been programmed as sequential motion using the mergeMode=SEQUENTIAL function parameter or as overriding motion using the mergeMode=IMMEDIATELY function parameter.
  In the case of sequential motions with immediate command advance (nextCommand=IMMEDIATELY and mergeMode=SEQUENTIAL), new commands to be entered can return with errors if the buffer is full.
  In the case of sequential motions with immediate command advance, if the motion command can be accepted by the system (nextCommand=WHEN_BUFFER_READY and mergeMode=SEQUENTIAL), the command does not advance until the motion command has been accepted by the system.
  In the case of mergeMode=NEXT_MOTION or mergeMode=IMMEDIATELY, the command can always be accepted by the system, because the next motion command in the command buffer or the current motion command in the interpolator is overwritten.

The following table shows the assignment of axis commands to command buffers.

Table 4-367 Allocation of commands to the command buffers

Command	Position
_continue() Resume motion	1
_stop() Stop a motion without traversing command abort	1
_stop() Stop a motion with traversing command abort	4
_stopEmergency() Stop the motion with cancellation of the motion commands without further motion commands having any affect	1
_disableAxis() Remove axis enable	2
_disableQFAxis() Remove enable for axis with hydraulic functionality	2
_enableAxis() Set axis enable	2
_enableQFAxis() Set enable for axis with hydraulic functionality	2
_adaptAxisConfigData() Adapts the characteristic data for motors and/or encoders	3
_disableAxisAdditiveTorque() Deactivate additive set torque	3
_disableAxisSimulation() Disable simulation mode	3
_disableForceLimiting() Deactivate force/pressure limiting	3
_disableMovingToEndStop() Disabling command for travel to fixed endstop	3
_disableTorqueLimiting() Deactivate torque limiting	3
_disableAxisInterface() Deactivate actuator interface	3
_disableAxisTorqueLimitNegative() Activate negative torque limiting	3
_disableAxisTorqueLimitPositive() Activate positive torque limiting	3
_disableMonitoringOfEncoder() Deactivate differential encoder monitoring	3
_disableVelocityLimiting() Deactivate velocity limiting	3

Command	Position
_enableAxisAdditiveTorque() Activate additive set torque	3
_enableAxisInterface() Activate actuator interface	3
_enableAxisSimulation() Enable simulation mode	3
_enableAxisTorqueLimitNegative() Activate negative torque limiting	3
_enableAxisTorqueLimitPositive() Activate positive torque limiting	3
_enableForceControlByCondition() Switch over to p(t) profile with switchover criterion	3
_enableForceLimitingByCondition() Switchover to force/pressure limiting when the switchover criterion defined in the command is reached	3
_enableForceLimitingValue() Activate force/pressure limiting with constant force/pressure limit value	3
_enableMonitoringOfEncoder() Activate differential encoder monitoring	3
_enableMotionInPositionLockedForceLimitingProfile() Force limiting profile related to an interconnected position (MotionIn)	3
_enableMotionInPositionLockedVelocityLimitingProfile() Velocity limiting profile related to an interconnected position (MotionIn)	3
_enableMovingToEndStop() Enabling command for travel to fixed endstop	3
_enablePositionLockedForceLimitingProfile() Activate force/pressure limiting with p(s) profile	3
_enablePositionLockedVelocityLimitingProfile() Activate velocity limiting with position-related limiting profile	3
_enableTimeLockedForceLimitingProfile() Activate force/pressure limiting with time-related limiting profile	3
_enableTimeLockedVelocityLimitingProfile() Activate velocity limiting with time-related limiting profile	3
_enableTorqueLimiting() Activate torque limiting	3
_enableVelocityLimitingValue() Activate velocity limiting	3
_redefinePosition() Reset actual and set position	3
_setAndGetEncoderValue() Synchronize measuring systems	3
_setAxisDataSetActive() Switch over data set	3

Command	Position
_homing() Homing	3 4 homingMode = ACTIVE_HOMING
_move() Rotate	4 3 for mergeMode = SUPERIMPOSED
_pos() Positioning	4 3 for mergeMode = SUPERIMPOSED
_runMotionInPositionLockedForceProfile() Force profile related to an interconnected position (MotionIn)	4 3 for mergeMode = SUPERIMPOSED
_runMotionInPositionLockedVelocityProfile() Velocity profile related to an interconnected position (MotionIn)	4 3 for mergeMode = SUPERIMPOSED
_runPositionBasedMotionIn() Activate MotionIn interface with position reference	4 3 for mergeMode = SUPERIMPOSED
_runPositionLockedForceProfile() Run a p(s) profile	4
_runPositionLockedVelocityProfile() Apply a v(s) profile	4 3 for mergeMode = SUPERIMPOSED
_runTimeLockedForceProfile() Run a p(t) profile	4
_runTimeLockedPositionProfile() Apply an s(t) profile	4 3 for mergeMode = SUPERIMPOSED
_runTimeLockedVelocity() Apply a v(t) profile	4 3 for mergeMode = SUPERIMPOSED
_runVelocityBasedMotionIn() MotionIn interface with velocity reference activated	4 3 for mergeMode = SUPERIMPOSED
_setForceCommandValue() Set force/pressure setpoint	4
_bufferAxisCommandId() Store command status permanently	5
_cancelAxisCommand() Abort command with the specified CommandID	5
_getAxisDataSetParameter() Read a data set	5
_getAxisErrorNumberState() Read out error number status	5

Command	Position
_getAxisErrorState() Read out error status, alarm number and alarm parameter of up to eight pending alarms	5
_getAxisInternalPosition() Convert from axis coordinates to encoder position values	5
_getAxisStoppingData() Calculate braking distance depending on a specified actual velocity, actual acceleration, traversing profile and dynamic response parameters	5
_getAxisUserPosition() Convert from encoder positions to axis coordinate system	5
_getForceControlDataSetParameter() Read a data set	5
_getMotionStateOfAxisCommand() Read out motion phase of a command	5
_getProgrammedTargetPosition() Display programmed absolute end position including superimposition	5
_getStateOfAxisCommand() Read out command status	5
_getStateOfMotionBuffer() Shows whether the command queue can be filled	5
_getQFAxisDataSetParameter() Read specific parameters for the axis with hydraulic functionality in the data set	5
_removeBufferedAxisCommandId() End permanent storage of the command status	5
_resetAxis() Reset axis	5
_resetAxisConfigDataBuffer() Clear the configuration data in the buffer without activation	5
_resetAxisError() Reset error on the axis	5
_resetMotionBuffer() Reset command queue	5
_setAxisDataSetParameter() Overwrite data set	5
_setAxisSTW() Specify control bits in STW1 directly	5
_setForceControlDataSetParameter() Overwrite data set	5
_setQFAxisDataSetParameter() Overwrite the specific parameters for the axis with hydraulic functionality in an inactive data set	5

Command	Position
_setQFAxisPCharacteristics() Set characteristics for P value	5
_setQFAxisQCharacteristics() Set characteristics for Q value	5

1) Buffer for emergency stop and stop-continue commands

2) Buffer for enable and disable commands

3) Buffer for superimposed commands

4) Buffer for overriding and sequential commands

5) Not allocated to the command buffers; commands are executed synchronously as called

Changing motion commands into the interpolator

A **DecodingConfig.decodeSequentialMotionCommand** configuration data item can be used to set when the next **SEQUENTIAL** or **NEXT_MOTION** command is switched in or executed in the interpolator - immediately in the same cycle clock or in the next **IPO** cycle clock.

- If the setting is **IMMEDIATELY** (default), the next command is switched in immediately and started in the same cycle clock once interpolation/execution of the current command in the IPO cycle clock is complete.
- If the setting is **NEXT_IPO_CYCLE**, the next command is not changed into the interpolator until the previous command has been completely interpolated.
  This prevents execution of multiple motion commands in the interpolator, thus preventing a greater-than-average interpolator load from being called forth in one cycle clock.

Motion transitions

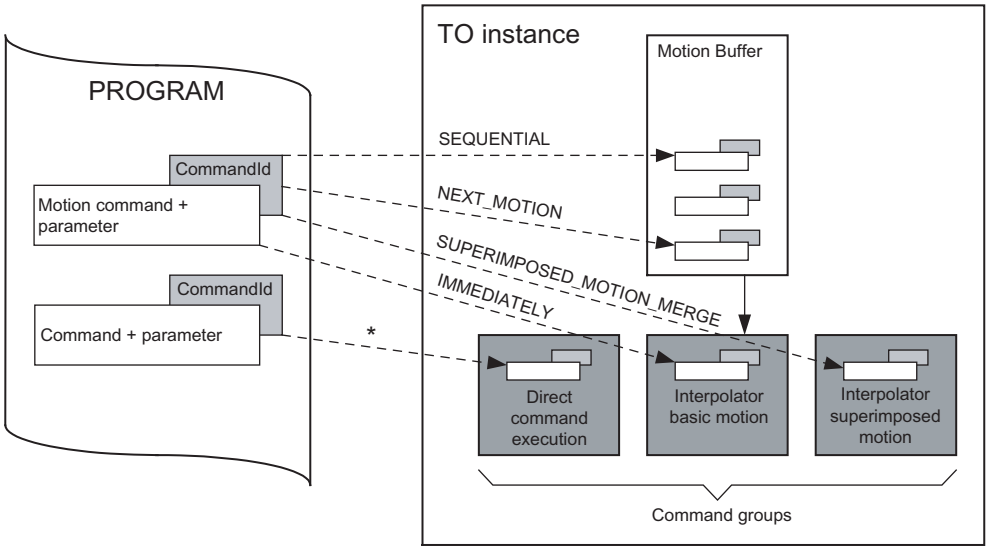
The behavior during a transition between two motions is defined by **mergeMode**.

The programmed motion transitions are decisive for the active motion. The priority of the task in which the motion command is issued does not affect the priority assignment of the command.

Definable motion transitions

- **IMMEDIATELY** (substitute)
  The motion specified with the command is activated immediately. Motions which are already active are overridden and pending commands/motions are aborted.
- **NEXT_MOTION** (attach, delete pending command)
  Execute after the active motion and delete further pending commands/motions.

- **SEQUENTIAL** (attach)
  Append to previous commands/motions.
- **SUPERIMPOSED_MOTION_MERGE** (superimpose)
  Superimposed motion on the axis is possible in addition to the basic motion



* Not allocated to the command buffers; commands are executed synchronously as called
(See also allocation 5) in the table titled "Allocation of commands to the command buffers)

Figure 4-886 Command reactions in the Axis technology object

Conditions for command advance

If the condition for the command advance is satisfied, the next command in the user program is executed. Specifying a step enabling condition affects the **execution time** of the next command in the same user task.

- **IMMEDIATELY**
  As soon as the command has been issued, irrespective of whether or not the commanded motion can be executed
- **WHEN_BUFFER_READY**
  After the command has been entered in the motion buffer
- **AT_MOTION_START** (motion start)
  After the command has been changed into the interpolator
- **WHEN_ACCELERATION_DONE** (end of acceleration)
  When the acceleration phase is completed
- **AT_DECELERATION_START** (start of deceleration phase)
  When the deceleration phase starts
- **WHEN_INTERPOLATION_DONE** (end of setpoint interpolation)
  When the setpoint interpolation for this command is completed
- **WHEN_MOTION_DONE** (positioning window reached)
  When the setpoint interpolation is complete and the configured positioning window has been reached

- **WHEN_COMMAND_DONE** (when command is completed or aborted)
  After completion of the command, for example, for commands that require time for their execution, but do not contain a motion element
- **WHEN_TORQUELIMIT_REACHED** (as soon as the torque is limited)
  When torque limiting is triggered
- **WHEN_TORQUELIMIT_GONE** (as soon as the torque limiting is switched off)
  When torque limiting is removed
- **WHEN_LIMITING_COMMAND_ACTIVATED** (when the velocity limiting command is activated)
  When velocity limiting is activated
- **WHEN_LIMIT_REACHED** (as soon as the velocity is limited)
  When velocity limiting is triggered
- **AT_PROFILE_START**
  Beginning of interpolation with profile
- **BY_PROFILE_END**
  End of setpoint interpolation with profile
- **WHEN_AXIS_HOMED** (when axis is homed)
  Axis was homed
- **WHEN_ENDSTOP_REACHED** (when clamping value is reached)
  Clamping value reached (travel to fixed endstop)
- **WHEN_FUNCTION_DISABLED** (when command is aborted or completed)
  Command is completed or aborted (travel to fixed endstop)

State model/axis status

Table 4-368 The axis status is indicated in:

• Axis inactive/can be activated:	control= INACTIVE
• Axis active:	control= ACTIVE
• Motion:	motionStateData.motionCommand= IN_MOTION
• Fault:	error= YES and ErrorReaction <> NONE
• StopEmergency:	stopEmergencyCommand.state= ACTIVE

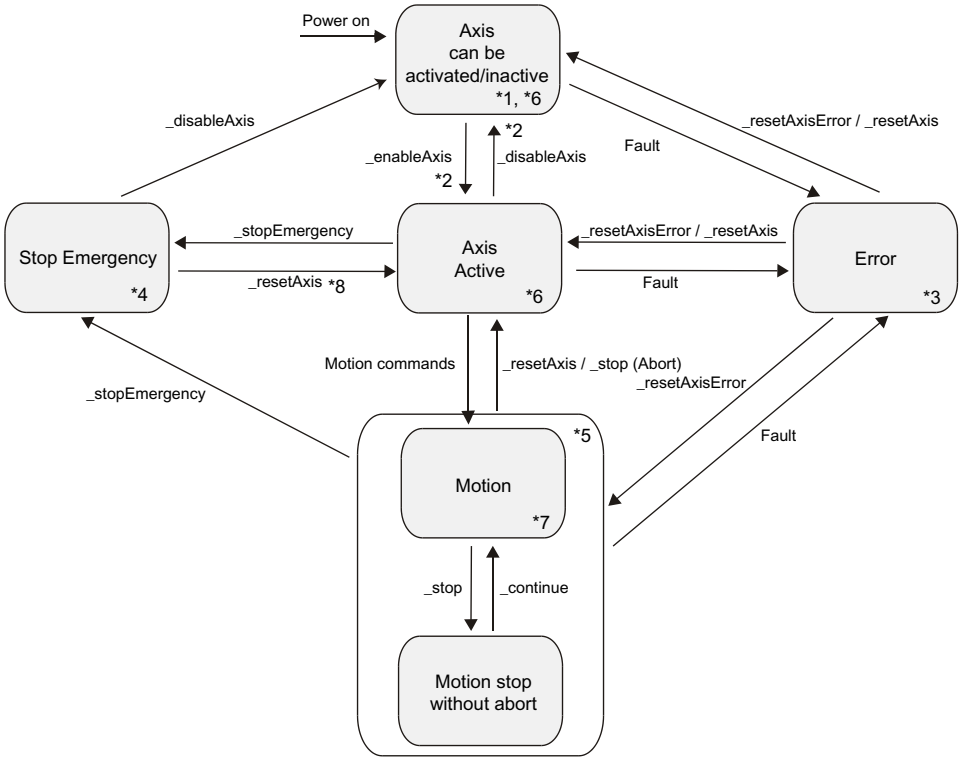


Figure 4-887 State model/axis status

When the axis is configured as an axis with hydraulic functionality (QFAxis) in **TypeOfAxis**, **_enableAxis()** must be replaced with **_enableQFAxis()** and **_disableAxis()** must be replaced with **_disableQFAxis()** in the state model for the axis.

The status of **_stopEmergency()** is displayed in the **stopEmergencyCommand** system variable. Following a reset, this variable must be scanned explicitly by means of **_disableAxis()**.

Table 4-369 The following commands and functions are active in the individual states of the axis:

***1** Axis can be enabled/is inactive with respect to motion control of the axis; also includes the disabled state

***2** For active drive, output and control:

- Switch from follow-up mode or to follow-up mode
- Enable/disable the control

***3** Depending on the stop or error states, **_disableAxis()** / **_disableQFAxis()** and **_stopEmergency()** are permitted

***4** Faults are handled according to existing criteria. Higher-priority local stop reactions can be handled.

***5** Superimposed motions and motions on the following axis are included.

***6** **resetAxis()** permitted

***7** Motion commands permitted

***8** If axis is in position control

Axis in inactive/can be activated state

When the control is switched on, the technology object goes into follow-up mode. In that case:

- All commands in the motion buffer are deleted
- The axis and controller are inactive
- System variables are set either to the configured values or to start values
- The motions commanded by motion commands are not executed; the axis is in follow-up mode
- The **_enableAxis()** or **_enableQFAxis()** command enables the controller and switches the technology object state to active
- Changing from STOP U operating state to RUN, and vice versa, has no effect on the Axis technology object
- During the transition from STOP to STOP U operating state, all alarms that can be reset are acknowledged and the motion buffer is cleared
- Encoders/actual value system is/are active in the STOP operating state
  The axis position is retained, unless an alarm is triggered.

Axis in active state

Motion commands can be issued and executed in this state.

Axis in motion state

- Motion jobs are executed and motion commands can be issued in this state.
- Motion can be stopped by sending the **_stop()** command, stopMode= STOP_WITHOUT_ABORT setting, and resumed by sending the **_continue()** command
- Motion is aborted with the **_stop()** command, stopMode= STOP_AND_ABORT

Axis in fault technology object state

In fault technology object state, the following actions are possible:

- Actions that reset the fault state
- Actions that cause a higher-priority stop reaction
- Actions that do not affect the state
- Actions that are generally permitted according to criteria for technological alarms

Motion jobs and the simulation command **_enableAxisSimulation()** are not executed.

The fault is remedied with the **_resetAxis()** or **_resetAxisError()** command if these commands are permitted for the fault in question.

The status commands **_getStateOfAxisCommand()** and **_getStateOfMotionBuffer()** are permitted, as are the reset commands **_resetMotionBuffer()** and **_disableAxis()** or **_disableQFAxis()**.

Aborted motion commands trigger a **technological alarm** and a notice in the alarm window.

The reactions on the axis can be configured in the technological alarm.

Note

Errors can be acknowledged in SIMOTION SCOUT, the program or the operating panel.

You can find additional information under Error handling in the *Motion Control Basic Functions* Function Manual.

Axis in StopEmergency state

The **_stopEmergency()** command

- Does *not* cause the alarm task to start immediately
- Does *not* disable the axis and drive
- Is *not* active if the axis is in follow-up mode
- Is *not immediately* active if a following error has built up during active torque limitation
- Is *not immediately* active if a pressure axis switches from closed-loop pressure control to pressure limitation

A **_stopEmergency()** command with a higher-priority stop reaction cancels a lower-priority reaction.

The **_stopEmergency()** command generates the **_stopEmergency_Status**. This status can be canceled with the **_disableAxis()** / **_disableQFAxis()** or **_resetAxis()** commands.

Commands active in the interpolator are aborted.

4.8.3.25 Data exchange between Axis technology object and DCC

For data exchange between the Axis technology object and DCC charts/DCC blocks, system variables of the technology object can be interconnected directly with block inputs and block outputs.

The update/effectiveness of the system variables is specified in the reference lists.

- Cyclically updated display data in the IPO include:
  - **motionStateData.actualVelocity**
  - **motionStateData.actualAcceleration**
  - **positioningState.actualPosition**
- Cyclically effective system variables in the IPO include:
  - **defaultMotionIn.x** (when activated by means of a command)
  - **defaultMotionIn.y** (when activated by means of a command)
  - **defaultMotionIn.z** (when activated by means of a command)
  - **override.velocity**
  - **override.acceleration**
  - **plusLimitsOfDynamics.velocity**
  - **plusLimitsOfDynamics.postiveAccel**
  - **plusLimitsOfDynamics.negativeAccel**
- Cyclically updated display data in the servo includes:
  - **sensorData[n].position**
  - **sensorData[n].velocity**
  - **sensorData[n].acceleration**
  - **sensorData[n].incrementalPosition**
- Cyclically effective system variables in the servo include:
  - **servoSettings.additionalCommandValue**
  - **servoSettings.additionalSetpointValue**

You can find additional information about DCC in the *Motion Control Basic Functions* Manual.

4.8.3.26 Drive communication based on DPV1 services

Drive communication based on PROFIdrive provides the basis for the digital SIMOTION/ SINAMICS drive system.
The focus is primarily on cyclic services. Acyclic DPV1 services also provide the option of on-demand data transfer, e.g. to set various parameters or options for slave devices during operation.

The LDPV1 library provides the basis for the quick and easy use of DPV1 services in applications.

Functions supported:

- Buffer management
- Time-of-day synchronization SIMOTION-SINAMICS
- Ramp-up coordination
- Assignment of SIMOTION technology objects to SINAMICS objects

- Reading of SINAMICS errors and warnings
- Activation and deactivation of technology objects and drive objects
- Reading and writing of SINAMICS parameters
- Functions for SINAMICS Safety Integrated

You can find the LDPV1 library in the *SIMOTION Utilities & Applications* included in the scope of delivery of SIMOTION SCOUT (under **Applications > Cross-sector applications > Drive communication**).

Each individual function supported is accompanied by documentation describing the actual application.

Note

As of SIMOTION firmware V4.2, time-of-day synchronization between SIMOTION and SINAMICS is automatic.

4.8.3.27 Links/interconnections to other technology objects

If you interconnect technology objects with one another, they must be configured in the same execution level - with the exception of synchronous axes.

If you need to connect a technology object in a different execution level with an axis, you can work with a virtual synchronous axis that is in the desired execution level and is connected to the actual axis. You can generally use this to evaluate cyclic data of an axis in other levels also (e.g. from the user program).

Note

Further information is available under Interconnection of technology objects in the Motion Control Basic Functions Function Manual.

4.8.4 Configuring an axis

4.8.4.1 Overview of axis configuration

Axes are configured using an axis wizard,
which is started automatically when a new axis is created. In order to change the axis settings, the configuration can be launched using *Configure displayed data set...* in the *Configuration* axis parameter assignment dialog box. Important axis parameters and drive connections are configured in the axis wizard.

Data sets are also managed in the *Configuration* axis parameter assignment dialog for the purpose of data set changeover and encoder configuration.

For more information, see Data sets (Page 3037).

You can specify other selected parameters via the axis parameter assignment dialog boxes, which can be accessed under Axis Object in the project navigator. You can also use the expert list to access all configuration data and system variables relating to the Axis technology object in list format.

System default settings of the configuration data

The system default information shows the settings of the configuration data, which are backward compatible (can also be used for older versions). These are documented in the reference lists for the configuration data.
When a technology object is created or when drives are assigned, the system may make other technological settings than the system defaults in order to support system optimizations or functions of the new versions for the respective context.

4.8.4.2 Linking digital drives

Overview of linking digital drives

The Assign dialog for the drive link is included in the axis wizard when setting up an axis. Once an axis has been set up, this dialog can also be called via the **...** button in the **Configuration** axis dialog or from the address list (**All addresses** view). Drives can also be assigned symbolically, see Coupling of digital drives (Page 2895).

Digital drives are linked to the SIMOTION Axis technology object via a PROFIdrive message frame.

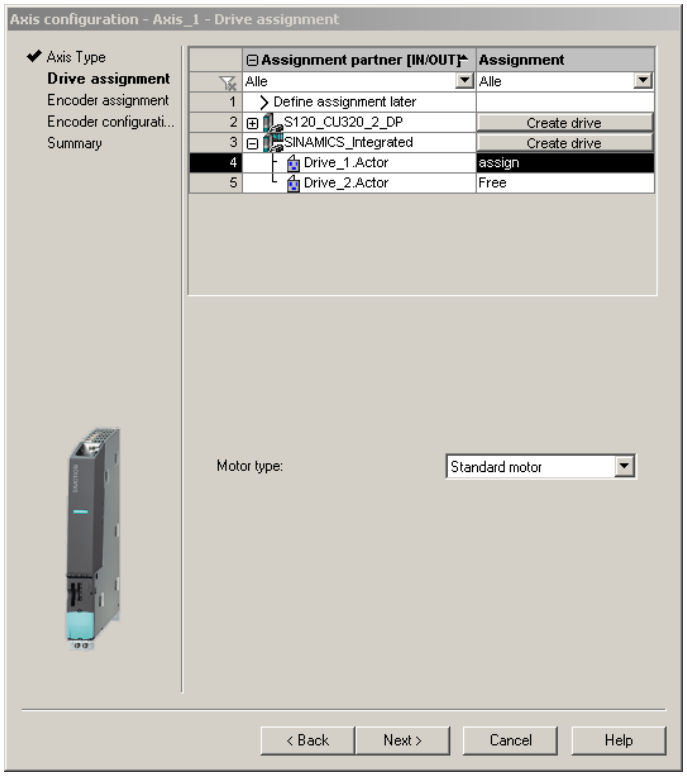

Figure 4-888 SINAMICS drive assignment

The dialog for drive assignment supports both immediate and retrospective drive assignment. Furthermore, a new drive can be created and assigned to the axis. See also Coupling of digital drives (Page 2895).

Configuring PROFIBUS DP in HW Config to optimize run-time

The configuration of PROFIBUS DP in HW Config to optimize run-time is described in the **Motion Control Basic Functions** manual under *Configuring PROFIBUS DP in HW Config to optimize run-time*.

4.8.4.3 Linking analog drives to SIMOTION

Connection of any drive with an analog setpoint interface to a SIMOTION device (e.g. C2xx).

Axis - analog drive relationship

For an axis with an analog drive, the speed setpoint is applied to the analog output as a voltage signal, and the actual value is read in via an encoder interface.

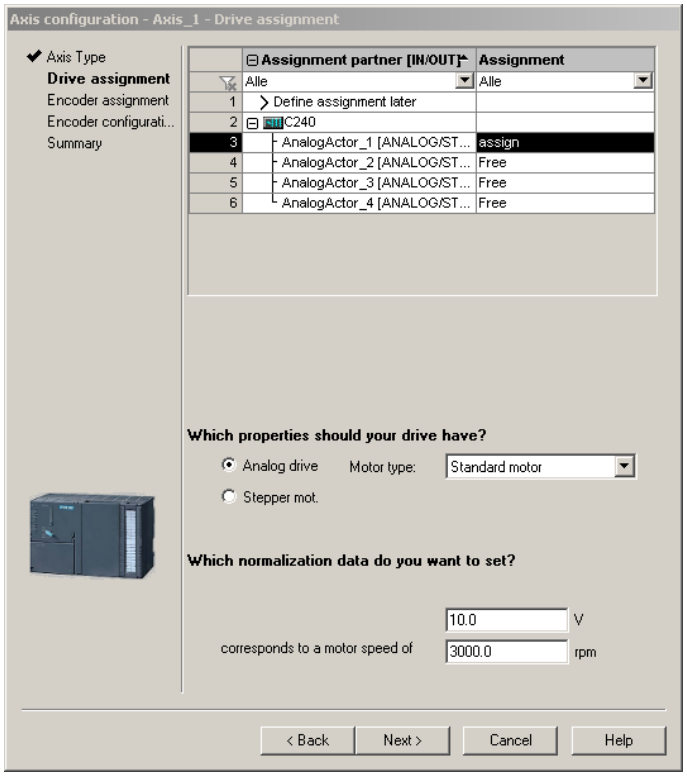

Figure 4-889 Drive assignment of analog drives

Drive

A drive is controlled with +/- 10 V via an **analog interface**.

Axis-drive connection

An axis is connected to a drive by entering the **logical address of the selected analog output** of the SIMOTION device when the axis is configured. Use the axis configuration wizard to do this.

If you change the hardware configuration in **HW Config** at a later time, the specified logical addresses may become incorrect. In this case, repeat the configuration in the hardware configuration wizard.

Make sure that the Volt >> Speed setting in the drive matches the setting in the axis.

ADI4/IM174

In addition to the option of operating analog axes on the onboard inputs of the C2xx, the ADI4 and IM 174 modules are available for use in all platforms as interfaces for analog drive connections. From the SIMOTION perspective, these modules behave like digital drive links. See also Coupling of digital drives (Page 2895) for more information.

You can find further information in the *ADI4 - Analog drive interface for 4 axes* and *Distributed I/O, PROFIBUS module IM174* manuals.

See also

Coupling of digital drives (Page 2895)

Setting as a real axis with analog drive link (Page 2877)

4.8.4.4 Axis with stepper motor connection

Connection of a stepper drive with a pulse/direction interface to a SIMOTION device (e.g. C2xx).

For an axis with stepper motor connection, there is one clock pulse, directional signal, and enable signal output per axis.

For a link via a bus system (e.g., to IM174 via PROFIBUS DP), the general information for configuring PROFIdrive drives is applicable, with special consideration of the behavior of a stepper motor (see Stepper drives (Page 2982)).

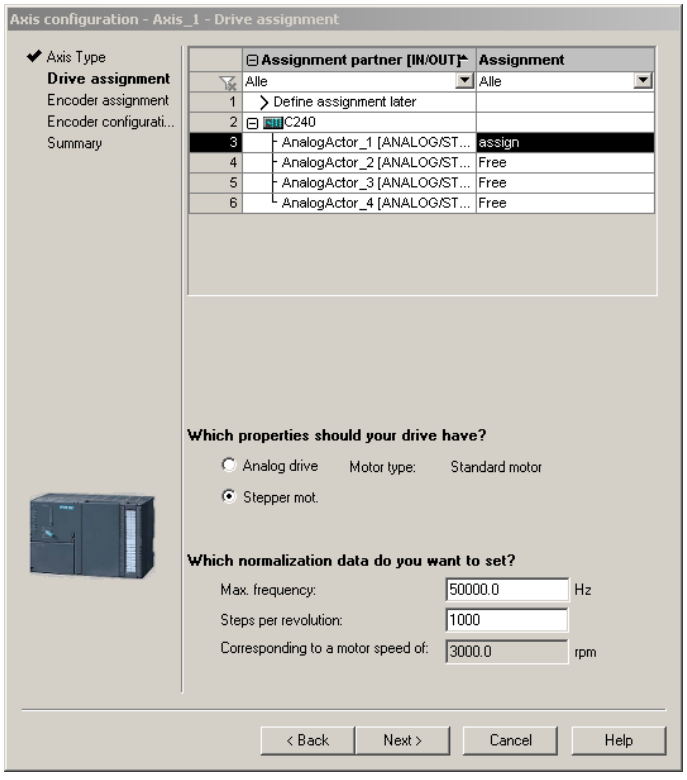

Figure 4-890 Drive assignment of the stepper motor

An axis with stepper motor connection can be moved either with or without an encoder. With an encoder, the actual value signals are read in via the encoder interface; without an encoder, the actual value information is generated from the output motor pulses.

Note

The product of the maximum frequency of the stepper motor and the reciprocal of the number of steps per motor revolution gives the maximum speed available to the control loop (corresponds to maxSpeed for conventional drives).

Note

When an encoderless stepper motor connection is configured on a position axis, an encoder input is still automatically reserved and cannot be used for an external encoder, for example.

With a drive axis, the encoder interface is available for and can be assigned to an Axis or External Encoder technology object.

For operation without an encoder, additional data can be specified in the configuration data for rotation monitoring.

- **NumberOfEncoders.Encoder_1.stepMotorMonitoring.enable** for enabling/disabling the monitoring function
- **NumberOfEncoders.Encoder_1.stepMotorMonitoring.beroCycleDistance** for setting the permitted deviation in terms of motor steps per revolution
- **NumberOfEncoders.Encoder_1.stepMotorMonitoring.beroCycleTolerance** for setting a tolerance range around the beroCycleDistance

Rotation monitoring can be activated for operation without an encoder:

An external zero mark is used and is connected to the associated external zero mark input of the axis channel.

For a linear axis, the external zero mark must monitor the rotation of the motor shaft.

If a signal is not received within the specified motor steps + tolerance, a technological alarm is issued.

IM174/PROFIBUS drives

In addition to the option of operating stepper drives on the onboard inputs of the C2xx, the IM174 module is available for use in all platforms as an interface for stepper drives. From the SIMOTION perspective, stepper drives linked via IM174 behave like digital drive links.

Alternatively, stepper drives can be linked with a PROFIBUS interface if they support the PROFIdrive profile. See Coupling of digital drives (Page 2895).

You can find more information in the *Distributed I/O IM 174 PROFIBUS Module Manual*.

Setting as a real axis with stepper drive C2xx (V3.2 and higher) (Page 2897)

Stepper drives (Page 2982)

4.8.4.5 Using the expert list for an axis

For the standard SIMOTION application, the required parameters (configuration data and system variables) are queried in the axis configuration wizard or are specified automatically. For the Axis technology object (TO), you can specify additional selected parameters via the axis parameter assignment dialog boxes (under Axis Object in the project navigator).

The expert list provides read/write access to all configuration data and system variables of the Axis technology object. The list includes data which cannot be set in the axis wizard or in axis parameter assignment dialog boxes.

With V4.1 SP1 and higher, the **Selected Parameters** tab in the expert list provides a default view of the most important configuration data and system variables.

This tab also shows the most important configuration data and system variables for programming and diagnostics of the virtual, drive, and position axis types, the following object of a following axis, and the external encoder.

Note

In individual SIMOTION applications, it may be necessary to change automatically specified parameters. These configuration data and system variables can only be displayed and changed in the expert list.

To open the expert list for the Axis technology object:

1. In the project navigator, double-click TO Axis. The configuration window appears in the working area and the **Axis** menu is displayed.
2. Double-click the **Expert list** entry under the Axis TO in the project navigator. The expert list is displayed in the working area.

Additional information on working with the expert list can be found in the **Motion Control Basic Functions** Function Manual.

4.8.4.6 Automatic controller setting

Overview of automatic controller setting (as of V4.1 SP1)

In the **Automatic Controller Setting** screen form, you can configure an automatic setting of the speed controller and the DSC position controller for SINAMICS drive units. The necessary steps for this calculation can be controlled from this screen form. The calculated parameter values for the speed controller or position controller are displayed and can then be transferred online to the drive or axis on the control.

Open the Automatic Controller Setting screen form

The following options are available for opening this screen form:

- Via the *Target System – Automatic Controller Setting* menu command from the main menu
- From the project navigator (under *Drive – Commissioning*)
- Via the main toolbar (in the Trace/Measuring Functions group)
- From the *Static Controller Data* dialog box for the axis via a button next to the Kv factor

Requirements

The conditions for the automatic speed controller setting and position controller setting are listed below. You can find additional requirements for the automatic position controller setting in the section about the automatic position controller setting (Page 3070).

- Drive is a SINAMICS drive
- Drive is operated in the "SERVO" operating type

- The control is performed with the motor encoder
- An online connection to the associated drive device exists

Note

The software limit switches for the axes do not function during automatic controller setting.

Note

In certain cases, automatic controller setting may not be able to determine the optimum controller settings for servo. This applies to the positioning of band-stops, for example.

Supported devices

An automatic controller setting is possible with the following devices: SINAMICS Integrated, CX32, CX32-2, S120 - CU320, S120 - CU320-2, S120 - CU310 and S120 - CU310-2.

Procedure

The sequence below must be followed for the automatic controller setting:

1. Set the speed controller
   (see also Automatic speed controller setting (as of V4.1 SP1) (Page 3067))
2. Set the DSC position controller
   (see also Automatic position controller setting (as of V4.1 SP1) (Page 3070))

Note

You can cancel automatic controller setting by pressing the SPACEBAR.

- The step currently being executed is canceled.
- The drive enable is inhibited.

See also

Overview of commissioning the position controller of positioning axes (Page 2986)

Assigning automatic controller optimization (Page 3177)

Automatic speed controller setting (as of V4.1 SP1)

In the **Automatic Controller Setting** screen form, you can select the SINAMICS drive unit and the drive for which you want to carry out an automatic speed controller setting.

The automatic setting is divided into individual steps in which the measuring functions on the drive can be initiated, among other things. Drive parameters are changed online to perform these steps. After an individual step has been executed or canceled, the parameter set is restored with its status before the step was performed.

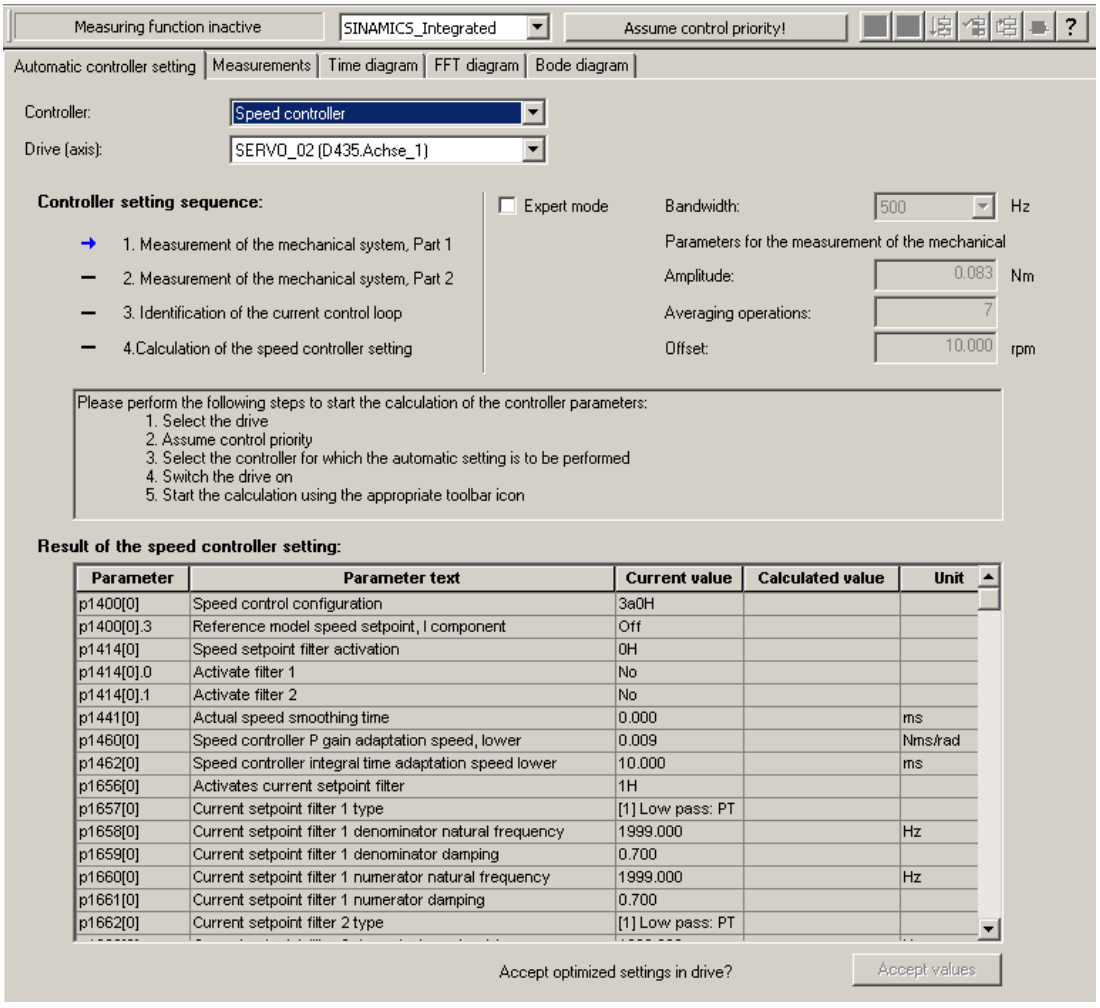

Figure 4-891 Automatic controller setting - Speed controller example

Features

The automatic speed controller setting has the following characteristics:

- Damping of resonances in the speed control section
- Setting of filters in the current setpoint branch
- Automatic setting of the Kp gain factor and the Tn reset time of the speed controller
- The speed setpoint filter and the reference model are not changed

The requirements for the speed controller setting are described in Overview of the automatic controller settings (Page 3066).

Save the current settings

Online drive parameters are changed during a step. It is recommended that the current settings are saved before setting the controller. If the online connection is canceled during the execution of a step, you can restore these saved settings.

Proceed as follows to make a backup:

1. In the project navigator, select the SINAMICS unit with the drive for which you want to perform the automatic setting
2. Load it to the programming device (*Target System - Load - Load to PG...*)

To restore the data, perform a download.

Procedure

Perform the following steps for the automatic setting of the speed controller:

1. Call the **Automatic Controller Setting** screen form (the automatic speed controller setting is already preset in the Controller field)
2. Select the drive unit and drive
3. Assume control priority
4. Enable the drive
5. Perform these four steps in automatic mode or in individual steps
6. Consider the calculation results for the relevant parameters
7. Transfer the calculated speed controller parameter values to the drive
8. Disable the drive
9. Return control priority
10. Save the online parameters

Note

Emergency cancelation of automatic setting with <space key>

The following actions are performed:

- The step currently being executed is canceled
- The drive is disabled

Transferring the calculated parameter values to the online parameters

You initiate the transfer of the calculated parameter values to the corresponding online parameters of the drive with the "Accept" button.

Backing up the automatically set parameters

Proceed as follows to save the parameters:

1. In the project navigator, select the SINAMICS unit with the drive for which you want to perform the automatic setting
2. Copy RAM to ROM (*Target System - Copy RAM to ROM*)
3. Load it to the programming device (*Target System - Load - Load to PG...*)

Note

If required, the automatic controller settings can be checked using the measuring functions.

See also

SIMOTION measuring functions (Page 3073)

Assigning automatic controller optimization (Page 3177)

Automatic position controller setting (as of V4.1 SP1)

In the **Automatic Controller Setting** screen form, you can select the SINAMICS drive unit and the drive for which you want to carry out an automatic DSC position controller setting. The necessary steps for this calculation can be performed from this screen form. The calculated Kv value is displayed and can then be accepted online in the configuration data of the axis that is assigned to the drive.

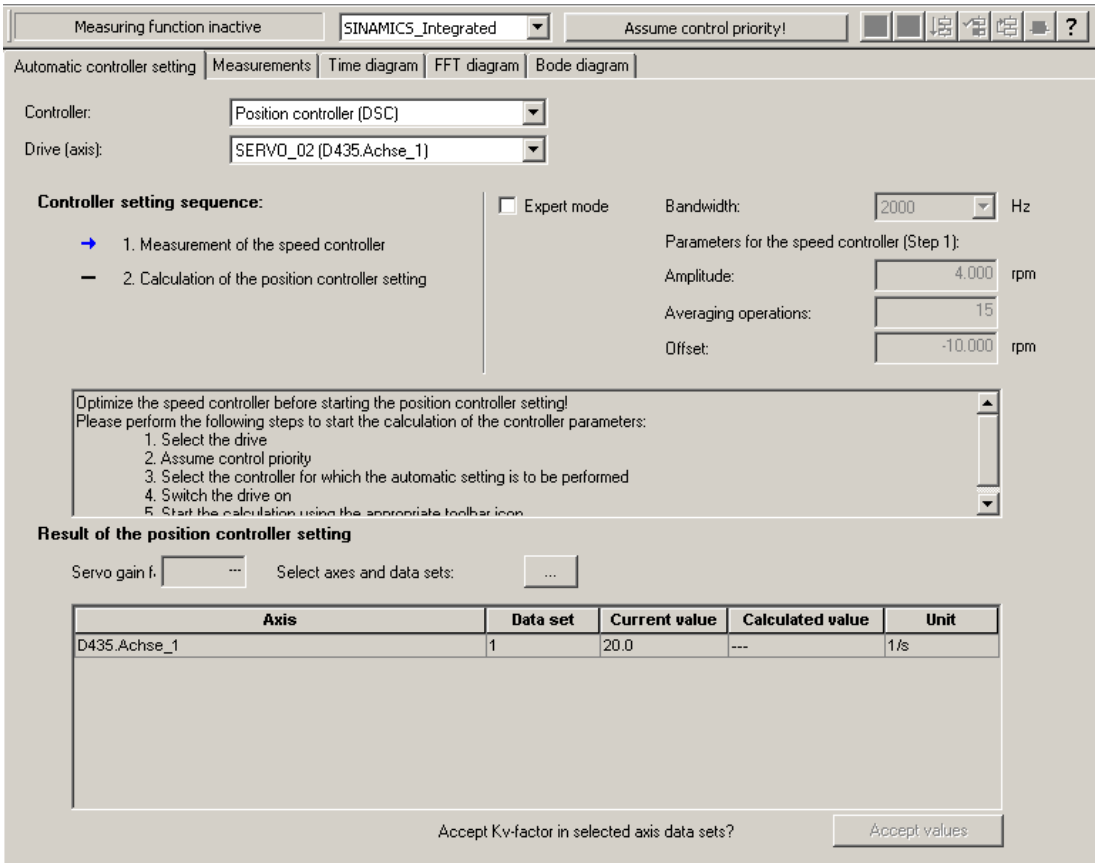

Figure 4-892 Automatic controller setting - Position controller example

Requirements and boundary conditions

In addition to the General requirements (Page 3066) for the automatic controller setting, the following requirements/boundary conditions apply:

- DSC or DSC with spline is required for the position controller setting.
  - You use a telegram that supports DSC (telegram 5, 6, 105, 106, 125 or 126)
  - If you have selected a telegram which does not support DSC, you must select one of the telegrams mentioned above instead.
    As various presettings are required for DSC that can only be set when running through the axis wizard the first time, you have to make these settings manually:
    - Static controller data: Precontrol with weighting factor 100%
      (**NumberOfDataSets.DataSet_1.ControllerStruct.PV_Controller.preCon** = YES and **NumberOfDataSets.DataSet_1.ControllerStruct.PV_Controller.kpc** = 100%)
    - Static controller data: Symmetry filter (extended symmetry filter active)
      (**NumberOfDataSets.DataSet_1.ControllerStruct.PV_Controller.balanceFilterMode** = MODE_2)
    - Static controller data: Fine interpolator (acceleration continuous interpolation)
      (**FineInterpolator._type** = CUBIC_MODE)
    - Dynamic controller data: Speed control loop 0.0 equivalent time and position control loop 0.0 equivalent time
      (**NumberOfDataSets.DataSet_1.DynamicData.positionTimeConstant** = 0.0 and **NumberOfDataSets.DataSet_1.DynamicData.velocityTimeConstant** = 0.0)
- The speed controller has been set previously (e.g. with the automatic speed controller setting).
- At least one axis is connected to the SINAMICS drive (servo).
- The actual values and the manipulated variables between the controller and the drive have been correctly scaled by the user. No validation is performed.
  Match the configurations of the SIMOTION controller with the drive, for example, using the "Transfer data from the drive" button in the axis wizard.
  The following parameters in the drive are used for SINAMICS:
  P2000: Normalization speed
  P1082: Maximum speed
  See also Coupling of digital drives (Page 2895).
- An online connection to the SIMOTION device must exist for the result of the automatic position controller to be transferred.
- The balancing filter is not changed.
- For operation without precontrol, the equivalent time constant of the position controller must be adjusted manually by the user (PostionTimeConstant = 1/Kv).
- Vibration on the load side is not taken into account for the position controller setting.

Procedure

Perform the following steps for the automatic setting of the position controller:

1. Open the **Automatic Controller Setting** screen form
2. Select the drive unit and drive (axis)
3. Specify the "Position controller (DSC)" controller preselection
4. Assume control priority

5. Enable the drive
6. Perform these two steps in automatic mode or in individual steps
7. Select the axis data sets to which the Kv factor are to be transferred
8. Transfer the calculated Kv factor to the axis data sets you have selected
9. Disable the drive
10. Return control priority
11. Back up the online parameters

Note

Emergency cancelation of the automatic setting with <spacebar>

The following actions are performed:

- The step currently being executed is canceled
- The drive is disabled

Transferring the calculated parameter values to the online parameters

You initiate the transfer of the calculated Kv factor to the axis data set of the target device with the "Accept" button.

Backing up the automatically set parameters

Proceed as follows to back up the parameters:

1. In the project navigator, select the SIMOTION unit with the axis for which you want to perform the automatic setting
2. Copy current data to RAM function (*Target System - Copy current data to RAM*)
3. Copy RAM to ROM (*Target System - Copy RAM to ROM*)
4. Load the configuration data to the programming device (*Target System - Load - Load Configuration Data to PG*)

Note

If required, the automatic controller settings can be checked using the measuring functions.

See also

SIMOTION measuring functions (Page 3073)

Assigning automatic controller optimization (Page 3177)

4.8.4.7 SIMOTION measuring functions

The SIMOTION measuring functions are used to commission the axis controller without requiring a user program. In SIMOTION SCOUT, the user can choose a predefined measuring function from a selection of functions. Based on this selection, parameters are then assigned in the target device for the SIMOTION Trace, the function generator, and the required axis enables and motion functions. The user can then launch these measuring functions via SIMOTION SCOUT and evaluate the resulting measurements in the SIMOTION Trace diagrams.

DSC with spline is deactivated when the measuring functions are executed.

The user can configure a user-defined measuring function in expert mode.

The following measuring functions are available:

- **Final controlling element jump (as of V4.0)**
- **Final controlling element frequency response (as of V4.0)**
- **Position control ramp (as of V4.0)**
- **Position control reference frequency response (as of V4.0)**
- **Expert mode (as of V4.0)**

In addition, the **circularity test** is also available for synchronous operation.

Table 4-370 Available measuring functions based on the axis type

	0	1	2	3	4	5	6	7
Positioning/following axis

0 Real electric axis (REAL_AXIS)

1 Virtual axis (VIRTUAL_AXIS)

2 Real electric axis with force/pressure control (REAL_AXIS_WITH_FORCE_CONTROL)

3 Real hydraulic axis (Q valve) (REAL_QFAXIS)

4 Real hydraulic axis with force/pressure specification (Q-valve and P-valve) (REAL_QFAXIS_WITH_OPEN_LOOP_FORCE_CONTROL)

5 Hydraulic axis with pressure/force control (Q valve) (REAL_QFAXIS_WITH_CLOSED_LOOP_FORCE_CONTROL)

6 Real hydraulic axis with force/pressure specification (P-valve) (REAL_QFAX-IS_WITH_OPEN_LOOP_FORCE_CONTROL_ONLY)

7 Real electric axis with master value output via encoder signal simulation (REAL_AX-IS_WITH_SIGNAL_OUTPUT)

Note

Requirements

- An online connection to the SIMOTION device must be established.
- The target device must contain the current axis configuration. If necessary, download the project or upload the configuration data for alignment purposes (Target system > Load > Load configuration data to PG).
- It must be permissible to change the operating mode to STOP_U in the SIMOTION device. An automatic switchover to the STOP_U operating mode will be performed.
- No alarms may be pending on the axis. If necessary, acknowledge the pending alarms in the alarm window and restart the measuring function.

Final controlling element jump measuring function (as of V4.0)

This measuring function can be used for optimizing the lower-level control loop or process (e.g. speed control) in the time range.

A jump function is superimposed on the manipulated variable.

Signal form	Jump with velocity offset
Superimposition point	internalServoSettings.additionalSetpointValue[0]
Measured variables	• Superimposed manipulated variable internalServoSettings.additionalSetpointValue[0] • Actual velocity sensorData[x].velocity **1)**

1) The index is based upon the selected measuring system. The measuring system is selected by the user.

Final controlling element frequency response measuring function (as of V4.0)

This measuring function can be used for optimizing the lower-level control loop or process (e.g. speed control) in the frequency range.
This measuring function can also be used to determine the frequency response of an actuator (e.g. hydraulic process).

A PRBS signal (Pseudo-Random-Binary-Signal) generated by the signal generator is superimposed on the manipulated variable. The control loop is opened.

Signal form	PRBS signal
Superimposition point	internalServoSettings.additionalSetpointValue[0]
Measured variables	• Superimposed manipulated variable internalServoSettings.additionalSetpointValue[0] • Actual velocity sensorData[x].velocity **1)**

1) The index is based upon the selected measuring system. The measuring system is selected by the user.

Position control ramp measuring function (as of V4.0)

This measuring function can be used to optimize the position controller in the time range.

A ramp function is superimposed on the position setpoint. The position control loop is closed.

There are two variations of this measuring function:

- Position control ramp:
  The signal is injected before the dynamic response adaptation.
- Position control ramp without precontrol and setpoint filter:
  The setpoint is injected directly before the summation point of the position controller.

Signal form	Rectangle + rectangular integrator
Superimposition point	• A) Position control ramp internalServoSettings.additionalCommandValue[0] • B) Position control ramp without precontrol and setpoint filter internalServoSettings.additionalControllerCommandValue[0]
Measured variables	• Superimposed setpoint Superimposition point A) or B) • Manipulated variable actorData.totalSetpoint • Actual velocity sensorData[x].velocity **1)**

1) The index is based upon the selected measuring system. The measuring system is selected by the user.

Position control reference frequency response measuring function (as of V4.0)

This measuring function can be used to optimize the position controller in the frequency range.

A PRBS signal (pseudo random binary signal) is superimposed on the position setpoint. The position control loop is closed.

There are two variations of this measuring function:

- Position control reference frequency response:
  The signal is injected before the dynamic response adaptation.
- Position control reference frequency response without precontrol and filter:
  The setpoint is injected directly before the summation point of the position controller.

Function generator 1 for reference frequency response (ramp)		
	Signal form	Ramp (continuous in 1st derivation)
	Superimposition point	• A) Position control reference frequency response internalServoSettings.additionalCommandValue[0] • B) Position control reference frequency response and precontrol and setpoint filter internalServoSettings.additionalControllerCommandValue[0]
Function generator 2 for reference frequency response		
	Signal form	PRBS signal
	Superimposition point	• C) Position control reference frequency response internalServoSettings.additionalCommandValue[1] • D) Position control reference frequency response and precontrol and setpoint filter internalServoSettings.additionalControllerCommandValue[1]
Measured variables		• Superimposed position setpoint 1, ramp Application of function generator 1 A) or B) • Superimposed set position 2, PRBS Application of function generator 2 C) or D) • Actual position sensorData[x].position 1) • Modulo overflow counter, actual value sensorData[x].moduloCycles 1)

1) The index is based upon the selected measuring system. The measuring system is selected by the user.

Expert mode measuring function (as of V4.0)

Various settings can be changed individually in expert mode. Thus, the signal type and superimposition point can be selected explicitly.

Possible signal types:

- PRBS (pseudo random binary signal)
- Jump
- Triangular
- Sinusoidal

The **internalServoSettings.~** structure contains internal system variables for setpoint and manipulated variable override of the measuring functions.

Table 4-371 Possible superimposition points (internalServoSettings.~ structure)

Identifier	Variable	Comment/function
Setpoint	additionalCommandValue	Setpoint superimposition before dynamic response adaptation Same function as servoSettings.additionalCommandValue
Manipulated variable	additionalSetpointValue	Manipulated variable superimposition Same function as servoSettings.additionalSetpointValue
Setpoint on the controller	additionalControllerCommandValue **1)**	Setpoint superimposition on the controller Setpoint superimposition before the summation point of the position/speed controller

1) For measurements that are performed without precontrol or setpoint filter (dynamic response adaptation, balancing filter), the setpoint excitation must occur directly before the summation point of the position or speed controller.

Note

The system variables for superimposition are intended for exclusive use by the SIMOTION measuring functions. These variables cannot be modified by the user.

Circularity test - evaluation of the axis dynamics for synchronous operation with angular synchronism

Minor deviations of amplitude and phase can be seen clearly in a circularity diagram. Another advantage of the circularity test is that it enables exclusive observation of actual values. In contrast, a disadvantage of a following error observation is that the following error (followingError system variable) is corrected, for example, with DSC, and is thus subject to error in a sense.

Function generator 1 of the circularity test, Axis 1		
	Signal form	Sinusoidal
	Superimposition point	• internalServoSettings.additionalCommandValue[0]
Function generator 2 of the circularity test, Axis 2		

	Signal form	Sinusoidal
	Superimposition point	• internalServoSettings.additionalCommandValue[0]
Measured variables		• Position setpoint, Axis 1 internalServoSettings.additionalCommandValue[0] • Position setpoint, Axis 2 internalServoSettings.additionalCommandValue[0] • Actual position, Axis 1 sensorData[x].position **1)** • Actual position, Axis 2 sensorData[x].position **1)** • Actual value modulo overflows, Axis 1 sensordata[x].moduloCycles **1)** • Actual value modulo overflows, Axis 2 sensordata[x].moduloCycles **1)**

1) The index is based upon the selected measuring system. The measuring system is selected by the user.

Setpoint superimposition (Page 2967)

Manipulated variable superimposition (Page 2976)

4.8.4.8 Axis control panel

The axis control panel is used to control and monitor individual axes without requiring a user program. You can use it to traverse axes along with the drive.

Application examples

- Function test on individual axes before the axes are traversed in a coordinated manner under the control of a program
- Traversing axes before the user program is available or if only parts of the user program are available
- Traversing the axes for optimization purposes (controller setting)
- Axis homing or absolute encoder adjustment
- Enabling and disabling an axis
- Acknowledging axis alarms
- Retracting **an axis**: Traverse the axis to another position quickly and independently of the program

Requirements

- An online connection to the SIMOTION device must be established.
- The target device must contain the current axis configuration. If necessary, download the project or upload the configuration data for alignment purposes (Target System - Load - Configuration Data to PG).

⚠ WARNING
Danger to life through unexpected machine movement
Failure to observe the safety instructions can result in personal injury and material damage.
Note the safety instructions in the **Assume Control Priority** SCOUT dialog box.

The system variable **controlPanel** indicates whether the control panel on the Axis technology object is active.

The control panel can be used in operating state STOPU and (from V4.4) in operating state RUN. Please refer to the additional information in the SCOUT Online Help (Axis control panel index).

4.8.5 Support for SINAMICS Safety Integrated Functions

4.8.5.1 Overview - Support of SINAMICS Safety Integrated Functions on the Axis technology object

SIMOTION provides support for SINAMICS drives that can perform safety-related functions. The safety status information of the drive is provided in the system variables.
As of V4.4, SIMOTION commands for triggering safety-related functions are possible on the drive (e.g. SBT).

The purpose of this support from SIMOTION is to prevent stop responses on the drive side by ensuring for the safety-related monitoring functions that the drive does not exit the monitored operating state.

As of SIMOTION V4.4, the SIMOTION-side support for *SINAMICS Safety Integrated Functions* has been simplified and adapted to a generic concept with Drive Safety Data Block (DSDB).

If symbolic assignment is activated (standard setting for new projects), communication is automatically adjusted to the safety-related functions enabled on the drive.

Always use the standard setting (DSDB) on the Axis technology object in conjunction with symbolic assignment for new projects as of V4.4.

For projects < V4.4, the compatibility mode with Safety Information Data Block (SIDB) is available.

The following figure provides decision guidance for managing projects < V4.4 with SCOUT as of V4.4.

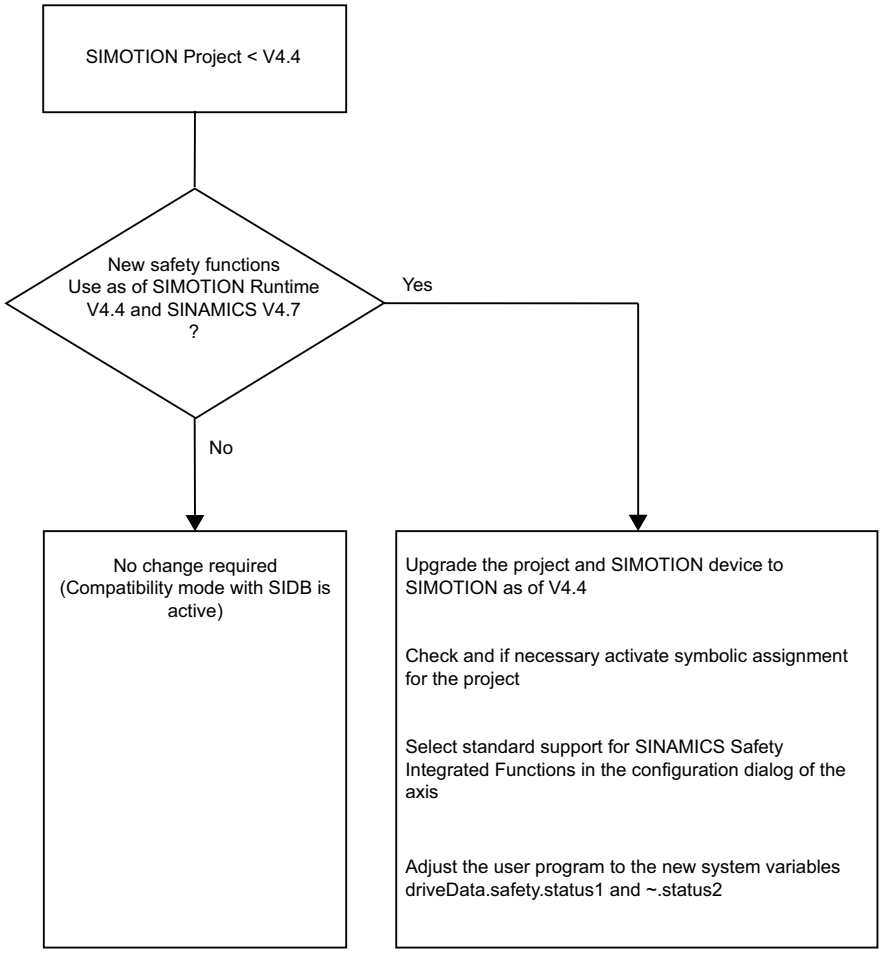

Figure 4-893 Using older SIMOTION projects with SIMOTION SCOUT as of V4.4

If the project was created with SCOUT < V4.2, please refer to Section Restrictions after switching from compatibility mode (SIDB) to standard (DSDB). (Page 3112).

The status information < V4.4 (Page 3093) is still provided for compatibility reasons, even with the standard setting (DSDB), with the exception of SSM.

Note

Further documentation

The safety-related functions of SINAMICS: are described comprehensively in the *SINAMICS Safety Integrated* Function Manual.

As of SIMOTION V5.3

- SLA - Safely-Limited Acceleration with fine resolution and acceleration filtering
- 2 ms monitoring cycle on a double-axis Motor Module

- SS2ESR (Safe Stop 2 Extended Stop and Retract) (The PROFIsafe telegram has been extended with the External Stop E)
- Reluctance motor can be used with Safety encoderless

As of SIMOTION V5.2

- Acceptance of the F destination address from HW Config (STEP 7) or HWCN (TIA Portal)
- Support of new safety-related functions SLA and SCA
- Support of PROFIsafe telegram 903
- SLP, SP, Safe Referencing, SCA. As of SINAMICS V5.1, Advanced Safety is required SP synchronous cannot be used with SIMOTION
- New safety licenses as of SINAMICS V5.1, see Safety licenses (Page 3087)

As of SIMOTION V4.5

- Selection of response to PROFIsafe failure (STOP B)

As of SIMOTION V4.4

Simplification and implementation of the SIMOTION-side support with DSDB

Extension of the safety-relevant functionality:

- SIMOTION-side support of the DSDB with automatic selection of telegram extension
- *SINAMICS Safety Integrated Basic Functions* support on the TO axis
- Support for new safety-related functions: SP, SLP, SBT
- Support for an additional PROFIsafe telegram (902 on the TIA Portal)

As of SIMOTION V4.3

Extension of the safety-relevant functionality:

- SDI function is available in SIDB
- SKS stage 1 can be evaluated with a factor transferred via PROFIsafe, whereby almost any SLS limit values can be specified online
- Support for new SINAMICS V4.5 functions
- Support for additional PROFIsafe telegrams (31 and 901)

As of SIMOTION V4.2

Extension of the safety-relevant functionality:

- SIMOTION-side support for SIDB with automatic telegram extension
- Additional generation of the technological alarm 50023 in the event of drive-autonomous changes in status
  Drive-autonomous changes in status occur e.g. when SS1 or SS2 is selected
- Read-out of the safety message buffer via system function

See also Coupling of digital drives (Page 2895).

As of SIMOTION V4.1 SP1

SIMOTION supports the *SINAMICS Safety Integrated Extended Functions* for the axis TO in the following way:

- Display of the status of safety-related functions in the drive in system variables of the technology object
- Message of a new safety event in the safety message buffer of the drive (alarm TO)
- Message of the status for SLS, SOS and SS2 (alarm TO)

See also

Technology data (Page 3018)

Safety status information (part of the DSDB) (Page 3088)

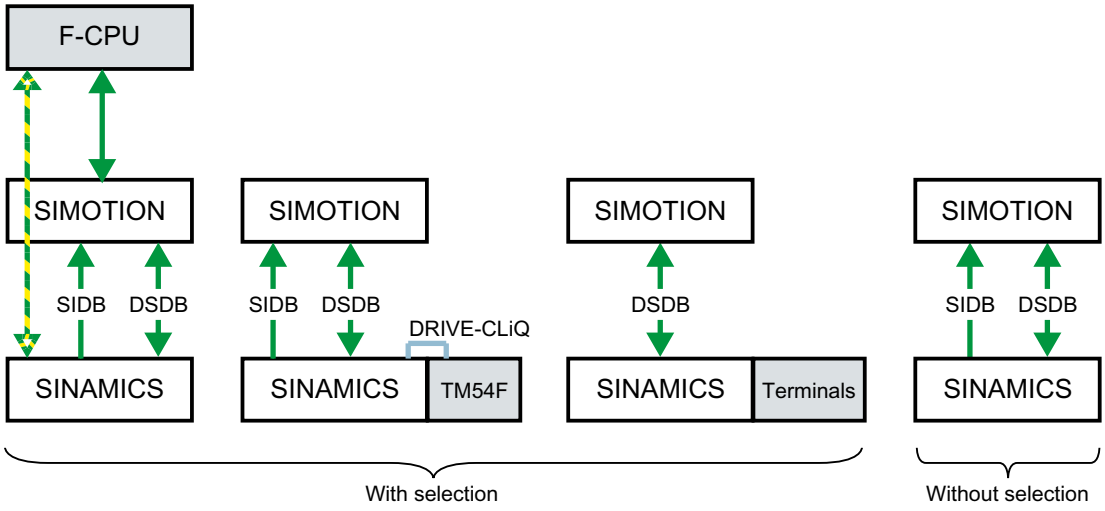
Safety channel and safety channel types (when symbolic assignment is deactivated) (Page 3085)

Standard (DSDB) as of SIMOTION V4.4 (Page 3087)

4.8.5.2 Communication

As of SIMOTION V4.4, the safety information is transferred between the drive and SIMOTION by default as a telegram extension via the DSDB. Both *SINAMICS Safety Integrated Basic Functions* and *SINAMICS Safety Integrated Extended Functions* are supported.

Prior to SIMOTION < V4.4, the safety information is transferred from the drive via the SIDB. *SINAMICS Safety Integrated Extended Functions* are supported.



Optional SIDB (compatibility mode) or DSDB (standard)
SIDB: Supports the SINAMICS Safety Integrated Extended Functions
DSDB (as of SIMOTION V4.4): Supports the SINAMICS Safety Integrated Basic & Extended Functions

Figure 4-894 Communication with DSDB or SIDB in different safety configurations

4.8.5.3 Main procedure for safety configuration with SIMOTION

To use the support for the *SINAMICS Safety Integrated Extended Functions* to the axis TO, proceed as follows:

- Start up the axis and the drive without safety functions
- Configure the safety-related functions in the drive (see *SINAMICS Safety Integrated* Function Manual)
- If the safety-related function is to be activated via PROFIsafe, configure PROFIsafe communication to a safety PLC (e.g. SIMATIC S7 CPU317F).
  See Section *PROFIsafe* in the *SIMOTION SCOUT Communication* System Manual.
- Activate the SIMOTION-side support for the safety-related functions:
  - Connect the drive symbolically in the axis configuration to the axis. To do so, click the ... button under drive assignment.
    or
  - Activate the safety-related functions in the safety dialog.
- Only if symbolic assignment is deactivated:
  Configure the DSDB or SIDB as extension in the telegram.
  As of SIMOTION V4.2, this is set up automatically by the system and interconnected in the drive if symbolic assignment is activated.

The safety status information transferred by DSDB (Page 3088) or SIDB (Page 3093) can be evaluated via system variables on the TO. The status is required for many safety functions to bring the axis into the permissible operating range via the user program.

The *SINAMICS Safety Integrated Functions* are displayed in the configuration dialog of the axis.

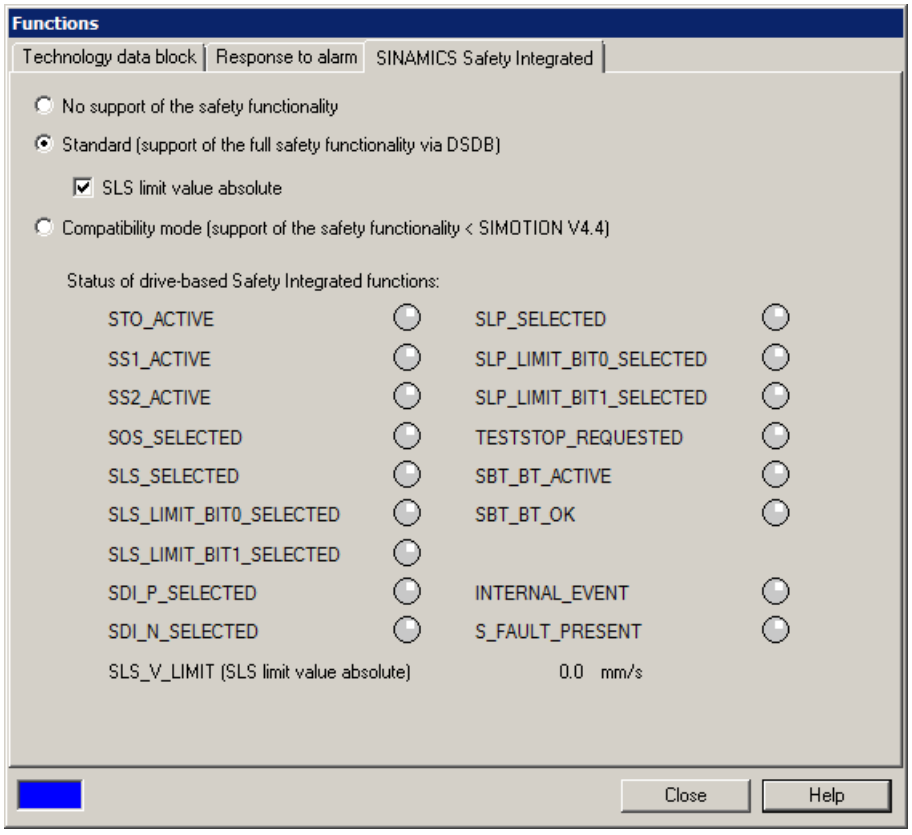


Figure 4-895 Safety dialog

Table 4-372 Support safety functions and their status information

	Safety-related function in the drive	**DSDB - standard (driveData.safety.status1 and driveData.safety.status2)**	**SIDB - compatibility mode (driveSafetyExtendedFunctionsInfoData.state)**
STO	Safe Torque Off	Status1 - bit 0 (STO_ACTIVE)	Bit 0 (STO_ACTIVE)
SS1	Safe Stop 1 (SS1)	Status1 - bit 1 (SS1_ACTIVE)	Bit 1 (SS1_ACTIVE)
SS2	Safe Stop 2 (SS2)	Status1 - bit 2 (SS2_ACTIVE)	Bit 2 (SS2_ACTIVE)
SOS	Safe operating stop	Status1 - bit 3 (SOS_SELECTED) Status2 - bit 4 (SOS_ACTIVE)	Bit 3 (SOS_SELECTED)
SLS	Safely Limited Speed	Status1 - bit 5 (SLS_SELECTED) Status1 - bit 6 (SLS_LIMIT_BIT0_SELECTED) Status1 - bit 7 (SLS_LIMIT_BIT1_SELECTED) Status2 - bit 5 (SLS_ACTIVE)	Bit 4 (SLS_SELECTED)
SSM	Safe Speed Monitor (SSM)	-	Bit 7 (SSM_ACTIVE)
SDI	Safe Direction (safe direction of motion)	Status1 - bit 8 (SDI_P_SELECTED) Status1 - bit 9 (SDI_N_SELECTED)	Bit 12 (SDI_P_SELECTED) Bit 13 (SDI_N_SELECTED)
SP	Safe Position SP synchronous cannot be used with SIMOTION	Status1 - bit 23 (REF_POS_LATCHED_OR_VALID) Status1 - bit 24 (REF_REQUESTED)	-

	Safety-related function in the drive	DSDB - standard (driveData.safety.status1 and driveData.safety.status2)	SIDB - compatibility mode (driveSafetyExtendedFunctionsInfoData.state)
SLP	Safely Limited Position (SLP)	Status1 - bit 11 (SLP_SELECTED) Status1 - bit 12 (SLP_LIMIT_BIT0_SELECTED) Status1 - bit 23 (REF_POS_LATCHED_OR_VALID) Status1 - bit 24 (REF_REQUESTED)	-
SBT	Safe Brake Test (SBT)	Status2 - bit 15 (SBT_SELECTED) Status2 - bit 16 (SBT_CONTROL_PRIO_DRIVE) Status2 - bit 17 (SBT_SIGN_LOAD) Status2 - bit 18 (SBT_BT_BRAKE_2) Status2 - bit 19 (SBT_BT_ACTIVE) Status2 - bit 20 (SBT_BT_OK) Status2 - bit 21 (SBT_BT_FINISHED) Status2 - bit 22 (SBT_BT_BRAKE_CLOSE_REQ)	-
SLA	Safely-Limited Acceleration	Status1 - bit 16 (SLA_SELECTED)	-
SCA	Safety-related function in the drive: Safe Cam	Standard: Status1 - bit 23 (REF_POS_LATCHED_OR_VALID) Status1 - bit 24 (REF_REQUESTED)	-

The stop responses in the drive (e.g. STOP A) for the applicable safety-related functions are described in the *SINAMICS Safety Integrated* Function Manual.

4.8.5.4 Safety channel and safety channel types (when symbolic assignment is deactivated)

This section is only applicable if the project standard setting **Use symbolic assignment** has been deliberately deactivated.

For communication, a distinction is made between various SC types (safety channel types). The various SC types can be used on the SC channels (SIDB, DSDB_1, DSDB_2).

In compatibility mode, the SIDB is the only SC type, so there is no need to distinguish between types.

Use of SIDB and DSDB is optional. Parallel use is not possible.

Table 4-373 List of SC types in SIDB

SC types of SIDB	Supported safety-relevant functions	Input parameter	Output parameter
SIDB	STO SS1 SS2 SOS SLS SDI	r9722.0 r9722.1 r9722.2 r9722.11 r9720.4, r9733[2] r9734.12, r9734.13	-

Note

Support for DSDB when symbolic assignment is deactivated

Note that the standard setting (DSDB) must not be used for SINAMICS drives < V4.7.

Table 4-374 List of SC types in DSDB

SC types of DSDB_x	Supported safety-relevant functions	Input parameter	Output parameter
SC1	STO SS1 SS2 SOS SLS SDI SLA	r9734	-
SC2	as SC1 SLP SP[1)] SCA	r9734 r9743	p10250
SC3	as SC2 SBT	r9734 r9743 r10234	p10250 p10235
SC100		r9733[2]	-

1) SC2 only when using SP with a safe absolute position

4.8.5.5 Safety licenses

SINAMICS makes a distinction between the following function groups:

- Safety Integrated Basic Functions
- Safety Integrated Extended Functions
- Safety Integrated Advanced Functions

As of SIMOTION V5.2 and SINAMICS V5.1, you require the Safety Integrated Advanced Functions license for SLP, SP and SCA.

4.8.5.6 Standard (DSDB) as of SIMOTION V4.4

DSDB is the standard setting for safety as of SIMOTION V4.4. The setting provide the complete safety functionality set up on the drive at the TO. Configuration is automatic and uses the DSDB channel (Drive Safety Data Blocks).

Note

The Drive Safety Data Block is an extension of the PROFIdrive axis telegrams. Transmission is according to PROFIdrive and is therefore not a secure safety telegram.

Display of SINAMICS Safety Integrated Functions in SIMOTION

If support for *SINAMICS Safety Integrated Functions is activated* (**technologicalData.numberOfDriveSafetyDataBlock** > 0), the following information is displayed via the system variable:

- **driveData.safety.status1**
  Contains safety status information to which the user program generally must respond immediately.
- **driveData.safety.status2**
  Contains safety status information to which no time-critical response is generally needed.
- **driveData.safety.slsSpeedLimitSelected**
  Effective absolute set velocity limitation in the drive from the DSDB.
  slsSpeedLimitSelected contains the maximum set velocity at which the Axis technology object may run.

  Note

  The value in **slsSpeedLimitSelected** is already weighted with drive parameter p9533. If p9533 < 100%, it does not represent the maximum possible actual velocity monitored by the drive (p9531[x]).

If **technologicalData.numberOfDriveSafetyDataBlock** (standard with DSDB) = 0 and **technologicalData.driveSafetyExtendedFunctionsEnabled** (compatibility mode with SIDB) = NO, there is no support for *SINAMICS Safety Integrated Functions* on the Axis technology object.

In the system variables, zero is displayed or the contents are irrelevant.

Axis configuration

If *SINAMICS Safety Integrated Functions* are configured in the drive, support is activated automatically on the Axis technology object if a drive is assigned.

The following configuration data settings are made:

- **technologicalData.numberOfDriveSafetyDataBlock** > 0
- **technologicalData.SafetyDataBlock_n** = type, logAddressIn, logAddressOut

Deactivated symbolic assignments

The rest of the chapter is only relevant if the project standard setting **Use symbolic assignments** is deliberately deactivated.

To configure the *SINAMICS Safety Integrated Functions*, proceed as follows:

- Select the SC type in the safety dialog for a maximum of two data blocks (DSDB_1 and DSDB_2) and enter the logical base addresses.
- Evaluate the status of the pulse enable of the drive on the Axis technology object (Page 3107).

If a safety commissioning of the *SINAMICS Safety Integrated Functions* in the drive has already been performed and the data has been loaded into the configuration (load into the PG), click the "Data transfer from the drive" button (drive assignment in the axis wizard) to make these settings.

If this is not required, *SINAMICS Safety Integrated Functions* support can be deactivated by setting the **technologicalData.numberOfDriveSafetyDataBlock**=0 configuration data element.

Safety status information (part of the DSDB)

The following tables show the structure of the safety status information in system variables on the TO axis.

Table 4-375 **Allocation of the system variable driveData.safety.status1**

Bit	State	Identifier	Interconnection in the drive
0	STO is active	STO_ACTIVE	r9734.0
1	SS1 is active	SS1_ACTIVE	r9734.1
2	SS2 is active	SS2_ACTIVE	r9734.2
3	SOS is selected	SOS_SELECTED	r9734.5
4	-	-	-
5	SLS is selected	SLS_SELECTED	r9734.6

4.8.5.7 Compatibility mode (SIDB) as of SIMOTION V4.1

The compatibility mode is available for the following projects:

- Projects < SIMOTION V4.4 with Safety Information Data Block (SIDB)
- Projects that have been converted upwards from < V4.4

This mode can only be activated if the *SINAMICS Safety Integrated Extended Functions* settings have been set on the drive.

Safety Information Data Block (SIDB)

The Safety Information Data Block (SIDB) shows the state of the activated *SINAMICS Safety Integrated Extended Functions* in SIMOTION.

Note

The Safety Information Data Block (SIDB) is an extension of the PROFIdrive axis telegrams. Transmission is according to PROFIdrive and is therefore not a secure safety telegram.

Table 4-377 Structure of the Safety Information Data Block (SIDB) in the actual value telegram

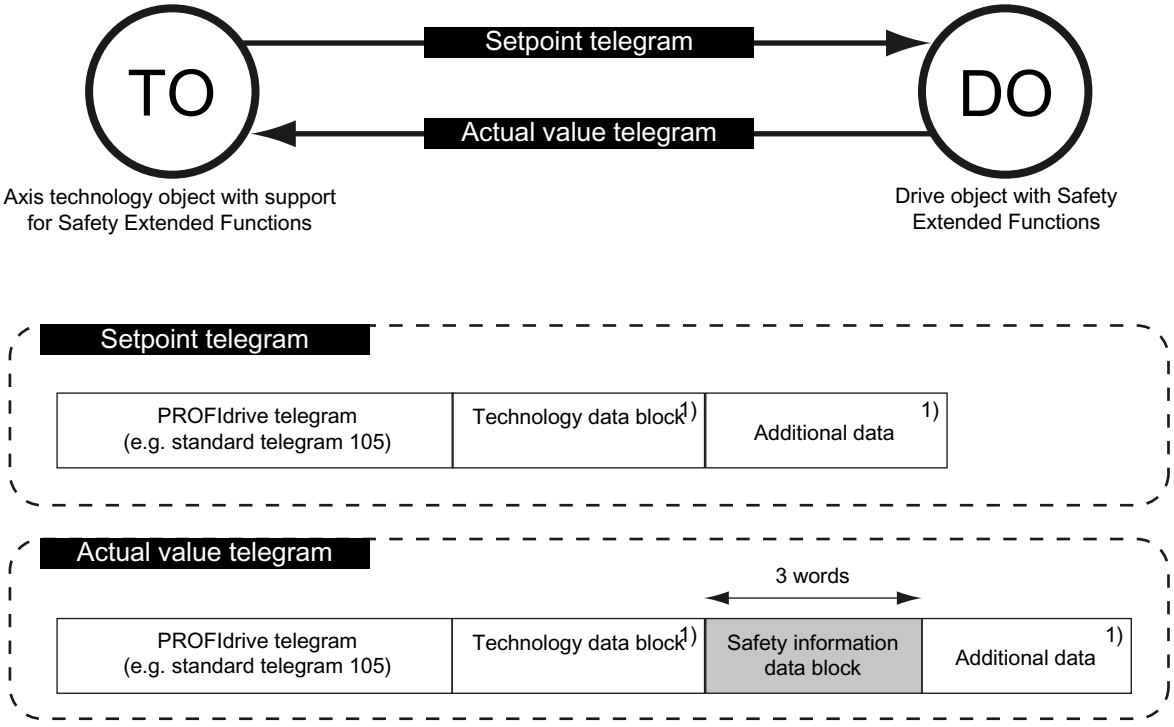
Word	Meaning
1	Safety status word (Page 3093)
2	Effective absolute set velocity limitation in the drive **Note:** This double word must be interconnected with r9733[0] (up to SINAMICS V4.4 only) or with r9733[2] (as of SINAMICS V4.4). For the *Interconnection of the Safety Information Data Block (SIDB) to the actual value telegram in the drive*, see figure below.
3	

As of SIMOTION V4.2, the Safety Information Data Block (SIDB) is set up by the system and automatically interconnected in the drive.

Telegram extension (V4.1 only or with symbolic assignment deactivated)

The rest of this chapter is only relevant if the project default setting **Use symbolic assignment** is deliberately deactivated as of V4.2, or if you are working with a project which uses SIMOTION V4.1.

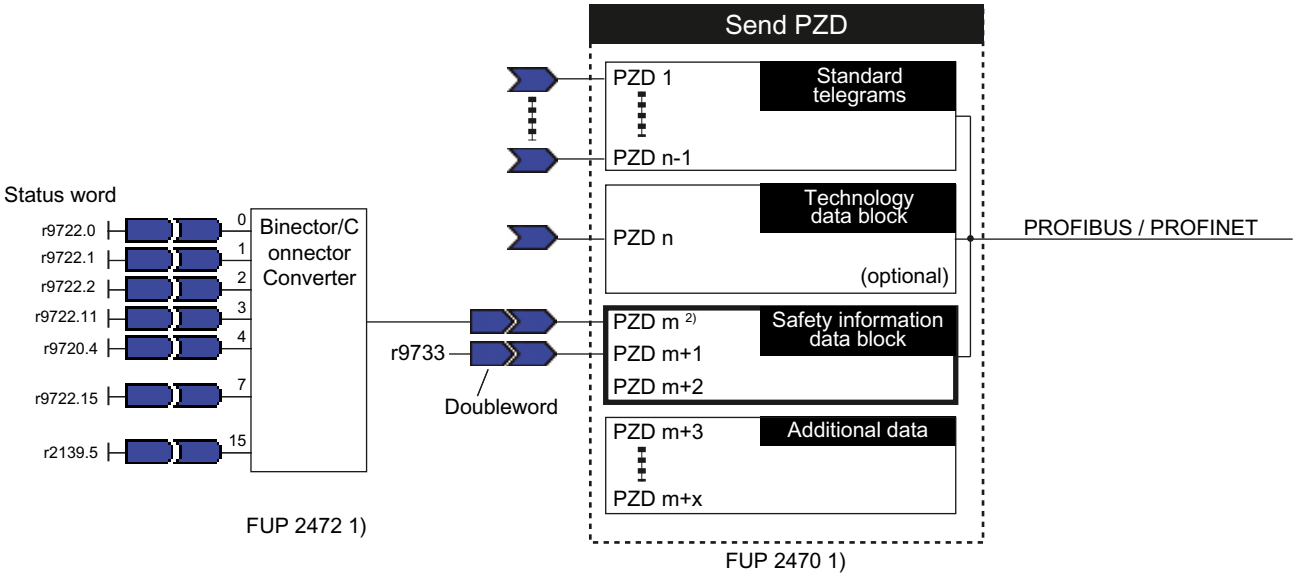
The SIMOTION support for **SINAMICS Safety Integrated Extended Functions** requires the actual value telegram to be extended by the Safety Information Data Block (SIDB) (three words).



1) Optional

Figure 4-896 Layout of a drive telegram with Safety Information Data Block

In order for the *SINAMICS Safety Integrated Extended Functions* to be displayed in SIMOTION, the corresponding SINAMICS parameters must be interconnected with the Safety Information Data Block (SIDB) using BICO.



1) Function charts can be accessed in online help via the “PDF documents” button
2) If technology data block is available: m = n + 1
If no technology data block is available: m = n

Figure 4-897 Interconnection of the Safety Information Data Block (SIDB) to the actual value telegram in the drive

The configuration of the telegram extension is configured using the SINAMICS device > Communication > Telegram configuration dialog with an extension of the input data of the axis telegram by three words.
Via *Configure telegram*, the interconnection of the user-defined PZDs can be carried out using a binector-connector converter.

The logical base address for the Safety Information Data Block (SIDB) **technologicalData.driveSafetyExtendedFunctionsInfoDataIn.logAddress** results as follows:
standard telegram base address + (m-1) * 2
(m is the number of the PZD where the Safety Information Data Block (SIDB) begins). (See also figure above).

Also refer to the information for creating the technology data block in Chapter Coupling of digital drives (Page 2895).

See also

Display of SINAMICS Safety Integrated Functions in SIMOTION (Page 3095)

Safety status information (part of the SIDB)

The following table shows the structure of the safety status word:

If standard SINAMICS Safety Integrated functionality with DSDB is activated, the displays in the safety status word of the SIDB are also updated for compatibility reasons. The content of the

driveSafetyExtendedFunctionsInfoData.state system variable then also displays the information for the *Safety Integrated Basic Function* in this case.

Table 4-378 Structure of the safety status word

Bit	State	Identifier		Interconnection in the drive
0	STO is active	STO_ACTIVE	1-active	r9722.0
1	SS1 is active	SS1_ACTIVE	1-active	r9722.1
2	SS2 is active	SS2_ACTIVE	1-active	r9722.2
3	SOS is selected	SOS_SELECTED	1-active	r9722.11
4	SLS is selected	SLS_SELECTED	0-active	r9720.4
5	Reserved	-	-	-
6	Reserved	-	-	-
7	SSM (n below limit) (See also Restrictions after switching from compatibility mode (SIDB) to standard (DSDB). (Page 3112))	SSM_ACTIVE	1-active	r9722.15
8	Reserved	-	-	-
9	Reserved	-	-	-
10	Reserved	-	-	-
11	Reserved	-	-	-
12	SDI positive selected (as of SINAMICS V4.4)	SDI_P_SELECTED	1-active	r9734.12
13	SDI negative selected (as of SINAMICS V4.4)	SDI_N_SELECTED	1-active	r9734.13
14	Reserved	-	-	-
15	Entry present in the SINAMICS safety fault buffer (See SINAMICS Safety Fault Buffer (Page 3110))	S_FAULT_PRESENT	1-active	r2139.5

Display of SINAMICS Safety Integrated Functions in SIMOTION

If support for *SINAMICS Safety Integrated Extended Functions* is activated (**technologicalData.driveSafetyExtendedFunctionsEnabled**=YES), the following information is displayed via the system variable:

- **driveData.driveSafetyExtendedFunctionsInfoData.state**
  Displays the safety status word (Page 3093).
  The status word can be used to evaluate the status of the safety functions in the drive in the controller. The status is required for many safety functions, in order to bring the axis from the user program to the permissible operating range. See also Overview (Page 3096).
- **driveData.driveSafetyExtendedFunctionsInfoData.safeSpeedLimit**
  Effective absolute set velocity limitation in the drive from the Safety Information Data Block (SIDB), see also the table for the Structure of the Safety Information Data Block (SIDB) (Page 3091).
  safeSpeedLimit contains the maximum set velocity at which the Axis technology object may run.

  Note

  The value in **safeSpeedLimit** is already weighted with drive parameter p9533. If p9533 < 100%, it does not represent the maximum possible actual velocity monitored by the drive (p9531[x]).

If **technologicalData.numberOfDriveSafetyDataBlock** = 0 (standard with DSDB) and **technologicalData.driveSafetyExtendedFunctionsEnabled** = NO (compatibility mode with SIDB), there is no support for *SINAMICS Safety Integrated Functions* on the Axis technology object.

In the system variables, zero is displayed or the contents are irrelevant.

Axis configuration

As of SIMOTION V4.2, if *SINAMICS Safety Integrated Extended Functions* are configured, support is activated automatically in SIMOTION.

The configuration data element **technologicalData.driveSafetyExtendedFunctionsEnabled** = YES is also set**.**

Symbolic assignments deactivated or SIMOTION < V4.2

The rest of this chapter is only relevant if the project default setting **Use symbolic assignment** is deliberately deactivated as of V4.2, or if you are working with a project which uses SIMOTION V4.1.

To configure the *SINAMICS Safety Integrated Extended Functions*, proceed as follows:

- Set the **technologicalData.driveSafetyExtendedFunctionsEnabled** configuration data element to YES. This activates the Extended Functions support.
- Enter the logical base address for the Safety Information Data Block (SIDB) in **technologicalData.driveSafetyExtendedFunctionsInfoDataIn.logAddress**.
- Evaluate the status of the pulse enable of the drive on the axis technology object (Page 3107).

If a safety commissioning of the *SINAMICS Safety Integrated Extended Functions* in the drive has already been performed and the data has been loaded into the configuration (load to PG), click the **Data transfer from the drive** button (drive assignment in the axis wizard) to make these settings.

If this is not required, *SINAMICS Safety Integrated Extended Functions* support can be deactivated by setting the **technologicalData.driveSafetyExtendedFunctionsEnabled** configuration data item to NO.

4.8.5.8 Behavior and user responses

Overview

The safety functions in the drive are selected and deselected either from a Safety PLC (e.g. SIMATIC S7 CPU317F) using secure PROFIsafe communication, from a safety-related SINAMICS terminal module TM54F or using the fail-safe terminals on the CU (D410-2, CU310-2 or CU305). The safety functions can be selected and deselected independently of the Motion Control user program.

Many safety functions (e.g. SOS, SLS) contain monitoring functions and must be supported by the SIMOTION user program so that the drive can be set to or kept in the monitored operating state. If the monitored limits are exceeded, this causes a safety-related stop response in the drive.

The user can evaluate the safety status word via system variables. See also the status information for DSDB (Page 3088) and SIDB (Page 3093).

General recommendation for the user program when using SINAMICS Safety Integrated Functions as of SIMOTION V4.2

The system responds automatically to the selection of SS1 or SS2 by switching the axis to follow-up mode. The following requirements must be satisfied to do this:

- Default settings for symbolic assignment
- Automatic telegram selection
- Evaluation of the pulses enabled bits must not be changed

When STO is selected, the drive shuts down automatically.
Therefore, safety functions STO, SS1, and SS2 do not require any provision to be made in the user program in terms of a response.

For other functions such as SOS or SLS, it must be ensured via the user program that the monitored operating state is not violated.

See also

Overview - Support of SINAMICS Safety Integrated Functions on the Axis technology object (Page 3079)

Display of SINAMICS Safety Integrated Functions in SIMOTION (Page 3095)

Overview of safety functions

How the drive reacts and what user responses we recommend in SIMOTION are described below.

Note

Design your user program in accordance with the priority of the safety drive functions. Take into account possible consecutive responses of the drive, e.g. STOP_B in the event of SLS limit value violation.

Evaluate the status bits cyclically in your user program.

Also take into account user responses for connected axes.

Table 4-379 Responses of the drive and responses in the user program when a safety function is selected

Function	Drive response	Recommended response in the user program
STO	Drive switches off immediately	No response possible
SS1E	Drive switches off after expiration of a delay time	Bring axis to a standstill before expiration of the delay time and switch off the drive
SS1	Drive decelerates on the OFF3 ramp and then switches off	Set axis to follow-up mode (automatic as of SIMOTION V4.2)
SS2	Drive decelerates on the OFF3 ramp and then monitors the operating stop	Set axis to follow-up mode (automatic as of SIMOTION V4.2)
SOS	Drive monitors the operating stop after expiration of the delay time	Bring axis to a standstill and remain at a standstill
SLS	Drive monitors the maximum permissible velocity after expiration of a delay time	Limit the axis velocity accordingly
SDI	Drive monitors the direction of motion after expiration of a delay time	Maintain or stop the direction of motion of the axis accordingly
SP	Drive transfers actual position to the F-CPU	-
SLP	Drive monitors compliance with a defined position range after expiration of a delay time	Maintain position range of the axis accordingly
SLA	The drive monitors the maximum permissible acceleration after expiration of a delay time	Limit the axis accelerations accordingly
SCA	The drive transfers safe cam information to the F-CPU	-

Safe Torque Off (STO)As of SIMOTION V4.1

When the **STO** is selected, pulse suppression will be activated directly in the drive: A moving motor coasts to standstill. If there is a motor holding brake and activation via sequential control system, the brake closes.

If the drive enables have been canceled by **STO**, they can be reset by the SIMOTION user program with the **_enableAxis()** command. An enable, however, is possible only when **STO** has been deselected again (safe power-on disable).

In compatibility mode with SIDB, **STO** is only supported in conjunction with the *SINAMICS Safety Integrated Extended Functions* on the axis.

Safety status information (part of the DSDB) (Page 3088)

Safety status information (part of the SIDB) (Page 3093)

Safe Stop 1 (SS1)As of SIMOTION V4.1

SS1 with OFF3

When **SS1** is selected, the drive independently decelerates on the OFF3 ramp in a speed-controlled manner (n=0) and enters pulse suppression after a configured delay time.

The drive is shut down when pulse suppression is achieved. This is indicated on the Axis technology object by alarm 20005 reason 4.

NOTICE
Abort of the OFF3 ramp
For certain settings, the OFF3 ramp cannot be aborted on the control side!
See SIMOTION system behavior with a drive-autonomous OFF3 ramp (Page 2893).

User response as of SIMOTION V4.2:

The system responds automatically to SS1 selection if the configuration data item **TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation** is set to YES (set accordingly when creating an axis as of SIMOTION V4.2).
At the start of the OFF3 ramp, TO alarm 50023 (drive makes transition to autonomous state, default local response = OPEN_POSITION_CONTROL) is signaled, switching the axis to follow-up mode automatically.
Consequently, both the position controller enable and following error monitoring are inactive during the OFF3 ramp, and no more motion commands are effective. The drive enables can be canceled with the **_disableaxis()** user command, for example.
Automatic follow-up mode is only activated for the axis concerned in each case. For a possible synchronous operation line-up, the corresponding responses must be converted in the application.

If the drive enables have been canceled by **SS1**, they can be reset by the SIMOTION user program with the **_enableAxis()** command. An enable, however, is possible only when **SS1** has been deselected again (safe power-on disable).

User response with SIMOTION V4.1 or TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation=COMPATIBILITY_MODE:

When SS1 is selected (status information SS1_ACTIVE=TRUE), the current axis motion must be canceled and the position setpoint switched to follow-up mode (with the **_stop()** command at velocity = 0 and movingMode=SPEED_CONTROLLED, for example). This prevents the enables for the drive from having to be canceled (as a result of alarm 50102, following error monitoring, for example).

SS1E external stop (as of SINAMICS V4.5 and SIMOTION V4.3)

If SS1E is selected, the drive switches off after a delay time (p9652 Safety Integrated Basic Functions / p9556 Safety Integrated Extended Functions) without being autonomously decelerated along the OFF3 ramp. Within the delay time, synchronous axes can be stopped synchronously via the user program.

User response to use of the DSDB (SIMOTION V4.4 and higher) or the SIDB (for Safety Integrated Extended Functions):

If SS1E is selected (status information SS1_ACTIVE = TRUE), stop the axis before the delay time elapses and switch off the drive.

User response to Safety Integrated Basic Functions in the user program in SIMOTION V4.3:

The following section is only relevant to SIMOTION V4.3 or if the DSDB is not used.

Transfer parameters p9772.2 and p9872.2 and check them cyclically, for example, in the IPO-synchronous task.

As soon as at least one of the two parameters is TRUE, the axis must be stopped before the delay time elapses and the drive switched off.

Control via terminals

If controlling via terminals, please see the *SINAMICS Safety Integrated* Functional Manual, Chapter *Simultaneity and tolerance time of the two monitoring channels*.

Safety status information (part of the DSDB) (Page 3088)

Safety status information (part of the SIDB) (Page 3093)

Safe Stop 2 (SS2)As of SIMOTION V4.1

When Safe Stop 2 is selected, the drive decelerates on the speed-controlled OFF3 ramp (n=0) and then switches to the Safe Operating Stop (SOS). The drive then decouples itself from the SIMOTION setpoint interface.

NOTICE
Abort of the OFF3 ramp For certain settings, the OFF3 ramp cannot be aborted on the control side! See SIMOTION system behavior with a drive-autonomous OFF3 ramp (Page 2893).

Note

If the drive is not yet ready to run and SS2 has already been selected, all drive enables can only be set once SS2 has been deselected.
This may be the case following a further ramp up of the selected SS2, for example.

The drive enables can be set using the **_enableaxis()** user command, for example.

User response as of SIMOTION V4.2:

The system responds automatically to SS2 selection if the configuration data item **TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation** is set to YES (set accordingly when creating an axis as of SIMOTION V4.2):
As a result, the user does not have to carry out cyclic evaluation of whether SS2 is selected.
At the start of the OFF3 ramp, TO alarm 50023 (drive makes transition to autonomous state, default local response = OPEN_POSITION_CONTROL) is signaled, switching the axis to follow-up mode automatically.
As long as SS2 is selected, the position controller enable and the following error monitoring therefore remain inactive and no more motion commands are effective. The drive enables can be canceled with the **_disableaxis()** user command, for example.
Automatic follow-up mode is only activated for the axis concerned in each case. For a possible synchronous operation line-up, the corresponding responses must be converted in the application.

After SS2 has been deselected, the position controller enable has to be reset with the **_enableaxis()** user command, for example, so that the axis can be traversed again.

User response with SIMOTION V4.1 or TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation=COMPATIBILITY_MODE:

When SS2 is selected (status information SS2_ACTIVE=TRUE), cancel the current motion on the axis and switch the position setpoint to follow-up mode, e.g. using the **_stop()** command at velocity = 0 and movingMode=SPEED_CONTROLLED. This prevents the enables for the drive from having to be canceled (as a result of alarm 50102, following error monitoring, for example).

Deselecting SS2 (status information SS2_ACTIVE=FALSE) terminates standstill monitoring in the drive. If no other safety function is active, the axis can be traversed again without the drive enables having to be reset.

See also

Safety status information (part of the DSDB) (Page 3088)

Safety status information (part of the SIDB) (Page 3093)

Safe Operating Stop (SOS)As of SIMOTION V4.1

When SOS is selected, the drive continues to follow the setpoint interface and activates the standstill monitoring after the delay time configured in the drive.

Response in the user program:

When SOS is selected (status information SOS_SELECTED=TRUE)), bring the drive to a standstill within the time parameterized in p9551/p9531 and keep it in this state.

When SOS is deselected, the standstill monitoring in the drive will be deactivated; the drive can traverse again without restriction provided no other safety function is active.

Safety status information (part of the DSDB) (Page 3088)

Safety status information (part of the SIDB) (Page 3093)

Safely-Limited Speed (SLS)As of SIMOTION V4.1

When SLS is selected, the drive continues to follow the setpoint interface and activates the maximum velocity monitoring after the delay time configured in the drive.

When using SLS, ensure that the checkbox **SLS limit value absolute** is selected in the safety dialog.

Response in the user program:

When SLS is selected (status information SLS_SELECTED), the velocity must be reduced to the defined maximum velocity (system variable **driveData.safety.slsSpeedLimitSelected**). For this purpose, ensure that the application observes the distance to the actual limit value monitored

in the drive. Reduction either on the drive side using the p9533 parameter or using a programming reduction factor.

Note

It should be noted that updating the system variables with the status information and the defined maximum velocity is not necessarily simultaneous. Two cases must therefore be allowed for in the user program:

1. SLS is selected in the drive
   The system variable with the status information reports this.
   The system variable **~.slsSpeedLimitSelected** still includes the maximum velocity of the axis and not the limited velocity.
2. SLS is deselected in the drive.
   The system variable with the status information still reports SLS selected.
   The system variable **~.slsSpeedLimitSelected** already contains the maximum velocity of the axis.

Please also see the note regarding the reduction factor for **~.slsSpeedLimitSelected** in Chapter Display of SINAMICS Safety Integrated Functions in SIMOTION (Page 3087)

The velocity limit value monitored in the drive can be changed by switching between the SLS levels. Therefore, the system variable **~.safeSpeedLimit** should be continuously monitored for changes while SLS is selected.

In the user program, the activation of velocity reduction or the change to the reduced speed must be cyclically checked and the current velocity setpoint must be compared with the safe maximum velocity.

A detailed procedure can be found in the table below.

Table 4-380 User responses for SLS

	SLS_{new} selected	**SLS active and new SLS speed activated**	
		SLS_{new} is greater than SLS_{old}	**SLS_{new} is less than SLS_{old}**
Production speed is less than the limited speed SLSnew	No response necessary	If production speed is greater than SLS_{old}, increase to production speed is possible	No response necessary
Production speed is greater than the limited speed SLSnew	Deceleration to limited speed SLS_{new} required	Increase to SLS_{new} is permissible	Deceleration to limited speed SLS_{new} required

Production speed = set velocity before selecting a safety function

Note

For active velocity monitoring on a following axis (synchronous coupling and with a fixed gear or coupling via MotionIn interface), the speed of the master axis is reduced or, if this is not possible, synchronous operation during the reduction is canceled.

Compatibility mode with SIDB

The defined maximum speed is saved in the system variable **driveData.driveSafetyExtendedFunctionsInfoData.safeSpeedLimit**.

Please also see the note regarding the reduction factor for **~.safeSpeedLimit** in Chapter Display of SINAMICS Safety Integrated Functions in SIMOTION (Page 3095)

Safety status information (part of the DSDB) (Page 3088)

Safety status information (part of the SIDB) (Page 3093)

Safe Direction (SDI)As of SIMOTION V4.3

After selecting SDI (status information SDI_P_SELECTED or SDI_N_SELECTED), the motion may only be performed in the enabled direction.

Response in the user program:

If the direction of motion is incorrect, the motion must be stopped via the SIMOTION user program and it must be ensured that the motion is only performed in the enabled direction.

See also

Safety status information (part of the DSDB) (Page 3088)

Safety status information (part of the SIDB) (Page 3093)

Safe Position (SP)

Function SP can be selected optionally with reference to an absolute position. Use of SLP with transfer of the safe position SP corresponds to using SP with reference to an absolute position.

To update the relevant status bits in DSDB, drive parameter p9501.27 must be set.

Using SP with a safe absolute position

As for SLP (Page 3104), safe homing of the drive is required.

The position transferred via PROFIsafe can be used in the F-CPU to evaluate the position.

Using SP without a safe absolute position

The position transferred via PROFIsafe can only be used in the F-CPU to ascertain the speed of the drive.

See also *SINAMICS S120 Safety Integrated* Function Manual.

Synchronous transfer of safe position values (SP)

An isochronous transfer of safe positions (isochronous PROFIsafe telegram) is not possible with SIMOTION.

Safely-Limited Position (SLP)As of SIMOTION V4.4

Monitor the absolute traversing range of an axis using SLP. You may define a maximum of two traversing ranges in the drive. The active traversing range is displayed in SLP_LIMIT_BIT0_SELECTED of the system variable **driveData.safety.status1**.

The motion limitation when SLP function is activated must be performed by the user program. SLP activation is displayed in SLP_SELECTED of system variable **driveData.safety.status1**.

To update the status bits relevant for SLP in the DSDB, drive parameter p9501.27 must be set.

Requirement

The safe limited position can only be monitored if the following conditions are met:

- The drive must be homed at standstill while the machine is being commissioned.
- User agreement must be set once during commissioning after homing.
  Exception: It is reset by the user or by a positional tolerance violation in the drive.
- The SLP acceptance test must be performed.

Status **REF_REQUESTED** of the system variable **driveData.safety.status1** indicates whether the drive has been homed and/or whether homing has been requested by the drive. Homing must be performed again, for example, after the CU has been started up.

Note

Status of user agreement

The DSDB does not indicate whether user agreement is lost after successful homing of the drive. Only the S_FAULT bit is set. Evaluation via acyclic read requests may take too long to recognize this state and trigger a response in the user program if SLP is selected or already active.

Make sure a suitable response is implemented in the F-CPU user program in this case. For example, evaluate the "safely homed" bit in the PROFIsafe telegram. For example, trigger SOS if the drive is not safely homed.

Homing and user agreement

Homing must be performed once and user agreement set during commissioning. This can be done in the expert list of the drive or via an HMI.

Therefore home the TO axis and set the user agreement via an HMI:

1. Home the TO axis to a position that you can check in situ and make the axis remain stationary at this position.
2. Transfer the current position of the axis to the drive and apply the home position at standstill (two acyclic **_writeDriveParameter()** requests).
3. Wait for at least five safety cycles, then read the actual position of the drive (r9708[0]) and transfer it to the HMI.
4. Check whether the position of the TO axis is the same as the drive position and that this position corresponds to the machine position.

5. If the positions in step 4. are equal, set the user agreement with a **_writeDriveMultiParameter()** command.

   Note

   If the command is executed and user agreement is active, user agreement will be reset.

6. Now perform the SLP acceptance test.

In the Internet, you will find a program example for homing and setting user agreement as an FAQ (https://support.industry.siemens.com/cs/ww/en/view/100778695).

Violation of the traversing range when the SLP Retraction function is activated

If an SLP limit is exceeded, a safety error is displayed on the drive. A safe stop response is triggered on the drive as error response.

The **INTERNAL_EVENT** in the system variable **driveData.safety.status1** displays the safety error on the Axis technology object.

Retract the axis after an SLP violation as follows:

1. Activate the SDI function in the opposite direction to the violated direction of travel. Depending on the application, implement further safety requirements. For example, additionally activate the lowest SLS level and/or ensure that the drive can only be retracted by the F-CPU when a button is permanently pressed.
2. Deactivate SLP as soon as SDI is active.
3. Acknowledge the safety errors.
4. Travel the axis manually back into the valid SLP traversing range.
5. Activate the SLP function.
6. Deactivate the SDI function as soon as SLP is active.

Safe Cam (SCA)

With SCA, you can define safe cams that are available for evaluation in the F-CPU.

To update the status bits relevant for SCA in the DSDB, drive parameter p9501.27 must be set. With safe cams, for example, other safety functions can be selected in the F-CPU for defined positions.

Requirement

- Use of PROFIsafe telegram 903
- The drive must be homed safely at standstill while the machine is being commissioned. This must be performed as for SLP (Page 3104).

SLA - Safely-Limited Acceleration (as of SIMOTION V5.2)

When SLA is selected, the drive continues to follow the setpoint interface and activates the maximum acceleration monitoring in the drive.

The activation of **SLA** is displayed in **SLA_SELECTED** of the **driveData.safety.status1** system variable.

Response in the user program

For selection, and so active SLA (**SLA_SELECTED** status information), the acceleration for traversal commands must be reduced to the defined maximum acceleration of the drive. For this purpose, ensure that the application observes the distance to the actual limit value monitored in the drive.

New functions as of SINAMICS firmware V5.2

As of SINAMICS FW V5.2, SLA has been extended with fine resolution and acceleration filtering. You can parameterize the acceleration limit value and the stop reaction on SLA, and the filter time as of V5.2.

If the determination of the acceleration results in very noisy signals, the drive cannot reasonably monitor the acceleration. Remedy: In this case, increase the **"SLA filter time" (p9576)**. Note that **SLA** reacts with a delay when you increase the filter time.

Transmission via SIC

Once **SLA** has been parameterized and selected, the monitoring results are also transmitted in **SIC** in status word **S_ZSW1B.8** (Section "Safety Info Channel and Safety Control Channel"). You will find this status word in telegrams 700 and 701.

4.8.5.9 Safety brake test as of SIMOTION V4.4

As of V4.4, SIMOTION support the SINAMICS safe brake test. It is triggered by a SIMOTION command from the Axis technology object. During the SBT, the drive no longer follows the controller setpoint.

During the test, the load torque applied at the motor is measured once. The test torque is then increased n times depending on the direction and the number of brakes, maintained for a period of time and then reduced again.

The brake test can be performed for a maximum of two brakes in one test cycle. One internal and one external or two external brakes are possible if there are two brakes. Each brake can be tested against two different holding torques.

Requirements for the safe brake test

- The axis must be enabled with the **_enableAxis()** command in mode **enableMode**=POWER with **servoControlMode**=INACTIVE.
- All brakes present on the motor must be open.

Perform the safe brake test for an internal brake as follows:

1. Start the test by calling the **_executeAxisSafetySbt()** function in the user program.
2. Monitor the status if necessary via the **driveData.safety.sbtState** system variable.
3. Wait until the function has finished and then check the return value of the function.

Perform the safe brake test as follows if there is at least one external brake:

1. Start the test by calling the **_executeAxisSafetySbt()** function in the user program.
2. If there are two external brakes:
   Check the status **SBT_BT_BRAKE2** of the system variable **driveData.safety.status2** to see whether brake 1 or 2 is tested.
3. Check the status **SBT_BT_BRAKE_CLOSE_REQ** of system variable **driveData.safety.status2** cyclically in the user program. Open or close the external brake, depending on the status.
4. Report the current status of the external brake to the system using the **_setAxisSafetySbtExtBrakeState()** function.
   After a change of status of **SBT_BT_BRAKE_CLOSE_REQ**, the feedback must be provided within 11 seconds.
5. Monitor the status if necessary via the **driveData.safety.sbtState** system variable.
6. Repeat steps 2 to 5 until the **_executeAxisSafetySbt()** function has ended and then check the return value of the function.

Note

External brakes

Take into account the brake opening and closing times for status feedback.

4.8.5.10 Pulse enable evaluation (when standard settings are deactivated)

This chapter is only applicable if standard settings such as **Use symbolic assignment** have been deactivated.

For *SINAMICS Safety Integrated Functions* support, the status of the pulse enable of the drive on the Axis technology object must be evaluated. This status information is transferred to various positions in the telegram depending on the telegram type.
This means the **driveControlConfig.pulsesEnabled.pzdNumber** and

driveControlConfig.pulsesEnabled.bitNumber configuration data as appropriate for the telegram configuration must be set as follows:

- Standard telegram 2-6
  pzd = 4; bit = 10 (ZSW2; "Enable pulses")
  (possible as of SINAMICS V2.6)
- Ten SIEMENS telegrams
  pzd = 5; bit = 13 (message word; "Enable pulses")
- Non-assigned telegrams
  The user has sole responsibility for ensuring that both of the configuration data settings referred to are set according to the position of the pulse enable status bit within the telegram.

Note

- Standard telegram 1 cannot be used to support safety functions SS1 and SS2, since it does not transmit the status of the pulse enable.
- Depending on the telegram used, set p2038 as follows:
  - For standard telegrams in the drive p2038=0
  - For SIEMENS telegrams in the drive p2038=1

4.8.5.11 Messages and alarms

The messages are displayed as technological alarms of the *SINAMICS Safety Integrated Extended Functions* on the SIMOTION Axis technology object.

Technological alarms:

- **Alarm 50023: Drive makes transition to autonomous state (as of SIMOTION V4.2)**
  If the drive behaves autonomously, e.g. braking on the OFF3 ramp in response to an SS2 selection, alarm 50023 is signaled.
- **Alarm 50201: Safety alarm in the drive (see SINAMICS Safety Message Buffer)**
  A new event is present in the safety message buffer of the drive.

Note

Acknowledgment of alarm 50201

Earlier than SIMOTION V4.4:
Then alarm can only be acknowledged permanently if there are no longer any entries in the safety message buffer.

As of SIMOTION V4.4 (with DSDB):
Then alarm can only be acknowledged permanently if neither S_FAULT_PRESENT nor INTERNAL_EVENT is set.

- **Alarm 50202: SINAMICS Safety Integrated Extended Function is selected**
  Alarm 50202 is signaled if the safety functions SS2/SOS/SLS are selected and, as of V4.4, SDI/SLP as well.
  Exceptions:
  - On transition to SOS with SS2 active (automatic transition or explicit selection), no new 50202 alarm is activated.
  - If the *SINAMICS Safety Integrated Extended Functions* are activated using PROFIsafe, alarm 50202 is generated after a SINAMICS reset without a safety function being selected.
  - If the *SINAMICS Safety Integrated Extended Functions* are activated using PROFIsafe, alarm 50202 is generated if the SIMOTION CPU or F-CPU switches to STOP.

  The alarm is used only for display in the SCOUT or HMI.
  User responses should reference system variable **driveData.safety.status1/ driveData.safety.status2** or **driveData.driveSafetyExtendedFunctionsInfoData.state**.
- **Alarm 50203: SINAMICS Safety Integrated Extended Function is deselected**
  Alarm 50203 is signaled if the last active safety function SS2/SOS/SLS is deselected and, as of V4.4, SDI/SLP as well.
  Exception:
  When controlling the *SINAMICS Safety Integrated Extended Functions* via PROFIsafe, the PROFIsafe driver is acknowledged (user action on the F-CPU side as an additional prerequisite for full drive enable (drive parameter r46.8)), alarm 50203 is generated without a safety function being deselected.
  The alarm is used only for display in the SCOUT or HMI.
  User responses should reference system variable **driveData.safety.status1/ driveData.safety.status2** or **driveData.driveSafetyExtendedFunctionsInfoData.state**.
- **Alarm 50209: Error on brake test**
  Alarm 50209 is signaled if an error occurs when the SBT brake test is performed.

Note

Alarm 50023 only becomes active on the Axis technology object if configuration data **TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation** is set to YES.

Alarms 50201, 50202 and 50203 are only displayed on the TO axis when DSDB and SIDB are activated.

No safety alarm is triggered when STO and SS1 are selected. Alarm 20005 reason 4 is signaled if the pulses are deleted by the drive. There is no alarm to signal that the functions have been deselected.

Illustration of safety alarm behavior (50202, 50203) based on a pulse diagram

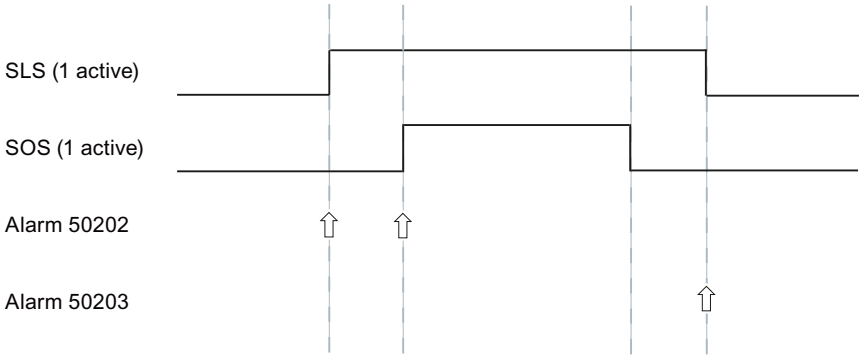

Figure 4-898 Pulse diagram illustrating safety alarm behavior

4.8.5.12 SINAMICS Safety Message Buffer

Errors in the safety function in the drive or stop responses that are triggered by the monitoring functions initiate messages.

Messages for the *SINAMICS Safety Integrated Basic Functions* are displayed in the drive's message buffer (r947).

Messages for the *SINAMICS Safety Integrated Extended Functions* are displayed in the safety message buffer (r9747).

Table 4-381 Basic structure of the message buffer

Parameter	Meaning
r944	Message buffer change count
r947 [0...63]	Message code
r949 [0...63]	Additional information
r952	Messages counter

Table 4-382 Basic structure of the safety message buffer

Parameter	Meaning
r9744	Message buffer change count
r9747 [0...63]	Message code
r9749 [0...63]	Additional information
r9752	Messages counter

Acknowledge

Errors in the safety functions or stop responses may only be acknowledged on a fail-safe basis. A distinction must be made here between the *Basic Functions* and *Extended Functions*.

Basic Functions: Acknowledgment via two-channel selection/deselection by STO.

Extended Functions: Acknowledgment of safety PLC via the PROFIsafe signal Internal_Event_Acknowledge - Bit 7 of the PROFIsafe control word or via a terminal on TM54F or F-DI OnBoard for D410-2.

With extended alarm acknowledgment, the messages can be acknowledged via the acknowledgment mechanism of the *Basic Functions*.

Note

Limitation for SINAMICS V2.5

Fail-safe acknowledgment via PROFIsafe bit or a fail-safe digital input following violation of SLS limit value is only possible if STOP C (p9563=2) has been configured as a fault response. For other stop responses, an acknowledgment is only possible by means of Power Off/Power On.

For further information, see the *SINAMICS Safety Integrated* Function Manual.

Display and evaluate an error message

An entry in the safety message buffer is displayed by S_FAULT_PRESENT in the system variable **driveData.safety.status1** (Bit 30).

The occurrence of a safety STOP response is displayed by INTERNAL_EVENT in the system variable **driveData.safety.status1** (Bit 31).

If this bit is set, the **50201 Safety Alarm in the drive** alarm will be triggered in SIMOTION.

The **_readDriveFaults()** system function can be used to read out the message code.

As of SIMOTION V4.2 it is possible to fetch data from the safety message buffer directly by setting faultType=SAFETY (drive parameter p9747). The additional information for the message code can be read out by the user program using the system function **_readDriveParameter()** from drive parameter r9749.

Compatibility mode with SIDB

An entry in the safety message buffer is displayed by S_FAULT_PRESENT in the system variable **driveData.driveSafetyExtendedFunctionsInfoData.state** (Bit 15). If this bit is set, the **50201 Safety Alarm in the drive** alarm will be triggered in SIMOTION.

4.8.5.13 Isochronous PROFIBUS operation

PROFIsafe data must be transferred isochronously.
When PROFIsafe data is transferred isochronously, additional configuration and programming steps are required or are useful.

Essential settings for isochronous PROFIsafe operation

1. Synchronization of the SIMOTION CPU with the F-CPU
   In the I-slave F-proxy and I-device F-proxy topologies, synchronize the connection from the SIMOTION user program to the **_enableDpInterfaceSynchronizationMode()** system function.
2. Consistent process image partition for the safety program
   Make sure that the update of the process image partition for isochronous operation is not performed during the processing of the safety program.
   An example can be found in Chapter *F-CPU: Isochronous operation and safety operation* of the FAQ Actuating internal drive safety functions via SIMOTION and PROFINET with PROFIsafe (https://support.industry.siemens.com/cs/ww/en/view/50207350).

Additional recommended settings for isochronous PROFIsafe operation

1. Check the "synchronous" status on the SIMOTION controller
   Check for error-free synchronization through an I/O status query of the PROFIsafe PZD ("synchronous").
2. Call the safety program on the F-CPU in a multiple of the SI monitoring cycle
   Select the cycle of the cyclic interrupt in which the safety program is called (typically OB35) as a multiple of the SI cycle (drive parameter p9500).
   In this way, you avoid problems during startup (SINAMICS fault 1611/1711 with fault value 6165).

4.8.5.14 Restrictions after switching from compatibility mode (SIDB) to standard (DSDB).

The following points should be noted when switching from compatibility mode (SIDB) to standard (DSDB):

- Safe Speed Monitor, **SSM**
  Safe speed monitoring via the SSM bit is no longer available after switching to standard (DSDB).
- System variable **safeSpeedLimit**
  The system variable is only provided after switching to standard (DSDB) if the following conditions are met:
  - The *SINAMICS Safety Integrated Extended Functions* are configured.
  - The **SLS limit value absolute** option is selected.
- Alarm 50201
  The alarm is only triggered by S_FAULT_PRESENT if the SIMOTION Runtime is less than V4.4.
  As of SIMOTION Runtime V4.4, the alarm can also be triggered by INTERNAL_EVENT.
  See also SINAMICS Safety Message Buffer (Page 3110).
- Always evaluate the pulses enabled bit
  The configuration data item **TypeOfAxis.DriveControlConfig.pulsesEnabledEvaluation** must be set to YES if the DSDB is used and correct transfer of the pulses-enabled bits must be ensured.

4.8.6 Part II Hydraulic Functionality

4.8.6.1 Hydraulic functionality overview

The hydraulic functionality is contained in the **Axis technology object (TO)**.

Like the electric axis, the hydraulic axis can be configured with the following technologies:

- Speed-controlled axis
- Positioning axis
- Synchronous axis

The user view of the electric and hydraulic axes is maintained together, to the extent possible.

Example:

- Motion commands
- Axis settings

Important differences compared to the electric axis include:

- Allowance for a valve characteristic curve
- Special compensation
- A valve can be switched between more than one axis
- No lower-level velocity limiting or torque control in the actuator / drive
- Separate actuators/valves for flow (Q valve) and force/pressure (P valve), if necessary

The hydraulic functionality is explained in the following sections, building on the description of the axis.

See also

Overview of axis technologies (Page 2861)

General information about axes (Page 2858)

4.8.7 Fundamentals of hydraulic functionality

4.8.7.1 Axis settings / drive assignment

Overview of axis settings / drive assignment

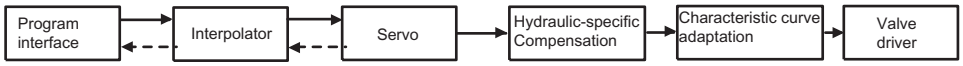

Figure 4-899 Overview of motion control for axes with hydraulic functionality

Valve types:

- **Q valve** (valve for closed-loop control of volumetric flow, path valve)
  Hydraulic valve for control of direction and volume of a material flow, suitable for closed-loop velocity control
- **PQ valve**
  Special Q valve suitable for force, position, velocity, and pressure control
- **P valve** (pressure limiting valve)
  Valve used for limiting the system pressure, suitable for protecting a hydraulic system against excessive pressure (overpressure protection)

Setting as a real axis with hydraulic functionality

The manipulated variable values for the final controlling elements (valves) are defined as analog or direct values.

Options are:

- Analog outputs on the C2xx
- Analog outputs in the I/O area
- Analog outputs on a PROFIBUS module, e.g. SINUMERIK ADI4, SIMATIC IM174
  With SIMODRIVE ADI4 and SIMATIC IM174, PROFIdrive profile standard message frame 3 must be used.

A specific enable signal is available for each final controlling element (see the drive enable signal for electric axes).

The enable signal for the Q valve is set/reset via the qOutputEnable parameter in the **_enableQFAxis()/_disableQFAxis()** command. The status of the enable signal is indicated in the **actorMonitoring.driveState** and **actorMonitoring.power** system variables. When the hydraulic output is connected to the IM174, these system variables are formed using the bits returned in the status word. The status of the Q output is displayed in **actorMonitoring.qOutputState**.

The enable signal for the P valve is set/reset via the fOutputEnable parameter in the **_enableQFAxis()/_disableQFAxis()** command. The status of the enable signal for the P valve is displayed with the **actorMonitoring.fOutputEnable** system variable. The status of the P output is displayed in **actorMonitoring.fOutputState**.

When defining an axis as an axis with hydraulic functionality, it is possible to assign several axes to a final controlling element during configuration. During runtime, they are assigned using the **_enableQFAxis()/_disable QFAxis()** enable/disable commands.

A real axis with hydraulic functionality has manipulated variables for the flow rate (Q, Q valve) and, if required, a separate manipulated variable for direct force/pressure limiting or force/pressure control (F, P valve).

On axes with a P valve, the technological commands and system variables for force/pressure limiting can be used to specify the force and pressure.

The addresses in the I/O area for outputting the Q value and, if applicable, for outputting the F/P value can be set on the axis.

Note

You can find application examples for hydraulic axes under *FAQs > Technology* in the *SIMOTION Utilities & Applications* provided with SIMOTION SCOUT.

Access to the same final controlling element from multiple axes (Page 3134)

Setting as a real axis with Q valve only

With hydraulic axes with Q valve only, the functions for traversing the axis, for velocity limitation, for force/pressure control, and for force/pressure limiting are available as with the electric axis.

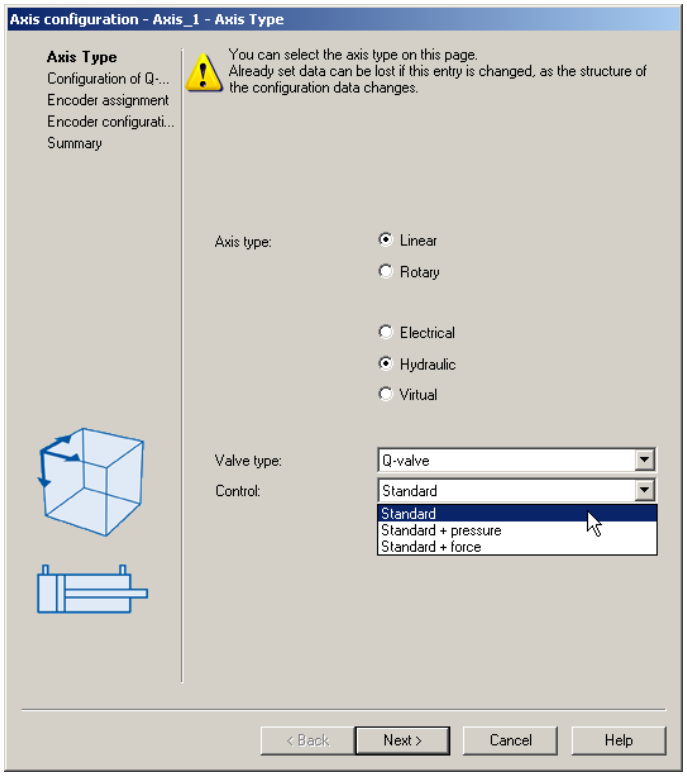

Figure 4-900 Setting the axis type

Table 4-383 Setting the control

Standard	Motion via Q valve
Standard+pressure	Motion and force/pressure control via Q valve Unit: Pascal, bar
Standard+force	Motion and force/pressure control via Q valve Unit: Newton

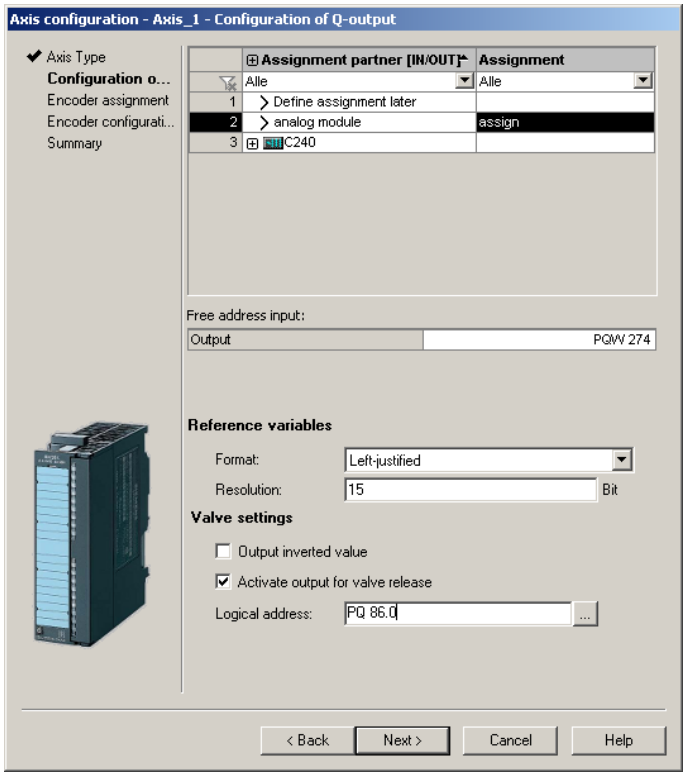

Figure 4-901 Example configuration of the Q output using analog output module

The bit resolution of the analog output module is set under Resolution.

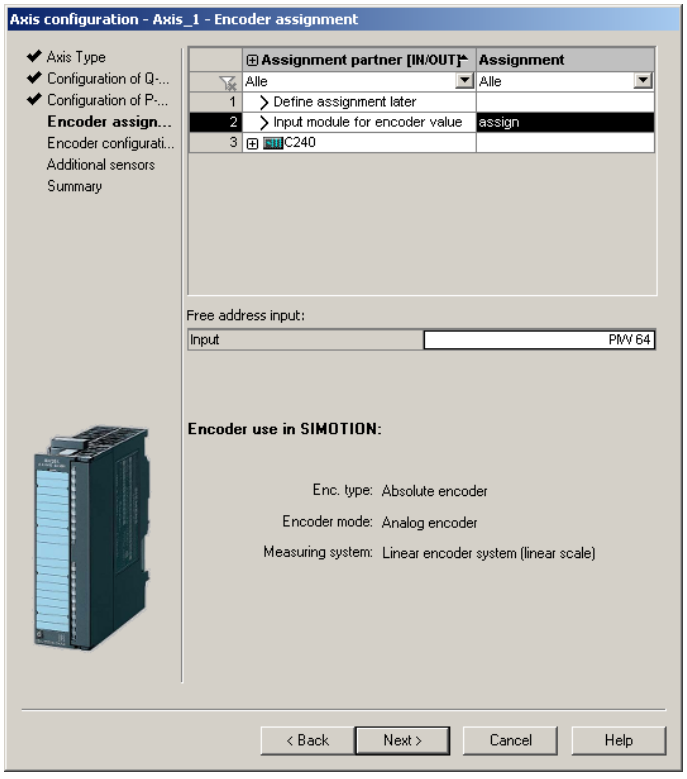

Figure 4-902 Example of configuration for the encoder assignment

The logical hardware address of the input module can be found in the HW Config in SCOUT.

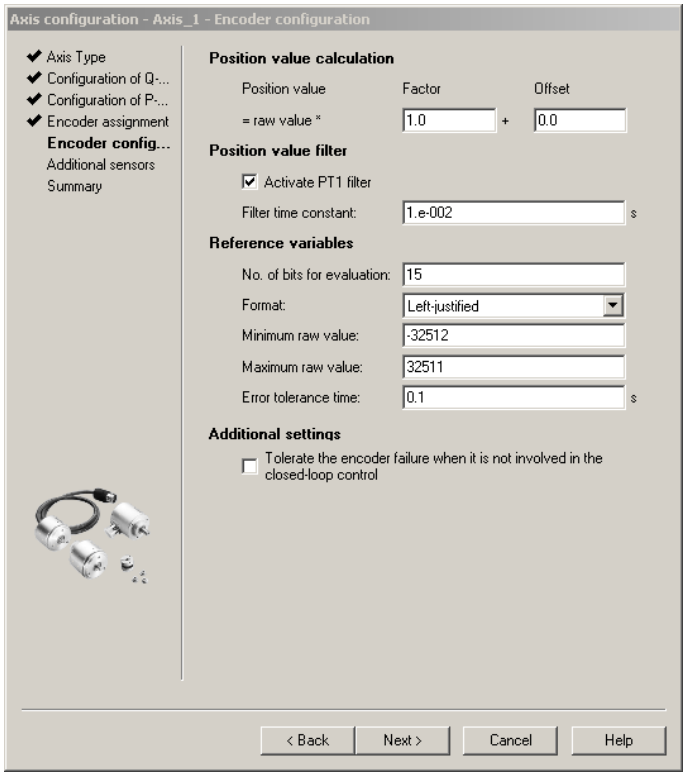

Figure 4-903 Example of configuration for the position value

The **Factor** (scaling factor) and **Offset** are used to convert the internal value into a physical variable that can be represented.

The value can be output as right-justified or left-justified within the word width (16 bits).

The minimum and maximum raw values are the limitations. If the measured actual value is outside these limits, technological alarm **50013: The permissible range limit has been exceeded** is issued and the internal actual value is set to the limit value.

The error tolerance time states how long an error can be pending before a technological alarm is set.

Setting for the hydraulic axis type (Page 2869)

TypeOfAxis configuration data (Page 2870)

Setting as a real axis with Q valve + P valve/F output

With hydraulic axes with Q valve + P valve/F output, the functions for traversing the axis (Q valve) are available. In addition, a manipulated variable can be controlled and output on the P valve/F output.

The following variants are available:

- Two valves (P valve and Q valve)
- One valve with two connections (analog)
- One variable-capacity pump

On the Axis technology object, one analog controller output is configured and controlled for the Q valve (flow, velocity) and one for the P valve (force/pressure limiting).

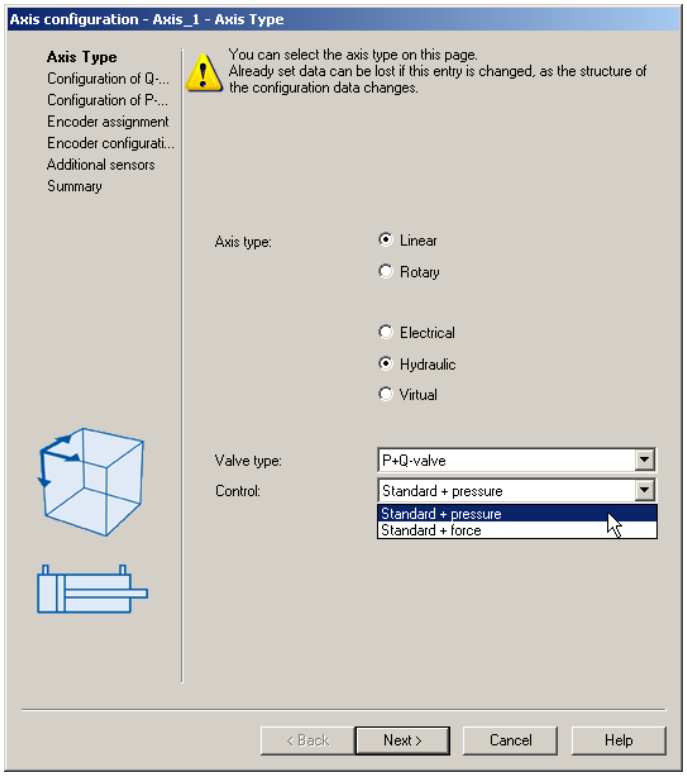

Figure 4-904 Setting the axis type

Table 4-384 Setting the control

Standard+pressure	Motion at the Q output and pressure limiting at the P valve/F output Unit: Pascal, bar
Standard+force	Motion at the Q output and force limiting at the P valve/F output Unit: Newton

Hydraulic axes with Q valve and P valve/F output do not have any pressure control (pressure control commands are rejected); in this case, the pressure limiting commands act on the P valve/F output. The pressure limiting value in the command is issued as a manipulated variable at the P valve/F output.

See also

Setting for the hydraulic axis type (Page 2869)

TypeOfAxis configuration data (Page 2870)

Setting an axis as a real axis with P valve only (V3.2 and higher)

At the P valve (F output of the axis), a time-related or actual-position-related profile or a manipulated variable can be output. This means that no position control, velocity control or force/pressure control takes place. There are no force/pressure sensors required, but they can be configured.

Position encoders cannot be configured.

You must configure a speed-controlled axis.

The following commands are possible on this axis:

- _resetAxis()
- _resetAxisError()
- _getStateOfAxisCommand()
- _bufferAxisCommandId()
- _removeBufferedAxisCommandId()
- _enableQFAxis()
- _disableQFAxis()

Commands to output a force/pressure limiting value or a force/pressure limiting profile can also be used:

- _enableForceLimitingValue()
- _enableTimeLockedForceLimitingProfile()
- _enableMotionInPositionLockedForceLimitingProfile()
- _disableForceLimiting()

Position encoders cannot be configured or activated.

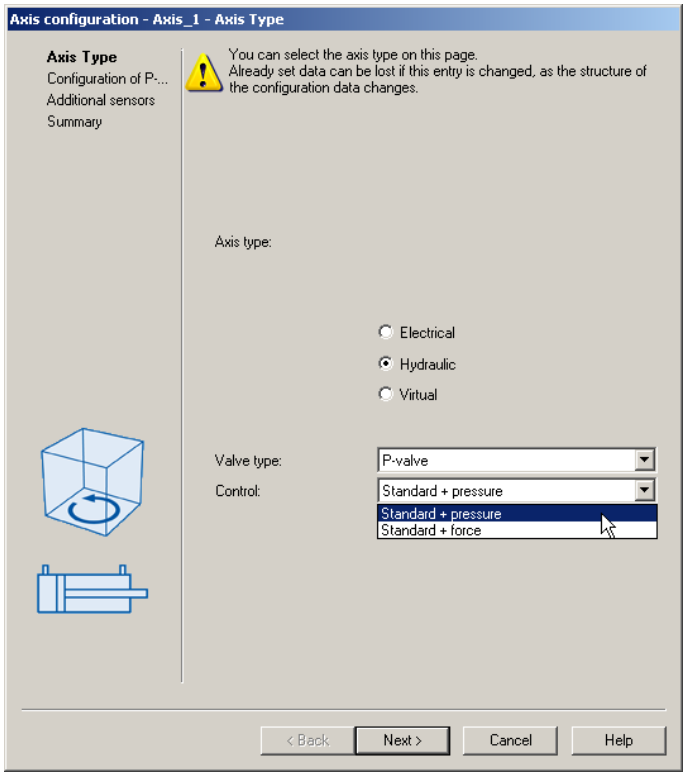

Figure 4-905 Creating an axis with P valve only

Overview of axis technologies (Page 2861)

Setting for the hydraulic axis type (Page 2869)

TypeOfAxis configuration data (Page 2870)

Setting an axis as a real hydraulic axis without a valve (axis simulation)

Hydraulic axes with manipulated variable output directly in the I/O area cannot be defined for axis simulation.

Axis simulation with hydraulic axes is only possible with a Q valve and with a digital drive interface or onboard C2xx.

For more information, see Setting as a real axis without drive (axis simulation) (Page 2899).

4.8.7.2 Input limits, technological limiting functions

Information about the system input limits and technological limitations is contained in Input limits, technological limiting functions (Page 2918).

4.8.7.3 Settings for axis and encoder mechanics

Note

With the hydraulic axis, not all of the setting options for the electric axis are required or displayed.

See also

Overview of setting options for axis and encoder mechanics (Page 2918)

4.8.7.4 Defaults

Information about default settings for system variables can be found in Defaults (Page 2922).

4.8.7.5 Homing

A short summary for homing, absolute encoder and incremental encoder is contained in Overview of homing (Page 2923).

4.8.7.6 Differential pressure measurement (V3.2 and higher)

The actual pressure value can be set as a pressure difference.

The pressure difference is implemented as a separate sensor type that determines the resulting differential pressure from two sensor-measured values using the following formula:

$F_{act} = (p_A \times A_A - p_B \times A_B) \times F_{factor}$
(F_{factor}: force factor)

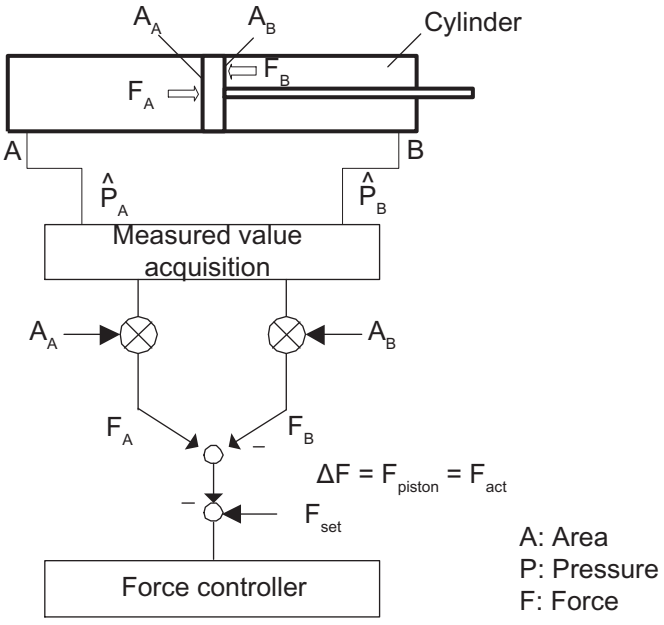

Figure 4-906 Example of a pressure difference measurement

Like the measuring sensors, the pressure difference is defined as force/pressure sensors.

Proceed as follows to specify the setting via the expert list:

- Configure at least two pressure sensors on the axis.
- In the expert list, increase the value of **TypeOfAxis.NumberOfAdditionalSensors.number** by 1.
- Set the other sensor as a "differential pressure sensor" with PRESSURE_DIFFERENCE_MEASUREMENT via the **TypeOfAxis.NumberOfAdditionalSensors.AdditionalSensor_n.additionalSensorType** configuration data element.
- The sensors whose values are being used and the individual factors are set in the elements of the **TypeOfAxis.NumberOfAdditionalSensors.AdditionalSensor_n.pressureDifferenceMeasurement** structure.

The pressure difference may be the pressure difference at a cylinder or another pressure difference. All sensors used for the pressure difference measurement must be configured on the same technology object.

The pressure difference measurement may also be applied to the electric axis.

If pressure difference measurement is used, force control is available in accordance with the function definition. In this case, the pressure sensors are also displayed in the force unit, dependent upon the system.

Using the expert list for an axis (Page 3065)

4.8.7.7 Differential position measurement (V3.2 and higher)

Information on differential position measurement is contained in Differential position measurement (V3.2 and higher) (Page 2937)

4.8.7.8 Monitoring/limiting functions

The monitoring/limiting functions of the electrical axis are applied.

For the hydraulic axis, the pressure control and limiting functions can also be applied to the drive axis.

See also

Overview of monitoring/limiting functions (block diagram) (Page 2938)

4.8.7.9 Motion profiles

The motion profiles that can be applied are the same as for the electrical axis.

See also

Overview of traversing with user-defined motion and force/pressure profiles (Page 3040)

4.8.7.10 Hydraulic axis with position control/velocity control

Position control for setting a positioning axis with hydraulic functionality

Block diagram of the hydraulic axis with closed-loop control:

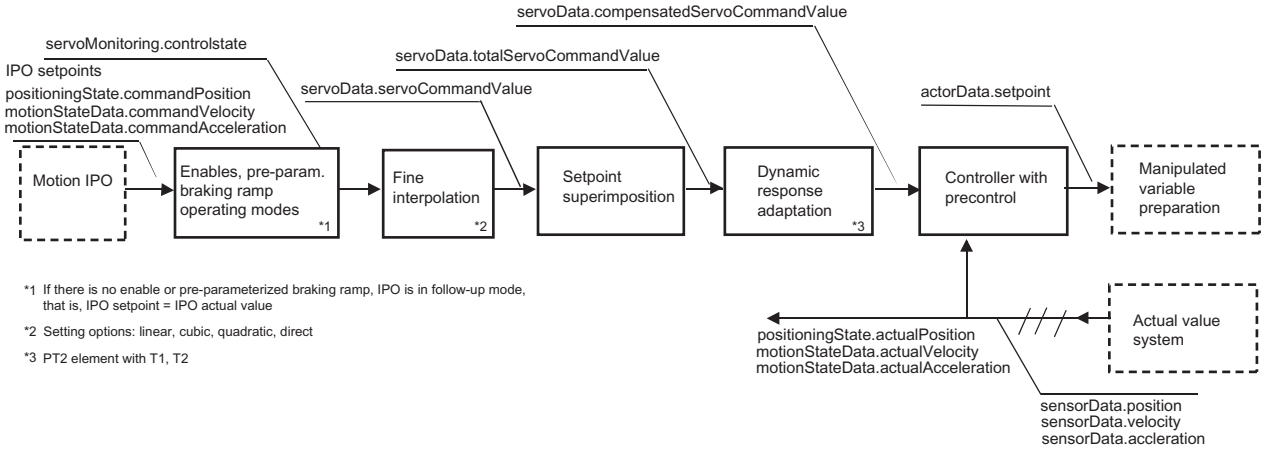

Figure 4-907 Overview of hydraulic axis with closed-loop control

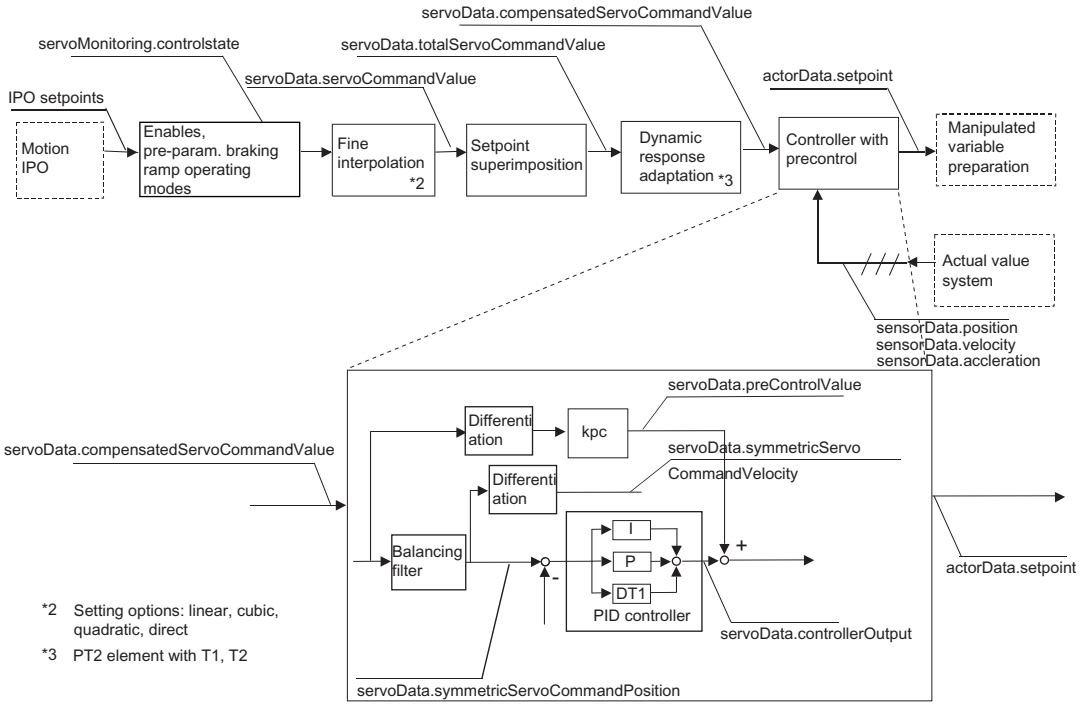

Figure 4-908 PID controller with precontrol

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

Remark

You can specify during configuration whether the D component of the controller refers to the control deviation or the actual value (in the **ControllerStruct.conType** configuration data element).

The dynamic behavior of the process is taken into account in the balancing filter.

With the hydraulic positioning axis, the dynamic response of the position control loop is specified in the **dynamicData.positionTimeConstant** configuration data element. The dynamic response of the process is specified in **dynamicQFData.qOutputTimeConstant**.

The hydraulic position axis can now be activated in non-position-controlled mode with the **_enableQFAxis()** command via the parameter **movingMode**= SPEED-CONTROLLED (as of V4.1 SP1).

Overview of positioning axis with position control (Page 2949)

Position control (Page 2950)

Velocity controller when setting speed-controlled axis with hydraulic functionality

When an axis is set as a drive axis with hydraulic functionality, the velocity controller is calculated in SIMOTION.

With the electric drive axis, the velocity controller is included in the drive and the control specifies the speed setpoint.

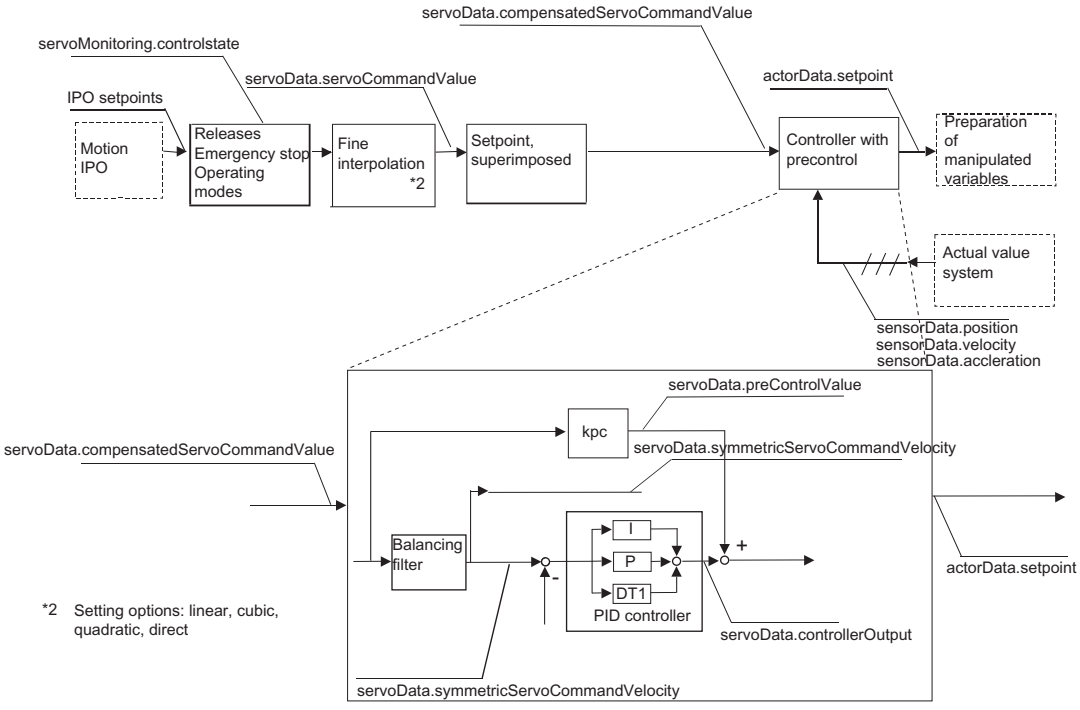

Figure 4-909 Block diagram of the velocity controller

Setting an axis as a drive axis with hydraulic functionality

Functionality:

- PID controller available as velocity controller
- Precontrol of the manipulated variable available
- Velocity monitoring available

If a controller is applied, the axis is traversed with closed-loop velocity control. If no controller is applied, the axis is traversed with open-loop velocity control.

Note

The closed-loop velocity-controlled hydraulic axis cannot be moved with open-loop velocity control via movingMode=SPEED_CONTROLLED.

The status of the velocity controller is displayed in the **servoControl.controlState** system variable.

Controller error monitoring is displayed in **servoMonitoring.controllerDifferenceError**.

The components **dynamicFollowingError**, **dynamicFollowingWarning**, **positioning**, and **standstill** in **servoMonitoring** are irrelevant.

With setting **ControllerStruct.conType** = DIRECT, the controller can be disconnected.

Monitoring

Data and statuses for the velocity controller on the axis are displayed in the **servoData** components.

See the list manuals for details.

For the velocity controller, the setpoints, actual values, and superimpositions refer to the velocity. Position-related information such as **actualPosition** or **symmetricServoCommandPosition** are irrelevant.

preControlValue displays the precontrol value.

In **servosettings**, the **additionalCommandValue** setting refers to the velocity.

Standstill monitoring is not available on the drive axis.

The standstill signal is available.

Remarks

Dynamic response adaptation is not active on the axis with hydraulic functionality.

Superimpositions are in effect.

With the hydraulic drive axis, the dynamic response of the velocity control loop is specified in the **dynamicQFData.velocityTimeConstant** configuration data element; the dynamic response of the process is specified in the **dynamicQFData.qOutputTimeConstant** configuration data element.

Overview of positioning axis with position control (Page 2949)

Preparation of manipulated variables for axis with hydraulic functionality

Preparation of manipulated variables for axis with hydraulic functionality, Q output

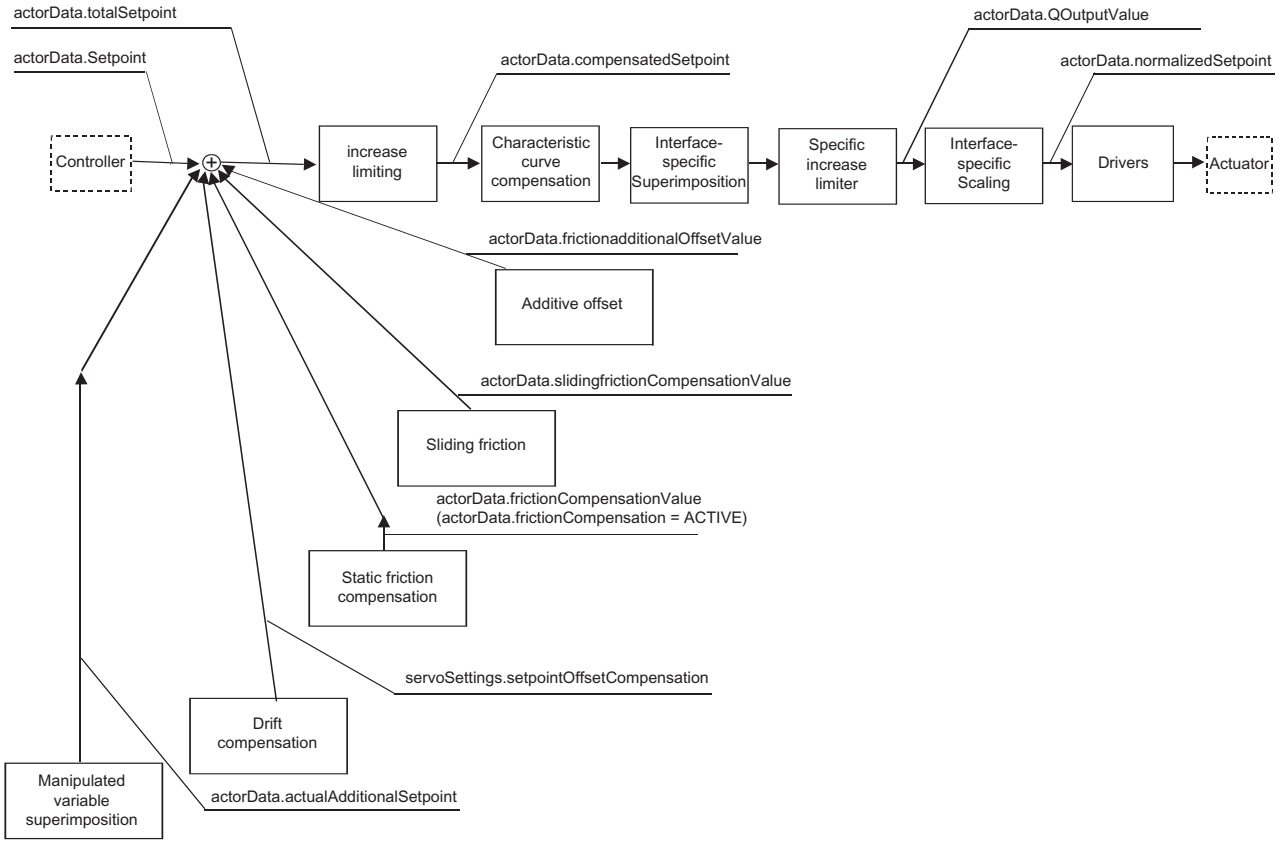

Figure 4-910 Preparation of manipulated variables for axis with hydraulic functionality, Q output

Preparation of manipulated variables for axis with hydraulic functionality, F output

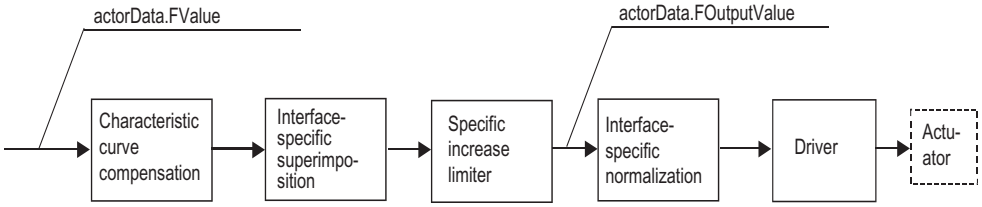

Figure 4-911 Preparation of manipulated variables for axis with hydraulic functionality, F output

Note

For hydraulic axes, a valve characteristic can be assigned to each output (P or Q). If this is not the case, a linear characteristic is used. Here, 100% corresponds to the limit value of the axis (**TypeOfAxis.MaxVelocity**, **TypeOfAxis.MaxForceCommandData**).

The interface-specific superimposition is specified as a percentage (%), e.g. for specifying manipulated variables when recording of the characteristic curve.

An increase limiting is specified in the command for output activation and for activation of the characteristic curve because the manipulated variable must be continuos on the valve, e.g. the increase limiting (ramp function) is used to prevent a step change. If the increase limiting is active, the I component is retained in the position controller or force/pressure controller.

The specific increase limiting after allowing for the valve characteristic is only in effect for the transition at **_setQFAxisFCharacteristics()**, **_setQFAxisQCharacteristics()**, and **_disableQFAxis()**, **_enableQFAxis()**. The increase limiting is specified in the command (default in **userDefaultQFAxis.maxDerivative**).

Note

If the RELEASE_DISABLE or OPEN_POSITION_CONTROL alarm responses occur, the setpoint or manipulated variable = 0 will be output. For hydraulic axes, the value 0 will be converted into an appropriate output value using the valve characteristic.

A velocity encoder must be present for speed-controlled operation. The control supports the following velocity encoders:

- Pulse encoder via SM335 or E510
- Analog velocity encoder via analog input modules

See also

Overview of positioning axis with position control (Page 2949)

Manipulated variable filtering (as of V4.1 SP1)

A man. var. filter can be set as a PT1 filter in the **setpointFilter** configuration data element. This filter acts after the controller and after the precontrol value and the additive manipulated variable value (additionalSetpoint) have been added.

A change in the filter data takes effect immediately.

Compensations that are active only on the axis with hydraulic functionality

A static compensation component (additive sliding friction) and a compensation component proportional to velocity (sliding friction) can be set on the axis with hydraulic functionality.

These settings are made in the Closed-Loop Control view in the project navigator under the axis. The Further Compensations tab appears when Expert mode is selected.

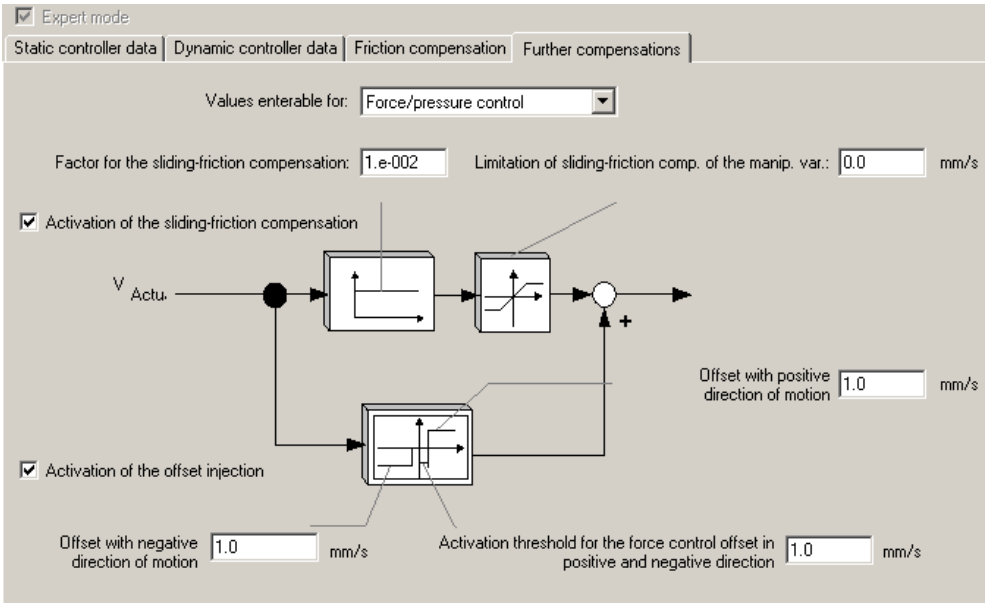

Figure 4-912 Sliding-friction compensation/additive sliding-friction compensation on an axis

Sliding-friction compensation

Sliding friction is applied relative to the velocity setpoint in axis motion via motion specification, and relative to the actual velocity value in axis motion via force/pressure specification.

The factor for sliding-friction compensation can be set specifically for axis motion via motion specification (**factorMotionControl**) and for axis motion via force/pressure specification (**factorForceControl**) in the structure elements for **SlidingFriction**.

The current value of the sliding-friction compensation is displayed in the **actorDataSlidingFrictionCompensationValue** system variable.

Additive sliding-friction compensation (offset application)

Additive sliding friction is applied relative to the velocity setpoint in axis motion via motion specification, and relative to the actual velocity value in axis motion via force/pressure specification.

The factor for **additive sliding friction** can be set specifically for axis motion via motion specification, and separately for each velocity direction, in factorMotionControlPositive and factorMotionControlNegative; it can be set for axis motion via force/pressure specification in factorForceControlPositive and factorForceControlNegative.

These factors are set in the structure elements for AdditionalOffset. The current value is set in **frictionAdditionalOffsetValue** (direction-dependent sliding-friction compensation value).

The current value for additive sliding friction is indicated in the **actorDataFrictionAdditionalOffsetvalue** system variable.

Overview of positioning axis with position control (Page 2949)

Consideration of valve characteristic when specifying a hydraulic axis

The existing non-linearity between the technological manipulated variable, for example, an oil flow rate (Q) or a velocity or force/pressure value (F), and the manipulated variable value of the valve is mapped by means of a characteristic curve in the open-loop control system and is taken into account in calculating the manipulated variable value.

The valve characteristic is set using a cam. See the Technology Objects Synchronous Operation, Cam description of functions.

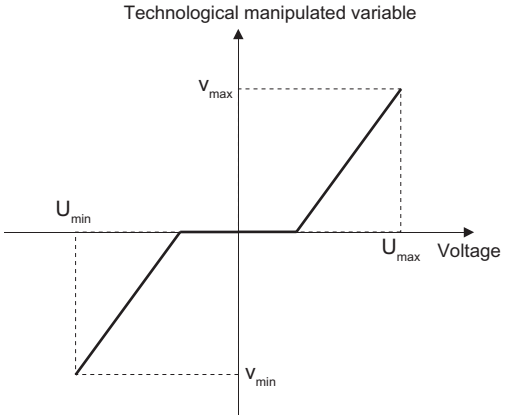

Figure 4-913 Characteristic curve setting for hydraulic axis

In the cams for the characteristic curves, the technological manipulated variable (velocity, pressure/force) is specified by means of the manipulated variable value of the final controlling element.

The valve characteristic curves are selected/switched using **_setQFAxisQCharacteristics()** or **_setQFAxisFCharacteristics()**. They can also be switched during the motion.

If several characteristic curves are interconnected with an axis, one characteristic curve must be explicitly selected with the command.

If only one valve characteristic curve is available for an axis, then a selection command is not required.

If there is no valve characteristic curve selected for the hydraulic axis under the Profiles screen form, the value in the **TypeOfAxis.MaxVelocity** configuration data element is determinative for the manipulated variable normalization. In the valve characteristic curve for the P output, the **TypeOfAxis.MaxForceCommandData** configuration data element is determinative.

Assignment of range limits

- The valve position is specified as a percentage (%).
  - Cam - master: manipulated variable -100% to +100%
  - Cam - slave: velocity or pressure -min% to +max%

  See the figure below for an example of how to assign characteristic curve parameters in SCOUT.
- The value specified in **maxSetpointVoltage** or **maxOutputVoltage** is assigned to 100%.
- A valve position of zero is mapped onto an output voltage of zero; thus, the mapping is defined explicitly.
- The interface-specific superimposition is specified as a percentage (%).
- The technology variable is specified in the application unit.

Procedure for recording the characteristic curve for a Q valve

- Enable the axis via **_enableQFAxis()** without controller
- Specify an output value between -100% and +100% via the **servosettings.additionalQOutputValue** (**servosettings.additionalFOutputValue** for P valve) system variable

  Note

  Only traverse the machine within valid range!

- Measure the actual velocity (QOutputValue and velocity can be recorded using the trace function)
- Read out the resulting technological variables
- Enter the values and the technological variables in the characteristic curve
  Each technological variable received for a specified output voltage is entered in the characteristic curve
- Assign the cam to the axis and activate it under Profiles/Valves

  Note

  With F output, the procedure applies for P valves accordingly.

Example of how to set the characteristic curve in SCOUT

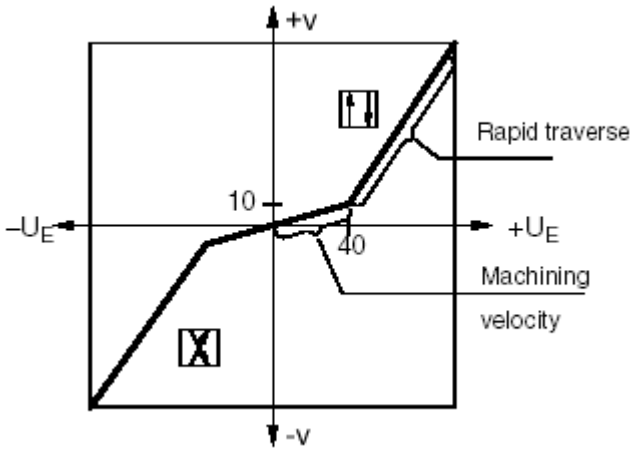

Figure 4-914 Valve characteristic curve from the manufacturer's catalog

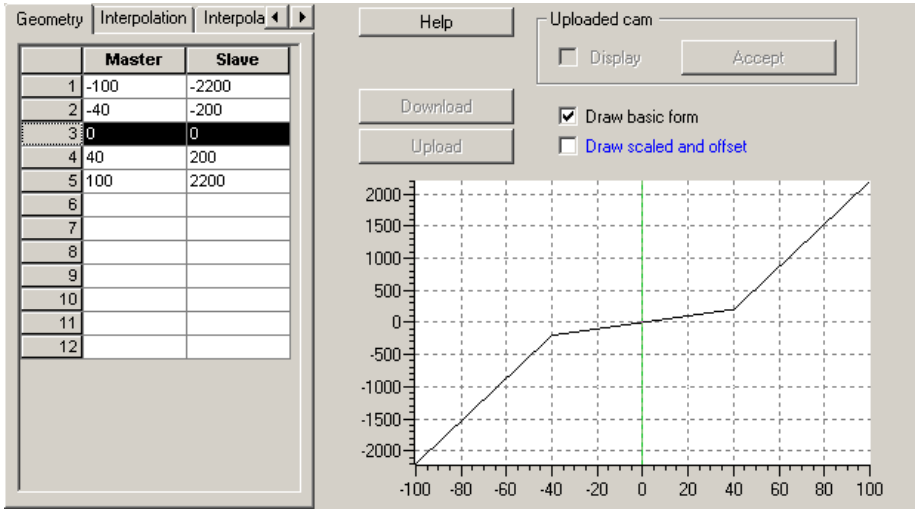

Figure 4-915 Assigning characteristic curve parameters in SCOUT

At 100% manipulated variable, a velocity of 2,200 mm/s is reached in the example (position axis).

See also

Overview of positioning axis with position control (Page 2949)

Access to the same final controlling element from multiple axes

The axis with hydraulic functionality has its own activation/deactivation command **_enableQFAxis()/_disableQFAxis()**.

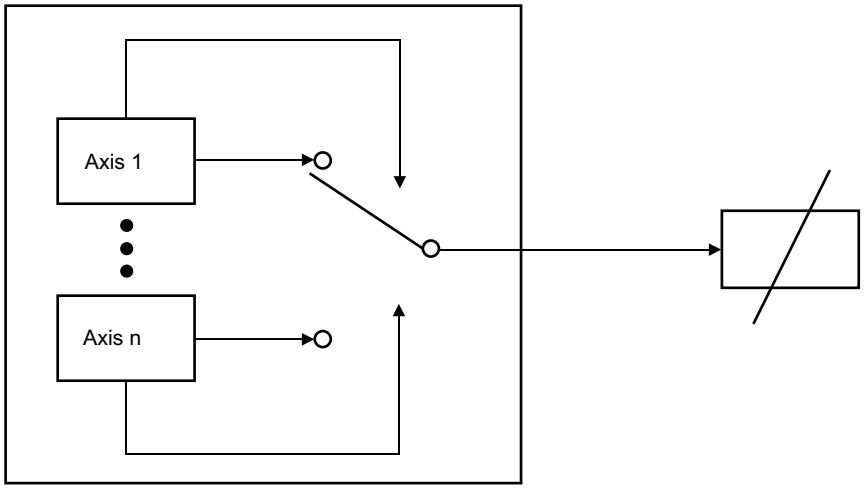

Figure 4-916 Axis with hydraulic functionality: one valve for several axes

When an axis is specified as an axis with hydraulic functionality, you can assign a final controlling element to more than one axis in the configuration. Only one axis can specify the setpoint for a final controlling element at a given time.

Application example: one variable-capacity pump for several axes. The axes are traversed sequentially. After the motion is ended, the axis is disabled (**_disableQFAxis()** with valve enable). Digital valves switch to the next axis. The next axis can be enabled.

This assignment is made during runtime using the **qOutput** or **fOutput** parameter in the **_enableQFAxis()**/**_disableQFAxis()** activation and deactivation commands and is displayed in the **actorMonitoring.qOutputState** or **actorMonitoring.fOutputState** system variable. A final controlling element that has been activated, and thus occupied, by an axis must be re-enabled by this axis before another axis can activate and occupy this final controlling element for itself.

Replacement values (stop values) can be predefined for enabling a final controlling element. This is achieved by enabling the final controlling element (command **_disableQFAxis()**, **qOutput/fOutput** = DISABLE) but without canceling the enabling signal (command **_disableQFAxis()**, **qOutputEnable/fOutputEnable** =. DO_NOT_CHANGE). The default replacement value 0% is output at the final controlling element. With **qOutputValueSetMode**/**fOutputValueSetMode** = set and **qOutputValue/fOutputValue** = 5 in the **_disableQFAxis()** command, a manipulated variable of 5% is output. The replacement value is output until a technology object occupies the final controlling element again (**_enableQFAxis()**).

The manipulated variable change is limited when the final controlling element with replacement value is applied or when changing to a different characteristic curve on the axis. These limits are specified in the **userDefaultQFAxis.maxDerivative** system variable.

The enabling signal for a final controlling element can be configured and set on multiple axes. The axis does not specifically occupy the enabling signal; rather, the enable is performed directly.

See also

Overview of positioning axis with position control (Page 2949)

4.8.7.11 Travel to fixed endstop

The travel to fixed endstop functionality is not available for hydraulic axes.

See also

Travel to fixed endstop (Page 3015)

4.8.7.12 Force/pressure control with hydraulic axes with Q valve only

On the hydraulic axis with Q valve only, the force/pressure control acts on the velocity setpoint (Q valve manipulated variable value) analogous to how the force/pressure control acts on the speed setpoint on the electric axis.

The handling requirements and functionality are therefore the same as for the electric axis.

The **_enableForceControlByCondition()** switchover command is active.

The **_enableForceLimitingByCondition()** switchover command is not active.

For the local RELEASE_DISABLE or OPEN_POSITION_CONTROL alarm response, the manipulated value 0 will be output using the valve characteristic value.

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

Note

Special Q valves (so-called PQ valves) also support pressure control.

See also

Overview of force/pressure control (Page 3026)

4.8.7.13 Force/pressure limiting with hydraulic axes with Q valve only

With hydraulic axes with Q valve only, the force/pressure limiting control is available the same as with the electric axis.

The handling requirements and functionality are therefore the same as for the electric axis.

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

See also

Overview of force/pressure limiting (Page 3033)

4.8.7.14 Force/pressure limiting with hydraulic axes with P valve

The specifications for force/pressure limiting are switched to the P valve/F output. The pressure limitation value in the commands is output on the P-valve/F output as a manipulated variable. The **_enableForceLimitingByCondition()** switchover command with condition is active. The pressure limiting value is not subject to fine interpolation if **_enableForceLimitingValue()** or **_enable...LimitingProfile()** with derivativeLimitingMode=WITHOUT_LIMITING is set.

When the event occurs, the motion is not aborted; the motion specifications continue to be output to the Q-valve. An application can be used to switch back to the motion.

No force/pressure limiting controller is in effect.

No force/pressure control is in effect.

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

4.8.7.15 Force/pressure control with hydraulic speed-controlled axes with Q valve only

Force/pressure control is available for hydraulic speed-controlled axes (V3.2 and higher). (**typeOfAxis**=REAL_QFAXIS_WITH_CLOSED_LOOP_FORCE_CONTROL)

On-the-fly switching between pressure control and speed control is possible (V4.0 and higher).

Note

Note the following points for the transitions from speed control to pressure control and vice versa:

- Apply the force/pressure control during motion (as of V4.0)
- Switch on pressure control at standstill (as of V3.2)
- Switch off pressure control at standstill (as of V3.2)
- Transition to speed control from force/pressure control (as of V4.0)
- If pressure control is active, only the RELEASE_DISABLE stop reaction is in effect. (V3.2)
  - No applying / overriding of the pressure control through motion
  - No preassigned braking ramp
- Switchover with condition not available

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

4.8.7.16 Force/pressure limiting with hydraulic speed-controlled axes with Q valve only (V4.0 and higher)

Force/pressure limiting on the hydraulic drive axis is available (V4.0 and higher).

With the hydraulic drive axis, the pressure limiting component is added to the velocity setpoint. The pressure limiting value is not subject to fine interpolation if **_enableForceLimitingValue()** or **_enable...LimitingProfile()** with derivativeLimitingMode=WITHOUT_LIMITING is set.

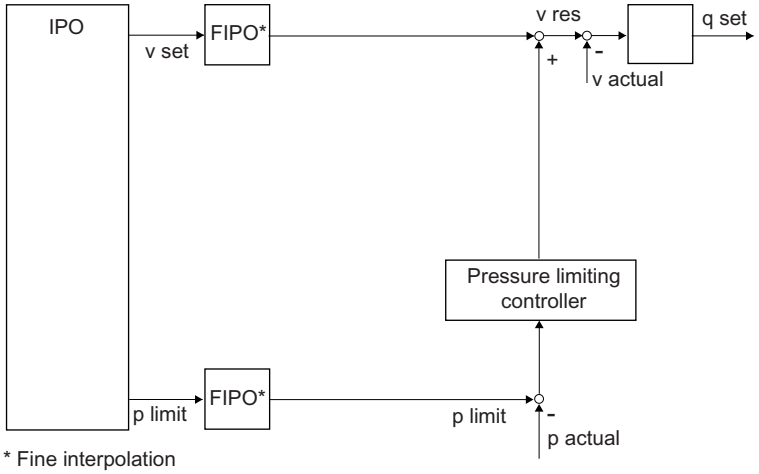

Figure 4-917 Overview of control structure for force/pressure limiting on hydraulic drive axis

Note

The *PDF documents* button can be used in the online help to locate the function charts with signal paths.

Features:

- Parallel pressure limiting
- Transition from pressure-limited to pressure-controlled
- Transition from pressure-controlled to speed-controlled (with/without pressure limiting)

The same controller is used as the pressure controller on the drive axis and as the force/pressure limiting controller.

On-the-fly switching between pressure control and speed control (open-loop and closed-loop) and vice versa is possible (as of V4.0).

Error responses / StopEmergency

If the FEEDBACK_EMERGENCY_STOP error response occurs in combination with the **_stopEmergency()** command with the STOP_WITH_COMMAND_VALUE_ZERO setting in active pressure control, the preassigned braking ramp is executed and the pressure limiting remains active. However, the pressure limiting can be deactivated via a command.

4.8.7.17 Velocity limiting with hydraulic axes

Velocity limiting on the hydraulic axis with Q valve only

This velocity limiting is available:

- On the positioning axis (V3.2 and higher)
- On the speed-controlled axis (V4.0 and higher)

Velocity limiting on the hydraulic axis with P valve and Q valve

The velocity limiting is output to the Q valve as velocity setpoints.

4.8.8 Part III Programming/Reference

4.8.8.1 Overview of commands

Note

You can also find information about the system functions in the *SIMOTION Cam Technology Package list manual*.

Overview of commands

Programming (execution of commands)

The axis is controlled by means of commands. These commands are used to enable and disable functions, specify and influence motions, specify data, and read out status information.

Commands for specification and control of motion on the axis

Table 4-386 Overview of commands for specification and control of motion on the axis

Command	Meaning	D	P	G
Enables, stop and continue commands, resets				
_enableAxis()	Enable axis	X	X	X
_enableQFAxis( )*	Enable hydraulic axis	X	X	X
_disableAxis()	Disable axis	X	X	X
_disableQFAxis( )*	Disable hydraulic axis	X	X	X
_enableForceControlByCondition()	Activating force/pressure control depending on switch-over conditions	-	X	X
_setForceCommandValue( )	Set force/pressure setpoint	-	X	X
_setQFAxisQCharacteristics*( )	Set characteristics for Q value	X	X	X
_setQFAxisPCharacteristics*( )	Set characteristics for P value	X	X	X
_stopEmergency()	Rapid stop with motion abort	X	X	X

Command	Meaning	D	P	G
_stop()	Stop axis motion with/without abort	X	X	X
_continue()	Resume an interrupted motion	X	X	X
_resetAxis()	Reset axis	X	X	X
_getAxisErrorNumberState()	Read out error number status	X	X	X
_resetAxisError()	Acknowledge axis error	X	X	X
_cancelAxisCommand( ), as of V4.1 SP1	Abort command with the specified CommandID	X	X	X
* Active only when the **TypeOfAxis** setting is **QFAxis**.				
Axis motions				
_homing()	Homing	-	X	X
_move()	Continuous turning (speed- or position-controlled)	X	X	X
_pos()	Positioning	-	X	X
_runTimeLockedVelocityProfile()	Rotational speed profile	X	X	X
_runTimeLockedPositionProfile()	Velocity profile	-	X	X
_runPositionLockedVelocityProfile()	Position-related velocity profile	-	X	X
_enableTorqueLimiting()	Switch on torque limitation	X	X	X
_disableTorqueLimiting()	Deactivate torque limitation	X	X	X
_enableAxisAdditiveTorque( )	Activate input interconnection for additive torque	X	X	X
_disableAxisAdditiveTorque( )	Deactivate input interconnection for additive torque	X	X	X
_enableAxisTorqueLimitPositive( )	Activate input interconnection B+	X	X	X
_disableAxisTorqueLimitPositive( )	Deactivate input interconnection B+	X	X	X
_enableAxisTorqueLimitNegative( )	Activate input interconnection B-	X	X	X
_disableAxisTorqueLimitNegative( )	Deactivate input interconnection B-	X	X	X
_enableVelocityLimitingValue()	Activate velocity limiting	X	X	X
_disableVelocityLimiting()	Deactivate velocity limiting	X	X	X
_enablePositionLockedForceLimitingProfile()	Activate force/pressure limiting with position-related force/pressure limiting profile	-	X	X
_enablePositionLockedVelocityLimitingProfile()	Activate velocity limiting with position-related limiting profile	-	X	X
_runTimeLockedForceProfile()	Starting the time-related force/pressure profile	-	X	X
_runPositionLockedForceProfile()	Starting the position-related force/pressure profile	-	X	X
_enableForceLimiting()	Enable force limiting	-	X	X
_disableForceLimiting()	Disable force limiting	-	X	X
_enableMovingToEndStop( )	Activate travel to fixed endstop	-	X	X
_disableMovingToEndStop()	Deactivate travel to fixed endstop	-	X	X
_enableTimeLockedVelocityLimitingProfile( )	Activate velocity limiting with time-related limiting profile	X	X	X
_enableTimeLockedForceLimitingProfile()	Activate force/pressure limiting with time-related limiting profile	-	X	X
Coordinate system				
_redefinePosition( )	Set actual value system	-	X	X
_setAndGetEncoderValue( )	Synchronize measuring systems	-	X	X
_enableMonitoringOfEncoderDifference()	Activate encoder difference monitoring	-	X	X
_disableMonitoringOfEncoderDifference()	Deactivate encoder difference monitoring	-	X	X
_getAxisUserPosition( )	Return user position for specified encoder value	-	X	X

Command	Meaning	D	P	G
_getAxisInternalPosition( )	Return encoder value for specified user position	-	X	X
Simulation				
_enableAxisSimulation()	Activate program simulation	X	X	X
_disableAxisSimulation()	Deactivate program simulation	X	X	X
Information functions / command buffers				
_getStateOfAxisCommand()	Reading the execution status of a motion command	X	X	X
_getMotionStateOfAxisCommand()	Reading current phase of motion	X	X	X
_bufferAxisCommandId()	Save CommandId	X	X	X
_removeBufferedAxisCommandId()	Remove buffered CommandId	X	X	X
_getStateOfMotionBuffer()	Read status of motion buffer	X	X	X
_resetMotionBuffer()	Reset motion buffer	X	X	X
_getProgrammedTargetPosition( )	Read the programmed absolute end position	-	X	X
_getAxisErrorNumberState()	Reading the status of a specific error on the axis	X	X	X
Data set commands				
_setAxisDataSetActive()	Activate data set	X	X	X
_setAxisDataSetParameter()	Write data set	X	X	X
_getAxisDataSetParameter( )	Read a data set	X	X	X
_setForceControlDataSetParameter()	Writing the force/pressure-specific data of a data set	-	X	X
_getForceControlDataSetParameter()	Reading the force/pressure-specific data of a data set	-	X	X
_resetAxisConfigDataBuffer( )	Clear the configuration data in the buffer without activation	X	X	X

D = drive axis

P = positioning axis

G = synchronized axis

PLCopen commands

The blocks listed below can be used in cyclic programs/tasks in SIMOTION.

They are used primarily in the LAD/FBD programming language. PLCopen blocks are available as standard functions (directly from the command library).

Table 4-387 SingleAxis functions for the axis (as of V4.0)

Function	Description
_MC_Power()	Enabling an axis
_MC_Stop()	Stopping the axes
_MC_Reset()	Resetting the axis
_MC_Home()	Homing axes
_MC_MoveAbsolute()	Absolute positioning axes
_MC_MoveRelative()	Relatively positioning axes
_MC_MoveVelocity()	Traversing axes at defined velocity (position axis travels position-controlled)
_MC_MoveAdditive()	Relative traversing of axes by a defined path additively to the remaining path
_MC_MoveSuperimposed()	Relative superimposing of a new motion on an existing motion

Function	Description
_MC_PositionProfile()	Traversing axis by a predefined and specified position/time profile
_MC_VelocityProfile()	Traversing axis by a predefined and specified velocity/time profile
_MC_ReadActualPosition()	Reading the actual position of axis
_MC_ReadStatus()	Reading the status of an axis
_MC_ReadAxisError()	Reading the error of an axis
_MC_ReadParameter()	Reading the axis parameter data type LREAL
_MC_ReadBoolParameter()	Reading the axis parameter data type BOOL
_MC_WriteParameter()	Writing the axis parameter data type LREAL
_MC_WriteBoolParameter()	Writing the axis parameter data type BOOL
Apart from the standard PLCopen functions, the following additional standard axis function is included:	
_MC_Jog()	Continuous or incremental jogging

Table 4-388 MultiAxis functions for the axis (as of V4.0)

Function	Description
_MC_CamIn()	Start camming between a master and a slave
_MC_CamOut()	End camming
_MC_GearIn()	Start gearing between a master and a slave
_MC_GearOut()	End gearing
_MC_Phasing()	Offsets the position of the slave axis relative to the master

Table 4-389 Functions for external encoder (as of V4.1 SP1)

Function	Description
_MC_Home()	Home external encoder
_MC_Power()	Enable external encoder
_MC_ReadStatus()	Read status of external encoder
_MC_ReadAxisError()	Read error of external encoder
_MC_Reset()	Reset external encoder
_MC_ReadParameter()	Read external encoder parameters of data type LREAL
_MC_ReadBoolParameter()	Read external encoder parameters of data type BOOL
_MC_ReadActualPosition()	Read actual position of external encoder

You can find additional information in the *PLCopen blocks* Function Manual and in the online help.

Command properties

Function parameters

Motion commands have the following function parameters:

- Information on the type of motion (**_pos()**, **_move()**, etc.) and any function parameters for specification (e.g. direction specification)
- Information regarding the response to active motions/commands (mergeMode)
- Parameters for the motion (dynamic response parameters)
- Parameters for advancing in the program (nextCommand)
- In the case of profile commands, information regarding the starting point within the profile, if required

The **dynamic response parameters** for motions and motion transitions (velocity, acceleration, and jerk) can be specified in the commands.

Additional properties

The following is applicable for profiles:

- The specified quantity corresponding to a cam-defined function is traversed
- Dynamic response parameters can be specified for travel to the start value in the cam or for travel from the end value
- If the profile is specified with a user-definable cam function, a value within the definition range of the cam must also be specified as the starting point from which the profile is to be applied
- The function in the cam is traversed to the end
- The definition range of the cam is evaluated in the user-defined time unit for time-related profiles and in the user-defined position unit for position-related profiles; the range is evaluated in the user-defined unit of the quantity to be traversed
- The direction of motion, velocity, and acceleration are calculated accordingly
- Behavior at the end of the profile can be configured
- The axis override function has no effect on the positioning profiles. The velocity override and acceleration override are included in the velocity profiles.

The status of motion commands can be seen from the **system variable** for the command; if necessary, additional information such as the braking distance and remaining distance for the positioning command is provided in the **posCommand** system variable.

Commands that contain a CommandId parameter allow the CommandId to be initialized to its defaults (value 0.0) (V3.1 and higher). This does not apply to **_getStateOf...CommandId()** commands, since initialization to defaults would not be practicable in this case. The CommandId should be explicitly specified here.

4.8.8.2 Enables, stop and continue commands, resets

Setting and canceling the axis enables

The commands for enabling and disabling the axis are:

- **_enableAxis(), _enableQFAxis()**
- **_disableAxis(), _disableQFAxis()**

The following enables can be set specifically for the electric axis using **_enableAxis()** / **_disableAxis()**:

- Controller enable
- Drive enable
- Power enable
- Follow-up mode (motion commands are not accepted/executed)
- Force/pressure enable

The following enables can be set specifically for the hydraulic axis using **_enableQFAxis()** / **_disableQFAxis()**:

- Controller enable
- Q output enable
- F output enable
- Follow-up mode (motion commands are not accepted/executed)
- Force/pressure enable

The axis enables for the virtual axis have exactly the same effect as for the electric axis.

Note

Drive and encoder error messages can be acknowledged, even when the error is still present. The same error is not to be signaled again.
The status of the actuator or sensor can be tested in the status indication of the corresponding system variable (**state**).

Activate/deactivate axis

- The **_enableAxis()** / **_disableAxis()** commands are used to enable/disable an axis as an electric axis where the **TypeOfAxis** is set to REAL_AXIS....
- The **_enableQFAxis()** / **_disableQFAxis()** commands are used to enable/disable an axis as a hydraulic axis where the **TypeOfAxis** is set to REAL_QFAXIS....

These commands can be issued while the axis is in motion. Canceling enables results in a technological alarm; the configured alarm response is executed.

Note

If, for example, **_disableAxis()** is called immediately after **_enableAxis()**, the commands can displace one another from the command buffer.

- With **_enableAxis()**, **_enableQFAxis()** the position controller in SIMOTION is enabled immediately, provided nothing different is set in the command parameters.
- The parameter **movingMode**=POSITION_CONTROLLED enables speed and position-controlled operation.
  With SPEED_CONTROLLED, speed-controlled operation is enabled. When activating in speed mode, command parameter **servoControlMode=**ACTIVE must be set so that the setpoint path is activated in the servo.
  In SPEED_CONTROLLED mode, the axis can be traversed if the encoder fails and there are no pending error responses (see section *Switching on the speed specification mode with _enableAxis (V4.0 and higher)*).
- As of V4.1 SP1, it is also possible to activate the hydraulic positioning axis in non-position-controlled mode using the **movingMode** = SPEED_CONTROLLED parameter with command **_enableQFAxis()**
  The closed-loop velocity-controlled hydraulic axis cannot be moved with open-loop velocity control via movingMode=SPEED_CONTROLLED.
- If, when activating the drive with **_enableAxis()**, the position controller is not enabled in SIMOTION or the axis remains in follow-up mode because user-defined functions such as motor identification, brake release, etc. are executed in the drive, settings options are available with **servoControlMode** = INACTIVE or **servoCommandToActualMode** = ACTIVE. Thus, the position controller does not position on the setpoint when **_enableAxis()** is activated.
  After the transition to the Operation or S4 drive state of the PROFIdrive state machine (displayed in the **actorMonitoring.power** = ACTIVE system variable), the position controller can then be enabled in SIMOTION with the **_enableAxis()** command and the **servoControlMode** = ACTIVE parameter setting or switched from follow-up mode with **servoCommandToActualMode** = INACTIVE.
- Axes can also be activated when the actual velocity is not equal to zero. You can use the configuration data item **decodingConfig.speedModeSetPointZero** to set the mode for getting the axis to zero velocity when the enables are set.
  - **decodingConfig.speedModeSetPointZero**=YES
    The velocity setpoint (and acceleration) of the axis are set directly to zero without a braking ramp.
    As of SCOUT V4.2, this is the standard setting when creating a new axis TO.
  - **decodingConfig.speedModeSetPointZero**=NO
    The axis is stopped via a braking ramp with the maximum dynamic values.
    See also Manipulated variable superimposition (Page 2976).
    Please note that braking may be superseded by other motions which become effective immediately after the axis is activated.

Axis enable and follow-up mode

In the following tables, the behavior and displays with different configurations of **_enableAxis()** / **_enableQFAxis()** are described.

Table 4-390 Behavior and displays for axis enable with **traversing mode "position and speed controlled"**

	Follow-up mode ACTIVE (Follow-up setpoint)	**Follow-up mode INACTIVE (Do not follow-up setpoint)**
Position controller ACTIVE (**servoControlMode**=ACTIVE)	Special case	**STANDARD SETTING**
	• Traverse of the axis using setpoint superimposition is possible (see Setpoint superimposition (Page 2967)) using **servosettings.additionalCommandValue** (e.g., for commissioning the position controller) • Axis is in position control (**servoMonitoring.controlState**= ACTIVE) • Motion commands CANNOT be performed (due to follow-up mode, **control**=INACTIVE) • Set position IPO is tracked • Servo set position is not tracked • Monitoring functions are not active	• Axis is in position control (**servoMonitoring.controlState**=ACTIVE) • Motion commands can be executed (**control**=ACTIVE)
Position controller INACTIVE (**servoControlMode**=INACTIVE)	Special case	Special case
	• The drive is only enabled for drive-autonomous motions and functions • Axis is NOT in position control (**~.controlState**=INACTIVE) • Motion commands CANNOT be executed • IPO set position and servo is tracked • Monitoring functions are not active	In real axes, "Do not follow up setpoint" is only effective if all the other enables have been assigned.

Table 4-391 Behavior and display for axis enable with traversing mode "**speed controlled**"

	Follow-up mode ACTIVE (Follow-up setpoint)	**Follow-up mode INACTIVE (Do not follow-up setpoint)**
Position controller ACTIVE (**servoControlMode**=ACTIVE)	Special case	**STANDARD SETTING**
	• Traversing the axis without position control using manipulated variable superimposition is possible (see Manipulated variable superimposition (Page 2976) using **servosettings.additionalSetpointValue** • Axis is NOT in position control (but servo setpoint enable is active, so **~.controlState**=ACTIVE) • Motion commands CANNOT be performed (due to follow-up mode, **control**=INACTIVE) • IPO set position and servo are tracked using following error model (set and actual position are offset by following error) • Monitoring functions are not active	• Axis is NOT in position control (but servo setpoint enable is active, so **~.controlState**=ACTIVE) • Motion commands for speed-controlled procedures are possible (**control**=ACTIVE) • Set position in IPO and servo are tracked using the following error model (set and actual position are offset by the following error) • Standstill monitoring is not active (internal follow-up mode, as speed-controlled mode)
Position controller INACTIVE (**servoControlMode**=INACTIVE)	Special case	Special case
	• The drive is only enabled for drive-autonomous motions and functions • Axis is NOT in position control (**~.controlState**=INACTIVE) • Motion commands CANNOT be executed • IPO set position and servo is tracked • Monitoring functions are not active	In real axes, "Do not follow up setpoint" is only effective if all the other enables have been assigned.

Remove axis enable

In the command **_disableAxis()** or **_disableQFAxis()**, (Remove axis enable) the position controller, drive and power enable withdrawn, "Do not follow up setpoint" has no effect.

Enabling line infeed

Infeed must be enabled before activating the axis.

Infeed can be activated and deactivated, and basic diagnostics can be carried out, with the **_LineModule_control** function block (as of V4.2).

The following infeeds are supported by the **_LineModule_control** function block:

- Basic Line Modules (BLM)
- Smart Line Modules (SLM)
- Active Line Modules (ALM)

The **_LineModule_control** function block is part of the command library of the SIMOTION SCOUT engineering system. You can find the function block under **Drives > SINAMICS**.

For more detailed information about the **_LineModule_control** function block, see the SIMOTION SCOUT online help (standard function for Line Modules) or the Function Manual *Standard Function for SINAMICS S120 Line Modules*.

The **LineModule_control** function block can be used for firmware versions < V4.2. You can find the block under *Applications > Cross-sector applications > Function block for controlling Line Modules* in the *SIMOTION Utilities & Applications*.

Monitoring

The status of the current drive and power enables for an electric axis is displayed in the following system variables:

- **actormonitoring.drivestate** (drive enable)
- **actormonitoring.power** (power enable)

In a hydraulic axis, the occupation status of the Q final controlling element and F controlling element is displayed in the following system variables:

- **actorMonitoring.QOutputState** (Q output)
- **actorMonitoring.FOutputState** (F output)
  The Q valve enable is displayed in **actormonitoring.drivestate**.

If the axis is switched from follow-up mode, the **Control** system variable switches to ACTIVE. The **Control** system variable indicates whether the axis is able to generate motions.

The axis goes into follow-up mode after control startup. Enables are not mandatory in follow-up mode.

For position-controlled axes, disabling an electric drive results in automatic disabling of the position controller. The position control enable signal is ignored for speed-controlled axes. For a hydraulic axis, enabling or disabling of the Q output results in disabling of the controller.

Behavior of electric axis should a digital drive be missing or switched off

If a digital drive is missing or switched off, the **_enableAxis()** command and motion commands behave as follows:

- If a drive is missing, **_enableAxis()** is aborted with an error message
- If the drive is switched on but is not yet in cyclic operation, if commands are issued synchronously, the system waits for the command; the command is not aborted and the command job is executed even if it is an asynchronous command; the command remains active even with asynchronous programming
- The **cyclicInterface** system variable on the axis indicates whether the drive is in cyclic operation, i.e. **cyclicInterface**= ACTIVE; cyclic operation is determined using the life-sign
  Comment:
  - On analog onboard axes, **cyclic operation active** is always indicated.
  - If a drive error is present (e.g. temperature error), the system variable displays INACTIVE.

Force/pressure control

Force/pressure control can be explicitly enabled using the **forceControlMode** function parameter in the enable/disable command. This requires that the axis is at a standstill (standstill signal **motionStateData.motionState**=STANDSTILL).

When enabled, the last actual force/pressure value is taken as the force/pressure setpoint.

Force/pressure control is deactivated using the **_disableAxis()** or **_disableQFAxis()** command, or by deselecting force/pressure control in the **_enableAxis()** or **_enableQFAxis()** command.

For switching over during motion, the conditional switchover with switchover criterion with active pressure limitation is available.

System variables

Table 4-392 System variables

Variable	State	Meaning
.control	Active / Inactive	Axis active or inactive
.servomonitoring.controlstate	Active / Inactive	Position controller active or inactive
.actormonitoring.drivestate	Active / Inactive	Drive enable (drive ON) for electric axis Q valve enable for hydraulic axis
.actormonitoring.power	Active / Inactive	Power enable (pulse enable) (for electric axis only)
.actorMonitoring.qOutputState	Active / Inactive	Q output active (for axis with hydraulic functionality only)
.actorMonitoring.fOutputState	Active / Inactive	F output active (for axis with hydraulic functionality only)
.actorMonitoring.fOutputEnable	Enabled / Disabled	Status of F output enable (for axis with hydraulic functionality only)

Variable	State	Meaning
.cyclicInterface	Active / Inactive	Communication active (only for DP, this is always active for analog or onboard axes; if a drive error is present (e.g. temperature error), the system variable displays INACTIVE.)
.velocityControllerServo Monitoring.controlstate	Active / Inactive	Velocity controller on the hydraulic drive axis active or inactive

Setting enables individually

For PROFIdrive-coupled drives, the BY_STW_BIT parameter of the **_enableAxis()** and **_disableAxis()** functions provide an interface for setting and canceling of individual enables. This allows the users to implement their own state machine transitions.

Bits 0 to 6 of the ctrl word1 control word can be set and reset using the BY_STW_BIT parameter:

_enableAxis() sets the bits transferred in the parameter in the control word

_disableAxis() clears the bits transferred in the parameter in the control word

For non-PROFIdrive-coupled drives, these bits have no significance and are rejected with 'illegal command parameters'.

The statuses can be read from status word STW via the **driveData** system variable. The state display in the **actorMonitoring.driveState** and **actorMonitoring.power** system variable remains unchanged.

Entering control bits 0 to 6 directly using the **_enableAxis()** and **_disableAxis()** functions can be combined with specifying the command mode (DRIVE or POWER).

For detailed information about linking drives using PROFIdrive, refer to Coupling of digital drives (Page 2895).

For information on defining the reaction to technological alarms, refer also to Section Adjustable response to RELEASE_DISABLE (Page 3185).

Note

STW1 is initialized by the drive and the **actorMonitoring.driveState** and **actorMonitoring.power** system variables are generated in STW1 according to the drive status. (as of V3.2)

The status display in these system variables is thus delayed by one cycle clock relative to the control word specifications. (as of V3.2)

Enabling the speed specification mode with _enableAxis (as of V4.0)

By enabling speed specification mode (parameter **movingMode**=SPEED_CONTROLLED of **_enableAxis()**), it is possible to continue motion in the event of the failure of a selected encoder that is not involved in closed-loop control. When activating in speed mode, command parameter **servoControlMode=**ACTIVE must be set so that the setpoint path is activated in the servo.

In position-controlled operation, the axis is brought to a standstill if a selected encoder involved in the position control fails. The drive enable to be canceled can be specified (**driveControlConfig.releaseDisableMode** configuration data element).

After the axis is stopped and the error is acknowledged, the axis can be switched to activation mode with speed specification. This allows non-position-controlled axis motion in the case of an encoder failure.

Note

- Failure of an encoder involved in the closed-loop control for position-controlled positioning still causes the axis to be brought to a standstill.
- In differential position measurement, all involved encoders are in the active state.
- If a command is issued to an encoder which has an error, alarm 20005 is issued as previously. This can be the case, for example, with an encoder that has an error in the data set.
- In SIMOTION, the encoder selected for closed-loop control is specified in the data set.

Command groups (Page 3047)

Enabling force/pressure control depending on switchover conditions (Page 3150)

Coupling of digital drives (Page 2895)

Dynamic limiting functions (Page 2999)

Positioning and standstill monitoring (Page 2941)

Enabling force/pressure control depending on switchover conditions

The **_enableForceControlByCondition()** command causes a switch to force/pressure control when the switchover criterion defined in the command is satisfied.

The switchover criterion is checked in the servo. The switchover criterion can be a position, pressure, time, or digital input. The conditions are specified in the command and can be logically combined in the command in multiple stages. Reissuing the command before the conditions are met enables you to switch between conditions.

After the switchover to force/pressure control, the axis executes the function specified in the cam according to the profile specification. The rise in pressure for any necessary transitional motions, e.g. for entering and exiting the profile, can be programmed in the command.

Force/pressure, position, and time are stored at the time of switchover and are available in the system variables.

Velocity limiting can also be activated as a dependent condition in the switchover command, and a velocity limit value can be set.

The velocity limit is set directly, or the current set velocity (manipulated variable) or actual velocity can be retained as the velocity limit (as of V4.1 SP1).

A pressure/time profile or a pressure/position profile (V4.1 SP1 and higher) is enabled or the pressure value can be directly specified (as of V4.1 SP1) when the switchover occurs.

Axis with Q valve

The conditional switchover is triggered by the **_enableForceControlByCondition()** command.

Axis with P valve

Only the force limiting commands have any effect; the conditional switchover is triggered by the **_enableForceLimitingByCondition()** command.

Stopping motions with _stopEmergency()

The **_stopEmergency()** function stops the axis with a programmable stop mode. If a motion command is active, it is aborted and cannot be continued with a **_continue** command. The axis does not switch to follow-up mode. The axis is prevented from receiving additional motion commands. This status can be reset with **_resetAxis()** or **_disableAxis ()**. The command becomes active immediately.

The motion on the axis is stopped according to the behavior set in the command; the position control is not affected. Torque limiting, any active torque reduction (including when traveling to fixed stop) and force/pressure limiting are retained.

Active and pending motion commands on the axis are aborted and cannot be resumed.

Note

When a motion is stopped using **_stopEmergency()** and a smooth velocity profile with jerk specification is present during the axis acceleration phase, the velocity can continue to increase until the acceleration is reduced by means of the jerk which has been set.

In extreme cases, the velocity can rise still further, until it reaches the configured maximum velocity. The axis is only decelerated once acceleration has been reduced by the jerk.

With the parameter **abortAcceleration** (as of V4.2.1), you can set that a possible acceleration does not exceed the jerk limitation, but is immediately cleared.

Status

The **stopEmergencyCommand.state= ACTIVE** status is set. Motion commands on the axis are not active in this status.

Table 4-393 System variable for _stopEmergency command

Variable	State	Meaning
stopEmergencyCommand.state	ACTIVE	The **_stopEmergency()** command was triggered.
	INACTIVE	No **_stopEmergency()** command was triggered, or the command was acknowledged with **_resetAxis()** or **_disableAxis()**.

stopEmergencyCommand=ACTIVE status is canceled with **_disableAxis()** or **_resetAxis()**.

Note

The **stopEmergencyCommand**=ACTIVE status may last longer than the **_disableAxis()** command is active, so the **stopEmergencyCommand**=INACTIVE status should be checked explicitly before the enables are reset.

The axis enables are not deactivated.

The command has no effect if the axis is in follow-up mode; the status is not set.

A **_stopEmergency()** command with a higher-priority stop response overrides a lower-priority response.

The stop behavior can be set using the **stopDriveMode** function parameter.

The priority setting is defined in the stop behavior as follows:

- Specification of timing for stop motion (STOP_IN_DEFINED_TIME), irrespective of current velocity
- Stopping with maximum dynamic response values on the axis (STOP_WITH_MAXIMAL_DECELERATION)
- Stopping with dynamic response parameters (STOP_WITH_DYNAMIC_PARAMETER) This is set during configuration.
- Stop axis with setpoint zero (STOP_WITH_COMMAND_VALUE_ZERO)

StopEmergency with dynamic response parameters (as of V3.2)

The stopDriveMode=STOP_WITH_DYNAMIC_PARAMETER setting allows dynamic values to be entered and enabled directly in the **_stopEmergency()** command.

The defaults defined in the **userDefaultDynamics** system variable are used as default parameters.

See also

Stopping with preassigned braking ramp (Page 3002)

Stopping motions with _stop()

The **_stop()** and **_continue()** commands can be used to stop and resume motions.

The **_stop** command is effective in the following technology object states: motion, motion stop without abort. It stops the entire motion or a portion of the motion of the axis using a programmed braking ramp.

The motion to be stopped can be interrupted or terminated. The portion of the motion to be stopped is specified using the **Command ID** or the type of motion.

An interrupted motion (entire motion or portion of motion) that was stopped with **_stop()**, stopMode=STOP_WITHOUT_ABORT and was not completely interpolated before the stop command was issued can be resumed using the **_continue()** command. When a motion is

resumed, the dynamic response parameters of the interrupted command, such as velocity profile, acceleration, etc., are used.

Motions interrupted by **_stop()** commands in **stopMode**=STOP_WITHOUT_ABORT can be overridden by motion commands with **mergeMode** IMMEDIATELY. The NEXT or SEQUENTIAL merge modes do not cause the motion to be executed immediately.

stopMode=STOP_AND_ABORT aborts the commands selected in the stop command. The aborted commands are returned with errors. When motion commands are aborted, the **Command Aborted** technology alarm is generated.

A command containing a position-controlled stop motion changes from ACTIVE to EXECUTED if the interpolation is completed, and the actual value is in the positioning window and the minimum dwell time has elapsed (MOTION_DONE). If the axis does not achieve this status, e.g., due to active torque limiting for deactivated following error monitoring and deactivated position monitoring (and therefore no canceling of a command due to a local alarm response), the command status remains ACTIVE.

Note

When a motion is stopped using **_stop()** and a smooth velocity profile with jerk specification is present during the axis acceleration phase, the velocity can continue to increase until the acceleration is reduced by means of the jerk which has been set.

In extreme cases, the velocity can rise still further, until it reaches the configured maximum velocity. The axis is only decelerated once acceleration has been reduced by the jerk.

With the parameter **abortAcceleration** (from V4.2.1), you can set that a possible acceleration does not exceed the jerk limitation, but is immediately cleared.

Stopping position-controlled axes in speed-controlled mode (V3.1 and higher)

- The **movingMode=SPEED_CONTROLLED** parameter of the **_stop()** and **_stopEmergency()** commands can be used to stop position-controlled axes in speed-controlled mode.
  The speed ramp takes effect immediately, and any pending following error is not removed. This also means that in force-controlled mode, force-limited mode, torque-limited mode, and velocity-limited mode, the axis is stopped immediately with the ramp via **_stopEmergency()** on switching over to speed-controlled mode.
- Axes can be stopped with position control in the **movingMode=POSITION_CONTROLLED** setting.
  With a drive axis, the **POSITION_CONTROLLED** setting is ignored.
- In the **movingMode=CURRENT_MODE** setting (default setting, compatibility mode), the axis is stopped in the last traversing mode set on the axis.
  In force-/pressure-controlled operation as well, the axis is stopped in the last traversing status (position-controlled or speed-controlled) set on the axis.

This enables a transition on the position-controlled axis with **_stopEmergency()** from each operating mode to speed-controlled mode and to position-controlled mode.

Comment:

Position-controlled commands cannot be resumed after the **_stop()** command is set with **movingMode= SPEED_CONTROLLED**; the motion command is aborted.

Resuming motions

The **_continue()** function resumes the complete motion or portion of a motion of the specified axis if it was stopped with **stop()** and STOP_WITHOUT_ABORT in the **stopMode** parameter.

The portion of the motion to be resumed is specified with the **Command ID** or by the type of motion.

When a motion is resumed, the dynamic response parameters of the interrupted command, such as velocity profile and acceleration, are used.

Resuming motions after _disableAxis() (V3.2 or higher)

With setting **TypeOfAxis.DecodingConfig.disableMotionOperation**=No, motion commands that are stopped with **_stop()** (stopMode=STOP_WITHOUT_ABORT) are not aborted by **_disableAxis()**, and may be resumed after **_enableAxis()** with **_continue()**.

The following restrictions apply:

- Only the main motion (basic motion) can be resumed.
- If motions are superimposed, continuation is only possible if the superimposed coordinate system is returned to while in the stop state.
  To do this, the **decodingConfig.transferSuperimposedPosition** configuration data element must be configured with TRANSFER_STANDSTILL.
- Relative positioning is started again, i.e. it is run through again in full after **_continue()**.

Note

_stopEmergency() is used to abort all motion commands; it is not possible to continue in this case.

Reset axis

The **_resetAxis()** command places the axis in a defined initial state.

- All active motions are stopped with a preassigned braking ramp, and the axis enables are retained.
- Commands in the motion buffer and commands pending at the motion buffer are deleted; synchronous commands are aborted. The **Command aborted** technology alarm is suppressed.
- Optionally, the axis can be restarted using a function parameter in the command.
- The command is executed synchronously.
- The command can also be executed asynchronously (V3.1 and higher).
- Pending errors on the axis are reset. The command is terminated with a negative acknowledgment if any errors occur that must not be acknowledged at this point.
- Any system variables changed by the program are reset to the configured values upon request. Actual values are retained.
- The homing status is retained.

Restart

When restart is activated on the technology object with the **activateRestart** parameter, the technology object performs a restart.

- An active motion on the axis is aborted without error messages or the like.
- The actual value system of the axis and, thus, the homing status is reset.
- All commands on the axis are aborted.
- All connections to other technology objects are removed and reestablished.

The **_resetAxis()** command stops any synchronous operation command that is in effect on this axis. The Synchronous Operation technology object on the synchronous axis is not reset.

Note

Setting **restartActivation** initiates a restart that is performed asynchronously. For this reason, it can take some time for the TO restart to begin.

If synchronous processing is required, **_resetAxis()** with the **ACTIVATE_RESTART** parameter must be used.

System variables

Table 4-394 System variables for the _resetAxis() command

Variable	State	Meaning
.reset	ACTIVE/INACTIVE	Reset command is active or not active
.restartActivation	ACTIVATE_RESTART	Setting the **restartActivation** variable to ACTIVATE_RESTART activates a restart of the technology object.
	NO_RESTART_ACTIVATION	Once the restart of the technology object is completed, the system resets the variable to NO_RESTART_ACTIVATION.

See also

Saving the Command ID (Page 3173)

Resetting an axis error

The **_resetAxisError()** function resets a specified error or all errors on the axis. The command is terminated with a negative acknowledgment if any errors occur that must not be acknowledged at this point.

The command is asynchronous. The command can also be issued synchronously (V3.1 and higher). If necessary, the error is not reset until the local reaction triggered by the error has been completed.

Please also note the information in the **Motion Control Basic Functions**manual under *Display and acknowledge technological alarms*.

System variables

Table 4-395 System variables for the _resetAxisError() command

Variable	State	Meaning
.error	NO/YES	No errors/warnings are pending on the axis, or one or more errors/warnings are pending on the axis.
.errorReaction	See the **EnumAxisErrorReaction** data type as defined in the reference list for the system variables	Indicates the response that occurs based on one or more technological alarms

Canceling/deleting an axis command (as of V4.1 SP1)

The **_cancelAxisCommand()** function cancels the execution of the command or function with the CommandId specified in the **_cancelAxisCommand()** command and removes the command from the job list.

With **_cancelAxisCommand()**, commands such as **_homing()** with setting **homingMode**=PASSIVE_HOMING can be canceled too, as long as they are not the active motion.

The motion is cancelled with the maximum dynamic values. This also applies to superimposed motions, whereby the dynamic values from either motion cannot exceed the maximum values.

4.8.8.3 Commands for axis motions

Homing

The **_homing()** command homes the axis.

Various homing modes can be set by means of the **homingMode** parameter:

- Active homing (**ACTIVE_HOMING**)
  The axis is homed according to the sequence defined in the configuration.
- Setting of current position value (**DIRECT_HOMING**)
  The axis coordinate system is set to the value of the home position coordinate. The axis does not move.
- Offsets the actual position value (**DIRECT_HOMING_RELATIVE**)
  The axis coordinate system is offset by the value of the home position coordinate. The axis does not move.

- Absolute encoder adjustment
  - **homingMode**=**ENABLE_OFFSET_OF_ABSOLUTE_ENCODER**
    The configured value for the absolute encoder adjustment is compensated additively with the retentively stored offset. The total offset is stored in the NVRAM and is available after the control is switched off.
  - **homingMode**=**SET_OFFSET_OF_ABSOLUTE_ENCODER_BY_POSITION (as of V4.1 SP1)**
    The value in the *homePosition* parameter is set as the current position, and the resulting absolute encoder offset is calculated based on this. The total offset is stored retentively and is available after the control is switched off.

    Note

    Once a new project has been downloaded to the control, the stored offset is no longer available.

- Passive homing (**PASSIVE_HOMING**)
  The **_homing()** command with the PASSIVE_HOMING setting does not itself trigger an active axis motion; rather, homing occurs during the next axis motion. The axis is homed according to the sequence defined in the configuration.
  The motion command can be triggered before or after the **_homing()** command.
  The **_homing()** command is active in parallel until the axis is homed.
  Disabling the command in SIMOTION versions earlier than V3.2
  - **_resetAxis()**
  - **_disableAxis()**

  Disabling the command as of SIMOTION V3.2 with
  - **_resetAxis()**
  - **_stopEmergency()**

The sequences for active homing, **homingMode**=ACTIVE_HOMING, and the criteria for passive homing, **homingMode**=PASSIVE_HOMING, are set in the configuration.

The dynamic parameters for homing are programmable and refer to all phases of the homing procedure.

An axis has **homed** status when the axis coordinate system has been aligned with the homing signal. The status can be read out in the **positioningstate.homed** system variable.

System variables

Table 4-396 System variables for the _homing() command

Variable	State	Meaning
.userDefaultHoming	See the **StructAxisHomingDefault** data type as defined in the reference list of the system variables	User defaults for homing
.homingCommand	See the **StructAxisHomingCommand** data type as defined in the reference list of the system variables	Status of the homing sequence
.positioningstate.homed	YES/NO	Axis is/is not homed

See also

Homing (Page 2923)

Moving

The **_move()** command can be applied to all axis types.

With the speed-controlled axis, the motion is implemented with speed specification.

With the positioning axis, the motion is implemented as velocity specification. In this case, the motion can be implemented with position-control (signal-integrated velocity) or only as a velocity specification without position control.

This selection is made using the **movingMode** parameter in the command.

- Position-controlled motion (POSITION_CONTROLLED)
- Speed-controlled motion (SPEED_CONTROLLED)

The **movingMode** parameter has no effect on the speed-controlled axis.

The **_move()** command can be applied as a superimposed command.

AS of SIMOTION V4.4, an existing acceleration or deceleration can be set to zero immediately when a motion is initiated by the **_move()** command. The existing acceleration or deceleration is not first reduced via the jerk. The **abortAcceleration** function parameter is available for this purpose.

Table 4-397 System variables for moving with _move()

Variable	State	Meaning
moveCommand.state	INACTIVE / ACTIVE_ABSOLUTE /ACTIVE_RELATIVE	Indicates that a **_move()** command is active on the axis. A distinction is made according to whether the **moveCommand.TargetVelocity** variable indicates an absolute or relative value.
moveCommand.TargetVelocity		Indicates the absolute or relative velocity.
moveCommand.relativeActual VelocityToTargetVelocity		Indicates the current velocity relative to the target velocity.

See also

Traversing the axis via velocity specifications (Page 3002)

Positioning

- The **_pos()** motion command moves the axis to the programmed target position using an assignable velocity profile.
- The position can be specified as an absolute or relative position.
- The direction of motion can be specified for modulo axes because the target position can be attained in various directions with such axes. The various modes must be entered using the **direction** parameter (see table).

- **_pos()** commands have a special **blending** mode that links the _pos command to the previous _pos command.
- The **_pos** commands can be applied as superimposing commands.

Note

While the positioning motion is active, if the setpoint system is reset using **_redefinePosition()** or **_homing()** (DIRECT_HOMING / PASSIVE_HOMING), the motion is resumed as follows:

- For absolute positioning, the target position is approached in the newly-defined coordinate system.
- For relative motion, the relative path is traveled. In this case, offsetting the logical coordinate system has no effect.

AS of SIMOTION V4.4, an existing acceleration or deceleration can be set to zero immediately when a motion is initiated by the **_move()** command. The existing acceleration or deceleration is not first reduced via the jerk. The **abortAcceleration** function parameter is available for this purpose.

The following table provides an overview of the possible combinations of direction specification, axis type, and positioning mode.

Table 4-398 Possible specifications for direction in the _pos( ) command

	Non-modulo axis / absolute positioning	**Non-modulo axis / relative positioning**	**Modulo axis / absolute positioning**	**Modulo axis / relative positioning**
POSITIVE	Direction determined from the target position	Positive direction	Positive direction	Positive direction
NEGATIVE	Direction determined from the target position	Negative direction	Negative direction	Negative direction
BY_VALUE	Direction determined from the target position	Direction determined from the sign of the distance specification	Direction determined from the sign of the position specification	Direction determined from the sign of the distance specification
SHORTEST_WAY	Direction determined from the target position	Direction determined from the sign of the distance specification	Direction is selected to achieve shortest distance to target	Direction determined from the sign of the distance specification

System variables

Positioning with blending (Page 3003)

Starting a time-related velocity profile

With the **_runTimeLockedVelocityProfile()** command, the axis is traversed via a user-definable time-related velocity profile.

The velocity profile is stored in a cam.

The profile is applied from a definable starting point to the end. The dynamic response parameters for any necessary transition motions, e.g. for entering the profile and exiting the profile, can be programmed on the command.

The traversing behavior at the end of the profile is set during configuration in **decodingConfig.behaviourAtTheEndOfProfile**.

For position-controlled axes, the **movingMode** parameter in the command can be used to specify whether the axis is to move with position control or at a defined velocity.

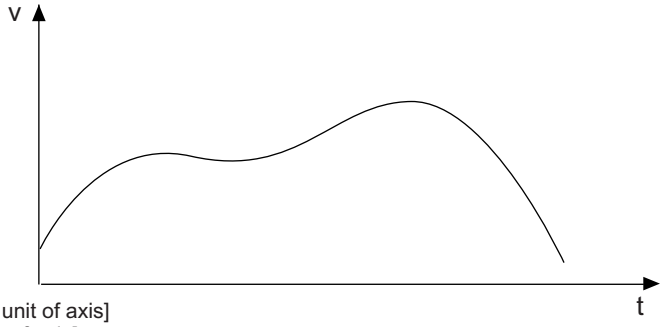

Figure 4-918 Example of a time-related velocity profile

The status and values are displayed in the elements of the **velocityTimeProfileCommand** system variable.

See also

Behavior at the end of the profile (V3.2 and higher) (Page 3045)

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Starting a position-related velocity profile

With the **_runPositionLockedVelocityProfile()** and **_runMotionInPositionLockedVelocityProfile()** commands, the axis is traversed via a user-definable position-related velocity profile.

The domain / the x coordinate of the cam corresponds to the absolute axis position (setpoint).

The profile is started at the current axis position. This must fall within the domain of the profile, otherwise the command is aborted and an alarm is triggered.

Note

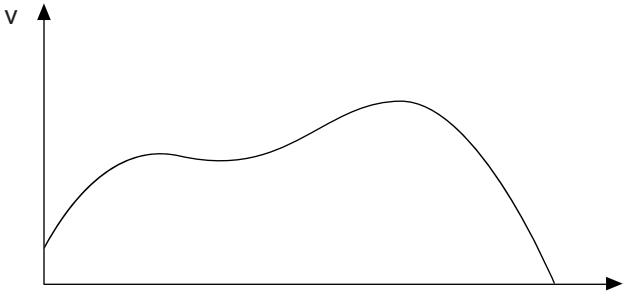
The set velocity must be a value other than zero at the starting point.

The dynamic response parameters for any necessary transition motions, e.g. for entering the profile and exiting the profile, can be programmed on the command.

The traversing behavior at the end of the profile is set during configuration in **decodingConfig.behaviourAtTheEndOfProfile**.

In addition, a tolerance for the detection of the end of the profile can be specified via the **TypeOfAxis.VelocityPositionProfile.endPositionTolerance** configuration data element. The tolerance is required if the above command has been preassigned with the WHEN_MOTION_DONE command transition.

The movingMode parameter in the command can be used to specify whether the axis is to move with position control or only at a defined velocity.



v [velocity unit of axis]
s [position unit of axis]

Figure 4-919 Example of a position-related velocity profile

The status and values are displayed in the elements of the **velocityPositionProfileCommand** system variable.

Behavior at the end of the profile (V3.2 and higher) (Page 3045)

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Positioning with user-definable position profile

With the **_runTimeLockedPositionProfile()** and **_runMotionInPositionLockedVelocityProfile()** commands, the axis is traversed via a user-definable time-related position profile. A starting point can be specified in the cam.

The profile is applied from a definable starting point to the end. An absolute or relative position reference can be selected in the command.

The traversing behavior at the end of the profile is set during configuration in **decodingConfig.behaviourAtTheEndOfProfile**.

A transition profile is generated by the axis for discontinuous transitions. The transition profile is specified in a dynamic response parameter using the acceleration, jerk, and velocity profile parameters of the command.

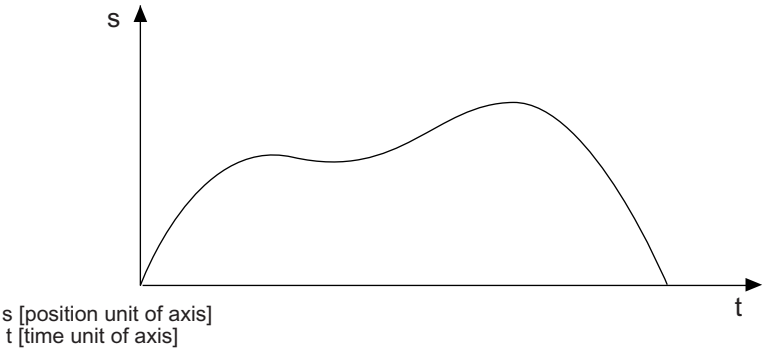

Figure 4-920 Example of a time-related position profile

The status and values are displayed in the elements of the **positionTimeProfileCommand** system variable.

Enabling and disabling torque limiting

The **_enableTorqueLimiting()** command enables torque limiting in the drive, which takes effect immediately. The limiting value is specified in the command.

Active motion commands and synchronous operation relationships continue to be executed.

The limiting functions can be enabled before a motion or simultaneously with a motion and can be switched by reissuing the command.

The commands for travel to fixed endstop (**_enableMovingToEndStop()**) and torque limiting (**_enableTorqueLimiting()**) cannot be active at the same time.

The **_disableTorqueLimiting()** command cancels the torque limiting.

System variables

Table 4-400 System variables for torque limiting

Variable	State	Meaning
TorqueLimitingCommand.State	ACTIVE/INACTIVE	Indicates the torque limiting status
UserDefaultTorqueLimiting.TorqueLimit		Default for torque limiting
actualTorque		Actual torque on the axis See also **Technology data**.

See also

Overview of torque limiting via torque reduction (Page 3010)

Technology data (Page 3018)

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Enable force/pressure limiting with position-related force/pressure limiting profile

With the **_enablePositionLockedForceLimitingProfile()** and **_enableMotionInPositionLockedForceLimitingProfile()** commands, the pressure limitation is activated with a position-related force/pressure limiting profile. The profile is set by means of a cam.

The domain of the cam to be used in the command is interpreted as a position, and the range as a force/pressure limiting value in the respective position and force/pressure units of the axis.

Behavior at the end of profile:

- Last value is still in effect
- Force/pressure limiting remains active

The profile is started at the current axis position. This must fall within the domain of the profile, otherwise the command is aborted and an alarm is triggered.

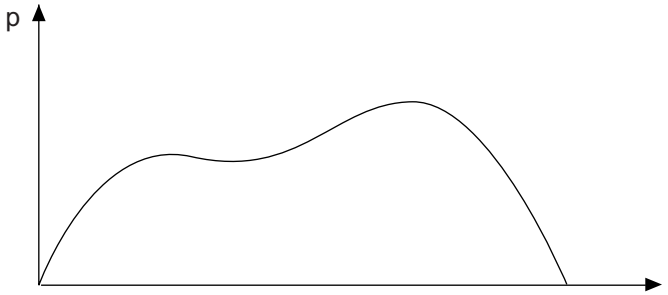

Figure 4-921 Example of a position-related force/pressure limiting profile

The status and values are displayed in the elements of the **forceLimitingCommand** system variable.

See also

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Enabling force/pressure limiting with time-related motion profile

The **_enableTimeLockedForceLimitingProfile()** command activates pressure limiting with a time-related limiting profile. The profile is set by means of a cam.

The starting point can be specified in the cam.

Behavior at the end of profile:

- Last value is still in effect
- Force/pressure limiting remains active

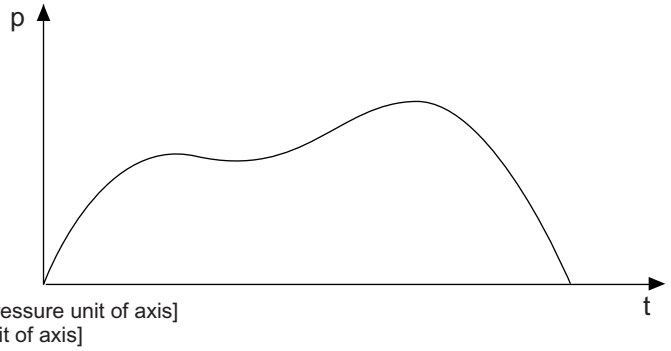

Figure 4-922 Example of a time-related limiting profile

With the axis setting **TypeOfAxis**=REAL_QFAXIS_WITH_OPEN_LOOP_FORCE_CONTROL, the profile is output as a manipulated variable on the F output.

See also

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Starting the time-related force/pressure profile

The **_runTimeLockedForceProfile()** command starts the time-related force/pressure profile.

The axis executes the function specified in the cam as a force/pressure profile.

The domain of the cam to be used in the command is interpreted as time, and the range as a force/pressure in the respective time and force/pressure units of the axis.

The profile is applied from a definable starting point to the end.

Behavior at the end of profile:

- Last value is still in effect
- Force/pressure limiting remains active

The derivation of pressure for any necessary transition motions, e.g. for entering and exiting the profile, can be programmed in the command. The behavior at the end of the profile is set during axis configuration.

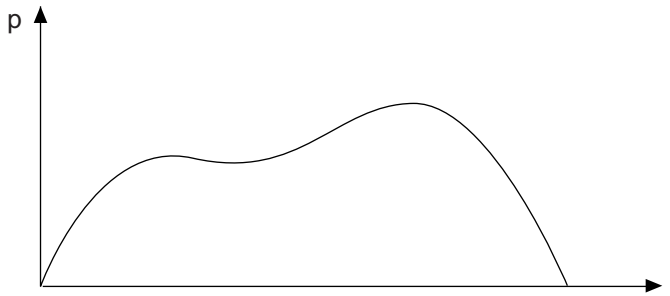

Figure 4-923 Example of a time-related force/pressure profile

The status and values are displayed in the elements of the **forceTimeProfileCommand** system variable.

If the step enabling condition is satisfied or the status is WHEN_INTERPOLATION_DONE, a pressure/time profile can switch from pressure control to position control.

See also

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Starting the position-related force/pressure profile

Possible start commands:

- **_runPositionLockedForceProfile()**
- **_runMotionInPositionLockedForceProfile()**

The axis executes the function specified in the cam as a force/pressure profile.

The definition range of the cam to be used in the command is interpreted as a position and the value range as a force/pressure in the relevant position and force/pressure units of the axis.

The profile is started at the current axis position. This must fall within the definition range of the profile, otherwise the command is aborted and an alarm is triggered.

Behavior at the end of profile:

- Last value is still in effect
- Force/pressure limiting remains active

The derivation of pressure for any necessary transitions, e.g. for entering and exiting the profile, can be programmed in the command. The behavior at the end of the profile is set during axis configuration.

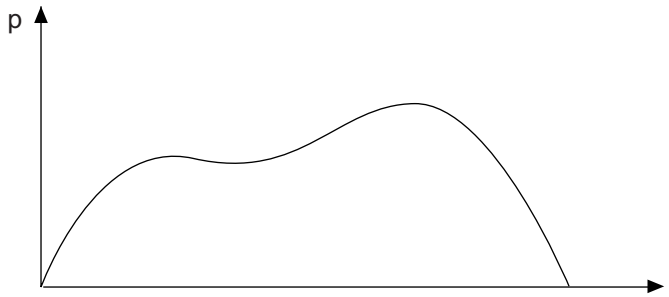

Figure 4-924 Example of a position-related force/pressure profile

The status and values are displayed in the elements of the **forcePositionProfileCommand** system variable.

See also

Traversing with user-defined motion and force/pressure profiles (Page 3040)

Enabling/disabling force/pressure limiting

The **_enableForceLimitingValue()** command enables force/pressure limiting on the axis. The limit value is specified in the command.

Active motion commands and synchronous operation relationships continue to be executed.

The limiting functions can be enabled before a motion or simultaneously with a motion. They can be switched by reissuing the command.

Active limiting disables the following error and positioning monitoring.

The **_disableForceLimiting()** command cancels the force/pressure limiting.

With the axis setting **TypeOfAxis**=REAL_QFAXIS_WITH_OPEN_LOOP_FORCE_CONTROL, a manipulated variable is output or canceled on the F output with these commands.

System variables

Table 4-401 System variables for force/pressure limiting

Variable	State	Meaning
forceLimitingCommand.state	ACTIVE / INACTIVE	Activation status of a command for the force limitation on the axis

See also

Overview of force/pressure limiting (Page 3033)

Enabling/disabling velocity limiting

The **_enableVelocityLimitingValue()** command enables velocity limiting on the axis. The limiting value is specified in the command.

If the velocity limit is reached, the **Anti-windup** functionality in the pressure controller is activated, i.e., the I component is stopped.

Velocity limiting can be enabled in parallel to motion commands.

In addition to a force/pressure specification, the velocity is limited in the case of dwell pressure, so that if an error occurs in the process, the velocity no longer increases, as is otherwise permitted.

In the event of an error, velocity limiting remains active except in the case of the RELEASE_DISABLE error reaction.

The **_disableVelocityLimitingValue()** command cancels velocity limiting.

System variables

Table 4-402 System variables for velocity limiting

Variable	Status	Meaning
velocityLimitingCommand.state	ACTIVE/INACTIVE	Status of the velocity limiting command on the axis

See also

Force/pressure control with velocity limiting (Page 3033)

Enabling velocity limiting with position-related velocity limiting profile

Possible enabling commands:

- **_enablePositionLockedVelocityLimitingProfile()**
- **_enableMotionInPositionLockedVelocityLimitingProfile()**

This command activates velocity limiting with a position-related velocity profile. The profile is set by means of a cam. The velocity limit value is not implicitly deactivated at the end of the profile.

For position-related profiles, the absolute position reference of the profile is the starting point. This also applies when modulo axes are used, thus allowing the profile to remain valid beyond the end of the modulo range.

The profile is started at the current axis position. This must fall within the definition range of the profile, otherwise the command is aborted and an alarm is triggered.

Behavior at the end of profile:

- Last value is still in effect
- Force/pressure limiting remains active

See also

Force/pressure control with velocity limiting (Page 3033)

Enabling velocity limiting with time-related velocity limiting profile

The **_enableTimeLockedVelocityLimitingProfile()** command activates velocity limiting with a time-related limiting profile. The profile is set by means of a cam. Force/pressure limiting is not implicitly disabled at the end of the profile.

The starting point can be specified in the cam.

Behavior at the end of profile:

- Last value is still in effect
- Force/pressure limiting remains active

See also

Force/pressure control with velocity limiting (Page 3033)

Travel to fixed endstop

The **_enableMovingToEndStop( )** and **_disableMovingToEndStop( )** commands are available for the travel to fixed endstop function.

See also

Travel to fixed endstop (Page 3015)

4.8.8.4 Commands for defining the coordinate system

Resetting the set and actual positions

The **_redefinePosition()** command is used to set/offset the axis coordinate system. Either the setpoint or actual value is specified. The value that is not specified is aligned to keep the following error constant. The servo values (actual values, setpoints) are not modified.

The **_redefinePosition** command is effective in the following technology object states: Active, Motion, and Motion stop without abort.

In the case of a virtual axis, the velocity and acceleration can also be set.

The setpoint and actual values of an axis can be changed using the **_redefinePosition()** command. The position value is specified as an absolute value or as a relative position offset. The behavior can be specified by means of the **RedefineSpecification** parameter:

- **COMMAND_VALUE** setting: The setpoint of the axis position is modified.
- **ACTUAL_VALUE** setting: The actual value of the axis position is modified.
- **COMMAND_VALUE_BASIC_MOTION** setting: Like COMMAND_VALUE, but with reference to the basic coordinate system
- **COMMAND_VALUE_SUPERIMPOSED_MOTION** setting: Like COMMAND_VALUE, but with reference to the superimposed coordinate system

The other value in each case is aligned.

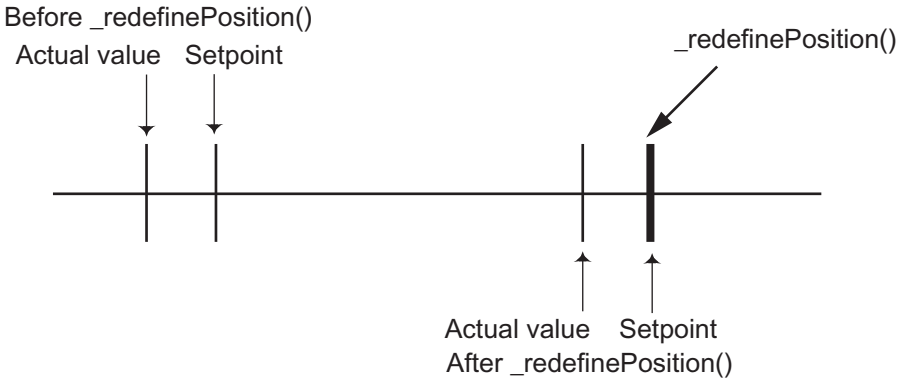

Figure 4-925 Absolute offset of axis position relative to setpoint

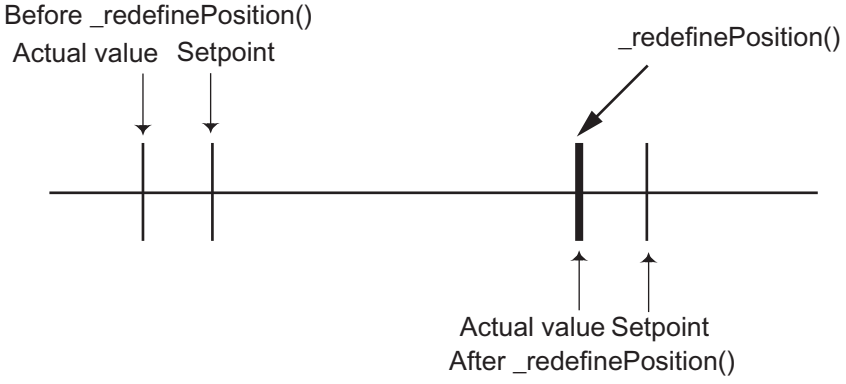

Figure 4-926 Absolute offset of axis position relative to actual value

If the set positions and/or actual positions of several axes must be re-set concurrently, this can be realized as follows:

- Programming of the **_redefinePosition()** commands for the various axes within the IPO-synchronous user task
  Requirement: For the associated axes, the appropriate IPO cycle clock must be set for this IPO-synchronous user task.
- Programming of the **_redefinePosition()** commands within a block for the synchronous processing
  (See **Motion Control Base Functions** manual, *Synchronous Start* section).

Basic coordinate system or superimposed coordinate system (as of V3.1)

_redefinePosition() can act on the basic coordinate system or the superimposed coordinate system. The behavior can be specified by means of the **RedefineSpecification** parameter.

See also

Superimposed motion (Page 3008)

4.8.8.5 Simulation commands

Enabling/disabling program simulation

The **_enableAxisSimulation()** command sets the axis to program simulation. If the axis is in motion, it is stopped using the preassigned braking ramp. As for a virtual axis, the actual values are taken from the setpoints. The axis enables and setpoint generation remain active, as do the active motion commands.

While simulation is active, the command variable is calculated and the actual value of the interpolator is set to the setpoint of the interpolator, irrespective of the real actual value of the axis. The real actual value of the axis is not affected by the program simulation.

If the axis is operated in simulation mode, a program with command variable calculation can be executed; in this case, motions are not executed by the axis, but are only simulated.

Terminate simulation.

The **_disableAxisSimulation()** command resets the axis out of program simulation. The real actual values then continue to be accepted. All other states remain unchanged. Any existing following error is removed immediately.

The following examples describe how to avoid the following error being removed immediately.

Example: Travel onwards from the actual position of axis

1. Switch the module off and on again.
2. Deactivate the simulation.

Before deactivation, the setpoint has been set to the actual value.

Example: Travel onwards from the new setpoint

1. Determine the different between the setpoint and actual value.
2. Set the setpoint to the actual value using **_redefinePosition()**.
3. Deactivate the simulation.
4. Travel the difference between the setpoint and actual value.

The **_resetAxis()** command also terminates the program simulation of the axis.

Effectiveness and status

The **_enableAxisSimulation()** and **_disableAxisSimulation()** commands are effective in the following TO states: Inactive, Active, Motion, and Motion stop without abort.

The current simulation mode can be scanned by means of the **simulation** system variable (program simulation).

Note

The outputting of setpoint values may be blocked by the simulation.

Axis errors, such as "Drive not connected" or "Encoder fault" cannot be avoided in this way; the axis must be functional same as a non-simulated axis.

System variables

Table 4-403 System variables for program simulation

Variable	State	Meaning
Simulation	ACTIVE/INACTIVE	Simulation status

See also

Setting as a real axis without drive (axis simulation) (Page 2899)

4.8.8.6 Information functions / command buffers

Overview of information functions/command buffer

The information commands on the axis can be used to read out the command and motion status of axis commands. It is possible to store the command status for longer than the period during which the command is in effect on the axis. The commands are identified with the **CommandId**. To scan the status, you need to specify the axis as well as the **CommandId** assigned to the command.

Reading the execution status of a motion command

The **_getStateOfAxisCommand()** command returns the execution status of a motion command. The status can be scanned while the command is being executed. Upon completion, the **CommandId** is deleted.

If a **CommandId** scan is required beyond this time period, it can be stored in a buffer and then cleared at any time, see **_bufferAxisCommandId** and **_removeBufferedAxisCommandId**.

The following statuses are reported:

- Command is being executed
- **CommandId** not known or command already completed
- Command is decoded, execution has not yet started
- Command is decoded, waiting for a synchronous start
- Execution of the command has been completed
- Execution of the command has been aborted

The "Execution of the command has been completed" and "Execution of the command has been aborted" statuses are only returned when the command status is stored. The **_bufferAxisCommandId( )** command can be used to store the **CommandId** and command status in the system beyond the end of the command.

For the "Execution of the command has been aborted" status (ABORTED), the reason for aborting is also given (V3.2 and higher)

System variables

None

Saving the Command ID (Page 3173)

Reading current phase of motion

The **_getMotionStateOfAxisCommand()** command returns the current phase of the motion.

The following statuses are reported:

- **NOT_EXISTENT**
  CommandId not known or command already completed
  See also Saving the Command ID (Page 3173)
- **BUFFERED**
  Command is in the command queue
- **IN_EXECUTION**
  Command is being executed
- **IN_ACCELERATION**
  The motion generated by the command is in the acceleration phase
- **IN_CONSTANT_MOTION**
  The motion generated by the command is in the constant motion phase
- **IN_DECELERATION**
  The motion generated by the command is in the deceleration phase
- **AXIS_HOMED**
  Axis synchronized
- **INTERPOLATION_DONE**
  The setpoint interpolation of the command is completed
- **SYNCHRONIZING**
  Synchronizing
- **DESYNCHRONIZING**
  Desynchronizing
- **SYNCHRONIZED**
  Synchronous operation
- **MODIFICATION_ACTIVE**
  Compensating movement is active with scaling or offset in synchronous operation

- **EXECUTED**
  Execution of the command has been completed
  See also Saving the Command ID (Page 3173)
- **ABORTED**
  Execution of the command has been aborted

System variables

None

See also

Saving the Command ID (Page 3173)

Saving the Command ID

The **_bufferAxisCommandId()** command causes the command status and the **CommandId** to be stored beyond the command execution time. This permits a command status to be queried even if the command has already been completed.

In V3.2 and higher, the command includes an additional parameter that can suppress deletion of the **CommandId** on resetting.

Note

The maximum number of **CommandIds** with command status that can be stored is specified in the **decodingConfig.numberOfMaxBufferedComandId** configuration data element. This must be managed by the user program. If the buffer overflows, the command will be rejected with a return value.

Canceling saving of Command ID

The **_removeBufferedAxisCommandId()** command clears the specified **CommandId** and the command status from the buffer. Alternately, all stored **CommandIds** can be deleted.

Reading the status of a specific error on the axis

The **_getAxisErrorNumberState()** command is used to read the status of a specific error on the axis.

Reading out pending alarms (V4.0 and higher)

The error status, alarm number, and alarm parameters of up to eight pending alarms can be read out with the **_getAxisErrorState()** command.

Reading the status of the motion buffer on the axis

The information command **_getStateOfMotionBuffer()** on the **MotionBuffer** can be used to manage the buffer on the axis. This can be used to check whether the axis is ready to accept motion commands before those commands are issued. All **sequentially** effective commands are stored in the motion buffer.

The **_getStateOfMotionBuffer()** command returns the status of the motion buffer on the axis: EMPTY, FULL, or WRITEABLE.

Clearing the motion buffer on the axis

The information command and the reset command on the motion buffer can be used to manage the motion buffer on the axis. This can be used to check whether the axis is ready to accept motion commands before those commands are issued.

The **_resetMotionBuffer()** command deletes all commands in the motion buffer and the commands pending for the motion buffer. The current command is not deleted. The **_resetMotionBuffer()** command is executed synchronously. The command is active in all axis states.

Activating data sets

Data set commands can be used to read, write, and activate data sets on the axis.

The **_setAxisDataSetActive()** command sets the data set specified in the function parameter to active.

System variables

Table 4-404 System variables for activating data sets

Variable	State/type	Meaning
dataSetMonitoring	See the **StructDataSetMonitoring** data type as defined in the reference list of the system variables	Information for data set changeover • State • Requested data set • Current data set

Note

If the active measuring system is switched via a data set changeover, the **_setAndGetEncoderValue()** system function should be used to synchronize the two measuring systems before the switchover takes place. This will prevent unwanted compensating motions of the position controller if differences in position are identified.

The data sets must have the same control loop structure and must not contain a change that requires a restart. This means that when DS_1 is with DSC, DS_2 must also be with DSC.

Settings that require a restart cannot be activated via a data set changeover.

See also

Data sets (Page 3037)

Writing a data set

The **_setAxisDataSetParameter()** command can be used to overwrite an inactive data set on the axis. The data set number is specified in the command.

See also

Data set overview (Page 3037)

Reading a data set

The **_getAxisDataSetParameter()** command can be used to read any data set on the axis. The data set number is specified in the command.

The command reads the data that can be written with the **_setAxisDataSetParameter()** command.

Data set overview (Page 3037)

Writing the force/pressure-specific data of a data set

The **_setForceControlDataSetParameter()** command can be used to overwrite the force/pressure-related data of an inactive data set. The data set number is specified in the command.

The following force-/pressure-related data is contained in the data set:

- Monitoring of the control deviation of the force controller
- Force controller data
  Force controller setting
  Limitations of the manipulated variable of the force controller
  PID controller setting
  Controller type
  Effective direction of the manipulated variable (can be switched with V4.2 and higher)
  Inversion of the force controller manipulated variable

Detailed information about the parameters can be found in the TP Cam System Functions Reference List.

Note

The force/pressure-specific data of the data set cannot be written on the speed-controlled axis.

Reading the force/pressure-specific data of a data set

The **_getForceControlDataSetParameter()** command can be used to read the force/pressure-related data in the data set. The data set number is specified in the command.

The command reads the data that can be written with the **_setForceControlDataSetParameter()** command.

Note

The force-/pressure-specific data of the data set cannot be read on the drive axis.

Writing the data of the data set (hydraulic functionality only)

The **_setQFAxisDataSetParameter()** command can be used to overwrite the specific parameters for the axis with hydraulic functionality in an inactive data set. The data set number is specified in the command.

The following specific parameters of the axis with hydraulic functionality are contained in the data set:

- Inversion of F output
- Dynamic response adaptation to the axis with hydraulic functionality
- Data for the speed controller on the drive axis with hydraulic functionality

Detailed information about the parameters can be found in the TP Cam System Functions Reference List.

Note

The specific data for the axis with hydraulic functionality in the data set cannot be written on the drive axis.

Reading the force/pressure-specific data of the data set (hydraulic functionality only)

The **_getQFAxisDataSetParameter()** command can be used to read the specific parameters for the axis with hydraulic functionality in the data set. The data set number is specified in the command.

The command reads the data that can be written with the **_setQFAxisDataSetParameter()** command.

Note

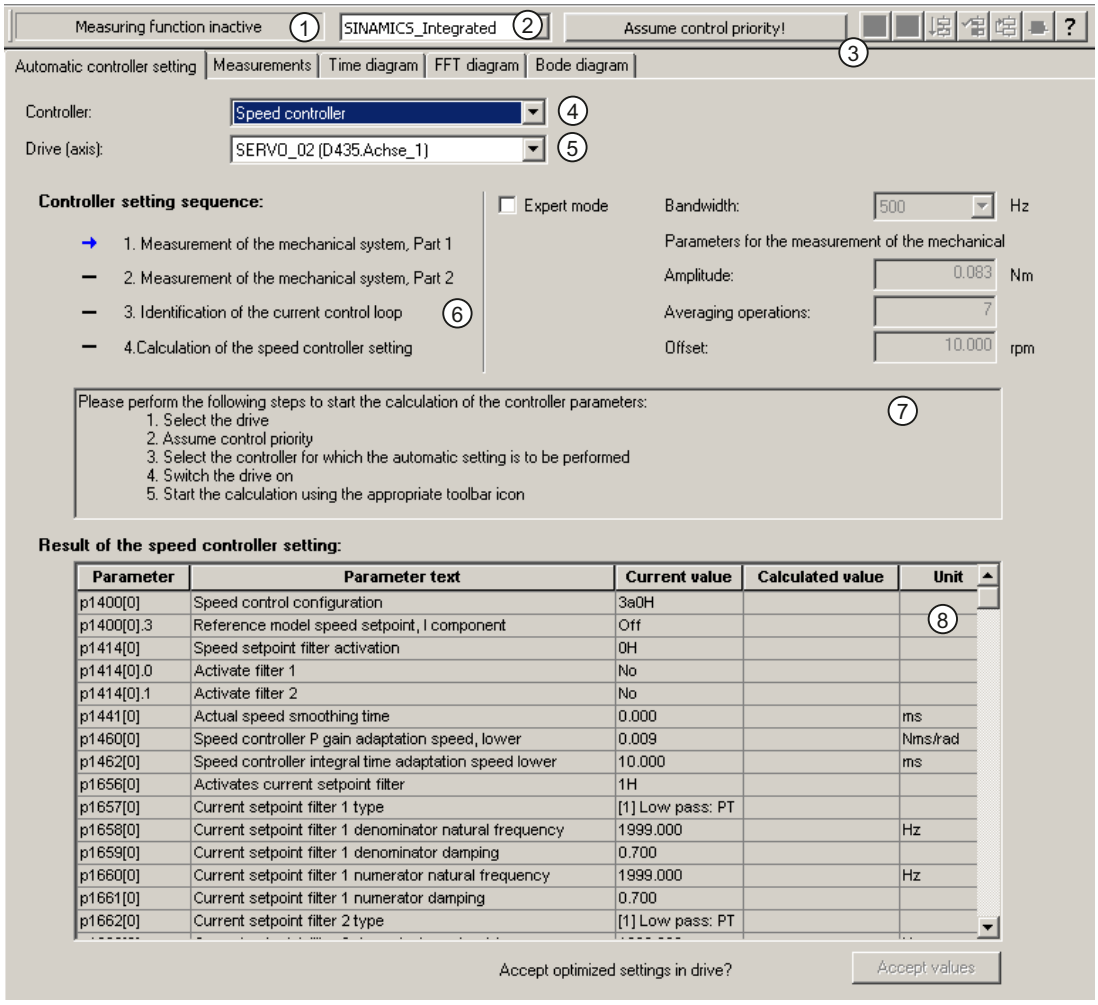
The specific data for the axis with hydraulic functionality in the data set cannot be read on the speed-controlled axis.

Command for calculating a braking distance

With the **_getAxisStoppingData()** command, the system calculates the braking distance as a function of a specified actual velocity, actual acceleration, motion profile, and dynamic response parameters.

4.8.8.7 Assigning automatic controller optimization

Here, you operate the automatic controller optimization. To perform the automatic controller setting, you must have an ONLINE connection to the drive device of the relevant drive.



1 Measuring functions status display
2 Drive unit
3 Operator buttons
4 Controller selection
5 Drive selection
6 Progress message box
7 Description of current step
8 Result display

Figure 4-927 Automatic optimization - Example: speed controller

The following operator input options and displays are available:

Field/Button	Meaning/Instruction
Measuring functions status display	This area shows whether or not the drive is active in the step. The following information is displayed: • Measuring function active Drive/axis is moving • Measuring function inactive Drive/axis is not moving
Drive unit	This combo box offers all the SINAMICS drive units in the open project that contain drives operated in the "SERVO" closed-loop control type and that the motor measuring system uses as encoders. Selection is possible provided the master control has not yet been assumed.
Assume control priority/ **Give up control priority**	This allows you to assume master control in order to perform automatic controller setting. Master control can be released only once the drive has been switched off.
Operator buttons	

Field/Button		Meaning/Instruction
		**Drive ON** This button can be pressed if master control has already been assumed. This enables the infeed and assigns the drive enable. This is not the same as a POWER ON of the hardware. Afterwards, the controller setting can be started. To cancel and then restart the function, perform the following operating input sequence: Switch off drive -> Switch on drive
		**Drive OFF** You can use this button to reset the functions initiated by *Drive ON*. This enables the infeed and inhibits the drive enable. This is not the same as a POWER OFF of the hardware. If it is detected that calculated parameters are present (the last step has been completed) that have not yet been transferred to the drive/axis, a confirmation prompt will be issued, asking whether the controller setting is now complete and, as a result, the calculated parameters should be discarded.
		**Automatic execution** Automatically performs all steps of the controller setting starting with the current selection on the step display. This button will be deactivated once the last possible step has been performed.
		**Execute step** The single step of the controller optimization selected on the step display will be performed and the step display then incremented by one step. This button will be deactivated once the last possible step has been performed.
		**Step back** Sets the step display back one step. If the step display is at step 1, the button is deactivated.
		**Cancel step** Cancels the execution of the current step; the step display remains at the canceled step.
		**Help** Opens the help for this screen form.
Controller selection		In **Controller selection**, you can select which controller to set. The view on the screen form will then show the appropriate controller. The combo box contains the following selection options: • "Speed controller" (always available) • "Position controller (DSC)" (offered only if SCOUT is installed on the PC). Before the setting is applied, a few call conditions are checked and any unfulfilled conditions are displayed. The selection can be changed at any time, provided no step is currently being executed.

Field/Button	Meaning/Instruction
Drive selection	In **Drive selection**, a drive corresponding to the setting in the **Drive unit** field can be selected. The following rules apply for the "Drive" input field: • The field is labeled "Drive". If SCOUT is installed on the PC, it is called "Drive (axis)". • If SCOUT is installed and the drive is connected to at least one axis, the connected axis is appended to the drive name in brackets, in the form "(<device>.<axis name>)". If the drive is to be connected to multiple axes, "..." is appended to the first axis name. • The tool tip for the Drive field contains all names in the syntax shown above for the axes connected with the drive. The field can only be operated provided the master control has not yet been assumed. As soon as the "Drive selection" field registers a change, the parameters of the newly selected drive are registered in the "Current value" column in the result display for a cyclic update.
Progress message box	The step control presents the status overview of the steps of the "automatic controller setting" on the left.
	The step has been executed.
	Selection of the step that will be executed next or is currently being executed.
	Step has not yet been executed.
Expert mode	Checkbox If the checkbox for **Expert mode** is selected, the **Amplitude**, **Bandwidth**, **Averaging operations**, and **Offset** input fields are displayed. The user can enter special settings for the next optimization step in these fields. The checkbox is deselected as the default setting. If the checkbox is deactivated, the parameter settings determined by the optimization tool are used for the measurement.
Kv factor (controller = position controller)	As a result of step 2 of the position controller optimization ("Calculation of the position controller setting"), the determined **Kv factor** is indicated. Provided no new value has been calculated, the display shows "–". This is also the standard display when the screen form starts.
Select axes and data sets button "..." (controller = position controller)	This button can be used to call a dialog that shows the possible axes (in accordance with the relevant requirements and supplementary conditions) and their axis data sets in which the Kv factor can be accepted.
Result display	This table displays the parameters whose values were determined during the controller optimization. The **Current value** column displays the current value of the parameter read out cyclically from the target device. The **Calculated value** column displays the value of the parameter determined from the controller setting. Provided no new value has been calculated, the "–" character is displayed instead of the value. This is also the standard display when the screen form starts.

Field/Button	Meaning/Instruction
Accept (controller = speed controller)	The **Accept** button is active only when step 4 of the speed controller optimization has been completed successfully. The calculated values are applied to the drive.
Accept (controller = position controller)	The **Accept** button is active only under the following conditions: • Step 2 for the position controller optimization must have completed successfully. • An online connection to the associated SIMOTION device must exist. • The axis is online-consistent. • The axis data set table contains at least one data set. The calculated values are applied to the drive.

Note

Emergency cancelation of automatic setting with <spacebar>

The following actions are performed:

- The step currently being executed is canceled
- The drive is disabled

See also

Overview of automatic controller setting (as of V4.1 SP1) (Page 3066)

4.8.8.8 Technological alarms

Alarm reactions

The reactions of the axis to **technological alarms** (local reaction) are implemented by the system.

The local reactions are preset on an alarm-specific basis or they can be set in the alarm configuration.

The following local reactions on the axis are available:

- **NONE**
  - No reaction
  - The responses can be specified by the user in the TechnologicalFaultTask.
- **DECODE_STOP**
  - Command processing aborted
  - The current motion (thus, for example, also the MotionIn command) and commands in the motion buffer are still executed.
  - New motion commands are rejected.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
- **END_OF_MOTION_STOP**
  - Abort at the end of the command causing the error
  - Stop of the motion at the end of the command
  - The current motion command (thus also the MotionIn command) is still executed.
  - New motion commands are rejected.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
- **MOTION_STOP**
  - Controlled motion stop with programmed ramp values.
  - The current motion command (thus also the MotionIn command) is stopped.
  - New motion commands are rejected.
  - Motion commands are not canceled and are resumed when the error reaction is acknowledged.
  - No more new motion commands are accepted.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
- **MOTION_EMERGENCY_STOP**
  - Controlled motion stop with maximum ramp values/limits for the axis.
  - The current motion command (thus also the MotionIn command) is stopped.
  - New motion commands are rejected.
  - Motion commands are not canceled and are resumed when the error reaction is acknowledged.
  - No more new motion commands are accepted.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.

- **MOTION_EMERGENCY_ABORT**
  - Controlled motion stop with maximum axis dynamic values (starting from the current setpoint).
  - Active commands (IPO) are aborted and signaled back to the user program with an error code.
  - The drive remains active.
  - The position controller remains active.
  - The IPO remains active.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
  - After the error is acknowledged with **_resetError()**, the axis can travel again. (provided that the cause of the error no longer exists)
- **FEEDBACK_EMERGENCY_STOP**
  - Motion stop with preassigned braking ramp.
    See Stopping with preassigned braking ramp (Page 3002).
  - Manipulated variable superimposition not effective.
  - Active commands (IPO) are aborted and signaled back to the user program with an error code.
  - The drive remains active.
  - The position controller remains active.
  - The IPO goes into follow-up mode, preassigned braking ramp servo (time specification in the servo for preassigned braking ramp)
    IPO and servo are then active again.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
  - After the error is acknowledged with **_resetError()** and the axis is reset with **_resetAxis()**, the axis can be traversed further (provided the cause of the problem no longer exists).

- **OPEN_POSITION_CONTROL**
  - Motion stop with speed setpoint zero and abort
  - The position control loop is decoupled from the setpoint circuit.
  - Active commands (IPO) are aborted and signaled back to the user program with an error code.
  - The position controller enable is canceled.
  - The control unit transmits the setpoint to the drive.
  - The drive stops (because of setpoint 0).
  - The drive remains active.
  - The Ipo goes into follow-up mode.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
  - After the error is acknowledged with **_resetError()** and the drive and position controller are activated with **_enableAxis()**, the axis can travel again (provided that the cause of the problem no longer exists).
- **RELEASE_DISABLE**
  - Motion disable with controller disable and abort of all commands
  - The drive enables are canceled.
    See also Coupling of digital drives (Page 2895) and Adjustable response to RELEASE_DISABLE (Page 3185).
  - The controller enables are canceled.
  - Active commands (IPO) are aborted and signaled back to the user program with an error code.
  - Position controller and Ipo go into follow-up mode.
  - Further reactions can be specified by the user in the TechnologicalFaultTask.
  - After the error is acknowledged with **_resetError()** and the drive and position controller are activated with **_enableAxis()**, the axis can travel again (provided that the cause of the problem no longer exists).

    Note

    Active commands are commands in the IPO or commands that are being executed; these commands are no longer in the motion buffer.

    When you acknowledge an error with **_resetAxisError()**, you must delete any commands in the motion buffer with **_resetMotionBuffer()**.

    The preset responses of the technology alarms can be overwritten by higher-priority stop responses.

    Global alarm reactions can be set on the technology object (execution system, FaultTasks).

See also

Jerk limitation for local stop response (V3.2 or higher) (Page 3007)

Adjustable response to RELEASE_DISABLE

The drive response to the RELEASE_DISABLE alarm response can be set (with a digital drive link).

See Coupling of digital drives (Page 2895).

See also

Alarm reactions (Page 3181)

Toleration of the failure of an encoder not involved in closed-loop control (V4.0 and higher)

If an encoder that is not involved in closed-loop control fails, the system should neither stop the axis nor disable the drive.

In the following cases, an encoder is not involved in closed-loop control:

- If the encoder is not selected.
  That is, one of the 8 possible encoders of the axis is configured and active (running) but it is not the selected encoder at the moment.
- If the encoder is selected but not involved in closed-loop control.

This behavior is set using the
typeOfAxis.numberOfEncoders.Encoder_1.sensorControlConfig.tolerateSensorDefect
configuration data element.

As of SINAMICS V2.6.2, the failure of an encoder not involved in closed-loop control is indicated by alarm 20015.

4.8.9 Part IV External Encoder - Description

4.8.9.1 External encoder overview

The External Encoder technology object ("ExternalEncoder") records a position and provides the position to the control. The determined position can be evaluated in the user program.

The reference of the encoder position to a defined position is produced by parameterization of the mechanical properties and a homing procedure.

The position is stated independently of the encoder type and depending on the selected unit system:

- **Linear unit system**
  The position is given as a length dimension, e.g. millimeters (mm).
- **Rotary unit system**
  The position is given as an angle dimension, e.g. degrees (°).

Information from the External Encoder technology object can be used as input variables for other technology objects, such as the Synchronous Operation technology object, Output Cam technology object, or Measuring Input technology object, or to display the actual value of an external motion.

The External Encoder technology object can be used with

- Incremental encoders
- Absolute encoders
- Resolvers
- Encoders on direct value/analog value
- Encoders on count value
- ...

An external encoder can be used only on one position-related encoder.

The external encoder is referred to by the data type **externalEncoderType** in reference lists and when programming.

From V3.2 onwards, the External Encoder technology object is included in the Cam and Cam_ext technology packages.

Interconnections

The External Encoder technology object can be interconnected with the following technology objects:

- **Synchronous Operation technology object**
  The External Encoder technology object is used to provide a master value.
- **TO output cam**
  The External Encoder technology object is used to provide a reference value.
- **TO cam track**
  The External Encoder technology object is used to provide a reference value.
- **TO measuring input**
  The External Encoder technology object is used to provide a reference value.

Programming commands/functions for the External Encoder technology object

The MCC and ST programming languages are available for programming external encoders.

See the *SIMOTION MCC* Programming Manual or the *MCC programming language* in the online help.

4.8.10 External Encoder Fundamentals

4.8.10.1 Actual values for the external encoder technology object

Each position actual value possible on the technology object type can be used as the actual value of the external encoder technology object.

These are, for example:

- Actual value (encoder1 or encoder2) from a PROFIdrive axis telegram
  - Encoder from a PROFIdrive axis telegram to a SINAMICS drive object
    With SINAMICS it is possible to configure multiple encoders, from which a maximum of two encoder values can be transmitted in each axis telegram.

    Note

    An encoder in a PROFIdrive axis telegram can only be used for an external encoder TO or for the encoder of a TO axis in cyclical operation if a TO axis is also created on the PROFIdrive telegram and is not deactivated.

  - Encoder from a PROFIdrive axis telegram to ADI4 (at least one axis must be created on the ADI4)
  - Encoder from a PROFIdrive axis telegram to IM174 (at least one axis must be created on the IM174)
  - Encoder from a PROFIdrive axis telegram to a non-SINAMICS drive
- Actual value from a PROFIdrive encoder telegram
  - Encoder from a PROFIdrive encoder telegram to a SINAMICS encoder object, e.g. to an SMC module
  - Encoder from a PROFIdrive encoder telegram to a PROFIBUS encoder module, e.g. SIMODRIVE sensor
  - Encoder from a PROFIdrive encoder telegram to a PROFINET encoder module, e.g. MC encoder
  - Encoder from a PROFIdrive encoder telegram to any other encoder module
- Actual value as a direct value in the I/O area
- Only C2xx: Actual value via encoder signal evaluation directly at the SIMOTION CPU

For further information, refer to the relevant hardware manuals.

4.8.10.2 Encoder mounting type

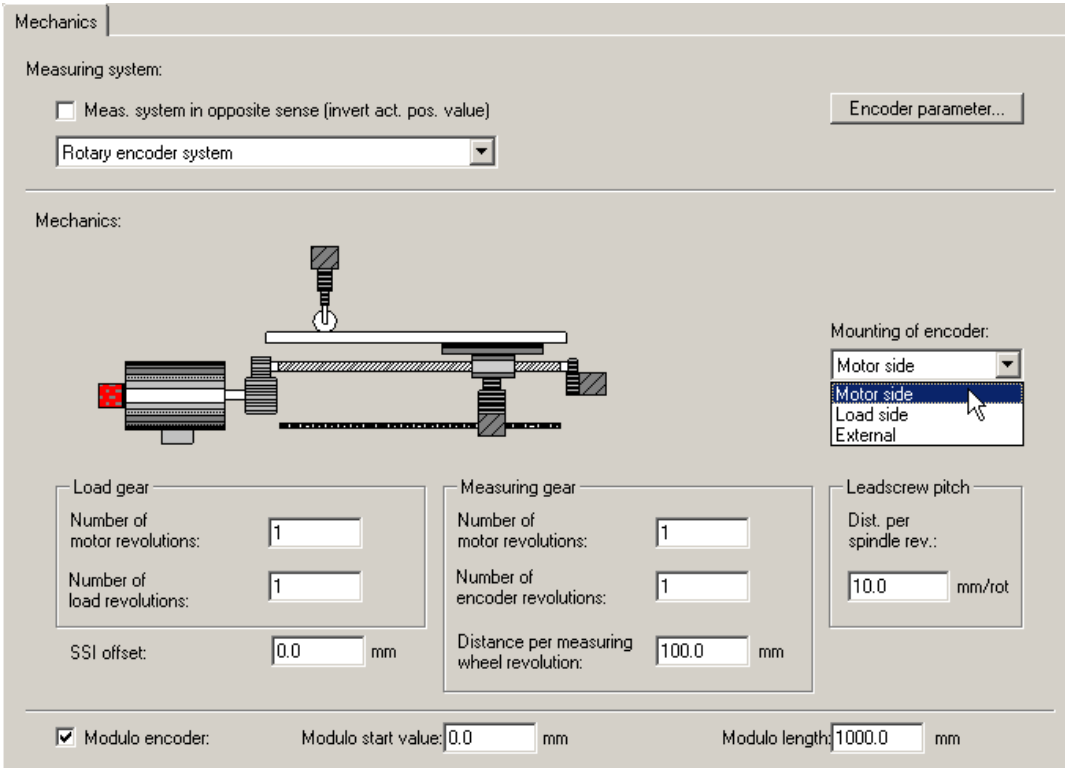


Figure 4-928 Definition of the mounting type of an external encoder in SIMOTION SCOUT

Mounting types for the external encoder

- On the drive side
- On the load side
- External

The transmission ratios must be entered via configuration data:

- For "drive side" mounting using the **adaptdrive** configuration data element
- For "load side" mounting using the **adaptload** configuration data element
- For "external" mounting using the **adaptextern** configuration data element
- For linear encoder system mounting, the transmission ratio is always 1.

4.8.10.3 Encoder for position

The controller uses an encoder to detect the axis position.

From a technological standpoint, the following encoder types can be differentiated:

- Incremental encoder
  On the controller side, only the difference between two read encoder values is evaluated. Values are read out in the servo cycle clock at equal intervals. In order to determine the mechanical axis position, the axis must be homed each time the system is switched on. Position zero is displayed after it is switched on.
- Absolute encoder
  This encoder supplies the absolute value or, in the case of an absolute value in the PROFIdrive message frame, the absolute value is read one time after the system is switched on. After this, the actual value is processed in the same way as with the incremental encoder.
  The absolute value supplied by the encoder is assigned to the associated mechanical axis position by means of the absolute encoder adjustment. The absolute encoder adjustment occurs only one time, and the controller remembers the compensation value/absolute encoder offset even after it is powered on/off.
  Certain situations, such as an encoder failure, a restart, etc., can require an absolute encoder re-adjustment. For more information, refer to the chapter titled *Absolute encoder homing/ Absolute encoder adjustment*.
  The following absolute encoder types are differentiated:
  - Absolute encoder with absolute encoder setting
    The measuring range of this encoder is greater than the axis traversing range.
    The axis position results directly from the current encoder value since this can be uniquely mapped.
    An offset may be entered - it is not necessary to hold overflows within the controller.
    There are no overflows of the absolute actual value stored when SIMOTION is switched off. The next time it is switched on, the actual position value is generated from the absolute actual value only.
  - Absolute encoder with cyclic absolute encoder setting
    The axis traversing range is greater than the range of values measured by the encoder, and the encoder returns an absolute value within its measuring range.
    The controller also counts the number of measuring ranges internally in order to hold a unique actual axis position beyond the range of measured values.
    When SIMOTION is switched off, the overflows of the absolute actual value are stored in the retentive memory area of SIMOTION. The next time it is switched on, the stored overflows are taken into account for the calculation of the actual position value.
    The actual position of the axis is passed internally in a 64-bit integer variable.
    Example of a single-turn encoder with 4,096 increments:
    The position of the encoder is mapped in bits 0 to 11, and the number of overflows of the encoder range in bits 12 to 63.
    Example of a multi-turn encoder with 4,096 x 4,096 increments:
    The position of the encoder is mapped in bits 0 to 23, and the number of overflows of the encoder range in bits 24 to 63.
    The overall position of the axis is retained after the controller is switched off. When the controller is switched on again, if the actual encoder value does not match the actual position stored in the controller, it will be corrected to a maximum of ± ½ the encoder measuring range.

    Note

    If the axis/encoder is moved by more than one half the encoder measuring range with the controller switched off, the actual value in the controller no longer matches the real axis.

See also

Absolute encoder homing / absolute encoder adjustment (Page 2934)

4.8.10.4 Encoder for velocity

Encoders for detection and display of the speed/velocity can only be applied to speed-controlled axes.

Options are:

- Incremental encoders/absolute encoders with number of increments or pulses/revolution (for electric axes)
- Interval counters (for hydraulic axes)
- Encoders providing the velocity as a direct value in the I/O area (for hydraulic axes)
- Read-out of the speed from the PROFIdrive message frame and provision for technological functionality, e.g. velocity monitoring

4.8.10.5 Encoder assignment and terminology

The encoder type is specified with the encoder mode.

Table 4-405 Definable encoder mode depending on the encoder type

Encoder mode	Encoder type		
	Absolute encoder	Cyclic absolute encoder	Incremental encoder
PROFIdrive (with adaptation [1]) (as of V4.2)	x	x	x
Endat (encoder data interface)	x	x	x
SSI (synchronous serial interface)	x	x	-
Sinusoidal	-	-	x
Rectangle	-	-	x
Resolver	-	x [2]	x
Analog encoder (value in the I/O area)	x	-	-

[1] The adaptation setting (set by the system by default with V4.2 or higher and SINAMICS) makes changes based on the encoder set in SINAMICS. The encoder resolution and fine resolution are adopted during runtime.

[2] Possible with single-pole-pair resolver only

When the encoder signals are evaluated in an encoder module or drive, the actual values are transferred to the controller in the normalized format according to the PROFIdrive profile. The type of measured value acquisition is dependent on the drive or encoder module, e.g. Sinus, SSI or Endat. The PROFIdrive encoder mode can therefore be set in the controller (as of V4.2).

As of SIMOTION V4.2, the system makes the settings for communication between SIMOTION and SINAMICS drive (encoder). The project setting **Use symbolic assignment** is activated by default for new projects as of V4.2. Telegrams are set automatically. Encoder characteristics such

as fine resolution, grid spacing, and the absolute value for data width are adapted automatically when the system ramps up.

For encoder data, refer to the data sheet or type plate of the encoder. With SINAMICS, encoder data can be transferred from the drive.

The rest of this chapter is only relevant if the project default setting **Use symbolic assignment** is deactivated as of V4.2, or if you are working with a project which uses SIMOTION V4.1.

Encoder pulses per revolution

The encoder pulses per revolution is specified on the encoder type plate as the number of signal periods per revolution (incremental encoder: Pulses/rev; absolute encoder: Pulses/rev; resolver: Number of pole pairs (for SINAMICS and MASTERDRIVES)).

Configuration data:

- **AbsEncoder.absResolution**
- **IncEncoder.incResolution**

Grid line spacing (linear encoder system)

The grid line spacing is specified on the type plate of the encoder as the distance between lines on the linear measuring system (linear scale).

Configuration data:

- **Resolution.distance**

Fine resolution

The fine resolution of the actual value is the interpolation result of a signal period of an encoder pulse.

The fine resolution steps are generated by the measuring electronics from the raw signal of the encoder pulses. Factors as a multiple of 2 are possible.

Example:

- A rectangle signal has a fine resolution of 1
- Two rectangle tracks (TTL signal) offset by 90° have a fine resolution of up to 4
- Depending on the measuring electronics, a sinusoidal signal can have any fine resolution, in principle, e.g. 2,048

Depending on the defined encoder type, the default value 0 is interpreted differently in SIMOTION (see table: *Default settings for fine resolution in SIMOTION*).

In SIMOTION, the multiplication factor is specified, rather than the shift factor/number of bits (x).

The actual value, including the fine resolution, is indicated in the **sensorData.incrementalPosition** system variable.

Configuration data:

- **AbsEncoder.absResolutionMultiplierCyclic**
- **IncEncoder.incResolutionMultiplierCyclic**

Data width of absolute value (without fine resolution) for absolute encoders

The data width of the absolute value (without fine resolution) is a result of the sum of the bits for representing the number of encoder pulses and the bits for representing the maximum number of revolutions that can be registered by the encoder according to the type plate.

Example:

4,096 pulses/rev (= 2^{12}) and a maximum of 4,096 revolutions that can be registered yields a 12 + 12 = 24-bit data width of the absolute value.

Configuration data:

- **AbsEncoder.absDataLength**

Fine resolution of absolute value in Gn_XIST2.

This parameter for the format of the Gn_XIST_2 is only relevant for encoders via PROFIdrive telegram (for more information, see *Encoder interconnection via PROFIdrive telegram*).

Configuration data:

- **AbsEncoder.absResolutionMultiplierAbsolute**

The fine resolution of the absolute value in Gn_XIST2 must be less than or equal to the fine resolution of the absolute value in Gn_XIST1.

Default setting for fine resolution.

Depending on the encoder mode, the default settings are evaluated by the system as described in the table below. The default settings are used if 0 is assigned to the value.

Table 4-406 Default settings for fine resolutions in SIMOTION

Encoder type	Encoder mode	Fine resolution (Gn_XIST1)	Fine resolution on the absolute value (Gn_XIST2)
Onboard C2xx			
Incremental encoder	Rectangle	4	-
	Stepper motor	1	-
Absolute encoder	SSI	1	1
Encoder in PROFIdrive axis telegram (applies to SINAMICS, SIMODRIVE 611U and MASTERDRIVES)			
Incremental encoder	Rectangle	2048	-
	Sinusoidal	2048	-
	Resolver	2048	-
	Endat	2048	-
Absolute encoder	Endat	2048	512
	SSI	1	1
...Cyclic absolute	Resolver (only pole pair number 1 possible)	2048	512
	Endat	2048	512
	SSI	1	1
PROFIBUS absolute encoder in PROFIdrive encoder telegram			
Absolute encoder	SSI	$2^{(32 - \text{Number of data bits})}$	1

These settings are aligned to the default parameter settings of the corresponding Siemens devices. If the behavior is different, alignment with the encoder should be performed by making a corresponding entry in the configuration data of the technology object or in the parameters of the drive or encoder. Depending on the device it may be necessary to assign the corresponding parameters in the drive or encoder with the value of the exponent (shift factor).

Device-specific features for Masterdrives with Endat encoders:

For Masterdrives with Endat encoders, Endat or SSI can be selected in the encoder mode. However, the fine resolution must always be configured in the axis wizard of the Axis or External Encoder technology object differently from the default settings (see Encoder list (Page 3193)).

Default setting:

- Fine resolution (**~Encoder.~ResolutionMultiplierCyclic**) = 0
- Fine resolution of the absolute encoder in Gn_XIST2 (**AbsEncoder.absResolutionMultiplierAbsolute**) =0
- If encoderMode=PROFIDRIVE, the values are evaluated as available, since the correct values are adapted by the drive. A default setting of 0 is not permitted for this setting.

See also

Encoder list (Page 3193)

4.8.10.6 Encoder list

For the most up-to-date list of encoders you can use with SIMOTION in conjunction with SINAMICS, SIMOVERT-MASTERDRIVES, and SIMODRIVE 611U, go to **http://support.automation.siemens.com/WW/view/de/18769911**.

The encoder list is also documented under *FAQs > Drives > Parameters of the connectable encoders* in the *SIMOTION Utilities & Applications* and in the online help (look for encoder parameter assignment in the index). *SIMOTION Utilities & Applications* is part of the scope of delivery of SIMOTION SCOUT.

4.8.10.7 Onboard encoder interface on SIMOTION C2xx

Incremental encoders with TTL signal and absolute encoders with SSI protocol can be connected directly to C230-2 or C240. (See the C230-2 and C240 operating instructions and Encoder list (Page 3193))

See also

Encoder assignment and terminology (Page 3190)

Encoder list (Page 3193)

4.8.10.8 Encoder interface using the PROFIdrive message frame

As of SIMOTION V4.2, the system sets up communication between SIMOTION and SINAMICS drive (encoder). For SINAMICS drives and encoders with V4.2 and higher, encoder resolution data is transferred directly from the drive during runtime. Telegrams are set automatically.

The rest of this chapter is only relevant if the project default setting **Use symbolic assignment** is deactivated as of V4.2, or if you are working with a project which uses SIMOTION V4.1.

The encoder values are transmitted in the PROFIdrive telegram (see Table *Telegram types* in Section *Setting as a real axis with digital drive coupling*).

Encoder forced values, status values, and actual values are transmitted in the PROFIdrive telegram.

The encoder behavior on SIMOTION is set as represented in the PROFIdrive protocol.

The encoder parameters are defined via the drive wizard during drive configuration (either user-defined or by selecting the encoder).

Encoder parameters that are entered subsequently in the SIMOTION axis wizard must match the encoder parameters in the drive.

Note

For SINAMICS drives with earlier versions than SIMOTION V4.2, it is possible to transfer the encoder parameters from the drive. When assigning encoders in the axis wizard, click **Data transfer from the drive**.

If you are using a DRIVE-CLiQ component with electronic type plate (e.g., SMI motor, DRIVE-CLiQ encoder) you must first upload the parameters from the drive and save them in the project (online commissioning). If the online commissioning is carried out at a later point, you can work with the default settings of the axis wizard in the meantime during offline configuration. Once online commissioning is complete, upload the drive parameters, save them in the project, run the axis wizard again, and perform the **Data transfer from drive** function.

If you change the encoder data in the drive, you must perform an alignment again in the axis wizard.

Further sources of information:

- Encoder list (Page 3193)
- User Manual *SIMODRIVE sensor Absolute encoder with PROFIBUS-DP*
- Operating Instructions *Absolute encoder with PROFINET IO* (Chapter *Operating with SIMOTION*)

Encoder value via PROFIdrive axis telegrams

For further information, refer to the commissioning manuals for the drives.

The first and (if present) second encoder of the PROFIdrive axis telegram can be assigned freely to an External Encoder technology object or to the encoder of an axis.

Encoder value via PROFIdrive encoder telegram 8x

PROFINET/PROFIBUS encoders can be set in accordance with the current specifications of the encoder profile with telegram type 81 and as of V4.2, with telegram type 83. These encoders can be assigned freely. See also **PROFINET/PROFIBUS absolute encoder via PROFIdrive encoder telegram** in the next chapter.

Inconsistent configuration

In the event of errors or inconsistencies between the configuration data in SIMOTION and the parameter settings for the encoder in the drive, a technological alarm is triggered as soon as an online connection is established between the control and the drive/encoder.

As off SIMOTION Runtime V4.4: **Technological alarm 20025** with applicable reason

In SIMOTION Runtime < V4.4: **Technological alarm error 20005: Device type:2, log.address:1234 faulty. (Bit:0, reason: 0x80h)**

For PROFIdrive encoders and encoders on the axes according to PROFIdrive, a comparison of the parameter assignment takes place via the following drive/encoder parameters:

P979 (SensorFormat) according to PROFIdrive, which contains information about the type, resolution, and shift factors.

For drives or encoders that do not support parameter P979, the configuration data is evaluated as valid without alarm message.

Actual value Gn_XIST1

The incremental actual value is transferred cyclically with the defined fine resolution in Gn_XIST1. The incremental actual value in Gn_XIST1 is steadily continued according to the actual value change and reset when the data width of Gn_XIST1 is exceeded. If operating with incremental and absolute encoders, the control evaluates the incremental actual value in Gn_XIST1 according to the settings made for encoder pulses per revolution and fine resolution, or grid line spacing for linear scaling.

When the controller is switched on, the fine resolution value within one encoder signal period is indicated correctly in Gn_XIST1. The initial value for the number of signal periods is set by the drive/encoder, and the actual value can then be steadily continued from this initial value.

In the PROFIdrive profile, the fine resolution is given as "shift factor" (x).

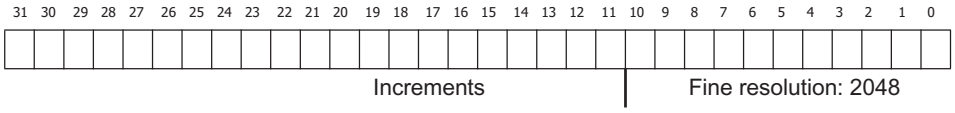

Figure 4-929 Example composition of the 32-bit encoder data of the cyclic actual value Gn_XIST1

Example of for an encoder with number of encoder pulses = 2048 (data width, 11 bits)

The fine resolution in SIMOTION in the **Inc/AbsResolutionMultiplierCyclic** configuration data element is set to the default setting 0 and is thus evaluated as a default fine resolution of 2048 (the default value depends on the encoder mode setting; see Table *Default settings for fine resolution in SIMOTION*).

SIMODRIVE 611U:

Table 4-407 Settings

SIMOTION		611U	
Encoder pulses per revolution [1]	=2048	P1007	=2048
Fine resolution [2]	=0 (≡ 2048)	P1042	=11

[1] Inc/AbsEncoder.Inc/AbsResolution

[2] Inc/AbsEncoder.Inc/AbsResolutionMultiplierCyclic

SINAMICS:

Table 4-408 Settings

SIMOTION		SINAMICS	
Encoder pulses per revolution [1]	=2048	P408	=2048
Fine resolution [2]	=0 (≡ 2048)	P418	=11

[1] Inc/AbsEncoder.Inc/AbsResolution

[2] Inc/AbsEncoder.Inc/AbsResolutionMultiplierCyclic

Note the information about the SINAMICS alignment.

Actual value Gn_XIST2

If the positions for the measuring input or homing functions are transferred to Gn_XIST_2 (n = 1 or 2, number of encoder), they are transferred with the fine resolution defined for the encoder. When the absolute value is read, the value in Gn_XIST_2 is evaluated based on the settings for the data width of the absolute value (without fine resolution) in **AbsEncoder.absDataLength** and the fine resolution absolute value in Gn_XIST2 is evaluated in **AbsEncoder.absResolutionMultiplierAbsolute**.

The fine resolution of the absolute value in Gn_XIST2 indicates the fine resolution factor included in the absolute value transfer. This can match the fine resolution of the actual value, but it can also be smaller, for example, if the 32-bit data width in Gn_XIST2 is not sufficient for the entire fine resolution factor as a result of the data width of the absolute value (without fine resolution).

Example:

Encoder pulses per revolution = 2048 (11 bits) and multi-turn resolution of 4,096 revolutions (12 bits)

Thus, the data width of the absolute value without fine resolution is 11 bits + 12 bits = 23 bits.

Therefore, 9 bits remain for the fine resolution in Gn_XIST2 (32 bits - 23 bits = 9 bits). The setting 0 for the fine resolution of the absolute value in Gn_XIST2 is thus evaluated by the system as 512 (= 9 bits).

Table 4-409 Setting the encoder data

Encoder pulses per revolution [1]	2048
Data width of absolute value (without fine resolution) [2]	23

Fine resolution of absolute value in Gn_XIST2 [3]	0 (= 512)
Fine resolution [4]	0 (= 2048)

[1] AbsEncoder.AbsResolution

[2] AbsEncoder.absDataLength

[3] AbsEncoder.absResolutionMultiplierAbsolute

[4] AbsEncoder.AbsResolutionMultiplierCyclic

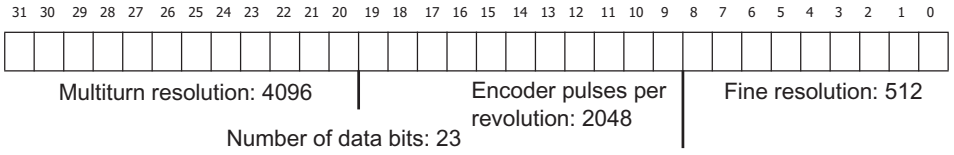

Figure 4-930 Example composition of the 32-bit encoder data of the absolute actual value Gn_XIST2

The number of bits resulting from the data width of the absolute value (without fine resolution) and the number of data bits for the fine resolution of the absolute actual value must not exceed 32. If it is less than 32, leading zeroes are added in Gn_XIST2.

Resolver in PROFIdrive axis telegram

For SINAMICS and MASTERDRIVES, parameters are assigned for the pole pair number of the resolver rather than the encoder pulses per revolution (example: 8-pole resolver = 4 pole pairs → input value = 4).

With SIMODRIVE, parameters are assigned for the encoder pulses per revolution based on parameter P1011.2

As of V4.1 SP1, the resolver with pole pair number 1 is supported as an absolute encoder with the cyclic absolute setting. (encoder pulses per revolution = 1, data width of the absolute value = 0, default value evaluation: fine resolution = 2048, fine resolution Gn_XIST2 = 512)

When a 1-pole resolver is used as Endat encoder, the p418(XIST1) and p419(XIST2) parameters must be set to "11" to prevent information loss of the absolute position. (Settings on the axis: absolute encoder, cyclic absolute, Endat, line count = 1, fine resolution = 2048, fine resolution absolute value = 2048, data width = 0)

See also the Encoder list (Page 3190).

PROFINET/PROFIBUS absolute encoder via PROFIdrive encoder telegram

The data width of the encoder value in the technology object configuration data in SIMOTION must match the parameter settings for the PROFINET/PROFIBUS absolute encoder in HW Config.

See also the Encoder list (Page 3190).

Example:

Parameter settings of a PROFIBUS absolute encoder in HW Config with 24-bit data width of the absolute value.

The 'SIMODRIVE isochronous sensor' PROFIBUS absolute encoder in HW Config is defined according to the default setting for 24-bit data width and encoder pulses per revolution of 4096: measuring steps per revolution = 4096
24-bit data width for the total resolution yields 0x01000000 (32-bit HEX number). This number, represented separately in HighWord and LowWord, equals 0x0100 in the HighWord and 0x0000

in the LowWord. The decimal values of these two parts (0x0100 = 256 decimal) are to be entered as follows:
total resolution (high) = 256
total resolution (low) = 0

This results in the following consistent configuration for the technology object:
the encoder value is transferred left-justified to Gn_XIST1; the unused bits of the fine resolution are set to 0 according to PROFIdrive, but must be specified in the fine resolution of the actual value. This results in a fine resolution of 8 bits (32 bits - 24 bits = 8 bits) (2^8 = 256 as a factor).

According to the setting above, the absolute value in Gn_XIST2 has a right-justified alignment and therefore a fine resolution of the absolute value in Gn_XIST2 of 0 bits (2^0 = 1 as a factor).

Encoder via PROFIdrive axis telegram on ADI4 and IM174

At least one electric or hydraulic axis must be configured on ADI4/IM174.

The defined update rate (BaudRate) for SSI encoders must be supported by the encoder.

See also the Encoder list (Page 3190).

For more information about configuration and operation, refer to the *ADI4 - Analog Drive Interface for 4 Axes Manual* and *Distributed I/Os IM 174 PROFIBUS Module Manual*. These documents are provided on the *SIMOTION Documentation* DVD.

Note

An encoder in a PROFIdrive axis telegram can only be used for an external encoder TO or for the encoder of a TO axis in cyclical operation if a TO axis is also created on the PROFIdrive telegram and is not deactivated.

Encoder assignment and terminology (Page 3190)

Encoder list (Page 3193)

4.8.10.9 Encoder interface as a direct value in the I/O area

Encoders can be used that

- Provide actual value information directly as absolute value in the input/output area.
- Provide a counter value in the peripheral area (as of V4.0).
- Provide an actual velocity in the peripheral area.

Actual value information directly as absolute value

These encoders must be parameterized and operated as absolute encoders, for example with respect to homing.

The following settings are provided to set the **adaptation to the properties of the measured value**:

- The **justification of the measured value** in the **NumberOfEncoders.Encoder_n.AnalogSensor.DriverInfo.format** configuration data element
  - Signed left-justified (VALUE_LEFT_MARGIN)
  - Signed right-justified (VALUE_RIGHT_MARGIN)
  - Unsigned left-justified (VALUE_LEFT_MARGIN_WITHOUT_SIGN)
  - Unsigned right-justified (VALUE_RIGHT_MARGIN_WITHOUT_SIGN)
- The **data width of the measured value** without the sign bit in the **NumberOfEncoders.Encoder_n.analogSensor.DriverInfo.resolution** configuration data
- The upper limit and lower limit, the **maximum limits of the measured value** in the following configuration data
  - **NumberOfEncoders.Encoder_n.AnalogSensor.DriverInfo.maxValue**
  - **NumberOfEncoders.Encoder_n.AnalogSensor.DriverInfo.maxValue**

Example: Use of an ET 200S, SSI module, or an analog input.

Justification of the measured value

The measured value is mapped to an internal 32-bit wide signed data value of the DINT type in accordance with the justification specification. The mapped value is then tested with actual value limitation against the maximum limits and evaluated using the weighting factor for the **NumberOfEncoders.Encoder_n.AnalogSensor.ConversionData.factor** direct value that specifies the technological resolution or assignment of the LSB.

⚠ WARNING

Weighting factor for analog sensors

The scaling or conversion in the value of the configuration data **ConversionData.factor** for the position of the analog sensor has changed in SIMOTION V4.4.

As of V4.4, the following applies:

The values are entered directly in inches and no longer converted from mm to inches for the configured Inch unit system. This can result in a higher velocity being detected (by a factor of 25) if it is an axis that works in inches.

The following applies for SIMOTION up to V4.4:

The values were entered in mm and then converted to inches (1 inch corresponds to approx. 25 mm). Please check the values entered for **ConversionData.factor** in older projects and correct them when necessary.

Regardless of the sign, the encoder resolution/measured value width is limited to maximum 31-bit, because the configuration data of the maximum limits are signed data values of the DINT type.

For the **Left-justified/Right-justified without sign** setting, the measured value for the setting of the encoder resolution/measured value width is processed as follows:

- At ≤16 bits the measured value left-justified/right-justified is mapped to the least-significant byte 1 and byte 2 of an internal data value of the DINT type. In this process, the missing 16 bits minus the measured value width of the least-significant byte 1 and byte 2 are right/left-padded with zeros and the most-significant byte 3 and byte 4 are filled with zeros.
- > At 16 bits the measured value left-justified/right-justified is mapped to an internal data value of the DINT type. In this process, the missing 32 bits minus the measured value width are right/left-padded with zeros.
  As this mapped measured value is tested against the maximum limits of the data type DINT, the encoder resolution/measured value width is limited to maximum 31 bits. This means the measuring range is limited to maximum 50% of the measured value width.

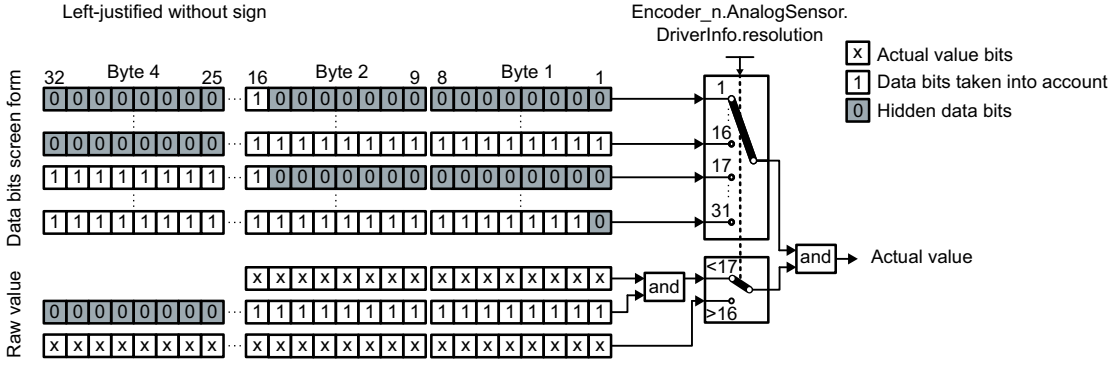

Figure 4-931 Masked reading of the analog IO value left-justified without sign

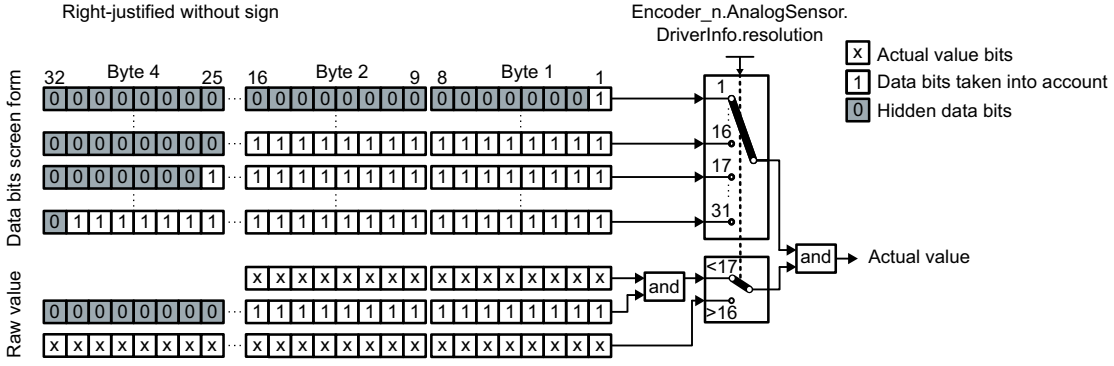

Figure 4-932 Masked reading of the analog IO value right-justified without sign

For the **Left-justified/Right-justified without sign** setting, the measured value for the setting of the encoder resolution/measured value width is processed as follows:

- At <16 bits the measured value left-justified/right-justified is mapped to the least-significant byte 1 and byte 2 of an internal data value of the DINT type. For left-justified, the missing 15 bits minus measured value width of the least-significant byte 1 and byte 2 are right-padded with zeros and the sign bit is extended left to bit 32. For right-justified, the sign bit is padded left to bit 32.
- At ≥16 bits the measured value left-justified/right-justified is mapped to an internal data value of the DINT type. For left-justified, the missing 31 bits minus measured value width are right-padded with zeros. For right-justified, the sign bit is padded left to bit 32.

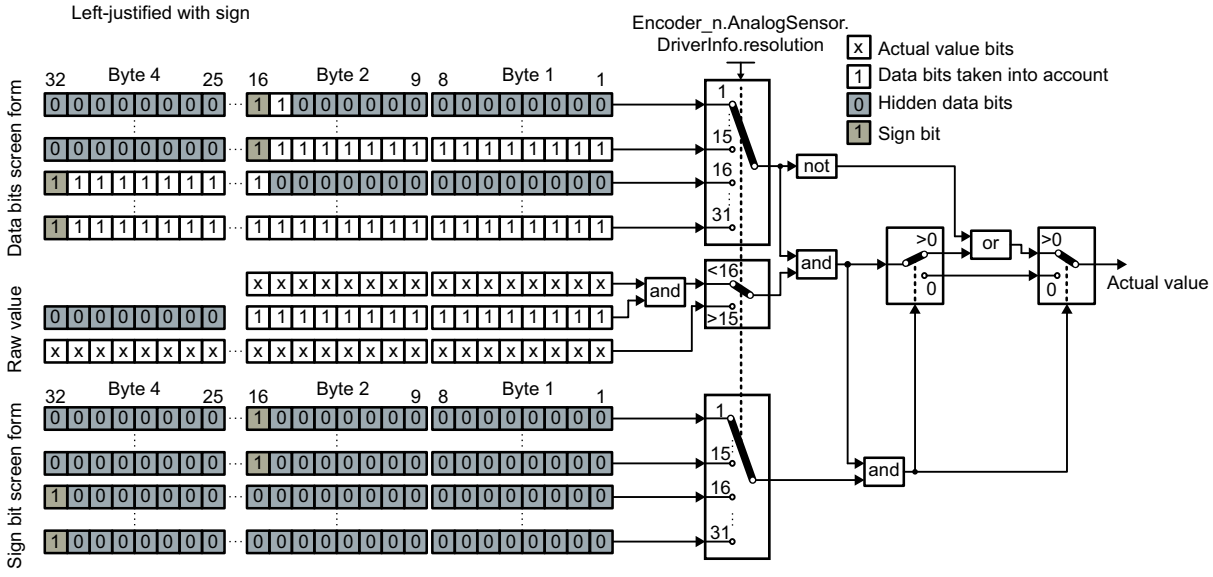

Figure 4-933 Masked reading of the analog IO value left-justified with sign

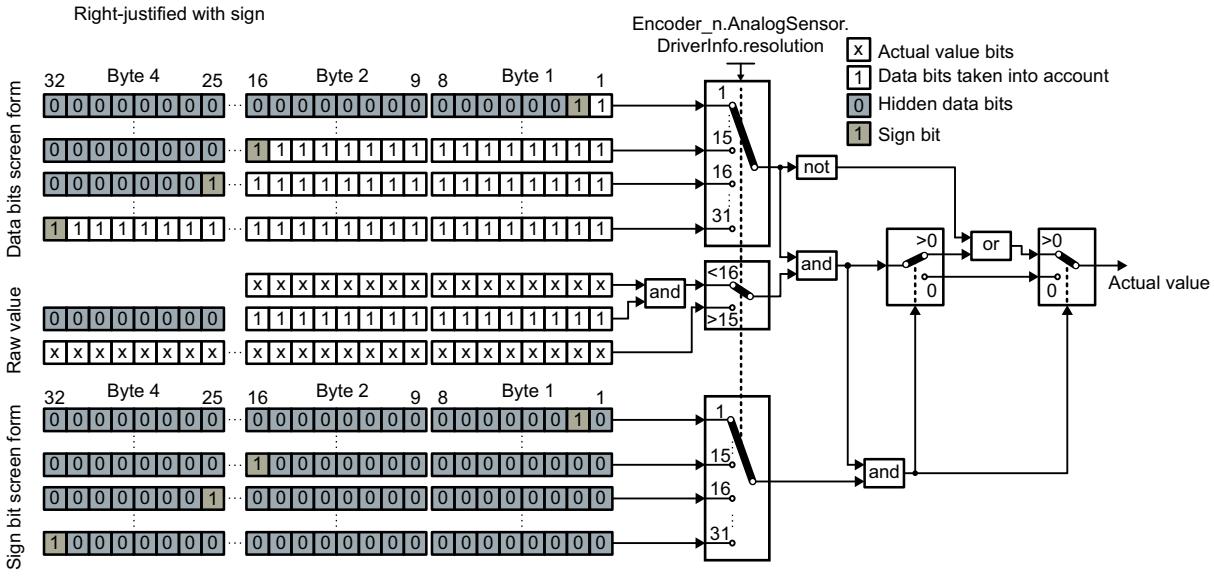

Figure 4-934 Masked reading of the analog IO value right-justified with sign

Counter value (as of V4.0)

The encoder is set as an incremental encoder. 16 bits or 32 bits can be set as counter value width.

Example: Use of an ET 200S, COUNT module

Actual velocity

The actual value information can include the number of pulses between two scans or, alternatively, the time interval between two sequential pulses. This type of encoder is used, for example, to measure actual velocities with the hydraulic axis functionality.

Example: Use of an ET 200S, COUNT module

Direct value as absolute value in I/O area (as of V4.1 SP1)

The following bits can be configured for the direct value as absolute value in the I/O area:

- **Ready bit** via the elements of the **analogSensor.readyStateMonitoring** configuration data element
- **Error bit** via the elements of the **analogSensor.errorStateMonitoring** configuration data element

These can be used for evaluation on the Axis technology object of a *ready identifier* and an *error identifier*, which are available from the peripheral module in addition to the measured value.

In SIMOTION V4.1 SP1, this configuration data is defined directly in the expert list.

If the *not ready* status or an error is displayed in these identifiers during operation, and the **ready bit** or **error bit** is configured, technology alarm 20005 is issued with the *sensor error* identifier.

If the Axis technology object is ready during ramp-up, but the direct value in the I/O area is not yet in ready status, the *WAIT_FOR_VALID Sensor* status is displayed on the encoder. (**sensorData[n].state** system variable)

As of V4.1 SP1, the direct value in the I/O area does not have to be updated in every equidistant communication cycle (for example, if an encoder connected to the peripheral module is not able to supply a new measured value in each cycle during a fast communication cycle clock due to measurement reasons or processing time reasons). In such cases, the actual value is extrapolated by the control.

The control supports the following options:

- The peripheral module displays the new measured value set in an update bit/update counter. The update bit or update counter is defined in the **analogSensor.UpdateCounter** configuration data element.
  UpdateCounter configuration: The update counter can be one (toggle) bit or several (counter) bits in width.
- The refresh cycle of the actual value in the peripheral module is known and is defined directly in the **analogSensor.UpdateCounter.updateCycle** configuration data element.
  Default setting with refresh cycle = 1 (default behavior for updating in every cycle clock)

4.8.10.10 Actual value system

Actual value processing for the external encoder is described using the actual value processing on the axis.

4.8.10.11 Overflow bit for modulo counting

The number of modulo revolutions (V3.2 and higher) is described in Chapter Actual value measurement / Actual value system.

See also

Actual value measurement / actual value system (Page 2969)

4.8.10.12 Actual value smoothing

The actual values are read in the position control cycle clock.

Other quantities, such as the velocity, are calculated from these data. The system variables for **SensorData** are calculated in the position control cycle clock, whereas the system variables for **MotionState** are calculated in the IPO cycle clock.

The filter for the velocity in the position control cycle clock is set in **typeOfAxis.Encoder_1.filter**.

The filter for the velocity in the interpolator cycle clock is set in **typeOfAxis.SmoothFilter**.

See also

Actual value measurement / actual value system (Page 2969)

4.8.10.13 Actual value extrapolation

In the case of synchronous operation with master value reference to external encoder position values, a setting can be made during configuration to specify whether the actual values are to be generated using extrapolation (see "Actual value coupling" in the Synchronous Operation description of functions).

The velocity is filtered / averaged separately using a filter that is set via **extrapolation.Filter**.

The extrapolated actual values are displayed in **extrapolationData.position** and **extrapolationData.velocity**.

See also

Actual value measurement / actual value system (Page 2969)

4.8.10.14 Standstill signal

The standstill signal **motionState.stillstandVelocity** is ACTIVE when the current velocity is less than a configured velocity threshold for at least the duration of the delay time.

The **StandStillSignal** configuration data element can be used to specify when the standstill signal is to be output.

4.8.10.15 Monitoring functions

- **Zero mark monitoring** for incremental encoders
  You can activate the function for monitoring the number of increments between two encoder zero marks.
- Permissible **changes to the actual value** of an absolute encoder
  The user can activate the function for monitoring permissible changes to the actual value for an absolute encoder.
- **Limiting frequency**
  The encoder limit frequency can be monitored.
- **Current velocity**
  The permissible maximum value of the actual velocity can be monitored. If the maximum value is exceeded, the system variable **sensordata.sensorMonitoring.velocity** is output as **limitexceeded**. The velocity is not limited to this value.
- **Cyclical data exchange** (as of V3.1)
  The system variable **sensorMonitoring.cyclicInterface** indicates whether cyclic data exchange is active on the active encoder. The cyclical data exchange is determined using the sign-of-life.
  Application: The encoder may be located on a different drive than the actuator of the axis, or it may even have its own protocol (PROFIBUS/PROFINET encoder).
- **Number of the active encoder** (as of V3.1)
  The number of the active encoder is output directly via system variable **sensorMonitoring.actualSensor**.

4.8.10.16 Synchronization / Homing

Overview of synchronization / homing

SIMOTION supports different synchronization/homing modes for the external encoders.

You can set the reference position of the external encoder using the **_synchronizeExternalEncoder()** function.

Synchronization/homing with incremental encoders

- **Direct homing / Set home position**
  Direct homing is set with the function parameter synchronizingMode=DIRECT_HOMING.
  The current actual position of the encoder is set to the value of the home position coordinate (**syncPosition** system variable) without a traversing motion having taken place.
- **Relative direct homing**
  Relative direct homing is set with the function parameter synchronizingMode=DIRECT_HOMING_RELATIVE.
  The current actual position of the encoder is offset by the value of the home position coordinate
  (**syncPosition** system variable), without a traversing motion having occurred.
- **Passive homing/flying homing**
  Passive homing is set with the function parameter synchronizingMode=PASSIVE_HOMING.
  At the synchronization point, the external encoder is set to the value of the home position coordinate.
  IncHomingEncoder.passiveHomingMode can be set as synchronization event in the configuration data:
- Encoder zero mark (ZM_PASSIVE)
- External zero mark (CAM_PASSIVE)
- Next encoder zero mark after homing output cam (CAM_AND_ZM_PASSIVE)
  The path traveled after the homing output cam is exited up until the encoder zero mark is reached can be monitored.
- Encoder zero mark or external zero mark system setting dependent on the encoder type (DEFAULT_PASSIVE).

See also

Passive homing/on-the-fly homing (Page 2932)

Direct homing/setting the home position (Page 2933)

Relative direct homing/relative setting of home position (V3.2 and higher) (Page 2933)

Synchronization/homing with absolute encoders

Direct homing/Set home position

Direct homing is set with the function parameter synchronizingMode=DIRECT_HOMING.

The current actual position of the encoder is set to the value of the home position coordinate (**syncPosition** system variable) without a traversing motion having taken place.

Relative direct homing

Relative direct homing is set with the function parameter synchronizingMode=DIRECT_HOMING_RELATIVE.
The current actual position of the encoder is offset by the value of the home position coordinate.

(**syncPosition** system variable), without a traversing motion having occurred.

Absolute value conversion

The value of the external encoder is set equal to the encoder value + absolute encoder offset using the **_synchronizeExternalEncoder()** command and the setting of the function parameter synchronizingMode=ENABLE_OFFSET_OF_ABSOLUTE_ENCODER. The absolute encoder offset is set in the **absHomingEncoder.absshift** configuration data.

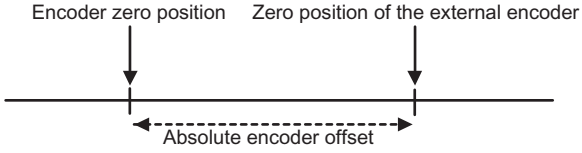

Figure 4-935 The external encoder value is the encoder zero position plus the absolute encoder offset.

The absolute encoder offset (as of V3.2) may be set as an additive or absolute value.

This absolute encoder offset is stored in the NVRAM and remains in effect until the next absolute encoder adjustment. This function must therefore be executed once when the control is commissioned.

The offset value and its calculation are set during **configuration**.

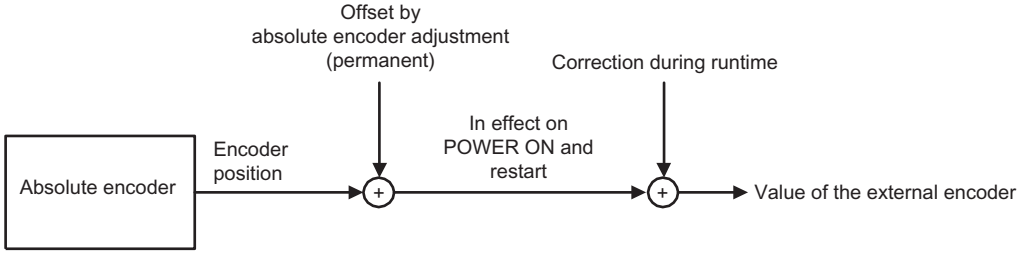

Figure 4-936 Incorporating the absolute encoder offset

A value may be set as a total offset using the **absHomingEncoder.setOffsetOfAbsoluteEncoder** and **absshift** configuration data.

Setting an additive offset

Setting **absHomingEncoder.setOffsetOfAbsoluteEncoder**=RELATIVE (default behavior):

- Actual external encoder value = actual encoder value + (previous offset already in effect + absshift)
- (new) offset = previous offset + absshift

absHomingEncoder.absshift is added to the existing absolute encoder offset whenever the **_synchronizeExternalEncoder()** function is called.

Setting an absolute offset (as of V3.2)

Setting **absHomingEncoder.setOffsetOfAbsoluteEncoder**=ABSOLUTE (as of V3.2):

absHomingEncoder.absshift is set as the absolute encoder offset whenever the **_synchronizeExternalEncoder()** function is called.

- Actual external encoder value = actual encoder value + **absshift**

Setting the value of the external encoder to a predefined position (as of V4.1 SP1)

When the synchronizingMode=SET_OFFSET_OF_ABSOLUTE_ENCODER_BY_POSITION function parameter is set on the **_synchronizeExternalEncoder()** command, the value in the syncPosition parameter will be set as the current position. The resulting absolute encoder offset is calculated with this value, indicated in the **absoluteEncoder[n].totalOffsetValue** system variable, and stored as a retain variable in the system.

The value in the **absHomingEncoder.absshift** configuration data element is not changed.

Displaying the offset

The offset can be read out. (as of V3.1)

The complete offset is indicated in the **absoluteEncoder.totalOffsetValue** system variable and the activation status of the complete offset indicated in the **absoluteEncoder.activationState** variable.

In addition, the status indicates whether the **_synchronizeExternalEncoder()** function with synchronizingMode= ENABLE_OFFSET_OF_ABSOLUTE_ENCODER has been executed at least once after the project was downloaded.

States that require a new setting of the external encoder value

- Once a new project has been downloaded to the control, the stored offset is no longer available.
  If the control already contains a project before the new project is downloaded, and if the technology object name is not changed, the stored offset is retained (as of V4.1 SP1). This behavior also applies for an upgrade, i.e. it is not version-dependent.
- After power is cycled off and on, the offset is deleted unless the project was saved to the ROM.
- After a memory reset.

4.8.11 Programming External Encoders/Reference

4.8.11.1 Commands

The External Encoder technology object can be addressed in the user program using the following commands:

- **_enableExternalEncoder()**
  Activate external measuring system; enables updating of actual values in the IPO.
- **_disableExternalEncoder()**
  Deactivate external measuring system; disables updating of actual values in the IPO. Actual values are frozen in the IPO, they remain unchanged until the next activation of the measuring system.
- **_resetExternalEncoder()**
  Reset External Encoder technology object.
- **_resetExternalEncoderError()**
  Reset an error on the External Encoder technology object.
- **_synchronizeExternalEncoder()**
  Homing of the measuring system by setting the synchronous position directly or by enabling the synchronous position with the next external zero mark / encoder zero mark / homing output cam and encoder zero mark or absolute encoder adjustment.
  The command is only performed in the **active** TO state.
- **_resetExternalEncoderConfigDataBuffer()**
  This function clears the configuration data collected in the buffer since the last activation without activating them.
- **_bufferExternalEncoderCommandID()**
  Enables the saving of commandId and the associated command status beyond the execution period of the command.
- **_removeBufferedExternalEncoderCommandId()**
  Stops the saving of commandId and the associated command status beyond the execution period of the command.
- **_enableMonitoringOfEncoderDifference()**
  Activates the monitoring of the maximum permissible difference between the measuring systems specified in the command.
- **_disableMonitoringOfEncoderDifference()**
  Deactivates the encoder monitoring.
- **_getStateOfExternalEncoderCommand()** (as of V3.1)
  Read out command status
- **_getExternalEncoderErrorNumberState()** (as of V3.1)
  Readout of error number status

- **_redefineExternalEncoderPosition()** (as of V3.2)
  Sets the encoder coordinate system
- **_cancelExternalEncoderCommand()** (as of V4.1 SP1)
  Cancels the command with the specified CommandID.

Note

You can also find information about the system functions in the *SIMOTION Cam Technology Package parameters manual*.

4.8.11.2 Technological alarms

Possible alarm reactions

- **NONE**
  No response.
- **DECODE_STOP**
  Command preparation aborted. The current function remains active.
  Processing on the technology object can be continued after **_resetExternalEncoder()** or **_resetExternalEncoderError()**.
- **SIMULATION_STOP**
  Calculation of the simulation value by a function is stopped. The simulation function is not aborted. Simulation can be continued with **_resetExternalEncoderError()**.
- **SIMULATION_ABORT**
  Calculation of the simulation value by a function is stopped. The simulation function is aborted.
- **ENCODER_DISABLE**
  Stops and aborts all commands.

Note

Local alarm responses are specified by means of the system.

4.9 Industrial Security

Preface

You can find information on the following topics at the following address (https://support.industry.siemens.com/cs/de/en/view/108464614):

- Ordering documentation/overview of documentation
- Additional links to download documents
- Using documentation online (find and search in manuals/information)

If you have any questions regarding the technical documentation (e.g. suggestions, corrections), please send an e-mail to the following address (mailto:docu.motioncontrol@siemens.com).

mySupport/Documentation

At the following address (https://support.industry.siemens.com/My/ww/en/documentation), you can find information on how to create your own individual documentation based on Siemens' content, and adapt it for your own machine documentation.

Training

At the following address (https://www.siemens.com/sitrain), you can find information about SITRAIN (Siemens training on products, systems and solutions for automation and drives).

FAQs

You can find Frequently Asked Questions in the Service&Support pages under Product Support (https://support.industry.siemens.com/cs/de/en/ps/faq).

SINUMERIK

You can find information about SINUMERIK at the following address (https://www.siemens.com/sinumerik).

SIMOTION

You can find information about SIMOTION at the following address (https://www.siemens.com/simotion).

SINAMICS

You can find information about SINAMICS at the following address (https://www.siemens.com/sinamics).

Target group

This documentation is intended for manufacturers of machine tools / production machines, particularly:

- Planners and project engineers
- IT departments of end users and OEMs

The following knowledge is a prerequisite for implementing the described security concepts:

- Administration of the IT technologies familiar from the office environment
- Configuration of the SINUMERIK/SIMOTION/SINAMICS products used

Benefits

The "Industrial Security" documentation contains the necessary measures and information for planning and configuring systems or plants. The documentation serves as a reference manual and guideline. This documentation cannot and does not want to suggest that there is 100% security because the current threat scenario is much too diverse and complex.

This documentation includes all of the necessary measures that should be taken into account for configuring systems in a secure environment. This documentation is intended to support machine manufacturers in safely operating their controls or plants. You, as operator, are responsible for implementing the security measures.

Note regarding the General Data Protection Regulation

Siemens observes standard data protection principles, in particular the principle of privacy by design. That means that

this product does not process / store any personal data, only technical functional data (e.g. time stamps). If a user links this data with other data (e.g. a shift schedule) or stores personal data on the same storage medium (e.g. hard drive) and thus establishes a link to a person or persons, then the user is responsible for ensuring compliance with the relevant data protection regulations.

Technical Support

Country-specific telephone numbers for technical support are provided on the Internet at the following address (https://support.industry.siemens.com/sc/ww/en/sc/2090) in the "Contact" area.

If you have any technical questions, use the online form in the "Support Request" area.

4.9.1 Fundamental safety instructions

4.9.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

If the safety instructions and residual risks in the associated hardware documentation are not observed, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

4.9.1.2 Warranty and liability for application examples

Application examples are not binding and do not claim to be complete regarding configuration, equipment or any eventuality which may arise. Application examples do not represent specific customer solutions, but are only intended to provide support for typical tasks.

As the user you yourself are responsible for ensuring that the products described are operated correctly. Application examples do not relieve you of your responsibility for safe handling when using, installing, operating and maintaining the equipment.

4.9.1.3 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit
https://www.siemens.com/industrialsecurity (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under
https://www.siemens.com/industrialsecurity (https://new.siemens.com/global/en/products/services/cert.html#Subscriptions).

Further information is provided on the Internet:

Industrial Security Configuration Manual (https://support.industry.siemens.com/cs/ww/en/view/108862708)

⚠ WARNING

Unsafe operating states resulting from software manipulation

Software manipulations, e.g. viruses, Trojans, or worms, can cause unsafe operating states in your system that may lead to death, serious injury, and property damage.

- Keep the software up to date.
- Incorporate the automation and drive components into a holistic, state-of-the-art industrial security concept for the installation or machine.
- Make sure that you include all installed products into the holistic industrial security concept.
- Protect files stored on exchangeable storage media from malicious software by with suitable protection measures, e.g. virus scanners.
- On completion of commissioning, check all security-related settings.
- Protect the drive against unauthorized changes by activating the "Know-how protection" converter function.

4.9.2 What is industrial security?

Definition of industrial security

Generally, industrial security is understood to be all of the measures for protecting against the following:

- Loss of confidentiality due to unauthorized access to data
- Loss of integrity due to data manipulation
- Loss of availability (e.g. due to destruction of data or Denial-of-Service (DoS))

Objectives of industrial security

The objectives of industrial security encompass:

- Fault-free operation and guaranteeing of availability of industrial plants and production processes
- Preventing hazards to people and production due to cyber security attacks
- Protection of industrial communication from espionage and manipulation
- Protection of industrial automation systems and components from unauthorized access and loss of data
- Practicable and cost-effective concept for securing existing systems and devices that do not have their own security functions
- Utilization of existing, open, and proven industrial security standards
- Fulfillment of legal requirements

An optimized and adapted security concept applies for automation and drive technology. The security measures must not hamper or endanger production.

4.9.3 Why is industrial security so important?

4.9.3.1 Networking and wireless technology

Overview

There are many new trends which affect industrial security:

- Cloud computing in general
  The number of network connections across the world is constantly increasing. This enables innovations such as cloud computing and the applications that go hand in hand with it. In conjunction with cloud computing, there has been a massive increase in the number of mobile devices, such as cell phones and tablet PCs.
- Wireless technology
  On the other hand, the increasing use of mobile devices has only become possible thanks to the ubiquitous availability of mobile networks. Wireless LAN is also becoming increasingly available.
- Worldwide remote access to plants, machines and mobile applications
- The Internet of Things (IoT)
  Millions of electronic devices are becoming network-capable and are communicating via the Internet, such as onboard computers in cars, which transmit warranty information to dealers, or water meter sensors that transmit water consumption data to municipal water suppliers via radio.

However, in order for everything from cloud computing to the Internet of Things to function disturbance-free, you require a reliable network infrastructure and applications that are well protected against attacks from malware and hackers.

4.9.3.2 Possible corporate security holes

Possible security holes or weak points

The security chain of a company is only as strong as its weakest link. Security holes can exist at numerous points. The following list gives only a few examples:

- Employees / external companies
- Production plants
- Network infrastructure
- Data centers / PC workstations
- Laptops/tablets
- Printers
- Smartphones/smartwatches
- Mobile data storage media

For this reason, a holistic approach is required to deal with the issue of security. Coordinated guidelines and regulations are required that cover all areas: Devices, systems, processes and employees.

The topic of data security and access protection (security) is becoming more and more important in industrial environments. The following technologies results in higher requirements placed on protecting and securing industrial plants and systems:

- The ongoing networking of complete industrial plants and systems
- The vertical integration and networking of various company levels
- New techniques, e.g. remote maintenance and/or remote access

The threats are diverse and the consequences are far-reaching:

Possible threats:

Potential threats come from the industry environment and involve the topic of confidentiality, integrity and availability. Examples of threats include the following:

- Espionage of data, recipes, etc.
- Sabotage of production plants
- System stoppage, e.g. due to virus infection and malware
- Manipulation of data or application software
- Unauthorized use of system functions

Possible effects of a security incident

- Loss of intellectual property
- Loss of production or reduced product quality
- Negative company image and economic damage

- Catastrophic environmental influences
- Danger to people and machines

4.9.4 Security measures in automation and drive technology

Siemens automation and drive technology concerns itself with security aspects at the following levels:

- **Application security** refers to products and functions that take into consideration the needs of industrial security in the field of automation. This involves particular consideration of the application and task at hand, as well as the people performing the actions in an automated plant. This allows industrial security to be easily implemented in production processes.
- **Security support** provides support during the analysis, planning, implementation, testing and optimization of industrial security - by means of specialists with special knowledge of networks and the industry. These services lead to the highest possible level of industrial security and operating capacity of the production plant.
  Siemens offers comprehensive customer support based on the "Implement Security" service: With this service you can implement protective measures to increase the security level of plants and production facilities. You can find more information about the entire "Implement Security" portfolio on the Internet.

See also

Implementing security (https://new.siemens.com/global/en/products/automation/topic-areas/industrial-security/implementation.html)

4.9.4.1 Security measures

With increasing digitalization, comprehensive security in the automation system is becoming ever more important. For this reason, industrial security is a core element of every product that can be networked.

Integration of security into the products

As manufacturer of automation and drive products, Siemens supports secure operation for its customers by **integrating security into its products**:

- All of the measures involving automation and drive technology are stored in the **Product Lifecycle Management (PLM) process**, which is certified by the German Technical Inspectorate (TÜV) based on IEC 62443-4-1.
- Analytically potential attack threats are detected and evaluated using **Threat and Risk Analyses (TRA)**. Identified critical threats are implemented in the product as necessary basic functions, based on the motto "Security by Design".
- Siemens regularly performs **code analyses** in order to identify and correct possible errors at an early stage during the formal check.

- In its products and its manufacturing process, Siemens has implemented **measures to secure integrity** to indicate any changes to the integrity.
- Siemens constantly checks the measures relating to **hardening**:
  - Operating systems are configured in such a way that **points of attack** (e.g. via ports, unneeded services) are **minimized**.
  - Siemens **tests its products** to detect weak points at an early stage.
  - Siemens offers a specific **hotfix/patch management**.

Protection of the development infrastructure and supply chain

As manufacturer of automation and drive products, Siemens supports secure operation for its customers by **securing the development infrastructure and supply chain**:

- The Siemens ProductCERT (https://www.siemens.com/cert/en/cert-security-advisories.htm) (**C**yber **E**mergency **R**eadiness **T**eam) is the central department for security-related incidents in the Siemens product and solution environment. Siemens ProductCERT supports development work with consulting and other services. **ProductCERT** provides information about current threats and vulnerabilities as well as the appropriate countermeasures.
- Industrial security is a dynamic and complex subject that requires continuous monitoring and adaptation of new security measures. Information on how Siemens protects its products and solutions against cyber attacks and how industry profits from the competence of Siemens can be found on the Internet (https://new.siemens.com/global/en/products/automation/topic-areas/industrial-security/always-active.html).

Provision of patches, security components, and appropriate services

As manufacturer of automation and drive products, Siemens supports secure operation for its customers through direct support of integrators and operating companies **by providing patches, security components and the appropriate services**:

- SIEMENS offers monitoring through a **SIEM system** to monitor residual risk. SIEM stands for Security Information and Event Management and has become an established term in IT security. Such systems are able to identify and evaluate security-relevant events and notify the administrator.

4.9.4.2 Siemens Industrial Holistic Security Concept

Siemens places great emphasis on protecting the integrity and guaranteeing the confidentiality of the processed data for its own products. Intellectual property and know-how of the Siemens products are also in focus.

To achieve this, the Siemens Industrial Holistic Security Concept (SI HSC) is applied which protects development departments and production plants (see the following diagram). Multi-level security systems and basic security improvements of the IT infrastructure are implemented. In parallel, process improvements have been introduced and training in security awareness provided in the development and production. These measures are being performed continuously by Siemens and clearly demonstrated by the security levels reached.

SI HSC also benefits the customers who Siemens has selected as partners for their industrial solutions, or who want to orientate themselves on the concept. Siemens suppliers are also

considered with regard to security so that Siemens already applies the same security standards when purchasing as for the manufacture of its own products.

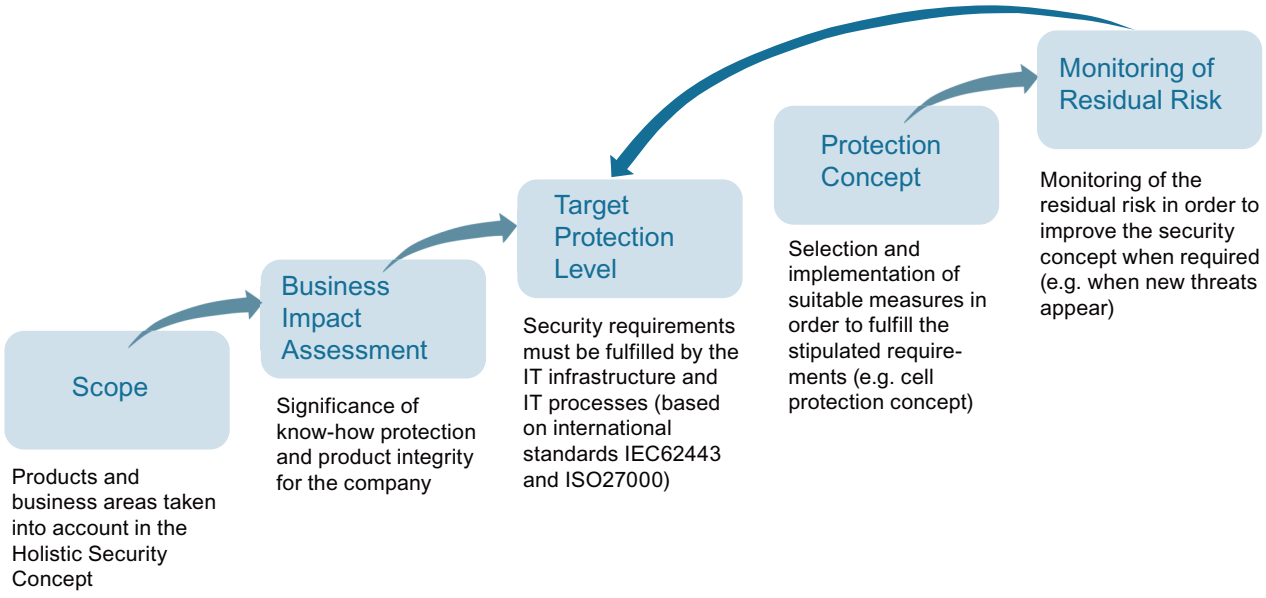

Figure 4-937 SI HSC security management process

Further information

Further information on the Siemens Industrial Holistic Security Concept is available on the Internet on page Always active (https://new.siemens.com/global/en/products/automation/topic-areas/industrial-security/always-active.html).

4.9.4.3 Standards and regulations

Siemens takes the applicable Industrial Security standards and regulations into consideration throughout the entire development process:

- ISO 2700X: Management of information security risks
- IEC 62443: IT security for industrial higher-level control systems – network and system protection

Further information on certifications and standards in the Industrial Security field can be found on the Internet (https://new.siemens.com/global/en/products/automation/topic-areas/industrial-security/certification-standards.html).

4.9.5 Security management

The security management process as a basis

Protect your system and your company. Security management according to IEC 62443 and ISO 27001 forms the basis for the successful implementation of industrial security.

The security management process is shown in the following:

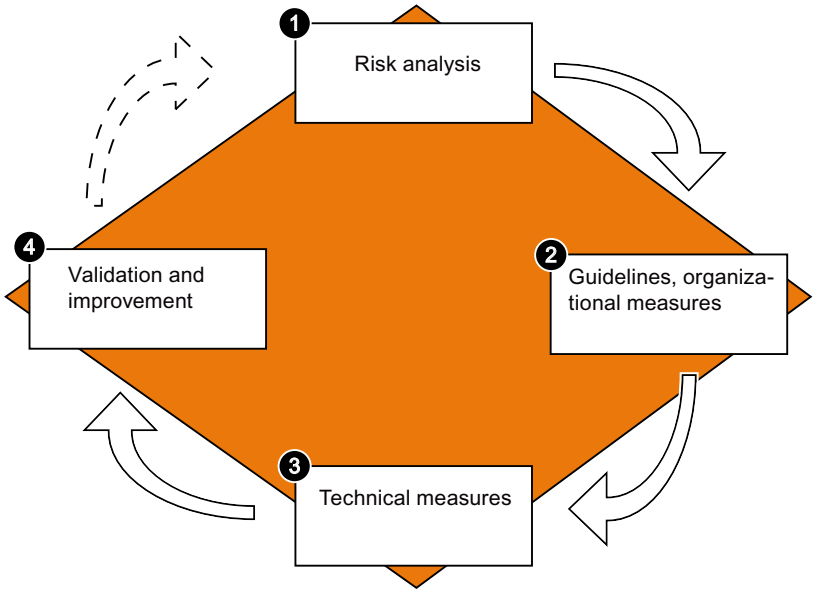

Figure 4-938 Security management process

1. Carry out a risk analysis. Determine all possible risks and define countermeasures for reducing the risk to an acceptable level. In detail, a risk analysis encompasses the following steps:
   - Identification of threatened objects
   - Analysis of value and potential for damage
   - Threat and weak point analysis
   - Identification of existing security measures
   - Risk evaluation
   - Evaluation of the effects with regard to the protection goals of confidentiality, integrity, and availability
2. Define guidelines and introduce coordinated, organizational measures. To this end, the awareness of the importance of industrial security must be borne by all levels of the company. In addition, define guidelines and processes in order to achieve a uniform procedure and to support compliance with the defined industrial security concept.

3. Introduce coordinated technical measures. You can find a list of general measures that help to protect your plant against threats in Section General security measures (Page 3220). You can find measures to be considered for SINUMERIK, SIMOTION and SINAMICS environments in Chapter Product-specific security measures (Page 3234).
4. A security audit must ensure that all of the measures have been implemented and that they have also eliminated or reduced the identified risks.

Note

Continuous process

Due to constantly changing security threats, **this process must be continuously repeated** in order to guarantee the security of your plant. For this reason, the security management process must be seen as a continuous process.

4.9.6 General security measures

In this chapter you will learn about the general security measures you must take in order to protect your system from threats.

Additional specific security measures for SINUMERIK, SIMOTION and SINAMICS products can be found in Section Product-specific security measures (Page 3234).

4.9.6.1 Defense in depth concept

To protect industrial plants and systems comprehensively against cyber attacks, measures must be applied simultaneously at all levels. From the operational up to the field level – from access control to copy protection. For this purpose, we use "Defense in Depth" as a general protection concept, according to the recommendations of ISA99 / IEC 62443, the leading standard for security in industrial automation.

Figure 4-939 Defense in depth strategy

Further information on the defense in depth concept and the planning of a protection concept for industrial plants can be found on the Internet (https://new.siemens.com/global/en/products/automation/topic-areas/industrial-security/planning.html).

Protection levels

A defense in depth model has a three level structure:

- **Plant security**
  Plant security represents the outermost protective ring. Plant security includes comprehensive physical security measures, e.g. entry checks, which should be closely coordinated with protective measures for IT security.
- **Network security**
  The measures, grouped under the keyword "Network security", form the core of the protective measures. This refers to the segmentation of the plant network with limited and secure communication between subnetworks ("secure islands") and the interface check with the use of firewalls.
- **System integrity**
  "System integrity" represents the combination of two essential protection aspects. PC-based systems and the control level must be protected against attacks. Steps include the following measures:
  - Integrated access protection mechanisms in the automation components to prevent unauthorized changes via the engineering system or during maintenance
  - The use of antivirus and whitelisting software to protect PC systems against malware
  - Maintenance and update processes to keep the automation systems up-to-date (e.g. patch management, firmware updates, etc.)

4.9.6.2 Plant safety

Unauthorized persons may be able to enter the production site/building and damage or alter production equipment as a result of gaps in a company's physical security. Confidential information can also be lost. This can be prevented if both the company's site and the production areas are protected accordingly.

Physical protection of critical production areas

Company security

The company's physical security can be ensured via the following measures:

- Closed off and monitored company premises
- Entry control, keys / card readers and/or security personnel

- Escorting of external personnel by company employees
- Security processes in the company are taught and followed by all employees

Physical production security

The physical security of a production location can also be ensured via the following measures:

- Separate access control for critical areas, such as production areas
- Installation of critical components in lockable control cabinets / switching rooms including monitoring and alarm signaling options. The control cabinets/contact chambers must be secured by a cylinder lock. Do not use simple locks, such as universal, triangular/square or double-bit locks.
- Configuration of the radio field to restrict the WLAN range so that it is not available outside the defined areas (e.g. factory building).
- Guidelines that prevent the use of third-party data storage media (e.g. USB sticks) and IT devices (e.g. notebooks) classified as insecure on systems.

Further information

Further information on integrated Siemens security solutions can be found on the Siveillance page (https://new.siemens.com/global/en/products/buildings/security/security-management.html).

4.9.6.3 Network security

Network security includes all measures taken to plan, implement and monitor security in networks. This includes the control of all interfaces, e.g. between the office network and plant network, or remote maintenance access via the Internet.

Network segmentation

Separation between production and office networks

One important protective measure for your automation or drive system is the strict separation of the production networks and the other company networks. This separation creates protection zones for your production networks.

Note

The products described in this manual must only be operated in defined protection zones.

Separation by means of a firewall system

In the simplest scenario, separation is achieved by means of an individual firewall system which controls and regulates communication between networks.

See also Network segmentation with SCALANCE S (Page 3224)

Separation via a DMZ network

In the more secure variant, the coupling is established via a separate DMZ network. In this case, direct communication between the production network and the company network is completely prevented by firewalls and only takes place indirectly via servers in the DMZ network.

Note

The production networks should also be divided into separate automation cells in order to protect critical communication mechanisms.

General security measures

Observe the general security measures even within protection zones, for example as listed in System hardening (Page 3227):

Network segmentation with SCALANCE S

Siemens provides SCALANCE S security modules to meet network protection and network segmentation requirements. Further information on SIEMENS SCALANCE S can be found on the Internet (https://siemens.com/scalance-s).

SCALANCE S security module

SCALANCE S security modules with Security Integrated provide:

- Stateful inspection firewall
  In order to implement user-specific control and logging, firewall rules can also be specified that only apply to certain users.
- VPN via IPsec (data encryption and authentication)
  This establishes a secure tunnel between authenticated users whose data cannot be intercepted or manipulated. The most important aspect is the protection against external access via the Internet.
- NAT/NATP (address translation)
- Router functionality (PPPoE, DDNS) for broadband Internet access (DSL, cable)
- SCALANCE S623 with additional VPN port (DMZ) enables the secure connection of an additional network for service and remote maintenance purposes. S623 also permits the secure, redundant connection of subordinate networks by means of routers and firewall redundancy.
- SCALANCE S615 has five Ethernet ports with which different network topologies can be protected by means of a firewall or Virtual Private Network VPN (IPsec and OpenVPN), and security concepts implemented flexibly.

Requirement

NOTICE
Data misuse Long distances between the device to be protected and the upstream security modules represent an invitation for data misuse. • Note that upstream security modules, such as SCALANCE S, must be installed close to the device to be protected in a locked control cabinet. This ensures that data cannot be manipulated here without notice.

Principle

The following application example shows cell segmentation by several SCALANCE S modules, each of which is upstream of the automation cells. The data traffic to and from the devices within automation cells can be filtered and controlled with the SCALANCE S firewall. If required, the traffic between the cells can be encrypted and authenticated. Secure channels and client access from the PCs to the cells can be established via SOFTNET Security Client, VPN client software for PCs.

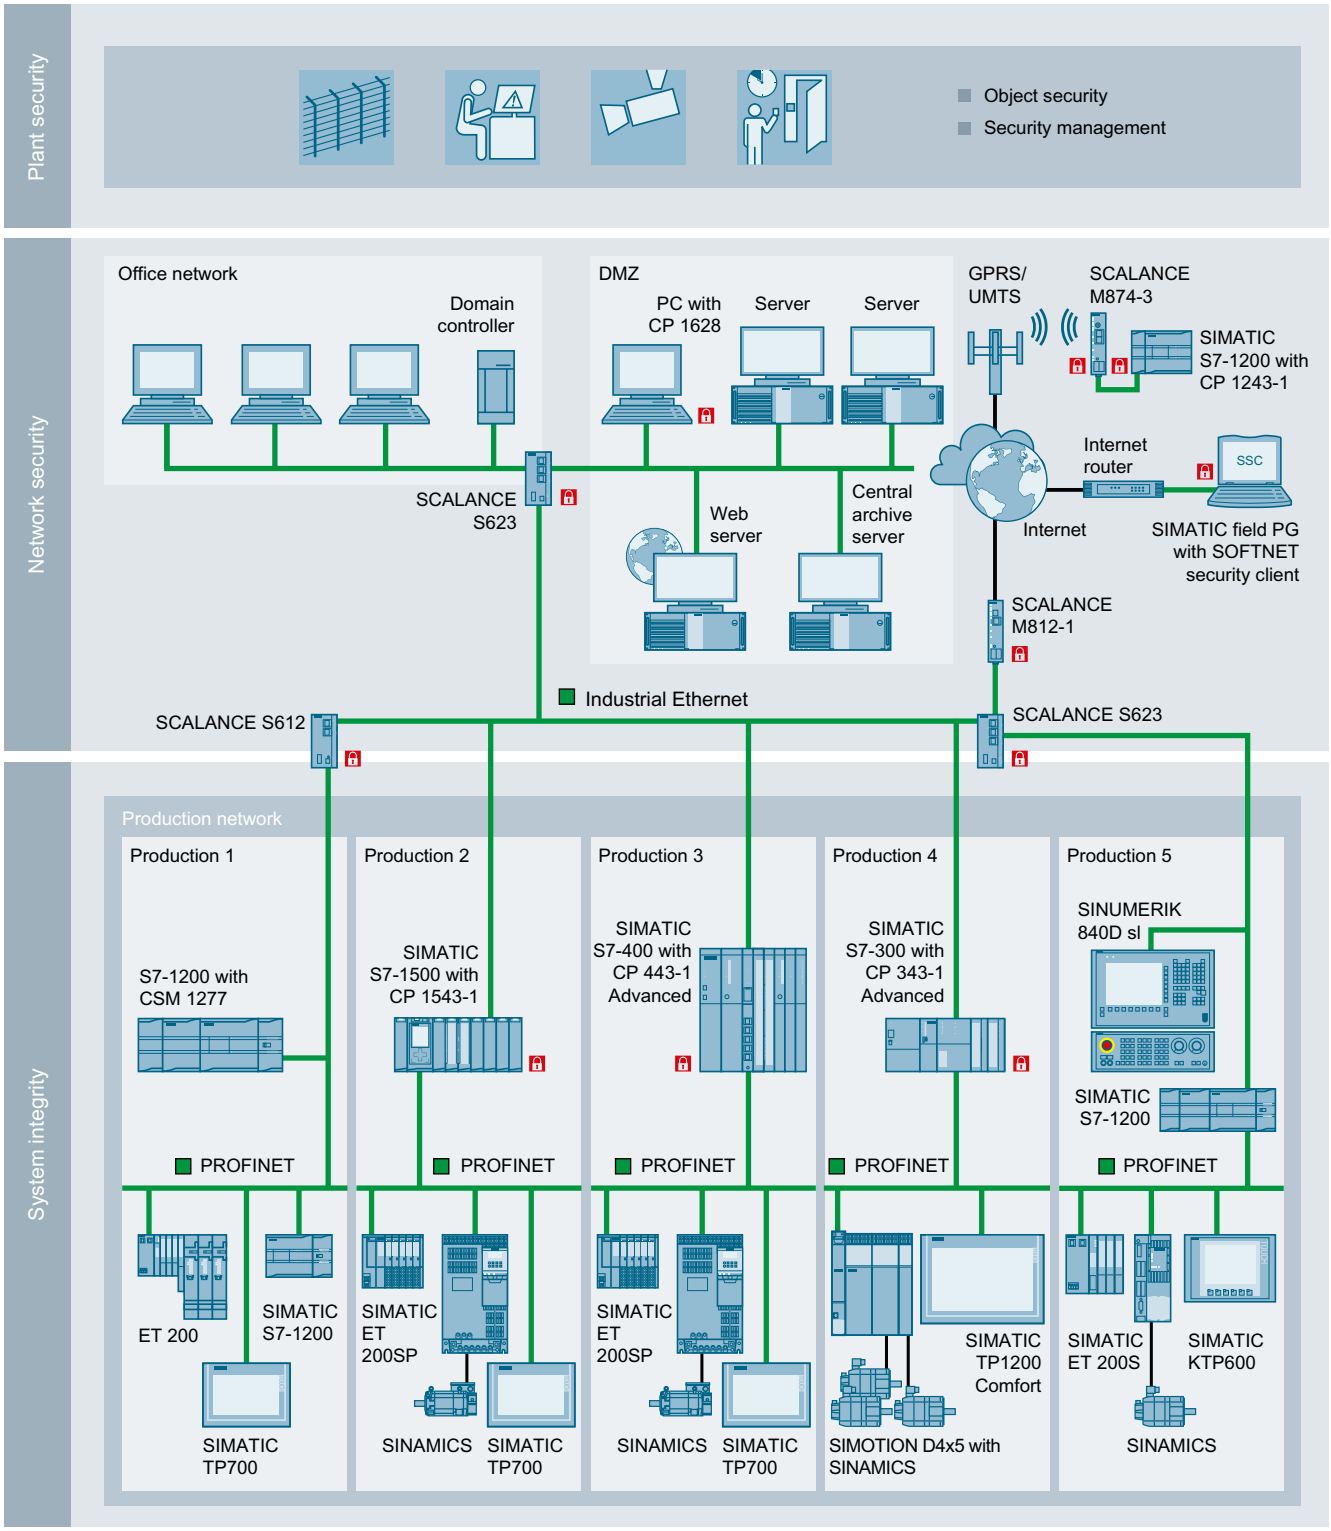

Figure 4-940 SCALANCE S application example

VPN access

Note

Note that a SCALANCE S security module must always be used for VPN access.

Cloud Security

Since cloud applications are becoming increasingly common and the cloud continues to grow in its significance, the issue of security in the cloud environment is also becoming more and more important.

The following addresses are designed to give you an idea of how you can make your system safe in the cloud environment. Inform yourself about the applicable requirements and tried and tested solutions/best practices.

Further information

- Companion Guide for Cloud - CIS Organization (https://www.cisecurity.org/press-release/cis-controls-companion-guide-for-cloud-now-available/)
- Questionnaire Cloud Security - CSA Organization (https://cloudsecurityalliance.org/artifacts/consensus-assessments-initiative-questionnaire-v3-0-1/)

4.9.6.4 System integrity

System integrity is understood to mean the "integrity" or "correctness" of the data or the correct response of the system. Thus, the following measures for protecting the system integrity should ensure that the data/functionality of the system cannot be manipulated by unauthorized persons or that manipulations can be detected.

System hardening

Services and ports

Activated services and ports represent a risk. To minimize the risk, only the necessary services for all of the automation components should be activated. Ensure that all activated services are taken into account (especially Web servers, FTP, remote maintenance, etc.) in the security concept.

A description of all of the ports used can be found in the Equipment Manuals/Function Manuals of the respective products.

User accounts

Any active user account that allows access to the system is thus a potential risk. Therefore, take the following security measures:

- Reduction of configured/activated user accounts to the actually needed minimum
- Use of secure access data for existing accounts. This also involves assigning a secure password.
- Regular checks, especially of the locally configured user accounts
- Regular change of passwords

PC/notebooks and mobile devices in an industrial environment

The terminal devices used in industrial environments (PCs, notebooks and mobile devices) must meet the generally applicable security requirements. Therefore, take the following measures:

- The terminal device that is used is set up, administered, regularly checked and patched by the appropriate departments. This ensures it is always kept up-to-date. This also means that software and operating systems which are supported and maintained by the manufacturer are always installed.
- A current virus scanner, which is adapted to the operating system used, must be installed on the terminal device that is used. Both the virus patterns and the software itself must be regularly updated. Or, alternatively, work with the Whitelisting (Page 3231) method.
- Activate a firewall with appropriate settings on the terminal device that is used.
- Use a configuration without admin. rights on the terminal device that is used.
- Encrypt all of the hard drives or mass storage units (e.g. eMMC or SSD) of the terminal device that is used to protect sensitive data against unauthorized access.
- Do not use the terminal device for other tasks, e.g. in the office network. This is part of the separation of networks dealt with in Chapter "Separation between production and office networks (Page 3224)".
- Secure terminal devices from data theft using a physical lock (e.g. Kensington lock) or do not leave them unmonitored.
- If you leave protected terminal devices at the workstation, always activate the lock mode of the operating system. This prevents access to the terminal device and the contents of the screen can no longer be read.
- Set up user accounts (Page 3228) for the access rights accordingly.
- Take appropriate measures to protect unneeded interfaces (e.g. USB, network, etc.) to prevent unauthorized access. This can be done physically using commercially available USB port locks or via corresponding software measures.

Data storage

Note

When you store security-relevant data on your PC, you are responsible for secure data storage.

These include, for example, the following measures:

- Consequent marking of your documents according to confidentiality levels by introducing a document classification.
- Protection of your encrypted storage locations, such as sharepoints, against manipulation.
- If absolutely necessary, only store your confidential or security-relevant data encrypted on your PC / systems or the network.
  Security-relevant data includes sensitive data, such as archives, passwords, or executable files (*.exe).
- Regularly back up your security-relevant data and carefully protect it against loss and manipulation.

Transporting data

Note

Apply the following measures when transporting data:

- Always encrypt your emails if you send confidential and/or security-relevant data by email.
- If you wish to transport confidential and/or security-relevant data on a data storage medium (USB flash drive, hard disk, etc.), carefully investigate as to which data storage media are considered secure. A regular virus check must be carried out for these data storage media. Always save your data on local data storage media so that the data is encrypted.

These measures are especially important for sensitive data, such as archives, passwords, or executable files (*.exe).

Passwords

NOTICE

Data misuse caused by using passwords that are not secure enough

Data can be easily misused by using passwords that are not secure enough. Insecure passwords can easily be guessed or decoded.

- Therefore, change the default passwords during the commissioning and adapt them at regularly defined intervals.
- Also change passwords for functions that you yourself do not use to ensure that such unused functions are not misused.
- Always keep your passwords secure, and ensure that only authorized persons have access to these passwords.

Note

Assigning secure passwords

Observe the following rules when creating new passwords:

- When assigning new passwords, make sure that you do not assign passwords that can be guessed, e.g. simple words, key combinations that can be easily guessed, etc.
- Passwords must always contain a combination of upper-case and lower-case letters as well as numbers and special characters. PINS must comprise an arbitrary sequence of digits.
- When assigning a password, always ensure you are adhering to the applicable company specifications, e.g. special password policy of the respective company.
- Observe that, in accordance with the applicable company specifications, passwords with the maximum required minimum length must be assigned.
- Wherever possible and where it is supported by the IT systems, a password must always have a character sequence as complex as possible.

Programs are available that can help you to manage your passwords. Using these programs, you can encrypt, save and manage your passwords and secret numbers – and also create secure passwords.

Further information on assigning secure passwords can be found in Chapter References (Page 3287).

Product security notifications

Note

Complying with product security notifications

Threats are extremely diverse in nature and are continually changing. As a consequence, always keep yourself up-to-date on a regular basis through the Industry Online Support (https://support.industry.siemens.com/sc/ww/en/sc/2090) regarding whether there are new and relevant product security notifications for your particular products. Comply with the instructions provided in the product security notifications.

Virus scanner

An anti-virus program, virus scanner or virus protection program is a software that can detect, block and, if required, eliminate computer viruses, computer worms or Trojans horses.

In principle, virus scanners can only detect known malware (viruses, worms, Trojans, etc.) or harmful logic and therefore cannot provide protection against all viruses or worms. For this reason, virus scanners can only be considered as a complement to general precautionary measures.

The use of a virus scanner must not impact the production operations of a plant. As the last consequence, this will lead to even a virus-infected computer not being permitted to immediately shut down if this would cause the control of the production process to be lost.

NOTICE
Data misuse when using online virus scanners If you use an online virus scanner, then security-relevant or confidential data can get into the wrong hands and be misused. • Therefore, do not check any security-relevant or confidential data via an online virus scanner.

Note

Keep virus scanners up-to-date

Always ensure that the virus scanner database is always up-to-date.

Note

Do not install several virus scanners together.

You must always avoid installing several virus scanners together in one system.

Note

Operation in a local network

Always use a virus scanner when locally connecting with the plant or system network.

Whitelisting

The basic philosophy of whitelisting is that all applications are mistrusted, unless they have been classified as trustworthy after an appropriate check. This means that a whitelist is maintained in the system. This whitelist therefore contains all applications that have been classified as trustworthy and consequently can be run on your PC systems.

Whitelisting mechanisms provide additional/alternative protection against undesired applications or malware and unauthorized changes to installed applications or executable files (.exe, .dll).

Heed the corresponding product-specific information (Page 3234) to determine whether the use of virus scanners and/or whitelisting is recommended.

Patch management

WSUS

The **WSUS** (Windows Server Update Service) system functionality provided by Microsoft is available for current Windows systems. WSUS supports administrators by providing Microsoft updates in large local networks. WSUS automatically downloads update packages (Microsoft update) from the Internet and offers them to the Windows clients for installation.

The fully automatic update process ensures that Microsoft security updates are always available on Siemens clients.

NOTICE
Security gaps for out-of-date operating systems Note that security updates, hotfixes, etc. are no longer supplied by Microsoft for obsolete operating systems < Windows 10. As a consequence, dangerous security gaps can occur with your operating system. • Therefore always upgrade your operating system - if possible - to the latest version. • If you work with an older operating system, take appropriate additional measures (e.g. whitelisting) to protect your system.

Note

Before installing Microsoft Updates, note the following important points:

- **Prior to the update**, back up the system status for a fallback, if necessary. Ensuring the compatibility of the update with the individual system configuration is the responsibility of the customer.
- Never establish a direct connection to the WSUS server in the Internet! Ensure that the environment is secure and install an intermediate layer (e.g. DMZ network, firewall, SCALANCE S modules, etc.).

Product software

Note

Out-of-date product software also represents a potential security gap for attacks.

- As a consequence, always install the latest product software versions.

Data integrity

Data integrity is understood to mean the correctness (integrity) of data and the correct functioning of systems. Ensuring the integrity of the data is thus an essential goal of information security. Integrity protection should not be confused with protecting the confidentiality.

NOTICE

Corruption of data and the resulting malfunctioning of the system

For automation and drive systems as well as controller components, data such as archives and programs can be imported from external sources. This data influences the behavior of these systems and should therefore be protected against unauthorized changes.

Data such as archives, programs, and OA applications can also be saved and archived. The systems currently do not provide the capability of ensuring the integrity of programs, archives, and OA applications.

Therefore take your own measures for ensuring integrity to guarantee the data integrity of your archives, OA applications, or other saved data:

- Apply the Siemens Industrial Holistic Security Concept.
- Use digital signatures to protect data.
- Ensure there is sufficient access protection:
  - Restrict access rights such as to data archives/Sharepoints accordingly.
  - Do not send any unencrypted/unsigned emails.

Disposal

The products are to be disposed of in accordance with the respectively valid national regulations. The products described in this manual are extensively recyclable on account of the low-toxic composition of the materials used. To recycle and dispose of your old equipment in an environmentally friendly way, please contact an appropriate disposal company.

NOTICE

Misuse of data resulting from insecure methods of deleting data

Incomplete or insecure deletion of data from memory cards or hard drives can lead to misuse of the data of the part programs, archives, etc. by third parties.

- Therefore ensure that all storage media are securely deleted **before disposing of the product** :
- There are programs that support you in securely deleting/formatting storage media. Alternatively, contact a certified data destruction specialist to take care of this task.

Also observe the special disposal information of the products in Chapter Product-specific security measures (Page 3234).

4.9.7 Product-specific security measures

In this chapter, you will find additional product-specific security measures for the SINUMERIK products and the CNC Shopfloor Management Software, SIMOTION, SINAMICS and SIMOCRANE.

4.9.7.1 SINUMERIK

The following chapter provides you with an overview of the security-related measures that you must take to protect your SINUMERIK control from threats. Detailed descriptions and procedures can be found in the corresponding SINUMERIK documentation.

Many products (SINUMERIK, SIMOTION, SINAMICS) contain OpenSSL. The following applies to these products:

- This product contains software (https://www.openssl.org/) that has been developed by the OpenSSL project for use in the OpenSSL toolkit.
- This product contains cryptographic software (mailto:eay@cryptsoft.com) created by Eric Young.
- This product contains software (mailto:eay@cryptsoft.com) developed by Eric Young.

Firewall and networking

NCU/PCU networking structure

The following graphic shows the networking of the control (NCU) and the IPC. X130 at the NCU and eth 1 at the IPC are used to establish a connection to the company network. A firewall protects these two interfaces against unauthorized access.

The NCU contains a packet filter functionality (firewall) that filters the connection to the factory network. This integrated firewall is preconfigured with optimum settings for the incoming and outgoing communication. The firewall is configured in such a way that access to the networks behind the firewall is blocked, and when several logon attempts are made from a certain IP address, this is identified, blocked and prevented. In this way, the control is protected against brute-force attacks.

The IPC has the firewall function via the Windows functionality.

NOTICE
Data misuse via an unprotected interface Since the X120 interface of the NCU or the eth2 port of the IPC are not protected by a firewall, there is a risk of misuse of data. The interface only provides the option of establishing a connection to the local plant/system network. • As a consequence, never connect this local network with the Internet/company network.

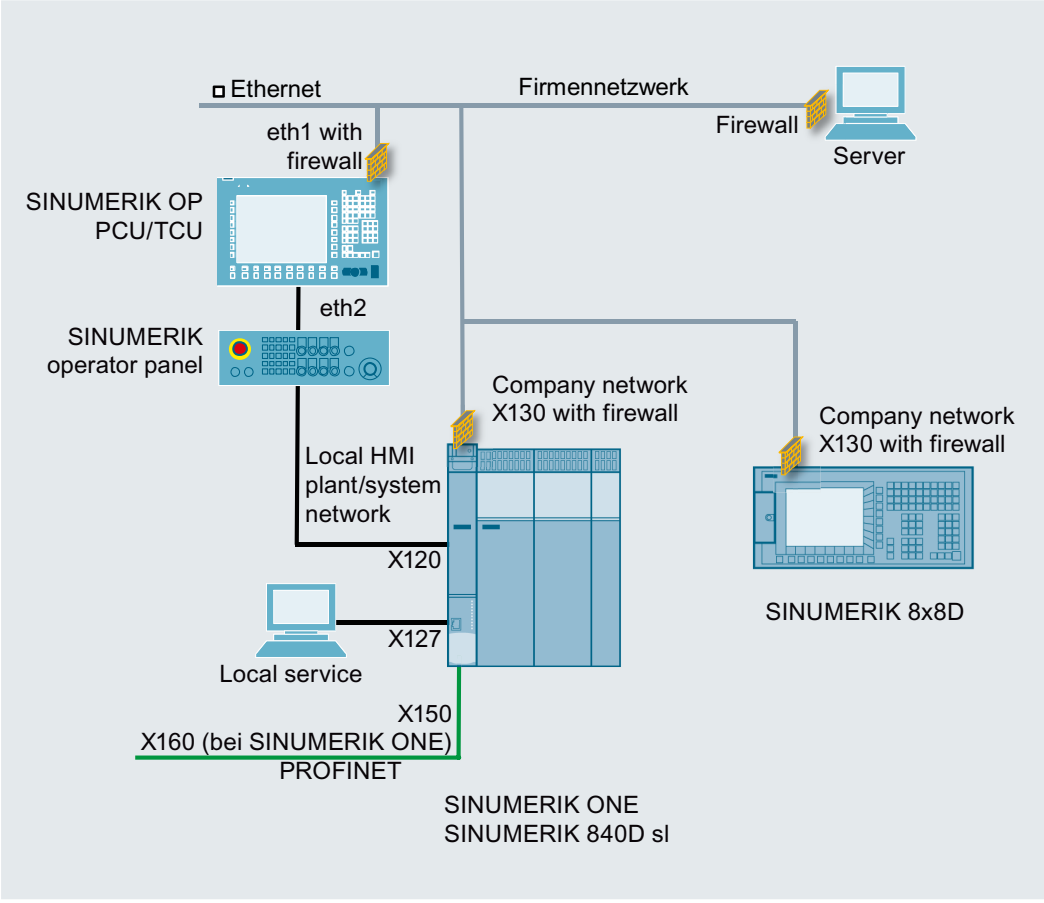

Figure 4-941 Networking of NCU/IPC

Firewall settings

Ethernet interface X130 of the NCU and the eth1 interface of the IPC are protected by a firewall for security reasons. If individual programs require access to a communication port for communication purposes, you can activate or deactivate the firewall via SINUMERIK Operate. Additional ports can be separately released.

Alternatively, you can configure the firewall via the "basesys.ini".

Further information

Further information on the configuration of the firewall and default settings can be found in the following manuals:

- SINUMERIK Operate (IM9) (https://support.industry.siemens.com/cs/de/en/view/109769186)
- Diagnostics Manual (808D) (https://support.industry.siemens.com/cs/de/en/view/109763685)

Physical protection of the NCU

NOTICE

Misuse, manipulation and theft

Modules, such as the NCU, are open equipment. If not protected, there is the risk of misuse by unauthorized personnel, manipulation or theft of data (e.g. CompactFlash Card).

- As a consequence, always install NCUs in housings and locked control cabinets or in electrical rooms. Only appropriately trained and authorized personnel may access these housings, electrical cabinets and electrical rooms. Information on the permitted locks can be found in Chapter Physical protection of critical production areas (Page 3222).
- **Further information** on the control cabinet installation of the NCU can be found in the SINUMERIK 840D sl NCU 7x0.3 PN Manual (https://support.industry.siemens.com/cs/de/en/view/99922219) or in the corresponding Equipment Manuals for SINUMERIK ONE: "NCU1750" and "NCU1760".

Machine control panels - SINUMERIK (MCP/MPP)

Machine control panels (**M**achine **C**ontrol **P**anels and **M**achine **P**ush Button **P**anels) are available for user-friendly operation of SINUMERIK machine functions.

Note

Only operate the machine control panels (MCP/MPP) on an internal, local machine network and secure them against any possible external access.

Note

Firmware update

For MCP/MPP/PP72-48 firmware updates or module diagnostics (Port 3845) contact Siemens Service&Support (https://support.industry.siemens.com/sc/ww/en/sc/2090).

Passwords (Page 3229)

System hardening

Deactivating hardware interfaces

Deactivating interfaces

Measure	Description
Deactivate/activate Ethernet interfaces in the BIOS of the PCU	You can activate or deactivate the Ethernet interfaces in the BIOS of the PCU. You can find detailed information on this in PCU-Basesoftware (IM8) Commissioning Manual (https://support.industry.siemens.com/cs/de/en/view/109748542), Chapter "BIOS settings".
Deactivating/activating USB interfaces	To prevent malware entering the control or the plant network via the USB interfaces, you can disable the USB interfaces of the NCU. Use the service command "sc_usb disable". Enter the relevant command on the Service Desktop in the "Run" dialog box or at the prompt. Use this function to make your system more secure and protect it from unwanted manipulation and malware. **Further information** can be found in the PCU-Basesoftware (IM8) Commissioning Manual (https://support.industry.siemens.com/cs/de/en/view/109748542), Chapter "How to disconnect the USB interfaces".

Deactivating ports

Measure	Description
Deactivating the PROFINET port for SINUMERIK 840D sl PLC	In STEP 7 HW Config, a PROFINET interface port of a SINUMERIK PLC can be deactivated (X150). It is activated by default. The SINUMERIK PLC cannot be accessed via a deactivated PROFINET interface port. **Further information** can be found in the SIMATIC S7-300 CPU 31xC and CPU 31x Equipment Manual: Technical specifications (https://support.industry.siemens.com/cs/de/en/view/12996906), Chapter "Configuration of the port properties". **No communication function.** Note that no communication functions, such as PG/OP functions, open IE communication or S7 communication (PROFINET IO), are possible via a deactivated port.
Deactivating the PROFINET port for SINUMERIK ONE PLC	The PROFINET port can be deactivated in the TIA Portal under "Device configuration". Select the PLC and then switch to the menu "General > PROFINET interface> Advanced options > Port > Port options". Uncheck the box for "Activate this port for use". **Further information** can be found in the TIA Portal online help.
Deactivating a PROFINET port of SCALANCE X switch (possible as of the X200 series)	For secure operation, only one defined access point should be available to the network for diagnostics/maintenance. All of the other ports to the controls, devices, or switches (Scalance X) should be deactivated. This prevents unauthorized access. **Further information** can be found in the SIMATIC NET Configuration Manual: SCALANCE X-200 Industrial Ethernet switches (https://support.industry.siemens.com/cs/de/en/view/109757352), Chapter "Ports".

Communication services and used port numbers

SINUMERIK supports certain communication protocols. The address parameters, the relevant communication layer as well as the communication role and the communication direction are decisive for each protocol.

This information allows you to match the security measures for the protection of the automation system to the used protocols (e.g. firewall).

Further information can be found in the product information for "SINUMERIK port lists" (available soon).

Note

System hardening for software solutions

When using SINUMERIK Integrate software and other PC applications (e.g. Create MyConfig (CMC) or Access MyMachine (AMM)), make sure that the PC on which the software is used, always fulfills the requirements of industrial security.

These include, for example:

- Current Microsoft security updates
- Current virus scanner software
- Activated firewall, etc.

Further information can be found in Section System integrity (Page 3227).

Secure Boot with SINUMERIK ONE

Note

Only signed software

The SINUMERIK ONE NCUs have a Secure Boot feature that ensures that only software that is signed by Siemens can be loaded onto the NCU. This concerns both GIV software versions of the controller and any other software (e.g. SINAMICS TEC). Once a *.tgz file is imported and there is no accompanying *.sig file, the NCU will no longer ramp up.

In this situation, the controller can no longer be accessed via any interface. The previously installed software can no longer be deleted.

Virus protection

In the context of the length of the service life of a machine tool, the use of antivirus software does not make sense.

The reasons for this are as follows:

- **Continuous pattern updates necessary**
  The protection of an antivirus program is only as good as the up-to-datedness of its virus patterns. Providing this in day-to-day production of the machine without a direct Internet connection is not possible without further action.
- **Changed patterns and background scans affect the runtime behavior of the controller**
  Scans that run in the background can influence the system load and thus the system behavior of the machine. The longer the pattern list, the more time and resource-consuming the scan, which means the influence increases as the machine ages.
- **Short support times**
  As a rule, updates and patterns for antivirus software are provided by the end of the operating system support, at the latest. However, a machine tool generally has a significantly longer service life than a Windows operating system. Therefore the protection becomes ineffective against new threats over time.
- **Unforeseeable backlash effects on machine functionality**
  In certain circumstances, a pattern update can result in a desired system function being detected by the antivirus software as a suspicious operation and prevented from executing, which can have unforeseeable consequences for the operation of the machine.

Reasons for whitelisting

The use of whitelisting makes sense for protecting a Windows-based IPC in the SINUMERIK system for the following reasons:

- In a normal scenario, whitelisting does not require updates to continuously protect the machine.
- Whitelisting does not lose its protective effect over the service life of the machine (apart from technical progress).
- Whitelisting also protects against malware that may not yet be known to an antivirus program.

Note

Measures for protecting against viruses in a CNC environment

Take all the necessary measures for virus protection in the CNC environment. This also includes the proper handling of data storage media, USB sticks and network connections, precautionary measures when copying data and during software installations, etc.

See also

Virus signatures (https://support.automation.siemens.com/WW/view/en/19577116)

Whitelisting

SINUMERIK application example

Using the McAfee Application Control Software as example, a description as to how SINUMERIK PCU 50 with Windows XP can be "hardened" is provided. The licensed software can be used with the PCU 50 as a standalone version (Solidifier/Solidcore). The whitelisting software is directly purchased from the manufacturer.

A detailed description of this application can be found on the Internet (https://support.industry.siemens.com/cs/ww/en/view/89027076).

Virus protection / memory card

The memory card must be handled with particular care for all SINUMERIK devices that use a memory card so that no malicious software is loaded to the system.

⚠ WARNING

Risk of death due to software manipulation when using exchangeable storage media

Storing files on exchangeable storage media poses an increased risk of infection, e.g. with viruses and malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect files stored on exchangeable storage media from malicious software using appropriate protection measures, e.g. virus scanners.

Security updates / patch management

For organizational reasons, it is not possible to provide the latest Windows security patch when the **PCU /** the **IPC** is shipped.

Windows 10-based SINUMERIK IPCs are basically delivered with variant LTSB 2016. This version of Windows not only provides extended support, but also gives you the capability of installing patches for specific problems and there are no compulsory updates.

Provide your Windows-based devices with the current security updates in a timely manner. These updates should not take place during machine operation. Therefore, use a local WSUS server (see Chapter Defense in depth concept (Page 3221)).

Note

Before installing Microsoft Updates, note the following important points:

- **Prior to the update**, back up the system status for a fallback, if necessary. Ensuring the compatibility of the update with the individual system configuration is the responsibility of the customer.
- Never establish a direct connection to the WSUS server in the Internet! Ensure that the environment is secure and install an intermediate layer (e.g. DMZ network, firewall, SCALANCE S modules, etc.).

Since it is usually difficult to regularly update the Windows operating system of an IPC for a machine that is in use, and no more updates are available after the end of the support period, you should ensure the IPC is protected in accordance with the Defense in Depth concept (Page 3221), e.g. by means of a security router and the use of a whitelisting solution.

Possibly identified security weak points of the **NCU** are taken into account or corrected in the current CNC software version.

Note

Availability

The availability of Microsoft security updates is published via Microsoft Security Bulletins. The use of security updates is entirely up to the customer and is their sole responsibility. This can be realized based on the "evaluation of maximum severity" provided in the Microsoft Security Bulletin. Microsoft publishes information on security updates for the PCU and download links on the Internet (https://technet.microsoft.com/en-us/security/bulletins).

Patch management (Page 3231)

Account management

Definition of access levels

Access to functions and machine data

The access concept controls access to functions and data areas. Access levels 1 to 7 are available, where 1 represents the highest level and 7 the lowest level. Access levels 1 to 3 are locked using a password and 4 to 7 using the appropriate key-operated switch.

Access level	Locked by	Area	Data class
1	Password: SUNRISE	Machine manufacturer	Manufacturer (M)
2	Password: EVENING	Service	Individual (I)
3	Password: CUSTOMER	User	User (U)
4	Key-operated switch setting 3	Programmer, machine setter	User (U)
5	Key-operated switch setting 2	Qualified operator	User (U)
6	Key-operated switch setting 1	Trained operator	User (U)
7	Key-operated switch setting 0	Semi-skilled operator	User (U)

Linux passwords / NCK

Level	User name	UID
1	manufact	102
2	service	103
3	user	104
4	operator3	105
5	operator2	106
6	operator1	107
7	operator	108

Corresponding to the named user, there is always a Unix group with the same name (also with the GID to the UIDs). As user, you are always member of your own group and also in all "lower-level" groups. For example, "operator2" is a member of the "operator2", "operator1" and "operator" groups. The file access rights are mainly controlled via these groups.

NOTICE

Data misuse caused by using passwords that are not secure enough

Data can be easily misused when passwords that are not secure enough are created. Passwords that are not secure enough can be easily hacked into.

The default passwords for the basic commissioning procedure are listed in the documentation.

- Therefore, always change the preassigned default passwords during commissioning
- Change the passwords at regularly defined intervals.
- For CNC software <V4.8: During commissioning, change the Linux password in addition to the SINUMERIK Operate passwords. You can find additional information in the Commissioning Manual "NCU operating system".
- A continuous warning appears on the SINUMERIK ONE if the default passwords are not changed.

Further information on assigning secure passwords can be found in Chapter Passwords (Page 3229).

Note

Changing passwords between SINUMERIK Operate and Linux

The access levels for SINUMERIK Operate and Linux are merged as of software version 4.8 SP3 (840D sl/828D) and 6.13 (SINUMERIK ONE). Changing a password for SINUMERIK Operate simultaneously changes the relevant password in Linux and vice versa. It is important to note the following behavior:

- When a general NC reset is performed, no passwords are reset to the default passwords.
- Following a software upgrade, the SINUMERIK Operate passwords apply to the NC unchanged.
- Once a password has been changed, it cannot be reset to its original state.
- When recommissioning the system with Restore [-full] (menu item in the Emergency Boot System "Recover system from USB memory stick (reformat CF card)"), the CF card is formatted and restored to a system in the delivery state. The passwords are not included in the SINUMERIK archive. Therefore, always change the default passwords after a Restore [-full] to individual passwords.

Safety Integrated password

In SINUMERIK Operate, commissioning data is generally protected via various access levels. You protect the safety-related drive parameterization additionally with the Safety Integrated password. This password is stored in the drive data so that it can be changed only by authorized persons who know the password.

Note

The SINAMICS Safety password must be used for SINUMERIK Safety

The assignment of the Safety Integrated password using the SINUMERIK Operate screen is supported as of V4.8 SP2 HF1. The assignment of the Safety Integrated password is also supported by a screen form of the SINUMERIK ONE Commissioning Tool.

- Always set a Safety password to prevent parameters from being changed using the external configuration software Starter or the commissioning software SINAMICS Startdrive.

Further information can be found in the Safety Integrated plus Commissioning Manual.

See also

SINUMERIK 840Dsl Safety Integrated plus Commissioning Manual (https://support.industry.siemens.com/cs/de/en/view/109777982)

Further information

You can find **further information** on how you can change the passwords of the access levels along with other information on access levels for programs and softkeys and access rights for files in the SINUMERIK Operate (IM9) Commissioning Manual (https://support.industry.siemens.com/cs/ww/en/view/109769186), Chapter "General settings > Access levels".

CNC lock function

You can use the "CNC lock function" and the encrypted file that was created with SINUMERIK Integrate Access MyMachine (AMM) application to activate a lock date in the control. This allows the use of the machine to be limited to the time until the lock date is reached. The NC Start function of the control is locked when the lock date is exceeded.

The CNC lock function supports the business model with time-limited use. This protects against unauthorized use beyond the set interval.

Note

Only for SINUMERIK 828D

Note that the CNC lock function is only available on the SINUMERIK 828D controller.

Further information on the CNC lock function and on the creation of a lockset file can be found at:

- "SINUMERIK Integrate Access MyMachine /P2P (PC)" Operating Manual (https://support.industry.siemens.com/cs/de/en/view/109770206)
- "PLC" Function Manual, Chapter "P4: PLC for SINUMERIK 828D > CNC lock function"

Deleting the preinstalled SSH key

Application

Removing the SSH key preinstalled by Siemens reduces the risk of data misuse. However, in order to ensure sufficient access to the system, you can define and install your own SSH key.

Service command

The service command 'sc' is a tool used for performing a range of service tasks on a SINUMERIK NCU:

Syntax:	sc clear preinstalled-keys
Alternative names:	---
Authorization level	service

This command deletes all of the SSH keys preinstalled by Siemens on the control. When called from the service system, the keys on the CompactFlash card are affected, and not the SSH keys on the service system itself.

Further information

You can find additional information in the Base Software and Operating Software Commissioning Manual (https://support.industry.siemens.com/cs/de/en/view/109763236).

PLC web server

In the delivered state, the PLC has no password and the Web server of the PLC is not activated.

Note

- If you activate the PLC Web server in the S7 project, you must define an appropriate user and an associated password for it. Create a secure password. When creating a new password, carefully follow the information provided in Chapter Passwords (Page 3229).
- Only use the HTTPS protocol to establish communication confidentiality and integrity.

Further information

Further information on the PLC web server can be found in the Function Manual S7-1500, ET 200SP, ET200pro web server (https://support.industry.siemens.com/cs/ww/en/view/59193560).

Access levels for softkeys

The display and operation of softkeys can be suppressed by both the OEM and the user. This allows the operating software to be specifically adapted to the required functional scope and therefore be configured as transparently as possible. To prevent access to functions in the operating software, or to restrict the possibility of operator errors, restricts the functional system scope.

Note

Applicability of modified access levels for softkeys

The setting of specific access levels for softkeys on a PCU only affects the respective PCU softkeys themselves. To implement access rights on the NCU, both the manufacturer and the user must use the appropriate mechanisms and set the rights accordingly.

Further information can be found in the SINUMERIK Operate (IM9) Commissioning Manual (https://support.industry.siemens.com/cs/ww/en/view/109769186), Chapter "Access levels for programs".

BIOS and AMT access protection

In order to prevent unauthorized access to the BIOS of the PCU 50 and the SIMATIC IPCs, make sure that you use a very secure BIOS password (see Section Passwords (Page 3229))

Further information

Further information on BIOS settings of the PCU 50 can be found in the PCU-Basesoftware (IM8) Commissioning Manual (https://support.industry.siemens.com/cs/de/en/view/109748542).

Setting the password for AMT (Intel® Active Management Technology)

The Active Management Technology (AMT) function is used for the remote management of the PCU. For remote management, generally suitable protective measures must be taken (such as network segmenting) in order to guarantee secure operation of the plant.

For security reasons, AMT is deactivated when a PCU is delivered. When you activate AMT the first time in the BIOS setup, assign a strong password to prevent misuse of the remote management.

Further information on the AMT function of the PCU as well as the procedure for changing the password can be found on the Internet (https://support.industry.siemens.com/cs/de/en/view/52310936).

Password protection for Create MyConfig (CMC)

NOTICE

Data misuse due to incorrect assignment of rights

Access data, such as the pre-configured passwords for access to the control system, can be stolen and misused.

- For that reason, set up organizational measures to ensure that only authorized persons are given access to these files.

Note

Password protection for linked external files

The protection mechanisms integrated into CMC (password protection) are ineffectual for linked external files that are integrated into the CMC context.

Note

Protecting CMC packages from reimporting

Note that CMC packages have to be protected by password against being reimported.

- For that reason, always set up a password against reimporting when you assign a password for a new project.

Know-how protection

The following functions provide protection of technological know-how and prevent unauthorized access to the SINUMERIK controllers:

SINUMERIK Integrate Lock MyCycles

Using the "SINUMERIK Integrate Lock MyCycles" (cycle protection) function, cycles can be encrypted and then stored protected in the control. The cycles are encrypted outside the control using the SINUMERIK Integrate Access MyMachine/P2P program.

For cycles with cycle protection, execution in the NC is possible without any restrictions.

In order to protect the manufacturer's know-how, any type of view is inhibited for cycles with cycle protection.

This software option is available for the SINUMERIK 808D, 828D and 840D sl controllers.

You can find an application example for cycle protection for SINUMERIK on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109474775).

Further information

Further information on cycle protection can be found in the SINUMERIK Access MyMachine / P2P (PC) Operating Manual (https://support.industry.siemens.com/cs/ww/en/view/109770206).

SINUMERIK Integrate Lock MyPLC

With the aid of block properties, you can protect the blocks created in the SIMATIC PLC from unauthorized changes, for example.

The block properties should be edited when the block is open. In addition to properties that can be edited, data that is only displayed for your information is also displayed in the respective dialog field: It cannot be edited.

A block that has been compiled using this option does not allow you to view the instruction section. The interface of the block can be viewed, but not changed.

Further information

You can find further information on block protection in the SIMATIC Programming with STEP 7 Programming and Operating Manual (https://support.industry.siemens.com/cs/de/en/view/109751825), Chapter "Block properties".

Note

The integrated CP in the SINUMERIK 840D sl does not support the "Module access protection / protection level" option.

Encryption of blocks

As of STEP 7 Version 5.5 SP3 and the CNC system software V4.5 SP2 for 840D sl/ 840D sl or V6.13 for SINUMERIK ONE, you can create encrypted block protection for functions and function blocks in the offline and online view. You can use this function to encrypt your blocks and protect the block code against external access.

The option "SINUMERIK" and, if required, "SIMATIC" must be selected for the encryption with SINUMERIK.

A detailed procedure of how to encrypt your blocks can be found on the Internet (https://support.automation.siemens.com/WW/view/en/45632073).

OPC UA

OPC UA (Unified Architecture) is a standardized, industrial communication protocol for access to control data, e.g. by higher-level control systems. Variables of a SINUMERIK 840D sl, SINUMERIK 828D or SINUMERIK ONE can be read and written to via this communication protocol using the SINUMERIK Integrate Access MyMachine /OPC UA software option.

NOTICE

Date misuse resulting from an insecure connection to the client

There is a danger of data misuse due to an unencrypted connection to the OPC UA client.

- Therefore, always encrypt your connection to the OPC UA client.
- Information on the encryption of the data connection can be found in the SINUMERIK Access MyMachine /OPC UA Configuration Manual (https://support.industry.siemens.com/cs/de/en/view/109777871).

NOTICE

Data misuse due to incorrect user administration / rights assignment

A significant security risk can ensue through incorrect user administration and faulty right assignment. Users can access data or actions for which they have not been authorized.

- As a consequence, always very carefully consider which users are assigned which rights. As administrator, you are responsible for professional user administration and assignment of rights.

Note

Selecting a secure password

Always set a secure password for your connection to the OPC UA client! Further information on selecting a secure password can be found in Section Passwords (Page 3229).

User administration in the TIA Portal

The TIA Portal gives you the capability of using user administration for projects. In this way, for example, a project can be protected against unintentional or unauthorized modification. A user sets up the project protection to activate user management. This user is created as a project administrator. Once the project protection has been activated, the project can only be opened and edited by authorized users. Note that project protection cannot be revoked.

User administration via the TIA Portal is available for the SINUMERIK 840D sl and SINUMERIK ONE controllers.

UMC - User Management Component

In addition, you can install the "User Management Component UMC" software package, which provides central user administration, on one or more computers.

Further information

Further information on the topic of secure user administration can be found in the TIA Portal online help.

SIMATIC Logon

User administration and traceability

The SIMATIC Logon option package is used to set up access rights for products and libraries in STEP 7. These projects can therefore only be accessed by an authorized group of people. SIMATIC Logon can be used in conjunction with SINUMERIK STEP 7.

More detailed information can be found in Chapter Secure access control with SIMATIC Logon (Page 3261).

Data backup

There are different archive forms and archiving methods in the SINUMERIK for the different components.

Time of the data backup

Perform a data backup at the following times:

- After commissioning
- After changing machine-specific settings
- After the replacement of a hardware component
- Before and after a software upgrade
- Before the activation of memory-configuring machine data

You can find **further information** in the following manuals:

- SINUMERIK 840Dsl Commissioning CNC Commissioning Manual (https://support.industry.siemens.com/cs/ww/en/view/109777906)
- Installation Manual SINUMERIK ONE New installation and upgrade

Note the general information on secure data storage with regard to archives in Section Data storage (Page 3229).

NOTICE
Misuse of confidential data on the control system On the control system, there is a risk of confidential data being misused. • As a consequence, it is not permissible to load confidential data to the control (e.g. using the "SINUMERIK Integrate Access MyMachine/P2P" software). • Always store confidential data in an encrypted form locally on an encrypted storage location in the network.

Disposal

NOTICE
Misuse of data resulting from insecure methods of deleting data Incomplete or insecure deletion of data from memory cards or hard drives can lead to misuse of the data of the part programs, archives, etc. by third parties. • Therefore ensure that all storage media are securely deleted **before disposing of the product** : • There are programs that support you in securely deleting/formatting storage media. Alternatively, contact a certified data destruction specialist to take care of this task.

4.9.7.2 CNC Shopfloor Management Software

The following chapter provides you with an overview of the security-related measures you can take to protect your CNC Shopfloor Management software products from threats. Detailed descriptions and procedures can be found in the corresponding documentation of the CNC Shopfloor Management software.

System overview

A leading-edge IT architecture is created based on the CNC Shopfloor Management Software, more specifically, at three levels – "In Cloud", "In Line" and "In Machine". These levels correspond to the 3 platforms "MindSphere", "SINUMERIK Integrate" and "SINUMERIK/SINUMERIK Edge", with their numerous tailored functions from the field to the cloud.

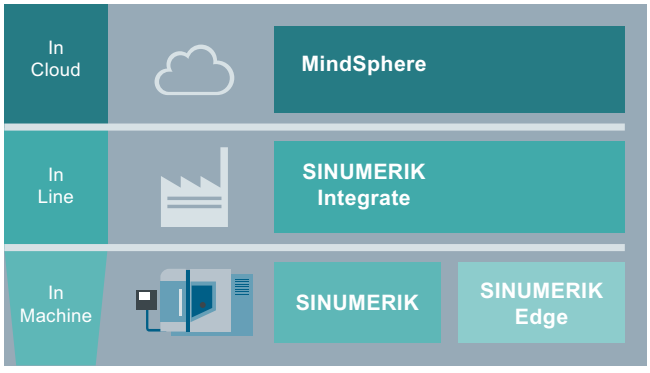

Figure 4-942 CNC Shopfloor Management Software

Cloud applications (In Cloud)

MindSphere provides state-of-the-art security during on-site data collection and when transferring and saving to the Cloud.

The security framework is oriented on the principles of industry standards, e.g. IEC 62443, International Organization for Standardization (ISO)/IEC 27001, and the Federal Office for Information Security (BSI) and recommendations from authorities on working with data in Cloud environments.

In accordance with proven communication practices of the industry, all communication between the client and MindSphere is protected by TLS V1.2 via public end points. Reliable x509 certificates from the Siemens Trust Center are used. These correspond to the requirements of the European Telecommunications Standards Institute (ETSI) and of the Certification Authority Browser Forum (CA/B Forum).

Further information on encryption for MindSphere can be found in the MindSphere Whitepaper (https://www.plm.automation.siemens.com/global/en/topic/mindsphere-whitepaper/28842).

Saved data is always saved by Siemens on high-performance servers in the computer centers of the infrastructure providers. All of the infrastructure centers meet the highest standards for data security and are protected against cyber threats. As commercial providers of a Cloud IaaS (Infrastructure as a Service), they provide higher security standards than typical private, local facilities for data storage. The computer centers are operated in accordance with the Best Practices of the industry.

As an additional layer of security, all of the Cloud infrastructure partners must ensure on-site security measures such as electronic photo ID badges, card owner access control, biometrics, digital video monitoring with recording and alarm monitoring.

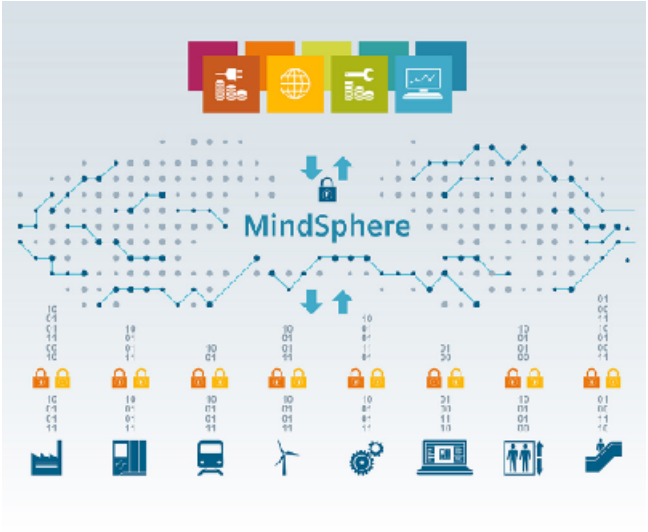

Figure 4-943 MindSphere

Manage MyMachines /Remote

Security measures and system hardening

Note

As a user of Manage MyMachines /Remote, always ensure that you operate the product with the latest versions of SINUMERIK Integrate client and Manage MyMachines /Remote Service Engineer and Machine Operator Clients. Also follow the guidelines for industrial security contained in Chapters 1.3 and 2.3 of the Manage MyMachines /Remote Function Manual (https://support.industry.siemens.com/cs/ww/en/view/109759394).

The connection of SINUMERIK controls to MindSphere via "TLS 1.2 /HTTPS" meets the highest security standards.

The automatic confirmation of the machine identity, used in conjunction with token provided in MindSphere for the onboarding of the machine, ensures that the correct machine is accessed during a remote session.

Disposal

To completely delete an installation of Manage MyMachines /Remote, you should ensure that all of the software and certificates have been properly deleted from your Windows device or SINUMERIK control system, including backup systems. The data will continue to be available in MindSphere, unless the tenant is closed.

Additional information on the topic of disposal can be found in the Manage MyMachines / Remote Function Manual (https://support.industry.siemens.com/cs/ww/en/view/109759394).

Further information on general concepts for secure remote access to industrial plants can be found in the following documents:

- cRSP IT Security Concept (https://support.industry.siemens.com/cs/ww/en/view/109759394)
- Siemens common Remote Service Platform (cRSP) (https://www.downloads.siemens.com/download-center/Download.aspx?pos=download&fct=getasset&id1=A6V11272777)

See also

cRSP IT security concept (https://www.downloads.siemens.com/download-center/Download.aspx?pos=download&fct=getasset&id1=A6V11272775)

PC/Server/Desktop applications (In Line)

SINUMERIK Integrate 4.1

Access to the resources of the SINUMERIK Integrate server

Note

Access to the resources of the SINUMERIK Integrate server

Read and write access to the file system and resources of the operating system (in particular to the Windows Registry) of the SINUMERIK Integrate server is only enabled for users with administrator rights. Make sure that these administrator IDs have sufficiently strong passwords.

NOTICE

Data manipulation possible

Within the production/machine network (Intranet), there is a risk that a hacker can access the file system of the SINUMERIK Integrate Servers or the variance SINUMERIK Integrate clients. There, the hacker can manipulate various system components (e.g. the content of databases). As a consequence, the attacker can change tool data, NC programs, machine archives or the system structure itself, for example. SINUMERIK Integrate cannot prevent this type of attack.

- As a consequence, as the person responsible for the machine network, it is imperative that you take the appropriate industrial security measures for the production/machine network.

Use of open programming interfaces

NOTICE

Data misuse by using open programming interfaces

There is a potential risk of data misuse when using open programming interfaces.

- Therefore, when using open programming interfaces, only use clients that at least communicate with the SINUMERIK Integrate server via "TLS 1.2 /https" communication paths.
- Note that the corresponding TLS version is not supported by every operating system.

System hardening

System hardening is the removal of all software components and functions that are not absolutely required by the desired application to fulfill the intended task.

System hardening of third-party software: Microsoft™ Internet Information Server, Microsoft™ SQL Server, browsers (Microsoft™ Internet Explorer, Mozilla Firefox)

SINUMERIK Integrate requires software from third parties: For example, the Microsoft™ Internet Information Server, Microsoft™ SQL Server products and various browsers. They must be hardened according to the latest technology. In particular, restrict access to the Microsoft™ SQL Server to the local host and protect access with a password. Encrypt access to the database. In addition, you should only use current browsers for communication with the SINUMERIK Integrate server. Secure communication cannot be guaranteed when using outdated browsers (SSL instead of TLS).

System hardening of neighboring products to SINUMERIK Integrate: For example, tool setting station, Teamcenter, AUVESY™ VersionDog

SINUMERIK Integrate communicates with neighboring software products, e.g. tool setting stations, Teamcenter and VersionDog. They must be hardened according to the latest technology so that there are no negative effects via this communication path.

Network file exchange via common drives

Note

Network file exchange via common drives (Server Message Block, SMB)

If you use SMBs for exchanging files with SINUMERIK Integrate functions, only use standard authentication mechanisms (user name / password). Also restrict the accesses for each user accordingly. Data storage on shared drives should be kept to a minimum.

Data backup

For data backup on machine tools, see Section "Data backup (Page 3249)". Also back up the server side. Relevant are the configuration and contents of the Microsoft SQL Server database, the SINUMERIK Integrate server and the following SINUMERIK Integrate applications:

- MMT
- SFT RM
- MMP
- AMC
- AMP

Perform a data backup at the following times:

- After commissioning
- When changing the hardware configuration
- After replacing the hardware
- Before and after upgrading the software

Communication security for SINUMERIK Integrate applications

The communication between the SINUMERIK Integrate server and various client forms (such as MMT or browsers) is preconfigured with HTTP. The required configuration should provide support for service technicians trained specially for SINUMERIK Integrate. If possible, switch the communication to HTTPS, which requires a separate certificate. It should be noted that HTTPS is not possible for all client/server combinations.

Cloud mode

If the AMM and AMC applications are used in cloud operation, the Siemens AG as operator ensures the security of the SINUMERIK Integrate server. Customers only have to ensure the security of the infrastructure on the machine side.

Firewall of the machine network

In contrast to standalone operation, a connection to the cloud server outside the machine and company networks is required when using the SINUMERIK Integrate AMM and AMC applications. The associated firewalls must enable the required ports. However, only the required ports should be opened. Further information on the required firewall settings can be found in the SINUMERIK Integrate Installation Manual, Section "System requirements".

Phishing for passwords

"Phishers" could attempt to obtain login data, which would allow them to carry out actions within SINUMERIK Integrate in the name of the user. Hackers could, for example, falsify e-mails and websites from SIEMENS and thus gain access to confidential information from SINUMERIK Integrate users. The users are then prompted, for example, to enter the access data in a form and then send it to their SINUMERIK Integrate organization.

Note

You should observe the following when you encounter suspicious e-mails:

- Be on your guard when you receive e-mails from someone you do not know, especially if the e-mails include links and attachments. Never open suspicious attachments and do not click on any links in the e-mail.
- Carefully check the sender’s complete e-mail address.
- Check the integrity of the links embedded in the e-mail (e.g. by moving the mouse over the link). Tell-tale signs are spelling mistakes or where links contain a confusing company name.
- Use digital signatures in emails.
- If in doubt, never divulge any confidential information.

Handling of confidential information

The communication route between the company's firewall and the SINUMERIK Integrate server is protected against malicious attacks by secure communication protocols (TLS). Third parties cannot eavesdrop on the transferred information or change it. Also note the company-specific guidelines for the transfer of confidential information via AMM and AMC.

Controller-related applications (In Machine, SINUMERIK Edge)

SINUMERIK Edge

Overview

The SINUMERIK Edge is a remote-controlled edge device that functions as a field gateway as well as a computation node for any user workload within an extended IoT/OT architecture. Thus, SINUMERIK Edge allows a vertical flow of information and data processing between all layers:

- In Machine
- In Line
- In Cloud

This also contains the temporary or permanent saving of process data. SINUMERIK Edge thus has the task, through its security architecture, of not allowing any regression/erosion of the present network security and of the data protection level. In order to not cancel the individual security mechanisms of the SINUMERIK Edge, organizational support is also needed here.

Security features and security measures

The SINUMERIK Edge is equipped with 2 physical network connections (RJ45), which, according to the manual, are to be used for connecting to the In Machine and In Line level. Ensure that the port assignment is correct due to the following reasons:

- The communication for the "In Machine" network is assumed to be unprotected for the most part.
- No uncontrolled connectivity to higher-level networks (In Line, In Cloud) is possible for the "In Machine" network.

Through a multi-level network architecture, the SINUMERIK Edge ensures the isolation of both networks, which is only overcome by an application-defined flow of data. Due to the use of container technology, there are additional mechanisms for isolating the workload (Edge application) with regard to network, memory and CPU resources.

Communication of the SINUMERIK Edge in the direction of "In Cloud" and "In Line" always takes place via an encrypted end-to-end channel (TLS 1.3). Supplemental to this, the integration into a PKI-based trust chain is supported. This ensures both its restriction to only permitted communication partners and a trustworthy transmission. For the In Line exchange of data in environments with special security requirements, client-based authorization via client certificates is also possible.

The initial exchange of the certificates needed for secure communication between the Edge Management System (MindSphere / In Cloud) and SINUMERIK Edge (In Line) takes place during the so-called onboarding procedure. Onboarding includes the exchange of a "shared secret", which connects a logical device (MindSphere asset) with a physical device (SINUMERIK Edge). Since this exchange does not take place via the same communication infrastructure, a compromise can be ruled out as early as the onboarding procedure. A second aspect of the onboarding is the linking/integration of the MindSphere IoT services (Timeseries Store, FileStore, Fleetmanager, etc.) in the correct MindSphere tenants. The SINUMERIK Edge platform also

ensures that no data flow into a tenant or asset that is not defined for this purpose can be established at any time.

Note

The requirement for using SINUMERIK Edge is a MindSphere tenant, including a valid MindAccess account (at least IoT value plan S).

The SINUMERIK Edge only communicates via "outgoing" connections. This means that no exposition of the SINUMERIK Edge on the In Line or In Cloud level is needed. Rather, this scenario is discouraged. Regardless of this configuration, the reachability of the MindSphere end points from the SINUMERIK Edge must be temporarily guaranteed. This concerns onboarding, the firmware update, or the (de)-installation of Edge applications. The SINUMERIK Edge allows applications (Industrial App) to not only provide data via a controlled path In Cloud, but these applications also provide user interfaces and/or interfaces (APIs), to allow new workflows (In Line) or to supplement existing ones. To this end, applications may provide separate user and access management options. The associated security information can be found in the relevant documentation.

Communication of the SINUMERIK Edge with the SINUMERIK only takes place via the "In Machine" network and is encrypted in accordance with the respective protocols. The authorization mechanisms vary depending on the protocol used, however. Since some protocols are protected using weak protection mechanisms, it is important in such cases to adhere to adequate password guidelines and to ensure within an organization that passwords are never saved or are only saved in urgent cases.

The SINUMERIK Edge is also protected against unwanted manipulation or weakening of the security features on both the firmware and application levels by the following features:

- Measured / Secured Boot
- Full Disk Encryption
- Rootless Access

To ensure a high level of security of the SINUMERIK Edge over a long period of time, the firmware is continuously being further developed and hardened. This is required to adapt to the ever intensifying cyber security threat situation. For this purpose, an update mechanism is available as part of the SINUMERIK Edge firmware, which is integrated into the corresponding IT process as part of a continuous security strategy.

4.9.7.3 SIMOTION

SIMOTION security measures

The following section provides an overview of the Industrial Security features available for SIMOTION (Motion Control) in order to protect your plant against threats.

Security functions

- There is only compiled code on the controller by default. For this reason, no upload and consequently no re-engineering is possible.
- No modifications can be made to the configuration without the matching engineering project.
- Know-how protection for source programs with password and encryption.
- Applicative copy protection for the configuration on the control system
- Detection of source code manipulation with the SIMOTION SCOUT engineering system.
- Activating/deactivating unused functions (web server, OPC UA server, ports, etc.)
- Use of the SIMATIC Logon for access to a project only with the appropriate rights.
- Virus scan and security updates for SIMOTION PC-based controllers (SIMOTION P).

A production plant is typically divided into several different network segments. These "segments" are components that have the required security functions connected upstream. They are shown with a padlock symbol in the overview graphic.

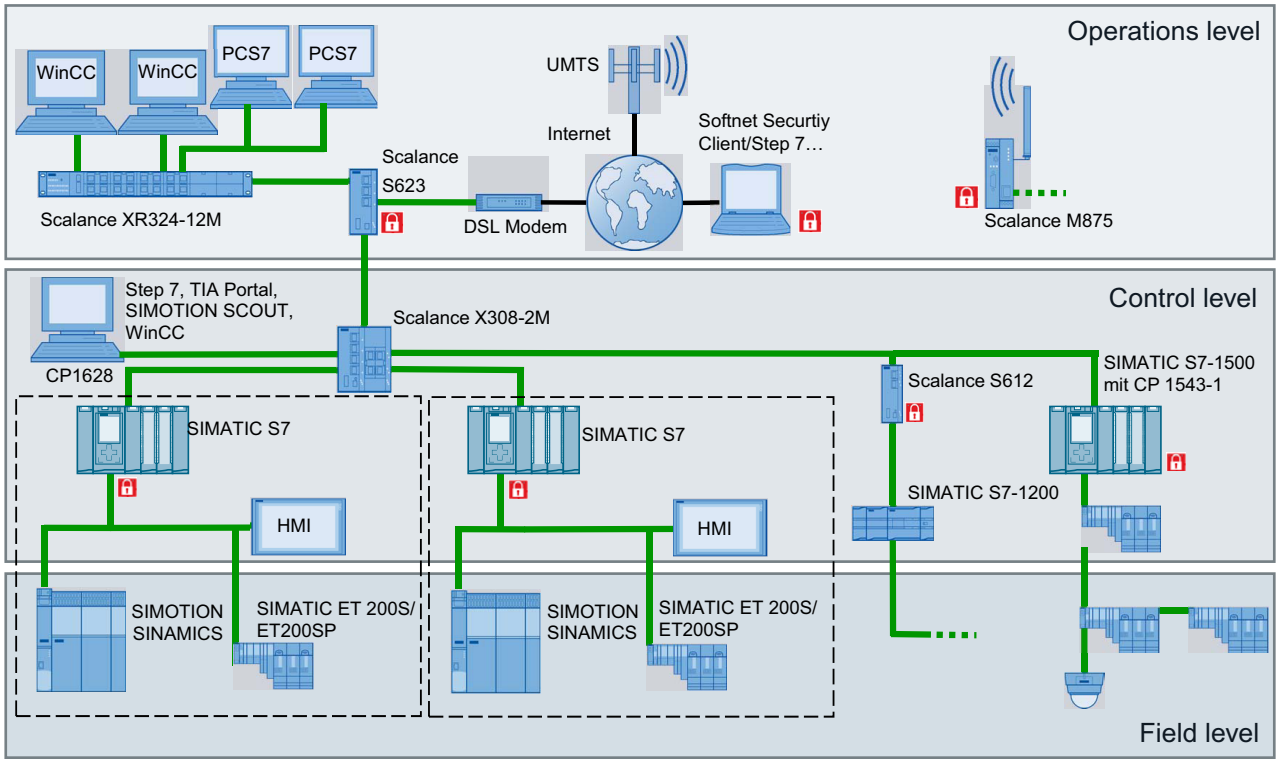

Figure 4-944 Display of a typical production plant with protected areas

Reference

Detailed descriptions and further procedures can be found in the corresponding SIMOTION documentation.

Many products (SINUMERIK, SIMOTION, SINAMICS) contain OpenSSL. The following applies to these products:

- This product contains software (https://www.openssl.org/) that has been developed by the OpenSSL project for use in the OpenSSL toolkit.
- This product contains cryptographic software (mailto:eay@cryptsoft.com) created by Eric Young.
- This product contains software (mailto:eay@cryptsoft.com) developed by Eric Young.

System hardening

Port security

Deactivating hardware ports

As of version 4.4, individual hardware ports of PROFINET interfaces (e.g. X150 interface ports) can be set to **Disable** in the engineering system (HW Config) for SIMOTION devices. This prevents devices being connected without permission and also increases security in terms of third-party access to the system. You should therefore deactivate unused ports.

Note

A SIMOTION device can no longer be accessed via a deactivated PROFINET interface hardware port.

The engineering system and the PN stack ensure that at least one port on each interface is not set to **Disable** to prevent users locking themselves out. The default setting is **Automatic settings**.

Further information

Further information on the logical Ethernet ports and protocols used for SIMOTION can be found in the Communication with SIMOTION System Manual (https://support.industry.siemens.com/cs/de/en/view/109767623), Chapter "Services used".

Virus scan, Windows security patches, SIMOTION P

General information on virus scanners

Once an industrial PC system is connected to the Internet, either directly or via an internal company network, there is a danger that it can become infected with a virus. However, malicious software is not only able to reach the system via the Intranet/Internet, but also, for example, via a removable storage device (such as a USB memory stick) attached to the system for backing up data.

SIMOTION P320 virus scanner

A virus scanner that runs on Microsoft Windows, as used in office or home computers, has a deep impact on a system's processes. There are, for example, processes such as real-time scans or regular system scans. Such interventions can cause performance issues for the system, and as a result, for the SIMOTION Runtime software. Although the SIMOTION Runtime software runs in a real-time environment, it still depends on the available system resources.

Note

Because of the resulting performance impairments, the installation and use of a standard virus scanner on a SIMOTION P320 during system runtime is not permitted.

Using a virus scanner

As a standard virus scanner cannot be used for SIMOTION P320, an alternative procedure is followed. The virus scanner is installed to a separately bootable Windows PE operating system. It is started, for example, from a CD or a USB storage device and then performs a virus scan.

Note

FAQ Service & Support portal

More information on using a virus scanner on a SIMOTION P320 can be found in the FAQ "How can a virus scanner be used on a SIMOTION P3x0?" (https://support.automation.siemens.com/WW/view/en/59381507) which is available as a download from the Service & Support portal.

Secure project storage

Project data storage in SIMOTION SCOUT

All relevant data, configurations and programs are stored in the project. Only the programs and libraries encrypted via the know-how protection can be stored in a project. To protect the entire project, you should protect the project data with conventional office solutions, e.g. password-protected archives or encrypted hard disks.

File structure

The SIMOTION SCOUT project data can come in the following formats:

Engineering data (ES)

- Standard storage: File structure in the project tree
  STEP 7/TIA Portal and SIMOTION SCOUT objects in the project directory. These objects are not secure and can be edited by anyone if there is no know-how protection for programs and libraries or external file encryption is used. Programs in this context programs are synonymous with units, which can contain the programs, function blocks and functions.
- XML data
  Project data created via an XML export/import. The know-how protection is retained.

Runtime data (RT) - data on the CF card

- ZIP archive of the SIMOTION project (not binary).
  The project archive is stored on the memory card of the respective SIMOTION controller (CFAST, CF card, MMC). The archive can be transferred, e.g. via SIMOTION SCOUT or using standard methods (FTP transfer).
- Binaries (zipped, unzipped)
  Binaries contain the compiled, executable project with the configurations and applications. Changes cannot be made during runtime without the SIMOTION SCOUT project because the project is stored as binary data on the SIMOTION controller.

The following figure shows an example of possible project data storage with display of the protected data.

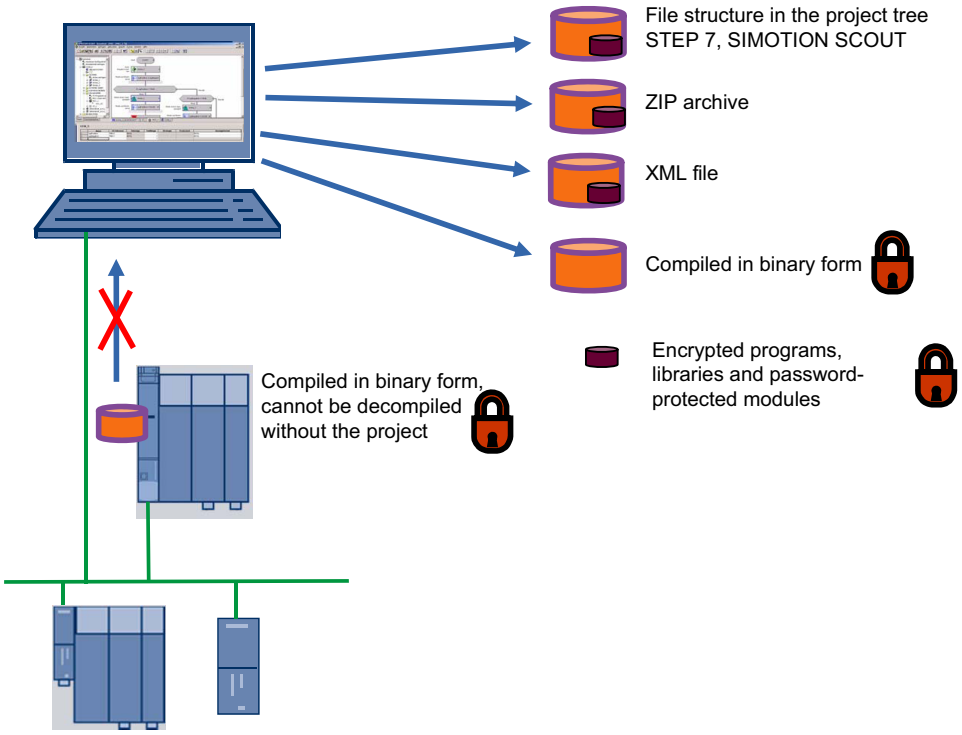

Figure 4-945 SIMOTION SCOUT project data storage

Know-how protection

Secure access control with SIMATIC Logon

User administration and traceability

The SIMATIC Logon option package is used to set up access rights for products and libraries in STEP 7. These projects can therefore only be accessed by an authorized group of people. SIMATIC Logon can be used in conjunction with SIMOTION SCOUT.

SIMATIC Logon supports the following functions:

- Assignment of individual authorization levels to users or user groups for the execution of specific actions (e.g. read, write, transfer blocks).
- Logging of online activities and logon actions on the computer. Access and changes in the project are reproducible.
- Assignment of authorization to users / user groups only for a limited time.
- Password aging strategies

Change log

A change log can be recorded when the access protection is activated. This includes, for example:

- Activation
- Deactivation
- Configuration of access protection and the change log
- Opening and closing of projects and libraries including their download to the target system as well as activities to change the operating state

Know-how protection in engineering

Know-how protection types

The know-how protection in SIMOTION SCOUT prevents unauthorized viewing and editing of your programs. Multiple logins are possible. The standard login can be set for the engineering session.

A distinction is made between two types of know-how protection:

- Know-how protection for programs and libraries
- Know-how protection for drive units (as of SINAMICS V4.5)

You set a login and a password under **Project -> Know-how protection**. The know-how protection for the program is activated via the **Set** menu command. The programs contained in the project are still visible to the user in this session, but the program names are displayed with a padlock symbol.

Programs and libraries

The know-how protection protects the programs and libraries in your project. Unauthorized viewing and editing of your programs is prevented when the know-how protection is activated. You can set the know-how protection for individual programs or for all programs in a project.

Access protection and encryption can be set in several levels for the following types of data:

- Programs (units in Structured Text (ST), Motion Control Chart (MCC) and LAD/FBD that contain programs, function blocks, and functions)
- Drive Control Charts (DCC)
- Libraries

You can select three different security levels for the encryption:

- **Standard**
  Access only with user login and password (backward compatible with versions before V4.2).
- **Medium**
  Improved coding of the password (due to a new procedure, no backward compatibility without knowledge of the password).
  Programs and libraries can be recompiled at any time even without knowledge of the password.
- **High** (only for ST source files in libraries)
  Compilation is only possible after the password has been entered.
  Protected libraries can also be used after an export without knowledge of the password, because in this case the compilation result is also exported.
  - **An export without source texts is also possible when exporting libraries**
    Highest protection. Complete removal of the source texts in the engineering upon export. The export only contains the compilation result (recompilation no longer possible).

The block interfaces are always visible.

Drive units in SIMOTION SCOUT

The know-how protection for drive units only applies online and is used to protect intellectual property, in particular, the know-how of machine manufacturers, against unauthorized use or reproduction of their products.

A detailed description can be found in Chapter Know-how protection (Page 3271).

Copy protection for the configuration on the control system.

Copy protection for SIMOTION projects

Measures can be taken to tie the configuration to the memory card or the controller. This prevents illegal duplication of the configuration.

The serial numbers of the CPU, memory card and DRIVE-CLiQ components in the application can be queried via system functions. This enables the machine manufacturer to create a block with an encryption algorithm which generates a key from the currently installed serial numbers during runtime and compares it with a machine key. Each machine configuration has a specific machine key which is generated by the machine manufacturer and stored in the application, and which can be entered by the end customer, for example, via the HMI, particularly during maintenance work.

In addition, special agreements can also be made regarding extended know-how protection and copy protection through the use of a SIMOTION Open Architecture technology package.

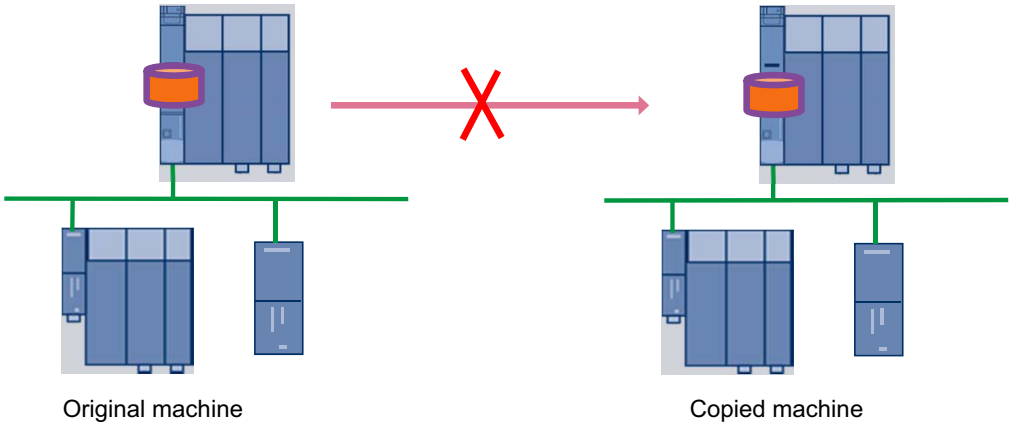

Figure 4-946 Copy protection of binary SIMOTION SCOUT projects

Offline/online comparison

Project comparison

You can use the SIMOTION SCOUT/STARTER **Project comparison** function (start this via the **Start object comparison** button) to compare objects within the same project and/or objects from different projects (online or offline).

The offline/online comparison is used to detect in detail any subsequent manipulations of the project data on the plant in comparison to your secured engineering data. Thus you check if any unauthorized third parties accessed the system.

The following comparisons are possible:

- Offline object with offline object from the same project
- Offline object with offline object from a different project
- Offline object with online object

The project comparison in SIMOTION SCOUT contains all objects in a project, such as SIMOTION devices, drive units, libraries, programs (units), technology objects, I/Os as well as the configuration of the execution system.

The offline/online comparison provides support for service jobs or for detecting changes to the project data.

It may, for example, be the case that inconsistencies are indicated when you switch to online mode in the project navigator, i.e. there are deviations between your project in SIMOTION SCOUT and the project loaded into the target system.

Possible causes can include, for example:

- A program has been changed
- The result of compiling a program is different
- There is a deviation on the global device variables
- The execution system has been changed

- The hardware configuration has been changed
- A library has been changed
- A configuration data item for an axis has been changed

The object comparison allows you to establish these differences and, if necessary, run a data transfer to rectify the differences.

Detailed offline/online comparison

You can determine specific differences between the offline and the online project by performing a complete project comparison. If there are discrepancies, you can determine the changes/ manipulation to the source code down to the program line level, when the additional information (source information) has also been stored on the target system during the download. This is also possible with the LAD/FBD and MCC graphical programming languages.

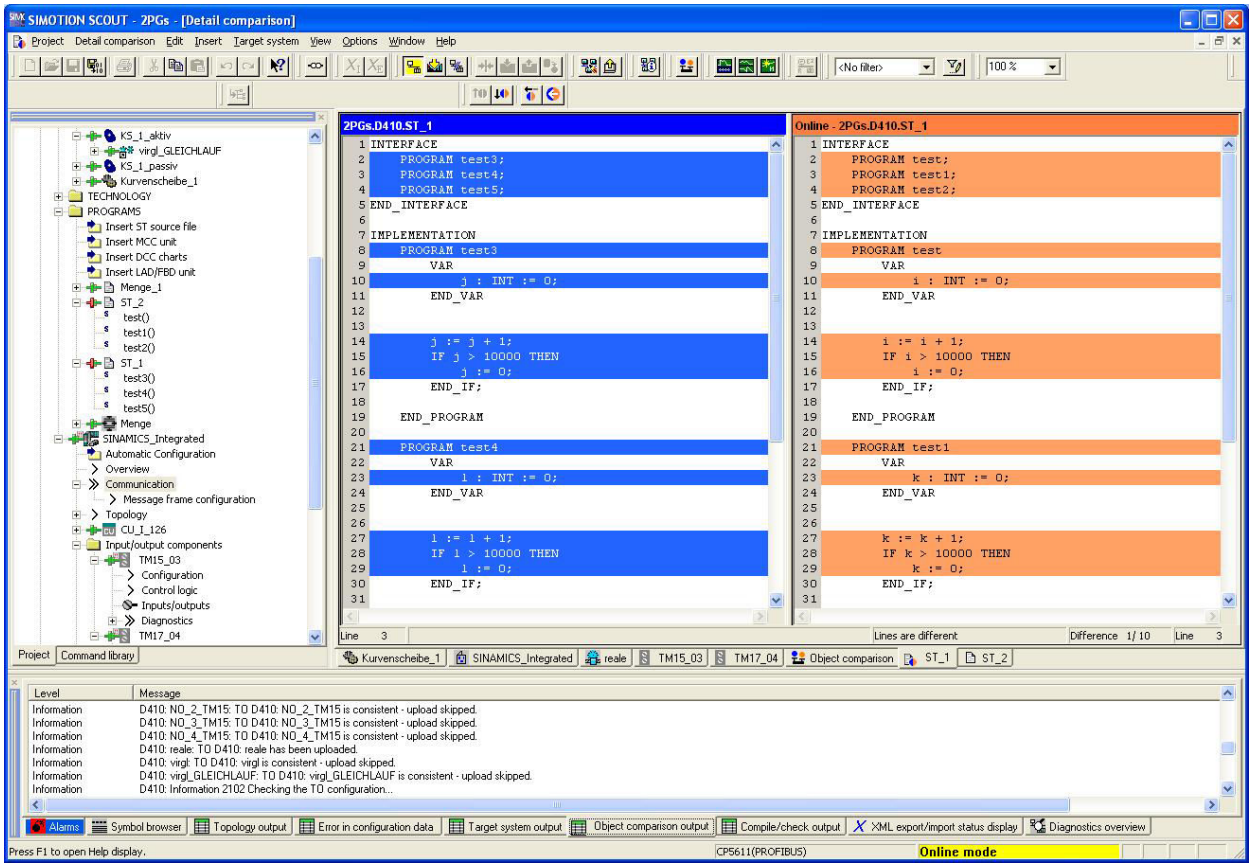

Figure 4-947 Example of ST detail comparison

SIMOTION IT Web server

Introduction

SIMOTION devices provide a Web server with preprepared standard websites. These websites can be displayed via Ethernet using a commercially available browser. Additionally, you have the option of creating your own HTML websites and incorporating service and diagnostic information. The web server can be deactivated. If the Web server is active, secure operation of the plant can be ensured via the integrated security concept and the user administration.

Deactivating/activating the Web server

The Web server with all functions and services can be activated or deactivated in the SIMOTION SCOUT or SIMOTION SCOUT TIA project under the hardware configuration of the controller. You can activate or deactivate individual functions.

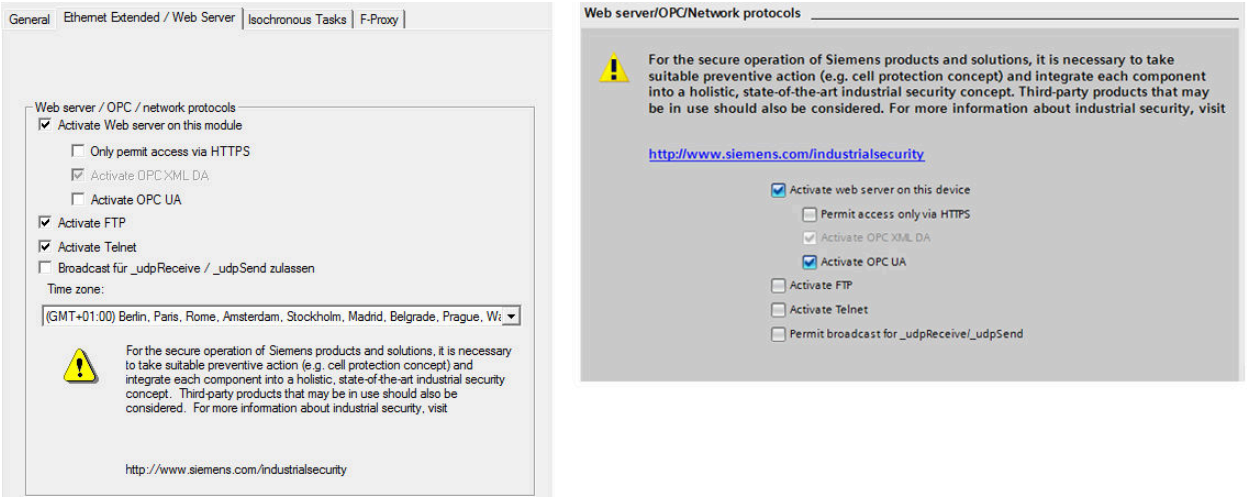

Figure 4-948 **Activating the SIMOTION IT Web server functions in SIMOTION SCOUT or SIMOTION SCOUT TIA**

Note

To activate the Web server, you must establish a user administration scheme with password-protected user access.

Security concept of HTTP/S, FTP and Telnet access on the Web server

As of version V4.4, access to the SIMOTION IT Web server is protected by a multi-level security concept.

The security status of the Web server is indicated by the security level on the website. This security level can have three different levels: Low, Normal, High

Security Level Low

The device is supplied with an empty user database. No projects exist yet. The security level is low to allow configuration of the device.

- In this state, access to the Web server as an anonymous user is possible to enable use of functions such as the project and firmware update or OPC XML.
- FTP and Telnet access are also possible.
- New users can be entered in the empty user database.

Security Level Normal

The controller has a user database. A project exists on the controller and HTTP, HTTPS, FTP, and Telnet are activated in the hardware configuration.

- User password authentication is required for access to websites with sensitive content (e.g. firmware update, watch table, etc.), FTP and Telnet.

As soon as a project has been loaded to the controller, Security Level Normal is active, with an empty user database as required. Standard websites are still visible. All other websites can only be accessed with the necessary authentication.

Security Level High

High security with maximum access protection:

- HTTP, HTTPS, FTP and Telnet have been deactivated via the project in the hardware configuration. Access to the Ethernet via the various ports of the services is then no longer possible. The Web server cannot be used.

User management

SIMOTION IT uses a user database to safeguard access to a device. The groups are stored in the user database along with their assigned users. The defined user groups can be assigned access rights to the individual Web server websites. The Web server is accessed after the authentication.

Authentication

- There are users (USERs).
- Each user has a password. This is encrypted.
- Users belong to groups (GROUP).
- Websites, directories, and applications are protected by secure areas defined for each group.
- Only users that belong to the secure area can access the protected website.
- Each secure area has a group of users who have access authorization.
- A user can belong to different groups.

Encrypted data transfer (HTTPS)

The Web server can be accessed via an HTTP as well as an HTTPS connection. The Secure Socket Layer protocol (SSL) in HTTPS enables encrypted data transmission between a client (browser) and the SIMOTION controller (Web server). Secure transmission can be forced by deactivation of the HTTP port for security reasons.

Certificates must be generated and installed for encrypted communication between the browser and the Web server. A device comes supplied with a standard root certificate and a private key of the Web server as a file. These files should be replaced with your own to increase the security of HTTPS access to the device.

Key files

- Delivery state
  In order for you to be able to access the SIMOTION controller via the SIMOTION IT diagnostics standard websites (in their delivery state) via HTTPS, a root certificate and a private key are supplied as a file on the device.
- Creating the SSL certificate yourself
  With the help of the Perl Tool and the supplied Perl Script (cert.pl), the certificates required for customer facilities (sites) can be generated and tied together to form loading packages.

There are two ways of acquiring your own server certificate (SSL certificate):

- Create a root certificate (self-signed) and a private key using a certificate software.
- Purchase a server certificate from a certificate authority.

Importing the SSL certificate into the browser

If you use SSL with your own certification authority, you will need to prepare your PCs for communication with the SIMOTION controller. To do this, the root certificate must be added to the list of certificates in your browser.

Further information

Further information on the SIMOTION IT web server can be found in the following documentation:

- SIMOTION IT Diagnostics and Configuration Diagnostics Manual (https://support.industry.siemens.com/cs/de/en/view/109767636)
- SIMOTION IT OPC UA Programming Manual (https://support.industry.siemens.com/cs/de/en/view/109767638)
- AUTOHOTSPOT
- SIMOTION IT Virtual Machine and Servlets Programming Manual (https://support.industry.siemens.com/cs/de/en/view/109767639)

See also

SIMOTION IT Programming and Web Services Programming Manual (https://support.industry.siemens.com/cs/de/en/view/109767637)

OPC UA server

Introduction

SIMOTION has implemented an OPC UA server with DA (Data Access).

OPC UA binary encoding is supported. Access to an arbitrary OPC UA client can be protected via authentication and encrypted data transfer.

Configuration

Note

Before connecting to the OPC UA server, ensure that the environment is secure and install a hardware-based intermediate layer (e.g. DMZ network, firewall, SCALANCE S modules, etc.).

The OPC UA server can be activated or deactivated via HW Config from TIA Portal or STEP 7.

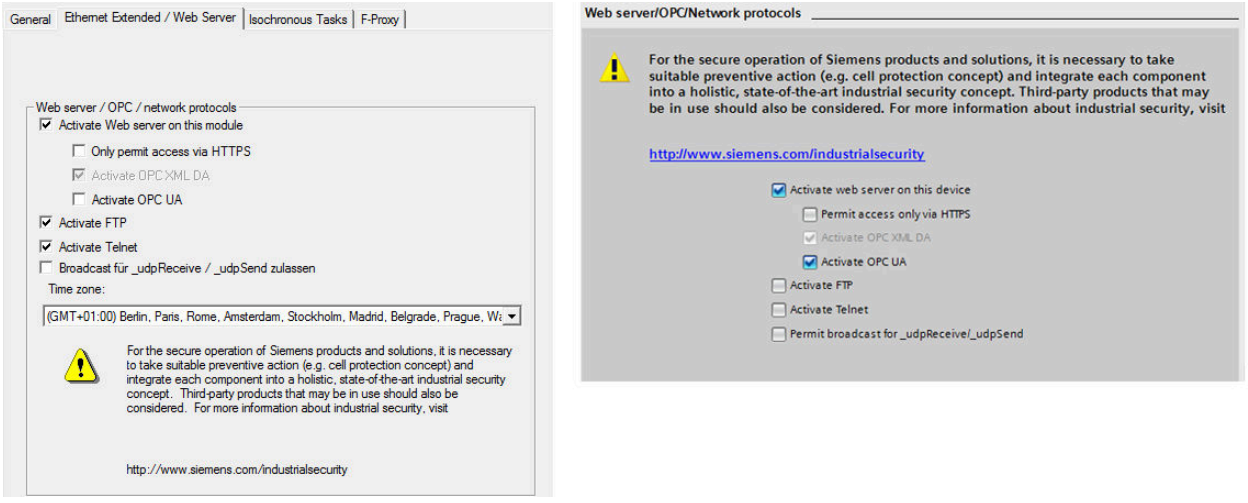

Figure 4-949 Activating the SIMOTION IT Web server functions in SIMOTION SCOUT or SIMOTION SCOUT TIA

Further settings are made via the SIMOTION IT Web server configuration masks:

- Enabling of the Ethernet interface and associated port of SIMOTION for the OPC UA access.
- Definition of the user name, password and user group as part of the user administration of the SIMOTION IT Web server.
- Handling of the certificates for the encryption of the data transfer.

Further information

Further information on the OPC UA server can be found in the SIMOTION IT OPC UA Programming Manual (https://support.industry.siemens.com/cs/de/en/view/109767638).

Disposal

NOTICE
Data misuse Unsafe disposal of the storage media (CF card/CFast/SSD) can lead to misuse of the data of the part programs, archives, etc. by third parties. • Therefore, ensure that the data on the storage media that is used is securely deleted before disposing of the product. Use programs that support you in securely deleting/formatting storage media.

4.9.7.4 SINAMICS

The following chapter provides you with an overview of the Industrial Security features available for SINAMICS to protect your converters from threats. In the following, you will find topics which you should pay special attention to regarding Industrial Security:

- Write and know-how protection
- Parameters: Access levels
- Using the memory card
- Note on Safety Integrated
- Communication services and used port numbers
- Web server
- Information about individual interfaces
- SINAMICS Startdrive and STARTER
- SINAMICS Drive Control Chart (DCC)

Detailed descriptions and procedures can be found in the corresponding SINAMICS documentation.

Many products (SINUMERIK, SIMOTION, SINAMICS) contain OpenSSL. The following applies to these products:

- This product contains software (https://www.openssl.org/) that has been developed by the OpenSSL project for use in the OpenSSL toolkit.
- This product contains cryptographic software (mailto:eay@cryptsoft.com) created by Eric Young.
- This product contains software (mailto:eay@cryptsoft.com) developed by Eric Young.

Network security

Note

SINAMICS products may only be used in a secure and trusted network. Observe the information on this topic in Chapter "Network segmentation (Page 3224)".

Know-how protection

Some SINAMICS converters provide you with a "Know-how protection" function: This function offers you protection of your intellectual property, especially the know-how of machine manufacturers against unauthorized use, modification or reproduction of their products.

Effect

Adjustable parameters which are not recorded in an exception list can neither be read nor written.

Exceptions

- The know-how protection does not affect parameters that are provided with the following attributes:
  - KHP_WRITE_NO_LOCK
    - These parameters are excepted from the know-how protection and can therefore be written to despite the know-how protection.
    - For a list of these parameters, see the List Manual of the respective product.
    - These parameters are not included in the exception list.
  - KHP_ACTIVE_READ
    - These parameters can also be read, but not written, with activated know-how protection.
    - For a list of these parameters, see the List Manual of the respective product.
    - These parameters are not included in the exception list.
- Know-how protection does not prevent the execution of certain functions:
  - In particular, the "Restore factory settings" function is still possible despite know-how protection.
  - For a full list of executable functions, please refer to the following references.

Further information

For more information on this topic, see the following references:

- SINAMICS S120 Drive Functions Function Manual (https://support.industry.siemens.com/cs/de/en/view/109763287)
  Chapter "Know-how protection"
- SINAMICS G110M operating instructions (https://support.industry.siemens.com/cs/de/en/view/109757594)
  Chapter "Know-how protection"
- SINAMICS G120 Operating Instructions
  Chapter "Know-how protection"

- SINAMICS S and SINAMICS G List Manuals
  Section "Parameters for write protection and know-how protection"
- SINAMICS G130, G150 and S150 Operating Instructions
  Chapter "Know-how protection"

Parameters: Access levels and password

For the G110M, G120, G130, G150, S110, S120 and S150 series devices, the SINAMICS parameters are divided into the access levels 0 to 4. With the aid of the access levels, you can specify which parameters can be modified by which user or input/output device:

- With the aid of parameter p0003, you can specify which access levels you can select with the BOP or IOP.
- Parameters of access level 4 are password-protected and only visible for experts up to SINAMICS RT V4.9.

The SINAMICS S and SINAMICS G List Manuals specify in which access level the parameter can be displayed and changed.

  Chapter "Parameters"

Using the memory card

The memory card must be handled with particular care for all SINAMICS devices that use a memory card so that no malicious software or erroneous parameterizations are spread between different commissioning PCs or inverters.

⚠ WARNING

Risk of death due to software manipulation when using exchangeable storage media

Storing files onto exchangeable storage media amounts to an increased risk of infection of the commissioning PCs, e.g. with viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect files stored on exchangeable storage media from malicious software using appropriate protection measures, e.g. virus scanners.

⚠ WARNING

Risk of death due to software manipulation when using exchangeable storage media

Storing the parameterization (incl. Safety Integrated parameterization) on exchangeable storage media carries the risk that the original parameterization (with Safety Integrated) will be overwritten, for example, by the memory card of another drive without Safety Integrated. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Ensure that only the memory card that belongs to the respective inverter is used.
- Ensure that only trained or authorized personnel have access to the enclosures, cabinets or electrical equipment rooms.

Safety Integrated

To actually reduce the risk for machines and plants through the use of Safety Integrated functions, working with Safety Integrated functions requires special care for all SINAMICS devices that have it.

⚠ DANGER

Unexpected movement of machines caused by inactive safety functions

Inactive or non-adapted safety functions can trigger unexpected machine movements that may result in serious injury or death.

- Observe the information in the appropriate product documentation before commissioning.
- Carry out a safety inspection for functions relevant to safety on the entire system, including all safety-related components.
- Ensure that the safety functions used in your drives and automation tasks are adjusted and activated through appropriate parameterizing.
- Perform a function test.
- Only put your plant into live operation once you have guaranteed that the functions relevant to safety are running correctly.

Note

Important safety notices for Safety Integrated functions

If you want to use Safety Integrated functions, you must observe the safety instructions in the Safety Integrated manuals.

Communication services and used port numbers

SINAMICS converters support specific communication protocols. The address parameters, the relevant communication layer, as well as the communication role and the communication direction are decisive for each protocol. You require this information to match the security measures for the protection of the automation system to the used protocols (e.g. firewall). Some of the security measures described here are restricted to Ethernet and PROFINET networks.

For detailed information on this topic, see the following references:

- SINAMICS S120
  - Starting from firmware Version 5.2
    SINAMICS S120 Communication Function Manual (https://support.industry.siemens.com/cs/ww/en/view/109771803)
  - Older firmware versions
    SINAMICS S120 Drive Functions Function Manual (https://support.industry.siemens.com/cs/de/en/view/109771805)
  - Including: Section "Communication services and used port numbers"
- SINAMICS G Function Manual Fieldbuses (https://support.industry.siemens.com/cs/ww/de/view/109757336/en)
  Section "Ethernet and PROFINET protocols that are used"
- SINAMICS G130, G150 and S150 Operating Instructions
  Chapter "Communication services and used port numbers"

Integrated web server

The SINAMICS web server provides information on a SINAMICS device via its websites. This is accessed via an Internet browser.

Data transfer

In addition to the normal (unsecured) transmission (http), the Web server also supports secure transmission (HTTPS). Secure transmission (HTTPS) is the recommended setting.

Note

Smart Access Module

The web server of the Smart Access Module does not support secure transmission (HTTPS). Alternatively, you can use an encrypted WLAN transmission.

By entering "HTTP://" or "HTTPS://" in front of the address of the drive, you can decide yourself whether normal or secure transmission is used to access the data.

For safety reasons, secure transmission can be forced by deactivation of the http port.

Access rights

The normal protection mechanisms of SINAMICS also apply for access via the web server, including password protection. Further protective mechanisms have been implemented especially for the Web server. Different access options have been set for different users, depending on the function. The parameter lists are protected so that only users with the appropriate rights can access or change the data.

Further information

For detailed information on this topic (e.g. the supported Internet browsers), see the following references:

- SINAMICS S120 Drive Functions Function Manual (https://support.industry.siemens.com/cs/de/en/view/109763287)
  Section "Web server"
- SINAMICS S210 Operating Instructions (https://support.industry.siemens.com/cs/ww/en/view/109771824)
- SINAMICS V20 Operating Instructions (https://support.industry.siemens.com/cs/de/de/view/109768394/en)
- SINAMICS G120 Smart Access Operating Instructions (https://support.industry.siemens.com/cs/ww/en/view/109771299)
- SINAMICS G130, G150 and S150 Operating Instructions

Certificates for the secure data transfer

Protecting the HTTPS access

The "Transport Layer Security" (TLS) protocol enables encrypted data transfer between a client and the SINAMICS drive. HTTPS access between the browser and the drive is based on Transport Layer Security.

The encrypted variant of communication between the browser and the Web server using HTTPS requires the creation and installation of certificates (default configuration, self-created certificates or server certificates from a certification authority).

TLS

Transport Layer Security (TLS V1.2 or higher) is a hybrid encryption protocol for secure transfer of data in the Internet.

Key files

You need 2 key files (a public certificate and a private key) for the encryption method used by the Transport Layer Security.

Certificate handling

The necessary certificate and key is generated on the drive so that you can access the drive via HTTPS in the SINAMICS as delivered. For this reason, the firmware certificate should only be used in secure networks (e.g. PROFINET below a PLC) or for direct point-to-point connections on the service interface X127.

Instead, use a certificate confirmed by an external certification center. The references cited in the following contain a detailed description of the procedure.

Further information

For detailed information on this topic, see the following references:

- SINAMICS S120 Drive Functions Function Manual (https://support.industry.siemens.com/cs/de/en/view/109771805)
  Section "Certificates for the secure data transfer"
- SINAMICS G130, G150 and S150 Operating Instructions

Information about individual interfaces

X127 LAN (Ethernet)

Ethernet interface X127 is intended for commissioning and diagnostics, which means that it must always be accessible. Note the following restrictions for the X127 interface:

- Only local access is possible
- No networking or only local networking in a locked control cabinet permissible

If you require remote access to the control cabinet, then you must apply additional security measures so that misuse through sabotage, data manipulation by unqualified persons and intercepting confidential data are completely ruled out.

X140 serial interface (RS232)

You connect an external HMI device for operator control/parameter assignment via the serial interface X140.

NOTICE
Access to the inverters only for authorized personnel Unauthorized persons may be able to damage or alter production equipment as a result of gaps in a company's physical security. Confidential information can also be lost or altered as a result of this. You can prevent this if you protect the company site and the production areas accordingly. • You can find information on suitable protective measures in Section "Physical protection of critical production areas (Page 3222)".

X150 LAN (Ethernet)

The network with which interface X150 is connected must be separated from the rest of the plant network in accordance with the Defense in Depth concept (see Chapter "General security measures (Page 3220)"). Access to cables and possibly open connections must be implemented in a protected fashion, as in a control cabinet.

X1400 LAN (Ethernet)

The network with which interface X1400 is connected must be separated from the rest of the plant network in accordance with the Defense in Depth concept (see Chapter "General security measures (Page 3220)"). Access to cables and possibly open connections must be implemented in a protected fashion, as in a control cabinet.

Further information

For detailed information on this topic, see the following references:

- SINAMICS S120
  - SINAMICS S120 Control Units and Additional System Components Equipment Manual (https://support.industry.siemens.com/cs/de/en/view/109763286)
    Section on the respective interfaces
  - Starting from firmware Version 5.2: SINAMICS S120 Communication Function Manual (https://support.industry.siemens.com/cs/ww/en/view/109771803)
  - Older firmware versions:
    SINAMICS S120 Drive Functions Function Manual (https://support.industry.siemens.com/cs/de/en/view/109763287)
- SINAMICS G and SINAMICS S Operating Instructions
- SINAMICS V90 Operating Instructions

Disposal

NOTICE

Data misuse resulting from unsafe disposal of the product

Unsafe disposal of the product can lead to misuse of the parameter data by third parties.

- Therefore, before disposal, restore all the parameters to the factory settings.

You can find further information on restoring the factory settings in the Function Manual or Operating Instructions of the respective product.

NOTICE

Data misuse resulting from unsafe disposal of the memory card

Unsafe disposal of the memory card can lead to misuse of the data etc. by third parties. Among other things, the data backups required for operating the converter are located on the memory card.

- Therefore, ensure that the data on the memory card is securely deleted before disposing of the product. There are programs that support you in securely deleting/formatting the memory card.
- This concerns all products that have a memory card.

Note

Deleting user-defined certificates

Make sure you securely remove all user-defined certificates before disposing of a SINAMICS product. A hacker can use your certificates to gain access to your protected data transmission.

- Products with memory card
  - Delete the files SINAMICS.key and SINAMICS.crt from the directory OEM\SINAMICS\WEB\WEBCONF\CERT on the memory card.
- Products with optional memory card (e.g. SINAMICS S210)
  - Create empty files ("SINAMICS.key" and "SINAMICS.crt") with the corresponding file names.
  - Copy these files to the memory card.
  - Insert the memory card into the converter.
  - Restart the converter.
  - Alternatively, when you no longer need data from the memory card: reformat the memory card.

You can find further information in the Function Manual or Operating Instructions of the respective product.

SINAMICS Startdrive and TIA Portal

Malfunctions of the machine as a result of incorrect or changed parameterization

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameter settings against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

SINAMICS Startdrive

Startdrive in the TIA Portal

SINAMICS Startdrive is an option package in the TIA Portal with which SINAMICS drives are commissioned. With regard to Industrial Security, you must consider the corresponding specifications for SINAMICS drives and for the TIA Portal.

In addition to the commissioning of single drives, you can also use Startdrive to configure drives on SIMATIC control systems such as the S7-1500. Information on how to proceed with SIMATIC controllers can be found in the TIA Portal online help at "Configuring networks".

Commissioning computer

Ensure the security of the commissioning computer. Follow the general security measures (Page 3220) for this purpose.

Device know-how protection

- You can protect the parameterization of your drive from unauthorized access via the "know-how protection" function.
- The function is only available online.
- Device know-how protection is supported as of Startdrive V16.

Security functions

- Activation/deactivation of unused functions (web server, ports)
- Write protection for the parameter assignment, p-parameters are readable, but not writeable, protects against unintentional changes to the parameter assignment (only available online).

Protecting backup files in the Windows file system

If you create backup files of charts or projects with Windows tools, also protect these files with Windows tools against unauthorized access using secure passwords. The Startdrive project itself is protected for integrity.

Scripting (Openness)

Scripts (Openness) are used for automating sequences in Startdrive. You must therefore test the scripts before using them on machines.

⚠ WARNING

Risk due to incorrect configurations for automated operating actions

Scripting provides the extensive automation options that are required to be able to automate manual operator actions in the Startdrive tools and therefore to optimize the time required for the recurring configuration of projects and tasks.

The script programmer and the script user are responsible for the operator actions implemented in scripting.

Incorrect configurations that are not discovered in tests can result in serious physical injury or death.

- Run systematic tests on new and modified scripts to verify and validate them.
- Before running a script, make sure it has the correct content. Verify and validate the results of script execution by tests on the machine.

As for DCCs, scripts can also be protected via know-how protection.

SINAMICS STARTER

Commissioning drives with STARTER

Drives of the MICROMASTER and SINAMICS families can be commissioned with STARTER. An integrated version of STARTER is contained in SIMOTION SCOUT. For information on SIMOTION SCOUT, see "SIMOTION (Page 3257)".

Commissioning computer

Ensure the security of the commissioning computer. Follow the general security measures (Page 3220) for this purpose.

Protecting backup files in the Windows file system

If you create backup files of charts or projects with Windows tools, also protect these files with Windows tools against unauthorized access using secure passwords.

Security functions

- Know-how protection for the parameter assignment, scripts and DCCs and DCC libraries with password and encryption
- Copy protection for the configuration on the drive unit. The project can only be opened together with the original card.
- Detection of parameter manipulation with STARTER via the project comparison, see also "Offline/online comparison (Page 3264)"
- Activation/deactivation of unused functions (web server, ports), see also "Integrated web server (Page 3274)"
- Write protection for the parameter assignment, p-parameters are readable, but not writeable, protects against unintentional changes to the parameter assignment (only available online).

Know-how protection for drive units

In addition to the know-how protection for DCCs, DCC libraries and scripts, you can also protect the parameter assignment of your drive against unauthorized access via the know-how protection for the drive. The function is only available online. See also "Know-how protection (Page 3271)".

Scripting

Scripts are used for automated execution in STARTER. You must therefore test the scripts before using them on machines.

⚠ WARNING

Risk due to incorrect configurations for automated operating actions

Scripting provides the extensive automation options that are required to be able to automate manual operator actions in the STARTER/SCOUT tools and therefore to optimize the time required for the recurring configuration of projects and tasks.

The script programmer and the script user are responsible for the operator actions implemented in scripting.

Incorrect configurations that are not discovered in tests can result in serious physical injury or death.

- Run systematic tests on new and modified scripts to verify and validate them.
- Before running a script, make sure it has the correct content. Verify and validate the results of script execution by tests on the machine.

As for DCC charts, scripts can also be protected via know-how protection.

SINAMICS Drive Control Chart (DCC)

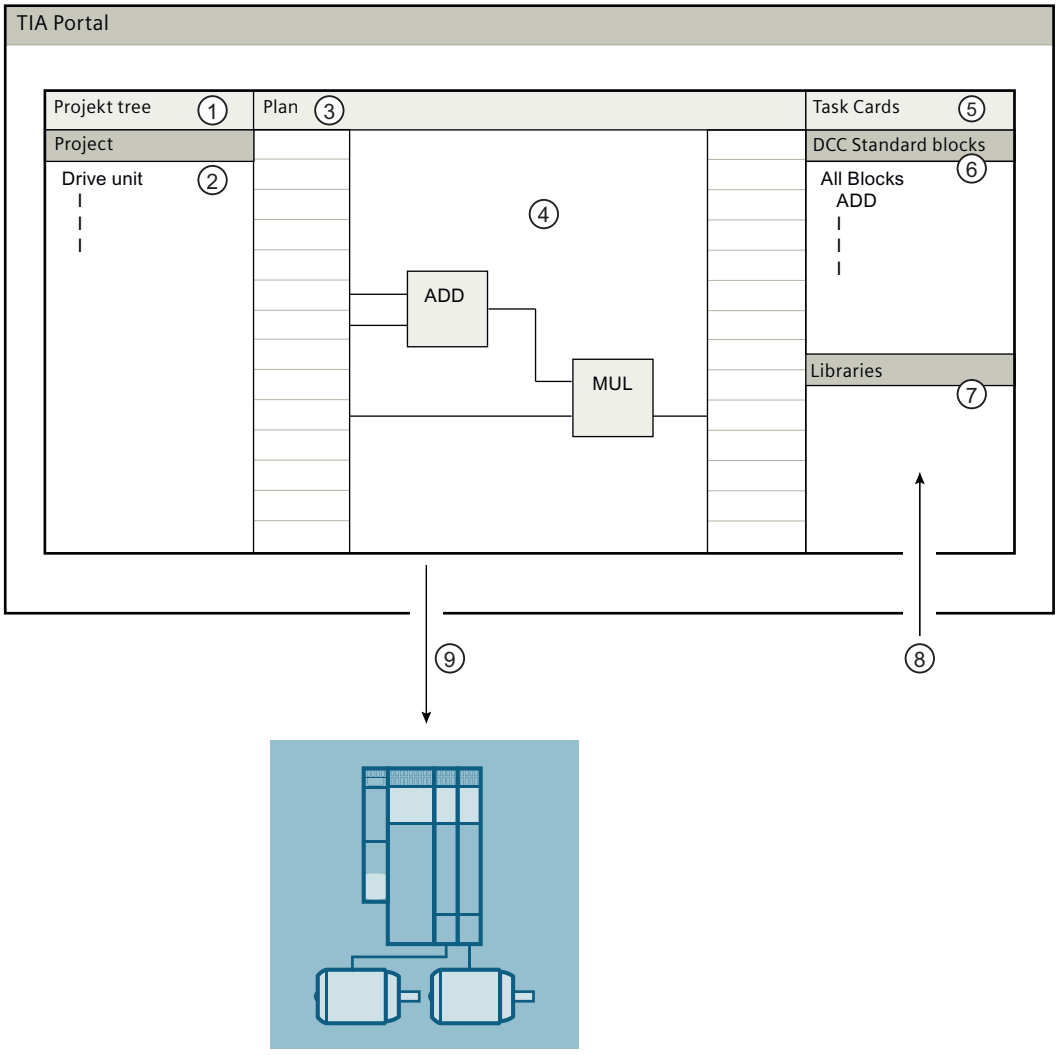
Industrial security with SINAMICS DCC

Overview

SINAMICS Drive Control Chart (DCC) offers a modular, scalable technology option, which has chiefly been developed for drive-related, continuous open-loop and closed-loop control engineering tasks within the drive.

With the Drive Control Chart Editor based on CFC, you configure the technology functions with DCC for SINAMICS drives graphically.

- Startdrive
  The following figure shows the data flow of the configuration data when configuring with SINAMICS DCC:



① Loading
② Import of DCB libraries

Figure 4-950 Flow of configuration data: TIA-DCC

- STARTER
  The following figure illustrates the data flow of the configuration data when configuring with SINAMICS DCC and the ways to protect the configured/programmed DCC sources:

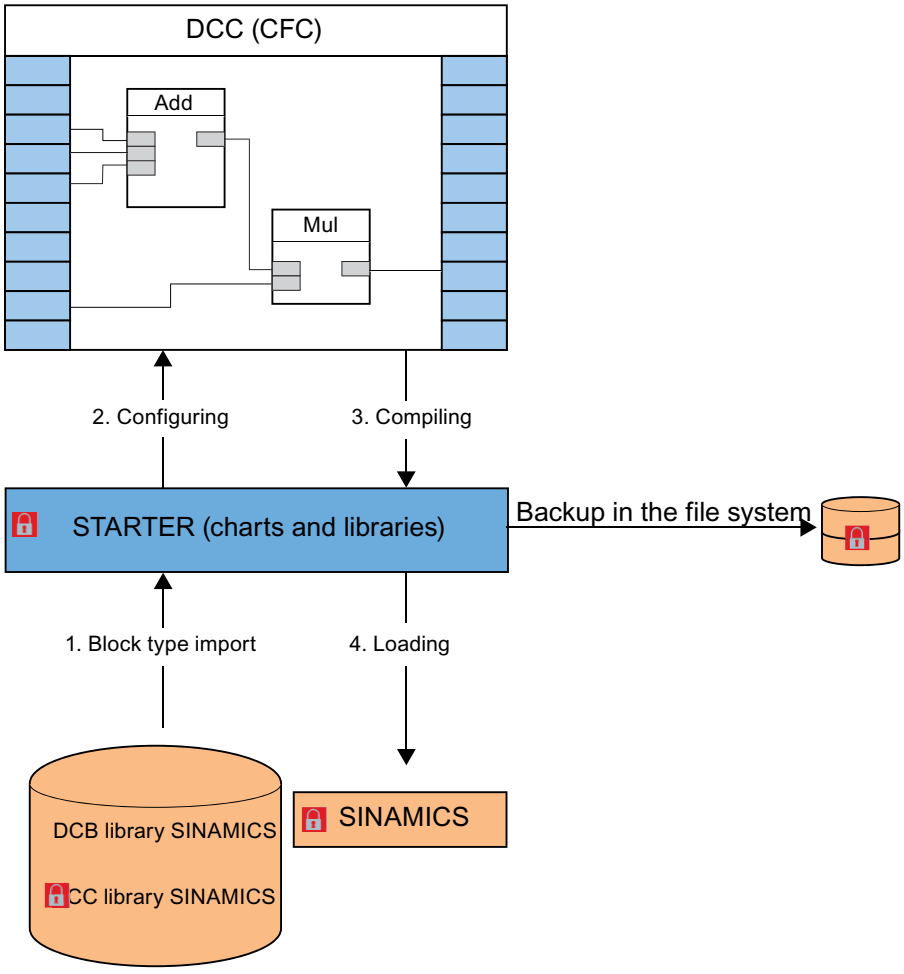


Figure 4-951 Flow of configuration data: Example for DCC Classic V2.1 ... V3.4 (STARTER)

Startdrive: Option package DCC

Note the following special features regarding Startdrive:

- DCC does not provide a backup in the file system.
- The DCB libraries used are loaded implicitly with the project into the target device
- DCC does not offer any chart know-how protection

Commissioning computer

Ensure the security of the commissioning computer. Follow the general security measures (Page 3220) for this purpose.

Using know-how protection

DCCs, DCC libraries, programs and backup files are subject to an increased risk of manipulation. Therefore, use the know-how protection, the write protection for drive units and the know-how protection for DCC charts and DCC libraries in STARTER, see also Use write and know-how protection (Page 3285).

Information on know-how protection can also be found in the "Motion Control SINAMICS/ SIMOTION Editor Description DCC" Programming and Operating Manual.

Protecting backup files in the Windows file system

If you create backup files of charts or projects with Windows tools, also protect these files with Windows tools against unauthorized access using secure passwords.

Note the information on SINAMICS and on the engineering systems

Also note the Industrial Security information for SINAMICS drives and engineering systems with which SINAMICS drives are commissioned. Particularly the information on network security is important, see also Network security (Page 3223).

Use write and know-how protection

Prevent unauthorized changes by means of know-how protection

⚠ WARNING

Danger to life through manipulation of DCC charts and DCC libraries

The use of unprotected DCCs and DCC libraries entails a higher risk of manipulation of DCCs, DCC libraries and backup files.

- Protect important DCCs and DCC libraries via "Know-how protection programs" or "Know-how protection drive units" in SCOUT or STARTER. Assign a strong password to prevent manipulation.
- Therefore, for "Know-how protection programs" or "Know-how protection drive units", use passwords which include at least eight characters, upper and lower case letters, numbers, and special characters.
- Make sure that only authorized personnel can access the passwords.
- Protect the backup files on your file system using a write protection.

SINAMICS Smart Access Module

The optional Smart Access Module offers you an intelligent solution for commissioning the SINAMICS V20 or G120 converter.

The Smart Access Module is a web server module with integrated WLAN connectivity. It allows web-based access to the converter from a connected device (conventional PC with WLAN

adapter, tablet or smartphone). This module is only intended for commissioning and therefore cannot be used with the converter for the long term.

NOTICE
WLAN: Changing a default password The misuse of passwords can also represent a considerable security risk. As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death. • After logging on to the Smart Access Module for the first time, change the module's default password. • Assign a secure password. Information on this can be found in the Operating Instructions of the respective converter.

NOTICE
Unauthorized access to the converter via the SINAMICS Smart Access Module Unauthorized access to the converter via the Smart Access Module as a result of cyber attacks could lead to interruptions in the process and thus to property damage or personal injury. • Before you log in to the web pages, check the status LED on the Smart Access Module. If the status LED is green or flashing, unauthorized access could have occurred: Switch the SINAMICS Smart Access Module off and then on again using the on-off switch to re-establish the WLAN connection.

For detailed information on this topic, see the following references:

4.9.7.5 SIMOCRANE

Availability, productivity, and safety are the decisive factors in crane applications. Since SIMOCRANE products are based on products from SIMOTION and SINAMICS, observe the product-specific hardening measures in Chapters SIMOTION (Page 3257) and SINAMICS (Page 3270) for hardening.

5.1 Task Trace

5.1.1 Preface

5.1.1.1 SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

5.1.1.2 Hotline and Internet addresses

Additional information

Click the following link to find information on the the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

http://www.siemens.com/motioncontrol/docu

Please send any questions about the technical documentation (e.g. suggestions for improvement, corrections) to the following e-mail address:
docu.motioncontrol@siemens.com

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

http://www.siemens.com/mdm

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

5.1.2 Overview

Field of application

The **SIMOTION Task Trace** supports you when troubleshooting in the SIMOTION multitasking environment. The SIMOTION Task Trace records the sequence of individual tasks, identifies user events that you can generate via a program command, and displays these graphically. This makes the interaction between programs and tasks easily traceable, thereby affording better control over them.

Structure of the Task Trace

The SIMOTION Task Trace includes two main components:

- The **SIMOTION Task Tracer**, which writes the task change and events to a buffer on the target device
- The **SIMOTION Task Profiler**, an application for displaying the recorded data

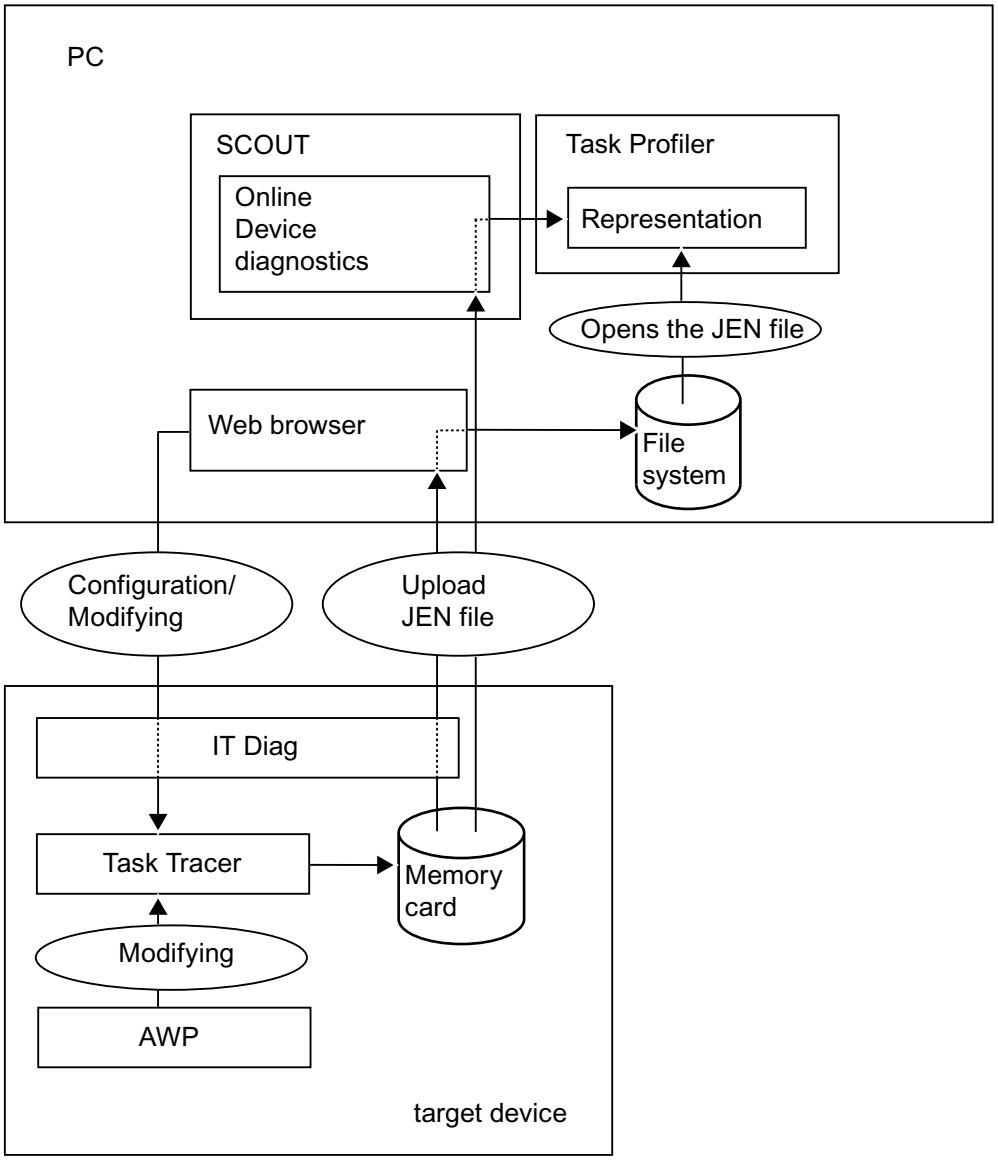

Figure 5-1 Schematic representation of SIMOTION Task Trace

SIMOTION IT DIAG (standard web pages) is used to configure the SIMOTION Task Tracer. The recording data is saved as a JEN file on the memory card of the target device.

If you start the Task Profiler via the device diagnostics, the trace data is automatically read from the memory card via the online connection and displayed. Alternatively, you can also save the JEN file from the target device to the file system of the PC using the SIMOTION standard web pages and then open the file in the SIMOTION Task Profiler.

5.1.3 Configuring

Overview

Configuring the SIMOTION Task Tracer is only necessary in exceptional circumstances, as the default configuration is used for recording. If you require a different configuration than the default, with Version V4.1.2 and higher this can be carried out on the target device via the standard web pages (SIMOTION IT DIAG).

Note

The functionality must be activated in the SIMOTION SCOUT project in the hardware configuration of the CPU. You can activate the required services in the hardware configuration on the "Ethernet extended/Webserver" tab in the object properties of the CPU.

Note

The changes you make to the configuration using the standard web pages remain in effect until the next time the target device is powered up. Following power-up, the default settings and the settings in the SIMOTION.ini file apply.

SIMOTION IT DIAG (standard web pages)

Configuration and control functionality of the Task Tracer are available on the standard web pages of SIMOTION IT DIAG.

Use the **Open IT Diag** button to start the standard web pages in the SCOUT device diagnostics.

Note

If there is no Ethernet connection from SCOUT to the target device, the button is deactivated (grayed out).

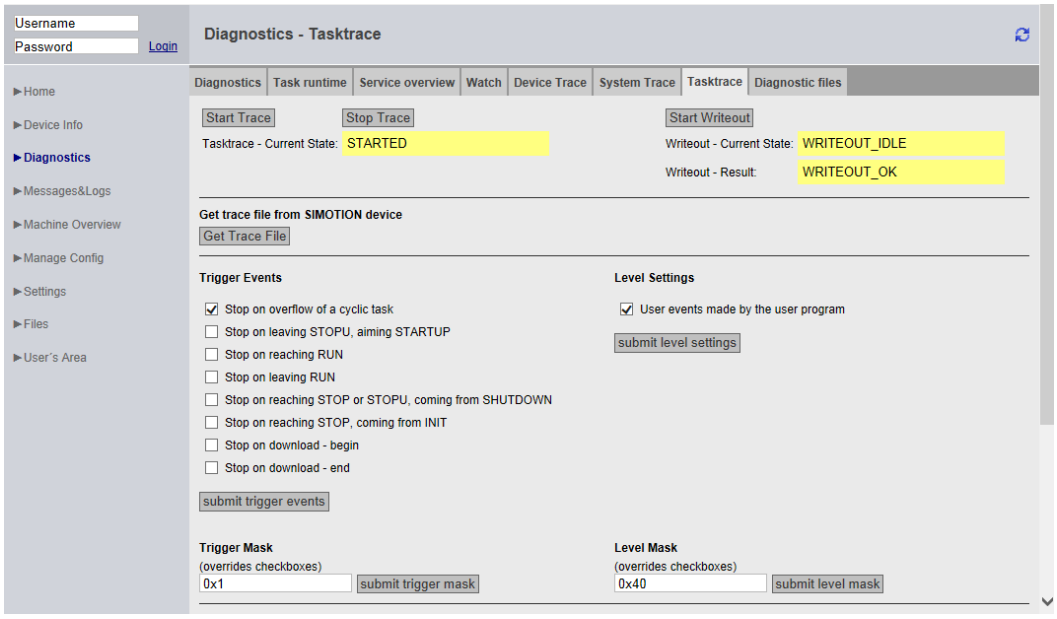

Figure 5-2 SIMOTION IT DIAG standard web pages - Task Trace (part 1)

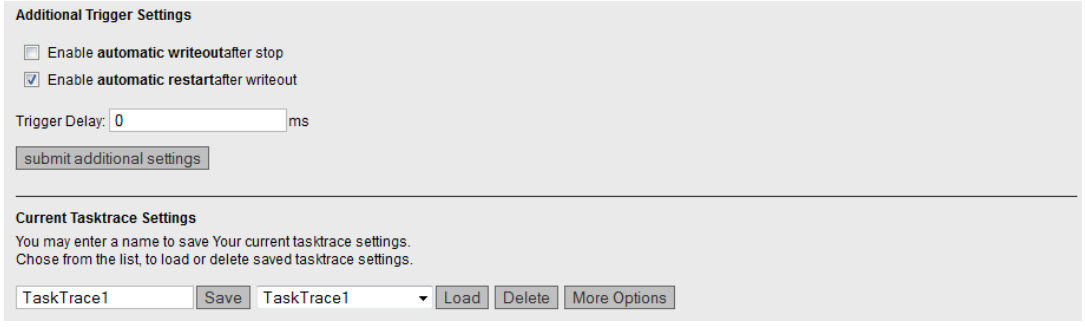

Figure 5-3 SIMOTION IT DIAG standard web pages - Task Trace (part 1)

Default configuration

The following table summarizes the default configuration of the Task Tracer and the setting options (configuration and control) using the standard web pages of the target device or the SIMOTION.ini file.

Note

The SIMOTION.ini is not created automatically and may need to be created and stored in the root directory of the memory card.

Note

For additional information regarding the configuration and status displays using standard web pages, refer to the "SIMOTION SCOUT Overview about Service and Diagnostic Options" documentation.

Table 5-1 Default configuration of the Task Tracer

Variable name in SIMOTION.ini	Meaning	Default setting	Can be changed via IT-Diag standard web pages
TT_BUFSIZE	Size of the trace buffer in KB	512,000 bytes (the maximum setting depends on the available RAM)	No
TT_WROUT	Activate automatic writing of the trace data to the memory card after the trace has stopped TT_WROUT =1	The trace data is not written automatically to the memory card (Because this is a default setting, no entry in the SIMOTION.ini)	Additional Trigger Settings: Enable **automatic writeout** after triggered stop
TT_RSTRTOFF	Trace is not started automatically after the trace data is written to the memory card TT_RSTRTOFF=1	The trace is started automatically once the trace data has been written to the memory card (Because this is a default setting, no entry in the SIMOTION.ini)	Additional Trigger Settings: Enable **automatic restart** after writeout
TT_LEVEL	Mask for specifying the events that are to be recorded in the Task Trace (see "Masking of events to be recorded") TT_LEVEL=0x0040	0x0040 (User_Events)	Level Settings
TT_TRIGGER	Mask for specifying the stop trigger of the trace (see "Masking of STOP trigger") TT_TRIGGER=0x0001	0x0001	Trigger Events or Trigger Mask
TT_TRGDELAY	Delay time [ms] after the trigger event until Task Trace is stopped	0 ms	Trigger Delay

Masking of events to be recorded

```
Level masks:
0x0040 user events made by the user program
```

Masking of STOP trigger

```
Trigger masks:
0x0001 stop on overflow of a cyclic task
0x0002 stop on leaving BZ STOPU, aiming STARTUP
0x0004 stop on reaching BZ RUN
0x0008 stop on leaving BZ RUN
0x0010 stop on reaching BZ STOP or STOPU, coming from SHUTDOWN
```

0x0020 stop on reaching BZ STOP, coming from INIT

0x0040 stop on leaving BZ INIT

0x0100 stop on Download-Begin

0x0200 stop on Download-End

You can also combine masking instances if required, for example 0x0009 from

0X0001 stop on overflow of a cyclic task and 0x0008 stop on leaving BZ RUN.

Creating the SIMOTION.ini file

The following example shows how you can modify the configuration using the SIMOTION.ini file. In this process, it should be specified that the CPU mode will be recorded until it changes to STOP mode. The buffer size is specified as 1,000,000 bytes. The automatic writing of the trace data to the memory card is activated once the trace has stopped.

Example:

TT_BUFSIZE = 1000000

TT_TRIGGER= 0x0010

TT_WROUT=1

Note

The maximum buffer size depends on the available memory capacity of the RAM and the memory card.

5.1.4 Working with the SIMOTION Task Profiler

5.1.4.1 Starting the SIMOTION Task Profiler

You can open the SIMOTION Task Profiler

- as an application from the STEP7 program folder or
- from the SCOUT device diagnostics.

Start via STEP7 program folder

You can open the SIMOTION Task Profiler as an application in the STEP 7 program folder (see figure below).

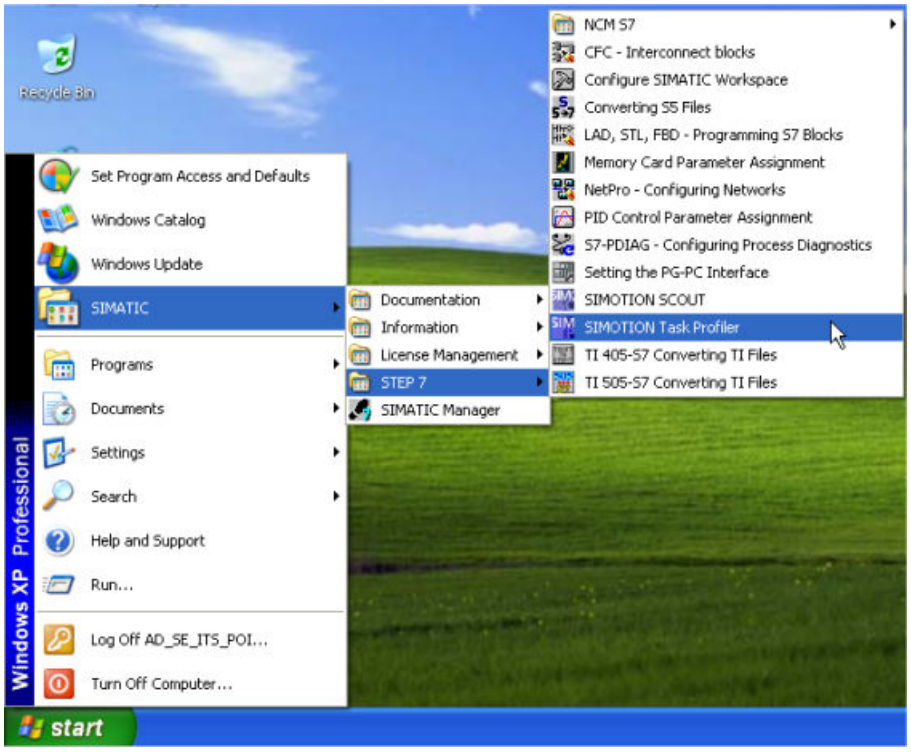

Figure 5-4 Opening the Task Profiler in the STEP7 program folder

When the Task Profiler is closed, the settings (e.g. most recently loaded Task Trace recording) are not saved. On reopening, the window for the display is empty (see figure below).

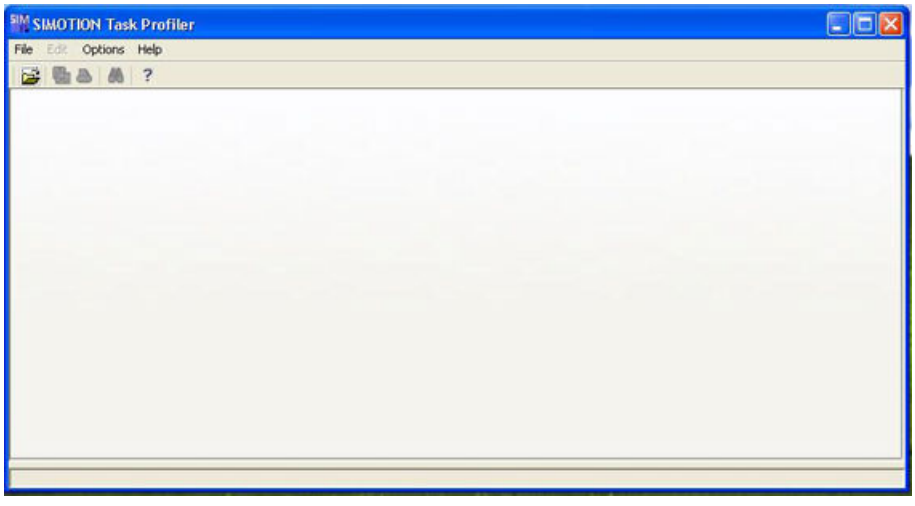

Figure 5-5 SIMOTION Task Profiler upon opening via the STEP7 program folder

Start using SCOUT device diagnostics

Note

In order to start the device diagnostics, an online connection to the target device must exist.

Start the Task Profiler in the device diagnostics as described below:

1. Switch to the **Task Manager** tab.
2. The following options are available:
   - Click the **Display** button. The Task Profiler starts. In addition, the trace file is loaded from the memory card of the target device and opened in a new tab in the Task Profiler. If you click the button again, the same file is read again.
   - Click the **Create snapshot** button. The setting that you have made using IT-Diag is reset to the default state. The settings made using the SIMOTION.ini file are retained. The Task Trace is started, written to the memory card, and then the Task Profiler started. If you click the button again, a new recording is started.

Note

If a trace file is not stored on the CF card of the target device, a new tab for the display is not shown.

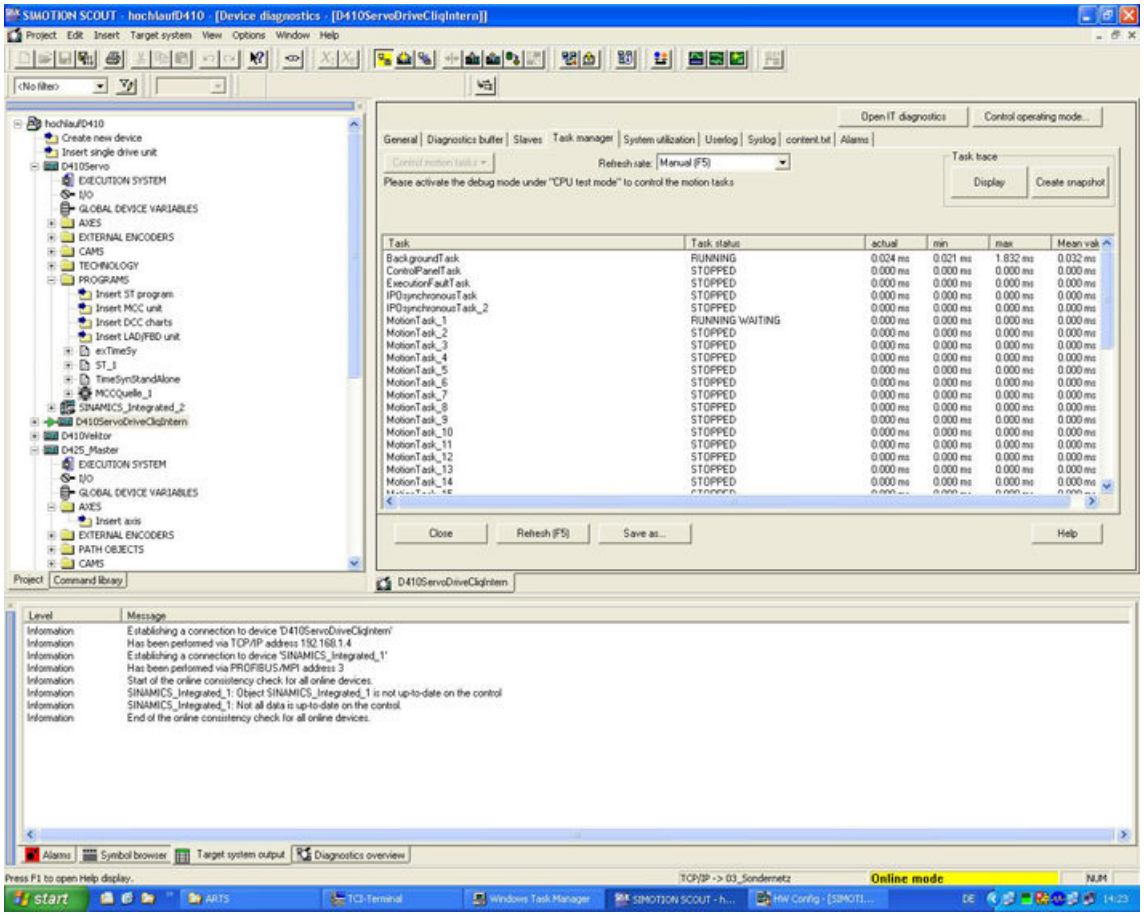

Figure 5-6 Start of Task Profiler via the device diagnostics

5.1.4.2 Structure of the SIMOTION Task Profiler

Structure of the interface

The structure of the SIMOTION Task Profiler is described below.

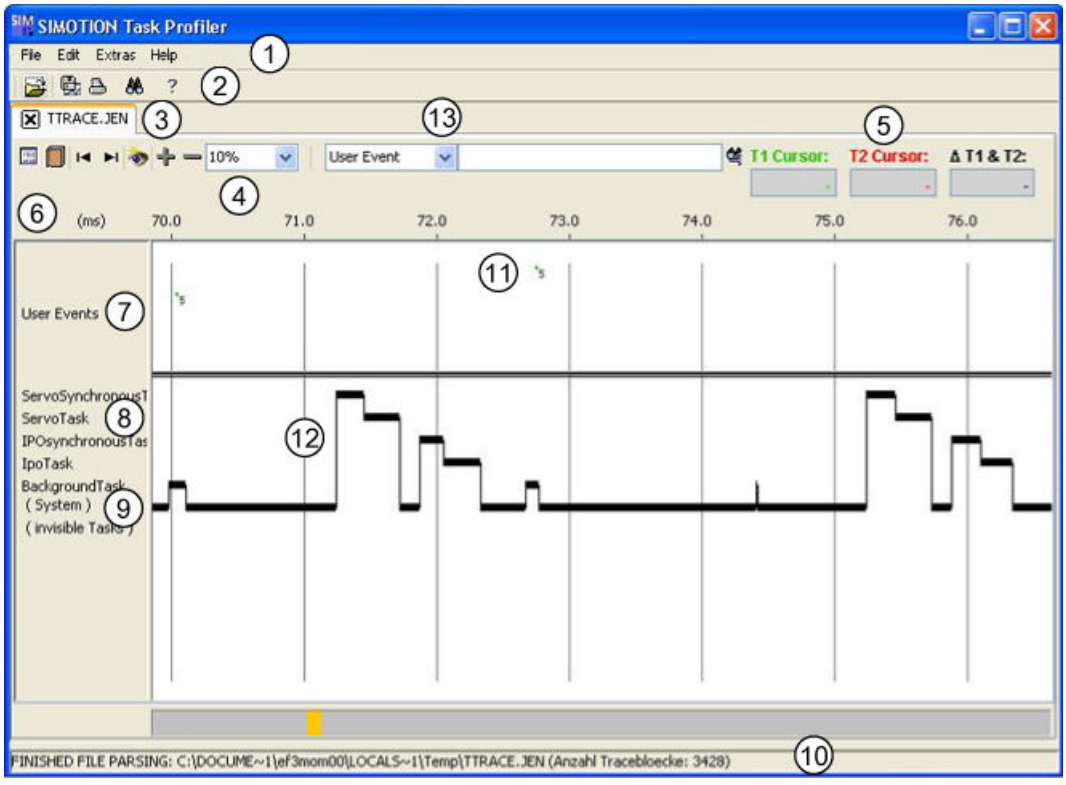

Figure 5-7 Structure of the user interface of the Task Profiler

No.	Description
1	Menu bar: File, Edit, Options, Help
2	Global toolbar
3	Tab with current trace. Several traces can be opened simultaneously.
4	Local toolbar
5	Display of T-measurement cursor
6	Time markings of the timing diagram
7	Labeling of user events
8	Display of task names
9	System tasks not displayed individually
10	Status bar
11	Marking of user events in the timing diagram
12	Timing diagram of tasks
13	Quick search

Structure of the menus

The menus are explained below. For more detailed information, refer to "Working with the SIMOTION Task Profiler".

File menu

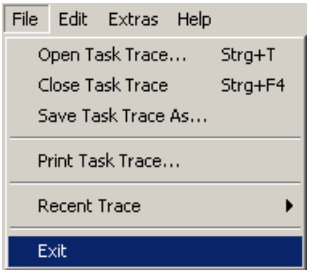

Figure 5-8 File menu

Table 5-2 Entries in the File menu

Entry	Description
Open Task Trace ...	Opens the JEN file
Close Task Trace ...	Closes the current Trace tab
Save Task Trace As ...	Saves the current trace
Print Task Trace ...	Prints the current trace
Recent trace	Selection of the most recently opened trace recordings
Exit	Exits the Task Profiler

Edit menu

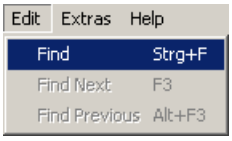

Figure 5-9 Edit menu

Table 5-3 Entries in the Edit menu

Entry	Description
Find	Opens the Find Options dialog box
Find Next	Searches for the next event corresponding to the Find Options
Find Previous	Searches for the previous event corresponding to the Find Options

Options - Menu

Figure 5-10 Options - Menu

Table 5-4 Entries in the Options menu

Entry	Description
User Event Configuration	Opens the dialog for assigning names to the user events of the current recording. You can export the configuration as an XML file and, if required, import it.

Help menu

Figure 5-11 Help menu

Table 5-5 Entries in the Help menu

Entry	Description
Help	Opens the Help system
About	Opens the About dialog box

Global toolbar

The following functions are available in the global toolbar:

Table 5-6 Global toolbar

Icon	Function
	Open Task Trace
	Saves Task Trace under a different name
	Print Task Trace
	Browses Task Trace for events
	Open help

For a description of the functions of the local toolbar, refer to "Analyzing a Task Trace".

5.1.4.3 Opening a Task Trace

Proceed as follows to open a trace file (trace stored on the PG/PC):

1. Open the **Open Task Trace...** dialog from the **File** > **Open Task Trace** menu

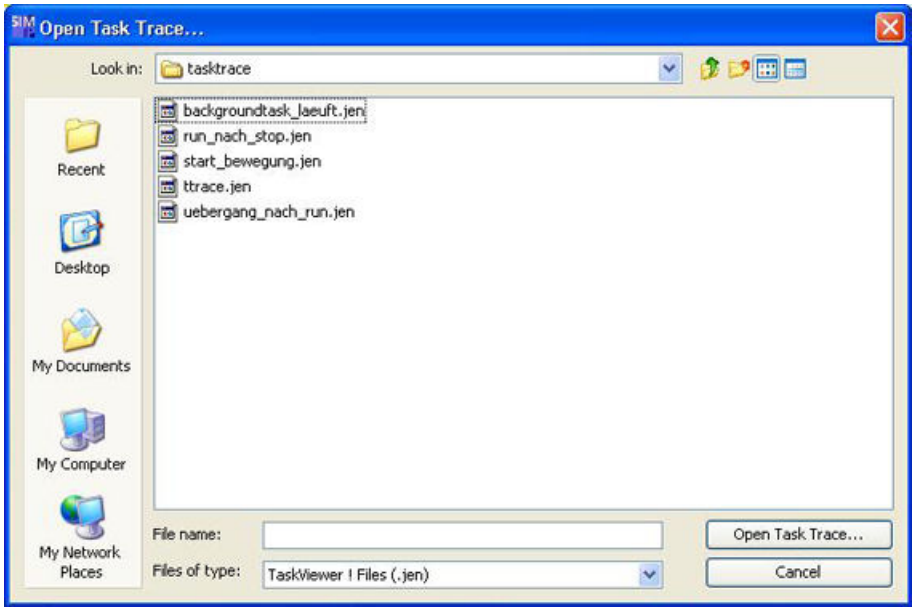

Figure 5-12 Open Task Trace

2. Select the JEN file you want to open in the Task Profiler, and confirm with **Open Task Trace...**

5.1.4.4 Control of Task Tracer

Control

You can control the Task Tracer using SIMOTION IT DIAG (standard web pages) of the target device or with system functions in the user program.

Note

For additional information, refer to the "Technology Packages System Functions" and "SIMOTION SCOUT Overview about Service and Diagnostic Options" documentation.

System functions in the user program

The following table provides an overview of the available system functions:

System function	Description
_taskTraceUserEvent	This function enters an event with a user-defined ID from 0 to 255 in the buffer of the SIMOTION Task Tracer.
_taskTraceStop	This function stops an active Task Tracer recording.

System function	Description
_taskTraceStart	This function starts the Task Trace recording. **Note:** When the function is called, whether or nor the Task Tracer has already been started is irrelevant. If the Task Tracer is active after the call, the function supplies 0 as return value.
_taskTraceWriteOut	The function stops a Task Trace recording that is already in progress and saves the Trace data as a JEN file (ttrace.jen) on the target device memory card under the following path: /USER/SIMOTION/HMI/SYSLOG/TASKTRACE/DIAG

5.1.4.5 Analyzing a Task Trace

Note

Peaks can occur during the recording, which indicate whether they can be re-started by means of background task testing. These peaks are irrelevant to the analysis.

The following options are available for analyzing the trace recording and for modifying the view:

Control via the local toolbar

Table 5-7 Functions of the local toolbar

Icon	Description
	Open the **Graph Settings** dialog. You can show or hide tasks and specify the color for each task in this dialog. 	Open the statistics. This dialog provides an overview of the tasks available in the system and their status at the end of the trace. 	Go to start of trace.
	Go to end of trace.

Icon	Description
	Open the **Go To** dialog. You can use this dialog to jump to the entered time value. 	Zoom In
	Zoom Out
	Zoom factor can be entered (between 1 and 5,000).
	Fast search using User Event or Task Switch

Control via the mouse

Table 5-8 Functions via mouse or shortcut

Click button or shortcut	Description
Right-click event icon	Info box on selected event.
Left- or right-click	Generates a red or green vertical guide line, at whose upper end the time is displayed in ms. The values are displayed in the following information panel. 
Shift + left- or right-click	Removes the red or green guide line.
Ctrl + left-click	Generates a horizontal guide marking. This can also be generated by directly left-clicking the task name.
Ctrl + right-click	Removes the horizontal marking. Clicking the currently selected task name also removes the horizontal marking.
Right-click task name	Info box for corresponding task.

5.1.4.6 Saving the trace data

The recorded trace data is stored as a JEN file (ttrace.jen) on the memory card of the target device under the following path: /USER/SIMOTION/HMI/SYSLOG/TASKTRACE/DIAG

To save trace data under a different name, follow the procedure described below:

1. Open the **Save Task Trace As** dialog from the **File** > **Save Task Trace As ..** menu.
2. Enter the desired file name and save it. If a file of the same name already exists, it is overwritten.

If required, you can use a card reader to read out the JEN files on the memory card.

5.1.4.7 Find

You can use the find function (can be invoked in the main menu using **Edit** > **Find**) to search for the next user event or the next task in the trace recording.

If you are searching for a specific event or task, you must also specify the event ID or the task designator. You can use the **Find Previous** or **Find Next** button to search backwards or forwards, respectively.

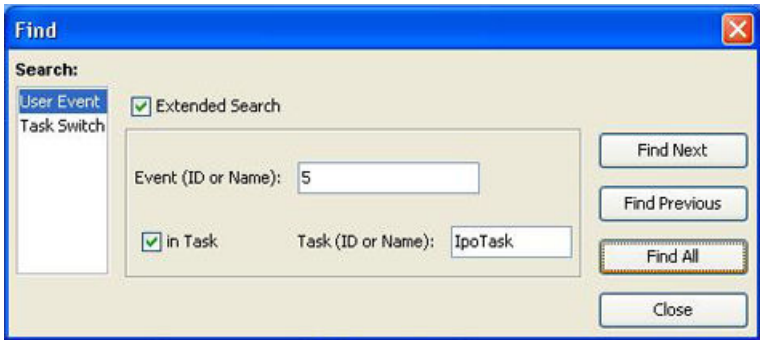

Figure 5-13 Find Event

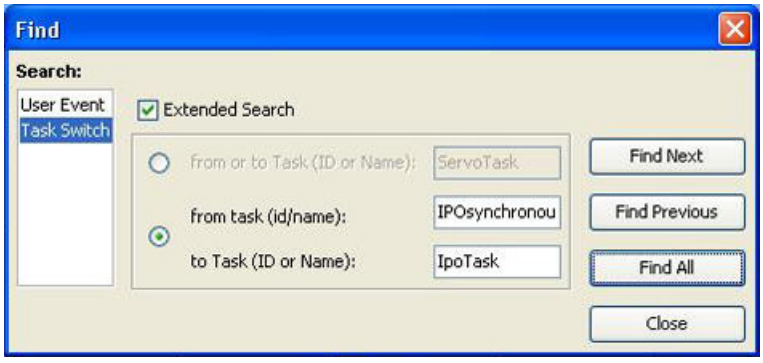

Figure 5-14 Find Task

5.2 Overview of service and diagnostics options

5.2.1 Preface

5.2.1.1 Preface

Contents

This document is part of the **SIMOTION Service and Diagnostics** documentation package.

Area of application

This manual is valid for SIMOTION V5.2.

Information blocks in this manual

The following is a list of sections included in this manual along with a description of the information presented in each section.

- **Part I: Service on the device**
  This section outlines the diagnostics options available on the device and contains references to additional descriptions as well as descriptions relating to specific devices.
- **Part II: Service without SCOUT Engineering System (PC-based, SIMOTION IT)**
  This section outlines the diagnostics options available with PC-based systems and with the SIMOTION IT web server, and contains references to additional descriptions.
- **Part III: Service with SCOUT Engineering System**
  This section outlines the diagnostics options available with the SCOUT Engineering System and contains references to additional descriptions.
- **Appendix**
  The appendix contains detailed descriptions and guidelines relating to the individual sections.
- **Index**
  Index for locating information.

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.2:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

5.2.1.2 Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

https://support.industry.siemens.com/cs/ww/en/view/109479653

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

5.2.2 Fundamental safety instructions

5.2.2.1 Safety instructions for electromagnetic fields (EMF)

⚠ WARNING

Danger to life from electromagnetic fields

Electromagnetic fields (EMF) are generated by the operation of electrical power equipment such as transformers, converters or motors.

People with pacemakers or implants are at a special risk in the immediate vicinity of these devices/systems.

- Ensure that the persons involved are the necessary distance away (minimum 2 m).

5.2.2.2 Handling electrostatic sensitive devices (ESD)

Electrostatic sensitive devices (ESD) are individual components, integrated circuits, modules or devices that may be damaged by either electric fields or electrostatic discharge.

NOTICE

Damage through electric fields or electrostatic discharge

Electric fields or electrostatic discharge can cause malfunctions through damaged individual components, integrated circuits, modules or devices.

- Only pack, store, transport and send electronic components, modules or devices in their original packaging or in other suitable materials, e.g conductive foam rubber of aluminum foil.
- Only touch components, modules and devices when you are grounded by one of the following methods:
  - Wearing an ESD wrist strap
  - Wearing ESD shoes or ESD grounding straps in ESD areas with conductive flooring
- Only place electronic components, modules or devices on conductive surfaces (table with ESD surface, conductive ESD foam, ESD packaging, ESD transport container).

5.2.2.3 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to

an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under (https://www.siemens.com/industrialsecurity).

5.2.2.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

5.2.2.5 Residual risks of power drive systems

When performing the risk assessment for a machine or plant in accordance with the respective local regulations (e.g. EC Machinery Directive), the machine manufacturer or plant constructor must take into account the following residual risks associated with the control and drive components of a drive system:

1. Unintentional movements of driven machine or system components during commissioning, operation, maintenance and repairs caused by, for example:
   - Hardware and/or software errors in the sensors, control system, actuators, and cables and connections
   - Response times of the control system and of the drive
   - Operation and/or environmental conditions outside the specification
   - Condensation/conductive contamination
   - Parameterization, programming, cabling, and installation errors
   - Use of wireless devices / mobile phones in the immediate vicinity of electronic components
   - External influences/damage
   - X-rays, ionizing radiation and cosmic radiation
2. Unusually high temperatures, including open flames, as well as emissions of light, noise, particles, gases, etc., can occur inside and outside the components under fault conditions caused by, for example:
   - Component failure
   - Software errors
   - Operation and/or environmental conditions outside the specification
   - External influences/damage
3. Hazardous shock voltages caused by, for example:
   - Component failure
   - Influence during electrostatic charging
   - Induction of voltages in moving motors
   - Operation and/or environmental conditions outside the specification
   - Condensation/conductive contamination
   - External influences/damage
4. Electrical, magnetic and electromagnetic fields generated in operation that can pose a risk to people with a pacemaker, implants or metal replacement joints, etc., if they are too close
5. Release of environmental pollutants or emissions as a result of improper operation of the system and/or failure to dispose of components safely and correctly

For more information about the residual risks of the drive system components, see the relevant sections in the technical user documentation.

5.2.3 Introduction

5.2.3.1 Overview of service and diagnostics options

This manual lists the system diagnostics options available for SIMOTION devices. It also contains references to additional manuals and online help texts featuring the detailed information that is applicable in each case. The Manuals and Commissioning Manuals for the individual platforms describe device-specific diagnostics options in detail.

Note

The full version of this manual is available as an online help containing links.

This manual (i.e. the PDF version) provides an overview of how this help text is organized and structured. It does not include links to subjects that are only covered in the online help. The relevant manual is referred to in each case.

Note

In the event of an fault (e.g. CPU STOP), analyze the entries in the diagnostic buffer. You can access this in any of the scenarios covered here (Parts I to III). An overview of the scenarios is provided later.

Comprehensive diagnostic data (Page 3359) can be generated to enable the machine manufacturer or SIEMENS to carry out a more in-depth analysis.

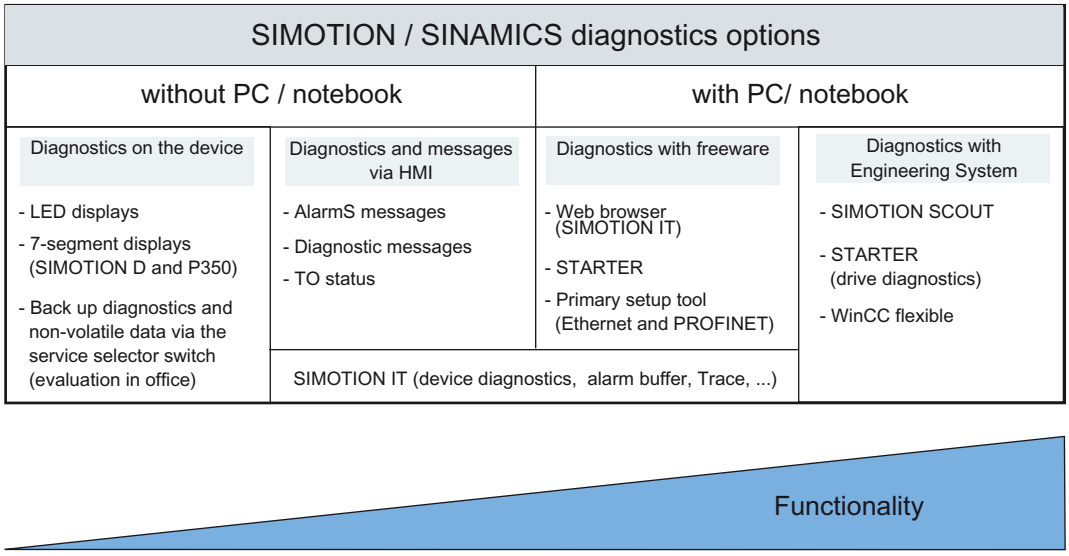

Figure 5-15 Overview of functions associated with diagnostics options

Note

If you contact the hotline for support, you should provide a description of the error/fault scenario that is as precise and detailed as possible.
Depending on the nature of the fault, the following information may be useful:

- Diagnostic buffer backup data (see also the descriptions of scenarios without the SCOUT Engineering System (Page 3360) and with the SCOUT Engineering System (Page 3382))
- Full alarm messages with numbers and all additional information
- State of LEDs/7-segment displays
- Installed software versions (SIMOTION SCOUT > Help > Information > System info...)
- Screenshots of error/fault messages and/or dialogs

Part I

Service on the device (Page 3319)

Part I describes the diagnostics and service options that can be implemented directly on the device.

Figure 5-16 Example: Module D445-2 DP/PN

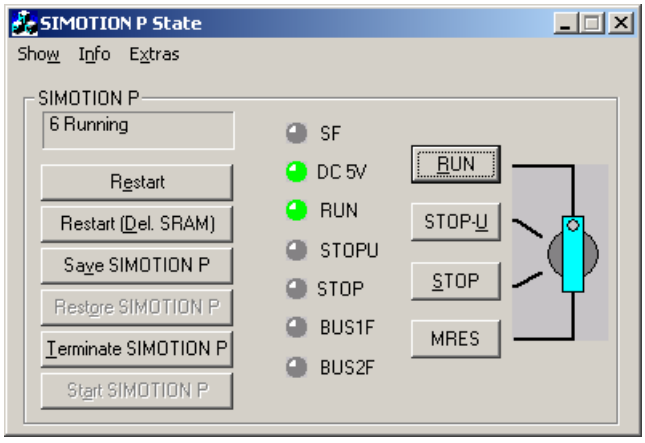

Figure 5-17 Example - SIMOTION P350 - P state

Part II

Service without SCOUT Engineering System (PC-based, SIMOTION IT) (Page 3352)

Part II describes the service options that can be implemented without the SCOUT Engineering System, via the Ethernet interface of SIMOTION devices. Diagnostic functions can be viewed using an Internet browser.

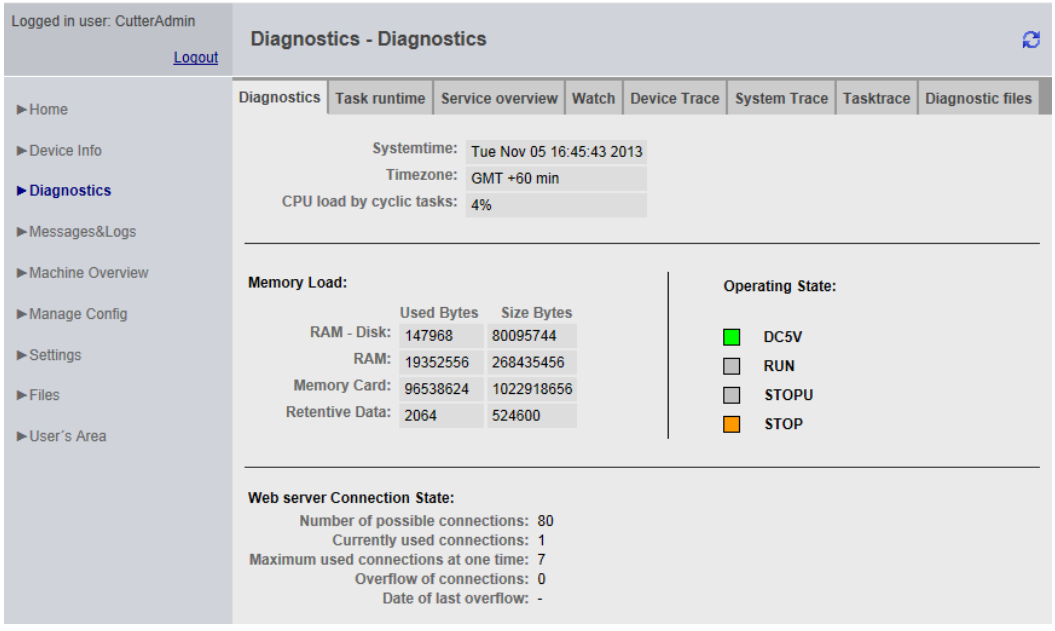

Figure 5-18 Example: SIMOTION IT web server - diagnostics in browser

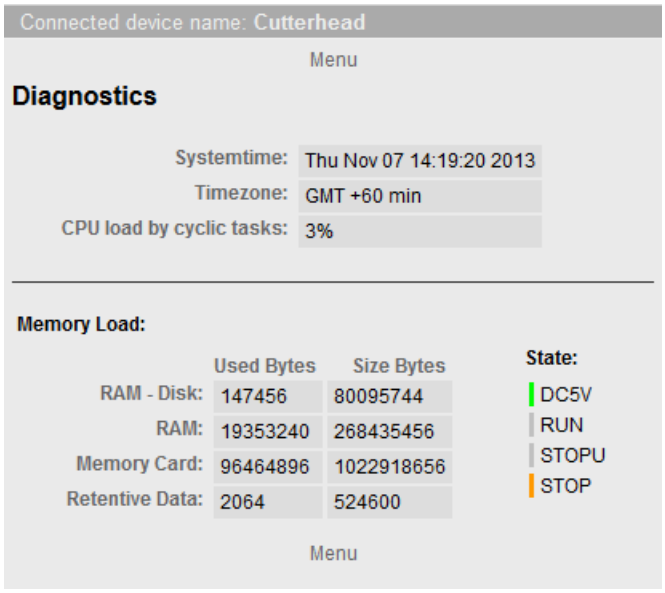

Figure 5-19 Example: simplified HTML pages, e.g. for PDA

Part III

Service with SCOUT Engineering System (Page 3367)

Part III presents the comprehensive range of SIMOTION SCOUT Engineering System functions that are available for error/fault diagnostics.

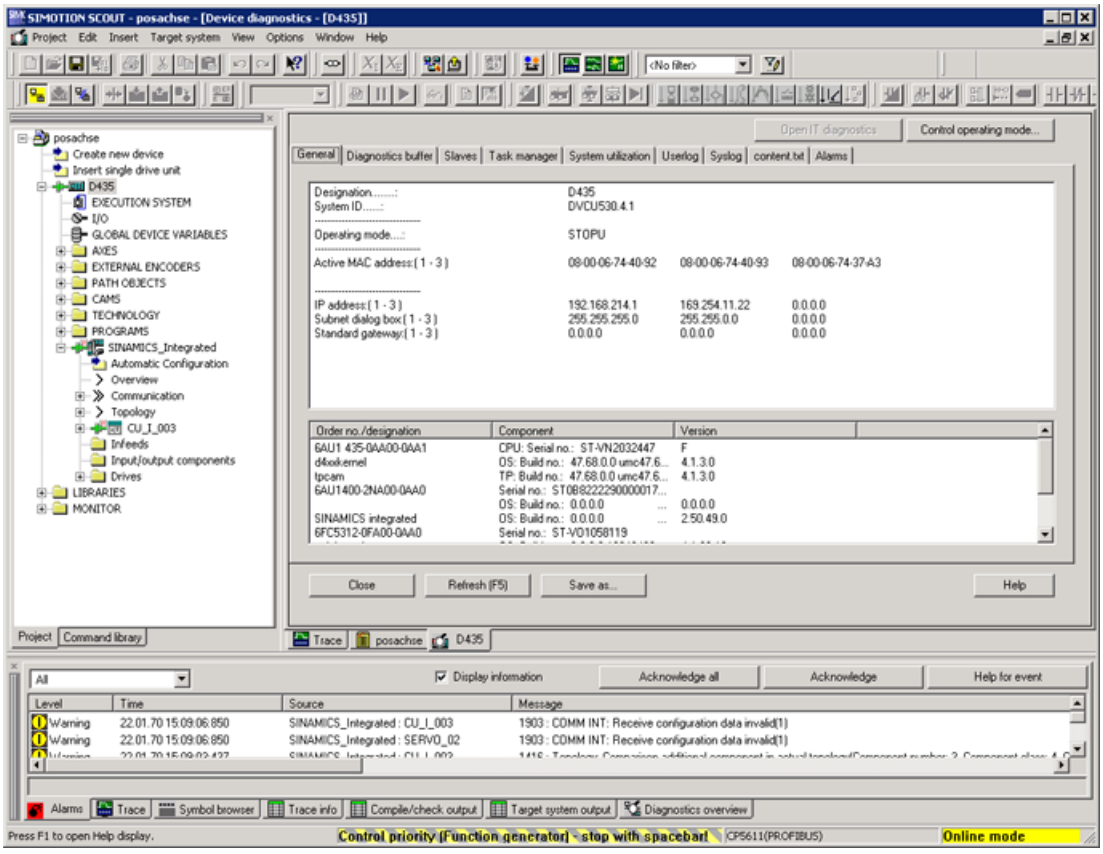

Figure 5-20 Example: SIMOTION SCOUT, Device diagnostics

5.2.4 Part I: Service on the device

5.2.4.1 Overview

The device hardware offers various displays and interfaces that may be used for diagnostics purposes. Diagnostic information can be displayed either directly on the device (e.g. by means of LEDs) or indirectly (e.g. HMI via Ethernet interface). In the case of SIMOTION D, a service selector switch can be used to initiate a backup of diagnostic data on the device and write this to the memory card.

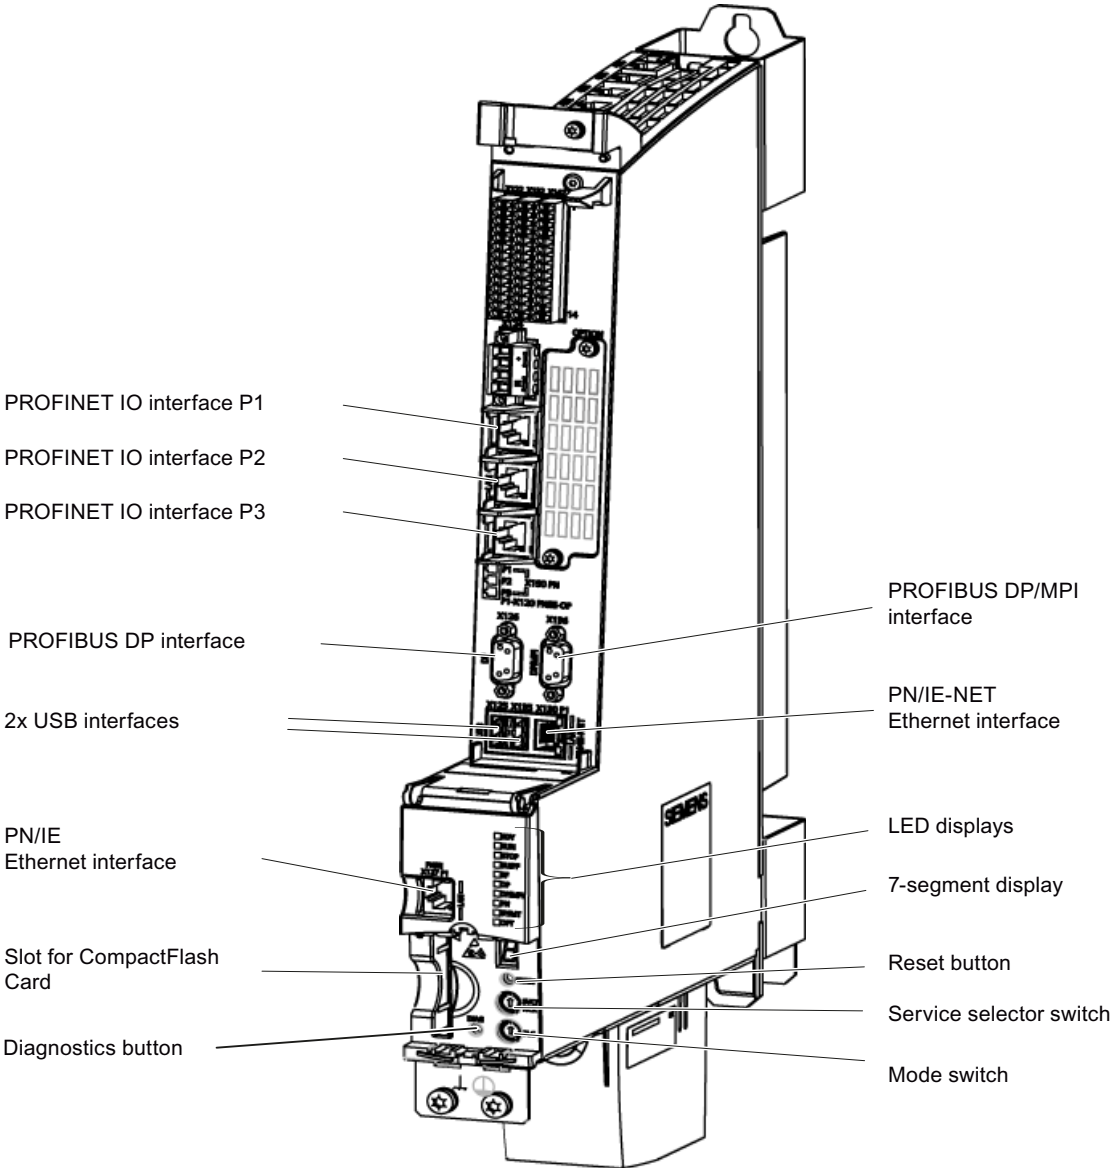

Figure 5-21 Interfaces and front panel elements - example of SIMOTION D445-2 DP/PN

Service selector switch/button

The service selector switch enables diagnostic data backed up in a SIMOTION device in the event of an error/fault to be stored offline without SIMOTION SCOUT. For details, see Backing up diagnostic data and non-volatile data (Page 3348).

SIMOTION D modules have a service selector switch that is important for service and diagnostic functions. In "normal" operation, this switch must remain in the 0 position. See also Backing up during operation using a service selector switch (Page 3396) and Backing up during ramp-up using a service selector switch or INI file (Page 3399).

With SIMOTION P320-3/P350-3, virtual versions of the service selector and mode switches and the LEDs appear in the *SIMOTION P state* application. See also Backing up during operation using a service selector switch (Page 3396) and Backing up during ramp-up using a service selector switch or INI file (Page 3399).

SIMOTION C does not provide any switches on the device for diagnostic functions. Errors/faults and states are displayed by means of LEDs.

Part II (Page 3359) contains a detailed description of how diagnostic data and non-volatile data should be handled.

Mode switch

You can use the mode switch to set the operating mode on the device. With SIMOTION P, the function of this switch is implemented by means of the SIMOTION P state application. It is also possible to change the operating mode via SIMOTION SCOUT.

Operating modes, based on the example of SIMOTION D4x5-2:

- RUN
  SIMOTION D4x5-2 is processing the user program.
  The technology packages are active in this state.
  They can execute commands from the user program.
- STOPU
  SIMOTION D4x5-2 is not processing a user program.
  The technology packages are active. Test and commissioning functions can be executed.
  The I/O modules are in a safe state. This means, for example, that digital outputs are "LOW" and analog outputs are de-energized (no current, no voltage).
- STOP
  SIMOTION D4x5-2 is not processing a user program.
  It is possible to load an entire user program.
  All system services (communication, ...) are active.
  The I/O modules are in a safe state. This means, for example, that digital outputs are "LOW" and analog outputs are de-energized (no current, no voltage).
  The technology packages are not active.
- MRES
  Switch position for overall reset of the module.

Note

Please take note of the information in the Manuals for the switches.

5.2.4.2 LEDs

Overview

Every SIMOTION device features LEDs that are used for device diagnostics. The LED displays indicate the different operating modes and any faults that occur. They do so by lighting up, flashing, or flickering in different colors.

With SIMOTION P320-3/P350, representations of the LEDs appear in the *SIMOTION P state* application.

Note

A STOPU LED may also light up if an axis control panel is activated.
The STOPU LED flickers when a CF/MMC card is being formatted. (D4x5-2: SU/PF-LED)

This does not indicate a fault.

Overview (Page 3359)

Backing up diagnostic data and non-volatile data (Page 3348)

Backing up during operation using a service selector switch (Page 3396)

Backing up during ramp-up using a service selector switch or INI file (Page 3399)

Part II: Service without SCOUT Engineering System (PC-based, SIMOTION IT) (Page 3352)

SIMOTION C

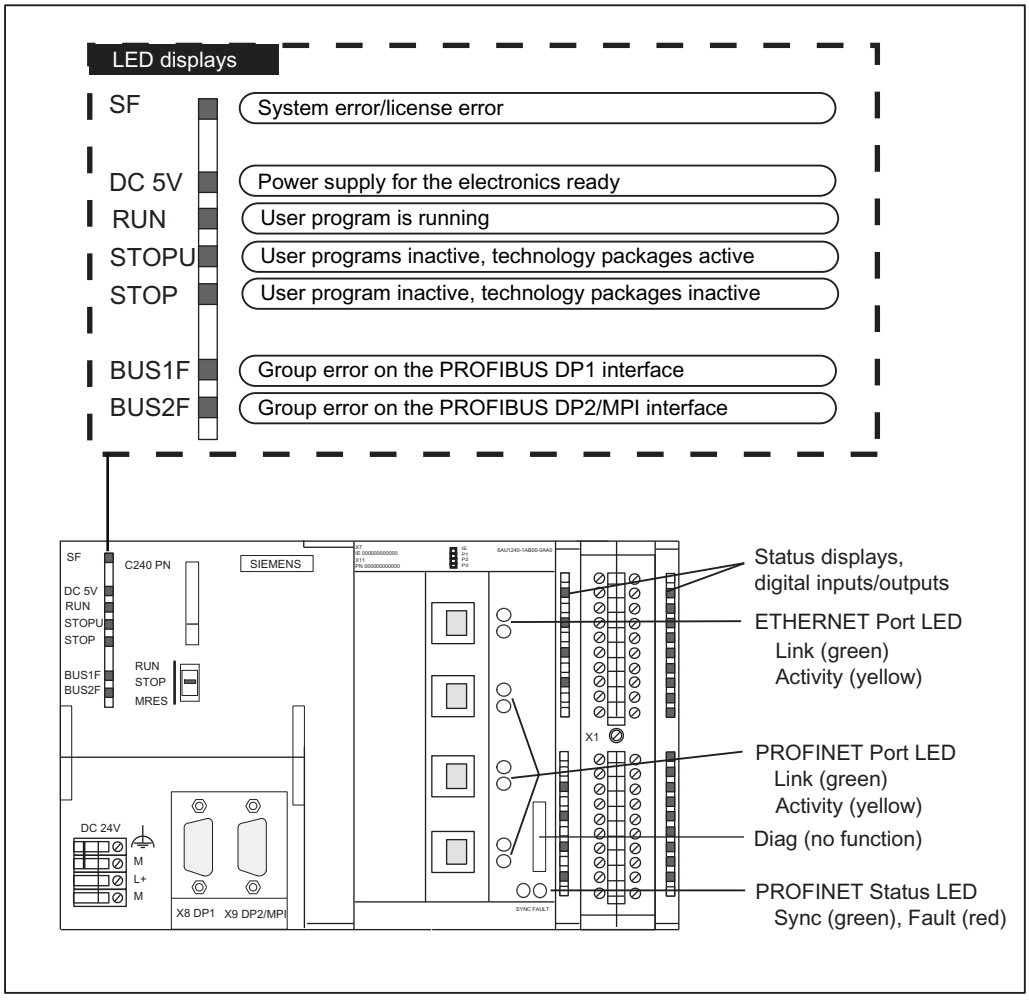

Figure 5-22 LED displays on the device - example of SIMOTION C240 PN

Note

The SIMOTION C Operating Instructions contain a detailed description of the LED displays, including all the possible combinations and flashing frequencies.

Typical faults

Table 5-9 Typical faults

Fault	Frequent causes	Remedy
SF LED lights up red (error/fault state on the SIMOTION C)		
	• An event that can be acknowledged is pending (alarm, message, note) • A fault has occurred to which the user program cannot respond.	Acknowledge the event. Switch the SIMOTION device off and then on again.
SF LED flashes red (error/fault state on the SIMOTION C)		
	• License missing for licensed technology/optional objects	Check the licenses.
5 VDC does not light up (supply voltage for electronics)		
	• No line supply connected or switched on • No specified load current supply connected • Module not connected correctly • Defective module	Check the line supply connection and the module
STOP LED lights up yellow (control is in STOP mode - diagnostics with Engineering System or web server)		
	• I/O access error • Program error (e.g. floating point exception) • Technological alarms with CPU STOP response	Correct I/O access **Localize error:** Check entries in the device diagnostics Example: Entry "Operating mode transition blocked" -> check error before this -> entry "I/O access error"
STOP LED flashes yellow (overall reset request)		
	• Memory card has been removed • The non-volatile data does not match up with the project on the memory card	Memory reset
STOPU LED lights up or flashes yellow (control in STOP mode of user program)		
	• The technology packages are active. • The user program is not active or is faulty • Device stuck at startup task	Check the entries in the diagnostic buffer and the user program. Switch the control to RUN mode.

Fault	Frequent causes	Remedy
BUS1F, BUS2F LED lights up red (fault on PROFIBUS DP interface)		
	• Terminating resistor missing or in the wrong place • Not all of the connected devices are switched on • Cabling fault • Incorrect baud rate configured or incorrect baud rate set on a bus node • Configuration error • Parameter assignment error	Check terminating resistor, bus nodes, cabling, baud rate, configuration settings, and configuration in HW Config

Table 5-10 Typical C240 PN errors

Fault	Frequent causes	Remedy
PROFINET Link LED does not light up		
	• There is no physical connection • The connected device is not switched on	Check the cabling, connectors, and device.
PROFINET Activity LED does not light up continuously		
	• There is no telegram traffic.	If the Link LED is green, use a ping command to check that the system is ready for communication
PROFINET Fault LED lights up (bus fault)		
	• No physical connection to a subnet/switch • Incorrect transmission rate • Full duplex transmission is not activated	Check configuration settings, check IO device, check connection
PROFINET Fault LED flashes red (bus fault)		
	• Failure of a connected I/O device. • At least one of the assigned I/O devices cannot be addressed • Incorrect or no configuration settings	Check configuration settings, check IO device
PROFINET Sync LED does not light up or flashes		
	• SIMOTION C task system is not synchronized with the send cycle of PROFINET IO IRT	Check configuration settings, check fault message in SINAMICS diagnostic buffer

Additional information

- Links in the *Guides* menu of the online help
- *SIMOTION C* Operating Instructions

SIMOTION P320-3/P350-3

The LEDs and mode switch, which are implemented as hardware on other SIMOTION platforms, are displayed in virtual form on the SIMOTION P system screen.

This is achieved via the *SIMOTION P state* application.

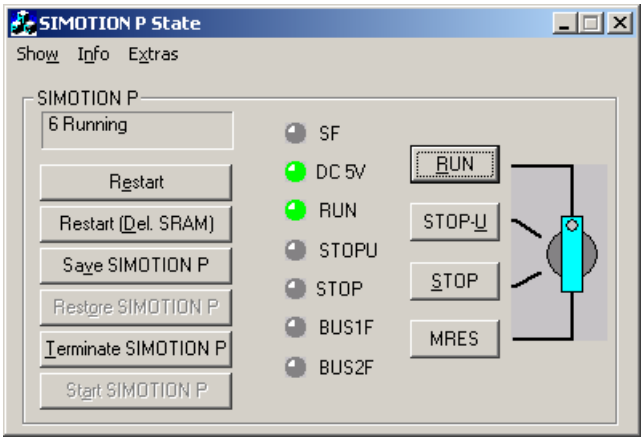

Figure 5-23 SIMOTION P state

Note

The relevant Manual/Commissioning Manual contains a detailed description of the LED displays, including all the possible combinations and flashing frequencies.

Typical errors

Table 5-11 Typical errors

Error	Frequent causes	Remedy
SF LED lights up red (error/fault state on the SIMOTION P)		
	• An event which can be acknowledged is pending (alarm, message, note) • A fault has occurred that does not allow a response from the user program	Acknowledge the event. Switch the SIMOTION device off and then on again.
SF LED flashes red (error/fault state on the SIMOTION P)		
	• License missing for licensed technology/optional objects	Check the licenses.
STOP LED lights up yellow (SIMOTION P in STOP mode)		
	• I/O access error • Program error (e.g. floating point exception) • Technological alarms with CPU STOP response	Correct I/O access **Localize error:** Check entries in the device diagnostics Example: Entry "Operating mode transition blocked" -> check error before this -> entry "I/O access error"
STOP LED flashes yellow (overall reset request)		

Error	Frequent causes	Remedy
	• Memory card has been removed • The non-volatile data does not match up with the project on the memory card	Overall reset
STOPU LED lights up or flashes yellow (SIMOTION P in STOP user program mode)		
	• The technology packages are active • The user program is not active or is faulty • Device stuck at startup task	Check the entries in the diagnostics buffer and the user program. Switch the control to RUN mode.
BUS1F, BUS2F LED (error/fault state on PROFIBUS DP interface, P350-3 only)		
	• Terminating resistor missing or in the wrong place • Not all of the connected devices are switched on • Cabling fault • Incorrect baud rate configured or incorrect baud rate set on a bus node • Configuration error • Parameter assignment error	Check terminating resistor, bus nodes, cabling, baud rate, configuration settings, and configuration in HW Config

SIMOTION D4x5-2/D4x5

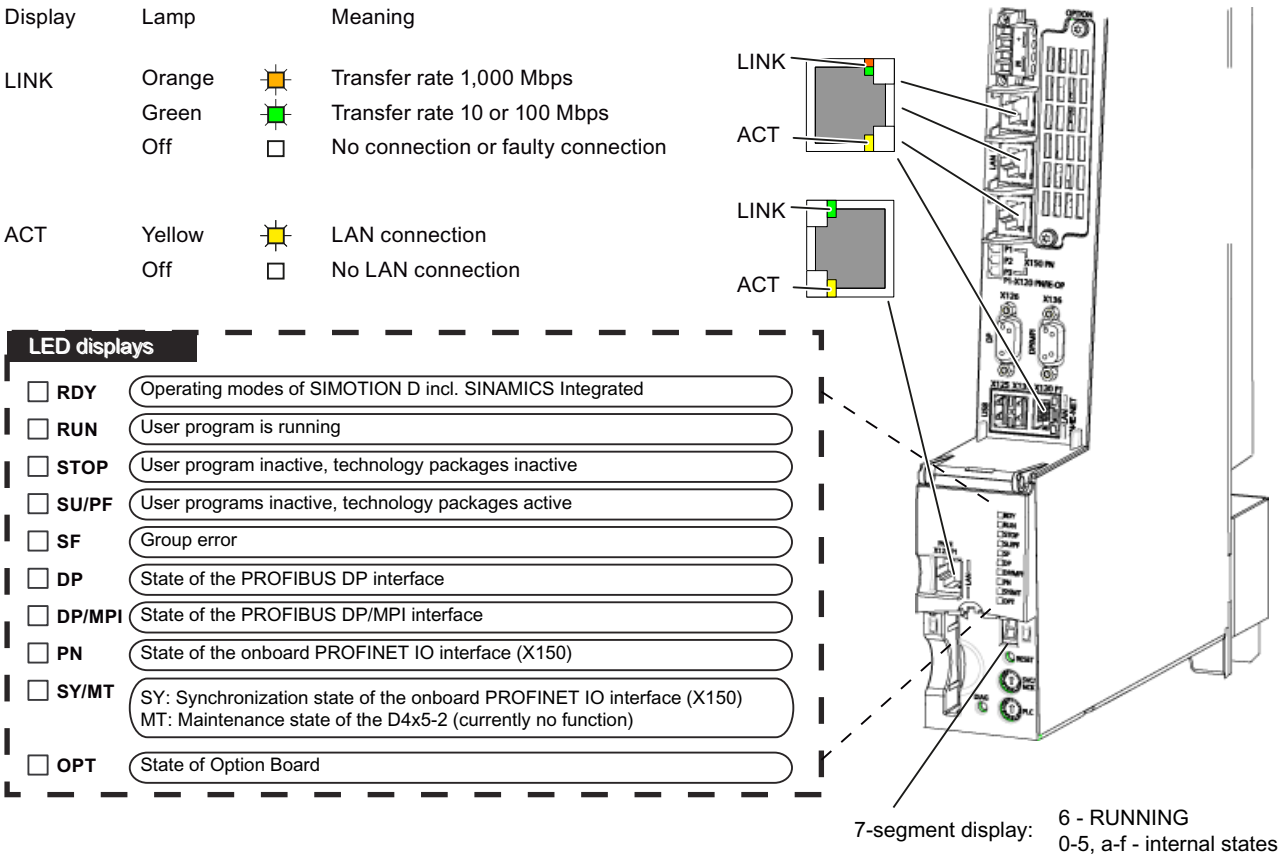

Figure 5-24 LED displays on the device - example of SIMOTION D4x5-2

In addition to the SIMOTION devices themselves, optional modules and interfaces such the PROFINET interface CBE30-2 for D4x5-2 DP/PN also feature LEDs for displaying states and fault diagnostics.

Note

The relevant Commissioning Manuals contain a detailed description of the LED displays, including all the possible combinations and flashing frequencies.

Typical faults

Table 5-12 Typical D4x5-2/D4x5 errors

Fault	Frequent causes	Remedy
RDY LED lights up red or flashes red, flashes quickly 2 Hz (SIMOTION D or SINAMICS Integrated fault)		
	• SINAMICS Integrated has not ramped up or is faulty	Correct and acknowledge fault Acknowledgment carried out with e.g. operator panel, engineering tool, etc. connected
STOP LED lights up yellow (control is in STOP mode - diagnostics with Engineering System or web server)		
	• I/O access error • Program error (e.g. floating point exception) • Technological alarms with CPU STOP response	Correct I/O access **Localize error:** Check entries in the device diagnostics Example: Entry "Operating mode transition blocked" -> check error before this -> entry "I/O access error"
STOP LED flashes yellow, slow flashing (0.5 Hz) (overall reset request)		
	• Memory card has been removed • The non-volatile data does not match up with the project on the memory card	Memory reset
SU/PF LED lights up or flashes yellow, fast flashing (2 Hz) (control in STOP mode of user program)		
	• The technology packages are active. • The user program is not active or is faulty • Device stuck at startup task	Check the entries in the diagnostic buffer and the user program. Switch the control to RUN mode.
SF LED lights up red (error/fault state on the SIMOTION D)		
	• An event that can be acknowledged is pending (alarm, message, note)	Acknowledge the event.
SF LED flashes red, slow flashing (0.5 Hz) (error/fault state on the SIMOTION D)		
	• License missing for licensed technology/optional objects	Check the licenses.
DP, DP/MPI LED lights up red (bus fault)		
	• Terminating resistor missing or in the wrong place • Not all of the connected devices are switched on • Cabling fault • Incorrect baud rate configured or incorrect baud rate set on a bus node	Check terminating resistor, bus node, cabling, and configuration settings
PN LED flashes red (bus fault)		

Fault	Frequent causes	Remedy
	• Failure of a connected I/O device. • At least one of the assigned I/O devices cannot be addressed • Incorrect or no configuration settings	Check configuration settings, check IO device
SY/MT LED does not light up or flashes		
	• SIMOTION D task system is not synchronized with the send cycle of PROFINET IO IRT • SINAMICS Integrated and ext. DP interfaces are not yet synchronized with the PROFINET IO IRT cycle	Check configuration settings, check fault message in SINAMICS diagnostic buffer
OPT LED lights up/flashes red, slow flashing (2 Hz)		
	• Bus fault (CBE30-2 in the case of D4x5-2 or CBE30 in the case of D4x5): – Failure of a connected I/O device – At least one of the assigned I/O devices cannot be addressed – Incorrect or no configuration settings • Firmware download faulty	Check devices (still set to factory settings?), check connection, check cycle clock
Link LED does not light up		
	• There is no physical connection • The connected device is not switched on	Check the cabling, connectors, and device.
Activity LED does not light up		
	• There is no telegram traffic.	If the Link LED is green, use a ping command to check that the system is ready for communication

Typical faults

Table 5-13 Typical D410-2/D410 faults

Fault	Frequent causes	Remedy
RDY LED lights up red or flashes red, flashes quickly 2 Hz (SIMOTION D or SINAMICS Integrated fault)		
	• SINAMICS Integrated has not ramped up or is faulty	Correct and acknowledge fault Acknowledgment carried out with e.g. operator panel, engineering tool, etc. connected
SF/BF LED lights up red (error/fault state on the SIMOTION D)		
	• An event that can be acknowledged is pending (alarm, message, note)	Acknowledge the event.
SF/BF LED flashes red, slow flashing (0.5 Hz) (error/fault state on the SIMOTION D)		
	• License missing for licensed technology/optional objects	Check the licenses.
SF/BF LED flashes red, fast flashing (2 Hz) (bus fault)		
	• A bus fault is pending – PROFIBUS master At least 1 slave is missing – PROFIBUS slave No parameter assignment master found – PROFINET Failure of a connected I/O device; at least one of the assigned I/O devices cannot be addressed; incorrect or no configuration settings	Check the bus nodes, cabling, configuration settings, and configuration in HW Config.
all LEDs light up yellow (D410-2) **RUN/STOP lights up red** (D410)		
	• Power-up of the SIMOTION D without CF card or with CF card without valid operating system (the boot loader may be defective).	Check the CompactFlash Card.
RUN/STOP LED lights up yellow		
	Control is in stop mode - diagnostics with Engineering System or web server	
	• I/O access error • Program error (e.g. floating point exception) • Technological alarms with CPU STOP response	Correct I/O access **Localize error:** Check entries in the device diagnostics Example: Entry "Operating mode transition blocked" -> check error before this -> entry "I/O access error"
	Control in STOP mode of user program	

Fault	Frequent causes	Remedy
	• The technology packages are active. • The user program is not active or is faulty • Device stuck at startup task	Check the entries in the diagnostic buffer and the user program. Switch the control to RUN mode.
RUN/STOP LED flashes yellow, slow flashing (0.5 Hz) (overall reset request)		
	• Memory card has been removed • The non-volatile data does not match up with the project on the memory card	Memory reset
OUT > 5V lights yellow or flashes yellow (electronic power supply for measuring system)		
	• Electronic power supply for measuring system > 5 V	The electronic power supply is configured for 24 V encoders. If you wish to connect a 5 V encoder, please check the parameter settings.
OUT > 5 V / SY off or flashes ("SY" only for D410-2 DP/PN)		
	• SIMOTION D task system is not synchronized with the send cycle of PROFINET IO IRT • SINAMICS Integrated and ext. DP interfaces are not yet synchronized with the PROFINET IO IRT cycle	Check configuration settings, check fault message in SINAMICS diagnostic buffer

CBE30-2/CBE30 Communication Board

The device is connected to PROFINET IO using the Communication Board Ethernet CBE30-2 interface module for the SIMOTION D4x5-2 DP/PN and the CBE30 interface module for the SIMOTION D4x5. The module supports PROFINET IO with isochronous Realtime Ethernet (IRT), PROFINET IO with RT, and standard TCP/IP communication. The Option Board has an X1400 interface with four ports and integrated switch functionality.

Note

A CBE30 can only be inserted into a SIMOTION D4x5. It cannot be inserted into a SIMOTION D4x5-2.

A CBE30-2 can only be inserted into a SIMOTION D4x5-2 DP/PN used as a second PROFINET interface. It cannot be inserted into a SIMOTION D4x5 or D4x5-2 DP.

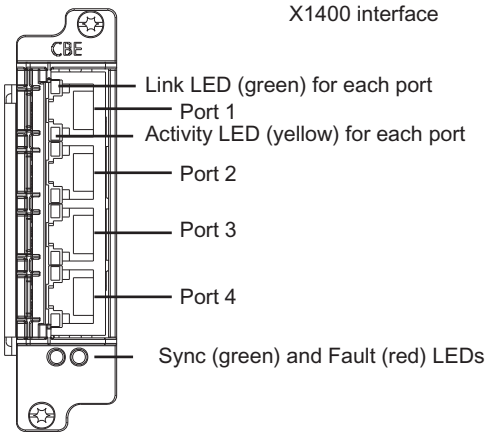

Figure 5-26 Ethernet CBE30-2/CBE30 Communication Board

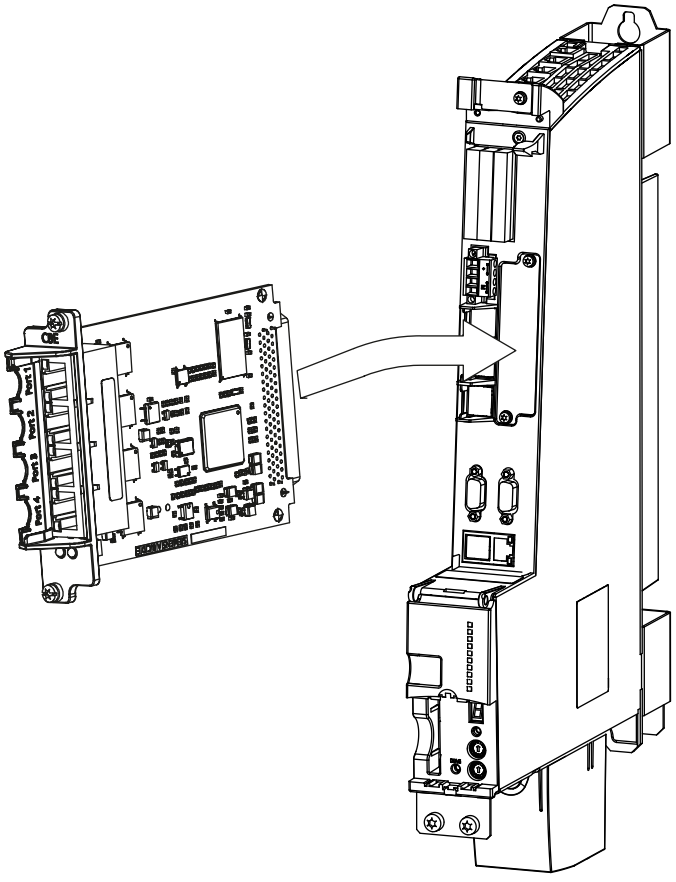

Figure 5-27 Example of D4x5-2: Inserting a CBE30-2

Typical faults

Table 5-14 Typical CBE30-2/CBE30 faults

Fault	Frequent causes	Remedy
Link LED does not light up		
	• There is no physical connection • The connected device is not switched on	Check the cabling, connectors, and device.
Activity LED does not light up		
	• There is no telegram traffic.	If the Link LED is green, use a ping command to check that the system is ready for communication
Fault LED lights up red (bus fault)		
	• No physical connection to a subnet/ switch • Incorrect transmission rate • Full duplex transmission is not activated	Check configuration settings, check IO device, check connection
Fault LED flashes red, fast flashing (2 Hz) (bus fault)		
	• Failure of a connected I/O device. • At least one of the assigned I/O devices cannot be addressed • Incorrect or no configuration settings	Check configuration settings, check IO device
Fault LED flashes red, slow flashing (0.5 Hz)		
	CBE30-2 startup stopped	CBE30-2 is plugged into wrong Control Unit. (CBE30-2 is only supported by SIMOTION D4x5-2 DP/PN, not by SIMOTION D4x5-2 DP)
Sync LED does not light up or flashes		
	• SIMOTION D task system is not synchronized with the send cycle of PROFINET IO IRT • SINAMICS Integrated and ext. DP interfaces are not yet synchronized with the PROFINET IO IRT cycle	Check configuration settings, check fault message in SINAMICS diagnostic buffer

CX32-2/CX32 Controller Extension

The Controller Extension enables scaling of the drive-side computing power of products within the SIMOTION D range. This allows additional drives to be connected, for example.

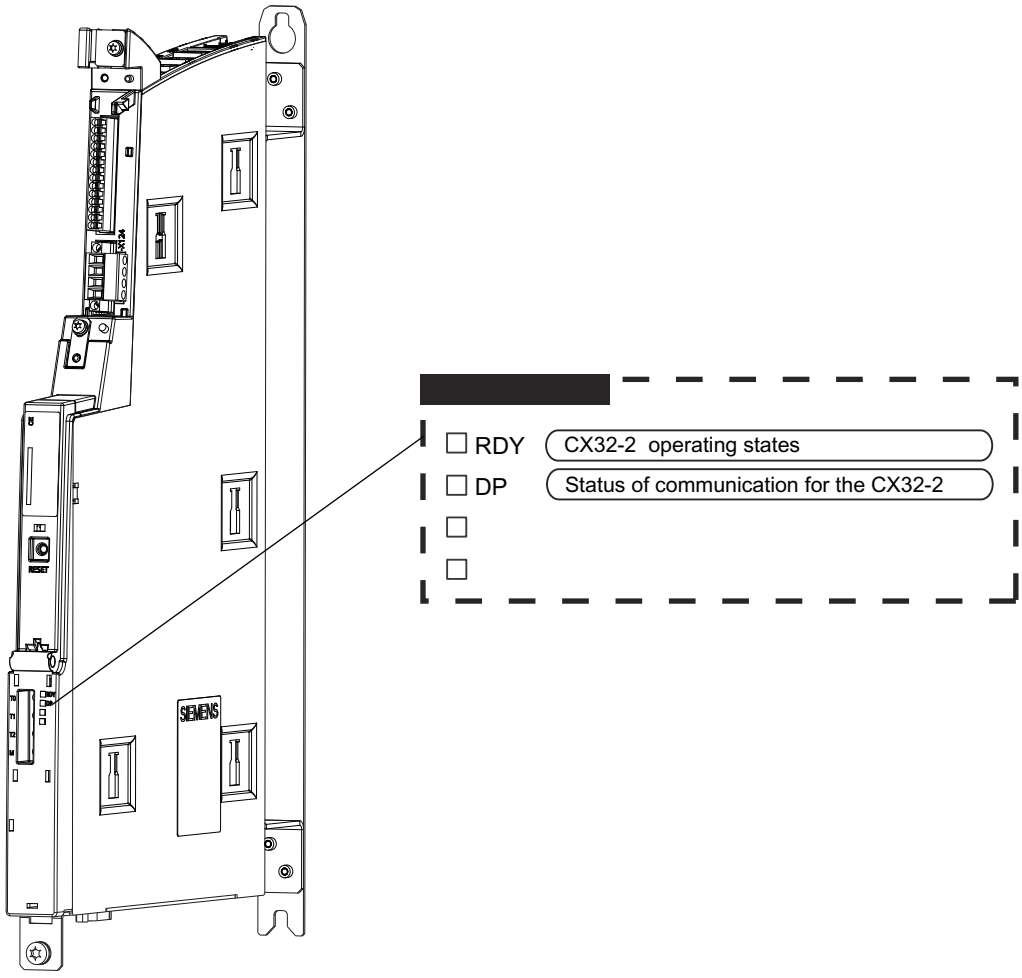

Figure 5-28 LED displays - example of CX32-2

Note

The *SIMOTION D4x5* Commissioning and Hardware Installation Manual and the *SIMOTION D4x5-2* Commissioning and Hardware Installation Manual contain detailed descriptions of the LED displays, including all the possible combinations and flashing frequencies.

Typical faults

Table 5-15 Typical CX32-2/CX32 faults

Fault	Frequent causes	Remedy
RDY LED does not light up (power supply)		
	• The electronic power supply is missing or outside the permissible tolerance range	Check power supply
RDY LED lights up red or flashes red, fast flashing 2 Hz (error on startup)		
	• At least one fault is pending (e.g. RESET, watchdog monitoring, basic system error) • CX32/CX32-2 is ramping up	Check messages in diagnostic buffer
RDY LED flashes red (boot error, CX32 only)		
	• Boot error (e.g. firmware cannot be loaded into the RAM)	Check connection to SIMOTION, check data on CF card, reinstall firmware if necessary
RDY LED flashes yellow, slow flashing (0.5 Hz)		
	• Updating the firmware of the connected DRIVE-CLiQ components	-
RDY LED flashes yellow, fast flashing (2 Hz)		
	• The DRIVE-CLiQ component firmware has been updated; wait for POWER ON of the affected component	Perform a POWER ON of the affected component
DP LED flashes red (CX32-2) **DP1 LED lights up red** (CX32)		
	• Not all of the connected devices are switched on • Cabling fault • CX32/CX32-2 not ready to run (e.g. after switch-on)	Check cabling and configuration settings Check messages in diagnostic buffer

Control Unit CU320-2/CU320

The Control Unit is a central control module in which closed-loop and open-loop functions are implemented for Line Modules and/or Motor Modules.

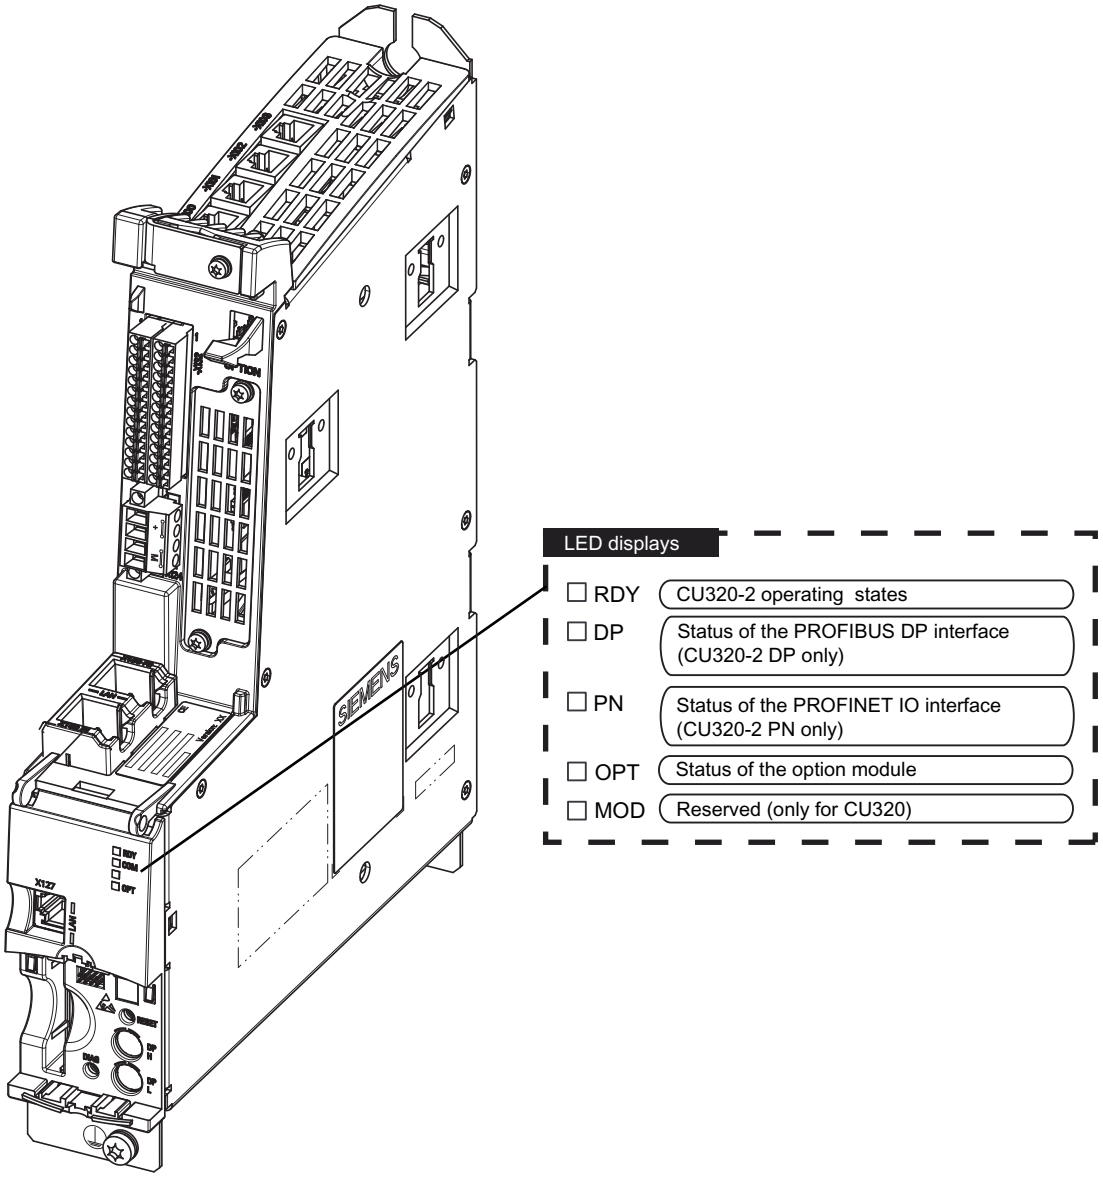

Figure 5-29 LED displays - example of CU320-2 PN

Note

The *SINAMICS S120 Control Units and Supplementary System Components* Manual contains a detailed description of the LED displays, including all possible combinations and flashing frequencies.

Typical faults

Table 5-16 Typical CU320-2/CU320 faults

Fault	Frequent causes	Remedy
RDY LED does not light up (power supply)		
	• The electronic power supply is missing or outside the permissible tolerance range	Check power supply
RDY LED lights up red or flashes red, fast flashing 2 Hz (error on startup)		
	• At least one fault is pending (e.g. RESET, basic system error) • CU320/CU320-2 is ramping up	Check messages in diagnostic buffer
RDY LED flashes red (CU320 only)		
	• Boot error (e.g. firmware cannot be loaded into the RAM)	Check data on CF card, reinstall firmware if necessary
RDY LED flashes yellow, slow flashing (0.5 Hz)		
	• Updating the firmware of the connected DRIVE-CLiQ components	-
RDY LED flashes yellow, fast flashing (2 Hz)		
	• The DRIVE-CLiQ component firmware has been updated; wait for POWER ON of the affected component	Perform a POWER ON of the affected component
DP LED flashes red (CU320-2 DP) **DP1 LED lights up red** (CU320)		
	• Terminating resistor missing or in the wrong place • Not all of the connected devices are switched on • Cabling fault • Incorrect baud rate configured or incorrect baud rate set on a bus node	Check terminating resistor, bus node, cabling, and configuration settings
PN-LED does not light up (CU320-2 PN only)		
	• Cyclic communication has not (yet) taken place.	-
PN-LED flashes green, slow flashing (0.5 Hz) (CU320-2 PN only)		
	• Full cyclic communication has not yet taken place.	-
PN-LED flashes red, slow flashing (0.5 Hz) (CU320-2 PN only)		
	• Bus error, incorrect parameter assignment/configuration	Adapt configuration between controller and devices.
PN-LED flashes red, fast flashing (2 Hz) (CU320-2 PN only)		
	• Cyclic bus communication has been interrupted or could not be established.	Remedy the fault
OPT LED does not light up		

Fault	Frequent causes	Remedy
	• The electronic power supply is missing or outside the permissible tolerance range • Option Board not present • No corresponding drive object created	Check power supply Check Option Board Create drive object
OPT LED lights up red		
	• At least one fault is pending • Option Board not ready to run (e.g. after switch-on)	Check messages in diagnostic buffer

Additional information

- *SINAMICS S120 Control Units and Supplementary System Components* Manual

Communication Board CBE20

The device is connected to PROFINET IO using the Communication Board Ethernet CBE20 interface module for SINAMICS S120. The module supports PROFINET IO with isochronous Realtime Ethernet (IRT), PROFINET IO with RT, and standard TCP/IP communication. The Option Board has an X1400 interface with four ports and integrated switch functionality.

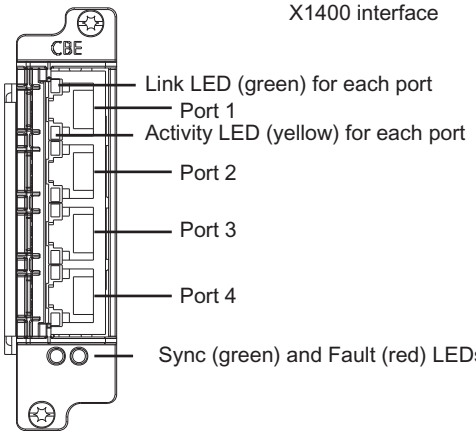

Figure 5-30 Communication Board Ethernet CBE20

Typical errors

Table 5-17 Typical errors

Error	Frequent causes	Remedy
Link LED does not light up		
	• There is no physical connection • The connected device is not switched on	Check the cabling, connectors, and device.
Activity LED does not light up		
	• There is no message frame traffic	If the Link LED is green, use a ping command to check that the system is ready for communication
Fault LED lights up red (bus fault)		
	• No physical connection to a subnet/ switch • Incorrect transmission rate • Full duplex transmission is not activated	Check configuration settings, check IO device, check connection
Fault LED flashes red (bus fault)		
	• Failure of a connected I/O device • At least one of the assigned I/O devices cannot be addressed • Incorrect or no configuration settings	Check configuration settings, check IO device
Sync LED does not light up		
	• If the Link LED is green: Control Unit task system is not synchronized with the IRT cycle clock. An internal substitute cycle clock is generated.	Check configuration settings, check error message in diagnostics buffer

Additional information

- *SINAMICS S120 Control Units and Supplementary System Components* Manual

5.2.4.3 7-segment display

In the case of SIMOTION D4x5-2/D4x5 and P350, a 7-segment display is used to indicate the SIMOTION state.

Meanings of the displays

- 6 - RUNNING
  SIMOTION has ramped up and the cyclic tasks are activated
- 0-5, a-f - internal states (displayed during start-up)
  If a state ≠ 6 is displayed continuously during start-up (i.e. for more than 3 minutes), please analyze the diagnostic buffer. If necessary, contact the hotline to clarify the meaning of the display.
- Flashing point
  Communication is taking place between SIMOTION and SINAMICS Integrated

5.2.4.4 Interfaces

SIMOTION devices feature integrated interfaces, to which an HMI device or engineering PC, for example, can be connected for the purpose of reading out diagnostic information. This equipment is connected via either a PROFIBUS or PROFINET/Ethernet interface.

Use the following tools or software for reading out the information:

- SIMOTION SCOUT Engineering System (see Part III: Service with SCOUT Engineering System (Page 3367))
- SIMOTION IT web interface via web browser (see Part II: Service without SCOUT Engineering System (PC-based, SIMOTION IT) (Page 3352))
- HMI devices, e.g. WINCC flexible

Bus analyzer for diagnosing bus or device faults:

- PROFIBUS DP, e.g.
  - SIMATIC ET200 diagnostic repeater
  - SIMATIC diagnostic repeater for PROFIBUS DP
  - BT 200 physical bus test device for PROFIBUS DP (https://support.industry.siemens.com/cs/ww/de/ps/15683/man)
- PROFINET / Ethernet, e.g.
  - BANY PNIO (http://www.industry.siemens.com/industrial-services/it/de/PRODUCTS/DIAGNOSTICS/BANY_PNIO.HTM) for PROFINET
  - Standard network protocol analyzer for Ethernet, e.g. Wireshark (http://www.wireshark.org/)

You will find information on establishing an online connection via an interface in Establishing a connection to the device (without SCOUT Engineering System) (Page 3353) or the individual sections in Going online (Page 3368) (with SCOUT Engineering System).

5.2.4.5 HMI

An HMI can be connected via the interfaces on the SIMOTION device not only for operator process control purposes, but also to enable diagnostics and display states. See also Interfaces (Page 3342).

In principle, the following message classes are available:

- User error messages
  These are usually messages from the process, containing information on how to resolve the error.
  Irrespective of the HMI system, they are transmitted by a method called bit messaging. The user him/herself assigns the texts to the bit numbers.
  The user can choose to acknowledge the messages via the HMI system or via the application.
  The message texts and their compilation data are located in the HMI.
- Technological alarms and drive messages, technical state alarms (info, warning), and fault messages (alarms) for devices/functions
  These are messages relating to malfuncions or faults, for example, in components such as CPUs or drives. The user can use the ALARM_S procedure from SIMATIC for these messages. ALARM_S is a message number procedure. The message numbers are automatically assigned during configuration in SIMOTION SCOUT. Message texts are uniquely assigned according to their name.
  The messages are called and acknowledged during runtime by means of appropriate system commands.
  The message texts and their compilation data are located in the SIMOTION SCOUT project.
- System messages (e.g. diagnostic buffer)
  These messages cannot be displayed directly in the WinCC flexible message window.
  If you wish to display the messages, you need to send them individually via the ALARM_S message procedure or read them out using the SIMOTION IT web server or the SCOUT engineering tool.

Warning and error messages relating to technology objects are usually output on the HMI and can be acknowledged by the operator.

Examples of Siemens HMI systems:

- Operator panels
- WinCC flexible
- WinCC

Note

Diagnostic buffer entries can also be displayed in a web browser via Ethernet (a PC-based method); see Part II: Service without SCOUT Engineering System (PC-based, SIMOTION IT) (Page 3352).

WinCC flexible

The discrete message procedure can be used to display messages stored on the device (even if these are in more than one language), e.g. information on machine states.

Additionally, S7-compliant message procedures can be used with Alarm_S messages (e.g. information on system errors).

Alarm_S messages are also available in SIMOTION. These messages are configured using the "Message configuration" editor in SIMOTION SCOUT. Alarm_S messages from SIMOTION are processed in WinCC flexible, in the same way as Alarm_S messages from STEP 7.

Special settings need to be made in WinCC flexible and the SIMOTION project in order to use this procedure.

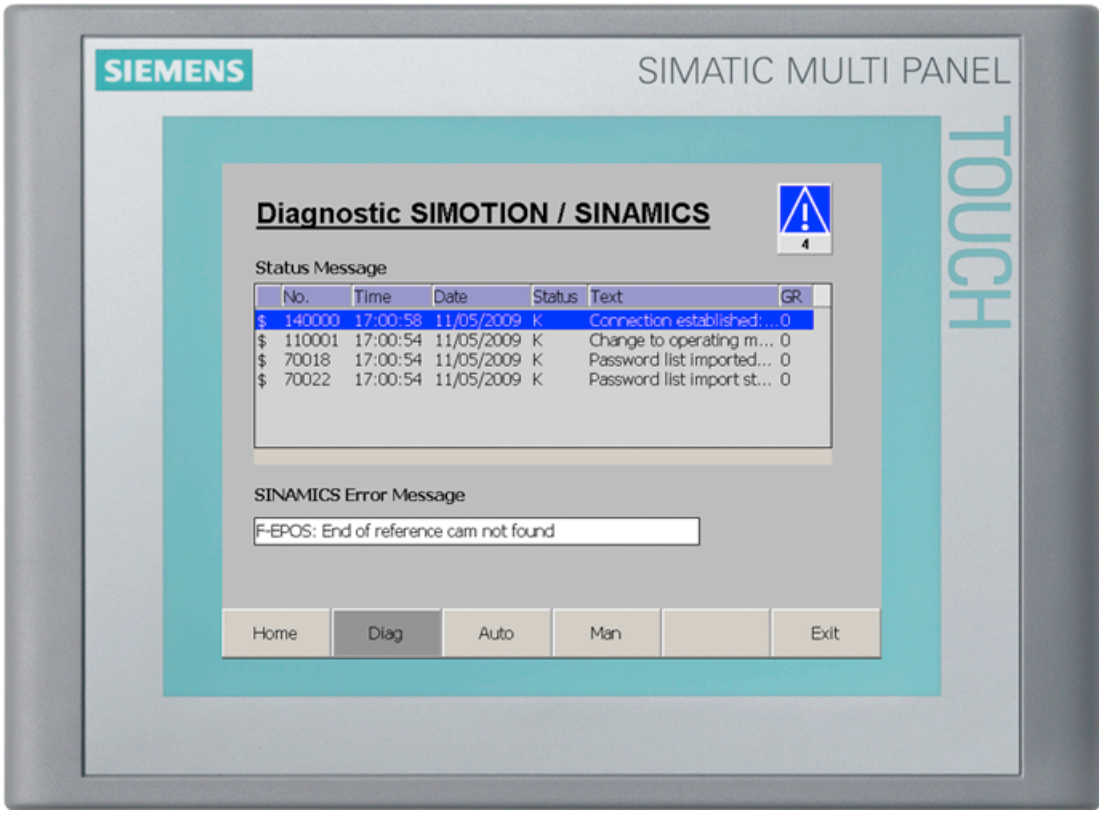

Figure 5-31 Message displays on the operator panel with WinCC flexible

How to activate Alarm_S and SIMOTION messages:

1. In WinCC flexible, open the **Message Settings** tab under **Messages > Settings**.

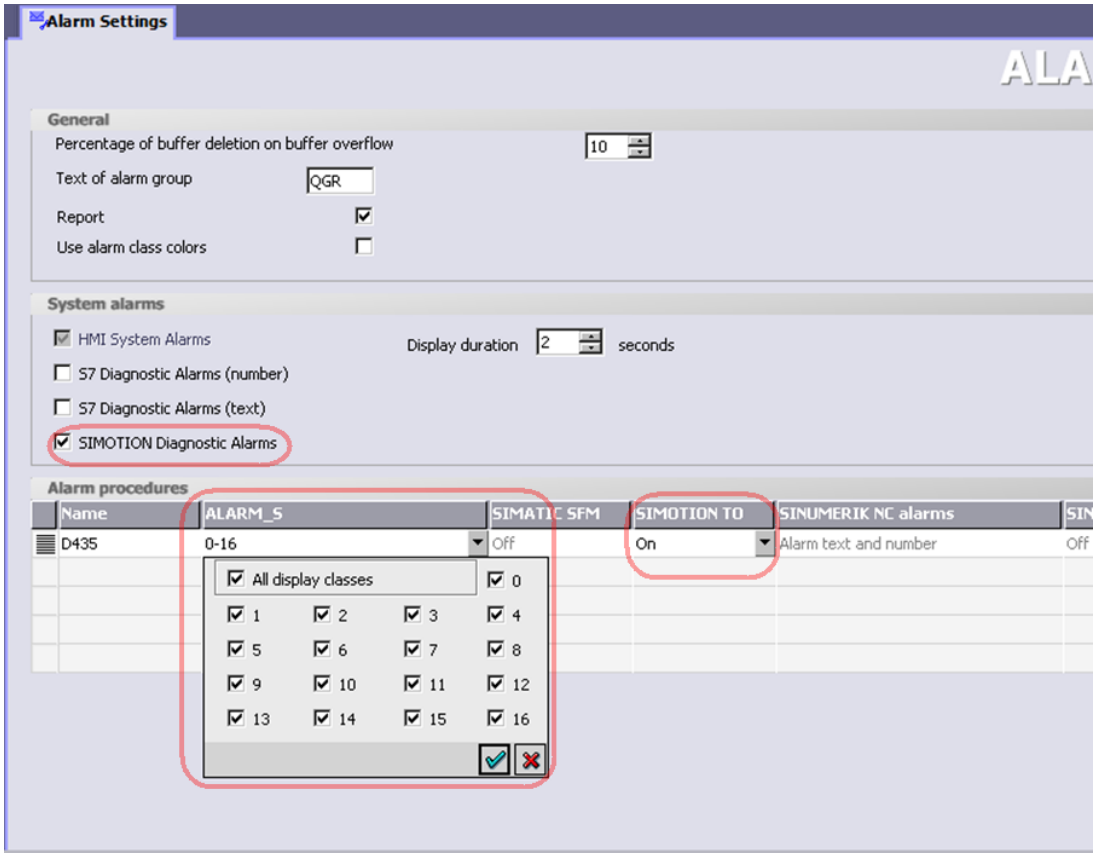

Figure 5-32 Message Settings in WinCC flexible

2. In the **Message procedures** table, activate the Alarm_S messages by assigning them to the message classes (activate the **All display classes** checkbox).
3. In the **Message procedures** table, activate the SIMOTION TO messages using the combo box.

How to activate the display for the Alarm_S and SIMOTION messages:

1. In WinCC flexible, open the **Message View** tab under **Messages > Settings**.

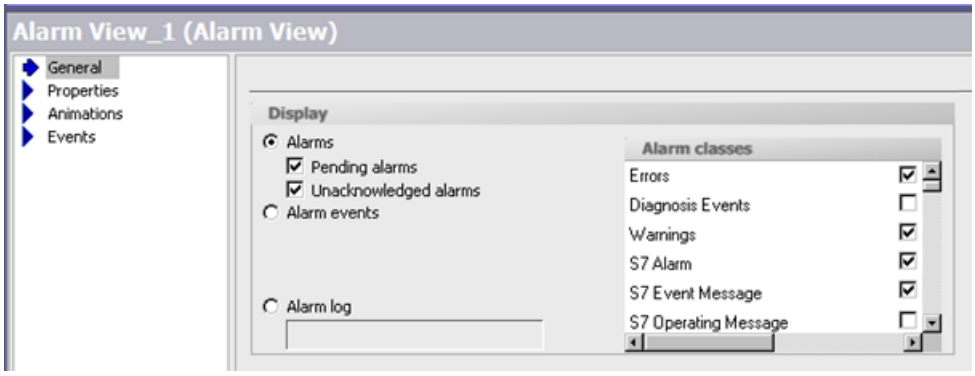

Figure 5-33 Message View dialog in WinCC flexible

2. Under **General**, activate the following message classes:
   - Faults
   - Alarms
   - S7 Message
   - S7 Event Message

How to activate CPU messages in SIMATIC Manager:

- In SIMATIC Manager, open the **CPU Messages** dialog by selecting **Target system > CPU messages...** for the SIMOTION device.
  Select the checkboxes in the **W** (Warning) and **A** (Alarm) columns for the SIMOTION module (see the image below).

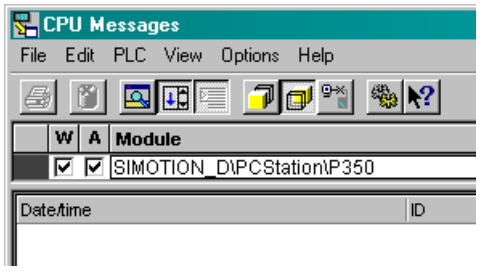

Figure 5-34 CPU Messages dialog in SIMATIC Manager

Additional information

- Links in the *Guides* menu of the online help

See also

Manuals for SIMATIC HMI (WinCC flexible) (https://support.industry.siemens.com/cs/ww/de/ps/14859/man)

5.2.4.6 Backing up diagnostic data and non-volatile data

Following a fault on a SIMOTION device, diagnostic data (e.g. diagnostics buffer content, up-to-date content of websites, etc.) can provide important information on the cause of the fault. With V4.1 SP2 and higher, the user has the option of backing up this data using a simple operation (e.g. a switch position). The data is stored on the CompactFlash Card/MMC in the case of SIMOTION D/C and on the hard disk in the case of SIMOTION P.

The process of backing up and restoring diagnostic data differs according to which SIMOTION platform is being used (C/P/D). SIMOTION D is the only SIMOTION device to feature both a service selector switch and a DIAG button.

This subject is covered in detail for all platforms in Part II, Diagnostic data and non-volatile data (retain data) (Page 3359).

5.2.4.7 Updating devices using the Device Update tool

In SIMOTION SCOUT, the Device Update tool can be used to create update data on the basis of one or more SIMOTION projects (menu **Project > Start Device Update tool**).

The update data created in this way can be uploaded to the SIMOTION device using the CF card/MMC, for example, or also using a USB stick in the case of SIMOTION D4x5-2/D4x5. An Engineering System is not required to do this. You can also update SIMOTION devices via the SIMOTION IT web server Backing up, updating, and restoring device data (Page 3365).

License keys are either retained or may need to be relicensed in the case of function extensions.

Updating does not only mean updating to a higher firmware version, but also involves a project update (for example).

The following update data can be selected and created:

- SIMOTION project (without technology packages)
- Technology packages
- Archive (ZIP file containing SIMOTION SCOUT project)
- User data
- Firmware

The update data contains all the information required for updating or restoring the data on a SIMOTION device.

Note

An up-to-date Firmware Support Package (FWSP) needs to be installed in order to update firmware (V4.1 SP2 and higher). The FWSP is provided with the SIMOTION SCOUT DVD2 under Add-ons and can also be obtained via the Internet at SIMOTION Firmware Support Package (https://support.industry.siemens.com/cs/ww/en/view/33119786).

Restoring refers to the process of reinstating the configuration that was backed up in the SIMOTION device when updating was last performed. If an attempt to update a SIMOTION device fails, for example, the device can be restored to the previous configuration. Restoring is performed via the SIMOTION IT web server and, in the case of SIMOTION D, optionally via the service selector switch.

Saving update data

When creating update data using the Device Update tool, you can select the following:

- Update medium (selection dependent on SIMOTION device)
  - USB stick
  - CF/MMC card
- SIMOTION IT file
- File system (update archive)

If you select the file system option, an update archive containing the **upd_tool.bat** batch file (amongst other things) will be created. By executing the **upd_tool.bat** file, you have the option of installing an update medium on a PC at a later date or creating a SIMOTION IT file. A SIMOTION SCOUT installation is not required on the PC for this purpose.

Transferring update data to the SIMOTION device

The starting point for this is the update media to which the the update data has already been written or a SIMOTION IT file.
An update medium (USB stick or CF/MMC card) is either inserted into the SIMOTION device to be updated, or the update data is transferred to the SIMOTION device via a communication connection (SIMOTION IT).

The update process is triggered by restarting or switching on the SIMOTION device to be updated. Once the update data have been transferred to the memory card in the device for the first time, the data are backed up in the SIMOTION device. (This applies to the USB memory stick and the SIMOTION IT Web server.) The update data is activated as the current configuration after the SIMOTION device has been restarted.

Behavior of the retain data during updating

After the update data has been transferred to the SIMOTION device, the device is restarted and the update data is applied.

During start-up, the non-volatile data that is saved in the SIMOTION device are checked to see if they match the current configuration.

For additional information, please refer to the chapter titled *Behavior of the retain data during updating* in the *Updating SIMOTION Devices* Operating Instructions.

Additional information

- Links in the *Guides* menu of the online help
- *Updating SIMOTION Devices* Operating Instructions

5.2.4.8 Licensing/License key

Overview

Depending on the type and number of RT components used in the project, licenses must be acquired as part of the licensing procedure for SIMOTION. The licenses required for a SIMOTION device are assigned to a hardware component. With SIMOTION C and D they are assigned to the memory cards, and with SIMOTION P to the Communication Board. One or more license keys are generated when the licenses are assigned to the hardware. The license key(s) are saved on the storage medium of the SIMOTION device or in file format during the licensing process.

When replacing the memory card or Communication Board (in the case of P350) or modifying the RT components (e.g. a new technology object), the license key(s) must be redetermined and stored on the virtual memory card.

See also

FAQ: Runtime licensing (http://support.automation.siemens.com/WW/view/en/42014324)

FAQ: Displaying the license key (https://support.industry.siemens.com/cs/ww/en/view/42614521)

Checking and amending licensing information

If the system is under-licensed, the SF LED will flash as a warning and an entry will be made in the diagnostics buffer. You can resolve this by licensing the system correctly.

A wizard for the licensing procedure is available in SIMOTION SCOUT. To open the wizard, select the device in the project navigator followed by **Edit > Licenses**.

Note

Before performing licensing, the configuration process should be completed. Once assigned to a hardware component, a license can no longer be used for any purpose other than that for which it has been issued.

Note

The chapter titled "Licensing" in the SIMOTION SCOUT Configuration Manual contains a detailed description of licensing.

You can also find information on licensing under *FAQs > Updating > Licensing SIMOTION runtime functions* in *SIMOTION Utilities & Applications*, which is part of the scope of delivery of SIMOTION SCOUT.

See also

Remedial measures in the event of loss (Page 3351)

Remedial measures in the event of loss

What to do if you lose the license key due to a faulty card:

1. Order a new card through your Siemens contact.
2. Contact the hotline with the serial numbers of the old and new card.
   The hotline will assign the licenses to the new card and give you the new license key, which you can then transfer to the new card.

The same procedure applies to a Communication Board in the context of SIMOTION P.

What to do if you lose the license key:

1. Connect to the Web License Manager (http://www.siemens.com/automation/license) via a browser.
2. Click **Show License Key**.
   The **Show License Key** screen is displayed.
3. Select **Hardware serial number** and enter the serial number of the memory card (taking care to ensure you enter it correctly).
4. Click the **Get License Key** button.
   The license key is displayed.

How to transfer the license key to the memory card:

1. Choose either of the options below for transferring the license key.
   - Copy the license key and enter it via the **Licenses** dialog in SIMOTION SCOUT (CPU context menu).
   - Save the license key as a text file and copy it to the "KEYS\SIMOTION" directory of the memory card using a card reader and the Explorer. This directory is created when the SIMOTION control is ramped up. If it does not yet exist on the memory card, however, you will need to create it using the Explorer.
2. If necessary, generate a license report on all the licenses assigned to the memory card.

Note

The license key is saved in the "KEYS\SIMOTION" directory on the SIMOTION memory card. With SIMOTION V4.1 SP1 and higher, the license key is copied to the boot sector of the card when the control is ramped up. From then on, it is safely backed up (so that it cannot be lost). If the license key is no longer present on the card, it will be written from the boot sector to the "KEYS\SIMOTION" directory again during ramp-up. This means that the system can rectify any instances of the key being deleted accidentally.

Licensing during hardware replacement

When replacing licensed SIMOTION components (MMC, CF, IsoPROFIBUS board, or MCI-PN board), the associated license key must be assigned to the new SIMOTION component. In this case, please contact customer support for assistance.

5.2.5 Part II: Service without SCOUT Engineering System (PC-based, SIMOTION IT)

5.2.5.1 Overview

It is possible to display diagnostic functions in an Internet browser via the Ethernet interface of SIMOTION devices. The connection may be local (direct) or remote (Internet connection).

The SIMOTION IT web server enables direct diagnosis of the SIMOTION devices. Access takes place using a standard browser (e.g. Internet Explorer) via the IP address of the SIMOTION device (e.g. `http://169.254.11.22`). You can use the preconfigured standard diagnostics pages or your own HTML pages for access.

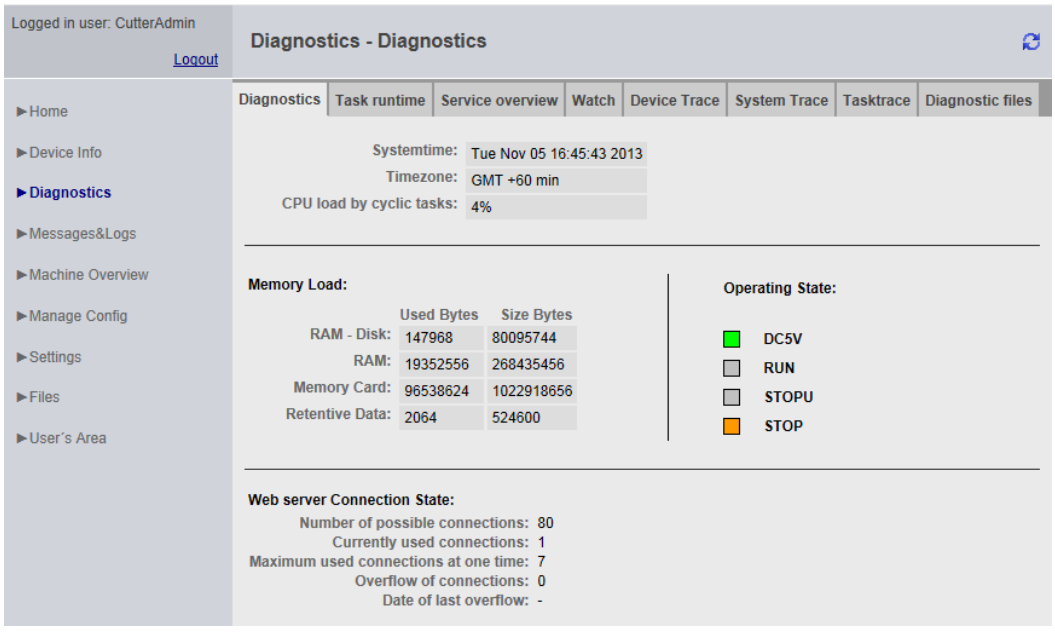

Figure 5-35 SIMOTION IT web server diagnostics

To enable the best possible display of SIMOTION IT web pages on devices such as cell phones or PDAs, a set of special pages is provided for version 4.1 SP4 and higher. You can access these pages via the address `http://<IPAddr>/BASIC`.

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*

5.2.5.2 Establishing a connection to the device

An online connection can be established via the Ethernet interface of the SIMOTION device. You can log on to the device directly using a local network or externally via a remote connection (modem, VPN, WLAN, etc.).

If necessary, establish what local settings are in place on your network (firewall, router, etc.) using your network administration facility.

To establish a connection via the Ethernet interface, you need the IP addresses of the nodes. If you do not know these addresses, you can find out what they are by following the instructions below.

How to determine the IP address of the PC:

1. Open the status dialog box of your local area connection by selecting **Start > Settings > Network Connections** and double-clicking the required network connection (e.g. **Local Area Connection**).
   The status dialog box opens.
2. Select the **Support** tab.
   The active IP address and subnet mask are displayed.

How to determine the IP addresses of SIMOTION devices:

You can determine the IP address of a SIMOTION device using the Primary Setup Tool (PST) (https://support.industry.siemens.com/cs/ww/de/view/19440762). Any additional information can be accessed via this Internet link.

In principle, you can use a ping command to check whether a system is ready for communication.

Typical faults

Table 5-18 Typical faults

Fault	Frequent causes	Remedy
Connection not established		
	• IP address of PG does not match SIMOTION IP address	Adapt the PG's Ethernet address so that the PG is in the same subnet as the connected SIMOTION Ethernet interface.
	• SIMOTION devices with multiple Ethernet interfaces: IP addresses of interfaces are in the same subnets, e.g. Ethernet 1: 192.168.214.1 (255.255.255.0) Ethernet 2: 192.168.214.2 (255.255.255.0)	The Ethernet interfaces of a SIMOTION device must be in different subnets
	• With version V4.4 and higher, access to the SIMOTION IT web server is protected by a multi-level security concept. Depending on the security level, you will either have no access or only limited access to the web pages. Authentication may be required for unlimited access.	If web server has not been deactivated: authentication required Access is also possible bypassing the user administration when the service selector switch is in position "8". Access is possible for 120 minutes. After this time has expired, the position of the service selector switch must be changed. This state is also indicated by the LED flashing. (SIMOTION D4xx-2 only)
	• Cabling	Check cabling (crosslink cable!) Patch cables can also be used on SIMOTION PROFINET ports, D4x5-2 Ethernet interfaces, and PCs/switches featuring autocrossing functionality.

Fault	Frequent causes	Remedy
	• Router	If you are using routers, do not select "TCP/IP Auto" as the communication protocol. Reason: Selecting "TCP/IP Auto" automatically assigns an address in the SIMOTION subnet, which means the input port on the router can no longer be accessed.
	• Ports on PG disabled (e.g. in the case of PCs configured by an IT department)	Check default ports (80, 102, etc.)
	• Proxy entered for Internet services In the case of PCs configured by an IT department, the entry for a configuration script can prevent the online connection from being established	Deactivate the checkbox for the **Use automatic configuration script** setting You can find this setting in Windows under **Internet Properties > Connections > LAN settings > Settings...** button.
	• Other	Voltage Off/On on the device

5.2.5.3 Device diagnostics

Overview

You can use SIMOTION IT to display SIMOTION device data on the preconfigured standard diagnostics pages or via variables (Variable Provider).

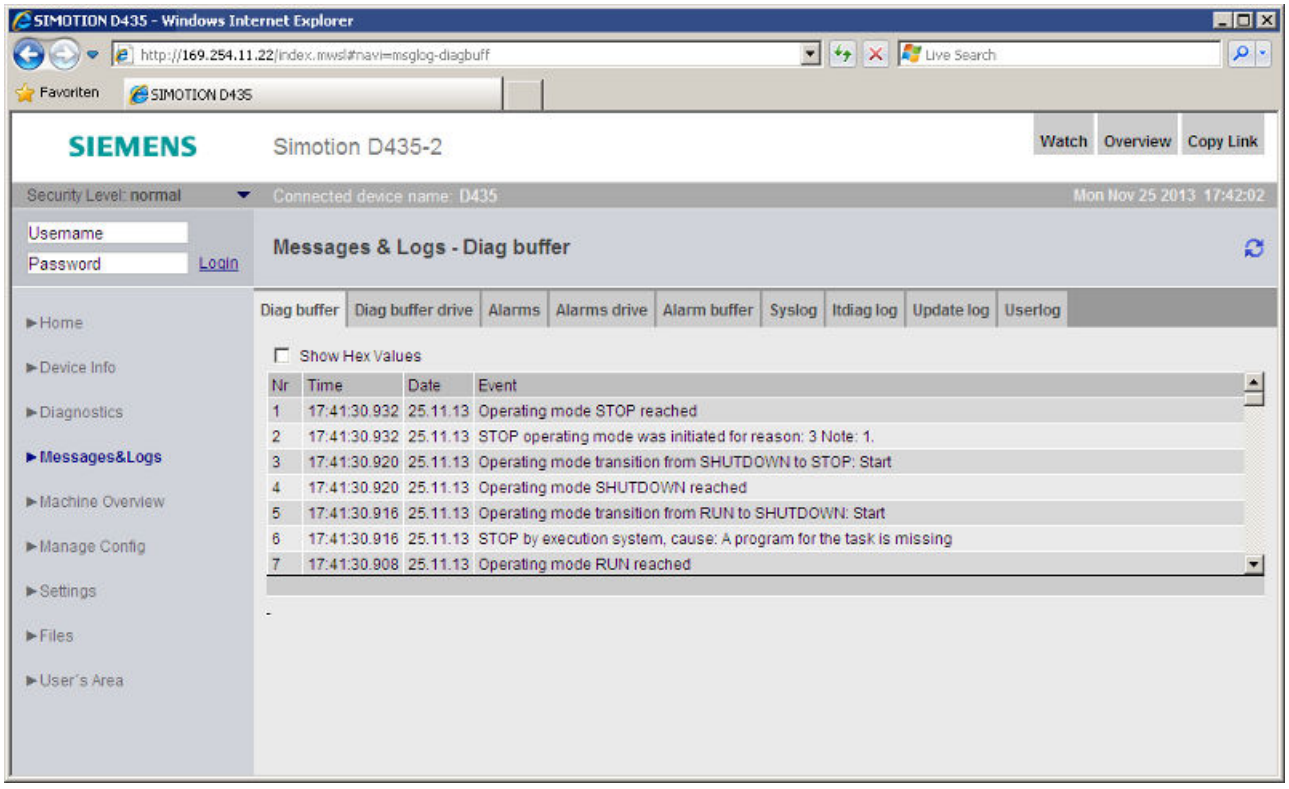

Figure 5-36 Example: SIMOTION IT web server - diagnostic buffer

The information that is available includes the following:

- Operating mode
- Component versions (I&M data)
- Firmware
- MAC and IP address
- Article numbers
- SIMOTION diagnostic buffer
- SINAMICS diagnostic buffer
- Status and runtimes of various tasks
- Memory size and assignment
- Processor utilization
- Current CPU utilization
- SIMOTION alarms
- SINAMICS alarms
- Drive parameters
- TO, I/O, and user variables
- Service overview with axis states

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*
- *Technology Packages Alarms* Diagnostics Manual
- SINAMICS List Manuals

See also

I&M (identification & maintenance) data (Page 3356)

I&M (identification & maintenance) data

I&M (identification & maintenance) information for most configurable PROFIBUS or PROFINET components is available in the module (e.g. SIMATIC ET200 or SINAMICS S120). This information enables service technicians to identify the module immediately in the event of a component failure and order the right version of the spare part required.

The PROFIBUS user organization standardizes the structure of this data and how it is meant to be interpreted (regardless of the component manufacturer) in itsI&M profile (http://www.profibus.com/nc/downloads/downloads/profile-guidelines-part-1-identification-maintenance-functions/display/). The data can be displayed on an HMI system, for example.

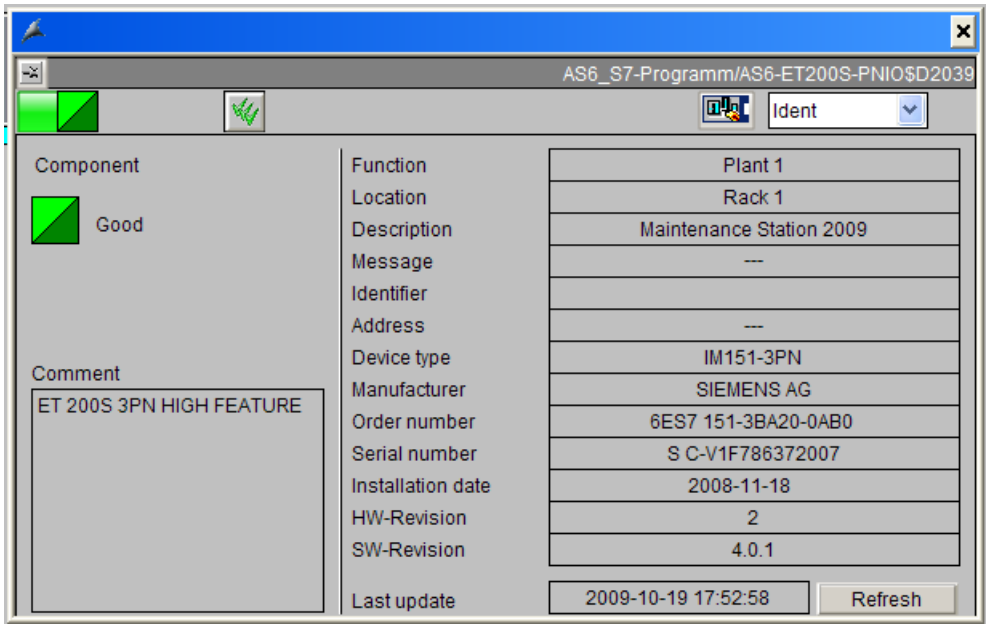

Figure 5-37 Example of I&M data

For SIMOTION, this data is available as a structure (under IM0-Data code) in the list of variables for the device.

Diagnostics buffer

The module states are logged in the diagnostics buffer. The standard site *Diag buffer* shows a list of the diagnostic events that have occurred, in chronological order.

Examples of possible diagnostic events include:

- Faults in a module
- Faults in the process wiring
- System errors in the CPU
- CPU operating mode transitions
- User-defined diagnostic events
- Technology object alarms
- Alarm_S messages
- Errors in the user program
- User-defined entries with the _writeAndSendMessage() function
- Compatibility errors, e.g. between the drive software and SIMOTION (SIMOTION D)

Note

Order of diagnostics buffer entries

The firmware of the devices is based on a real-time capable operating system that is controlled by interrupts and priorities. For this reason, an event can have several diagnostics buffer entries whose time stamps can vary by a few milliseconds. These entries might not be arranged in strict chronological order.

Therefore, when evaluating the diagnostics buffer, the adjacent previous and subsequent entries should also be taken into account.

System utilization

System utilization

You can locate and display information on system utilization using the diagnostics variables of the *SIMOTION diagnostics* variable provider. You will find a detailed description of this in the *SIMOTION IT Diagnostics and Configuration* Diagnostics Manual.

Tasktrace

The Tasktrace page of the SIMOTION IT web server enables you to set up and control the SIMOTION task trace. The SIMOTION Task Trace supports you when troubleshooting in the SIMOTION multitasking environment. The SIMOTION Task Trace records the sequence of individual tasks, identifies user events that you can generate via a program command, and displays all this information graphically.

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*

Analyzing user data

Watch table

To enable variable monitoring, the SIMOTION IT web server provides a watch table with a symbol browser The SIMOTION and drive parameters are displayed in a tree structure. The selected parameters are displayed in a table alongside this.

Trace

To enable variable monitoring, the SIMOTION IT web server provides a variable trace via a web service. Variables can be selected here.

Records can be displayed graphically in the WebTraceViewer for evaluation purposes.

The WebTraceViewer is included with *SIMOTION Utilities & Applications* in SIMOTION V4.1 SP5 and higher, and can also be obtained via account managers (PridaNet); see WebTraceViewer - information (https://support.industry.siemens.com/cs/ww/de/view/31716712). *SIMOTION Utilities & Applications* is part of the scope of delivery of SIMOTION SCOUT.

Note

With V4.1 SP5 and higher, the WebTraceViewer is included in the firmware of SIMOTION devices. The standard diagnostics page "Trace" on the SIMOTION IT web server also provides a download link for setting up the WebTraceViewer.

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*

5.2.5.4 Diagnostic data and non-volatile data (retain data)

Overview

With version 4.0 and higher, you have the option of backing up diagnostic data. This can be done during operation or start-up. The settings required for this depend on what platform you are using and are described in detail in the following sections and the manuals referred to below.

With SIMOTION D, for example, you can use the service selector switch (V4.1 SP2 and higher) to write diagnostic data and non-volatile data to the CF card. SIMOTION P320-3/P350-3 provides a *diagnostic switch* as part of the *SIMOTION P state* application. The diagnostic data can then be sent to the technical support department (of the machine manufacturer or Siemens) for evaluation.

The information that is backed up includes retain data, diagnostic buffers, alarms, and HTML pages with up-to-date content (snapshots).

The data that is backed up can provide important information after a fault has occurred.

You can use non-volatile data (retain data) in situations where this has not been saved on the data medium using the *_savePersistentMemoryData()* system function and you wish to restore the non-volatile data after a CPU has been replaced.

Table 5-19 Overview of diagnostics options

SIMOTION device	Backing up diagnostic data		Storing diagnostic data	Replacing a CPU without SIMOTION SCOUT
	During start-up	During operation		
C2xx	simotion.ini	Web server	MMC [2)]	Yes
D4x5	Service selector switch simotion.ini	Service selector switch Web server	CompactFlash Card [2)]	Yes
D410-2/D4x5-2	Service selector switch DIAG button simotion.ini	Service selector switch DIAG button Web server	CompactFlash Card [2)]	Yes

SIMOTION device	Backing up diagnostic data		Storing diagnostic data	Replacing a CPU without SIMOTION SCOUT
	During start-up	During operation		
D410 [1]	Service selector switch simotion.ini	Service selector switch Web server[1]	CompactFlash Card [2]	Yes
P320-3/P350	Diagnostic switch simotion.ini	P state Web server	Hard disk	Yes

[1] D410 PN only; not D410 DP (an Ethernet or PROFINET interface is required for the SIMOTION IT web server)

[2] Read out with card reader

With the SIMOTION IT web server, the diagnostic data can be read out as a ZIP file in the *Diagnostic files* dialog box.

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*
- *SIMOTION C* Operating Instructions
- *SIMOTION D4x5* Manual
- *SIMOTION D4x5* Commissioning and Hardware Installation Manual
- *SIMOTION D4x5-2* Manual
- *SIMOTION D4x5-2* Commissioning and Hardware Installation Manual
- *SIMOTION D410* Manual
- *SIMOTION D410*-2 Manual
- *SIMOTION D410* Commissioning Manual
- *SIMOTION D410-2* Commissioning and Hardware Installation Manual
- *SIMOTION P320-3 and Panels* Commissioning and Hardware Installation Manual
- *SIMOTION P350-3 and Panels* Commissioning and Hardware Installation Manual

Backing up diagnostic data and non-volatile data

During operation

The advantage of backing up diagnostic data and non-volatile data during operation is that enhanced diagnostic information via HTML pages and TO alarm information are also available.

The HTML pages contain the contents of the standard pages including Watch tables and of user-defined pages with the current variable values.

Initiating the backup process

- **SIMOTION P**
  Via the *SIMOTION P state* application, in menu **Options** > **Set Diagnostic Switch**
- **SIMOTION D**
  Via the service selector switch and, in the case of D410-2/D4x5-2, via the DIAG button too, see Backing up during operation using a service selector switch (Page 3396)
- **SIMOTION IT web server** (all platforms)
  Via the *Diagnostic files* dialog box, see Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*, AUTOHOTSPOT and Backing up during operation using the SIMOTION IT web server (Page 3401)

During start-up

Backing up diagnostic data and non-volatile data during start-up provides you with diagnostic information, but without HTML pages/TO alarm information.

Possible applications for backing up during start-up

- Backing up data of a SIMOTION device that is unable to run/has crashed
- **SIMOTION P**
  If it is not possible to back up data via the SIMOTION IT web server or P state, e.g. in the case of P350 without an operator panel.

Initiating the backup process

- **SIMOTION P**
  By activating the diagnostic switch; see description in appendix
- **SIMOTION D**
  Via the service selector switch and, in the case of D410-2/D4x5-2, via the DIAG button too; see description in appendix
- **INI file** (all platforms)
  An INI file stored on the data medium is detected during start-up and initiates the backup process.

See also Backing up during start-up using a service selector switch (SIMOTION D) or INI file (Page 3399).

See also

Restoring non-volatile data (Page 3365)

Storing diagnostic data and non-volatile data

Diagnostic data and non-volatile data are stored identically for the **SIMOTION C**, **SIMOTION D** and **SIMOTION P** hardware platforms in the following directory:

- `\USER\SIMOTION\HMI\SYSLOG\DIAG`
  On the CompactFlash card or MMC (SIMOTION C / SIMOTION D), CFast card (SIMOTION P)

If necessary, you should provide the relevant technical support department with this information. With a CF card/MMC, diagnostic data is read out via a standard card reader or the standard SIMOTION IT web server pages.

Table 5-20 Diagnostic data and non-volatile data

File	Application
DIAGBUF.TXT	Diagnostic buffer in a simple text format: Numerical values; no specific plain text. A text editor is used for evaluation purposes.
PMEMORY.XML	Non-volatile data (retain data) An operator action can restore the non-volatile data backed up after a CPU has been replaced, see Restoring non-volatile data (Page 3365).
TOALARMS.TXT	Text file containing the pending TO alarms. Only TO IDs, alarm numbers, and auxiliary HEX values. **Note** The TO alarms are only generated if diagnostic data has been created during operation (STOP / STOPU / RUN).
HTML page	If the diagnostic data is backed up, the URLs are requested from the text file (DIAGURLS.TXT) and stored as HTML pages together with their contents, see also Displaying diagnostic data via websites (Page 3362). **Note** The HTML pages are only stored if diagnostic data is created during operation (STOP / STOPU / RUN).
Other files	All other files stored in the directory are only of relevance to technical support.

Note

Use HTML pages if you wish to back up diagnostic data in text format. HTML pages enable user-friendly diagnostics. In addition to the standard SIMOTION IT diagnostics pages, you have the option of creating your own HTML pages (e.g. for the axis status or for machine diagnostics). Customized diagnostics pages or even watch tables stored in the device are particularly suitable for application problems, as you can define the content yourself.

Displaying diagnostic data via websites

In the `DIAGURLS.TXT` text file found in the `...\USER\SIMOTION\HMI\SYSLOG\DIAG` directory, you can specify HTML files whose status is to be stored on the data carrier when diagnostic data is created during operation (e.g. `devinfo.mwsl` must be entered for the `devinfo.htm` HTML page)

Since the pages in question are stored together with their most up-to-date content, this enables archiving of the latest state information regarding the SIMOTION device, as well as the machine/system, from the point at which the diagnostic data was created (e.g. when the service selector switch or DIAG button was activated).

In addition to the standard SIMOTION IT diagnostics pages, it is possible to store customized pages. You can find out how to create pages of this type in, for example, the article *Creating WEB pages for SIMOTION IT* under *SIMOTION IT* in *SIMOTION Utilities & Applications*. *SIMOTION Utilities & Applications* is part of the scope of delivery of SIMOTION SCOUT.

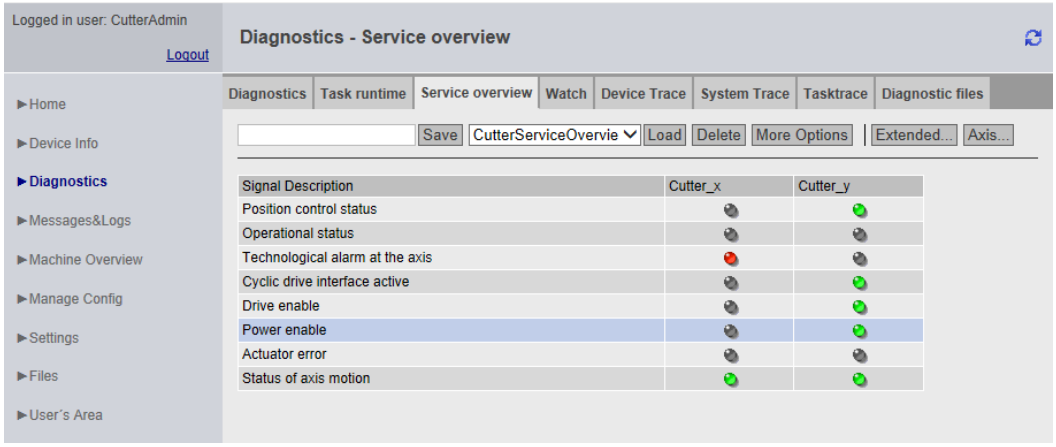

Figure 5-38 Example of service overview

DIAGURLS.TXT

The following points must be noted for the `DIAGURLS.TXT` file:

- A `DIAGURLS.TXT` file containing the standard SIMOTION IT pages is created automatically if you have not saved your own `DIAGURLS.TXT` file.
- Standard SIMOTION IT pages are entered "without" a path specification (e.g. "devinfo.mwsl" for the standard SIMOTION IT page "devinfo.htm").
- Customized SIMOTION IT pages (such as "user.htm") in the `...\USER\SIMOTION\HMI\FILES` directory on the CF card must contain the `FILES/` path specification.
- If you have created subfolders (e.g. "myfolder" in the FILES directory), these must also appear in the path.
- Only 1 file name may be used per line.
- Empty lines are not permitted (an empty line will be interpreted as the end of the list).
- No distinction is made between upper-case and lower-case letters.
- It does not matter whether you use "\" or "/" in the path name.

Backing up diagnostic data and non-volatile data via the SIMOTION IT web server

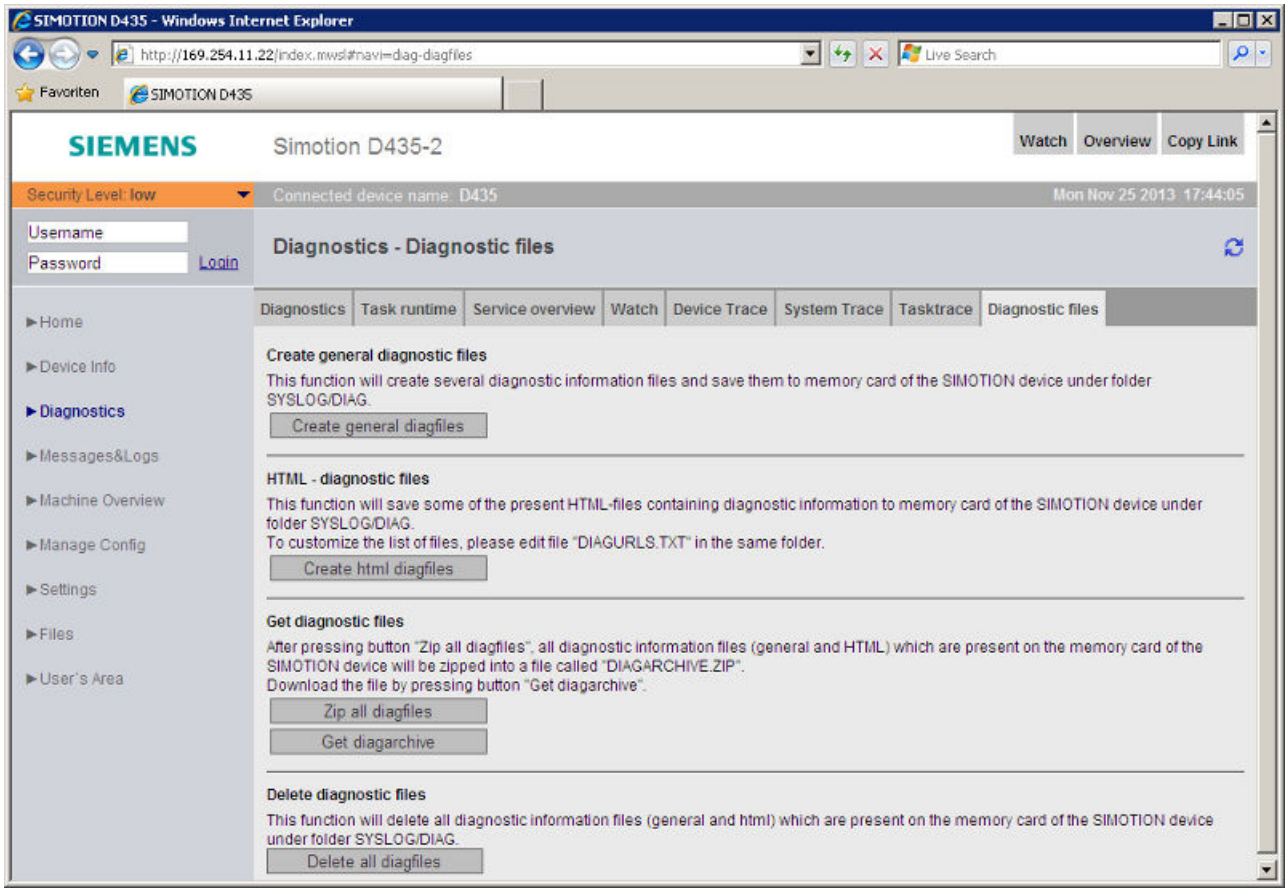

Figure 5-39 Example of diagnostics via an HTML page

Table 5-21 Diagnostic files dialog

Button	Description
Create general diagfiles	Saves diagnostic data and non-volatile data in the `...\USER\SIMOTION\HMI\SYSLOG\DIAG` directory. HTML files used for diagnostics purposes are not saved.
Create html diagfiles	Diagnostics HTML pages are saved on the data medium. It should be noted that only those pages that are listed in the `DIAGURLS.TXT` file in directory `...\USER\SIMOTION\HMI\SYSLOG\DIAG` are saved.
Zip all diagfiles	Stores all files and folders in a ZIP file in directory `...\USER\SIMOTION\HMI\SYSLOG\DIAG`, while retaining the folder structure.
Get diagarchive	The ZIP file is saved on a connected PG/PC.
Delete all diagfiles	Deletes all data stored in directory `...\USER\SIMOTION\HMI\SYSLOG\DIAG`. The directory itself is not removed, however.

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*

Restoring non-volatile data

After a CPU has been replaced, the non-volatile data is restored automatically (provided it was saved beforehand).

The data can be saved on the data medium using the **_savePersistentMemoryData()** system function (for example, see the Commissioning Manual AUTOHOTSPOT)

With V4.1 SP2 and higher, it is possible to create non-volatile data on all SIMOTION platforms using a specific operation. The process of backing up this data can be initiated, for example, via the SIMOTION IT web server or, for SIMOTION D, using a service selector switch or DIAG button. See also Backing up diagnostic data and non-volatile data (Page 3360).

The process of restoring data is different for SIMOTION P and SIMOTION C/D. With SIMOTION P, the non-volatile data is restored on the basis of a backup copy on a PC data medium, and with SIMOTION C/D it is restored on the basis of a backup copy on the MMC or CF card.

The appendix contains a detailed description of Restoring non-volatile data (Page 3402) created in this way.

See also

Storing diagnostic data and non-volatile data (Page 3361)

5.2.5.5 Backing up, updating, and restoring device data

Some of the options the *Manage Config* standard page of the SIMOTION IT web server offers are: importing device updates, backing up selected items of data from the device, and restoring the most recent update that was imported.

The **Get selected data** button transfers the currently active device data that is selected to the PC. You can choose from the following data items:

- Firmware
- Technology packages
- Project
- Archive (archived SIMOTION SCOUT project)
- User data
- SIMOTION IT files

The data that was backed up can be reimported into the device.

When you press the **Send update data** button, the update data created with the Device Update tool is loaded onto the memory card in the SIMOTION device. The data for the existing configuration is renamed and backed up automatically, and can be retrieved again at any time. This data is accessed if a restore process is carried out.

Following this, the SIMOTION device is restarted. When the device is booted, the data which has recently been imported is applied as the current configuration and activated.

Note

If no structural change has been made, the retain data are always kept, regardless of the firmware version.

If structural changes are made during the update, the retain data can be saved before updating begins and then transferred again (see SIMOTION SCOUT function "Save and restore variables").

Additional information

- Links in the *Guides* menu of the online help
- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*

See also

Updating devices using the Device Update tool (Page 3348)

5.2.5.6 User-defined service and diagnostics information

SIMOTION IT also offers the option of creating user-defined web pages. Among other things, you can use these additional, individually created web pages to display and change device data that is relevant to your application as well as machine-specific data.

In addition, you can back up these web pages together with their most up-to-date content (snapshots); see also Displaying diagnostic data via websites (Page 3362).

For information on how to create user-defined pages see, for example, the article in *SIMOTION Utilities & Applications* under the category of SIMOTION IT. *SIMOTION Utilities & Applications* is part of the scope of delivery of SIMOTION SCOUT.

Additional information

- Diagnostics Manual *SIMOTION IT Diagnostics and Configuration*

5.2.6 Part III: Service with SCOUT Engineering System

5.2.6.1 Overview

The SIMOTION SCOUT Engineering System offers a comprehensive range of functions for fault/error diagnostics. These functions are outlined in the sections that follow.

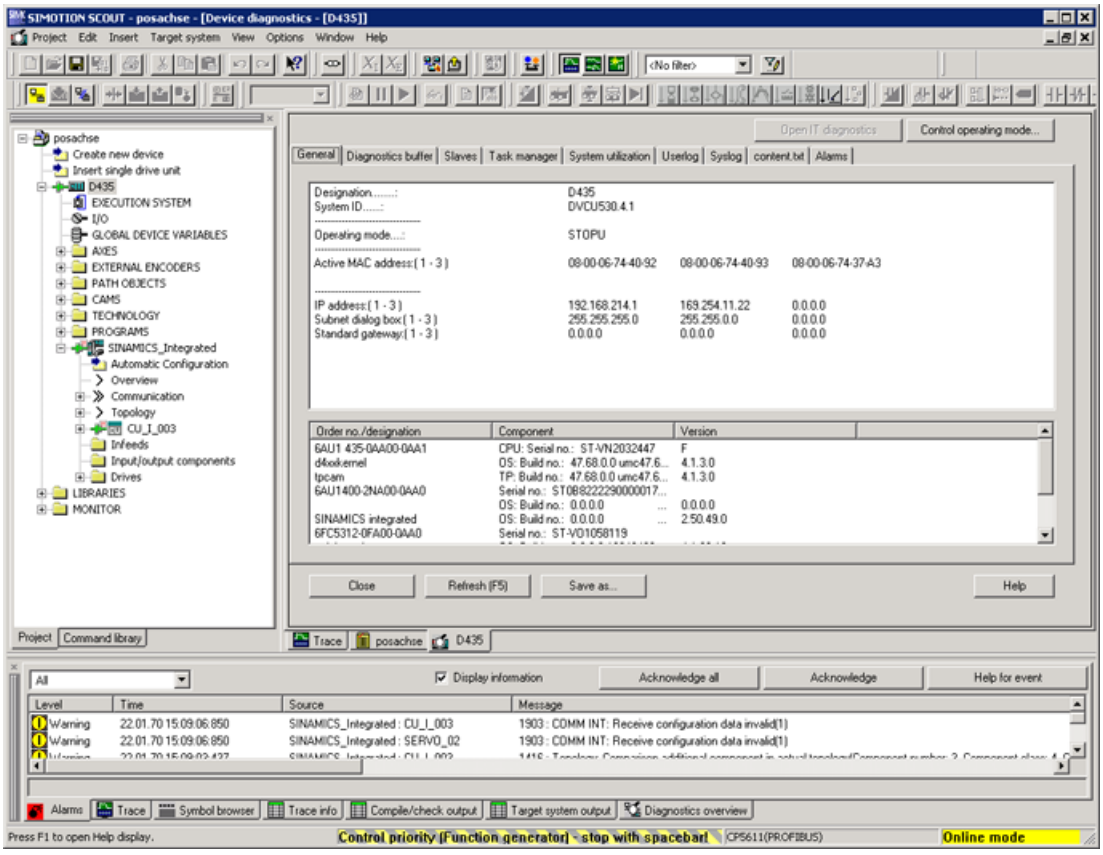

Figure 5-40 Example: SIMOTION SCOUT, Device diagnostics

Use the current project on the machine and the SIMOTION SCOUT software version that is compatible with this. See also Compatibility list (https://support.industry.siemens.com/cs/ww/de/view/36955304).

SIMOTION networks

SIMOTION supports PROFIBUS and PROFINET/Ethernet (TCP/IP). With these network solutions, you can connect the SIMOTION devices in accordance with the requirements of your application.

The sections below draw a distinction between using PROFIBUS and Ethernet/PROFINET for the connection to the SIMOTION device, and between using SIMOTION SCOUT with and without an existing project.

See also

SIMOTION -- Diagnostics -- Analyzing error messages (https://support.industry.siemens.com/cs/ww/de/view/68425516)

5.2.6.2 Going online

Overview

You have the choice of communicating with the control via PROFIBUS DP, PROFINET, or Industrial Ethernet. The S7ONLINE option allows you to communicate with all directly connected controls via the system network specified in the project (e.g. via PROFINET/PROFIBUS/MPI). This access method, which is specified once, enables you to use routing to reach other controls and drives connected to the SIMOTION control via PROFIBUS/PROFINET. This assumes that the nodes support routing.

These options require an online access method to be specified during initial commissioning. To do this, you need to connect the PG/PC interface of the device to the communication interface concerned in NetPro (yellow line in NetPro to PG/PC; see also figures in PROFIBUS (Page 3369) and Ethernet/PROFINET (Page 3372)).

Note

In NetPro, the actual computer being used to create the configuration settings is entered as the PG/PC. If the project is edited using another computer, then the PG/PC needs to be changed to this one. It is recommended that you enter multiple PGs in NetPro if several different persons are taking turns at working on the same project with their PGs.

Note

In addition to the S7Online connection option for the PG/PC interface, with SIMOTION V4.2 and higher you can also set up a second, direct connection to the drive. This enables you to connect STARTER/SIMOTION SCOUT to the device at various locations (e.g. from the control room and directly (locally) on the drive in the workshop) via the interfaces provided, without the need to reconfigure the PG/PC interface.

Note

You will also find a detailed explanation of the procedure in the Internet as FAQ Establishing an online connection to SIMOTION and STEP7 V5.5 SP3 (https://support.industry.siemens.com/cs/ww/en/view/79161896).

PROFIBUS

The PG/PC must be equipped with a PROFIBUS interface for connection purposes.

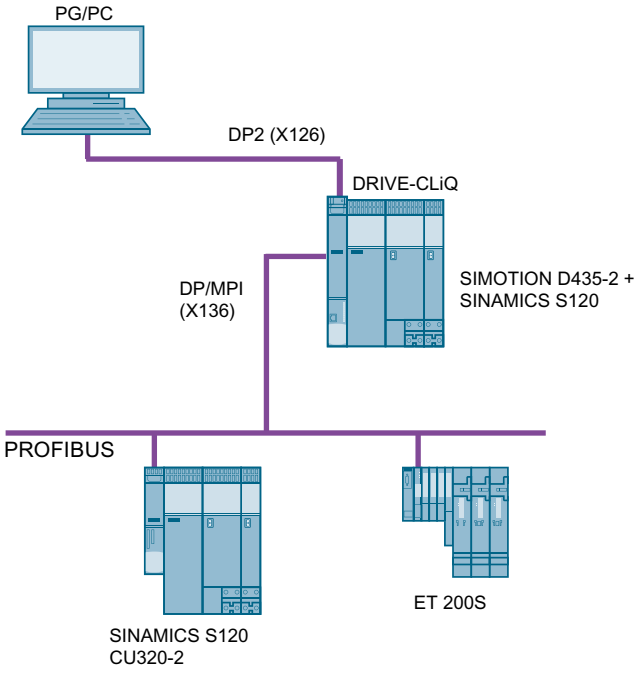

Figure 5-41 Example of a PROFIBUS application

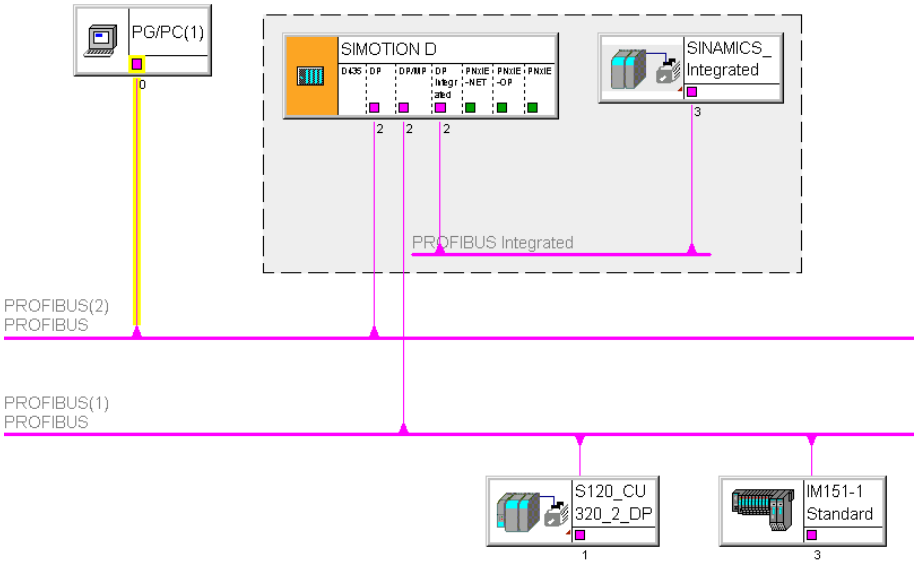

Figure 5-42 Example of a PROFIBUS application - configuration settings in SIMATIC NetPro for PG/PC

Check whether the nodes can be accessed.

In SIMOTION SCOUT, the network settings in menu **Options > Set PG/PC interface...** must match the existing network/interface on the SIMOTION device in order to establish the online connection.

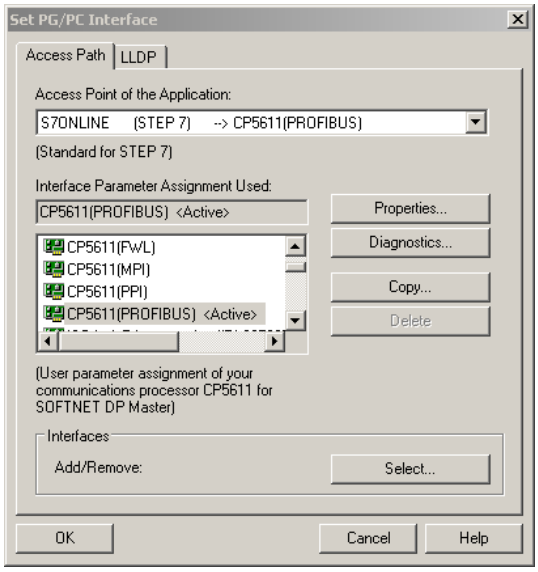

Figure 5-43 Setting the PG/PC interface to S7Online -> PROFIBUS

Pressing the **Diagnostics...** button in the **Set PG/PC Interface** dialog opens a diagnostics dialog, which you can use to check whether the PG/PC interface is functional and whether the right settings have been made for it.

For PROFIBUS, there is also an extended diagnostics option which opens in a separate dialog.

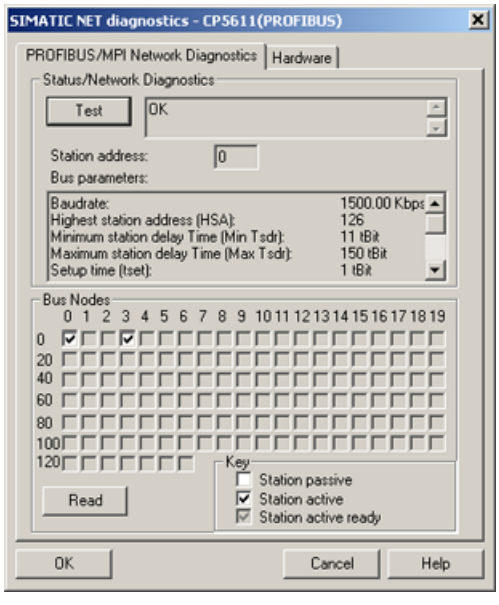

Figure 5-44 SIMATIC NET diagnostics

Table 5-22 Using the SIMATIC NET diagnostics dialog

Button	Description
Test	To check the operating status, click **Test**. If the module is ready to run, **OK** will appear in the field to the right of the button. In this case, the station address is displayed along with the additional current bus parameters and version data.
Read	To display the bus nodes, click **Read**. If the module is ready to run, a list of all the active nodes on the bus will be created. If the module is already communicating and the module supports this function, the list of bus parameters will be created using local information from the module. If the module is not currently communicating or it does not support the creation of a local list, the individual station addresses will be queried via the network. This creates a load on the bus and can take several seconds.

How to identify the bus nodes

1. Use the  button to execute the Accessible nodes function.
   The interfaces, device type, firmware, and addresses that can be used to access the nodes are displayed.

Typical faults

Table 5-23 Typical faults

Fault	Frequent causes	Remedy
Connection via PROFIBUS not possible		
	• Terminating resistor missing or in the wrong place • Not all of the connected devices are switched on • Cabling fault • Incorrect baud rate configured or incorrect baud rate set on a bus node	Check terminating resistor, bus nodes, cabling, and configuration settings, and check whether any PROFIBUS addresses have been assigned more than once. A diagnostic repeater installed in the network may provide additional diagnostic information.

Additional information

- Links in the *Guides* menu of the online help
- *SIMOTION C* Operating Instructions
- *SIMOTION D4x5* Commissioning and Hardware Installation Manual
- *SIMOTION D4x5-2* Commissioning and Hardware Installation Manual
- *SIMOTION D410* Commissioning Manual
- *SIMOTION D410-2* Commissioning and Hardware Installation Manual
- *SIMOTION P320-3 and Panels* Commissioning and Hardware Installation Manual
- *SIMOTION P350-3 and Panels* Commissioning and Hardware Installation Manual
- *SIMOTION SCOUT Communication* System Manual

See also

PG/PCs and CPs - Manuals and Operating Instructions (https://support.industry.siemens.com/cs/ww/de/ps/15683/man)

Ethernet/PROFINET

The PG/PC must be equipped with a standard Ethernet interface.
Since PROFINET is based on Industrial Ethernet, a PROFINET network is accessed using the same mechanisms as those used for an Ethernet network.

Note

If the integrated ports on the SIMOTION devices are not enough for your requirements, you can use an external SCALANCE switch. If PROFINET IO with IRT communication is to be enabled downstream of the switch, a suitable switch (which supports IRT) must be used.

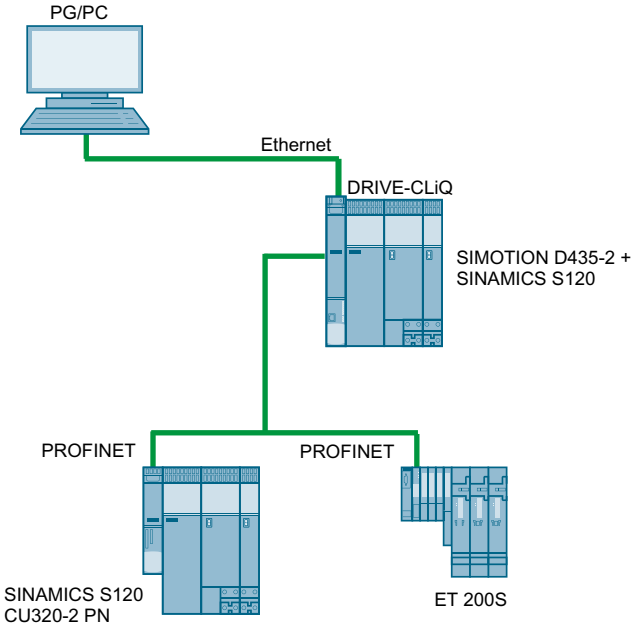

Figure 5-45 Example of an Ethernet/PROFINET application

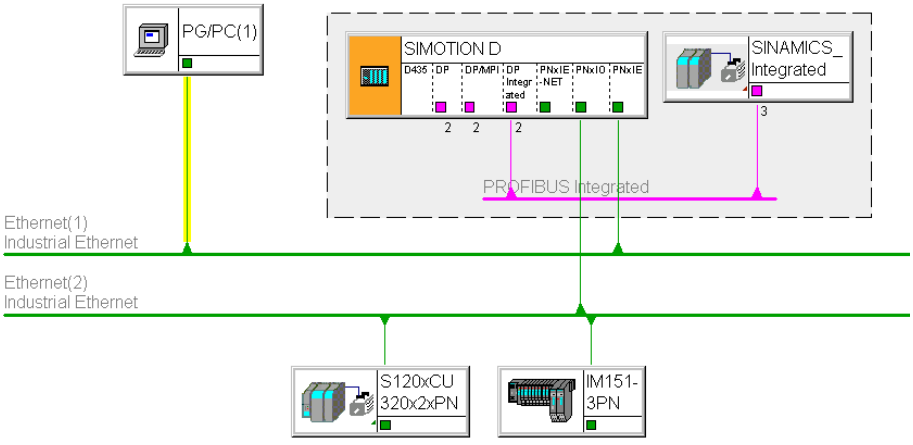

Figure 5-46 Example of an Ethernet/PROFINET application - configuration settings in NetPro

Note

SIMOTION supports internal routing as of V4.1 SP2. This, for example, makes connections from Ethernet (e.g. PN/IE X127) to PROFINET (PN-IO X150) possible.

Check whether the nodes can be accessed.

In SIMOTION SCOUT, the network settings in menu **Options > Set PG/PC interface...** must match the existing network/interface on the SIMOTION device in order to establish the online connection.

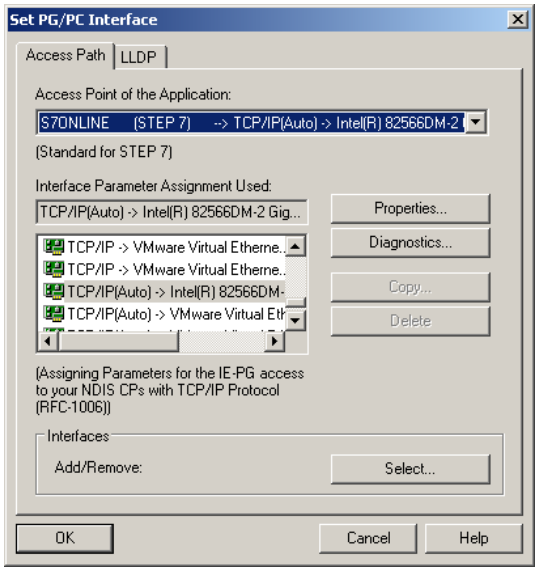

Figure 5-47 Setting the PG/PC interface to S7Online -> TCP/IP

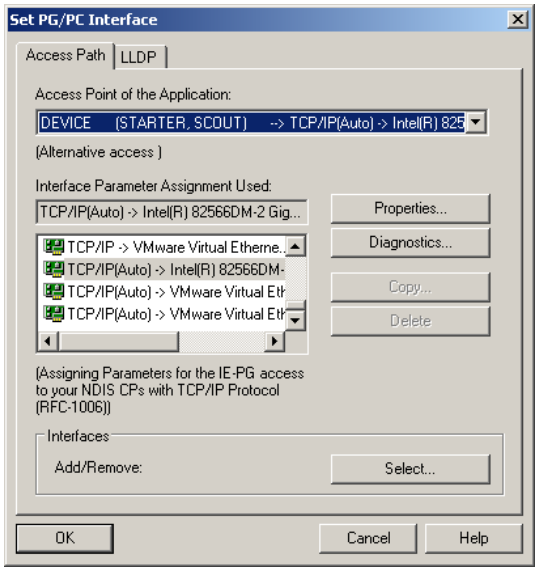

Figure 5-48 Setting the PG/PC interface to DEVICE -> TCP/IP (SIMOTION V4.2 and higher)

Setting the interface to DEVICE (SIMOTION V4.2 and higher) enables different PGs to be used, for example, without the need to reconfigure the PG/PC interface. Additional information can also be found via the list of links for this section in the relevant online help menu.

Pressing the **Diagnostics...** button in the **Set PG/PC Interface** dialog opens a diagnostics dialog, which you can use to check whether the PG/PC interface is functional and whether the right settings have been made for it. The Diagnosis Hardware function or SR protocol does not check the connection to the SIMOTION device, only whether the interface is suitable for establishing an S7Online connection.

To establish a connection via the Ethernet interface, you need the IP addresses of the nodes. If you do not know these addresses, you can find out what they are by following the instructions below.

How to determine the IP address of the PC:

1. Open the status dialog of your local area connection by selecting **Start > Settings > Network Connections** and double-clicking **Local Area Connection**.
   The **Local Area Connection Status** dialog opens.
2. Select the **Support** tab.
   The active IP address and subnet mask are displayed.

How to identify the IP addresses of the SIMOTION devices (example without a project):

1. Use the button to execute the Accessible nodes function.
   The interfaces, device type, firmware, and addresses that can be used to access the nodes are displayed. If nodes are present in other subnets, only the IP address will be displayed and a relevant message will be output.

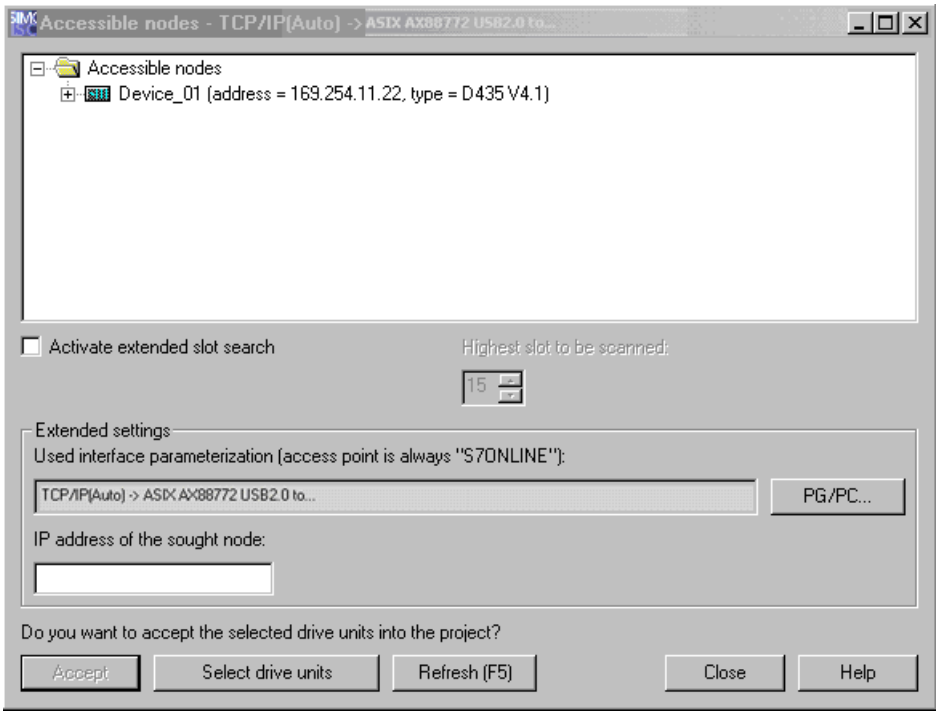

Figure 5-49 Accessible nodes dialog - example of Ethernet node

How to determine the IP addresses of the SIMOTION devices (example with a project):

1. Open HW Config by double-clicking the SIMOTION device in SIMOTION SCOUT.
2. In HW Config, select **Target system > Ethernet > Edit Ethernet node...** .
   The **Edit Ethernet node** dialog opens.
3. Start the search using the **Browse...** button.
   The devices which can be accessed via the unique MAC addresses are identified and displayed.
4. Pressing the **Flashing** button causes a flash telegram to be transmitted for the selected module. In turn, this causes the module to display a signal on the interface being addressed. Please refer to the device documentation to find out which display element is used for signaling (e.g. the SF LED flashes at a fast frequency with SIMOTION D4x5-2).

Note

Make sure the IP addresses are unique on the network before you go online with your PG/PC. Identical IP addresses on the network may cause communication and operating faults.

Contact your network administrator if you do not have all the information you need for network operation.

Typical faults

Table 5-24 Typical faults

Fault	Frequent causes	Remedy
Connection via Ethernet /PROFINET not possible		
	• IP address of PG does not match SIMOTION address	The PG/PC must be in the same subnet as the SIMOTION device
	• IP address assigned twice	Adapt the Ethernet address of a node (PG)
	• Cabling	Check cabling (crosslink cable) Patch cables can also be used on SIMOTION PROFINET ports, D4x5-2 Ethernet interfaces, and PCs/switches featuring autocrossing functionality.
	• Other	• Voltage Off/On on the device • If the Link LED is green, use a ping command to check that the system is ready for communication
See also typical errors/faults for the LED displays (Page 3322)

Going online without a user project

Configuration settings cannot be changed or extended unless a user project matching the project in the SIMOTION device is available on the PG/PC. However, the section below describes how to establish an online connection to the device even if you do not have this, so that you can read device diagnostics or determine the firmware version of the devices, for example.

The process used to establish the connection depends on the interface being used and is described in the following sections:

- PROFIBUS (Page 3369)
- Ethernet/PROFINET (Page 3372)

Once you have successfully identified the nodes using the Accessible nodes function, in this same dialog you can right-click the required device to select it and then call up the device diagnostics (for example) via the context menu.

The diagnostics options of the SIMOTION IT web server (Page 3352) are also available.

See also

Device diagnostics (Page 3382)

Going online with a user project

Checking the PG/PC assignment

A project contains a PG/PC assignment configured in NetPro. This PG/PC assignment specifies which PG/PC interface is used to access a specific interface of the SIMOTION device.

You also need to take into account the interface settings in the SIMOTION device.

How to check whether a PG/PC assignment is active in the project:

1. Open the SIMOTION project.
2. Open NetPro using the  button.
   The network configuration settings for the project are displayed.
3. A PG/PC assignment is active if the following apply:
   - A PG/PC block is present
   - A connection to the SIMOTION device has been created
   - The connection from the PG/PC to the network is marked in yellow

Going online

1. Open HW Config by double-clicking the SIMOTION device in SIMOTION SCOUT.
2. In HW Config, select **Target system > Ethernet > Edit Ethernet node...** .
   The **Edit Ethernet node** dialog opens.
3. Start the search using the **Browse...** button.
   The devices which can be accessed via the unique MAC addresses are identified and displayed.
4. Pressing the Flashing button causes a flash telegram to be transmitted for the selected module. In turn, this causes the module to display a signal on the interface being addressed. Please refer to the device documentation to find out which display element is used for signaling (e.g. the SF LED flashes at a fast frequency with SIMOTION D4x5-2).

Note

Make sure the IP addresses are unique on the network before you go online with your PG/PC. Identical IP addresses on the network may cause communication and operating faults.

Contact your network administrator if you do not have all the information you need for network operation.

Typical faults

Table 5-25 Typical faults

Fault	Frequent causes	Remedy
Not possible to connect using the accessible nodes		
	• NetPro settings not made or incorrect	Check the NetPro settings. Multiple PG/PC stations can also be created. The connection from the assigned, active PG/PC to the network is shown in yellow.
	• Configured firmware version in the project is different to the firmware version in the device	Check the entries in the SIMOTION SCOUT message window (incorrect firmware message) Check the versions of SIMOTION SCOUT and the device firmware. You can find out which device firmware version requires which SIMOTION SCOUT version by consulting the Compatibility list (https://support.industry.siemens.com/cs/ww/de/view/36955304) or contacting the hotline.
	• Not possible to go online even though NetPro settings have been configured and firmware is correct	Check whether the cable is also connected to the interface configured in NetPro (e.g. PN/IE X127). Notice: The SIMOTION device can still be accessed via Accessible nodes.
Connection has been established, but project is not consistent with online data (red symbols in project navigator)		
	• SIMOTION inconsistent	Determine where exactly the differences lie using the Project comparison (Page 3389) function, and align the data
	• SINAMICS inconsistent	Determine where exactly the differences lie using the Project comparison (Page 3389) function, and align the data
Connection has been established, but downloading is not possible		
	• Causes are displayed on the Target system output tab in SIMOTION SCOUT • Too little memory with P320-3/ P350-3	Check the information on the Target system output tab Allocate more memory space in the SIMOTION P control manager

Factory settings for SIMOTION devices

Factory settings for interfaces

The factory settings for the interfaces are outlined in the Commissioning Manuals. In the online help, you can access the relevant sections directly via the links for this section (*Guides* menu).

Table 5-26 Factory settings for SIMOTION devices

Interface	Setting
C2xx	
Ethernet PNxIE X7	169.254.11.22 (subnet 255.255.0.0)
PROFINET PNxIO X11 (only C240 PN)	192.168.0.1 (subnet 255.255.255.0)
PROFIBUS DP1 X8	2 (baud rate 1.5 Mbit/s)
PROFIBUS DP2/MPI X9	2 (baud rate 1.5 Mbit/s)
D4x5	
Ethernet IE1-OP X120	192.168.214.1 (subnet 255.255.255.0)
Ethernet IE2-NET X130	169.254.11.22 (subnet 255.255.0.0)
PROFIBUS DP1 X126	2 (baud rate 1.5 Mbit/s)
PROFIBUS DP2/MPI X136	2 (baud rate 1.5 Mbit/s)
D4x5-2	
Ethernet PNxIE X127	169.254.11.22 (subnet 255.255.0.0)
Ethernet PNxIE-NET X130	192.168.2.1 (subnet 255.255.255.0)
Ethernet PNxIE-OP X120 (only D4x5-2 DP)	192.168.213.1 (subnet 255.255.255.0)
PROFINET PNxIO X150 (only D4x5-2 DP/PN)	192.168.1.1 (subnet 255.255.255.0)
PROFIBUS DP X126	2 (baud rate 1.5 Mbit/s)
PROFIBUS DP/MPI X136	2 (baud rate 1.5 Mbit/s)
D410 DP	
PROFIBUS DP/MPI X21	2 (baud rate 1.5 Mbit/s)
D410 PN	
PROFINET PN-IO X200	192.168.0.1 (subnet 255.255.255.0)
D410-2 DP	
PROFIBUS X21 DP/MPI	2 (baud rate 1.5 Mbit/s)
PROFIBUS X24 DP	2 (baud rate 1.5 Mbit/s)
Ethernet PNxIE X127	169.254.11.22 (subnet 255.255.0.0)
D410-2 PN	
Ethernet PN/IE X127	169.254.11.22 (subnet 255.255.0.0)
PROFIBUS DP/MPI X21	2 (baud rate: 1.5 Mbits/s)
PROFINET PNxIO X150	192.168.1.1 (subnet 255.255.255.0)
P320-3	
Ethernet PNxIE X2	169.254.11.21 (subnet 255.255.0.0)
PROFINET PNxIO X3	192.168.0.1 (subnet 255.255.255.0)

Interface	Setting
P350-3	
Ethernet IE1 ETH1	169.254.11.21 (subnet 255.255.0.0)
Ethernet IE2 ETH2	192.168.214.1 (subnet 255.255.255.0)
PROFIBUS X101 DP (IsoPROFIBUS board)	2 (baud rate 1.5 Mbit/s)
PROFIBUS X102 DP/MPI (IsoPROFIBUS board)	2 (baud rate 1.5 Mbit/s)
PROFINET X21 (MCI-PN board)	192.168.0.1 (subnet 255.255.255.0)
CBE30-2/CBE30	
PROFINET X1400	192.168.0.1 (subnet 255.255.255.0)

Note

PROFINET addresses are only assigned by means of a project download; see also Ethernet/ PROFINET (Page 3372).

Restoring the factory settings

If there is definitely nothing wrong with the connection and it is not possible to download anything, you can restore the factory settings on the device.

NOTICE

Data loss

This will cause all data to be lost, with the exception of the SIMOTION kernel and licenses. For this reason, you should back up the non-volatile data before you do this. See also Backing up diagnostic data and non-volatile data (Page 3360).

First, the device should be restored to its delivery state (factory settings). The method for establishing the delivery state differs for the SIMOTION devices.

The Commissioning Manuals and Operating Instructions describe the process of restoring the factory settings. In the online help, you can access the relevant sections directly via the links for this section (*Guides* menu).

Note

The existing IP settings for the CBE30-2/CBE30 are restored to the factory settings.

Once the factory settings have been established, transfer the project and the previously backed-up non-volatile data to the device (see also Restoring non-volatile data (Page 3365)).

Establishing a connection to the device (Page 3353)

5.2.6.3 Device diagnostics

Overview

The device diagnostics provide an overview containing operating information about the system and the individual devices in the project. The device diagnostics are only available in ONLINE mode and, in the case of SINAMICS devices, as of SINAMICS firmware version V2.5 SP1. SINAMICS device messages can be found in the diagnostic buffer, starting from the entry `>>>>>> SINAMICS Integrated: Start diagnostic buffer, station address = x <<<<<<`.

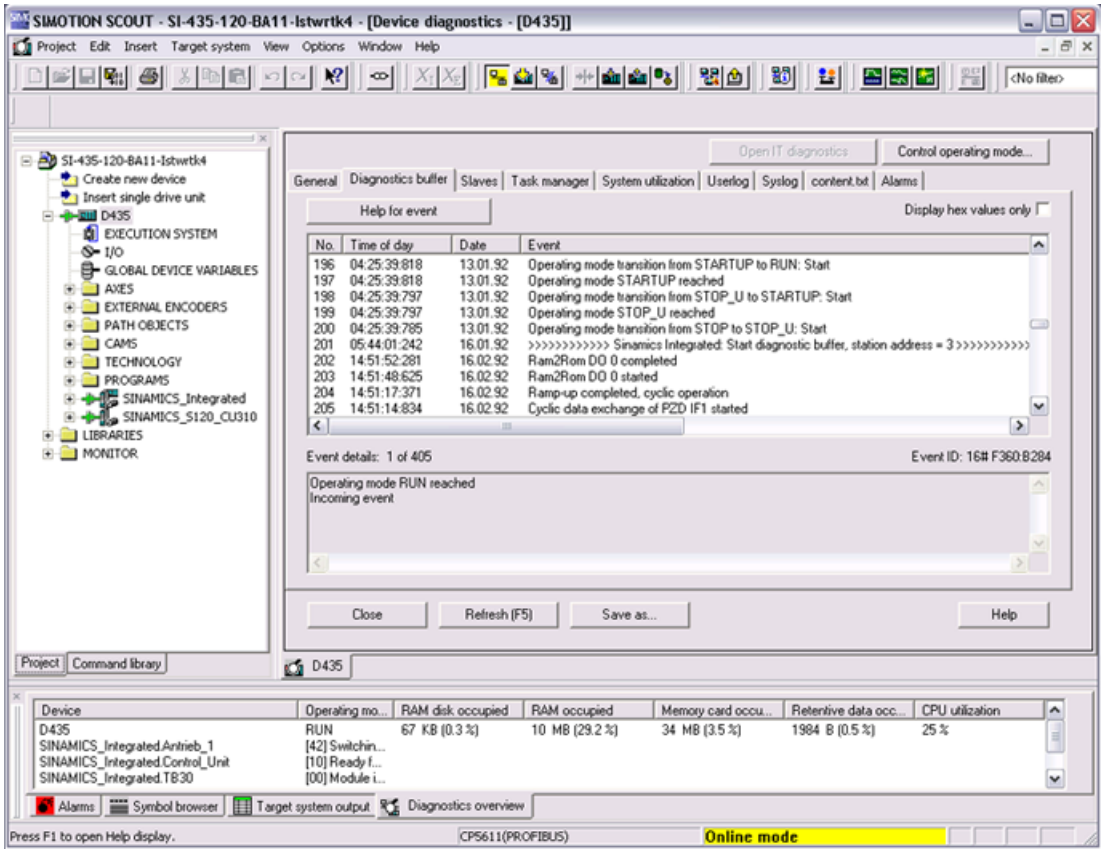

Figure 5-50 Example: D435 diagnostic buffer

In addition to the individual tabs, there are also buttons for accessing other functions, such as **Open IT diagnostics**.

Note

As well as the fault and alarm buffer, there is also a buffer for safety messages in the case of SINAMICS S120 (firmware version V2.5 SP1 and higher). These are displayed on the **Alarms** tab in the detail view.

Table 5-27 Functions that can be called up using buttons

Button	Function
Open IT diagnostics	When an Ethernet connection is present, this opens the Ethernet-based HMI and diagnostic function in an Internet browser. In addition to customized web pages and comprehensive device/diagnostic information, one of the options that the SIMOTION IT web server offers is the ability to perform firmware and project updates using an Internet browser.
Control operating mode...	The current operating mode of the SIMOTION device is displayed in the dialog. You can change the operating mode in ONLINE mode depending on the position of the mode switch.

To open the device diagnostics:

1. Select **Project > Connect to target system**.
   The PC/PG is connected to the target system.
2. Select the device in the project navigator or on the **Diagnostics overview** tab in the detail view.
3. Select **Target system > Device diagnostics**.
   The **device diagnostics** are displayed in the working area.

Note

When evaluating messages, it is beneficial if the SIMOTION and SINAMICS times of day are synchronized. With V4.2 and lower, times of day must be synchronized via the application. With V4.2 and higher, however, they can be synchronized in the SIMOTION SCOUT Engineering System, via the CPU context menu: **Setting on the device > Perform time synchronization with SINAMICS drive units**.

For application-based time-of-day synchronization, you need to use the **Time-of-day Synchronization (SIMOTION -> SINAMICS)** block from the LDPV1 program library. You can find this program library in *SIMOTION Utilities & Applications*, which is part of the scope of delivery of SIMOTION SCOUT. If necessary, get in touch with your Siemens contact.

You can use the **Save as...** button to save the data as a text file so that you can evaluate it offline.

Information and options provided by device diagnostics

- **General**
  General information on the SIMOTION device and versions
  - Device designation
  - Operating mode
  - MAC address and IP address
  - Components with article number/designation and version (I&M data)
  - SIMOTION version
  - BIOS version
  - Versions of SINAMICS Control Unit
  - Internal version/stamp
- **Diagnostic buffer**
  Shows the logged module states together with the diagnostic events that have occurred, in list format
- **Slaves**
  Shows the devices configured as slaves in HW Config, together with addresses and states
- **Task manager**
  Shows status and runtime of tasks created in the project; MotionTasks can also be controlled
- **System utilization**
  Information on memory and CPU
- **Userlog**
  Option of entering user information that is stored in the target system. This enables information about changes to the SIMOTION system to be documented, for example. Since the text is stored on the device, this information is always available regardless of which PG/PC or offline project is being used
- **Syslog**
  Shows logged ROM actions such as Copy RAM to ROM
- **content.txt**
  Shows the SIMOTION and SINAMICS firmware components on the card, as well as the card version
- **Alarms**
  Shows pending alarms (TOs and DOs). The alarms can be acknowledged.

Additional information

- Links in the *Guides* menu of the online help
- *SIMOTION SCOUT* Configuration Manual

See also

I&M (identification & maintenance) data (Page 3356)

Diagnostics buffer

The module states are logged in the diagnostics buffer. The Diagnostics buffer tab shows a list of the diagnostic events that have occurred, in chronological order.

Examples of possible diagnostic events include:

- Faults in a module
- Faults in the process wiring
- System errors in the CPU
- CPU operating mode transitions
- User-defined diagnostic events
- Technology object alarms
- Alarm_S messages
- Errors in the user program
- User-defined entries with the _writeAndSendMessage() function
- Compatibility errors, e.g. between the drive software and SIMOTION (SIMOTION D)

Note

Sequence of the diagnostic buffer entries

The firmware of the devices is based on a real-time capable operating system that is controlled by interrupts and priorities. For this reason, an event can have several diagnostics buffer entries whose time stamps can vary by a few milliseconds. These entries might not be arranged in strict chronological order.

Therefore, when evaluating the diagnostics buffer, the adjacent previous and subsequent entries should also be taken into account.

Note

Number of diagnostic buffer entries

An event can result in several diagnostic buffer entries. For this reason, identical entries can occur in the diagnostic buffer for one event. This can be the case particularly for errors in the communication (e.g. failure of a device of connection interrupted). Note therefore that conclusions cannot be drawn on the number of diagnostic events through the number of identical diagnostic buffer entries. As a rule, only one error is the trigger for diagnostic events in this case.

System utilization

The System utilization tab displays the current memory assignment, free memory, and CPU utilization.

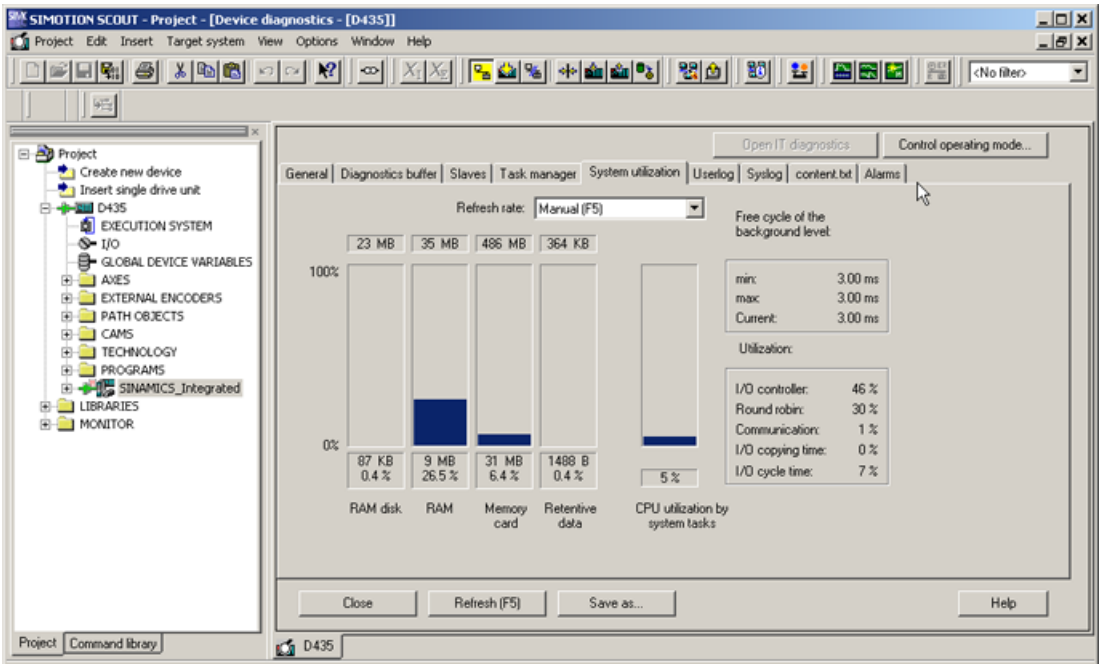

Figure 5-51 System utilization

Here, you can check the system utilization and adjust the system settings in line with the individual software configuration settings and user programs in the SIMOTION tasks. Adjustable gear ratios between the bus task, servo, and IPO support optimum load distribution and system utilization.

With SIMOTION P320-3/P350-3, you can check the CPU utilization in the *SIMOTION P state* application.

Userlog/Syslog

Userlog

The user log offers the option of entering user information that is stored in the target system. This enables information about changes to the SIMOTION system to be documented, for example. Since the text is stored on the device, this information is always available regardless of which PG/PC or offline project is being used

Syslog

For the SIMOTION CPU, the Syslog tab provides a syslog file for device diagnostics. This file contains all the actions that change a non-volatile configuration on the memory card.

The following actions are entered in the syslog file:

- Copy RAM to ROM
- Memory reset
- Formatting the card using the mode switch

content.txt

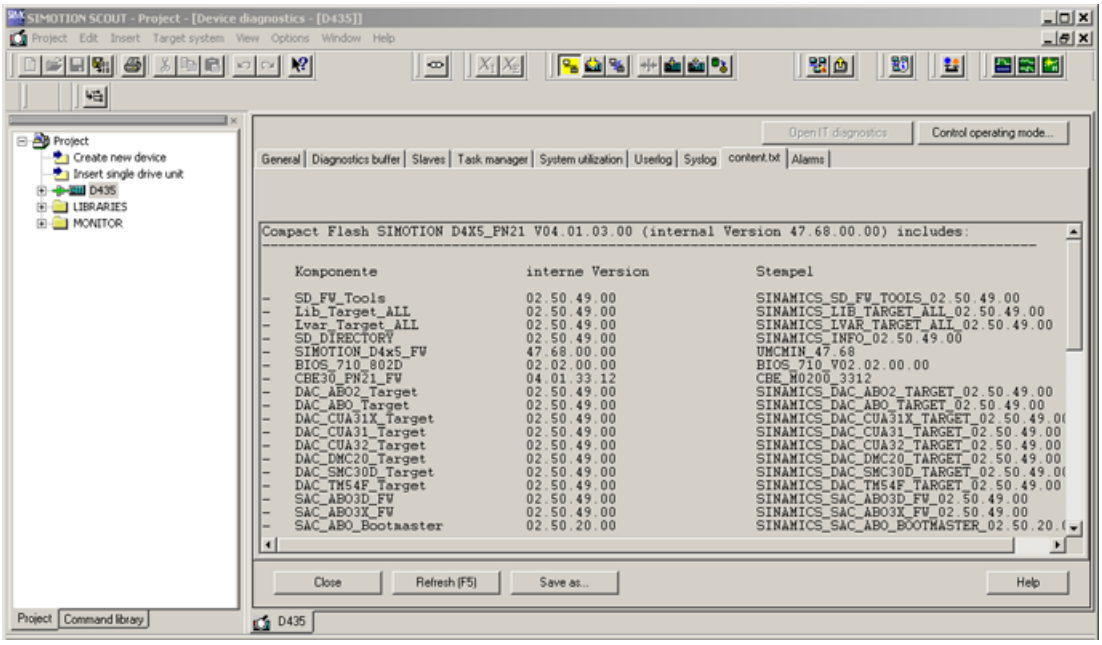

Figure 5-52 content.txt - example SIMOTION D

All the SIMOTION and SINAMICS firmware components available on the card are displayed on the content.txt tab of the device diagnostics. In addition to the card version, each individual firmware component is displayed together with its internal version code; this information can be saved in file format using the **Save as...** button. This file can be sent via e-mail for support purposes, for example.

This information will be required if the hotline needs to be contacted.

Note

It is available with SIMOTION V4.1 SP2 and higher, but not with older device types such as C230-2 or P350-2.

Service overview

In online mode, the service overview shows a complete overview of all configured axes in the project, in tabular format. The current state (including values from system variables) is displayed along with error/fault states.

The service overview is called up via the **Target system > Service overview** menu.

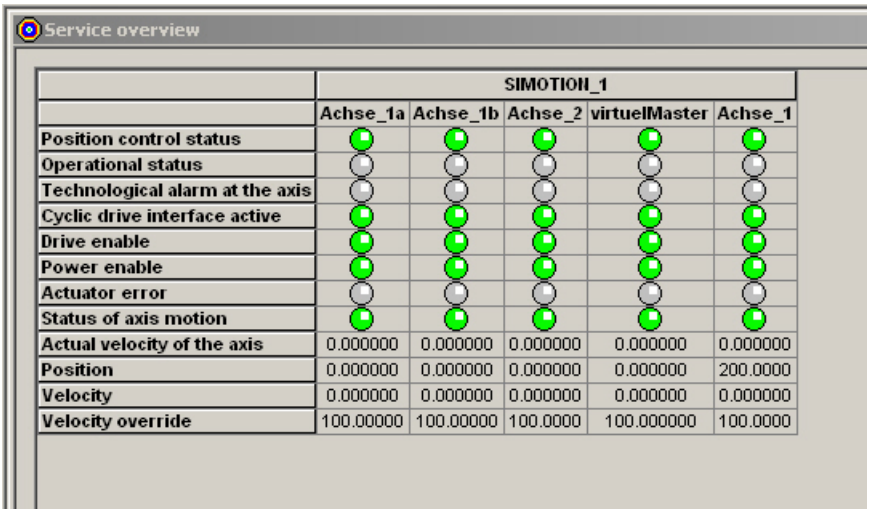

Figure 5-53 Service overview

Meanings of lamps

- Green
  Axis (system variable) is active/on or axis is stopped
- Red
  An error/fault is present
- Yellow
  Axis is in motion (constant velocity, acceleration, deceleration) or a warning is pending
- Gray
  Axis (system variable) is not active

Example

Position control status (**servomonitoring.controlstate**) has the Enum EnumActiveInactive

- Green lamp: ACTIVE, position control active
- Gray (no lamp): INACTIVE, position control not active

5.2.6.4 Ethernet/PROFINET topology

For PROFINET IO systems, the topology editor in HW Config features an integrated error/fault diagnostics facility. Start the topology editor with the **Edit > PROFINET IO > Topology...** menu command in HW Config or NetPro.

How the error/fault diagnostics facility works:

- Graphically displays the error/fault situation
- Online/offline comparison
- Displays faulty/missing components, e.g. CPU, I/O, switch, etc.

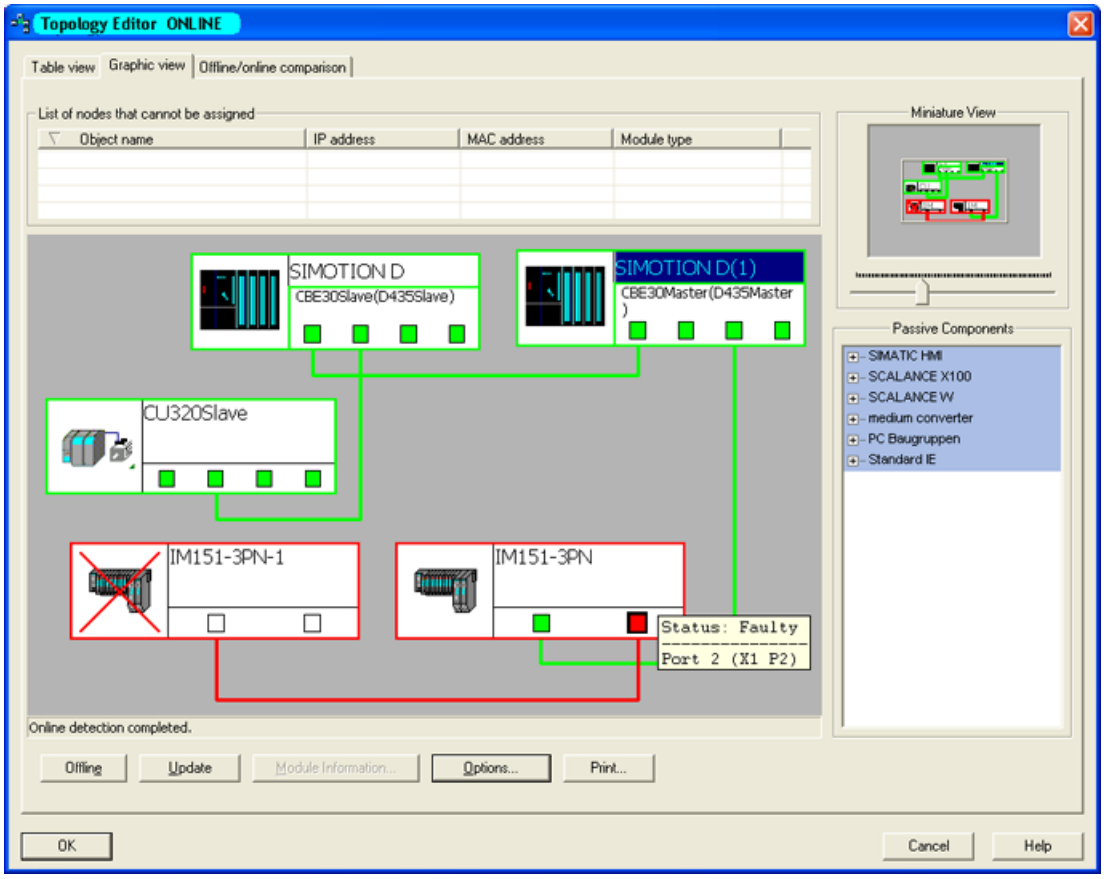

Figure 5-54 Example of topology editor - connection error

Additional information

- Links in the *Guides* menu of the online help
- *Communication* System Manual

5.2.6.5 Comparing projects

You can use the Project comparison function in SIMOTION SCOUT/STARTER (which is started via the button) to compare objects within the same project (offline/offline and offline/online) and/or objects from different projects (offline/offline). Objects are devices, programs, technology objects (TOs) or drive objects (DOs), and libraries. It is not possible to use an empty project in a comparison.

If inconsistencies are displayed in the project navigator when you switch to online mode, for example, you can carry out a project comparison to locate the differences between the SIMOTION SCOUT project and the target system project.

To enable you to analyze differences when comparing objects, there is a range of comparison attributes for each object type, which break an object down into smaller units (comparison features) and, as a whole, contain all the object data that are of relevance to execution.

Information relating to the SINAMICS devices used in the project is also displayed on the same screen. This includes DOs or individual parameters, for example.

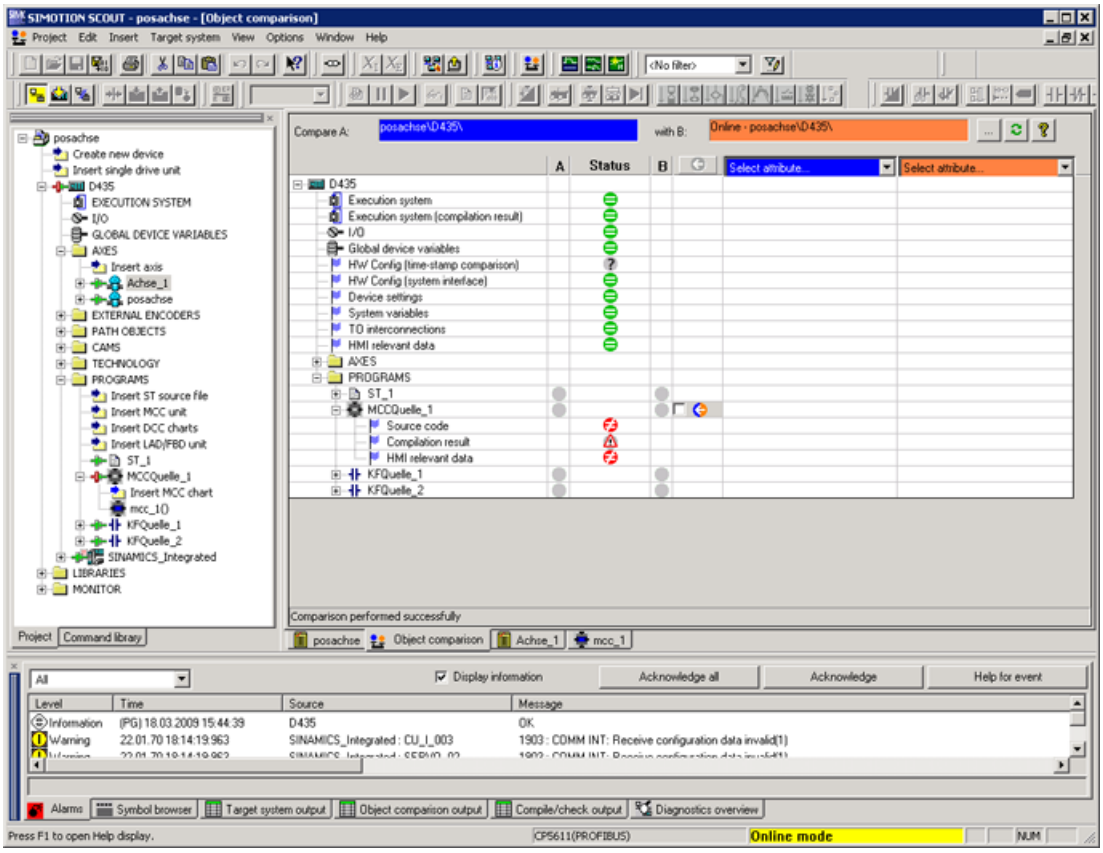

Figure 5-55 SIMOTION object comparison user interface

Possible reasons for inconsistencies in the project navigator (online mode):

- A program has been changed
- The result of compiling a program is different
- There is a deviation on the global device variables
- The execution system has been changed
- The hardware configuration has changed
- An ST program in a library has been changed
- A piece of configuration data for an axis has been changed

The object comparison allows you to establish these differences and, if necessary, run a data transfer in order to rectify them. The comparison can be carried out on an object-by-object or line-by-line basis.

The following comparisons are possible:

- Offline object with offline object from the same project
- Offline object with offline object from a different project
- Offline object with online object

Note

A comparison with online objects is only possible if there is already an online connection.

To enable detailed comparisons, the *Store additional data and sources on the target device* option must have been activated during the download carried out beforehand.

No implicit connection is established when the comparison is started.

Additional information

- Links in the *Guides* menu of the online help
- *Project comparison* Function Manual

5.2.6.6 Error handling in technology objects

Possible errors in technology objects

The following basic errors are possible when programming technology objects:

- The technology object itself cannot execute the function required by the application or reports certain events or states:
  A **technological alarm** is output.
  You can find information on the individual alarms in the SIMOTION Reference Lists
- The command sent to a technology object cannot be executed:
  The **return value** of the command provides information about the cause.
  You can find information on the return values of the commands in the SIMOTION Reference Lists
- Error while accessing configuration data, system variables, or I/O variables
  The ExecutionFaultTask is called in the event of errors when configuration data or variables are being read or written

The Trace technology object is a very effective way of analyzing processing in the technology objects.

Technological alarms

If an event (error, note) occurs on a technology object, the object issues a **technological alarm**.

Configuring technological alarms

Individual responses are preset for each alarm.

You can change this default presetting as follows:
In the project navigator, select the **Execution system** path. The Execution System window opens. Select the **SystemInterruptTasks** > **TechnologicalFaultTask** path.
Then click the **Alarm configuration...** button in the window.

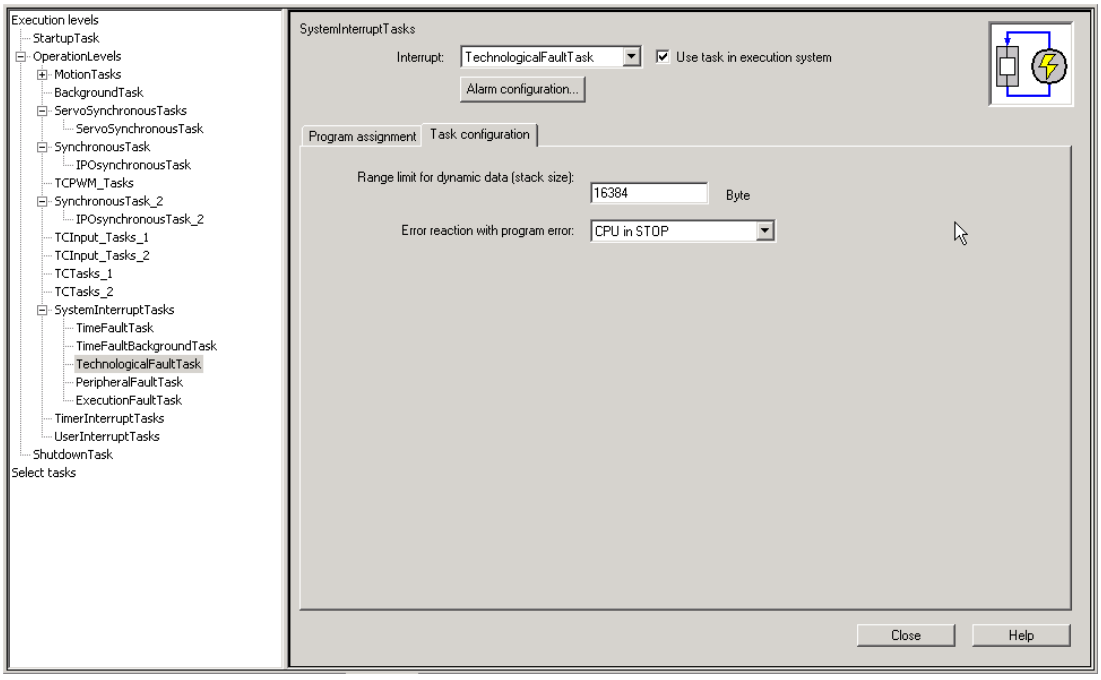

Figure 5-56 Configuring a technological alarm

Displaying and acknowledging technological alarms

Technological alarms can be evaluated and acknowledged in different ways:

- When SIMOTION SCOUT is in **online mode**, alarms and messages are displayed on the **Alarms** tab in the detail view of the workbench.
  Clicking **Acknowledge** deletes all alarms of the associated type.
- The alarms can be output, displayed, and acknowledged via the Human Machine Interface (HMI). See also HMI (Page 3343).
- All pending or individually selected alarms of a technology object can also be queried, evaluated, and acknowledged via the user program.

Acknowledging via SIMOTION SCOUT

1. Select the alarm on the **Alarms** tab of the detail view
2. Click **Acknowledge**.

All alarms of the associated type are then deleted.

Note

Because drive alarms usually generate technology object alarms as well, you can try using the Acknowledge (TO) switch to delete the drive alarms too. If, however, the cause of a drive alarm still exists, then a new TO alarm will be triggered immediately. In this case, first correct the cause of the drive alarm.

5.2.6.7 Advanced functions in the address list

With SIMOTION V4.2, advanced I/O diagnostic functions are available in the address list. This information is displayed in the **Availability** column in online mode. If you position the cursor over the relevant cell, detailed information is displayed in a tooltip.

How to open the address list

1. In the project navigator, navigate to the folder of your device.
2. Double-click the **ADDRESS LIST** entry.
   The address list is opened in the detail area.

The following diagnostic information is recorded

- I/O stations that have completely failed
- Modules that have been removed (e.g. with ET200S)
- Deactivated I/O stations
- I/O variables working with replacement values
- I/O stations whose set topology is different from the actual topology
- I/O stations that have been configured as isochronous, but are not operating isochronously
  - Distributed synchronous operation
  - Drive units
  - Isochronous I/O
- Partner device is in stop mode (e.g. I device, I slave)
- For PROFINET devices: Provider state/consumer state shows errors
  - Controller
  - I/O device
  - Modules
  - Submodules

See also the description of the **_quality()** system function in the section titled *Detailed status of the I/O variables (as of kernel V4.2)* in the *SIMOTION ST Structured Text* Programming and Operating Manual.

Additional information

- Links in the *Guides* menu of the online help
- *SIMOTION ST Structured Text* Programming and Operating Manual

5.2.6.8 Testing programs

To facilitate program testing, a range of debugging and error handling options are available for the individual programming languages:

- Variable status
- Variable status in source code (online mode)
- Program status
- Single step
- Breakpoints
- Variable trace (see Commissioning functions (Page 3394))

In the watch tables, assigned variables for all SIMOTION devices and parameters of the SINAMICS drives can be monitored and controlled in the project.

Additional information

- Links in the *Guides* menu of the online help
- *SINAMICS/SIMOTION Editor description DCC* Programming and Operating Manual.
- *SIMOTION LAD/FBD* Programming and Operating Manual
- *SIMOTION MCC Motion Control Chart* Programming and Operating Manual
- *SIMOTION ST Structured Text* Programming and Operating Manual

5.2.6.9 Commissioning functions

SIMOTION SCOUT provides the following support functions for the commissioning and optimization of technology objects and user programs:

- Device trace/function generator
- System trace (as of V4.2)
- Measuring function
- Automatic controller setting
- Task Trace
- Technology object trace (as of V4.2)

Device trace/function generator

You can use the device trace to record and evaluate parameters, system variables, and program variables.

The device trace for system variables is mainly used to analyze time-synchronous sequences in the real-time system.

Program variables can be traced in order to find logical errors in the execution system or in user programs. For this purpose, an event-triggered measuring task can be used in the runtime system rather than a time-triggered measuring task. The event that causes the measurement to be recorded is the execution of a specific code position in the user program. In addition, a trigger event based on the variable can be selected on the Device trace tab in order to start the recording (for example, on a positive edge, a tolerance band, or a bit pattern).

The function generator can be used for test purposes to dynamically generate setpoints with defined shapes (e.g. rectangle, sine) for various system variables. With the aid of the device trace, the system response can then be recorded in order to optimize the controllers, for example.

System trace (as of V4.2)

You can use the system trace to record and evaluate parameters, system variables, and program variables from multiple CPUs at the same time. It is essential that the CPUs communicate via PROFINET. There must be an isochronous connection between the CPUs.

The function generator, mathematics functions, and bit tracks are not available for recording with the system trace.

Task Trace

The Task Trace is a tool for troubleshooting in the SIMOTION multitasking environment. The Task Trace offers the following options:

- Graphic display of the sequence of individual tasks and user events (generated using a program command)
- Trace of individual user tasks
- Option of configuring the Task Trace using the SIMOTION IT web server or via the user program (system functions).
- Storage of the trace file on a memory card
- Starting the SIMOTION Task Profiler as a separate application using the SIMOTION IT web server or SIMOTION SCOUT device diagnostics.

Measuring function

The measuring function is used for controller optimization.

The SIMOTION measuring functions are used to commission the axis controller without requiring a user program.

With the SINAMICS measuring function, you can directly inhibit the influence of higher-level control loops by means of simple parameterization, and analyze the dynamic response of individual drives.

Automatic controller setting

The automatic controller setting function can be used to configure the speed controller in the drive and the DSC position controller in the control (SIMOTION SCOUT only) for SINAMICS drive units.

Additional information

- Links in the *Guides* menu of the online help
- *Task Trace* Function Manual

5.2.7 Appendix

5.2.7.1 Diagnostic data and non-volatile data (retain data)

Backing up during operation using a service selector switch

The advantage of backing up diagnostic data and non-volatile data during operation is that enhanced diagnostic information via HTML pages and TO alarm information are available.

Backing up diagnostic data and non-volatile data during operation using the service selector switch (SIMOTION D):

1. Set the service selector switch to "Diagnostics".
   – For D4x5-2: upper rotary switch (SVC/NCK) to position "13" (hex: D)

   – For D4x5: left rotary switch (SIM/NCK) to position "13" (hex: D)
   – for D410-2: upper rotary switch (SVC) to position "13" (hex: D)
   – For D410: DIP switch "7" to ON

   It does not matter what position the D410 mode switch is in.
   The diagnostic data and non-volatile data can be created in STOP, STOPU, and RUN modes.

2. The diagnostic data and non-volatile data are backed up to the CF card.
   The status LEDs display the backup process as follows:

Status	D410/D410-2	D4x5/D4x5-2
Backup in progress	RUN/STOP LED flashes yellow (2 Hz)	STOP LED and SU/PF LED flash yellow (2 Hz)
Backup complete	RUN/STOP LED flashes green (2 Hz) and SF LED lights up continuously	RUN LED flashes green (2 Hz) and SF LED lights up continuously

3. Once the backup is complete, switch the SIMOTION D off.
4. Remove the CF card and reset the service selector switch to its original setting.

Note

SIMOTION D410-2/D4x5-2 modules feature a DIAG button. As an alternative to setting the service selector switch to the "D" position, you have the option of backing up diagnostic data and non-volatile data by briefly pressing the DIAG button.

This method is preferable for D410-2/D4x5-2.

Backing up diagnostic data and non-volatile data during operation using SIMOTION P state (SIMOTION P):

1. Make sure that SIMOTION P has completed startup, e.g. with SIMOTION P state.
2. Activate the diagnostic switch using the following option:
   SIMOTION P state menu command **Options > Set Diagnostic Switch**
   The diagnostic data is recorded during operation and the **Options > Set Diagnostic Switch** switch is automatically reset after the data has been written.

Please contact Product Support for the evaluation of the recorded data.

Backing up diagnostic data and non-volatile data (Page 3360)

Backing up during ramp-up using a service selector switch or INI file

Backing up diagnostic data and non-volatile data during start-up using the service selector switch (SIMOTION D):

1. Set the service selector switch to "Diagnostics".
   - For D4x5-2: upper rotary switch (SVC/NCK) to position "13" (hex: D)

   - For D4x5: left rotary switch (SIM/NCK) to position "13" (hex: D)
   - for D410-2: upper rotary switch (SVC) to position "13" (hex: D)
   - For D410: DIP switch "7" to ON

     It does not matter what position the D410 mode switch is in.

2. Switch the SIMOTION D off and on again.
3. Wait for the device to start up.
   The diagnostic data and non-volatile data is backed up to the CF card during startup, provided that this is still possible and is not prevented by hardware defects, for example.
4. Once the backup is complete, switch the SIMOTION D off.
5. Remove the CF card and reset the service selector switch to its original setting.

Note

SIMOTION D410-2/D4x5-2 modules feature a DIAG button. As an alternative to setting the service selector switch to the "D" position, you have the option of backing up diagnostic data and non-volatile data by pressing the DIAG button. When backing up data during start-up, the DIAG button must be held down until the backup process is complete. As this can easily take 20-30 seconds, it is better to use position "D" in this case.

Backing up diagnostic data and non-volatile data during start-up using the SIMOTION P state application (SIMOTION P):

1. Terminate the SIMOTION P with **Terminate SIMOTION P** from SIMOTION P state.
2. Activate the diagnostic switch using the following option:
   SIMOTION P state menu command **Options > Set Diagnostic Switch**
   The diagnostic data is recorded during start-up and the **Options > Set Diagnostic Switch** switch is automatically reset once the data has been written.

Backing up diagnostic data and non-volatile data during start-up using an INI file (SIMOTION C/P/D):

1. Use a text editor (such as Notepad) to create a file called `simotion.ini`.
2. Add the following text to it: `DIAG_FILES=1`
   You must use a text editor and may not use any formatting in the text.
3. Copy `simotion.ini` to the main directory of the data medium (`D:\Card` with SIMOTION P320 or `F:\Simotion\user\Card` with SIMOTION P350).
4. With SIMOTION C/D: Insert the data medium into the module while it is switched off.
5. Switch the module on and allow the SIMOTION device to start up.
   The diagnostic data and non-volatile data is backed up to the data medium during start-up, provided that this is still possible and is not prevented by hardware defects, for example.
6. Once the backup is complete, switch off the SIMOTION device.
7. With SIMOTION C/D: Remove the data medium.

NOTICE
Diagnostics mode To suppress start-up in diagnostics mode again, you must delete the `simotion.ini` file from the data medium.

Backing up diagnostic data and non-volatile data (Page 3360)

Backing up during operation using the SIMOTION IT web server

SIMOTION devices feature pre-configured, standard SIMOTION IT diagnostic pages. These pages can be displayed via Ethernet using a commercially available browser. Additionally, you have the option of creating your own HTML pages and incorporating service and diagnostic information.

You can also use the SIMOTION IT Web server to back up diagnostic data and non-volatile data. The web page is opened by entering the IP address of the SIMOTION device in the address line of the browser; e.g. http://192.168.0.22

This opens the start screen of the web server. To back up diagnostic data and non-volatile data, call the "Diagnostic files" page from the "Diagnostics" menu.

Backing up and saving diagnostic data and non-volatile data on the PG/PC

1. If any diagnostic data is present, delete it using the **Delete all diagfiles** button.
2. Initiate the backup process using the **Create general diagfiles** button.
3. Compress the files using the **Zip all diagfiles** button.
4. Transfer the compressed diagnostic data to the PG/PC using the **Get diagarchive** button.

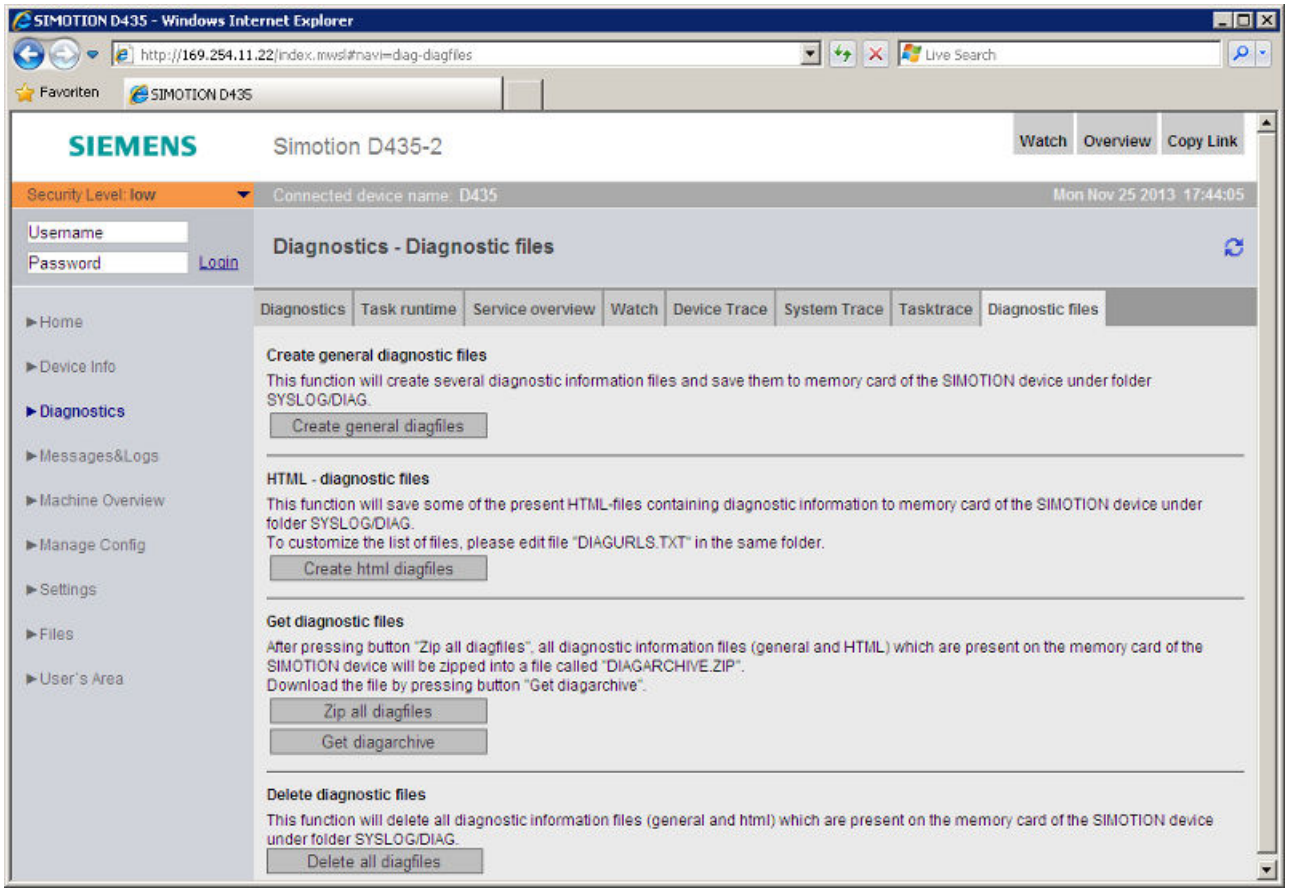

Figure 5-57 SIMOTION IT web server

Table 5-28 Functions on the "Diagnostic files" HTML page

Button	Function
Create general diagfiles	This button saves diagnostic data and non-volatile data in the ...\USER\SIMOTION\HMI\SYSLOG\DIAG directory. HTML files used for diagnostics purposes are not saved.
Create html diagfiles	This button is used to save diagnostics HTML pages on the data medium. It should be noted that only those pages that are listed in the DIAGURLS.TXT file in directory ...\USER\SIMOTION\HMI\SYSLOG\DIAG will be saved (see Displaying diagnostic data via websites (Page 3362)).
Zip all diagfiles	The "zip all Diagfiles" button enables you to compress diagnostics files. This stores all files and folders in a ZIP file in directory ...\USER\SIMOTION\HMI\SYSLOG\DIAG, while retaining the folder structure.
Get diagarchive	This button is used to save the ZIP archive to connected PGs/PCs.
Delete all diagfiles	This button is used to delete all data stored in the ...\USER\SIMOTION\HMI\SYSLOG\DIAG directory; the directory itself is not removed, however.

Restoring non-volatile data

SIMOTION C/P

Prerequisite

The diagnostic data and non-volatile data have been backed up to the MMC/data medium.

Procedure

1. With SIMOTION C and SIMOTION P320/P350, copy file `PMEMORY.XML` from directory `...\USER\SIMOTION\HMI\SYSLOG\DIAG` to directory `...\USER\SIMOTION`.
2. Following this, carry out an overall reset to force the non-volatile data to be reimported.

In principle, you can use the procedure that has just been described for SIMOTION D too, but we recommend using the method described below instead.

SIMOTION D

Prerequisite

The diagnostic data and non-volatile data have been backed up to the CF card.

Procedure

As of V4.3, the non-volatile SIMOTION data are restored automatically when a module is replaced. The non-volatile data can also be restored manually (by manual operation).

The CF card may contain backups of non-volatile SIMOTION data in various storage locations:

- data backed up with the system function _savePersistentMemoryData
  Storage location on CF card:
  - /USER/SIMOTION/PMEMORY.XML
  - /USER/SIMOTION/PMEMORY.BAK (backup file)
- manually by service selector switch / web server / DIAG button, backed-up data
  Storage location on CF card:
  - /USER/SIMOTION/HMI/SYSLOG/DIAG/PMEMORY.XML

On manual restoration, the position of the service selector switch defines which of these data will be preferably restored.

During restoration, the non-volatile SIMOTION data are first deleted and then the non-volatile SIMOTION data are restored via the PMEMORY backup file.

If restoration is not possible (e.g. file does not exist or corrupt), the next file in the priority list is accessed.

Table 5-29 Restoration of the non-volatile SIMOTION data

Position of the service selector switch	Use case	Priority sequence for use of the data backups
D410-2/D4x5-2/D4x5: Rotary switch position "1" D410: DIP switch "5" to ON	The data backed up with the system function _savePersistentMemoryData are preferably restored	1. /USER/SIMOTION/PMEMORY.XML 2. /USER/SIMOTION/PMEMORY.BAK 3. /USER/SIMOTION/HMI/SYSLOG/DIAG/PMEMORY.XML
D410-2/D4x5-2 (V4.4 and higher): Rotary switch position "A"	The data backed up by service selector switch position "D" / web server / DIAG pushbutton are preferably restored	1. /USER/SIMOTION/HMI/SYSLOG/DIAG/PMEMORY.XML 2. /USER/SIMOTION/PMEMORY.XML 3. /USER/SIMOTION/PMEMORY.BAK

Note

Firmware / kernel < V4.4

Because switch position "A" is only supported as of V4.4, for < V4.4, restoration must be performed with switch position "1." To force restoration of the data backed up by service selector switch position "D" / web server / DIAG button, it may be necessary to delete existing files PMEMORY.XML and PMEMORY.BAK in the directory /USER/SIMOTION/ on the CF card.

Restoring data with switch position "1" or "A"

Procedure

To restore the non-volatile SIMOTION data, proceed as follows:

Step	Switch position "1"	Switch position "A" (as of V4.4)
1.	Insert the CF card into the new SIMOTION D. The SIMOTION D must be switched off!	
2.	Set the service selector switch to "**1**." The position of the mode switch is not relevant, i.e. the set operating mode remains unchanged.  Service switch position 1	Set the service selector switch to "**A**." The position of the mode switch is not relevant, i.e. the set operating mode remains unchanged.  Service switch position A
3.	Switch on the SIMOTION D.	Switch on the SIMOTION D. The flickering green SF LED indicates that restoration is requested via position "A."
4.	Restoration is started automatically.	Turn the service selector switch to "1" to start restoration.
5.	Once restoration has been completed, the module will start up automatically.	
6.	Switch the module off and turn the service selector switch back to "0."	
7.	Switch the SIMOTION D on again.	

Note

For the SIMOTION D410, the data are restored by setting DIP switch "5" to ON

5.3 Project comparison

Preface

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4.3:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Additional information

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

5.3.1 Fundamental safety instructions

5.3.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

5.3.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

5.3.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

5.3.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

5.3.2 Overview of project comparison

You can use the SIMOTION SCOUT/STARTER **Project comparison** function (start this via the **Start object comparison** button) to compare objects within the same project and/or objects from different projects (online or offline). Objects in the project comparison are SIMOTION devices, drive units, libraries. The project comparison is available with SIMOTION SCOUT and STARTER. Comparing projects is useful if you need to carry out service work on the system.

It may, for example, be the case that inconsistencies are indicated when you switch to online mode in the project navigator, i.e. there are deviations between your project in SIMOTION SCOUT/STARTER and the project loaded to the target system.

Examples of possible causes for this are:

- A program has been changed
- The result of compiling a program is different
- There is a deviation on the global device variables
- The execution system has been changed
- The hardware configuration has been changed
- An ST program in a library has been changed
- A piece of configuration data for an axis has been changed

The object comparison allows you to establish these differences and, if necessary, run a data transfer to rectify the differences. The following comparisons are possible:

- Offline object with offline object from the same project
- Offline object with offline object from a different project
- Offline object with online object (not for libraries)

The first comparison partner, the reference object (A), is in the open project, while the second partner, the comparison object (B), can be a comparison object in the open project, in a different project, or the online partner.

Note

When comparing to a project that has been created with a SIMOTION SCOUT/STARTER Version < 4.3, you must first convert the project to SIMOTION SCOUT/STARTER Version 4.3. For the comparison attributes, aspects and subaspects to be displayed, you must recompile the project after it has been upgraded.

The project comparison function is also available when using devices with older firmware versions if you have edited or converted the project with SIMOTION SCOUT or STARTER V4.3.

The highest level for a comparison is a device, not the project. The comparison can be started via a

- SIMOTION device,
- Drive unit, or
- Library.

A detail comparison of the individual objects is available for the programming languages ST (Structured Text), LAD/FBD (ladder logic/function block diagram), and MCC (Motion Control Chart) as well as for DOs (drive objects) and TOs (technology objects) and simply structured data such as CPU system variables, TO interconnections, among others.

Note

Reliable statements on the comparison status of the creation data (e.g. compilation result of a program) can only be made when the project has been compiled. For example, changing an interface in source A has an effect on the compilation result of source B, which uses this interface.

Note

The displayed values are of generic nature, for example, as calculated in the CamEdit configuration, and are not rounded off.

Differences between the project comparison and the online/offline comparison

In terms of drive objects, the project comparison produces precise results compared to the online/offline method. This is because the project comparison compares the contents of projects whereas the online/offline method only evaluates on the basis of a change counter. The consistency information for DOs, displayed in the project navigator, is also based on the change counter.

Example: For a particular DO, the project navigator shows an inconsistency between the project data in the PG/PC and the project data in the target system. The online/offline comparison may highlight a difference, while the results of the project comparison show everything to be the same.

5.3.3 General information on object comparison

You can use the SIMOTION SCOUT/STARTER Object comparison function (start this via the **Start object comparison** button) to compare objects within the same project and/or objects from different projects (online or offline), see also Project comparison overview. Objects are devices, programs, technology objects (TOs) or drive objects (DOs), and libraries. Below you will find an overview of the elements and structure of the **Object Comparison** dialog box. You can start the detail comparisons from this dialog box, e.g. for LAD/FBD, ST or also for CPU system variables.

- The user interface
- Comparison icons
- Comparison tree
- Comparison attributes, aspects, and sub-aspects
- Object attributes

5.3.3.1 The user interface

A user interface in which the differences in the various objects have been detected has been selected as an example for the screenshot below. In the case of programs, all the data from this user interface could be transferred and it would be possible to carry out a detailed comparison for two programs.

Table 5-30 The user interface elements of the project comparison

No.	Description
1	Comparison partner A and comparison partner B (online/offline)
2	Comparison tree made up of comparison partner elements
3	Object present (column A, column B): The columns indicate whether or not a tree object is present for comparison partner A and/or comparison partner B.
4	Result of comparison: The comparison result is shown in this column (same/different). (See Comparison icons) **Note:** If the comparison is no longer up-to-date or when offline during online comparisons, the status column heading is displayed hatched.
5	Select/change comparison partner
6	Update comparison
7	Call up online help
8	Display object attributes (see Object attributes) The attributes of the comparison partners are compared in two columns.
9	Start detailed comparison
10	Comparison attributes of an object (see Comparison attributes, aspects and sub-aspects)
11	Aspects of a comparison attribute (see Comparison attributes, aspects and sub-aspects)
12	Aspect, created data
13	Data transfer: Transfer of data from comparison partner B into the open project.
14	Status bar
15	Object comparison tab
16	Settings for transferring objects

Figure 5-58 SIMOTION object comparison user interface

See also

Comparison icons (Page 3412)

Object attributes (Page 3414)

Comparison attributes, aspects, and sub-aspects (Page 3413)

5.3.3.2 Comparison icons

Below you will find an overview of the icons used in columns A and B, and their status.

Table 5-31 Overview of icons used

Icon	Description
	Object is present (displayed in columns A and/or B).
	Object is not present (displayed in column A and/or B).
	Difference in at least one subordinate object or comparison attribute (only displayed if the folder or object is collapsed).
	The comparison attribute is the same.
	The comparison attribute is different.
	The compilation result does not match the source status of comparison partner A or B.
	A same/different statement cannot be made. An example of a possible cause of this is that the hardware configuration is being compared using the time stamp. If the time stamp deviates, a same/different statement cannot be made.

Please note the following:

- Columns A and B are not completed for comparison attributes. The same objects have the same attributes, i.e. they are present. However, the characteristic of the attributes may be the same or different; this same or different characteristic is indicated accordingly.
- If an object does not have a comparison partner, the comparison attributes cannot be seen (the objet cannot be expanded in the tree).
- Folders which do not contain any objects are not shown in the comparison tree.

5.3.3.3 Comparison tree

The way in which the comparison tree is displayed reflects how trees are displayed in the project navigator. The comparison tree is extended by displaying the comparison attributes (see the chapter titled Overview of comparison attributes (Page 3452)).

A single tree is produced from the two trees/subtrees of the comparison partners. If it has been possible to assign two of the comparison partners' objects (see the Assigning objects in object comparison (Page 3419) section), there will be **one** entry in the tree, and columns **A** and **B** will contain the **Object available** symbol. If it has not been possible to assign any comparison partners, the **Object present** or **Object not present** icon is displayed in the column for comparison partner A or comparison partner B, depending on which it belongs to (see example below).

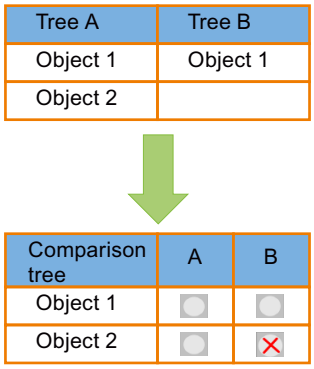

Figure 5-59 Example of merging comparison partners

If an object is only present for one comparison partner, no comparison attributes are shown in the tree. Subordinate folders and objects are shown.

If the comparison partners are different , the tree is shown expanded. This gives you a quick overview of the differences.

The comparison tree shows a snapshot. As a result of changes in the open project, the comparison status may no longer be up to date. You will be informed of this status by means of

- the shaded column heading  and
- the message **The comparison is no longer up-to-date** in the status bar.

Since the comparison tree is not automatically updated, you have to explicitly start the update by clicking the **Update** button.

Note

The comparison only displays parameter differences which are relevant to the download; differences relating to current data are not displayed. For the DOs, the download parameters are compared (please also refer to the Display filter for DO detail comparison) section; the configured values are compared for the TOs.

5.3.3.4 Comparison attributes, aspects, and sub-aspects

In order to be able to analyze differences when comparing objects, there is a range of comparison attributes for each object type, which structure an object into smaller units (aspects and sub-aspects) and which, as a whole, contain all the object data that is of relevance to execution.

You will already be familiar with some of the comparison attributes from the project navigator (e.g. global device variables). In addition to this, there are comparison attributes into which various items of data can be incorporated, such as the compilation result for programs, where the global and local compiler settings are also included.

Categorization of comparison features

Comparison features are divided into attributes, aspects, and sub-aspects on the basis of object type (sub-aspects are only available for MCC and LAD/FBD POUs). This enables you to determine the causes of differences as precisely as possible.

Comparison features are available in singular or multiple format (such as OEs) and their content can be empty, e.g. exported variables of a program. The comparison features are displayed in the object comparison, regardless of whether or not they are empty.

You will find an overview of the specific comparison attributes, plus their associated aspects and sub-aspects, for SIMOTION, SINAMICS, and MICROMASTER objects in the section titled Overview of comparison attributes (Page 3452).

To enable the attributes to be compared as efficiently as possible, information is calculated (e.g. a checksum) and is then stored online along with the project or objects. If this information is not available (e.g. in the case of the hardware configuration), a statement on the comparison cannot be made (indicated in the comparison tree by **?**).

5.3.3.5 Object attributes

You can select the following object attributes in the two right-hand columns in the object comparison.

Table 5-32 Overview of object attributes

Name	Description
Name	Name of object[1)]
Type	Type of object Objects with the same name but of a different type are not compared in the case of automatic assignment.
Object address	Unique object address[1)] You need the object address to address the objects via the HMI, for example.
Author	Name of the author[1)]
Version external	External version identifier[1)]
Version internal	Internal version identifier of object, e.g. the technology package version in the case of TOs
Creation version	SIMOTION SCOUT version with which the object was created
Know-how protection for programs	Login for all know-how-protected objects
Time stamp of last change	Date and time of last change
Comment	Comment[1)]
[1)] from the Object properties dialog.	

5.3.4 Functions

5.3.4.1 Downloading additional data

In order that can carry out a detailed comparison and, if necessary, a complete data transfer into the PG/PC during an offline/online comparison, when downloading the project to the target device you must also save the additional data, such as sources, icon information etc. This is a setting in SIMOTION SCOUT or STARTER.

If you only want to accept selected data from the additional data, you can do this via the detailed comparison.

Note

It is also possible to load supplementary data when using SIMOTION devices with older firmware versions if you have edited or converted the project with SIMOTION SCOUT V4.1 SP2. The project then has to be recompiled and loaded.

Further information on loading additional data can be found in the basic functions, Loading data from the target device to the PG/PC.

Procedure

Proceed as follows:

1. Select **Tools > Settings**.
   The **Settings** window appears.
2. Switch to the **Download** tab.
3. Activate **Save additional data on the target device** and confirm using **OK**.

The next time the project is downloaded to the target device, the additional data will be saved on the target device. If deactivated, the additional data will be deleted the next time downloading to the target device takes place. In addition, this option can be selected during each download (CPU-related).

5.3.4.2 Starting an object comparison

Object comparisons are only performed using saved data. Changes made after the object comparison was performed may mean that the object comparison and the detailed comparison have different results.

You must note the following during an online comparison and a comparison with a different project:

The comparison only uses the saved data in the open project.

During an **online comparison**, the device being used for comparison purposes is implicitly uploaded. Therefore, the comparison is made with a copy of the online data.

Note

We recommend compiling the project prior to starting the project comparison. This ensures that you obtain a reliable comparison result (e.g. compilation result of a program).

Note

A comparison with online objects is only possible if there is already an online connection.

Note

If you delete a comparison partner and then update the comparison, an error message is displayed.

Note

The object comparison does not display differences of current data (current data values). Only download-relevant parameter differences are displayed.

Note

In an offline/online comparison, the comparison result is still marked as current after restoring the factory settings. The status only changes when you have changed the project in SCOUT or have performed an online comparison and have then gone offline.

Starting the object comparison and selecting comparison partners

How to start the object comparison:

1. Click on the device with which you want to run the comparison in the project navigator.
2. Either start the object comparison via
   - The menu bar, using **Options > Compare...**,
   - Using the  button or
   - The context menu of the comparable objects (**Compare...**).
     The following dialog appears:

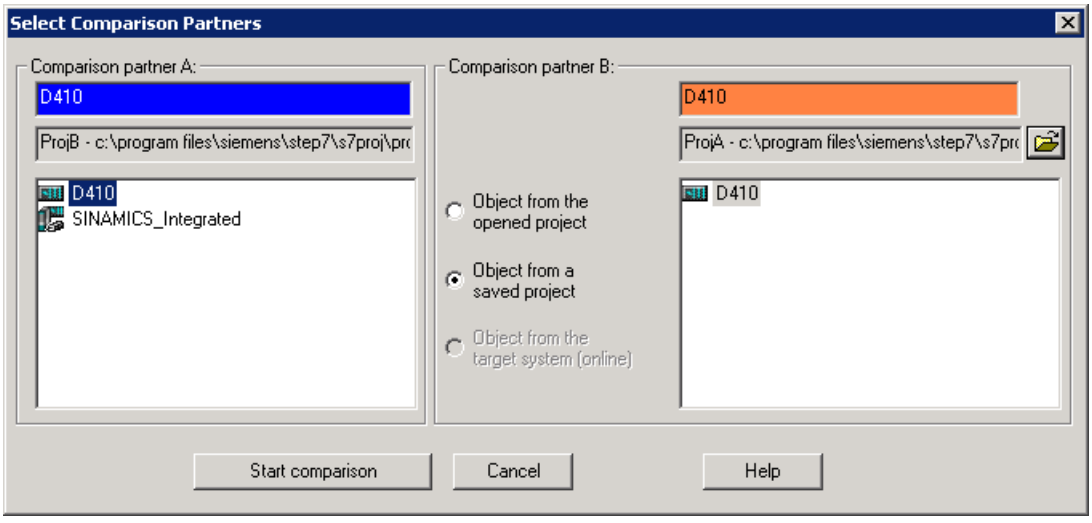

Figure 5-60 Select comparison partner dialog

The object you selected previously in the project navigator is highlighted as comparison partner A. If you did not select an object, the first object in the list is highlighted.

3. Select comparison partner B. The following options are available:
   - Object from the open project:
     You can choose from the objects in the open project.
   - Object from a saved project:
     First open a saved project using the button: 
     You can choose from the objects in this project.
   - Object from the target system (online): (only possible in ONLINE mode and if the project is present in the target system).
     The object from SCOUT or STARTER is compared with the object on the target system.

   Note

   Only comparable devices are displayed as comparison partners.

4. The **Start comparison** button is activated once you have selected the object with which the comparison can be run. Open the object comparison using the **Start comparison** button.

Different versions detected (offline comparison with saved project)

Note

If you are carrying out a comparison with a different project, the project concerned must be available in SIMOTION SCOUT/STARTER Version 4.2; otherwise, you will have to convert the project first.

If the comparison partner is in a different project created using an older version of SIMOTION SCOUT, a comparison cannot be carried out. The following note is displayed:

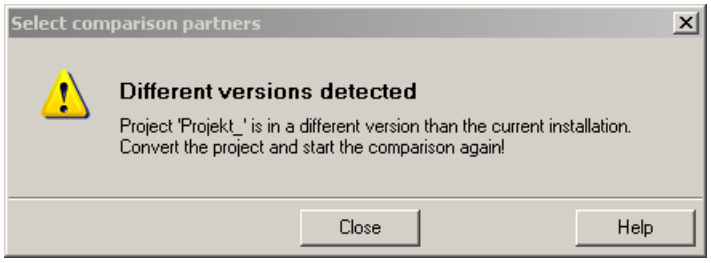

Figure 5-61 Different comparison partner versions

In this case, first convert the project to the current version of SIMOTION SCOUT. Then restart the comparison.

Object comparison with projects converted to a higher version

Requirement

To be able to perform an object comparison, where projects have been created with SIMOTION SCOUT/STARTER versions < 4.2, you first need to convert these projects to a higher version.

Display of new comparison attributes

As part of SIMOTION SCOUT/STARTER version 4.2, new comparison attributes and aspects have been introduced for object comparison purposes. This results in the following scenarios when carrying out comparisons:

- You convert a project to V4.2, go online, and perform a comparison with an object on the target system:
  The new comparison attributes are not displayed, as they are not available on the target system.
- You convert two projects to V4.2 and compare these offline:
  The new comparison attributes are not displayed.
- You convert two projects to V4.2, compile one of the two projects, and compare these offline:
  The new comparison attributes are displayed. However, no comparison is possible because the attributes in the non-compiled project are not available.

Note

The new comparison attributes are calculated when the projects are compiled with SIMOTION SCOUT/STARTER V4.2. When projects are recompiled, the previous comparison attributes are also recalculated.

Display of aspects

Aspects are updated when the comparison attribute is opened, making them available for comparison.

Going offline after online comparison (comparison is no longer up to date)

Comparison no longer up-to-date

Certain pieces of status information depend on the online connection. If you go offline after performing an online comparison, it means that

- A comparison attribute cannot be expanded (unless it was previously opened)
- A detail comparison can no longer be started
- It is no longer possible for entire objects to be transferred

If you attempt to execute one of the functions, the message **Target device is offline** is displayed.

Column header display is hatched

The hatching of column headers means that the comparison is no longer up-to-date. Update the comparison.

Hatching occurs in the following situations:

- If you have made a change on an open project (comparison partner A).
  If a change has been made with a comparison partner B, e.g. with another SCOUT, there is no hatching.
- If you have performed an online comparison and then go offline.

5.3.4.3 Assignment of objects in object comparison

Object assignment

The object comparison only allows you to compare objects which are sufficiently similar, for example, SIMOTION C240 can be compared with SIMOTION D445-2, but SIMOTION D445-2 cannot be compared with an ST source file. After you have decided which objects are to be compared (see the Starting the object comparison and selecting comparison partners section), the lower-level Simotion SCOUT/STARTER objects will be assigned automatically. The rules described in the next section apply within this context.

Automatic assignment of the subordinate comparison objects

During automatic assignment, all objects below the selected comparison object are assigned, taking their position in the tree into account. For example, axis_1 and axis_2 are assigned in the comparison. Similarly, the automatic assignment of lower-level objects will attempt to assign the measuring inputs under axis_1 to the measuring inputs under axis_2.

During a specific object-to-object assignment, a distinction is made between TOs/DOs and other objects:

Assignment of TOs/DOs using object addresses

TOs/DOs are assigned using their object address and name. In this case, the object address appears after the name: <Name>(<Object address>). Since the name of the object may differ in this case, both names are shown in the event of deviation.

When assignment uses the object address, it may be, for example,

1. that a measuring input under axis **A1** has the same object address as the measuring input under axis **A1** in the comparison project, although the object addresses of the axes are different.

Example before object address change

Tree A	Tree B
Axis A1 (17) └ Measuring input M1 (40)	Axis A1 (10) └ Measuring input M1 (40)
Axis A2 (25) └ Measuring input M2 (20)	Axis A2 (25) └ Measuring input M2 (20)

Comparison tree	A	B
Axis A1 (17) └ Measuring input M1 (40)	○ ○	✕ ✕
Axis A2 (25) └ Measuring input M2 (20)	○ ○	○ ○
Axis A1 (10) └ Measuring input M1 (40)	✕ ✕	○ ○

Example after object address change

Tree A	Tree B
Axis A1 (17) └ Measuring input M1 (40)	Axis A1 (17) └ Measuring input M1 (40)
Axis A2 (25) └ Measuring input M2 (20)	Axis A2 (25) └ Measuring input M2 (20)

Comparison tree	A	B
Axis A1 (17) └ Measuring input M1 (40)	○ ○	○ ○
Axis A2 (25) └ Measuring input M2 (20)	○ ○	○ ○

Figure 5-62 Example of assignment where axes have different object addresses

2. A measuring input under axis **A1** has the same object address as the measuring input under axis **A2** in the comparison project:

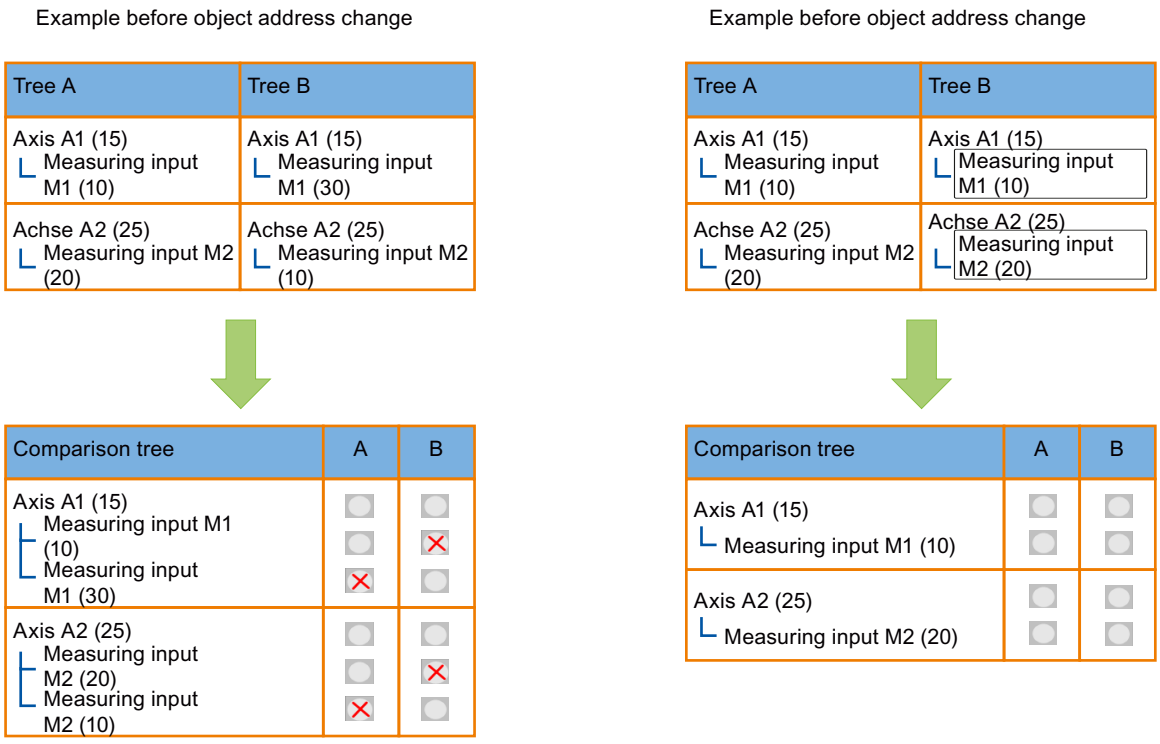

Figure 5-63 Example of assignment where measuring inputs have different object addresses

Since the object addresses are assigned automatically, this may occur if the objects are created in a different order or using script, for example.
However, this assignment is not desirable as it would result in incorrect object assignment. Therefore, the object address is only taken into account within the same hierarchy level during assignment; not across hierarchy levels.

If necessary, you can change the object addresses of TOs yourself. This allows you to enforce correct assignment of the objects later on.

Note

It is recommended that you explicitly assign the object address for TOs in all cases (see Changing the object address (Page 3422)). You **cannot** change the address of DOs.

Assignment of other objects using names

Other objects, i.e. all objects outside the TOs/DOs, are assigned using their names.

Note

If objects are not automatically assigned despite having the same name and are therefore positioned one above the other in the comparison tree, this is because the type is different.

Changing the object addresses of TOs

Procedure

To change a TO object address:

1. Select the appropriate TO in the project navigator.
2. In the context menu, open **Properties...**.
3. Click the **Object address** tab.
4. Change the object address in the **New address** field.
5. Click the **Assign** button and confirm with **OK**.

5.3.4.4 Detailed comparison

Introduction

The following section provides you with an overview of which detail comparisons are available and how you can make use of the respective types.

Detail comparison

You can compare and partially transfer the content of data in the detail comparison. If differences are detected during an object comparison, you can start a detail comparison for

- ST programs
- LAD/FBD (ladder logic/function block diagram)
- MCC (Motion Control Chart)
- TOs (configuration data, system variables), and

- DOs (parameters).
- Simply structured data:
  - I/O variables
  - Global device variables
  - Alarm configuration
  - Execution system
  - Compiler settings
  - CPU system variables
  - Technology object interconnections
  - Used technology packages
  - HW Config (system interface)
  - Cam configuration
  - Topology serial numbers
  - Message configuration (used symbols/IDs)

Note

If you have compared individual data items, such as the device name, then this is called "scalar" in this context. Differences are then displayed in a dialog box.

Know-how protection for programs

In the case of know-how-protected sources, differences are only displayed in the object comparison / detail comparison to a limited extent. Know-how protection for programs protects the source data, but not the attributes or properties. If you want to expand the source code comparison attributes, you will need to enter the password for the protected source. The source code aspects are only displayed when you are logged in.

Starting the detailed comparison

Requirement

The detail comparison can be started from the comparison tree by clicking the  button.

You can only start the detail comparison if

- you have found differences and
- if the additional data required is available for the online comparison.

In the detail comparison, the corresponding contents are shown next to each other, the differences marked, and the transfer of changes from the comparison object to the reference object made possible if required.

Note

You can only start the detail comparison provided the relevant program of comparison partner A is not already open in an editor. The editor is automatically closed when a detail comparison is started.

The detail comparison cannot process projects that are opened with write protection. You must first cancel the write protection.

Procedure

1. First, carry out an object comparison on the desired device (see Starting the object comparison).
2. The **Start detail comparison** button is shown in the Status column for objects for which a detail comparison can be run.

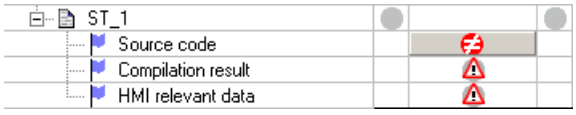

Figure 5-64 Example of a detail comparison for two ST programs

3. Click the **Start detail comparison** button. The corresponding editor in the working area will open and the differences will be highlighted and displayed next to each other.

Settings for transferring object addresses

With the setting, you can transfer the object addresses from comparison partner B to comparison partner A.

Note

For a successful transfer, the comparison objects must match in their fundamental parameters

For example, axes must match in their name, type and object address.

Introduction: ST, LAD/FBD, MCC detail comparison

The following section provides an overview of the function buttons and the menu commands for ST, MCC, and LAD/FBD detail comparisons.

Detail comparison function buttons

The following section provides an overview of the function buttons for ST, MCC, and LAD/FBD detail comparisons.

Table 5-33 Detail comparison function buttons

Button	Description
	Jump to next difference
	Jump to previous difference
	Transfer highlighted line(s) to source (from comparison partner B to A)
	Complete transfer of differences to the source (from comparison partner B to A)

Detail comparison menu

The following section provides an overview of the menu commands for ST, MCC, and LAD/FBD detail comparisons.

Table 5-34 Detail comparison menu

Menu	Description
Jump to next difference	Jumps to next difference
Jump to previous difference	Jumps to previous difference
Accept current line / Accept current network (LAD/FBD networks only)	Transfers highlighted line(s)/highlighted network to source (from comparison partner B to A)
Accept all differences	Transfers all differences (as regards current tab) to the source (from comparison partner B to A)
Display line numbers (ST only)	Displays the line numbers of comparison partners A and B
Ignore indents (ST only)	Indents in the source are ignored; you need to define this before accepting changes for the first time, as you cannot change the setting for the current comparison after you have done this.
Accept changes into project	Changes are accepted in the project and saved
Close and open editor	Opens comparison partner A in the editor. The detail comparison closes.
Close	Closes the detail comparison.

ST detail comparison

Introduction

The ST detail comparison allows you to run a textual comparison on ST sources. The compared sources are shown next to one another and the differences highlighted in color.

Missing lines (highlighted in gray) are added so that the display of identical lines can be synchronized.

In addition, an overview tab appears in the project navigator. In this case, all lines of the source code are compressed and any differences are highlighted. Simply click on the differences on the overview tab to jump directly to each difference in the source code.

The differences in the source code can be transferred either on a line-by-line basis or simultaneously by marking several lines at once. You have to open the ST editor for editing. You cannot edit in the detail comparison.

Note

Note the information provided in the status bar at the end of the working area.

Note

In isolated cases, a difference may be detected as a result of a control character such as a line break despite the fact that this is of no relevance to the source text.

Example: ST detail comparison

Example of an ST detail comparison

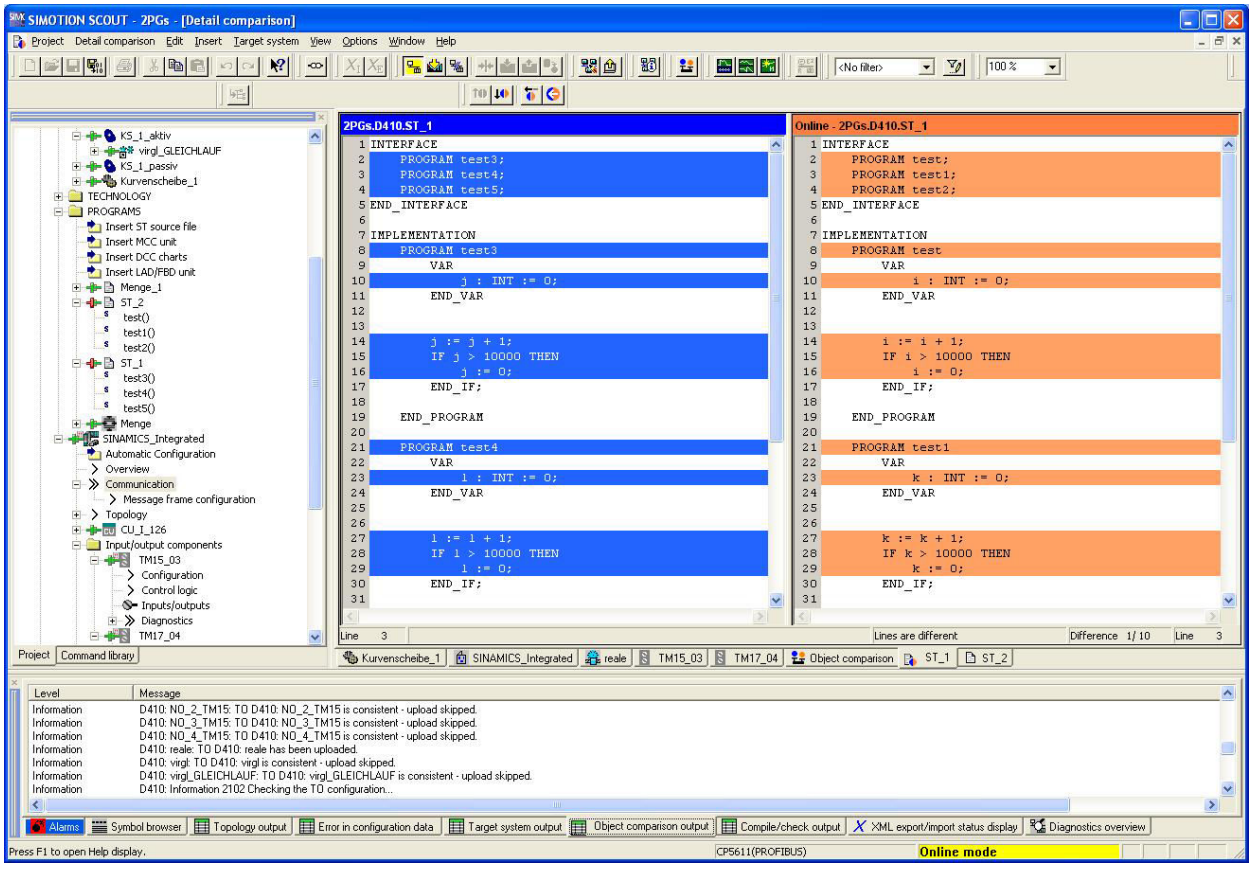

Figure 5-65 Example of ST detail comparison

MCC and LAD/FBD detail comparison of declaration tables

Introduction

The detail comparison helps you to identify differences between comparison partner A and B in the declarations. This concerns:

- MCC units and LAD/FBD units: Global unit declarations, "INTERFACE" section
- MCC units and LAD/FBD units: Global unit declarations, "IMPLEMENTATION" section
- MCC charts and LAD/FBD programs: POU local declarations

If differences have been detected within a tab during a detail comparison, this tab is underlined in the respective color for both comparison partners and appears in the foreground. If differences have been detected within a number of tabs, all the relevant tabs are underlined in the respective colors.

The reference order for the declarations is provided by comparison partner A. The order for comparison partner B is resorted accordingly, in order to see at a glance whether declarations

are missing or the extent to which declarations differ in terms of content. Color highlighting in the column with the line numbering indicates differences in the order.

Note

If the order differs for comparison partners A and B, you can only align them by accepting all the differences.

If there are differences between the declarations for comparison partners A and B, you can correct the differences identified line by line.

Special features of enumerations, structures, and pragmas

In future, pragmas will be used to mark the beginning of a new block both in the context of MCC and of LAD/FBD.

When the declarations of the two comparison partners are matched up, variables have to be located below a pragma for both comparison partners in order to be assigned to one another. If there is a pragma for one of the comparison partners, but not for the other one, the appropriate number of empty lines will be inserted for the comparison partner that does not have a pragma. Pragmas are assigned on the basis of names.

Note

If there are matching pragmas, you can accept subordinate variables to suit your specific requirements.

If the comparison partner has no matching assignment for a pragma, you must accept the pragma along with the variable declarations.

Example: Detail comparison of declaration tables

Example of a detail comparison for declaration tables

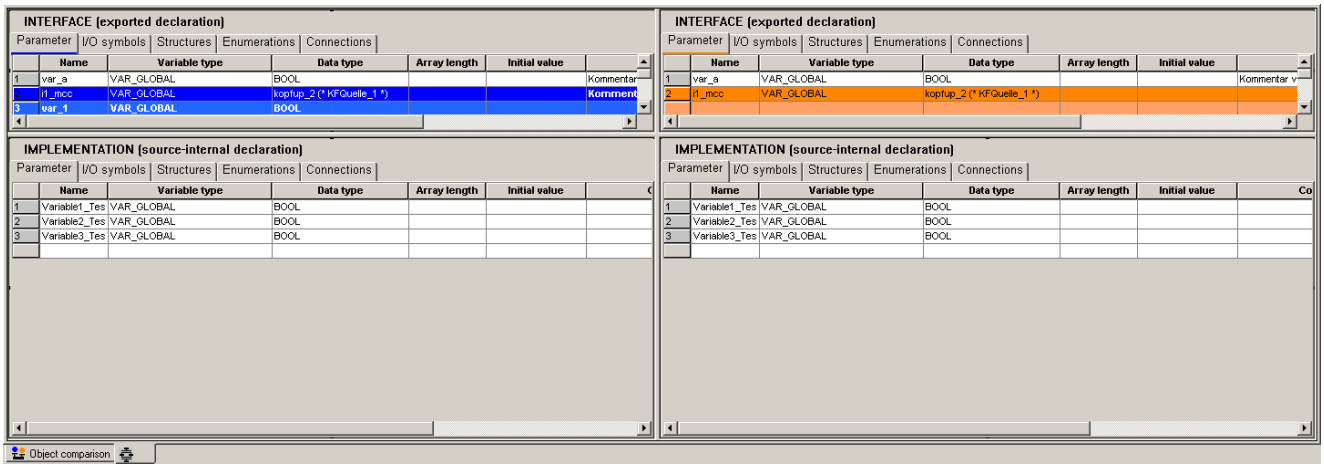

Figure 5-66 Example of a detail comparison for declaration tables

MCC detail comparison of charts

Introduction

The detail comparison is subdivided into the following areas: The upper area, which contains the local variable declarations for the comparison partner, and the lower area, which contains the two charts whose command blocks have been synchronized.

You can navigate between all the differences identified and align individual differences in accordance with your specific requirements.

In addition, an overview tab appears in the project navigator. This displays the differences in compact form. Simply click on the differences on the overview tab to jump directly to each difference in the chart.

Modules

In general, it is possible to zoom in on/zoom out from the module in the case of both comparison partner A and comparison partner B.

If two modules have been matched up with one another, the commands within each zoom level are compared with one another (as in the case of a chart without modules).

Note

At every zoom level, you have the option of viewing the differences in terms of command parameterization and accepting individual commands in accordance with your specific requirements.

If there is a module for only one comparison partner or if a module has been assigned to comparison partner A, but not to comparison partner B, although you can zoom in on/zoom out from the module, you can only accept the module in its entirety.

Command blocks

In order to analyze and align differences in terms of command block parameterization, you can open the generic detail comparison once a discrepancy has been identified.

Note

You can align differences in terms of parameterization by selecting checkboxes in accordance with your requirements. If a particular parameter cannot be aligned, no checkbox is made available.

Examples: MCC detail comparison of charts

Possible differences in the detail comparison

The following table provides you with an overview of the possible differences and how they are identified. This is illustrated on the basis of specific examples (see figure below).

Nature of difference	Identification
Differences in the local variable declarations	Differences are highlighted using the object comparison colors (1).
A command or several related commands are missing for comparison partner A or B	There is a corresponding gap in the chart for comparison partner A or B. Any subsequent elements that are assigned to one another become synchronized again after the difference. As regards the comparison partner, where the relevant command or set of related commands is/are present, this/these are displayed using the object comparison color of orange (2).
Differences in structures	In general, only structures of the same type are assigned to one another. Structures of different types are shown staggered. If there is a structure with subordinate commands for one comparison partner but the other comparison partner only features commands with a superordinate structure, the commands are still assigned.
There is a discrepancy between the parameterizations for a command or for several commands of the same type	The command blocks of the same type that are assigned to one another are displayed on one level and are color-coded using the object comparison colors (blue on the left and orange on the right) (3). When you double-click on a command where there is a discrepancy (whether for A or B), a dialog opens showing the parameterization differences, matched up and highlighted in color (see *Detail comparison command block*)
Differences in commented-out commands	The same rules apply as for commands. You also need to be aware of the following points: If the only difference between two commands that have been assigned to one another is that the command is commented out for one comparison partner but not for the other one, both commands are color-coded using the object comparison colors (blue on the left and orange on the right). Where commented-out commands have been assigned to one another but are subject to differences in parameterization, when you double-click on the command where there is a discrepancy, a dialog opens showing the parameterization differences, matched up and highlighted in color.
Differences in the brief comments	Background highlighted using object comparison colors
Parameterization differences affecting an ST zoom	When you double-click either of the ST zooms, the detail comparison window opens (only if there are parameterization differences).

Nature of difference	Identification
Parameterization differences affecting a comment block	When you double-click either of the comment blocks, the textual detail comparison window opens (only if there are parameterization differences).
Modules	Modules are always matched up for the comparison partners, if the majority of command blocks within the module are of the same command type. If this criterion is not met, the modules for both comparison partners are highlighted in color and shown staggered. If a module is only present for one of the two comparison partners, this is color-coded accordingly. There is a gap in the chart for the comparison partner that does not have this module. In general, it is possible to zoom in on/zoom out from the module in the case of both comparison partner A and comparison partner B. See description below.

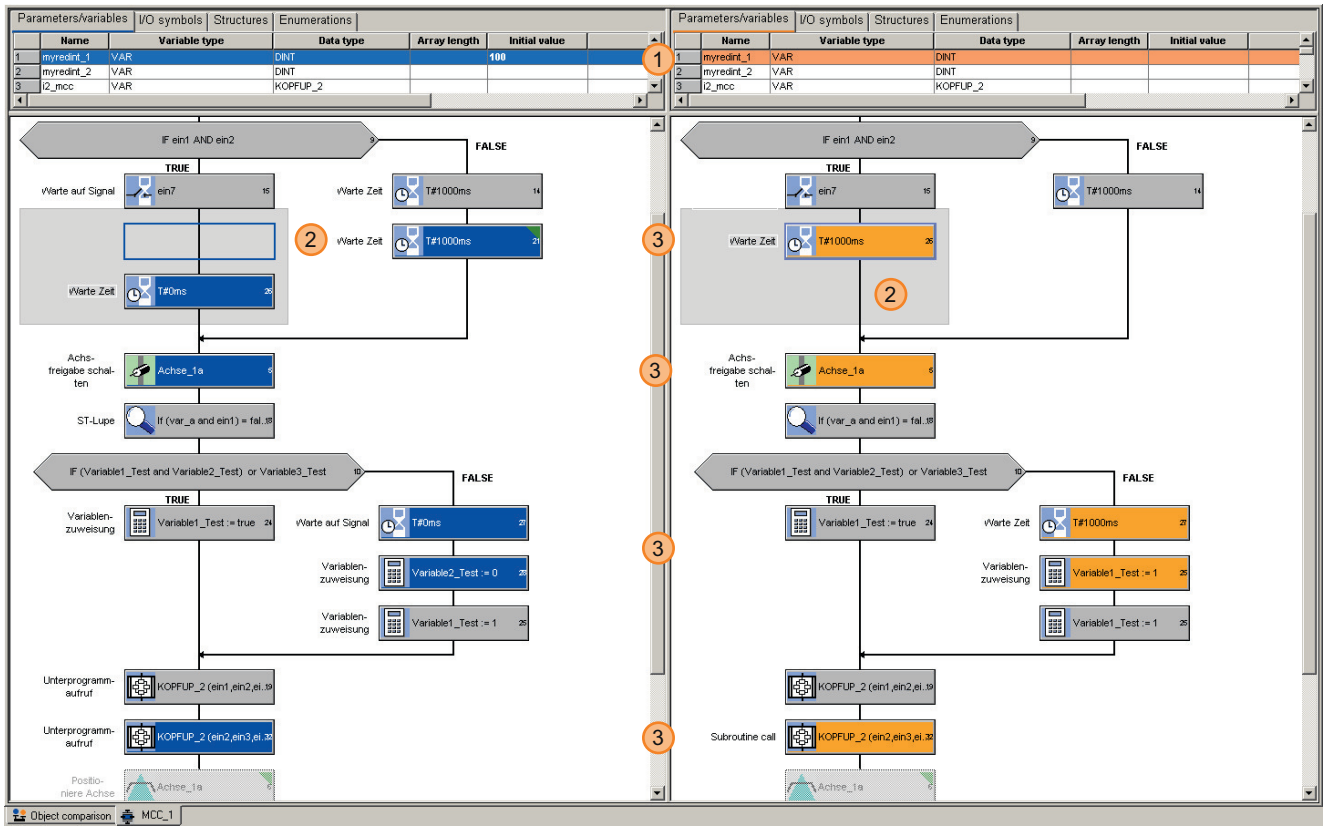

Figure 5-67 MCC detail comparison of charts

Detail comparison command block

The following example shows the detail comparison of a command block.

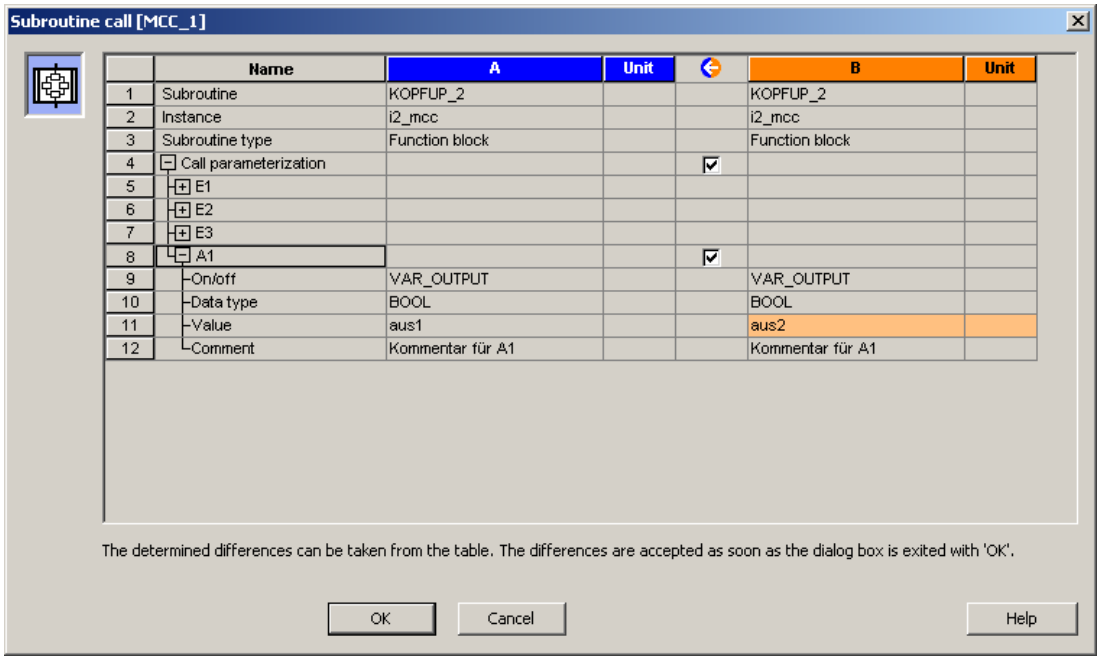

Figure 5-68 Detail comparison command block

Detail comparison overview tab

On the overview tab, you will find the following information in compact form:

- Differences in the numbers of commands (1)
- Differences in the parameterization of the commands (2)
- Missing elements for A or B (3)

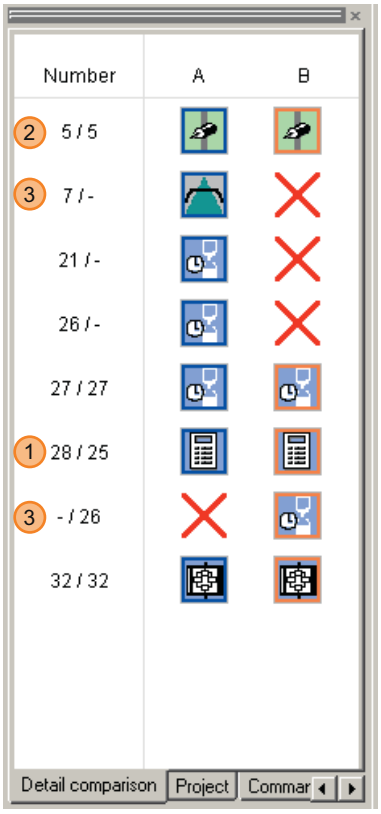

Figure 5-69 MCC detail comparison overview tab

LAD/FBD detail comparison of networks

Introduction

The detailed comparison is subdivided into the following areas: The upper area, which contains the local variable declarations for the comparison partner, and the lower area, which contains the two networks that have been synchronized accordingly.

You can navigate between all the differences identified and align individual differences in accordance with your specific requirements.

In addition, an overview tab appears in the project navigator. This displays the differences between the networks in compact form. Simply click the differences on the overview tab to jump directly to each difference in the network.

Assignment of networks

The networks are matched up on the basis of the comparison result content. Two networks are assigned to each other, if:

- They are 100% identical
- The structure of the two networks is absolutely identical
  (i.e. the number and position of blocks/elements are identical, all of these have a matching counterpart in the comparison partner, the connections are the same, the only differences relate to parameterization (different variables or constant values on the same pins) or instantiation (different instance names))
- Or if a relatively large number (for example, more than 50%) of elements can be assigned.

Detailed comparison of networks of different types (LAD vs. FBD or FBD vs. LAD)

LAD/FBD programs within an LAD/FBD unit are assigned on the basis of names. This makes it possible to assign two LAD/FBD POUs with the same name to one another even though the network type differs. If an LAD POU is assigned to an FBD POU, these POUs are marked as *non-identical* (i.e. aspect, comments, and formats).

When you open the detailed comparison, the differences can only ever be displayed in the same format. An attempt is made to switch POU B to the format used for POU A. If this is not possible, an attempt is made to switch POU A to the format used for POU B.

If the switch is not possible, the following error message is displayed:

- The detailed comparison is not possible.
- The network type of comparison partner B is switched over.

Note

The automatic switching process described above is only used for display purposes and is not saved automatically.

Examples: LAD/FBD detail comparison of networks

Possible differences in the detail comparison

The following table provides you with an overview of the possible differences and how they are identified. This is illustrated on the basis of specific examples (see figure below).

Nature of difference	Identification
Different PINs	Differences are highlighted using the comparison partner color.
Operations without a matching counterpart in the respective comparison partner	Operations are highlighted using the comparison partner color (1).
Differences in the network comments	Differences are highlighted using the comparison partner color (2).

Nature of difference	Identification
Network is missing completely for one comparison partner	The network that is present is color-coded (3).
Differences in the variables	Differences are highlighted using the comparison partner color (4).

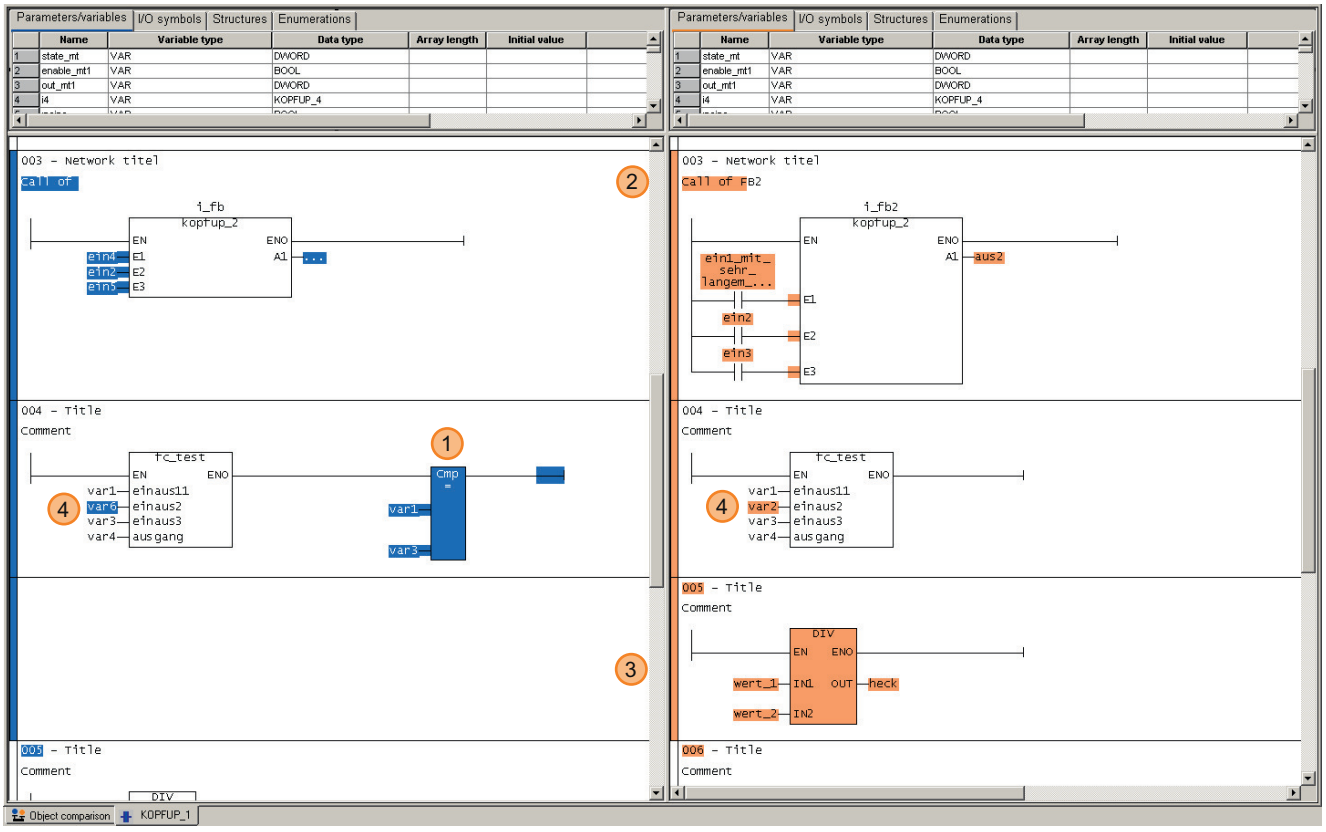

Figure 5-70 LAD/FBD detail comparison of networks

Detail comparison overview tab

The overview tab displays the following information in compact form for both LAD and FBD:

- Differences in the number of networks (1)
- Number of different networks (2)

- Missing networks for A or B (3)
- Areas with identical networks (4)

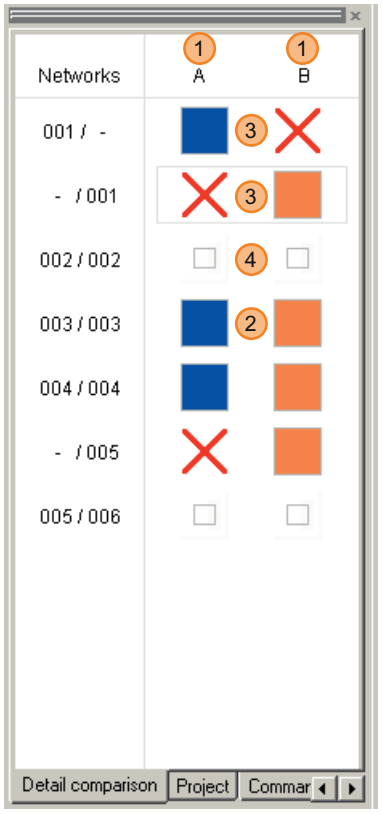

Figure 5-71 Detail comparison of LAD/FBD networks overview tab

DCC detailed comparison

Introduction

For SINAMICS DCC charts on the drive object (DO) and in the DCC library, a detailed comparison of two DCC charts can be started in the project comparison as of STARTER V4.4 / SCOUT V4.4. The detailed comparison of the DCC charts can be started from the object DCC chart in the project comparison.

The chart contents of two charts are compared on the basis of chart data, also known as chart sources, or compilations. The comparison result is displayed in tabular form. This feature is only available for SINAMICS DCC charts in SCOUT, not for SIMOTION DCC charts.

For comparison attributes which display a question mark or not equal sign in the object comparison, it is possible to open the detailed comparison.

The detailed comparison can be started for the following comparison attributes:

- Source code (time stamp comparison)
- Blocks
- Interconnections

- Execution groups
- @ parameters and external references

Requirements for the detailed comparison

- A CFC license and a CFC editor installation are required to start the detailed comparison for the "Source code (time stamp comparison)" comparison attribute. For this comparison attribute, comparisons are made on the level of the DCC chart data. The project must be converted to a suitable CFC data management when opening. If the DCC trial license is still available for activation, you can open the licensing box to activate the license.
  If no valid license is available, the following message is output and the operation is aborted: "DCC chart sources cannot be compared because a valid license has not been found".
- A CFC editor installation is required to start the detailed comparison for the "Execution groups", "Blocks" and "Interconnections" comparison attributes. For these comparison attributes, the compilation result, the so-called compilation, is compared with the DCC chart. This means that the result can differ from the "Source code (time stamp comparison)" comparison attribute. A CFC license is not required. The project must be converted to a suitable CFC data management when opening.
  If a CFC editor is not installed, the following message is output and the operation is aborted: "A CFC editor is not installed. DCC chart sources cannot be compared".
- Neither a DCC editor license nor a CFC editor installation are required to start the detailed comparison for the "@ parameter and external references" comparison attribute

Comparison attribute / requirement	CFC editor required	CFC license required	Project should be converted to CFC data management
Source code (time stamp comparison)	Yes	Yes	Yes
Blocks	Yes	No	Yes
Interconnections	Yes	No	Yes
Execution groups	Yes	No	Yes
@ parameters and external references	No	No	No

- The detailed comparison for DCC SINAMICS libraries is only possible in the offline-offline comparison.
- For calling up the detailed comparison in the offline-online comparison, the DCC chart data are required at comparison partner A. In the offline-offline comparison, the DCC chart data are only required at one of the two comparison partners.
- If the comparison results of the two comparison partners differ excessively, a meaningful comparison is not possible. A detailed comparison cannot be carried out.
- If conversion is required for comparison, note that reconversion is not possible. If a conversion is not wanted, you can create a copy of the projects, convert these projects and then run the comparison.

Note

If the CFC data management of a comparison project is not converted, an error message is output.

Note that the conversion cannot be undone. You can perform the conversion with a copy of the project and start the detailed comparison again.

Method of operation of the detailed comparison

The detailed comparison is offered when the  and  icons are display in the project comparison. Start the detailed comparison by clicking the respective icon.

The detailed comparison enables possible inconsistencies between the DCC charts to be precisely identified when going online or when activating the test mode in the CFC editor.

If the test mode is not switched on in the CFC editor or can only be switched on with limited functionality, then change to STARTER/SCOUT. You can then have SINAMICS display the differences in the DCC charts in the project comparison.

The detailed comparison is characterized by the following:

- If the comparison attributes (source code, blocks, interconnections, execution groups, @parameters) are not consistent, a comparison result is provided with detailed information.
- Tabular list of the comparison result.
- With an inconsistent comparison result, you can jump to the appropriate position in the DCC by double-clicking a difference in the table. This avoids unnecessary searching in the DCC chart. For this, you require the source of the DCC chart.
- As with the project comparison, the detailed comparison of DCC charts can be performed with the same comparison partners. This means that the detailed comparison can be performed between DCC charts and the project. The DCC charts and the project can be in the offline-offline or offline-online states respectively.
- If one of the comparison partners has a know-how-protected DCC chart, the detailed comparison of this DCC chart is only possible after specification of the login and password. The know-how protection of charts is only guaranteed when the chart sources are explicitly protected with know-how protection. This know-how protection is effective on the level of the chart sources, of the loaded execution code, for exported chart sources and in the detailed comparison.
  Even if the chart sources have been deleted in the project, the know-how protection must also be set for the protection of the export, compilation and detailed comparison.
- The DCC libraries are also contained implicitly as "DCC chart" comparison object.

The following figure illustrates the relationships between the comparison attributes and the data sources:

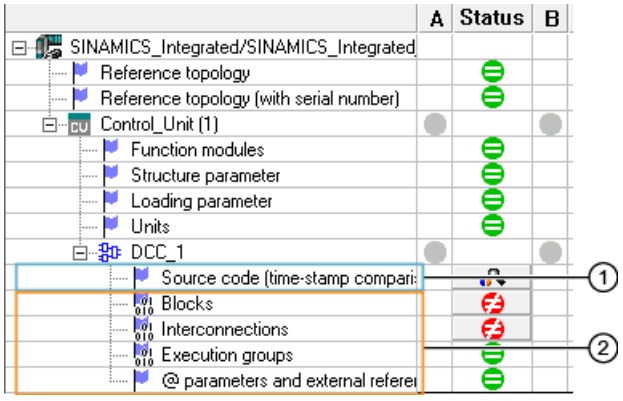

Figure 5-72 Relationships between comparison attributes and data sources

① Chart data

② DCC compilation + DCC parameter

Overview of comparison values

The values that are taken into account in the DCC detailed comparison are shown in the following table.

Value	Description
Chart properties	
Name	DCC name
Chart version in the CFC editor	Version of the chart that has been set in the DCC chart (default value: 0.0001)
Parameter number base	Base value for parameter numbers which has been set for the DCC chart
Libraries	
<Libraries>	List of the libraries used and their version numbers
Blocks	
<Blocks>	List of all blocks in the DCC chart with their properties (e.g. position, inputs, outputs or interconnections)
Block sequence	
<Execution groups>	List of the execution groups and the sequence of the blocks in them
Execution group sequence	
<Execution groups>	List of the execution groups in their set sequence
Chart structure	
<Subcharts>	List of the subcharts and their position in the DCC chart

Example: DCC detailed comparison

Example

You can only start the detailed comparison from the project comparison by clicking the or button. You cannot start the detailed comparison from the CFC editor.

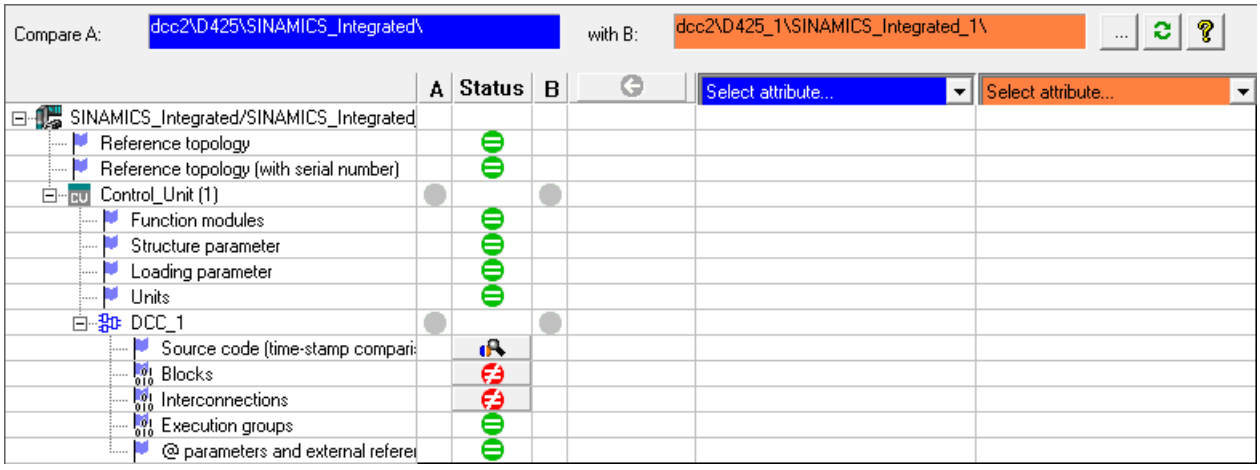

Figure 5-73 Example: Project Comparison

The detailed comparison that opens provides a tabular display of all differences.

		dcc2\D425\SINAMICS_Integrated\	dcc2\D425_1\SINAMICS_Integrated_1\
1	**Chart properties**		
2	**Libraries**		
3	**Blocks**		
4	ADD	1	1
5	Position	A(55:168)	A(55:168)
6	X1	2.0	1.0
7	X2	4.0	2.0
8	X3	6.0	3.0
9	X4	8.0	4.0
10	Y	0.0	0.0
11	Interconnection to	2.X1	
12			
13	SUB	2	
14	Position	A(65:156)	
15	X1	0.0

25	**Execution group sequence**		
26	Execution group 1	DCC_1	DCC_1

Figure 5-74 Example: Display of the differences in the detailed comparison

Double-click a difference in the table to jump to the appropriate position in the DCC chart.

Detail comparison of simply structured data

Introduction

The detail comparison can help you to analyze and align simply structured data, for example, for CPU system variables and TO interconnections.

User interface

The following figure shows the structure of the detail comparison.

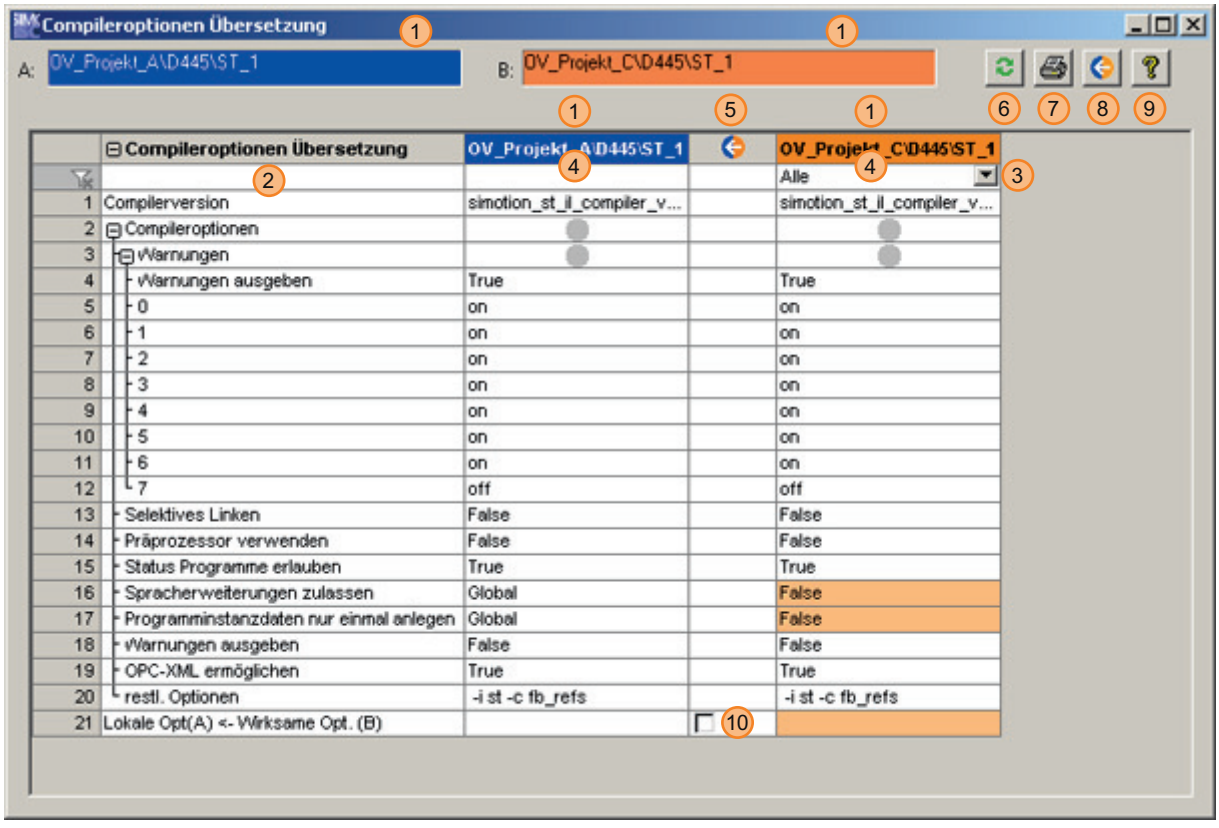

Figure 5-75 User interface of the detail comparison

Table 5-35 The user interface elements of the detail comparison

No.	Description
1	Comparison partner A and comparison partner B
2	Comparison tree made up of comparison partner elements
3	Filter The filter can be used to determine whether the entire data volume should be displayed or just the differences. The selection is set by default to **Differences only**.
4	Result of comparison
5	Data transfer of the selected differences See note below.

No.	Description
6	Update comparison
7	Print comparison
8	Data transfer of all differences See note below.
9	Call up online help
10	Checkbox for data transfer (if no transfer is possible, the checkbox is not displayed) See note below.

Note

Data transfers are not always possible, for example, during TO interconnections or generally for write-protected projects. In this case, checkboxes are not displayed for the transfer

Rules for data transfer

- Checkboxes for the data transfer are only displayed once a difference has occurred. If there are not any differences on one level, checkboxes are also not displayed on the higher level.
- As a general rule, data is structured in hierarchical order. As such, you can either fully transfer a hierarchy level with subordinate hierarchy levels/objects or just individual subordinate hierarchies/objects.
- Please note the following when changing the transfer selection:
  - Activate or deactivate the superordinate level:
    The checkboxes of the hierarchically subordinate elements assume the same value.
  - Activate or deactivate subordinate elements:
    The checkbox of the subordinate hierarchy level is disabled, as long as activated and deactivated checkboxes are located below the level.

- The **Data transfer** button (see figure below user interface, No. 5) is only activated once at least one checkbox has been activated for the transfer.
- The data transfer is only activated by clicking the **Data transfer** button.
  - If you only wish to transfer the selected differences, click on the **Data transfer** button in the column header (see figure below user interface, No. 5).
  - If you wish to transfer all differences, click on the **Data transfer** button on the toolbar (see figure below user interface, No. 8).

Note

In certain cases, a difference may still be displayed following successful transfer, for example, different CPUs may have a different number of MotionTasks.

Note

Differences in the source properties

A unit that does not exist can be transferred from comparison partner B to A. In this case, the new unit is created in the project and also the compile options. If the compilation result is now updated, the comparison still shows a difference in the compilation settings. This can be resolved easily by recompiling the CPU.

Data transfer failure

Errors can occur during the data transfer. For example, the transfer of a non-existent A1 IO variable can fail if an A1 global device variable already exists. If the transfer fails, the following message is output: **Errors occurred during data transfer!**.

The comparison is updated following the transfer. In the case of transfer failure, the differences continue to be displayed.

Examples: Detail comparison of simply structured data

The following section shows an example of a detail comparison of the HW Config system interface and global device variables.

HW Config (system interface)

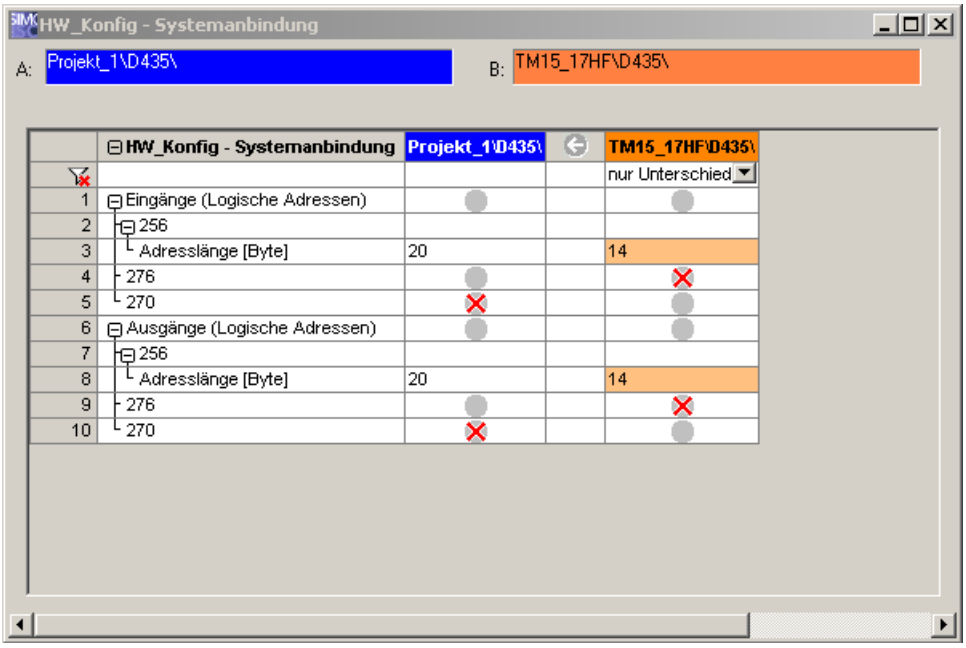

Figure 5-76 Detail comparison of HW Config system interface

Global device variables

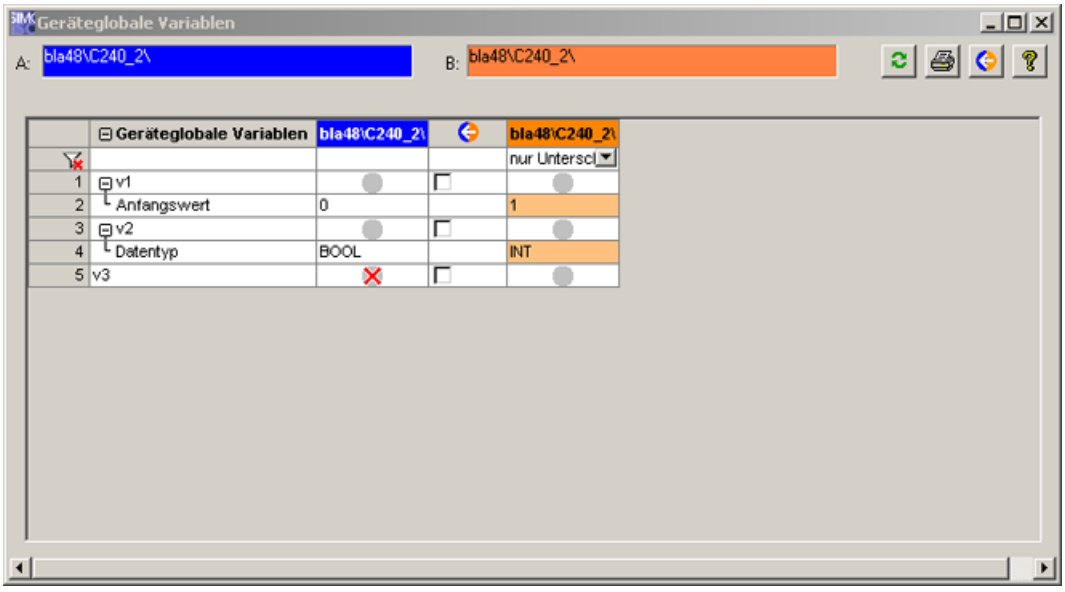

Figure 5-77 Detail comparison of global device variables

TO/DO detailed comparison

Differences between TO/DO detailed comparison and experts list comparison

The differences between the TO/DO detailed comparison and expert list comparison are summarized in the table below.

Table 5-36 Comparison of detailed comparison and Expert list comparison

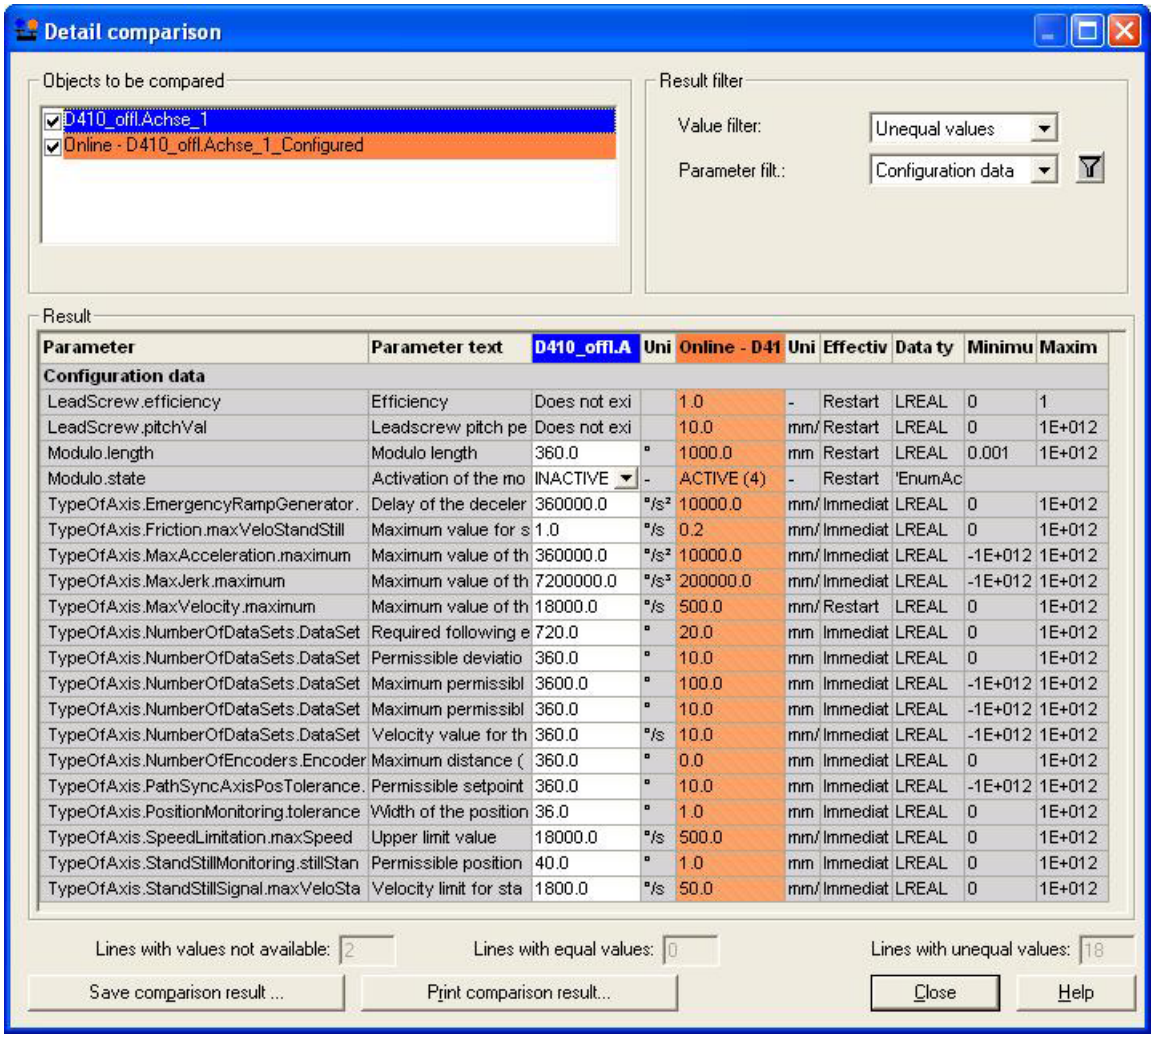
Feature	Detailed comparison	Expert list comparison
Number of comparison objects	1	1 ... n
Origin of comparison objects	Objects from different projects	Objects from the open project only
Values to be compared[1)]	Configured values; actual values are not included in the comparison	Actual values
Indication of differences (structural differences)	Full indication of all parameters (DOs) or system variables and configuration data (TOs), regardless of whether they occur in comparison partner A, B, or both.	Only the parameters and system variables and configuration data of comparison partner A are displayed. Therefore, you only see whether or not the parameters contained in the reference object are present in the comparison objects. Parameters that only the comparison objects contain (not the reference object) are not checked.
Access to online values	Always possible	Only if the structure is consistent with the offline object
Options for changing data in the comparison objects[2)]	Change to data in comparison partner A (reference object) only during offline comparison **Note**: You can use the context menu for the table cells of comparison partner B to transfer the value from B to A.	Change to data in all objects shown in the comparison
Topicality of online data	Snapshot from execution time of object comparison	Snapshot from execution time of expert list comparison

[1)] Differences between configured values and actual values are only of any consequence if the comparison partner is an online TO. Offline, parameters only ever have one (configured) value.
There is only one value for online objects of DOs, and the following applies:
actual value = configured value.

[2)] Fields hatched out in the detailed comparison cannot be edited.

TO detailed comparison

Example of a TO detailed comparison:



Parameter	Parameter text	D410_offl.A	Uni	Online - D41	Uni	Effectiv	Data ty	Minimu	Maxim

r7872[0]		+		Status changes drive object, Sum	9	0	
r9409				Number of parameters to be save	3	0	

Figure 5-78 Example of a DO detailed comparison

Note

For more detailed information, refer to the sections titled Differences between TO/DO detail comparison and expert list comparison and Comparison - Expert list.

Display filter for DO detail comparison

The display filter for the DO detail comparison is the same as for the expert list, with the following exception:

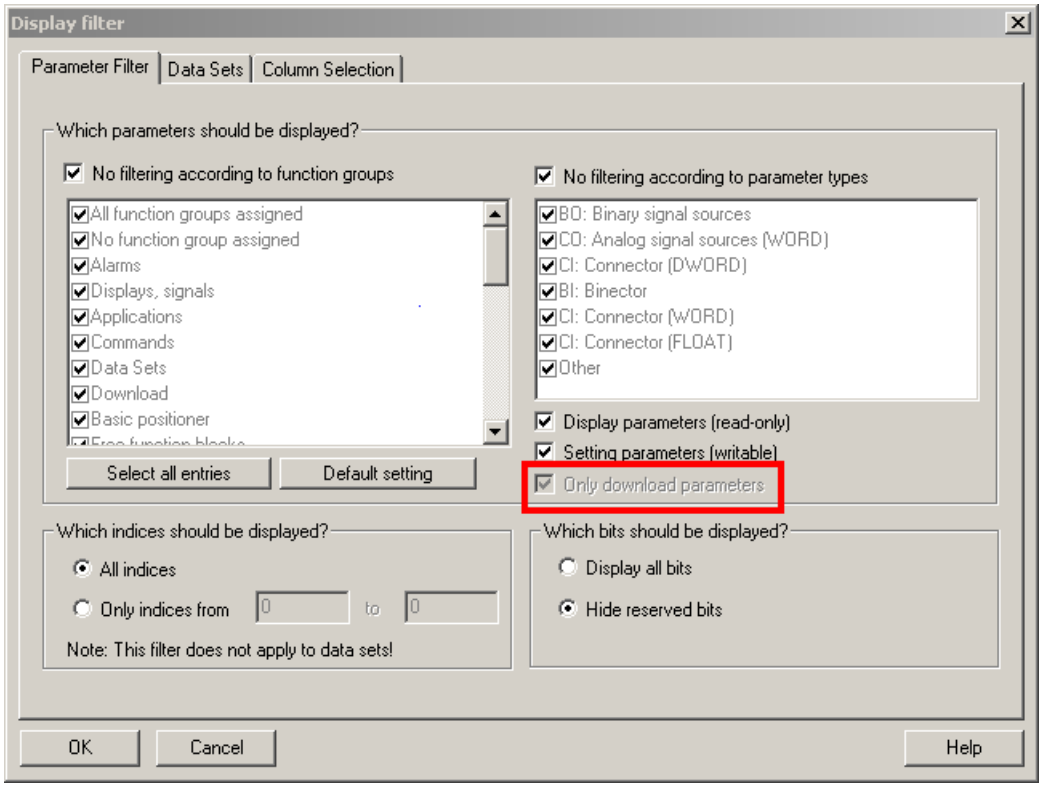

Figure 5-79 Display filter for DO detail comparison

The **Only download parameters** setting on the **Parameter filter** tab is always activated and cannot be changed. This ensures the detail comparison only includes parameters involved with the download. These are those parameters whose values will actually be loaded into the target device for a download from the PG. In contrast, adjustable parameters can only be changed online.

Note

For more information, refer to AUTOHOTSPOT.

5.3.4.5 Data transfer

Function

You can use the **Data transfer** function in the object comparison to transfer the data of the comparison object (B) to the open project (A). You can transfer individual data items from the detailed comparison. You can run a complete online calibration from B to A using the function **Download into PG/PC** or from A to B using **Download to target device**.

Note

In the event of errors when downloading to the PG, note the information in the detailed view on the **Object comparison** tab.

Note

You have to save in order to achieve online consistency after the data transfer of TOs. Programs are compiled after the data transfer, whereby these can become implicitly consistent.

Rules for data transfer

General rules for data transfer

The following rules apply to transfer procedures:

- A transfer is only possible from B to A.
- When you transfer an object, the complete content is transferred (including compiler settings, for example) and overwrites the data in the reference project (A). This means changes that you made in your project may be lost!
- If the comparison partner is a target system, the corresponding supplementary data must be downloaded. If this is not the case, the transfer cannot be performed.
- DOs cannot be transferred.
- A TO/program can be transferred to an existing TO/program. TOs/programs can be created in cases where there is no TO in A, but there is one in B, for example. TOs or a program entry in the execution system then still need to be linked manually.
- TOs/program can also be deleted by transferring them, e.g. if there is a TO/program in A, but not in B.
- When entire objects are transferred, the object address is also transferred (see Duplicate assignment of an object address (Page 3452)).
- If you only wish to transfer individual pieces of data from an object, rather than an entire object, it is only possible to do this in the detail comparison. Here, you can transfer one particular change to an ST program, for example (see Detailed comparison (Page 3422)).

Data transfer of POUs

MCC and LAD/FBD POUs are elements that you can accept individually in the object comparison. All the other elements (e.g. variables) can only be accepted in the specific detailed comparisons.

Rules for transferring:

- When POUs are transferred, the data is transferred in its entirety, including for example the properties (creation type, author, comment, etc.).
- If an object is present only for B, the POU is created for A during transfer. (A transfer is only possible if the higher-level source for A already exists.)
- If an object is present only for A, the POU is deleted for A during transfer.
- If the comparison partner is a target system, the corresponding information must be available online (see above: General rules for data transfer).
- If the source containing the POU is know-how protected (for A and/or B), then special rules apply (see below: Data transfer with know-how protected projects).

Data transfer for write-protected projects

If projects have been created in older SCOUT versions, you can open them as write-protected projects following an upgrade. The write-protected project allows you to perform an object comparison or detail comparison, but no data transfer is possible.

Data transfer with know-how protected projects

You can transfer know-how protected objects. You must be logged in to ensure that aspects are displayed and that you are able to transfer individual POUs.

Procedure for data transfer

To transfer data, proceed as follows:

1. Place a check mark in the check box (see diagram below) for the object you want to transfer.

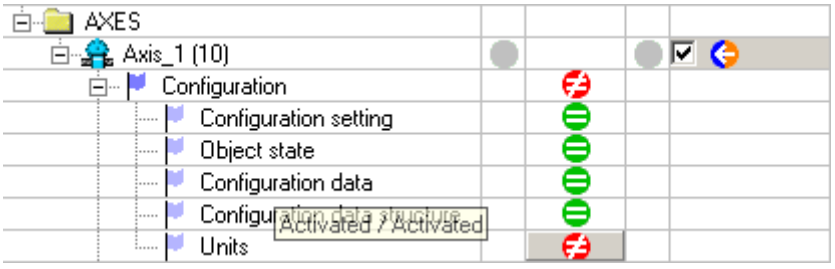

Figure 5-80 Selection and transfer of objects

2. Start the transfer by clicking the **Data transfer** button, and confirm the dialog that follows with **OK**.

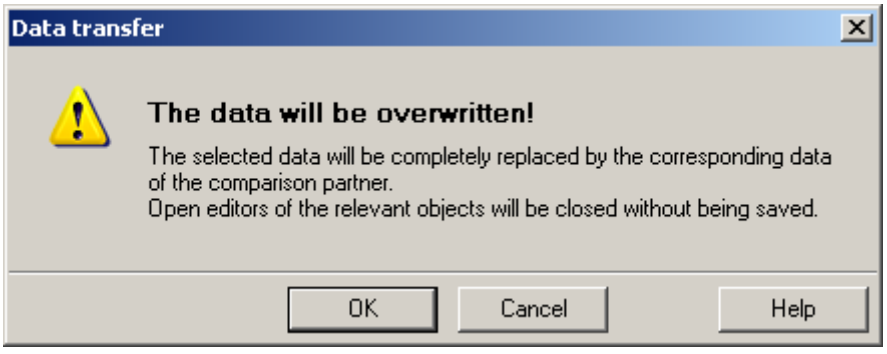

Figure 5-81 Data transfer dialog

3. Once the data have been transferred successfully, the check box is replaced with a check mark. The result of the comparison in the object comparison is then no longer up to date. This is indicated in the status bar at the end of the view.
You can, however, perform addition detail comparisons and data transfers without updating the comparison.

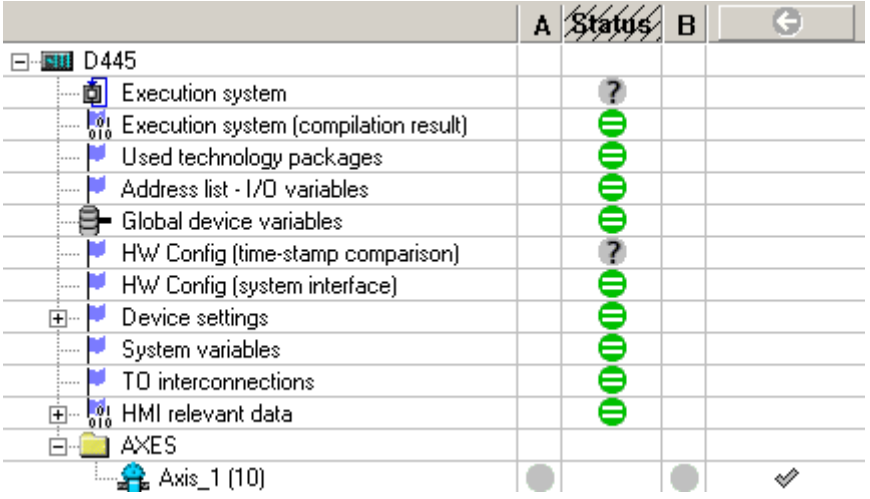

Figure 5-82 View following transfer

Duplicate assignment of an object address

When transferring entire objects, the object address is also transferred. Because the object address in the address space of a SIMOTION device must be unique, address conflicts may arise. Transfers which would result in duplicate assignment are not carried out. The object affected by the address conflict is entered in the log in the detailed view.

As of V5.1, it is possible with an occupied object address to perform a transfer.

To do so, click on the "Settings for transferring objects" check box and select the "Transfer without object address (recommended)" option or change the object address (see Chapter Changing the object address (Page 3422)).

5.3.5 Overview of comparison attributes

Below you will find an overview of the comparison attributes, along with their associated aspects/sub-aspects, for SIMOTION, SINAMICS, and MICROMASTER objects.

The comparison attributes are made up of several comparison features. There are various reasons for differences in comparison attributes. A difference in the compilation result may result from program changes (source code), for example, and/or a change to the compiler settings. The tables below describe the comparison attributes for the individual object types. These should help you to quickly establish the causes of a difference if a detailed comparison is not available.

We recommend the following procedure for efficiently finding the reason for a difference to a comparison attribute:

- If necessary, compile projects (A + B) if the compilation results are no longer up-to-date
- Start the detailed comparison, if available
- Search for the description of the comparison attribute in the object table
- Check the comparison features

Note

In conjunction with the detailed comparison, the term "scalar" means that only a single data item, such as the device name, is compared. Differences are then displayed in a dialog box.

Note

Online/offline comparison

- Please note that no current parameter values are compared during an online/offline comparison. Only parameter differences which are relevant to the download are displayed.
- A statement is not possible for the HW Config time stamp and the system display in an online/offline comparison. Therefore, a "?" is displayed in this case.

5.3.5.1 SIMOTION objects

SIMOTION device

Table 5-37 Comparison attributes of a SIMOTION device

Comparison attributes of a SIMOTION device	Aspects/Sub-aspects	Detailed comparison / scalar
Execution system	Configuration of the execution system: • The assignment of programs to the tasks • Configuration of tasks in the **Task configuration** tab • System cycle settings using the **Set system cycles...** function (Servo, Ipo, Ipo_2, TControl) **Note:** Compile the project prior to starting the project comparison. In this way, you will obtain a meaningful comparison result.	Execution system
Execution system - compilation result	The part which results from the project's compilation process. The compilation result includes: • The configuration of the execution system (see above) • The technology packages used	No detailed comparison
Selected technology packages	The technology packages selected in SCOUT with associated version.	Used technology packages
Address list of I/O variables	• Configuration of I/O variables **Note**: Structural changes to the I/O variables are also included in the **HMI-relevant data** comparison attribute.	Address list of I/O variables
Global device variables	• Configuration of global device variables **Note**: Structural changes to the global device variables are also included in the **HMI-relevant data** comparison attribute.	Global device variables
HW Config (time stamp-comparison)	Comparison of the hardware configuration is based solely on a time-stamp comparison. The time stamp of the most recent change is used. If a comparison is carried out on this basis, a statement on the equivalence is only possible when the time stamp is the same. If the time stamp is different, the hardware configuration may be the same or different. This will be the case if the most recent change has been undone, for example. STEP7 SIMATIC Manager offers a block comparison for such cases. **Offline comparison** The comparison is undertaken as described above. **Online comparison** A statement is not possible for the HW Config time stamp comparison. Therefore, a "?" is displayed in this case. The statement is that the hardware configuration is not included in the comparison. Displaying this attribute prevents the SIMOTION device from being displayed as inconsistent in the project navigator; however, everything is the same in the object comparison (the only difference is in HW Config).	No detailed comparison

Comparison attributes of a SIMOTION device	**Aspects/Sub-aspects**	**Detailed comparison / scalar**
HW Config (system integration)	The data from the hardware configuration which is included in the SIMOTION configuration: • I/O addressing (in HW Config) • DP cycle (bus cycle) • Equidistant bus cycle **Online comparison** A statement is not possible for the HW Config system display. Therefore, a "?" is always displayed in this case. The comparison attribute is only available offline.	HW Config (system interface)
Device settings		No detailed comparison
	• Device name	Scalar
	• Device address Required for distributed synchronous operation; see Object properties (Object address tab)	Scalar
	• Device type	Scalar
	• Behavior of dynamic data during STOP/RUN transition	Scalar
	• Fixed process image	Scalar
	• Time-of-day synchronization	Scalar
	• Fast I/O configuration (onboard I/Os, TM15/TM17 High Feature) [1)]	No detailed comparison
	Devices loaded with a SCOUT/STARTER version <= V4.0: This comparison attribute is not available.	
System variables	• Configuration of system variables in the SIMOTION device	Detailed comparison, CPU system variables
TO interconnections	• Interconnections of TOs on the device	Detailed comparison, technology object interconnections
HMI-relevant data	Records the structural setup (data type of variables, number of variables) of the data which an HMI system can access. If the setup changes, the HMI configuration must be updated. • Structure information of I/O variables • Structure information of global device variables	No detailed comparison
For every library used: Compilation result <Libname>	• Compilation result of the specific device version This comparison attribute is only shown if a library is used. A library comparison can be carried out for a detailed comparison.	No detailed comparison
1) Refers to the appropriate telegram of the fast I/O configuration. A difference is due to a discrepancy in terms of the fast I/O configuration (see drive units), or the failure to carry out HW Config alignment.		

Technology object (TO)

Table 5-38 Comparison attributes of a technology object

Comparison attributes of a technology object (TO)	Aspects/Sub-aspects	Detail comparison/ Scalar
Configuration	Contains the configuration of a technology object.	No detail comparison
	• Configuration setting For example, linear/rotary axis; technology object activated/deactivated	Scalar
	• Object state Values: Activated/deactivated	Scalar
	• Configuration data (see Comparing expert lists) Records the values and units	Detail comparison, expert list
	• Configuration data structure Records the data volume, for example the number of data sets or encoders	Detail comparison, expert list
	• Units (Indirect influence of unit configuration[1)])	Detail comparison, unit configuration
System variables	• The system variables of the TO Records the values and units (Indirect influence of unit configuration and configuration settings[1)])	Detail comparison, expert list
Alarm configuration	• Configuration of TO alarms (see TechnologicalFaultTask)	Detail comparison, alarm configuration
HMI-relevant data	Records the structural setup (data type of variables, number of variables) of the data which an HMI system can access. If the setup changes, the HMI configuration must be updated. Data included:	No detail comparison
	• The configuration data	Detail comparison, expert list
	• The object address (see TO properties)	Scalar
	Indirect influence of unit configuration and configuration settings[1)]	
Configuration data For TO cam only!	Configuration data of cam disc (e.g. support points, interpolation, scaling)	Detail comparison, configuration data
[1)] The unit and value of a technological parameter are always viewed separately (i.e. not the resultant parameter). This means: If a unit configuration is changed, the configuration data and system variables will be different to the original setting, even if the values in the new unit have been converted and the resultant variable is the same. A linear axis/pressure uses different physical variables to a linear axis/force; even if the numerical values are the same, these different variables will result in a difference. Not applicable to cams.		

Note

Modified data is only considered in the comparison once **Copy current data to RAM** has been performed.

Source

The following overview applies to ST, LAD, FBD, and MCC.

Note

Differences in the source after recompilation

If you recompile the source code of projects in version V4.0 or V4.1 in SCOUT in a newer version, differences for the sources can be displayed in a project comparison (old with new). This is because the signatures after the compilation are different for versions V4.0 and V4.1 and newer versions. In newer SCOUT versions, the signature is formed via the graphic programming languages LAD/FBD/MCC and not via ST.

Note

Sources with larger version jumps

With larger version jumps (e.g. from 3.2 to 4.1), the signatures of functions can change (for example for system functions, new parameters are added that are assigned useful default values). Therefore, the code generated by MCC changes during the compilation; the generated code however is still functionally identical.

Simultaneously, the difference is detected in the parameterization and also when editing the source, and can be adapted there.

As long as the source is not touched, it is identical in the project comparison.

If the source is edited on the V4.4 side, the project comparison and the detailed comparison find differences. If, however, the source is compiled without editing, only the project comparison finds differences, not the detailed comparison.

Table 5-39 Comparison attributes of a source

Comparison attributes of a source	Aspects/Sub-aspects	Detailed comparison / scalar
Source code (ST)	Source text (based on ASCII)	Detailed comparison
	• Execution-relevant source code Everything apart from comments and formats such as spaces, empty lines	No detailed comparison
	• Comments and formats	No detailed comparison

Comparison attributes of a source	**Aspects/Sub-aspects**	**Detailed comparison / scalar**
Source code (MCC/LAD/FBD)	Source text (based on ASCII)	No detailed comparison
	• INTERFACE (exported declaration) Declarations and connections (the detailed comparison shows the first interface difference)	Detailed comparison unit [1]
	• IMPLEMENTATION (source-internal declaration) Declarations and connections (the detailed comparison shows the first difference in implementation)	Detailed comparison unit [1]
	• Comment language	Scalar
	• Comments Only displayed if the comment language has the same value (the detailed comparison shows the first comment difference)	Detailed comparison unit [1]
	• POU (n times, n>= 0)	No detailed comparison
	Declarations	Detailed comparison
	Execution-relevant source code	Detailed comparison
	Formats Only displayed if the comment language is not the same	
	Comments and formats Only displayed if the comment language is the same Examples of formatting: spaces, empty lines, network or block numbers	Detailed comparison
Properties [2]	• Compiler options Corresponds to: Properties tab, Compiler and Additional settings	Detailed comparison for local options incl. processor settings
	• Object address	Scalar
Effective compiler options	Corresponds to: Properties tab, Compilation The "effective" compiler options are developed from the combination of "global" and "local" computer settings. Any transfer of the global compiler options is impossible as these options are not saved at the source. In order to achieve an identical compilation result, the "effective" compiler option can be transferred to the source properties as a "local" compiler option via the setting "Local Opt(A) <- Effective Opt. (B)" in the project comparison. In this case, click this option in the object comparison. This setting cannot be transferred for libraries.	Detailed comparison

Comparison attributes of a source	**Aspects/Sub-aspects**	**Detailed comparison / scalar**
Compilation result	The compilation result for a source includes:	
	• The source text of relevance to execution, i.e. everything apart from comments and formats	No detailed comparison
	• The compiler settings (local and global)	
	• The compiler version (e.g. compilation with new SCOUT)	
	• External references – Interfaces of other sources used – Interfaces of libraries used – Global device variables used – I/O variables used – TOs used – Tasks used in the task control commands	No detailed comparison
	• Message configuration (used symbols/IDs) If a different number has been assigned to an alarmS configuration icon, and this icon has been used in this program, then the source code is the same in both cases but the compilation result is different. If you need to work out online which number has been used for an icon, you upload a device into an empty project. Here, you can look in the message configuration (the icons and the assigned numbers are entered in this during the upload).	Detailed comparison
	• Data structure of retain data	No detailed comparison
	• Data structure of non-retain data	No detailed comparison
	• Exported interface (effective) Exported data and data types used [3)] Exported POUs	No detailed comparison
HMI-relevant data	Records the structural setup (data type of variables, number of variables) of the data which an HMI system can access. If the setup changes, the HMI configuration must be updated. Data included:	No detailed comparison
	Offline comparison • VAR_GLOBAL variables of the source	For ST: Detailed comparison, Var block displayed Otherwise: Detailed comparison unit
	• The object address (see source properties)	Scalar
	Online comparison Currently, the comparison attribute does not produce a meaningful result.	

1) First difference is displayed

2) Not relevant for online consistency

3) "Data types used" means that they are used in the exported global variables or in the exported POUs. Constants plus default and initialization values are not taken into account.

DCC chart

Table 5-40 Comparison attributes of a DCC chart

Comparison attributes of a DCC chart	Aspects/Sub-aspects
Source code Time stamp comparison - for time stamp "Last modified on (STEP7)"	**Offline only** • Changes in the DCC editor based on a time stamp (Last modified on (STEP7)). The comparison only relates to a statement about an offline/offline comparison, as the time stamp is not stored online. **Note**: The comparison is based on a time-stamp comparison only. The time stamp of the most recent change is used. If a comparison is carried out on this basis, a statement on the equivalence is only possible when the time stamp is the same. If the time stamp is different, the source code may be the same or different (e.g. if the most recent change was reversed). In such cases, it is not possible to make any statements regarding this in the object comparison. This is shown by a **?**.
Blocks	Block instances and their properties, such as • Type • Name • Address • Constant values (initial values) of inputs and outputs • Assignment to execution group • Change the predecessor of the execution group by inserting or deleting execution groups • Change to the run sequence
Interconnections	The comparison attribute for interconnections indicates differences in terms of chart interconnections. This includes: • Interconnections of all the inputs within the chart • Interconnection/assignment of @ parameters to inputs and outputs • SIMOTION: Interconnections with execution groups • SIMOTION: Interconnections with operands (TOs/sources, global device variables, IO) • External references for the chart (referenced operands, DCB and DCC libraries used) **Notes**: When interconnecting a chart's output with another chart's input, the interconnection is always incorporated in the chart's comparison attribute along with the input. If you have defined a BICO @ parameter for an input with SINAMICS while making another interconnection at the same time, the interconnection will be executed as a BICO interconnection and, as such, will be incorporated in the "@ parameters and external references" attribute rather than the "interconnections" attribute. Interconnections with operands are only incorporated in the interconnections attribute with SIMOTION. With SINAMICS, all interconnections with operands are executed as BICO interconnections and, as such, contained within the "@ parameters and external references" attribute. Interconnections depend on external references. The external references include not only non-DCC objects, but also the used DCB/DCC libraries.

Comparison attributes of a DCC chart	**Aspects/Sub-aspects**
Execution groups	Chart execution groups and their properties • Name • Task assignment (only applies to SIMOTION) • Predecessor execution group • Initial state of execution group (active/inactive)
@ parameters and external references	**SIMOTION:** • Published parameters • Compiler settings • External references – Interfaces of referenced sources (programs: ST, MCC, LAD/FBD) – Reference parameters of other DCC charts – Interfaces of DCC libraries used – Global device variables used – I/O variables used – TO system variables used **SINAMICS**: • Parameter values of the @ parameters (p parameters: Values of the adjustable parameters and BICO interconnections on BICO sinks) • Adjustable parameter for DCC (p21000[0 to 9])
HMI-relevant data	Records the structural setup (data type of variables, number of variables) of the data which an HMI system can access. If the setup changes, the HMI configuration must be updated. Data included: **SIMOTION**: **Offline/offline comparison**: • Data that can be addressed by the HMI • The object address (see chart properties) **Offline/online comparison <= device version V4.1.2:** No aspects **Offline/online comparison with device versions as of V4.2:** • Data that can be addressed by the HMI • The object address (see chart properties) **SINAMICS:** • Not relevant

Note

No detailed comparison is available for the comparison features of the DCC charts!

Note

If a published connection is changed in offline mode, the Online/Offline Comparison window is not opened when the online mode is opened.

The difference between the target device and the project in the DCC chart can only be seen at **Target system output** and in the project navigator.

If a connection that has not been published is changed in offline mode, the **Online/Offline Comparison** window is opened when the online mode is opened.

Library

Table 5-41 Comparison attributes of a library

Comparison attributes of a library	Aspects/Sub-aspects	Detail comparison/Scalar
Properties	• Compiler options Corresponds to: Properties tab, Compiler	Detail comparison for local options
	• Used technology packages <device type> See compilation result, dynamic aspect	Detail comparison, used technology packages
Effective compiler options	Corresponds to: Properties tab, Compilation	Detail comparison
Compilation result <Device type> Compilation result	Depending on the setting in the properties dialog (technology packages), the compilation result is shown for each device type or as unrelated to the device type. The following data is included in the comparison: • The source code of relevance to execution, i.e. everything apart from comments and formats • The compiler settings • The compiler version (e.g. compilation with new SCOUT) • External references (sources, libraries, TPs, TOs, I/Os, global device variables, tasks) • As with the compilation result <Device type> Compilation result unrelated to device type	No detail comparison

Source in a library

Table 5-42 Comparison attributes of a source in a library

Comparison attributes of a source in a library	Aspects/Sub-aspects	Detail comparison/ Scalar
Source code (ST)	Source text (based on ASCII)	Detail comparison
	• Execution-relevant source code Everything apart from comments and formats such as spaces, empty lines	No detail comparison
	• Comments and formats	No detail comparison
Source code (MCC/LAD/FBD)	Source text (based on ASCII)	No detail comparison
	• INTERFACE (exported declaration) Declarations and connections (the detail comparison shows the first interface difference)	Detail comparison unit [1]
	• IMPLEMENTATION (source-internal declaration) Declarations and connections (the detail comparison shows the first difference in implementation)	Detail comparison unit [1]
	• Comment language	Scalar
	• Comments Only displayed if the comment language has the same value (the detail comparison shows the first comment difference)	Detail comparison unit [1]
	• POU (n times, n>= 0)	No detail comparison
	Declarations	Detail comparison
	Execution-relevant source code	Detail comparison

	• Object address	Scalar

DCC chart in a library

Table 5-43 Comparison attributes of a source in a DCC library

Comparison attributes of a DCC library	Aspects/Sub-aspects
Source code (time stamp comparison)	**Offline only** • Changes in the DCC editor based on a time stamp (most recent change). If values are changed in online mode, the changes and, therefore, the time stamp are detected offline. **Note**: The comparison is based on a time stamp comparison only. The time stamp of the most recent change is used. If a comparison is carried out on this basis, no statement can be made concerning whether the source code is the same unless the time stamp is the same. If the time stamp is different, the source code may be the same or different (e.g. if the most recent change was reversed). In such cases, it is not possible to make any statements regarding this in the object comparison. This is shown by a **?**.
Blocks	Block instances and their properties, such as • Type • Name • Address • Constant values (initial values) of inputs and outputs • Assignment to runtime group • Predecessor in runtime group
Interconnections	The following interconnections are included in the comparison: • Chart interconnections • Interconnection of all the chart's inputs • Interconnections with runtime groups • Interconnections with @ parameters • Interconnections with non-DCC objects within SIMOTION (TOs/sources, global device variables, I/Os)
Runtime groups	Chart runtime groups and their properties • Name • Task assignment • Predecessor execution group • Initial state of runtime group (active/inactive)

Note

No detail comparison is available for the comparison features of the DCC charts in a library!

5.3.5.2 SINAMICS objects

Drive unit

Table 5-44 Comparison attributes of a drive unit

Comparison attributes of a drive unit	Aspects/Sub-aspects	Detail comparison/Scalar
Reference topology	• The reference topology With this comparison attribute, the serial number is not taken into account in the comparison.	No detail comparison (see note below)
Topology (with serial number)	• Reference topology With this comparison attribute, the serial number is taken into account in the comparison.	Detail comparison, reference topology serial number

Note

The "Reference topology (with serial number)" comparison attribute acquires the same data as the "Reference topology" comparison attribute. The serial numbers are also acquired. In detailed comparison to the "Reference topology (with serial number)", only the differences to the serial numbers are displayed. No differences are displayed in the detailed comparison for differences in the reference topology, although the serial numbers are the same.

If differences in the reference topology emerge during an online/offline comparison, you can use the topology editor to determine the differences. Please ensure the reference topology is selected for both comparison partners.

Drive object (DO)

Table 5-45 Comparison attributes of a DO

Comparison attributes of a drive object (DO)	Aspects/Sub-aspects	Detail comparison/Scalar
Function modules	• Function modules (see Parameter r108 in the DO expert list or the properties dialog box of the DO)	Detail comparison, expert list
Structure parameters	• Parameters that determine the structure, e.g. r51 (drive data set DDS effective). These parameters are indexed, i.e. they form enums and bit arrays (arrays of a different dimension), in order to offer several selection options/settings or display values for a parameter. These parameters are identified in the expert list by a "+".	Detail comparison, expert list
Download parameters	• Download parameters (see DO Expert list). These are the parameters whose values will be downloaded to the device.	Detail comparison, expert list
Units	• Units Values: Name of the unit system, e.g. "SI unit system" This comparison feature does not determine the structure.	Scalar

DCC chart

Description of comparison attributes: See DCC chart (Page 3459) in the chapter titled "SIMOTION objects"

5.3.5.3 MICROMASTER and SINAMICS G120 objects

Drive unit

There are no comparison attributes for these drive units.

Drive object (DO)

Table 5-46 Drive object comparison attributes (DO)

Comparison attributes	Aspects/Sub-aspects	Detail comparison/ Scalar
Device version	• Power unit/infeed (configuration vector specifies the device version of a device type) (Only available with G120, not MM4 or Combimaster)	No detail comparison (see note below)
	•	
Download parameters	• Download parameters (see Comparing experts lists)	Detail comparison, expert list
Units	**Device version as of V4.4:** Values: Name of the unit system, e.g. "SI unit system"	Scalar

Note

If you use the settings on the Workbench tab to activate the option **Display Online/offline comparison for the connection**, a comparison will be displayed when you go online. This is not the same as a project comparison.

5.3.5.4 Display warnings

The "Display Warnings" dialog box opens when the "Warning(s)" selection box is activated.

You require a comparison project for the online comparison. This is generated based on the open project. The upload of the device to be compared is performed in this shadow project. This does

not alter the open project. Restoration of the offline data through an upload is not always complete, but this is not relevant for the comparison result.

- Missing supplementary data means that a detailed comparison or a data transfer is not possible.
- Changed know-how protection data means that a detailed comparison may not be possible because you cannot log on.

5.3.6 Appendix A

5.3.6.1 Frequently Asked Questions (FAQs)

Note

As a general rule, the project comparison can only be performed based on saved data. For this reason, data is automatically saved prior to performing the comparison.

We recommend compiling the project prior to starting the project comparison.

Differences are detected in the project comparison, yet the detail comparison does not display any differences.

Possible causes:

- The project compilation is not up-to-date.
- The project comparison is no longer up-to-date, changes have been made to the project following the start of the project comparison (such as transfers in the detail comparison) which directly affect the detail comparison.
- Parts of the project were created with a SCOUT version earlier than 4.0 and therefore can no longer be changed (I/O variables). In this case, the hash codes required for the project comparison have not yet been calculated correctly.
- In the online-offline comparison, the execution system is displayed as different.
  This can occur for a comparison with SCOUT as of V4.4 and a Runtime version up to V4.4. Namespaces have also been introduced for the execution system with SIMOTION SCOUT V4.4. A difference is detected because of the changed data format of the execution system (different hash codes). However, the detailed comparison does not show any differences because this is based on the actual data.

In the online/offline comparison, a question mark is always displayed next to the HW Config system interface.

For the online/offline comparison, only SIMOTION data is downloaded to the offline PG project, in the same way as uploading to the PG. As a result, only this data can be used for the comparison. This is the reason why no statements can be made with regard to differences/ similarities.

The DCC source code time-stamp comparison displays a question mark.

In the case of DCCs, comparison results can only be calculated correctly if the chart compilations are up-to-date.

This applies to both the online/offline comparison (if necessary, update the offline project compilation) and the offline/offline comparison (both project compilations must be up-to-date here).

Following transfer to the online/offline comparison, the object in question is still inconsistently online.

Possible causes:

Following the transfer, the project must be saved to ensure that it is consistently online.

When transferring individual programs, global settings such as compiler settings are not applied. The compilation result is therefore not always consistent. In this case, consistency can only be achieved by means of a download.

The configuration data of an axis has been changed by the system, yet the project comparison still does not display any differences.

Possible causes:

The project comparison compares only configured values (offline and online). Modifications to configuration data initially only change current data, i.e. configured data remains unchanged. To be able to compare the adapted data with the project comparison, you must firstly perform **Copy current data to RAM**.

The online/offline comparison displays differences, yet there are no buttons available for the detail comparison.

Possible causes:

It is likely that no supplementary data is available in the target system.

Program differences are highlighted in the online/offline comparison, but the source text folder can no longer be opened in the overview.

- If no supplementary data has been downloaded to the target system, statements cannot be made regarding the program details. The folder can therefore not be opened
- If the programs in the target system are know-how protected, details can only be displayed once the password has been entered.

There are program differences in the online/offline comparison, so why is there no data transfer button?

Possible causes:

- If there are no differences in source code, then there is no transfer button.
- If there is no supplementary data, then no transfer button is available.

In the detail comparison (online/offline comparison) for the execution system, no values are displayed for the cycles, only a question mark is displayed.

The cycle settings, which are displayed in the detail comparison of the execution system, are only partially based on SCOUT settings. Under the basic cycle clock, for example, the settings made in the HW Config are displayed. Due to the fact that HW Config cannot be used in the online

comparison, it is not possible to upload HW Config via SCOUT and, as a result, no statements can be made regarding differences/similarities.

Unknown values are displayed in the detail comparison (online-offline comparison) for the execution system

This can be TCMRM_MeasureSyncFuncs and TCMRM_BlockSyncFuncs, for example. These values show the internal representation of the configuration.

The displayed differences describe the existing differences in the configuration. The following applies:

- TCMRM_MeasureSyncFuncs = leave time monitoring active
- TCMRM_BlockSyncFuncs = discontinue time monitoring and interrupt the task

At the time of configuration, these values are indirectly set via the drop-down list box in the execution system of the IPO/ServoSynchronousTasks at "Monitoring during the execution of synchronous functions".

In the programs, a difference is displayed in the source text, yet the comparison of all POUs does not show any differences.

The project comparison enables fast comparison of online and offline projects based on hash calculations. In the case of detail comparisons, the original data is then applied.

Occasionally (such as following an upload), this may result in the calculated hash values no longer corresponding.

Save and compile the project and then perform a download.

The comparison tool displays numerous question marks.

To correctly display the comparison values, the projects to be compared must both be converted to SCOUT version 4.2 and preferably also compiled using this version. If necessary, also open the comparison project and re-compile it.

Objects are recreated during the import.

The project that has been exported and then imported again is subsequently no longer the same as the original project because the objects are recreated during the import. For example, the FastIO displays differences in the comparison.

Online-offline comparison refers to the device

The online-offline comparison always only refers to one device Therefore, cross-device TO interconnections are always displayed as non-existent online.

Converting DCC libraries

As of Version 4.3 it is possible to easily convert DCC libraries from SIMOTION libraries to SINAMICS libraries and vice versa. Complex conversion mechanisms are used in both directions. Therefore, a library that is copied back to the original location in this way is not identical to the original library.

5.4 Updating SIMOTION Devices

Preface

Content

This document is part of the **SIMOTION Service and Diagnostics** documentation package.

Scope of validity

This document is valid for SIMOTION SCOUT product version V5.4:

- SIMOTION SCOUT V5.4 (engineering system of the SIMOTION product family)
- SIMOTION Kernel V5.4, V5.3, V5.2, V5.1, V4.5, V4.4, V4.3, V4.2, V4.1 SP2
- SIMOTION technology packages CAM, PATH, Cam_ext and TControl in the relevant version for the kernel.

Sections in this documentation

This documentation describes a simple way of exchanging the configuration or firmware of one or more SIMOTION devices. This process is referred to as upgrading.

- Overview
  General overview of upgrade data and media, of upgrade scenarios, and of the people involved.
- Upgrading
  Description of the individual upgrading steps.
- Downgrading
  Information about downgrading

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT

- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

5.4.1 Fundamental safety instructions

5.4.1.1 General safety instructions

⚠ WARNING

Electric shock and danger to life due to other energy sources

Touching live components can result in death or severe injury.

- Only work on electrical devices when you are qualified for this job.
- Always observe the country-specific safety rules.

Generally, the following six steps apply when establishing safety:

1. Prepare for disconnection. Notify all those who will be affected by the procedure.
2. Isolate the drive system from the power supply and take measures to prevent it being switched back on again.
3. Wait until the discharge time specified on the warning labels has elapsed.
4. Check that there is no voltage between any of the power connections, and between any of the power connections and the protective conductor connection.
5. Check whether the existing auxiliary supply circuits are de-energized.
6. Ensure that the motors cannot move.
7. Identify all other dangerous energy sources, e.g. compressed air, hydraulic systems, or water. Switch the energy sources to a safe state.
8. Check that the correct drive system is completely locked.

After you have completed the work, restore the operational readiness in the inverse sequence.

⚠ WARNING

Electric shock if there is no ground connection

For missing or incorrectly implemented protective conductor connection for devices with protection class I, high voltages can be present at open, exposed parts, which when touched, can result in death or severe injury.

- Ground the device in compliance with the applicable regulations.

⚠ WARNING

Electric shock due to connection to an unsuitable power supply

When equipment is connected to an unsuitable power supply, exposed components may carry a hazardous voltage. Contact with hazardous voltage can result in severe injury or death.

- Only use power supplies that provide SELV (Safety Extra Low Voltage) or PELV- (Protective Extra Low Voltage) output voltages for all connections and terminals of the electronics modules.

⚠ WARNING

Electric shock due to equipment damage

Improper handling may cause damage to equipment. For damaged devices, hazardous voltages can be present at the enclosure or at exposed components; if touched, this can result in death or severe injury.

- Ensure compliance with the limit values specified in the technical data during transport, storage and operation.
- Do not use any damaged devices.

⚠ WARNING

Electric shock due to unconnected cable shield

Hazardous touch voltages can occur through capacitive cross-coupling due to unconnected cable shields.

- As a minimum, connect cable shields and the conductors of power cables that are not used (e.g. brake cores) at one end at the grounded housing potential.

⚠ WARNING

Spread of fire from built-in devices

In the event of fire outbreak, the enclosures of built-in devices cannot prevent the escape of fire and smoke. This can result in serious personal injury or property damage.

- Install built-in units in a suitable metal cabinet in such a way that personnel are protected against fire and smoke, or take other appropriate measures to protect personnel.
- Ensure that smoke can only escape via controlled and monitored paths.

⚠ WARNING

Unexpected movement of machines caused by radio devices or mobile phones

The use of radio devices or mobile telephones in the immediate vicinity of the components can result in equipment malfunction. Malfunctions may impair the functional safety of machines and can therefore put people in danger or lead to property damage.

- If you come closer than around 2 m to such components, switch off any radios or mobile phones.
- Use the "SIEMENS Industry Online Support app" only on equipment that has already been switched off.

⚠ WARNING

Fire due to inadequate ventilation clearances

Inadequate ventilation clearances can cause overheating of components with subsequent fire and smoke. This can cause severe injury or even death. This can also result in increased downtime and reduced service lives for devices/systems.

- Ensure compliance with the specified minimum clearance as ventilation clearance for the respective component.

NOTICE

Overheating due to inadmissible mounting position

The device may overheat and therefore be damaged if mounted in an inadmissible position.

- Only operate the device in admissible mounting positions.

⚠ WARNING

Unrecognized dangers due to missing or illegible warning labels

Dangers might not be recognized if warning labels are missing or illegible. Unrecognized dangers may cause accidents resulting in serious injury or death.

- Check that the warning labels are complete based on the documentation.
- Attach any missing warning labels to the components, where necessary in the national language.
- Replace illegible warning labels.

⚠ WARNING

Unexpected movement of machines caused by inactive safety functions

Inactive or non-adapted safety functions can trigger unexpected machine movements that may result in serious injury or death.

- Observe the information in the appropriate product documentation before commissioning.
- Carry out a safety inspection for functions relevant to safety on the entire system, including all safety-related components.
- Ensure that the safety functions used in your drives and automation tasks are adjusted and activated through appropriate parameterizing.
- Perform a function test.
- Only put your plant into live operation once you have guaranteed that the functions relevant to safety are running correctly.

Note

Important safety notices for Safety Integrated functions

If you want to use Safety Integrated functions, you must observe the safety notices in the Safety Integrated manuals.

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

5.4.1.2 Safety instructions for electromagnetic fields (EMF)

⚠ WARNING

Danger to life from electromagnetic fields

Electromagnetic fields (EMF) are generated by the operation of electrical power equipment such as transformers, converters or motors.

People with pacemakers or implants are at a special risk in the immediate vicinity of these devices/systems.

- Ensure that the persons involved are the necessary distance away (minimum 2 m).

5.4.1.3 Handling electrostatic sensitive devices (ESD)

Electrostatic sensitive devices (ESD) are individual components, integrated circuits, modules or devices that may be damaged by either electric fields or electrostatic discharge.

NOTICE

Damage through electric fields or electrostatic discharge

Electric fields or electrostatic discharge can cause malfunctions through damaged individual components, integrated circuits, modules or devices.

- Only pack, store, transport and send electronic components, modules or devices in their original packaging or in other suitable materials, e.g conductive foam rubber of aluminum foil.
- Only touch components, modules and devices when you are grounded by one of the following methods:
  - Wearing an ESD wrist strap
  - Wearing ESD shoes or ESD grounding straps in ESD areas with conductive flooring
- Only place electronic components, modules or devices on conductive surfaces (table with ESD surface, conductive ESD foam, ESD packaging, ESD transport container).

5.4.1.4 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

5.4.1.5 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

5.4.1.6 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

5.4.1.7 Residual risks of power drive systems

When performing the risk assessment for a machine or plant in accordance with the respective local regulations (e.g. EC Machinery Directive), the machine manufacturer or plant constructor must take into account the following residual risks associated with the control and drive components of a drive system:

1. Unintentional movements of driven machine or system components during commissioning, operation, maintenance and repairs caused by, for example:
   - Hardware and/or software errors in the sensors, control system, actuators, and cables and connections
   - Response times of the control system and of the drive
   - Operation and/or environmental conditions outside the specification
   - Condensation/conductive contamination
   - Parameterization, programming, cabling, and installation errors
   - Use of wireless devices / mobile phones in the immediate vicinity of electronic components
   - External influences/damage
   - X-rays, ionizing radiation and cosmic radiation
2. Unusually high temperatures, including open flames, as well as emissions of light, noise, particles, gases, etc., can occur inside and outside the components under fault conditions caused by, for example:
   - Component failure
   - Software errors
   - Operation and/or environmental conditions outside the specification
   - External influences/damage
3. Hazardous shock voltages caused by, for example:
   - Component failure
   - Influence during electrostatic charging
   - Induction of voltages in moving motors
   - Operation and/or environmental conditions outside the specification
   - Condensation/conductive contamination
   - External influences/damage
4. Electrical, magnetic and electromagnetic fields generated in operation that can pose a risk to people with a pacemaker, implants or metal replacement joints, etc., if they are too close
5. Release of environmental pollutants or emissions as a result of improper operation of the system and/or failure to dispose of components safely and correctly

For more information about the residual risks of the drive system components, see the relevant sections in the technical user documentation.

5.4.2 Overview

SIMOTION offers a convenient solution for upgrading SIMOTION devices or SIMOTION projects for machine manufacturers and machine operators.

Upgrading does not simply refer to an update to a higher version of firmware; rather, in general terms it refers to switching to a defined configuration, e.g. a project update. It is also possible to return (downgrade) to a previous configuration.

Upgrade or downgrade procedures can easily be performed on SIMOTION devices locally or remotely. The data can be imported to a SIMOTION device via a portable, easy-to-use storage medium or a communication connection.

Options and advantages

An extensive range of options is available for upgrading SIMOTION devices. These include, for example:

- The user-friendly creation of upgrade data is via SIMOTION SCOUT / SIMOTION SCOUT TIA with the aid of the Device Update Tool (at the machine manufacturer's site).
- Time- and location-independent upgrade of the SIMOTION devices (without SIMOTION SCOUT for the machine operator).
- The upgrade data can be sent from the machine manufacturer to the machine operator via e-mail or post.
- There is no need to use license keys, as licenses are either retained or upgraded at the same time.
- Retain data is retained.
- An update which has been imported can be discarded again, and the previous configuration downgraded.
- You can upgrade either a single SIMOTION device or multiple devices of one or more SIMOTION projects.
- You can limit the upgrade to configuration subsets, e.g. only project data.

Single or multiple upgrades

Various upgrade scenarios are possible: When performing a single upgrade, only one SIMOTION device is upgraded, whereas one or more SIMOTION devices from one or more projects can be upgraded when performing a multiple upgrade.

Upgrade data

Upgrade data is the data created via SIMOTION SCOUT based on one or more SIMOTION projects. The upgrade data contains all the information required for upgrading or downgrading the data on a SIMOTION device. This includes:

- SIMOTION project
- Technology packages

- User data (unit data, SIMOTION IT data)
- Firmware

Handling upgrade data

The upgrade data is created by the machine manufacturer's application developer via SIMOTION SCOUT. The upgrade data can then be handled flexibly depending on the SIMOTION device (SIMOTION C, D, or P) and the customer requirements:

- Creating upgrade data and then copying it to a storage or upgrade medium:
  - CF / MMC card
  - USB memory stick
  - SIMOTION IT file or
  - Creating an upgrade archive
- Alternatively, the upgrade data can be created and stored in an archive on the computer, so that it can be imported to an upgrade medium that is compatible with the SIMOTION device later.
- The data can be transferred to an upgrade medium at either the machine manufacturer's site or the machine operator's site. For this purpose, the machine manufacturer transfers the upgrade archive to the user's at the machine operator's site.
- The user is prompted to import the upgrade data into the SIMOTION device(s), without any involvement by the application developer, thereby upgrading the SIMOTION device(s). SIMOTION SCOUT does not need to be available on site.

5.4.2.1 Data flow and handling update data

The machine manufacturer's application developer creates the update data using the SIMOTION SCOUT engineering system. He or she writes the SIMOTION applications and puts them into operation.

The user at the machine operator's site carries out service work on the machine. The user receives the update data from the application developer and transfers them to the machine. There is no need for SIMOTION SCOUT to be available on-site in order to transfer the update data to the SIMOTION device or to update a SIMOTION project.

The user at the machine operator's site can import the previously created update data, which are located on an update medium, to the SIMOTION device.

The figure below provides an overview of how the update data are handled. Update media include CF/MMC card, USB memory stick and SIMOTION IT file.

Alternatively, the user has the option of creating and storing update data in an update archive, and then creating the update medium at a later point. This can be carried out by either the application developer at the machine manufacturer's site or by the user at the machine operator's site.

The update data can be imported to an update medium immediately after they have been created by the application developer. The update media CF / MMC card or USB memory stick can be sent by post, or electronically by SIMOTION IT file and update archive to the machine operator.

The update data are generally transferred to the SIMOTION devices by the user at the machine operator's site.

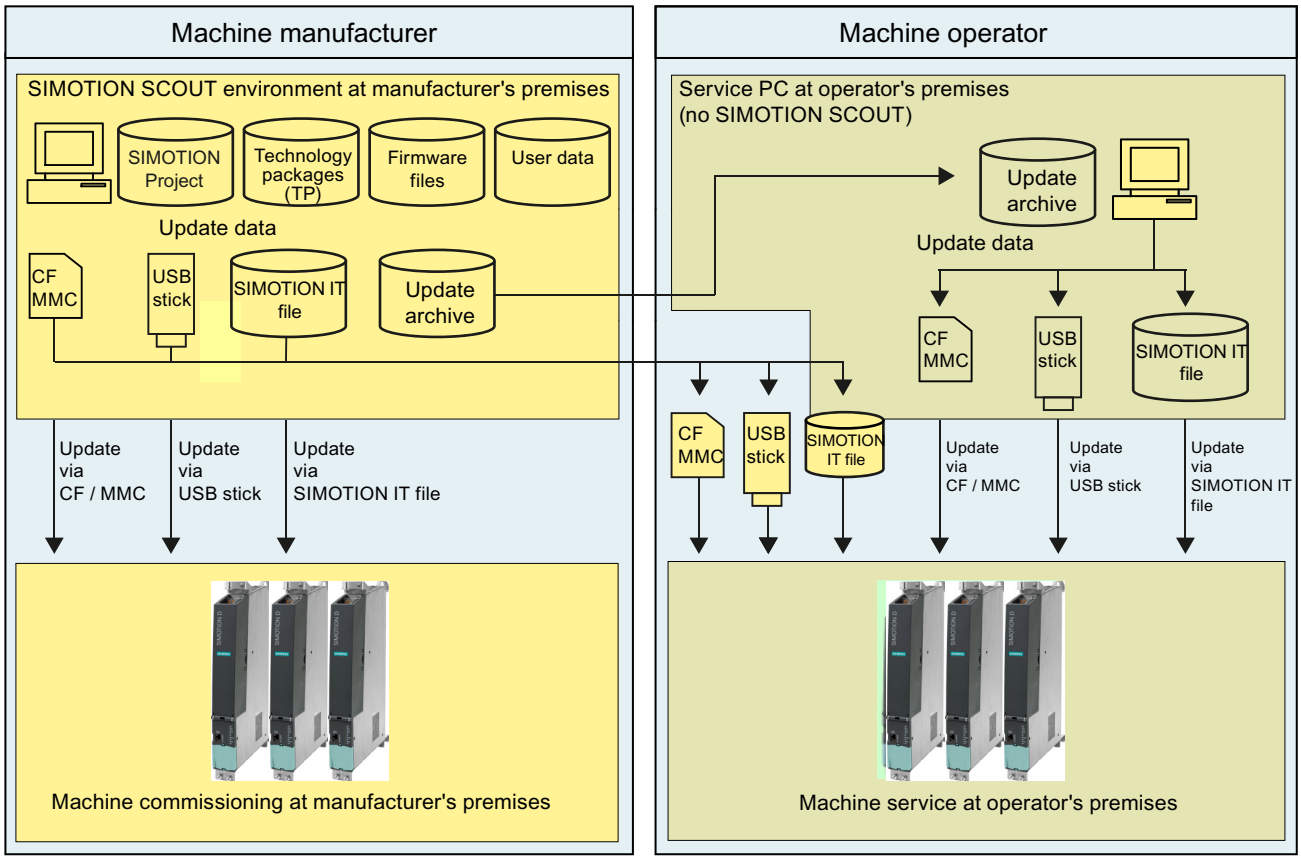

Figure 5-83 Data flow and handling of the update data at the machine manufacturer's and machine operator's sites

5.4.2.2 Update data, update archive, and update media

Update data is required to update a SIMOTION device or SIMOTION project. The newly created update data can be stored in an update archive or saved onto an update medium immediately.

The advantage of the update archive or the update media is that the update data created at the machine manufacturer's site can be used by the machine operator anywhere and at any time. SIMOTION SCOUT is not required in order to transfer the update data on-site.

Update data

The configuration is determined on the basis of the composition of the update data.

Update data is all the data required for an update procedure. The update data is created using SIMOTION SCOUT.

The update data contains the following data:

- Firmware (FW):
  The firmware comprises all the firmware components that are required to operate the respective SIMOTION device (e.g. drive FW, CBE FW, TM FW, BIOS, etc.)
- Project data:
  The project data contains all the data required to operate the respective SIMOTION device. SIMOTION D also contains the drive configuration for the SINAMICS Integrated and the CX32/ CX32-2.
- Technology packages (TP)
- User data (e.g. HTML pages, SSL key, SIMOTION project for storing data on memory cards, SIMOTION IT data, JAVA programs and unit data sets)
- SCOUT project archive (for data storage on the memory card)

It is assumed, in principle, that all of the update data components referred to above are to be updated. However, only individual update data components can be updated, e.g. only the technology packages. This is at the discretion of the user and is defined when the update data is created.

Note

For SIMOTION P, there are currently only plans to update the project data, technology packages and user data.
The firmware **cannot** be updated because of its dependence on other Windows components.

Update archive

The update data created using SIMOTION SCOUT is stored in an update archive if it is not imported to an update medium.
The update archive is a directory tree in which all of the update data is saved.

Update media

The term "update media" is used to refer to storage media on which the update data is saved before being imported to the SIMOTION devices to be updated.
Update media used for SIMOTION are USB memory sticks, CF / MMC cards and SIMOTION IT files.

The choice of update media depends on the SIMOTION devices to be updated.

For updating an individual device in the case of SIMOTION C or SIMOTION D, a CF/MMC card can be loaded or a SIMOTION IT file can be generated (also for several devices).

SIMOTION D4x5-2 also supports the option of using a USB memory stick as the update medium. The USB memory stick can be used to update one or more SIMOTION devices.

In the case of SIMOTION P, you can select either a USB memory stick or a SIMOTION IT file as an update medium for either an individual device or for several devices.

To find an overview of which update medium is suitable for which SIMOTION device, please see Device-specific update media (Page 3487).

5.4.2.3 Update data behavior within a SIMOTION device

Each SIMOTION device has a memory card containing the most important data for the device, such as firmware, technology packages, project data, and backed up retain data.

In the case of SIMOTION D this is the CF card (Compact Flash Card), and with SIMOTION C the MMC (Micro Memory Card).

With SIMOTION P, it depends on the hardware version of the SIMOTION P320-4 and is either the CFast card or the SSD (Solid State Disk); both variants function as an operational data carrier and are not intended for use as update media.

If a SIMOTION device is updated, the data on the memory card in the SIMOTION device behaves as follows:

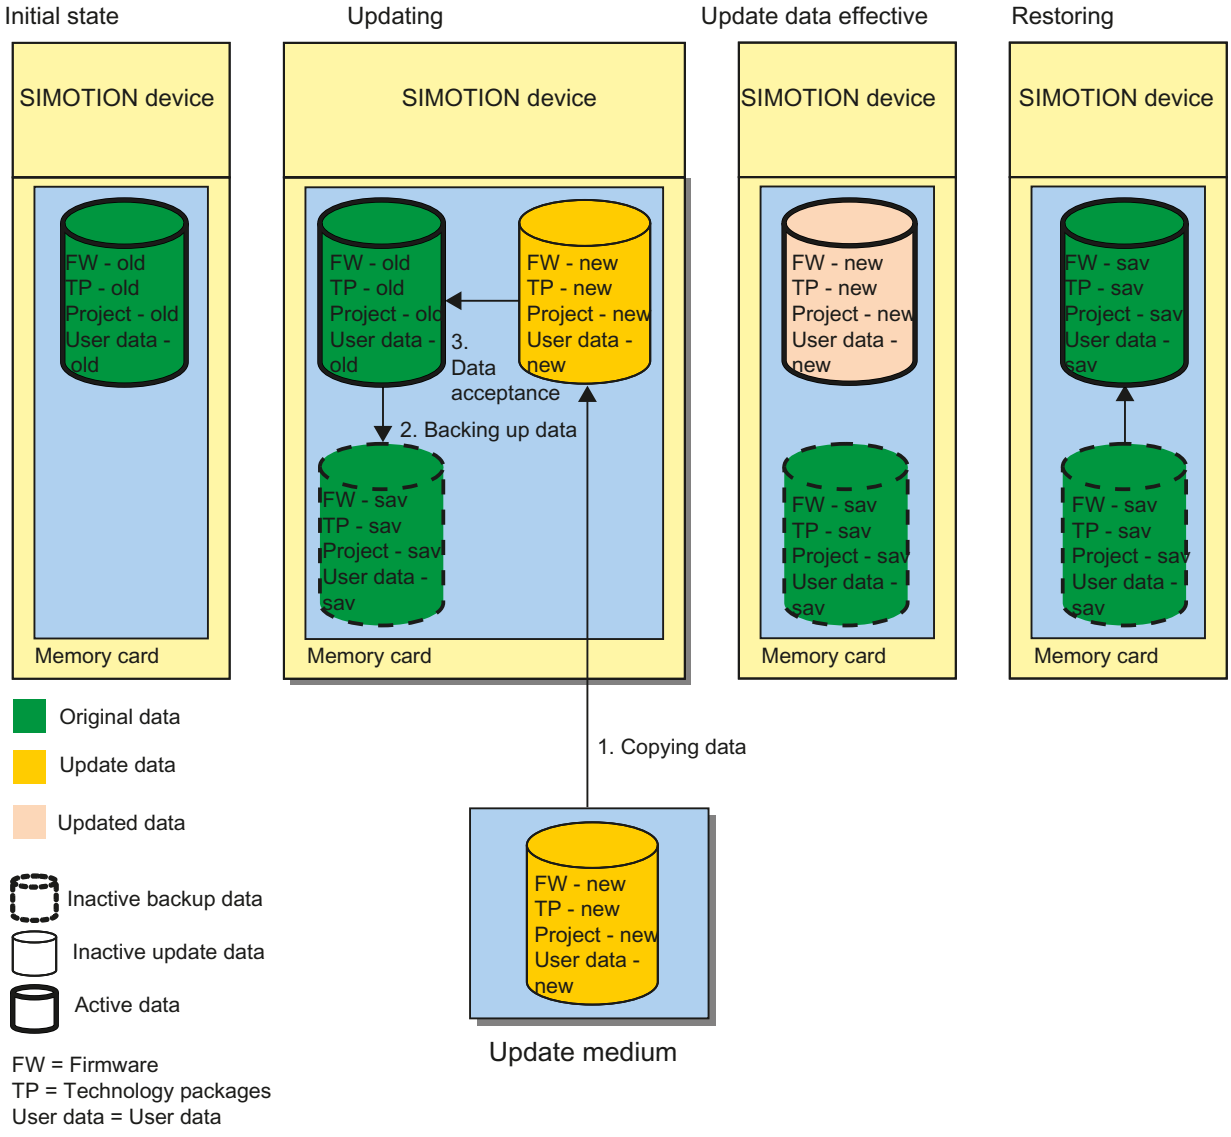

Figure 5-84 Update data behavior within a SIMOTION device

1. The update data is transferred from the update medium to the memory card in the SIMOTION device. (USB memory stick, SIMOTION IT)
   With the CF / MMC card, the equivalent mechanism is a CF / MMC adapter.
2. The existing data is then saved on the memory card.
3. The update data takes effect after restarting the device.
4. The memory card now contains both the update data and, concurrently, the saved data from the previous configuration.
5. In the event of an error, or if the new application does not meet your requirements, you can revert back to the saved data.
   This data is activated when you perform a restore function, overwriting the update data.

Note

Note the following when backing up restore data in the SIMOTION device

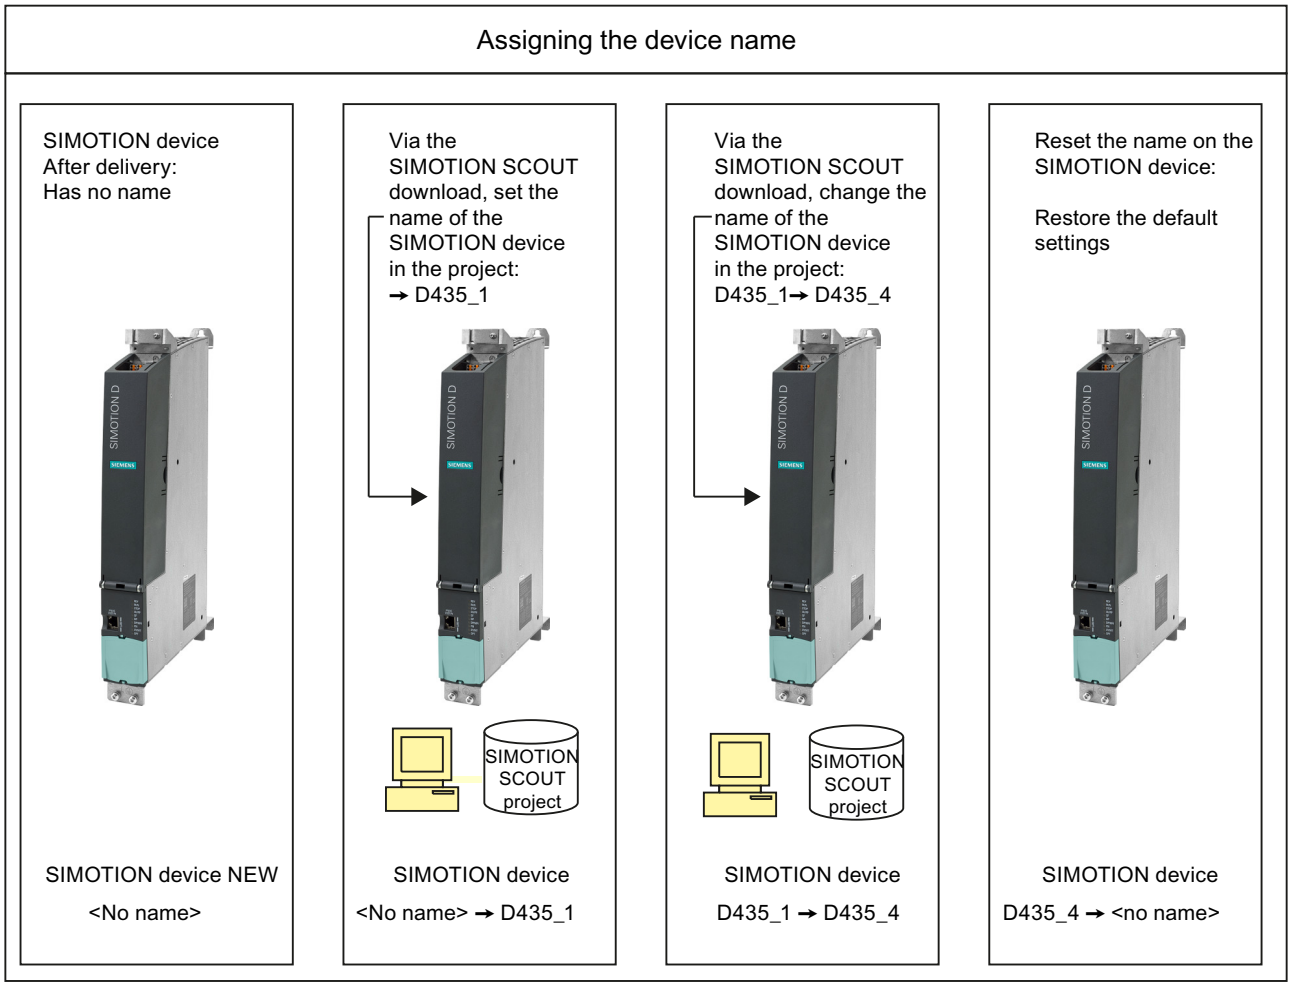
The current configuration data is saved as restore data when updating. The SIMOTION device has only one backup.

If the same update data is imported twice by mistake, the backed up restore data will also be overwritten.

In order to back up data over a longer period of time, the update archive can be backed up separately (onto a DVD, for example).

5.4.2.4 Assigning update data to devices

The device name which was saved in the project is contained in the update data. This name is used for assigning the update data to the relevant device. The name is saved persistently on the device. Since the name is saved persistently within the SIMOTION device, a corresponding device assignment takes place during the update.



5.4.2.5 Single and multiple updates

Upgrade data can be created for a single SIMOTION device or multiple SIMOTION devices relating to one or more SIMOTION projects.

Note

Creating upgrade data in SIMOTION SCOUT TIA

Note that you can create upgrade data in SIMOTION SCOUT TIA only for the currently opened project.

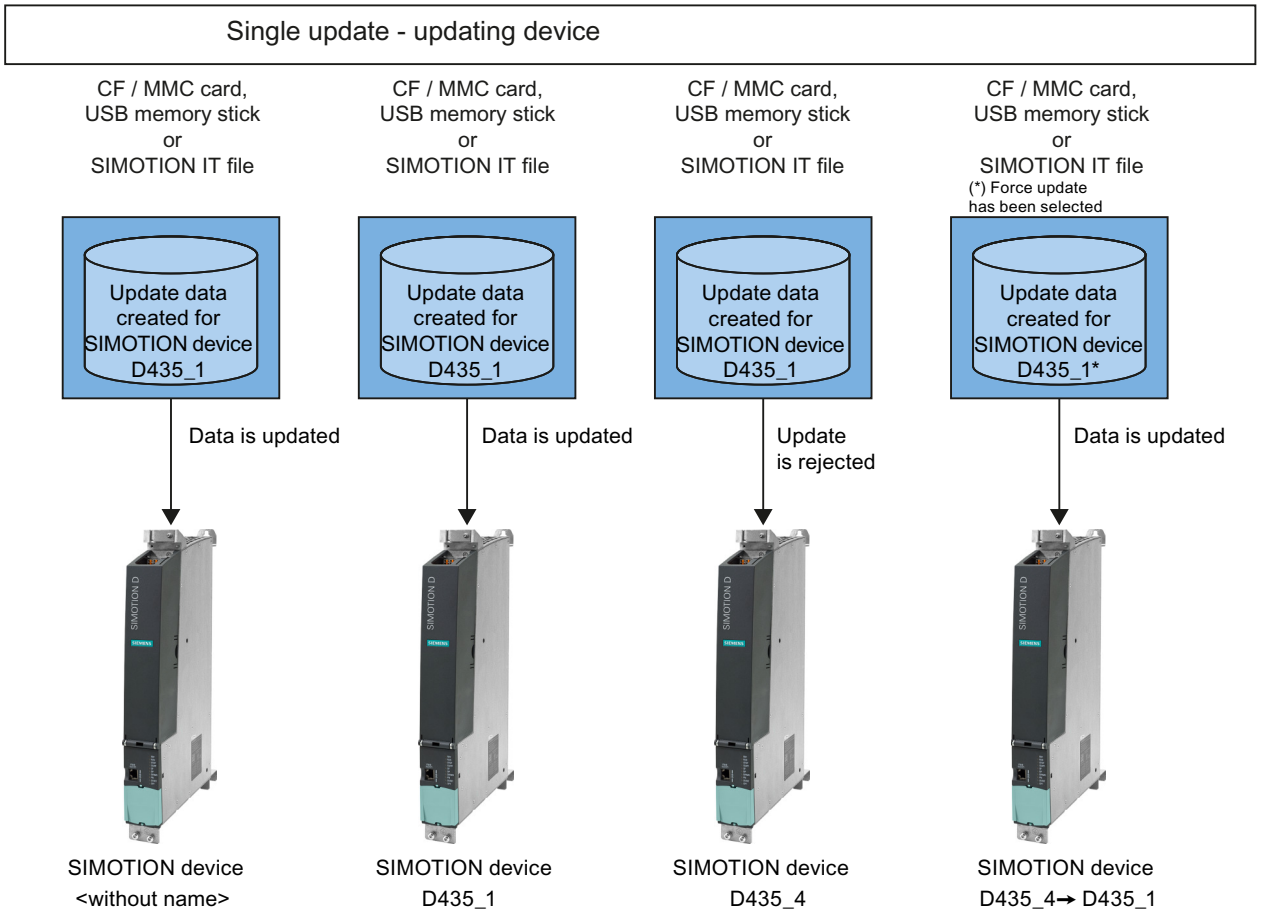
During **multiple upgrades**, i.e. when upgrading at least two SIMOTION devices, it is imperative that device names are assigned. If the device names in the upgrade datado not match the persistently saved names of the devices to be upgraded, the upgrade cannot take place.

An exception to this is the **single upgrade** of a device that has not yet been assigned a persistently saved name. In this case, the device receives its name from the upgrade data.

In a **single upgrade** scenario, it is also possible to force an upgrade if the device names do not match.

Single upgrade

Upgrade data for a single SIMOTION device is created during a single upgrade. This scenario is recommended in the case of large projects, for example, in which only one SIMOTION device from a project is to be upgraded.



The following scenarios are depicted in the figure:

- The SIMOTION device to be upgraded does not have a name.
  The upgrade is performed and the SIMOTION device to be upgraded is assigned the SIMOTION device name D435_1 from the upgrade data.
- The SIMOTION device to be upgraded and the SIMOTION device from which the upgrade data has been created have the same name. The data is upgraded without any prompt.

- The SIMOTION device to be upgraded and the SIMOTION device from which the upgrade data originates do not have the same name.
  It is assumed that they are two different SIMOTION devices, and that the data is not upgraded.
- If there is an explicit request for the data from SIMOTION device D435_1 to be applied by SIMOTION device D435_4, the **Force update** option, i.e. force upgrade can be selected. This means that the SIMOTION device is assigned the complete set of new data, including the device name.
  The **Force upgrade** option is available only when upgrading a single SIMOTION device.
  Further information can be found at Assigning upgrade data to devices (Page 3484)

Multiple upgrade

When multiple upgrades are concerned, the upgrade data is created for at least two or all SIMOTION devices of one or more SIMOTION projects.

Note

Multiple upgrade for SIMOTION SCOUT TIA

Note that you can create upgrade data in SIMOTION SCOUT TIA for just one SIMOTION project.

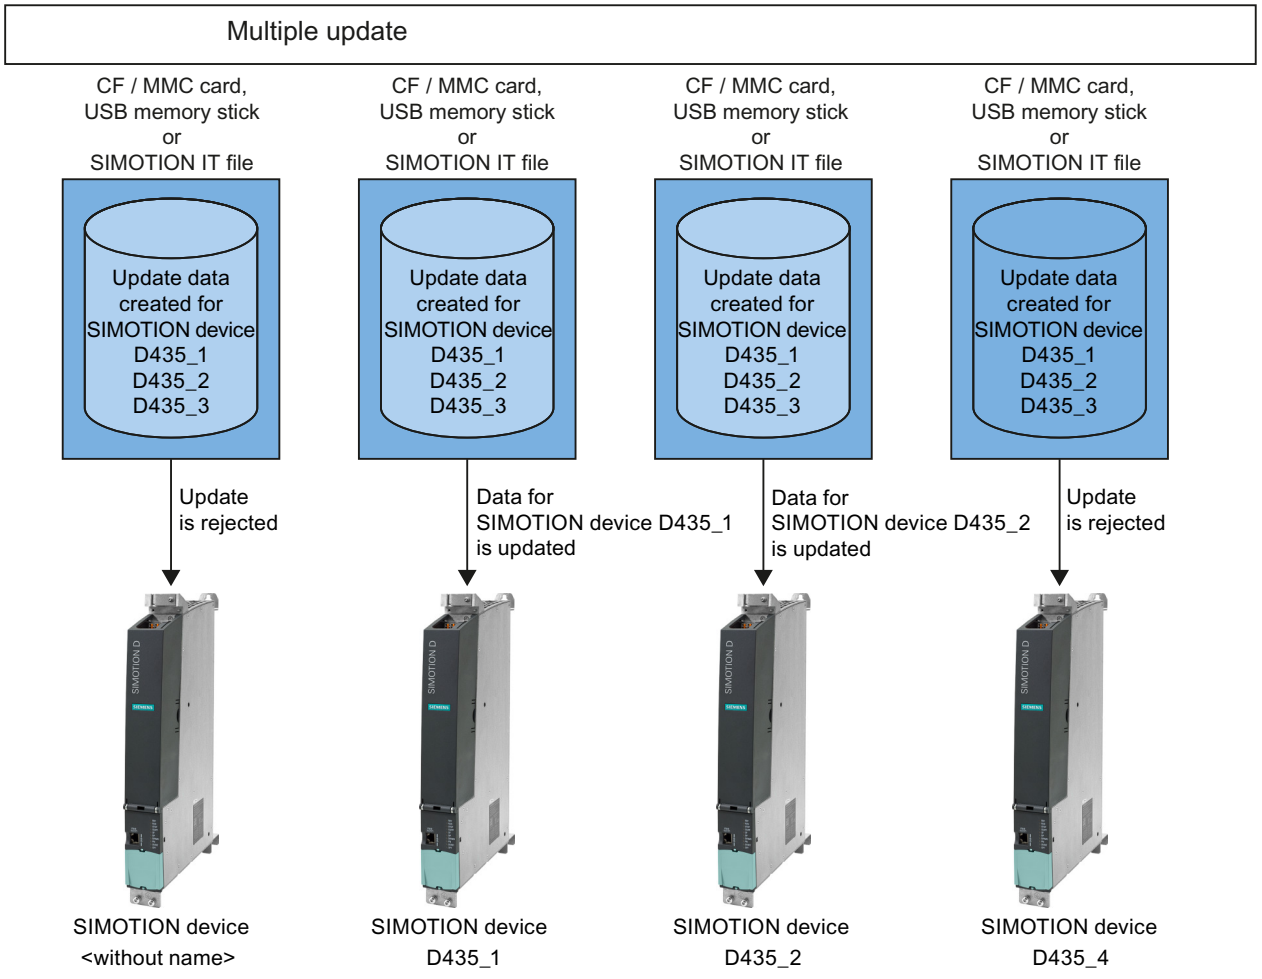
Either components of the upgrade data of a project or the entire project can be upgraded. This is at the discretion of the user.

However, it is imperative that the devices from the upgrade data and the devices to be upgraded have the same names. Upgrade data from two different SIMOTION devices with the same name (e.g. from different projects) may not be created at the same time because the data cannot be assigned.

Further information can be found at Assigning upgrade data to devices (Page 3484)

The graphic below shows the pool of upgrade data that has been created for the SIMOTION D435_1, D435_2, and D435_3 devices, and which is still located on an upgrade medium.

When multiple upgrades are concerned, the device names from the upgrade data must match the persistently saved device names from the SIMOTION devices to be upgraded to guarantee that the upgrade data is assigned correctly. If this is not the case, the upgrade **cannot** be performed.



5.4.2.6 Device-specific update media

The table below provides an overview of which update media can be used for which SIMOTION devices, and in which update scenarios:

Table 5-47 Overview of the update scenarios in combination with SIMOTION devices and update media

SIMOTION device	USB memory stick	SIMOTION IT	CF / MMC card
D4x5-2	Single/multiple update	Single/multiple update	Single update
D410-2	-	Single/multiple update	Single update
P320-4 E / P320-4 S	Single/multiple update	Single/multiple update	-

Note

Requirement for updating or restoring:

- SIMOTION SCOUT V4.1 SP2 or higher
- Firmware on the SIMOTION device to be updated, V4.1 SP2 or higher
- Firmware contained in the update data V4.1 SP2 or higher if firmware is selected.

Note

Upgrading using a USB memory stick

The SIMOTION device is started from the USB memory stick when updating devices via a USB memory stick. For this reason, a bootable USB memory stick must be used.

We recommend SIMATIC memory sticks. Due to the rapid developments within the market for USB memory sticks, it is not possible to make any additional recommendations.

Information on this is available on the Internet at:

https://support.industry.siemens.com/cs/ww/de/view/32580863 (https://support.industry.siemens.com/cs/ww/en/view/32580863)

Note

Because of the size of the memory card, the update or restore function is not possible for the SIMOTION C230-2.

With the SIMOTION C240, a 64 MB MMC must be used for the update or restore function because a 32 MB MMC (supplied with V4.0 HF2) does not have sufficient memory space.

For SIMOTION C240 / C240 PN >= V5.2, the function is not possible because of the available memory space on the MMC.

Information on this is available on the Internet at:

http://support.automation.siemens.com/WW/view/en/42349674

5.4.2.7 Transferring device-specific user data to the update data

Directory structure of the user data

The user data must be stored in a defined directory structure, as shown in the figure below.

The directory structure is created using a new folder in Windows Explorer. The structure must be accessible via Windows Explorer. The data can be saved on the hard disk, a USB memory stick, or in a network folder, for example.

The ID of the user-specific folder is defined by the user.

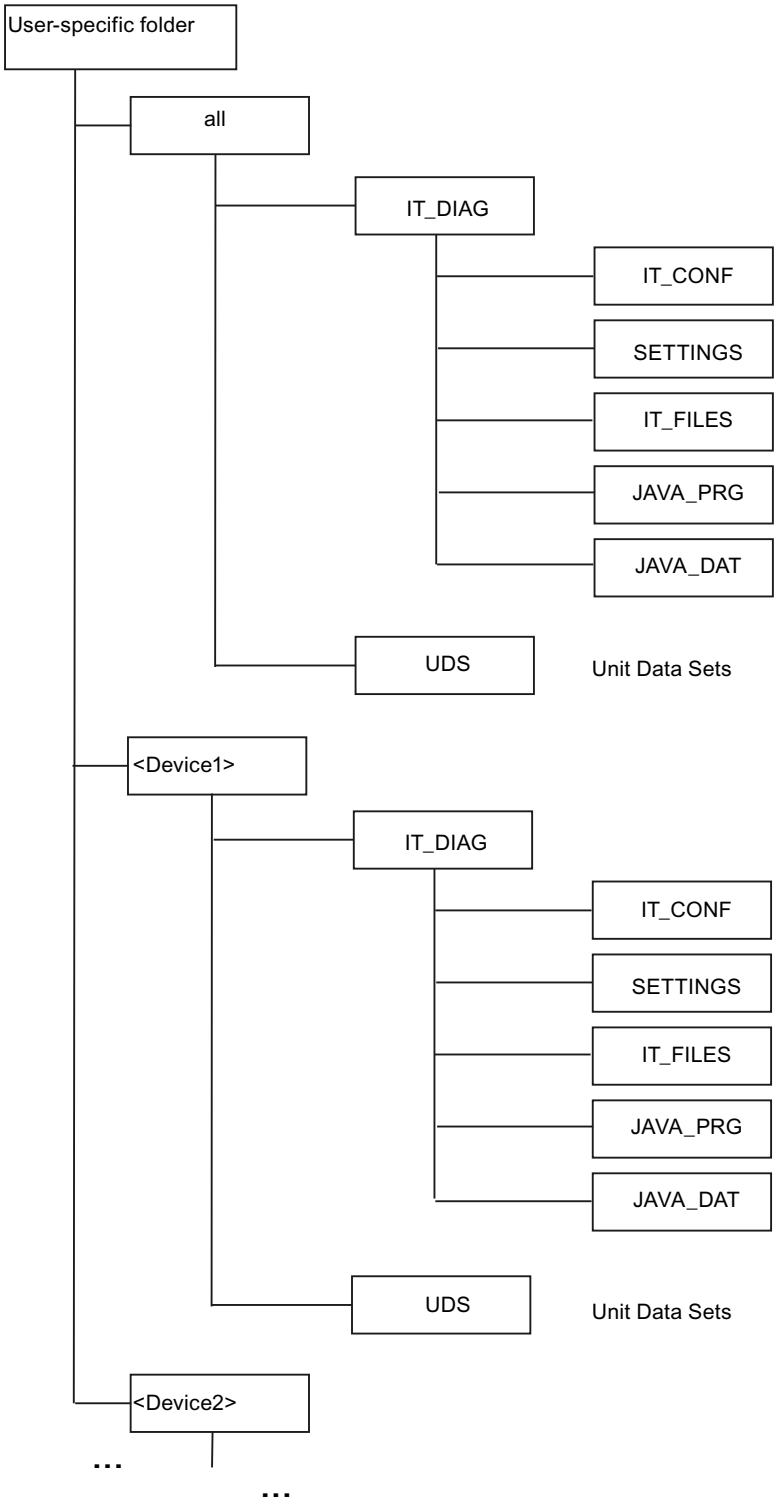


Figure 5-85 Directory structure for saving user data

The entire directory **UPP** \ **UNITDS** with the unit data sets it contains must be stored in the UDS folder.

The path to a user-specific file must be specified when importing user data via the Device Update Tool.
See also: Creating upgrade data with the Device Update Tool (Page 3492), dialog **Select additional options**.

The user data for all the devices from the projects are located in the user-specific folder. Data saved in the subdirectory **all** is imported to all the devices to be upgraded.

Data saved in device-specific folders, e.g. <**Device1**>, is only imported to the SIMOTION device whose name matches the folder name.

In the event of a conflict, if data is available for a device from both the **all** subdirectory and a device-specific folder (e.g. <**Device1**>), the user data from the device-specific folder is used.

Definition of user data

The following data is **not** part of the SIMOTION project within the context of upgrading and must, therefore, be provided by the user:

For example, at the following path:
E: \ update \ userdata \ all \ IT_DIAG

The following structure **must** be created in the IT_DIAG folder:

• **IT_DIAG**		
	IT_CONF Data for configuring the Web server (SIMOTION IT) and user rights	
		UserDataBase \ UserDataBase.XML User administration (file UserDataBase.XML in folder UserDataBase)
		WebCfg.XML Configuration data The data can be found on the CF card at: \USER\SIMOTION \HMICFG\ For further information, see: SIMOTION IT Diagnostics and Configuration Diagnostics Manual
	SETTINGS Settings for watch tables and traces from SIMOTION IT	
	IT_FILES User websites	
	JAVA_PRG Java programs (*.class, *.jar)	
	JAVA_DAT Files which are used from Java	

- **Unit data sets (UDS)**
  In the unit data sets, values from unit variables (e.g. machine data from commissioning) can be saved during runtime in data sets on the memory card using _save / _exportUnitDataSet. These are uniquely identified by the unit name and data set number (refer also to the Basic Functions Function Manual, section "Backing up data from the user program").
  In order to be able to use the data sets in the user data when upgrading, they must first be transferred via a Card-Reader or, for example, FTP, from the memory card to the PC.
  The data sets are available at **\ USER \ SIMOTION \ USER_DIR \ UPP \ UNITDS ** after they have been saved to the card.
  Alternatively, the SIMOTION SCOUT function **Save variables** can be used.

Assigning user data to the SIMOTION device

Only the user knows that user data has been assigned to the SIMOTION device to be upgraded. The following points must be clarified in order to enable user upgrade data to be transferred:

- Which user data is involved here? (Content)
- Where is the user data located? (Source)
- Where should the data be imported to? (SIMOTION device)

To ensure that all information is available, the user data must be provided in a directory structure that has already been defined.

5.4.3 Updating

5.4.3.1 Overview

Updating procedure

The following section provides an overview of the procedure for updating a SIMOTION device:

- Creating update data (machine manufacturer)
  Update data is created on an operator-guided basis via the Device Update Tool at the machine manufacturer's site, using the SIMOTION SCOUT engineering system. This is conducted by the application developer as part of commissioning or service.
- Copying the update media (machine manufacturer or machine operator)
  Once the update media has been created, it can either be saved directly to an update medium or stored as an update archive.
  If data is to be copied to the update medium at a later date, the update data that has been created is saved in an update archive (File system). This can be called up at any time and imported to an update medium.
  Data are copied to an update medium without SIMOTION SCOUT: This can be performed by either the application developer at the machine manufacturer's site or by the user at the machine operator's site.
- Transferring data from the update medium to the SIMOTION device (machine operator)
  Update data can also be imported from the update medium to the SIMOTION device, irrespective of time and place, using the Device Update tool on an operator-guided basis.

Note

If the parameterization of the SINAMICS Safety Integrated functions is contained in the update data, these functions must be activated after the update. See also *SINAMICS S120 Safety Integrated Function Manual*.

Saving update data to the update media or as an update archive

The special features for saving on the update media USB memory stick, CF / MMC card or SIMOTION IT file are described according to the procedure using the Update Tool device. The creation of the update archive is also examined.

- Creating update data with SIMOTION SCOUT and transferring data to an update medium
  - Creating update data, including copying to a USB memory stick (Page 3509)
  - Creating update data, including copying to a CF / MMC card (Page 3510)
  - Creating update data including generating a SIMOTION IT file (Page 3511)
  - Creating update data as an update archive (Page 3511)
- Copying to the update media on the basis of an update archive
  - Copying data to a USB memory stick (Page 3518)
  - Copying data to a CF / MMC card (Page 3519)
  - Creating a SIMOTION IT file and copying the update data (Page 3519)

Transferring update data from the update medium to SIMOTION devices

- Updating a module with a USB memory stick (Page 3530)
- Updating a module with a CF / MMC card (Page 3533)
- Updating a module with a SIMOTION IT file (Page 3534)

5.4.3.2 Creating upgrade data via SIMOTION SCOUT / SIMOTION SCOUT TIA

The section below describes how upgrade data is created.

The upgrade data is created user-prompted using SIMOTION SCOUT or SIMOTION SCOUT TIA. The individual data items are selected step-by-step using a wizard.

Creating update data with the Device Update tool

Requirement

The following data is required in order to create upgrade data:

- Installed SIMOTION SCOUT as of V4.1 SP2 or
  SIMOTION SCOUT TIA as of V4.5
- SIMOTION project(s)
- One or more SIMOTION devices (firmware as of V4.1 SP2)
- Current SIMOTION FWSP (Firmware Support Package) is installed (applies as of > V4.1 SP2)
- User data

Note

SIMOTION SCOUT TIA

Upgrade data is created only for the currently opened project.

Upgrade data creation procedure

Upgrade data is essentially created via SIMOTION SCOUT/ SIMOTION SCOUT TIA as follows:

- Call the Device Update Tool from the menu
- Choose whether to create upgrade data or downgrade data
- Select a project
- Select a device
- Select data
- Select further options (e.g. user data)
- Enter the version details
- Display the summary
- Copy the upgrade data to an upgrade medium or save it in an archive (to be copied to an upgrade medium at a later date)

How to create upgrade data

Call the Device Update Tool via **SIMOTION SCOUT** or **SIMOTION SCOUT TIA**. You are prompted step-by-step for creating the required upgrade data that is then either saved in an upgrade archive or imported directly to an upgrade medium.

Note

Creating upgrade data in SIMOTION SCOUT

If you call up the Device Update Tool via an open project, the project is automatically selected in the dialog.

If you also wish to save an archived SIMOTION SCOUT project in the upgrade data, you must close the project before creating the upgrade data.

1. Select the **Project > Start Device Update Tool** menu directly in **SIMOTION SCOUT**.

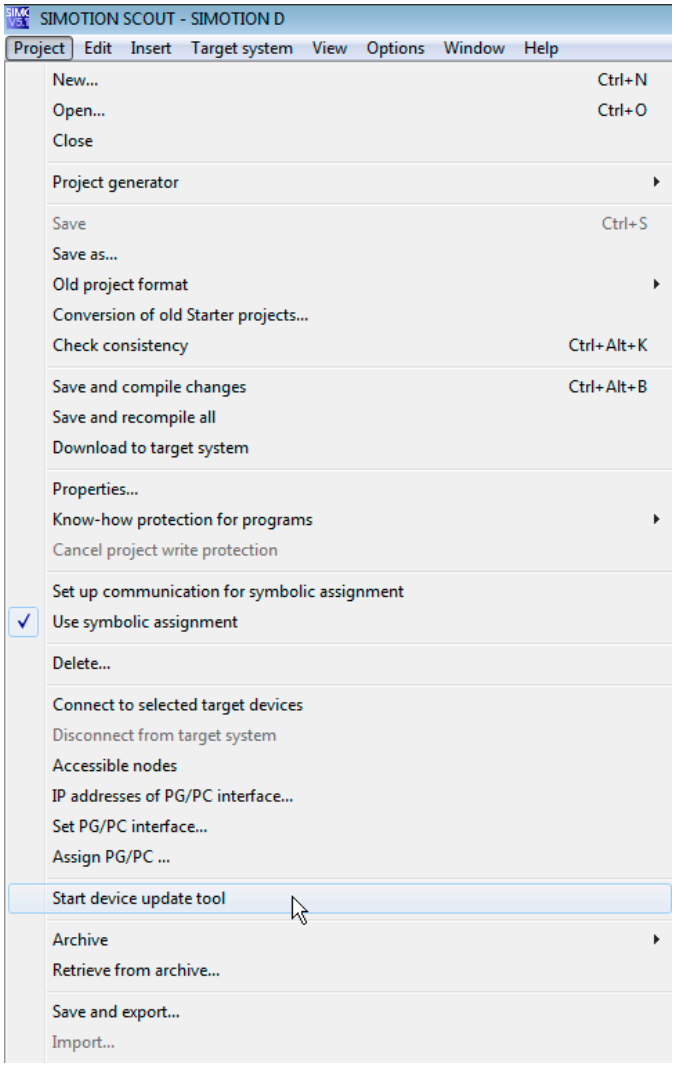

Figure 5-86 SIMOTION SCOUT: Start Device Update Tool

SIMOTION SCOUT TIA is also called via the **Project > Start Device Update Tool** menu.

Note

Creating upgrade data in SIMOTION SCOUT TIA

Note that you can create upgrade data in SIMOTION SCOUT TIA only for the currently opened project.

The processing in SIMOTION SCOUT TIA Step 3 **Select SIMOTION projects** is so omitted from the following description.

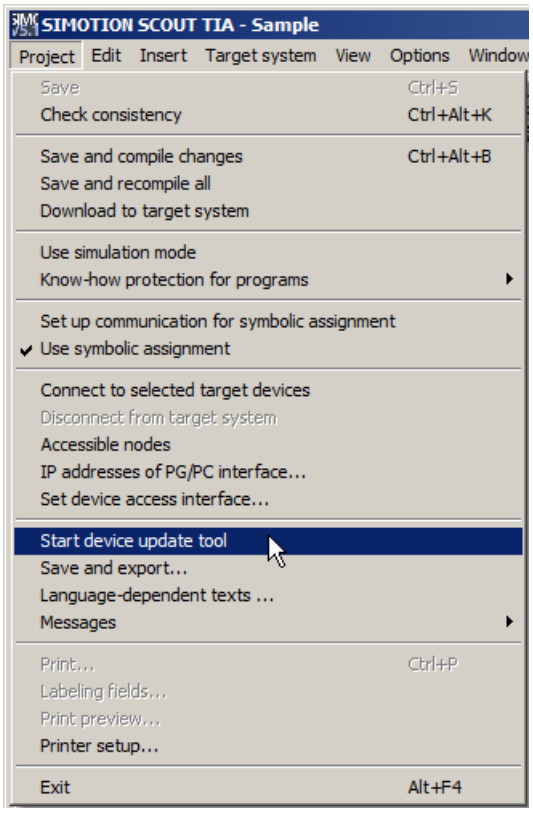

Figure 5-87 Call Device Update Tool via SIMOTION SCOUT TIA

2. The Device Update Tool opens at the start screen **Welcome to the SIMOTION Device Update tool**. (The Device Update Tool is in English.)
   Here, you can decide whether data is to be created for the purpose of upgrading or downgrading a SIMOTION device or a SIMOTION project.

   – Select **Create update data** if you wish to create data for upgrading a device or project. "Upgrading" means changing to a specific, defined configuration from upgrade data components; this may even be an older version than the current SIMOTION device.

   – Select the **Select configuration of data which were formerly stored** option if you are already upgrading a device/devices or a project/projects for a second time and wish to restore the default settings for projects, devices, and data from the last upgrade. This information can be obtained either from an upgrade archive or directly from an upgrade medium.
   Enter the path to the target folder of the upgrade archive or SIMOTION IT file or the drive for the upgrade medium plugged into the PC (USB memory stick, CF / MMC).
   The Device Update Tool will execute step-by-step. The default settings can also be changed if required.
   If you have selected this option, the **Version information** dialog is also displayed and write-protected (refer to point 7).

– Select **Create restore trigger** if you wish to create data for downgrading a device or project.
When downgrading data, activate the configuration saved on the memory card for the SIMOTION device during the last upgrade.
Further information can be found in the section Downgrading (Page 3538).

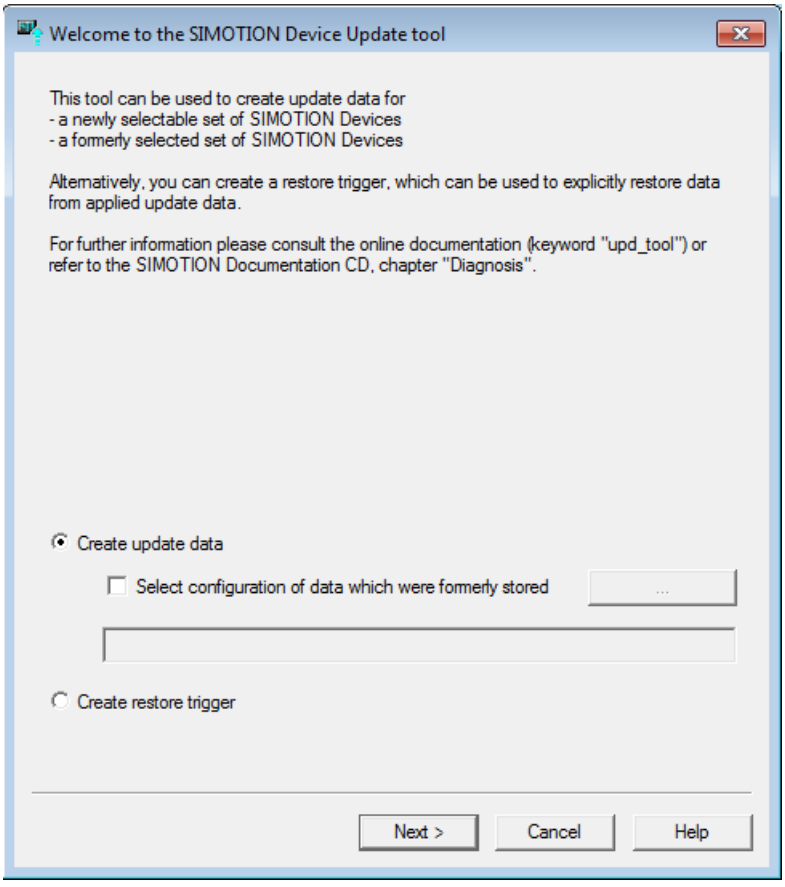

Figure 5-88 Start screen for Device Update Tool

Always click button **Next** to proceed to the next dialog box.

3. The **Select SIMOTION projects** dialog then opens. All the projects that have been saved for SIMOTION SCOUT in the default path or have already been opened on this computer using SIMOTION SCOUT appear here.

Note

Only SIMOTION SCOUT

The **Select SIMOTION projects** dialog applies only to SIMOTION SCOUT.

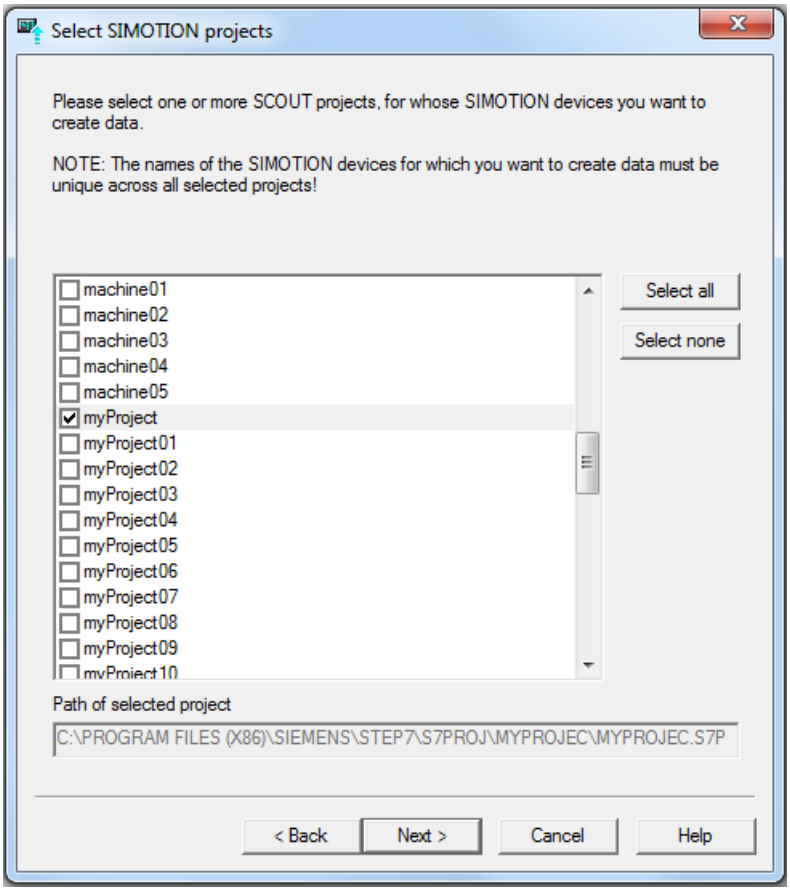

Figure 5-89 Select SIMOTION projects dialog

Please select one or more SIMOTION projects for which you wish to generate upgrade data.
The currently open project is automatically selected.
Via button **Select all** you can select all displayed projects.
Via **Select none** you can undo the project selection.
Under **Path of selected project** the path of the selected project is displayed.

4. In the next dialog (**Select Devices**), all devices assigned to the previously selected projects are displayed.
   Select the device(s) for which you wish to create upgrade data.
   Using the **Select all** button, select all devices shown that were selected in the previous dialog.
   You can deselect the devices by clicking **Select none**.
   The path for the project containing the selected device is displayed at **Project path of selected device**.

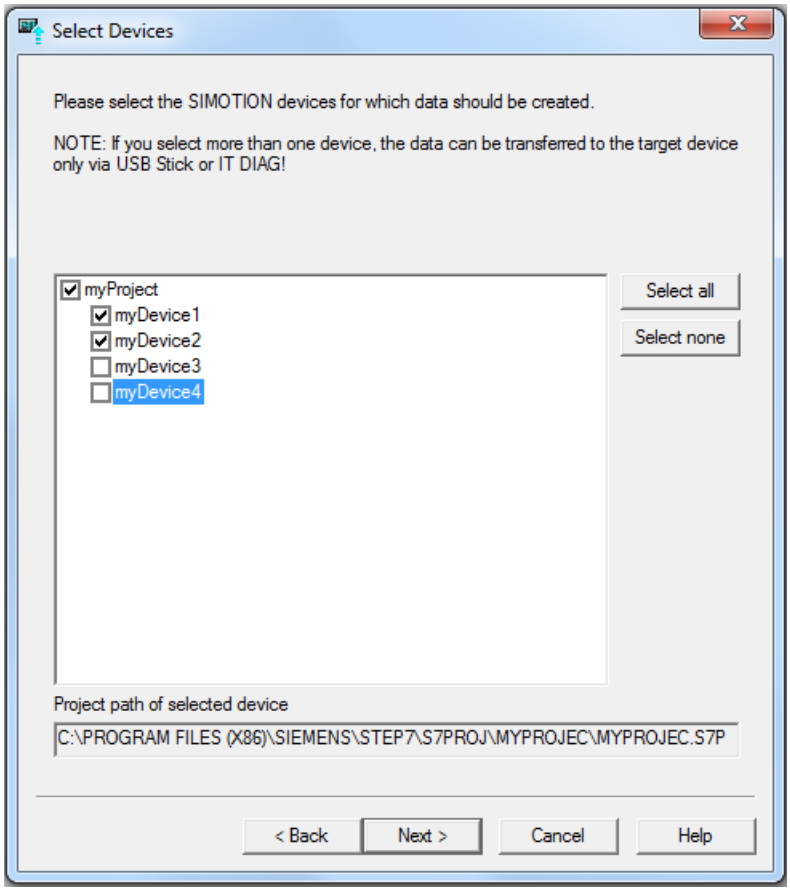

Figure 5-90 Select Devices dialog

Note

The selected devices from the selected projects must possess different device names. If there are two devices with the same name, only one of them can be selected.

See also: Assigning upgrade data to devices (Page 3484)

5. In the **Select data** dialog, select the data to be stored in the upgrade archive for each selected device. The options for choosing the upgrade data to be created can be selected separately for each SIMOTION device.

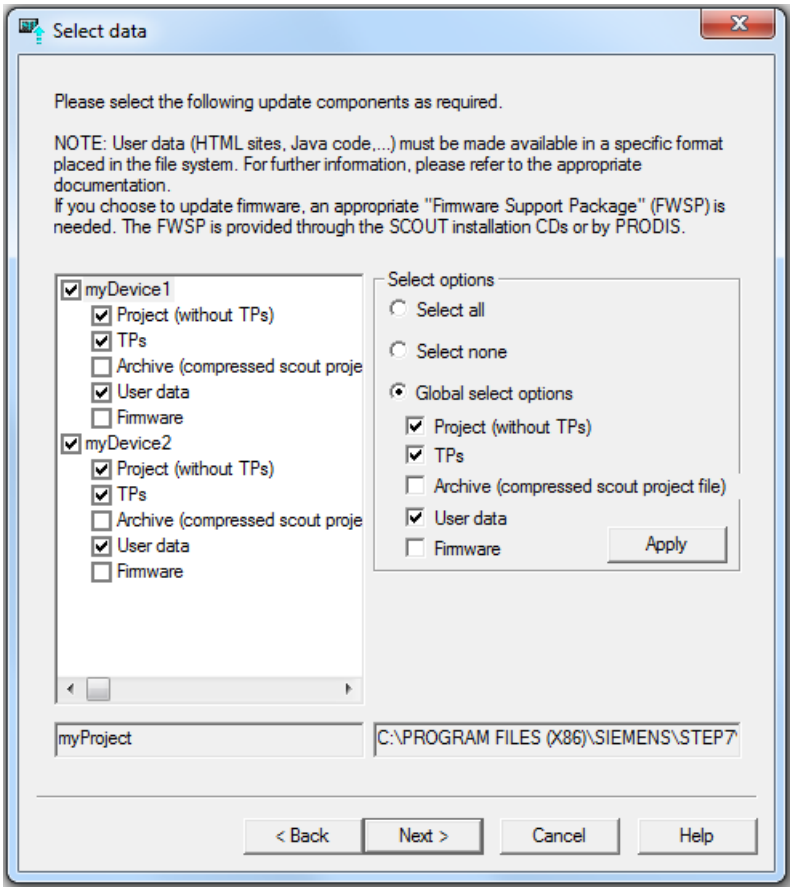

Figure 5-91 Select data dialog

The following options can be selected on the **left-hand side** of the dialog in the device tree:

- **Project (without TPs)**:
  Project data without technology packages
- **TPs** (technology packages)
  The technology packages selected in the **Select Technology Packages** dialog box in SIMOTION SCOUT are added to the upgrade data.

- **Archive (compressed scout project file)**:
  The archive data contains the entire archived SIMOTION SCOUT project belonging to this device (ZIP file).
  If the upgrade data is created via an **open** SIMOTION project, the archive cannot be created.

  Note

  If SCOUT projects already archived on the memory card are to be deleted, this can be performed via a card reader or FTP.

  Note

  Upgrading archive data in SIMOTION SCOUT TIA

  To upgrade archive data in SIMOTION SCOUT TIA, you must archive the project in the TIA Portal beforehand.

- **User data**:
  Your user data
  Further information about user data can be found at:
  Transferring device-specific user data to the update data (Page 3488)
- **Firmware**:
  In order to be able to add the firmware to the upgrade data, it is necessary to install a corresponding SIMOTION FWSP (Firmware Support Package).

  Note

  SIMOTION Firmware Support Package

  The compatible **SIMOTION FWSP** (SIMOTION Firmware Support Package) is automatically supplied as of SIMOTION SCOUT installation V4.1 SP4.

  Subsequent hotfixes (HFs) are also provided as SIMOTION FWSPs via the SIMOTION Product Support pages on the Internet at:

  SIMOTION Firmware Support Package (https://support.industry.siemens.com/cs/ww/en/view/33119786)

  Only one FWSP version can be installed within a main version.
  Check whether the installed FWSP corresponds to the desired firmware version. If this is not the case, install the correct FWSP.

You can define the selection options for all devices using the checkboxes on the **right-hand side of the dialog**:

- Using **Select options** , you can select all data for all devices with the **Select all** option.
- Selecting **Select none** deselects all devices.
- Using **Global select options** , you can select certain options which are assigned to all devices.
  For example, in this case **Project** (project data), **TPs** (technology packages), and **User data** have been selected on a global basis for the selected devices as upgrade data to be created.
- By clicking the **Apply** button, the selection made on the right-hand side of the dialog is assigned to the left-hand side, thereby validating the selection for the devices.

– The settings on the right-hand side of the dialog are not saved for the next time the Device Update Tool is run.

Note

SIMOTION P320-4

Provision is made for upgrading the project data, technology packages and user data for SIMOTION P320-4.
The firmware cannot be upgraded because of its dependence on other Windows components.

6. In the **Select additional options** dialog, you can select additional options and specify whether the user data is to be replaced or extended.

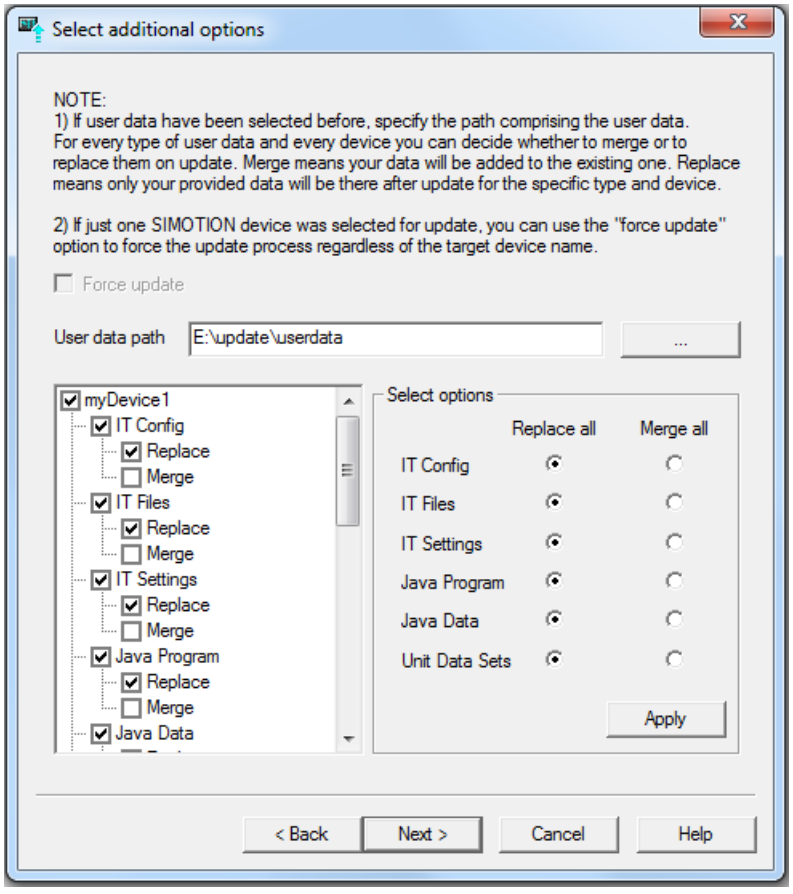

Figure 5-92 Select additional options dialog

– Using the **Force update** option, you can perform an upgrade even if the name of the device from the upgrade data is not identical to the persistently saved device name of the SIMOTION device to be upgraded.
  The device to be upgraded receives the name of the device from the upgrade data if you click **Force update**. This option is only available if precisely one device has been selected (single upgrade).
  The option is deactivated in the example shown because two devices have been selected.
– Enter the path to the user data at **User data path**. This option can only be selected if the User data is selected as the upgrade data to be created in the **Select data** dialog box.

– The data provided from the **User data path** is displayed in the folder structure on the **left-hand side of the dialog box**. The option **Merge** or **Replace** must be selected separately for each SIMOTION device.
The selection of the user data is already defined in the user-specific folder.

Note

Replace / Merge options

The options **Replace** and **Merge** refer to the directory level, i.e. file contents are not changed.

Further information about the behavior for Replace and Merge is at the end of this section.

– On the **right-hand side of the dialog** at **Select options** you can specify whether the user data is to be split and replaced according to **IT Config**, **IT Files, IT Settings, Java Program, Java Data** and **Unit Data Sets** (**Replace all**), or whether the existing data is to be merged with new information (**Merge all**).
For the significance of user data, refer to Acceptance of device-specific user data into upgrade data (Page 3488)
For example, if Unit Data Sets and Replace all are selected, and no data is contained within the relevant user-specific folder, the Unit Data Sets (unit data) on the memory card are deleted.
By clicking the **Apply** button, the selection on the right-hand side of the dialog is assigned to the left-hand side, thereby validating the selection for all devices.
The settings on the **right-hand side of the dialog** are not saved for the next time the Device Update Tool is run.

– The options can also be selected separately for each SIMOTION device on the **left-hand side of the device dialog** in the device tree.

– If the button **Next** is grayed after the option has been selected, this indicates that the selection is not complete (the option selection is checked automatically).
Please check if in the directory at **User data path** no user data has been saved for a device or if the selection on the left-hand side in the device tree or on the right-hand side in the dialog at **Select options** is incomplete.

7. Enter the version information for the upgrade data in the **Add version information** dialog:
   - Author
   - Version
   - Date
   - Comment
     The upgrade information is attached to the upgrade data and can be displayed throughout the entire upgrade procedure.

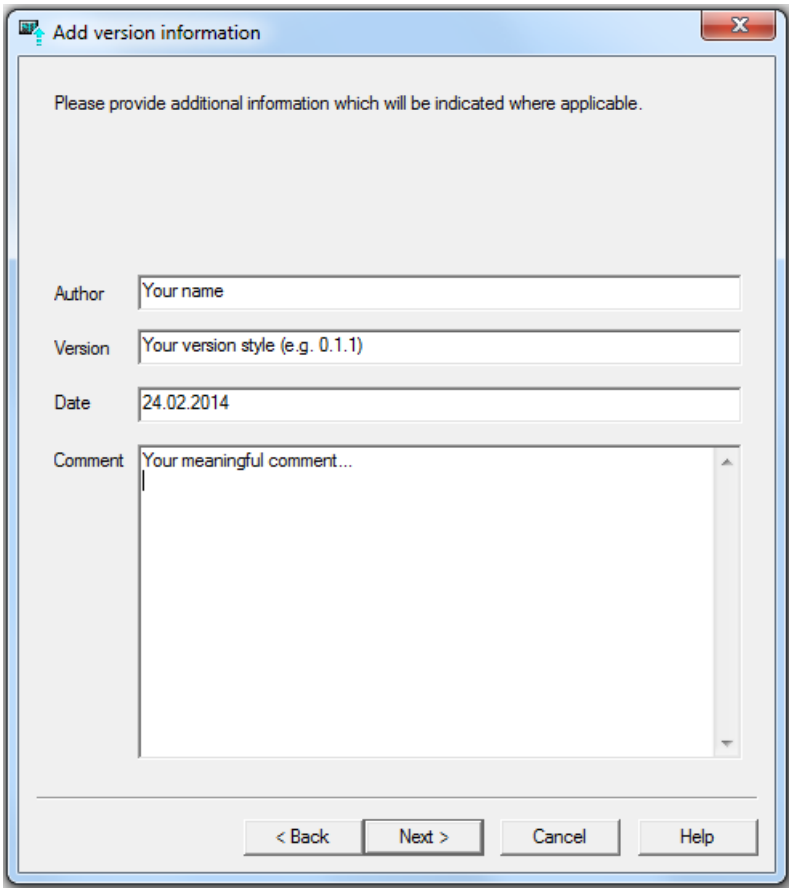

Figure 5-93 Add version information dialog

8. You can call up a summary of the projects and devices you have selected, as well as their associated components, in the **Summary** dialog box.

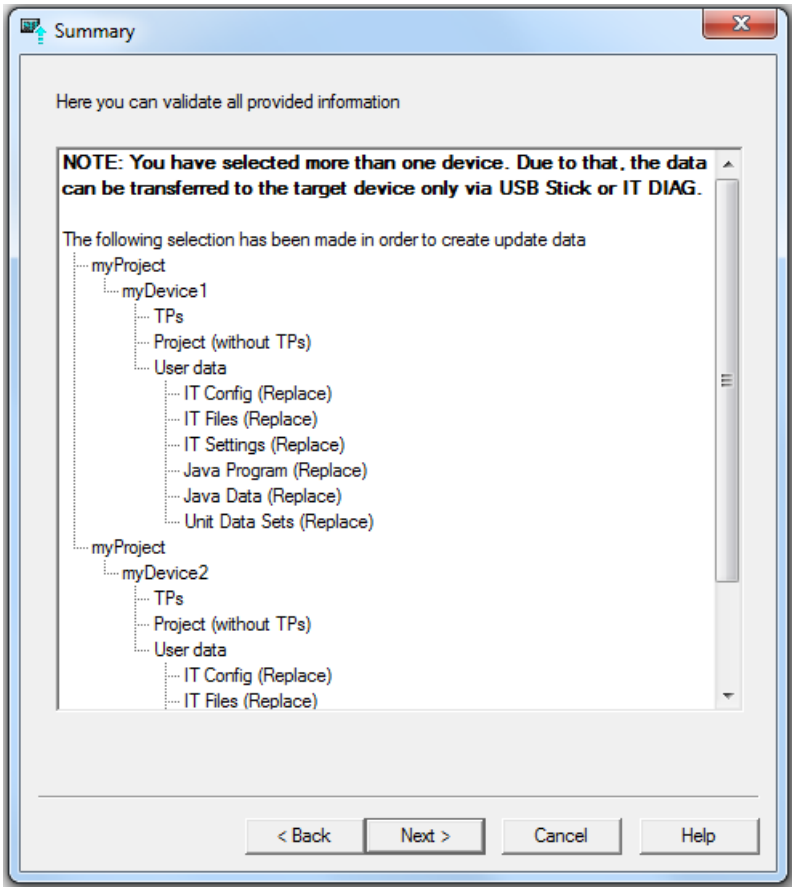

Figure 5-94 Summary dialog

9. In the **Select storage location/media** dialog, you can specify whether the upgrade data created is to be copied to a specific upgrade medium, or is to be saved in an upgrade archive in order to be written to an upgrade medium at a later date.

   – **File system** (upgrade archive)
   The data is exported to a **File system** in order to be written to an upgrade medium at a later date. An upgrade archive is created which can be called up at a later date outside the SIMOTION SCOUT context in order to load an upgrade medium (USB memory stick, CF / MMC card) or to transfer the data through a communication link (SIMOTION IT file).
   See also Creating upgrade data as an upgrade archive (Page 3511)
   To call up the upgrade archive, refer to Transferring the upgrade data (Page 3512)

   – **USB memory stick**
   If you select **USB memory stick**, the upgrade data is written directly to a USB memory stick inserted previously.
   Check the drive setting.
   This USB memory stick will have to be formatted before it can be used for upgrading purposes for the first time. Select the **Format as update stick** option.
   See also Creating upgrade data, including copying to a USB memory stick (Page 3509)
   Should you wish to undo the formatting of the USB memory stick, refer to Restoring the original status of a USB memory stick (Page 3546)

   – **CF/MMC**
   If you select **CF/MMC**, the upgrade data is written directly to a CF / MMC card.
   See also Creating upgrade data, including copying to a CF / MMC card (Page 3510)

– **SIMOTION IT file**
If you select **SIMOTION IT file**, the upgrade data will be written to a SIMOTION IT file. If upgrade data is created for several SIMOTION devices, one SIMOTION IT file will always be created **per** device with the name of the device (<devicename>.zip).
See also Creating upgrade data including creating a SIMOTION IT file (Page 3511)

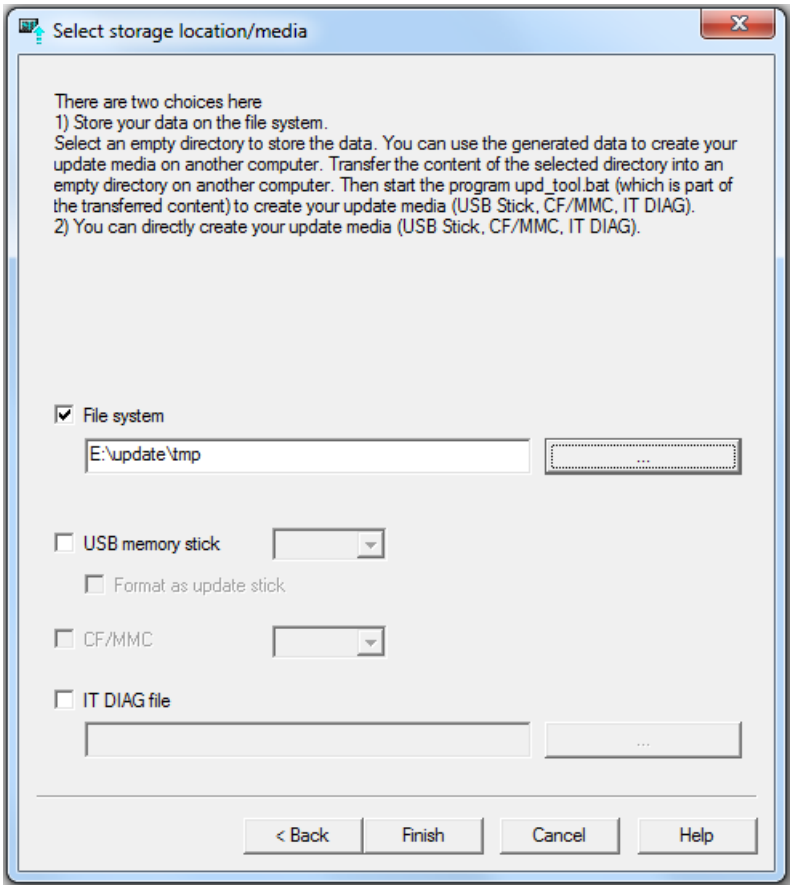

Figure 5-95 Select storage location/media dialog

Once you have selected the upgrade medium, click button **Finish** to activate the creation of the upgrade data.

10. After the upgrade data has been created, the **Succeeded** dialog appears. All successfully created upgrade data is listed here and the storage location recorded.
Close the Device Update Tool by clicking the **Close** button.

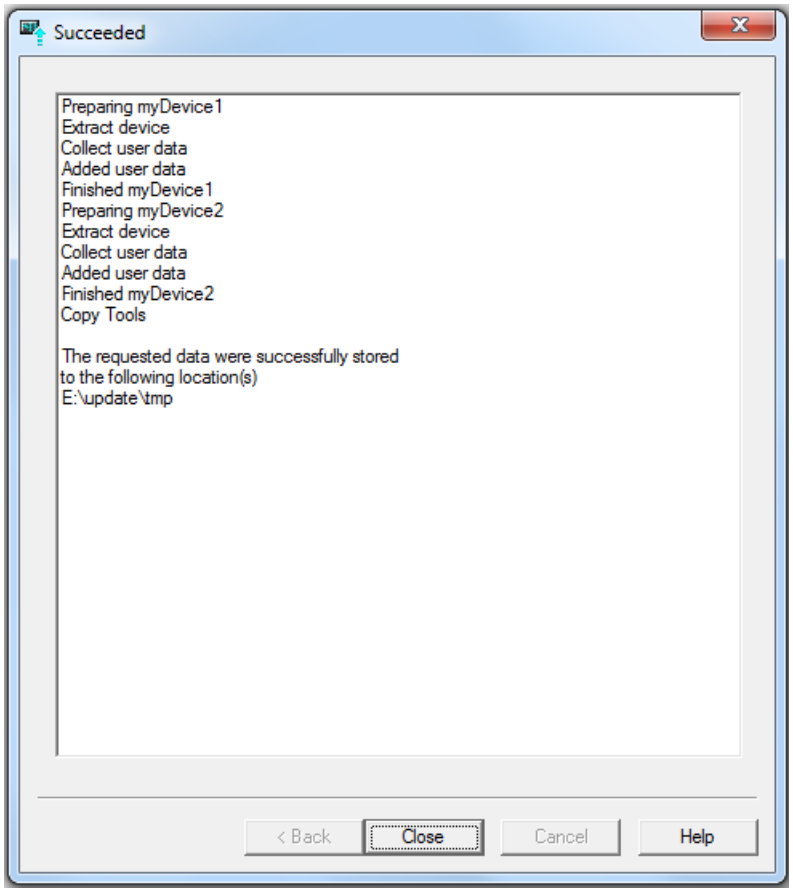

Figure 5-96 Closing window for the Device Update Tool

Canceling the Device Update Tool

As a rule, the Device Update Tool can be canceled after every step by clicking the **Cancel** button. If the write operation to the upgrade medium has already commenced, you cannot cancel this action until the procedure is complete.

Note

Exiting SIMOTION SCOUT TIA terminates the device update tool functionality

Note that when exiting SIMOTION SCOUT TIA or closing the project in SIMOTION SCOUT TIA, the functionality of the device update tool is also terminated.

- If required, close the open "Device Update Tool" dialog box with "Cancel".

Behavior after Merge or Replace

The following table shows the behavior of original and new files after **Merge** or **Replace** .

Original files	Upgrade files	After Merge	After Replace	Backup files
File 1 (original)	-	File 1 (original)	-	File 1 (original)
* File 2 (original)	File 2 (new)	File 2 (new)	File 2 (new)	File 2 (original)
File 3 (original)	-	File 3 (original)	-	File 3 (original)
--	* File 4 (new)	File 4 (new)	File 4 (new)	--
* In the example, File 2 is replaced and File 4 is added.				

With the **Merge** option, the original files are accepted and only replaced by new files with the same name or merged with new files.

With the **Replace** option, only the new files are accepted.

The original files are backed up with **Merge** and **Replace** and can be downgraded.

Creating update data, including copying to a USB memory stick

The USB memory stick can be used for single as well as multiple updates with SIMOTION D4x5-2 and SIMOTION P320-4 devices, i.e. you can update either a single device or multiple devices.
See also Device-specific update media (Page 3487)

Particular aspects of saving update data on a USB memory stick

- The USB memory stick, with at least a 512 MB capacity, appears as a logical drive when plugged into the PC.
- The USB memory stick must be formatted when it is used for the first time (**Format as update stick** option). You require administrator rights to do this.

The following hardware is required in order to update a SIMOTION D4x5-2 using a USB memory stick:

Table 5-48 Hardware required for USB memory stick updates

Module	Article no.	Minimum required HW version [1]
SIMOTION D425-2 DP	6AU1 425-2AA00-0AA0	from delivery
SIMOTION D425-2 DP/PN	6AU1 425-2AD00-0AA0	from delivery
SIMOTION D435-2 DP	6AU1 435-2AA00-0AA0	from delivery
SIMOTION D435-2 DP/PN	6AU1 435-2AD00-0AA0	from delivery
SIMOTION D445-2 DP/PN	6AU1 445-2AD00-0AA0	from delivery
SIMOTION D455-2 DP/PN	6AU1 455-2AD00-0AA0	from delivery
[1] The hardware release is listed on the SIMOTION D nameplates		

Note

Please note the following information about the USB memory stick

- The SIMOTION device is started from the USB memory stick when updating devices via a USB memory stick. For this reason, a bootable USB memory stick must be used.
  Due to the rapid developments within the market for USB memory sticks it is not possible to give any concrete recommendations except for SIMATIC USB memory sticks.
  Further information can be obtained on the Internet under Industry Online Support, SIMOTION: Which USB memory sticks are recommended for updating a module using a USB? (https://support.industry.siemens.com/cs/ww/en/view/32580863)
- If you are using the USB memory stick to update SIMOTION devices for the first time, it is **imperative** that you format the stick first. Unless it is formatted, the USB memory stick will not work, nor will the update process.
  Once the USB memory stick has been formatted, the amount of space which can be used in Windows is limited to 450 MB, irrespective of how much memory capacity is actually available.
- During formatting, all the existing data on the USB memory stick is permanently deleted.
- The system checks the size of the USB memory stick. If this is less than 512 MB, this option is not available in the **Store data** dialog box.
- The USB memory stick has to be restored to its original formatting if you wish to use it for any other purpose.
  Refer to: Restoring the original status of a USB memory stick (Page 3546).

Creating update data, including copying to a CF / MMC card

The CF / MMC card can only be used to perform single updates for SIMOTION C and SIMOTION D devices, i.e. only one device can be updated.
See also Device-specific update media (Page 3487)

Particular aspects of saving update data on a CF / MMC card

- The CF / MMC card is inserted into the PC or CF / MMC card adapter and is visible as a logical drive

  Note

  Note the following information regarding the CF / MMC card

  - You can only perform updates using a CF / MMC card if there already is a bootable SIMOTION system present on the target card, i.e. at the very least, executable firmware ≥ V4.1 SP2 must be present.
    A blank CF / MMC card cannot be updated.
  - If the **Device Update Tool** has not finished or the copying procedure has been interrupted, updating with the CF / MMC card will not be possible.
  - If an error such as PowerFail occurs while data are being written to the CF / MMC card, all the data on the card may be lost.
  - In the case of MMC (SIMOTION C), restoring can only be accomplished using a restore archive or SIMOTION IT.

Creating update data including generating a SIMOTION IT file

With SIMOTION IT, you can carry out single and multiple updates, i.e. both single and multiple SIMOTION devices can be updated.

SIMOTION IT is suitable as an update medium for **all** update scenarios and **all** SIMOTION devices.

If update data are created for several SIMOTION devices, essentially one SIMOTION IT file will be created **per** device with the name of the device (<devicename>.zip).
See also Device-specific update media (Page 3487)

Specifics for saving update data as a SIMOTION IT file

Note

Please note the following information about SIMOTION IT file

- If there is already a SIMOTION IT file in the selected directory, an error message will appear and the procedure will be aborted.
- First delete the existing SIMOTION IT file from the directory before storing the new SIMOTION IT file.

Creating update data as an update archive

The update data are created by an operator-guided process using the Device Update Tool in SIMOTION SCOUT, and then saved as an update archive in a directory.

Select the **File system** option in the second-to-last dialog box of the Device Update Tool **Select storage location/media** . Enter the path to a blank directory here. As soon as the Device Update Tool is closed, the update data selected and created previously are written to the directory and stored there for later use.

The update archive can be called up independently of SIMOTION SCOUT at a later point in time, so that it can be copied to an update medium.

Particular aspects of saving the update data as an update archive

Note

Note the following information about the update archive

- If data are already present in the directory selected, an error message is output and the process is stopped. No data is written.
  Select another blank directory in the **Select storage location/media** dialog. The update data are then written to the newly selected directory.
- If a CF / MMC card has been selected as an update medium, the update medium may only contain one device.

5.4.3.3 Copying to the update media on the basis of an update archive

Copying to an update medium without SIMOTION SCOUT

Requirements

- The update data has already been created and is located in an update archive
- SIMOTION Device Update Tool (update archive component)
- SIMOTION SCOUT does **not** need to be installed
- Released for the Windows XP SP3, Windows 7 Ultimate and Windows 7 Professional operating systems

Sequence

The data is copied to the update media independently of SIMOTION SCOUT; this can therefore be carried out at either the machine manufacturer's site or the machine operator's site.

All that is required is the update archive in which all the update data and the SIMOTION Device Update Tool are saved.

Transferring the update data

The SIMOTION Device Update Tool is part of the update archive that is created within the context of SIMOTION SCOUT.

You call up the Device Update Tool for the purpose of transferring update data from the update archive to an update medium. This involves starting the SIMOTION Device Update Tool via a batch file independently of SIMOTION SCOUT.

Proceed as follows:

1. Open the update archive directory.
2. Start the **upd_tool.bat** batch file from the directory. The SIMOTION Device Update Tool is started.

3. The **Welcome to the SIMOTION Device Update tool** dialog appears as the start screen.
   The Device Update Tool is in English.

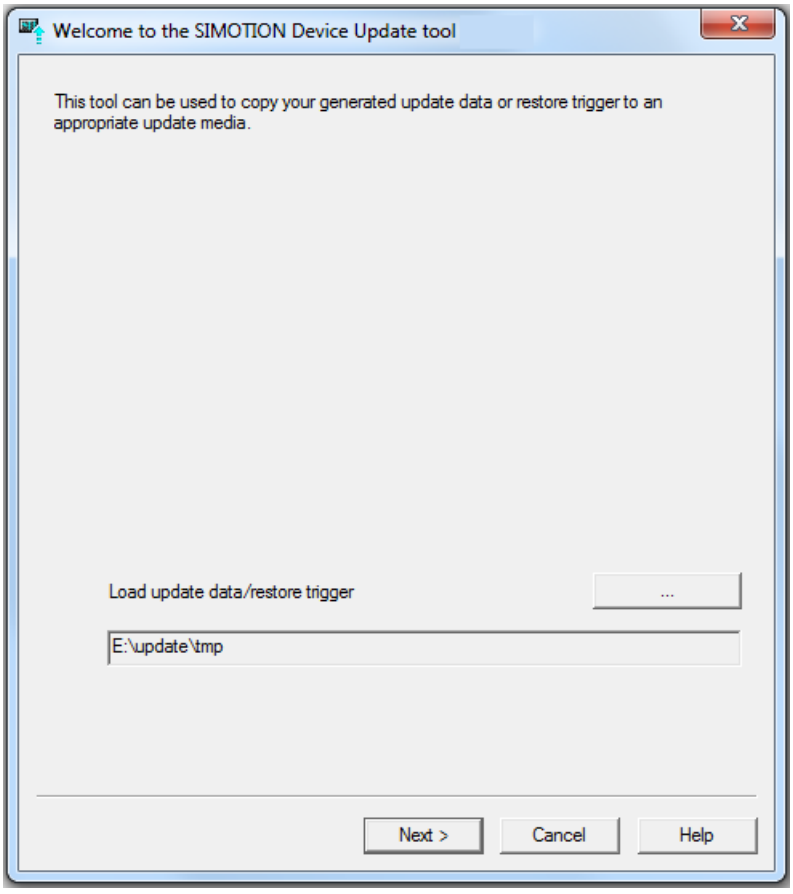

Figure 5-97 Device Update Tool start screen for transferring update data to an update medium

4. Click **Load update data/restore trigger** to call up either an update archive created using SIMOTION SCOUT or a restore archive.
   Select the path in which the update archive has been stored.
   Click button **Next** to proceed to the next dialog box.

5. The **Version Information** dialog box contains the stored identification data that was entered as the update data was created.

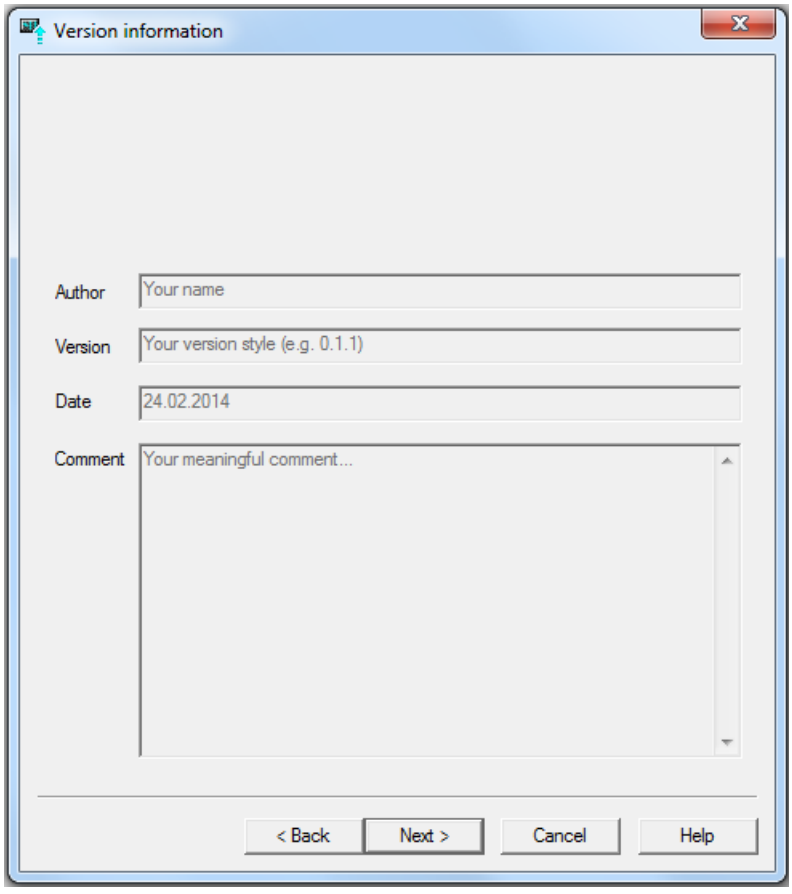

Figure 5-98 Displaying the identification data for the update archive

6. Select an update medium in the **Select storage location/media** dialog box. Data will then be written directly to this medium. You can select from the following:
   - USB memory stick
   - CF / MMC card
   - SIMOTION IT
     The update medium you can use depends on the SIMOTION device or on whether a single or a multiple update is taking place.
     You can find an overview under: Device-specific update media (Page 3487)

   Click button **Finish** to activate and execute the copying of data to the update medium.
   The following data can be created during this procedure:

   - **USB memory stick**
     Update medium for SIMOTION D4x5-2 and SIMOTION P320-4
     Update data for one or more SIMOTION devices is saved on this update medium.
     If you are using the USB stick as an update medium for the first time, you must format it. To do this, select **Format as update stick**.
     See also Copying data to a USB memory stick (Page 3518)
   - **CF- / MMC**
     Memory cards are an update medium for single updates on the SIMOTION C and SIMOTION D.
     Update data for a single SIMOTION device is saved on this update medium.
     See also Copying data to a CF / MMC card (Page 3519)

– **SIMOTION IT file**
SIMOTION IT is an update medium suitable for all update scenarios (single and multiple updates) and for all SIMOTION hardware platforms (SIMOTION C, D, P).
If update data is generated for several SIMOTION devices, essentially one SIMOTION IT file is created **per** device with the name of the device (<devicename>.zip) is created.
See also Creating a SIMOTION IT file and copying the update data (Page 3519)

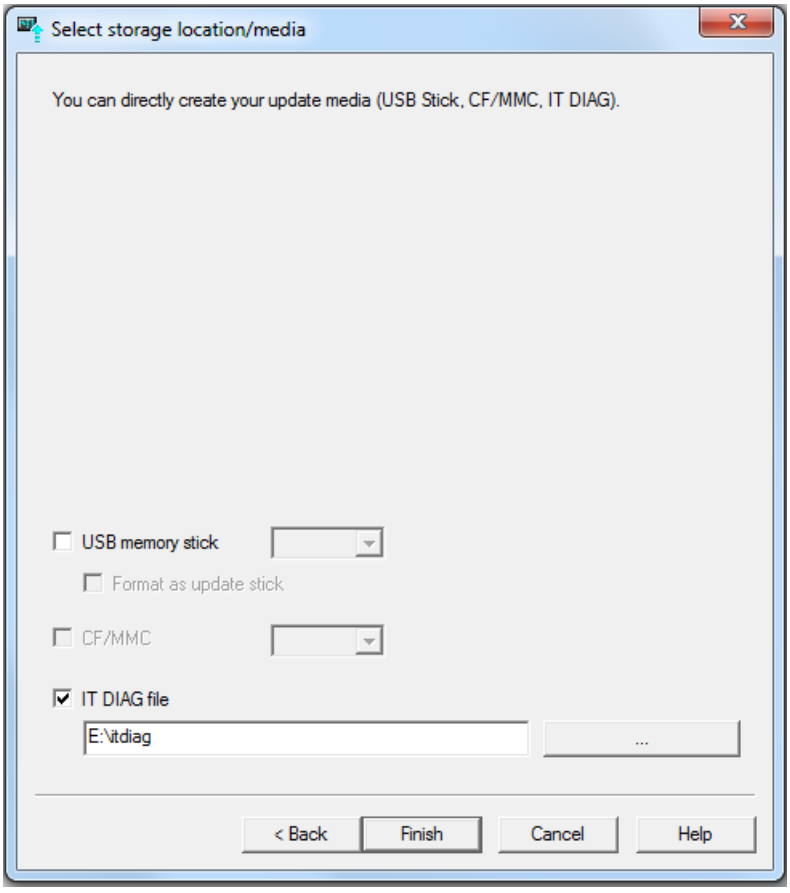

Figure 5-99 Selecting the update medium

7. The final **Succeeded** dialog in the Device Update Tool shows the devices for which update data from the update archive has been stored, and at what location.

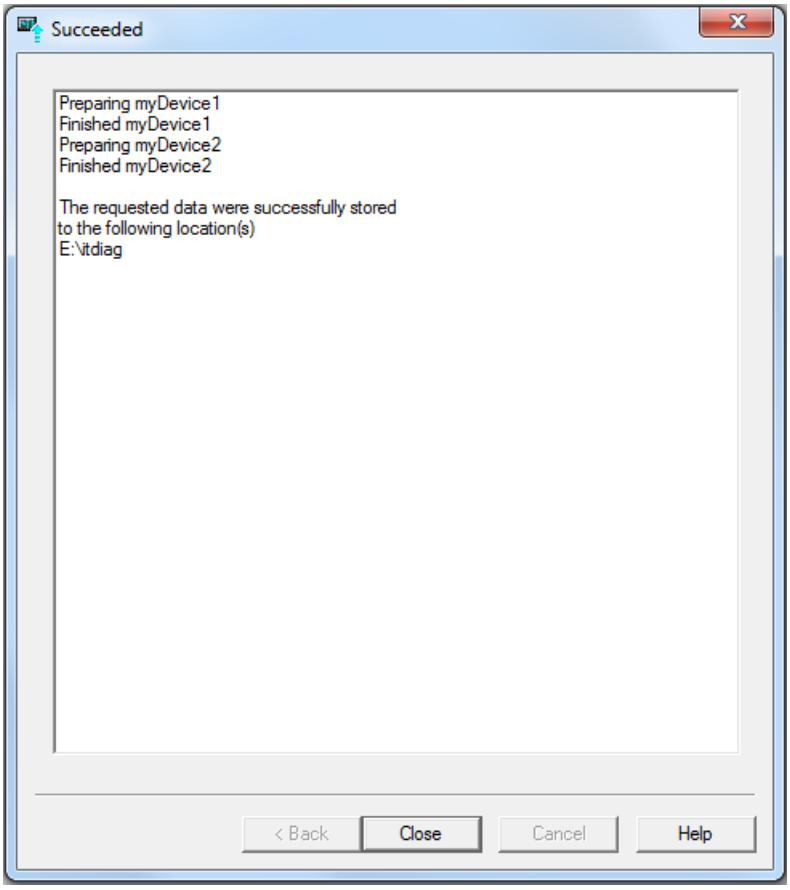

Figure 5-100 Final dialog Succeeded

Canceling the Device Update Tool

The Device Update Tool can be canceled after every step with the **Cancel** button. However, if the data write operation to the update medium has already started, you cannot exit from the tool until the write operation is complete.

Copying data to a USB memory stick

The USB memory stick can be used for single as well as multiple updates with SIMOTION D4x5-2 and SIMOTION P320-4 devices, i.e. you can update either a single device or multiple devices.
See also Device-specific update media (Page 3487)

Note

The SIMOTION device is started from the USB memory stick when updating devices via a USB memory stick. For this reason, a bootable USB memory stick must be used.

With the exception of SIMATIC USB memory sticks, due to the rapid developments within the market for USB memory sticks it is not possible to make any other concrete recommendations.

For information on this, go to:

https://support.industry.siemens.com/cs/ww/de/view/32580863

Particular aspects of transferring update data from the update archive to a USB memory stick

- The USB memory stick, with at least a 512 MB capacity, appears as a logical drive when plugged into the PC.
- The USB memory stick must be formatted when it is used for the first time (**Format as update stick** option). You require administrator rights to do this.
- The following hardware is required in order to update a SIMOTION D4x5-2 using a USB memory stick:

Table 5-49 Hardware required for USB memory stick updates

Module	Article no.	Minimum required HW version [1]
SIMOTION D425-2 DP	6AU1 425-2AA00-0AA0	from delivery
SIMOTION D425-2 DP/PN	6AU1 425-2AD00-0AA0	from delivery
SIMOTION D435-2 DP	6AU1 435-2AA00-0AA0	from delivery
SIMOTION D435-2 DP/PN	6AU1 435-2AD00-0AA0	from delivery
SIMOTION D445-2 DP/PN	6AU1 445-2AD00-0AA0	from delivery
SIMOTION D455-2 DP/PN	6AU1 455-2AD00-0AA0	from delivery
[1] The hardware release is listed on the SIMOTION D nameplates		

Note

Please note the following information about the USB memory stick

- If you are using the USB memory stick to update SIMOTION devices for the first time, it is **imperative** that you format the stick first. Unless it is formatted, the USB memory stick will not work, nor will the update process.
  Once the USB memory stick has been formatted, the amount of space which can be used in Windows is limited to 450 MB, irrespective of how much memory capacity is actually available.
- During formatting, all the existing data on the USB memory stick is permanently deleted.
- The system checks the size of the USB memory stick. If this is less than 512 MB, this option is not available in the **Store data** dialog box.
- The USB memory stick has to be restored to its original formatting if you wish to use it for any other purpose.
  Refer to: Restoring the original status of a USB memory stick (Page 3546).

Copying data to a CF / MMC card

The CF / MMC card can only be used to perform single updates for SIMOTION C and SIMOTION D devices, i.e. only one device can be updated.
See also Device-specific update media (Page 3487)

Particular aspects of transferring update data from the update archive to a CF / MMC card

- The CF / MMC card is inserted into the PC or CF / MMC card adapter and is visible as a logical drive.

Note

Note the following information about the CF / MMC card

- You can only perform updates using a CF / MMC card if there already is a bootable SIMOTION system present on the target card, i.e. at the very least, executable firmware ≥ version V4.1 SP2 must be present.
  A blank CF / MMC card cannot be updated.
- If the Device Update Tool has not finished or the copying procedure has been interrupted, updating with the CF / MMC card will not be possible.
- If an error such as PowerFail occurs while data are being written to the CF / MMC card, all the data on the card may be lost.
- If the update fails using MMC (in the case of C2xx) or if the previous configuration has to be accessed for other reasons, the restore data must be created through SIMOTION SCOUT at the machine manufacturer's site or the data can be restored using SIMOTION IT.

Creating a SIMOTION IT file and copying the update data

With SIMOTION IT, you can carry out single and multiple updates, i.e. both single and multiple SIMOTION devices can be updated. SIMOTION IT is suitable as an update medium for all update scenarios and all SIMOTION devices.

If update data are created for several SIMOTION devices, essentially one SIMOTION IT file will be created **per** device with the name of the device (<devicename>.zip).
See also Device-specific update media (Page 3487)

Specifics when transferring update data from the update archive to the SIMOTION IT file

Note

Note the following information

- If there is already a SIMOTION IT file in the selected directory, an error message will appear and the procedure will be aborted.
- First delete the existing SIMOTION IT file from the directory before storing the new SIMOTION IT file.

5.4.3.4 Transferring update data to the SIMOTION device

After update data has been created, it must be transferred to the relevant SIMOTION device.

This operation is based on the update media to which the update data has already been written. An update medium is either plugged into the SIMOTION device being updated (USB memory stick or CF / MMC card) or the update data can be transferred through a communication link to the relevant SIMOTION device (SIMOTION IT).

The update procedure is triggered by restarting the SIMOTION device to be updated. After the update data have first been transferred to the memory card in the device (this applies to both the USB memory stick and the SIMOTION IT), the data is backed up. The update data is activated as the current configuration after the SIMOTION device has been restarted.

Note

If the parameterization of the SINAMICS Safety Integrated functions is contained in the update data, these functions must be activated after the update.

See also *SINAMICS S120 Safety Integrated Function Manual*.

Requirements for updating:

- Firmware on the SIMOTION device to be updated, V4.1 SP2 or higher
- Update data must contain firmware V4.1 SP2 or higher (if firmware is selected).

Updating devices

- Updating a module with a USB memory stick (Page 3530)
- Updating a module with a CF / MMC card (Page 3533)
- Updating a module with SIMOTION IT (Page 3534)

Behavior of the retain data on updating (and restoration)

Overview

After the update data has been transferred to the SIMOTION device, the device is restarted and the update data is accepted.

During start-up, the non-volatile data stored in the SIMOTION device is checked to see if it is compatible with the current configuration.

Compatibility checks are conducted in relation to:

- Retain kernel data
- Device-global retain variables
- Unit retain variables
- TO retain data

Behavior of SIMOTION retain data during updating / restoring (as of V4.4)

During updating, existing retain data are retained under the following conditions:

- If no changes have been made to the retain data.
- In the case of TO retain data, if the TO name is unchanged.
- In the case of structural changes to unit-global retain data segments of program units, if
  - the name and type of a variable is unchanged.
  - the name of a variable is unchanged but its data type has changed and the value to be restored fits the value range of the new data type.

Otherwise the retain data will be initialized.

If no retain data is contained in the new project, the entire retain memory will be initialized in the control.

Behavior of the SINAMICS retain data

The SINAMICS retain data are kept during updates. All SINAMICS retain data can be located in the retain memory and interpreted by a new version of the firmware.

Receiving unit data

Behavior of SIMOTION unit data during updating

After the update data has been transferred to the SIMOTION device, the device is restarted and the update data is applied.

When loading a unit data set, a check is executed for compatibility with the current unit. Data saved with _saveUnitDataSet is only compatible if the data structure within the unit has not changed.

Data backed up using _exportUnitDataSet() also remains compatible after structure changes of the unit. This means that the data is retained even after a version or project change (when the unit and the data have the same name).

Whether existing unit data sets should be kept (Merge) or deleted (Replace) can be specified using the **Device Update Tool**.

New unit data sets can replace the existing sets (Replace) or be merged with them. **Replace** means that all existing unit data sets are deleted and the new ones are accepted. **Merge** means that all existing unit data sets are retained and the new unit data sets are merged with them. The only exception are the unit data sets with identical names. In this case, the existing unit data sets will be replaced by the new ones.

For more information about the Replace and Merge options, see:

Creating update data with the Device Update tool (Page 3492) in the **Select additonal options** dialog box.

Additional references

Additional information on the functions can be found in:

- SIMOTION Basic Functions Function Manual
- SIMOTION System Functions/Variables Devices List Manual

- SIMOTION SCOUT Online help

SIMOTION device status during updating

Status of SIMOTION devices

The table below provides an overview of the possible statuses, the corresponding LEDs, and their significance for SIMOTION devices during the update procedure.

Table 5-50 LED display on SIMOTION D for "Copying update data via USB memory stick to the memory card"

LED display	Status	Meaning	Description
RDY LED flashes yellow/ green at 0.5 Hz; later longer green and yellow phases (< 10 s)	USB in Progress	Update running, data is being copied from the USB memory stick to the memory card.	Update in progress. Do **not** switch off the SIMOTION device.
RDY LED constantly red	USB ERROR 1	Error copying from the USB memory stick.	Error occurred while copying. SIMOTION device is waiting. No communication possible with the SIMOTION device. **Required operator actions:** 1. Switch off the device. 2. Remove the USB memory stick. 3. Switch on the device. The device boots up in the starting configuration.
RDY LED must be constantly green for > 10 s so that the procedure is completed.	USB Done	Data has been successfully copied from the USB memory stick to the memory card.	SIMOTION device is waiting. No communication possible with the device. **Required operator actions:** 1. Switch off the device. 2. Remove the USB memory stick. 3. Switch on to start the actual update procedure (see following table: LED display when updating the devices).
RDY LED flashes yellow at 0.5 Hz (longer than 10 s)	USB BOOT ERROR	Booting is not possible from the used USB memory stick.	See Device-specific update media (Page 3487).

Table 5-51 LED display when updating the devices

LED display	Status	Meaning	Description
SIMOTION D/P: SF LED flashes green at 0.5 Hz SIMOTION C: SF LED flashes red at 2 Hz	IN PROGRESS	Update running	Update in progress. Do not switch off the SIMOTION device.
SF LED flickers red (10 Hz)	ERROR 2	**Possible errors are**: • Error backing up the configuration; update has not been accepted. • Defective update; update data has been copied, but is defective.	SIMOTION device is booting up in **STOP with start inhibit** After OFF/ON, the device boots up in the starting configuration. If required, a restore must be activated.
SF LED off [1]	DONE 1	Update successfully completed	SIMOTION device boots up with the updated configuration.

[1] The update has been successfully completed when the SF LED goes out; the device then boots up automatically in the updated configuration. (SF LED display then depends on the respective mode of the device.)

The update status is shown not only via the LEDs, but also in the device diagnostics on the **Syslog** tab. **Syslog** can also be read via SIMOTION IT.

Flow diagram: "Copying update data via USB memory stick to the memory card"

The figure below illustrates the processes that run during updating within the SIMOTION device, using the USB memory stick as an example of an update medium.
The status and corresponding LED are displayed with different colors by way of analogy.

Transferring update data from the update medium to SIMOTION devices

Updating a module with a USB memory stick

Requirement

USB memory stick updates are supported by the SIMOTION D4x5-2 and SIMOTION P320-4 devices.

Requirements for updating with a USB memory stick:

- USB memory stick to which the required update data has already been copied.
- SIMOTION device or devices that need to be updated.
- A CF card with sufficient memory capacity for the data to be copied must be inserted into the SIMOTION device(s) to be updated.

The following hardware is required in order to update a SIMOTION D4x5-2 using a USB memory stick:

Table 5-52 Hardware required for USB memory stick updates

Module	Article no.	Minimum required HW version [1]
SIMOTION D425-2 DP	6AU1 425-2AA00-0AA0	from delivery
SIMOTION D425-2 DP/PN	6AU1 425-2AD00-0AA0	from delivery
SIMOTION D435-2 DP	6AU1 435-2AA00-0AA0	from delivery
SIMOTION D435-2 DP/PN	6AU1 435-2AD00-0AA0	from delivery
SIMOTION D445-2 DP/PN	6AU1 445-2AD00-0AA0	from delivery
SIMOTION D455-2 DP/PN	6AU1 455-2AD00-0AA0	from delivery
[1] The hardware release is listed on the SIMOTION D nameplates		

Note

SIMOTION D4x5-2 - upgrading using a USB memory stick

When upgrading using a USB memory stick, the points listed below must be noted.

The version information refers to the firmware version on the CF card (that is, the original version from which upgrading is to take place).

- Version V4.2: Update via USB memory stick is not supported.
- Version < V4.3 SP1 HF12: The USB memory stick may only be inserted when the Control Unit is switched off.
- Version ≥ V4.3 SP1 HF2: The USB memory stick can be inserted when the Control Unit is switched on or off.

Sequence of operations for updating SIMOTION D4x5-2

When using a USB memory stick to perform an update, proceed as follows:

1. Check the position of the service selector switch
   (with D4x5-2: **SVC/NCK**).
   The switch position must be at **0**.
2. Insert the USB memory stick into one of the two USB interfaces on the SIMOTION D4x5-2 after it has been switched on. (Only one USB memory stick may be inserted.)
3. Switch the device OFF/ON or reset it using the RESET button.
4. SIMOTION D4x5-2 will now begin copying the data from the USB memory stick to the CF card.
   The copying procedure starts with some LED state changes and is finally displayed by a yellow/green flashing RDY LED (0.5 Hz).
   In the end phase of the update, the RDY LED has longer green and yellow phases (< 10 s).
   After completion of the copying procedure the RDY LED changes to:
   - **Constant green**, only when the RDY LED is constantly green for > 10 s, has the copying procedure been completed successfully.
   - **Constant red**, if copying was not successful.

Meaning of the 7-segment display	Description
0	No memory card available.
1	Internal error.
2	Internal error.
3	No or incomplete update data available on the USB memory stick.
4	No update data can be copied because there is no project available in the SIMOTION device, but update data for several SIMOTION devices is available on the USB memory stick. Because of the missing project on the SIMOTION device, assignment to the data on the USB memory stick is not possible.
5	The update data cannot be copied, for example, because there is not sufficient memory space.
6	Internal error.
7	Unknown update data available on the USB memory stick.

5. Switch off the SIMOTION D4x5-2 and remove the USB memory stick.
6. Switch the SIMOTION D4x5-2 on again. The system now starts the update procedure.
   The **SF LED** flashes green (0.5 Hz) during the update. The procedure can take several minutes.
7. Observe the green flashing of the **SF LED**:

- As soon as the update procedure has been completed successfully, the **SF LED** goes out. The device then boots up automatically in the updated configuration.
  (The **SF LED display** then depends on the respective operating state of the device.)
- If the update procedure was not successful, the **SF LED** flickers red (10 Hz).

Note

If the update has not been successful in terms of the application (for example, the machine is not behaving as desired), it can be undone using an operator action.

Note

If the firmware is being updated for SIMOTION D, depending on the firmware version on the SINAMICS components (DRIVE-CLiQ components, TB30, PM340, etc.), the component firmware will also be automatically updated. This procedure can take up to several minutes and is indicated by LED displays.

A firmware update on DRIVE-CLiQ components is indicated by the RDY LED flashing red and green:

- FW update running: RDY-LED flashes slowly (0.5 Hz)
- FW update complete: RDY-LED flashes rapidly (2 Hz), **POWER ON** required

These flashing patterns are also displayed on the yellow RDY LED on the SIMOTION D/CX32/CX32-2, and indicate that the firmware update has been carried out on components connected to the SIMOTION D/CX32/CX32-2 or that all components have completed the firmware update.

Components that require a POWER ON after the firmware update will signal this through a rapidly flashing RDY LED.
Switch the 24 V supply for initializing Off/On (POWER ON) for the relevant components.

Sequence of operations for updating SIMOTION P320-4

1. The USB memory stick to which the update data has been copied is inserted into one of the available USB ports on the SIMOTION P320-4. Updating or restoring is started automatically.
2. If the SIMOTION P320-4 is running at that point, you will be prompted to terminate the SIMOTION P.

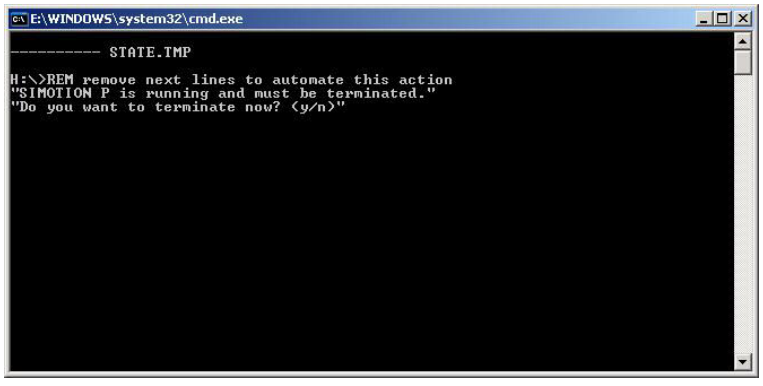

Figure 5-101 SIMOTION P: Query after the USB memory stick is inserted

3. After you click **y** to confirm, the device is switched off, and the update is started automatically. The data is copied from the USB memory stick to the SIMOTION P's hard disk. While this process is running, you will be kept informed of progress via SIMOTION P Update.
4. Once the copying procedure is complete, you will be prompted whether you wish to restart the SIMOTION P. If you click **y** to confirm, the SIMOTION P is restarted.

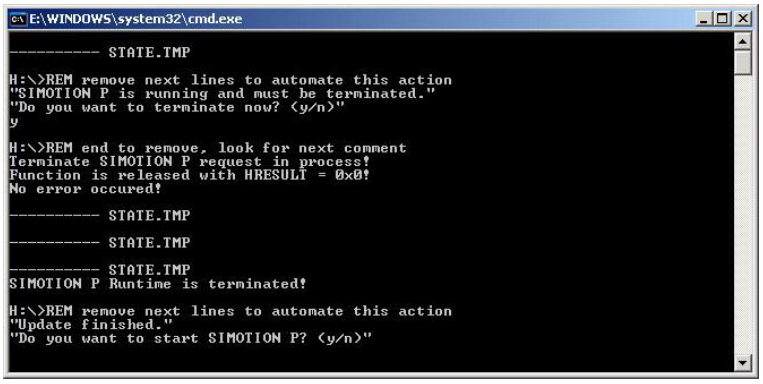

Figure 5-102 SIMOTION P: Device restart enquiry

5. The update or restore is activated when the SIMOTION P is restarted.

Updating a module with a CF / MMC card

Precondition

- CF / MMC card to which the required update data has already been copied.
- SIMOTION device which is to be updated.
- Sufficient storage space on the memory card for the active configuration, update data and backup.

Note

Only update data for exactly one SIMOTION device can be stored on the CF / MMC card

Procedure

1. Switch off the SIMOTION device to be updated.
2. Insert the CF / MMC card into the SIMOTION device.

3. Switch the SIMOTION device on again. The system now starts the update procedure. During the update, the **SF LED** flashes:
   - Green for SIMOTION D (0.5 Hz)
   - Red for SIMOTION C (2 Hz)
     The update procedure can take several minutes.
4. Observe the flashing of the **SF LED**:
   - When the update procedure has been completed successfully, the SF LED goes out. The device then boots up automatically in the updated configuration.
     (The **SF LED display** then depends on the respective operating state of the device.)
   - If the update procedure was not successful, the **SF LED** flickers red (10 Hz).

Note

If the firmware is being updated for SIMOTION D, depending on the firmware version on the SINAMICS components (DRIVE-CLiQ components, TB30, PM340, etc.), the component firmware will also be automatically updated. This procedure can take up to several minutes and is indicated by LED displays.

An FW update on DRIVE-CLiQ components is indicated by the RDY LED flashing red/green:

- FW update running: RDY LED flashing slowly (0.5 Hz)
- FW update complete: RDY-LED flashes rapidly (2 Hz), **POWER ON** required

These flashing patterns are also displayed on the yellow RDY LED on the SIMOTION D/CX32/CX32-2, and indicate that the firmware update has been carried out on components connected to the SIMOTION D/CX32/CX32-2 or that all components have completed the firmware update.

Components that require a POWER ON after the firmware update will signal this through the rapidly flashing RDY-LED.
Switch on the 24 V supply to initialize the OFF/On (Power ON) for the respective components.

Updating a module with a SIMOTION IT file

Requirement

- The update or restore data have already been created and are available as *.zip in a SIMOTION IT file.
- There is a browser installed on the computer that is in use.
- The computer is connected via TCP/IP to the SIMOTION device to be updated.
- A memory card with sufficient memory capacity for the data to be copied must be inserted into the SIMOTION device(s) to be updated.

- It is **imperative** that updating / downgrading a SIMOTION device using SIMOTION IT takes place when the operational status is **STOP** .
- Sufficient memory capacity on the CF / MMC card: Memory capacity is required for the current configuration, the backup copy and the ZIP file.

Note

Switching off the control during data transfer may lead to loss of data on the CF/MMC card.

Procedure

1. Establish a connection via the browser to the SIMOTION device to be updated. The system sends the HTML start screen to the browser.
2. Select the **Manage Config** page and then the **Device Update** tab.
   The system sends the authentication page to the browser.
3. Log in on the **Manage Config** page using the password.
4. In the **Device Update** tab under **Send new update data**, select the stored SIMOTION IT file (the update data) using the  button.
5. Click button **Send update data** to copy the update data to the memory card in the SIMOTION device.
   The data from the existing configuration is renamed and backed up, and can be retrieved again at any time. In the event of a data restore, this data is activated again.
6. The SIMOTION device is restarted. When the device is booted, the data which has recently been imported is applied as the current configuration and activated.

Note

If the firmware is being updated for SIMOTION D, depending on the firmware version on the SINAMICS components (DRIVE-CLiQ components, TB30, PM340, etc.), the component firmware will also be automatically updated. This procedure can take up to several minutes and is indicated by LED displays.

A firmware update on DRIVE-CLiQ components is indicated by the RDY LED flashing red/ green:

- FW update running: RDY-LED flashes slowly (0.5 Hz)
- FW update complete: RDY-LED flashes rapidly (2 Hz), **POWER ON** required

These flashing patterns are also displayed on the yellow RDY LED on the SIMOTION D/CX32, and indicate that the firmware update has been carried out on components connected to the SIMOTION D/CX32/CX32-2 or that all components have completed the firmware update.

Components that require a POWER ON after the firmware update will signal this through the rapidly flashing RDY-LED.
Switch on the 24 V supply to initialize the Off/On (POWER ON) for the respective components.

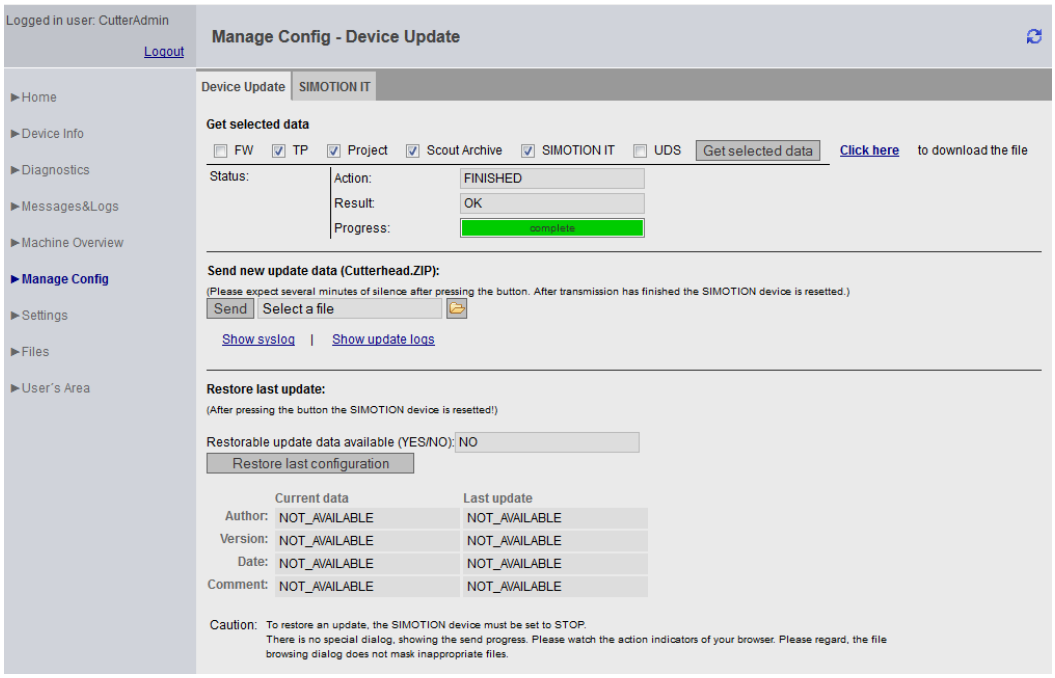

Figure 5-103 SIMOTION IT - Manage Config, tab Device Update

Saving and archiving the current configuration

Button **Get selected data**:
Select this button if you wish to save and archive the current configuration of the SIMOTION device externally. The data is saved on the PC as a *.zip file.
The configuration saved in this way can be reloaded and activated at a later time using Send update data (e.g. in the case of a memory card defect).
You can choose whether you want to archive the entire configuration or just specific subsets, e.g. firmware (FW), technology packages (TP), project and/or user data (SCOUT Archive, SIMOTION IT and UDS (Unit Data Sets)).

Further information about button **Restore last update** can be found in section: Restoring a SIMOTION device (Page 3538).

Literature

More information on SIMOTION IT can be found in the following documents:

- SIMOTION IT Diagnostics and Configuration
- SIMOTION IT, Programming and Web Services
- SIMOTION IT Virtual Machine and Servlets
- SIMOTION IT OPC UA

5.4.3.5 Possible error messages for the Device Update tool

Error messages and possible solutions

The error messages in the following list can occur when the **Device Update Tool** is being run. The error messages are in English.

Possible causes and remedies are described in the table below.

Error message	Cause	Solution
To add firmware to the updata data, the firmware must be provided by installing a **FW Support Package (FWSP)**. Currently, there is no appropriate FWSP installed. Please refer to the SCOUT documentation to get more information about the FWSP.	The firmware must be updated for at least one device. The corresponding SIMOTION FWSP (Firmware Support Package) is not available.	Please install the SIMOTION FWSP (Firmware Support Package). FWSP for versions, service packs (SPs) and hotfixes (HFs) are provided on the SIMOTION Product Support pages on the Internet at: https://support.industry.siemens.com/cs/ww/de/view/33119786 (https://support.industry.siemens.com/cs/ww/en/view/33119786)
The following selected projects are not consistent: ... In order to generate update data out of those projects, you must recompile them first.	The selected projects are not compiled in SIMOTION SCOUT. Compiled and consistent projects are required for updating.	Projects that you wish to update must first be compiled in SIMOTION SCOUT and checked for consistency. With the project open, select: • Project > Save and compile changes • Project > Check consistency
To add the selected archive data, the corresponding SCOUT project must not be opened by SCOUT. Please close the corresponding project within SCOUT or deselect the project within the SIMOTION Device Update tool.	Projects opened in SIMOTION SCOUT cannot be archived.	Close the project in SIMOTION SCOUT before you call and run the **Geräte Update Tool** .
The selected projects contain devices with identical names. To generate update data, all device names must be unique. Please deselect appropriate projects or rename the corresponding devices names to become unique. This applies to the following devices	Several projects were selected as the update data were being created and devices with identical names exist within this project.	Create the update data individually for each project or assign unique names to the devices.
The selected directory already contains data. Please select an empty directory, or delete all the data in the choosen directory.	The target directory for the update data must be empty.	Select an empty directory or delete the data from an existing one.

Error message	Cause	Solution
No Access to scout.	Error occurred while accessing the project.	If SIMOTION SCOUT is online, go offline. Contact the hotline in other cases.
<Device name> not found on card.	An attempt has been made to copy update data to a CF / MMC card. A project is already stored on the card. The existing device name does not match the device name in the update data.	If you want to overwrite the project on the card, select the option **Select additional options** in the **Force update** dialog.

5.4.4 Restoring

In the following cases it is recommended that you perform a restore on a SIMOTION project or device:

- Restoring to a previous configuration whenever an error occurs during updating
  Since a SIMOTION device update may fail, this ensures that communication capability is maintained, even after an update failure. If, for instance, the updated firmware is not recognized, the SIMOTION device may be restored to the firmware that was previously valid.
- Restoring in situations where a SIMOTION device or project has been successful but the new configuration has failed to perform as required; option of returning to the previous configuration.

5.4.4.1 Restoring a SIMOTION device

Overview

During restore procedures, it makes no difference whether the previous update was successful or unsuccessful. In both cases, the device is restored to the configuration backed up most recently.

If the update could not be carried out, the communication capability of the device is restored. The restore operation is initiated by an explicit user action.

When a restore is carried out, the SIMOTION device reverts to the configuration saved at the last update.
As long as the initial state of the SIMOTION device is not restored after an unsuccessful update attempt, the device remains in the state STOP with start inhibit. This means that, at the very least, communication capability will be ensured.
A restore procedure is necessary in order to resume work on a SIMOTION project following an unsuccessful update.

Even after a successful update, the device can be restored specifically to the data that had been backed up previously. This is the case if, for example, the new configuration has failed to perform as required and you wish to return to the previous configuration.

A backup is created as the first step in every update procedure. The device can only be restored to this backup.

Characteristics of a failed update

A project failure may manifest itself as follows:

- The SIMOTION device will not switch to RUN.
- The SIMOTION device switches to RUN but performs incorrectly.
- The new firmware has not been updated. The previous firmware state is restored, as a result of which the new project or the new technology packages cannot be loaded.
- The causes of this behavior are displayed in the diagnostics buffer entries. The stated information can be determined using the diagnostic pages in SIMOTION IT, for example.
- The SIMOTION device displays a request for an overall reset.

Requirements for performing a restore

A backup of the previous configuration was created during the update procedure which ensured that a backup of the data exists.

The configuration includes firmware (FW), technology package(s) (TP), project(s), and any user data which may exist.

Triggering a restore

A restore operation is triggered by saving the restore archive to the memory card, by operator control actions at the SIMOTION device or by use of the button **Restore last update** in the **Manage Config** dialog (SIMOTION IT).

In the case of SIMOTION D, restore can be triggered by means of switch settings on the device. Alternatively, restore can be initiated in all SIMOTION devices by transferring the restore archive. See Particular aspects of restoring SIMOTION devices (Page 3543).

Backup data

The backed up data from a SIMOTION device is retained as long as the backup exists, i.e. until it is overwritten by another update. Should errors occur during the update procedure, the device can be restored to the backup.

SIMOTION data behavior during restoring

- Current retain data
  The retain data will be restored only if the firmware is restored or if the data structures are not compatible. Behavior is described under: Behavior of the retain data during updating (Page 3521).
- Current diagnostics buffer
  The content at the time of backup is activated again.

You can find additional information in the section Particular aspects of restoring SIMOTION devices (Page 3543)

Behavior of the SINAMICS retain data during restoring

After a firmware restore has been carried out, the SINAMICS retain data is in the same state as when the data was backed up.

5.4.4.2 SIMOTION device status during restoring

Status of SIMOTION devices

The table below provides an overview of the possible statuses, the corresponding LEDs, and their meanings for SIMOTION devices during the restore process.

Table 5-53 Overview of SIMOTION device status during restoring

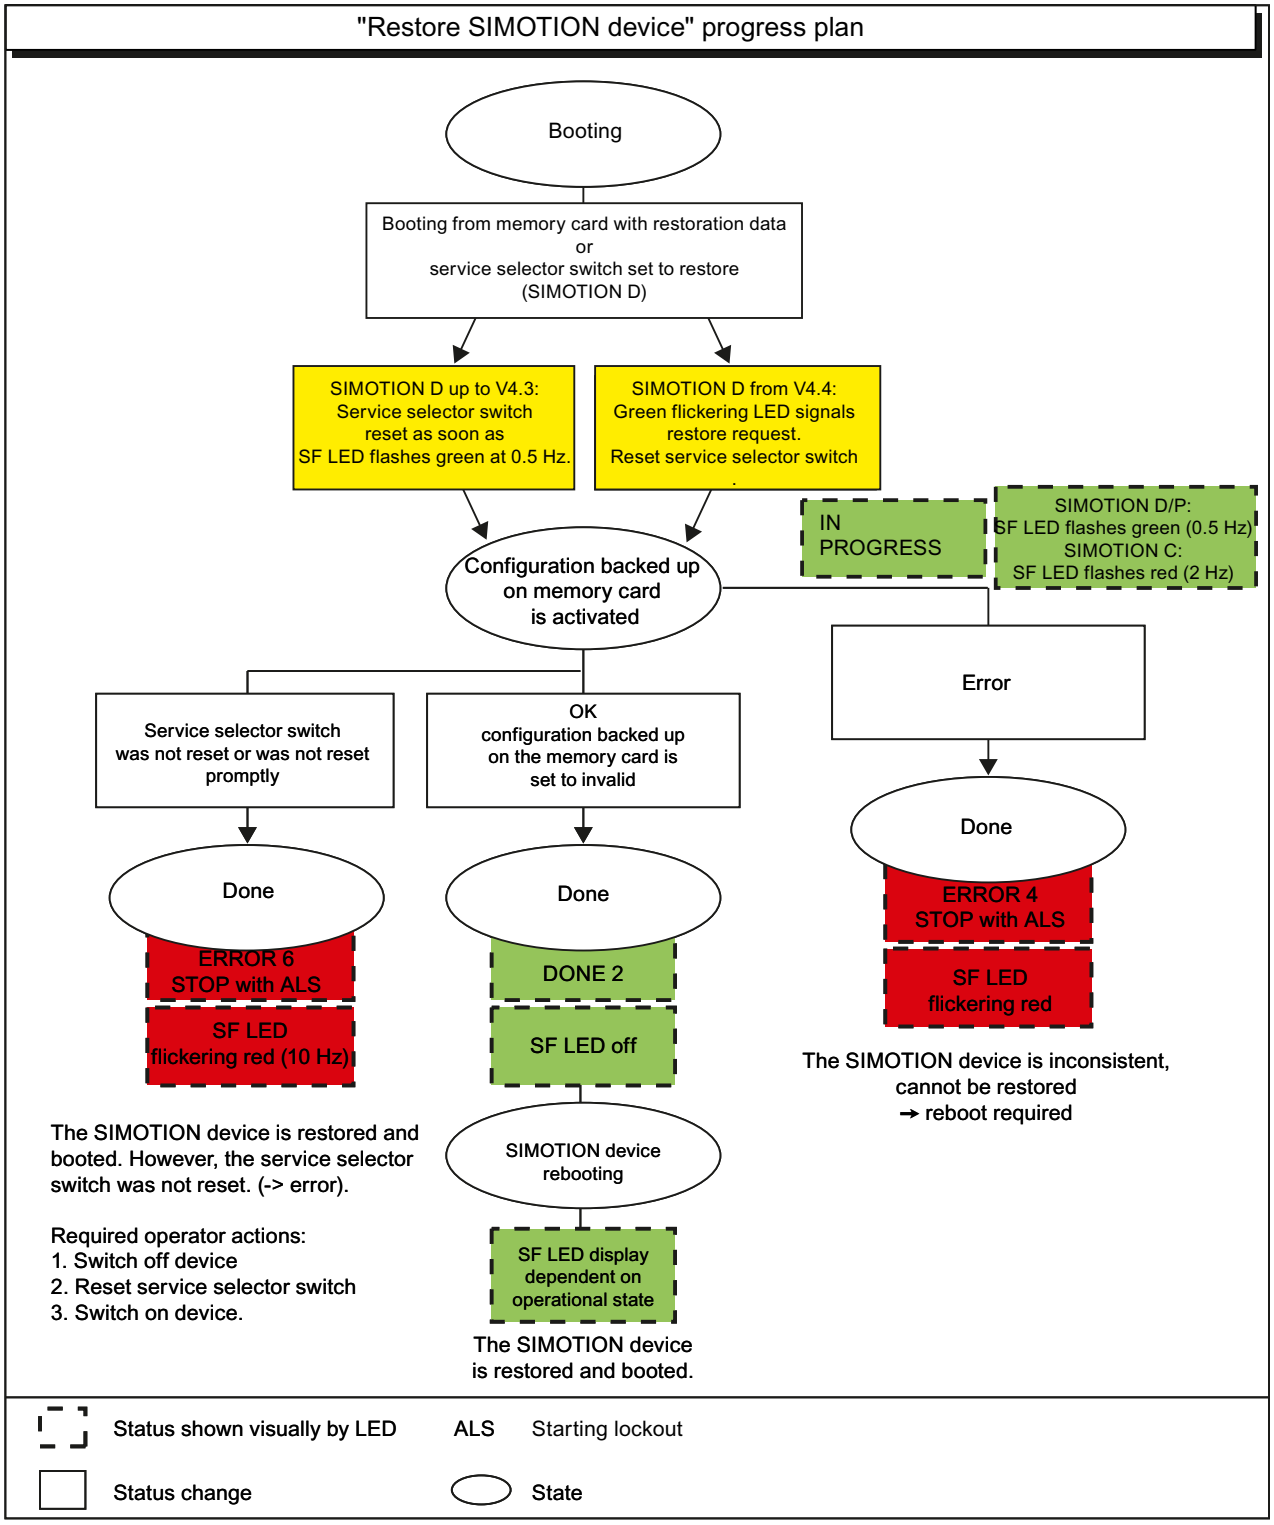
LED display	Status	Meaning	Description
SF LED flickers green (from V4.4)	IN PROGRESS	Restore requested.	The flickering green SF LED indicates that a restore is requested. The restore procedure is started by resetting the service selector switch.
SIMOTION D/P: SF LED flashes green at 0.5 Hz **SIMOTION C**: SF LED flashes red at 2 Hz	IN PROGRESS	Restore active.	Restore in progress. **Note** Do not switch off the SIMOTION device.
SF LED flickers red (10 Hz)	ERROR 4	Restore error.	SIMOTION device is booting up in **STOP with start inhibit**. After OFF/ON, the device boots up in STOP with start inhibit.
SF LED off [1]	DONE 2	Restore successfully completed.	SIMOTION device boots up with the restored configuration
SF LED flickers red (10 Hz)	ERROR 6	Error **SIMOTION D only:** Service selector switch is still set at Restore.	SIMOTION device boots up in **STOP with start inhibit**. Switch off the device, reset the service selector switch and switch the device back on. If the restore operation was otherwise successful, the devices boots up with the restored configuration.

[1] The restore has been successfully completed when the SF LED goes out; the device then boots up automatically in the restored configuration.
The SF LED display depends on the relevant operating state of the device.

The restore status is shown not only via the LEDs, but also in the device diagnostics on the tabs "Diagnostics buffer" and Syslog.

Flow chart: Restoring a SIMOTION device

The chart below shows how a SIMOTION device restore may proceed once the restore archive has been transferred to the memory card of the SIMOTION device.
The status displays appear in different colors by way of analogy.



"Restore SIMOTION device" progress plan
Booting
Booting from memory card with restoration data or service selector switch set to restore (SIMOTION D)
SIMOTION D up to V4.3: Service selector switch reset as soon as SF LED flashes green at 0.5 Hz.
SIMOTION D from V4.4: Green flickering LED signals restore request. Reset service selector switch
IN PROGRESS
SIMOTION D/P: SF LED flashes green (0.5 Hz) SIMOTION C: SF LED flashes red (2 Hz)
Configuration backed up on memory card is activated
Service selector switch was not reset or was not reset promptly
OK configuration backed up on the memory card is set to invalid
Error
Done
ERROR 6 STOP with ALS
SF LED flickering red (10 Hz)
Done
DONE 2
SF LED off
Done
ERROR 4 STOP with ALS
SF LED flickering red
The SIMOTION device is restored and booted. However, the service selector switch was not reset. (-> error).
Required operator actions:
1. Switch off device
2. Reset service selector switch
3. Switch on device.
SIMOTION device rebooting
SF LED display dependent on operational state
The SIMOTION device is restored and booted.
The SIMOTION device is inconsistent, cannot be restored
→ reboot required
Status shown visually by LED
ALS Starting lockout
Status change
State

Note

Restore request from Version V4.4

From Version V4.4 the restore request is indicated by a green flickering SF LED.

The restore procedure starts once the service selector switch is reset.

In the case of SIMOTION < V4.4, the restoration starts once the module is switched on. Here, the service selector switch must be reset immediately once the flash code is displayed (SF LED flashes green at 0.5 Hz).

If the service selector switch is not reset or not reset promptly, this will lead to the error status "Service selector switch is still at restore" (SF LED flickers red).

5.4.4.3 Particular aspects of restoring SIMOTION devices

Precondition

During restoring procedures, it makes no difference whether the previous update was successful or unsuccessful. The procedure is identical for every SIMOTION device.

A distinction is made between SIMOTION devices where a restore can be requested via an operator control. In the case of SIMOTION devices with Ethernet / PROFINET interfaces, the user can also request a restoration using SIMOTION IT. For all SIMOTION devices, restore data can be created as a restore archive on an operator-guided basis via the **Device Update Tool**. These can then be saved to the memory card of the SIMOTION device.

Table 5-54 Assignment of restore options to SIMOTION devices

SIMOTION device	Restore options	Method
C2xx	Create the restore archive by means of the Device Update Tool.	Machine manufacturer
D4x5-2	**Preferred solution**: Via service selector switch on the device **Alternative**: Create the restore archive by means of the Device Update Tool.	Machine operator
D410-2	**Preferred solution**: Via service selector switch on the device **Alternative**: Create the restore archive by means of the Device Update Tool.	Machine operator
P320-4	Create the restore archive by means of the Device Update Tool.	Machine manufacturer

Restoration using SIMOTION IT is essentially possible for all SIMOTION devices with Ethernet interfaces for all restore scenarios and can be carried out by the machine operator.

Restoring SIMOTION D410-2/D4x5-2 using the operating element on the device

The user at the machine operator's premises can restore using the operating element independently of the machine manufacturer because no SIMOTION SCOUT is required.

1. Switch off the SIMOTION D410-2/D4x5-2 device.
2. Set the service selector switch to position **B** (in the case of D410-2: SVC, in the case of D4x5-2: SVC/NCK).
3. Switch the SIMOTION D410-2/D4x5-2 device back on again.
   The flickering green SF LED indicates that a restore is requested.
4. Reset the service selector switch to position **0**.
   The system restores the data saved during the update. The data from the update procedure will be deleted.
   The restore will be signaled by a green flashing SF LED (0.5 Hz) and this may take several minutes.
   After a successful restore operation, the module will start up automatically. (SF LED display will then depend on the respective operating status of the device).
   If the restore procedure was not successful, the SF LED will flicker red.

Note

Starting the restore procedure (SIMOTION < V4.4)

In the case of SIMOTION < V4.4, the restore procedure starts when the module is switched on (see Step 3).
The service selector switch must be turned to position **0** immediately the flash code is displayed (SF LED flashes green at 0.5 Hz).

If the service selector switch is not reset to position **0** or not reset there promptly, this will lead to the error status "Service selector switch is still at restore" (SF LED flickers red).

In this case, switch off the SIMOTION D Control Unit, reset the service selector switch and switch the Control Unit back on again. If the restore was otherwise successful, the Control Unit will start up with the restored configuration.

Restoring firmware for SIMOTION D

Note

If the firmware is being restored for SIMOTION D, depending on the firmware version on the SINAMICS components (DRIVE-CLiQ components, TB30, PM340, etc.), the component firmware will also be automatically restored. This procedure can take up to several minutes and is indicated by LED displays.

A FW update on DRIVE-CLiQ components is signaled by red-green flashing of the LED RDY:

- FW update running: LED **RDY** flashes slowly (0.5 Hz)
- FW update complete: LED **RDY** flashes rapidly (2 Hz), **POWER ON** required

This flash pattern is additionally displayed at the yellow LED **RDY** of the SIMOTION D/CX32/CX32-2 and signals that components connected to the SIMOTION D/CX32/CX32-2 are carrying out a FW update or that all components have completed the FW update.

After the firmware update has been completed on all components, a POWER ON must be carried out for all restored components.

Restoring via the restore archive

A restore archive is created at the machine manufacturer's site using the Device Update Tool function in SIMOTION SCOUT.

When restoring, you are guided by the Device Update Tool (in exactly the same way as with updating).

1. Select **Project > Start Device Update Tool** in the open SIMOTION project.
2. The **Device Update Tool** opens with the start screen **Welcome to the SIMOTION Device Update tool**.
   In this screen you can decide whether data is to be created for updating or restoring a SIMOTION device.
   Select **Create restore trigger** since you wish to create data for restoring a device.
3. The subsequent steps in this procedure are identical to those involved in updating.
   Refer to: Creating update data with the Device Update Tool (Page 3492)

Restoring using SIMOTION IT

The user at the machine operator's premises can perform a restore using the SIMOTION IT web server independently of the machine manufacturer because no SIMOTION SCOUT is required.

To do this, select **Manage Config** , tab Device Update and button **Restore last update** in order to activate the backup in the device.

The system restores the data backed up during the update. The data from the update will be deleted. Once this is complete, the SIMOTION device restarts. After rebooting, the configuration is restored to its pre-update status.

5.4.5 Appendix A

5.4.5.1 Restoring the original status of a USB memory stick

Requirement

A USB memory stick has to be formatted once before it can be used as an update medium for the first time. A bootable update medium is created during formatting. The USB stick's memory is limited to a fixed value of 450 MB, irrespective of how much memory capacity is actually available. Various partitions, which are required for updating, are created.

To restore the USB memory stick to its original status, it is not enough to simply format it as the partitions have to be deleted first.

Note

A USB memory stick formatted using the **Device Update Tool** can **only** be restored under **Windows XP** and can then be used again.

Procedure

Before formatting the USB memory stick, the existing partitions must be deleted and a partition encompassing the entire USB memory stick must be created.

The procedure is as follows:

1. Insert the USB memory stick that has been formatted as an update medium into a USB port on the computer.
2. Right-click the **My Computer** icon on your desktop and select **Manage** from the context menu.
   Alternatively, you can also open the Windows Explorer. Right-click **My Computer** in the Start menu window and select **Manage** from the context menu.
   The **Computer Management** window opens.

3. Scroll down the Computer Management window until you reach **Disk Management**.
   In this example the USB memory stick appears under drive letter (F:). The total memory capacity of the USB memory stick is shown at the top right-hand side of the window under Capacity.
   The different partitions and the memory capacity that is currently available for use appear in the bottom right of the window under **Disk 2**.
   The USB memory stick is divided into three partitions:

   – VOLUME (F:) - 456 MB FAT32 - Error-free:
     The area on the left is the partition which is visible in Windows; this contains the update data.

   – 30 MB - Error-free:
     The area in the middle is the partition containing the LINUX system.

   – 1.45 GB - Not allocated:
     The area on the right is the partition containing the part of the USB memory stick which is of no relevance to the update data. The size varies depending on the memory capacity of the USB memory stick. This partition is not allocated and cannot, therefore, be read by Windows either.

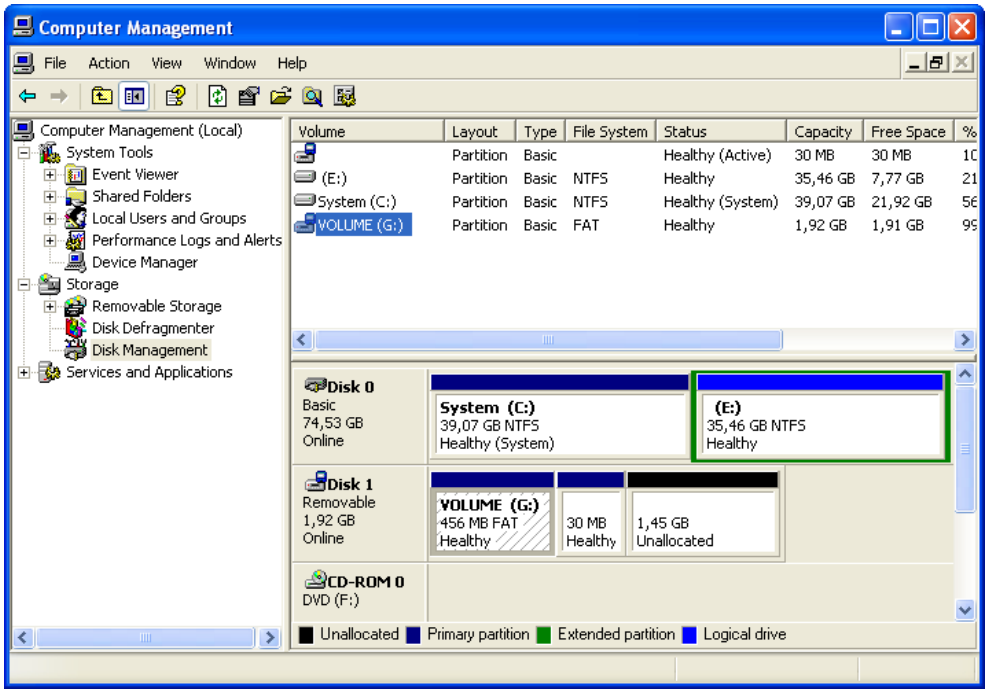

Figure 5-104 Computer Management window

4. In order to create a complete partition again, the LINUX partition which is not visible in Windows must be deleted.
   Right-click the middle partition (in this case 30 MB) and select **Delete Partition...** from the context menu.

5. Click **Yes** in the dialog box that appears to confirm that you wish to delete the partition.

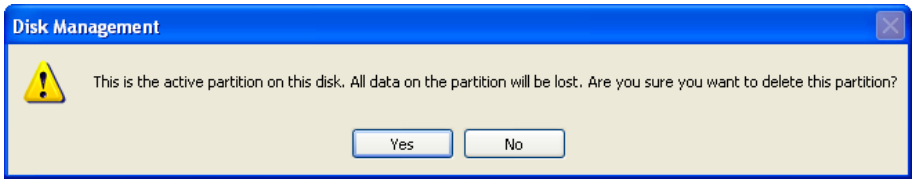

Figure 5-105 Disk Management

6. There is now only a single **unallocated** partition available under **Disk 2** in the Computer Management window.
Selecting the middle partition also automatically deletes the partition on the left-hand side containing the update data.

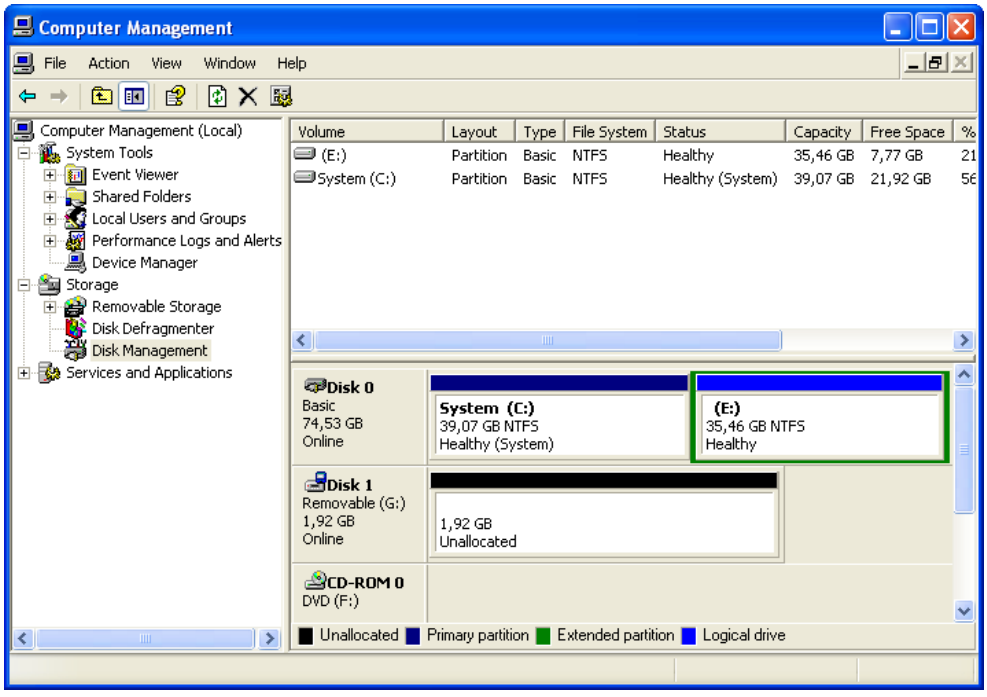

Figure 5-106 Computer Management window

In order to create a new partition, right-click the **unallocated** partition and select **Activate new partition** in the context menu.

7. The **New Partition Wizard** appears.
   Run the wizard, as indicated in the steps below.
   Click **Next** to proceed to the next window.

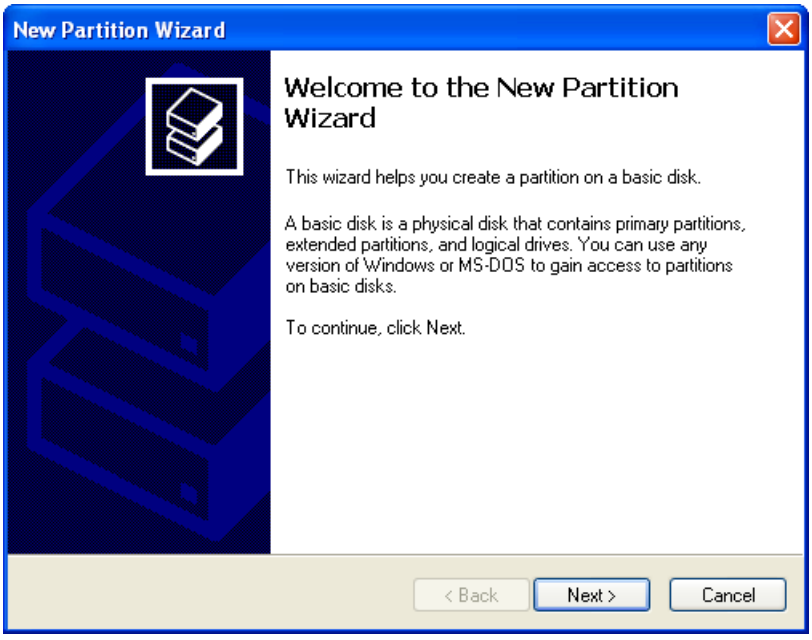

Figure 5-107 "New Partition Wizard" start screen

8. Confirm **Primary partition** as the partition type.

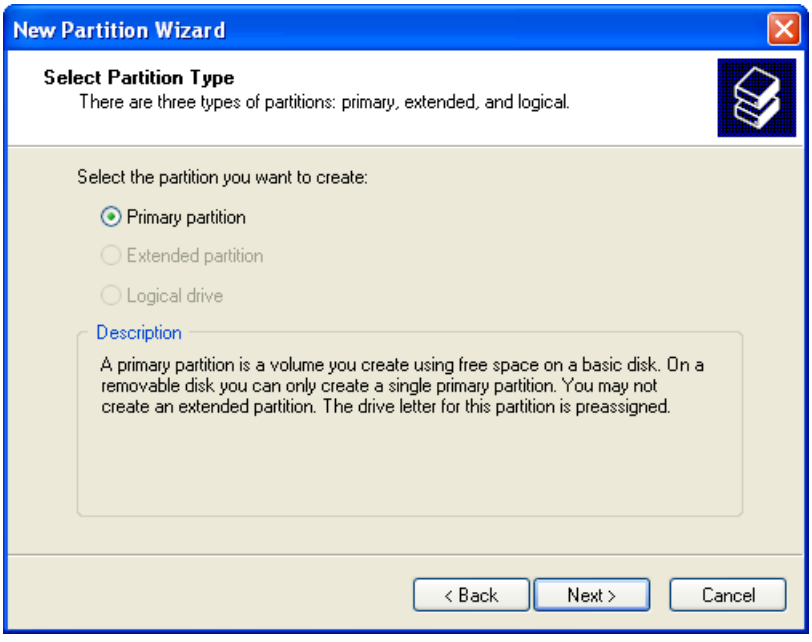

Figure 5-108 Wizard: Defining the partition type

9. Confirm the partition size.

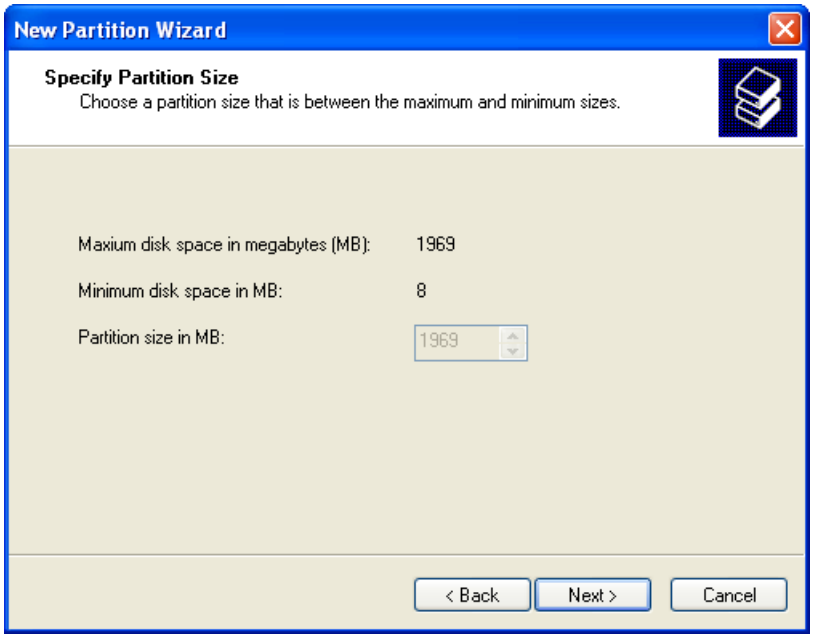

Figure 5-109 Wizard: Defining the partition size

10. Assign the drive into which the USB memory stick is to be inserted.

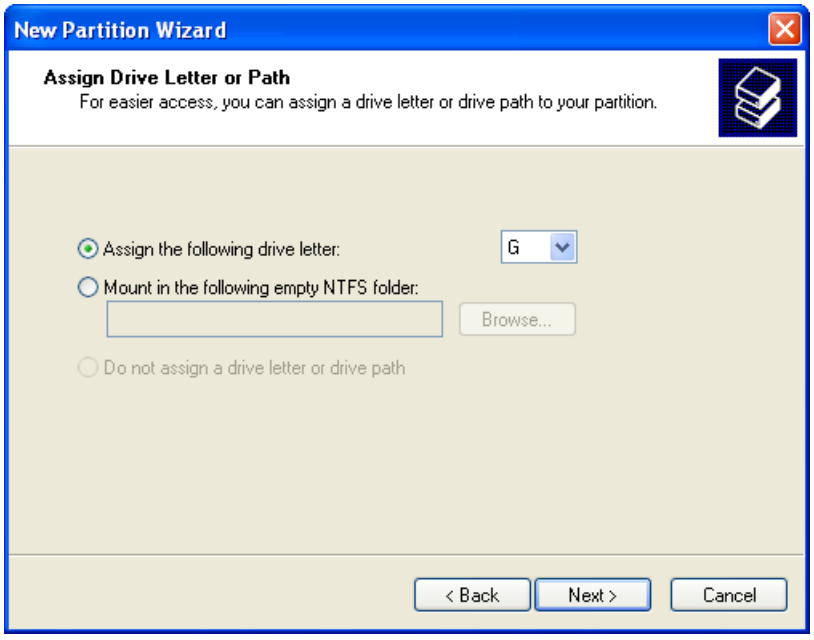

Figure 5-110 Wizard: Assign the drive letter or path.

11. Choose the following settings in order to format the partition:
   - File system to be used: FAT
   - Allocation unit size: Standard
   - Volume identifier: Volume

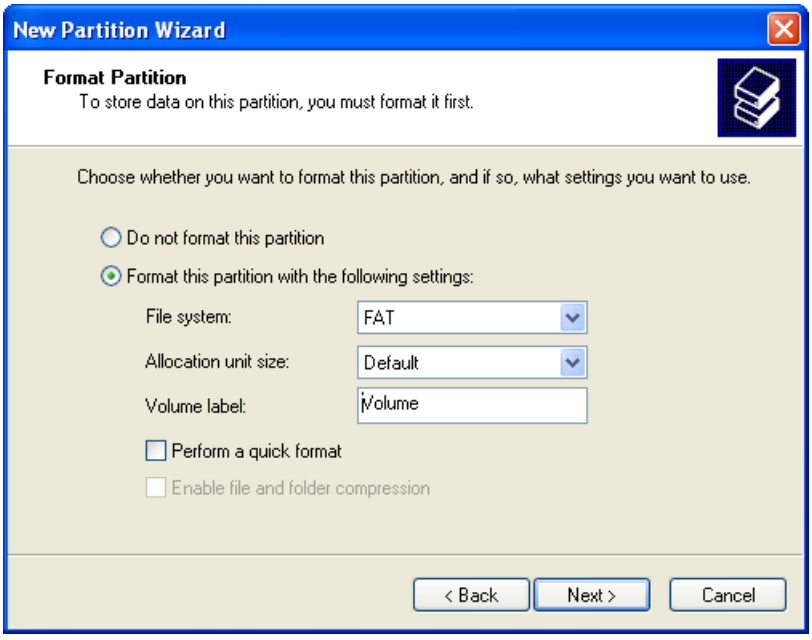

Figure 5-111 Wizard: Format a partition

12. The settings selected are displayed in the closing window for the wizard.
    Click **Finish** to close the wizard.

13. The changed partition appears in the **Computer Management** window under **Disk 2**. The USB memory stick is restored to its original status. The entire memory capacity will now be available again in a partition and displayed in Windows.

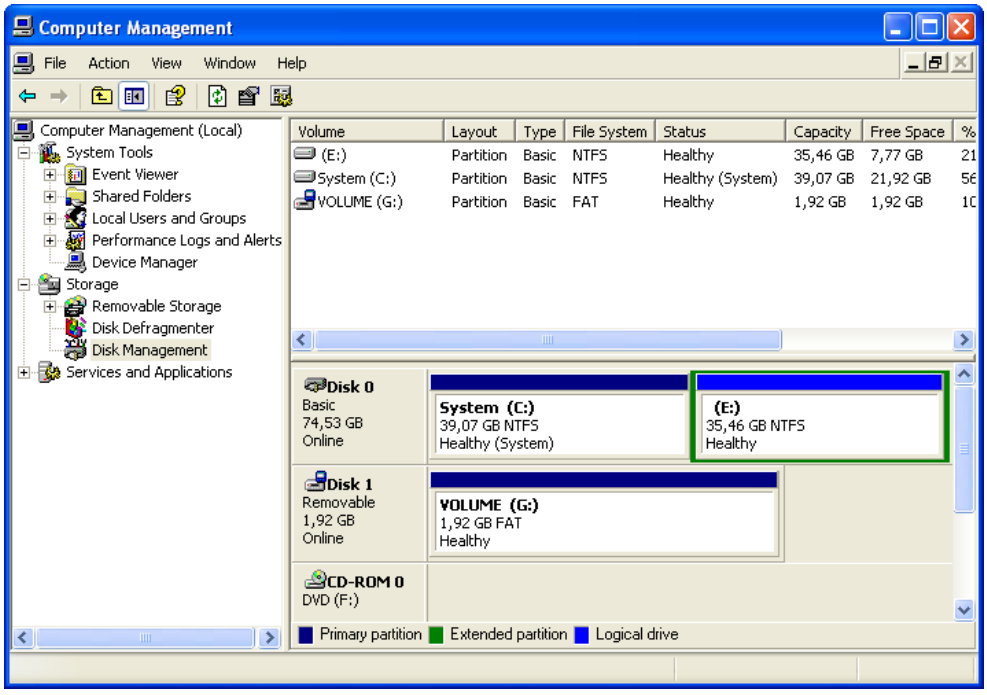

Figure 5-112 Computer Management - View of the newly created partition

SIMOTION IT 6

6.1 SIMOTION IT Diagnostics and Configuration

Preface

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

https://support.industry.siemens.com/cs/ww/en/view/109479653

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

6.1.1 Fundamental safety instructions

6.1.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

6.1.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

6.1.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

6.1.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

6.1.2 Introduction

6.1.2.1 Overview of SIMOTION IT

Overview of SIMOTION IT manuals

The "SIMOTION IT Ethernet-based HMI and diagnostic functions" are described in four manuals (IT = Information Technology):

- **SIMOTION IT Diagnostics and Configuration**
  This present manual describes the direct diagnosis of SIMOTION devices. Access is by means of a standard browser (e.g. Firefox) via the IP address of the SIMOTION device. You can use the standard diagnostic pages or your own HTML pages for access.
- **SIMOTION IT Programming and Web Services**
  This manual describes the creation of user-defined Web pages and access to the diagnostic functions via the two Web services provided by SIMOTION IT.
  A Web service enables users to create their own client applications in any programming language. These applications then communicate with the SIMOTION device using Web technologies. The SOAP (Simple Object Access Protocol) communication protocol is used for transferring commands.
  The manual includes information on programming such clients, as well as a description of the SIMOTION IT Web services (OPC XML-DA, Trace via SOAP TVS) via which data and operating states of the controller can be accessed and the variable trace functions can be used.
  See the SIMOTION IT Programming and Web Services manual.
- **SIMOTION IT Virtual Machine and Servlets**
  This manual describes the Java-based function packages. The Jamaica Virtual Machine (JamaicaVM) is a runtime environment for Java applications on the SIMOTION device. It is an implementation of the "Java Virtual Machine Specification."
  The Servlets section of the manual describes the use of servlets in a SIMOTION device.
  See the SIMOTION IT Virtual Machine and Servlets manual.
- **SIMOTION IT OPC UA**
  The manual describes access to SIMOTION devices via OPC UA.

PDF in the Internet: SIMOTION IT Programming and Web Services (https://support.industry.siemens.com/cs/ww/en/view/109476528)

PDF in the Internet: SIMOTION IT Virtual Machine and Services (https://support.industry.siemens.com/cs/ww/en/view/109476529)

6.1.2.2 Schematic diagram of the function packages in the SIMOTION device

Access to a device with SIMOTION IT

SIMOTION IT allows HTTP/S access to a device by several means, which are shown in the diagram.

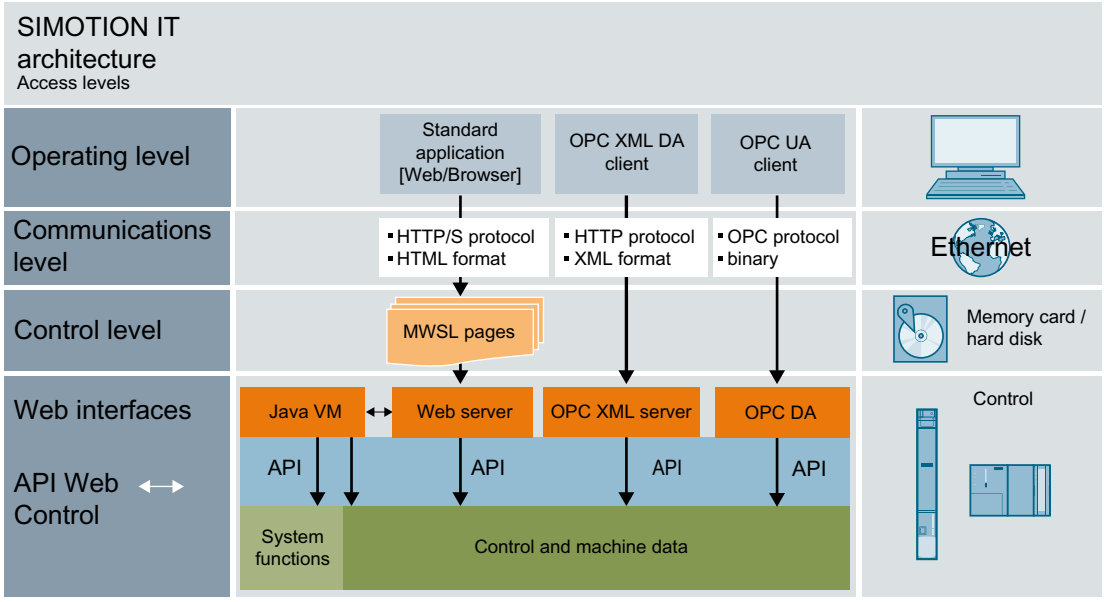

Figure 6-1 SIMOTION IT architecture of the HTTP/S access levels

The Web server of the SIMOTION controller is called Miniweb-Server.

Representation of the function packages

The following figure is a schematic diagram of the function packages in the SIMOTION device.

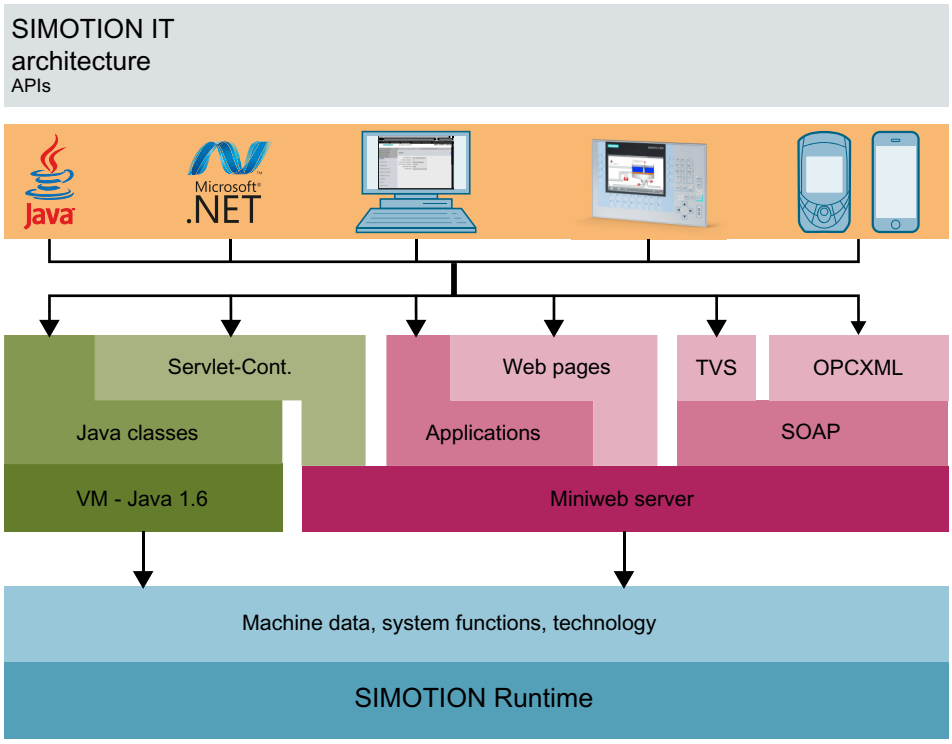

Figure 6-2 SIMOTION IT architecture of the APIs

As further access possibility to the SIMOTION controller, OPC UA access has been added as of version 4.5.

6.1.2.3 Form of delivery

Form of delivery

"SIMOTION IT Ethernet-based HMI and Diagnostic Functions" are included in the controller firmware.

Note

The functionality must be activated in the SIMOTION SCOUT project in the hardware configuration of the controller. You can activate the Web server services in the hardware configuration on the "Ethernet extended / Web server" tab in the object properties of the controller. Further information about project settings is contained in the "Activating communications services in SCOUT Classic" section.

The "Activating communications services in SCOUT TIA" section describes how the Web server can be activated in the TIA Portal.

Documentation, tools, examples, and configuration files

The documentation, tools, examples, configuration files and other supplementary features are available on the "Documentation, Utilities & Applications" DVD.

Runtime licenses before Version 4.2

The older versions require an OPC XML-DA single-user license for access to the Watch page, for example.

When any of these pages is opened, the following is displayed:

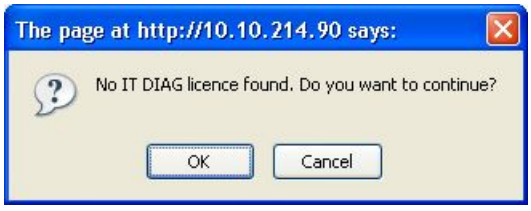

Figure 6-3 Warning - Missing license

Clicking the **OK** button opens the requested page. You can thus continue even without a license. However, an entry is made in the diagnostic buffer and the error LED on the controller starts to flash.

6.1.2.4 Possible applications

Standard information

Application of diagnostic pages

The Web pages from SIMOTION IT provide information on a SIMOTION device. The information is accessed via the Web browser and the Ethernet.

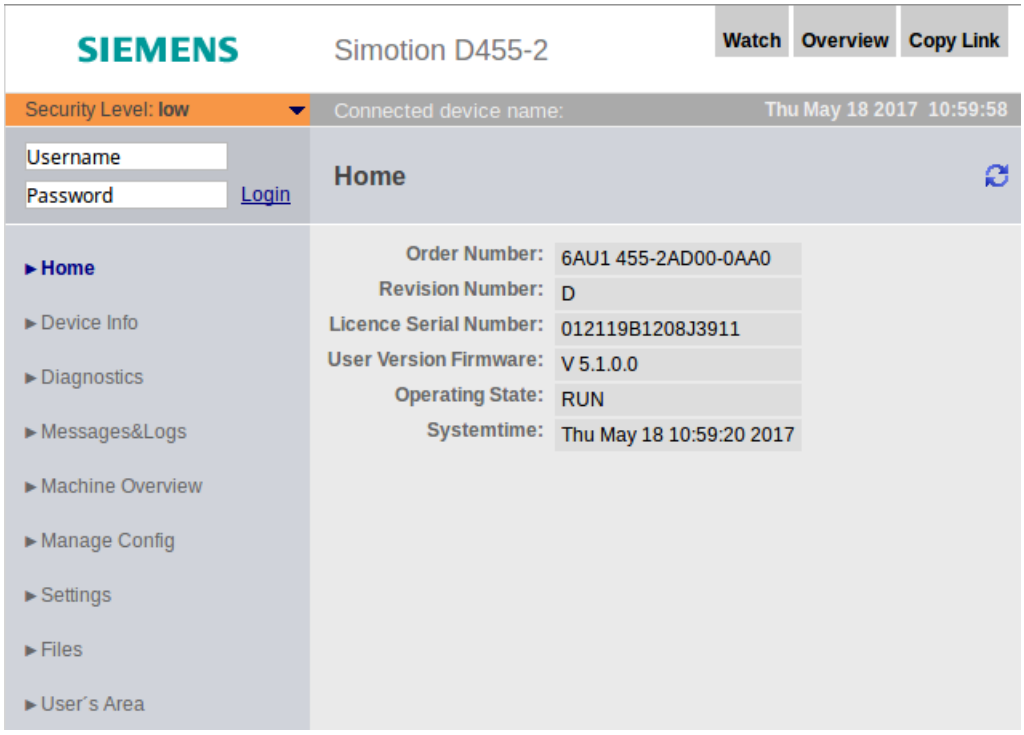

Figure 6-4 Home

The SIMOTION device is connected to the local Ethernet for this purpose. Diagnostic pages can then be accessed from any computer in the network using the IP address of the device.

HTTPS connections are also supported. The HTTPS connection should be used where possible because, with HTTP, the login and passwords are not encrypted for transmission.

The use of SIMOTION IT standard pages does not require a special installation. The device is already appropriately set up.

Security concept (Page 3569)

Log-in administration (Page 3658)

TLS/SSL certificates (Page 3574)

Secure Socket Layer (Page 3702)

User-defined information

Displaying information in user-defined pages

In addition to displaying the standard pages, SIMOTION IT allows you to create your own Web pages. The *SIMOTION IT Programming and Web Services* manual describes the methods for creating your own Web pages.

With the aid of a JavaScript library, device data can be queried and displayed in a Web page.

A further option is the use of the MiniWeb Server Language (MWSL). This is a language based on an ECMA script that is executed on the server side.

The "variable providers" can be used to read and write the following information on a Web page:

- System variables of the SIMOTION device
- System variables and configuration data of the technology objects
- Global unit variables
- Drive parameters
- I/O variables
- Global device variables
- Connection monitoring

User-defined pages provide numerous options for displaying device information.

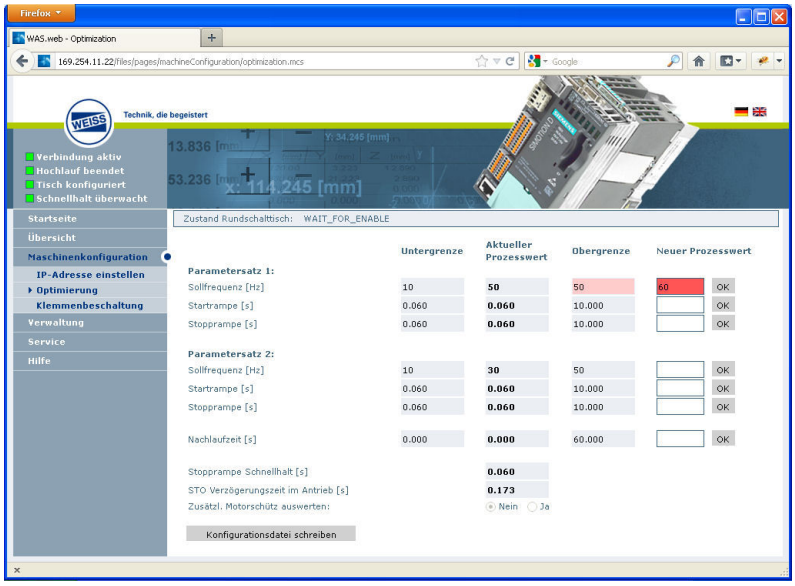

Figure 6-5 Example of a user-defined SIMOTION IT Web page of WEISS GmbH

MWSL

The MWSL is executed on the server side. It enables the creation of dynamic HTML code on Web pages. You can also use the MWSL if the created pages are displayed on devices that do not support JavaScript. Variable functions can be executed faster and more directly (closer to the system) than when using JavaScript.

Note, however, that the MWSL code evaluation requires server resources. For loaded controllers, this code evaluation can take a long time, and delay other Web processes and Web queries.

JavaScript

SIMOTION IT supports you in creating dynamic and flexible Web pages thanks to an extensive JavaScript library. Unlike MWSL, JavaScript runs in the browser. The use of JavaScript relieves the load on the controller and provides considerably more options than the MWSL. For display purposes, however, a modern browser with corresponding JavaScript support is required; this is something that cannot be guaranteed in all automation environments.

6.1.2.5 New features

Overview of the innovations

Version 5.2

- Cross Site Request Forgery (CSFR) Protection. Prevention of non-authorized HTTP requests.Cross Site Request Forgery (CSFR) (Page 3673)
  The activation of the CSFR protection has major effects and requires customizations for some accesses to the Web server. CSFR protection affects:
  - User-created Web pages
  - OpcXml DA in Web pages and external clients
  - POST/GET requests in Java applications and servlets
- Service selector switch position "8" receives a time-controlled disconnection. Resetting the security level from normal to low (Page 3569)

Version 5.1

- Encrypted connections are possible only as of TLS 1.2. Encryption (Page 3574)
- For security reasons, access to the file system is possible only with Javascript. The **Files** Web page uses a new File Manager for displaying the file system.

Version 4.5

- OPC UA server. The OPC UA server is described in the SIMOTION IT OPC UA manual.
- Separate authentication for read and write accesses for OPC XML.
- Revised WebCfg.xml.

Version 4.4

- Security concept (Security Level)
- Revised login administration (Page 3658). Separate storage of user data in file UserDataBase.xml. New page Users & Passwords (Page 3630) for editing user data.
- New version of the MiniWeb
- Output of messages by the messaging system on the SIMOTION IT pages without an adverse impact on processing.
- New display formats for floating-point numbers in the Watch (Page 3589) table
- New variables provider ITDiag
- Traces (WTRC files) can now be loaded and displayed in SIMOTION SCOUT.

6.1.3 Commissioning

6.1.3.1 Hardware and software requirements

Hardware requirements

- SIMOTION device
- Web-enabled device such as PC, notebook, smartphone with a minimum resolution of 320x240 pixels.

Software requirements

- Browser: Firefox as of version 3, Microsoft Internet Explorer as of version 11 and Microsoft Edge.

6.1.3.2 Activating communications services in SCOUT Classic

Activating the SIMOTION IT Web server in HW Config

The Web server of the SIMOTION controller can be activated in the HW Config. To do that, navigate via **Device object properties** to the **Ethernet extended / Web server** tab.

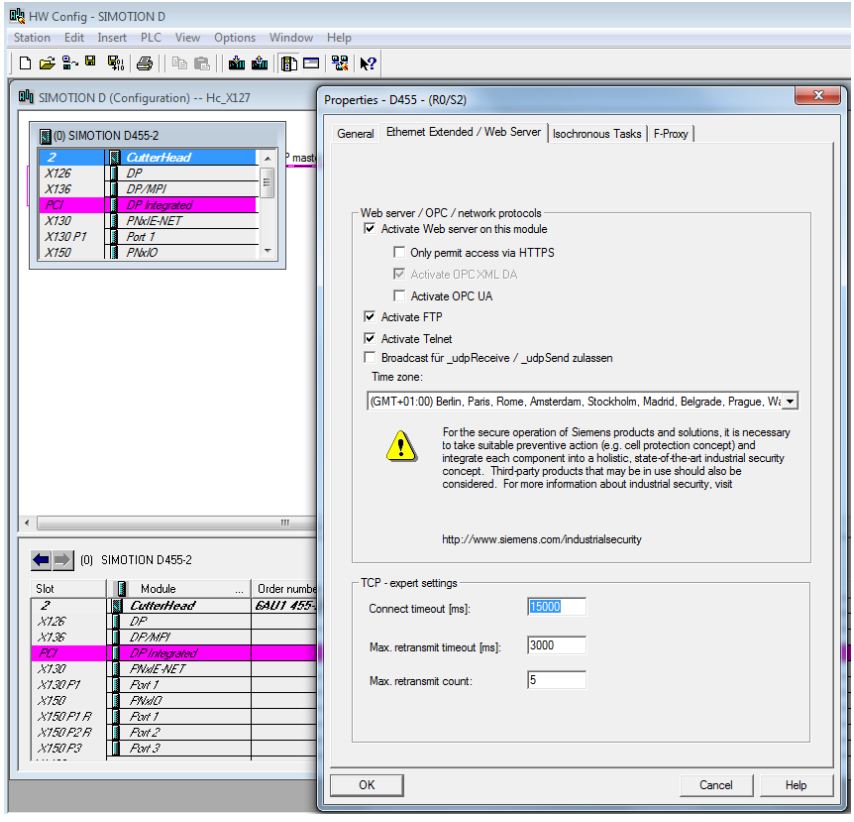

Figure 6-6 HW Config settings

The screenshot shows the default Web server settings. When you deactivate a service, the corresponding communications port is closed. If no service is activated, the Web server of the controller is also deactivated.

The Web server is addressed via HTTP/S. FTP and Telnet are connected only to the user administration. OPC UA activates the OPC UA access to the Web server.

Service	Port
HTTP (Browser, OPC XML)	Setting in the WebCfg.xml – default 80
HTTPS (Browser, OPC XML)	Setting in the WebCfg.xml – default 443
OPC UA	Setting in WebCfg.xml – in the URL attribute of the <END-POINTDESCRIPTION> tag.
FTP	21
Telnet	23

Setting the time zone

The applicable time zone of the Web server can be set in two ways. One possible way is the setting shown in the screenshot made via the drop-down list in the HW Config dialog.

The second way is to make the setting in the Web page **Settings**. In this case, the value from the HW Config dialog will be ignored.

Calling up HW Config from SCOUT

In SCOUT, you can access the settings in HW Config via **Gerät > Eigenschaften > Einstellungen** with the link **Web server settings in HW Config**.

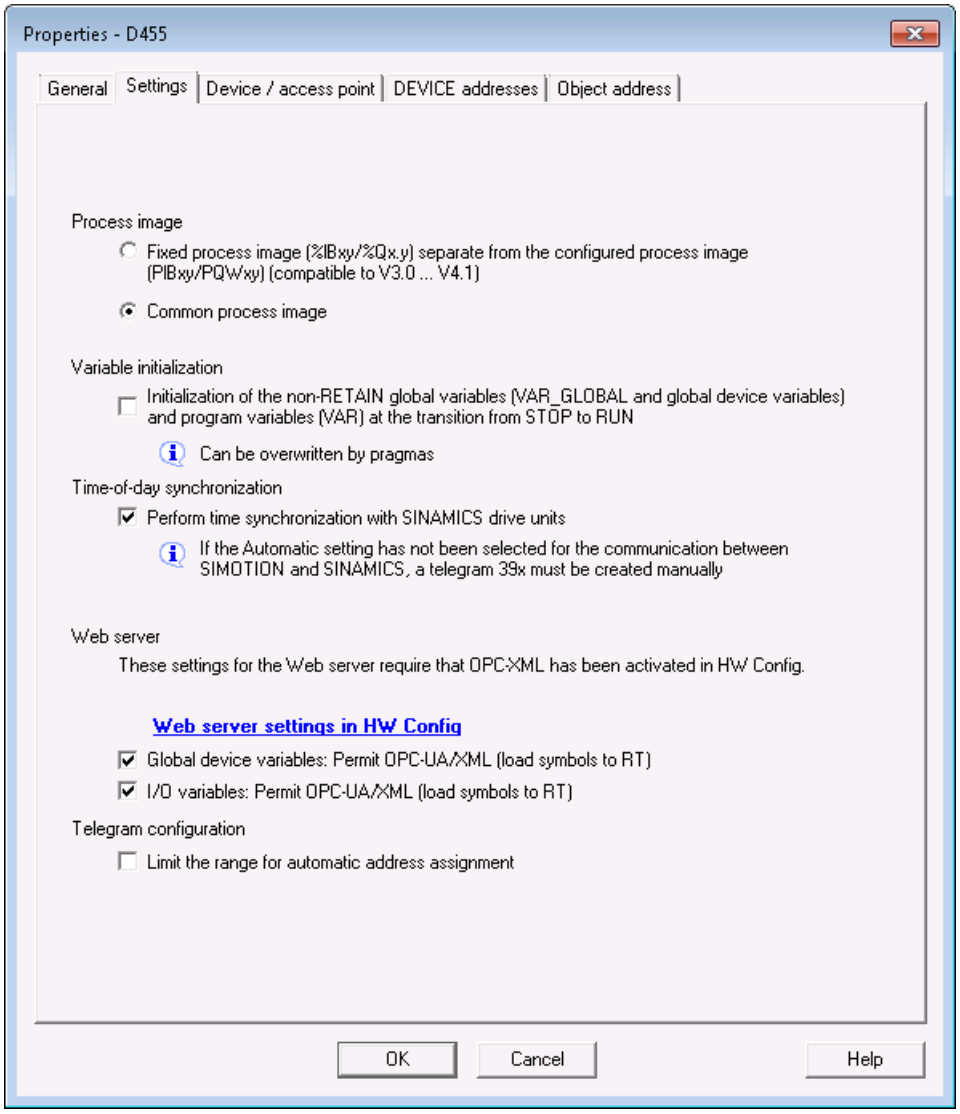

Figure 6-7 SCOUT connection to HW Config

Settings (Page 3639)

6.1.3.3 Activating communications services in SCOUT TIA

Procedure

To activate the Web server in the TIA Portal, proceed as follows:

1. Select the SIMOTION device in the network view / device view.
2. In the Inspector window, select the "Properties" tab and click the "General" tab.
3. Select "Web server / OPC / Network protocols".
   The Web server is deactivated in the basic setting. You must activate the relevant checkboxes so that the CPU displays the Web pages.

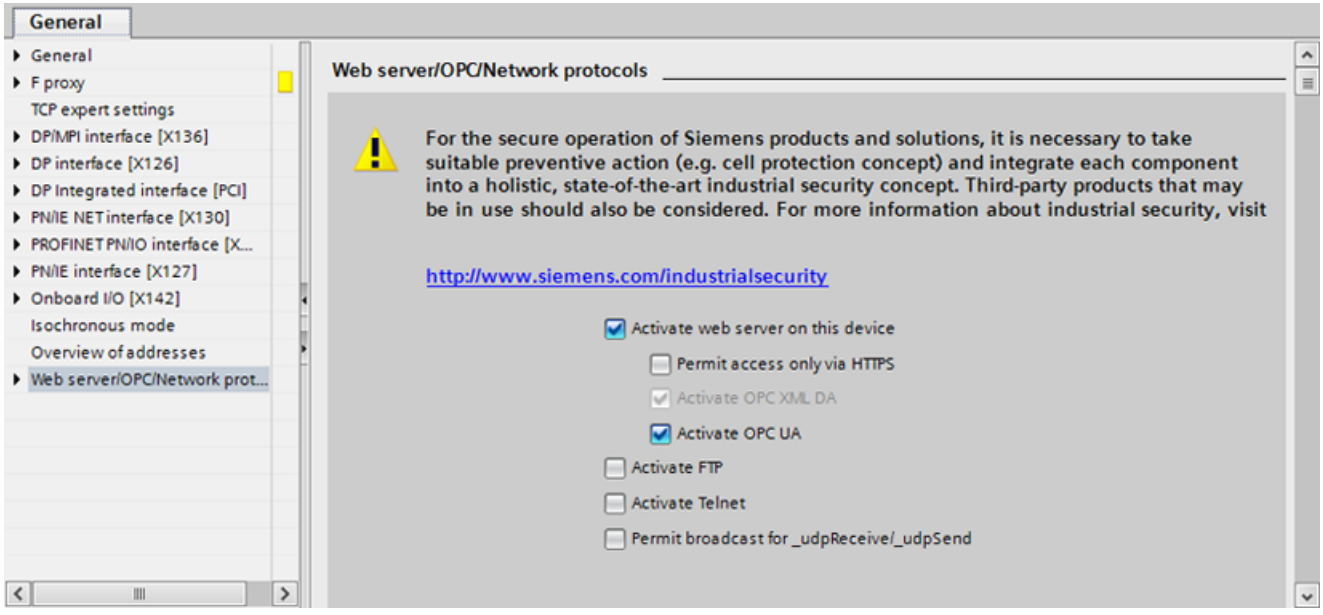

Figure 6-8 Activating the Web server

The Web server is addressed via HTTP/S. FTP and Telnet are connected only to the user administration. OPC UA activates the OPC UA access to the Web server.

Displaying SIMOTION websites in TIA Portal WinCC CA

To use the WebBrowserControl (HTML web browser), activate "ScrollViewer" mode in TIA Portal in the runtime settings of the HMI device. To do this, follow these steps:
Under "Runtime settings > Screens > Scrolling in Controls", select the "ScrollViewer" scrolling mode.

Note

Only the HTML web browser based on the WebKit engine works in connection with SIMOTION Web server. Error messages may occur in the HTML web browser with ActiveX support.

- Navigate to the HTML web browser type and choose the setting "Web browser based on a WebKit engine".

Calling the HW Config from SIMOTION SCOUT TIA

You can switch directly to the appropriate tab of the Inspector window in the TIA Portal via SIMOTION SCOUT TIA.

Proceed as follows:

1. Select the SIMOTION device in the project navigator.
2. Select the "Properties" entry in the context menu.
   The "Properties" dialog box opens.
3. Switch to the "Settings" tab and click the "Web server settings in HW Config" link.
   You can now make the web server settings in the TIA Portal.

See also

Activating communications services in SCOUT Classic (Page 3564)

6.1.3.4 Configuring the SIMOTION device interface

Configuration of the Ethernet interface

SIMOTION IT can be accessed via any Ethernet interface used with SIMOTION, including the PROFINET IO interface.

To establish a connection between the standard diagnostics pages and a SIMOTION device via a browser, the following steps for configuring the Ethernet interface must be performed:

Table 6-1 Configuring the interface

Step	Procedure
1	The functionality must be activated in the SIMOTION SCOUT project in the hardware configuration of the CPU. You can activate the relevant services in the hardware configuration on the "Ethernet extended / Web server" tab in the object properties of the CPU. As of V4.1.2, HTTP/S, FTP and Telnet are activated in the delivery state. In TIA Portal, the services are disabled by default.
2	SIMOTION IT uses a user database called UserDataBase.xml to control access to the device. If no user database is found on the device, an empty user database is created when the controller starts up. You cannot login until a user has been created. See Log-in administration (Page 3658)
3	To display the standard diagnostics pages in the browser, you must enter the IP address of the SIMOTION device, e.g. http://169.254.11.22. The preset IP addresses are documented in the manuals for the respective controls. This factory setting can be changed in the HW Config and then loaded to the SIMOTION device.

Note

This requires suitable protective measures (e.g. network segmentation for IT security) to ensure safe system operation. You can find more information on Industrial Security on the Internet at:

www.siemens.de/industrialsecurity.

6.1.3.5 Security concept

Safety concept HTTP/S, FTP and Telnet access

As of version V4.4, access to the SIMOTION IT Web server is protected by a multi-level security concept.

The security state of the Web server is indicated by the Security Level on the Web page. This Security Level can have three different levels: Low, Normal, High.

Security Level Low

The device is supplied with an empty user database. No project exists yet on the device. The security level is low to allow configuration of the device.

Note

As of V5.3 SP1 HF4, the Telnet access has been changed by default.

1. Telnet remains activated after loading the firmware.
2. When a new project is created, Telnet is deactivated in the hardware configuration by default. This means that Telnet is deactivated on the CPU after first loading a new project.

This change only affects SIMOTION SCOUT. In SCOUT TIA, Telnet is deactivated by default as previously.

- In this state, access to the Web server as an anonymous user is possible. Functions, such as project and firmware update or OPC XML, are consequently available.
- FTP access is open.
- New users can be entered in the empty user database.

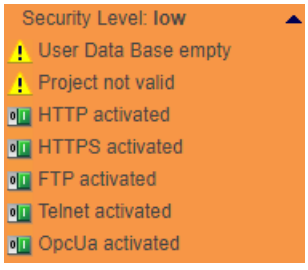

Figure 6-9 Security Level Low

In this state, series commissioning is possible via the Web server.

NOTICE
Protecting the device Security Level Low security level should only be used for commissioning and service as otherwise the device is not adequately access protected.

Security Level Normal

The controller has a user database. A project exists on the controller and HTTP, HTTPS, FTP, and Telnet are activated in HW Config.

- User password authentication is mandatory for access to Web pages with sensitive content (e.g. firmware update, watch table, ...), FTP and Telnet.

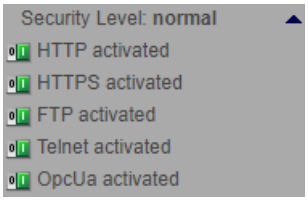

Figure 6-10 Security Level Normal

Security Level High

High security with maximum access protection:

- HTTP, HTTPS, FTP and Telnet were activated via the project in HW Config. Access to the Ethernet via the various ports of the services is then no longer possible. The Web server cannot be used.

Authentication

Many different access scenarios are made possible by the various security levels.

Table 6-2 Access control Security Level Low

	HTTP/S Web pages without authorization	HTTP/S Web pages with authorization	FTP	Telnet
No project exists on the controller and service selector switch not in position "8"				
No user in UserDataBase.xml	Access permitted	Access permitted	Access permitted	Access permitted
Whether or not the project exists on the controller and service selector switch in position "8"				
No user in UserDataBase.xml	Access permitted	Access permitted	Access permitted	Access permitted
User exists in UserDataBase.xml	Access permitted	Access permitted	Access permitted	Access permitted

Table 6-3 Access control Security Level Normal

	HTTP/S Web pages without authorization	HTTP/S Web pages with authorization	FTP	Telnet
No project exists on the controller and service selector switch not in position "8"				
User exists in UserDataBase.xml	Access permitted	Password	Password	Password
Project exists on the controller, the appropriate checkboxes are activated in HW Config and service selector switch not in position "8" If a checkbox has not been activated in HW Config, access to the port of the respective service is denied.				
No user in UserDataBase.xml	Access permitted	Password*	Password*	Password*
User exists in UserDataBase.xml	Access permitted	Password	Password	Password

Password = access only after authentication

Password* = login is not possible because there is no entry in UserDataBase.xml.

Table 6-4 Access control Security Level High

	HTTP/S Web pages without authorization	HTTP/S Web pages with authorization	FTP	Telnet
Project exists, but checkbox for HTTP/S, FTP and Telnet not activated in HW Config. Access to the controller via HTTP/SS, FTP and Telnet is locked.				
	Access blocked	Access blocked	Access blocked	Access blocked

State transition from Security Level Low to Normal

On receipt of the device on delivery, the user creates a project and loads it onto the device. This can be done by using the download functions of the SCOUT, by loading it directly onto the memory card, or via the Web page Manage Config.

Whichever method is used, a project download to the device from the point of view of the Web server corresponds to a transition from **Security Level Low** to **Security Level Normal**.

Resetting the security level from Normal to Low

If the user forgets to edit the UserDataBase.xml during initial commissioning, it will no longer be possible to access FTP, Web services, or access-protected pages during use.

In order to be able to subsequently configure the Web server, **Security Level Low** must be restored. Various methods are available for this purpose:

If there is no mechanical access to the memory card or the device, this can be achieved with the SCOUT function "Delete user data on card". After setting up the user administration, the project must be downloaded again.

Alternatives without SCOUT

Setting the service selector switch to position "8" restores **Security Level Low**. Using this method, the device can always be reset to **Security Level low** by hardware means.

This function of the switch is envisaged only for commissioning purposes and should not be used permanently in normal operation. As of V5.2, the switch position is handled as follows:

- If the switch is already set to "8" at ramp-up, it is ignored.
- The service mode stops immediately when position "8" is exited.
- For safety reasons, a time-controlled disconnection of the service selector switch is performed in position "8". Service mode ends after 120 minutes.
- It is possible to retrigger the disconnection at any time by turning the switch briefly from "8" to "7" and back, for example.
- An LED signal indicates the service mode. For SIMOTION D4X5-2, the service mode causes a slow red flashing of the SF LED.

Because only SIMOTION D modules are fitted with a service selector switch, this functionality is implemented on other SIMOTION modules by making an entry in the simotion.ini file. This requires that the `SERVICE_SELECTOR_MODE=8` entry is set.

For SIMOTION P modules, the PSTATE program is provided for this purpose.

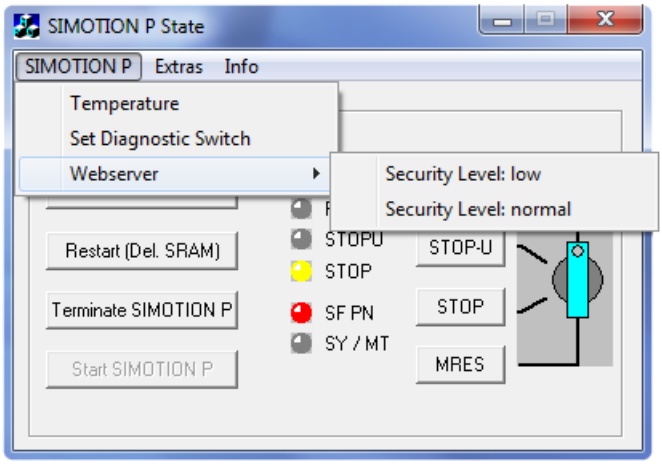

Figure 6-11 SIMOTION P state

Changing the simotion.ini or the setting of the status via the SIMOTION P menu as described above is interpreted as being an intentional action during the commissioning. The service mode is indicated on the Web page.

Note

SSL certificate

Replace the server certificate of the controller with your own to protect HTTPS access.

Note

The availability of the OPC UA server

The availability of the OPC UA server depends on the security level. This means that (similar to security level "normal") the OPC UA server is only accessible even in the "low" security level if:

- The OPC UA is activated in the HW configuration and
- OPC UA is activated in SIMOTION IT (Manage Config -> SIMOTION IT -> OPC UA)

See also

Activating communications services in SCOUT Classic (Page 3564)

TLS/SSL certificates (Page 3574)

Creating key files with the script cert.pl (V4.1 and higher) (Page 3704)

6.1.3.6 User administration

User database UserDataBase.xml

For secure access to the SIMOTION IT pages, users must be created in the user database. Users and groups are stored in file UserDataBase.xml.

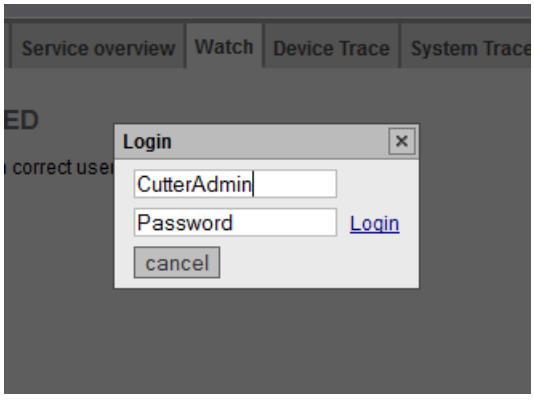

Figure 6-12 Login dialog

The web page Mange Config > SIMOTION IT > Users & Passwords allows user data to be edited in the browser. Alternatively, the file can also be edited offline and then sent to the control.

Chapter Login administration (Page 3658) describes how a user database is set up and edited.

6.1.3.7 Encryption

HTTPS connection with TLS 1.2 and SHA-2

Since the beginning of year 2017, all popular browsers issue an error message when an attempt is made to establish a connection from SHA-1. Consequently, the Web server permits only connections with encryption protocol as of TLS 1.2. SHA-2 functions are used to generate the hash code.

The RSA encryption is replaced by methods of the elliptic curve cryptography. SHA-512 or later is used as hash function.

If the required server certificates are not available, they are generated by the Web server.

Users are provided with Default Root certificates that are also created with SHA-512.

6.1.3.8 TLS/SSL certificates

Securing HTTPS access

Certificates

Certificates must be generated and installed to perform encrypted communication between the browser and Web server.

The as-delivered state includes a device with a standard server certificate and a private key of the Web server provided as a file. These files should be replaced with your own to increase the security of HTTPS access to the device.

There are two ways of acquiring your own server certificate:

- Create a server certificate (self-signed) and a private key using certificate software (e.g. OpenSSL)
- Purchase a server certificate from a certificate authority

On establishing a connection to the Web server, the firmware creates a new server certificate from the root certificate and the private key, if none exists. The server certificate is individualized for the IP address of the interface used for the communication.

Self-signed certificate

When the user makes a connection via HTTPS with the SIMOTION on which the self-signed certificate was stored, the server sends the server certificate belonging to that interface using the SSL protocol.

Browsers will now display a warning that an attempt is being made to communicate via an untrustworthy certificate.

The user can load and install the server certificate via a link to the browser. From now on, the browser is known to the signing certificate authority and no more warnings appear.

Server certificate of a certificate authority

If a certificate of a certificate authority is preinstalled in the browser, the connection is established without a warning message because the certificates are preinstalled in the browser.

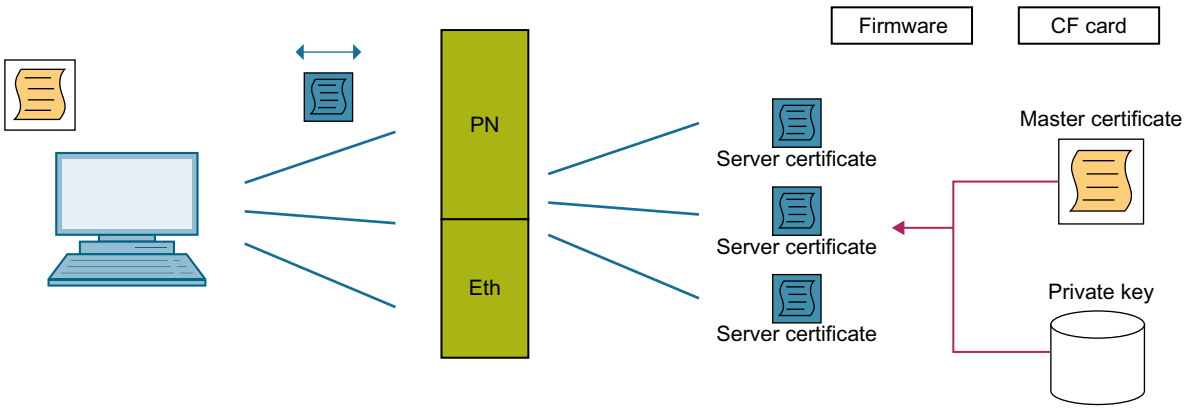

Figure 6-13 Certificate handling concept

Secure Socket Layer (Page 3702)

6.1.3.9 Setting the language for AlarmS and user-defined diagnostics buffer messages

Any of the SIMOTION SCOUT languages can be used when setting the language for AlarmS and user-defined diagnostics buffer messages.

Language localization

SIMOTION IT uses four rules for language selection. The first rule that applies is used:

1. Configuration constant ForceUserMsgLanguageID

The language can be set with the configuration constant `ForceUserMsgLanguageID`. This variable is set to the corresponding country code (decimal value) for this purpose. The selected language must exist. If it does not, the HEX display is used.

To change the AlarmS language setting, change the configuration constant "ForceUserMsgLanguageID".

- Activate the set language selection. To do this, upload the user-defined AlarmS and diagnostic buffer messages exported from SCOUT to the CPU again.

You will find more information about the configuration constants in section *Configuration constants* in the *SIMOTION IT Programming and Web Services* Manual. The LCID country codes (Page 3735) are listed in the appendix.

2. SIMOTION SCOUT-Export

Performing a SCOUT export of user-defined AlarmS and diagnostic buffer messages and then uploading (Page 3636) this data, sets the SIMOTION IT language to the same language as is set in SCOUT.

3. Language of system diagnostics buffer texts

An attempt is made to find the language that matches the installed system diagnostics buffer texts.

4. Other language settings

If no matching language is found among the system diagnostics buffer texts, the system default language is selected instead.

The language which has been selected is documented in the syslog file.

6.1.3.10 Access protection

Description

The TO configuration contains essential machine configurations (e.g. axis settings, cams, coupling types, controller settings, etc.).

With access protection enabled it is possible to prevent read back of the TO configuration, the cams, the SIMOTION device configuration and the SINAMICS drive data as follows:

- Data can only be uploaded from the controller with a password.

- Data can only be read out with the web server with a password

- Data cannot be read/analyzed from a CF card without a password

Note

The extended functionality results in improved access protection for the configuration of the TO configuration.

As a further security measure, the user should ensure that unauthorized persons have no access to the memory card.

Management

- Access protection is based on SIMOTION IT and is managed via SIMOTION IT.
  If access protection is not yet active, a new password can be defined on the "Access protection" page.
  Defining the password sets up read protection for the project data on the card in the background. The current page is then re-loaded.
- If access protection has already been set up and is active (i.e. you have not yet successfully authorized yourself against the access protection), a login page is loaded.
- If access protection has already been set up and you have successfully authorized yourself against the access protection, you have the options to remove the access protection (read protection of project data on the card is removed), change the password, or activate the access protection (lock SIMOTION IT and project). The previous password does not have to be entered again.

  Note

  If you want to remove the access protection and the access protection password is not known, you must delete the entire card and reload the Siemens card image. It is not sufficient to delete the USER directory.

Scope of access protection

The following are locked without authorization with the correct password:

- IT Diag
- FTP (even when enabled in HW Config)
- OPC UA (even when enabled in HW Config)
- Upload from SCOUT
- Access protection is retained with switch position 8

Read protection of project data

To protect the TO data (axes, cams, ...), the project data on the card is protected against being read out. As a result, the following use cases are not supported when access protection is active:

- Upgrade using device update tool
- System function _activateConfiguration() (modular machine)

Authorization

The authorization is lost during a reset if you authorize yourself at the access protection and then perform a download with reset in this state.

Authorize yourself again after the controller has restarted. Only then can the SCOUT establish a new online connection and continue the download.

6.1.4 Operation (software)

6.1.4.1 SIMOTION IT Diagnostics overview and general functions

Overview

The SIMOTION device manages predefined diagnostic standard pages. These pages can be displayed using a generally available browser via Ethernet.

SIMOTION IT can be accessed via all available Ethernet interfaces of SIMOTION, including the PROFINET IO interface.

You can also create your own HTML pages and integrate servicing and diagnostics information.

Purpose and benefits

The purpose and benefits of HTML diagnostics pages are as follows:

- Preconfigured diagnostics pages are available to the user for the direct diagnosis of the SIMOTION device.
- Service and diagnostics information of the device can be accessed without manufacturer-specific programs to assist in production monitoring or diagnostics.
- User-defined HTML pages can be integrated.

6.1.4.2 SIMOTION IT log-on and log-off

Log on

If the control is in security level **Normal**, it is necessary to log on to access the protected pages of the control.

Figure 6-14 Login without registration

Login will only be successful if the associated password has been created in the User administration (Page 3658).

Figure 6-15 Login with registration

See also

Security concept (Page 3569)

Logging off

Logout from SIMOTION IT is performed via the **Logout** link in the login area.

Note

Exiting the browser without logout

Exiting the browser without logout results in the session remaining active on the server for another 5 minutes before it is closed. The technical reason for this behavior is the FormBased Authentication.

This behavior can be improved by deleting the cookies after closing the browser.

6.1.4.3 Standard pages

General links

Each SIMOTION IT page includes three general links:

Figure 6-16 General links

- "Watch" gives you access to the watch function (Page 3589).
- "Overview" displays in the service overview (Page 3586).
- "Copy Link" copies the URL of the current page to the clipboard.

Watch link

The Watch link provides fast access to the Watch page in a separate browser window.

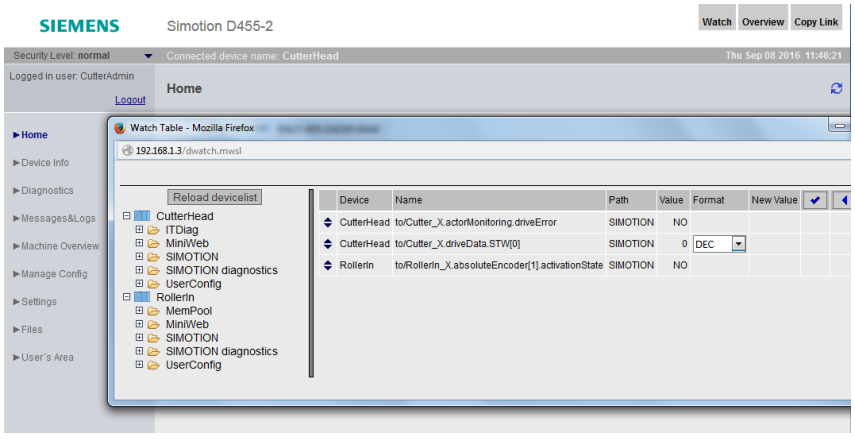

Figure 6-17 Watch link

Overview link

The Overview link calls the Overview page in a separate browser window.

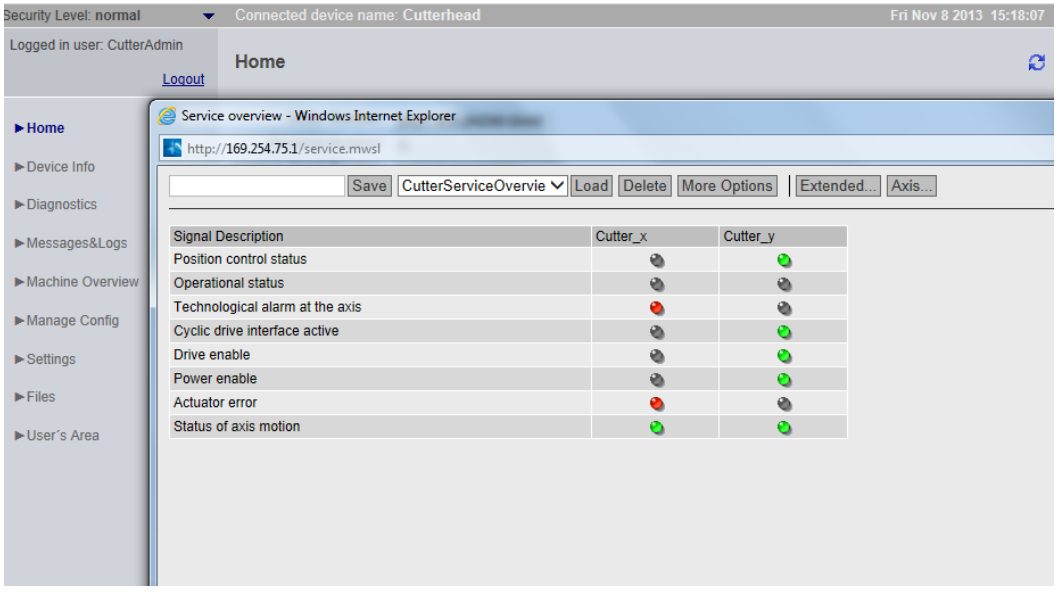

Figure 6-18 Overview link

Copy Link

The **Copy Link** copies the URL of the current page to the clipboard.

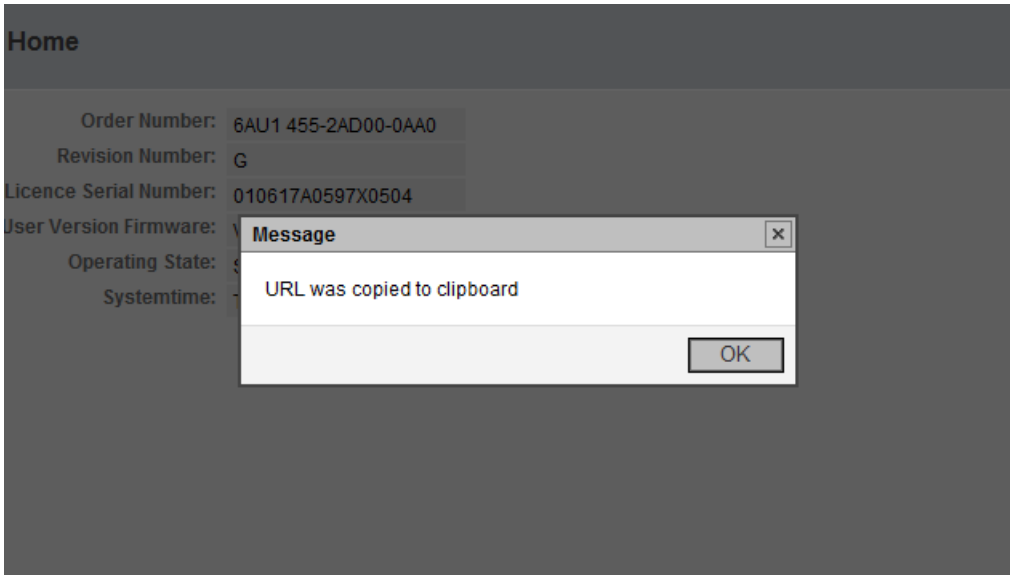

Figure 6-19 Copy link Internet Explorer

The screenshot shows the Internet Explorer message. In Firefox, another dialog opens that allows the link to be copied manually with **Ctrl+C**.

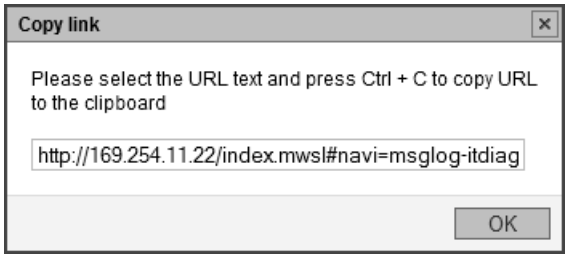

Figure 6-20 Copy link Firefox

Message system

The message system of SIMOTION IT shows additional information as pop-up messages at the bottom right-hand edge of a page.

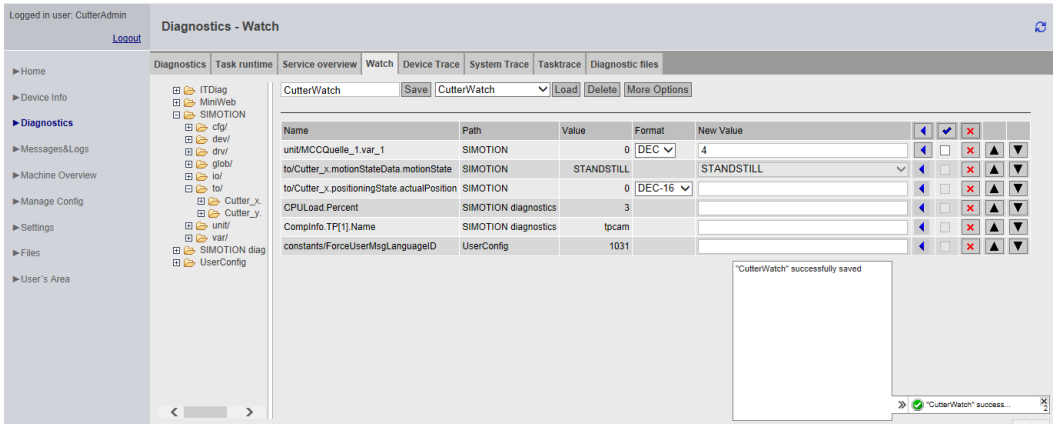

Figure 6-21 Message system example

The message system displays additional information. In this example, successful storage of the Watch settings is displayed as "CutterWatch".

Processing is not interrupted when a message is displayed. The numeric value **2** in the above example shows the time in seconds that the message remains visible.

Home

SIMOTION device data

The following current data of the SIMOTION device is displayed on the home page:

Order Number	Article number of the device
Revision Number	Hardware version
Licence Serial Number	The license key is tied to this serial number
User Version Firmware	SIMOTION kernel user version
Operating State	Operating state of the SIMOTION device RUN, STOP, STOPU
Systemtime	Current time-of-day of the SIMOTION device

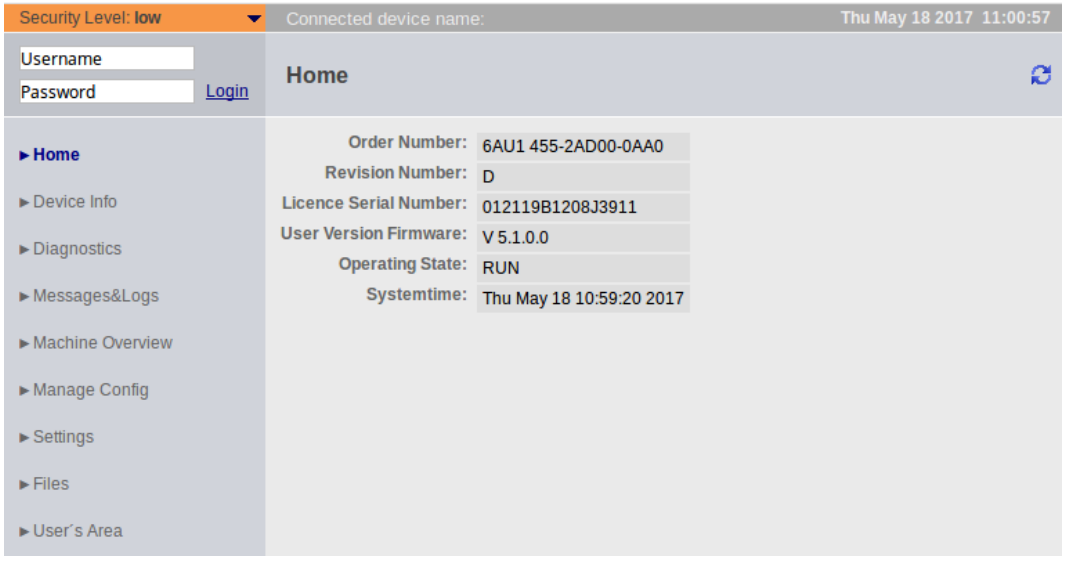

Figure 6-22 Home page

The screenshot shows the appearance of the Home page before a user or password has been created in the `UserDataBase.xml` user database.

An empty user database causes security level **Security Level low** if no project exists already on the controller. You can access the page where you create the user and passwords via the **User & Passwords** link. All subsequent screenshots show the SIMOTION IT pages after login of the user CutterAdmin and security level **Security Level normal**. The user CutterAdmin is used in the manual as an example and accordingly must exist the user database.

For more information regarding the current device data, refer to the "Device Info (Page 3582)" page.

See also

Watch (Page 3589)

Service overview (Page 3586)

Device Info

Hardware and firmware information

The following current hardware and firmware information of the SIMOTION device is displayed on the **Device Info** page:

Manufacturer Name	Siemens AG
Order Number	Article number of the device
Revision Number	Hardware version
Serial Number	Serial number of the SIMOTION device

User Version Firmware	SIMOTION Kernel user version
Build Number	Internal version number
Additional Hardware	Installed components of the SIMOTION device including: Article number, serial number, revision number, firmware name, user version number, internal version number
Technological Packages	Loaded technology packages including: Package name, user version number, internal version number

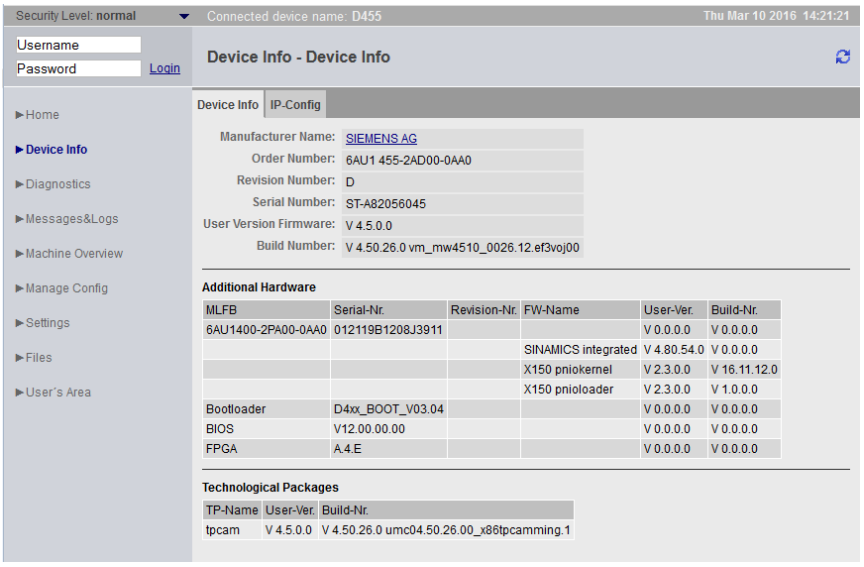

Figure 6-23 Device Info

Here, the Device Info page is shown after the example user has successfully logged in CutterAdmin.

IP Config

Data of the Ethernet and PROFINET interfaces of the SIMOTION device

The following current Ethernet and PROFINET interfaces data of the SIMOTION device is displayed on the **IP-Config** page:

IP Address	Address of the interface
Subnet Mask	Subnet mask of the interface
MAC Address	Physical address of the network card

Gateway	Default gateway of the interface The corresponding information is always displayed in the first column. It is not necessarily directly related to the IP address of the column and may even have been configured for the other interfaces.
Ethernet-port status:	Overview of Ethernet ports. The port speed and communication type are output for active ports.

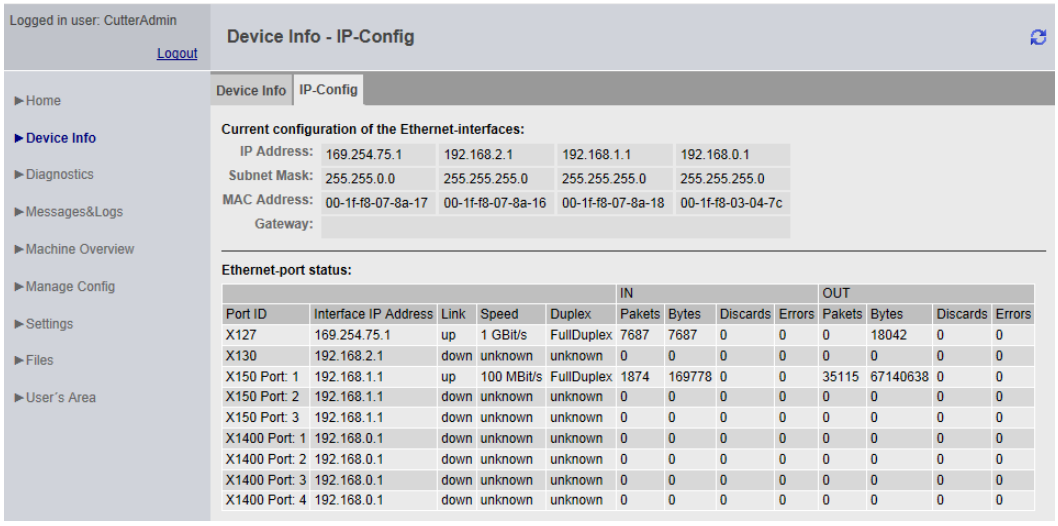

Figure 6-24 IP Config

Port ID	Name of the Ethernet or PROFINET port as stated on the hardware housing.
Interface IP Address	IP address of the interface
Link	Switching property of the port
Speed	Communications speed of the port
Duplex	Communications type of the port
Pakets - IN	Number of packets received at this port.
Bytes - IN	Number of octets received at this port.
Discards - IN	Number of received packets rejected for internal system reasons (e.g. due to system overload).
Errors - IN	Number of received packets not processed by higher protocol layers because of a detected error. For example, transmission/reception faults of the block and collisions.
Pakets - OUT	Number of packets sent at this port.
Bytes - OUT	Number of octets sent at this port.
Discards - OUT	Number of transmission requests for packets that were rejected. Packets that were rejected even though no errors that would have prevented transmission were detected are also counted.
Errors - OUT	Number of packets that were not sent due to an error.

Diagnostics

Overview of the general state of the SIMOTION device

The following states of the SIMOTION device are displayed on the **Diagnostics** page:

Systemtime	Current time-of-day of the SIMOTION device
Timezone	Current difference between the Systemtime and GMT in minutes
CPU Load by cyclic Tasks	Computation time of servo and IPO levels as a percentage of the total computation time
Memory Load	Size and allocation of the RAM disk, memory, memory card, and non-volatile memory
Operating State	Current operating state of the SIMOTION device
Web server Connection State	Information about the current connection status of the Web server.

Select the tabs on the page to access more detailed information.

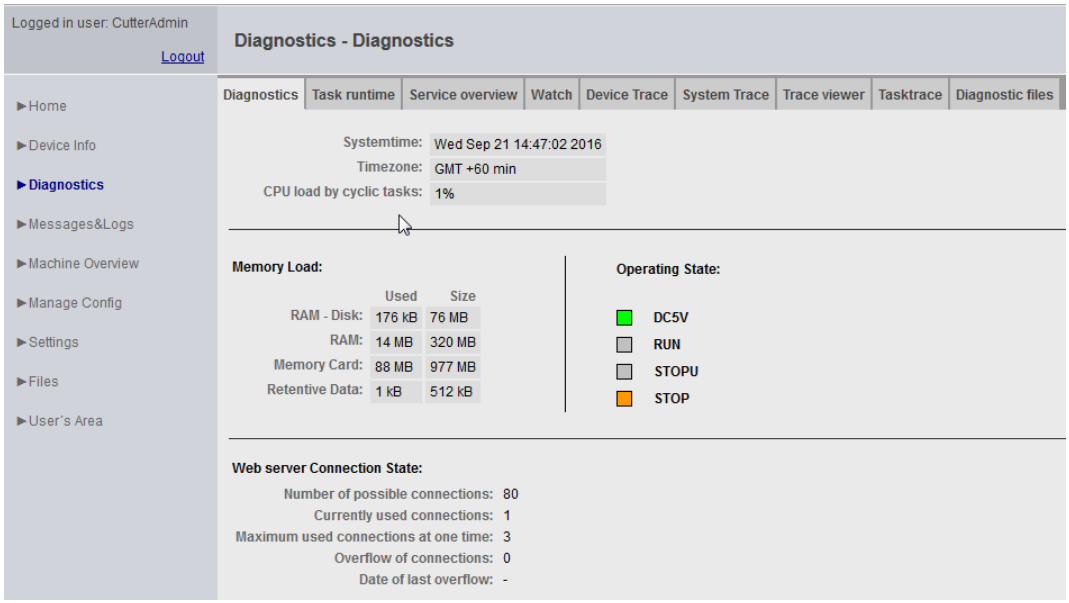

Figure 6-25 Diagnostics

Task runtime

Information on task runtimes and states

On the **Task runtime** page (opened via **Diagnostics > Task runtime**), you can view the following information:

Taskname	Name of the task
Status	Current status of the task

Actual	Current runtime of the task in ms
Min	Minimum runtime of the task in ms
Max	Maximum runtime of the task in ms
Average	Average runtime of the task in ms

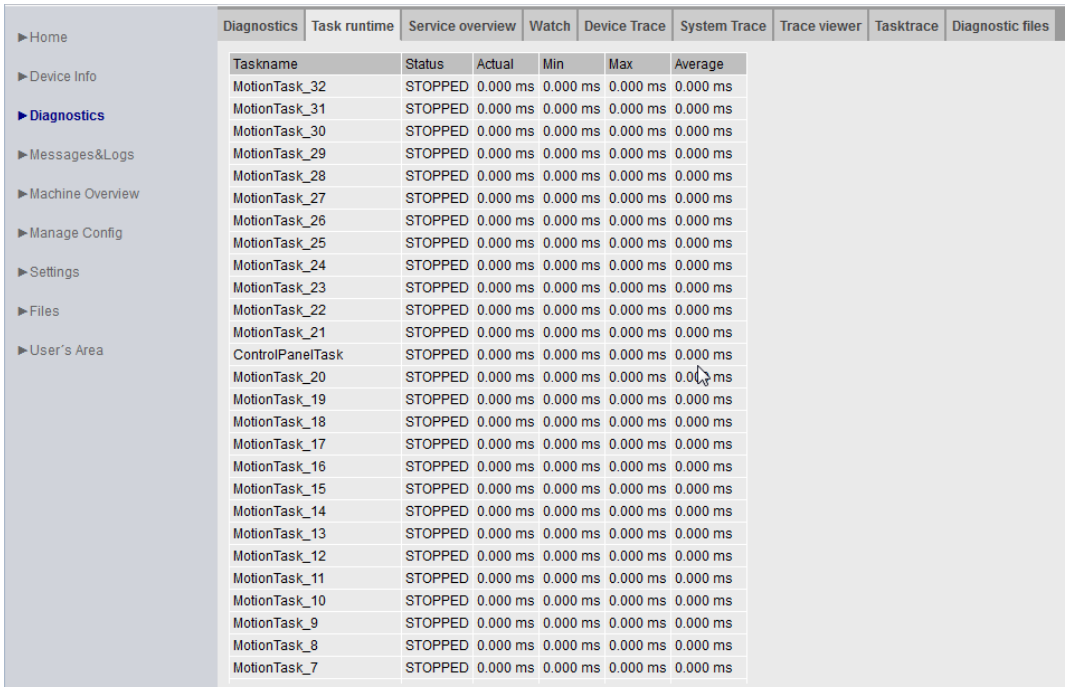

Figure 6-26 Task Runtime

Service overview

Service overview

SIMOTION SCOUT provides an overview screen that displays the state of the axes available in the project. The Web server provides a corresponding page.

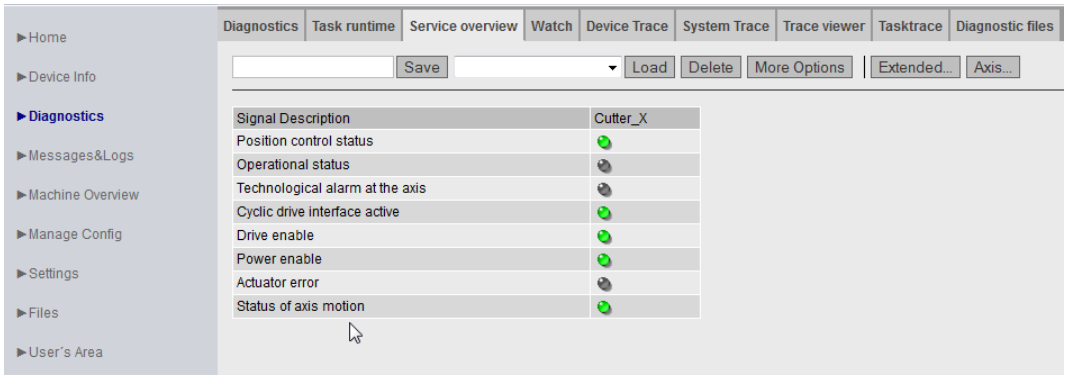

Figure 6-27 Service overview

The columns in the table represent each of the axes. The **Axis** button displays a selection of all the available axes from which the required axes can be selected.

The **Save** button saves the current setting in the device. A name for the setting must be entered in the input field to the left of the **Save** button.

The **Load** button loads a setting. The **Delete** button deletes a setting.

The **Extended...** button opens a window in which the required system variables can be selected.

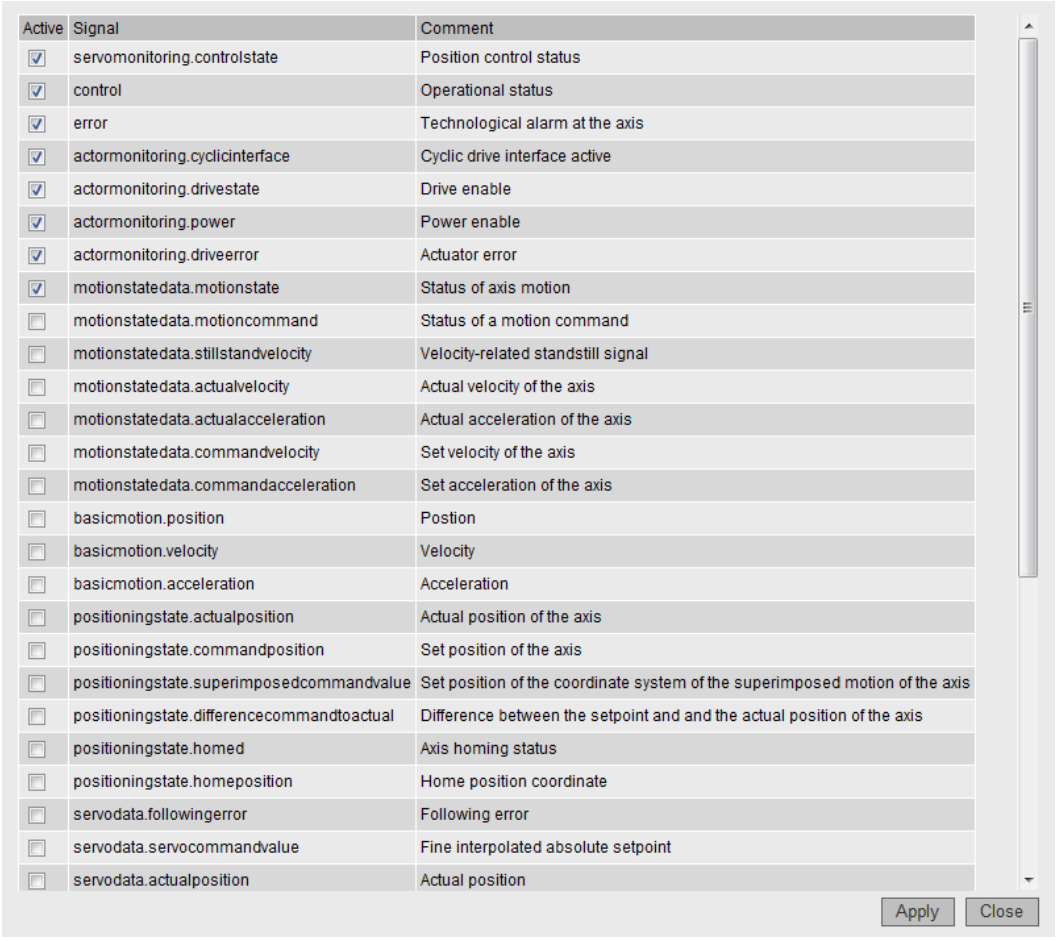

Figure 6-28 **Extended... button**: Selection of variables

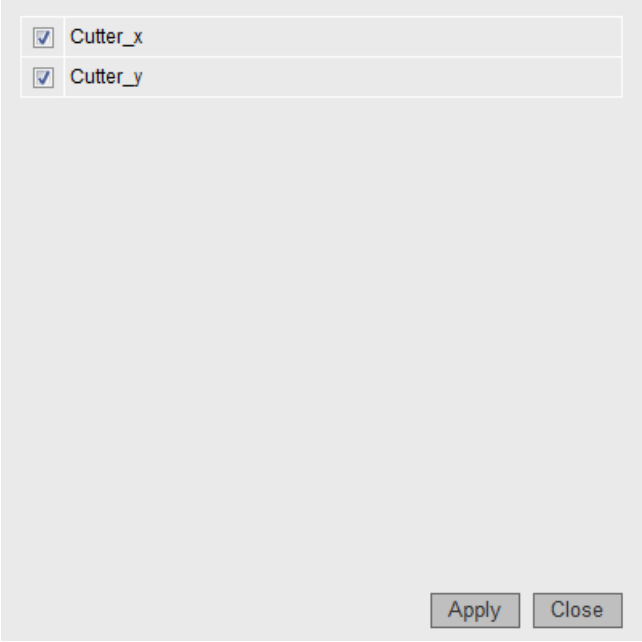

Figure 6-29 **Axis... button**: Selecting the axes

More Options

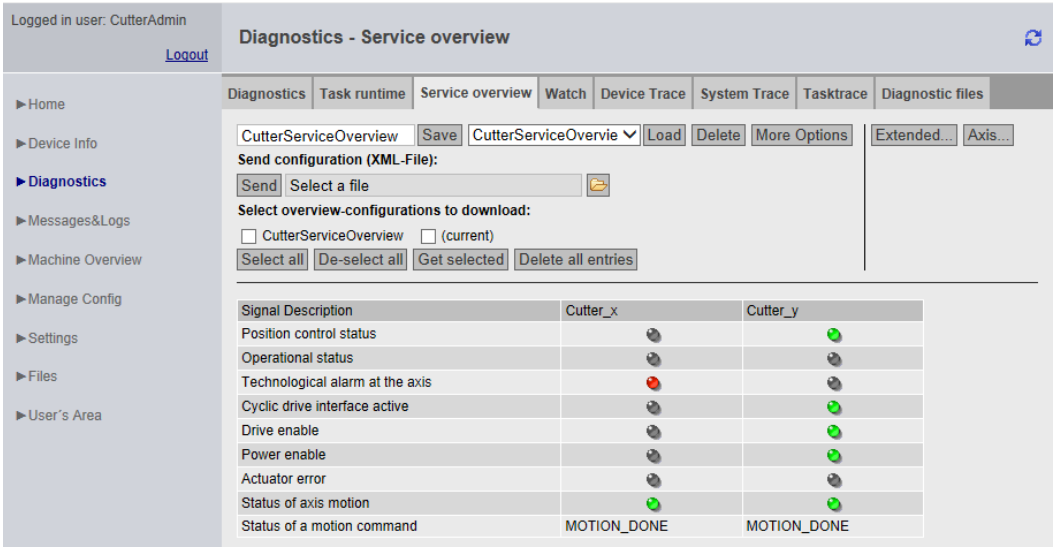

Figure 6-30 Service overview More Options

The **More Options** button extends the upper screen area to display additional functions. Additional buttons for selecting signals are displayed on the Service Overview page.

If multiple configurations are saved on the device, these configurations are offered for selection, can be selected and saved. The **Send** button loads a previously saved configuration to the device.

Watch

Watch table

This page combines a variable browser and a watch table. The variables are entered in the watch table with the aid of the browser. Variables of several devices are combined in the watch table.

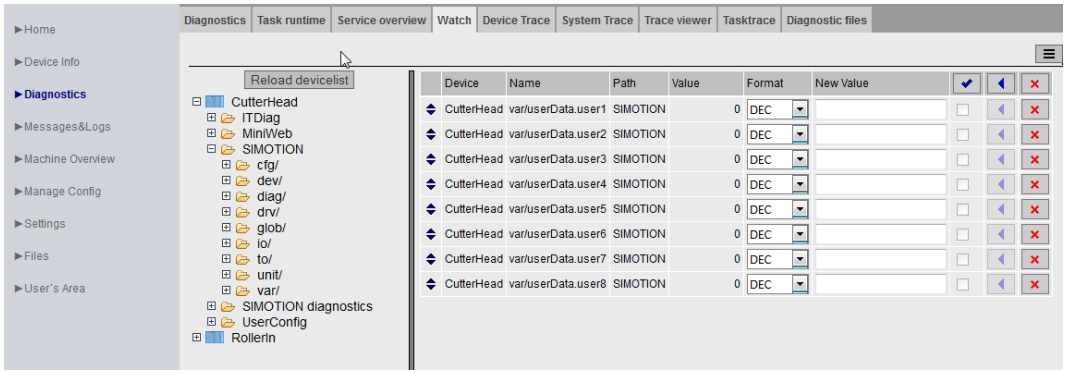

Figure 6-31 Watch table

For monitoring variables, the Web server provides a watch table and a symbol browser. The symbol browser allows browsing the variable management area of the CPUs connected with the SIMOTION controller. The variables are displayed in a tree topology on the left-hand side. The selected variables are displayed on the right-hand side and can be edited for the Watch. A maximum of 600 variables and array elements can be represented in the watch table.

In order to monitor unit variables, the "Permit OPC-UA/-XML" option must have been activated in the compiler settings for the associated unit. See Making unit variables available (Page 3701)

Only users who have logged in can access this page. See Log-in administration (Page 3658)

Device monitoring

Previously detected devices are monitored for sign-of-life. The **Reload devicelist** button causes all active devices to be detected and displayed next to the variables table.

If it is determined that a device is no longer available, the affected device and the associated entries in the variables list are displayed red.

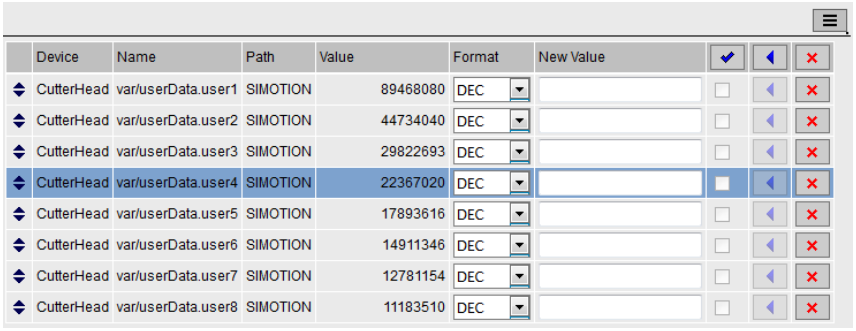
The variable monitoring is resumed after restoring an interrupted connection. All affected displays are then displayed in the normal color again.

Operating the watch table

The watch table can be operated not only with the mouse, but also with the keyboard. The focus within the table can be moved to any input field with the arrow keys.

The first column serves for marking and moving table cells.

Rows can be marked, and with pressed Shift key, by moving the cursor up or down (the blue-marked field) with either the mouse or the arrow keys on the keyboard.

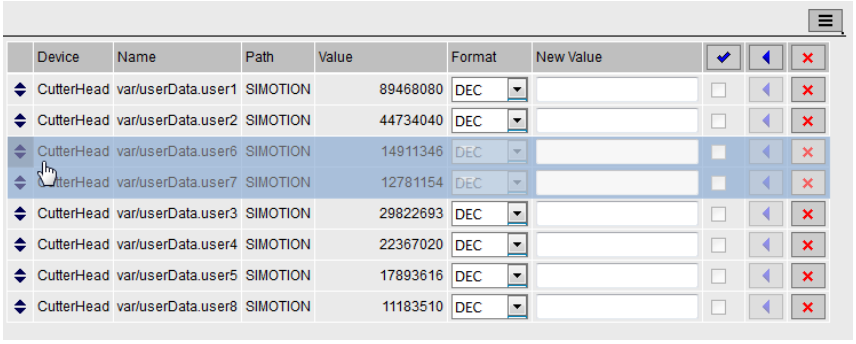


Device	Name	Path	Value	Format	New Value
CutterHead	var/userData.user1	SIMOTION	89468080	DEC	
CutterHead	var/userData.user2	SIMOTION	44734040	DEC	
CutterHead	var/userData.user3	SIMOTION	29822693	DEC	
CutterHead	var/userData.user4	SIMOTION	22367020	DEC	
CutterHead	var/userData.user5	SIMOTION	17893616	DEC	
CutterHead	var/userData.user6	SIMOTION	14911346	DEC	
CutterHead	var/userData.user7	SIMOTION	12781154	DEC	
CutterHead	var/userData.user8	SIMOTION	11183510	DEC	

Figure 6-32 Marking watch table entries

Moving a selection

The cursor can be moved without deleting the marked area by pressing the Ctrl key and the arrow keys.



Device	Name	Path	Value	Format	New Value
CutterHead	var/userData.user1	SIMOTION	89468080	DEC	
CutterHead	var/userData.user2	SIMOTION	44734040	DEC	
CutterHead	var/userData.user6	SIMOTION	14911346	DEC	
CutterHead	var/userData.user7	SIMOTION	12781154	DEC	
CutterHead	var/userData.user3	SIMOTION	29822693	DEC	
CutterHead	var/userData.user4	SIMOTION	22367020	DEC	
CutterHead	var/userData.user5	SIMOTION	17893616	DEC	
CutterHead	var/userData.user8	SIMOTION	11183510	DEC	

Figure 6-33 Moving watch table entries

The row in which the cursor is positioned can also be marked with pressed Ctrl key and pressing the spacebar or also with pressed Ctrl key and left-click without deleting any other existing marking.

Marked rows can be grabbed with the mouse in the first column within the marking and then moved up or down. Alternatively, you can move using the keyboard by pressing the Alt key and the arrow keys, Home or End.

Marked rows can be deleted by pressing the <Del> key.

Copying a selection

Marked rows can be copied to an internal clipboard by pressing <Ctrl>-<C> and appended at the end of the watch table by pressing the <Ctrl>-<V>.

	Device	Name	Path	Value	Format	New Value			
	CutterHead	var/userData.user1	SIMOTION	89468080	DEC				
	CutterHead	var/userData.user2	SIMOTION	44734040	DEC				
	CutterHead	var/userData.user3	SIMOTION	29822693	DEC				
	CutterHead	var/userData.user4	SIMOTION	22367020	DEC				
	CutterHead	var/userData.user5	SIMOTION	17893616	DEC				
	CutterHead	var/userData.user6	SIMOTION	14911346	DEC				
	CutterHead	var/userData.user7	SIMOTION	12781154	DEC				
	CutterHead	var/userData.user8	SIMOTION	11183510	DEC				
	CutterHead	var/userData.user1	SIMOTION	89468080	DEC				
	CutterHead	var/userData.user2	SIMOTION	44734040	DEC				

Figure 6-34 Copy-and-Paste watch table

Editing an entry

The example shows the situation after copying and pasting the first two rows.

	Device	Name	Path	Value	Format	New Value			
	CutterNew	var/userData.user1	SIMOTION	UNKNOWNDEVICE					
	CutterHead	var/userData.user2	SIMOTION	44734040	DEC				
	CutterHead	var/userData.user3	SIMOTION	29822693	DEC				
	CutterHead	var/userData.user4	SIMOTION	22367020	DEC				
	CutterHead	var/userData.user5	SIMOTION	17893616	DEC				
	CutterHead	var/userData.user6	SIMOTION	14911346	DEC				
	CutterHead	var/userData.user7	SIMOTION	12781154	DEC				
	CutterHead	var/userData.user8	SIMOTION	11183510	DEC				

Figure 6-35 Editing a watch table

The associated entry can be edited by clicking in one of the Device, Name or Path fields.

This screenshot shows the situation after entering a non-connected device. Consequently, the first row is shown red.

Loading and saving of watch tables with the Menu button

The Menu button at the right above the watch table bundles the functions for saving and loading the watch tables.

In addition, a selection of saved watch tables can be exported to and reimported from a connected computer.

Similarly, watch tables exported from SCOUT can be imported.

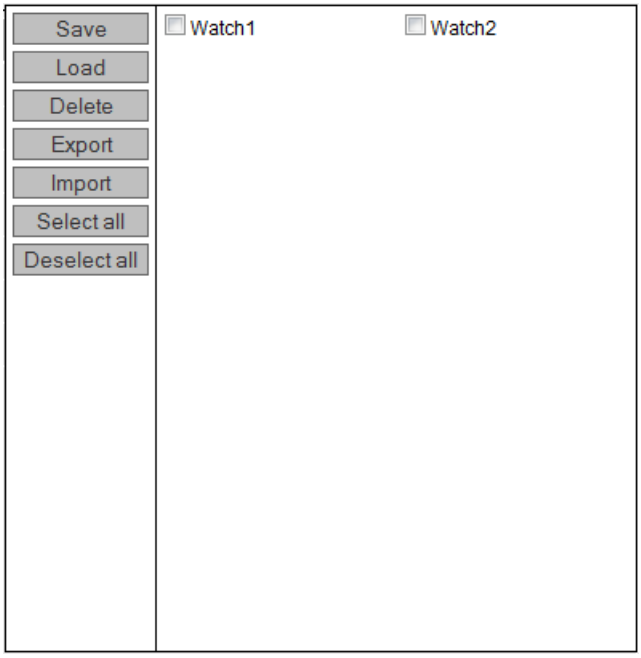


Figure 6-36 Menu button dialog box

- Save - Saves the selected watch tables after the specification of a name (Watch1, Watch2, ...).
- Load - Loads the selected watch tables.
- Delete - Deletes the selected watch tables.
- Export - Exports the selected watch tables to a connected computer as an XML file.
- Import - Imports watch tables from a connected computer. This function imports watch tables exported from SCOUT. Not only individual variables, but also structures and arrays can be imported. Before being entered in the watch table, they are resolved into individual variables. The variables that belong to a structure or array are determined online by browsing. This operation can take quite some time, depending on the number of variables and the CPU loading. The renewed saving of the watch table resolved into individual variables makes future imports much faster.
- Select all - Deletes all entries selected in the dialog box.
- Deselect all - Revokes the selection for all entries of the dialog box.

Note

After loading a watch table and adding new drive parameters, it is possible that the display no longer responds.

Display formats

The **Format** column allows you to change the display format for integer and floating-point variables.

- DEC for decimal display (default).
- HEX for hexadecimal display.
- BIN for binary display.

All control values are interpreted according to this setting.

Table 6-5 Display formats for floating-point numbers

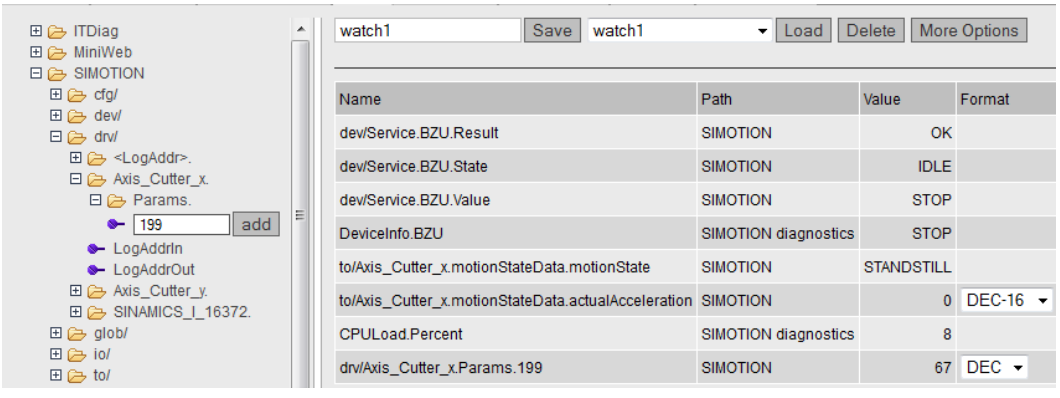
Format	Lowest value	Highest value	EXP notation
DEC-10	0.000000001	9999999999	*.*********E+-*
DEC-16	0.000000000000001	9999999999999999	*.**************E+-*
DEC-20	0.00000000000000000001	99999999999999999999	*.**************E+-*
DEC n.3	Three decimal places are displayed or EXP format if the value < 0.001 or > 1e+21		
EXP	*.**********E+-*		

Accessing the drive parameters

The drive parameters are accessed via a tree topology. The parameters are selected using the same method as when accessing variables via the variable provider. See Variable providers (Page 3676)

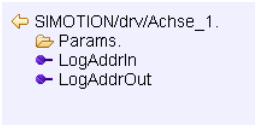
Simply click a variable in the tree overview to select it. Depending on the variable type, additional values, such as the parameter numbers, are also queried.

Parameters are displayed as a number without a preceding 'p' or 'r'. For example, parameter r0002 becomes 0002.

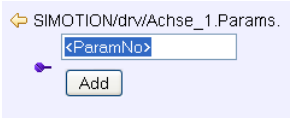


Three options are provided for accessing the drive parameters:

1. Axis technology object

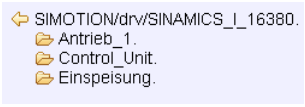


Selecting a technology object.

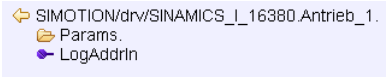


Selecting a drive parameter.

2. Drive object addressing



Selecting a drive object. The name is generated from the diagnostic address.



Selecting a drive.

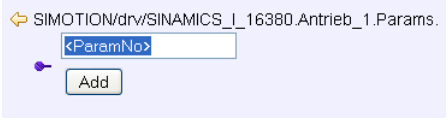


Figure 6-37 Selecting a DO parameter

3. Logical address

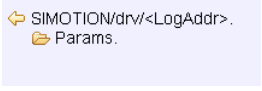

Figure 6-38 Selecting a logical address

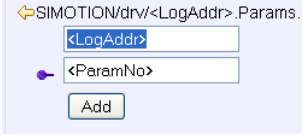

Selecting a drive parameter and a logical address.

Device Trace

Setting up a Device Trace

The SIMOTION controller provides the user with the option of setting up a device trace via a Web service.

As of Version 4.2 not only the device trace described in this section is provided, but also a distributed trace (Page 3598) (System Trace).

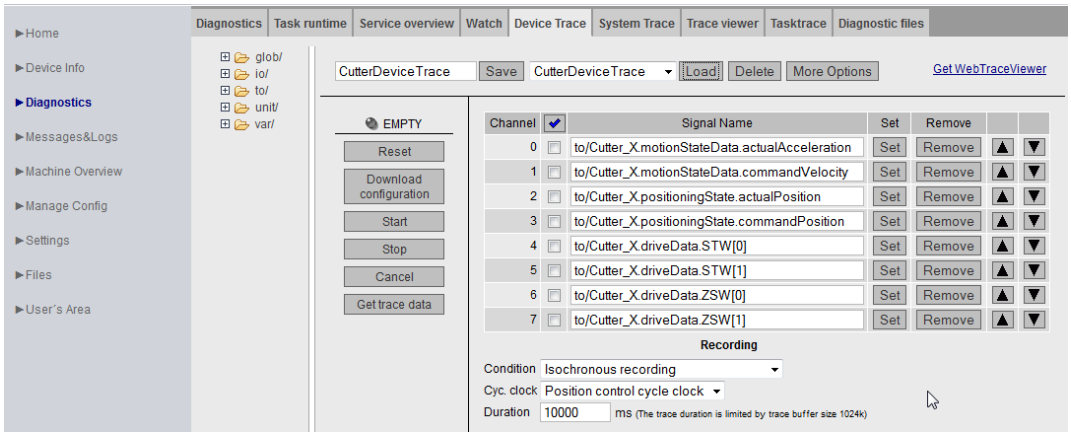

Figure 6-39 Device trace

Procedure for creating and executing a device trace:

- Select the **Device Trace** radio button
- Select the required signal from the provider list (glob, io, to, unit or var)
- The marked symbol is placed on the required signal with the **Set** button, double-clicking, or by drag-and-drop.
- Set the recording and trigger conditions
- **Download configuration** – Load the settings to the controller
- **Start** – Start the trace
- **Stop** – Stop the trace (only required for a manual trace)
- **Cancel** – Delete the settings from the controller
- **Get trace data** – Load the trace results to the device memory or to a file on the PC.
  - View the trace data on the Trace Viewer (Page 3709) page.
  - View a trace file stored in WTRC format with the WebTraceViewer or SCOUT.

In order to monitor unit variables, the "Permit OPC-UA/-XML" option must have been activated in the compiler settings for the associated unit. See Making unit variables available (Page 3701).

Note

Data types

TIME and STRING data types cannot be recorded

- Not all elementary data types can be tracked in the trace.
- Only the bit data types and numeric data types can be tracked in the trace.
- However, it is not possible to track TIME and STRING data types.

Trace display

Up to 128 signals can be displayed simultaneously in the WebTraceViewer. By contrast, only 8 signals can be displayed simultaneously in SCOUT.

Once the signals have been selected, the desired recording and trigger conditions must then be assigned.

The WebtraceViewer can be downloaded and installed from the **Get WebTraceViewer** link.

The **More Options** button expands the upper area of the screen to include options for saving the device trace settings on a PC and subsequently reloading them to the controller.

Only users who have logged in can access this page. See Login administration (Page 3658)

Note

Only a limited amount of memory, arranged as a ring buffer, is available for the Trace. 512 KB is available for SIMOTION C, SIMOTION D410-2, and 1024 KB is available for all other SIMOTION modules.

Trace modes

The device trace can be run in three modes:

1. Isochronous recording (recording immediately)
   The trace starts immediately and runs until the recording time set at Duration is reached.
2. Isochronous recording - manual trace (recording immediately)
   The trace starts immediately and runs until it is stopped by the operator. The trace buffer then contains data which was recorded for the time set in Duration before stop was triggered.
3. Isochronous recording – triggered (recording triggered)
   The trace starts when a trigger event occurs and stops when a parameterizable time expires or when the trace buffer is full.
4. EndlessIsochronous recording – endless
   The trace starts immediately and runs until it is ended with Stop. The trace data can be monitored during recording in the Tab Trace Viewer. You can save recordings made by endless trace in CSV format.

Trigger

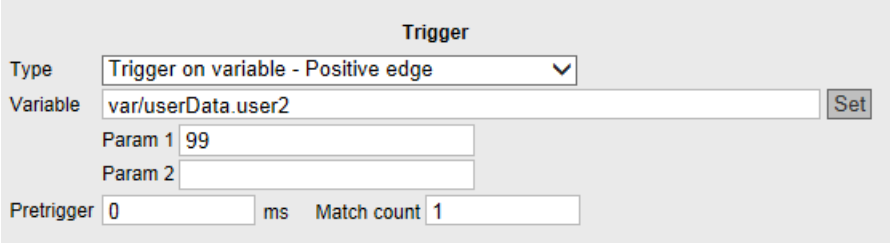

Figure 6-40 Device trace trigger

You can find a description of the recording settings and trigger conditions in the System trace (Page 3598) section.

Saving and loading a trace configuration

You can save a configuration with a name on the device with the **Save** button and load it again with the **Load** button. You can find a more detailed description of the **More Options** functionality in the Service overview (Page 3586) section.

Drag-and-drop

The drag-and-drop functionality enables variables to be dragged to the table rows of the signals.

Moving table rows

Using drag-and-drop you can move the table rows containing the signals. This functionality is also available in similar tables on the Watch and System Trace page.

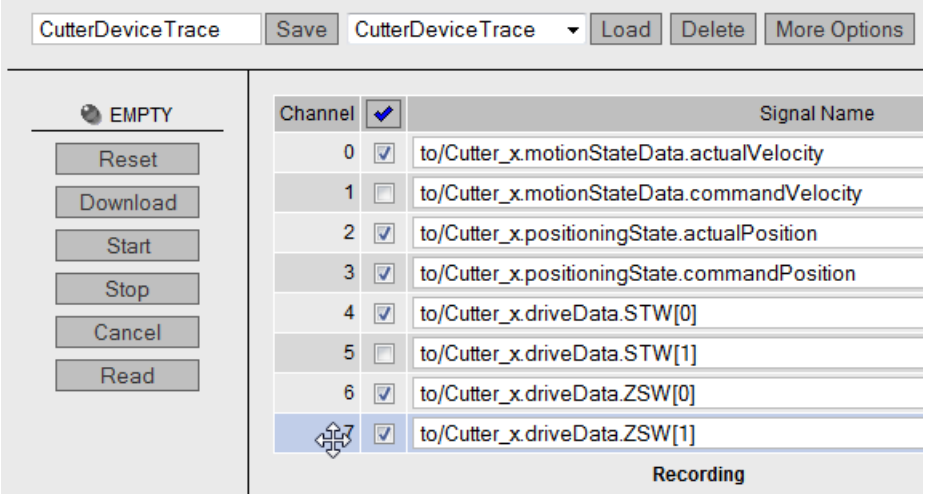

Figure 6-41 Drag-and-drop table rows

Select the required table row. Keep the left mouse button pressed and move the row to the desired position.

System Trace

Setting up and executing a system trace

The system trace is available as of SIMOTION Version 4.2. The system trace records a trace involving multiple devices.

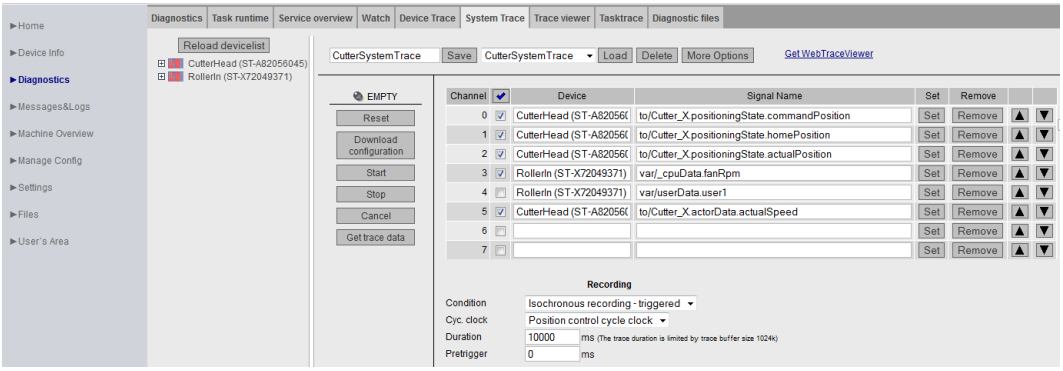

Figure 6-42 System trace (partial view)

Requirements for the system trace:

- It is essential that the CPUs communicate via PROFINET.
- There must be an isochronous connection between the CPUs.
- Direct data exchange (peer-to-peer communication) must be configured.
- The PROFINET Sync Master must be a SIMOTION device.

Procedure for creating and executing a system trace:

- Select the **System Trace** radio button
- Select the required signal from the provider device list (glob, io, to, unit or var)
- The marked symbol is placed on the required signal with the Set button, double-clicking, or by drag-and-drop.
- Set the recording and trigger conditions
- **Download configuration** – Load the settings to the controller
- **Start** – Start the system trace
- **Stop** – Stop the system trace (necessary only for manual trace)
- **Get trace data** – Load the trace results to the device memory or to a file on the PC.
  - View the trace data on the Trace Viewer (Page 3709) page.
  - View a trace file stored in WTRC format with the WebTraceViewer or SCOUT.

In order to monitor unit variables, the "Permit OPC-UA/-XML" option must have been activated in the compiler settings for the associated unit. See Making unit variables available. (Page 3701)

Note

Data types

TIME and STRING data types cannot be recorded

- Not all elementary data types can be tracked in the trace.
- Only the bit data types and numeric data types can be tracked in the trace.
- However, it is not possible to track TIME and STRING data types.

Requirements

The devices must be connected and synchronized via PROFINET IO for time synchronization of the distributed trace to function correctly.

Note

Error message: Error while synchronizing timestamp

If multiple controllers with the same IP address are involved on a system trace over sync domains, this error message is issued. The trace is then not recorded.

Remedy: Unique IP addresses must be used.

Quantity structures

Number of devices

- 128 signals on 128 CPUs are possible. 32 signals per CPU are possible.

Number of triggers

- Just one trigger is possible for each device. A total of four triggers are possible for the entire configuration. Depending on the utilization of the devices, the number of different possible devices can vary. As a recommendation, no more than 10 different devices should be used at the same time.

Trace display

Up to 128 signals are displayed simultaneously in the WebTraceViewer. By contrast, only 8 signals can be displayed simultaneously in SCOUT.

Once the signals have been selected, the desired recording and trigger conditions must then be assigned.

The WebtraceViewer can then be downloaded and installed from the **Get WebTraceViewer** link.

Trace modes

The system trace can only be run in 'triggered' mode. The trace starts when a trigger event occurs and stops when a parameterizable time expires or when the trace buffer is full.

Recording settings

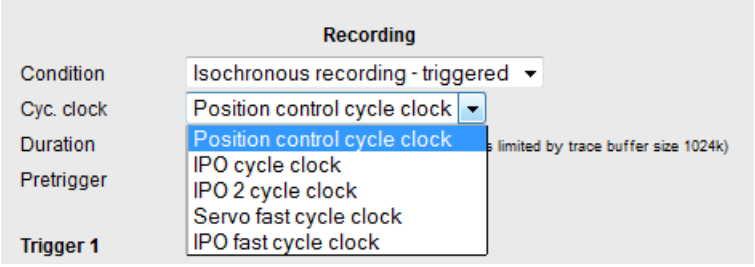

Figure 6-43 Recording basic cycle clock setting

- Condition: Measured value acquisition
- Cyc. Clock: Basic cycle clock
- Duration: Recording in a ring buffer. 512 KB memory (SIMOTION C, SIMOTION D410-2) or 1024 KB (all others)

- Pretrigger = Time in ms when the trigger is activated, this "run-in" is included in the recording

Trigger conditions

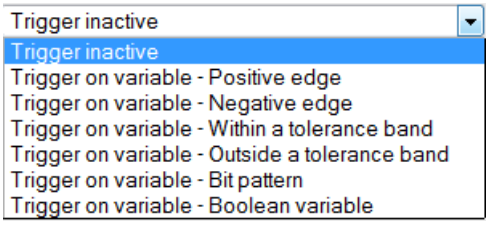

Figure 6-44 Trigger setting

Designation	Description	Operand 1	Operand 2
Positive Edge	Positive edge Triggers when the variable was below the threshold and then overshoots it.	Threshold value	-
Negative Edge	Negative edge Triggers when the variable was above the threshold and then undershoots it.	Threshold value	-
Within a tolerance band	Within a value range Triggered if variable is within the specified interval.	Lower limit of the interval	Upper limit of the interval
Outside a tolerance band	Outside a value range Triggered if variable is outside the specified interval.	Lower limit of the interval	Upper limit of the interval

Designation	Description	Operand 1	Operand 2
Bit pattern	The bit pattern triggers if the relevant bit is 1 both in the variable and in the bit pattern.	Bit pattern	-
Boolean Variable	Boolean variable Triggers depending on operand 1.	0 = trace triggered after a 1 →0 transition 1 = trace triggered after a 0 →1 transition	

Overview of trigger conditions

All mentioned operands must be specified for the download to function. In this case, "Trigger expression invalid" is displayed as error message.

Initialization

The trace variables and trigger conditions are transferred to the devices concerned in order to initialize the trace. If the initialization has been completed without errors on at least one device, the trace can start.

Note

Deleting a trace

A SCOUT trace is not deleted by SIMOTION IT diagnostics.

A SIMOTION IT Diagnostics trace can be deleted by SIMOTION SCOUT. In this case, a dialog appears in SIMOTION SCOUT in which it can be specified whether the available trace parameterization should be overwritten.

Deleting a trace up to Version 4.3

A SIMOTION SCOUT trace is not deleted by the SIMOTION IT Diagnostics.

A SIMOTION IT Diagnostics trace is not deleted by SIMOTION SCOUT.

Note

Downloading a trace

If a SIMOTION SCOUT trace exists on the device, a SIMOTION IT Diagnostics trace cannot be loaded.

Viewing the trace

The trace data can be displayed with the WebTraceViewer PC program or SIMOTION SCOUT as of V4.4.

Drag-and-drop

Variables can easily be moved into the trigger conditions using drag-and-drop.

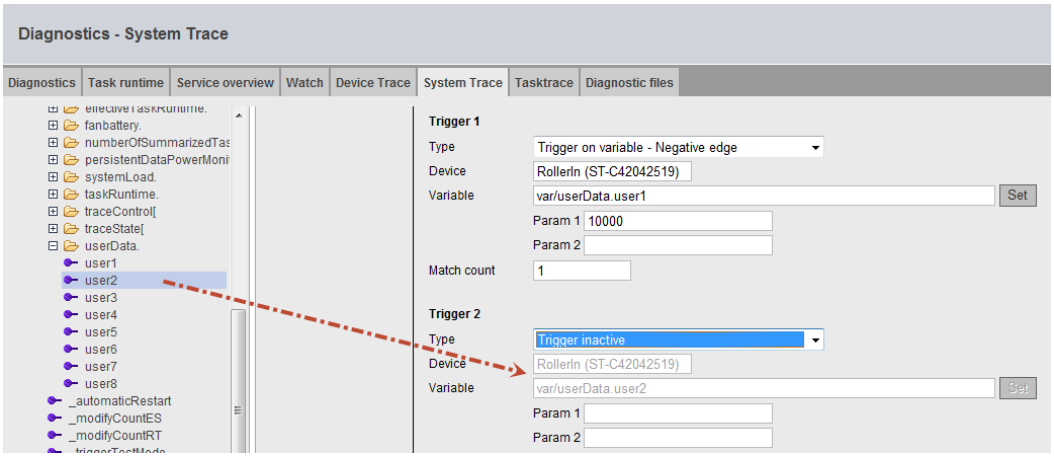

Figure 6-45 System Trace drag-and-drop

See also

Device Trace (Page 3595)

Trace Viewer

Trace data display

The Trace viewer page displays previously recorded trace data as a curve diagram.

To use this page you require a current browser version (Internet Explorer as of Version 10, Firefox, Chrome).

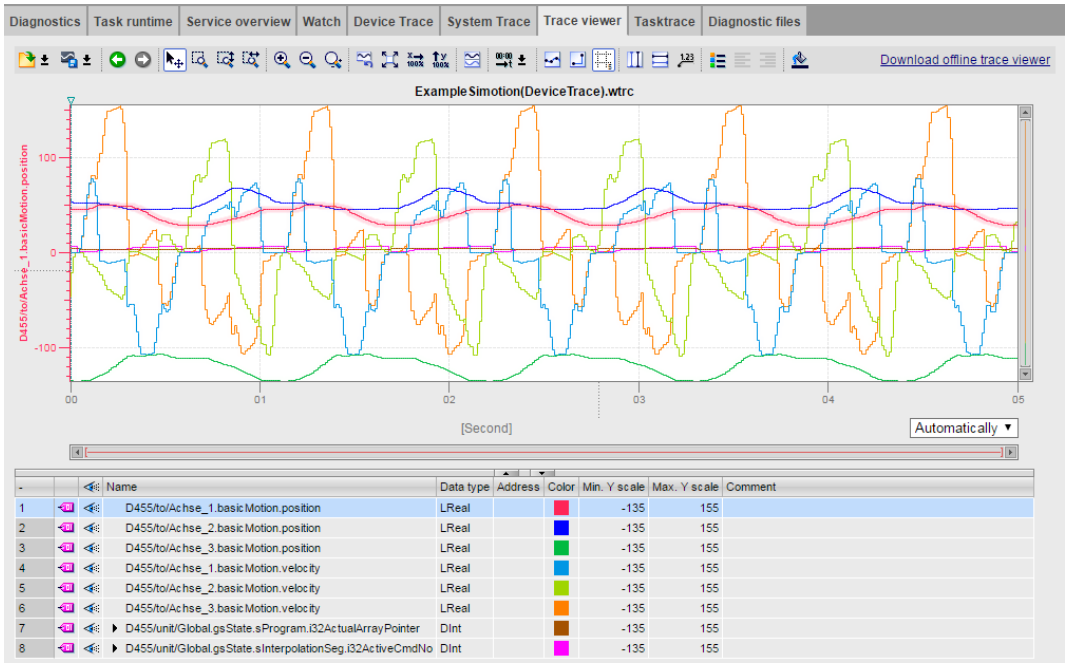

Figure 6-46 Trace viewer

The Trace Viewer shows only completed measurements. The measurements can be loaded from the device or a stored file.

The Trace viewer is described in detail in the Trace Viewer (Page 3709) chapter.

Tasktrace

Tasktrace

This page enables you to configure and control the SIMOTION Tasktrace (including trigger conditions).

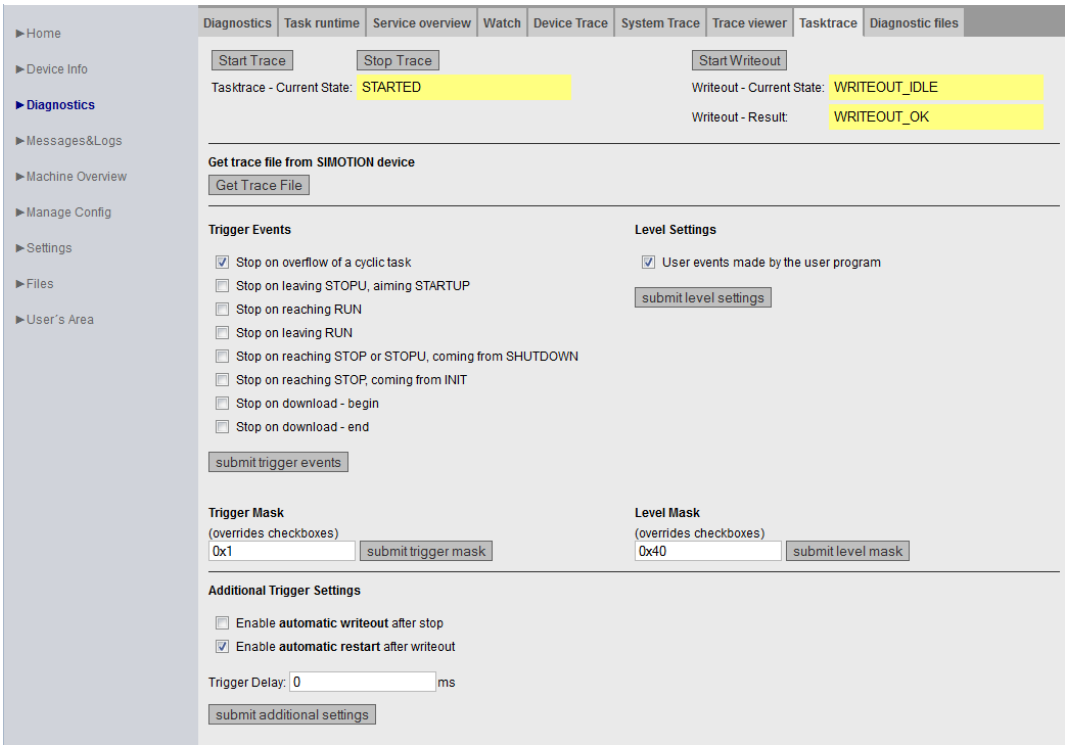

Figure 6-47 Tasktrace

The Tasktrace provides a diagnostics option during runtime which can be used to obtain reliable information about the processes in the individual tasks (e.g. task change).

The trace recording is continuously written to a ring buffer.

Once underway, a trace recording can be stopped manually or held conditionally by a trigger event. The recording can then be loaded to the PC and displayed with the Task Profiler with the **Get Trace File** button.

Start Trace

The **Start Trace**button starts the Tasktrace with the settings that have been made previously and have been transferred to the device using **Submit**.

Stop Trace

The trace is stopped manually with the **Stop Trace** button.

The state of the trace is displayed in the **Tasktrace - Current State:** field.

Start Writeout

The **Start Writeout** button writes the content of the trace buffer to the "/USER/SIMOTION/HMI/SYSLOG/TASKTRACE/DIAG/TTRACE.JEN" file on the device.

The state of the write process is displayed in the **Writeout - Current State:** and **Writeout - Result:** fields.

Get Trace File

The **Get Trace File** button loads the TTrace.jen file to the PC and displays with the TaskProfiler program. The setup of the TaskProfiler can be found in the tasktrace_viewer.zip file in the SCOUT setup directory \scout\release\VOL1\InstData\SCOUT\Media\.

Trigger Events

The **Trigger Events** can be selected and combined as you wish using various checkboxes. The **submit trigger events** button transfers the selection to the device.

Trigger Mask

The **Trigger Mask** input field enables the expert to input **Trigger Events** as coded number. The **submit trigger mask** button transfers the input to the device and overwrites all previous inputs.

Level Settings / Level Mask

You can use these settings to determine which events are entered in the Tasktrace.

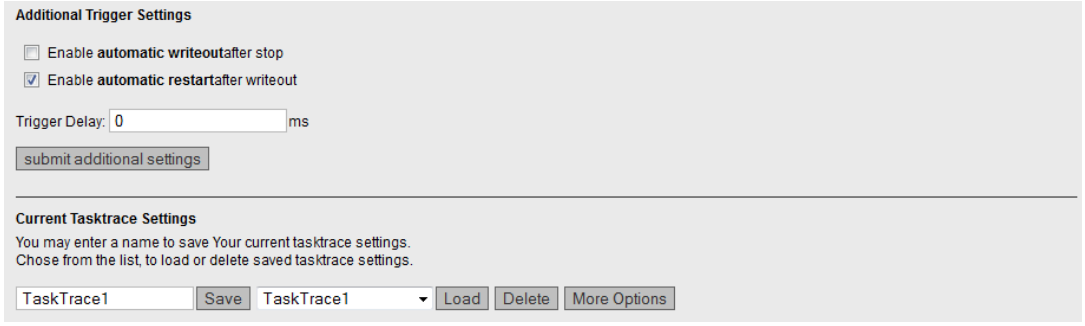

Figure 6-48 Tasktrace Additional Settings

Additional Trigger Settings

These settings enable you to back up a trace automatically.

- **Enable automatic writeout after stop**: The trace data is automatically backed up after the occurrence of a trigger event.
- **Enable automatic restart after writeout**: The trace is restarted after backing up the trace data.

Trigger Delay sets the time during which the trace remains active after a trigger condition occurs.

Current Tasktrace Settings

You can back up, load or delete a setting here.

Saving the trace settings

The current trace settings can be saved in the XML file "/USER/SIMOTION/HMI/FILES/PERSIST/TTRACE.XML" on the storage medium of the controller. This file is evaluated during startup. As a result, it is also possible to activate the trace of system function calls from the Web user interface. In addition, the Web server allows you to delete this file.

Diagnostic files

Backing up diagnostic pages of the Web server

You can use this page to back up general diagnostic data and individual HTML pages of SIMOTION IT .

The standard HTML pages of the Web server contain valuable information for analyzing problems that can occur during operation of the SIMOTION controller.

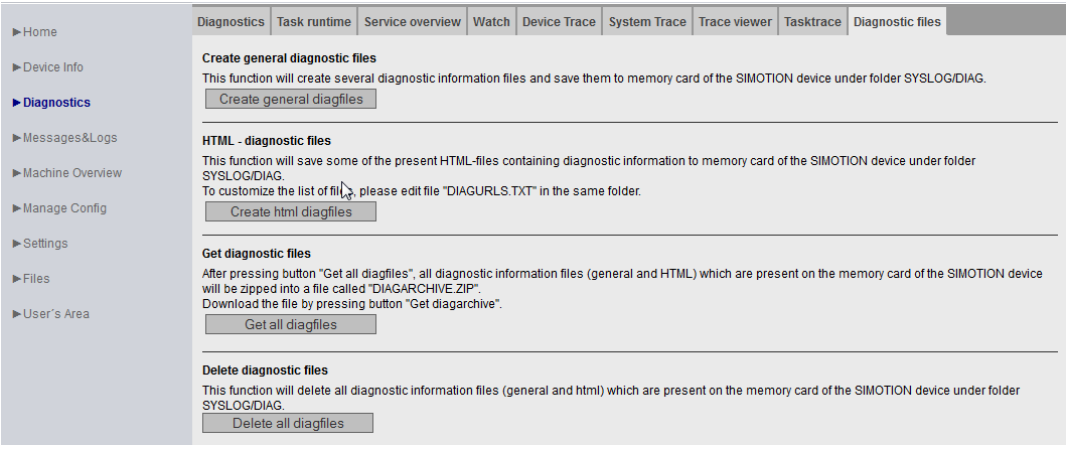

Figure 6-49 Diagnostic files

Create general diagnostic files
This function saves diagnostic data for Support.

SIMOTION device	Storage medium	Path
D, C	CF card / MMC	\USER\SIMOTION\HMI\SYSLOG\DIAG
P350	Hard disk	F:\Simotion\user\Card\USER\SIMOTION\HMI\SYSLOG\DIAG
P320	CF card	D:\Card\USER\SIMOTION\HMI\SYSLOG\DIAG
P320-4 E P320-4 S	External CFast card	D:\USER\SIMOTION\HMI\SYSLOG\DIAG

Directory paths for saving the diagnostic data

This function corresponds, for example, to actuating the service selector switch on the SIMOTION D controller.
HTML files used for diagnostics purposes are not saved.

HTML - diagnostic files
A selection of relevant diagnostic pages are saved on the data medium as HTML pages. You can use the DIAGURLS.TXT file to control which HTML pages will be saved.

Get diagnostic files
A selection of relevant diagnostic pages are saved on and loaded from the DIAGARCHIVE.ZIP data medium as HTML pages.

Delete all diagfiles
Deletes all diagnostic files present in the ...\USER\SIMOTION\HMI\SYSLOG\DIAG directory. The directory itself is retained.

Messages&Logs

Diag buffer

Diagnostic buffer information

On the **Diag buffer** page (opened via **Messages&Logs > Diag buffer**), you can view the latest content of the controller diagnostic buffer.

Time	Time of the event
Date	Date of the event
Event	Displays the event as text. If the DGBUFTXT.EDB language file is missing, the texts are displayed in English. English texts are pre-installed on the device.

Note

The text is displayed in English by default. To display the Event text in a different language, you must transfer the relevant language versions of the DGBUFTXT-XX.EDB, DGEXTTXT.EDB and TOALARM.ADB files to the .../USER/SIMOTION/HMICFG directory on the SIMOTION controller memory card. A detailed description of this topic is available in the DiagBuffer group (Page 3690) and Alarms (Page 3609) sections.

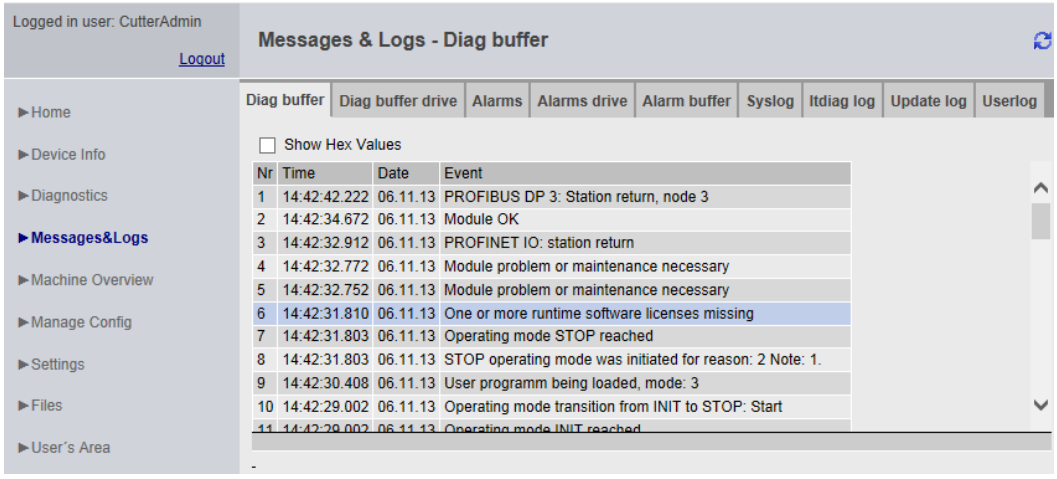

Figure 6-50 Diag buffer

Diag buffer drive

Representation of the drive diagnostic buffer

Like the SIMOTION diagnostic buffer, there is also a diagnostic buffer for the integrated drives only for the SIMOTION D.

Time	Time of the event
Date	Date of the event
Event	Displays the event as text. If the DGEXTTXT.EDB language file is missing, the display is in English. English texts are pre-installed on the device.

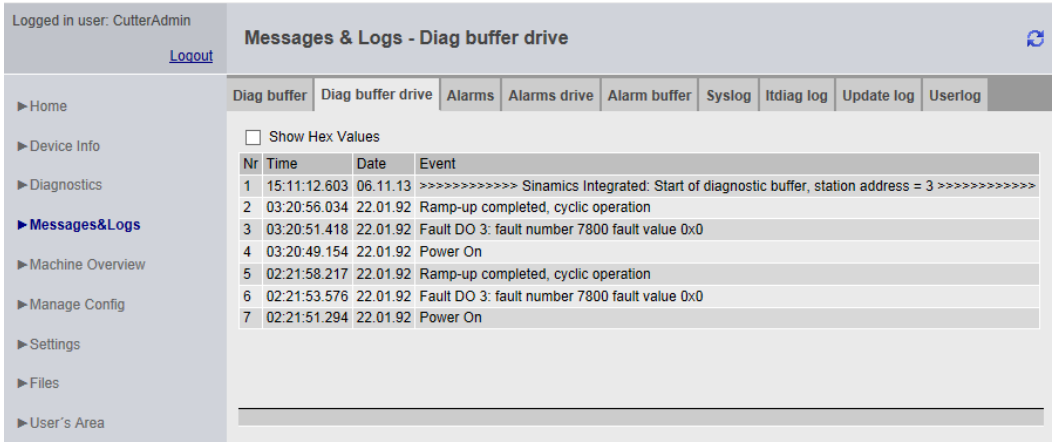

Figure 6-51 Display of the diagnostics buffer for the integrated drives

The diagnostics buffer of a CX (Controller Extension) module is displayed in this way.

Alarms

Information about alarms

The alarm and AlarmS/SQ messages of the device are displayed on the **Alarms** page.

Technological Alarms

Level	Category of the alarm
Time	Time of the alarm
TO	Technology object that triggered the alarm
Alarm	Alarm number
Text	Message displayed as text

Process Alarms (AlarmS/SQ)

AlarmNo	Number of the AlarmS/SQ
State	Status of the AlarmS/SQ
Time	The time when the AlarmS/SQ occurred.
Type	Type of the AlarmS/SQ
Text	Message displayed as text (message text)
More Info	Additional information (Infotext)

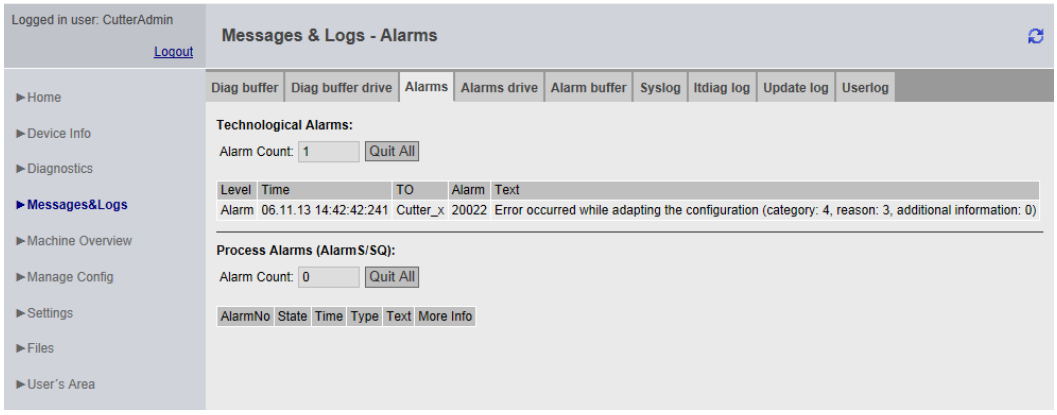

Figure 6-52 Alarms

The **Quit All** button allows you to close all alarms requiring acknowledgment.

Language setting of the technological alarms text

Alarm texts are displayed in English by default. To display the technological alarm texts in a different language, you must transfer the TOALARM.ADB file in the relevant language to the SIMOTION controller memory card.

Only one language can be saved in SIMOTION at a time.

Procedure SIMOTION D,C

1. Open the AddOn\4_Accessories\SIMOTION_IT\4_Alarm_Messages\< directory version >\ on the SIMOTION SCOUT Add-Ons DVD. For the language, you can choose between ger (German), eng (English), ita (Italian) and fra (French). The TOALARM.ADB file is located in the corresponding directory.
2. Insert the SIMOTION memory card in a reader/writer.
3. Copy the TOALARM.ADB file to the \USER\SIMOTION\HMICFG directory. You must create the directory if it does not yet exist.
4. Insert the memory card in the SIMOTION device again.

Procedure SIMOTION P350, P320

1. Shut down the SIMOTION P.
2. Open the \AddOn\4_Accessories\SIMOTION_IT\4_Alarm_Messages\< directory version >\ on the SIMOTION SCOUT Add-Ons DVD. For the language, you can choose between ger (German), eng (English), ita (Italian) and fra (French). The TOALARM.ADB file is located in the corresponding directory.
3. Copy the TOALARM.ADB file to the F:\SIMOTION\USER\CARD\USER\SIMOTION\HMICFG directory (for the P350 default installation) or theD:\CARD\USER\SIMOTION\HMICFG directory (for the P320 default installation).
4. Start the SIMOTION P.

Procedure SIMOTION P320-4 E, P320-4 S

1. Shut down the SIMOTION P.
2. Open the \AddOn\4_Accessories\SIMOTION_IT\4_Alarm_Messages\< directory version >\ on the SIMOTION SCOUT Add-Ons DVD. For the language, you can choose between ger (German), eng (English), ita (Italian) and fra (French). The TOALARM.ADB file is located in the corresponding directory.
3. Copy the TOALARM.ADB file to the D:\USER\SIMOTION\HMICFG directory.
4. Start the SIMOTION P.

To have the correct path, replace the <version> with the SIMOTION version, such as V4.5.

Note

Data type and output format

When using the associated values (process values) of the alarms, ensure that the output format matches the data type of the value. Otherwise, errors may occur when displaying the values on the Web pages. Unlike SIMOTION SCOUT or TIA Portal, the Web server does not have any information on the data type of the variables used.

Additional notes are provided in the 'Syntax for process values in message texts' section in the SCOUT documentation.

Example

"My Alarm Message with LREAL Value: @1O%10d@" => incorrect display on the Web pages, as the LREAL value is to be output as decimal number (%d).

"My Alarm Message with LREAL Value: @1O%10.2f@" => correct display on the Web pages, as the LREAL value is to be output as floating-point number (%f).

SIMOTION IT Text Databases (Page 3636)

Alarms drive

Drive faults and warnings

Similar to the technological alarms of the controller, a page containing fault and warning messages of the drive is also available. As of V5.1, the alarm texts for the drive alarms are available.

The following are displayed:

Time	Fault time
Type	Error type
Source	DO name
No.	Fault code
Value	Fault value

If DOs (Drive Objects) are present in the device by name, they are also output by name.

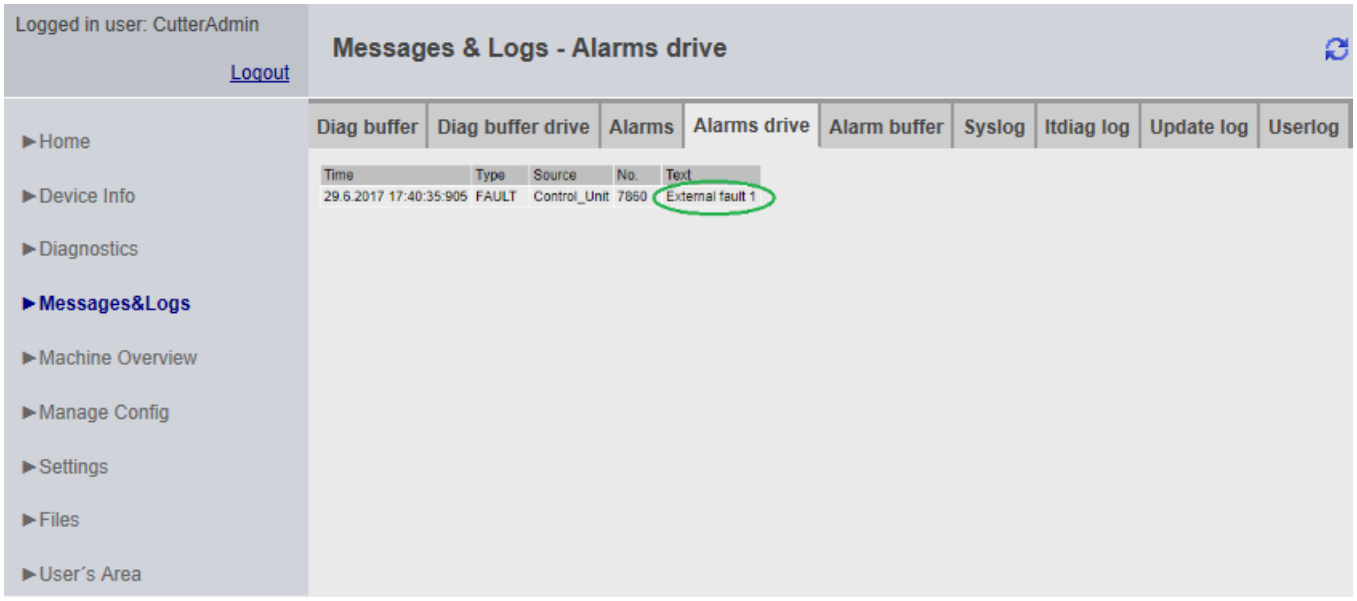

Figure 6-53 DriveAlarms

The drive alarms for the CX32/CX32-2 controller extension and external CUs can also be displayed.

Alarm buffer

Contents of the alarm buffer

On the **Alarm buffer** page, you can view the following information:

Index	Numbering of entry
Time	Time of the alarm
TO	Instance of the technology object
Alarm	Alarm number
Text	

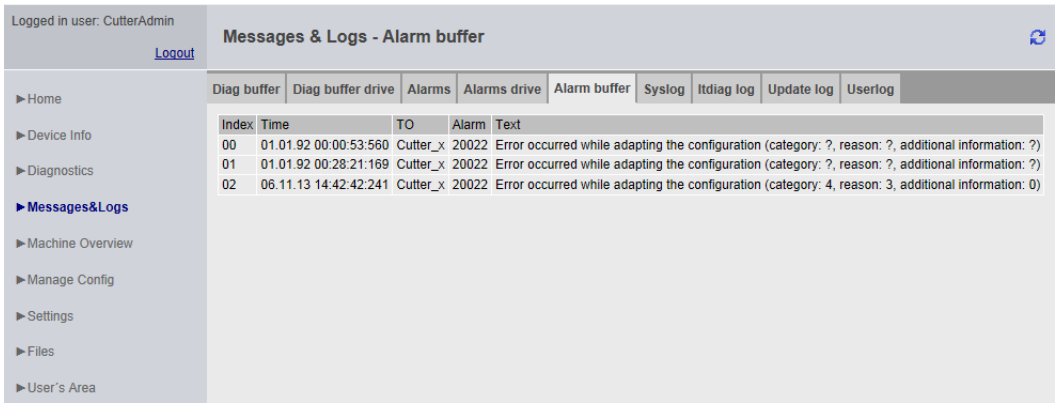

Figure 6-54 Display of the alarm buffer

In contrast to the **Alarms** page, which shows the alarms that are currently pending, the **Alarm buffer** page shows a history of all the alarms.

Syslog

Syslog

The **Syslog** page displays the syslog file for the relevant device.

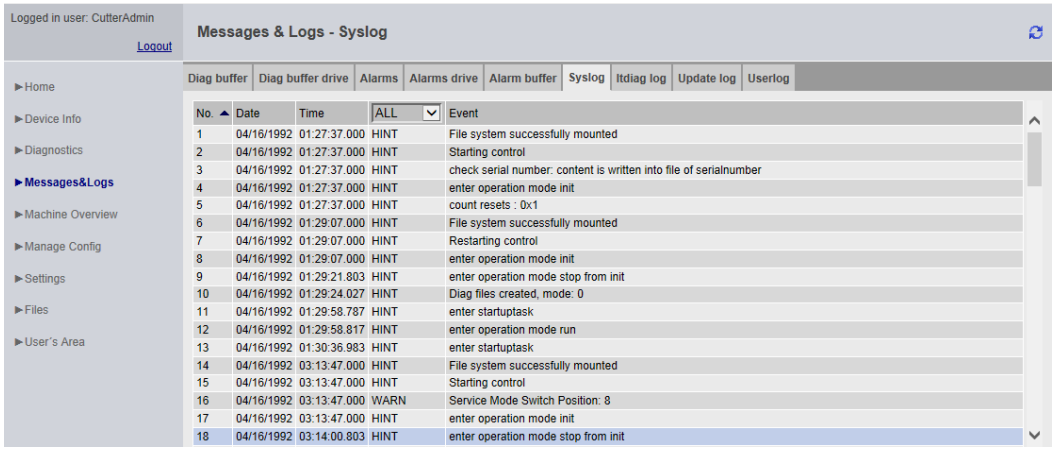

Figure 6-55 Syslog

This file is maintained by the system. Events that are important for diagnostic purposes are documented, such as RAM2ROM. When you start the page, all events are displayed. On the title page of the table, you can limit the display by deselecting **ALL**.

Itdiag log

Itdiag log

The messages from SIMOTION IT are output on the **Itdiag log** page.

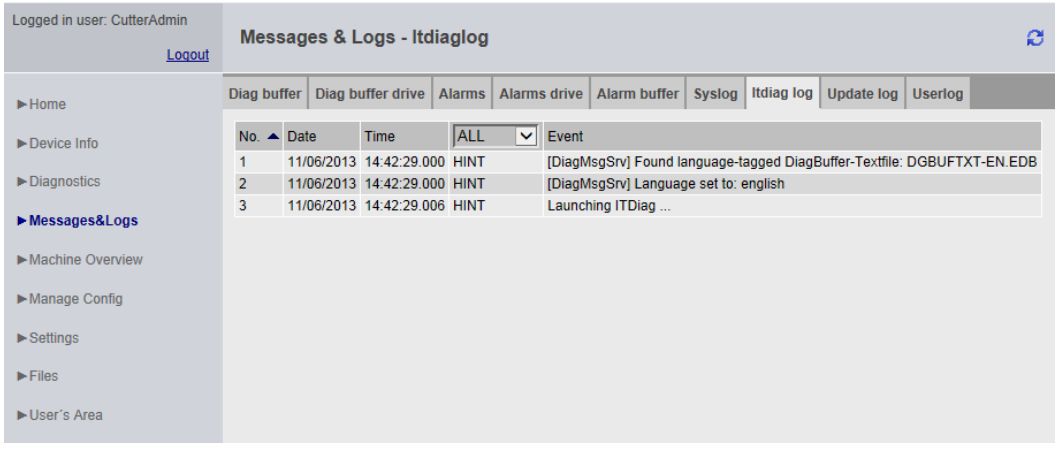

Figure 6-56 Itdiag log

SIMOTION IT-specific log outputs are displayed on this page.

Update log

Update log

The download and upload messages are displayed on the **Update log** page.

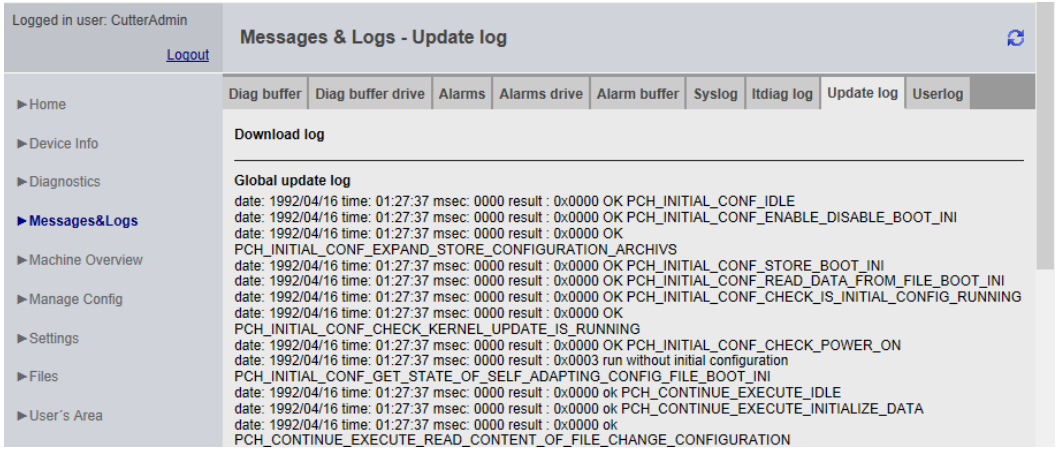

Figure 6-57 Update log

Messages that are generated during the project update are displayed on the Update log page.

Userlog

Userlog

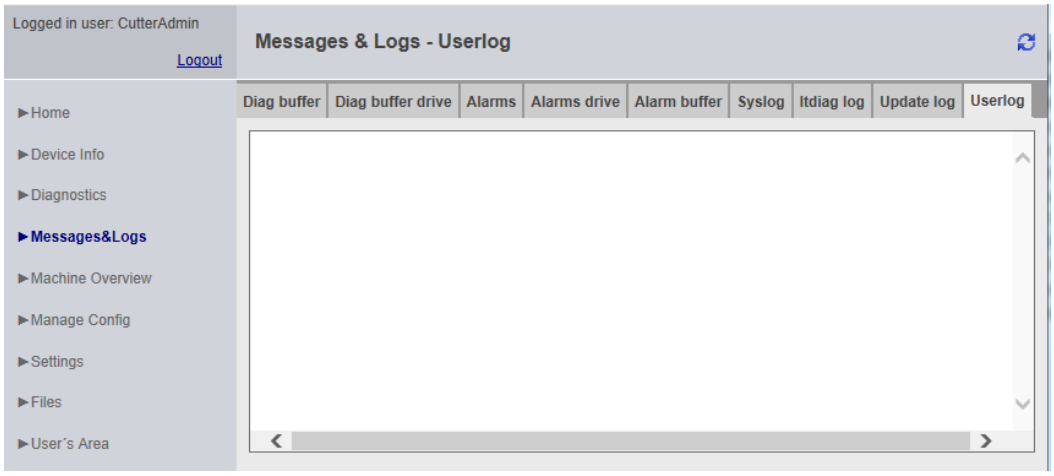

Figure 6-58 Userlog

The Userlog shows free texts entered by users in SIMOTION SCOUT (**Device Diagnostics** > **Userlog**). The texts are saved in a file on the memory medium of the control and displayed on the web page (in read-only format).

Machine Overview

Module information

Overview of configured modules

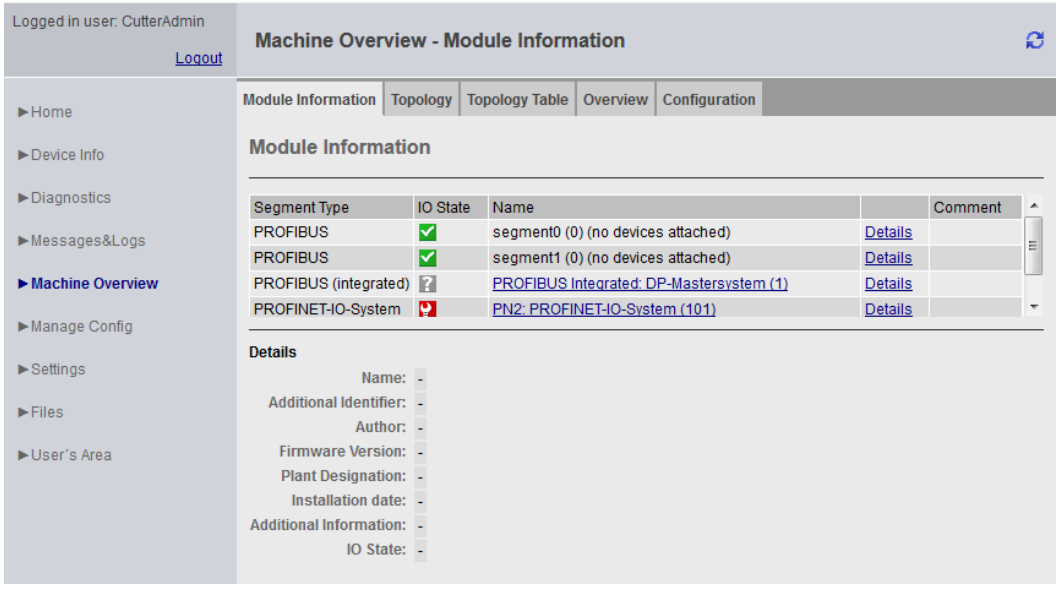

Figure 6-59 Module information

Overview of all modules configured on the machinery. Starting from the segment, you can navigate hierarchically to the element and call up information about it.

Note

For a correct representation of the information contained in the pages of the **Machine Overview**, it is necessary to load an HW Config in SIMOTION IT. The loaded HW Config must match the loaded SCOUT project, otherwise incorrect information is displayed.
See Configuration (Page 3620)

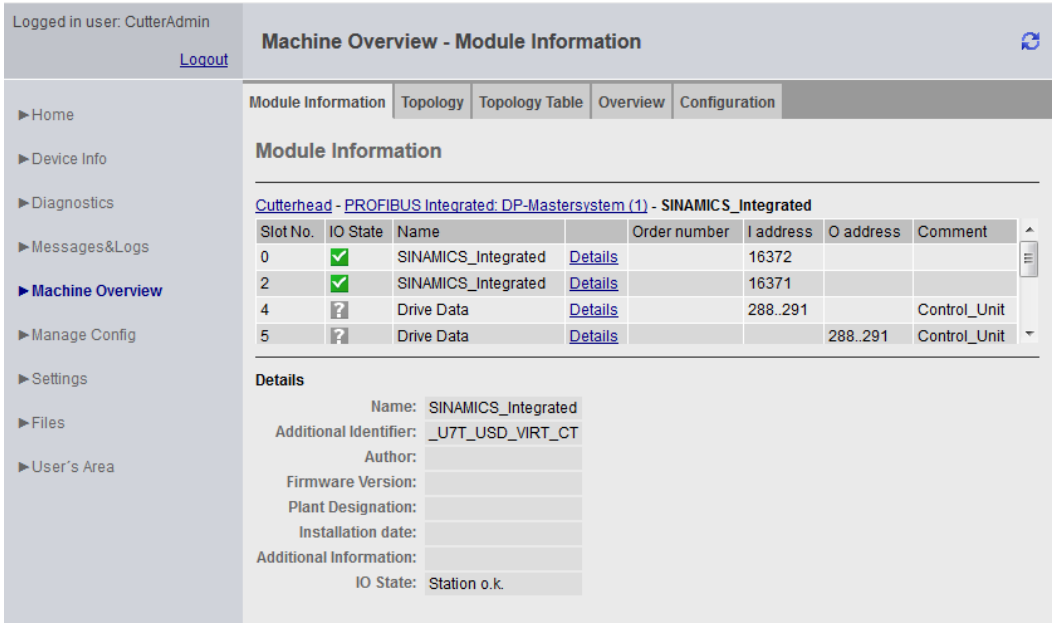

Figure 6-60 Module information - detail information

The hierarchy is always as follows: Segment > Device > Slot > Subslot (if present). Elements without subelements are not clickable.

Clicking on the segment displays all of the devices in the segment (PROFIBUS Integrated: DP-Mastersystem (1)).

Clicking on **Details** displays further information at the bottom (SINAMICS_Integrated).

Links allow you to jump back to the previously selected elements (breadcrumbs).

Topology

Overview of the configured topology

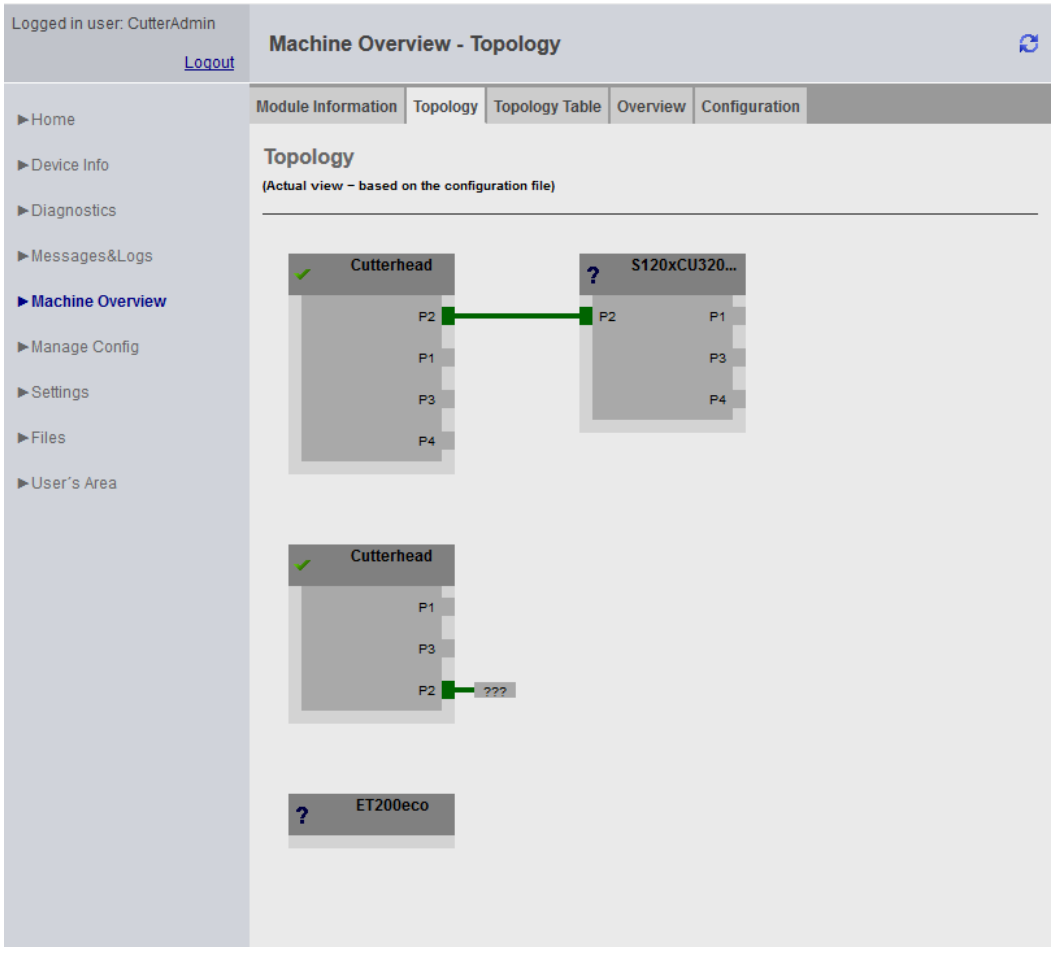

Figure 6-61 Topology of the device

The configured topology of a device is depicted on this page. Inaccessible nodes are highlighted in red.

The topology display shows how the nodes must be wired.

Topology table

Tabular overview of the configured topology

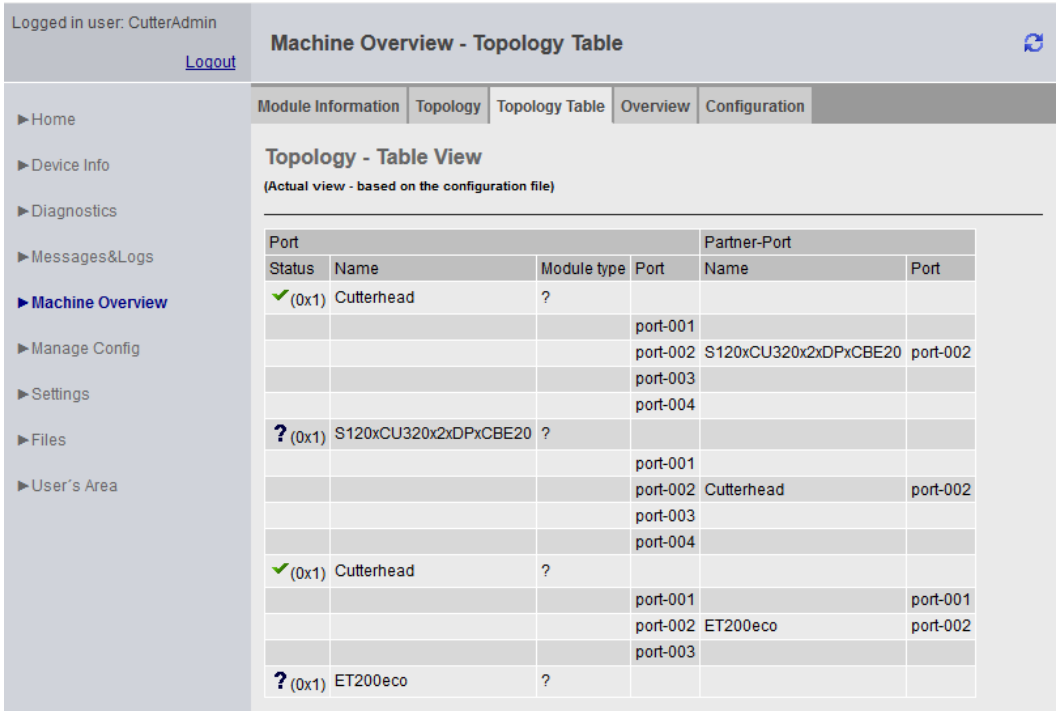

Figure 6-62 Tabular topology table

This page offers a quick overview of the wiring in text form.

The information displayed corresponds to that of the topology (Page 3618) page.

Overview

Overview of all modules configured on the network

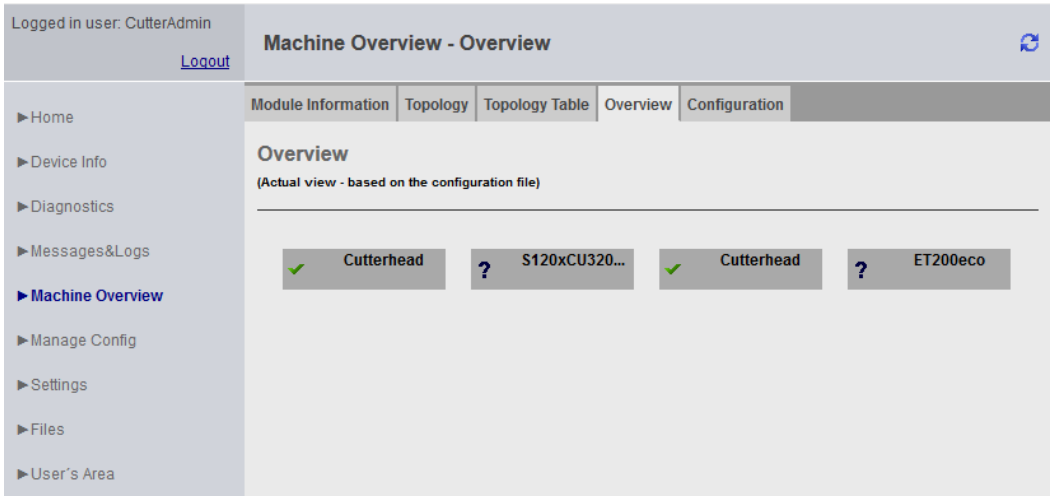

Figure 6-63 Overview

This overview displays all modules configured on the network without topology information. This overview is primarily intended for very large projects.

Inaccessible or failed nodes are shown in red.

Configuration

Downloading a configuration

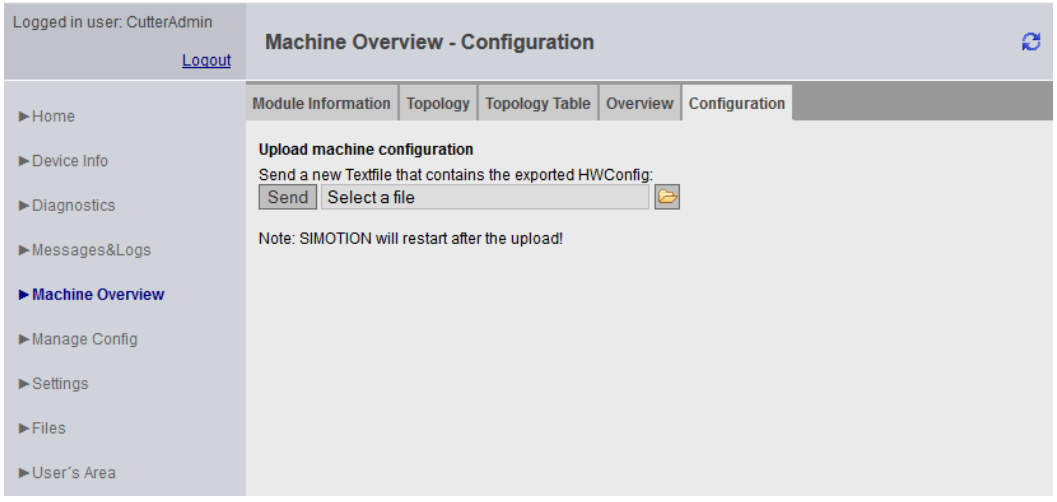

Figure 6-64 Configuration

Downloading HW Config information to SIMOTION IT

An HW Config export file must be loaded to SIMOTION IT. The texts and designations of the installed modules are only present once this has been done. The controller must be in STOP operating state for this purpose.

The HW Config export file and the loaded SCOUT project must match, otherwise incorrect information is displayed.

Note

TIA Portal

The TIA Portal does not provide any possibility to load the HW Config data.

Exporting in HW Config

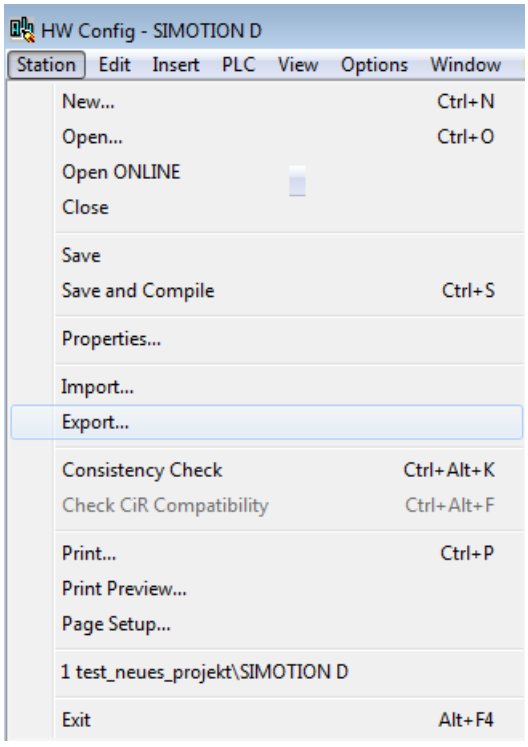

Figure 6-65 HW Config export

- Open HW Config
- Menu **Station Export**
- Save the file.
- The controller must be in STOP operating state.
- Load the resulting file using the form on the SIMOTION IT page.
- The SIMOTION controller subsequently performs a restart.

The file can then be found on the card in the directory /USER/SIMOTION/HMICFG/HWCONFIG.CFG

Alternatively, you can also directly copy the file to the card using a card reader.

⚠ WARNING

HW Config export file and SCOUT project

The HW Config export file and the loaded SCOUT project must match, otherwise incorrect information is displayed.

- If the HW Config is changed, the file must be reloaded.

Manage Config

Device update

Device update of the device

This page enables you to load a device update. The device update allows selected data to be saved to the PC from the device.

If several update archives have been written to the controller successively, you have the option of restoring a previous configuration.

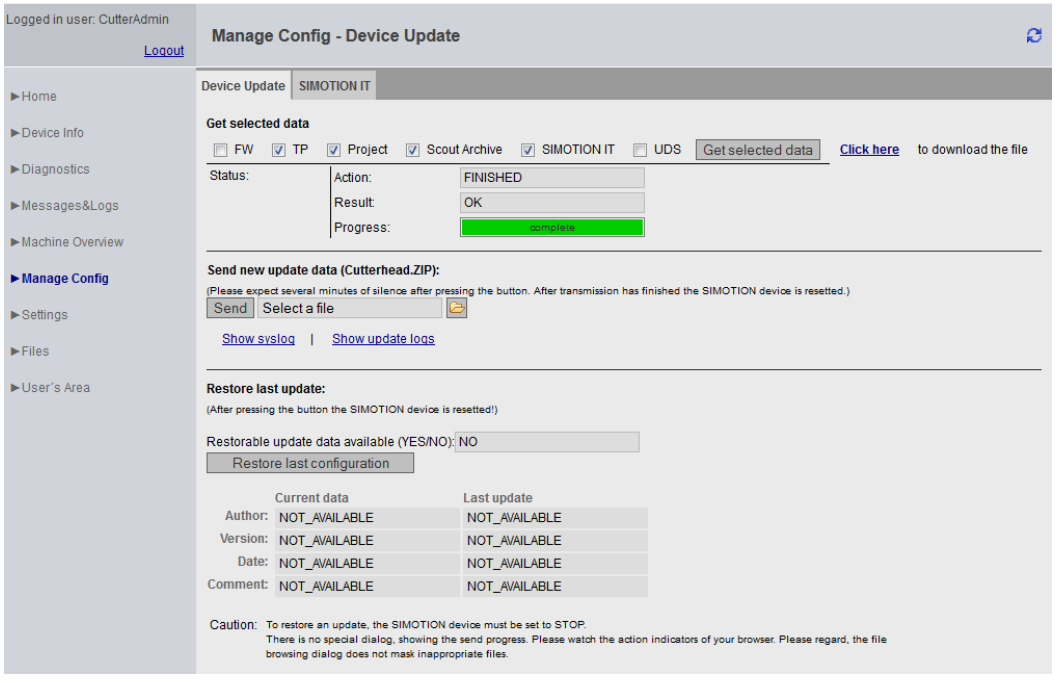

Figure 6-66 Manage Config - Device Update

- **Get selected data** transfers the currently active device data to the PC.
  The saved data has a format that allows it to be reimported to the device. To correctly save the project and the technology packages, a RAM2ROM must be performed in the SCOUT. Alternatively, the data can be saved directly in the file system on the card in the `\USER \SIMOTION\RT_DIR` directory.
  - **FW** (firmware)
  - **TP** (technology packages)
  - **Project** (current project)
  - **Scout Archive** (including the SCOUT backup)
  - **SIMOTION IT** (SIMOTION IT configuration)
  - **UDS** (including the **Unit Data Sets**)

  Note

  Transmission duration

  If the capacity utilization of the controller is very high at the cyclic levels, this operation may take some time. In individual cases, transmission times may be longer than 30 minutes.

- **Send new update data** transfers a file generated with the device update tool or SIMOTION IT **Get selected data** to the device.
  This process can take several minutes and restarts the device.

  Note

  No other SIMOTION IT pages may be called during the update. A progress bar shows how the update is progressing. Cancellation of the update is logged in the system log.

- **Restore last update** reactivates the last version of the device data of the preceding software update.

You will find more information on this topic in the "Updating SIMOTION Devices" Operating Instructions.

⚠ DANGER

The controller must be put into the STOP state.

To send or download a project or firmware, the controller must be switched to STOP state.

Type and contents of the file are not checked during transmission.

If an invalid configuration is used, the USER directory must be deleted from the memory card.

Note

SIMOTION P

The SIMOTION P controller does not support firmware download.

Note

Memory

If low-capacity cards (32 MB/64 MB) are used, problems may be encountered during the update due to insufficient memory space.

The amount of memory space required is determined by the size of the existing configuration plus that of the update.

Only users who have logged in can access this page. See Log-in administration (Page 3658)

Use of existing configuration data

Existing configuration data that was created with the SIMOTION SCOUT **Load to File System** function can continue to be loaded using SIMOTION IT.

The ZIP file generated by SCOUT as part of this process can be transferred to the device using **Send update data**.

Although the installation of an older version is generally possible via **Send update data**, the function is not envisaged for this purpose. If a previous version is installed, the operability of the device is not guaranteed. A manual customization of the configuration, the user database, etc. is required in this case.

Updating the firmware to V4.5

The update of the firmware to version 4.5 causes an existing WebCfg.xml to be converted to the new format. If a problem occurs during the migration, the error cause is noted in a diagnostic buffer entry.

Further information about the migration strategy is provided in the Structure of the webcfg.xml configuration data (Page 3657) section.

Updating the firmware to V4.4

When updating the firmware to Version 4.4, an attempt is made to convert the configuration file WebCfg.xml to the new format. A UserDataBase.xml is created and filled with the old WebCfg.xml.

The original file is renamed to WebCfg.xml.deprecated.

This conversion might fail for the following reasons:

1. The version of the WebCfg.xml is for firmware before V4.2, which cannot be updated.
2. An error occurred during an attempt to apply individual user settings.
3. The user administration UserDataBase.xml contains an invalid entry. If the user 'simotion' and the password 'simotion' are found, conversion will be canceled. An error message indicating this will then be placed in the diagnostic buffer.

If this error occurs, the configuration files have to be corrected manually.

Converting firmware from V4.4 to V4.3

When converting a module of SIMOTION V4.4 back down to firmware V4.3, the configuration file WebCfg.xml has to be converted because the formats are incompatible.

Control behavior

If the conversion archive does not contain WebCfg.xml, a check is made to see whether directory USER/SIMOTION/HMICFG contains a file WebCfg.xml.deprecated. The file is then restored.

If the file WebCfg.xml.deprecated does not exist, the WebCfg.xml file for SIMOTION V4.4 is deleted. The first time the module starts up with firmware SIMOTION V4.3, the associated Default WebCfg.xml is created.

Upgrading firmware prior to V4.2

A firmware update involving versions lower than Version 4.2 can result in the following: An old WebCfg.xml is retained on the device and and causes empty diagnostic pages to be displayed.

Option for avoiding this problem:

- Explicit deleting of WebCfg.xml in the /USER/SIMOTION/HMICFG directory.

After the next reset, a new WebCfg.xml is generated by the device. The old WebCfg.xml should be backed up first so that settings can be transferred from the old configuration to the new WebCfg.xml .

See also

Device update (Page 3622)

Upgrading firmware from V4.1 to V4.2

When upgrading the firmware from Version 4.1 to Version 4.2 or higher, WebCfg.xml must always be deleted. If WebCfg.xml is not deleted, the web pages will be incorrectly displayed.

Note

When upgrading from V4.2 to V4.3 or higher, this restriction is no longer valid. WebCfg.xml then no longer has to be deleted.

Editing function

Editing functions of the SIMOTION IT Standard pages

The WebCfg.xml and UserDataBase.xml configuration files can be edited on some standard pages via the browser. The editing functions are always structured in the same way and are explained in this section.

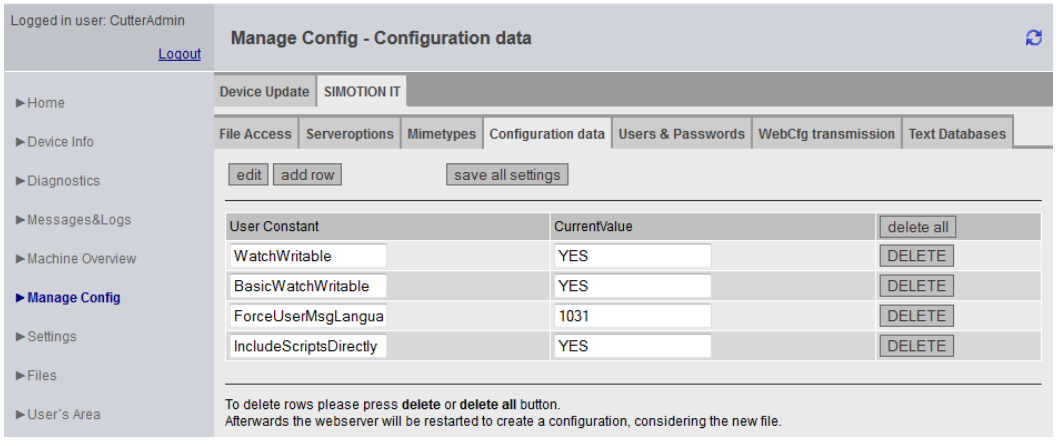

Figure 6-67 Editing functions

The **add row** button inserts one line.

To change the line, first click the **EDIT** button. The input fields can then be edited.

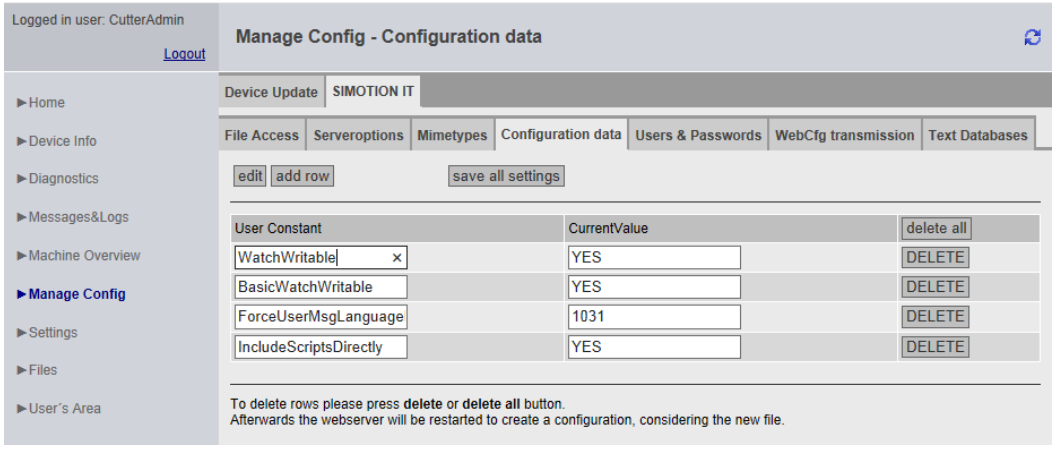

Figure 6-68 Editing functions input field active

The **DELETE** button deletes the inputs in the relevant line. The change is stored and the Web server is restarted immediately.

The **delete all** button deletes all lines.

The **save all settings** button saves all changes made on the controller.

SIMOTION IT tab

Web pages for making changes to the configuration

The SIMOTION IT tab summarizes the web pages that are used for configuring SIMOTION IT pages.

All changes under**Users & Passwords** are written to file UserDataBase.xml. All other tabs cause changes to the WebCfg.xml. As an alternative to editing using the web pages, changes can be made directly in these XML files.

SIMOTION IT File Access

Editing file and directory accesses

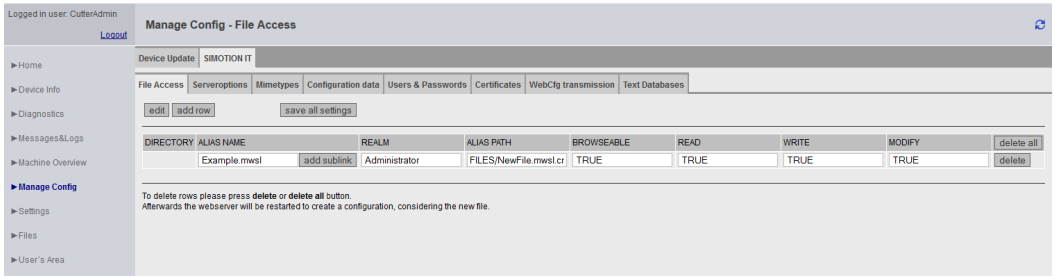

Figure 6-69 SIMOTION IT File Access

The tab File Access allows editing of file and directory accesses.

Attributes	Type	Example
ALIAS NAME	String	Example.mwsl
REALM	String	A group name: Administrator
ALIAS PATH	String	ALIAS="FILES/NewFile.mwsl.cms"
BROWSEABLE	true/false	
READ	String	One or more group names: Administrator,Servicegroup
WRITE	String	One or more group names: Administrator,Servicegroup
MODIFY	String	One or more group names: Anyone

Attribute overview tab File Access

Configuration of the file system (Page 3665)

SIMOTION IT Serveroptions

Basic settings

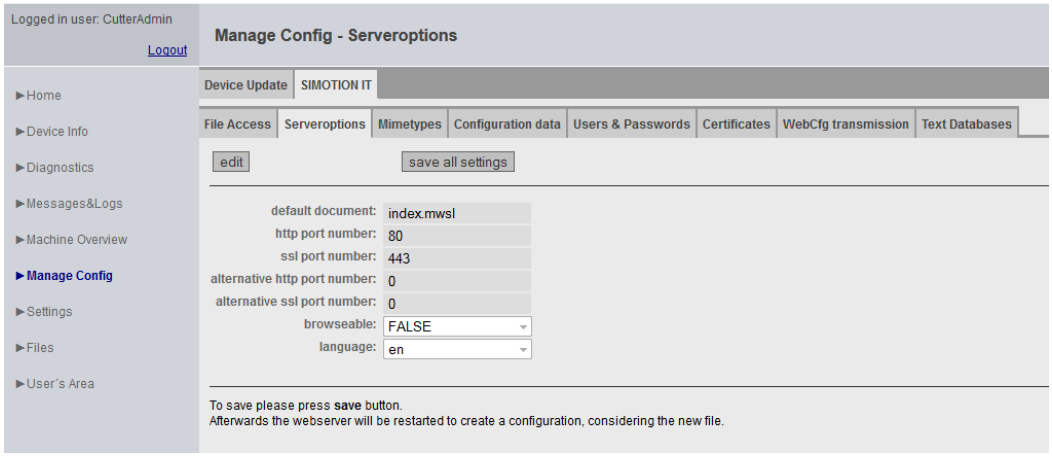

Figure 6-70 SIMOTION IT Serveroptions

This tab enables you to set basic parameters for the Web server.

Various settings for the `<SERVEROPTIONS>` tag in WebCfg.xml can be made on this page.

- <DEFAULTDOCUMENT> (Page 3728) enables you to change the home page. The default setting is `index.mwsl`.
- Default Port (Page 3730) defines the TCP/IP port for the output of the Web server pages. The default setting is port 80 (http).
- SSL Port (Page 3732) defines the TCP/IP port for the encrypted output of the Web server pages. The default setting is port 443 (https).
- Alternative Default Port (Page 3731) defines an additional TCP/IP port for the output of the Web server pages.
- Alternative SSL Port (Page 3733) defines an additional TCP/IP port for the encrypted output of the Web server pages.
- As of version 4.4, <BROWSEABLE> no longer has any effect.
- <LANGUAGE> saves the selected language in the WebCfg.xml in the `<LANGUAGE>` tag in the `VALUE` attribute. English language setting: `<LANGUAGE VALUE="en"/>`.

SIMOTION IT Mimetypes

MIME types

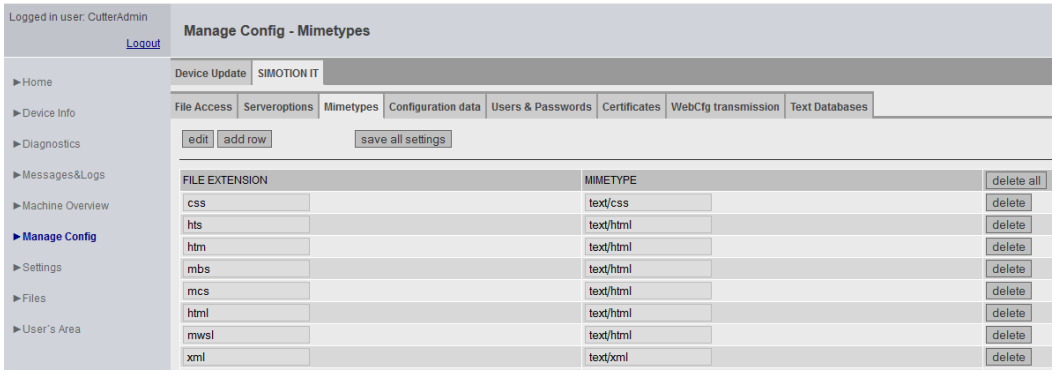

Figure 6-71 SIMOTION IT Mimetypes

A MIME type can be linked to a file extension on this tab.

The MIME type is used to signal to the browser, by means of the HTTP header, what type of data is being transmitted.

User-defined variables (Page 3698)

SIMOTION IT Users & Passwords

User database

The Users & Passwords page enables the user administration. Passwords, group rights, and access rights can be assigned to users here.

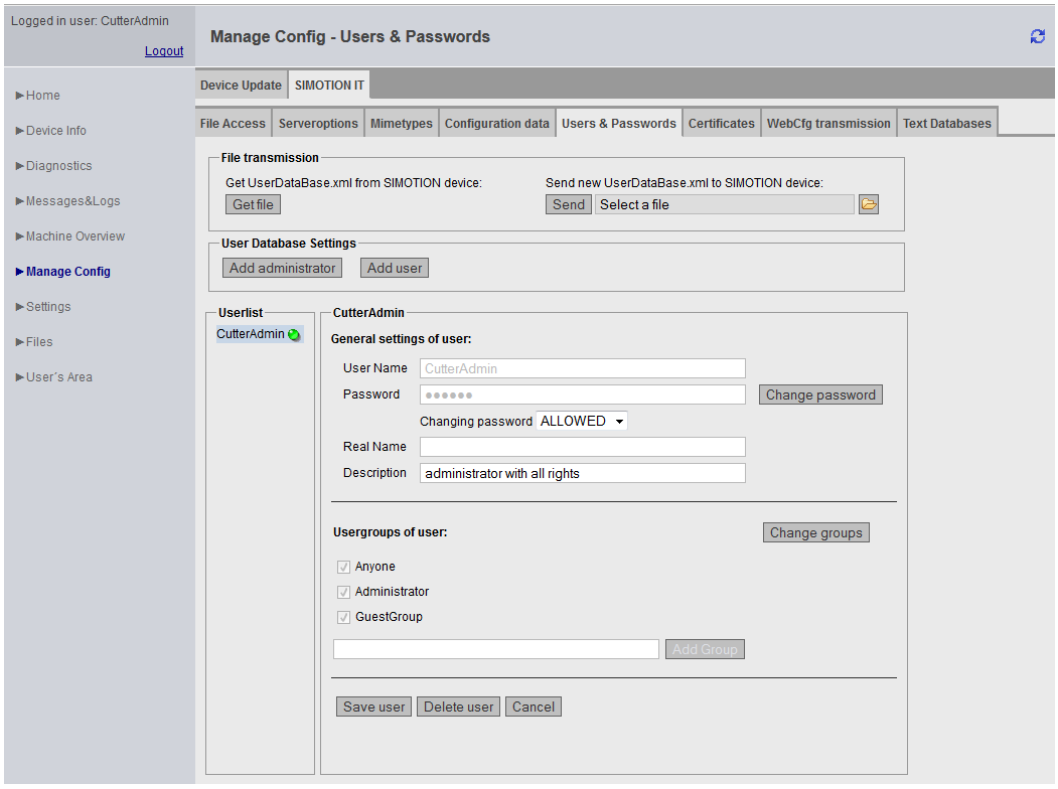

Figure 6-73 User database

File transmission

You can make a local backup of UserDataBase.xml of the controller with **Get file**. You can load a UserDataBase.xml onto the controller with **Send**.

Adding users

The **Add administrator** button creates administrators; the **Add user** button creates users.

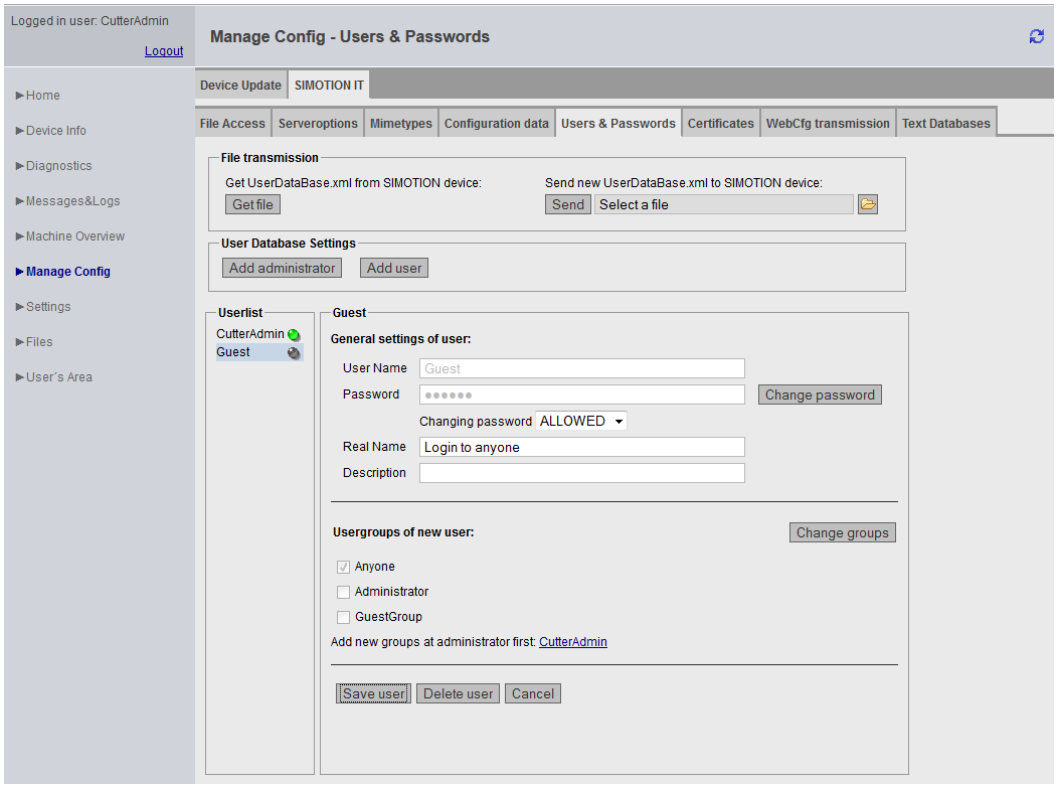

Figure 6-74 Benutzer Guest

This screenshot shows the situation after adding a user Guest who only belongs to the Anyone group.

Setting up a new group

A new group is only set up once the administrator has been assigned membership of that group. The **CutterAdmin** link in the above example opens the dialog box with the settings of the administrator CutterAdmin.

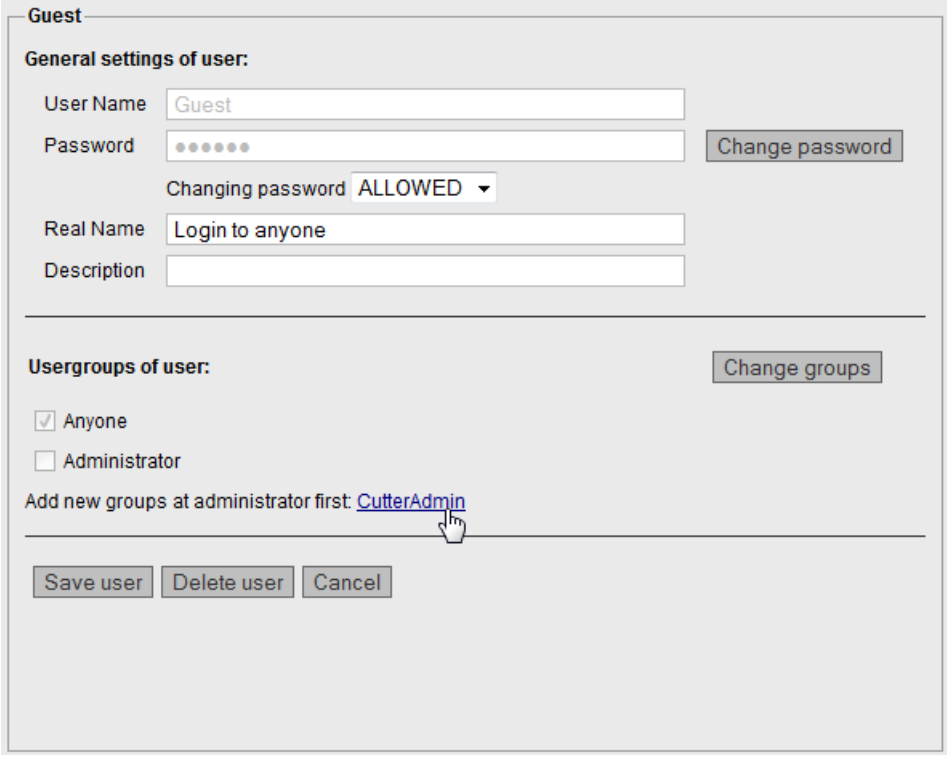

Figure 6-75 Creating a new group: Opening the administrator

The administrator can now create a new group with the **Add Group** button.

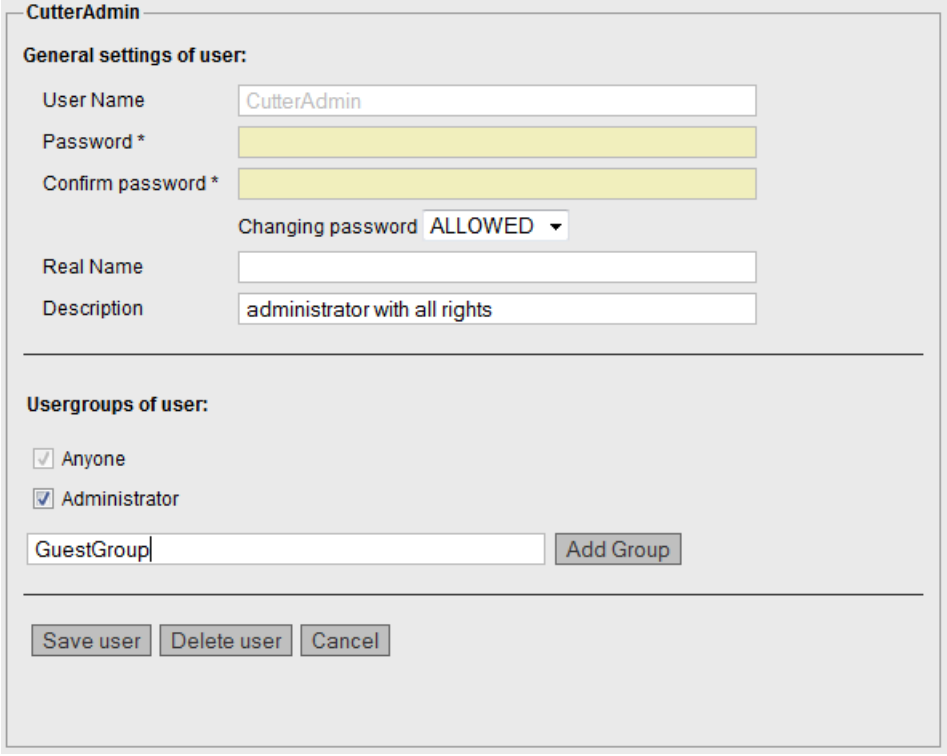

Figure 6-76 Creating a new group: Administrator creates the group

The new group GuestGroup can now be entered.

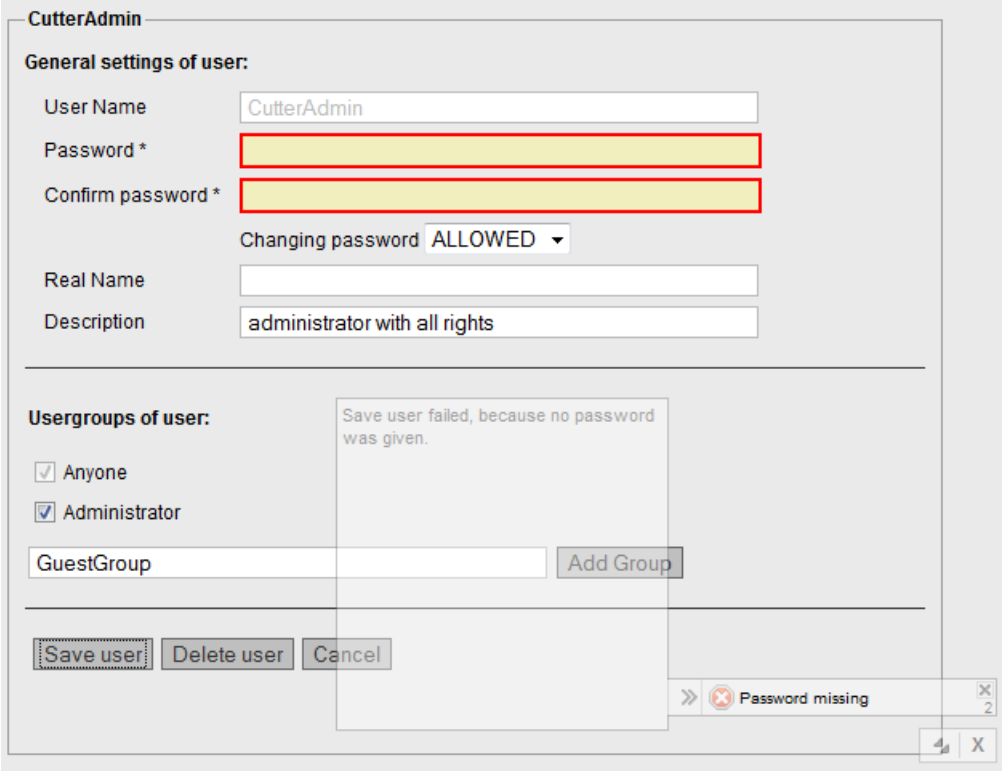

Figure 6-77 Creating a new group: Administrator password required

A new group can only be saved if the user is logged in as an administrator.

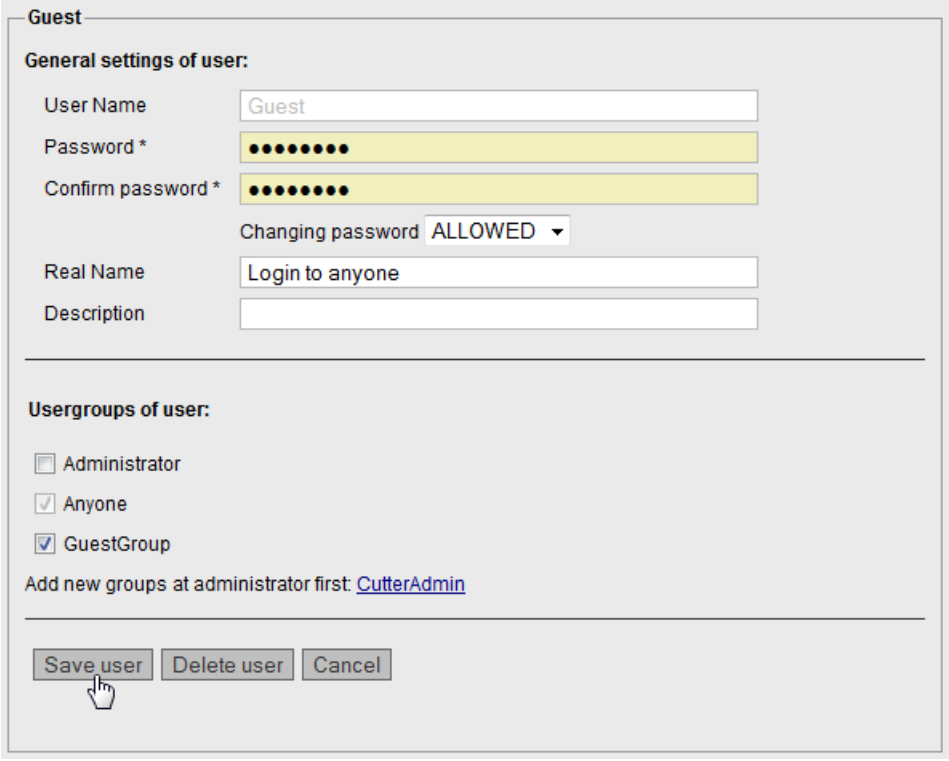

Figure 6-78 Creating a new group: Assigning a new group

Once the new group has been created, the group GuestGroup can be assigned to the user.

Note

Strong password

Only a strong password guarantees access to the device. The complexity and the length of the password must be appropriate for the type of data to be protected.

See also

Log-in administration (Page 3658)

SIMOTION IT Certificates

Uploading and downloading certificates

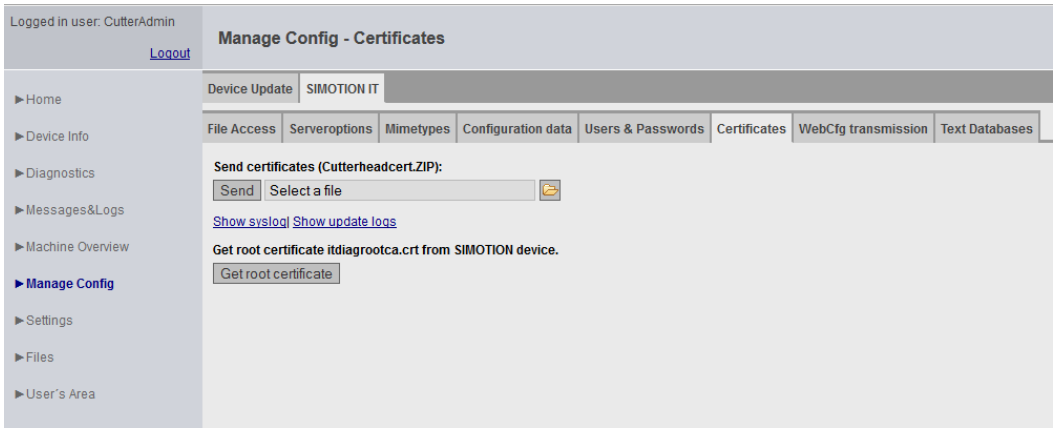

Figure 6-79 Certificates

The Certificates page enables certificates to be transferred to the controller. The ZIP file must have the same directory structure as is created when generating certificates with OpenSSL.

The **Get root certificate** button fetches the server certificate from the controller.

Encryption methods (Page 3703)

SIMOTION IT WebCfg Transmission

Transferring configurations to the device

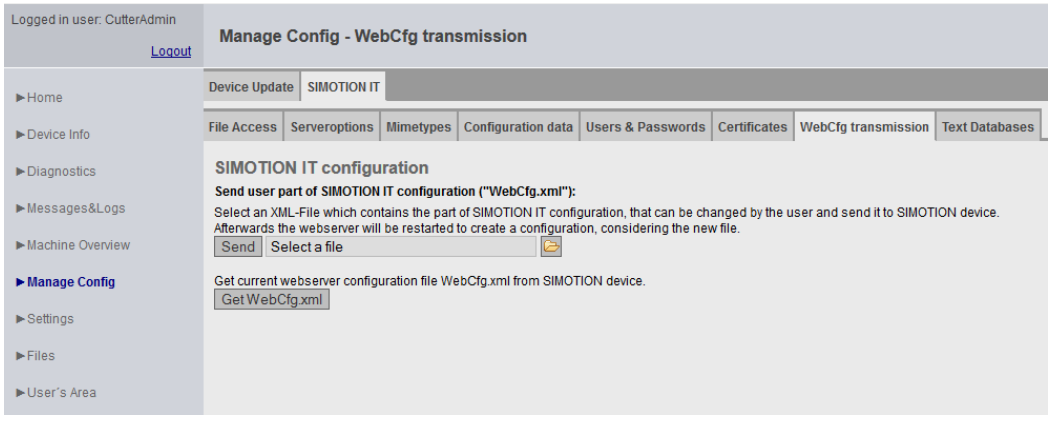

Figure 6-80 WebCfg transmission

The configuration data can be sent to or received by the device via this page.

The **Send** button transfers a locally edited WebCfg.xml to the device. As soon as the new WebCfg.xml has been sent, the Web server reboots and takes account of the new file.

SIMOTION IT Text Databases

Transmission of user-defined messages from SIMOTION SCOUT to the device

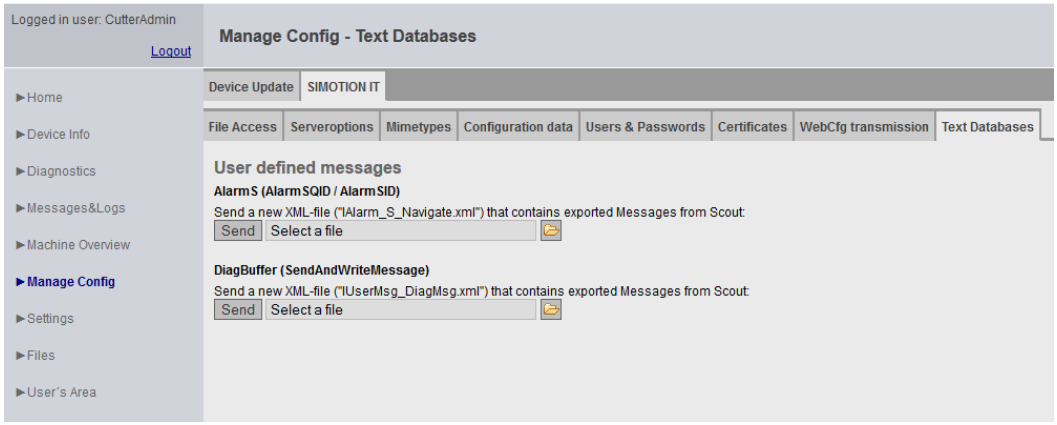

Figure 6-81 Text Databases

On this page, SIMOTION IT provides the option to transfer user-defined AlarmS and DiagBuffer messages, which have previously been exported into SIMOTION SCOUT, to the device.

For AlarmS, select the IAlarm_S_Navigate.xml file, and for DiagBuffer, select the IUserMsg_Navigate.xml file of a SIMOTION SCOUT language export. It is possible to select different languages for AlarmS and DiagBuffer messages.

Once the files have been transferred to the device, the messages exist in two files:

- dgusralarm.edb
- dgusrtxt.edb

in the /USER/SIMOTION/HMICFG directory. These files can be transferred to other controllers.

Language export from SIMOTION SCOUT

In SIMOTION SCOUT, the **Project > Language-dependent texts** and **Project > Messages** menu items enable export of user-defined messages.

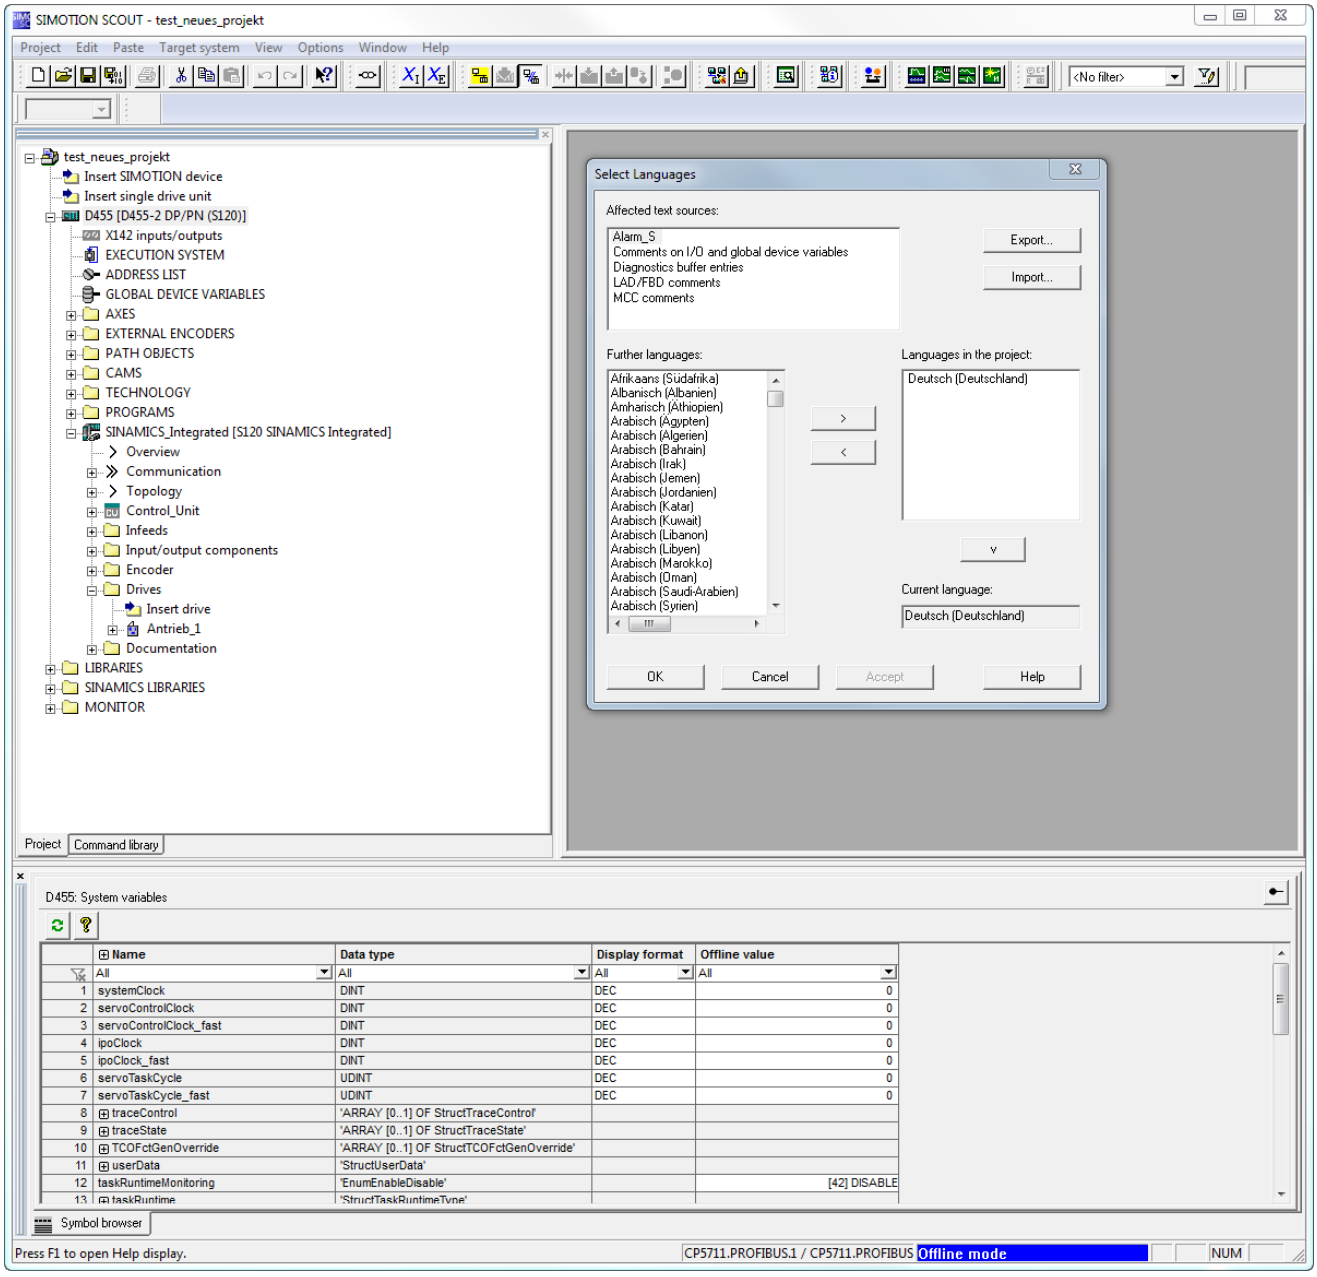

Figure 6-82 SIMOTION SCOUT language export language selection

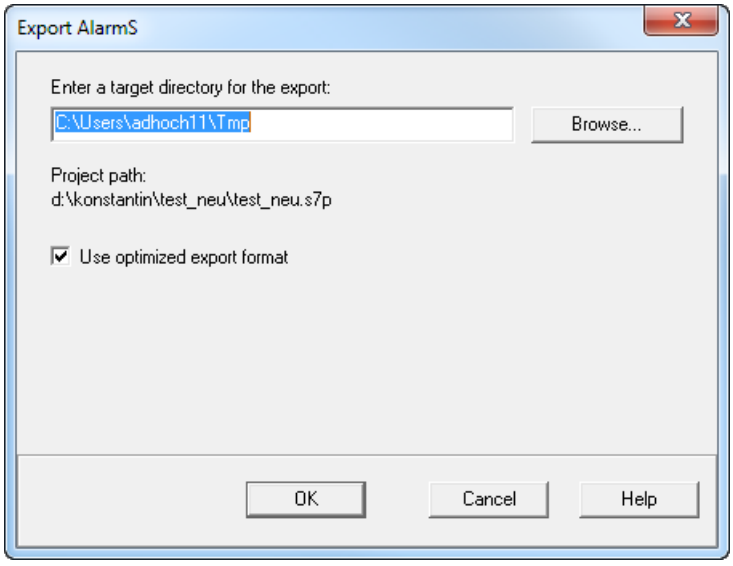

Figure 6-83 SIMOTION SCOUT language export, specification of the target directory

The **Project > Messages > Export AlarmS** menu item exports all user-defined texts in all available languages as XML files. During the upload to the device, only the language preselected in SIMOTION SCOUTis saved.

Every change made in SIMOTION SCOUT requires the texts to be exported and uploaded again.

Note

Special characters in AlarmS messages

Characters that cannot be represented are shown as question marks in messages.

The @ character is a reserved character for SCOUT. The $ character is a reserved character for SIMOTION IT. These characters must not be present in a AlarmS message.

OPC UA

For access to OPC UA, the interface and the TCP/IP port are activated on this page.

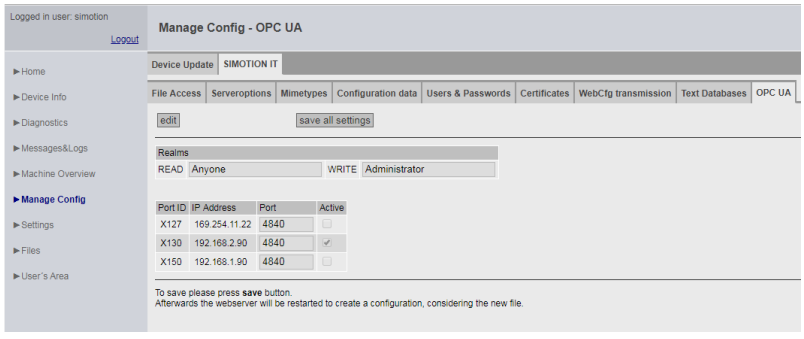

Figure 6-84 Activating OPC UA interfaces

You can find additional information about OPC UA in the **SIMOTION IT OPC UA** Manual.

Settings

This page enables you to change various settings.

Settings for the SIMOTION device can be changed in the **Control Operation state** and **Time Settings** areas.

In the **User Pages** area, you can change how user-defined pages and the **SIMOTION IT** menu editor appear.

⚠ WARNING

Danger to life as a result of incorrect or modified parameterization

As a result of incorrect parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- The Settings page is password-protected. See Login administration (Page 3658)

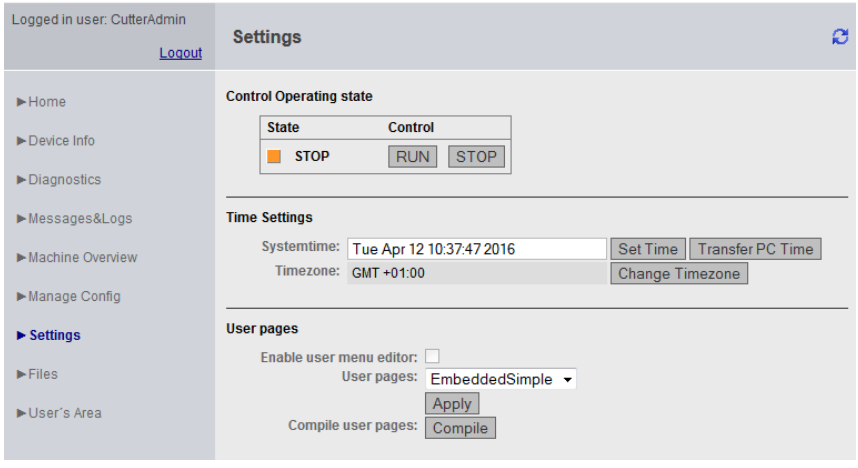

Figure 6-85 Settings

Changing the state of the SIMOTION device

Control Operation state

In the field for the operating state of the SIMOTION device, the request to change the operating state can be triggered by pressing the appropriate **RUN** or **STOP** button.

The switch on the controller has a higher priority than this input, i.e. if this switch is set to STOP , then RUN is not possible.

Note: For the purpose of transferring a project or firmware, the current operating state must be set to STOP.

⚠ DANGER

Danger to life posed by uncontrolled changeover between operating states

Uncontrolled changeover between operating states can cause machines to malfunction, which in turn can lead to injuries or death.

- Include the effects of changeover between operating states in the risk analysis

Time Settings

The system time and the time zone for the SIMOTION device are set in hours, including sign, in the field for the time settings.

Systemtime	Local time-of-day of the SIMOTION device
Timezone	Difference between the Systemtime on site (i.e. local time) and GMT

The **Transfer PC Time** button transfers the current time of the device on which the Web browser runs with SIMOTION IT to the Systemtime input field. The **Set Time** button sets the system time of the controller.

The system time and the time zone are relevant for the OPC XML DA access.

The OPC XML DA client expects all times sent by the SIMOTION device to be in GMT. However, a SIMOTION device is set to local time (GMT + X); therefore, a time zone must be set for the SIMOTION device.

The **Change Timezone** button opens a list of time zones, from which one time zone can be selected.

The time zone can also be set under **Hardware configuration > Object properties of the CPU > "Ethernet Extended" > OPC XML / diagnostic pages** and then applied by running a download. These settings are possible only when **Time Settings** and the <TIMEZONE> in the WebCfg.xml have never been changed.

User Pages

The **Enable user menu editor** checkbox enables you to activate the menu editor link on the user-defined pages. This option will only take effect once **Embedded** has been selected from the **User Pages** drop-down box.

The **User Pages** drop-down box affects how the user-defined pages are displayed. See the SIMOTION IT Programming and Web Services Manual , Section Embedded user-defined pages .

All MWSL pages on the controller can be compiled explicitly with the **Compile** button. This action is required, for example, whenever new MWSL pages are loaded onto the controller by FTP.

<TIMEZONE> (Page 3734)

Files

Files

The subdirectories and files on the memory card of the SIMOTION device can be deleted on the **Files** page.

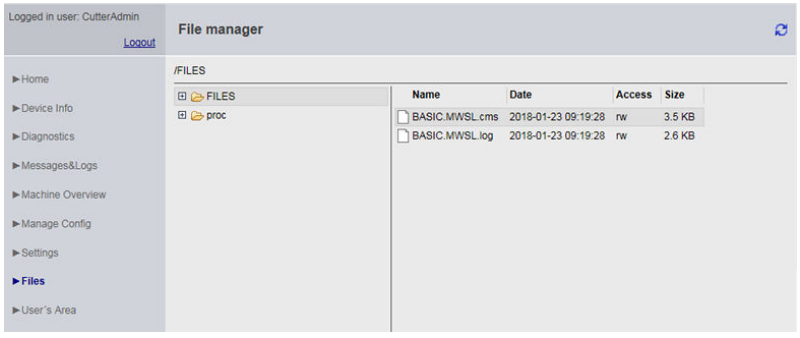

Figure 6-86 Files - User with administrator rights: rw

The File Manager consists of three areas:

- The path line at the top
- The directory tree on the left-hand side
- The directory and file list on the right-hand side

The path line shows which directory content is currently loaded on the right-hand side of the File Manager.

The directory tree shows only directories.

The directory and file list on the right-hand side is shown as a table. The width of the columns in this table is automatically adapted to the content. The unit of the file size in the **Size** column is shown as Bytes, KB, MB or GB depending on the file size.

Access rights

Users with administrator rights have full access to the directories and files of the File Manager.

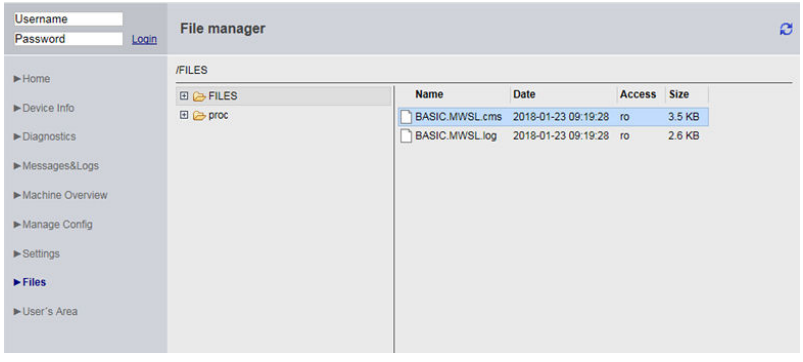

Figure 6-87 Files - User with restricted access rights: ro

The access rights displayed in the File Manager reflect the rights granted to the user. The `ro` access attribute in the above figure shows that only read rights to the files exist.

File Manager functions

The File Manager can be operated with mouse, keyboard and the context menu.

Directories can be created, renamed and deleted. In directories, files can be uploaded, downloaded and deleted.

Note

The following characters are permitted in directory and file names:

- (A-z, -, _)

Context menus

The context menus change depending on whether a directory or a file is selected.

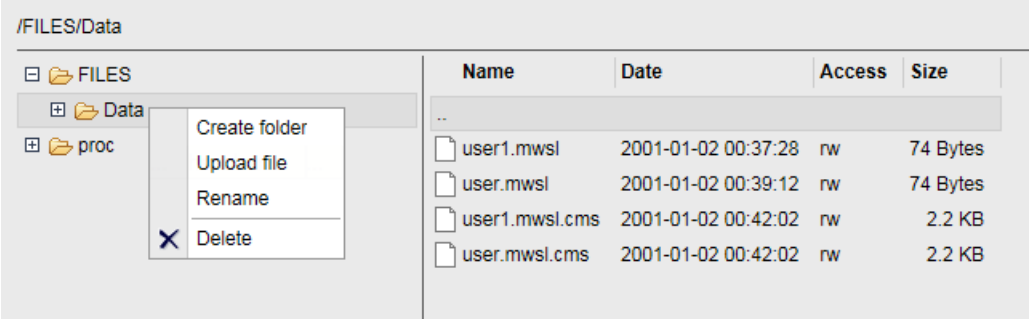

Figure 6-88 Context menu - Directory

When deleting directories, ensure that they do not contain any files.

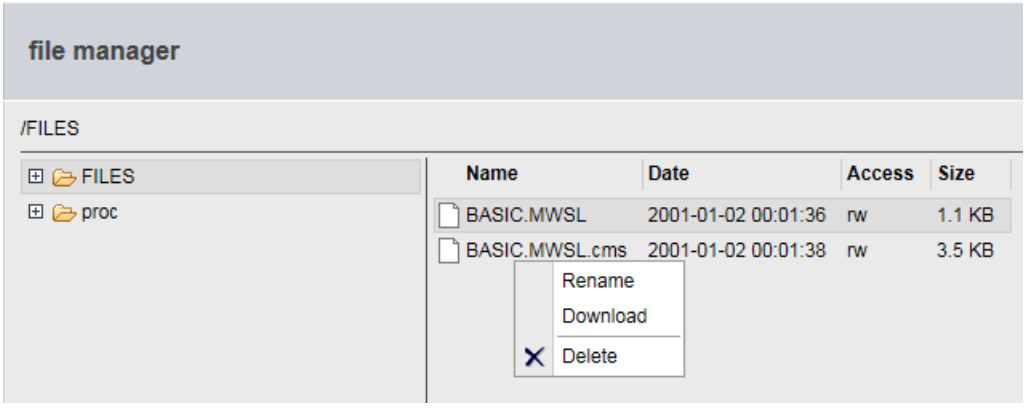

Figure 6-89 Context menu - File

The context menu of a selected file allows this file to be downloaded and deleted. The upload of a file opens the context menu of the directory.

Uploading files to the SIMOTION controller

The **Upload file** button transfers one or more files from the local file system to the SIMOTION controller. The **Download** button of the context menu transfers a file from the controller to the local file system.

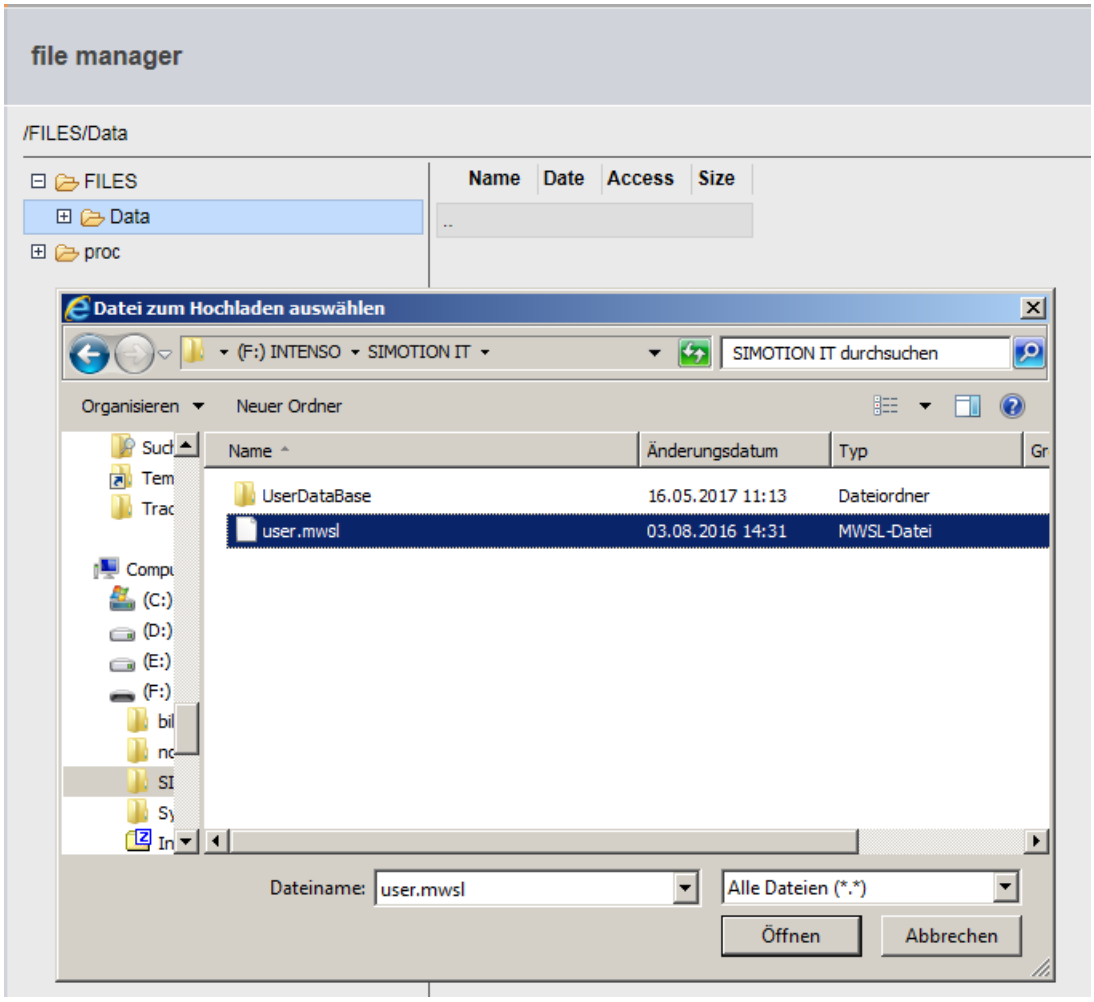

Figure 6-90 Context menu - "Upload file" file dialog

Note

Overwriting existing files

If you upload a file with the same name as one already saved in the SIMOTION controller, the existing file will be overwritten.

Note

Large files

If files that are larger than the remaining space on the memory card are transferred, a different error message will be displayed depending on the browser used.

Browsers do not check prior to transfer whether there will be sufficient memory space on the card for the file. The server cannot compensate for this browser response.

Uploading files with drag-and-drop

If one or more files have been selected, for example in the Explorer, they can be dragged to the desired directory of the File Manager. Because multiple files cannot be transferred concurrently, a queue is created that is processed in the background.

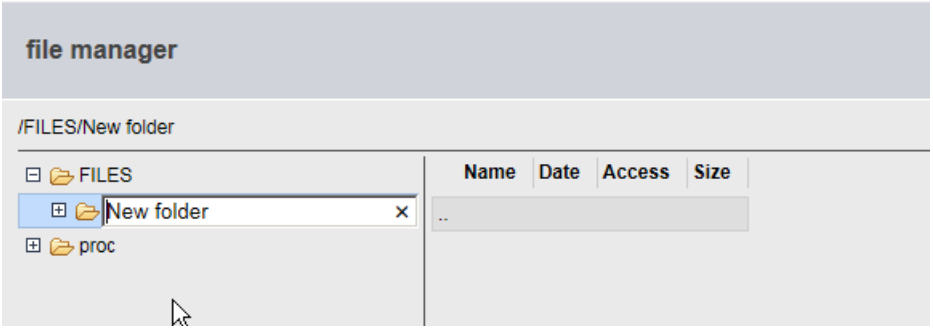

Figure 6-91 Renaming a directory

Appropriate confirmations or messages depending on the action are shown. For example, a confirmation is required when a file or directory is deleted.

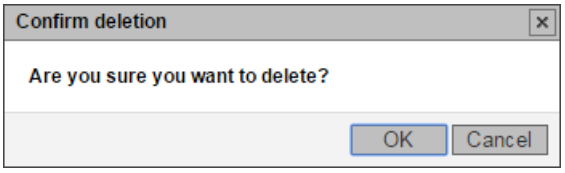

Figure 6-92 Delete file confirmation

File Manager keyboard assignment

Key	Description
Up	Select the previous (above) element.
Down	Select the next (below) element.
Left	Close the directory selected in the directory tree or select a higher-level element in the directory hierarchy.
Right	Open the directory selected in the directory tree or select the first lower-level element, if present.
F2	Activate the editing of a file or directory name.
Del	Delete a file or directory.
Input	Display the directory content in the right-hand area or download a file.
Esc	Cancel the editing of a file or directory name.
Tab	Switch between the directory tree and the list.

Device-specific directory paths

The user-specific directories and files are stored in a separate directory. These directories differ depending on the SIMOTION devices. The information in the table refers to a default installation.

SIMOTION device	Path
C, D	\USER\SIMOTION\HMI\FILES
P350	F:\SIMOTION\USER\CARD\USER\SIMOTION\HMI\FILES
P320	D:\Card\USER\SIMOTION\HMI\FILES
P320-4 E P320-4 S	D:\USER\SIMOTION\HMI\FILES

Note

Available memory space on the card

The memory available on the card is shown on the Diagnostics page in the "Memory Card" line. (Diagnostics (Page 3585)).

Proc

Accessing the device variables using the Proc file system

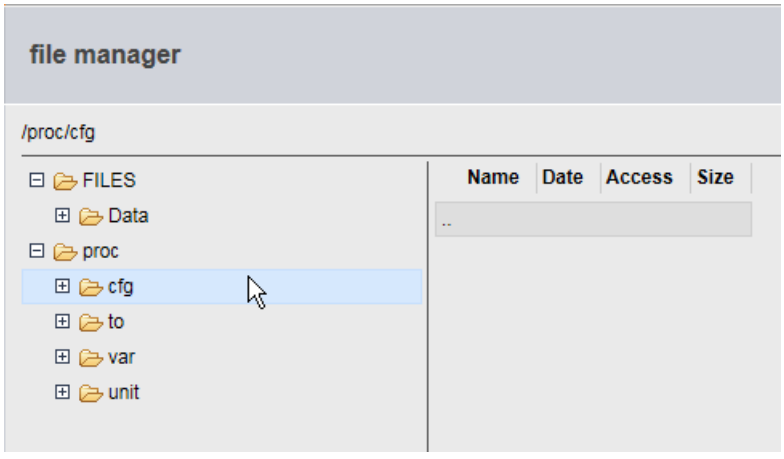

Figure 6-93 Proc file system

The Proc file system shows the device variables as a drive in the browser. This enables device variables to be read out via FTP, for example.

To give an FTP client access to the Proc drive of the controller, reassign the target drive to drive P:

Variables are accessed via a path specification and the addition of the extension "bin" to the name of the variable.

Variables	Path
TO configuration data	/cfg/<toname>/<varname>.bin
TO system variables	/to/<toname>/<varname>.bin
Device system variables	/var/<varname>.bin
Program variables	/unit/<unitname>/<varname>.bin

Arrays are also accessed via a path.

- Variable: unit/UnitName.StructName.StructCompSimple
- Path: /unit/UnitName/StructName/StructCompSimple.bin

Access to arrays and structures

- Variable: unit/UnitName.Array[5].StructName.StructCompSimple
- Path: /unit/UnitName/Array/5/StructName/StructCompSimple.bin

The files in the Proc file system comprise the contents of variables in binary format in the representation (Endianess) of the associated controller.

User's Area

The User's Area displays user-defined pages. The manual *SIMOTION IT Programming and Web Services* describes the creation of user-defined pages.

Figure 6-94 User's Area

6.1.4.4 Simplified standard pages

BASIC pages

Showing SIMOTION IT Diagnostics pages on devices with small displays

As of version 4.1.3, special pages are provided for the optimum display of SIMOTION IT Diagnostics pages on devices such as smartphones.

The following minimum configuration is recommended for the display of the basic SIMOTION IT Diagnostics pages:

- Mobile operating system with installed Web browser that supports the HTML 4 standard
- Minimum screen resolution of 320 x 240 pixels and color display
- Touch screen or stylus-operated device
- JavaScript (ECMA-262) is required if the full scope of functions is required.

You can access these pages via the http://<address>/BASIC/ address or https://<IP address>/BASIC/.

Figure 6-95 Start screen for simplified HTML pages

Device Info

Hardware and firmware information

The following up-to-date hardware and firmware information for the SIMOTION device is displayed on the **Device Info** page:

Manufacturer Name	Siemens AG
Order Number	Article number of the device
Revision Number	Hardware version
Serial Number	Serial number of the SIMOTION device
User Version Firmware	SIMOTION kernel user version
Build Number	Internal version number
Licence Serial Number	License serial number of the device
Operating State	Operating mode of the SIMOTION device (RUN, STOP, STOPU)
Systemtime	Current time-of-day of the SIMOTION device
Additional Hardware	Installed components of the SIMOTION device including: Article number, serial number, revision number, firmware name, user version number, internal version number
Technological Packages	Loaded technology packages including: Package name, user version number, internal version number

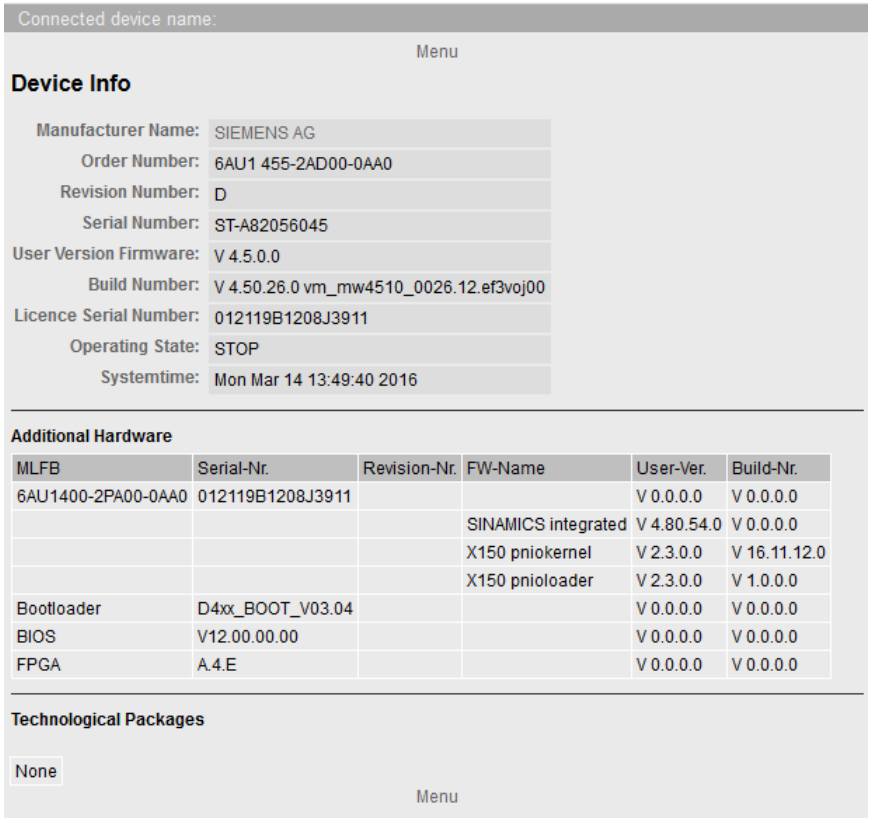

Figure 6-96 Device info on simplified HTML pages

Diagnostics

Overview of the general state of the SIMOTION controller

The **Diagnostics** page displays the following states of the SIMOTION controller:

Systemtime	Current time-of-day of the SIMOTION controller
Timezone	Current difference between the Systemtime and GMT in minutes
CPU Load by cyclic Tasks	Computation time of servo and IPO levels as a percentage of the total computation time
Memory Load	Size and allocation of the memory (RAM), RAM disk, memory card, and non-volatile memory. The memory space details are adapted dynamically to the size (B, kB, MB, etc.).
State	Current operating mode of the SIMOTION controller

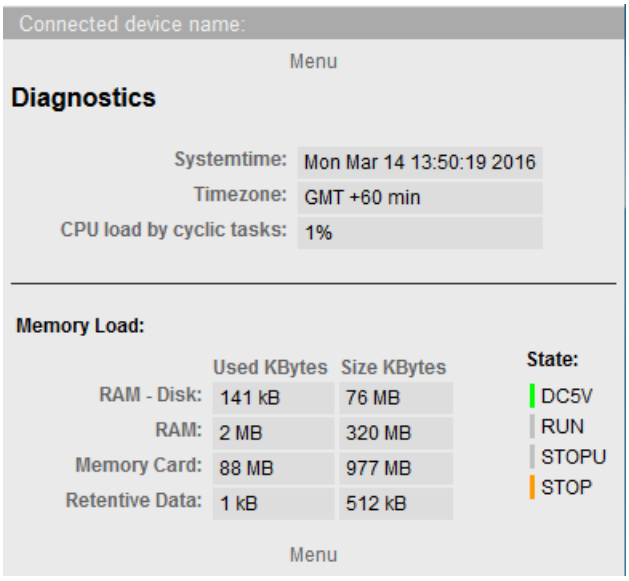

Figure 6-97 Diagnostics shown on simplified HTML pages

Diagnostic files (Page 3606)

Diag buffer

Diag buffer information

The **Diag buffer** page shows the events in the diagnostics buffer.

Time	Time of the event
Date	Date of the event
Event	Displays the event as text. If the DGBUFTXT.EDB language file is missing, the display is in English. English texts are pre-installed on the device.

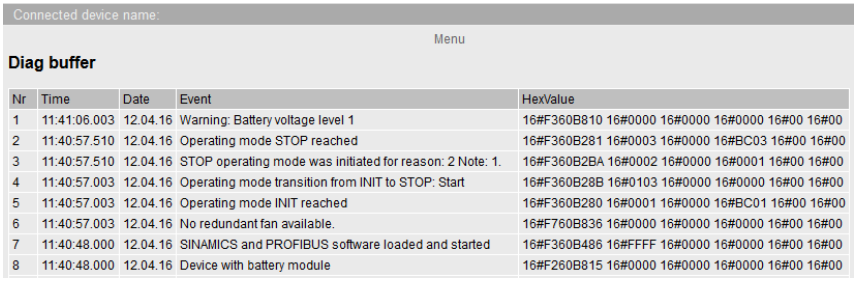

Figure 6-98 Diagnostics buffer shown in simplified format

See also

Diag buffer (Page 3607)

Diag buffer drive

Diag buffer drive information

The **Diag buffer drive** page shows the events in the drive diagnostics buffer for the integrated drives.

Time	Time of the event
Date	Date of the event
Event	Displays the event as text. If the DGEXTTXT.EDB language file is missing, the display is in English. English texts are pre-installed on the device.

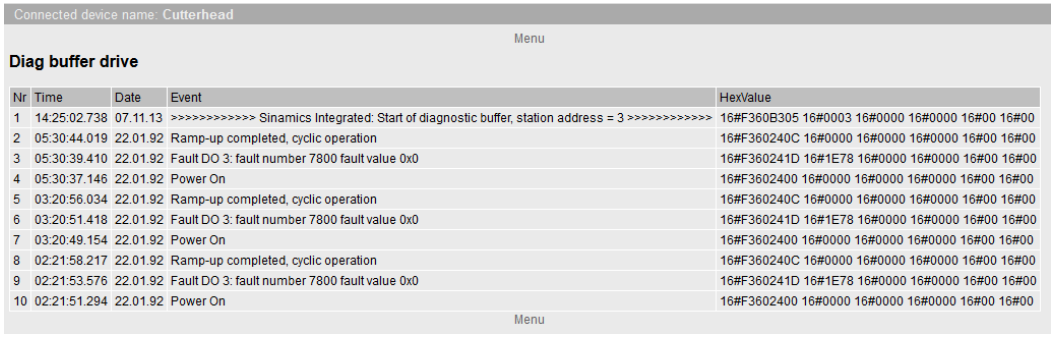

Figure 6-99 Diag buffer drive

Alarms

Information about alarms

Level	Category of the alarm
Time	Time of the alarm
TO	Technology object that triggered the alarm
Nr	Alarm number
Text	Displays the alarm message as text

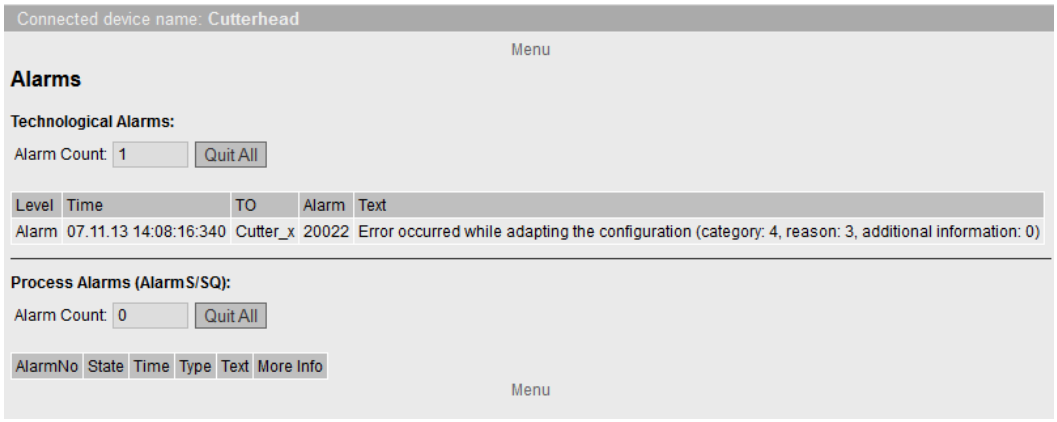

Figure 6-100 Alarms shown in simplified format

IP Config

Data of the SIMOTION controller Ethernet interface

IP Address	Address of the interface
Subnet Mask	Subnet mask of the interface
MAC Address	Subnet mask of the network card
Gateway	Default gateway of the interface
	The corresponding information is always displayed in the first column. It is not necessarily directly related to the IP address of the column and may even have been configured for the other interfaces.
Ethernet-port status:	Overview of the Ethernet ports. The port speed and communication type are output for active ports.

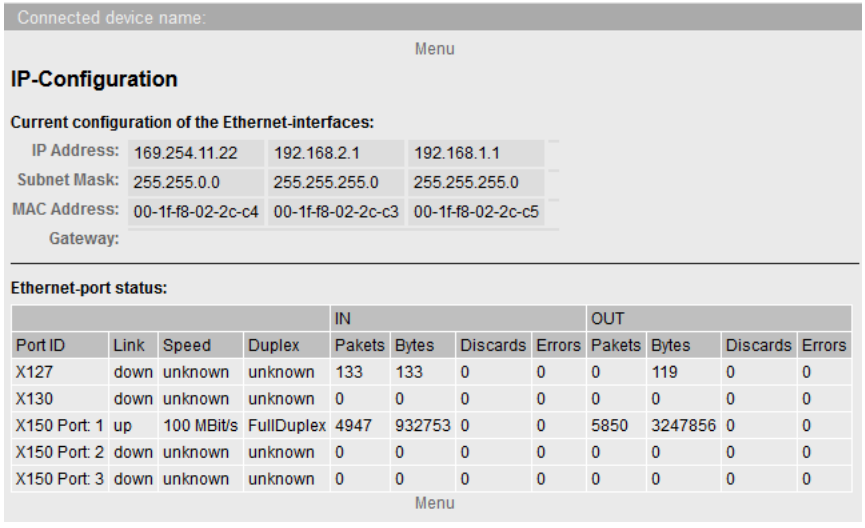

Figure 6-101 IP Config

Port ID	Designation of the Ethernet or PROFINET port as stated on the hardware housing.
Link	Switching property of the port
Speed	Communications speed of the port
Duplex	Communications type of the port
Pakets - IN	Number of packets received at this port.
Bytes - IN	Number of octets received at this port.
Discards - IN	Number of received packets rejected for internal system reasons (e.g. due to system overload).
Errors - IN	Number of received packets not processed by higher protocol layers because of a detected error. For example, transmission/reception faults of the block and collisions.
Pakets - OUT	Number of packets sent at this port.
Bytes - OUT	Number of octets sent at this port.
Discards - OUT	Number of transmission requests for packets that were rejected. Packets that were rejected even though no errors that would have prevented transmission were detected are also counted.
Errors - OUT	Number of packets that were not sent due to an error.

Diagnostic files

Backing up diagnostic pages of the web server

You can use this page to back up general diagnostic data and individual SIMOTION IT Diagnostics HTML pages.

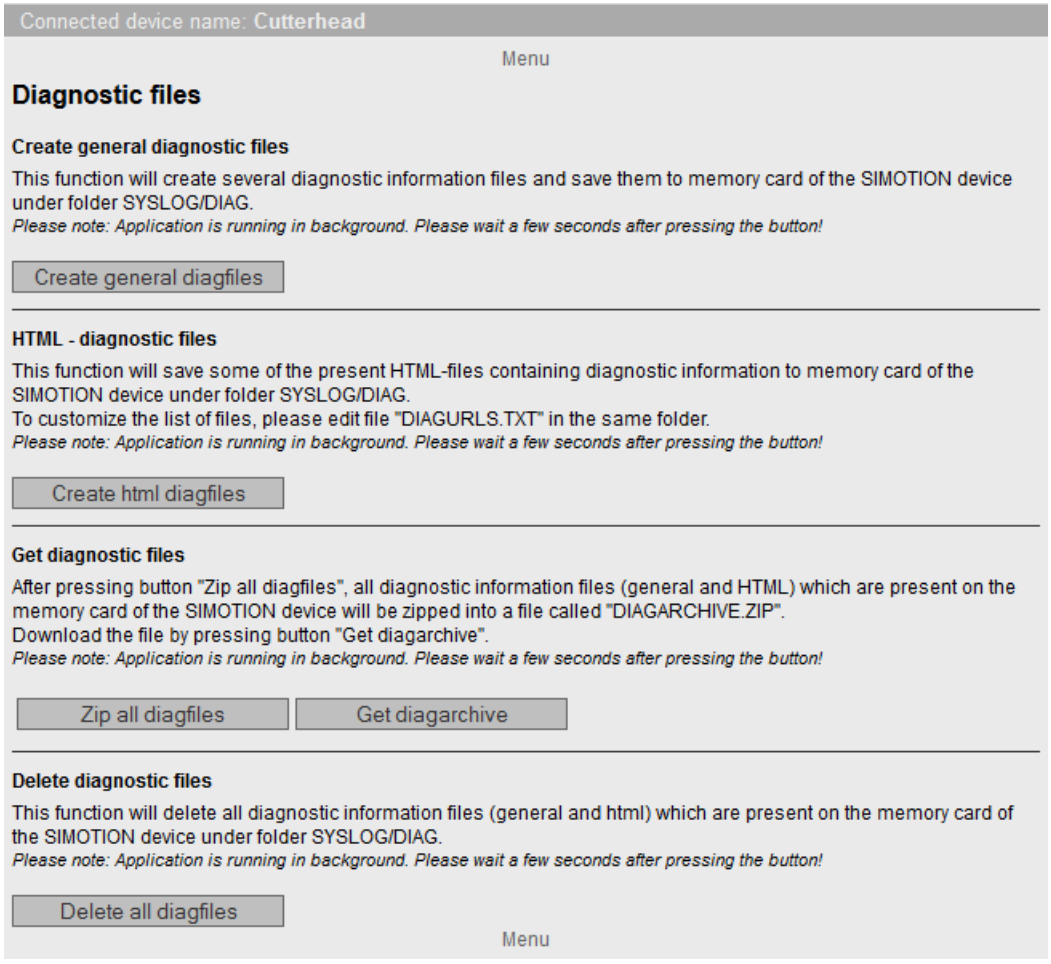

Figure 6-102 Diagnostic files

Watch tables

Watchtables

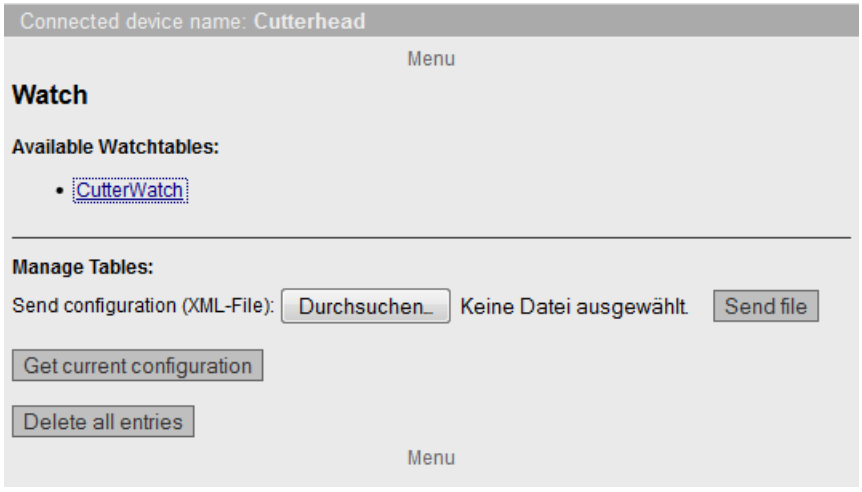

Figure 6-103 Watchtables

This page shows all created watch tables. These watch tables are identical with those on the standard SIMOTION IT Diagnostics page. They can be saved, deleted, and uploaded.

User’s Area

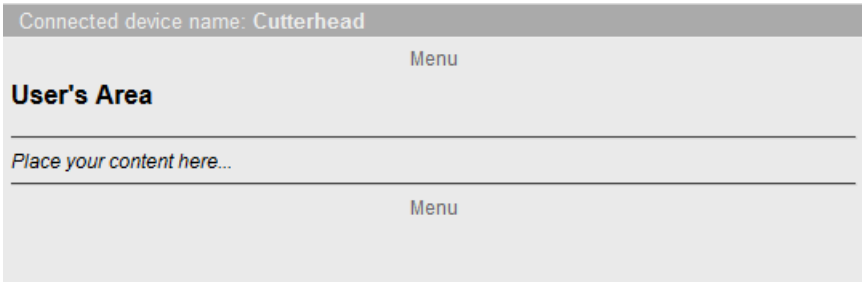

Figure 6-105 User's Area

User-defined pages are displayed in the User's Area .

6.1.4.5 SIMOTION IT configuration

Introduction

The UserDataBase.xml and WebCfg.xml configuration files are used to make user-relevant settings in the Web server.

UserDataBase.xml

File UserDataBase.xml contains user data of the controller. Access to the controller is controlled by the user administration. To back up a device, an administrator must be set up who can set up all other users and groups. See Section Login administration (Page 3658).

WebCfg.xml

All non-user-specific settings are made in the WebCfg.xml file. The file is subdivided into several different sections, e.g. server options and virtual file system.

The WebCfg.xml can be reloaded during runtime that causes a restart of the Web server. The modified settings are available after the restart. The restart of the Web server also causes restart of the OPC UA and OPC XML-DA server. The Java VM is not restarted.

The **Manage Config > SIMOTION IT** standard pages can be used to safely modify entries in WebCfg.xml . See SIMOTION IT File Access (Page 3627)

Structure of the webcfg.xml configuration data

The configuration file is divided into various areas:

- Virtual file system: Representation of the physical file system of the memory card in XML format.
- Server options: Replace the home page of the standard diagnostic pages with your own home page (see the *SIMOTION IT Programming and Web Services* Manual, *User-defined home page* section), port settings.
- Configuration area: Module-specific configuration data
- File types: Specification of the Mime type in the HTTP header.

The WebCfg.xml file can be found either on the SIMOTION controller memory card in the USER \SIMOTION\HMICFG\ directory or on the supplied DVD in the 3_Configuration directory (in the default state).

The individual tags of the WebCfg.xml (Page 3721) are listed with examples in the appendix.

MiniWeb versions and WebCfg.xml

The WebCfg.xml has been changed with SIMOTION Version 4.5. If this file exists in an older format, a migration strategy is deployed and any error messages will be entered in the diagnostic buffer.

- If a WebCfg.xml file in the older format with incompatible content is found, the diagnostic buffer entry has the form:
  "Web server: The WebCfg.xml configuration data exists in an older format and will be updated".
- If problems occur during the conversion that cause cancellation, the diagnostic buffer entry is, for example:
  "Webserver: The WebCfg.xml configuration data text could not be updated! Reason: Insufficient memory space available".
- In earlier versions of the MiniWeb, missing `READ`-, `WRITE`- and `REALM` tags resulted in complete write and read authorization of the file and the directory. In the current MiniWeb version, all rights are taken for missing tags.
- To ensure compatibility during the upgrade from an earlier version and on absence of all tags, `READ="Anyone"` and `WRITE="Anyone"` are added. Consequently, it is possible that the file system is open after a migration. The administrator should restrict access to the file system.
- The migration strategy is deployed only for configuration files before version 4.5.
- If the READ and WRITE tags are missing in WebCfg.xml, no further access is possible as of Version 4.5.

Further information about the differences in the various versions of WebCfg.xml is contained in section Updating the firmware to V4.4 (Page 3624).

See also

<HEADER> (Page 3729)

Authentication and login administration

Log-in administration

Structure of the login administration

SIMOTION IT uses a user database to safeguard access to a device. The UserDataBase.xml file contains this user data.

If the controller is started without a user database, a user database is automatically created when the controller starts up. This user database contains no users and is therefore empty.

If Web pages are called in this condition, the anonymous user `Anonymous` is active. This user has no special access rights.

The Web pages can only be used if the Web server has been activated via SCOUT or HW Config. If the Web server has not been activated, communication with the device is not possible. The services are activated by default when a new device is set up, and they must be explicitly deactivated to prevent access. In TIA Portal, the services are disabled by default.

The user administration is based on the Administrator user group. If no user who belongs to the Administrator user group exists in the UserDataBase.xml, no users can be set up, edited, or deleted via the User's & Passwords Web page.

There are many application cases related to the Web server and UserDataBase.xml that differ in terms of the individual files on the memory card.

Empty memory card, no SCOUT project exists on the memory card and empty UserDataBase.xml

The memory card only contains the firmware and the licenses.

In the as-delivered state, file UserDataBase.xml contains no users and is "empty" as far as the system is concerned.

In this case, the status of the controller is **Security Level Low**. To make it possible to perform commissioning via the Web server, all the Web pages can be used without login in this status. The FTP and Telnet can be accessed with any user name and password.

Users can be set up in the following ways to create a valid user database.

1. Call page **Manage Config > SIMOTION IT > Users & Passwords**. Add a user with Administrator group. As soon as the user is saved, the Web server switches to the **Security Level normal** condition because the user database now contains a valid entry.
2. Create a UserDataBase.xml file with content as described below. Upload via the Web page **Manage Config > SIMOTION IT > Users & Passwords**.
3. Create a **UserDataBase.xml** file with content as described below. Connect the CF card to the PC via a card reader and save the XML file at /USER/SIMOTION/HMICFG/USERDATABASE/.
4. Create a UserDataBase.xml file with content as described below. Use the device update tool and save the UserDataBase.xml file to the USERDATABASE folder in directory IT Config.

SCOUT project exists on the memory card and empty UserDataBase.xml

If a valid project exists on the card, the **Security Level normal** status applies to the Web server, in which the Web pages, FTP and Telnet are protected by a login. However, if the

UserDataBase.xml file is in the as-delivered state, it contains no users. In this case, login will not be possible.
The user database can be edited in any of the following ways:

1. Delete project with **Delete user data on card** in SCOUT. The Web server assumes the **Security Level Low** status. The user database can be edited as described above.
2. Create a UserDataBase.xml file with content as described below. Connect the CF card to the PC via a card reader and save the XML file at /USER/SIMOTION/HMICFG/USERDATABASE/.
3. Create a UserDataBase.xml file with content as described below. Use the device update tool (but not via the Web pages) and store file UserDataBase.xml in a folder USERDATABASE in directory IT Config.
4. Service switch 8, simotion.ini or the PSTATE program can be used to reset to Security Level low and thus change the password.

SCOUT project exists on the memory card and UserDataBase.xml contains valid users

If a valid project exists on the card, the **Security Level normal** status applies to the Web server, in which the Web pages, FTP and Telnet are protected by a login.

The user database can be edited in any of the following ways:

1. Call page **Manage Config > SIMOTION IT > Users & Passwords**. After logging in successfully with administrator rights, new users can be created and existing users edited. This however assumes that at least one user who belongs to the Administrator group has already been set up.
2. Create a UserDataBase.xml file with content as described below. Connect the CF card to the PC via a card reader and save the XML file at /USER/SIMOTION/HMICFG/USERDATABASE/.
3. Create a UserDataBase.xml file with content as described below. Use of the device update tool (but not via the Web pages) and storage of the file UserDataBase.xml in a folder USERDATABASE in directory IT Config.

Authentication

The authentication is constructed as follows:

- There are USERs.
- Every USER has a password that can be entered as plain text before startup. After startup, the password exists as A1 Hash .
- Users belong to groups (GROUP).
- Web pages, directories, and applications are protected by secure realms (REALM) defined for each group.
- Only users that belong to the realm can access the protected page.
- Each realm has a group of users who are authorized for access.
- A user can belong to multiple groups.

If a login attempt fails, this is logged in the system log.

Note

Editing the UserDataBase.xml file

- If the UserDataBase.xml file is not adapted, after the SCOUT project has been downloaded, it will no longer be possible to login to the Web pages or access with FTP and Telnet, because no valid user exists.
- The user database UserDataBase.xml must contain at least one user who is a member of group Administrator. Group Administrator is the REALM that the system expects for accessing protected applications, whose access rights cannot be set via WebCfg.xml.
- The editor used for editing UserDataBase.xml must be set to UTF-8 encoding.
- If file UserDataBase.xml contains illegal characters or the XML syntax contains errors, the file cannot be evaluated by the system. This makes login impossible.
- After startup, all plain text passwords are deleted and only exist in encrypted form. Neither can they be ascertained by the administrator. However, the administrator can assign a new password without knowing the old password.
- Since the password is no longer available in plain text in UserDataBase.xml, the password must be entered again each time a change is made to the groups of an existing user, otherwise the A1-Hash cannot be calculated.
- After loading via FTP, the controller must be restarted to transfer the UserDataBase.xml file. A restart the Web server does not suffice.

Structure of the UserDataBase.xml file

The user data is stored in UserDataBase.xml. UserDataBase.xml is located in directory /USER/SIMOTION/HMICFG/USERDATABASE

Sample configuration

UserDataBase.xml before startup

```
<?xml version="1.0" encoding="UTF-8"?>
<UserDataBase>
  <USER NAME="service"
    PASSWORD="a67_YjH"
    ChangePassword="never"
    DESCRIPTION="Administrator with all rights"
    REAL_NAME="">
      <GROUP NAME="Anyone"/>
      <GROUP NAME="Administrator"/>
  </USER>
  <USER NAME="user1"
    PASSWORD="93!ujEa"
    ChangePassword="allowed"
    DESCRIPTION="Normal user"
    REAL_NAME="">
      <GROUP NAME="Anyone"/>
  </USER>
</UserDataBase>
```

UserDataBase after startup

```
<?xml version="1.0" encoding="UTF-8"?>
<UserDataBase>
  <USER NAME="service"
    ChangePassword="never"
    DESCRIPTION="Administrator with all rights"
    REAL_NAME="">
      <GROUP NAME="Anyone"         A1="0302831a41b222c5f5bfc22e5ff80620"/>
      <GROUP NAME="Administrator"
A1="fa712df9294b40baa1e7504f8dd2b0d5" />
  </USER>
  <USER NAME="user1"
    ChangePassword="allowed"
    DESCRIPTION="Normal user"
    REAL_NAME="">
      <GROUP NAME="Anyone" A1="c5a15667e4d0cadff85d35354ea0fbb6"/>
  </USER>
</UserDataBase>
```

Table 6-6 Attributes of the USER node

Attribute	Permissible values	Description
NAME	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Login name
PASSWORD	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Password in plain text
CHANGEPASSWORD	ALLOWED ⇒ The password can be changed by the user in the Web page (default setting). NEVER ⇒ The password cannot be changed by the user in the Web page.	Behavior when user logs in via Web pages. No effect when opening the file in the file system
DESCRIPTION	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Description of the user
REAL_NAME	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Actual name of the user

Table 6-7 Attributes of the GROUP node

Attribute	Permissible values	Description
NAME	Numerals, letters, special characters but not: : =, " , <,>, %, &, \, `,'	Name of the group.
A1	Valid hash value (numerals, letters)	Hash value that is expressed as a MD5 checksum via USER NAME, USER PASSWORD and GROUP NAME. If none exists, generated after the controller starts up.

NOTICE
Invalid XML file
Using impermissible values may invalidate the XML file so that it cannot be read.

Login and WebCfg.xml

Differentiated protection of Web pages, directories, and applications with WebCfg.xml

The realms are assigned for individual Web pages, directories, and applications in configuration file WebCfg.xml. Content requiring protection is labeled REALM Administrator. The users belonging to this group are specified in file UserDataBase.xml.

Besides REALM Administrator used by the system, the user can create and apply his own realms to protect Web pages, etc.

Example

Excerpt UserDataBase.xml:

```
…
<USER NAME="user1"
    PASSWORD=""
    ChangePassword="allowed"
    DESCRIPTION="Service with restricted rights"
    REAL_NAME="John Smith">
<GROUP NAME="Anyone"
        A1="c5a15667e4d0cadff85d35354ea0fbb6"/>
<GROUP NAME="Servicegroup"
        A1="45735fdcee4d0cdfafde825354ea0aa17"/>
</USER>
…
```

Excerpt WebCfg.xml:

```
…
<settings.mwsl.cms ALIAS="html/standard/settings.mwsl.cms"
REALM="Servicegroup" READ="Servicegroup" WRITE="Servicegroup"
MODIFY="Servicegroup"/>
…
```

`user1` has been inserted. This user belongs to the new group `Servicegroup` and has access to the `settings.mwsl` page. However, any user who wants to open the Settings page must belong to the `Servicegroup` group. It is therefore recommended that administrators belong to all the groups that exist in the user database.

Realms for applications

Besides the realms for individual MWSL pages and directories, the REALM of some of the applications of the Web server are also defined in the configuration file WebCfg.xml.

These realms can be adapted if necessary.

⚠ CAUTION

Deleting a REALM

If you delete a REALM, the associated pages can be accessed without a login. So carefully check which pages were protected by the REALM.

- Web service for OPC-XML DA and therefore reading, writing, monitoring of the variables of all providers
  ```
  <WEBSERVICE NAME="OpcXml" URL="/SOAP/OPCXML"
  REALM="Administrator" />
  ```

  Note

  As-delivered state without REALM

  In the as-delivered state, this value has no REALM to ensure downward compatibility reasons! It is therefore recommended to prepare the OPC-XML DA client currently being used for password and user name use and to set the REALM here.

- Application for writing variables in all providers on the HTML diagnostics pages:
  <VarApp REALM="Administrator" />
- Application for updating project and firmware:
  <FWUpdtApp REALM="Administrator" />
- Application for reading and writing the user database UserDataBase.xml
  <UserDataBaseApp REALM="Administrator" />
- Application of Jamaica VM for calling servlets
  <JApp REALM="Administrator" />

In addition, there are system applications that require login of a user who belongs to the Administrator group.

A1 hash

Composition of the A1 hash

The A1 hash is formed by generating an MD5 hash value from a combination of user name, password, and REALM.

MD5 (Message-Digest Algorithm 5) is a cryptographic hash algorithm, which saves a character string requiring protection in the configuration but not as plain text.

Saving the password in plain text would have the disadvantage that a hacker could read it and use it to gain unauthorized access to the system. Instead, the password is saved as what is known as a Hash. The Hash is a fingerprint of the password.

To authenticate a user, the client (in this case the Web browser) sends the password to the server, which then generates the hash and the Hash. This Hash can be compared with the one saved in the configuration and the system can respond accordingly. This procedure is considered one of the most secure of its type. More information is available on the Internet, for example at: http://de.wikipedia.org/wiki/Message-Digest_Algorithm_5

Delete password

Deletion of a password in the user database depends on whether the user has administration rights.

Deleting user passwords

The Administrator can always overwrite user passwords. See SIMOTION IT Users & Passwords (Page 3630).

Deleting Administrator passwords

If the Administrator's password is no longer available, one of the methods described below can be used to modify the user database:

- Deleting UserDataBase.xml from the memory card. An empty UserDataBase.xml is created at startup.
- A password can be entered in plain text in UserDataBase.xml on the memory card. Example: `<USER NAME="CutterAdmin" PASSWORD="New password" ....>` The controller overwrites existing A1-Hashes if a `PASSWORD` attribute is found. A new A1-Hash is formed from the found `PASSWORD`.
- By setting the service selector switch to position "8", it is possible to send a UserDataBase.xml to the controller.

Configuration of the file system

Links to the physical file system (ALIAS)

Access to the physical file system of the memory card via the Web server is limited for security reasons.

To access a file via a URL, this file must be located in the so-called WWWRoot. In addition, the Web server recognizes the memory card area SystemRoot. The SystemRoot cannot be accessed via URLs and is used to store configuration files.

Table 6-8 Paths of the Web server areas

WWWRoot	/USER/SIMOTION/HMI
SystemRoot	/USER/SIMOTION/HMICFG

The URL of a file in the file system is always relative to the WWWRoot.

Example

The file mypage.mwsl is located in directory /USER/SIMOTION/HMI/FILES.

The URL for calling the file is: `http://<IP-Address>/Files/mypage.mwsl`

By making settings in file WebCfg.xml, it is possible to create references to individual files or directories in the physical file system. In addition, by assigning REALMS (Page 3668), the access rights to resources can also be assigned.

For that, the physical file system is mapped on XML data nodes. The node `<BASE>` corresponds to the WWWRoot - /USER/SIMOTION/HMI.

Each child node of <BASE> is a reference to a file or directory. Using these references, a direct call without specifying the entire path is possible. The tag name corresponds to the name of the file.

The optional ALIAS attribute creates a reference to a file that can be located in a different directory. The path specification of the ALIAS attribute is relative to WWWRoot. This allows the file to be accessed by several URLs. Each of these URLs must be saved individually.

Table 6-9 Example URL, physical file system and WebCfg.xml

URL	Target in the physical file system	Entry in WebCfg.xml	Remark
<ip address>/ myfile.mwsl	/USER/SIMOTION/HMI/FILES/ myfile.mwsl.cms	<BASE> <myfile.mwsl.cms ALIAS="/FILES/ myfile.mwsl.cms" REALM="Anyone" READ="Anyone" WRITE="Anyone" MODIFY="Anyone" /> </BASE>	ALIAS to a file.
<ip address>/mydir	/USER/SIMOTION/HMI/FILES/mydir	<BASE> <mydir ALIAS="/FILES/mydir" REALM="Anyone" READ="Anyone" WRITE="Anyone" MODIFY="Anyone" /> </BASE>	ALIAS to a directory.

MWSL Files are located in the physical file system in a compiled format with file name extension .cms and must be referenced accordingly.

See also

ALIAS attribute (Page 3723)

Browsing of directories

Note

Changed behavior as of Version 4.4

As of version 4.4, the BROWSEABLE and MODIFY attributes no longer have any effect.

Browsing of directories can be activated or deactivated. This is controlled using the `BROWSEABLE` attribute. If the attribute is `TRUE`, a directory view is permitted.

Setting the value of the BROWSEABLE global tag to true enables the browsing of directories by default.

Table 6-10 Examples of paths

```
/
 /Datei1

 /Directory1/
 /Directory1/Datei2.mwsl
 /Directory1/Datei3.mwsl
 /Directory1/Directory2

 /Datei4
```

The root directory / is the same as the FILES directory.

Table 6-11 WebCfg.xml:

```
<?xml version="1.0" standalone="yes"?>
<SERVERPAGES>
  [...]
  <BASE ALIAS="/">
    <www ALIAS="/" BROWSEABLE="true" .../>
  </BASE>
  [...]
</SERVERPAGES>
```

The client requests the URL http://<IP-Address>/www/Directory1.

In the XML file system, the parser searches for www in the root directory and finds ALIAS="/".

In the physical file system, the parser searches for /Directory1.. The "/" forward slash in this path is retained, because this was specified in the ALIAS="/" tag. Directory1 refers to the path.

The Directory1 directory exists in the physical file system. Because Browseable = true and no default HTML page has been specified, the browse view of the directory is returned.

See also

<DEFAULTDOCUMENT> (Page 3728)

Security concept of the file system

Permission information in the form of attributes can be stored at each XML node of the XML file system:

- REALM (secure area)
- READ (reading rights)
- WRITE (writing rights)
- MODIFY (modification rights)

REALM may only contain one group name, while READ, WRITE, and MODIFY may contain a list of group names separated by "," characters. No spaces or other Whitespace characters may be used.

A set of user groups is assigned to each user.

If a file is requested by a user, the XML file system is searched through for this file. The XML tree is run through corresponding to the file path. If several XML nodes are run through, the logged-in user must have rights for all of the "touched" nodes.

Example:

```
<?xml version="1.0" standalone="yes"?>
<SERVERPAGES>
  [...]
  <BASE ALIAS="/">
    <FILES ALIAS="FILES/" BROWSEABLE="true" REALM="Anyone"
           READ="Anyone" WRITE="Anyone" MODIFY="Anyone">
      <www ALIAS="/WebPages/"
           BROWSEABLE="true"
           READ="Administrator"
           WRITE="FileAdministrator" />
    </FILES>
    <Test.mwsl.cms ALIAS="/Tests/Test.mwsl.cms/"/>
    <XMLDir>
    </XMLDir>
  </BASE>
[...]
</SERVERPAGES>
```

Table 6-12 Types of file permissions

URL	Access	Groups	Comment
/<File>.mwsl	Read	None	
/<File>.mwsl	Write	None	Access not permitted
/MainDir/<File>.mwsl	Read	USER	Login mask if USER group is not present

REALM

Setting up a security area

Realm is used to designate a secure area in the WWW environment. If a directory is entered and the user is not a member of the specified Realm (or the user has not yet logged in), a login prompt appears (Authentication required).

If a file protected by REALM is accessed, the client must be authenticated. Web browsers usually display a login screen requiring users to enter their user name and password.

The REALM attribute can be used to enable or force a user login.

Note

Only one REALM can be specified for a directory. In a directory hierarchy, different REALM must be separate, not overlap.

Because the file objects are accessed on a hierarchical basis, different hierarchy levels may well have different security groups. In this case, no user can access the relevant files because it is not possible to change the realm during a request. An access is always connected to a maximum of one realm even if the user is a member of several security groups.

```
<?xml version="1.0" standalone="yes"?>
<SERVERPAGES>
  [...]
  <BASE>
    <Motion REALM="Operator">
      [...]
    </Motion>
    <Tests REALM="Tester" >
      [...]
    </Tests >
  </BASE>
  [...]
</SERVERPAGES>
```

In this example, a user with the "Operator" and "Tester" security groups has access to Motion and Tests as well their subordinate objects.

NOTICE

ALIAS and XML file system

If you have linked a file or directory with an ALIAS and set the user rights, you must do the same for the XML file system!

```
<?xml version="1.0" standalone="yes"?>
<SERVERPAGES>
  [...]
  <BASE ALIAS="/">
  <Test.mwsl.cms ALIAS="/Files/Test.mwsl.cms/"
            BROWSEABLE="true"
            READ="Administrator"
            WRITE="Administrator"
            MODIFY="Administrator" />
  [...]
  </BASE>
[...]
</SERVERPAGES>
```

With this configuration, the login window appears when you call

```
http://<IP-Adresse>/Test.mwsl
```

However, access to this page is still possible via:

```
http://<IP-Adresse/Files/Test.mwsl
```

To prevent this, the configuration must be made as follows:

```
<?xml version="1.0" standalone="yes"?>
<SERVERPAGES>
  [...]
  <BASE ALIAS="/">
    <FILES ALIAS="FILES/"
           BROWSEABLE="true"
           READ="Anyone"
           WRITE="Anyone"
           MODIFY="Anyone">

      <Test.mwsl.cms
                BROWSEABLE="true"
                READ="Administrator"
                WRITE="Administrator"
                MODIFY="Administrator" />
    </FILES>

    <Test.mwsl.cms ALIAS="/Files/Test.mwsl/"
              BROWSEABLE="true"
              READ="Administrator"
              WRITE="Administrator"
              MODIFY="Administrator" />

      [...]
  </BASE>
  [...]
</SERVERPAGES>
```

Special features for the administrator

A user with the `Administrator` group/realm can access all pages. The rules of other Realms that have been set up for security reasons do not apply for this user. A directory that has been set to `BROWSEABLE="false"`, is also visible for a user with administrator rights.

Note

Administrator rights prior to V4.4

Prior to V4.4, the behavior for users with administrator rights was different. A user assigned to the `Administrator` user group could only access pages that had been released for this user via the group/Realm. The pages of the CPU were not visible for the user.

See also

REALM attribute (Page 3726)

READ

Creating read authorization with the READ attribute

If the `READ` attribute is specified for a file or directory, the user must be a member of one of the groups specified for the `READ`–attribute. Several groups can be specified for `READ`; they must be separated with commas. Whitespace characters may not be used.

Example

```
<MyDir READ="User,Administrator" />
```

Users that belong to the User or Administrator group (or both) may read the content of the directory.

If users do not have read rights, i.e. they do not belong to any of the groups that are specified with `READ` , a FORBIDDEN message is generated. A login for the client is not initiated.

If no `READ` attribute is present for a directory, read access is always permitted.

See also

READ attribute (Page 3725)

WRITE

Setting write authorizations with the WRITE attribute

If a file or directory has the `WRITE` attribute and the logged-in user is a member of one of the specified groups, this user may create new files only in this directory.

The user may:

- Not create any new directories
- Not overwrite any files
- Not delete any files
- Create new files

Note

To create files, the user also needs READ rights!

See also

WRITE attribute (Page 3727)

Creating directories and files

If directories or files are created, they inherit the authorizations of the directory that contains them.

Rights cannot be changed via the directory browser. Rather, they can only be changed directly by modifying the WebCfg.xml file.

Browsing the file system

The web server allows you to visualize a (physical) directory in the client.

For this purpose, the BROWSEABLE attribute for the ALIAS tag or the global <BROWSEABLE>-tag must be set to true.

If a client accesses this link, a directory view of the directory is created. Navigation from this directory to subdirectories is also possible (also to higher-level directories if browsing is allowed for them).

Provided you have sufficient permissions, you can send, receive and delete files as well as create and delete directories. The appearance of the directory in the client can be freely configured.

If there is no authentication mechanism on the web server, write access is generally not permitted (see Security concept).

```
<?xml version="1.0" standalone="yes"?>
<SERVERPAGES>
   [...]
   <BASE>
      <www ALIAS="/UserData" BROWSEABLE="true"
           REALM="GuestUser"/>
      <Test.mwsl.cms LINK="/Tests/Test.mwsl.cms/"/>
   </BASE>
   [...]
</SERVERPAGES>
```

In this example, a directory view of the local directory "/UserData" (relative to WWWRoot!) would be returned to the client if it requests the URL /www and has been authenticated as a user of the REALM "GuestUser."

Write access to the directory is not possible because a WRITE or MODIFY attribute has not been specified for the directory entry.

File access via FTP/Telnet

Access via FTP/Telnet

The configuration of the interfaces can be found in Section Configuring the SIMOTION device interface (Page 3568).

Note

As of V4.1.2, HTTP/S, FTP and Telnet are activated in the delivery state. In TIA Portal, these services are disabled by default.

Security concept of HTTP/S, FTP, and Telnet access on the Web server

As of version V4.4, access to the SIMOTION IT Web server is protected by a multi-level security concept.

The security state of the Web server is indicated by the security level on the website. This security level can have three different levels: Low, normal, high.

Further information on the safety concept of the connection via FTP/Telnet can be found Section Security concept (Page 3569).

Access within the user program

Access within the user program can influence the FTP transfer. For example, write access is only possible when the user program has closed the relevant files.

Currently set state of FTP/Telnet

You can see the currently set state of FTP/Telnet with a browser by clicking the arrow in the "Security Level" field when the Web server is active.

Securing FTP access

In the UserDataBase.xml file, a user must be in the Administrator group in order to log in to the FTP. During the FTP login, the user name and password entered there must be authenticated.

⚠ WARNING
FTP access with security level low If the security level is low, the user name and password will not be checked. Any values can be entered.

CSRF protection

Cross Site Request Forgery (CSFR)

Cross Site Request Forgery is an attack scenario with which the attacker without knowledge of the authorized user reloads or forwards an HTTP request (GET/POST). The HTTP request can initiate damaging actions on the Web server or even the complete SIMOTION controller. To protect the SIMOTION IT Web pages and the Web server, proven techniques have been implemented that prevent unauthorized access to the data.

Example of a CSRF attack

A logged in user is tempted to click a URL that executes an unwanted call in its user context.

```
http://<mydevice>/stop
```

The reason for this behavior is that the HTTP is a state-less protocol. After a successful authentication, the browser stores the session data in a Cookie. For every subsequent request, the session data is also sent, which means the Web server always receives a valid call of a logged in user. Consequently, a manipulated link is not detected.

CSFR protection in the MiniWeb

CSRF protects all applications or Web services for which it is potentially possible to generally impair the status of the Web server and/or of the controller. Examples are the provocation of STOP/RUN transitions, the manipulation of project data or the changing of Web server settings. Furthermore, unauthorized fetching of data is prevented. To achieve this, applications that only display information, but do not manipulate the status of the system, are also included in the CSFR protection.

Note

CSRF tokens and login

After a login, CSRF tokens are available, because they are linked with the login data.

A token generated by MiniWeb is placed in Web pages that issue an endangered HTTP request (GET/POST). This token is sent as additional request parameter to the target application, and validated there. If the token is valid, the application is performed.

Where necessary, the standard pages have been extended with the token technology. No further processing of these pages is required.

CSRF protection settings

To activate and deactivate the CSRF protection, the tag `<CSRFProtection disabled="false|true" />` is added to the WebCfg.xml for the device ramp-up. The setting is displayed on the **Manage Config SIMOTION IT Serveroptions** Web page, and can be changed.

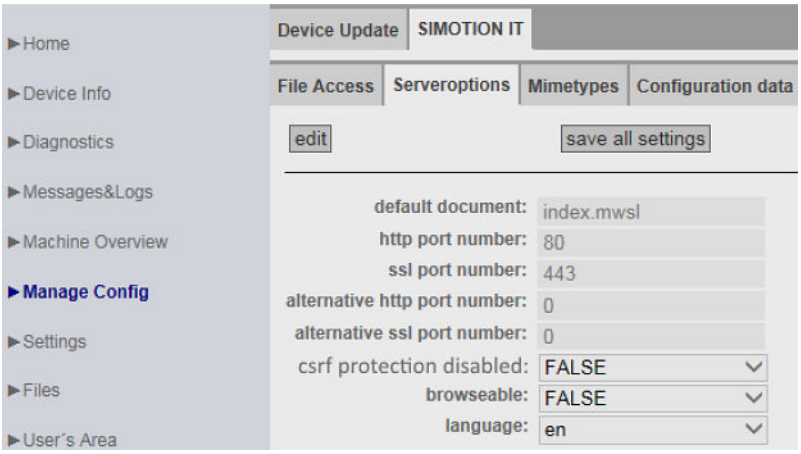

Figure 6-106 CSRF Serveroptions

CSRF protection is activated in the delivered state. The CSRF protection is deactivated for ramp-up with Security Level Low.

Activation of the CSRF protection in the WebCfg.xml: `<CSRFProtection disabled="false" />`

If CSRF protection is activated, all applications and services of the MiniWeb that receive GET/POST requests, and are considered to be protection-worthy with regard to a CSRF attack, respond correctly only when the appropriate tokens were also sent.

Note

CSRF protection and individually-created pages

Users who have created and programmed their own pages must customize these pages or deactivate the CSRF protection.

The following table provides an overview of which applications relevant for the user must be customized for the CSRF protection.

Table 6-13 **List CSRF protection in MiniWeb applications**

Application	URL	Further information	Request type	Token type
JavaApp	`http://<host>/JApp/jvmRestart`	Manual SIMOTION IT Virtual Machine and Servlets	GET	SUT
			POST	-
ServletApp	`http://<host>/servlet/myServlet`	Manual SIMOTION IT Virtual Machine and Servlets	GET	SUT
			POST	MUT
VarApp	`/VarApp`	Manual SIMOTION IT Programming and Web Services	GET	-
			POST	MUT

MUT = Multi Use Token
SUT = Single Use Token

Users must change any user-implemented Web pages in which the above mentioned URLs are called. The affected Web pages must be extended by passing the appropriate token.

Multi Use Tokens can be used more than once. Single Use Tokens are valid just once.

The aspect that an attacker "eavesdrops" the connection, and so also determines the multiple-valid tokens, is not considered. Because a Man-In-The-Middle attack is not a protection goal of the CSRF protection. This must be guaranteed, for example, by using HTTPS.

Single Use Tokens are recommended for deployment with all GET requests to be protected, because the token as parameter, is part of the URL. Because popular Web servers or appropriate company-internal security guidelines store this URL in log files, the use of tokens that lose validity immediately after deployment is recommended. Although the MiniWeb server does not maintain such logs, this criterion is adopted for the selection of the tokens.

6.1.4.6 Variable providers

Overview

Variable providers

The data of the SIMOTION device can be accessed via the "variable providers". Each provider enables access to certain variables.

At present there are five variable providers; these are described in the section below.

- SIMOTION
- SIMOTION diagnostics
- UserConfig
- MiniWeb
- ITDiag

You can access the data supplied by the variable providers from SIMOTION IT OPC XML-DA, OPC UA, SIMOTION IT Diagnostics standard pages, or, if necessary, from user-defined HTML pages.

SIMOTION

You can access SIMOTION process variables via the "SIMOTION" provider. As of V4.1, you can also change the operating status, initiate backups with RamToRom and ActiveToRam, and access drive parameters and technological alarms.

Note

You will find a description of the storage concept in the online help of SIMOTION SCOUT in section "SIMOTION storage concept (in the target device)".

Variables syntax of the "SIMOTION" provider

With OPC XML DA V1.0, access to the variables of the SIMOTION device is via the terms "ItemPath" and "ItemName". In MWSL functions, they are accessed via the "ItemName".

ItemPath

The name for "ItemPath" is always "SIMOTION" for SIMOTION process variables for use in the MWSL and SSI. It is not necessary to specify the ItemPath with MWSL and SSI.

```
ItemPath="SIMOTION"
```

Note

The "ItemPath" is only required for accessing via OPC XML-DA. None of the other SIMOTION IT accesses to the variable provider "SIMOTION" use "ItemPath".

Overview of variable access

Table 6-14 OPC XML-DA variable access

Variables	Variable declaration	Availability	Access syntax	Requirements for access
Global device variables (Page 3682)	*Variable type*			The appropriate checkmark in the properties dialog of the CPU must be set (CPU > Properties > Settings)
	retain	x	glob/<var name>	
	not retain	x	glob/<var name>	
I/O variables (Page 3684)	*Access modes*			
Addresses 0..63	"PI../PQ.. (without assignment to a process image)"		io/_direct.<var name> io/_image.<var name> io/_quality.<var name>	
	"PI../PQ.. (with assignment to a process image)"	x	io/_direct.<var name> io/_image.<var name> io/_quality.<var name>	
	%I../%Q..	-	-	
Addresses >63	"PI../PQ.. (without assignment to a process image)"	x	io/_direct.<var name> io/_quality.<var name>	
	"PI../PQ.. (with assignment to a process image)"	x	io/_direct.<var name> io/_image.<var name> io/_quality.<var name>	
Unit (MCC/ST/LAD-FBD) (Page 3678)	*Variable type*			The compiler option "Permit OPC-UA/-XML (load symbols to RT)" must be set at the source

Internal functionality

The SIMOTION variables provider contains variables that can be used to implement internal functionality.

- diag/ (komplett)
- dev/Device

- dev/DiagIfc
- dev/Licence
- dev/PNDiag
- dev/Service/HTTPDiag
- dev/Service/ManageConfig
- dev/Service/SecLev
- dev/Service/Tasktrace
- dev/Special
- dev/Trace
- dev/dTrace

Accessing system variables/technology object system variables

For **system variables**, the **ItemName** syntax is:

ItemName="var/name"
Example: ItemName="var/userData.user3"

For **TO system variables**, the **ItemName** syntax is:

ItemName="to/name.variable"
Example: ItemName="to/Achse_1.positioningState.actualPosition"

Note

The names of the system variables and technology object system variables to be used can be found in the online help for SIMOTION SCOUT in "System Functions, System Variables and Configuration Data".

Access to unit variables (as of V4.1)

For **unit variables** in the interface, the **ItemName** syntax is:

ItemName="unit/name.variable"
Example: ItemName="unit/prog_1.var_1"

Note

The names to be used for the unit variables in the interface correspond to the program and variable names **in lower case characters**.

Accessing technology object configuration data (V4.1 and higher)

For **technology object configuration data**, the **ItemName** syntax is:

ItemName="cfg/TOName.activeConfigData|setConfigData.variable"

activeConfigData:	Currently valid configuration files, read-only
setConfigData:	Data set image, write access possible The data can be write-accessed if the "effectiveness" property has the "CHANGEABLE_WITH_RESTART" or "CHANGEABLE_WITHOUT_RESTART" value. In the case of "CHANGEABLE_WITH_RESTART," the change does not take effect until the respective technology object has been restarted.

Example: ItemName="cfg/Axis_0.setConfigData.Restart.restartActivationSetting"

Note

The names of the TO configuration data to be used can be found in the online help for SIMOTION SCOUT in "System Functions, System Variables and Configuration Data".

Accessing drive parameters (V4.1 and higher)

For **drive parameters**, the **ItemName** syntax is:

ItemName="drv/TOName|LogAddr.Params.ParamNo"

TOName:	Specifies the technology object name (possible if an Axis technology object exists for the drive object)
LogAddr:	Specifies the logical drive address
ParamNo:	Parameter number If an attempt is made to write-access a read-only drive variable, the drive issues a feedback message (error code) to this effect.

Example 1: ItemName="drv/Axis_0.Params.105"

Example 2: ItemName="drv/256.Params.5"

Accessing technological alarms (V4.1 and higher)

For **technological alarms**, the **ItemName** syntax is:

ItemName="dev/Alarm.Variable|Values-Array

Variable:
- State
  Status of query:
  READY
  BUSY
  ERROR
- Version
  Incremented each time the alarm buffer is modified. By entering this variable in a subscription, you can be notified each time a change is made to the alarm buffer.
- EventCount
  Number of currently pending alarms
- QuitAll
  Acknowledges all pending alarms

Values array: Array with the currently pending alarms

This array contains as many elements as are entered in EventCount.

Example: ItemName="dev/Alarm.Version"

For a currently pending alarm, the **ItemName** syntax is:

ItemName="dev/Alarm.Values[ValueNumber].ArrayElement"

ValueNumber: Index of an alarm in the list of currently pending technological alarms

ArrayElement:
- AlarmNo
  Alarm number
- To
  Name the technology object that generated the alarm
- Time
  Time of the alarm entry
- Text
  Alarm text
- Quit
  Acknowledges the alarm
- Type
  Classification of the technological alarm:
  ALARM
  WARNING
  INFORMATION

Example: ItemName="dev/Alarm.Values[0].AlarmNo"

Changing the operating mode (V4.1 and higher)

For setting the operating mode, the **ItemName** syntax is:

ItemName="dev/Service.BZU.Variable"

Variable:
- Value
  Writing one of the following values changes the operating mode accordingly:
  - STOP
  - STOPU
  - RUN
- State
  Displays the execution states during an operating mode change
  The states change from IDLE to ACTIVE to READY.
- Result
  Shows the result of the operating mode change (when State = READY)
  Result = OK if the operating mode has been changed successfully. Otherwise, Result = Error ID

Example: ItemName="dev/Service.BZU.Value"

RamToRom (V4.1 and higher)

For execution of **RamToRom**, the **ItemName** syntax is:

ItemName="dev/Service.RamToRom.Variable"

Variable:
- Value
  Save operation starts with Value = 0
- State
  Displays the status of the save operation
  The display starts with 0% and continues to 100%.
- Result
  Shows the result of the save operation (when State = 100%)
  Result = OK if the save operation has been completed successfully. Otherwise, Result = Error ID

Example: ItemName=" dev/Service.RamToRom.Value"

Note

Ram ToRom only works with the configuration data. System variables have their download value again after a 'Power on/off.'

ActiveToRam (V4.1 and higher)

For execution of **ActiveToRam** (after changing the configuration data), the **ItemName** syntax is:

ItemName="dev/Service.ActToRam.Variable"

Variable:
- Value
  Save operation starts with Value = 0
- State
  Displays the status of the save operation
  The display starts with 0% and continues to 100%.
- Result
  Shows the result of the save operation (when State = 100%)
  Result = OK if the save operation has been completed successfully. Otherwise, Result = Error ID

Example: ItemName=" dev/Service.ActToRam.Value"

Accessing the global variables (V4.2 and higher)

The way to access the control's "global device variables" created by the user in SCOUT is via /glo/.

For the **global device variables**, the **ItemName** syntax is:

ItemName="glob/name"

To make these variables visible, the symbol information must be

downloaded to the control. For this purpose, the relevant checkmark must be made under **Device > Properties > Settings** in SCOUT.

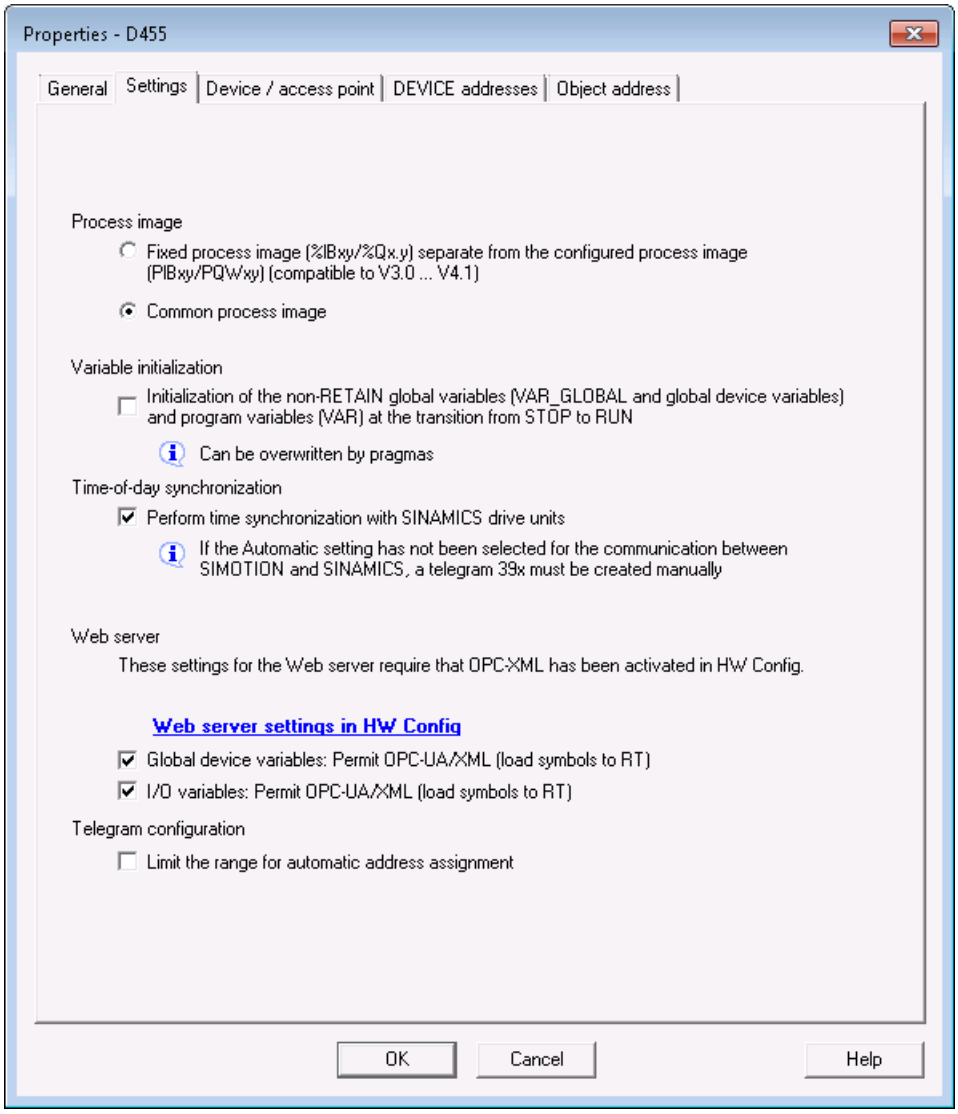

Figure 6-107 SCOUT setting global variables

Accessing the IO variables (V4.2 and higher)

There are three different ways to access the address list of the control's I/O variables that have been created in SCOUT:

- /io/_direct/
  addresses the direct I/O access (current value) of the I/O variables.
  This form of access is offered for all I/O variables.
- /io/_image/
  Addresses the process image of I/O variables.
  Only the I/O variables assigned to a process image are displayed. This applies for I/O variables in the address range 0 to 63 that are accessed via PI... /PQ... I/O variables in this address range that are accessed with %I... /%Q... cannot be displayed via /io/_image.
  All I/O variables outside the address range of 0-63 that are explicitly assigned to a process image in the address list are also displayed.
- /io/_quality/
  addresses the quality of I/O variables, i.e. the I/O status of the subslot (from HW Config) which contains this I/O variable.
  This is a 32-bit pattern. An overview of the possible bit pattern values can be found in the *SIMOTION ST Structured Text* manual, in the section entitled 'Access to I/O variables (as of V4.2)'.
  The quality is the same for all I/O variables in a subslot. The quality is given as an integer for the individual I/O variables of the basic data types (BIT, BYTE, WORD, DWORD) and for arrays. It is not given for array elements (i.e. arrays cannot be expanded).

For the IO **variables**, the **ItemName** syntax is:

ItemName="io/_direct|_image|_quality/name"

The symbol information must be loaded to the control in order to make these variables visible. For this purpose, the relevant checkmark must be made under **Device > Properties > Settings** in SCOUT.

Accessing the AlarmS messages (V4.2 and higher)

Access to the AlarmS messages created by the user in SCOUT and triggered by the controller.

For **AlarmS messages**, the **ItemName** syntax is:

ItemName="dev/AlarmS.Values[ValueNumber].ArrayElement"

ValueNumber: Index of an AlarmS in the list of currently pending technological alarms

ArrayElement:
- AlarmNo
  Alarm number
- AddInfo
  Additional information
- EventCount
- Time
  Time of the AlarmS entry
- Text
  AlarmS text
- Quit
  Acknowledge the AlarmS
- QuitAll
  Acknowledge all AlarmS messages
- Type
  S / SQ
- State
  Status of the AlarmS
- Version

Example: ItemName="dev/AlarmS.Values[0].AlarmNo"

SIMOTION diagnostics

Introduction

Access to diagnostics variables

The diagnostics variables of a SIMOTION control can be accessed via the "SIMOTION diagnostics" provider.

Most of the variables have read-only access and a few (e.g. operating mode) also have write access. All variables are of the string type. Therefore, numerical values are converted into strings by the provider.

The variable management area is dynamic and depends on the current configuration of the SIMOTION control. The provider supports browsing via OPC XML DA V1.0, meaning that the current variable management area can be viewed.

Variables groups of the "SIMOTION diagnostics" provider

The diagnostics variables of the "SIMOTION diagnostics" provider are combined into groups.

A variable name is made up of the group name and variable name:

For example: Group.Variable

DeviceInfo group

General information about the SIMOTION device

The DeviceInfo group contains general information about the SIMOTION device. The 10 variables of this group are always available.

Table 6-15 Variables of the DeviceInfo group

Variable	Description
DeviceInfo.Board	Specifies the system being used, read only
DeviceInfo.Licence-Serial-Nr	License serial number for this device, read-only
DeviceInfo.BZU	Access to the operating state, read and write, valid values for writing: STOP, STOPU, RUN
DeviceInfo.Systemtime	Access to the system time, read and write, the time must always be specified as in the following example: "Tue Aug 05 17:00:00 2003", any other format is not accepted.
DeviceInfo.Timezone	Time offset in minutes, read and write, valid values are -720 to +720
DeviceInfo.Active-MAC-0, ...-1, -2, -3	Active MAC address, read-only
DeviceInfo.Remanent-MAC-0, ...-1, -2, -3	Retentive MAC address, read-only
DeviceInfo.IP-Address-0, ...-1, -2, -3	IP configuration data (address, subnet mask and gateway), read-only
DeviceInfo.Subnet-Mask-0, ...-1, -2, -3	
DeviceInfo.Gateway	

CompInfo group

This group supplies information about the components of the device. The number of variables varies in this group depending on the number of technology packages or additional hardware components.

All variables are read-only.

Information about the CPU

The following variables of the CompInfo group supply information about the CPU.

Table 6-16 Variables of the CompInfo group

Variable	Description
CompInfo.Cpu.MLFB	CPU MLFB / article number
CompInfo.Cpu.Serial-Nr	CPU serial number
CompInfo.Cpu.Revision-Nr	Revision number
CompInfo.Cpu.Kernelname	Kernel name
CompInfo.Cpu.Build-Nr	Build number
CompInfo.Cpu.User-Version	User version (firmware)

Information about the technology packages (TPs) and hardware

The number of available TPs or hardware components can be determined with the following variables.

Table 6-17 Variables of the CompInfo group

Variable	Description
CompInfo.TP-Count	Number of available technology packages
CompInfo.HW-Count	Number of components from HW Config without TPs and CPU itself, => quantity of Additional Hardware on DeviceInfo.mwsl

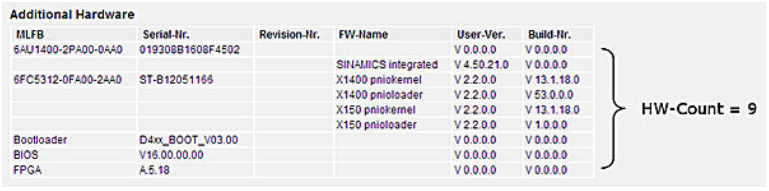

Figure 6-108 Example of CompInfo.HW-Count

When TPs are available, information about the individual TPs can be obtained with CompInfo.TP[x].<variable> (whereby x stands for the TP number).

The first TP is allocated the number 1 (not 0), for example: CompInfo.TP1.Name

The following information is available:

Table 6-18 Variables of the CompInfo group

Variable	Description
CompInfo.TP[x].Name	Name of the TP
CompInfo.TP[x].User-Version	User version of the TP
CompInfo.TP[x].Build-Nr	Build number of the TP

If additional hardware components are available, information about the individual hardware components can be obtained with CompInfo.HW[x].<variable> (whereby x stands for the HW number).

The first hardware component is allocated the number 1 (not 0), for example: CompInfo.HW1.Firmwarename

The following information is available:

Table 6-19 Variables of the CompInfo group

Variable	Description
CompInfo.HW[x].MLFB	MLFB / article number
CompInfo.HW[x].Serial-Nr	Serial number
CompInfo.HW[x].Revision-Nr	Revision number
CompInfo.HW[x].Firmwarename	Firmware name
CompInfo.HW[x].Build-Nr	Build number
CompInfo.HW[x].User-Version	User version

As the information is dynamic and the scope is not known beforehand, the following variables also exist to simplify the display of hardware components and TPs in HTML:

Table 6-20 Variables of the CompInfo group

Variable	Description
CompInfo.TableHead.TP	Supplies the header of an HTML table with all information about the TPs, e. g. "<tr><th>TP name</th><th>User ver.</th> <th>Build no.</th></tr>"
CompInfo.Table.TP	Supplies an HTML table with all the information about all the available TPs
CompInfo.TableHead.HW	Supplies the header of an HTML table with all the information about the hardware components, e. g. " <tr><th>MLFB</th><th>Serial no.</th> <th>Revision no.</th><th>FW name</th> <th>User ver.</th><th>Build no.</th></tr> "
CompInfo.Table.HW	Supplies an HTML table with all the information about all the available hardware components

Note

Separate access to the table and the table header enables separate formatting.

CPULoad group

Information on CPU load

The CPULoad group supplies information on the load of the CPU. Access to all variables is read-only.

Table 6-21 Variables of the CPULoad group

Variable	Description
CPULoad.Percent	CPU load in percent
CPULoad.Mintime	Minimum runtime of the BackgroundTask (free cycle) in ms with 5 decimal places
CPULoad.Acttime	Actual runtime of the BackgroundTask (free cycle) in ms with 5 decimal places
CPULoad.Maxtime	Maximum runtime of the BackgroundTask (free cycle) in ms with 5 decimal places

MemoryLoad group

Information about memory load

The MemoryLoad group supplies information on the load of the storage media. The unit of the memory details is variable and determined by the _sunit value.

Access to all variables is read-only.

Table 6-22 Variables of the MemoryLoad group

Variable	Description
MemoryLoad.Flash-Size	Size of the Flash memory.
MemoryLoad.Flash-Size_sunit	Unit of memory value.
MemoryLoad.Flash-Used	Currently occupied Flash memory.
MemoryLoad.Flash-Used_sunit	Unit of memory value.
MemoryLoad.RAM-Size	Size of the RAM.
MemoryLoad.RAM-Size_sunit	Unit of memory value.
MemoryLoad.RAM-Used	Currently occupied RAM.
MemoryLoad.RAM-Used	Unit of memory value.
MemoryLoad.RAMDisk-Size	Size of the RAM disk.
MemoryLoad.RAMDisk-Size_sunit	Unit of memory value.
MemoryLoad.RAMDisk-Used	Currently occupied RAM disk memory.
MemoryLoad.RAMDisk-Used_sunit	Unit of memory value.
MemoryLoad.Remanent-Size	Size of the retentive memory.
MemoryLoad.Remanent-Size_sunit	Unit of memory value.
MemoryLoad.Remanent-Used	Currently occupied retentive memory.
MemoryLoad.Remanent-Used_sunit	Unit of memory value.

TaskRT group

Variables of the TaskRT group

The TaskRT group supplies information about the task runtimes and the task states of the SIMOTION device. The same values are supplied as in the SIMOTION SCOUT under device diagnostics, task runtimes. Access to all values is read-only. The number of variables varies and depends on the current configuration of the execution system in SIMOTION SCOUT.

Table 6-23 Variables of the TaskRT group

Variable	Description
TaskRT.TaskCnt	Supplies the number of currently available tasks

Task names

The following information can be obtained for the individual tasks via TaskRT.Task-name.Variable-Name. The tasks have the same name in SIMOTION IT and SCOUT .

The same information can be obtained for every task; here is an example of the first MotionTask.

Example:

TaskRT.MotionTask_1.Status

Current task status, can be an appropriate combination of the following values:
STOP_PENDING, STOPPED, RUNNING, STOP_UNCOND, WAITING, SUSPENDED,

WAITING_FOR_NEXT_CYCLE, WAITING_FOR_NEXT_INTERRUPT, LOCKED, SUSPENDED_BY_DEBUG_MODE

Additional variables of the TaskRT group

Table 6-24 Variables of the TaskRT group

Variable	Description
TaskRT.MotionTask_1.Actual	Current runtime of the task in ms, with 5 decimal places
TaskRT.MotionTask_1.Min	Minimum runtime of the task in ms, with 5 decimal places
TaskRT.MotionTask_1.Max	Maximum runtime of the task in ms, with 5 decimal places
TaskRT.MotionTask_1.Average	Average runtime of the task in ms, with 5 decimal places

As the information is dynamic and the scope is not known beforehand, the following variables also exist to simplify the display of task information in HTML:

Table 6-25 Variables of the TaskRT group

Variable	Description
TaskRT.TableHead	Supplies the header of an HTML table with all the information about the tasks, e.g. " <tr><th>Taskname</th><th>Status</th> <th>Actual</th><th>Min</th><th>Max</th> <th>Average</th></tr> "
TaskRT.Table	Supplies an HTML table with all the information about the available tasks; all runtime values are entered with the unit as, unlike the individual value query, they can vary between s and ms. Three decimal places are displayed.

DiagBuffer group

The DiagBuffer group supplies information about the events in the DiagBuffer . Access to all variables is read-only.

Events can be output in English, French, German, Italian, and Spanish text.

Requirement

Text is output in English by default. To display event text in a different language, a file in the relevant language must be downloaded to the SIMOTION controller memory card.

Language	File name
English	DGBUFTXT-EN.EDB
German	DGBUFTXT-DE.EDB
French	DGBUFTXT-FR.EDB
Italian	DGBUFTXT-IT.EDB
Spanish	DGBUFTXT-ES.EDB

Language-specific file names of the DiagBuffer texts

Procedure SIMOTION D,C

1. Open the \3_Diag_Buf_Messages\Diag_Buf_Messages directory on the SIMOTION IT DVD.
2. Insert the SIMOTION controller memory card in a reader/writer.
3. Copy the DGBUFTXT-XX.EDB file for the required language to the \USER\SIMOTION\HMICFG directory. You must create the directory if it does not already exist.
4. Insert the memory card in the SIMOTION device again.

Procedure for SIMOTION P350

1. Shut down the SIMOTION P controller.
2. Open the AddOn\4_Accessories\SIMOTION_IT\3_Diag_Buf_Messages \Diag_Buf_Messages directory on the SIMOTION SCOUT Add-Ons DVD.
3. Copy the DGBUFTXT-XX.EDB file for the required language to the F:\SIMOTION\USER\CARD \USER\SIMOTION\HMICFG directory (for the default installation).
4. Start the SIMOTION P controller.

Procedure for SIMOTION P320

1. Shut down the SIMOTION P controller.
2. Open the AddOn\4_Accessories\SIMOTION_IT\3_Diag_Buf_Messages \Diag_Buf_Messages directory on the SIMOTION SCOUT Add-Ons DVD.
3. Copy the DGBUFTXT-XX.EDB file for the required language to the D:\Card\USER\SIMOTION \HMICFG directory (for the default installation).
4. Start the SIMOTION P controller.

Procedure for SIMOTION P320-4 E, P320-4 S

1. Shut down the SIMOTION P controller.
2. Open the AddOn\4_Accessories\SIMOTION_IT\3_Diag_Buf_Messages \Diag_Buf_Messages directory on the SIMOTION SCOUT Add-Ons DVD.
3. Copy the DGBUFTXT-XX.EDB file for the required language to the D:\USER\SIMOTION\HMICFG directory (for the default installation).
4. Start the SIMOTION P controller.

Note

On delivery and following a firmware update, the English version will be present on the device in all cases.

If the English language version is deleted and a different language version stored on the memory card, the English language version will be recreated at the next startup. The stored (non-English) language version is activated.

For reasons of compatibility, a DGBUFTXT.EDB file is recognized, even if no DGBUFTXT-XX.EDB file is found. If both files are present, priority is given to DGBUFTXT-XX.EDB.

Variables of the DiagBuffer group

The following variables are available for enhancing the display:

Table 6-26 Variables of the DiagBuffer group

Variable	Description
DiagBuffer.TableHead	Supplies the header of an HTML table with all events. The contents are: <tr><th>Nr</th><th>Time</th><th>Date</th><th>Event</th></tr>
DiagBuffer.Table	Supplies the contents of an HTML table with all events. The structure of each row is as follows: <tr><td>NUMBER</td><td>TIME</td><td>DATE</td><td>EVENT</td></tr> **Note:** The NUMBER, TIME, DATE , and EVENT texts specified in this format are replaced with the corresponding value of each event.
DiagBuffer.ExtendedTable	Supplies the contents of the HTML table with all events, including the extended entries displayed via the Info button.
DiagBuffer.ExtendedTableStatic	
DiagBuffer.HexValue[]	
DiagBuffer.HexValuesCloak	
DiagBuffer.PlainDataJScript	
DiagBuffer.ExtendedBufferJScript	Supplies the dynamically generated JavaScript fragment required to display the table.
DiagBuffer.LText[]	Supplies an array that enables access to the entire text of the diagnostics buffer entry. The index matches the index of the diagnostics buffer entry. The individual elements of a diagnostics buffer entry (time, date, text, extended entry text) are separated by "/@@/".

The following variables can be used for direct access to the data of certain events in the diagnostics buffer:

Table 6-27 Variables of the DiagBuffer group - direct access

Variable	Description
DiagBuffer.EventCnt	Number of events currently in the diagnostics buffer
DiagBuffer.CplEventCnt	Event counter beyond the circular buffer limit During startup, the buffer is initialized with the current number of diagnostics buffer entries. Each time an entry is made, the value is incremented, even beyond the maximum number of diagnostics buffer entries.
DiagBuffer.Time_1 bis DiagBuffer.Time[]	Array with the times of the associated events

Variable	Description
DiagBuffer.Date_1 bis DiagBuffer.Date[]	Array with the date details of the associated events
DiagBuffer. Text_1 bis DiagBuffer.Text[]	Array with the texts of the associated events **Note:** If the event text number and its parameters cannot be resolved, the number and parameters are output in HEX format. The variable in HEX format is a string of 20 hexadecimal characters (without separators).

Example of an HTML page

```
<html>
 <head>
  <title>SIMOTION <%=DeviceInfo.Board%> - Diagnostics</title>
  <script type="text/javascript">
   <%=DiagBuffer.ExtendedBufferJScript%>
  </script>
 </head>
 <body style="font-family: Arial">
  <h2>Diag Buffer (extended)</h2>
  <table border="2" cellspacing="1" cellpadding="5">
   <font size="4">
    <%=DiagBuffer.TableHead%>
    <%=DiagBuffer.ExtendedTable%>
   </font>
  </table>
 </body>
</html>
```

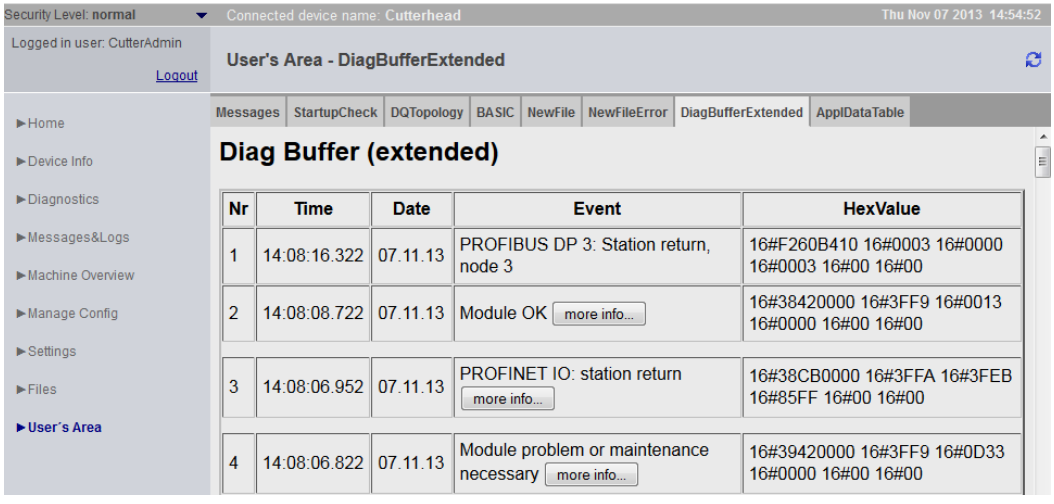

Figure 6-109 Example code result

DiagBufferDrv group

The DiagBufferDrv group provides information about the drive diagnostics buffer. Access to all variables is read-only.

Variables of the DiagBufferDrv group

Variable	Description
DiagBufferDrv.TableHead	Supplies the header of an HTML table with all events. The contents are: <tr><th>Nr</th><th>Time</th><th>Date</th><th>Event</th></tr>
DiagBufferDrv.Table	Supplies the contents of an HTML table with all events. The structure of each row is as follows: <tr><td>NUMBER</td><td>TIME</td><td>DATE</td><td>EVENT</td></tr> **Note:** The NUMBER, TIME, DATE , and EVENT texts specified in this format are replaced with the corresponding value of each event.
DiagBufferDrv.ExtendedTable	Supplies the contents of the HTML table with all events, including the extended entries displayed via the Info button.
DiagBufferDrv.ExtendedBufferJScript	Supplies the dynamically generated JavaScript fragment required to display the table.
DiagBufferDrv.LText[]	Supplies an array that enables access to the entire text of the diagnostics buffer entry. The index matches the index of the diagnostics buffer entry. The individual elements of a diagnostics buffer entry (time, date, text, extended entry text) are separated by "/@@/".

The following variables can be used for direct access to the data of certain events in the drive diagnostics buffer:

Table 6-28 Variables of the DiagBufferDrv group - direct access

Variable	Description
DiagBufferDrv.EventCnt	Number of events currently in the drive diagnostics buffer
DiagBufferDrv.CplEventCnt	Event counter beyond the circular buffer limit During ramp-up, the counter is initialized with the current number of drive diagnostics buffer entries. Each time an entry is made, the value is incremented, even beyond the maximum number of drive diagnostics buffer entries.
DiagBufferDrv.Time[1] bis DiagBufferDrv.Time[n]	Time of each event
DiagBufferDrv.Date[1] bis DiagBufferDrv.Date[n]	Date of each event
DiagBufferDrv. Text[1] bis DiagBufferDrv.Text[n]	Text of each event **Note:** If the event text number and its parameters cannot be resolved, the number and parameters are output in HEX format. The variable in HEX format is a string of 20 hexadecimal characters (without separators).

Alarms group

Information about alarm table

The Alarms group provides information about the pending alarms. Access to all variables is read-only.

Table 6-29 Variables of the Alarms group

Variable	Description
Alarms.AlarmCnt	Number of alarms
Alarms.Table	HTML table with all pending alarms
Alarms.TableHead	Table header for the HTML table of pending alarms
Alarms.TableHeadBuffer	HTML table (header only) of the alarm buffer
Alarms.TableHeadUser	HTML table (header only) of the AlarmS
Alarms.TableBodyBuffer	HTML table (content only) of the alarm buffer
Alarms.TableBodyUser	HTML table (content only) of the AlarmS
Alarms.TableBuffer	HTML table of the alarm buffer
Alarms.UserAlarmCnt	Number of AlarmS

AlarmsDrv group

Information about drive alarm table

The AlarmsDrv group provides information about the active drive alarms. Access to all variables is read-only.

Table 6-30 Variables of the AlarmsDrv group

Variable	Description
AlarmsDrv.AlarmCnt	Number of drive alarms
AlarmsDrv.AlarmDsc	JavaScript code for the standard page **Alarms drive**
AlarmsDrv.Table	HTML table with all active drive alarms
AlarmsDrv.TableHead	Table header for the HTML table of active drive alarms

The SIMOTION C and P do not support the AlarmsDrv group.

Comparison with the device diagnostics of SIMOTION SCOUT

Comparison with device diagnostics in SIMOTION SCOUT

The variables described in this section are based on the view of the device diagnostics in SIMOTION SCOUT. The following figures show the connection between the "SIMOTION diagnostics" variables and the device diagnostics in SIMOTION SCOUT.

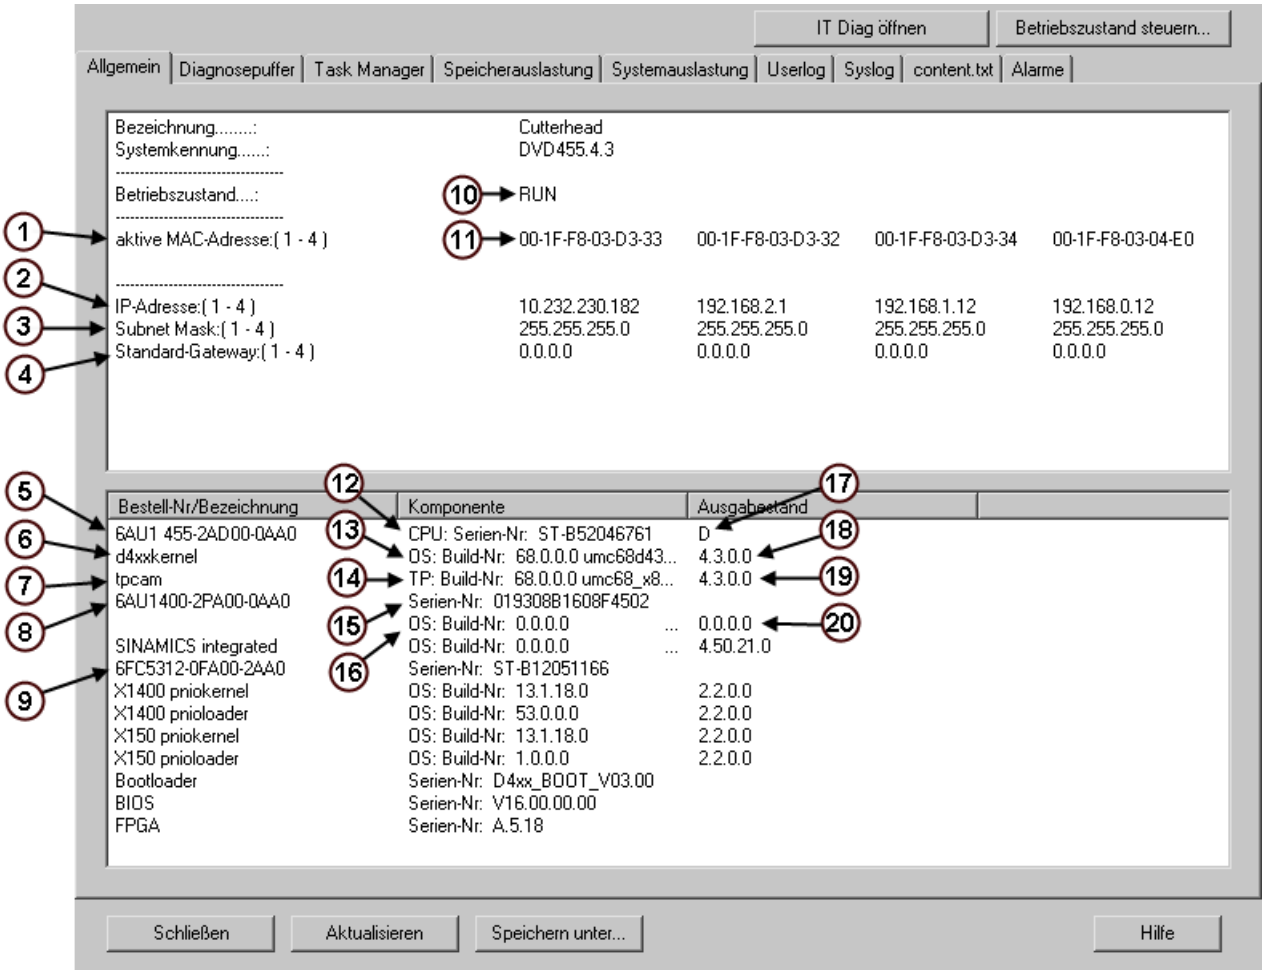

Figure 6-110 "General" device diagnostics

Table 6-31 Explanations

1	DeviceInfo.Active-MAC-0, ...-1, -2, -3	11	The active DeviceInfo MAC addresses 1-4
2	DeviceInfo.IP-Address-0, ...-1, -2, -3	12	CompInfo.Cpu.Serial-Nr
3	DeviceInfo.Subnet-Mask	13	CompInfo.Cpu.Build-Nr
4	DeviceInfo.Gateway	14	CompInfo.TP[1].Build-Nr
5	CompInfo.Cpu.MLFB	15	CompInfo.HW[1].Serial-Nr
6	CompInfo.Cpu.Kernelname	16	CompInfo.HW[1].Build-Nr
7	CompInfo.TP[1].Name	17	CompInfo.Cpu.Revision-Nr
8	CompInfo.HW[1].Firmwarename	18	CompInfo.Cpu.User-Version

9	CompInfo.HW[2].Firmwarename	19	CompInfo.TP[1].User-Version
10	DeviceInfo.BZU	20	CompInfo.Cpu.HW[1].User-Version

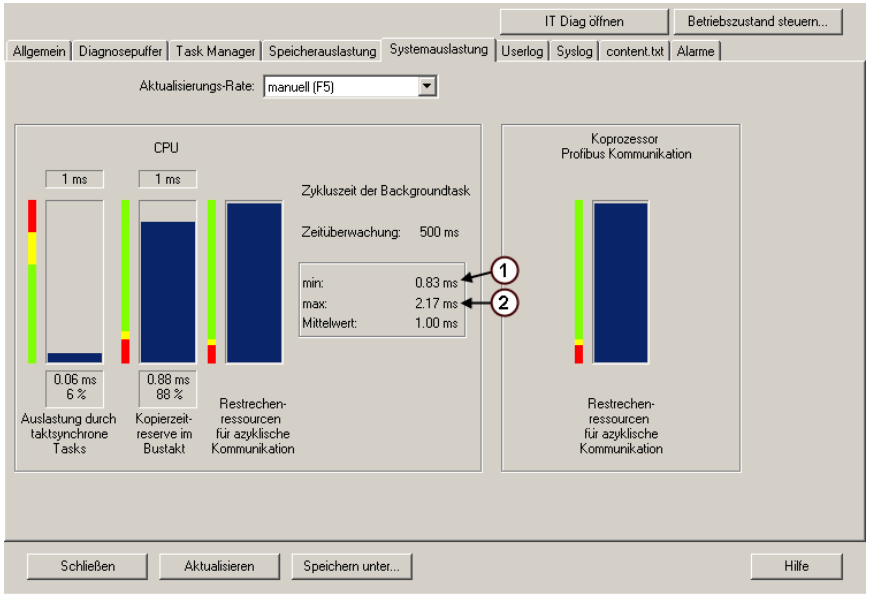

Figure 6-111 "System load" device diagnostics

Table 6-32 Explanations

1	CPULoad.Mintime
2	CPULoad.Maxtime

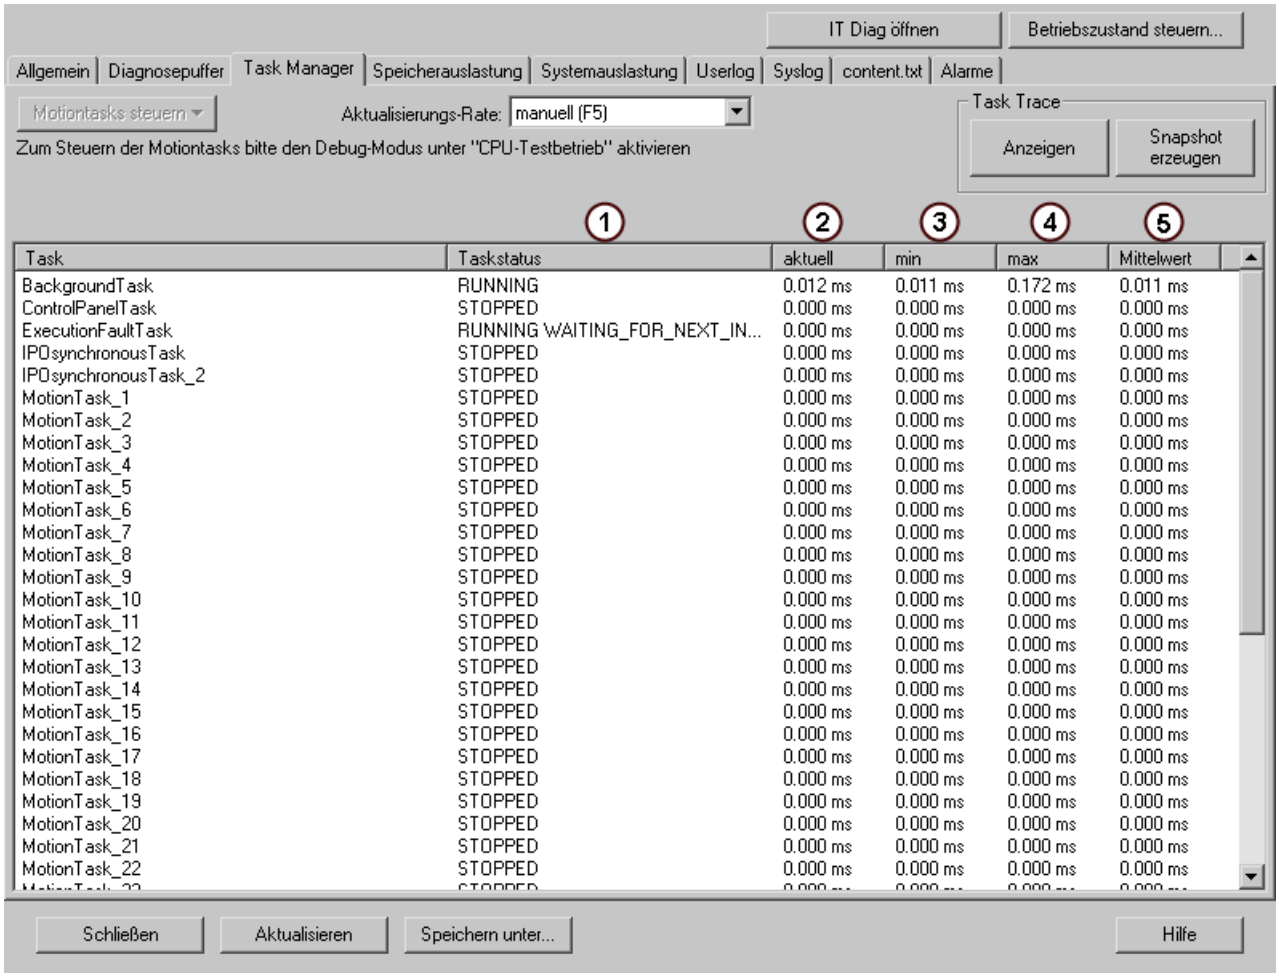

Figure 6-112 "Task runtimes" device diagnostics

Table 6-33 Explanations

1	TaskRT.MotionTask_11.Status
2	TaskRT.MotionTask_11.Actual
3	TaskRT.MotionTask_11.Min
4	TaskRT.MotionTask_11.Max
5	TaskRT.MotionTask_11.Average

UserConfig

User-defined variables

User-defined variables are declared in the UserConfig tag in the `<USERCONFIG>` file and can be read with the variable provider WebCfg.xml.

Some constant variables are predefined in the <USERCONFIG> tag. These variables are accessed via the **variable provider** UserConfig/constants.

Table 6-34 Overview of the predefined constant variables

Name	Type	Description
ForceUserMsgLanguageID	Integer (LCID)	Specifies the language to be used when importing user-defined messages (diagnostics buffer or AlarmS).Setting the language for AlarmS and user-defined diagnostics buffer messages (Page 3575)
WatchWritable	YES / NO Default setting: YES	Specifies whether watch tables may be edited and deleted on the standard pages.
BasicWatchWritable	YES / NO Default setting: YES	Specifies whether watch tables may be edited and deleted on the basic pages.
IncludeScriptsDirectly	YES / NO Default setting: YES

SIMOTION IT Configuration data (Page 3629)

<CONFIGURATION_DATA> (Page 3728)

MiniWeb

Variable provider MiniWeb

The variable provider MiniWeb contains variables of the basic settings of the Web server.

Cannot be configured by the user:

- MiniWeb_Build
- MiniWeb_Version
- Plattform
- SystemRoot
- Time
- UpTime
- WWWRoot

Can be configured in WebCfg.xml and via **Manage Config > SIMOTION IT > Serveroptions**:

- HTTP_PORT
- ALTERNATIVE_HTTP_PORT
- SSL_PORT
- ALTERNATIVE_SSL_PORT

ITDiag

Variable provider ITDiag

Representation of Web server contents

The ITDiag provider represents the connection data of the Web server. The variables have mostly a diagnostic function, and are used by software developers and service personnel for performance and fault analysis.

Table 6-35 Overview of the variables provided by ITDiag

Name	Description
ActiveConnections	The number of connections on which data is currently being transferred (Request or Response).
MaxConnections	Maximum total number of possible connections for clients and servers. Remark: Client and server connections are each limited to a separate maximum number.
MaxConnectionsUsed	Maximum number of connections that have been open since the controller was switched on.
MaxIndisposableConnectionsUsed	Maximum number of simultaneously open connections without "SleepingConnections".
MaxSimultaneousConnections	Maximum number of connections that can be managed in the Select mechanism of the protocol stack.
OpenConnections	Number of connections that are currently open.
Overflows	Number of failed connection attempts since controller power-on.
SimultaneusConnections	Number of connections that are currently being managed in the Select mechanism of the protocol stack.
SleepingConnections	Number of connections that are still open because of a connection marked as "Keep-Alive". They are closed by the Web server as required.
WaitingConnections	The number of connections through which a complete Request, but not yet any response, have been transferred.
resetMaxUsedConnections	By writing "true" to this variable, the statistics variables can be reset.
MaxIndisposableConnectionsUsed-Time	The time when the MaxIndisposableConnectionsUsed occurred.
OverflowTime	Instant at which the last overflow occurred.

The information relevant to the user is shown on the Diagnostics (Page 3585) Web page.

Making unit variables available

To make variables available on the SIMOTION IT OPC XML DA server, you must declare them as VAR_GLOBAL.

Declaring unit variables in the interface

In the declaration table, you define the data type for each variable. Only variables declared as VAR_GLOBAL are available for OPC XML-DA.

The following figure shows an example of unit variable declarations in an MCC program.

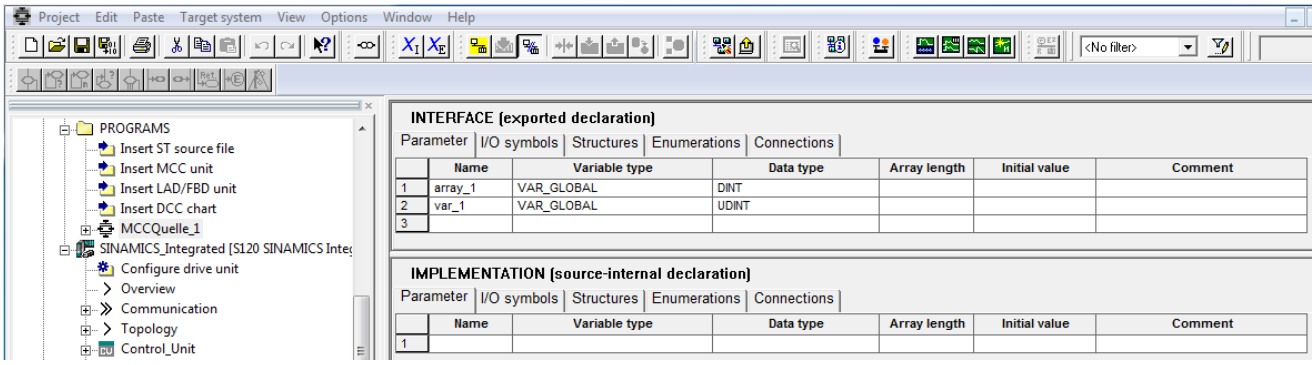

Figure 6-113 Declaring global variables

Permit OPC XML

To activate the variables for OPC XML DA, proceed as follows:

1. Open the **Properties** of the unit/source.
2. Select the **Compiler** tab.
3. Activate **Permit OPC-UA/-XML**, if it is not already activated (standard setting).

The following figure shows how to activate the unit variables from an MCC source.

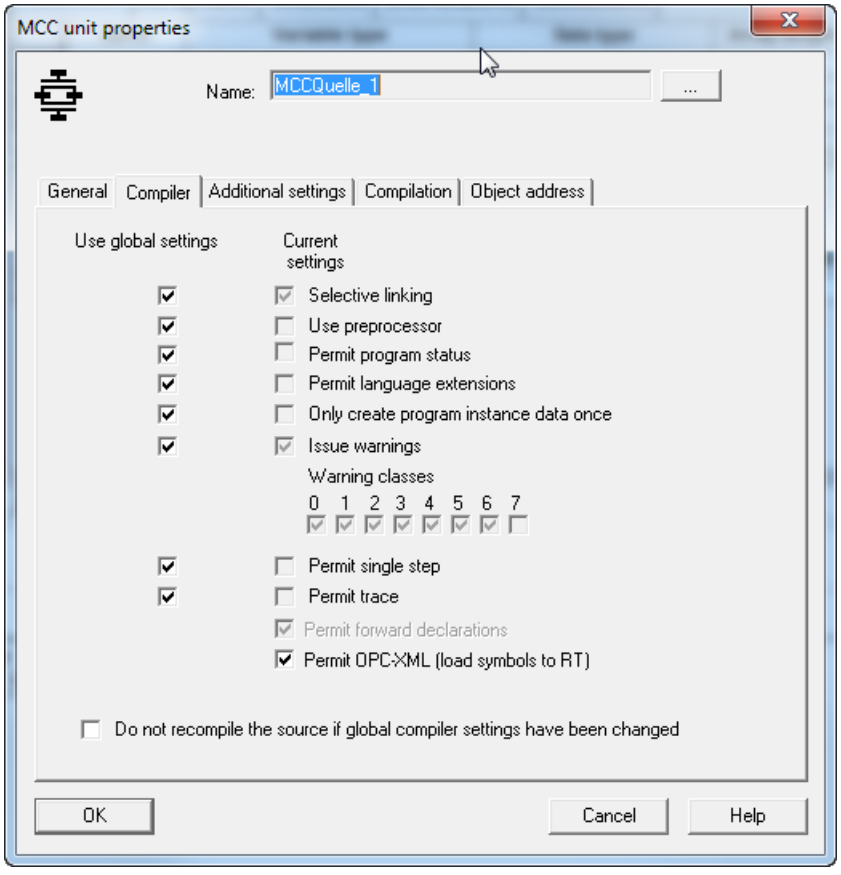

Figure 6-114 Making variables available for OPC XML DA

Note

The OPC XML activation applies also to variables in LAD/FBD and ST programs. To make variables available for OPC XML-DA in an ST program, they must be defined in a global variable block (VAR_GLOBAL and VAR_GLOBAL_RETAIN). This must be located in the interface section.

6.1.4.7 Secure Socket Layer

Introduction

The Secure Socket Layer protocol (SSL) enables encrypted data transmission between a client and SIMOTION. HTTPS access between the browser and the SIMOTION control is based on the Secure Socket Layer protocol.

Encrypted access to SIMOTION can take place via both SIMOTION IT OPC XML-DA and SIMOTION IT user-defined pages.

This section tells you which steps you need to follow to enable encrypted data communication between a client and SIMOTION. The possibilities are as follows:

1. You use the default configuration of the as-delivered condition.
2. You have a Certification Authority (CA) in your organization and the necessary key files are available.
3. You do not have a CA in your organization. In this case, you will need to create the key files yourself.

Note

HTTPS connections are supported in SIMOTION V3.2 and higher.

See also

Key files (V4.1 and higher) (Page 3703)

Encryption methods

You need two key files for the encryption method used by the Secure Socket Layer protocol. You need a public certificate and a private key. The pair of keys is created individually for each SIMOTION control. This ensures that the address requested matches the SIMOTION control accessed during HTTPS communication.

Note

Encrypted access to the SIMOTION control is only possible with the control identifier (name/IP address) specified when the key was created.

You can find further information about Secure Socket Layer certificates at http://www.verisign.de (http://www.verisign.de).

Key files (V4.1 and higher)

As delivered

So that you can access the SIMOTION controller via HTTPS in the delivery state of the SIMOTION IT diagnostics standard pages, a server certificate and a private key are supplied as a file on the device.

When you attempt HTTPS access using the key files supplied with the system, you will be warned that the certificate is unknown and that the current address of the controller does not match the name of the controller in the certificate.

Note

Secure data transmission

A HTTPS connection via the preinstalled certificate is not the most secure way of accessing the controller. The preinstalled certificate should therefore only be used if no self-created or purchased certificate can be used.

Creating key files with the script cert.pl (V4.1 and higher)

Overview

Note

HTTPS connections are supported as of SIMOTION V3.2.

If no Certification Authority (CA) is available in your organization, we recommend that you follow the steps described in the following section. The certificate and the key files are created with the OpenSSL tool and a Perl script cert.pl

Carry out the following steps:

No.	Working step	Remark
1.	Install a Perl runtime environment	If Perl is not installed
2.	Install OpenSSL	
3.	Create the certificate and key files with Perl script	
4.	Import the created certificate to the PC browser	This step must be performed once for each PC.

HTTPS access is available after the SIMOTION controller ramps up.

Installation of a Perl runtime environment

Install Perl if the Perl runtime environment is not present on your PC. You can download a free setup for Windows from the following websites, for example:

- http://www.activestate.com (http://www.activestate.com)
- http://www.perl.org (http://www.perl.org)

Installation of OpenSSL

You can download a free OpenSSL setup for Windows, for example, from the following website:

- http://slproweb.com/products/Win32OpenSSL.html (http://slproweb.com/products/Win32OpenSSL.html)

Application cert.pl

The cert.pl Perl script generates certificates for the controller. The script is on the AddOn-DVD in the \Addon\4_Accessories\SIMOTION_IT\6_Tools directory.

First, create a new directory <CertDir> (e.g. C:/cert) on your PC and copy the cert.pl file into it.

Call syntax cert.pl

```
Usage: perl cert.pl [-h][-?][-cert CertPath][-site <Site name>][-cpu
<CPU name>]
                  [-ip <IPAddr>[,<IPAddr>,...]][-ossl <path>][-tools
<path>]
                    [-d <duration>][-img <path>][-wcfg <WebCfgPath>]
                    [-ca][-srvn][-srvu][-ksize size]

Options:

  -cert <certpath>: Directory used for the creation of certificates;
must be given as absolute path e.G. C:\cert (default: current
directory)

  -site <site name>: Name of the site the cpu is belonging to

  -cpu <CPU name>: Name of the cpu

  -ip <IPAddr>[,<IPAddr>,...]: List of IP addresses belonging to 1
cpu (no spaces allowed)

  -ca: Create new root CA

  -srvrn: Create new server certificate

  -srvru: update existing server certificate

  -d <duration>: Duration of validity (in days)

  -tools <path>: Absolute Path to the tools dir containg eg. 7z.exe

  -img <path>: Path to the output dir (default: <certpath>)

  -e: Export the certificates of 1 cpu to the path specified by the -
img option

  -ossl <path>: Absolute Path to an openssl installation (eg. C:/
OpenSSL-Win64)

  -ksize <size>: Key size (default: 2048)

  -h: Print this help

  -?: Print this help

  -wcfg WebCfgFile: Use <WebCfgFile> as a template
```

The path to the OpenSSL installation is determined via the "OPENSSL_CONF" environment variable from the program. This environment variable is created during the installation of OpenSSL with a setup program. If the environment variable is not set, then the "-ossl" option must be used.

Creating a ZIP file for upload

If the created certificates are to be loaded into the controller afterwards via the standard page "Manage Config -> SIMOTION IT -> Certificates" , the ZIP tool `7-Zip` must be installed in addition. Download the program from the Internet (http://www.7-zip.org/download.html). After unpacking, copy the `7z.exe` program (`7za.exe` in older versions) to the `<certpath>` directory. Alternatively, when you call `cert.pl` , you can transfer the installation directory containing the `7z.exe` file with the option `-tools <toolpath>`.

See also

Importing the SSL certificate into the browser (Page 3709)

Creating a SSL certificate yourself

The cert.pl Perl tool can be used to generate the certificates required for customer systems (sites) and combine them into packages for loading.

Generation of root and server certificates

As of SIMOTION Version 4.4, there are two applications for which the tool can be used:

Automatic generation of the certificate

In the first application, the required server certificates and their private keys are generated automatically on first access to the controller via HTTPS. A root certificate and the associated private key are required for this purpose.
The root certificate and the associated private key are generated using the Perl tool.

Call: `perl cert.pl -ca -ossl C:/OpenSSL-Win64`

Name of the server certificate:	ITDiagRootCA.crt
Name of the private key:	ITDiagRootCA.key
Storage location in the file system:	<certpath>/CA

Note

UaExpert

Version 1.4.4 of the UaExpert functions only with a binary certificate in DER format. The certificate in DER format is stored in the /USER/SIMOTION/HMICFG/CERTSTORE/CA path in the "ITDiagRootCA.zip" ZIP file on the memory card of the controller.

The data of the certification institution is queried:

- Country (2-character code, e.g. DE)
- State (e.g. Bavaria)
- City (e.g. Erlangen)
- Company (e.g. MyCompany Corp.)
- Department (e.g. IT Development)

- Common name (e.g. ITDiagRootCA)
- E-mail (e.g. sepp@MyCompany.com)

Self-generated certificates

In this case, the required server certificates must be generated in addition to the root certificate.

Call:

```
perl cert.pl [-ca] [-cert <certpath>] [-site <sitename>] -cpu
<cpuname> -ip <IP-Addr1>,<IP-Addr2>,.... -srvn -ossl <opensslpath>
```
or
```
perl cert.pl [-ca] [-cert <certpath>] [-site <sitename>] -cpu
<cpuname> -ip <IP-Addr1>,<IP-Addr2>,.... -opcuacert -ossl
<opensslpath>
```

Name of the generated root certificate	ITDiagRootCA.crt, bzw. ITDiagRootCA.zip
Name of the private key	ITDiagRootCA.key
Storage location in the file system	<certpath>/CA

Name of the generated server certificates	<IP-Addr>.SSL.crt (z.B. 192.168.2.90.SSL.crt)
Name of the private key	<IP-Addr>.SSL.key (z.B. 192.168.2.90.SSL.key)

or

Name of the generated server certificates	<IP-Addr>_OPCUA.crt (z.B. 192.168.2.90_OPCUA.crt)
Name of the private key	<IP-Addr>_OPCUA.key (z.B. 192.168.2.90_OPCUA.key)
Storage location in the file system	<certpath>/<sitename>/<cpuname>/<IP-Addr>

The root certificate will only be generated if none already exists. For all subsequent calls, the existing root certificate is used to sign the newly generated server certificates. The generation of a new root certificate can be forced with the -ca option.

The list of IP addresses (<IP-Addr1>, <IP-Addr2>) must not contain any blanks. This also applies to all other parameters.

The data of the applicant is queried when creating the first server certificate of a site. If `-site` was not specified, of a CPU, the applicant data is queried:

- Country (2-character code, e.g. DE)
- State (e.g. Bavaria)
- City (e.g. Erlangen)
- Company (e.g. MyCompany Corp.)
- Department (e.g. IT Development)
- E-mail (e.g. sepp@MyCompany.com)

Note

Validity duration of the certificates

The default validity is 30 years (effectively infinite).

The d option generates certificates with a shorter validity. In this case, HTTPS communication will no longer function after the validity has expired.

The user is responsible for installing the new valid certificates on all affected controllers.

Update of existing server certificates

If one of the parameters essential for the generation of the server certificates (e.g. the server certificate, the lifetime or the configuration) changes, an update can be started for the server certificates.

Call: `perl cert.pl [-cert <certpath>] [-site <sitename>] [-cpu <cpuname>] -srvu -ossl <opensslpath>`

This call also affects the certificates for OPC UA.

If the `-cpu` parameter is missing, all certificates of the CPUs belonging to the site are renewed.

If the `-site` parameter is also missing, all certificates are renewed.

Deletion of existing server certificates

Server certificates can be deleted:

Call: `perl cert.pl [-cert <certpath>] [-site <sitename>] [-cpu <cpuname>] [-ip <IP-Addr1>,<IP-Addr2>,....] -svrr -ossl <opensslpath>`

Export of existing server certificates

The generated certificates can be exported for each CPU.

Call: `perl cert.pl [-cert <certpath>] [-img <path>] [-site <sitename>] -cpu <cpuname> [-ip <IP-Addr1>,<IP-Addr2>,....] -e -ossl <opensslpath>`

The path to the exported images can be specified with the `-img` option.

Storage location in the file system: `<path>/images/<sitename>/<cpuname>`

A directory structure can be found at `<imgpath>/images/<sitename>/<cpuname>/image` which can be copied to the `/USER/SIMOTION/HMICFG` directory of the CF card. An upload-capable ZIP archive (<cpuname>.zip) is also generated under `<imgpath>/images/<sitename>/<cpuname>` if the zipper 7z.exe (7za.exe in older versions) is in `<toolspath>` (option `-tools <toolspath>`).

- The archive can be unpacked in the HMICFG directory. Any existing server certificates have to be removed. To do this, the complete `/USER/SIMOTION/HMICFG/certstore/servercerts` directory is deleted. The controller then has to be restarted.
- The server certificates can also be loaded to the CPU via the **Certificates** website at **Manage Config**. Unnecessary files and directories are deleted and a restart of the Web server triggered.

SIMOTION versions prior to Version 4.4

For SIMOTION versions prior to Version 4.4, the functionality of the tool is retained.

Generated server certificates are entered in a copy of a template of the WebCfg.xml file.

The template is sought in one of the following directories in the specified order:

```
- –wcfg Option
- <certpath>/<sitename>/<cpuname>/<ipaddr>
-<certpath>/<sitename>/<cpuname>
- <certpath>/<sitename>
-<certpath>
```

See also

7-Zip Download (http://www.7-zip.org/download.html)

Importing the SSL certificate into the browser

If you use SSL with your own certification authority, you will need to prepare your PCs for communication with the SIMOTION controller. To do this, the "ITDiagRootCA.crt" root certificate must be included in the list of certificates in your browser.

Please follow the instructions of your browser when importing the certificate.

Various types of certificate use:

1. Browser import of the "ITDiagRootCA.crt" root certificate (e.g. from the "<certpath>\images \<site>\<cpu>\image\certstore\CA" directory).
2. If an HTTP connection is established to the device, the root certificate can be saved via the **Manage Config > Certificates** page with the **Get root certificate** button.
3. During HTTPS access to a device without previous import of the root certificate, a prompt appears in the browser as to whether the associated server certificate is to be imported. This import enables the secure connection to **one** device and must be repeated for all other devices. For this reason, import of the root certificate is always preferred.

6.1.4.8 Trace Viewer

Trace display

SIMOTION IT allows traces to be displayed on the Trace Viewer (Page 3602) Web page. Alternatively, you can use the WebTraceViewer (Page 3719) external program to display traces.

The Trace Viewer shows only completed measurements. Measurements are imported directly from the device or a file.

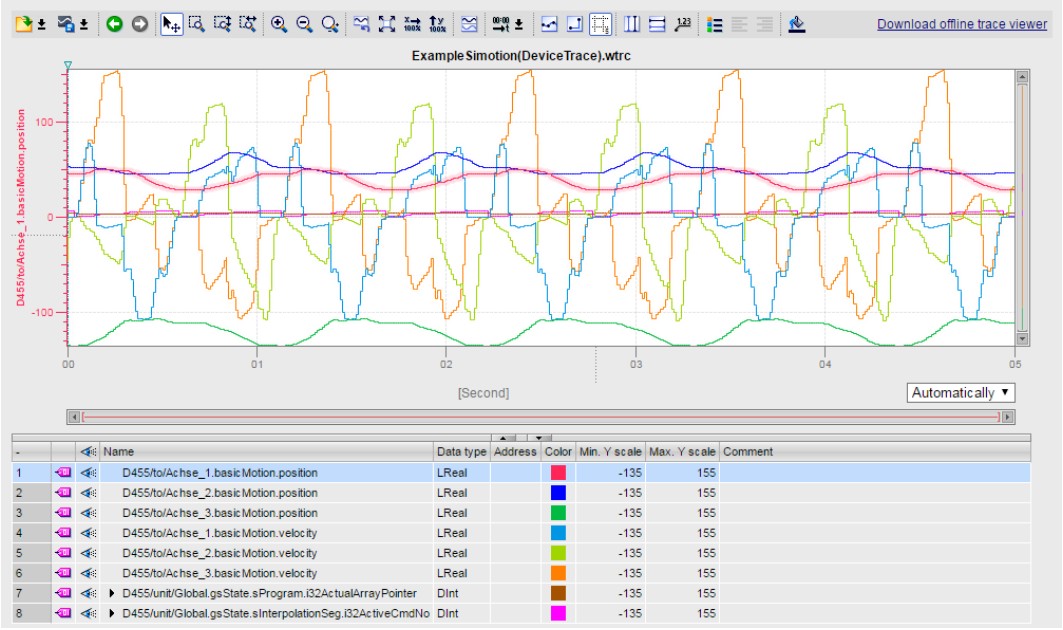

Figure 6-115 Trace Viewer working area

The working area of the Trace Viewer is divided into two areas. The upper area shows the curve diagram (Page 3711); the lower area shows the signals table (Page 3717).

Data import

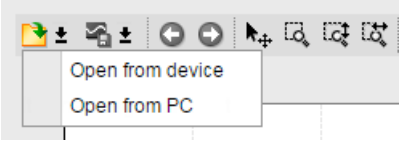

Figure 6-116 Trace Viewer data import selection

Open from device imports data directly from the device in WTRC format.

Open from PC imports data from a file in WTRC or CSV format. The Device Trace and System Trace Web pages provide with the **Get trace data** button the possibility to save trace data in WTRC format.

Trace files exported in CSV format from the TIA Portal can also be imported.

Conversion of trace data

1. WTRC data loaded in Trace viewer can be saved locally as CSV and WTRC.
2. CSV data loaded in Trace viewer can be saved only as CSV (copy).

The WTRC format is identical with that of the WebTraceViewer (Page 3719). The CSV format can be displayed only with the Trace Viewer.

Files can be imported by drag-and-drop to the working area of the Trace Viewer.

Curve diagram

The curve diagram displays the selected signals of a recording. Bits are shown in the lower diagram as a bit track. You can adjust the display of the signals in the signal table and with the toolbar of the curve diagram.

Setting options and displays in the curve diagram

The following figure shows a sample representation in SIMOTION IT.

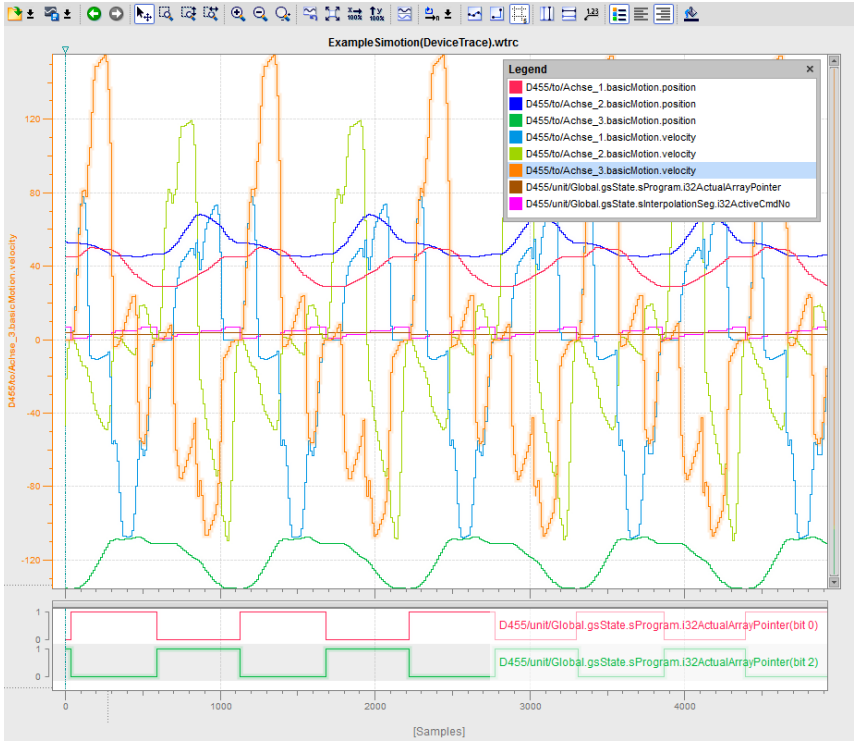

Figure 6-117 Trace Viewer legend

The scale in the diagram applies to the selected (orange background) signal in the legend. The vertical scale is also displayed in the color of the selected signal. The legend can be moved and its size can be adjusted with the mouse. Only signals, but no bits, are displayed in the legend.

The ▽ symbol shows with a vertical line the trigger instant with the trigger time of the device. The trigger time is displayed in a tooltip when hovering with the mouse.

Shortcut menus

A signal in the curve diagram can be selected with the cursor when **Move view** is activated in the toolbar. A right-click opens the shortcut menu that allows the curve to be zoomed or hidden automatically for the Y axis.

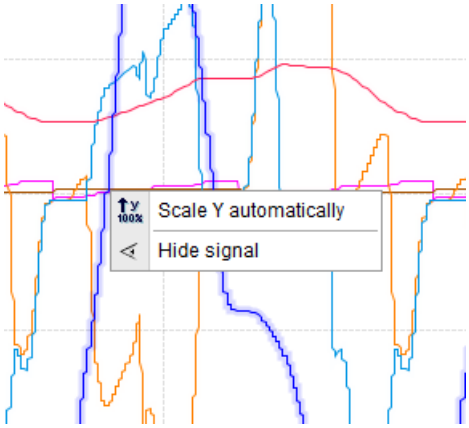

Figure 6-118 Signal shortcut menu

Further shortcut menus are provided in legends, in the signal table (depending on the signal type) and in the curve diagram.

Functions using the mouse wheel

The following table shows which functions are possible in the curve diagram using the mouse wheel:

Function of the mouse wheel	Description
Move the curve diagram vertically	Turning the mouse wheel moves the display in the upper curve diagram up or down. If the signals are arranged in tracks, the display of the group located below the cursor is moved. The cursor must be positioned above the upper curve diagram. Keyboard: Up and down arrow keys. Pg Up and Pg Dn.
Move the curve diagram horizontally	Turning the mouse wheel with the <Shift> key pressed down moves the display in the curve diagram to the left or the right. The cursor must be positioned above the curve diagram. Keyboard: Right and left arrow keys Home and End.
Zoom in and Zoom out of the curve diagram	Turning the mouse wheel with pressed <Ctrl> key zooms the display in the curve diagram and the display of the bit tracks. The cursor position is the starting point for zooming in or out. The cursor must be positioned above the curve diagram. Keyboard: Press the <+> or <-> key.

Functions in the vertical scale

The following table shows which mouse actions are possible in the vertical scale:

Function	Description
Scroll mouse wheel	Turning the mouse wheel scrolls the display. Turning the mouse wheel with pressed <Ctrl> key zooms the display in the curve diagram.
Zoom mouse wheel	Turning the mouse wheel with pressed <Ctrl> key zooms the display of the selected signal in the curve diagram.

Function	Description
Zoom left mouse button	Moving the mouse up or down with pressed left mouse button zooms the signal.
Zoom <Shift> left mouse button	Moving the mouse up or down with pressed left mouse button and pressed <Shift> key zooms the signal, whereby the upper and lower limits are synchronized.

Toolbar of the curve diagram

Tools are available for adapting the display via buttons.

The following table shows the functions of the buttons:

Symbol	Function	Description
	Load measurements	Measurements can be imported from the device memory (WTRC format) or a file (WTRC, CSV format).
	Save measurements	The displayed measurement can be saved in a file. Measurements that were imported in WTRC format can also be saved in WTRC and in CSV format. Measurements that were imported in CSV format can be saved only in this format.
	Undo the last action.	Undo the last action that was performed. Actions that can be undone: Zoom, colors, X axis unit, signal selection, display and hide. If several zoom functions have been executed, they can be undone step-by-step.
	Redo the last action	Redo the last undone zoom function. If several zoom functions have been undone, they can be redone step-by-step.
	Move view	Move the display of the curve diagram Keyboard: <M>, <Esc> Pressing these keys deactivates the keys of the zoom toolbar which causes the started zoom actions to be cancelled. If "move view" is active and the <Ctrl> key is pressed, the "zoom selection" is then activated.
	Zoom selection	Select an arbitrary range with the mouse button pressed. The display is scaled to the range selection. Keyboard: <Z>
	Vertical zoom selection	Select a vertical range with the mouse button pressed. The display is scaled to the range selection. Keyboard: <V>
	Horizontal zoom selection	Select a horizontal range with the mouse button pressed. The display is scaled to the range selection. Keyboard: <H>
	Zoom in	Enlarge the display. The ranges of the time axis and value axis are reduced every time the button is clicked. The curves are displayed larger. Keyboard numeric keypad: <+>

Symbol	Function	Description
	Zoom out	Reduce the display. The ranges of the time axis and value axis are increased every time the button is clicked. The curves are displayed smaller. Keyboard numeric keypad: <->
	Zoom within the graphic	Moving the pressed cursor within the graphic changes the zoom area. The zoom effects differ depending on the position of the cursor and the direction in which the cursor is moved: • To zoom the graphic from the left-hand side, click in the left-hand half of the graphic and move the mouse in the desired direction. • To zoom the graphic from the upper side, click in the upper half of the graphic and move the mouse in the desired direction. • The action for the lower and right-hand sides is identical. Pressing the Shift key synchronizes these actions.
	Standard view of the zoom settings	The standard view of the zoom settings is restored. All displayed signals are scaled in the visible area, whereby relative positionings (vertical separations) are retained.
	Display all	Scale the display of the available data so that the entire time range and all values are displayed.
	Display the complete time range	Scale the display so that the values for the complete time range are displayed in the currently displayed value range. All signal points are adapted (or scaled) to the visible width irrespective of whether the signal was selected. This is equivalent to the state after the original loading of a file.
	Automatic scaling of the value axis	Scale the display so that all values are displayed for the currently displayed time range. The relative scaling ratio between the signals changes.
	Arrange in tracks	Display the signals in separate tracks. The signals are arranged below each other with the associated value axes. Signal groups are displayed in the same track. This setting does not affect the display of the bit tracks.
	Unit change of the time axis	Change the unit of the time axis. The following units are adjustable: • Measurement points • Time (relative time related to the trigger time) • Absolute time Only the relative time can be displayed for system trace recordings. A change is not possible in this case.
	Display measurement points	The measurement points are displayed as small circles on the curves.

Symbol	Function	Description
	Interpolation mode	Change the interpolation mode.
	Display grid	Change the grid display. The brightness setting of the grid can be changed in the shortcut menu or with the <B> key.
	Display vertical measurement cursors	Display the vertical measurement cursors. The vertical position of the two measurement cursors can be moved with the mouse. The associated measured values and the difference of the measurement cursors corresponding to the position are shown in the signal table. Selecting a measurement line with the mouse causes the line to be displayed solid. A selected measurement line can be moved from measurement point to measurement point with the keyboard arrow keys. If the <Ctrl> key is pressed in addition, the line is moved pixel-by-pixel.
	Display horizontal measurement cursors	Display the horizontal measurement cursors. The horizontal position of the two measurement cursors can be moved with the mouse. The selected measurement line can also be moved pixel-by-pixel with the arrow keys.
	Display the measured cursor values	Change the display of the measured cursor values in the curve diagram.
	Display chart legend	Show or hide the legend in the curve diagram and the bit track labels.
	Display the bit-track designation left-justified	Display the bit-track designations on the left-hand side of the curve diagram.
	Display the bit-track designation right-justified	Display the bit-track designations on the right-hand side of the curve diagram.
	Change background color	Switch between three different background colors (white, dark blue, black).

Measurement cursor pane

The "Measurement cursor" pane shows the position of the measurement cursor in the curve diagram and the values at the intersection points.

Setting options and displays of the "Measurement cursor" pane

The figure below shows the "Measurement cursor" pane:

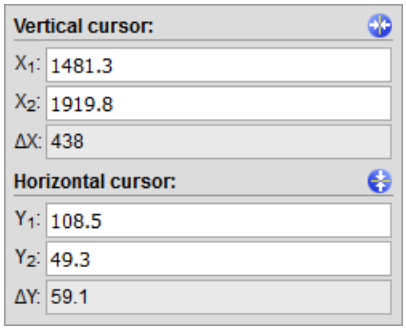

Figure 6-119 "Measurement cursor" pane

The blue buttons at the top right return the measurement cursor to the visible area.

The following table describes the settings and displays:

Setting/display		Description
Horizontal measurement cursor		
	Y1	Position of first measurement cursor The value states the position in relation to the scale of the signal currently selected. You also have the option of specifying a new position for the measurement cursor in this entry field for moving with the mouse.
	Y2	Position of the second measurement cursor The value states the position in relation to the scale of the signal currently selected. You also have the option of specifying a new position for the measurement cursor in this entry field for moving with the mouse.
	ΔY	Display of the position difference between the first and the second measurement cursor
Vertical measurement cursor		
	X1	Position of first measurement cursor You also have the option of specifying a new position for the measurement cursor in this entry field for moving with the mouse.
	X2	Position of the second measurement cursor You also have the option of specifying a new position for the measurement cursor in this entry field for moving with the mouse.
	ΔX	Display of the position difference between the first and the second measurement cursor

Measurement cursor and curve diagram example

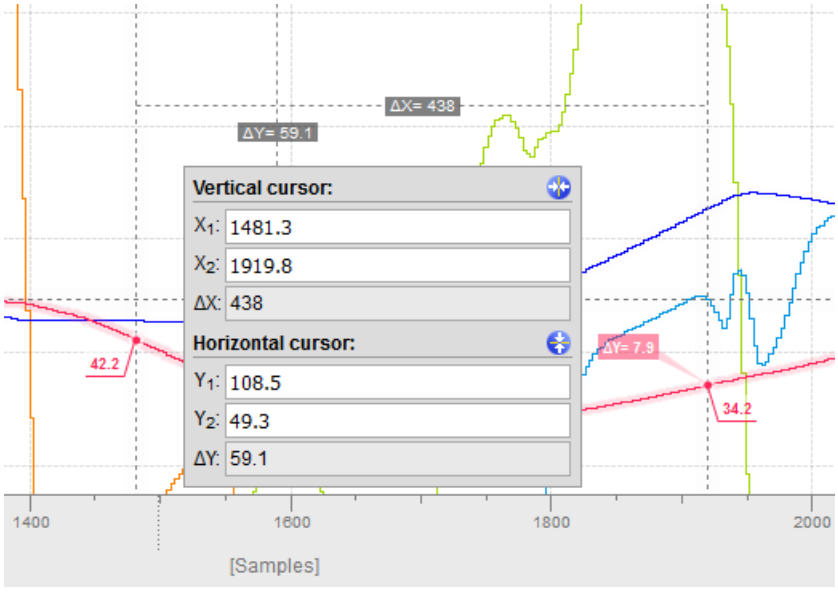

Figure 6-120 Measurement cursor and curve diagram pane

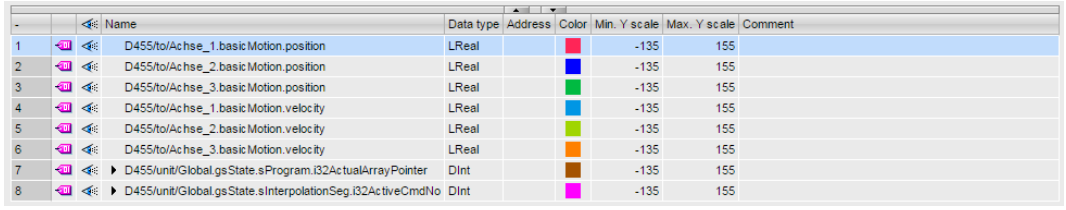
Signal table

The signal table lists the signals of the selected measurement and provides setting options for some properties.

Setting options and displays in the signal table

The following figure shows a sample representation of the signal table:



-		Name	Data type	Address	Color	Min. Y scale	Max. Y scale	Comment
1		D455/to/Achse_1.basicMotion.position	LReal			-135	155	
2		D455/to/Achse_2.basicMotion.position	LReal			-135	155	
3		D455/to/Achse_3.basicMotion.position	LReal			-135	155	
4		D455/to/Achse_1.basicMotion.velocity	LReal			-135	155	
5		D455/to/Achse_2.basicMotion.velocity	LReal			-135	155	
6		D455/to/Achse_3.basicMotion.velocity	LReal			-135	155	
7		D455/unit/Global.gsState.sProgram.i32ActualArrayPointer	DInt			-135	155	
8		D455/unit/Global.gsState.sInterpolationSeg.i32ActiveCmdNo	DInt			-135	155	

Figure 6-121 Trace viewer Signal table

Clicking the symbol in the table header shows or hides the signals and bit tracks.

The following table shows the settings and displays of the recorded signals:

Column	Description
	Static display of the signal symbol
	Selection for the display in the curve diagram The point indicates that at least one bit has been selected for display as bit track for the signal in the bit selection.

Column	Description
"Name"	Signal name display A click on the name of a displayed signal updates the scale in the curve diagram. The scale assumes the set color. The name is formed from the device name and the signal name.
▶	Open bit selection For simple integer data types, individual bits can be selected for display as bit track in the lower curve diagram: Example of an opened bit selection for the DInt data type:  Trace viewer Signal table bit display Select or deselect the associated bit for display by clicking the symbol or from the shortcut menu.
"Data type"	Display the data type
"Address"	Display the address of the signal The address is empty for a SIMOTION trace. This column can be filled for a CSV import from the TIA Portal.
"Color"	Display and setting option for the signal color. Clicking the color box opens a dialog for the color selection in which any color can be set.
"Min. Y-Scale"	Display the minimum value for scaling the signal
"Max. Y-Scale"	Display the maximum value for scaling the signal
"Y(t1)"	Display only for activated vertical measurement cursor
"Y(t2)"	Display only for activated vertical measurement cursor
"ΔY"	Display only for activated vertical measurement cursor
"Comment"	Display a comment for the signal

Shortcut menu commands

The following table shows the shortcut menu commands of the signal table:

Shortcut menu command	Description
"Scale Y automatically"	Scales the selected signal on the Y axis.
"Show signal"	Displays the selected signals in the curve diagram.
"Hide signal"	Hides the selected signals in the curve diagram.
Bit signals	
"Show bit"	Displays the selected bit signals in the curve diagram.
"Hide bit"	Hides the selected bit signals in the curve diagram.

WebTraceViewer

The WebTraceViewer PC program enables the trace data to be displayed.
The **GetWebTraceViewer** link can be used to save the WebTraceViewer on the PC. This link is not available with SIMOTION C modules. Alternatively, you can copy the WebTraceViewer from the Addon DVD.

This program is able to graphically display the data saved in a WTRC file.

As of SIMOTION V4.4, you can also load and display WTRC files in SIMOTION SCOUT.

Functions

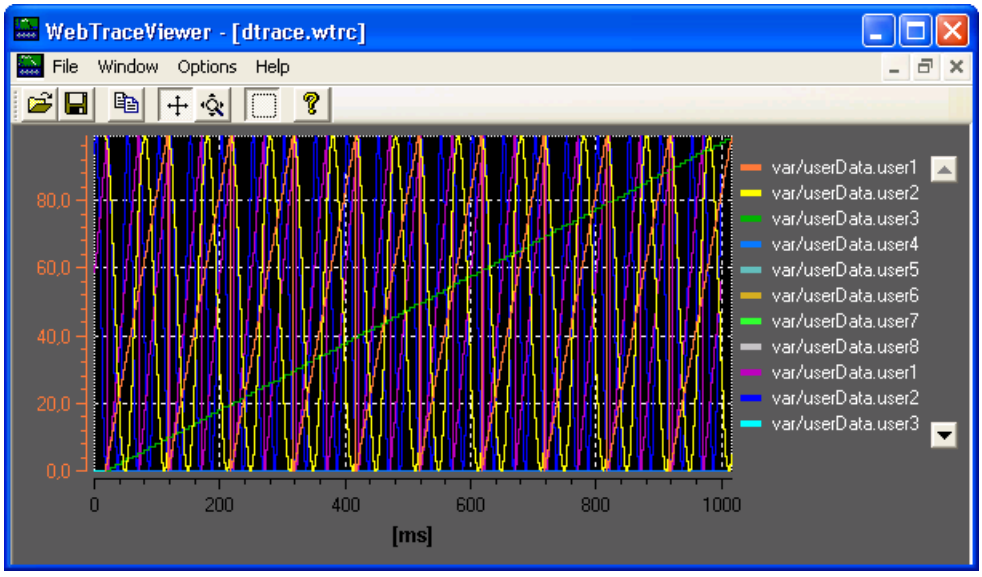


Figure 6-122 WebTraceViewer

Functions of the buttons

1. Open file: Enables you to open WTRC files.
2. Save file: Enables you to save WTRC files.
3. Copy: Copies the content of the current WTRC window to the clipboard in bitmap format. This enables the graphic to be copied to a word processing program, for example.
4. Scroll mode: Enables you to shift the visible area of the graphic using the mouse.
5. Zoom mode: Enables you to expand and compress the graphic using the mouse.
6. Selection mode: If this button is pressed, only a rectangular area of the graphic can be selected. Buttons 4 and 5 can then no longer be used.

Files

The **File Export** menu item allows you to save the trace data in CSV format so you can import it into a spreadsheet, for example.

Defective WTRC files

If WebTraceViewer imports a defective file, it provides information about the error.

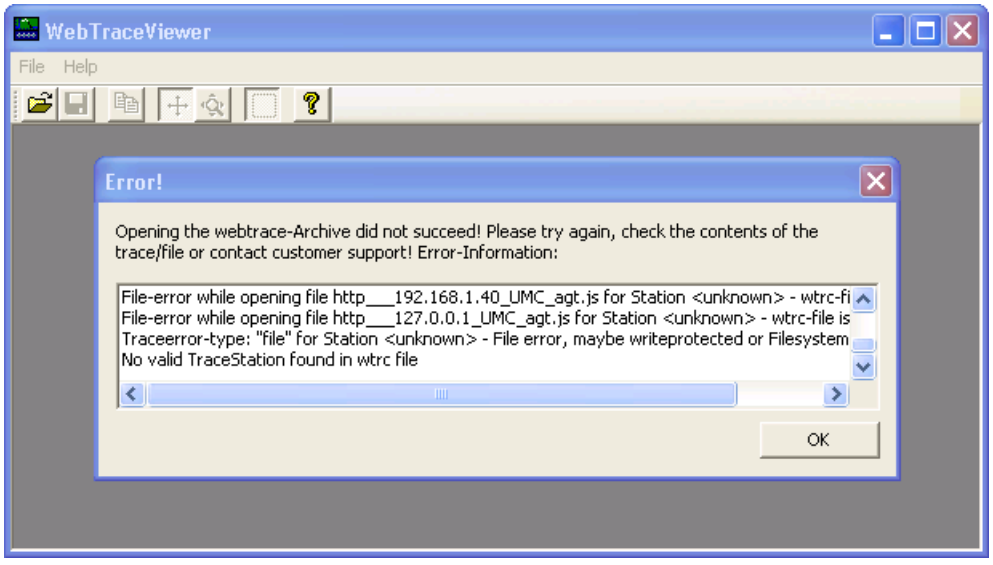

Figure 6-123 WebTraceViewer with faulty WTRC file

Note

The WebTraceViewer requires the "MS Visual C++ 2008 Redistributable Package" or an installed MS Visual Studio 2008 for program execution.

The "MS Visual C++ 2008 Redistributable Package" can be downloaded from the Microsoft Web page. It can also be found on the SIMOTION SCOUT Installation DVD "VOL1\Disk1\Setup \vcredist_2008".

6.1.5 List of abbreviations/acronyms

Abbreviations

CA	Certification Authority
CSS	Cascading Style Sheets
CSV	Character Separated Values
DO	Drive Object (Drive object)
DOM	Document Object Model
ECMA	European Computer Manufacturers Association
FTP	File Transfer Protocol
GMT	Greenwich Mean Time
HTML	Hypertext Markup Language
HTTP	Hypertext Transfer Protocol

HTTPS	Secure HTTP
JS	JavaScript
MWSL	MiniWeb Server Language
OPC	Denotes a standard interface for communication in automation technology. See OPC Foundation (https://opcfoundation.org/)
OPC XML-DA	OPC XML Data Access
SSI	Server Side Includes
SSL	Secure Socket Layer
TO	Technology Object (Technology object)
TVS	Trace Via SOAP
URI	Uniform Resource Identifier
URL	Uniform Resource Locator
UTC	Universal Time Coordinated
XML	Extensible Markup Language
XSL	Extensible Stylesheet Language
XSLT	XSL Transformation

6.1.6 Appendix

6.1.6.1 WebCfg.xml tags and attributes

SIMOTION IT diagnostics files

DIAGURLS.TXT

Structure of the DIAGURLS.TXT file

DIAGURLS.TXT contains the names of the SIMOTION IT diagnostics pages that are backed up when the diagnostics button is pressed or the pages are requested via **Diagnostics > Diagnostics files > Create general diagfiles**. The file is in directory /HMI/SYSLOG/DIAG and can be expanded with further URLs if necessary.

Here is an example of how this file might look like in the delivery state:

```
alarms.mwsl
alarmsdrvifrm.mwsl
alarmbufifrm.mwsl
devinfo.mwsl
basic/b_extdiag.mwsl
basic/b_diagbufdrv.mwsl
diagnost.mwsl
ipconfig.mwsl
mempool.mwsl
start.mwsl
taskrunt.mwsl
timezone.mwsl
```

Content of the file DIAGURLS.TXT

See also

Diagnostic files (Page 3606)

BASE

<BASE>

Tag	<BASE>
	The link lists for user-defined HTML pages are stored in the <BASE> tag of WebCfg.xml .
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE ALIAS="/"> [...] <myIndex.mwsl.cms ALIAS="mydir/myIndex.mwsl.cms" /> [...] </BASE> [...] </SERVERPAGES>

ALIAS attribute

Tag	Any node: <BASE> and all child nodes	
Attribute	ALIAS	The ALIAS attribute is a link to the physical file system, relative to the WWWRoot path /USER/SIMOTION/HMI. The file name must be identical to the file name in the ALIAS; otherwise, the file will not be found. Each data node of the XML file system can have a ALIAS attribute, including the <BASE> node. The <BASE> node corresponds to the WWWRoot of the file system.
Example	<?xml version="1.0" encoding="UTF-8" standalone="yes"?> <SERVERPAGES version="04.50"> [...] <BASE> <myfile.mwsl.cms ALIAS="/FILES/myfile.mwsl.cms" REALM="Administrator" READ="Administrator" WRITE="Administrator" MODIFY="Administrator" /> </BASE> [...] </SERVERPAGES> In this example, the myfile.mwsl.cms file can now be called via the following URL: http://<IP-Address>/myfile.mwsl	

BROWSEABLE attribute

Note

Changed behavior as of Version 4.4

As of version 4.4, the BROWSEABLE attribute no longer has any effect.

Tag	Any node: <BASE> and all child nodes or as a global switch, via the <BROWSEABLE> tag.	
Attribute	BROWSEABLE	BROWSEABLE can have the value "true" or "false". When a client accesses this link, a directory view of the directory is created. Navigation from this directory to subdirectories is also possible. Other higher-level directories can also be navigated to if browsing is also permitted for them. Provided you have sufficient rights, you can send, receive, and delete files as well as create and delete directories.
Example	<?xml version="1.0" encoding="UTF-8" standalone="yes"?> <SERVERPAGES version="04.50"> [...] <BASE> <FILES ALIAS="FILES/" BROWSEABLE="true" REALM="Anyone" READ="Anyone" WRITE="Anyone" MODIFY="Anyone"> <myFile ALIAS="/FILES/myfile.mwsl.cms" BROWSABLE="true" REALM="Administrator" READ="Administrator" WRITE="Administrator" MODIFY="Administrator" /> </FILES> </BASE> [...] </SERVERPAGES>	

MODIFY attribute

Note

Changed behavior as of Version 4.4

As of version 4.4, the MODIFY attribute no longer has any effect.

Tag	Any node: <BASE> and all child nodes	
Attribute	MODIFY	If a directory has a MODIFY attribute and the logged-in users are members of one of the specified groups, they may perform all write operations in this directory. They may • Create new directories • Overwrite files • Delete files • Create new files Users must, of course, have READ rights as well (otherwise, they would not have access to the directory anyway).

READ attribute

Tag	Any node: <BASE> and all child nodes	
Attribute	READ	If a READ attribute is specified for a directory, the user must be a member of one of the groups specified for the READ attribute. With READ , several groups can be specified. These must be separated with commas and no Whitespace characters may be used.
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE ALIAS="/"> <FILES ALIAS="FILES/" BROWSEABLE="true" REALM="Anyone" READ="Anyone" WRITE="Anyone" MODIFY="Anyone"> <www ALIAS="/WebPages/" BROWSEABLE="true" READ="Administrator" WRITE="FileAdministrator" /> </FILES> <Test.mwsl.cms ALIAS="/Tests/Test.mwsl.cms/"/> <XMLDir> </XMLDir> </BASE> [...] </SERVERPAGES>	

REALM attribute

Tag	Any node: <BASE> and all child nodes	
Attribute	REALM	The REALM attribute is used to set up a secure area. REALM may only contain one group name. The REALM attribute enables one login for all users of a group. For all users that do not belong to this group, access is blocked.
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE ALIAS="/"> <FILES ALIAS="FILES/" BROWSEABLE="true" REALM="Anyone" READ="Anyone" WRITE="Anyone" MODIFY="Anyone"> <www ALIAS="/WebPages/" REALM="Anyone" BROWSEABLE="true" READ="Administrator" WRITE="FileAdministrator" /> </FILES> <Test.mwsl.cms ALIAS="/Tests/Test.mwsl.cms/" /> <XMLDir> </XMLDir> </BASE> [...] </SERVERPAGES>	

WRITE attribute

Tag	Any node: <BASE> and all child nodes	
Attribute	WRITE	If a directory has a WRITE attribute and the logged-in users are members of one of the specified groups, they may only create new files in this directory. They may • Not create any new directories • Not overwrite any files • Not delete any files • Create new files Users must, of course, have READ rights for the directory as well (otherwise, they would not have access to the directory anyway).
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE ALIAS="/"> <FILES ALIAS="FILES/" BROWSEABLE="true" REALM="Anyone" READ="Anyone" WRITE="Anyone" MODIFY="Anyone"> <www ALIAS="/WebPages/" BROWSEABLE="true" READ="Administrator" WRITE="FileAdministrator" /> </FILES> <Test.mwsl.cms ALIAS="/Tests/Test.mwsl.cms/"/> <XMLDir> </XMLDir> </BASE> [...] </SERVERPAGES>	

<CONFIGURATION_DATA>

Tag	<CONFIGURATION_DATA>
	Each module provides the option of defining module-specific configuration data within this tag. The format of the individual items of configuration data depends exclusively on the modules. Therefore, it cannot be described in general terms.
Example	<SERVERPAGES> [...] <CONFIGURATION_DATA> <USERCONFIG> [...] <IncludeScriptsDirectly>NO</IncludeScriptsDirectly> <!-- Add your constants here --> <ForceUserMsgLanguageID>1031</ForceUserMsgLanguageID> </USERCONFIG> </CONFIGURATION_DATA> [...] </SERVERPAGES>

<DEFAULTDOCUMENT>

Tag	<DEFAULTDOCUMENT>
	Specification of the document that is to be displayed if the URL received from the browser does not contain explicit page information. This is often called Default.mwsl or Index.mwsl There can be only one default document. If no default document is found and file browsing is permitted, the directory itself is returned.
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE> [...] </BASE> <SERVEROPTIONS> <DEFAULTDOCUMENT VALUE="Default.mwsl" /> [...] </SERVEROPTIONS> [...] </SERVERPAGES> If, for example, the URL http://<IP-Address>/MyDir is used to query a directory, the Web server appends the file name "Default.mcs" to the URL (http://<IP address>/MyDir/Default.mwsl) and then attempts to resolve the URL: • If this succeeds, Default.mwsl is returned to the client. • If this is not successful, either a directory view is returned or an HTTP 404 "Not Found" error message is issued (depending on configuration).

<HEADER>

Tag	<HEADER>
	The Web server offers with HEADER elements within the HEADERS element the option of mapping the file extensions of a file to an associated Mime type.
Explanation	The content of a file is designated in the file system by its file extension (e.g. "txt" for text files). An assignment is not mandatory in a transport protocol such as HTTP. For this reason, an HTTP header that contains this information about the content type is inserted. **Caution**: If there are more than 60 HEADER entries, the controller is not started and cannot be used.

Example	`<?xml version="1.0" encoding="UTF-8" standalone="yes"?>`
	`<SERVERPAGES version='05.10.15'>`
	`[...]`
	`<HEADERS>`
	`<!-- 60 entries allowed, otherwise MiniWeb will not start up -->`
	`[...]`
	`<EXTENSION Value="dvi">`
	`<HEADER Name="Content-Type" Value="application/x-dvi" />`
	`</EXTENSION>`
	`[...]`
	`</HEADERS>`
	`[...]`
	`</SERVERPAGES>`
	
	The Mime type `application/x-dvi` is specified for the `dvi` file extensions.
	For more information about MIME types, refer to the RFCs 2045 ff.

<LANGUAGE>

Tag	<LANGUAGE>
	Setting the language.

<MWSL2>

Tag	<MWSL2>
	This tag is used for internal purposes only and should not be changed.

<LISTEN> Primary HTTP port

Tag	<LISTEN ... Id="primary-http >
	Every TCP/IP server (or service) has a so-called well-known port number that can be used by a client to address it. For Web servers, this port is normally port number 80. The attributes of the <LISTEN> tag permit the setting of the port number. If no port number has been set, 5001 is set automatically as port. This prevents an address collision with an existing Web server.
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <SERVEROPTIONS> [...] <SERVERS> <LISTEN Address="any" Port="80" Family="HTTP" Id="primary-http" > <HOST IgnoreCase="true" FQDN="*" /> </LISTEN> [...] </SERVEROPTIONS> [...] </SERVERPAGES> In this example, the port number of the Web server HTTP access is set to 80.

<LISTEN> Alternative HTTP port

Tag	`<LISTEN ... Id="alternate-http" IsAlternate="true" >`
	Additional port for requests for the Web server. Every TCP/IP server (or service) has a so-called well-known port number that can be used by a client to address it. For Web servers, this port is normally port number 80. The Web server can also "listen" to a second port number. For example, by adding a firewall you can establish a firewall-controlled security concept. If the value is set to 0, no alternative port is available. This is the default setting.

Example	`<?xml version="1.0" standalone="yes"?>`
	`<SERVERPAGES>`
	`[...]`
	`<BASE>`
	`[...]`
	`</BASE>`
	`<SERVEROPTIONS>`
	`<SERVERS>`
	`[...]`
	`<LISTEN Address="any" Port="81" Family="HTTP" Id="alternate-http" IsAlternate="true" >`
	`<HOST IgnoreCase="true" FQDN="*" />`
	`</LISTEN>`
	`[...]`
	`</SERVERS>`
	`</SERVEROPTIONS>`
	`[...]`
	`</SERVERPAGES>`
	
	In this example, the alternative port number of the Web server is set to 81.

<LISTEN> Primary HTTPS port

Tag	`<LISTEN ... Family="HTTPS" Id="primary-https" IsSslServer="true" >`
	For the SSL protocol (Secure Socket Layer), an additional well-known port number is needed. This is normally port number 443. If SSL is used in the Web server, the port number for SSL can be set. If nothing is set, the number 5443 is set automatically in order to prevent a collision with any existing Web server.

Example	`<?xml version="1.0" standalone="yes"?>`
	`<SERVERPAGES>`
	`[...]`
	`<BASE>`
	`[...]`
	`</BASE>`
	`<SERVEROPTIONS>`
	`<SERVERS>`
	`[...]`
	`<LISTEN Address="any" Port="443" Family="HTTPS" Id="primary-https" IsSslServer="true" >`
	`<HOST IgnoreCase="true" FQDN="*" />`
	`</LISTEN>`
	`[...]`
	`</SERVERS>`
	`[...]`
	`</SERVEROPTIONS>`
	`[...]`
	`</SERVERPAGES>`
	
	In this example, the port for the HTTPS call is set to 443.

<LISTEN> Alternative HTTPS port

Tag	`<LISTEN ... Family="HTTPS" Id="alternate-https" IsSslServer="true" IsAlternate="true" >`
	For the SSL protocol (Secure Socket Layer), an additional well-known port number is needed. The standard port number of the SSL protocol is 443. The Web server can also "listen" to a second port number. For example, by adding a firewall you can establish a firewall-controlled security concept. Another application of this alternative port uses the DAV module. The DAV module detects with the used port whether a DAV request or a Web request is involved.

Example	`<?xml version="1.0" standalone="yes"?>`
	`<SERVERPAGES>`
	`[...]`
	`<BASE>`
	`[...]`
	`</BASE>`
	`<SERVEROPTIONS>`
	`<SERVERS>`
	`[...]`
	`<LISTEN Address="any" Port="5443" Family="HTTPS" Id="alternate-https" IsSslServer="true" IsAlternate="true" >`
	`<HOST IgnoreCase="true" FQDN="*" />`
	`</LISTEN>`
	`[...]`
	`</SERVERS>`
	`[...]`
	`</SERVEROPTIONS>`
	`[...]`
	`</SERVERPAGES>`
	
	In this example, the alternative port number for SSL is set to 5443.

<SERVEROPTIONS>

Tag	<SERVEROPTIONS>
	The "Server Options" tag includes all basic parameters of the web server. The settings made within the tag affect the core of the web server.
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE> [...] </BASE> <SERVEROPTIONS> [...] </SERVEROPTIONS> [...] </SERVERPAGES>

<TIMEZONE>

Tag	<TIMEZONE>
	Sets the time zone of the Web server. To enable time zones to be synchronized with other partners (in other words, to enable the local time-of-day setting of the Web server to be converted to UTC), the Web server must know which time zone has been set for the control's local clock. The value specified here represents the deviation from UTC +/- minutes. In the as-delivered state, this entry is missing and either the default value "UTC +60" (if the project is missing) or the time zone set in HW Config for the Web server will be valid. If the TIMEZONE node is added, the value from the HW Config will not be considered.
Example	<?xml version="1.0" standalone="yes"?> <SERVERPAGES> [...] <BASE> [...] </BASE> <SERVEROPTIONS> <TIMEZONE VALUE="+60" /> [...] </SERVEROPTIONS> [...] </SERVERPAGES> In this example, the time zone is set to "UTC + 60 minutes". This corresponds to MET winter time.

6.1.6.2 SIMOTION IT diagnostics files

DIAGURLS.TXT

Structure of the DIAGURLS.TXT file

DIAGURLS.TXT contains the names of the SIMOTION IT diagnostics pages that are backed up when the diagnostics button is pressed or the pages are requested via **Diagnostics > Diagnostics files > Create general diagfiles**. The file is in directory /HMI/SYSLOG/DIAG and can be expanded with further URLs if necessary.

Here is an example of how this file might look like in the delivery state:

```
alarms.mwsl
alarmsdrvifrm.mwsl
alarmbufifrm.mwsl
devinfo.mwsl
basic/b_extdiag.mwsl
basic/b_diagbufdrv.mwsl
diagnost.mwsl
ipconfig.mwsl
mempool.mwsl
start.mwsl
taskrunt.mwsl
timezone.mwsl
```

6.2 SIMOTION IT Programming and Web Services

Preface

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

6.2.1 Fundamental safety instructions

6.2.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

6.2.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

6.2.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

6.2.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

6.2.2 Introduction

6.2.2.1 Overview of SIMOTION IT

Overview of SIMOTION IT manuals

The "SIMOTION IT Ethernet-based HMI and diagnostic functions" are described in four manuals (IT = Information Technology):

- **SIMOTION IT Diagnostics and Configuration**
  This manual describes the direct diagnosis of SIMOTION devices. Access is by means of a standard browser (e.g. Firefox) via the IP address of the SIMOTION device. You can use the standard diagnostic pages or your own HTML pages for access.
  See the SIMOTION IT Diagnostics and Configuration Manual.
- **SIMOTION IT Programming and Web Services**
  This manual describes the creation of user-defined Web pages and access to the diagnostic functions via the two Web services provided by SIMOTION IT.
  A Web service enables users to create their own client applications in any programming language. These applications then communicate with the SIMOTION device using Web technologies. The SOAP (Simple Object Access Protocol) communication protocol is used for transferring commands.
  The manual includes information on programming such clients, as well as a description of the SIMOTION IT Web services (OPC XML-DA, Trace via SOAP TVS) via which data and operating states of the controller can be accessed and the variable trace functions can be used.
- **SIMOTION IT Virtual Machine and Servlets**
  This manual describes the Java-based function packages. The Jamaica Virtual Machine (JamaicaVM) is a runtime environment for Java applications on the SIMOTION device. It is an implementation of the "Java Virtual Machine Specification".
  The Servlets section of the manual describes the use of servlets in a SIMOTION device.
  See the SIMOTION IT Virtual Machine and Servlets manual.
- **SIMOTION IT OPC UA**
  The manual describes access to SIMOTION devices via OPC UA.

6.2.2.2 New features

Overview of the innovations

Version 5.2

- Cross Site Request Forgery (CSFR) Protection. Prevention of non-authorized HTTP requests.CSFR protection in MWSL pages (Page 3749) Example of a client application (Page 3847)

Version 5.1

- For security reasons, access to the file system is possible only with Javascript.

Version 4.5

- OPC UA server. The OPC UA server is described in the SIMOTION IT OPC UA manual.

Version 4.4

- New way of creating MWSL pages (Page 3746). The HTML files stored in MWSL format on the controller are compiled online. An offline compilation as for .mcs is no longer necessary.
- New MWSL functions (Page 3815)
  createGUID, die, DecodeString, EncodeString, ExistFile, GetLanguage, IsAuthAlgo, isFinite, isNaN, IsSSL, parseFloat, parseInt, ReadFile, ReplaceString, ShareRealm
- New version of the MWSL server language
- New MWSL operators (Page 3809)
- File extensions for Web pages have been changed from .mcs/.mbs to .mwsl/.mwsl.cms.

6.2.3 Software programming

6.2.3.1 User-defined pages

User-defined Home page

You can create your own home page and display it instead of the home page for the standard diagnostic pages of the control. To do this, you need to change the default page of the web server in the WebCfg.xml file.

Procedure

1. Creating your own home page. Save this home page, for example, as `MyIndex.mwsl`.
2. Transmit the home page to the memory card of the SIMOTION device using the **Files** page.
3. Open the WebCfg.xml file in an available editor. The file can be found either on the supplied DVD in the 3_Configuration directory (in the default state) or on the SIMOTION device memory card (possibly in a modified state) in directory \USER\SIMOTION\HMICFG.

4. Replace the file name index.mwsl in the <SERVEROPTIONS> in element <DEFAULTDOCUMENT VALUE="index.mwsl" /> with the name of your home page, including the path name "files" (all user-defined HTML pages are stored in the FILES directory).
   Example: <DEFAULTDOCUMENT VALUE="files/MyIndex.mwsl" />
5. Save the changed WebCfg.xml on the memory card via the **Manage Config > WebCfg transmission** page.

Introduction

Individually designed web pages with access to device data

SIMOTION IT DIAG offers the option of storing machine-specific pages on the SIMOTION control. They are stored in a separate binary format (*.mwsl.cms). The following resources can be used to integrate the process values of the SIMOTION control.

- **Server Side Includes (SSI):** Server-side, static, simplest, unformatted display (Page 3839). In the HTML code of the page, process values can be integrated simply and without a representation option (e.g. number of decimal points) at any point.
- **MiniWeb Server Language (MWSL):** Server-side, static, formatted display using scripts in the SIMOTION control (Page 3796).
  The generation of HTML code and the formatted integration of process values (e.g. in HEX or decimal value representation) can be selectively controlled with this script language.
- **OPC XML-DA web service:** Dynamic, formatted display using JavaScript in the browser (Page 3755).
  The OPCXML.JS library offers elegant use of process values for JavaScript when dynamizing HTML pages.

The creation of user-defined pages requires knowledge of HTML and JavaScript programming.

Key words for advanced programming: XML, HTTP Request, Ajax, and web services.

The following figures shows an example of a simple user-defined page.

Figure 6-124 Example of a simple user-defined page

Loading of MWSL pages into the controller

The source code of an MWSL page must be created as a file with the extension .mwsl. An MWSL file is an HTML file with MWSL extensions to be able to copy the control information.

The source code files is converted to the internal format of the controller in different ways:

- Load the files via the **Files > Files** page**.**
- Copy the files onto the card using a card reader.
- Load the files via FTP.

When loading via a card reader or FTP, the files must be stored in directory /USER/SIMOTION/HMI/FILES.

See also

Structure of a MWSL file (Page 3798)

Embedded, user-defined pages (Page 3750)

Compiling MWSL files

The .mwsl files have the same basic structure as standard HTML pages. The source code file should be coded with UTF-8 if special characters are to be displayed correctly.

1. Create the MWSL pages with a tool of your choice. The pages are assigned the file extension .mwsl
2. Compile the page. The converted files will appear in the target directory with the same name as the associated source files having the file extension .mwsl.cms
3. Check and test the page in the **User's Area**.
4. Errors that occur when compiling the MWSL file are output in the log file. Errors that occur when the Web page is called are written in the source text of the MWSL page as error messages.

The /FILES directory and all subdirectories are examined for the corresponding file types. The compiler replaces the original file with the compiled code. The compiled files have the extension *.cms

Compilation of the MWSL pages

There are three ways of compiling MWSL pages:

1. Click the **Compile** button. All files of the FILES directory are compiled. This option is recommended, for example, after an FTP upload.
2. When the controller boots. All files of the FILES directory are compiled.
3. Compile the first time the page is called via its URL. This is also the case when the users area is called.

Note

Backing up the originals

Because the .mwsl files are deleted during conversion, the originals should always be backed up on the PC and only a copy put on the card.

Successfully compiled pages with the .cms extension

The following example shows compilation via the **Files** page. On the **Files** page, you find the Directory Operations with which the MWSL pages can be loaded into the controller via the **Send** button and compiled.

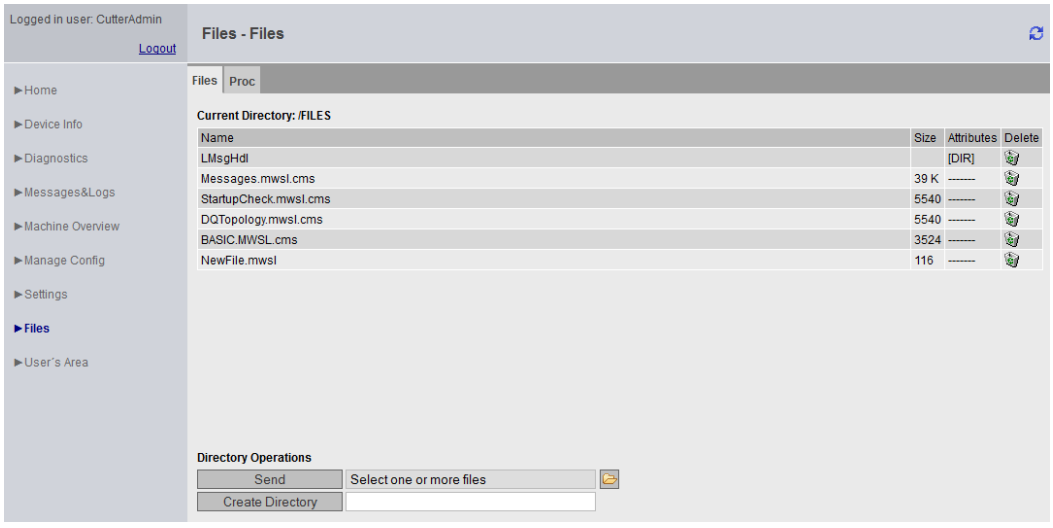

Figure 6-125 Loading of MWSL files

If a file has been loaded without error, it is given the extension .cms

Note

Files with errors do not have an .cms extension. In the above example, there is a problem with the file NewFile.mwsl

Example of compilation of a user-defined page

An MWSL page can be created using any text editor.

```
<html>
<head/>
<body>
<br>  State: <MWSL>WriteVar("DeviceInfo.BZU");</MWSL>
</body>
</html>
```

NewFile.mwsl

In this example, the source text is saved as a file with the name NewFile.mwsl.

The MWSL is used in the example to output device data. Structure of a MWSL file (Page 3798)

The device data is accessed in the MWSL-Ausdrücken by means of the variables provider. See Section Variables Provider (Page 3676) in the SIMOTION IT Diagnostics and Configuration Manual.

The page can only be displayed if the User's Area settings are correct. In this example, the EmbeddedSimple version has been selected. Embedded, user-defined pages (Page 3750)

Figure 6-126 User's Area Edition NewFile.mwsl.cms

The page outputs can be checked in the User's Area. The screenshot shows the output of the sample file. If there are errors in compilation, the file is named NewFile.mwsl.cms

Error analysis

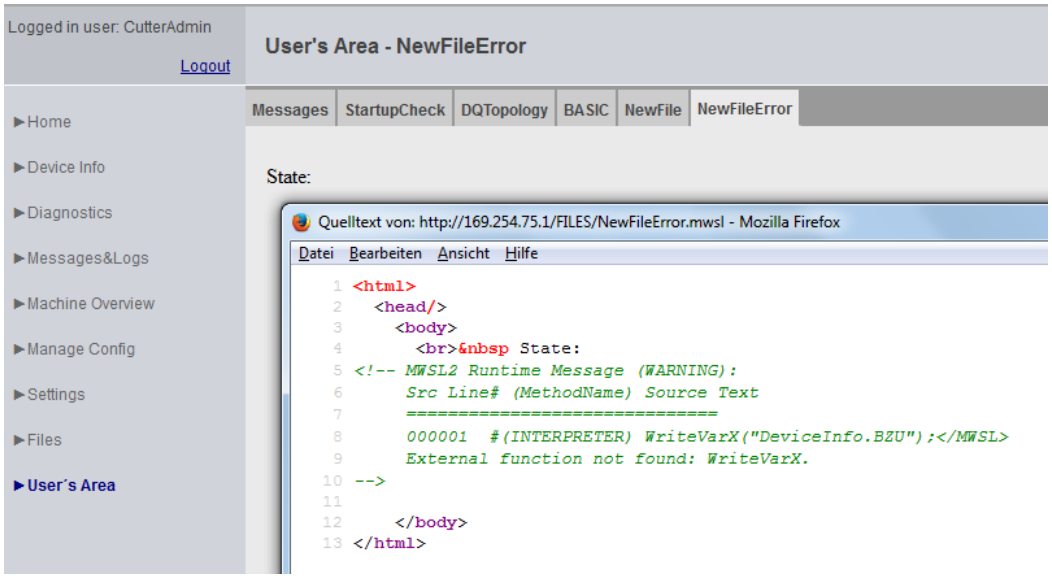

Figure 6-127 User's Area MWSL error message

Error messages that occur when the page is executing are inserted in the source text of the MWSL page as a comment. You can access the source text in the browser by displaying the source text of the current frame. In the example, an attempt is made to access the function `WriteVarX()`, which does not exist.

Errors occurring during compilation are output in a log file formed by appending ".log" to the file name.

Files in the old MBS and MCS format

Interpretation of MCS and MBS files (e.g. user-defined files) is still supported in Version 4.4 to ensure downward compatibility. A diagnostic buffer entry indicates that the format is obsolete. For future versions, this downward compatibility is not ensured. For this reason, old pages should be stored in the new format.

CSFR protection in MWSL pages

To protect MWSL pages against Cross-Site-Request-Forgery (CSFR) attacks, as of V5.2, a CSRF token must be set in the program. If the CSRF token is not set, this causes an error in the browser.

Example program:

```
<html>
<head>
    <title>SIMOTION Demopage CSRF Token Passing</title>
</head>
<body text="#000000" bgcolor="#FFFFFF" link="#FF0000"
alink="#FF0000" vlink="#FF0000">
    <h1>Demopage - CSRF Token Passing</h1>
    <p>
        Demovariable: <b>dev/Service.BZU.Value</b><br>
        current value: <b><%= dev/Service.BZU.Value %></b><br>
        RawMultiUseToken: <b><%=RawMultiUseToken%></b>
    </p>
    <p>
        <form method="post" action="/VarApp">
            write test value: <b>dev/Service.BZU.Value</b>:
           <!-- CSRF Token input _must_ be at 1. place in form !!! -->
            <input type="hidden" name="MultiUseToken" value="<
%=RawMultiUseToken%>" />
          <input type="text" name="dev/Service.BZU.Value" value="<%=
dev/Service.BZU.Value %>" />
            <input type="submit" value="Wert schreiben" />
        </form>
    </p>
</body>
</html>
```

The tag for CSFR protection is shown bold. This tag must be the first `<input>` tag within the form.

`MultiUseToken` designates a CSFR token that permits the same token to be used for the repeated call of a page.

The value of the CSFR token is set with the Server Side Include <%=RawMultiUseToken%> by the server.

Figure 6-128 Representation of the example program in the browser

Embedded, user-defined pages

Integrating user-defined pages

As of Version 4.1.3, user-defined pages can be embedded in the framework of the SIMOTION IT standard pages.

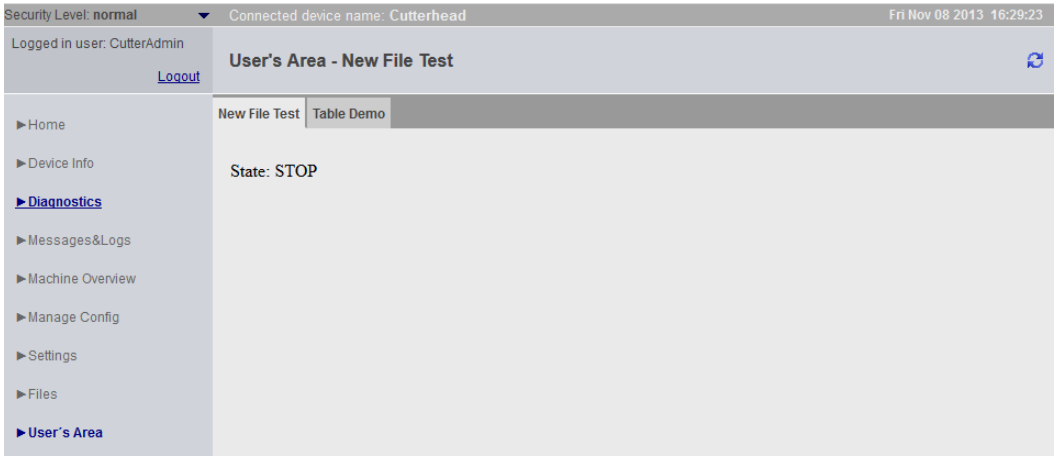

Figure 6-129 User's Area with embedded page

The menu in the **User`s Area** includes the files in the FILES folder in two different ways:

- EmbeddedSimple: The **User`s Area** page loads all Web pages contained in the FILES folder as tabs. The file name is shown without file extension.
- Embedded: The page loads a user-definable tab.

You can switch between EmbeddedSimple and Embedded on the**Settings** page. See the Manual SIMOTION IT Diagnostics and Configuration, Section Standard pages.

Settings in WebCfg.xml

In WebCfg.xml , the appearance of the User's Area can be set with the configuration constants <UserArea> and <UserDir> .

The <UserArea> tag can be used to set how the tab is displayed (the default setting is shown in bold):

```
<UserArea>( StandAlone | Embedded | EmbeddedSimple )</UserArea>
```

<UserDir> denotes the directory for the tab files relative to the FILE directory.

```
<UserDir></UserDir>
```

StandAlone

```
<UserArea>StandAlone</UserArea>
```

Access to the **User's Area** is permanently linked to the user.mwsl file. To display the **User's Area** , this file must exist and be available for calling.

Example user.mwsl

```
<html>
  <head/>
  <body>
    <br>  user.mwsl content ...
  </body>
</html>
```

This file must be stored in the FILES directory of the controller. The file can be copied from the **Files** page or directly to the memory card.

On the Settings page, a change can then be made at **User pages** to **StandAlone**.

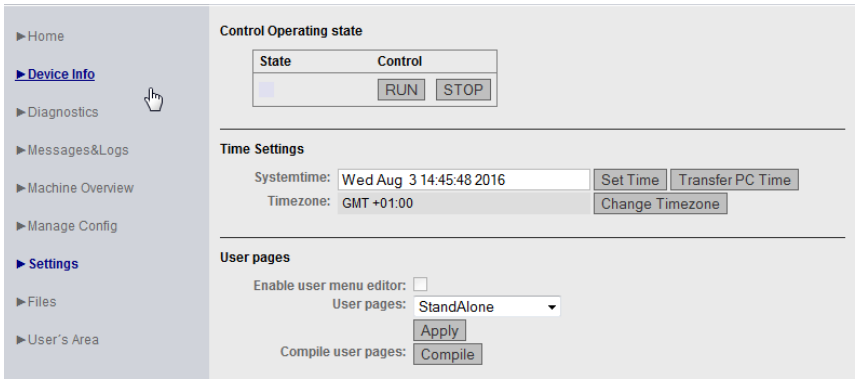

Figure 6-130 User pages: Stand alone

The page is activated by clicking the **Apply** button. Clicking User's Area displays the contents of the page.

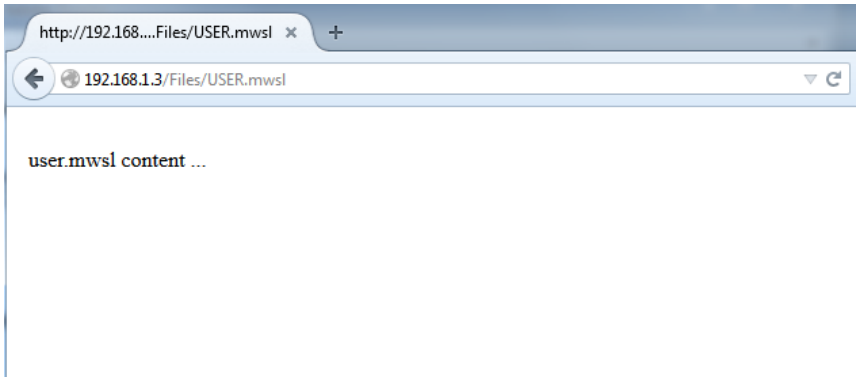

Figure 6-131 User pages: Stand alone Display user.mwsl

EmbeddedSimple

```
<UserArea>EmbeddedSimple</UserArea>
```

Select this option to use all the files found in the directory labeled `<UserDir>` to create the tab.

The respective file name (without the extension) is used as the title, and the corresponding link refers to this file.

Embedded - Using the menu editor

```
<UserArea>Embedded</UserArea>
```

If the **Enable user editor** checkbox has been activated on the **Settings** page, the menu editor (Page 3752) in which menus can be customized is displayed in the **User's Area**.

Example WebCfg.xml:

```
<SERVERPAGES version="78.00">
  [...]
  <CONFIGURATION_DATA>
    <USERCONFIG>
      <UserArea>Embedded</UserArea>
      <UserDir/>
    </USERCONFIG>
  </CONFIGURATION_DATA>
  [...]
</SERVERPAGES>
```

Menu editor

Creating individual menus using the menu editor

As of Version 4.1.3, the menu editor is called with the **User's Area** link. The menu editor can be used to customize the layout of the menus displayed in the User's Area.

Prerequisites for using the menu editor

To use the menu editor, in WebCfg.xml, the configuration constant <UserArea> must be set to Embedded. Alternately, on the **Settings** page, **User pages** can be set to **Embedded**.

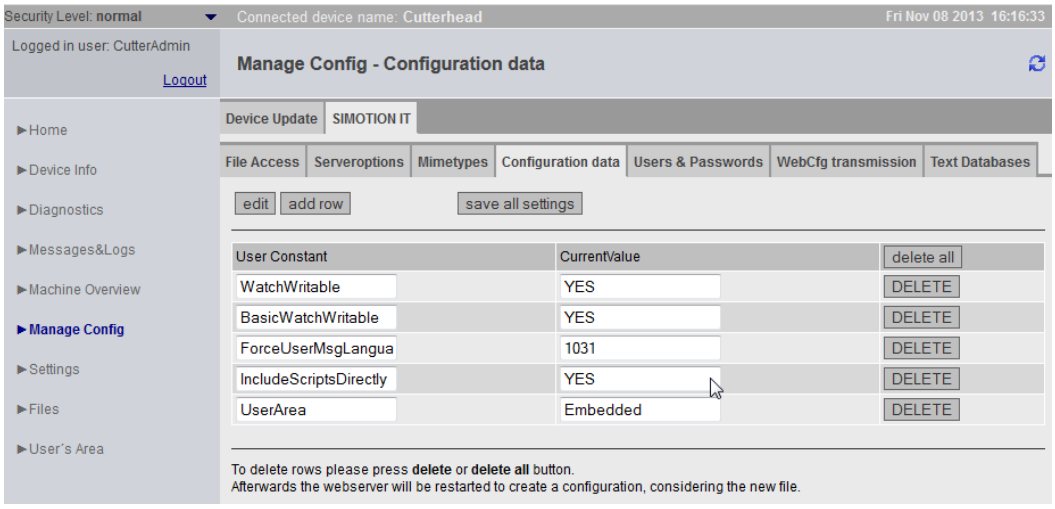

Figure 6-132 Configuration data menu editor

The **Enable user menu editor** option must then be selected on the **Settings** page.

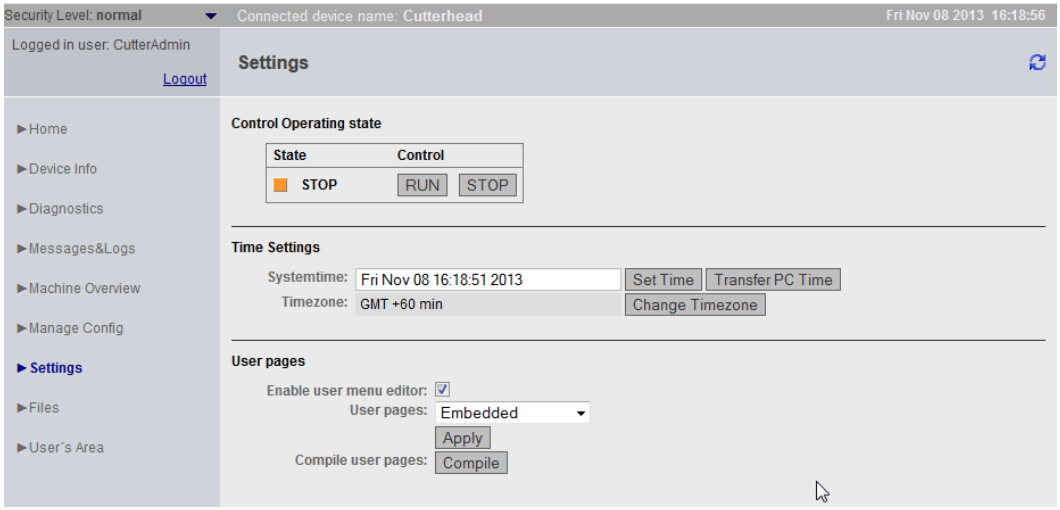

Figure 6-133 Settings menu editor

Working with the menu editor

The **User's Area** page now contains the **Menu editor** tab.

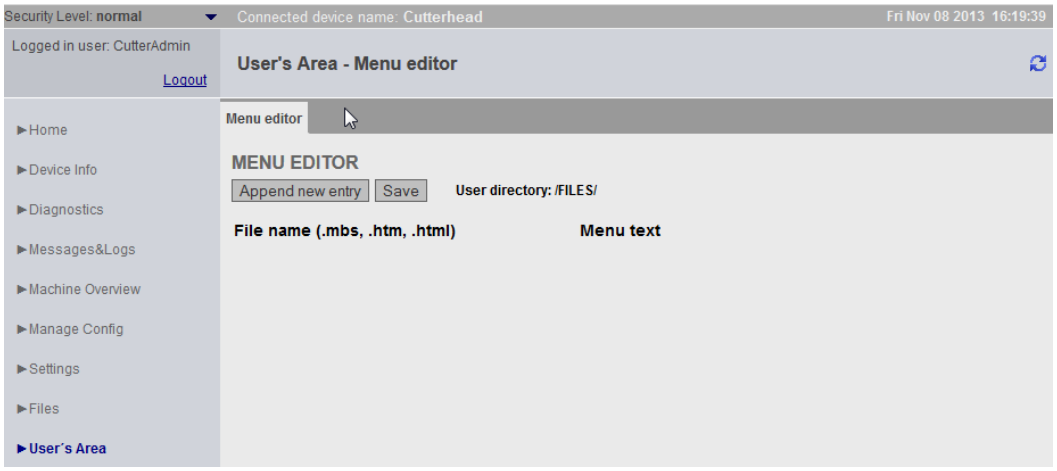

Figure 6-134 Starting the menu editor for the first time

The first time the menu editor is launched, a largely blank page appears.

New menu items can be created with the **Append new entry** button.

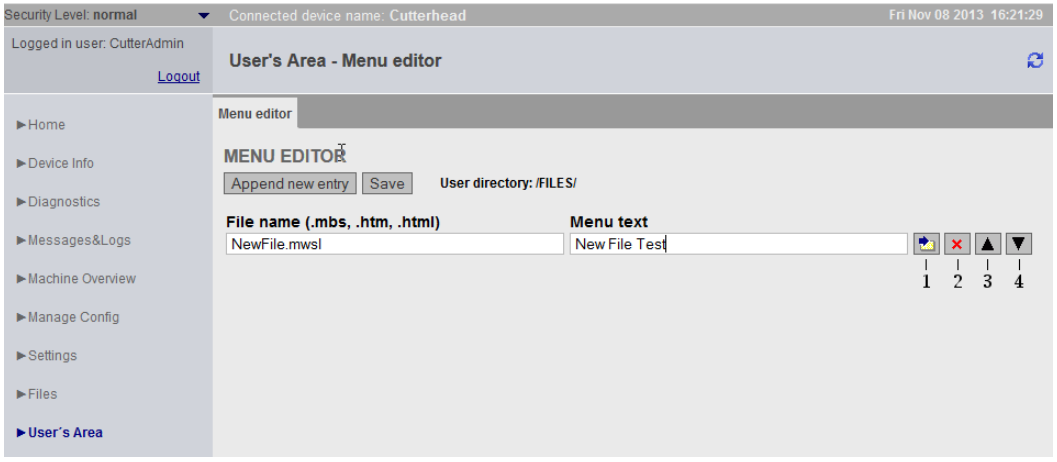

Figure 6-135 Menu editor with several items

In the screenshot above, the NewFile.mwsl file has been added. The buttons can be used to add or delete files, or change their position.

The names of the files to be displayed for the corresponding menu commands are entered in the **File name** column.

The **Menu text** column contains the name of the menu item.

The ① button creates new menu items that are inserted before each current item.

The ② button deletes the associated menu item.

The ③ button moves the menu item up.

The ④ button moves the menu item down.

Example

Two files are entered in the menu editor.

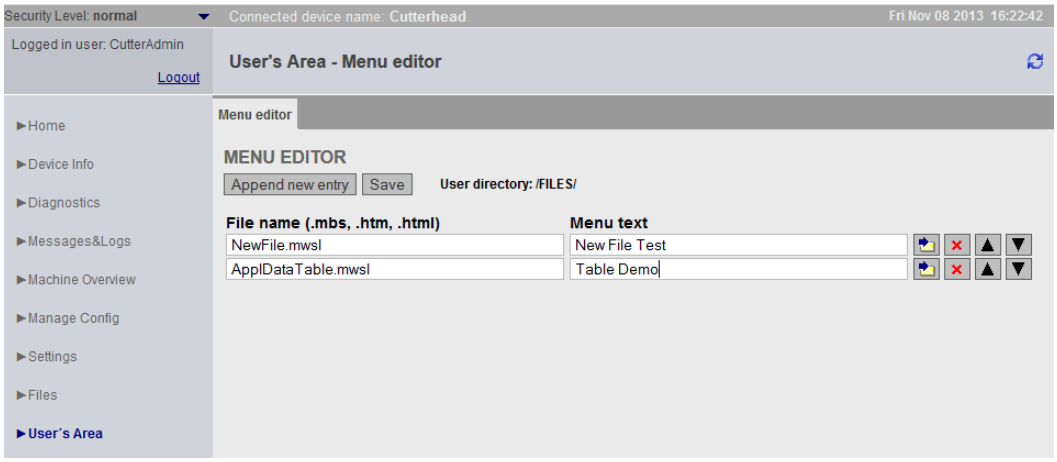

Figure 6-136 Example menu editor

The **User's Area** now only shows the selected pages.

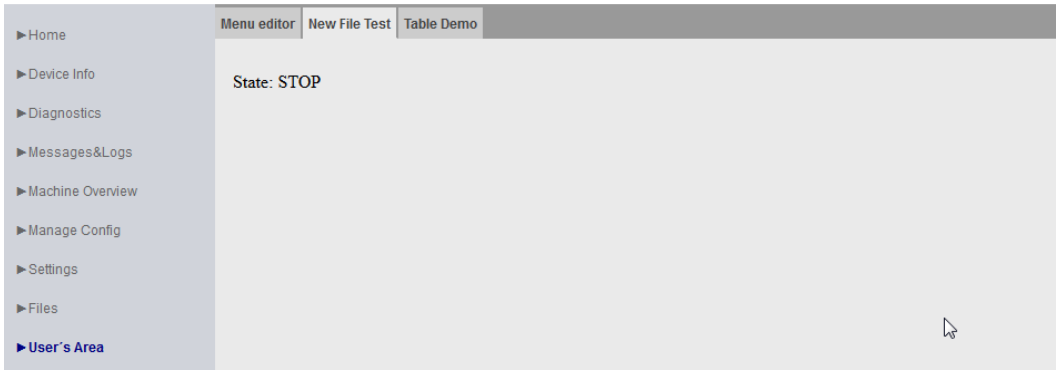

Figure 6-137 Example Menu Editor - display of Users's Area

To hide the tab **Menu editor** on the page, on the **Settings** page, the option **Enable user menu editor** must be deactivated.

JavaScript and web services

Variable access with JavaScript and web services

Access to a device with the JavaScript library

Using the DOM functionality of JavaScript , it is possible to implement simple Web service clients. This opens up a multitude of new options within a browser, e.g.:

- Reading and cyclic updating of variable contents using an OPC XML-DA Read command
- Writing of variables using an OPC XML-DA Write command

- Browsing of the entire SIMOTION variable management area
- Setting up and querying an OPC XML-DA Subscription

The functionality is provided by several JavaScript files:

- opcxml.js: Contains functions for the structure of the necessary XML documents and for communication with an OPC XML-DA server.
- appl.js: Based on opcxml.js and implements the following objects:
  - Variable browser. Representation of the SIMOTION variable management area in a tree topology within the browser
  - Property viewer: Representation of variable properties (value, data type, access rights, Enums) in the form of a table within a browser. For writable variables, the table contains an entry field for changing the variable content.
  - Watch table: Representation of a watch table in the browser

CSFR protection

As of V5.2, the firmware contains new versions of the appl.js and opcxml.js that are prepared for the CSFR protection. Older versions of the files may cause errors for execution with V5.2. Replacing the files rectifies the problem.

Communication with the OPC XML DA server (opcxml.js)

OPCReadRequest

The `OPCReadRequest` class can be used to read the values for a list of variables.

```
function OPCReadRequest(parLocaleId,parResultCB)
```

Transfer parameters:

- `parLocaleId`: Language identifier ("DE", "EN")
- `parResultCB`: Callback function that must be provided by the caller
  This function is called by OPCReadRequest when a response has arrived from the OPC XML DA server. The OPCReadRequest object is disposed of automatically (by calling the "destructor" method) if the callback function returns the value "true".

  ```
  function OPCReadRequestCB(parResponse)
  ```

  Transfer parameters:

  – `parResponse`: Array of ItemValues with the result of the read request.

  ```
  function OPCItemValue()
  {
     this.mItemPath;
     this.mItemName;
     this.mItemHandle;
     this.mItemValue;
     this.mItemResultId;
  }
  ```

User interface:

- `addItem(parItemPath,parItemName)` adds a variable to the variables list
- `removeItem(parItemHandle)` deletes a variable from the variables list
- `sendReadRequest()` sends the read request
- `destructor()` releases the entire request object

If `mItemResultId` is defined, an error occurred during reading. In this case, `mItemResultId` is assigned the OPC XML DA error ID.

Example:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
   "http://www.w3.org/TR/html4/loose.dtd">
<html>
   <head>
      <meta http-equiv="Content-Type" content="text/html;
            charset=ISO-8859-1">
      <script type="text/javascript" src="/common.js"></script>
      <script type="text/javascript" src="/opcxml.js"></script>
      <script type="text/javascript">
         function read()
         {
             var tmpReadCB = function(parResponse)
             {
                 tmpResultStr = "";
                 for (var tmpIndex = 0; tmpIndex < parResponse.length;
                      tmpIndex++)
                 {
                    var tmpItemValue = parResponse[tmpIndex];
                    var tmpValue = (tmpItemValue.mItemValue) ?
                                    tmpItemValue.mItemValue :
                                    tmpItemValue.mItemResultId;
                    tmpResultStr += tmpItemValue.mItemPath
                                    + "::"
                                    + tmpItemValue.mItemName
                                    + " = "
                                    + tmpValue
                                    + "\n";
                 }
                 alert(tmpResultStr);
                 return true;
              }
              var tmpReadRequest = new OPCReadRequest("DE",tmpReadCB);
              tmpReadRequest.addItem("SIMOTION","var/userdata.user1");
              tmpReadRequest.addItem("SIMOTION","var/userdata.user2");
              tmpReadRequest.addItem("SIMOTION","var/userdata.user10");
              tmpReadRequest.sendReadRequest();
         }
      </script>
      <title>Insert title here</title>
   </head>
   <body>
      <input type="button" onclick="read();" value="Read"/>
   </body>
</html>
```

OPCGetPropertiesRequest

The `OPCGetPropertiesRequest` class can be used to read the properties of variables:

- Values
- Data types

- Access rights
- Enum components

```
function OPCGetPropertiesRequest(parLocaleId,parResultCB)
```

Transfer parameters:

- `parLocaleId`: Language identifier ("DE", "EN")
- `parResultCB`: Callback function that must be provided by the caller.
  This function is called by OPCGetPropertiesRequest when a response has arrived from the OPC XML DA server. The OPCGetPropertiesRequest object is disposed of automatically (by calling the "destructor" method) if the callback function supplies "true" as a return value.

  `function OPCGetPropertiesRequestCB(parResponse)`
  parResponse: Array of PropertyResults that contain the properties of variables:

```
function OPCPropertyResult()
{
   this.mItemPath;
   this.mItemName;
   this.mName;
   this.mItemHandle;
   this.mIsItem;
   this.mHasChildren;
   this.mResultId;
   this.mValue;
   this.mType;
   this.mAccessRights;
   this.mEffectiveness;
   this.mEnums;
   this.mIsEnum;
}
```

User interface:

- `addItem(parItemPath,parItemName)` adds a variable to the variables list
- `removeItem(parItemHandle)` deletes a variable from the variables list
- `sendGetPropertiesRequest()` sends the read request
- `destructor()` releases the entire request object

Example:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
    "http://www.w3.org/TR/html4/loose.dtd">
<html>
   <head>
      <meta http-equiv="Content-Type" content="text/html;
            charset=ISO-8859-1">
      <title>GetProperties</title>
      <script type="text/javascript" src="/common.js"></script>
      <script type="text/javascript" src="/opcxml.js"></script>
      <script type="text/javascript">
      function getProperties()
      {
         var tmpGetPropertiesCB = function(parResponse)
         {
             tmpResultStr = "";
             for (var tmpIndex = 0; tmpIndex < parResponse.length;
                   tmpIndex++)
             {
                 var tmpPropertyResult = parResponse[tmpIndex];
                 var tmpEnums = "";
                 if (tmpPropertyResult.mEnums &&
                     (tmpPropertyResult.mEnums.length > 0))
                {
                    for (var tmpIndex = 0;
                         tmpIndex < tmpPropertyResult.mEnums.length;
                         tmpIndex++)
                    {
                        tmpEnums += " " +
                           tmpPropertyResult.mEnums[tmpIndex] + "\n";
                    }
                 }
                 if (!tmpPropertyResult.mResultId)
                 {
                   tmpResultStr += tmpPropertyResult.mItemPath +
                                   "::" +
                                   tmpPropertyResult.mItemName +
                                   ":\n Type = " +
                                   tmpPropertyResult.mType +
                                   "\n value = " +
                                   tmpPropertyResult.mValue +
                                   "\n AccessRights = " +
                                   tmpPropertyResult.mAccessRights +
                                   "\n Enums = \n" + tmpEnums +"\n";
                 }
                 else
                 {
                     tmpResultStr += tmpPropertyResult.mItemPath +
                                     "::" + tmpPropertyResult.mItemName
                                     + ":\n ResultId = " +
                                     tmpPropertyResult.mResultId +
                                     "\n\n";
                 }
              }
              alert(tmpResultStr);
```

```
            return true;
          }
          var tmpGetPropertiesRequest =
           new OPCGetPropertiesRequest("DE",tmpGetPropertiesCB);
          tmpGetPropertiesRequest.addItem("SIMOTION",
                                          "var/userdata.user1");
          tmpGetPropertiesRequest.addItem("SIMOTION",
                                          "var/userdata.user20");
          tmpGetPropertiesRequest.addItem("SIMOTION",
                                          "dev/Service.BZU.value");
          tmpGetPropertiesRequest.sendGetPropertiesRequest();
        }
      </script>
   </head>
   <body>
      <input type="button" onclick="getProperties();"
             value="getProperties"/>
   </body>
</html>
```

OPCWriteRequest

`OPCWriteRequest` writes three values of one or more variables.

```
function OPCWriteRequest(parLocaleId,parResultCB)
```

Transfer parameters:

- `parLocaleId`: Language identifier ("DE", "EN")
- `parResultCB`: The callback function that must be provided by the caller.
  The function is called on conclusion of the send request.

  `function OPCWriteRequestCB(parResultList)`
  parResultList is an array of ItemValues that contains the results of the write request.

  ```
  function OPCItemValue()
  {
     mItemPath
     mItemName
     mItemHandle
     mItemValue
     mItemResultId
  }
  ```

  The OPCWriteRequest object is discarded automatically (by calling the "destructor" method) if the callback function returns the value "true".

User interface:

- `addItem(parItemPath,parItemName,parType)` adds a variable to the variables list and returns a variable handle, which can be used to reference the variable within the request. ParType designates the OPC XML DA data type to be used for writing. If parType is not passed, the "xsi::string" data type is applied.
- `removeItem(parItemHandle)` removes a variable from the variables list
- `setItemValue(parItemHandle,parValue)` sets the value that is to be written for a variable
- `sendWriteRequest()` sends the write request
- `destructor()` releases all resources occupied by the write object

Note

Variable count for the write request

A maximum of 100 variables per write request is recommended.

Example:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
    "http://www.w3.org/TR/html4/loose.dtd">
<html>
   <head>
      <meta http-equiv="Content-Type" content="text/html;
            charset=ISO-8859-1">
      <script type="text/javascript" src="/common.js"></script>
      <script type="text/javascript" src="/opcxml.js"></script>
      <script type="text/javascript">
      function writeValues()
      {
          var tmpWriteCB = function(parWriteResult)
          {
              var tmpString = "";
              for (var tmpIndex = 0; tmpIndex < parWriteResult.length;
                   tmpIndex++)
              {
                var tmpItemValue = parWriteResult[tmpIndex];
                var tmpValue = (tmpItemValue.mItemResultId) ?
                 tmpItemValue.mItemResultId : tmpItemValue.mItemValue;
                tmpString += tmpItemValue.mItemPath + "::" +
                  tmpItemValue.mItemName + " = " + tmpValue + "\n";
              }
              alert(tmpString);
          }
          var tmpWrite = new OPCWriteRequest("DE",tmpWriteCB);
          var tmpItemHandle = tmpWrite.addItem("SIMOTION",
                                               "var/userdata.user1");
          tmpWrite.setItemValue(tmpItemHandle,"123");
          tmpItemHandle = tmpWrite.addItem("SIMOTION",
                                           "var/userdata.user2");
          tmpWrite.setItemValue(tmpItemHandle,"234");
          tmpItemHandle = tmpWrite.addItem("SIMOTION",
                                           "var/userdata.user10");
          tmpWrite.setItemValue(tmpItemHandle,"345");
          tmpWrite.sendWriteRequest();
      }
      </script>
      <title>Write</title>
   </head>
<body>
<input type="button" value="Write" onclick="writeValues()"/>
</body>
</html>
```

OPCBrowseRequest

The `OPCBrowseRequest` class can be used to browse the variable management area of a control.

```
function OPCBrowseRequest(parclaaLocaleId,parResultCB)
```

Transfer parameters:

- `parLocaleId`: Language identifier ("DE", "EN")
- `parResultCB`: Callback function that must be provided by the caller
  The function is called on conclusion of the send request.

  ```
  function OPCBrowseRequestCB(parResult,parItemPath,parItemName)
  ```

  `parResult` is an array of type `BrowseResult` and contains the Browse information.

  ```
  function BrowseResult()
  {
     mItemPath;
     mItemName;
     mName;
     mIsItem;
     mHasChildren;
  }
  ```

  `parItemPath` and `parItemName` are the path and name of the directory whose content is displayed in `BrowseResult`.

User interface:

- `sendBrowseRequest(parItemPath,parItemName)` sends the Browse request.
  `parItemPath` and `parItemName` are the path and name of the directory to be browsed.

Example:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://
www.w3.org/TR/html4/loose.dtd">
<html>
   <head>
       <meta http-equiv="Content-Type" content="text/html;
             charset=ISO-8859-1">
       <script type="text/javascript" src="/common.js"></script>
       <script type="text/javascript" src="/opcxml.js"></script>
       <script type="text/javascript">
       function browse()
       {
           var tmpBrowseRequestCB = function(parBrowseResult,
                                             parItemPath,
                                             parItemName)
           {
             var tmpString = parItemPath + "::" + parItemName + "\n";
             for (var tmpIndex = 0; tmpIndex < parBrowseResult.length;
                  tmpIndex++)
             {
                 var tmpBrowseResult = parBrowseResult[tmpIndex];
                 tmpString += tmpBrowseResult.mItemName + "\n";
             }
             alert(tmpString);
           }
           var tmpBrowseRequest =
             new OPCBrowseRequest("DE",tmpBrowseRequestCB);
           tmpBrowseRequest.sendBrowseRequest("SIMOTION","var/");
        }
        </script>
        <title>Browse</title>
   </head>
   <body>
       <input type="button" value="Browse" onclick="browse();"/>
   </body>
</html>
```

OPCSubscriptionRequest

The `OPCSubscriptionRequest` class can be used to set up, poll, and delete an OPC XML DA subscription.

```
function OPCSubscriptionRequest(parLocaleId,parResultCB,parCancelCB)
```

Transfer parameters:

- `parLocaleId` Language identifier ("DE", "EN").call
- `parResultCB` Callback function that must be provided by the user. This callback function is called following setup and a refresh action.

  `function OPCSubscriptionRequestCB(parResultList,parResult)`
  `parResultList` is an array of type `OPCItemValue`, which contains the variable values which have been determined.

```
function OPCItemValue()
{
   mItemPath
   mItemName
   mItemHandle
   mItemValue
   mItemResultId
}
```

- `parCancelCB` Bback function that must be provided by the user. This callback function is called after a subscription is released.

  `function OPCSubscriptionCancelCB()`
  The function has no transfer parameters to be passed.

User interface:

- `addItem(parItemPath,parItemName)` adds the passed variable to the internal list of subscription variables
- `removeItem(parItemHandle)` deletes the passed variable from the list of subscription variables.
- `cancel()` logs out an active subscription on the server
- `refresh()` reads the current variable values.
  Only variables whose values have changed since the preceding query are passed. The first call of refresh after generating the OPCSubcription object or the first call after a cancel causes the subscription to log in with the current internal variable list on the server. Refresh must be called cyclically. The hold time mechanism of the OPC XML DA subscription is not supported, i.e. a wait time must be programmed between each 2 refresh cycles by means of a JavaScript timer. However, the wait time of the OPC XML DA subscription is active, i.e. a response to a refresh call is sent only after the wait time elapses, provided a variable value has not changed in the meantime.
- `destructor()`
  Logs out the subscription on the server and releases the resources occupied by the subscription object. Destructor must be called before releasing the object.

Example:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://
www.w3.org/TR/html4/loose.dtd">
<html>
   <head>
      <meta http-equiv="Content-Type" content="text/html;
            charset=ISO-8859-1">
      <script type="text/javascript" src="/common.js"></script>
      <script type="text/javascript" src="/opcxml.js"></script>
      <script type="text/javascript">
          var gloSubscription;
          var gloItemHandle_1;
          var gloItemHandle_2;
          function subscription()
          {
              if (!gloSubscription)
              {
                  var tmpSubscriptionCB = function(parValues)
                  {
                      for (var tmpIndex = 0;
                           tmpIndex < parValues.length;
                           tmpIndex++)
                      {
                          var tmpItemHandle =
                              parValues[tmpIndex].mItemHandle;
                          var tmpItemValue =
                              parValues[tmpIndex].mItemValue;
                          if (tmpItemHandle == gloItemHandle_1)
                          {
                              var tmpValueNode =
                                 document.getElementById("user1");
                              tmpValueNode.firstChild.nodeValue =
                                 tmpItemValue;
                          }
                          else if (tmpItemHandle == gloItemHandle_2)
                          {
                              var tmpValueNode =
                                 document.getElementById("user2");
                              tmpValueNode.firstChild.nodeValue =
                                  tmpItemValue;
                          }
                      }
                    var tmpTimerCB = function()
                    {
                        gloSubscription.refresh();
                    }
                    setTimeout(tmpTimerCB,300);
                }
                var tmpCancelCB = function()
                {
                    if (gloSubscription)
                    {
                        gloSubscription.destructor();
                        gloSubscription = null;
                    }
                }
```

```
                gloSubscription =
                   new OPCSubscriptionRequest("DE",
                        tmpSubscriptionCB,tmpCancelCB);
                gloItemHandle_1 =
                   gloSubscription.addItem("SIMOTION",
                                           "var/userdata.user1");
                gloItemHandle_2 =
                   gloSubscription.addItem("SIMOTION",
                                           "var/userdata.user2");
                gloSubscription.refresh();
             }
          }
          function cancel()
          {
             if (gloSubscription)
                gloSubscription.cancel();
          }
       </script>
          <title>Subscription</title>
       </head>
       <body>
          <div>
             <input type="button" value="Start"
                    onclick="subscription();"/>
             <input type="button" value="Cancel" onclick="cancel();"/>
          </div>
          <table>
             <tr>
                 <td>user1</td>
                 <td id="user1">user1</td>
             </tr>
             <tr>
                 <td>user2</td>
                 <td id="user2">user2</td>
             </tr>
          </table>
       </body>
</html>
```

OPCSubscriptionAutoRefresh

`OPCSubscriptionAutoRefresh` provides the same function as `OPCSubscriptionRequest`, with the exception that the timer-controlled call of the refresh function occurs automatically.

```
function
OPCSubscriptionAutoRefresh(parLocaleId,parResultCB,parCancelCB,
 parCycleTime)
```

Transfer parameters:

- `parLocaleId`
- `parResultCB`

- `parCancelCB`
  See OPCSubscriptionRequest
- `parCycleTime`
  Cycle time in which the refresh function is called, in ms

User interface:

- `startRefresh()` starts the query cycle
- `cancel()` See OPCSubscriptionRequest
- `addItem(parItemPath,parItemName,parItemHandle)` See OPCSubscriptionRequest
  After the variable is added, the refresh cycle is restarted automatically.
- `removeItem(parItemHandle)`
- `destructor()`

Example:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
   "http://www.w3.org/TR/html4/loose.dtd">
<html>
   <head>
      <meta http-equiv="Content-Type" content="text/html;
            charset=ISO-8859-1">
      <script type="text/javascript" src="/common.js"></script>
      <script type="text/javascript" src="/opcxml.js"></script>
      <script type="text/javascript">
         var gloSubscription;
         var gloItemHandle_1;
         var gloItemHandle_2;
         var gloItemHandle_3;
         function subscription()
         {
             if (!gloSubscription)

         <td id="user2">user2</td>
    </tr>
```

```
        <tr>
           <td>user3</td>
           <td id="user3">user3</td>
        </tr>
       </table>
    </body>
</html>
```

Representation of OPC XML-DA data in the browser (appl.js)

appl.js

The JavaScript library **appl.js** assembles classes for the representation of the data determined with OPC XML-DA requests.

ApplDataTable

`ApplDataTable` implements a dynamic table in which process variables can be displayed. The variable values are updated cyclically with an OPC XML-DA subscription.

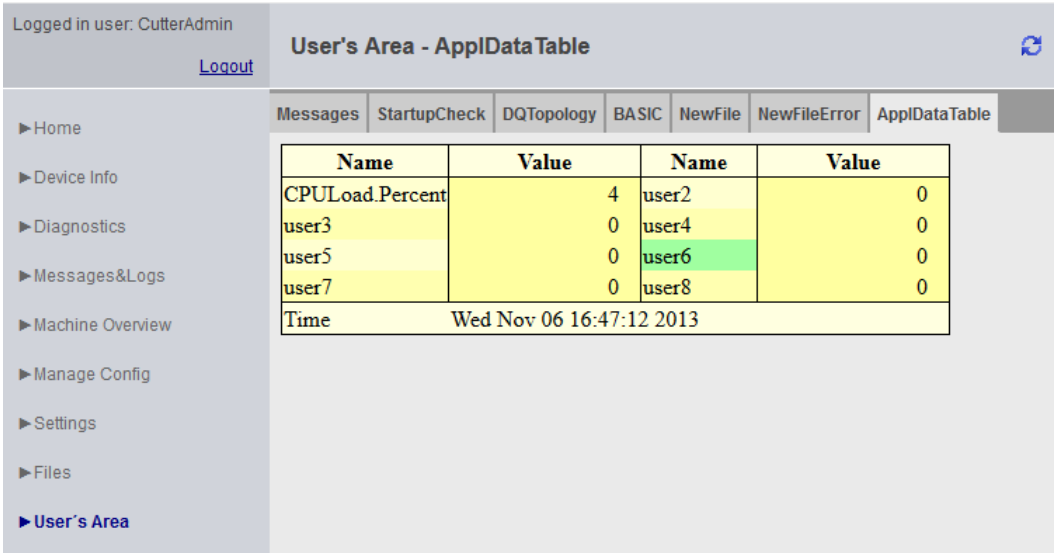

Figure 6-138 Example of implementing a dynamic table (ApplDataTable)

```
function
ApplDataTable(parDocument,parClassName,parColumnClasses,parColumnIds
,parHeader)
```

Transfer parameters:

- `parDocument`: JavaScript document used to generate elements
- `parClassName`: Entered as "class" attribute in the "Table" tag of the HTML table

- parColumnClasses: Array whose "length" attribute specifies the number of table columns. The values of the array are used as a "class" attribute for the table columns (<td class="...">).
- parColumnIds
  : Array whose values are used together with the parRowId parameter (described below) for the "id" attributes of the table columns. The value of the "id" attribute is produced by chaining together the ColumnId and RowId (in that order).
- parHeader: Array containing the column headings of the table

The transfer parameters passed are used to set the "class" and "id" attributes such that the table display can be specified using style sheets.

User interface:

The user interface of class ApplDataTable consists of a series of functions that are useful for general use in the web site and their passed and returned parameters.

- addRow(parRowId,parRowClass) appends a new row to the table
  - parRowId: Used as a value for the id attribute of row (<tr id="...">)
  - parRowClass: Used as a value for the "class" attribute of row (<tr class="...">)
- addElement(parElement,parDestructor,parColSpan,parColClass)
  Inserts the HTML element passed using parElement in the table.
  - parElement: HTML element to be inserted in the table
  - parDestructor (optional)
    Function that is called if the HTML element is deleted from the table (used in Internet Explorer to prevent memory leaks).
  - parColSpan (optional)
    : Specifies the number of columns the element is to span.
  - parColClass (optional)
    parColClass can be used to overwrite the ColClass assigned when the ApplDataTable object is created, if special formatting is to be applied for the current element.
- addVariable(parPath,parName,parColSpan,parColClass)
  : Inserts a variable in the table. The value of the variables is updated cyclically.
  - parPath
    Variable path (e.g. "SIMOTION" or "SIMOTION diagnostics")
  - parName
    Variable name (e.g. "var/userdata.user1")
  - parColSpan (optional)
    See addElement
  - parColClass (optional)
    See addElement

- `addText(parText,parColSpan,parColClass)` : Inserts text in the table.
  - `parText`
    : Text to be inserted.
  - `parColSpan` (optional)
    See `addElement`
  - `parColClass` (optional)
    See `addElement`
- `addRemoveButton (parRemoveCB,parRemoveData,parImage)`
  Inserts a button in the table for removing the current row.
  - `parRemoveCB(parData)` (optional)
    Transfer parameter passed to the Callback function. Data passed when addRemoveButton is called
  - `parRemoveData` (optional)
    Data passed as a parameter when parRemoveCB is called.
  - `parImage`: (optional)
    Optional parameters: DOM object of an HTML img element (e.g. created with document.createElement("img")), which is to appear on the button
- `addImage(parImage)`
  Inserts an image in the table.
  - `parImage`: URL of the image to be inserted
- `getVariables()` supplies an array of all variables of the table
  Each entry of the array consists of an object with the elements `mItemPath`, `mItemName`, and `mItemHandle`.
- `addRefreshCB(parRefreshCB)` registers a Callback function on the table object, which is called on completion of a refresh cycle; an array of `OPCItemValue`-Objekten is passed to the Callback function.

```
OPCItemValue
{
   mItemPath
   mItemName
   mItemHandle
   mItemValue
   mItemResultId
}destructor() must be called if the table is no longer required.
```

This function releases all the resources occupied by the table. In particular, the subscription used by the table is logged off on the OPC XML DA server. The function must also be called when the page is exited (onunload).

Example:

```
<html>
   <head>
      <meta http-equiv="Content-Type" content="text/html;
            charset=ISO-8859-1">
      <script type="text/javascript" src="/common.js"></script>
      <script type="text/javascript" src="/opcxml.js"></script>
      <script type="text/javascript" src="/appl.js"></script>
      <script type="text/javascript">
      var gloApplDataTable = null;
      function init()
      {
          if (gloApplDataTable == null)
          {
              var tmpColumnIds     = new Array("Name_0","Value_0",
                                               "Name_1","Value_1");
              var tmpColumnClasses = new Array("Name","Value",
                                               "Name","Value")
              var tmpHeader        = new Array("Name","Value",
                                               "Name","Value");
              gloApplDataTable = new ApplDataTable(document,
                                                   "ReadTableClass",
                                                   tmpColumnClasses,
                                                   tmpColumnIds,
                                                   tmpHeader);
              gloApplDataTable.addRow("Row_0","RowClass_0");
              gloApplDataTable.addText("CPULoad.Percent");
              gloApplDataTable.addVariable("SIMOTION diagnostics",
                                           "CPULoad.Percent");
              gloApplDataTable.addText("user2");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user2");
              gloApplDataTable.addRow("Row_1","RowClass_1");
              gloApplDataTable.addText("user3");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user3");
              gloApplDataTable.addText("user4");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user4");
              gloApplDataTable.addRow("Row_2","RowClass_0");
              gloApplDataTable.addText("user5");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user5");
              gloApplDataTable.addText("user6");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user6");
              gloApplDataTable.addRow("Row_3","RowClass_1");
              gloApplDataTable.addText("user7");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user7");
              gloApplDataTable.addText("user8");
              gloApplDataTable.addVariable("SIMOTION",
                                           "var/userdata.user8");
              gloApplDataTable.addRow("Time","Time");
              gloApplDataTable.addText("Time",1,"Time");
              gloApplDataTable.addVariable("SIMOTION diagnostics",
```

```
                                                "DeviceInfo.Systemtime",
                                                 3,"Time");

                var tmpTableRoot =
                              document.getElementById("TableRoot");
                if (tmpTableRoot)
                {
                   tmpTableRoot.appendChild(gloApplDataTable.mTable);
                }
             }
          }
          function close()
          {
             if (gloApplDataTable != null)
             {
                 gloApplDataTable.destructor();
             }
         }
         </script>
         <style type="text/css">
           table.ReadTableClass {background-color:#FFFFE0;
                                 border:1px solid black;
                                 border-collapse:collapse;}
           th.Name {border:1px solid black;}
           th.Value {border:1px solid black;}
           td.Name {width:80px;border-right:1px solid black;}
           td.Value {background-color:#FFFFA0;width:120px;
                     text-align:right;
                     border-right:1px solid black;padding-right:15px;}
           td.Input {width:200px;}
           td.Time {border-top:1px solid black;}
           tr.RowClass_0 {background-color:#FFFFD0;border:0px;}
           tr.RowClass_1 {background-color:#FFFFB0;border:0px;}
           #Name_1Row_2 {background-color:#A0FFA0;}
         </style>
         <title>Table</title>
      </head>
      <body onload="init();" onunload="close();">
         <div id="TableRoot"></div>
      </body>
   </html>
```

In the final section of the source code, the <style> tag demonstrates how the colors of table rows and individual table cells can be changed using CSS formatting.

This means that the tr.RowClass_0 declaration, for example, can ensure that a yellow background is produced when gloApplDataTable.addRow("Row_0","RowClass_0"). is called.

ApplBrowser

`ApplBrowser` enables the variable management area of the control to be queried.

After you have created an object of this type, the 1st browse operation is started automatically. If the browse information of a subtree has been received, the callback function `parNewTreeFct` is first called. Afterwards, the callback function `parNewNodeFct` or `parNewLeafFct` is called, depending on the type of information (node or leaf). All callback functions receive an object of type `ApplBrowseElement` as the first parameter.

User interface ApplBrowseElement:

- `getElement()` supplies an HTML anchor object (<a ...>) for displaying information
- `setCB(parCB)`
  : Registers a Callback function at the ApplBrowseElement-Objekt; this function is called if a user clicks the anchor object This function also receives an `ApplBrowseElement-Objekt` as a passed transfer parameter.
- `destructor()` must be called if the object is no longer required. This also applies to exiting the page (`onunload`).

```
ApplBrowser(parDocument,
            parItemPath,
            parItemName,
            parNewTreeFct,
            parNewNodeFct,
            parNewLeafFct)
```

Transfer parameters:

- `parDocument`: JavaScript document used to generate elements
- `parItemPath`, `parItemName` specifies the starting point for browsing the variable management area
- `parNewTreeFct(parBackElement,parItemPath,parItemName)` : Callback function that is called when the structure of a new subtree begins.
  - `parBackElement` object of type `ApplBrowseElement`
    The content describes the start node. If a user clicks the HTML anchor of this object, the elements of the preceding subtree (if present) are determined.
  - `parItemPath,parItemName`: Path and name of the current subtree
- `parNewNodeFct(parBrowseElement)` : Callback function that is called for a node element
  - `parBrowseElement` object of type `ApplBrowseElement`
    The content describes a node. If a user clicks the HTML anchor of this object, a browse operation is started for the subtree connected to this node.
- `parNewLeafFct(parBrowseElement)` Callback function that is called for a leaf element
  - `parBrowseElement` object of type `ApplBrowseElement`
    The content describes a leaf.

User interface:

- `destructor` releases all resources occupied by the browser

Example:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/
html4/strict.dtd">
<html>
   <head>
    <title>Browser demo</title>

    <script type="text/javascript" src="/opcxml.js"></script>
    <script type="text/javascript" src="/appl.js"></script>
    <script type="text/javascript">
      var gloBrowseTable = null;
      var gloBrowser = null;
      function addItem(parBrowseElement)
      {
        var tmpBodyElement = gloBrowseTable.firstChild;
        var tmpTableRowElement = document.createElement("tr");
        var tmpTableDataElement = document.createElement("td");
        var tmpLinkElement = parBrowseElement.getElement();
        tmpTableDataElement.appendChild(parBrowseElement.getElement());
        tmpTableRowElement.appendChild(tmpTableDataElement);
                       tmpBodyElement.appendChild(tmpTableRowElement);
      }
      function browse()
      {
        var tmpNewTreeFct =
         function(parBrowseElement,parItemPath,parItemName)
         {
            var tmpBrowseTableHook =
                      document.getElementById("BrowseTable");
            if (tmpBrowseTableHook.firstChild)
               tmpBrowseTableHook.removeChild(
                                  tmpBrowseTableHook.firstChild);
            gloBrowseTable = document.createElement("table");
            var tmpBodyElement = document.createElement("tbody");
            gloBrowseTable.appendChild(tmpBodyElement);
            tmpBrowseTableHook.appendChild(gloBrowseTable);
            if (parBrowseElement)
            {
               parBrowseElement.getElement().firstChild.nodeValue =
                  "< " +
                  parBrowseElement.getElement().firstChild.nodeValue;
               addItem(parBrowseElement);
            }
            alert("Path: " + parItemPath + "\nName: " + parItemName);
         };
         var tmpNewNodeFct = function(parBrowseElement)
         {
             parBrowseElement.getElement().firstChild.nodeValue =
                 "+ " +
                 parBrowseElement.getElement().firstChild.nodeValue;
             addItem(parBrowseElement);
         };
         var tmpNewLeafFct = function(parBrowseElement)
         {
             var tmpCB = function(parBrowseElement)
             {
```

```
                    var tmpText = "Path: " +
                                  parBrowseElement.mItemPath + "\n" +
                                  "Name: " +
                                   parBrowseElement.mItemName + "\n";
                    alert(tmpText);
                }
                parBrowseElement.setCB(tmpCB);
                addItem(parBrowseElement);
            };
            gloBrowser = new ApplBrowser(document, "", "",
                                         tmpNewTreeFct,
                                         tmpNewNodeFct,
                                         tmpNewLeafFct);
        }
        function leave()
        {
            if (gloBrowser)
            gloBrowser.destructor();
        }
     </script>
    </head>
    <body onload="browse();" onunload="leave();">
        <div id="BrowseTable"></div>
    </body>
 </html>
```

ApplBrowseTree

`ApplBrowseTree` builds upon the `ApplBrowser` and displays the browse result in tree format.

```
ApplBrowseTree(parDocument,
               parItemPath,
               parItemName,
               parTablePrefix,
               parLeafCB,
               parNodeCB,
               parBackCB,
               parFilterCB,
               parLeafImg,
               parNodeImg,
               parBackImg)
```

Transfer parameters:

- `parDocument`
  : JavaScript document used to generate elements
- `parItemPath`, `parItemName`
  : Specifies the starting point for browsing the variable management.
- `parTablePrefix`
  Prefix for referencing elements in CSS
- `parLeafCB`
  Callback function that is called if a leaf is clicked
- `parNodeCB`
  Callback function that is called if a node is clicked. Each of the callback functions receives an `ApplBrowseElement` as a first parameter.
- `parBackCB`
  Callback function that is called if the first element of the tree is clicked
- `parLeafImg`, `parNodeImg`, `parBackImg`
  : Symbols that are displayed by a back, node, or leaf element.

User interface:

- `getElement()`
  Supplies a table element that contains the browse results.
- `destructor()`
  Releases the table and all resources connected to it

Example:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/
html4/strict.dtd">

      </script>
    </head>
    <body onload="browse();" onunload="leave();">
      <div id="BrowseTree"></div>
    </body>
  </html>
```

JavaScript and file accesses

File access with JavaScript

The SIMOTION Web server provides a JavaScript API with which file operations can be performed.

Delete	Delete a file.
Rename	Rename a file.
Read	Read a file.
Write	Write a file.
Stat	Read the file properties (creation date, access rights, ...).
Browse	Browse the content of a directory.
MakePath	Create a directory path.
DeleteDir	Delete a directory.

Transactions

To perform consistent multiple file operations, a transaction mechanism is provided for the file accesses. All function calls (transaction API and the File Manager API) are made asynchronously.

A transaction is initiated by calling the `Begin` function. The transaction object is provided for successive operations that must be performed consistent. After the operation sequence has been processed, the transaction is completed by calling the `Commit` function.

To abort an operation sequence, the `Abort` function of the transaction must be called. In this case, all operations performed previously as transaction are rolled back.

Transactions are time-monitored in the runtime system. If a transaction is inactive for longer than 5 seconds, it is terminated automatically and all previous operations are rolled back.

Each function can be passed a data object that is returned in the Callback function.

```
function Transaction
{
 Begin: function(parData, parCB) {...};
 Commit: function(parData, parCB) {...};
 Abort: function(parData, parCB) {...};
```

```
 // private
 Run: function(parParams, parData, parCB) {...};
}
```

Begin

The `Begin` function initiates a transaction. The time monitoring is started and a transaction ID is generated.

`Begin: function(parData, parCB)`

Transfer parameters:

- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

`function(parRetVal)`

Transfer parameters:

- `parRetVal::`
  ```
  {
   "Result": <ReturnCode>
   "Data": <UserData>
  }
  ```
  `"Result":`
  - `"RC_OK"`: The function completed successfully.
  - `"RC_UNREACHABLE"`: The target controller cannot be reached.
  - `"RC_TA_ABORTED"`: The transaction was aborted by the user.
  - `"RC_TA_FINISHED"`: The transaction has already been completed with `Commit`.
  - `"RC_TA_IDLE"`: The transaction has not yet been activated with `Begin`.
  - `"RC_TA_TIMEOUT"`: The transaction has been completed by a timeout.

  `"Data":`
  - Variables defined by the user passed as `parData` parameters for the function call.

Commit

The `Commit` function completes a transaction.

`Commit: function(parData, parCB)`

Transfer parameters:

- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- `parRetVal::`
  ```
  {
   "Result": <ReturnCode>
  }
  "Result":
  ```
  - "`RC_OK`": The function completed successfully.
  - "`RC_UNREACHABLE`": The target controller cannot be reached.
  - "`RC_TA_ABORTED`": The transaction was aborted by the user.
  - "`RC_TA_FINISHED`": The transaction has already been completed with `Commit`.
  - "`RC_TA_IDLE`": The transaction has not yet been activated with `Begin`.
  - "`RC_TA_TIMEOUT`": The transaction has been completed by a timeout.

Abort

The `Abort` function aborts a transaction. All performed operations that belong to this transaction are rolled back.

```
Abort: function(parData, parCB)
```

Transfer parameters:

- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- parRetVal::
  {
   "Result": <ReturnCode>
  }
  "Result":
  - "RC_OK": The function completed successfully.
  - "RC_UNREACHABLE": The target controller cannot be reached.
  - "RC_TA_ABORTED": The transaction was aborted by the user.
  - "RC_TA_FINISHED": The transaction has already been completed with Commit.
  - "RC_TA_IDLE": The transaction has not yet been activated with Begin.
  - "RC_TA_TIMEOUT": The transaction has been completed by a timeout.

File Manager object

The File Manager API uses JavaScript file library to perform file operations that lie within the valid range of the Web server.

```
function FileManager(parTransaction)
{
 Delete: function(parParams, parData, parCB) {...};
 Rename: function(parParams, parData, parCB) {...};
 Read: function(parParams, parData, parCB) {...};
 Write: function(parParams, parData, parCB) {...};
 Stat: function(parParams, parData, parCB) {...};
 Browse: function(parParams, parData, parCB) {...};
 MakePath: function(parParams, parData, parCB) {...};
 DeleteDir: function(parParams, parData, parCB) {...};
}
```

Delete

The Delete function deletes the passed file.

```
Delete: function(parParams, parData, parCB)
```

Transfer parameters:

- `parParams`
  ```
  {
   "Path": <Path>
  }
  ```
  `"Path"`: The absolute path name of the file to be deleted.
- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- `parRetVal::`
  ```
  {
   "Result": <ReturnCode>
   "Data": <UserData>
  }
  ```
  `"Result":`
  - "`RC_OK`": The function completed successfully.
  - "`RC_UNREACHABLE`": The target controller cannot be reached.
  - "`RC_TA_ABORTED`": The transaction was aborted by the user.
  - "`RC_TA_FINISHED`": The transaction has already been completed with `Commit`.
  - `"RC_TA_IDLE"`: The transaction has not yet been activated with `Begin`.
  - `"RC_TA_TIMEOUT"`: The transaction has been completed by a timeout.
  - `"RC_FS_PATH_NOT_FOUND"`: The desired file does not exist.
  - `"RC_FS_ACCESS_DENIED"`: The current access rights do not suffice to perform the desired action.

  `"Data":`
  - Variables defined by the user passed as `parData` parameters for the function call.

Rename

The `Rename` function renames a file or a directory.

```
Rename: function(parParams, parData, parCB)
```

Transfer parameters:

- parParams
  {
   "SrcPath": <Path>
   "DestPath": <Path>
  }
  "SrcPath": The absolute path name of the file to be renamed.
  "DestPath": New file name without path details.
- parData: User-defined data mirrored by the Callback function.
- parCB: The Callback function that is called after completion of the action.

parCB: Callback function

function(parRetVal)

Transfer parameters:

- parRetVal::
  {
   "Result": <ReturnCode>
   "Data": <UserData>
  }
  "Result":
  - "RC_OK": The function completed successfully.
  - "RC_UNREACHABLE": The target controller cannot be reached.
  - "RC_TA_ABORTED": The transaction was aborted by the user.
  - "RC_TA_FINISHED": The transaction has already been completed with Commit.
  - "RC_TA_IDLE": The transaction has not yet been activated with Begin.
  - "RC_TA_TIMEOUT": The transaction has been completed by a timeout.
  - "RC_FS_PATH_NOT_FOUND": The desired file does not exist.
  - "RC_FS_ACCESS_DENIED": The current access rights do not suffice to perform the desired action.
  - "RC_FS_EXISTS": The new file name exists already.

  "Data":
  - Variables defined by the user passed as parData parameters for the function call.

Read

The Read function reads a file.

Read: function(parParams, parData, parCB)

Transfer parameters:

- `parParams`
  ```
  {
   "Path": <Path>
   "Type": <FileType>
  }
  ```
  `"Path"`: The absolute path of the file to be read.
  `"Type"`: Describes the content of a file.
  - `"xml"`: The file contains an XML document.
  - `"json"`: The file contains a JSON object.
  - `"text"`: The file contains a UTF8 document.
  - `"binary"`: The file contains binary data with Base64 coding.
- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- parRetVal::
  {
   "Result": <ReturnCode>
   "Data": <UserData>
   "File": <FileDsc>
  }
  "Result":
  - "RC_OK": The function completed successfully.
  - "RC_UNREACHABLE": The target controller cannot be reached.
  - "RC_TA_ABORTED": The transaction was aborted by the user.
  - "RC_TA_FINISHED": The transaction has already been completed with Commit.
  - "RC_TA_IDLE": The transaction has not yet been activated with Begin.
  - "RC_TA_TIMEOUT": The transaction has been completed by a timeout.
  - "RC_FS_PATH_NOT_FOUND": The desired file does not exist.
  - "RC_FS_ACCESS_DENIED": The current access rights do not suffice to perform the desired action.
  - "RC_FS_EXISTS": The new file name exists already.

  "Data":
  - Variables defined by the user passed as parData parameters for the function call.

  "File":
  - File type and content
    {
     "Type": <FileType>,
     "Content": <FileData>
    }
    "Type": Describes the content of a file (see above).
    "Content": The content of the file in the appropriate "Type" format.

Write

The Write function writes a file.

```
Write: function(parParams, parData, parCB)
```

Transfer parameters:

- `parParams`
  ```
  {
   "Path": <Path>
   "File": <FileDsc>
  }
  ```
  `"Path"`: The absolute path of the file to be written.
  `"File"`: File type and content.
  ```
    {
      "Type": <FileType>,
      "Content": <FileData>
    }
  ```
  `"Type"`: Describes the content of a file.
  - `"xml"`: The file contains an XML document.
  - `"json"`: The file contains a JSON object.
  - `"text"`: The file contains a UTF8 document.
  - `"binary"`: The file contains binary data with Base64 coding.

  `"Content"`: The content of the file in the appropriate `"Type"` format.
- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- parRetVal::
  {
   "Result": <ReturnCode>
   "Data": <UserData>
  }
  "Result":
  - "RC_OK": The function completed successfully.
  - "RC_UNREACHABLE": The target controller cannot be reached.
  - "RC_TA_ABORTED": The transaction was aborted by the user.
  - "RC_TA_FINISHED": The transaction has already been completed with Commit.
  - "RC_TA_IDLE": The transaction has not yet been activated with Begin.
  - "RC_TA_TIMEOUT": The transaction has been completed by a timeout.
  - "RC_FS_PATH_NOT_FOUND": The desired file does not exist.
  - "RC_FS_ACCESS_DENIED": The current access rights do not suffice to perform the desired action.
  - "RC_FS_EXISTS": The new file name exists already.
  - "RC_FS_DISK_FULL": The storage medium is full.

  "Data":
  - Variables defined by the user passed as parData parameters for the function call.

Stat

The Stat function returns information about the element (file or directory) specified with Path.

```
Stat: function(parParams, parData, parCB)
```

Transfer parameters:

- parParams
  {
   "Path": <Path>
  }
  "Path": The absolute path of the file or directory.
- parData: User-defined data mirrored by the Callback function.
- parCB: The Callback function that is called after completion of the action.

parCB: Callback function

```
function(parRetVal)
```

Transfer parameters:

- `parRetVal::`
  `{`
  `"Result": <ReturnCode>`
  `"Data": <UserData>`
  `"Element": <Properties>`
  `}`
  `"Result":`
  - "`RC_OK`": The function completed successfully.
  - "`RC_UNREACHABLE`": The target controller cannot be reached.
  - "`RC_TA_ABORTED`": The transaction was aborted by the user.
  - "`RC_TA_FINISHED`": The transaction has already been completed with `Commit`.
  - "`RC_TA_IDLE`": The transaction has not yet been activated with `Begin`.
  - "`RC_TA_TIMEOUT`": The transaction has been completed by a timeout.
  - "`RC_FS_PATH_NOT_FOUND`": The desired file does not exist.

  `"Data":`
  - Variables defined by the user passed as `parData` parameters for the function call.
- `"Element":`
  - Contents
    `{`
    `"Name":` <ElementName>,
    `"Type":` <ElementType>
    `"Access":` <AccessAuthorization>,
    `"Size":` <FileSize>,
    `"CTime":` <DateAndTime>
    `}`
    `"Name":` File name without path details.
    `"Type":` Unit type.
    - "`DIR`": It refers to a directory.
    - "`FILE`": It refers to regular file.

    `"Access":` Current access authorization.
    - "`rw`": Read and write.
    - "`ro`": Read-only.
    - "`wo`": Write-only.

    `"Size":` The size of the file in bytes (present only for regular files).
    `"CTime":` The date and time when created.

Browse

The `Browse` function reads the content of a directory.

```
Browse: function(parParams, parData, parCB)
```

Transfer parameters:

- `parParams`
  ```
  {
   "Path": <Path>
  }
  ```
  `"Path"`: The absolute path of the directory.
- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- `parRetVal::`
  `{`
  `"Result": <ReturnCode>`
  `"Data": <UserData>`
  `"Elements": <ElementList>`
  `}`
  `"Result":`
  - "`RC_OK`": The function completed successfully.
  - "`RC_UNREACHABLE`": The target controller cannot be reached.
  - "`RC_TA_ABORTED`": The transaction was aborted by the user.
  - "`RC_TA_FINISHED`": The transaction has already been completed with `Commit`.
  - "`RC_TA_IDLE`": The transaction has not yet been activated with `Begin`.
  - "`RC_TA_TIMEOUT`": The transaction has been completed by a timeout.
  - "`RC_FS_PATH_NOT_FOUND`": The desired file does not exist.
  - "`RC_FS_ACCESS_DENIED`": The current access rights do not suffice to perform the desired action.
  - "`RC_FS_NO_DIRECTORY`": The passed path is not a directory.

  `"Data":`
  - Variables defined by the user passed as `parData` parameters for the function call.
- `"Elements"::` The array elements of a directory.
  - `Elements`
    `[`
    `{`
    `"Name":` <ElementName>,
    `"Type":` <ElementType>
    `"Access":` <AccessAuthorization>,
    `"Size":` <FileSize>,
    `"CTime":` <DateAndTime>
    `}`
    `"Name":` File name without path details.
    `"Type":` Unit type.
    - `"DIR"`: It refers to a directory.
    - `"FILE"`: It refers to a regular file.

    `"Access":` Current access authorization.
    - `"rw"`: Read and write.
    - `"ro"`: Read-only.
    - `"wo"`: Write-only.

    `"Size":` The size of the file in bytes (present only for regular files).
    `"CTime":` The date and time when created.
    `]`

MakePath

The MakePath function creates the passed path recursively.

```
MakePath: function(parParams, parData, parCB)
```

Transfer parameters:

- `parParams`
  ```
  {
   "Path": <Path>
  }
  ```
  `"Path"`: The path to be created.
- `parData`: User-defined data mirrored by the Callback function.
- `parCB`: The Callback function that is called after completion of the action.

`parCB`: Callback function

```
function(parRetVal)
```

Transfer parameters:

- `parRetVal::`
  ```
  {
   "Result": <ReturnCode>
   "Data": <UserData>
  }
  ```
  `"Result":`
  - `"RC_OK"`: The function completed successfully.
  - `"RC_UNREACHABLE"`: The target controller cannot be reached.
  - `"RC_TA_ABORTED"`: The transaction was aborted by the user.
  - `"RC_TA_FINISHED"`: The transaction has already been completed with `Commit`.
  - `"RC_TA_IDLE"`: The transaction has not yet been activated with `Begin`.
  - `"RC_TA_TIMEOUT"`: The transaction has been completed by a timeout.
  - `"RC_FS_ACCESS_DENIED":` The current access rights do not suffice to perform the desired action.
  - `"RC_FS_DISK_FULL":` The storage medium is full.

  `"Data":`
  - Variables defined by the user passed as `parData` parameters for the function call.

DeleteDir

The `DeleteDir` function deletes the passed directory. The directory can be deleted only when it is empty.

```
DeleteDir: function(parParams, parData, parCB)
```

Transfer parameters:

- parParams
  ```
  {
   "Path": <Path>
  }
  ```
  "Path": The absolute path of the directory to be deleted.
- parData: User-defined data mirrored by the Callback function.
- parCB: The Callback function that is called after completion of the action.

parCB: Callback function

```
function(parRetVal)
```

Transfer parameters:

- parRetVal::
  ```
  {
   "Result": <ReturnCode>
   "Data": <UserData>
  }
  ```
  "Result":
  - "RC_OK": The function completed successfully.
  - "RC_UNREACHABLE": The target controller cannot be reached.
  - "RC_TA_ABORTED": The transaction was aborted by the user.
  - "RC_TA_FINISHED": The transaction has already been completed with Commit.
  - "RC_TA_IDLE": The transaction has not yet been activated with Begin.
  - "RC_TA_TIMEOUT": The transaction has been completed by a timeout.
  - "RC_FS_ACCESS_DENIED": The current access rights do not suffice to perform the desired action.
  - "RC_FS_NO_DIRECTORY": The passed path is not a directory.
  - "RC_FS_NOT_EMPTY": The directory is not empty.

  "Data":
  - Variables defined by the user passed as parData parameters for the function call.

MiniWeb Server Language (MWSL)

Mode of operation of the MWSL

The web server language is a scripting language that is interpreted on the web server. This scripting language is fairly similar to JavaScript, but is only a small subset of the complete language.

The MWSL enables the client to be operated with a simple browser without scripting, because the web server generates the pages dynamically.

MWSL enables access and processing of variables. Among other things, MWSL allows access to process variables that are present on the web server system. MWSL and the integrated template mechanism can then be used very effectively to process and evaluate these variables.

The template mechanism used to produce the dynamic pages is similar to a very simplified XSLT process. See W3C XSL transformation (http://www.w3.org/standards/xml/transformation)

The client requests a URL on the web server. The address is converted to the access to an MWSL file in the web server. From this file, the MWSL service generates a temporary HTML file on the web server. This file is then sent to the client and displayed there.

Note

Enabling access to the process variables

Access to the process variables with the MWSL functions GetVar and SetVar requires activation of the setting **Enable OPC_XML (load symbols to RT)** in SCOUT.

You can find more information in the manual SIMOTION IT Diagnostics and Configuration, in the chapters 'Accessing the global variables (V4.2 and higher)' and 'Making unit variables available'.

Structure of a MWSL file

An MWSL file is basically an HTML file which also contains MWSL tags. To distinguish them from HTML files, MWSL files have the extension ".mwsl." Loading of MWSL pages into the controller (Page 3746)

Example:

```
<HTML>
   <HEAD>
      …
   </HEAD>
   <BODY>
      <table>
         <tr>
            [...]
            <td>
               <MWSL>
               //MWSL code to be executed
               </MWSL>
            </td>
            [...]
            <td>
               <MWSL>
               //MWSL code to be executed
               </MWSL>
            </td>
            [...]
         </tr>
      </table>
   </BODY>
</HTML>
```

If the MWSL functionality is required, the following tags must be added:

- The <MWSL>–tag introduces an MWSL script
- The </MWSL>-tag marks the end of the script

For reasons of clarity, the examples below do not always include the HTML code and begin directly with the <MWSL>" tag.

Error messages

MWSL error messages

Errors that occur while an MWSL page is being used are output in two different ways:

1. Errors that occur when compiling the MWSL file are output in the logfile. The name of the log file is formed by appending ".log" to the file name.
2. Errors that occur when executing a web page, that is, when the page is called from the server, are written into the source text of the MWSL page as error messages.

Error output in the MWSL page

The source text of a page can be loaded to the editor in the Internet Explorer by right-clicking and selecting the menu command **Show Source Text**.

Example

This example shows the comment associated with the query relating to an unavailable variable.

exec.mwsl

```
<html>
  <head>
    <title>SIMOTION
      <MWSL>
        WriteVar("DeviceInfo.Board");
      </MWSL>
    </title>
    <meta name="DC.Subject" content="SIMOTION">
    <meta name="DC.Publisher" content="Siemens AG">
    <meta name="DC.Format" content="text/html">
    <meta name="DC.Language" content="en">
    <meta name="DC.Rights" content="Copyrights Siemens AG 2003">
  </head>
  <body style="font-family: Arial">
    <p>
    <MWSL>WriteVar("var/userData.user8");</MWSL>
    </p>
    <p>
    <MWSL>WriteVar("var/userData.user9");</MWSL>
    </p>
  </body>
</html>
```

In exec.mwsl file, the statement `WriteVar("var/userData.user9");` is used to query a non-existent variable.

Source text for the output page:

```
<html>
 <head>
  <title>SIMOTION D435</title>
  <meta name="DC.Subject" content="SIMOTION">
  <meta name="DC.Publisher" content="Siemens AG">
  <meta name="DC.Format" content="text/html">
  <meta name="DC.Language" content="en">
  <meta name="DC.Rights" content="Copyrights Siemens AG 2003">
 </head>
 <body style="font-family: Arial">
  <p>
  495399
  </p>
  <p>

<!-- MWSL2 Runtime Message (WARNING):
     Src Line# (MethodName) Source Text
     ============================
     000003  #(INTERPRETER) WriteVar("var/userData.user9");</MWSL>
     External function returned an error: E6B20014.
-->

  </p>
 </body>
</html>
```

The MWSL2 Runtime Message comment contains a description of the error cause.

Note

Unambiguity of error messages

Error messages are not always unambiguous. This can be with regard to the specification of the function as well as the error line.

Variable types

MWSL distinguishes between script variables and global variables:

- Script variables are defined within the script
- Global variables are provided by variable sources

Note

Global variables are not part of the script engine. Rather, they represent information from the web server environment. Variables are accessed exclusively via access functions. The global variables are grouped into variable sources according to their origin.

Script variables

Script variables are variables that are only valid on the current page.

The variables apply beyond MWSL tags, i.e. they can be created in one MWSL tag and be used starting in the next MWSL tag.

For these variables, no distinction is made between variable types, i.e. there is no Int, Char, etc.

A variable is created as follows:

```
var <Variablenname> = <Wert>;
```

The variable type is determined internally by the variable assignment.

Example:

```
<MWSL>
   var string1 = "Hello";
   var string2 = "World";
   write(string1 + " " + string2);
</MWSL>
```

Two variables are created in the example shown above: `string1` and `string2`.

The two strings are strung together (with spaces).

The `write` command outputs the result. See write (Page 3878)

Output: Hello World

Example:

```
<MWSL>
   var num1 = 5;
   var num2 = 7;
   var Result;
   Result = num1 + num2;
</MWSL>
```

Two variables are created in the example shown above: `num1` and `num2`.

The two numbers are added, and the result is stored in the `Result` variable.

`Result` contains the value 12.

The data type is converted in the same way as ECMA Script 262. See ECMA script (http://www.ecma-international.org/publications/standards/Ecma-262.htm)

Keyword var

The keyword var introduces a variable declaration. In ECMA script, variables do not have to be explicitly declared.

Syntax:

```
var VarName = InitalValue, VarName2 = InitialValue2, …;
```

Multiple variables are declared and (optionally) initialized with initial values.

You can specify several declarations, separated by commas.

For further information, please refer to the ECMA Script Definitions.

Ranges of visibility and validity

The visibility and validity of variables is analogous to ECMA script. (However, MWSL currently does not recognize any functions.)

Example:

```
<MWSL>
   var MyVar = 10;
   {
      MyVar = 20;
      write ("Inner:" + MyVar + "," );
   }
   write ("Outer:" + MyVar + "\n" );
</MWSL>
```

Output: Inner: 20, Outer: 20

In this example, the variable `MyVar` of the outer level will be accessed in the operation block, because a variable named `MyVar` was not declared on the operation block level.

Therefore, the `MyVar = 20` operation changes the value of the variable on the outer level.

```
<MWSL>
   var MyVar = 10;
   {
       var MyVar = 20;
       write ("Inner:" + MyVar + "," );
   }
   write ("Outer:" + MyVar + "\n" );
</MWSL>
```

Output: Inner: 20, Outer: 10

In this example, the variable `MyVar` is created new at the inner level, which leaves the value of the variable `MyVar` having the same name at the outer level unchanged.

Global variables

Definition

Global variables enable access to the variable management area of the web server. There are different types of global variables:

- PROCESS variables enable access to normal variables of the web server. This is known as standard access.
- DEFAULT variables are identical to the PROCESS variables.
- URL variables provide access to variables contained in a URL.
- HTTP variables return the content of variables in the HTTP header.
- COOKIE variables allow access to cookies.

A variable can be accessed using the following command:

```
GetVar("var/userData.user1", "PROCESS");
```

The variable source `PROCESS` must be written in upper case. If the `var/userData.user1` variable is not present, "null" is returned.

`PROCESS` is the standard variable source. Therefore, `PROCESS` can also be omitted.

```
GetVar("var/userData.user1");
```

If a variable provider is to be addressed directly, the name of the desired provider can be specified instead of the variable source `PROCESS`.

Format string for the GetVar and WriteVar functions

The format string always starts with a % sign, followed by the specification of the number of characters. This is then followed by the type information.

The following type information is available:

- %d for Integer values
- %f for Float values
- %e for representing the value with exponent
- %s for Strings

Examples

```
GetVar("var/systemClock", "PROCESS", "%d");
```

```
GetVar("var/modeOfOperation", "PROCESS", "%s");
```

Table 6-41 Format strings

Example	Meaning
"%.6s"	Outputs the first 6 characters of the specified variable (as a string).
"%.3s"	Outputs the first 3 characters of the specified variable (as a string).
"%.s"	Outputs the complete variable (as a string).
"%3.2f"	Outputs the variable interpreted as Float. The 3 indicates that 3 total places are output. The 2 indicates that, of the 3 places, 2 places after the decimal point will be displayed.
"%4d"	Outputs the variable interpreted as Integer. Four places are output. This parameter can only be passed if the variable source "PROCESS" has also been passed.

If the format string is omitted, the complete variable content is returned.

Float numbers are rounded at output. For example, the number pi is output with the formatting "`%4.3f`" as `3,142`

GetVar (Page 3869)

WriteVar (Page 3879)

Special variables

Via the variable source HTTP, the value of the special variable `Username` can be queried.

```
GetVar("Username", "HTTP")
```

This call of `GetVar` returns the user currently logged on to the Web server.

The special variable `HTTP` supplies information on the HTTP connection.

```
GetVar( "HTTP", "HTTP")
```

Output:

```
Host: 192.168.1.1User-Agent: Mozilla/5.0 (Windows NT 6.1; WOW64;
rv:28.0) Gecko/20100101 Firefox/28.0Accept: text/html,application/
xhtml+xml,application/xml;q=0.9,*/*;q=0.8Accept-Language: de,en-
US;q=0.7,en;q=0.3Accept-Encoding: gzip, deflateReferer: http://
192.168.1.1/index.mwslConnection: keep-alive
```

Configuration constants

Accessing constants of the WebCfg.xml configuration file

It is possible to create constant variables in the WebCfg.xml file. Accessing these constants enables more flexible programming, meaning that user-defined pages can be controlled using relevant configuration parameters.

A constant is defined in the following section of WebCfg.xml:
/SERVERPAGES/CONFIGURATION_DATA/UserConfig

```
<SERVERPAGES>
  <CONFIGURATION_DATA>
    <USERCONFIG>
      <MyParam>MyParamValue</MyParam>
    </USERCONFIG>
  </CONFIGURATION_DATA>
</SERVERPAGES>
```

It is possible to access the `MyParam` constant in an HTML page by specifying the "`constants/MyParam`" path.

```
<html>
  <head>
  </head>
  <body style="font-family: Arial">
    <table width="100%" height="100%" bgcolor="#00349A">
      <tr>
        <td style="color: #FFFFFF">
          <b><MWSL>WriteVar("constants/MyParam");</MWSL></b>
        </td>
      </tr>
    </table>
  </body>
</html>
```

Result:

```
<html>
  <head>
  </head>
  <body style="font-family: Arial">
    <table width="100%" height="100%" bgcolor="#00349A">
      <tr>
        <td style="color: #FFFFFF">
          <b>MyParamValue</b>
        </td>
      </tr>
    </table>
  </body>
</html>
```

Variables and URL parameters

MWSL offers the option of editing URL parameter values using the `WriteVar`, `GetVar`, `SetVar`, and `ExistVariable` functions.

Example of a URL with appended parameters. The line break has been added for better readability:

```
http://localhost/MWSL/StringOperationtest.mwsl?
Parameter1=Hallo&Parameter2=du!&StartValue=2&EndValue=5
```

The URL points to the page StringOperationtest.mwsl and transfers the parameters `Parameter1`, `Parameter2`, `StartValue` and `EndValue`.

The following command outputs the URL variable Parameter1:

```
WriteVar("Parameter1", "URL");
```

Note that "URL" must be written in upper case.

If a URL variable that is not present in the URL is requested, an empty string ("") is always returned. This return is not a script error.

Parameters in URLs

In a URL, parameter passing begins after the "?" character. Individual parameters are separated by "&" characters. The value is assigned after the "=" character.

Certain characters require a coding in order to be passed correctly. The following table provides an overview of the most commonly used escape codes.

Table 6-42 URL escape codes

Character	Escape code
Blank	%20
<	%3C
>	%3E
#	%23
%	%25

Character	Escape code
{	%7B
}	%7D
|	%7C
\	%5C
^	%5E
~	%7E
[	%5B
]	%5D
`	%60
;	%3B
/	%2F
?	%3F
:	%3A
@	%40
=	%3D
&	%26
$	%24

The coding consists of the '%' character followed by the ASCII hexadecimal value of the desired character.

You can find more information on the Internet, e.g. at http://de.selfhtml.org/.

COOKIES

The following example shows how a cookie can be created in an MWSL file.

For this purpose, insert the <META> tag into the <HEAD> tag:

```
http-equiv="SET-COOKIE" content="siemens_automation_language=de;"
```

Example:

```
<HTML>
   <HEAD>
      <META http-equiv="SET-COOKIE"
            content="siemens_automation_language=de;">
   </HEAD>
   <BODY>
      [...]
   </BODY>
</HTML>
```

For more information on cookies: http://de.selfhtml.org/

Setting a cookie as an HTTP header

It is possible to set HTTP header for the HTTP response from MWSL. For example, this allows a cookie to be set via the HTTP header and not as a <META> tag.

Example:

```
<MWSL>
   var strCookie;
   strCookie = "Set-cookie: siemens_automation_language=";
   strCookie = strCookie + GetVar( "Language", "URL");
   strCookie = strCookie + ", path=/\r\n";
   AddHTTPHeader( strCookie );

   write("HTTP lang: " + GetVar("Cookie", "HTTP"));
</MWSL>
```

In this example, a cookie for detection of the language setting is set.

Variables and access to COOKIES

The access occurs similarly as for the URL parameters. The single difference is that the variable type is now `COOKIE` instead of `URL`.

The variable specified in the example can be accessed with the following command, for example:

```
GetVar("siemens_automation_language", "COOKIE");
```

Note that `COOKIE` must be written in upper case.

If the `COOKIE siemens_automation_language` is set with `en`, for example, the above call would return this value.

For more information on cookies: http://de.selfhtml.org/

If the variable is not present, there is no output.

Variables and HTTP header information

Using the variable source `HTTP`, the values are read out of the HTTP query header fields. These are, for example, `Accept`, `Content-Type`, or `User-Agent`.

Table 6-43 Example output of an HTTP header field

```
WriteVar("User-Agent", "HTTP");

Output of the Mozilla Firefox browser:
  Mozilla/5.0 (Windows NT 6.1; WOW64; rv:25.0) Gecko/20100101 Firefox/25.0
```

Table 6-44 Example of generation of an HTTP HEADER with the HTML META tag

Example:

```
<HTML>
   <HEAD>
      [...]
      <META http-equiv="Accept-Language" content="de">
      [...]
   </HEAD>
   <BODY>
      [...]
   </BODY>
</HTML>
```

In this example, the HTTP variable `Accept-Language` is defined in the META tag using the "`http-equiv="Accept-Language"` command. It is initialized by the `content` attribute with the value `de`.

Additional information on META information: http://de.selfhtml.org/html/kopfdaten/meta.htm#allgemeines

This variable is accessed similarly as for the URL parameters. The difference is that the variable source is `HTTP` and not `URL`. The variable specified in the example can be accessed with the following command:

```
GetVar("Accept-Language", "HTTP");
```

The variable source `HTTP` must be written in upper case.

Format string for the GetVar and WriteVar functions

As the third parameter of the functions `GetVar` and `WriteVar`, a format string can be specified. The format string defines from which position how many characters of the variable source will be returned.

```
GetVar("Accept-Language", "HTTP", "[3,5]")
```

In the above example, 5 characters of the HTTP variables `Accept-Language` are returned starting from the third character.

The format string can only be passed if a variable source, such as `HTTP` in the above example, has also been passed.

If the format string is omitted, the complete variable content is returned.

WriteVar (Page 3879)

Operators

MWSL operators

All operators presented here behave as defined in ECMA 262. For more information, refer to the ECMA 262 Specification.

Boolean values are converted to numerical values 0 (for false) and 1 (for true) where applicable.

Table 6-45 Relational operators

Operator	Comment
`x < y`	This operator returns true if the `x` variable is less than the `y` variable. Otherwise, the value returned is false.
`x <= y`	This operator returns true if the `x` variable is less than or equal to the right `y` variable. Otherwise, the value returned is false.
`x > y`	This operator returns true if the `x` variable is greater than the `y` variable. Otherwise, the value returned is false.
`x >= y`	This operator returns true if the `x` variable is greater than or equal to the `y` variable. Otherwise, the value returned is false.
`x == y`	This operator returns true if the `x` variable is equal to the `y` variable. Otherwise, the value returned is false.
`x != y`	This operator returns true if the `x` variable is not equal to the `y` variable. Otherwise, the value returned is false.

Table 6-46 Logic operators

Operator	Remark
`!x`	Logical NOT This operator returns a false if `x` is true. if `x` is false, the value returned by the operator will be true.
`x && y`	Logical AND This operator returns true if `x` and `y` have the value true. Otherwise, the value returned is false.
`x || y`	Logical OR This operator returns a false if x and y have the value false. Otherwise, the value returned is true.

Table 6-47 Object operators

Operator	Remark
`new`	Creating an object This operator creates on object. The object can be of a pre-integrated or a user-defined type.
`delete`	Deleting an object This operator deletes an object created with `new`.

Table 6-48 Bit-by-bite operators

Operator	Remark
x & y	Bit-by-bit AND If x and y are one at a bit position, this bit position will have the value one. All bit positions are checked.
x | y	Bit-by-bit OR If x or y are one at a bit position, this bit position will have the value one. All bit positions are checked.
x ^ y	Bit-by-bit XOR If x or y is one at a bit position, but they are not both one, this bit position will have the value one. All bit positions are checked.
x >> y	Right shift considering the sign In x, the bits are shifted right by y digits. If x is positive, zeroes are filled in from the left; if x is negative, ones are filled in from the left.
x >>> y	Right shift without considering the sign In x, the bits are shifted right by y digits. Zeroes are filled in from the left.
x << y	Left shift In x, the bits are shifted left by y digits. Zeroes are filled in from the right.
~x	Bit-by-bit NOT Inverted bits of x.

Table 6-49 Arithmetic operators

Operator	Remark
x + y	Plus operator This operator adds x and y.
++x	Increment Increments the value of x by one. x++ or ++x is possible.
x − y	Minus operator This operator subtracts the value y from x.
−−x	Decrement Decrements the value of x by one. x−− or x is possible.
x / y	This operator divides x by y. The return value is a float.
x % y	Modulo This operator returns the integer remainder of a division of x and y.
x * y	This operator multiplies x by y.

Table 6-50 Assignment operators

Operator	Remark
`x = y`	Assignment operator This operator assigns the value of the right-hand expression to `x`, in this case the variable `y`.
`x += y`	Addition Assigns `x` the value of `x + y`.
`x -= y`	Subtraction Assigns `x` the value of `x - y`.
`x *= y`	Multiplication Assigns `x` the value of `x * y`.
`x /= y`	Division Assigns `x` the value of `x / y`.
`x ^= y`	Bit-by-bit OR Assigns `x` the value of `x ^ y`.
`x |= y`	Bit-by-bit OR Assigns `x` the value of `x | y`.
`x &= y`	Bit-by-bit AND Assigns `x` the value of `x | y`.
`x %= y`	Modulo Assigns to `x` the integer remainder of a division with `y`.
`x >>= y`	Bit-by-bit right shift Assigns `x` the value of `x >> y`.
`x <<= y`	Bit-by-bit left shift Assigns `x` the value of `x << y`.

Table 6-51 Conditional operator

Operator	Remark
`Condition ? x : y`	Conditional operator This operator has the value `x`, if the `condition` is true. Otherwise, the value of the operator is `y`.

Conditional operations

if Conditions

The `if` condition is familiar from Ecma 262.

Syntax
```
if(<condition>)
   Operation1
 else
   Operation2;
```

If the condition is true, instruction 1 is run.

If the condition is false, instruction 2 is run. If no `else` part is present, processing continues in accordance with the `if` operation.

Example:
```
<MWSL>
  [...]
  if (ExistVariable("Parameter", "PROCESS"))
  {
    WriteVar("Parameter");
  }
  [...]
</MWSL>
```

If the `Parameter` process variable exists, its content is output.

If not, the instruction is skipped and the program execution is then resumed. In the example above, this would be the code that follows after the closing curly bracket.

If an `else` branch is present, it is run provided that the condition has not been fulfilled.

Example:
```
<MWSL>
  [...]
  if (ExistVariable("Parameter") && GetVar("Parameter")>=3)
  {
    write("The parameter value is:");
    WriteVar("Parameter");
    write("This is a valid value!");
  }
  else
  {
   write("Parameter process variable is not permitted or is not available");
  }
  [...]
</MWSL>
```

If the Parameter variable is not present, the `else` part is executed. A message is then output, indicating that no variable with the specified name exists.

As the examples show, an operation can be replaced by an operation block.

An operation block is a list of operations that is enclosed in curly brackets.

Example:
```
<MWSL>
  [...]
  if (ExistVariable("Parameter") && GetVar("Parameter")>=3)
  {
    WriteVar("Parameter");
  }
  else
  {
    write("Parameter process variable is not permitted or is not
available");
  }
  [...]
</MWSL>
```

If the Parameter process variable exists and the content is greater than or equal to 3, it is output. Otherwise, a corresponding output is made.

switch Condition

The `switch` operation makes it possible to compare an <expression> with many conditions <value1>, <valuet2>, etc.

```
switch (<expression>)
{
  case <value1>:
    //Program block
    break;
  case <value2>:
    //Program block
  break;
    //etc.
 default:
    //Program block
}
```

Loops

for Loop

The MWSL provides a loop mechanism, such as is already familiar from JavaScript.

For a detailed description, refer to the ECMA 262 Specification.

Syntax
```
for( Start statement; End condition; Run statement)
{
    Loop body, code to be executed
}
```

Sequence:

1. The start instruction is executed
2. The loop body is executed
3. The run operation is executed
4. As long as the end condition is true, the processing is repeated starting from the loop body (2.).

Example:

```
for(i=1; i<5; i++)
{
    write(i);
}
```

```
Output: 1234
```

`do while` Loop

In the `do while` loop, the body of the loop is first run then the while <condition> is tested.

```
do
{
 //Operation block
} while (<condition>);
```

break continue

To break or resume loop execution, two operations `break` and `continue` are available.

With the `break` operation, the loop is always exited immediately without testing the <condition> again.

The `continue` operation jumps immediately to the head of the loop.

Functions

A user-defined function consists of the function operation and a program block of operations. No or multiple parameters can be passed.

A <Wert> can be returned. If no return value is specified, the function will return `undefined`.

```
function Function name([<parameter1>,
<parameter2>, ...])
{
   //Program block
   return <Wert>;
}
```

Comments

Comments can comprise one or more lines in the MWSL.

```
// One-line comment. All characters are
ignored up to the line break.

/*
   Multi-line comment starts with '/*'
and
   must be ended with '*/'.
*/
```

Overview of MWSL functions

The MWSL provides a variety of functions, which are presented in the following overview table. For detailed descriptions of the functions, refer to the appendix.

Table 6-52 MWSL functions

Function name	Explanation
AddHTTPHeader(<Http header>) (Page 3865)	Insert <Http Header> in a page.
createGUID() (Page 3865)	Generates a unique alphanumeric ID in the system.
DecodeString(<string>) (Page 3866)	Converts a string encoded with EncodeString back to its original.
die(<Param0>,<Param1>,...) (Page 3866)	Abort program execution.
EncodeString(<string>) (Page 3866)	Replaces special characters by their URL-coded hex value (%hh).
ExistFile(<file name>) (Page 3867)	Checks whether a file with the name <parFile-Name> exists. The function returns the file length as returned value.
ExistVariable(<variable name>, <variable source>) (Page 3868)	Query of the existence of a variable.
GetLanguage() (Page 3868)	Returns the currently set language in English.
GetVar(<variable name>, <variable source>, <format string>) (Page 3869)	Return the value of a variable of the corresponding variable source
InsertFile(<text file>) (Page 3871)	Import of a <Test File>. A path can be specified.
IsAuthAlgo(<parAuthMethod>) (Page 3872)	Returns true if the user logged in at the time of calling could be identified by the authentication method specified in parAuthMethod.
isFinite(<value>) (Page 3872)	Returns false if the passed value is NaN or infinite.
isNaN(<value>) (Page 3872)	Checks whether the passed value is an invalid Double.
IsSSL() (Page 3873)	Returns true if the client is connected to the server via an SSL connection.
parseFloat(<string>) (Page 3873)	Conversion of a string to a double value.
parseInt(<value>,[<basis>]) (Page 3873)	Conversion of a string to an integer value.
ProcessXMLData(<DATA>, <TEMPLATE>) (Page 3875)	Generation of dynamic HTML files with special XML files.
string ReadFile(<file name>) (Page 3876)	Returns the content of the file as the return value.

Function name	Explanation
ReplaceString<variable name>,<search pattern>,<replacement string>) (Page 3876)	Replacement of strings matching the search pattern.
SetVar(<variable name>, <value>) (Page 3876)	Sets values of variables.
ShareRealm(<group name>) (Page 3877)	Indicates whether the current user is a member of the group that is passed as a parameter. The return value can be true or false.
write(<text>) (Page 3878)	Writes <text> strings to the HTML page. <Text> can also be the return value of functions.
WriteVar(<variable name>, <variable source>, <format string>) (Page 3879)	Output of a variable value. The syntax is identical to the GetVar() function.
WriteXMLData (<DATA>, <TEMPLATE>) (Page 3881)	Outputs the data directly in contrast to ProcessXMLData().

Table 6-53 MWSL process variables

Process variable	Explanation
NodeIndex (Page 3882)	Parse process variable for the template. This variable outputs the number of nodes that have already been run.
NodeLevel (Page 3882)	Parse process variable for the template. This variable outputs the hierarchy level of the current node.

Mode of operation of the template mechanism

A Template is applied to data elements of a data source. This mechanism allows separate implementation of data and processing.

The Template-mechanism is started by the `ProcessXMLData()` and `WriteXMLData()` commands.

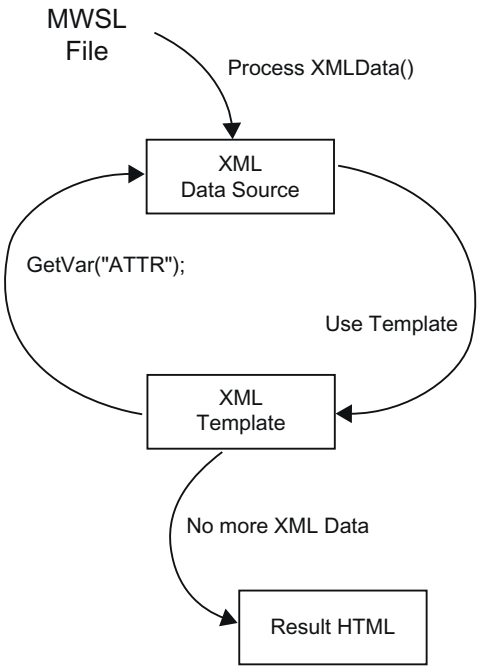

Figure 6-139 Basic overview of the template mechanism

The data file contains structured data that can be output as transformed data using the Template-mechanism.

An XML file consists of a series of XML nodes. A name as well as a set of attributes are assigned to each XML node. An attribute, in turn, consists of a name and a value.

The Template file contains a set of transformation operations.

A transformation operation can be assigned to an XML node (with a certain name).

During the transformation process, the data fragment is read node-by-node from top to bottom. If a Template can be assigned to a node, this Template is executed and the attributes of the current node are available to the Template as variables.

Structure of the template file

The Template file is an XML file whose data nodes contain the transformation operations for processing a data file.

Example

```
<?xml version="1.0" ?>
<TEMPLATES>
   [...]
    <TEMPLATE NAME="Variable">
       [...]
       <POSITION NAME="LINE">
       <![CDATA[
          [...]
          <MWSL>Name()</MWSL>
          [...]
       ]]>
        </POSITION>
       [...]
    </TEMPLATE>
    [...]
</TEMPLATES>
```

The Template file evaluates the data nodes of the data file.

The individual Template tags are defined in the <TEMPLATES> tag (in the example above, only one template tag is defined).

The line <TEMPLATE NAME="Variable"> defines that this Template (the subsequent code) is only run for data notes of the "Variable" type. The type of a data node is specified either through the name of the data node or through a special attribute named "Template".

```
<POSITION NAME="LINE">
   [...]
</POSITION>
```

This tag is used to specify the area of the web page in which the content of the template is to be output.

The positions HEAD, LINE, and FOOT are available and are run in that order during processing.

The content of the POSITION is encapsulated in a CDATA–block in order to protect it from the XML parser:

```
<![CDATA[   [...]]]>
```

MWSL can now be used to access the attributes of the current data node and to output them or use them in other operations.

Example:

```
<MWSL> WriteVar("Name")</MWSL>
```

Structure of a data source

A data source is an XML fragment, in which the nodes of the XML fragment form the data elements.

Note

If the XML fragment does not contain a root node, MWSL itself generates a root node so that the data source conforms to XML.

The XML fragment can also be a complete XML document.

Example:

```
<?xml version="1.0" standalone="yes"?>
   [...]
   <Variable Name="ZUFUEHRUNG.STATE"
             Type="String"
             InitialValue="good"
             Behavior="Manual"
             Description="Status of part infeed."
   />
   [...]
   <Variable Name="Language"
             Type="String"
             InitialValue="de_DE"
             Behavior="Manual"
             Description="Language setting of web page"
   />
   [...]
```

The example defines data nodes (in the example: `Variable`) with the associated attributes.

The different nodes can be evaluated using a corresponding template file.

A further option is the creation of a data structure (hierarchy). That is, data nodes can be created that, in turn, contain other data nodes.

Example:

```
<?xml version="1.0" standalone="yes"?>
   [...]
   <StructVariable Name="Farbe"
                   Type="String"
                   InitialValue="gelb"
                   Behavior="Manual"
                   Description="Fictitious value">
   [...]
   <Subvar Name="Rotteil"
           Type="Integer"
           InitialValue="128"
           Behavior="Manual"
           Description="The red proportion of the color"
   />
   <Subvar Name="Blauteil"
           Type="Integer"
           InitialValue="128"
           Behavior="Manual"
           Description="The blue proportion of the color"
   />
   <Subvar Name="Gruenteil"
           Type="Integer"
           InitialValue="128"
           Behavior="Manual"
           Description="The green proportion of the color"
   />
   [...]
   </StructVariable>
   [...]
```

This example uses the data node of type `StructVariable`. This data node contains several data nodes of type `Subvar`.

Different templates can be used for the different types of data nodes.

Template transformation

The `ProcessXMLData()` command dynamically generates an HTML file (or just a text fragment) from an XML data file and an XML template file.

For this purpose, the parser runs through the data file step by step, from top to bottom.

The parser reads in a data node. Following this, a search is performed in the template file for a matching template for this data node. If a template is found, this template will be applied to the data node. The template is an MWSL fragment. The sole difference is that the attributes of the XML data node in the template are available as standard process variables if a variable source is not specified. If there are identical names, the XML attributes overlay the corresponding process

variables. If the variable source PROCESS is specified explicitly, the process variables are always used.

Example:
```
Prozessvariable
Color Value "Green"
```

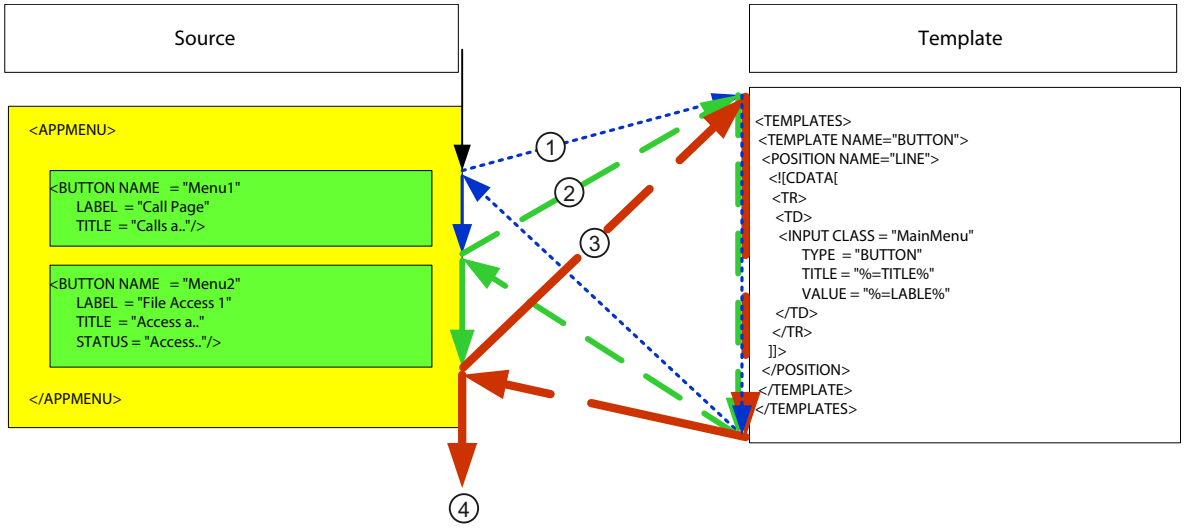
Data file:
```
<?xml version="1.0" standalone="yes"?>
[...]
<Variable Name="ZUFUEHRUNG.STATE"
          Farbe="Red"
/>
[...]
<Variable Name="Language"
/>
[...]
```

Template file:
```
<?xml version="1.0" ?>
<TEMPLATES>
   <TEMPLATE NAME="Variable">
      <POSITION NAME="LINE">
      <![CDATA[
         <MWSL>write (GetVar("Name")+":");</MWSL>
         <MWSL>write (GetVar("Color")+"\r\n");</MWSL>
      ]]>
      </POSITION>
   </TEMPLATE>
</TEMPLATES>
```

Output:

```
ZUFUEHRUNG.STATE: Red
Language: Green
```

Sequence of a Template-process



The figure shows the sequence of the Template Parse-process.

The Template is run through once for each data element (yellow and green blocks). The attributes of the current data element can thereby be accessed as variables.

Chronological sequence

1. The <APPMENU> tag is found in the Source and the Template is run. No processing operation is found for this tag in the Template, therefore, no data element is written to the output.
2. The first <BUTTON> tag is found and processed by the Template .
3. The second <BUTTON> tag is found and processed by the Template .
4. No other tags are found; processing is complete.

Another example:

Calling MWSL file

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://
www.w3.org/TR/html4/loose.dtd">
  <HTML>
    <HEAD>
      <TITLE> MWSL Template Test Page</TITLE>
    </HEAD>
    <BODY>
    <MWSL>
      write(ProcessXMLData(

```

Call the `ProcessXMLData` command to start the parser with the data file variables.xml. The `<Provider>` tag is found first.

In the variablesTemplate.xml template file, a search is performed in order to ascertain whether a template has been defined for this type.

The `Position="HEAD"` area is executed.

The parser reads the next tag from the data file and generates the additional lines of the HTML file to be output based on the appropriate template in the template file.

The same happens with the next tag.

The footer part of the template provider is executed with the end tag `</Provider>`.

In the following expression, the generated parts are shown bold.

Figure 6-140 Generated file in the browser display

MWSL in XML attributes

As part of template parsing, it is also useful to write MWSL-statements to XML attributes of the data file, which are then evaluated at the time of parsing.

Example:

```
<?xml version="1.0" standalone="yes"?>
<Motor Name="M1"
       Nummer="1"
       Type="Dreh"
       Nennleistung = "7"
       Drehzahl="3"
       Alter="2"
       Farbe="RED"
       Prozess="&MWSL;WriteVar(&quot;CPULoad.Percent&quot;,&quot;PROCESS&qu
ot;,
                                &quot;%e&quot;); &END_MWSL;"
/>
```

The example uses the following MWSL command:

```
"&MWSL;WriteVar(&quot;CPULoad.Percent&quot;,&quot;PROCESS&quot;,&quot;%e&q
uot;);
&END_MWSL;"
```

The command would appear as follows in a template file or an MWSL file:

```
<MWSL>WriteVar("CPULoad.Percent", "PROCESS", "%e");</MWSL>
```

This command outputs the value of the `CPULoad.Percent` variables from the `PROCESS` variable source.

Please note that `<MWSL>` must be replaced with `&MWSL;`, and `</MWSL>` with `&END_MWSL;`. In addition, double quotation marks `"` must be replaced with `&quot;` .

The rest conforms to the MWSL syntax.

Examples

Examples of how MWSL can be used

The examples shown here outline the options for using MWSL.

Setting variable values using the SetVar function

```
<MWSL>
   SetVar(GetVar("VARNAME"), GetVar(GetVar("VARNAME"), "URL"));
</MWSL>
```

In this example, the variable whose name is saved in the `VARNAME` process variable is initialized with the value of the `VARNAME` URL variable.

For illustration

`GetVar("VARNAME")` supplies the content of the `VARNAME` process variable. This value will be viewed, in turn, as a variable name.

If we assume that the content of the `VARNAME` process variable is "Jack", the complete call already looks much simpler:

Complete call: `SetVar("Jack", GetVar("Jack", "URL"));`

If we were to assume that the URL variable "Jack" had the content "is a great guy", this would be equivalent to the following expression:

```
SetVar("Jack", "is a great guy");
```

TestTemplate.mwsl

This example will be used to briefly explain the template mechanism again.

For illustrative purposes, a few passages in the respective files are marked.

The template produces a table.

The called file

TestTemplate.mwsl

```
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://
www.w3.org/TR/html4/loose.dtd">
<HTML>

 </TEMPLATE>
</TEMPLATES>
```

In this case, the template file consists of multiple templates. The `Provider` template provides the header and footer parts for the data (table header and footer).

The `Variable` template is appointed for the lines of data output (one table row per variable entry).

The data is inserted after the corresponding attributes.

The data file `variables.xml`

```
<?xml version="1.0" standalone="yes"?>
<Provider Name="SIMOTION">
  <Variable Name="dev/Service.BZU.Value"
    Type="STRING"
    InitialValue="INIT"
    Behavior="Automatic"
    Description="Current operating state"
  />

  <Variable Name="var/userData.user1"
    Type="DINT"
    InitialValue="0"
    Behavior="Manual"
    Description="Variable that can be assigned freely by the user"
  />
</Provider>
```

                />
             </td>
             <td>
                <input class = "MainMenu"
                       type = "BUTTON"
                       title = "Test environment for MWSL."
                       value = "MWSL Test"
                       OnClick = "NavigateApp('/MWSL/Start.mwsl')"
                />
             </td>
             <td>
                <input class = "MainMenu"
                       type = "BUTTON"
                       title = "Browse the Filesystem"
                       value = "File Browser"
                       OnClick = "NavigateApp('/www')"
                />
             </td>
             [...]
             <td>
                <input class = "MainMenu"
                       type = "BUTTON"
                       title = "PKI Interface."
                       value = "CSSA"
                       OnClick = "NavigateApp('/CSSA/Main.mwsl')"
                />
             </td>
             <td>
                <input class = "MainMenu"
                       type = "BUTTON"
                       title = "Simulate several variables."
                       value = "VarSimulator"
                       OnClick = "NavigateApp
                                   ('/Simulator/Simulator_index.mwsl')"
                />
             </td>
          </tr>
      </table>
   </body>
</html>
```

AppNavigation.mwsl

Call:

```
<MWSL>
   WriteXMLData("<EXTERNAL SRC=\"" + GetVar("XML", "URL") + "\"/>",
                  "<TEMPLATES><EXTERNAL SRC=\"" +
                  GetVar("TEMPLATE", "URL") + "\"/></TEMPLATES>");
</MWSL>
```

When the call is made, the data and the template file are transferred from the URL.

In this example, the transferred template file is assumed to be AppNavigation.xml and the transferred data file MWSLTestMenu.xml.

MWSLTestMenu.xml

```
<?xml version="1.0" ?>
<APPMENU>
   <MENU>
      <BUTTON NAME = "Menu1"
              LABEL = "Variablentest"
              TITLE = "Tooltip"
              STATUS = "Statusline"
              CLIENTAREA = "/MWSL/Variablentest.mwsl?Parameter=4711"
      />
      [...]
      <BUTTON NAME = "Menu9"
              LABEL = "Versuch"
              TITLE = "Tooltip"
              STATUS = "Statusline"
              CLIENTAREA = "/MWSL/Versuch.mwsl" />
   </MENU>
</APPMENU>
```

In the following template file, some attributes are queried as to their existence and the corresponding lines executed.

In this case, only the condition for `CLIENTAREA` is run since no other queried attribute is present.

AppNavigation.xml

```
<?xml version="1.0" standalone="yes"?>
<TEMPLATES>
   <TEMPLATE NAME="BUTTON">
      <POSITION NAME="LINE">
      <![CDATA[
         <TR>
            <TD>
               <INPUT CLASS = "MainMenu"
                      TYPE = "BUTTON"
                      TITLE = "<MWSL>TITLE()</MWSL>"
                      VALUE = "<MWSL>LABEL()</MWSL>"
                  <MWSL>
                  if ( ExistVariable( "CLIENTAREA" ))
                  {
                     write("OnClick=
                       \"top.ClientArea.window.navigate('"+
                           GetVar("CLIENTAREA") + "')\"");
                   }
                   if ( ExistVariable ( "TOP" ))
                   {
                       write("OnClick = \"top.window.navigate('" +
                        GetVar("TOP") + "')\"");
                    }
                    if ( ExistVariable ( "WIN" ))
                    {
                        write("OnClick = \"window.open('" +
                                 GetVar("WIN") + "')\"");
                    }
                    if ( ExistVariable ( "ACTION" ))
                    {
                       write("OnClick = \"top.ClientArea.window." +
                         GetVar("ACTION") + "\"");
                    }
                    </MWSL>
                 />
              </TD>
          </TR>
      ]]>
      </POSITION>
   </TEMPLATE>
</TEMPLATES>
```

The template file contains `if` conditions in which attributes from the data file are queried. This results in different statements for each data node during runtime.

The generated HTML file will then only contain the line corresponding to the respective data node.

</TR>
```

Server Side Includes (SSI)

Integration of process values

You can include process values in the user-defined HTML pages using Server Side Includes (SSI).

Note

In SIMOTION controller V4.1 and higher, HTML pages with SSI must be available as a binary file to display process values. A standard HTML page can be converted to a binary file using the supplied conversion tool (Page 3746).

HTML pages with static content only do not have to be converted.

Integration of process values

The variables are integrated in the HTML page using the `<%=IDENTIFIER %>` character string. `IDENTIFIER` is a placeholder, which you must replace with variables from the variable providers. For example, the variable `<%=DeviceInfo.Board%>` returns the name of the controller. On a D435, for example, the value is "D435".

Details of the variables and syntax can be found in the *Variable providers* chapter of the *SIMOTION IT Diagnostics and Configuration* manual.

The source text below shows an example for integrating the variable `userData.user1`. The value of the variable is first output (system variable `userData.user1`: `<%=var/`

userData.user1 %>). The value of the variable is used as a default in the input field and can be overwritten by a user input.

Up to V5.2

```
<html>
   <head>
      <title>Demo Seite</title>
   </head>
   <body text="#000000" bgcolor="#FFFFFF" link="#FF0000"
   alink="#FF0000" vlink="#FF0000">
      Demoseite<br>
      Systemvariable userData.user1 : <%= var/userData.user1 %> <br>
      <form method="post" action="/VarApp">
            SIMOTION C: userData.user1:
            <input type="TEXT" name="var/userData.user1" value="<
            %= var/userData.user1 %>" />
            <input type="submit" value="Wert schreiben" />
      </form>
   </body>
</html>
```

As of V5.2

```
<html>
    <head>
        <title>Demo Seite</title>
    </head>
    <body text="#000000" bgcolor="#FFFFFF" link="#FF0000" alink="#FF0000"
    vlink="#FF0000">
        Demoseite<br>
        Systemvariable userData.user1 : <%= var/userData.user1 %> <br>
        <form method="post" action="/VarApp">
                SIMOTION C: userData.user1:
                <!-- CSRF Token input _must_ be at 1. place in form !!! -->
                <input type="hidden" name="MultiUseToken" value="<
                %=RawMultiUseToken%>"/>
                <input type="TEXT" name="var/userData.user1" value="<%= var/
                userData.user1 %>" />
                <input type="submit" value="Wert schreiben" />
        </form>
    </body>
</html>
```

As of V5.2, the `MultiUseToken` attribute is required. This attribute provides Cross Site Request Forgery protection. Further information can be found in the *CSRF protection* chapter in the *SIMOTION IT Diagnostics and Configuration* manual.

The value of the `MultiUseToken` attribute is set by the Server Side Include `<%=RawMultiUseToken%>` by the Web server.

6.2.3.2 OPC XML-DA web service

Web services introduction

A SIMOTION IT web service supports application programs in text-based access to process values. The application program performs strictly symbolic access independently of the programming language, the operating system, and the time of programming. Details of the international standard of web services can be researched on the Internet or in technical literature.

The SIMOTION control offers the OPC XML-DA web service for data access in accordance with the OPC XML-DA definition V1.01 of the OPC Foundation and the Trace Via SOAP web service (TVS) for the use of the SIMOTION Runtime Trace.

- Addon\4_Accessories\SIMOTION_IT\7_Webservices\WSDL\OPC XMLDA 1.01.wsdl
- Addon\4_Accessories\SIMOTION_IT\7_Webservices\WSDL\TVS.wsdl

An example of a client using the OPC XML-DA service is supplied.

- Addon\4_Accessories\SIMOTION_IT\7_Webservices\Example

Web services can also be used with JavaScript in HTML pages. The standard diagnostics pages of SIMOTION IT use these. See Variable access with JavaScript and web services (Page 3755)

Required knowledge for programming: OPC XML-DA, web services, XML, SOAP, Javascript/AJAX.

Key words for advanced programming: Structuring of applications with model, view, controller architecture, if, for example, dynamic variable values are to be displayed and updated in the background.

Overview

The SIMOTION IT OPC XML DA server enables access via Ethernet to data and operating modes of the SIMOTION device.

What is OPC XML DA?

OPC stands for Open Connectivity and denotes a standard interface for communication in automation technology

With OPC XML DA, it is possible to communicate with a controller using Ethernet-based standard telegrams.

Commands are transmitted via the SOAP (Simple Object Access Protocol) communication protocol.

The interface is defined in a configuration file using a description language (WSDL) based on XML vocabulary. It describes the format of the HTTP request and response telegrams with which

function calls are output (see OPC XML-DA R1.0 Specification: OPC Foundation Download (http://www.opcfoundation.org/Downloads.aspx)).

This interface can only be used by client applications.

The figure below shows an example client of the OPC Foundation . The client enables browsing via the system, interface, IO, and global device variables.

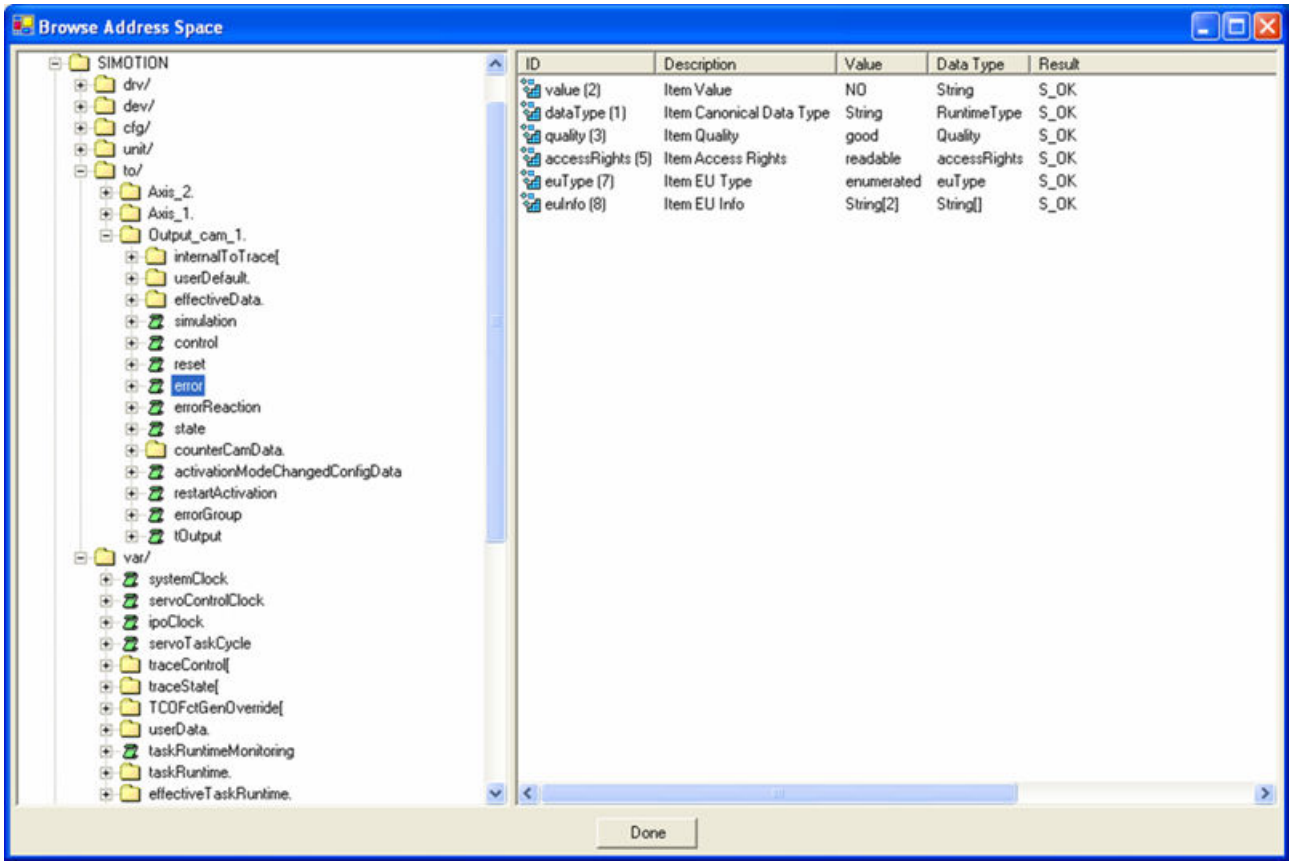

Figure 6-141 OPC Foundation Client

Purpose and benefits

The purpose and benefits of SIMOTION IT OPC XML-DA server are as follows:

- Symbolic access (without project information) to the data of the controller. Only knowledge of the variable names is required.
- Non-dependence on the engineering and project versions. The client can still access the data even if the control program has been modified.
- The server can be addressed by any client application which conforms to the OPC XML-DA V1.0 standard, regardless of its operating system (e.g. Linux).

What previous knowledge is required?

For the user to understand the SIMOTION IT OPC XML-DA server described in this chapter, prior knowledge of the terms associated with OPC XML-DA (see OPC XML-DA R1.0 Specification) is necessary.

Comparison of OPC XML DA / SIMATIC NET OPC DA

Comparison

The "SIMATIC NET OPC Server for SIMOTION" product exists in addition to the SIMOTION IT OPC XML DA server. This package also allows access to data and operating modes of the SIMOTION device via SIMATIC NET OPC DA.

The following table compares the two packages and describes the basic procedure:

Table 6-54 Basic procedure for accessing data

SIMOTION IT OPC XML DA	SIMATIC NET OPC DA
No configuration (OPC export) necessary with SIMOTION SCOUT.	OPC export with SIMOTION SCOUT required, which has to be repeated for every project change.
Symbols are resolved in the SIMOTION device, communication by means of text format (XML).	Symbols are resolved during OPC export and stored in the OPC server on the Windows system in binary format; binary communication -> higher data throughput.
At present only SIMOTION with OPC XML DA. Access to S7 devices not possible at present.	Simultaneous access to SIMOTION and S7 devices.
Client can run on any operating system.	Based on Windows COM/DCOM technology; client and server can only run on Windows operating systems.
Communication using standard protocols (TCP/IP, XML, SOAP) does not require vendor-specific (SIEMENS) tools or drivers on the client system.	S7 protocol used for communication, appropriate manufacturer-specific drivers required on the client.
Communication is only possible via Ethernet (e.g. PROFINET).	Communication is possible via PROFIBUS/MPI and Ethernet (e.g. PROFINET).
Direct addressing via firewalls is possible.	Generally, DCOM communication is not released for firewalls.

Schematic representation of creating the client application

Example arrangement

The figure below shows an arrangement example of the relevant software for the creation of a client application on a PC. The PC and the SIMOTION device are networked via Ethernet.

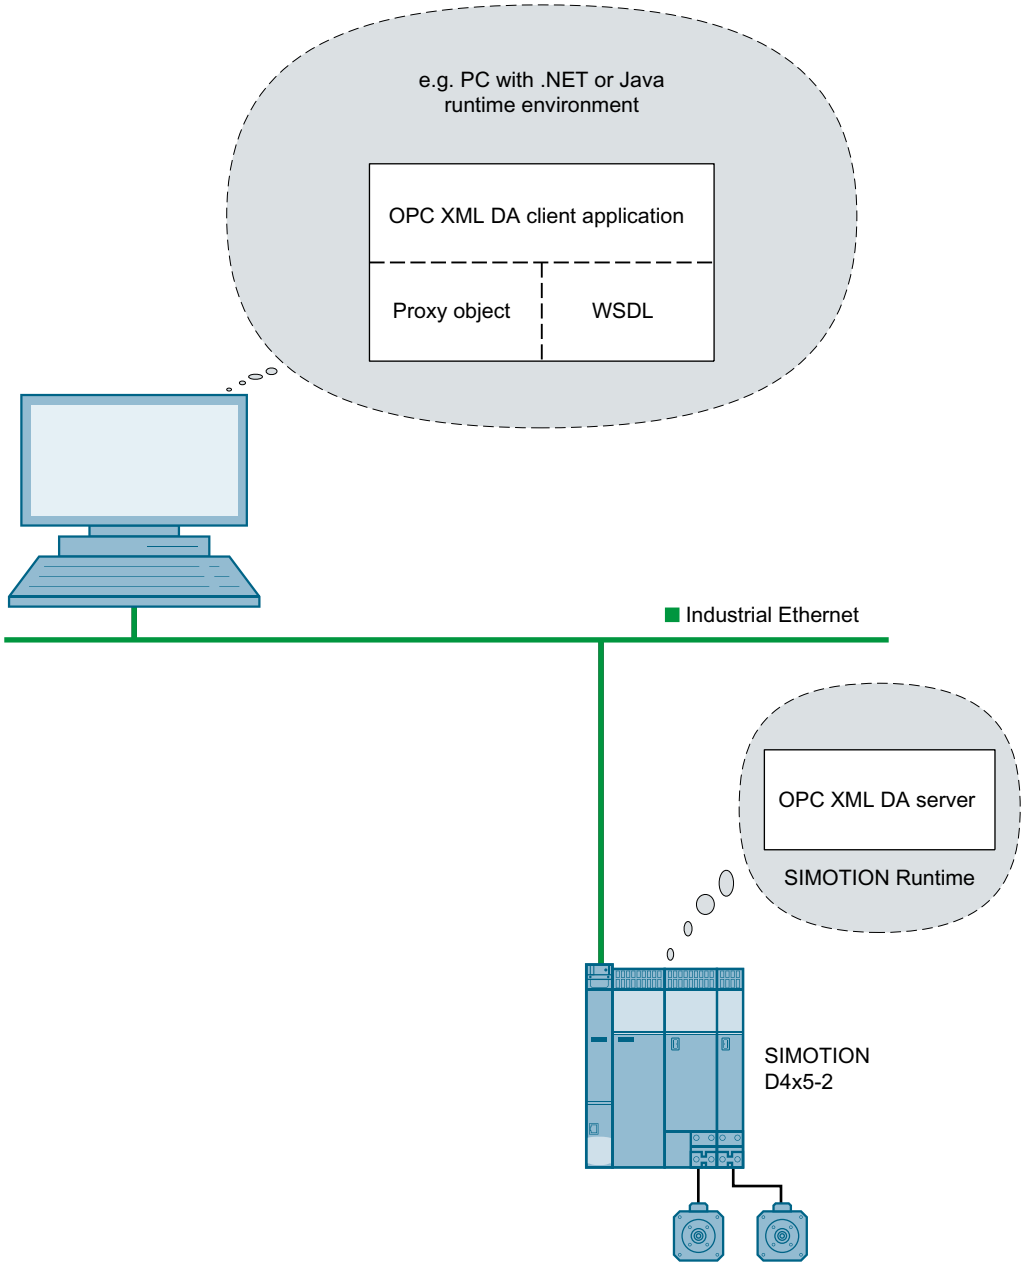

Figure 6-142 Design stage overview (example)

Schematic representation at runtime of the client application

Example arrangement

The figure below shows an example of accessing the OPC XML-DA server of a SIMOTION device via Ethernet during runtime. The example shows other devices connected to the SIMOTION device via PROFIBUS.

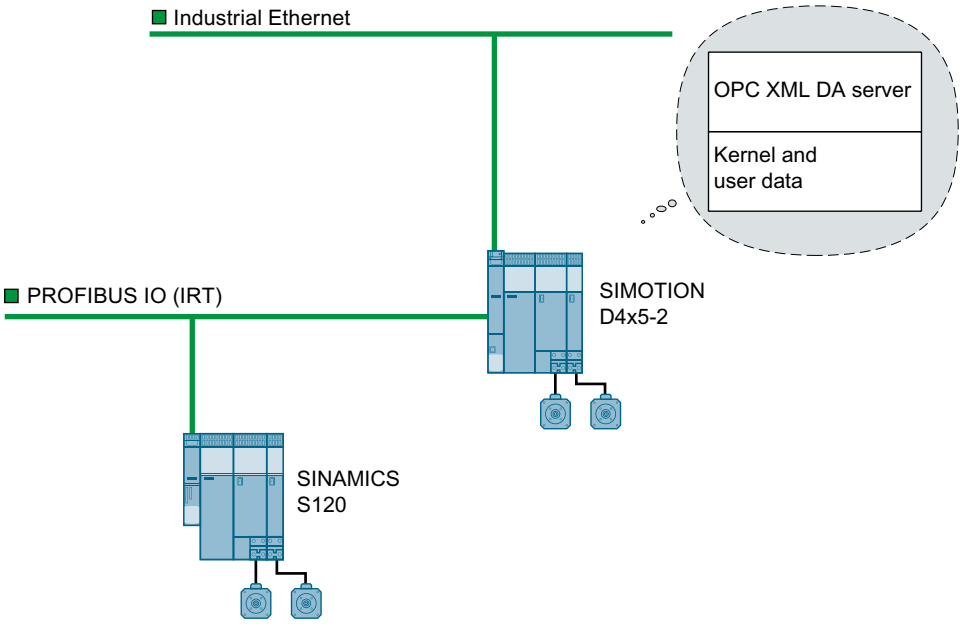

Figure 6-143 Overview at runtime (example)

Installation

Hardware and software requirements for creating the client application

Hardware requirements at the design stage

Note

You can freely select the programming environment. The following requirements are examples of Microsoft Visual Studio .NET, but are not mandatory.

Table 6-55 Hardware requirements at the design stage

Feature	Minimum requirement
Processor	Intel Pentium III or compatible, 800 MHz
Main memory	128 MB RAM

Software requirements at the design stage

Note

You can freely select the programming environment. The following requirements are an example for Microsoft Visual Studio .NET, but they are not binding.

- Microsoft Visual Studio .NET:
  http://msdn.microsoft.com/vstudio/ (http://msdn.microsoft.com/en-us)
  http://www.microsoft.com/net/ (http://www.microsoft.com/net/)
- Configuration file (WSDL), according to OPC XML- R1.0 Specification.

Configuring the SIMOTION device interface for using the client application

Configuring the interface

In order to establish a connection between a PC and a SIMOTION device when the system is running, you must carry out the following steps for the configuration of the Ethernet interface:

Table 6-56 Configuring the interface

Step	Procedure
1	You must activate the functionality in the SIMOTION project when configuring the control hardware via the "Ethernet Extended / Webserver" properties in the "Simotion IT - Web server settings" function.
2	The IP address of the SIMOTION control via which the OPC XML-DA server is accessed must be known. The IP address can be configured using the interface settings in HW Config.

OPC XML DA access protection

Settings for the OPC XML-DA access protection

WebCfg.xml provides a way of defining the access protection for OPC XML-DA via a `REALM`.

```
<CONFIGURATION_DATA>
...
  <SOAPAPP>
    <STATIC>
      <!--
        place all statically linked WebServices here
      -->
      <WEBSERVICE NAME="OpcXml" URL="/SOAP/OPCXML"
                  REALM="OPC_XML_USER_GROUP" />
      <WEBSERVICE NAME="TVS" URL="/SOAP/TVS" />
```

```
    </STATIC>
  </SOAPAPP>
...
</CONFIGURATION_DATA>
```

Authentication for read and write accesses

WebCfg.xml also allows read and write accesses to the OPC-XML server to be enabled or disabled depending on the logged in user.

The `<OpcXml>` entry in WebCfg.xml controls the associated access via a `REALM`.

```
<CONFIGURATION_DATA>
  <OPCBASESERVICE>
    <OpcXml READ="<ReadRealm>" WRITE="<WriteRealm>" />
    <OpcXmlWeb READ="<ReadRealm>" WRITE="<WriteRealm>" />
  </OPCBASESERVICE>
</CONFIGURATION_DATA>
```

OPC XML-DA variable access

Access to the OPC XML-DA data uses the same access syntax as that described in the Variable providers section of the SIMOTION IT Diagnostics and Configuration Manual.

Table 6-57 Examples of accessing variables

Variables	Access syntax
Global device variables	glob/<var name>
I/O variables	io/_direct.<var name> io/_image.<var name> io/_quality.<var name>
Unit (MCC/ST/LAD-FBD/DCC)	unit/<unit name>.<var name>

Access to the I/O variables (access syntax)

"_direct" addresses the direct I/O access (current value) to the I/O variables.

"_image": addresses the process image of the I/O variables

"_quality": addresses the Quality, i.e. the detailed status of the I/O variables

Example of a client application

Example

An example showing what a minimal client application for an OPC client can look like is included on the AddOn-DVD in the \VOL2\Addon\4_Accessories\SIMOTION_IT\7_Webservices\Example directory. The example explains the most important programming steps for the "Read" method with the Microsoft Visual Studio development environment.

The application example displays a **Read** button in a dialog box. When the button is pressed, the client connects to the SIMOTION IT OPC XML DA server and reads a variable. The result is displayed in the output field of the dialog box.

The dialog box of the application example is shown in the following figure:

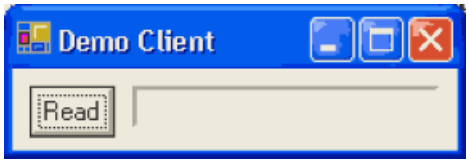

Figure 6-144 Demo client

Programming steps

The following programming steps are needed:

1. Create a new project with Microsoft Visual Studio .NET and import the WSDL file as interface description ("Add Web Reference" menu).
2. Create a dialog box with a text field and a **Read** button.
3. Enter the name assigned for the reference, e.g. "OPCXMLServer", in the program (`using DemoClient.OPCXMLServer`).
4. Declare the server URL in the program as follows:
   http://<IP-Adresse>/soap/opcxml
   Enter the IP address of your SIMOTION controller at <IP address>.
5. Instantiate the server proxy object in accordance with the code example and provide the call-up with the required parameters.
6. The required data is returned.

SIMOTION IT OPC XML–DA server interface

Overview

Introduction

This section describes the methods you can run across the interface to the OPC XML-DA V1.0 server. The server itself is integrated in the SIMOTION device.

For firmware version V4.2 and higher, a license is no longer required for using the OPC XML-DA server.

This is just a brief overview. These methods are described in detail in the document "OPC XML-DA Specification R1.0" of OPC Foundation.

You can find an up-to-date and detailed interface description on the home page of the OPC Foundation: http://www.opcfoundation.org (http://www.opcfoundation.org)

Methods which can be called synchronously

The SIMOTION IT OPC XML DA server provides the following methods, which can be called synchronously, under the "OpcXmlDaService" type:

Description of methods

Browse

The "Browse" method allows you to navigate through the available variables.

GetProperties

The "GetProperties" method can query the settings for a specific variable (e.g. access rights, time stamp, data type).

GetStatus

The "GetStatus" method supplies information about the server status, the program version and the supported interface version.

Read

The "Read" method reads out variable lists.

Subscribe

The "Subscribe" method passes a list of variable names and receives a handle for the subscription. This handle can be used in the SubscriptionPolledRefresh method to poll the values of the previously defined variables again. See Basics of subscriptions (Page 3853).

The buffering property, which corresponds to the "EnableBuffering" attribute, is not supported. This has an effect on the "SubscribeRequestItem" and "SubscribeRequestItemList" methods.

SubscriptionPolledRefresh

The "SubscriptionPolledRefresh" method returns the values of the variables written beforehand using the Subscribe method. The handle specifying the subscription is used as a parameter.

The "Holdtime" parameter defines the earliest possible response time. This limits the frequency of data transmission.

The "ReturnAllterms" parameter determines how the "WaitTime" parameter is used.

- True
  "WaitTime" is ignored, all requested values are returned immediately.
- False
  For the period set in the "WaitTime" parameter, the server checks whether one of the requested values has changed since the last call.
  If the specified time expires without a value having been changed, an empty response is returned.
  If values change during the specified time, the changed values are returned immediately and the polling ended.

SubscriptionCancel

The "SubscriptionCancel" method cancels the subscription and returns the subscription handle.

Which subscription is to be canceled, must be specified at the call.

If an asynchronous call form is used, the client is informed later of which subscription has been canceled, via a client handle.

Note

Once the subscription has been canceled, the subscription handle ceases to be valid for the client.

Write

The "Write" method writes variable lists.

Access to variables

Variable access using methods

Variables can be accessed via the methods which can be called synchronously and asynchronously.

Note

Information on accessing the variables of the different providers can be found in the *Variable providers* chapter of the *SIMOTION IT Diagnostics and Configuration* manual.

To make variables available on the SIMOTION IT OPC XML DA server, you have to declare them as VAR_GLOBAL. See the *Making unit variables available* chapter of the *SIMOTION IT Diagnostics and Configuration* manual.

6.2.3.3 Trace Interface via SOAP (TVS) web service

Trace overview

Introduction

The SOAP-based service provides a trace service option.

WebTrace uses the same runtime mechanisms as SIMOTION SCOUT Trace. The useful options are described in the chapters *Trace (device trace)* and *Trace (system trace)* of the *SIMOTION IT Diagnostics and Configuration* manual.

Trace-Service

The "Trace Interface via SOAP" web service enables variable values to be written to a buffer. The values are packed in files and can be retrieved asynchronously via an HTTP request.

This interface can only be used by client applications. The client enables the time characteristic of variables to be traced.

A WSDL file is available for creating the application.

Trace sequence

Introduction

When working with a trace, the trace can assume various states. The following graphic shows the possible states and transitions. The methods named are described in chapter "Trace interface".

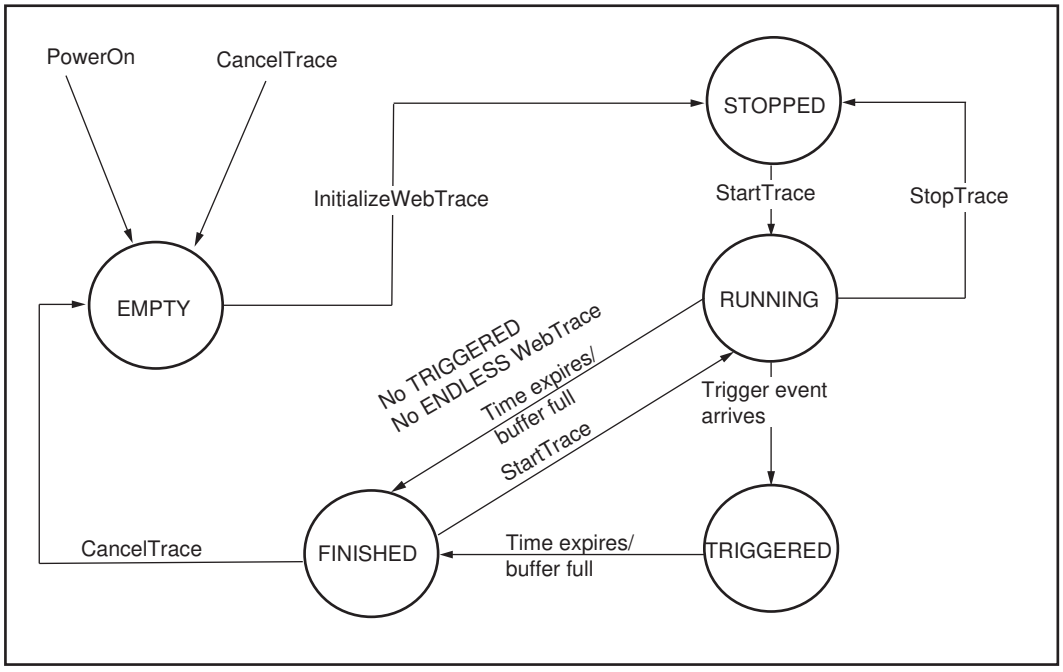

Figure 6-145 WebTrace

States

After a trace has been created with "InitializeWebTrace", this trace is in the STOPPED state. With "StartTrace", a trace starts up and writes the desired data to the buffer. Accordingly, a trace can be stopped again with "StopTrace". After the start, a trace switches to the RUNNING state. If the time specified in the call has expired, a trace assumes the FINISHED state. A trace can be deleted at any time with "CancelTrace" in order to create a new trace, for example.

Procedure/terms

HTTP methods - data exchange

The trace data are stored as compiled data on the RAM disk using the ReadData method. This data must be retrieved via ordinary HTTP requests.

Note

The data are not deleted by retrieval alone! To prevent the RAM disk from overflowing, an HTTP DELETE call to this URL must follow an HTTP GET call. (Reason: The use case under consideration is one in which a client may have to request the same trace data more than once, e.g. to compare traces that have already been executed.) These temporary data are completely deleted only after a CancelTrace operation, regardless of whether they have already been retrieved or not.

TRIGGERED

The trace offers a triggering option. Depending on the trigger method, different constants or variable symbols must be specified for this. The trace starts with:

- A rising edge (RE),
  if the variable exceeds the value of a constant.
- A falling edge (FE),
  if the variable falls below the value of a constant.
- Within a tolerance band (WIB),
  if the variable lies between two constants.
- Outside of a tolerance band (OOB),
  if the variable lies outside of a tolerance band.
- Bit mask has value (BHV),
  if the variable has a specified value after masking with a constant.

If the trace is set up in TRIGGERED mode, a trigger condition as described below must be specified. This trigger acts as a SingleShot. However, the MatchCountTriggerPoint parameter can be used to set the trigger for repeated occurrences (e.g. five: start trace/data recording only on the fifth time appearance of the trigger condition).

In this case, the trace takes place only after the trigger. The data are recorded for the duration specified during setup.

IMMEDIATE / ENDLESS

The counterpart to the TRIGGERED trace is the IMMEDIATE trace, which begins the trace immediately after the "StartTrace" call has occurred. In this case as well, the data are recorded for the duration specified during setup.

The ENDLESS Trace uses a ring buffer trace. Trigger conditions are not evaluated. ENDLESS Trace starts as soon as the StartTrace event arrives. However, it is terminated only when StopTrace is called explicitly. The size of the ring buffer must also be specified using the duration for the initialization call. Thus, an appropriate value must be found that uses fewer resources, but is sufficient to retrieve data in a timely manner via HTTP.

The size of the ring buffer (B) is determined from the number of variables (N), their size (S), the transferred time duration (t) and the cycle clock (T) in which they are traced.

$$B = t/T * \sum_{i=0}^{n-1} S^i$$

Within the transferred time duration, the buffer must be discharged at least once by calling the "readData" function in order to prevent the oldest trace data from being overwritten each time.

If the parameters require a larger memory area, the recording duration is reduced such that no more than the available memory space is occupied.

512 KB is available for SIMOTION C, SIMOTION D410-2, and 1024 KB is available as ring buffer for all other SIMOTION modules.

Error handling

All implemented methods of the TVS (trace via SOAP) supply either the requested data or status information, or an SOAP_FAULT. This behavior enables the use of the SoapFaultError in the .NET framework. The Try-Catch mechanism enables convenient error handling.

Basics of subscriptions

Introduction

"GetStatus" must be called in order to query the status of a trace. The fastest possible detection of a status change requires extremely frequent polling, which places an unnecessary load on the CPU in the control and causes heavy traffic on the network.

To optimize this operation, OPC XML DA provides "subscriptions". With subscriptions, a query does not receive a response until the required variable changes or a timeout occurs. Thus, the connection is kept open without causing traffic. As soon as relevant data are available for the client, these data are sent to the client.

The trace supports this mechanism via the SOAP web service also. However, in this case, only the status of the trace object is checked, as this is the only valuable information in this environment.

As soon as the status changes (e.g. RUNNING -> FINISHED), the clients that issued the query receive a response accordingly. In essence, any number of clients is possible (as long as there are sufficient resources).

Operational sequence

The operational sequence of a subscription is as follows:

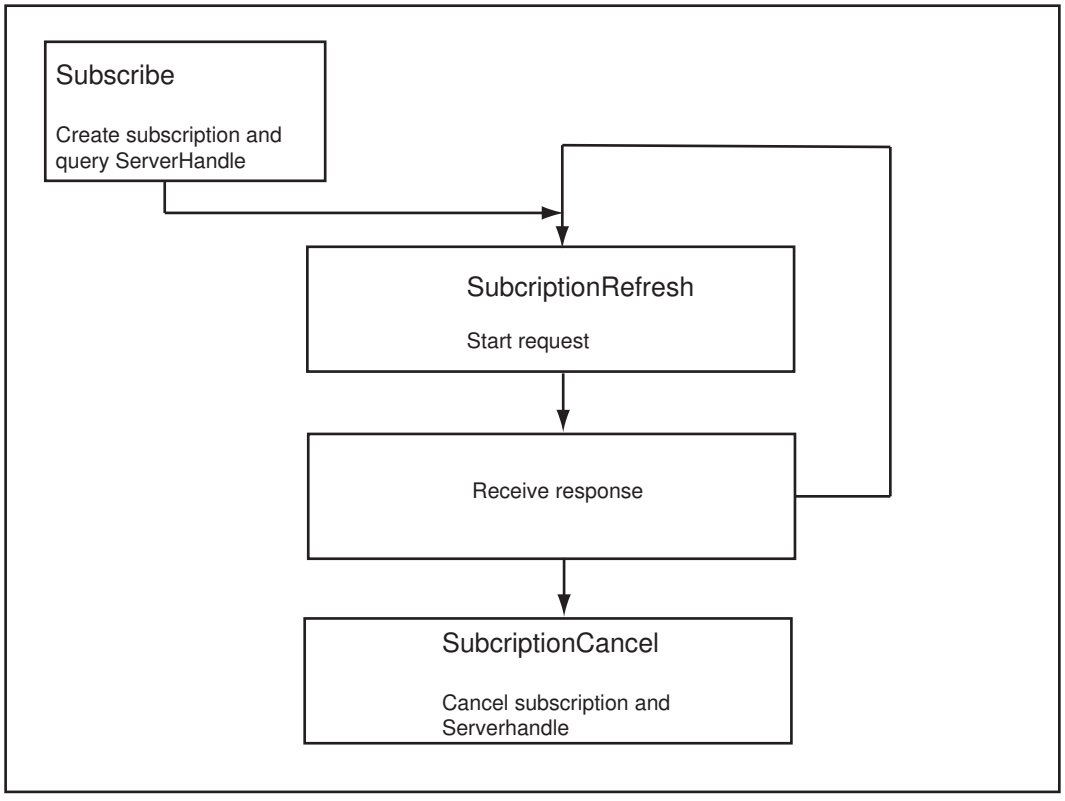

Figure 6-146 Subscription

First, a subscription must be created. It is answered with a unique ServerHandle, which is required for further communication.

Note

Up to 8 subscriptions per server are available

- With larger data requests, reduce the number of subscriptions and request more variables in fewer subscriptions.

SubscriptionRefresh can be called as often as necessary to start a new query. This request receives two time specifications in milliseconds as parameters:

- HoldTime:
  This time indicates the minimum hold time for the response, irrespective of whether the status has changed.
- WaitTime:
  The WaitTime begins after the HoldTime has expired. If the trace status has changed, the response to the current status is sent immediately. If there is no change, the response is sent once the WaitTime has expired.

The exact method calls are explained in the next section.

Interface

Global definitions

TraceStateEnum

Enumerator that indicates the status of the trace object.

Declaration:

```
public enum TraceStateEnum
{
  RUNNING,
  STOPPED,
  ERROR,
  EMPTY,
  FINISHED,
  TRIGGERED
}
```

TraceDataCycleEnum

Enumerator that specifies the cycle clock in which the data are to be traced. It must be noted here that large traces may cause a level overflow.

Declaration:

```
public enum TraceDataCycleEnum
{
  IPO1,
  IPO2,
  SERVO
}
```

Structure VDSC

Structure that contains information about the traced variables. These are:

- Variable name `VarName`
- Variable type `VarType` in S7 notation (e.g. DINT or BYTE)
- `VarOffset` specifies the offset of the variable within the data stream (relative to the start of the I/O container)
- Variable length `VarLen` (optional)

Declaration:

```
public class VDSC
{
  public string VarName;
  public string VarType;
  public System.UInt32 VarOffset;
  public System.UInt32 VarLen;
}
```

TriggerCondition

Structure indicating the trigger of a trace. The TriggerCondition contains the variable to be compared in symbolic names according to VarProvider notation.

- `Variable` refers to the variable for comparison.
- `Constant1` is a constant which is set according to the trigger type.
- `Constant2` is a constant which is set according to the trigger type.
- `Operation` indicates the comparison type as enumerator `TriggerOperationType`.
- `MatchCountTriggerPoint` indicates how many times the trigger condition must apply before the trigger is activated and data tracing starts.
- `GlobalTriggerID` is optional and contains the unique ID, which is generated by the browser when a distributed trace is set up.

Declaration:

```
public class TriggerCondition
{
  public string Variable;
  public string Constant1;
  public string Constant2;
  public TriggerOperationType Operation;
  public System.UInt32 MatchCountTriggerPoint;
  public System.UInt32 GlobalTriggerID;
}
```

For this purpose, the comparison type:

Call:

```
public enum TriggerOperationType {
 RE,
 FE,
 WIB,
 OOB,
 BHV
 }
```

The following table gives an overview of various possible combinations of trigger types and constants.

Trigger type	Symbol	Description	Constant1	Constant2
Rising Edge	RE	Triggered if variable exceeds the value of Constant1 in positive direction	Limit exceeded	-Not used-
Falling Edge	FE	Triggered if variable exceeds the value of Constant1 in negative direction	Limit exceeded	-Not used-
Within a tolerance Band	WIB	Triggered if variable is located within the interval spanned by Constant1 and Constant2	Lower limit	Upper limit
Out of tolerance Band	OOB	Triggered if variable is located outside the interval spanned by Constant1 and Constant2	Lower limit	Upper limit
Bit pattern	BHV	The bit pattern triggers if the relevant bit is 1 both in the bit mask and in the comparison result. ((v&c1)==c2)	Bit mask	Result of comparison

Overview of trigger types and constants

Enumerator that determines the type of trace.

Call:

```
public enum TraceStartTypeEnum
{
  IMMEDIATE,
  ENDLESS,
  TRIGGERED
}
```

Methods

StartTrace

The `StartTrace` method starts an initialized trace. The SoapFault "No Trace available" is returned if a trace has not yet been initialized. `StartTrace` is ignored (with a positive result) if the trace is already in progress.

The `GlobalTriggerID` must be transferred for a distributed trace. The trigger ID is a unique ID, which unambiguously identifies the station currently responsible for triggering; the same ID is used for all stations.

When a trace is restarted, the trigger ID must be reassigned so that the trigger events can be distinguished from one another.

Call:

```
public TVS_Client.TVS.StartTrace_Response StartTrace
(
  uint GlobalTriggerID
)

public class StartTrace_Response
{
  public TraceStateEnum TraceState;
}
```

StopTrace

The `StopTrace` method stops a trace in progress. The "No Trace available" SoapFault is returned when a trace has not yet been initialized. This is ignored (with a positive result) if the trace has already stopped.

Call:

```
public TVS_Client1.TVS.StopTrace_Response StopTrace ( )

public class StopTrace_Response
{
  public TraceStateEnum TraceState;
}
```

CancelTrace

The `CancelTrace` method deletes an active trace. The traces switches to EMPTY status, and all trace data are deleted. (Note: Data blocks of the WebTrace that have been requested but have not yet been retrieved are also deleted (see WebTrace::ReadData())

The "No Trace available" SoapFault is returned when a trace has not yet been initialized.

Call:

```
public TVS_Client.TVSIO.CancelTrace_Response CancelTrace ()

public class CancelTrace_Response
{
  public TraceStateEnum TraceState;
}
```

GetStatus

The `GetStatus` method returns the current status of the trace. When a trace object is deleted or has become invalid, then TraceIsValid will contain "false". In this case, the trace must be deleted via `CancelTrace`.

Call:

```
public TVS_Client.TVSIO.GetStatus_Response GetStatus ( )

public class GetStatus_Response
{
  public bool TraceIsValid;
  public TraceStateEnum TraceState;
}
```

ReadData

The `readData` method saves trace data on the RAM disk and supplies the URLs of the files in the return value. These data can be retrieved from the client with an HTTP-GET request.

The "No Tracedata available" SoapFault is returned if no trace data are available.

Call:

```
public ReadData_Response ReadData()

public class ReadData_Response
{
  public TraceStateEnum TraceState;
  public string[] URL;
}
```

InitializeWebTrace

A trace is created with `InitializeWebTrace`. `VariablesToTrace` is the list of symbolic names in accordance with VarProvider notation. `TraceDataCycle` determines the cycle clock in which the data is to be recorded. `TraceStartType` determines the type of trace. `Duration` specifies the duration of the recording in milliseconds. With an endless trace, this parameter specifies the size of the ring buffer in milliseconds.

`MatchCountTriggerPoint` in `TriggerInformation` determines how often the trigger must occur before it actually performs a trigger operation and, as a result, starts the recording. `Pretrigger` specifies the number of values which are to be recorded prior to triggering ("history").

Call:

```
public InitializeWebTrace_Response InitializeWebTrace
(
  string[] VariablesToTrace,
  TraceDataCycleEnum TraceDataCycle,
  TraceStartTypeEnum TraceStartType,
  uint Pretrigger,
  uint Duration,
  TriggerCondition TriggerInformation,
  string[] DevicesInvolved
)
```

```
public class InitializeWebTrace_Response
{
  public VDSC[] CurrentlyTracedVariables;
  public TraceStateEnum TraceState;
  public string UID;
  public string[]DevicesInvolved;
}
```

InitializeWebTraceEx

InitializeWebTraceEx is identical to InitializeWebTrace apart from the return value, where the variables are sorted according to their particular offset.

GetTraceParameters

`GetTraceParameters` can be used to read out an existing trace configuration.

Only one WebTrace is returned (if one actually exists).

Call:

```
public GetTraceParameters_Response GetTraceParameters
(
  string UID
)

public class GetTraceParameters_Response
{
  public TraceTypeEnum TraceType;
  public VDSC[] CurrentlyTracedVariables;
  public TraceStateEnum TraceState;
  public TraceDataCycleEnum TraceDataCycle;
  public string UID;
  public TraceStartTypeEnum TraceStartType;
  public unsignedInt Pretrigger;
  public unsignedInt Duration;
  public TriggerCondition TriggerInformation;
  public unsignedInt IOContainerOffset;
  public unsignedInt IOContainerLength;
  public hexBinary ClientHandle;
  public string[]DevicesInvolved;
}
```

EnableTrigger

Only for the distributed trace.

When a distributed trace has been set up and started, this activates the triggers. The `TriggerID` must be unique so that the stations can differentiate between them and do not lose their way on the network. The sequence is important: All traces should be running before the trigger is activated, to avoid loss of trigger events.

Return value: TriggerState activated or not activated.

Call:

```
public EnableTrigger_Response EnableTrigger
(
    uint TriggerID
)

public class EnableTrigger_Response
{
  public TraceStateEnum TraceState;
}
```

ReadData

With ReadData, the TVS service is requested to read out the trace buffer and pack the data in temporary files. These can then be accessed via HTTP under the relative paths specified in URL. If the buffer is empty, a response is made to the request with the "No Tracedata available" SoapFault. Currently, a maximum of 8 compiled files with a maximum of 8,192 recording points are provided for each request.

ReadDataArchive

If a trace is in the STOPPED state, this function can be used to request the recorded data.

The function supplies a URL, from which a WTRC data archive can be downloaded and then displayed in the WebTraceViewer.

Note

The WTRC file is deleted as soon as it has been downloaded.

Call:

```
public ReadDataArchive_Response ReadDataArchive ()

public class ReadDataArchive_Response
{
  public TraceStateEnum TraceState;
  public string URL;
}
```

ReadDataArchives

Only for the distributed trace.

ReadDataArchives automatically retrieves the trace data for all stations involved in a distributed trace and combines them in a WTRC file. The `URLField` array is used to transfer a list of the URLs for all the stations involved in the trace. The trace must be in the STOPPED state in order to use this method.

The return value is identical to that for ReadDataArchive.

Call:

```
public ReadDataArchives_Response ReadDataArchives
(
  public string[] URLField;
)

public class ReadDataArchives_Response
{
  public TraceStateEnum TraceState;
  public string URL
}
```

Subscriptions

Introduction

The subscription methods are listed below.

Subscribe

A subscription is created using the `Subscribe` method. The response is a `ServerHandle` that can be used to uniquely identify a subscription operation. In addition, the current TraceStatus is supplied.

Call:

```
public TVS_Client.TVS.Subscribe_Response Subscribe ( )

public class Subscribe_Response {
  public System.UInt32 ServerHandle;
  public TraceStateEnum TraceState;
}
```

SubscriptionRefresh

SubscriptionRefresh is used to query the status of the trace again; the trace was previously queried with the Subscribe method. The server response is received after HoldTime (milliseconds) + WaitTime (milliseconds), if the status has not changed during this time, or the response is received (at the earliest) after the HoldTime has expired and before the WaitTime has expired, if the status of the trace changes during the WaitTime . As such, the response is never expected before the HoldTime has elapsed.

In the response, StateChanged indicates whether the status has changed between request and response (true) or whether the TraceState status matches the status during the request (false = WaitTime expired).

Call:

```
public TVS_Client.TVS.SubscriptionRefresh_Response SubscriptionRefresh (
  System.UInt32 ServerHandle ,
  System.UInt32 WaitTime ,
  System.UInt32 HoldTime
)

public class SubscriptionRefresh_Response {
 public bool StateChanged;
 public TraceStateEnum TraceState;
}
```

SubscriptionCancel

With `SubscriptionCancel`, a subscription is canceled and the resource is enabled. The response indicates whether the Cancel operation was successful. Any current SubscriptionRefreshs are cancelled and responses sent immediately.

Call:

```
public TVS_Client.TVS.SubscriptionCancel_Response SubscriptionCancel (
  System.UInt32 ServerHandle )

public class SubscriptionCancel_Response {
  public bool SubscriptionCanceled;
 }
```

6.2.4 Appendix

6.2.4.1 MWSL functions

AddHTTPHeader

Syntax	`AddHTTPHeader(<Http-Header>)` This command can be used to add HTTP headers from MWSL . These are then not transmitted as part of the document but rather in the protocol portion of HTTP. The `AddHTTPHeader` command must therefore come before the HTML tag of a page. However, it is important to make sure that no MWSL functions that result in output into the page are used before the HTML tag.	
Parameters	`<Http-Header>`	Character string that ends with \r\n. If multiple HTTP headers are to be entered (only possible with `Set-cookie`), the individual headers must be separated by \r\n.

MWSL example	`<MWSL>`
	`var strCookie;`
	`strCookie = "Set-cookie: siemens_automation_language=de";`
	`AddHTTPHeader( strCookie );`
	</MWSL>
	`<html>`
	`<head>`
	`<title>`
	`MWSL Function AddHTTPHeader`
	`</title>`
	`</head>`
	`<body style="background-color:#DCDCDC">`
	`<h2>Testpage</h2>`
	`</body>`
	`</html>`	

createGUID

Syntax	`String createGUID()` Generates a unique alphanumeric ID in the system.	
Parameters		

Example	`<MWSL>`
	`write(createGUID());`
	`</MWSL>`	

Output	5022420B-02A7-0000-B362-3B7F4E87148D	
Valid as of	V4.4	

DecodeString

Syntax	`string DecodeString(<string>)` Converts a string encoded with EncodeString back to its original.	
Parameters	`<string>`	String in which URL-coded special characters are converted back to normal characters.
Example	`<MWSL>` `  var tmpString = "Straße Flüsse Gelände Vögel";` `  write("Original: " + tmpString + " ");` `  var tmpEncodedString = EncodeString(tmpString);` `  write("Encoded: " + tmpEncodedString + " ");` `  var tmpDecodedString = DecodeString(tmpEncodedString);` `  write("Decoded: " + tmpDecodedString);` `</MWSL>`	
Output	`Original: Straße Flüsse Gelände Vögel ` `Encoded:` `Stra&#xdf;e&#x20;Fl&#xfc;sse&#x20;Gel&#xe4;nde&#x20;V&#xf6;gel ` `Decoded: Straße Flüsse Gelände Vögel`	
Valid as of	V4.4	

die

Syntax	`die(<Param0>,<Param1>,...)` Break program execution.	
Parameters	<Param0>,<Param1>,...	Concatenation and output of the parameters.

Example	`<MWSL>`
	`  function dieTest()`
	`  {`
	`  write("Is there a life after die?");`
	`  die("--- ",123," ---");`
	`  };`
	`  dieTest();`
	`  write("There is a life after die");`
	`</MWSL>`	

Output	Is there a life after die?--- 123 ---	
Valid as of	V4.4	

EncodeString

Syntax	`string EncodeString(<string>)` Replaces special characters by their URL-coded hex value (%hh).	
Parameters	`<string>`	String in which the replacement will be performed.

Example	<MWSL>
	var tmpString = "Straße Flüsse Gelände Vögel";
	write("Original: " + tmpString + "
	");
	var tmpEncodedString = EncodeString(tmpString);
	write("Encoded: " + tmpEncodedString + "
	");
	var tmpDecodedString = DecodeString(tmpEncodedString);
	write("Decoded: " + tmpDecodedString);
	</MWSL>

Output	Original: Straße Flüsse Gelände Vögel Encoded: Straße Flüsse Gelände Vögel Decoded: Straße Flüsse Gelände Vögel
Valid as of	V4.4

ExistFile

Syntax	long ExistFile(<file name>) Checks whether a file with the name <file name> exists. The function returns the file length as the returned value. Special aspect due to the MWSL Compiler: Because all files that are associated with the MWSL Compiler (*.mwsl, *.msl, *.xsl, *.js, *.xmlf, *.css) are only present on the memory card in a compiled form, a ExistFile call must always be made to the compiled file (*.cms) in this case.	
Parameters	<file name>	Name of the sought file. The file path refers to the root directory of the user USER/SIMOTION/HMI.

Example	<MWSL>
	var tmpLength = ExistFile("/files/test.mwsl.cms");
	write("File length:"+ tmpLength);
	</MWSL>	

Output	File length: 38	
Example	<MWSL> var tmpLength = ExistFile("/files/mydata.txt"); write("File length:"+ tmpLength); </MWSL>	
Output	File length: 22	
Valid as of	V4.4	

ExistVariable

Syntax	`bool ExistVariable(<Variable Name>, <Variable Source>)` This function queries the presence of a variable. It returns `true` or `false`.	
Parameters	`<variable name>`	Variable name
	`<variable source>`	See GetVar (Page 3869)
Example	`ExistVariable("DeviceInfo.BZU", "PROCESS")`. If the process variable "DeviceInfo.BZU " existis, `true` is returned, otherwise `false`.	

See also

Conditional operations (Page 3812)

GetLanguage

Syntax	`String GetLanguage()` Returns the currently set language. The return value depends on whether one of the following values is found in the displayed sequence: 1. Content of the cookie `siemens_automation_language` if the cookie exists. 2. Value of the HTTP header `Accept-Language` if the value exists. 3. Return of the `SERVEROPTIONS` value `language` set in WebCfg.xml.	
Parameters		

Example	`<MWSL>`
	`  write("The currently set language is'" + GetLanguage() + "'");`
	`</MWSL>`	

Output	The currently set language is 'de'	
Valid as of	V4.4	

GetVar

Syntax	`GetVar(<Variable Name>, <Variable Source>, <Format String>);` This function returns the value of a variable from a variable source. If a parameter does not exist, "null" will be returned.	
Parameters	`<variable name>`	Variable name
	`<variable source>`	Name of variable source Valid values: • `URL` • `HTTP` • `PROCESS` Read variables from the providers. • `COOKIE` Read variables from the HTTP header of the cookie • `XML` • `SENDPAGE` • `DEFAULT` The default setting is `PROCESS`. If not source is stated, `DEFAULT` is selected, that is, the variable provider. The name of the variable providers, such as `SIMOTION`, `MINIWEB`, etc., are not designations for variable sources. The suitable provider is searched for in the web server based on the variable name.
	`<Format String>`	The handling of the format string depends on the variable source. Thus, this property is not possible for the variable sources `COOKIE` and `URL`. Syntax of an HTTP variable: Variables and HTTP header information (Page 3807) Syntax of a process variable: Global variables (Page 3802)

Example	`GetVar("var/userData.user1");` Returns the content of the variable `var/userData.user1`. Because `PROCESS` is the default variable source, the result corresponds to that of the following call. `GetVar("var/userData.user1", "PROCESS");` Returns the content of the variable `var/userData.user1`, the variable source `PROCESS`. `GetVar("Parameter", "URL");` Returns the content of the `Parameter` variable from the URL. `GetVar("Accept-Language", "HTTP", "?-" )` Returns the content of the HTTP variable `Accept-Language`. The format string "`?-`" indicates that all characters up to the first occurrence of the "–" character will be returned. `GetVar("var/userData.user1", "PROCESS", "[2,3]");` Returns three characters, starting from position 2 of the process variable `var/userData.user1`. The result is characters 2-5 of the process variable. `GetVar("Accept-Language", "HTTP", "[3,0]" )` Returns the content of the HTTP variable `Accept-Language` starting from the third character.

InsertFile

<table>
<tr><td>Syntax</td><td colspan="2">InsertFile(<File name>)

This command allows an existing text file to be imported individually.
The text file is interpreted before insertion with MWSL and embedded into the existing source text at the insertion point in the target file.
If the file has an ending (*.mwsl, *.msl, *.xsl, *.js, *.xmlf, *.css) associated with the MWSL compiler, the MWSL scripts it contains will be run.
URL parameters can be passed with usual syntax (<file name>?<parameter>=<value>).</td></tr>
<tr><td>Parameters</td><td><file name></td><td>Name of text file, including path.</td></tr>
<tr><td>Example</td><td colspan="2">
<pre>
<HTML>
  <HEAD>
  </HEAD>
  <BODY>
   [...]
   <table>
     [...]
     <tr>
        <td>
          An HTML file is now displayed on the right-hand page.
        </td>
        <td>

        </td>
        <td>
          <MWSL>
          if(ExistFile("/FILES/TMPL/Output.mwsl.cms") > 0)
          {
             InsertFile("/FILES/TMPL/Output.mwsl?myparam=123");
          }
          </MWSL>
        </td>
     </tr>
     [...]
   </table>
   [...]
  </BODY>
</HTML>
</pre>
In the right-hand column of the table, the content of the file Output.mwsl is inserted and displayed in HTML format.
</td></tr>
</table>

IsAuthAlgo

Syntax	`bool IsAuthAlgo(<parAuthMethod>)` Returns true if the user logged in at the time of calling was successfully identified by the authentication method specified in `parAuthMethod`.	
Parameter	`<parAuthMethod>`	Possible specifications: `FormulaAuthentication`, `DigestAuthentication`, `BasicAuthentication`, `CertificateAuthentication`

Example	`<MWSL>`
	`  write(IsAuthAlgo("FormulaAuthentication"));`
	`</MWSL>`	

Output	1	
Note	`IsAuthMethod` returns the value '1' if no user is logged in. This behavior depends on the system because the 'Anonymous' is always logged in even when nobody else is logged in.	
Valid as of	V4.4	

isFinite

Syntax	`bool isFinite(<value>)` Returns false if the passed value is `NaN` or infinite.	
Parameters	`<value>`	Value for the check.
Example	`<MWSL>` `  write("Test of the number 123456 - isFinite: ");` `  write(isFinite(123456) + " ");` `  write("Test of NaN - isFinite: ");` `  write(isFinite(parseInt("ABC", 2)));` `</MWSL>`	
Output	`Test of the number 123456 - isFinite: 1` `Test of NaN - isFinite: 0`	
Valid as of	V4.4	

isNaN

Syntax	`bool isNaN(<value>)` Checks whether the passed value is an invalid double.	
Parameters	`<value>`	Value for the check.
Example	`<MWSL>` `  write("Test of 123456 - isNaN: ");` `  write(isNaN(123456) + " ");` `  write("Test of NaN - isNaN: ");` `  write(isNaN(parseInt("ABC", 2)));` `</MWSL>`	
Output	`Test of 123456 - isNaN: 0` `Test of NaN - isNaN: 1`	
Valid as of	V4.4	

IsSSL

Syntax	`bool IsSSL()` Returns true if the client is connected to the server via an SSL connection.	
Parameters		

Example	`<MWSL>`
	`write("If the client is connected to the server via an SSL connection:");`
	`write(IsSSL());`
	`</MWSL>`	

Output	`If the client is connected to the server via an SSL connection: 1`	
Valid as of	V4.4	

parseFloat

Syntax	`double parseFloat(<string>)` Conversion of a string to a double value.	
Parameters	`<string>`	String to be converted
Example		
Output		
Valid as of	V4.4	

parseInt

Syntax	`int parseInt(<value>,[<base>])` Conversion of a string to an integer value.	
Parameters	`<value>`	String to be converted If a value starts with `0x`, it will be interpreted as hexadecimal. Values starting `0` will be interpreted as octal. All other values are shown in decimal format. Maximum value: `0x7FFFFFFF`. If values exceed the upper limit, the maximum value `2147483647` is returned. If the value shall be shown as a negative number, put "–" in front.
	<base>	Basis to which the string shall be converted. Values: "2" = binary, "8" = octal, "16" = hexadecimal. No value = decimal interpretation.

Example	<MWSL>
	var tmpVar0 = "0x1";
	var tmpVar1 = "0x2";
	var tmpSum = tmpVar0 + tmpVar1;
	write(tmpSum + "
	");
	var tmpVarInt0 = parseInt(tmpVar0);
	var tmpVarInt1 = parseInt(tmpVar1);
	tmpSum = tmpVarInt0 + tmpVarInt1;
	write(tmpSum + "
	");
	tmpVar0 = "101";
	tmpVar1 = "100";
	tmpSum = tmpVar0 + tmpVar1;
	write(tmpSum + "
	");
	tmpVarInt0 = parseInt(tmpVar0,"2");
	tmpVarInt1 = parseInt(tmpVar1,"2");
	tmpSum = tmpVarInt0 + tmpVarInt1;
	write(tmpSum + "
	");
	tmpVar0 = "A";
	tmpVar1 = "B";
	tmpSum = tmpVar0 + tmpVar1;
	write(tmpSum + "
	");
	tmpVarInt0 = parseInt(tmpVar0,"16");
	tmpVarInt1 = parseInt(tmpVar1,"16");
	tmpSum = tmpVarInt0 + tmpVarInt1;
	write(tmpSum + "
	");
	
	</MWSL>

Output	0x10x2 3 201 9 AB 21
Valid as of	V4.4

ProcessXMLData

Syntax	`ProcessXMLData( <DATA>, <TEMPLATE>)` With this command, dynamic HTML files can be generated based on a data and template file. The parameter `<DATA>` contains the data that is interpreted with the template in parameter `<TEMPLATE>`. `ProcessXMLData` combines the two files into one HTML file. The data nodes of the data file are evaluated by the template file to be displayed. This produces a separation of the data from the content. With a subsequent change to the template file, the appearance of the pages can be altered without changing the data. This makes it easier to add to data. Using different templates, it is possible to generate pages with the same data but completely different appearances. Additional information about the template mechanism: Mode of operation of the template mechanism (Page 3816)	
Parameter	`<DATA>`	Data for the dynamic HTML file A file or a variable containing the data can be passed as a parameter. File: "`<EXTERNAL SRC=\"/datafile.xml \"/>`", in which `datafile.xml` is the file containing the data. Variable: `<variable name>` Specifies the variable name.
	`<TEMPLATE>`	Template (how the data is displayed) A file or a variable containing the templates can be passed as a parameter. File: "`<TEMPLATES><EXTERNAL SRC=\"/Template.xml\"/> </TEMPLATES>`", in which "Template.xml" is the file that contains the templates. Variable: `<variable name>` Specifies the variable name.

Example	`ProcessXMLData("<EXTERNAL SRC=\"/FILES/MWSL/variables.xml \"/>",`
	`"<TEMPLATES><EXTERNAL`
	`SRC=\"/FILES/MWSL/variablesTemplate.xml\"/></TEMPLATES>");`	

Example MWSL	An example can be found in Chapter 'MiniWeb Server Language (MWSL)' in the 'Examples' (Page 3827) section in the TestTemplate.mwsl program.	

ReadFile

Syntax	`string ReadFile(<file name>)` This function is similar to the function `InsertFile`, except that the content of the file is not written, but only returned as a return value.	
Parameters	`<file name>`	Name of text file, including path.

Example	`<MWSL>`
	`  var tmpFile = ReadFile("/files/include.mwsl");`
	`  write(tmpFile);`
	`</MWSL>`	

Output	The content of file `include.mwsl` is written to variable `tmpFile` and then written into the output.	
Valid as of	V4.4	

ReplaceString

Syntax	`ReplaceString(<variable name>,<search pattern>,<replacement string>)` Replacing strings.	
Parameters	`<variable name>`	Variable in which the characters shall be replaced.
	<search pattern>	Search pattern for replacing the characters.
	<replacement string>	string that is inserted.

Example	`<MWSL>`
	`  var tmpString = "Ein String";`
	`  var tmpOutString;`
	`  tmpOutString = ReplaceString(tmpString,"n","N");`
	`  write("Result: " + tmpOutString);`
	`</MWSL>`	

Output	Result: EiN StriNg	
Valid as of	V4.4	

SetVar

Syntax	`SetVar(<Variable Name>, <Value>)` This function is used to place process variables.	
Parameters	`<variable name>`	Variable name
	<value>	The new variable value.
Example	`SetVar("var/userData.user1", "NewUserData");` Sets the process variable `var/userData.user1` to the value `NewUserData`.	

ShareRealm

Syntax	`ShareRealm(<Group>)` Indicates whether the current user is a member of the group that is passed as a parameter. The return value can be `true` or `false`.	
Parameters	`<Group>`	The following groups are currently allowed as parameters: • `NO_REALM` No group association • `ANY_REALM` Any group association • `[group name]` Member of group `[group name]` Groups depend on configuration.
Example	`write(ShareRealm ("ANY_REALM"));` If the current user is in any defined group, 1 is output. Otherwise, 0 is output.	

MWSL example	`<MWSL>`
	`  if (ShareRealm("ANY_REALM"))`
	`  {`
	`  write ("<tr valign=\"baseline\">\r\n");`
	`  write ("<td><H2>Hello " + GetVar( "Username",  "HTTP") +`
	`  ", you're successfully logged in.</H2></td>\r\n");`
	`  write ("</tr>\r\n");`
	`  }`
	`</MWSL>`
	If the user is a member of any group, the instructions in the curly brackets are carried out.	

write

Syntax	`write(<Text>)` The `write` function writes text to the output of an HTML page.	
Parameters	`<Text>`	Text, return values of functions, or variable contents can be passed.

Example	`<MWSL>`
	` write("Hello World");`
	` // Output: Hello World`
	
	` write("Hello" + " " + "World");`
	` // Output: Hello World`
	
	` write(GetVar("Parameter", "URL"));`
	` // Output of the content of variable Parameter in the URL.`
	
	` write(5+6);`
	` // Output: 11`
	
	` var zahl1 = 5;`
	` var zahl2 = 7;`
	` var string = "Hello";`
	` write(string + ": " + zahl1 + zahl2);`
	` // Output: Hello: 57`
	
	` write(zahl1 + zahl2);`
	` // Output: 12`
	
	` write("Content of Parameter: " + GetVar("Parameter", "URL"));`
	` // Ausgabe: Content of Parameter: Hello`
	` // if Parameter contains the string "Hello".`
	`</MWSL>`	

WriteVar

Syntax	`WriteVar(<Variable Name>, <Variable Source>, <Format String>);`
	
	This command writes the content of a variable to the output.
	
	The functionality of the function `WriteVar` is similar to that of the function `GetVar`.
	`WriteVar` is equivalent to the call: `WriteVar(…) === write( GetVar (…) )`
	
	The sole difference is that `WriteVar` outputs the content of the specified variable, while `GetVar()` returns the content as a return value.	

Parameters	`<variable name>`	Variable name
	`<variable source>`	Name of variable source Valid values: • `URL` • `HTTP` • `PROCESS` Read variables from the providers. • `COOKIE` Read variables from the HTTP header of the cookie • `XML` • `SENDPAGE` • `DEFAULT` The default setting is `PROCESS`. If not source is stated, `DEFAULT` is selected, that is, the variable provider. The name of the variable providers, such as `SIMOTION`, `MINIWEB`, etc., are not designations for variable sources. The suitable provider is searched for in the web server based on the variable name.
	`<Format String>`	The handling of the format string depends on the variable source. Thus, this property is not possible for the variable sources `COOKIE` and `URL`. The call syntax is equivalent to that of the GetVar() (Page 3869) function.

Example	<MWSL>
	write(GetVar("Parameter", "URL"));
	// The content of the variable Parameter is output here.
	//GetVar returns the value of the variable,
	// which is then written to the output with write.
	// (See also GetVar() and write().)
	// The same output can also be achieved with the following
	// command.
	WriteVar("Parameter", "URL");
	//WriteVar writes directly to the output and supplies
	// no return value
	
	WriteVar("var/userData.user1");
	// Outputs the content of var/userData.user1, which is a
	// process variable.
	
	WriteVar("Accept-Language", "HTTP", "?-")
	// Outputs the content of the HTTP variable "Accept-Language"
	// up to the "-" character.
	
	WriteVar("var/userData.user1", "PROCESS", "[2,3]");
	// Outputs characters 2 - 5 of the process variable var/userData.user1.
	
	WriteVar("Accept-Language", "HTTP", "[3,0]")
	// Outputs the content of the HTTP variable "Accept-Language"
	// starting from the third character.
	</MWSL>

Example	<MWSL>
	// Identical calls
	WriteVar("var/modeOfOperation");
	WriteVar("var/modeOfOperation", "PROCESS");
	WriteVar("var/modeOfOperation", "DEFAULT");
	</MWSL>

See also

Global variables (Page 3802)

WriteXMLData

Syntax	`WriteXMLData ( <DATA>, <TEMPLATE>)` WriteXMLData outputs the data in contrast to ProcessXMLData. Instead of `write( ProcessXMLData(…));` , you can also write `WriteXMLData(…);` . `WriteXMLData();` is assigned the same parameters as `ProcessXMLData();`.	
Parameter	`<DATA>`	Data for the dynamic HTML file A file or a variable containing the data can be passed as a parameter. File: "`<EXTERNAL SRC=\"/Datendatei.xml \"/>`", in which "data file.xml" is the file containing the data. Variable: `<variable name>` Specifies the variable name.
	`<TEMPLATE>`	Template (how the data is displayed) A file or a variable containing the templates can be passed as a parameter. File: "`<TEMPLATES><EXTERNAL SRC=\"/Template.xml\"/></TEMPLATES>`", , in which "Template.xml" is the file containing the templates. Variable: `<variable name>`

Example	`WriteXMLData("<EXTERNAL SRC=\"/FILES/MWSL/variables.xml \"/>",`
	`"<TEMPLATES><EXTERNAL`
	`SRC=\"/FILES/MWSL/variablesTemplate.xml\"/></TEMPLATES>");`
	
	Additional information about the template mechanism: Mode of operation of the template mechanism (Page 3816)	

NodeIndex

Variable	NodeIndex	NodeIndex is a process variable that is available when a template is parsed. This variable outputs the number of nodes that have already been run through. The access is exactly the same as for other variables of the PROCESS variable source. Additional information about the template mechanism: Mode of operation of the template mechanism (Page 3816)
Example	<?xml version="1.0" ?> <TEMPLATES> <TEMPLATE NAME="Variable"> <POSITION NAME="LINE"> <![CDATA[<MWSL> WriteVar("NodeIndex ") </MWSL>]]> </POSITION> </TEMPLATE> </TEMPLATES>	

NodeLevel

Variable	NodeLevel	NodeLevel is a process variable that is available when a template is parsed. This variable outputs the hierarchy level of the current node. The access is exactly the same as for other variables of the PROCESS variable source. Additional information about the template mechanism: Mode of operation of the template mechanism (Page 3816)
Example	<?xml version="1.0" ?> <TEMPLATES> <TEMPLATE NAME="Variable"> <POSITION NAME="LINE"> <![CDATA[<MWSL> WriteVar("NodeLevel") </MWSL>]]> </POSITION> </TEMPLATE> </TEMPLATES>	

6.3 SIMOTION IT OPC UA

6.3.1 Preface

6.3.1.1 Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

https://support.industry.siemens.com/cs/ww/en/view/109479653

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

6.3.1.2 SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4.3:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

6.3.2 Fundamental safety instructions

6.3.2.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

6.3.2.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

6.3.2.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

6.3.2.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

6.3.3 Introduction

6.3.3.1 SIMOTION IT Overview

SIMOTION IT Overview Manuals

The "SIMOTION IT Ethernet-based HMI and diagnostic functions" are described in four manuals (IT = Information Technology):

- **SIMOTION IT Diagnostics and Configuration**
  This manual describes the direct diagnosis of SIMOTION devices. Access is by means of a standard browser (e.g. Firefox) via the IP address of the SIMOTION device. You can use the standard diagnostic pages or your own HTML pages for access.
  See the SIMOTION IT Diagnostics and Configuration Manual.
- **SIMOTION IT Programming and Web Services**
  This manual describes the creation of user-defined Web pages and access to the diagnostic functions via the two Web services provided by SIMOTION IT.
  A Web service enables users to create their own client applications in any programming language. These applications then communicate with the SIMOTION device using Web technologies. The SOAP (Simple Object Access Protocol) communication protocol is used for transferring commands.
  The manual includes information on programming such clients, as well as a description of the SIMOTION IT Web services (OPC XML-DA, Trace via SOAP TVS) via which data and operating states of the controller can be accessed and the variable trace functions can be used.
  See the SIMOTION IT Programming and Web Services Manual.
- **SIMOTION IT Virtual Machine and Servlets**
  This manual describes the Java-based function packages. The Jamaica Virtual Machine (JamaicaVM) is a runtime environment for Java applications on the SIMOTION device. It is an implementation of the "Java Virtual Machine Specification".
  The Servlets section of the manual describes the use of servlets in a SIMOTION device.
  See the SIMOTION IT Virtual Machine and Servlets Manual.
- **SIMOTION IT OPC UA**
  This manual describes access to SIMOTION devices via OPC UA.

6.3.3.2 Introduction

OPC Unified Architecture (OPC UA)

For OPC UA, this is an extension to the OPC industry standard. Functions such as platform-independence, scalability, high availability and Internet capability have been added to the standard.

Standardized communication via the Internet and firewalls

For data exchange, OPC UA uses a TCP-based, optimized, binary protocol. Whereby, port 4840 entered for the IANA is used for data transfer. As option, HTTP and Web service are also supported.

Just enabling port 4840 suffices to ensure data transfer.

Service-oriented architecture

OPC-UA defines generic services based on the Service Oriented Architecture (SOA) design paradigm. This architecture provides service providers with requests that can be edited and whose results are returned as response.

A WDSL for describing the services, as required for classic Web services, is no longer necessary. Generic services are already defined and standardized for OPC UA.

Security concept

To protect against unauthorized access, the data is encrypted using recognized Internet standards (SSL, TLS, AES). The security mechanisms belong to the standard and are mandatory for manufacturers.

Accessibility and reliability

A robust architecture, with reliable communications mechanisms, configurable timeouts and automatic error detection, permits fail-safe systems with maximum reliability.

Simplification thanks to standardization

OPC-UA defines an integrated address space and an information model. Process data, alarms and historical data, together with function calls, can be represented in the information model. Whereby, OPC UA combines all classic OPC functionality, and describes complex procedures and systems in standardized object-oriented components.

Information consumers that only support the base rules can also process data without needing to know the relationships of the complex server structures.

6.3.4 Software description

6.3.4.1 OPC UA implementation

OPC UA implementation

The Data Access (DA) of the OPC UA server functionality has been implemented.

OPC UA binary encoding is supported. Encrypted and non-encrypted data transfer are possible.

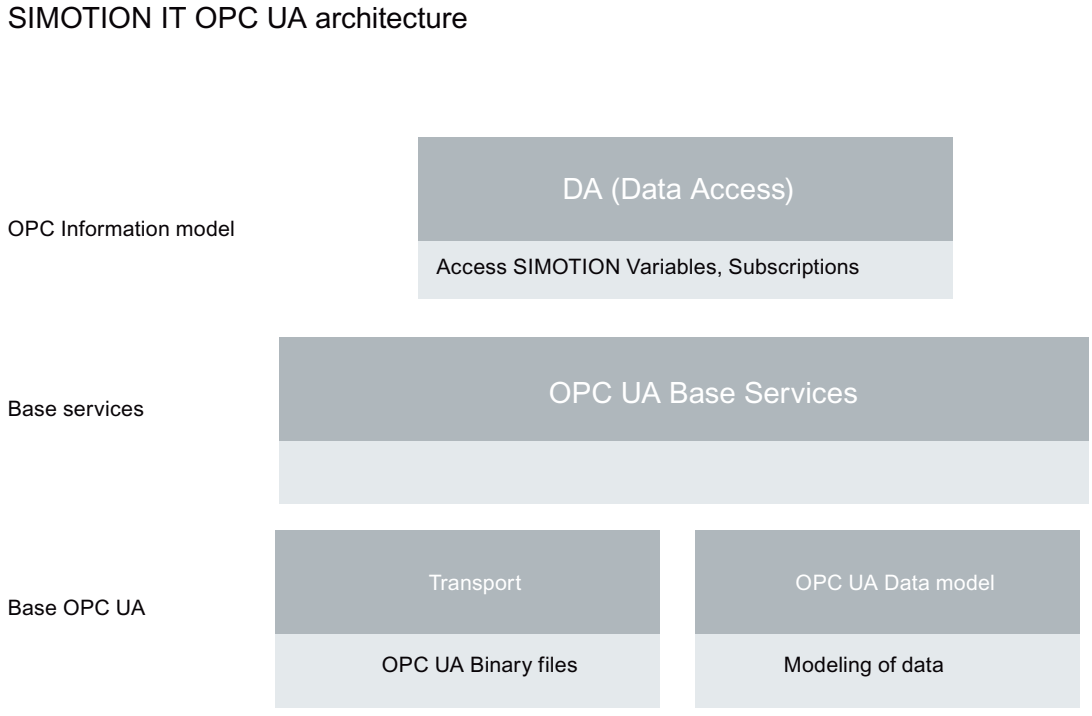

Figure 6-147 Excerpt from the OPC UA layer model

6.3.5 Commissioning (software)

6.3.5.1 Commissioning

Commissioning

To access OPC UA , an interface of the SIMOTION device for access must be activated and a TCP/IP port must be assigned on the OPC UA. page. A Realm must be set for the read and write rights.

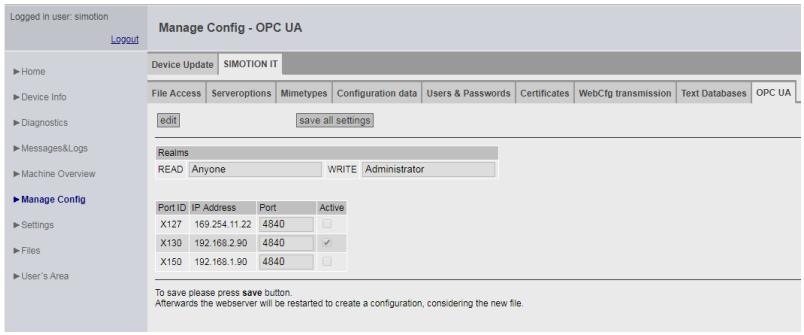

Figure 6-148 OPC UA Activate interfaces

Inputs on the OPC UA page saved with **save all settings** cause a change to be made in WebCfg.xml.

If the IP address of an interface is changed, the Web server is restarted; this disconnects all connections, including the OPC UA connections.

Activation of OPC UA in HW Config

The Web server of the SIMOTION controller is activated in the HW Config. To do that, navigate via **Device object properties** to the **Ethernet extended / Web server** tab.

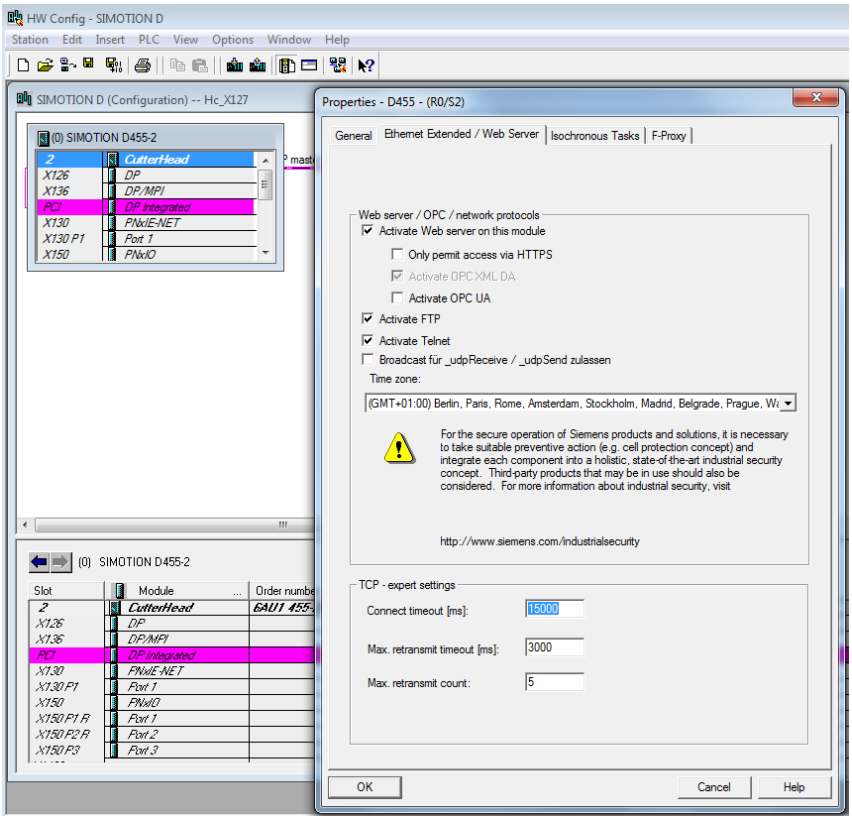

Figure 6-149 HW Config settings

The screenshot shows the default Web server settings. When you deactivate a service, the corresponding communications port is closed. If no service is activated, the Web server of the controller is also deactivated.

Click **Activate OPC UA** to activate the access.

Activation of OPC UA in the TIA Portal

To activate the Web server in the TIA Portal, proceed as follows:

1. Select the SIMOTION device in the network view / device view.
2. In the Inspector window, select the "Properties" tab and click the "General" tab.
3. Select "Web server / OPC / Network protocols".
   The Web server is deactivated in the basic setting. You must activate the relevant checkboxes so that the CPU displays the Web pages.

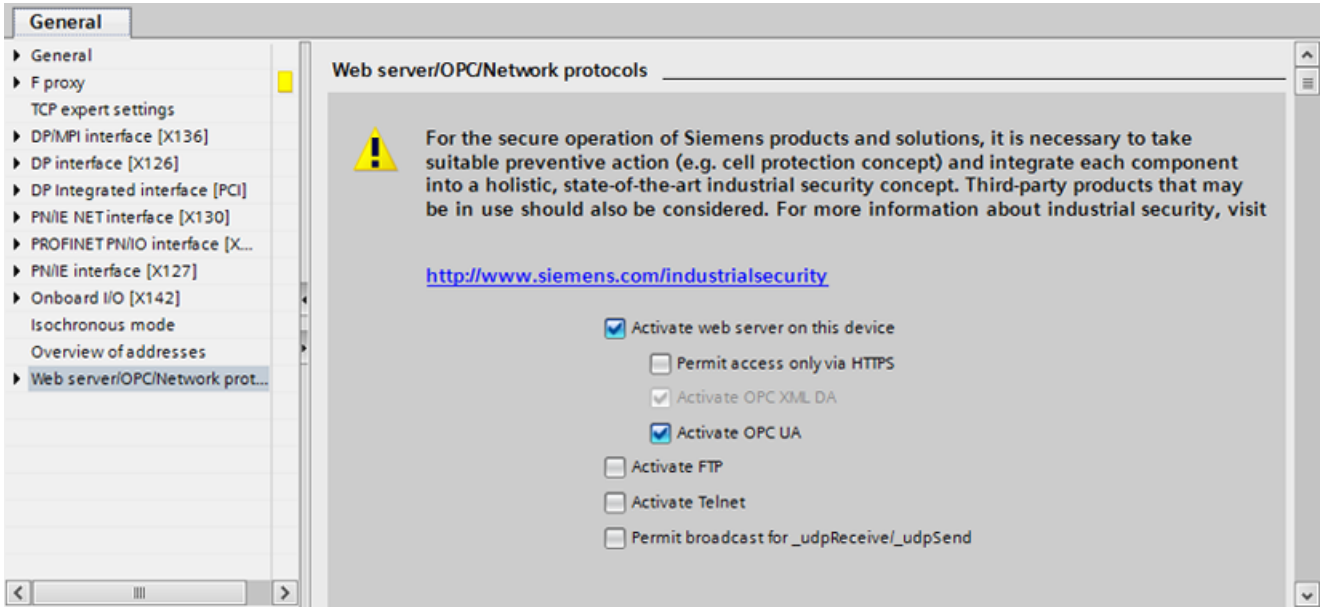

Figure 6-150 Activating the Web server

Activate the Web server and OPC UA.

Configuration prior to Version 4.5

WebCfg.xml must be changed in order to enter the OPC UA IP address.

The IP address with the port is stored in the <ENDPOINTDESCRIPTION> element.

```
<CONFIGURATION_DATA>
   ...
   <OPCUAAPPLICATION READ="<ReadRealm>" WRITE="<WriteRealm>"
      <ENDPOINTDESCRIPTION URL="X127:4840"/>
   </OPCUAAPPLICATION>
   ...
</CONFIGURATION_DATA>
```

The user authentication is supported with the READ, WRITE and BROWSE attributes. These attributes link Realm with the associated access type. The associated rights are assigned in the Realm.

The IP address with which the server can be accessed is entered in the URL attribute of the <ENDPOINTDESCRIPTION> element.

Example SIMOTION IP address (factory setting)

```
<ENDPOINTDESCRIPTION URL="X127:4840"/>
```

SIMOTION IT configuration

Further information for configuring the controller can be found in the SIMOTION IT Diagnostics and Configuration Manual. The 'Commissioning' section contains information for activating the Web server in the HW Config and in TIA Portal. The 'SIMOTION IT configuration' section explains the structure of the WebCfg.xml configuration file and the user administration.

6.3.5.2 SIMOTION IT configuration

Settings via the Web server

OPC UA access to the controller requires that some settings must be set via the SIMOTION IT Web server:

- Configuration of a user database UserDataBase.xml
- Access protection with OPC UA certificates

Note

Commissioning prerequisite

The successful commissioning, as described in the 'Commissioning' chapter, is prerequisite for configuring the controller.

This chapter includes several sections from the "SIMOTION IT Diagnostics and Configuration" manual. This chapter explains the user database and accessing with certificates to the controller.

Log-in administration

Structure of the login administration

SIMOTION IT uses a user database to safeguard access to a device. The UserDataBase.xml file contains this user data.

If the controller is started without a user database, a user database is automatically created when the controller starts up. This user database contains no users and is therefore empty.

If Web pages are called in this condition, the anonymous user `Anonymous` is active. This user has no special access rights.

The Web pages can only be used if the Web server has been activated via SCOUT or HW Config. If the Web server has not been activated, communication with the device is not possible. The services are activated by default when a new device is set up, and they must be explicitly deactivated to prevent access. In TIA Portal, the services are disabled by default.

The user administration is based on the Administrator user group. If no user who belongs to the Administrator user group exists in the UserDataBase.xml, no users can be set up, edited, or deleted via the User's & Passwords Web page.

There are many application cases related to the Web server and UserDataBase.xml that differ in terms of the individual files on the memory card.

Empty memory card, no SCOUT project exists on the memory card and empty UserDataBase.xml

The memory card only contains the firmware and the licenses.

In the as-delivered state, file UserDataBase.xml contains no users and is "empty" as far as the system is concerned.

In this case, the status of the controller is **Security Level Low**. To make it possible to perform commissioning via the Web server, all the Web pages can be used without login in this status. The FTP and Telnet can be accessed with any user name and password.

Users can be set up in the following ways to create a valid user database.

1. Call page **Manage Config > SIMOTION IT > Users & Passwords**. Add a user with Administrator group. As soon as the user is saved, the Web server switches to the **Security Level normal** condition because the user database now contains a valid entry.
2. Create a UserDataBase.xml file with content as described below. Upload via the Web page **Manage Config > SIMOTION IT > Users & Passwords**.
3. Create a **UserDataBase.xml** file with content as described below. Connect the CF card to the PC via a card reader and save the XML file at /USER/SIMOTION/HMICFG/USERDATABASE/.
4. Create a UserDataBase.xml file with content as described below. Use the device update tool and save the UserDataBase.xml file to the USERDATABASE folder in directory IT Config.

SCOUT project exists on the memory card and empty UserDataBase.xml

If a valid project exists on the card, the **Security Level normal** status applies to the Web server, in which the Web pages, FTP and Telnet are protected by a login. However, if the UserDataBase.xml file is in the as-delivered state, it contains no users. In this case, login will not be possible.
The user database can be edited in any of the following ways:

1. Delete project with **Delete user data on card** in SCOUT. The Web server assumes the **Security Level Low** status. The user database can be edited as described above.
2. Create a UserDataBase.xml file with content as described below. Connect the CF card to the PC via a card reader and save the XML file at /USER/SIMOTION/HMICFG/USERDATABASE/.
3. Create a UserDataBase.xml file with content as described below. Use the device update tool (but not via the Web pages) and store file UserDataBase.xml in a folder USERDATABASE in directory IT Config.
4. Service switch 8, simotion.ini or the PSTATE program can be used to reset to Security Level low and thus change the password.

SCOUT project exists on the memory card and UserDataBase.xml contains valid users

If a valid project exists on the card, the **Security Level normal** status applies to the Web server, in which the Web pages, FTP and Telnet are protected by a login.

The user database can be edited in any of the following ways:

1. Call page **Manage Config > SIMOTION IT > Users & Passwords**. After logging in successfully with administrator rights, new users can be created and existing users edited. This however assumes that at least one user who belongs to the Administrator group has already been set up.
2. Create a UserDataBase.xml file with content as described below. Connect the CF card to the PC via a card reader and save the XML file at /USER/SIMOTION/HMICFG/USERDATABASE/.
3. Create a UserDataBase.xml file with content as described below. Use of the device update tool (but not via the Web pages) and storage of the file UserDataBase.xml in a folder USERDATABASE in directory IT Config.

Authentication

The authentication is constructed as follows:

- There are USERs.
- Every USER has a password that can be entered as plain text before startup. After startup, the password exists as A1 Hash .
- Users belong to groups (GROUP).
- Web pages, directories, and applications are protected by secure realms (REALM) defined for each group.
- Only users that belong to the realm can access the protected page.
- Each realm has a group of users who are authorized for access.
- A user can belong to multiple groups.

If a login attempt fails, this is logged in the system log.

Note

Editing the UserDataBase.xml file

- If the UserDataBase.xml file is not adapted, after the SCOUT project has been downloaded, it will no longer be possible to login to the Web pages or access with FTP and Telnet, because no valid user exists.
- The user database UserDataBase.xml must contain at least one user who is a member of group Administrator. Group Administrator is the REALM that the system expects for accessing protected applications, whose access rights cannot be set via WebCfg.xml.
- The editor used for editing UserDataBase.xml must be set to UTF-8 encoding.
- If file UserDataBase.xml contains illegal characters or the XML syntax contains errors, the file cannot be evaluated by the system. This makes login impossible.
- After startup, all plain text passwords are deleted and only exist in encrypted form. Neither can they be ascertained by the administrator. However, the administrator can assign a new password without knowing the old password.
- Since the password is no longer available in plain text in UserDataBase.xml, the password must be entered again each time a change is made to the groups of an existing user, otherwise the A1-Hash cannot be calculated.
- After loading via FTP, the controller must be restarted to transfer the UserDataBase.xml file. A restart the Web server does not suffice.

Structure of the UserDataBase.xml file

The user data is stored in UserDataBase.xml. UserDataBase.xml is located in directory /USER/SIMOTION/HMICFG/USERDATABASE

Sample configuration

UserDataBase.xml before startup

```
<?xml version="1.0" encoding="UTF-8"?>
<UserDataBase>
  <USER NAME="service"
    PASSWORD="a67_YjH"
    ChangePassword="never"
    DESCRIPTION="Administrator with all rights"
    REAL_NAME="">
      <GROUP NAME="Anyone"/>
      <GROUP NAME="Administrator"/>
  </USER>
  <USER NAME="user1"
    PASSWORD="93!ujEa"
    ChangePassword="allowed"
    DESCRIPTION="Normal user"
    REAL_NAME="">
      <GROUP NAME="Anyone"/>
  </USER>
</UserDataBase>
```

UserDataBase after startup

```
<?xml version="1.0" encoding="UTF-8"?>
<UserDataBase>
  <USER NAME="service"
    ChangePassword="never"
    DESCRIPTION="Administrator with all rights"
    REAL_NAME="">
      <GROUP NAME="Anyone"         A1="0302831a41b222c5f5bfc22e5ff80620"/>
      <GROUP NAME="Administrator"
A1="fa712df9294b40baa1e7504f8dd2b0d5" />
  </USER>
  <USER NAME="user1"
    ChangePassword="allowed"
    DESCRIPTION="Normal user"
    REAL_NAME="">
      <GROUP NAME="Anyone" A1="c5a15667e4d0cadff85d35354ea0fbb6"/>
  </USER>
</UserDataBase>
```

Table 6-58 Attributes of the USER node

Attribute	Permissible values	Description
NAME	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Login name
PASSWORD	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Password in plain text
CHANGEPASSWORD	ALLOWED ⇒ The password can be changed by the user in the Web page (default setting). NEVER ⇒ The password cannot be changed by the user in the Web page.	Behavior when user logs in via Web pages. No effect when opening the file in the file system
DESCRIPTION	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Description of the user
REAL_NAME	Numerals, letters, special characters but not: =, " , <,>, %, &, \, `,'	Actual name of the user

Table 6-59 Attributes of the GROUP node

Attribute	Permissible values	Description
NAME	Numerals, letters, special characters but not: : =, " , <,>, %, &, \, `,'	Name of the group.
A1	Valid hash value (numerals, letters)	Hash value that is expressed as a MD5 checksum via USER NAME, USER PASSWORD and GROUP NAME. If none exists, generated after the controller starts up.

NOTICE
Invalid XML file
Using impermissible values may invalidate the XML file so that it cannot be read.

Login and WebCfg.xml

Differentiated protection of Web pages, directories, and applications with WebCfg.xml

The realms are assigned for individual Web pages, directories, and applications in configuration file WebCfg.xml. Content requiring protection is labeled REALM Administrator. The users belonging to this group are specified in file UserDataBase.xml.

Besides REALM Administrator used by the system, the user can create and apply his own realms to protect Web pages, etc.

Example

Excerpt UserDataBase.xml:

```
...
<USER NAME="user1"
```

```
    PASSWORD=""
    ChangePassword="allowed"
    DESCRIPTION="Service with restricted rights"
    REAL_NAME="John Smith">
<GROUP NAME="Anyone"
        A1="c5a15667e4d0cadff85d35354ea0fbb6"/>
<GROUP NAME="Servicegroup"
        A1="45735fdcee4d0cdfafde825354ea0aa17"/>
</USER>
…
```

Excerpt WebCfg.xml:

```
…
<settings.mwsl.cms ALIAS="html/standard/settings.mwsl.cms"
REALM="Servicegroup" READ="Servicegroup" WRITE="Servicegroup"
MODIFY="Servicegroup"/>
…
```

`user1` has been inserted. This user belongs to the new group `Servicegroup` and has access to the `settings.mwsl` page. However, any user who wants to open the Settings page must belong to the `Servicegroup` group. It is therefore recommended that administrators belong to all the groups that exist in the user database.

Realms for applications

Besides the realms for individual MWSL pages and directories, the REALM of some of the applications of the Web server are also defined in the configuration file WebCfg.xml.

These realms can be adapted if necessary.

⚠ CAUTION

Deleting a REALM

If you delete a REALM, the associated pages can be accessed without a login. So carefully check which pages were protected by the REALM.

- Web service for OPC-XML DA and therefore reading, writing, monitoring of the variables of all providers
  `<WEBSERVICE NAME="OpcXml" URL="/SOAP/OPCXML"`
  `REALM="Administrator" />`

  Note

  As-delivered state without REALM

  In the as-delivered state, this value has no REALM to ensure downward compatibility reasons! It is therefore recommended to prepare the OPC-XML DA client currently being used for password and user name use and to set the REALM here.

- Application for writing variables in all providers on the HTML diagnostics pages:
  <VarApp REALM="Administrator" />
- Application for updating project and firmware:
  <FWUpdtApp REALM="Administrator" />

- Application for reading and writing the user database UserDataBase.xml
  <UserDataBaseApp REALM="Administrator" />
- Application of Jamaica VM for calling servlets
  <JApp REALM="Administrator" />

In addition, there are system applications that require login of a user who belongs to the Administrator group.

As delivered

So that you can access the SIMOTION controller via HTTPS in the delivery state of the SIMOTION IT diagnostics standard pages, a server certificate and a private key are supplied as a file on the device.

When you attempt HTTPS access using the key files supplied with the system, you will be warned that the certificate is unknown and that the current address of the controller does not match the name of the controller in the certificate.

Note

Secure data transmission

A HTTPS connection via the preinstalled certificate is not the most secure way of accessing the controller. The preinstalled certificate should therefore only be used if no self-created or purchased certificate can be used.

Creating key files with the script cert.pl (V4.1 and higher)

Overview

Note

HTTPS connections are supported as of SIMOTION V3.2.

If no Certification Authority (CA) is available in your organization, we recommend that you follow the steps described in the following section. The certificate and the key files are created with the OpenSSL tool and a Perl script cert.pl

Carry out the following steps:

No.	Working step	Remark
1.	Install a Perl runtime environment	If Perl is not installed
2.	Install OpenSSL	
3.	Create the certificate and key files with Perl script	
4.	Import the created certificate to the PC browser	This step must be performed once for each PC.

HTTPS access is available after the SIMOTION controller ramps up.

Installation of a Perl runtime environment

Install Perl if the Perl runtime environment is not present on your PC. You can download a free setup for Windows from the following websites, for example:

- http://www.activestate.com
- http://www.perl.org

Installation of OpenSSL

You can download a free OpenSSL setup for Windows, for example, from the following website:

- http://slproweb.com/products/Win32OpenSSL.html

Installation of cert.pl

The cert.pl Perl script generates certificates for the controller. The script is on the AddOn-DVD 2 in the \Addon\4_Accessories\SIMOTION_IT\6_Tools directory.

A new <CertDir> directory (e.g. c:/cert) is first created on the PC and the cert.pl file is copied into it.

Call syntax cert.pl

```
Usage: perl cert.pl [-h][-?][-cert CertPath][-site <Site name>][-cpu
<CPU name>]
                   [-ip <IPAddr>[,<IPAddr>,...]][-ossl <path>][-tools
<path>]
                     [-d <duration>][-img <path>][-wcfg <WebCfgPath>]
                     [-ca][-srvn][-srvu][-ksize size]

Options:

  -cert <certpath>: Workspace used for the creation of certificates
(default: current directory)

  -site <site name>: Name of the site the cpu is belonging to

  -cpu <CPU name>: Name of the cpu

  -ip <IPAddr>[,<IPAddr>,...]: List of IP addresses belonging to 1
cpu (no spaces allowed)

  -ca: Create new root CA

  -srvrn: Create new server certificate

  -srvru: update existing server certificate

  -d <duration>: Duration of validity (in days)

  -tools <path>: Path to the tools dir containg eg. 7za.exe

  -img <path>: Path to the output dir (default: <certpath>)

  -e: Export the certificates of 1 cpu to the path specified by the -
img option

  -ossl <path>: Path to an openssl installation (eg. C:/OpenSSL-Win32)

  -ksize <size>: Key size (default: 2048)
```

```
-h: Print this help
-?: Print this help
-wcfg WebCfgFile: Use <WebCfgFile> as a template
```

The path to the OpenSSL installation is determined via the "OPENSSL_CONF" environment variable from the program. This environment variable is created during the installation of OpenSSL with a setup program. If the environment variable is not set, then the "-ossl" option must be used.

Creating a SSL certificate yourself

The cert.pl Perl tool can be used to generate the certificates required for customer systems (sites) and combine them into packages for loading.

Generation of root and server certificates

As of SIMOTION Version 4.4, there are two applications for which the tool can be used:

Automatic generation of the certificate

In the first application, the required server certificates and their private keys are generated automatically on first access to the controller via HTTPS. A root certificate and the associated private key are required for this purpose.
The root certificate and the associated private key are generated using the Perl tool.

Call: `perl cert.pl -ca -ossl C:/OpenSSL-Win64`

Name of the server certificate:	ITDiagRootCA.crt
Name of the private key:	ITDiagRootCA.key
Storage location in the file system:	<certpath>/CA

Note

UaExpert

Version 1.4.4 of the UaExpert functions only with a binary certificate in DER format. The certificate in DER format is stored in the /USER/SIMOTION/HMICFG/CERTSTORE/CA path in the "ITDiagRootCA.zip" ZIP file on the memory card of the controller.

The data of the certification institution is queried:

- Country (2-character code, e.g. DE)
- State (e.g. Bavaria)
- City (e.g. Erlangen)
- Company (e.g. MyCompany Corp.)
- Department (e.g. IT Development)
- Common name (e.g. ITDiagRootCA)
- E-mail (e.g. sepp@MyCompany.com)

Self-generated certificates

In this case, the required server certificates must be generated in addition to the root certificate.

Call:

```
perl cert.pl [-ca] [-cert <certpath>] [-site <sitename>] -cpu
<cpuname> -ip <IP-Addr1>,<IP-Addr2>,.... -srvn -ossl <opensslpath>
or
perl cert.pl [-ca] [-cert <certpath>] [-site <sitename>] -cpu
<cpuname> -ip <IP-Addr1>,<IP-Addr2>,.... -opcuacert -ossl
<opensslpath>
```

Name of the generated root certificate	ITDiagRootCA.crt, bzw. ITDiagRootCA.zip
Name of the private key	ITDiagRootCA.key
Storage location in the file system	<certpath>/CA

Name of the generated server certificates	<IP-Addr>.SSL.crt (z.B. 192.168.2.90.SSL.crt)
Name of the private key	<IP-Addr>.SSL.key (z.B. 192.168.2.90.SSL.key)

or

Name of the generated server certificates	<IP-Addr>_OPCUA.crt (z.B. 192.168.2.90_OPCUA.crt)
Name of the private key	<IP-Addr>_OPCUA.key (z.B. 192.168.2.90_OPCUA.key)
Storage location in the file system	<certpath>/<sitename>/<cpuname>/<IP-Addr>

The root certificate will only be generated if none already exists. For all subsequent calls, the existing root certificate is used to sign the newly generated server certificates. The generation of a new root certificate can be forced with the -ca option.

The list of IP addresses (<IP-Addr1>, <IP-Addr2>) must not contain any blanks. This also applies to all other parameters.

The data of the applicant is queried when creating the first server certificate of a site. If `-site` was not specified, of a CPU, the applicant data is queried:

- Country (2-character code, e.g. DE)
- State (e.g. Bavaria)
- City (e.g. Erlangen)
- Company (e.g. MyCompany Corp.)
- Department (e.g. IT Development)
- E-mail (e.g. sepp@MyCompany.com)

Note

Validity duration of the certificates

The default validity is 30 years (effectively infinite).

The d option generates certificates with a shorter validity. In this case, HTTPS communication will no longer function after the validity has expired.

The user is responsible for installing the new valid certificates on all affected controllers.

Update of existing server certificates

If one of the parameters essential for the generation of the server certificates (e.g. the server certificate, the lifetime or the configuration) changes, an update can be started for the server certificates.

Call: `perl cert.pl [-cert <certpath>] [-site <sitename>] [-cpu <cpuname>] -srvu -ossl <opensslpath>`

This call also affects the certificates for OPC UA.

If the `-cpu` parameter is missing, all certificates of the CPUs belonging to the site are renewed.

If the `-site` parameter is also missing, all certificates are renewed.

Deletion of existing server certificates

Server certificates can be deleted:

Call: `perl cert.pl [-cert <certpath>] [-site <sitename>] [-cpu <cpuname>] [-ip <IP-Addr1>,<IP-Addr2>,....] -svrr -ossl <opensslpath>`

Export of existing server certificates

The generated certificates can be exported for each CPU.

Call: `perl cert.pl [-cert <certpath>] [-img <path>] [-site <sitename>] -cpu <cpuname> [-ip <IP-Addr1>,<IP-Addr2>,....] -e -ossl <opensslpath>`

The path to the exported images can be specified with the `-img` option.

Storage location in the file system: `<path>/images/<sitename>/<cpuname>`

A directory structure can be found at `<imgpath>/images/<sitename>/<cpuname>/image` which can be copied to the `/USER/SIMOTION/HMICFG` directory of the CF card. An upload-capable ZIP archive (<cpuname>.zip) is also generated under `<imgpath>/images/<sitename>/<cpuname>` if the zipper 7z.exe (7za.exe in older versions) is in `<toolspath>` (option `-tools <toolspath>`).

- The archive can be unpacked in the HMICFG directory. Any existing server certificates have to be removed. To do this, the complete `/USER/SIMOTION/HMICFG/certstore/servercerts` directory is deleted. The controller then has to be restarted.
- The server certificates can also be loaded to the CPU via the **Certificates** website at **Manage Config**. Unnecessary files and directories are deleted and a restart of the Web server triggered.

SIMOTION versions prior to Version 4.4

For SIMOTION versions prior to Version 4.4, the functionality of the tool is retained.

Generated server certificates are entered in a copy of a template of the WebCfg.xml file.

The template is sought in one of the following directories in the specified order:

- –wcfg Option
- <certpath>/<sitename>/<cpuname>/<ipaddr>
- <certpath>/<sitename>/<cpuname>
- <certpath>/<sitename>
- <certpath>

6.3.6 Operator control (software)

6.3.6.1 Functionality

Functionality

The following functionality is available:

- Browse the variable management area
- Read and write variables
- Subscriptions

6.3.6.2 Access to the variable management area

Variable access

Access can be made to the SIMOTION variable management area data:

- Device system variables
- TO system variables
- TO configuration variables
- Drive parameters
- Global user variables
- Interface variables for units
- I/O variables

As of version 4.5, all data of the Simotion OPC UA provider is available. Only simple data types (arrays), such as Integer, Float, character strings and enumerations, are supported.

As of version 5.3, structures are also available.

Data types

The assignment of the SIMOTION data types to the data types in OPC UA is shown in the following:

SIMOTION data type	OPC UA data type (UaExpert)
BOOL	Boolean
BYTE	Byte
WORD	UInt16
DWORD	UInt32
SINT	Sbyte
USINT	Byte
INT	Int16
DINT	Int32
UDINT	UInt32
REAL	Float
LREAL	Double
UINT	Uint16
TIME	String
DATE	String
TIME_OF_DAY	String
DATE_AND_TIME	DateTime
STRING	String

UAExpert section

6.4 SIMOTION IT Virtual Machine and Servlets

Preface

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.2:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P

- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

https://support.industry.siemens.com/cs/ww/en/view/109479653

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

6.4.1 Fundamental safety instructions

6.4.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

6.4.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

6.4.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

6.4.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

6.4.2 Introduction

6.4.2.1 Overview of SIMOTION IT

Overview of SIMOTION IT manuals

The "SIMOTION IT Ethernet-based HMI and diagnostic functions" are described in four manuals (IT = Information Technology):

- **SIMOTION IT Diagnostics and Configuration**
  This manual describes the direct diagnosis of SIMOTION devices. Access is by means of a standard browser (e.g. Firefox) via the IP address of the SIMOTION device. You can use the standard diagnostic pages or your own HTML pages for access.
  See the SIMOTION IT Diagnostics and Configuration Manual.
- **SIMOTION IT Programming and Web Services**
  This manual describes the creation of user-defined Web pages and access to the diagnostic functions via the two Web services provided by SIMOTION IT.
  A Web service enables users to create their own client applications in any programming language. These applications then communicate with the SIMOTION device using Web technologies. The SOAP (Simple Object Access Protocol) communication protocol is used for transferring commands.
  The manual includes information on programming such clients, as well as a description of the SIMOTION IT Web services (OPC XML-DA, Trace via SOAP TVS) via which data and operating states of the controller can be accessed and the variable trace functions can be used.
  See the SIMOTION IT Programming and Web Services Manual.
- **SIMOTION IT Virtual Machine and Servlets**
  This manual describes the Java-based function packages. The Jamaica Virtual Machine (JamaicaVM) is a runtime environment for Java applications on the SIMOTION device. It is an implementation of the "Java Virtual Machine Specification".
  The Servlets section of the manual describes the use of servlets in a SIMOTION device.
- **SIMOTION IT OPC UA**
  The manual describes access to SIMOTION devices via OPC UA.

6.4.2.2 SIMOTION IT Virtual Machine

The Jamaica Virtual Machine (JamaicaVM) is an implementation of the "Java Virtual Machine Specification", and is a runtime system for executing Java applications.

This document describes how the SIMOTION-integrated JamaicaVM is parameterized, and how a Java user program is commissioned.

It also contains essential information on how to use the SIMOTION API, which contains classes for data access and logging. More detailed information about the SIMOTION API exists in HTML format.

The SIMOTION-integrated JamaicaVM will only be started automatically if the configuration file VMCONFIG.INI is on the target system (see also VMCONFIG.INI (Page 3945) and Installation (Page 3912)).

The Java main program ("InvocationManager"), which is also contained in the SIMOTION API, is executed by default. The InvocationManager reads the settings from the relevant configuration file and then starts the Java user programs (see VMCONFIG.INI (Page 3945)).

The InvocationManager can also open a TCP socket interface, which can be used to load and execute user programs interactively (see Interactive InvocationManager interface (Page 3951)).

Program and system variables of the target system, for example, can be accessed in the user programs. Network support (DatagramSocket, ServerSocket, Socket, ...) and file functions are also available.

6.4.2.3 SIMOTION IT Servlets

SIMOTION IT Servlets are the implementation of a servlet container.

Servlets are programs written in Java, which extend the capabilities of servers that communicate via a request/response protocol. Theoretically, they are not bound to a server protocol (HTTP), but they are usually used only in conjunction with HTTP/web servers.

The Web container provides the runtime environment for Web applications with its servlets, and it can run on a different machine to the Web server (load distribution, safety/redundancy).

In a SIMOTION context, servlets run in SIMOTION IT Virtual Machine (implementation of a Java runtime environment) and are, therefore, afforded the option of using the SIMOTION API (giving access to SIMOTION RT, NVRAM, and logging objects).

The following are described in the relevant chapters

- Implemented scope of functions (Page 3958)
- Parameterization of the servlet container (Page 3960)
- Start-up of a servlet using an example (Page 3965).

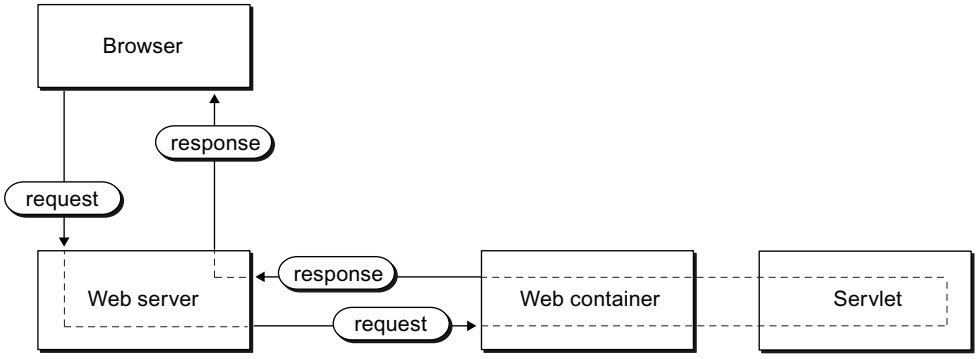

Figure 6-152 Servlet command sequence

6.4.3 Software installation

6.4.3.1 SIMOTION IT Virtual Machine

The JamaicaVM is only started if configuration file VMCONFIG.INI is available on the target system.

A configuration file that contains the directory settings specified in the recommendations referred to above, and which can be used to activate the JamaicaVM, is included in the SIMOTION IT Virtual Machine scope of delivery.

To make special settings in the configuration file, see also: JamaicaVM configuration (VMCONFIG.INI). (Page 3945)

Configuration file VMCONFIG.INI and Java library SIMOTION.JAR contain the InvocationManager and the API for data access and logging. These must be stored on the target system. The default setting dictates that the Java library is expected to be in the root directory of drive B: However, the root directory can also be set differently if required (see BOOTCLASSPATH (Page 3945)).

User programs must be zipped into a Java library (JAR or ZIP file) and stored in the current working directory of the target system.

On the target system, the default current working directory is the root directory of drive B:, but this can be changed if required (see CURRENTDIR (Page 3945)).

To start a user program automatically, all you need to do is enter the relevant information in configuration file JINVOKE.XML. This configuration file must also be stored in the current working directory of the target system.

6.4.3.2 SIMOTION IT Servlets

Installation and configuration of SIMOTION IT Virtual Machine is a requirement for SIMOTION servlets.

To operate SIMOTION servlets, Java libraries svltapi.jar and svltimpl.jar must be stored on the target system.

In the case of an empty CF card, these Java libraries must be stored in the following directory as of SIMOTION V4.1 SP4

- /SIEMENS/SIMOTION

The configuration files supplied assume that the SIMOTION Java system libraries are located in this directory.

meaning that Java library svltapi.jar, which contains the standard servlet API, needs to be incorporated into the JamaicaVM path.

The most straightforward way of doing this is to expand the setting for the BOOTCLASSPATH accordingly in VMCONFIG.INI:

BOOTCLASSPATH= b:/siemens/simotion/simotion.jar;b:/siemens/simotion/svltapi.jar

Note

In SIMOTION IT Virtual Machine, the semicolon must always be specified as a CLASSPATH separator.

To start the servlet container automatically, you need to insert the following line in JINVOKE.XML:

<AUTOSTART LIBRARY="B:/SIEMENS/SIMOTION/SVLTIMPL.JAR" CLASSNAME="com.siemens.ad.SIMOTION.servlets.ServletContainer"/>

User servlets must be zipped into a Java library (JAR or ZIP file) and stored in the current working directory of the target system.

To load a user servlet, all you need to do is enter the relevant information in configuration file JSERVER.XML. This configuration file must also be stored in the current working directory of the target system.

Note

The software/libraries are available on the U&A DVD at \VOL2\AddOn\4_Accessories\SIMOTION_IT\5_SIMOTION_VM

6.4.4 Software programming

6.4.4.1 SIMOTION IT Virtual Machine

Scope of delivery

The following files are integral parts of SIMOTION IT Virtual Machine:

File name	Description
SIMOTION.JAR	Java library containing the SIMOTION API and the default main program (InvocationManager).
SIMOTION_DOC.ZIP	Online SIMOTION API documentation (HTML format).
SIMOTION_DEMO.ZIP	Java source code for sample programs and tools.
JINVOKE.XML	Sample AUTOSTART configuration file
VMCONFIG.INI	JamaicaVM configuration file
Jam1.st	Sample ST program that defines and exports ST program variables.
nanoxml.jar	Java library that is required to start the InvocationManager program on a development computer.
simotion_systemclasses.jar	Java library that can be used as a reference for compilation on a development computer.

Supported Java packages

In principle, the following packages from JDK 6 are supported by the JamaicaVM integrated in SIMOTION.

- java.io
- java.lang
- java.lang.reflect
- java.math
- java.net
- java.text
- java.util
- java.util.jar
- java.util.zip

Additional Java libraries can be integrated into the user code by importing.

Default directories

SIMOTION V4.1. SP4 includes some important new features in terms of both the directories recommended for SIMOTION IT Virtual Machine and the Java programs based on these.

In particular, specific default directories for Java program files and Java data files are recommended so that the new CPU update feature can be used for SIMOTION IT Virtual Machine as well.

All of the configuration files and sample programs supplied with SIMOTION V4.1. SP4 and higher are compatible with these new features.

The recommended default directories are specified as follows:

- Default directory for Java program files and SIMOTION IT Virtual Machine configuration file JINVOKE.XML: /USER/SIMOTION/HMI/JAVA/PROG/
- Default directory for Java data files: /USER/SIMOTION/HMI/JAVA/FSROOT/

For reasons of compatibility, the default values for the relevant settings have not been changed, meaning that you can continue to use existing configurations/installations.

However, these recommended default directories are used for the relevant settings in the configuration files supplied.

In particular, the /USER/SIMOTION/HMI/JAVA/PROG/ directory is set as a value for CURRENTDIR in the VMCONFIG.INI file supplied; CURRENTDIR denotes the current working directory and is, therefore, the default directory for Java program files, for example.

SIMOTION.JAR

As of SIMOTION V4.1 SP4, the Java library SIMOTION.JAR must be stored in the following directory:

- /SIEMENS/SIMOTION

The configuration files supplied assume that the SIMOTION Java system libraries are located in this directory.

Since old SIMOTION Java system libraries can, in principle, be used in newer versions of SIMOTION (without the additional features of these newer versions, of course), it is also possible to continue using existing configurations/installations without making any changes to them.

However, in such cases it is strongly recommended that you adapt the configuration of SIMOTION IT Virtual Machine too, so that the /SIEMENS/SIMOTION directory is used for these Java libraries (see BOOTCLASSPATH (Page 3945)).

Only in environments that are adapted in this way is it possible to automatically use the SIMOTION Java libraries that are compatible with the relevant firmware version during the course of a CPU update.

Restrictions and special features

Overview

Limited resources (memory) and special implementations (file system, network) result in some restrictions and special features being present on the target system. These are described in the section that follows.

Number of threads

The required number of Java user threads can be set (see SIMOTIONVM_NUMUSERTHREADS (Page 3945)).

If user programs request more threads than are actually available, an error message is written to the output file (see Output file JCONSOLE.TXT (Page 3949)).

Network functions

No name service is available on the target system. For this reason, only the "raw" IP addresses can be used and not symbolic host names.

Examples:

- 157.163.237.50 instead of r1014.erlf.siemens.de.
- Especially also 127.0.0.1 instead of localhost.

The `get-/setSoTimeout` functions, for the socket functions' time watchdog, are not implemented. Consequently, it is not possible to apply a timeout to the process of receiving data via a socket connection, for example.

File system

The file system on the target system has the following features:

- All file names – with the exception of the target file when renaming files – must contain a drive letter (usually A: or B:) .
- A slash (/) is used as a file separator.
- No distinction is made between upper- and lower-case letters.

However, to write independent user programs from the platform, the file names must not be specially initialized for the target system (e.g. B:/DEMO/MYFILE.TXT).

Instead, a file name should be created dynamically (e.g. from the current working directory, the separator to be used, and the actual file name).

It is possible, for example, to test programs on a development computer this way.

Example:

```
// Retrieve the current working directory
String currDir = System.getProperty("user.home");
// Compile the file name
File f;
f = new file(currDir, "DEMO" + File.separator + "MYFILE.TXT");
```

The `get-/setLastModified` functions, for handling file time stamps, are not implemented.

Synchronization with the PLC

The JamaicaVM continues running even when the PLC is in the STOP state. It is possible to synchronize with the control section by accessing the current operating state of the PLC. However, no special notifications are given if the operating state changes.

Effects on the target system and user programs

It goes without saying that using the JamaicaVM will have consequences for the entire system.

Depending on the application case, approx. 3 MB of RAM are required to operate the JamaicaVM. This may make it impossible to load any larger user programs. As of SIMOTION V4.1 SP1, the memory required for the JamaicaVM is no longer provided by the USER memory, which means that operating the JamaicaVM no longer creates a drain on the memory resources available for user programs.

The individual Java threads are tied to their corresponding SIMOTION tasks on a round-robin level. This means that any other SIMOTION tasks on this level will have correspondingly less computing time.

Connecting to SIMOTION SCOUT

The JamaicaVM is not connected to SIMOTION SCOUT.

SIMOTION SCOUT merely indicates a missing license or a serious error when the JamaicaVM starts up by means of a corresponding entry in the diagnostics buffer.

Debugging Java programs

With SIMOTION V4.2 and higher, remote debugging of Java programs is possible on the target system.

A network connection is always used for communication between the debugger and JamaicaVM. The target system is configured as standard as the debugging server. For this purpose, the JamaicaVM must be made to open a remote debugging port by means of parameterization.

To connect with a debugger, a network connection to the target system is thus necessary. In addition, the debugger must be activated by means of the relevant specifications in VMCONFIG.INI.

Eclipse or also jdb (the Java debugger of Sun Microsystems Inc.) can be used, for example, as the debugger frontend.

Example of connecting with the jdb, specifying the IP address and port number:

```
jdb -connect
com.sun.jdi.SocketAttach:hostname=192.168.214.1,port=8000
```

For the setting of breakpoints to function correctly, it is extremely important that the Java application loaded in the target system and the Java source files used match precisely. The Java source files are used for determining breakpoints. If, for example, a Java source file that has been changed in relation to the Java application loaded in the target system is used by mistake, it can happen that the debugger simply does not stop at the breakpoint. This behavior arises because the relevant line number in the Java source file within the loaded Java application does not describe an executable program line.

However, the SIMOTION API can be operated in simulation mode for the software development phase. In this way, the application can be tested and debugged on the development computer as an initial step (basic program execution). See DATA_ACCESS element (Page 3944)

Debugging with Eclipse

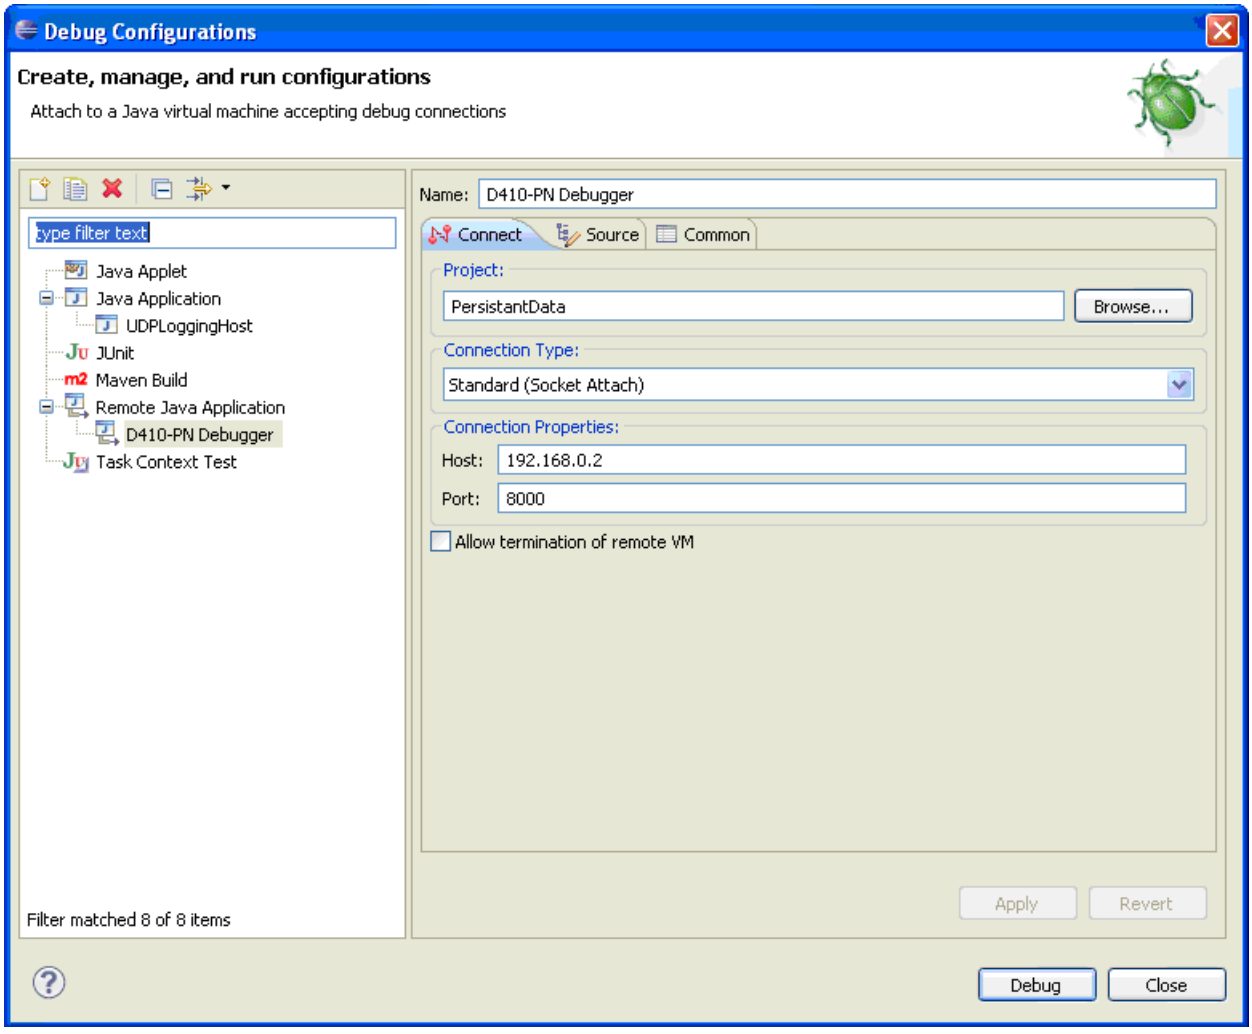

Figure 6-153 Example of remote debugging settings in Eclipse

See also

VMCONFIG.INI (Page 3945)

SIMOTION API

Overview

The SIMOTION API contains Java classes. These allow you to:

- Access runtime system variables, including the option of marshalling (variable values can be set on the basis of byte arrays and written to byte arrays)
- Call system functions of a technology object (TO)

- Access the parameters, parameter description, and error buffer of a drive
- Output logging information

Variable access

Overview

Relevant Java package:

- com.siemens.ad.SIMOTION.da

The "object server" (RTObjectServer), acting as the central class, and classes for the type-safe representation of variables are available for the purpose of accessing data on the runtime system. There is a corresponding Java class for each ST standard data type (RTVariableBOOL, etc.).

The variable provider of the runtime system supports the conversion of elementary data types to strings and vice versa. This means, all variables of the runtime system can also be accessed using a "string" variable.

Table 6-60 Mapping elementary data types to variable classes

ST standard data type	Java variable class
BOOL	RTVariableBOOL
SINT	RTVariableSINT
USINT, BYTE	RTVariableUSINT
INT	RTVariableINT
UINT, WORD	RTVariableUINT
DINT	RTVariableDINT
UDINT, DWORD	RTVariableUDINT
REAL	RTVariableREAL
LREAL	RTVariableLREAL
TIME	RTVariableSTRING
DATE	RTVariableSTRING
TIME_OF_DAY (abbreviation: TOD)	RTVariableSTRING
DATE_AND_TIME (abbreviation: DT)	RTVariableSTRING
STRING	RTVariableSTRING
Any ST standard data type	RTVariableANY

Regardless of this, any Java RTVariable (except for RTVariableANY) can provide its value in Java string format, or set it according to a specified string.

RTVariableANY is a special case. This type of variable can be used to read the native data type and content of a runtime system variable (but only in the form of "raw bytes"). However, the runtime system variable must be of one of the elementary data types listed in the table above.

After an RTVariableANY variable has been successfully read, a corresponding typesafe variable can be created using the object server.

The object server has the following tasks:

- Creating variables
- Reading/writing variables or variable groups
- Deleting variables
- Browsing variables
- Reading variable properties

The variables have the following tasks:

- Storing the variable value
- Type-safe reading/setting of the variable value
- Converting the variable value from/to string format

Converting the variable value from/to byte array format (marshaling)

Accessing the configuration data of a TO

Accessing the configuration data of a TO enables you to configure an axis, or even to determine the logical base address of the drive assigned to the axis.

Please note that there are several types of configuration data:

- Active configuration (current value)
- Configuration that may have changed but is not yet active (next value)

It is possible to access both the currently active configuration and the configuration that is not yet active. In SIMOTION SCOUT, these data sets are referred to as "current value" and "next value" respectively.

The specified variable name is used to determine which data set is to be accessed (see also Variable names (Page 3920)).

The parameters that are available depend on the TO type and, in the case of an axis, for example, on the type of axis. In addition to this, specific parameter settings demonstrate interdependencies (these are implemented in the SCOUT by integrating the test routines created during generation). There is no special support for access via Java in this case.

Please also note the various options for changing configuration data:

- Download (can no longer be changed)
- Restart (the TO must be restarted to make the change effective)
- Immediate (the change is effective immediately).

Reading the variable properties allows you to determine whether a configuration variable can be changed, and whether it will be necessary to restart the TO following a change (see also Reading variable properties (Page 3923)).

Variable names

No distinction is made between upper- and lower-case letters when it comes to variable names.

They consist of a prefix and the name of the variable itself.

For device system variables, the prefix is "var/". For variables from a source (ST/MCC/LAD/FBD), the prefix is "unit/".

Only the variables declared in the interface are available.

When accessing system or configuration variables of a TO, the following rules apply:

- The prefix for TO system variables is: to/<TOname>.
- The prefix for TO configuration variables is: cfg/<TO-Name>.
  When accessing the current configuration variables, activeConfigData must also be specified after the TO name. For accessing the configuration to be adopted, which is designated in SIMOTION SCOUT as the Next value, setConfigData must be specified after the TO name.

Table 6-61 Accessible variables (variable name structure and example):

Variable type	Variable name structure	Example
Device system variables	var/	var/userData.user1
TO system variables	to/<TOname>.<Variable>	to/axis_1.basicMotion.position
TO configuration variables	cfg/<TOname>.activeConfigData.<Variable>	cfg/axis_1.activeConfigData.Modulo.state
TO configuration variables	cfg/<TOname>.setConfigData.<Variable>	cfg/axis_1.setConfigData.Modulo.state
Global device variables	glob/ <Variable>	Glob/myGlobalVar1
IO variables	io/_direct .<Variable> io/_image .<Variable> io/_quality .<Variable>	io/_direct.myOut1 io/_image.myOut1 io/_quality.myOut1
Program interface variables	unit/<Unitname>.<Variable>	unit/awp01.ug_stringvar1

Access to I/O variables has been possible since Version V4.2. Access to the diagnostics buffer is currently not possible.

Access to SIMOTION variables

```
// Create the object server
RTObjectServer myServer = RTObjectServer.createRTObjectServer();

RTVariableUDINT myVar = zero;

// Create an RTVariable to access a SIMOTION variable
myVar = myServer.createRTVariableUDINT(
                        "unit/delay.ug_udruntimedelay" );

// Read the variables (the SIMOTION variable value is retrieved in the
// RTVariable).
myServer.read( myVar );

// Read the variable value
long myValue = myVar.getValue();

// Convert to string format
// Any RTVariable can supply its value in string format
String: myValueAsString = myVar.getAsString();
```

```
// Marshalling
Byte [] myBuffer = new byte[20];
int myIndex = 2;
boolean bAsBigEndian = true;

// Any RTVariable can write its value to a byte array
//(beginning with the index specified); option of
// Big or Little Endian format
myVar.getValue( myBuffer, myIndex, bAsBigEndian );

// Delete the RTVariable
// Important for re-enabling the
// management information created within the variable providers.
myServer.delete( myVar );
```

It is also possible to access a group of RTVariables simultaneously:

```
RTVariable [] myVars = new RTVariable[2];
myVars[0] = myServer.createRTVariableUDINT(
                        "unit/delay.ug_udruntimedelay" );
myVars[1] = myServer.createRTVariableREAL(
                        "unit/delay.ug_rvalue" );

myServer.read( myVars );
```

Example: Using RTVariableANY

```
// Create the object server
RTObjectServer myServer = RTObjectServer.createRTObjectServer();

RTVariableANY v = zero;
String myStringValue = "";

try
{
    // Use RTVariableANY
    v = myServer.createRTVariableANY("to/axis_1.error" );

    // Read the variables (reads type)
    myServer.read( v );

    // Information about the data type read
    short vDatatype = v.getDatatype();

    // Use the information read to create a
    // typesafe variable
    RTVariable v2 = myServer.createRTVariable( v );

    // Read the variables (reads value)
    myServer.read( v2 );
```

```
    // Following this, a value can be assigned to the variables
    // in string form.
    v2.setFromString(myStringValue);
}
catch( DataAccessException e )
{
    …
}
```

Browsing variables

The object server offers the option of browsing variables. Browsing means that all the variable names will be listed starting from a particular level (as specified by a search pattern).

Browsing is particularly worthwhile in applications where it is necessary to determine dynamically which technology objects are present in the runtime environment, so that these can subsequently be accessed (e.g. for the purpose of reading out the error variable of each technology object).

Example: Browsing variables

```
// Use the RTObjectServer to list all
// technology objects
String [] vTOs = mServer.listVariables( "to/*" );
```

Reading variable properties

The `readProperties` function is available for the purpose of reading variable properties.

Reading variable properties is particularly worthwhile in generic applications.

It enables you to determine during runtime whether a variable may only contain special values of an enumeration, for example. For this kind of enumeration variable, a list containing all the permitted values (the enumeration itself) is also provided in the variable properties. This can then be used, for example, to construct a drop-down list box containing these values.

In the case of configuration variables, the "effectiveness" of a value change is also indicated in the variable properties. In other words, a program can establish whether a value can ever be changed during runtime, and whether it will be necessary to restart the technology object following a value change.

The `readProperties` function delivers the variable properties in an object within the `RTProperties` class.

The `RTProperties` class has the following tasks:

- Defining the names for the individual properties

Currently, the following property names have been defined in `RTProperties`:

- DATA_TYPE — Data type
- VALUE — Current value
- ACCESS_RIGHTS — Access rights

- ENUMERATION_TYPE — Enumeration type
- ENUMERATION_INFO — The enumeration itself (if enumeration type)
- EFFECTIVENESS — Effectiveness

Not all properties are available for all variables. For instance, ST program variables do not have the EFFECTIVENESS property.

Please also note that enumeration variables of an ST program are mapped internally as straightforward DINT variables, meaning that the list of permitted values is not available for these ST program enumeration variables.

The variable properties also contain the current value for the variable at hand. However, particularly where cyclic access to the variable value is concerned, a corresponding `RTVariable` should be used for reasons of performance.

Example: Reading variable properties

```
// Use the RTObjectServer to read the properties of
// the "var/traceState[0].fctGenState" variable
RTProperties myProperties =
    mServer.readProperties("var/traceState[0].fctGenState" );

// Retrieve the enumeration type
String sEnum =
    myProperties.getProperty( RTProperties.ENUMERATION_TYPE );

// Establish whether the variable may only contain values
// of an enumeration
if( "enumerated".equals( sEnum ) )
{
    // Continue by, for example, retrieving the enumeration itself,
    // i.e. ENUMERATION_INFO
    ...
}
```

Accessing drive data

Relevant Java package:

- com.siemens.ad.SIMOTION.sys

The `RTDrive` class is available for accessing the drive data of a runtime system. Each drive is identified by its logical base address, which must be specified when creating an `RTDrive` object.

The `RTDrive` class has the following tasks:

- Reading/writing drive parameters
- Reading the description of drive parameters
- Reading the error memory of a drive

The `RTDriveParameter` class is used to access the drive parameters themselves. This class stores information on which parameter is to be accessed (parameter number; parameter index for array parameter where applicable), and transports the actual parameter values.

A Java `double` is always used for setting/reading the value within an `RTDriveParameter` object, which makes it easy to create generic applications (regardless of the actual data type of a parameter, its value can be easily read and displayed, e.g. for diagnostic purposes).

If an application requires type-safe values (e.g. for calculations), these values can easily be converted to the right data type:

byte vValue = (byte)param.getValue();

The `RTDriveParameter` class has the following tasks:

- Storing the information on the parameter that is to be accessed
- Storing the parameter value
- Storing the data type of the parameter
- Reading/setting the parameter value

The parameter data type can only be detected following the first successful access procedure (read access or write access). If the parameter has not yet been accessed, the stored data type corresponds to the value `RTDatatypes.DT_UNKNOWN`.

The `RTDriveParameterDescription` class is used to determine drive parameter properties. Reading drive parameter properties allows you to determine, for example, the actual data type, or information on whether you are dealing with an array parameter or not (incl. the array length).

The `RTDriveParameterDescription` class has the following tasks:

- Storing information about the drive parameter
- Reading parameter information

If any errors occur when accessing drive parameters, the special exception `DriveAccessFailedException` will be triggered.

The `DriveAccessFailedException` class has the following tasks:

- Storing the parameter numbers
- Storing the error code of the access function
- Storing the parameter-specific error code

This information can be read out from the relevant exception object when a `DriveAccessFailedException` occurs.

Refer to the SIMOTION documentation (e.g. SIMOTION SCOUT online help) for the meanings of the error codes.

Example: Accessing drive data

```
Try
{
    // Example of a logical base address of a drive,
    // depends on the SIMOTION project configuration.
    int vLogDriveAddress = 256;

    // Create the RTDrive object
    RTDrive vDrive   = new RTDrive( vLogDriveAddress );
```

```
    // Example of a parameter number; describes the:
    // "Drive state" parameter of a SINAMICS G110
    long vParameterNumber = 2;

    // Create the parameter
    RTDriveParameter vParameter =
                      new RTDriveParameter( vParameterNumber );

    // Read the parameter
    vDrive.read( vParameter );

    // Check the "Drive ready" state of the drive
    if( (int)vParameter.getValue() == 1 )
    {
        ...
    }
}
catch( DriveAccessFailedException e )
{
    // Access to parameter failed
    ...
}
catch( DataAccessException e )
{
    // Another error,
    // e.g. BadArgumentException...
    ...
}
```

Accessing target system functions

Overview

Relevant Java package:

- com.siemens.ad.SIMOTION.sys

The `RTDevice` class is available for accessing target system functions.

The `RTDevice` class has the following tasks:

- Reading/setting the current operating mode
- Copying actual data to RAM
- Copying RAM to ROM
- Unzipping a SIMOTION archive file (e.g. project archive)
- Restarting the target system
- Reading version information

When target system functions are called, in addition to purely technical causes of errors (such as a "System function failed" call), other causes of errors such as "Function cannot be executed in current state" are possible.

So that errors occurring as a result of purely technical problems can be distinguished from others, special exceptions of type `DeviceFunctionFailedException` are triggered in these cases.

The `DeviceFunctionFailedException` class does not have any other tasks, nor does it transport any other special information apart from, of course, the error message, which is as detailed as possible and is included in all exceptions.

The majority of situations causing errors can be determined. An example is when there is not enough space on the memory medium for copying from RAM to ROM:
`Device function failed with result: DISK_FULL`

If it is not possible to set the operating state due to the setting of the mode switch on the target system:
`Device function failed with result: NOT_ALLOWED`

However, the exact cause of an error cannot be determined in all situations. For example, it is not possible to distinguish between a situation where copying from RAM to ROM cannot be executed because the target system is not in the STOP mode, and one where the SCOUT or an ST program has already initiated the function at the same time. In this kind of case, the `DeviceFunctionFailedException` would only contain general information: `Device Function execution failed`.

Accessing the target system operating state

The `getOperatingState/setOperatingState` functions are available for reading/ setting purposes.

The operating state of the target system is returned as a string in this way. When writing, the operating state must also be transferred as a string.

The operating states that are currently supported are:

- `RUN`
- `STOPU`
- `STOP`
- `SERVICE`

Comment:

When the current operating state is being read, values that deviate from the currently supported operating states may be provided. The reason for this is that the system adopts various interim states during the course of changing its operating state.

The SERVICE target system operating state is not currently supported for writing operations.

The target system's state selector switch is crucial when it comes to selecting the target system operating state. The program cannot set the operating state if the target system operating state is STOP.

Refer to the SIMOTION SCOUT documentation for the exact meanings of the individual operating states.

Example: Accessing the target system operating state

In the following example, the current operating state is queried. If the target system is not in STOP, it will be stopped.

```
try
{
    //  Create object for accessing
    RTDevice vDevice = RTDevice.createRTDevice();

    // Query the current operating state
    String: vCurrentState = vDevice.getOperatingState();

    // If the target system is not
    // in the STOP operating state...
    if( !RTDevice.STOP.equals( vCurrentState ) )
    {
        // ... Stop
        vDevice.setOperatingState( RTDevice.STOP );
    }

    // If the program gets to this point,
    // the target system is in the STOP state
}
catch( DataAccessException e )
{
    // Access to operating state failed
}
```

Copying actual data to RAM/from RAM to ROM

The `copyActualToRam/copyRamToRom` functions are available for the purpose of "copying actual data to RAM"/"copying from RAM to ROM".

Example: Copying actual data to RAM/from RAM to ROM

In the example below, the actual data is copied to RAM first, and then from RAM to ROM.

```
try
{
    //  Create object for accessing
    RTDevice vDevice = RTDevice.createRTDevice();

    // Copy actual data...
    vDevice.copyActualToRam();

    // Copy from RAM to ROM...
    vDevice.copyRamToRom();
}
catch( DeviceFunctionFailedException e )
{
    // Function could not be executed,
    // e.g. Device function failed with result: DISK_FULL
```

```
}
catch( DataAccessException e )
{
    // Another error has occurred
}
```

Unzipping a SIMOTION archive file (e.g. project archive)

The `unpackArchive` function is available for unzipping a SIMOTION archive file.

This system function can be used to unzip a SIMOTION archive file, such as a user project that has been properly stored using SIMOTION SCOUT.

It must be noted that the target system must be in the STOP operating state to allow unzipping of the archive file.

Following successful unzipping, both the temporary work directory and the archive file are deleted by the system function.

The modified data does not become active until the target system is restarted.

Restarting the target system

The `restart` function is available for restarting the target system.

This function restarts (resets) the target system.

It is necessary to restart the target system once a user project has been successfully unzipped, for example.

Example: Unzipping a user project and restarting the target system

In the example below, the user project archive file is unzipped, and the target system is then restarted so that the new user project can be activated.

```
File myPrjFile = new file( System.getProperty("user.dir"),
                           "MYPROJ.ZIP" );

// Create work directory
// This is necessary because the system function removes the
// specified work directory after unzipping of the archive file
File workDir = new File( System.getProperty("java.io.tmpdir"),
"JVM_PRJUPD" );
if( !workDir.isDirectory() )
{
    if( !workDir.mkdir() )
    {
        // Creation of work directory has failed
        return;
    }
}

try
{
    //  Create object for accessing
```

```
    RTDevice vDevice = RTDevice.createRTDevice();

    // Unzip the archive file
    vDevice.unpackArchive(
                          workDir.getCanonicalPath(),
                          myPrjFile.getCanonicalPath()
                         );

    try
    {
        // Caution: If successful, it will not be possible to undo
this call!
        vDevice.restart ();
    }
    catch( OperationFailedException e )
    {
        // Restart failed...
    }
}
catch( Exception e )
{
    // Unzipping the archive has failed;
    // there may not be a correct SIMOTION user project archive
}
```

Reading version information

The `getFirmwareVersion/getDriveVersion` functions are available for the purpose of reading version information.

The `getFirmwareVersion` function provides the version number of the SIMOTION firmware.

The `getDriveVersion` function provides the version number of the integrated drive. On target systems without an integrated drive, a corresponding exception will be triggered.

Example: Reading version information

In the example below, the version numbers of the SIMOTION firmware and the integrated drive are read. The firmware version number is read first, as the access to the integrated drive that follows may trigger an exception (on target systems without an integrated drive).

```
String v1 = "n/a";
String v2 = "n/a";

 try
{
    //  Create object for accessing
    RTDevice vDevice = RTDevice.createRTDevice();

          short [] v;

          v = vDevice.getFirmwareVersion();
          v1 = "V " + v[0] + "." + v[1]+ "." + v[2]+ "." + v[3];
```

```
            v = vDevice.getDriveVersion();
            v2 = "V " + v[0] + "." + v[1]+ "." + v[2]+ "." + v[3];
}
catch( OperationFailedException e )
{
    // Reading of the version failed;
    // possibly target system without integrated drive
}
```

Additional functions

The following additional functions are available:

- `getName`
- `copyFile`

The `getName` function provides the name assigned to the target system within the SIMOTION user project.

The `copyFile` function copies an existing file with the aid of the relevant file system function. Particularly in the case of large files, using this function may represent a much faster option than using a straightforward file copying function implemented in Java.

Calling system functions

Overview

Relevant Java package:

- com.siemens.ad.SIMOTION.sys

The `RTSystemFunctions` class is available for the purpose of calling system functions of a technology object (TO).

The `RTSystemFunctions` class has the following tasks:

- Creating a command ID
- Calling the system functions of a TO
- Reading the type UID of a TO

Creating a command ID

Most system functions expect a command ID as a parameter. The `getCommandId` method provides an object from the `RTCommandId` class as a return value.

Please note that a command ID consists of two values (internally): Id_low and Id_high. If the method used to call a system function is the one that expects the input parameters to be received in the form of an object[], the two values must be transferred separately (Id_low first).

The `RTCommandId` class has the following tasks:

- Storing a unique command ID
- Reading the two internal command ID values, so that they can be specified as parameters for calling a system function

Calling the system functions of a technology object

The `callSystemFunction` method is a general function that can be used to call a system function of a TO. The method receives the name of the TO as a parameter, the name of the system function to be called, the input parameters of the system function, and dummies for the output parameters of the system function called (incl. the number of output parameters).

The current system function can always be found by specifying the function name. If a new version of SIMOTION includes any changes to the signature or semantics of a system function, this must be taken into account in the user program.

Currently, it is possible to call the following system functions:

- _move
- _getStateOfAxisCommand
- _getAxisErrorNumberState
- _stopEmergency
- _stop
- _enableQFAxis
- _resetAxis
- _resetAxisError
- _disableAxis
- _disableQFAxis
- _continue
- _getAxisErrorState
- _enableAxis
- _pos
- _homing
- _ getIPConfig
- _ setIPConfig

Important note:

Please note that, for the majority of system functions, the name of the TO for which the system function is to be executed must be specified again within the input parameters. The object is usually the first input parameter of a system function. Here, please note that this parameter describes another TO, which may not even be available. However, this is not a mistake. Possible consequences of this may be the execution of functions for another TO, or error situations such

as Function not found" (if this parameter describes an existing TO that is not supported by the system function on account of the TO type), or even "TO not found".

Two versions of the `callSystemFunction` method are available.

Since various parameter types must be transported, and the number and sequence of the input parameters also depends on the system function that has actually been called, each input parameter is passed as either a straightforward `Object[]` or an `ArrayList`, depending on the version.

The `java.lang.Long` and `java.lang.String` object types are supported by both versions as input parameter types. Numerical parameters must be stored in a long object, with floating-point numbers converted accordingly (`doubleToLongBits` method of `java.lang.Double`). TO names should be passed as string-format parameters.

The method that expects the input parameters in `ArrayList` format is more user-friendly; as well as this, it supports `java.lang.Double` and `RTCommandId` parameters. However, due to the type monitoring that is necessary during runtime and the parameter conversions, it is considerably slower than the version that expects the input parameters in `Object[]` format.

A command ID is required for executing system functions. This command ID must be created anew for each call, and passed in the input parameters accordingly.

Refer to the SIMOTION documentation (e.g. SIMOTION SCOUT online help) for the number and sequence of input parameters in a system function. Precisely this number of input parameters must be stored in the passed parameter container (Array or ArrayList), in precisely this sequence. In other words, the container with the input parameters must not contain any additional elements.

This method provides the call result in the form of a return value (`ErrorCodes.RT_ERR_IS_OK` if it was possible to execute the system function call; otherwise, one of the predefined `ErrorCodes`).

Here, potential errors include, in particular:
`ErrorCodes.RT_ERR_SYSFCT_TO_NOT_FOUND:`

The TO could not be found. A project that contains the TO with the specified name must be loaded on the target system.
`ErrorCodes. RT_ERR_SYSFCT_FCT_NOT_FOUND:`

The function could not be found. For example, a straightforward speed-controlled axis does not support the "_pos" system function.

`ErrorCodes. RT_ERR_SYSFCT_MISSING_INPUT_PARAM:`

Too few input parameters were specified.
`ErrorCodes. RT_ERR_SYSFCT_CANT_WRITE_OUTPUT_PARAM:`

The dummy array for the output parameters of the system function is too small.

The actual return value of the system function is always located in the output parameters of the system function.

An `Object[]` must be specified as a dummy for the output parameters. The length of the array must at least equal the number of output parameters of the actual system function, so that all output parameters can be accommodated. The individual array elements do not, however, have to be initialized. Once the system function has been successfully called, an object corresponding to each output parameter is created; here, only the `java.lang.Long` and `java.lang.String` object types are supported.

Refer to the SIMOTION documentation (e.g. SIMOTION SCOUT online help) for the number and sequence of output parameters in a system function.

Reading the type UID of a technology object

Currently, the actual type of a TO (drive axis, position axis, synchronized axis, etc.) can be queried.

The `RTUID` class has the following tasks:

- Storing a unique UID for the runtime system
- Predefining recognized type UIDs (e.g. `RTUID.POS_AXIS`), in order to compare them to a read type UID.

The comparison method `equals` must be used to carry out a comparison with one of the UIDs predefined in `RTUID`.

Example: Calling a technology object system function

In the example below, the system function "resetAxisError" is called for the TO named "Axis_1".

```
// Create object for accessing system functions
RTSystemFunctions vSystemFunctions = new RTSystemFunctions();

// The name of the TO
String vName = "Axis_1";

// ArrayList for the input parameters
      ArrayList vParamsIn = new ArrayList();

// TO name (name of the axis)
vParamsIn.add( vTOName );

// errorResetMode - ALL_ERRORS
vParamsIn.add( new long( 10 ) );

// errorNumber - n/a because ResetMode == ALL_ERRORS
vParamsIn.add( new long( 0 ) );

// nextCommand - IMMEDIATELY
vParamsIn.add( new long( 60 ) );

// commandId
vParamsIn.add(  vSystemFunctions.getCommandId() );

// Array as dummy for the output parameter
Object [] vParamsOut = new object[1];

// Dummy for the number of output parameters
int [] vNumParamsOut = new int[1];

// Call system function
short callResult = vSystemFunctions.callSystemFunction
```

```
(
        vName,
        "_resetAxisError",
        vParamsIn,
        vParamsOut,
        vNumParamsOut
);

// If the system function call has been successfully executed and
// the function result has been stored in the output parameter array
if( callResult == ErrorCodes.RT_ERR_IS_OK && vNumParamsOut[0] == 1 )
{
    // Can the actual function result be retrieved and
    // evaluated.
    int fctResult = (int)((Long)vParamsOut[0]).longValue();

    if( fctResult == 0 )
    {
        // All executed without errors
    }
    else
    {
        // Error code as per description for _resetAxisError
    }
}
else
{
    // System function call unsuccessful
    // Error code is one of the predefined
    // ErrorCodes
}
```

Example: Querying the actual type of a TO

In the example below, the actual type of the "Axis_1" TO is determined.

```
// Create object for accessing system functions
RTSystemFunctions vSystemFunctions = new RTSystemFunctions();

// The name of the TO
String vName = "Axis_1";

// Read type UID
RTUID vId = vSystemFunctions.getTypeUID( vName );

if( RTUID.POS_AXIS.equals( vId ) )
{
    // Position axis recognized,
    // _pos system function could be used...
}
```

Using persistent data (NVRAM)

Overview

Relevant Java package:

- com.siemens.ad.SIMOTION.da

The `RTNVRAMData` class is available for the purpose of using persistent data.

The `RTNVRAMData` class has the following tasks:

- Creating/opening areas within the NVRAM
- Reading/writing areas within the NVRAM
- Querying whether NVRAM areas are valid/setting valid areas
- Closing/deleting areas within the NVRAM

Persistent memory areas are identified by a name.

A non-existent memory area must be created and an existing memory area must be opened.

The data can then be read (though, in the case of newly created memory areas, only after data has been initialized by means of writing), or written.

Where cyclic access is concerned, from a performance standpoint it is better to keep the memory area open, rather than reopening it before and closing it after each access procedure.

Data exchange takes place via a byte array; a start index (within both the persistent memory area and the transferred byte array) and length can be specified.

Only one instance of each persistent memory area can be opened at a time, so the latest point at which memory areas must be closed is on exiting of the user program (or when another user program needs to open the same persistent memory area).

Persistent memory areas that are no longer required can also be deleted.

A straightforward internal marking procedure has been implemented in order to support recognition of inconsistencies within the stored data. This stores information regarding whether the most recent write operation was completed successfully. This marking procedure applies across the entire data area.

For each write operation, the data is marked as "invalid" immediately before it is actually written to the NVRAM, and is then reset to "valid" immediately after the data has been written. If the most recent write operation was not completed successfully, the data area is marked as invalid.

If the data has not been written in its entirety (e.g. there was a power failure during the write operation), an attempt to read the data area triggers the special exception `NVRAMInvalidContentException`, allowing the user program to react accordingly (e.g. by using default values).

As far as handling invalid data areas is concerned, there are also methods of not only determining whether the data area is valid, but also marking it as valid.

The ability to determine the validity of a data area even before it has been read serves as an alternative to troubleshooting using exceptions.

Once a valid data area has been set, `NVRAMInvalidContentException` will not be triggered while the data is being read. The user program is responsible for interpreting the data, which is likely to be inconsistent. This is useful for user programs which implement fault-tolerant archiving of data and can, therefore, reconstruct the most recently valid data.

Newly created data areas are also marked as "invalid", i.e. their data must be "initialized" by means of a write operation before it can then be read. The user program is responsible for initializing the entire data area. Non-initialized parts of the data area cannot be recognized by the internal marking procedure (important for user programs which access individual parts of the data area, and do not always access the entire data area).

Example: Initialization sequence within a user program

```
try
{
    // Length and buffer for application data
    int vLength = 10;
    byte [] vData = new byte [vLength];

    // Variable, whether valid data has been read
    boolean bInitializationDataAvailable = false;

    RTNVRAMData vNVRAM = new RTNVRAMData( "MyData" );

    try
    {
        // Initial attempts to open the area
        vNVRAM.open();

        try
        {
            // Open, data can be read
            vNVRAM.read( vData );

            // After reading, it is ensured that
            // valid initialization data is available
            bInitializationDataAvailable = true;
        }
        catch( DataAccessException e )
        {
            // Reading failed
            // No initialization data available
        }
    }
    catch( DataAccessException e )
    {
        // Opening failed, create memory area
        vNVRAM.create( vLength );

        // Memory area created
        // Initialization data not available
```

```
    }

    if( bInitializationDataAvailable )
    {
        // Valid initialization data available
        // This can be evaluated accordingly
        ...
    }
    else
    {
        // Since no initialization data is available,
        // default values, for example, must be used
        ...
    }
}
catch( DataAccessException e )
{
    // Neither opening nor creation has functioned correctly
    // This is a serious problem, e.g. output exception in log
    // in order to determine cause of error...
}
```

Logging

Overview

Relevant Java package:

- com.siemens.ad.SIMOTION.log

The `Logger` is the central class of the logging API.

Currently, logging outputs are possible in a file or via a socket connection (UDP).

For a description of the format for logging outputs, refer to Format of logging outputs (Page 3956).

Example: Logging

The easiest way of using the logger is as follows:

```
static final String APP_NAME = "MyApplication";

public static void main( String [] args )
{
  // Create the logging object
  Logger vLogger = Logger.getLogger( APP_NAME );

  // Logging output
  vLogger.log( Logger.INFO, "Starting up" );
```

In the example above, exactly the same settings as those in configuration file JINVOKE.XML are used for logging (see LOGGING element (Page 3941)). These have been stored as Java system properties by the InvocationManager.

However, it is also possible to make explicit settings:

```
// Create a logger that only outputs error messages
// (i.e. FATAL and ERROR) without stack trace information
vLogger = Logger.getLogger( APP_NAME, Logger.ERROR, false );

// The messages should be output to log file MYFILE.LOG,
// and the file size should not exceed 16 KB.
// It is IMPORTANT to specify where the logging outputs
// are to be output (file or UDP) before the
// logger is used for the first time.
vLogger.addDestination( new FileLog( "MYFILE.LOG", 16 ) );

// Logging output
vLogger.log( Logger.FATAL, "Terminating" );
```

Note

Particularly in cases where several user programs are being operated simultaneously and logging outputs are output to a file, it may be helpful to assign each user program its own log file. Since the process of writing to the log file is synchronized, logging outputs from different user programs to the same log file could impair performance.

Creating user programs

User programs are created on a development computer.

To enable the Java compiler to find the classes referenced within the SIMOTION API, the relevant Java library must be specified during compilation.

For example:

```
javac –classpath simotion.jar ...
```

To ensure that the user program will not use any Java system classes that are not available within the SIMOTION Jamaica runtime environment, the Java library with system classes can also be specified as a reference during compilation.

For example:

```
javac –bootclasspath simotion_systemclasses.jar –classpath
simotion.jar ...
```

Following compilation, all of the user program classes must be zipped into a Java library.

For example:

```
jar –cvf test.jar ...
```

The Java library and user program can then be transferred to the target system and started up.

Configuration files

AUTOSTART configuration (JINVOKE.XML)

Overview

The settings for user programs that are to be started automatically must be made in configuration file JINVOKE.XML.

Settings for the interactive InvocationManager interface and logging can also be made in this file.

XML notation must be used for the structure of the configuration file. A simple XML parser (Nano/XML/Lite) is integrated in SIMOTION IT Virtual Machine that is perfectly adequate for editing the configuration file.

Before storing the configuration file on the target system, you are advised to display it in a web browser, for instance, so that any syntax errors can be made immediately apparent (if the configuration file has not been created using a special XML editor). NanoXML, in particular, deals with error messages very economically.

The individual XML configuration file elements are described below.

ROOT element

SIMOTION must be used as the ROOT element:

```
<?xml version="1.0" standalone="yes"?>
<SIMOTION>
  <!-- AUTOSTART elements, for example, are listed here -->
</SIMOTION>
```

All other elements must then be specified within the Root element. The above example contains only one comment line.

AUTOSTART element

An AUTOSTART element contains information about a user program that is to be started automatically.

You can specify several AUTOSTART elements. Therefore, it is possible to start several user programs. The start sequence corresponds to the sequence in which the AUTOSTART elements are specified.

The following attributes are evaluated:

LIBRARY

Name of the Java library (JAR or ZIP file) that contains the program to be started.

The name specification can be either absolute or relative.

If the specification is relative, i.e. only the file name is specified without the path, the file itself must be in the current working directory (see CURRENTDIR (Page 3945)).

CLASSNAME

Name of the class containing the method to be executed.

METHODNAME

Name of the method to be executed.

This method must be declared as `public static`, and must accept a string array as a single argument. Any value can be returned for the method.

Specification of the method name is also unnecessary. In this case, the main method is searched for.

ARGUMENT element

An AUTOSTART element can contain any number of ARGUMENT elements.

The arguments are stored in the sequence in which they were specified in the string array transferred to the method to be executed.

An ARGUMENT element only has one attribute, called VALUE.

Example: AUTOSTART elements

In this example, the MyClass class is first loaded from Java library USER.JAR, and its main method is then executed. The string array transferred to the main method contains the Argument1 and Argument2 strings.

Following this, the Test class is loaded from Java library TEST.JAR and its main method is executed. Since no arguments are specified, the string array transferred to the main method is empty.

```
<AUTOSTART LIBRARY="USER.JAR" CLASSNAME="MyClass">
  <ARGUMENT VALUE="Argument1"/>
  <ARGUMENT VALUE="Argument2"/>
</AUTOSTART>

<AUTOSTART LIBRARY="TEST.JAR" CLASSNAME="Test"/>
```

LOGGING element

Overview

The LOGGING element contains default settings for logging.

These default settings take effect when user programs use the logging API without explicit settings (see Logging (Page 3938)).

The following attributes are evaluated:

DEFAULT_DESTINATION

Currently, the default settings dictate that messages are output to a file and transferred to a host via the UDP network connection.

Possible specifications:

- FILE
- UDP

DEFAULT_LEVEL

This determines the default logging level.

Possible specifications:

- FATAL
- ERROR
- WARN
- INFO
- DEBUG

If nothing has been specified, or a specification that does not appear in the list above has been made, the logging level is set to DEBUG.

PRINT_STACKTRACE

Stack trace information is generally useful for error analyses in Java programs. If PRINT_STACKTRACE is activated, when an exception is logged the relevant stack trace information will automatically be written to the log.

Possible specification:

- true

If nothing has been specified, or a specification other than "true" has been made, no stack trace will be logged.

FILE element

The FILE element writes the default values for the log outputs to a file, and contains the following attributes.

FILENAME ... Name of the log file
MAXSIZE_IN_KB ... Maximum size of the log file in kilobytes

The file name specification can be either absolute or relative.

If the file name specification is relative and without the path, the file is generated in the current working directory (see CURRENTDIR (Page 3945)).

The log file resembles a ring buffer in terms of the way entries are made, i.e. when the maximum size that has been specified is exceeded, the process loops back to the beginning of the file. The most recent log entry is always followed by the character string `$$END$$`, which acts as a kind of separator between old and new log entries and makes it easy to find the most recent log entry.

UDP element

The UDP element writes the default values for the log outputs via a UDP socket connection, and contains the following attributes:

HOST	... IP address of the log outputs host
PORTNUMBER	... Port number for the log outputs receiver

Example: LOGGING element

In this example, the logging level is: DEBUG, and logging outputs, including stack trace information, are output to log file LOGFILE.LOG by default; their maximum size is limited to 64 KB.

The default values set for UDP logging are 157.163.237.50 for the host and 20000 for the port number.

```
<LOGGING DEFAULT_DESTINATION="FILE" DEFAULT_LEVEL="DEBUG"
PRINT_STACKTRACE="true">
  <FILE FILENAME="LOGFILE.LOG" MAXSIZE_IN_KB="64"/>
  <UDP HOST="157.163.237.50" PORTNUMBER="20000"/>
</LOGGING>
```

INVOCATION_MANAGER element

Overview

The INVOCATION_MANAGER element may contain other information for the InvocationManager, which is mainly used for setting the interactive socket interface.

The following attributes are evaluated:

PORTNUMBER

If a port number has been specified, the InvocationManager opens a server socket under this number and waits for requests.

It is then possible to load and start programs interactively via a socket connection.

If no port number has been specified, the InvocationManager ends after the AUTOSTART elements have been processed.

PORTRANGE

PORTRANGE is useful while developing and testing user programs if the JamaicaVM (and, therefore, the InvocationManager) is restarted frequently. Many TCP/IP implementations reserve this port number for a specific time. During this time, renewed opening of the server socket is not permitted under this port number.

If a port range has been specified, the InvocationManager attempts to use the next highest group of port numbers, until the server socket can be opened.

The port number that is currently used to access the InvocationManager is always output by means of a logging output.

Comment:

The InvocationManager attempts to create the server socket cyclically, i.e. even if no port range is specified, the socket connection can be reestablished after the delay time has elapsed.

CONSOLE_OUTPUT

Instead of the default target for logging outputs, the InvocationManager uses the screen. The screen output is useful in simulation environments, since it means that no log files need to be evaluated, for example.

Possible specification:

- true

If no specification has been made, or something other than "true" has been specified, the default target for logging outputs is used.

Example: INVOCATION_MANAGER element

In this example, once the AUTOSTART entries have been processed, the InvocationManager opens a server socket under port number 10000 and waits for requests.

If this port number cannot be used, the InvocationManager also tries port numbers 10001 to 10010.

```
<INVOCATION_MANAGER PORTNUMBER="10000" PORTRANGE="10"/>
```

DATA_ACCESS element

Overview

The DATA_ACCESS element is optional: Only the SIMULATION attribute, via which simulation mode can be activated for the data access API, is evaluated.

SIMULATION

Possible specification:

- true

Simulation mode is activated by specifying true. No accesses are made to the target hardware. Simulation mode is useful for the fundamental testing of user programs, also in advance, (e.g. on a development computer) without the need for target hardware.

When reading or writing variables and drive parameters, the current content of each Java variable remains unchanged. Calling system functions returns a positive function result in each case.

However, for the purpose of accessing persistent memory areas (NVRAM), simulation mode is restricted in that an attempt to open a memory area will always fail. No persistent data is simulated.

If nothing has been specified, or a specification other than "true" has been made, simulation mode will be deactivated.

JamaicaVM configuration (VMCONFIG.INI)

Overview

The configuration file VMCONFIG.INI is only evaluated in the target system. This file is not evaluated in tests on a development computer.

Default values are permanently specified for all JamaicaVM settings, i.e. it is possible to operate the JamaicaVM with the relevant default values without the need to make any special settings.

Specific default directories for Java program files and Java data files are recommended as of SIMOTION V4.1 SP4 so that the CPU update feature can be used for Java programs as well. These settings are included in the configuration files supplied and should be accepted without making any modifications to them.

However, the file must be available for the JamaicaVM to start at all.

If necessary, settings for the JamaicaVM itself can be made in configuration file VMCONFIG.INI. The settings take effect when the JamaicaVM is started up.

Each parameter must be specified in a single line, with the following format:

Parameter=Value

.

Blank lines are permitted. Spaces are also permitted, but not within the parameter or the value.

Comment lines must begin with "#".

Each of the parameters and their default values are outlined below:

VMCONFIG.INI

With SIMOTION V4.1 SP4 and higher, the configuration file VMCONFIG.INI is searched for primarily in the directory:

- /USER/SIMOTION/HMICFG/

.

This means that if file VMCONFIG.INI is found in directory /USER/SIMOTION/HMICFG/, it is evaluated and the JamaicaVM is started with the relevant settings.

For reasons of compatibility, VMCONFIG.INI is still evaluated even if it is located in the root directory, However, evaluation only takes place if no VMCONFIG.INI file has been found in the /USER/SIMOTION/HMICFG/ directory. This means that you can continue to use existing configurations/installations without making any changes to them.

SIMOTIONVM_HEAPSIZE

The size of the memory reserved for the JamaicaVM in bytes. The JamaicaVM reserves the entire memory, even when starting up. If the memory is not available, an error message is output to the output file (see Output file JCONSOLE.TXT (Page 3949)).

Default: 4194304

SIMOTIONVM_NUMUSERTHREADS

Number of Java user threads required.

The JamaicaVM creates the required number of threads as soon as it starts up. If the JamaicaVM is restarted, it will no longer be possible to change this setting.

If the required number of threads cannot be created, an error message is output to the output file (see Output file JCONSOLE.TXT (Page 3949)).

Default: 4

Maximum number that can be set: 28

This number also contains the main Java program executed by default ("InvocationManager").

In the default setting, three Java threads are thus available for user programs. This means three user programs can be run in parallel.

For special solutions, the InvocationManager can also be replaced by a user-defined program: This makes all Java user threads available for user programs.

SIMOTIONVM_STACKSIZE

Size of each Java thread stack.

Default: 40000

Maximum number that can be set: 81920

This parameter must only be changed in special cases. Such a special case could be a memory problem, for example. Reducing the stack size could help with this problem.

If the JamaicaVM is restarted, it will no longer be possible to change this setting.

SIMOTIONVM_ANALYSE

The JamaicaVM can be instructed to output information relating to the maximum amount of memory required during execution of the previous Java programs, once the JamaicaVM has been exited.
