Drive Control Chart (DCC) allows you to implement your regulating and control tasks in a drive-related manner. For this there is a set of blocks (DCB) available to you that you can interconnect graphically via a configuration tool (DCC editor) in so-called charts. The DCBs are available to you in the form of a library (DCBLIB).

Note

One exception in the DCC tasks does not call up a SIMOTION fault task.

Thus the charts created can be executed on the SIMOTION platforms as well as on SINAMICS drives.

Only DCC for Simotion is described below.

Additional references

DCB lib DCC editor description

Sequence model for DCC blocks (DCB)

Description

The individual DCC blocks (DCB – Drive Control Block) are organized as runtime groups in the DCC editor. You can freely assign these runtime groups to the DCC tasks in the DCC editor (task T1 to T5). The DCC tasks in the DCC editor correspond to the DCC tasks in the SIMOTION execution system.

Task in the DCC editor	Execution level	Task
T1	Servo	servoDcc
D2	IPO	ipoDcc
T3	IPO_2	IpoDcc_2
T4	DccAux	dccAux
T5	DccAux_2	dccAux_2

Execution groups can be activated or deactivated via binary outputs of blocks. Detailed description in the editor.

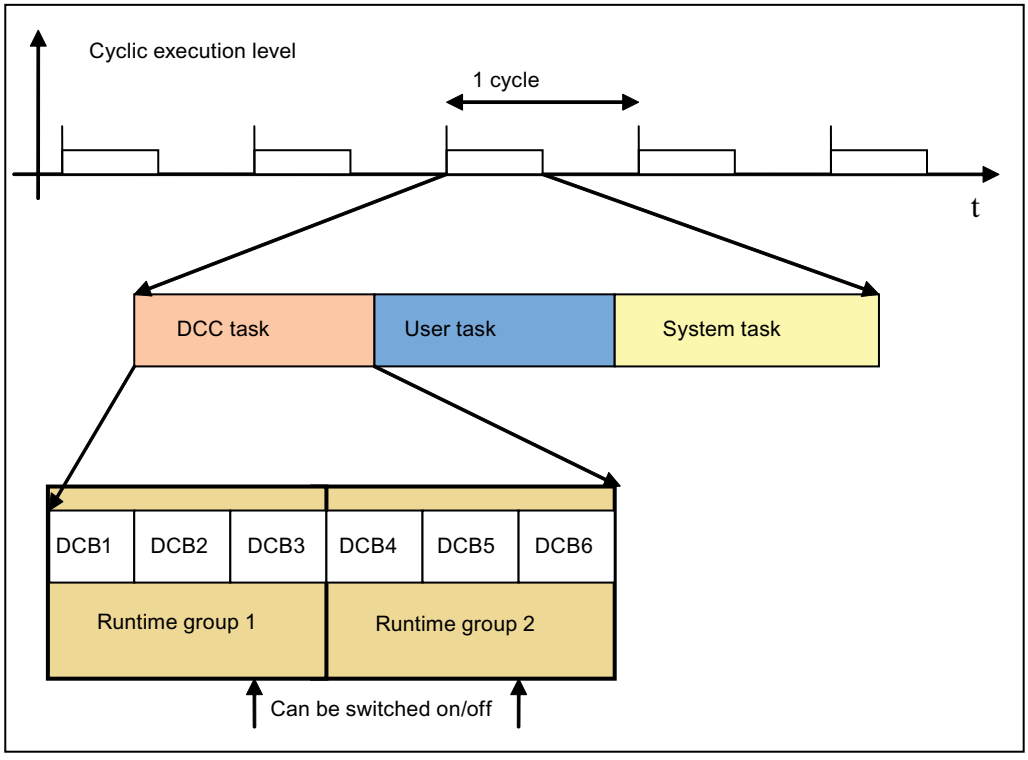

Figure 4-146 Sequence model of the runtime groups for DCBs

In the user model, the DCC task assigns itself in the execution level next to the user program tasks (execution environment for user programs in ST, MCC, LAD/FBD) and the system tasks. If required, the DCC task is created by the Engineeringsystem (ES); this means it is *not* present in the system as standard.

Execution of the DCC diagrams

The execution of DCC diagrams is linked to the task status but rather to the status of the runtime group assigned to it. They are enabled and disabled depending on the mode changes.

Mode	Action
STARTUP->RUN	ON runtime groups
SHUTDOWN->STOPU	OFF runtime groups
SHUTDOWN->STOP	OFF runtime groups

All other changes in the mode cause no changes to the runtime groups.

Execution levels for DccAux and DccAux_2 (Page 1398)

servoDccTask in the servo level

Description

The T1(DCC) task runs in the servo level of the SIMOTION execution system. The servo level is called synchronous to the data exchange with the isochronous I/O and used primarily for fast control tasks.

- At the start, the cyclic I/O data for the technology objects and servo-synchronous I/O variables is copied from the interface to the isochronous I/O in the execution system.
- At conclusion, the cyclical I/O data is copied again from the execution system and, for example, transferred with PROFIBUS to a PROFIBUS node.

The following graphic shows the chronological sequence of a task in the servo level.

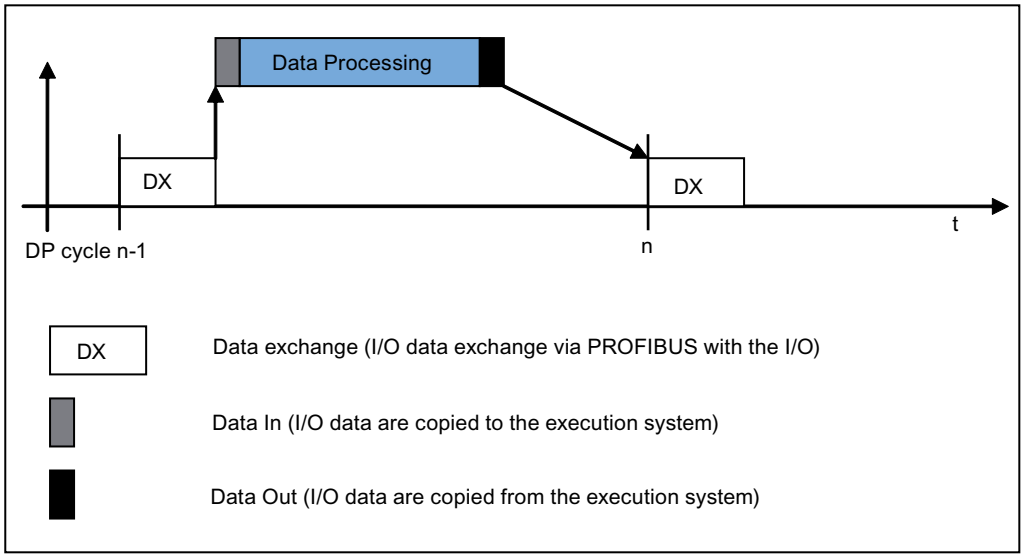

Figure 4-147 T1(DCC) task in the servo level

The T1(DCC) task is automatically started and executed at the begin of the servo level.

The following graphic shows the sequence of the tasks in the servo level.

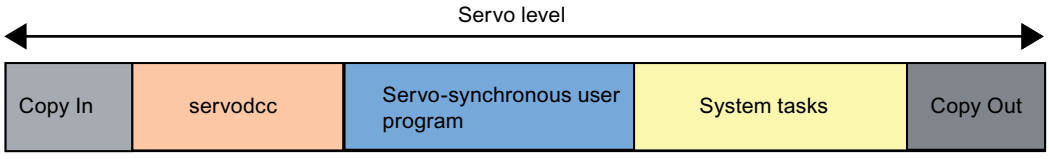

Figure 4-148 Servo level with T1(DCC) task

Level overflow in the servo level

Tasks in the servo level run with the same priority and so do not interrupt each other. If all tasks of the servo level cannot be calculated in a single cycle, a level overflow occurs and the system enters STOP mode and the start-up lock is set. Only after a new startup (power on/off) or download can the system return to RUN mode.

Defining system cycle clocks (Page 1350)

ipoDcc Task in the IPO level

Description

The IPO level runs with the same cycle time as the servo level or in an integer reduction ratio. Tasks in the servo level have a higher priority and so can interrupt tasks in the IPO level. In addition, in the IPO level all I/O data not copied in the servo level are copied into the execution system. The data can come both from the isochronous and the non-isochronous I/O.

The command processing and the setpoint generation of the technology objects run in the system task of the IPO level.

The following graphic shows the chronological sequence in the IPO level.

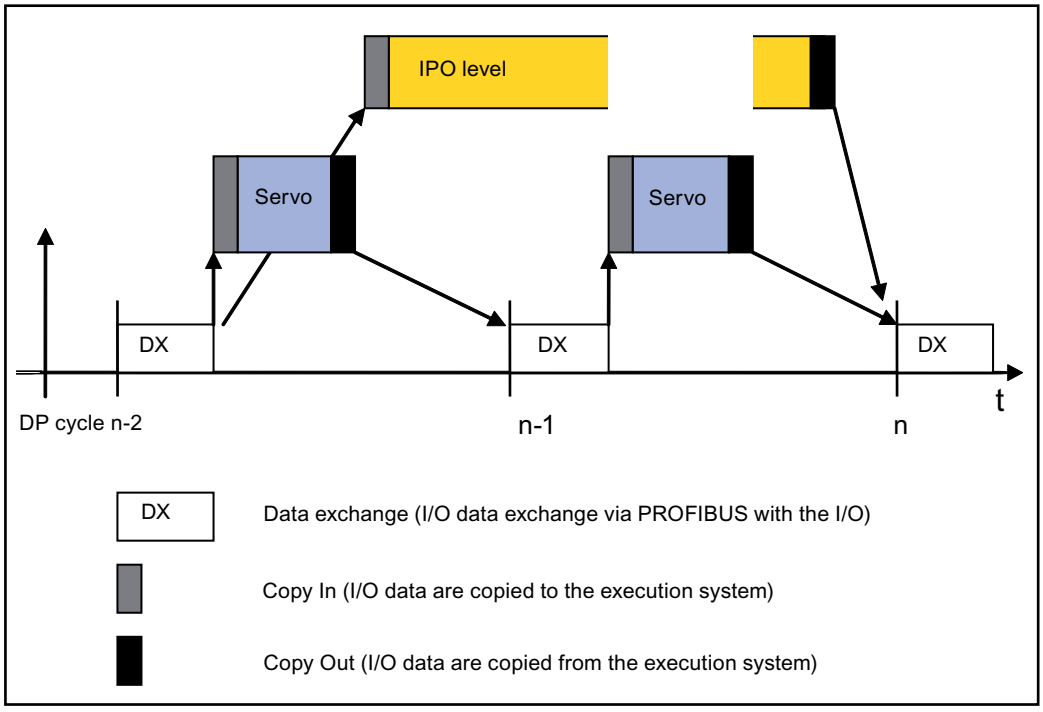

Figure 4-149 IPO level with T2(DCC) task

The T2(DCC) task is automatically started and executed at the begin of the IPO level.

The following graphic shows the execution sequence in the IPO level.

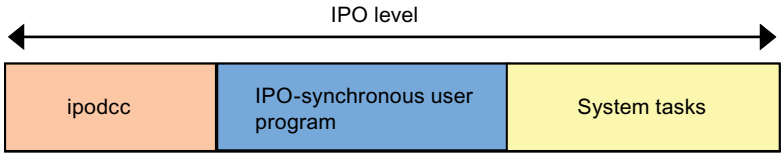

Figure 4-150 Execution sequence in the IPO level

Execution overflow in the IPO level

Tasks in the IPO level run with the same priority and so do not interrupt each other. A task in the higher priority servo level can at anytime interrupt the processing in the IPO level; this can possibly cause a level overflow, because not all tasks in the level can be processed.

With the standard behavior, for a level overflow the device enters into STOP mode and the start-up lock is set. Only after a new startup (power on/off) or download can the system return to RUN mode.

However, you can also configure the system for toleration of up to five successive overflows. You must set the behavior appropriately in the task configuration.

Timeouts and level overflows (Page 1360)

SynchronousTasks (Page 1326)

Isochronous data processing (Page 1385)

ipoDcc_2 Task in the IPO2 level

Description

The cycle time of the IPO2 level is an integer multiple of the cycle time of the IPO level. However, it is not possible to set the IPO2 cycle clock equal to the IPO cycle clock.

The cycle time of the IPO2 level is shorter than that of the IPO level. Consequently, both the IPO level and the servo level can interrupt the processing.

The T3(DCC) task is assigned in the IPO2 level as follows:

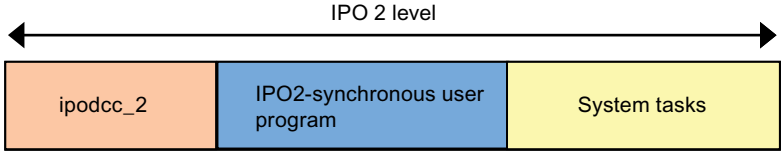

Figure 4-151 Order of processing in the IPO2 level

Level overflow in the IPO2 level

In the case of a level overflow, the IPO2 level behaves like the IPO level.

Defining system cycle clocks (Page 1350)

Execution levels for DccAux and DccAux_2

Description

The two DCC execution levels, DccAux and DCCAux_2, are called synchronous to the system.

The DCCAux and DCCAux_2 levels have the following properties:

- DccAux has a multiple of the Ipo_2 cycle clock.
- DccAux_2 has a multiple of the DccAux cycle clock.
- DccAux has a higher priority than DccAux_2
- Synchronous trace recordings are possible.

- Up to five level overflows are tolerated (the default is 1). The current number of level overflows can be fetched.
- In the case of a level overflow, the DCCTask is calculated to completion in the next task.

Table 4-77 System variables for fetching level overflows

System variable	Data type	Meaning
_device.numberOfSummarized-TaskOverflow.DccAux	UDINT	Number of overflows of the DccAux level since system startup
_device.numberOfSummarized-TaskOverflow.DccAux_2	UDINT	Number of overflows of the DccAux_2 level since system startup

Defining system cycle clocks (Page 1350)

Data exchange between blocks

Data exchange between blocks (overview)

Overview

In the DCC editor, you can interconnect the connections of various blocks. Three basic scenarios must be differentiated for the data exchange between the blocks:

- You have connected connections of blocks with each other that lie in the same execution level.
- You have interconnected the output of one block with the input of a block in a higher execution level.
- You have interconnected the output of one block with the input of a block in a lower execution level.

See also

Data exchange between blocks in the same level (Page 1400)

Data for blocks from a lower-priority level (Page 1402)

Data for blocks from a higher-priority level (Page 1405)

Data exchange between blocks in the same level

Description

If you have interconnect the blocks in the same execution level, the data will be transferred in accordance with the execution sequence of the blocks. The guarantees that the value is current at the input of the execution sequences.

If you have defined the execution sequence in accordance with the data flow, no additional dead time results in the level.

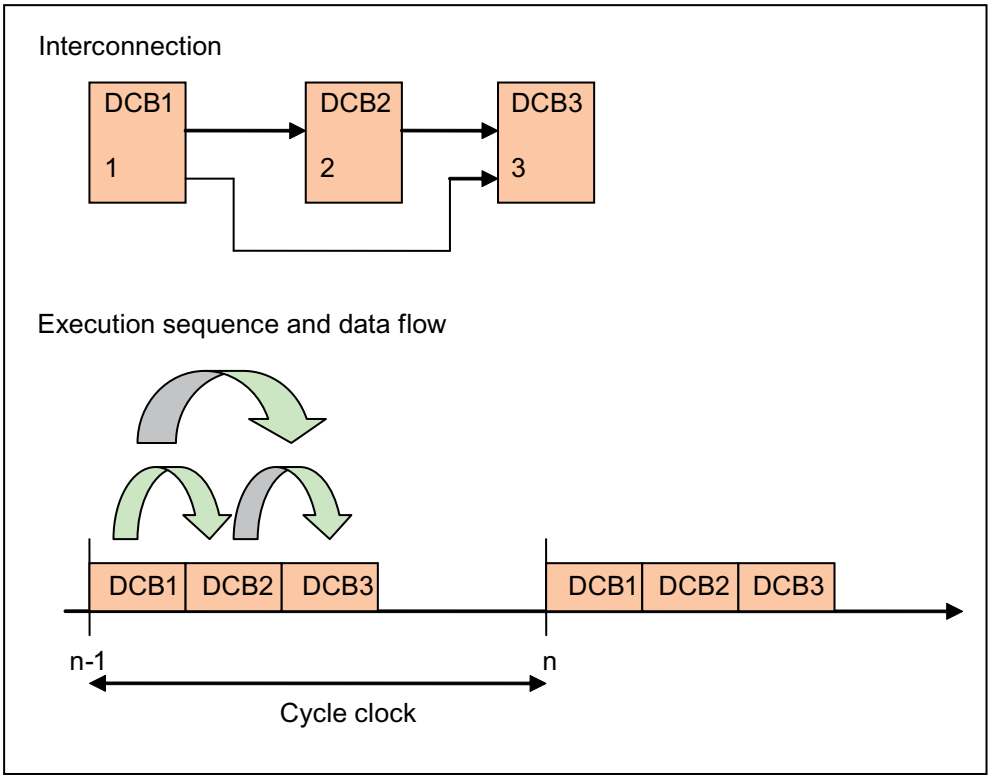

Figure 4-152 Interconnection sequence and execution sequence are identical

If the execution sequence of the blocks in the level does not correspond to the data flow, additional dead times result, because at the input access has been made to values from the previous cycle clock.

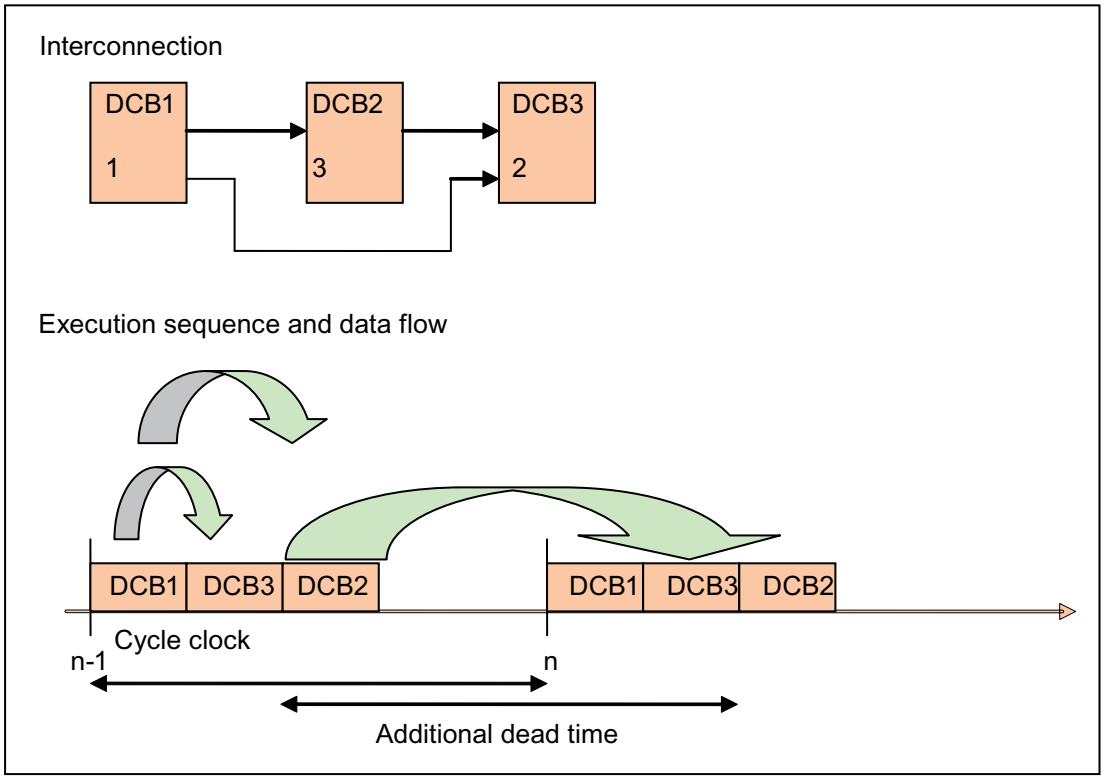

Figure 4-153 Interconnection sequence and execution sequence differ

To optimize the dead times, always orient the execution sequence on the data flow.

Data for blocks from a lower-priority level

Description

All blocks in an execution level must be calculated before their output values are made available to blocks at the input in a different execution level. Output values from a higher-priority level are accessed in a dedicated cycle clock (acceptance cycle clock) in order to ensure isochronism of input values. The following graphic illustrates the isochronous value transfer in a higher-priority level.

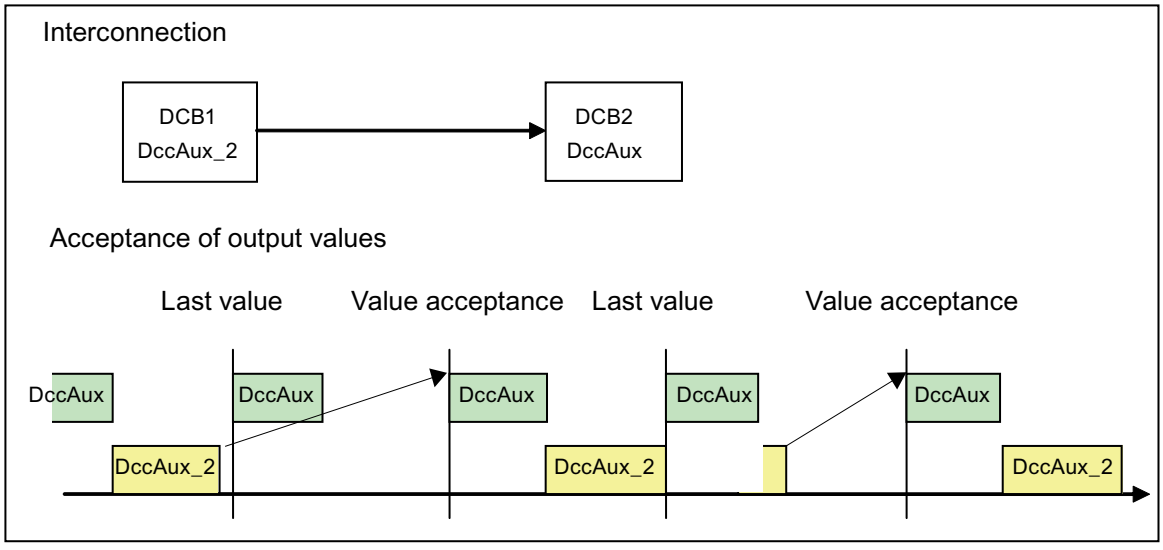

Figure 4-154 Example for the data exchange from a lower priority level

The cycle clock ratio between the levels is 1:2. The task in the higher-priority level always accepts the value in a second cycle clock, independent of whether the lower-priority task was already calculated to the end in the previous cycle clock.

Level overflow of the lower-priority level

If a level overflow of the lower-priority level occurs, the current values have not yet been calculated at the acceptance cycle clock. In this case, the old value is used for calculations at the input until the next acceptance cycle clock.

The following graphic illustrates the overflow behavior for a cycle clock ratio of 1:2. A level overflow for T2 occurs. This means the old values are transferred to the higher-priority task at the acceptance time (cycle clock 1). A new value is accepted at the next acceptance time, namely two cycle clocks later.

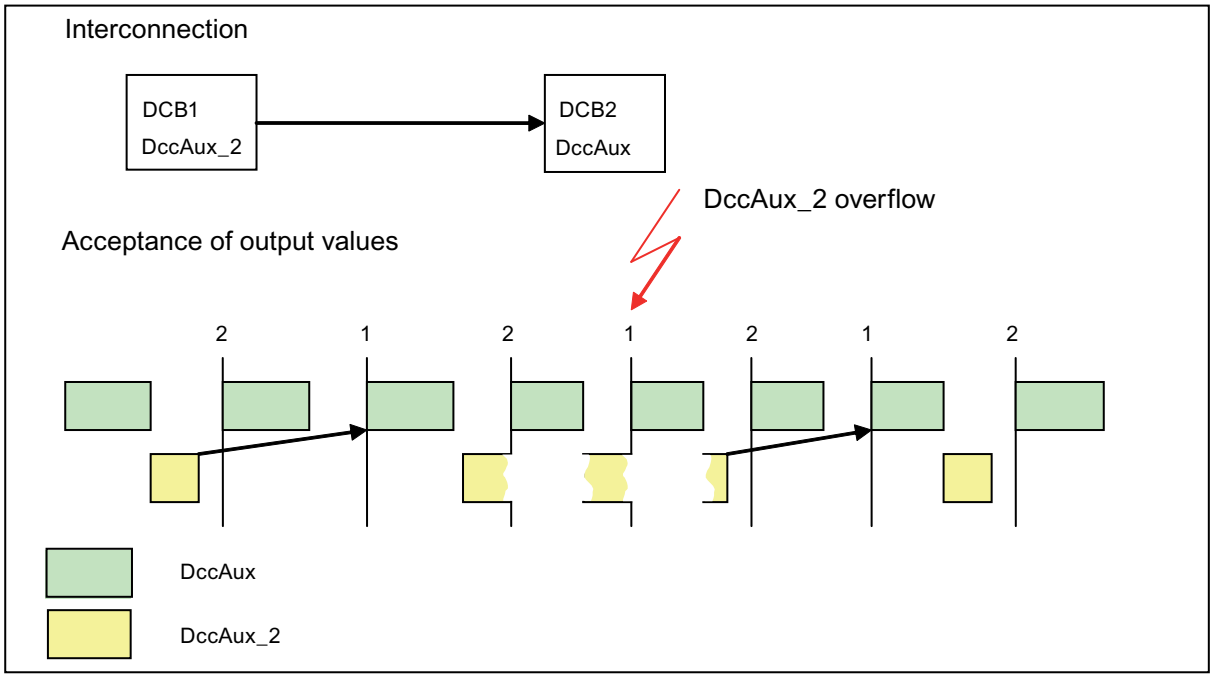

Figure 4-155 Data exchange from a lower-priority level with overflow

The described overflow scenario is true only for an ideal system. In a real application, user tasks and system tasks also run in a level together with the DCC task.

Example consideration of user programs and system tasks

If overflow occurs during the processing of the iposynchronous UP or of the IPO system task, the values have already been calculated in the IPoDCC task and can be transferred to the higher-priority level. However, no new value is calculated in the next cycle clock. If the ipoDCC task already causes an overflow, a correct value will only be accepted again two cycle clocks later. In the two cycle clocks between, the value is accepted delayed by one cycle clock.

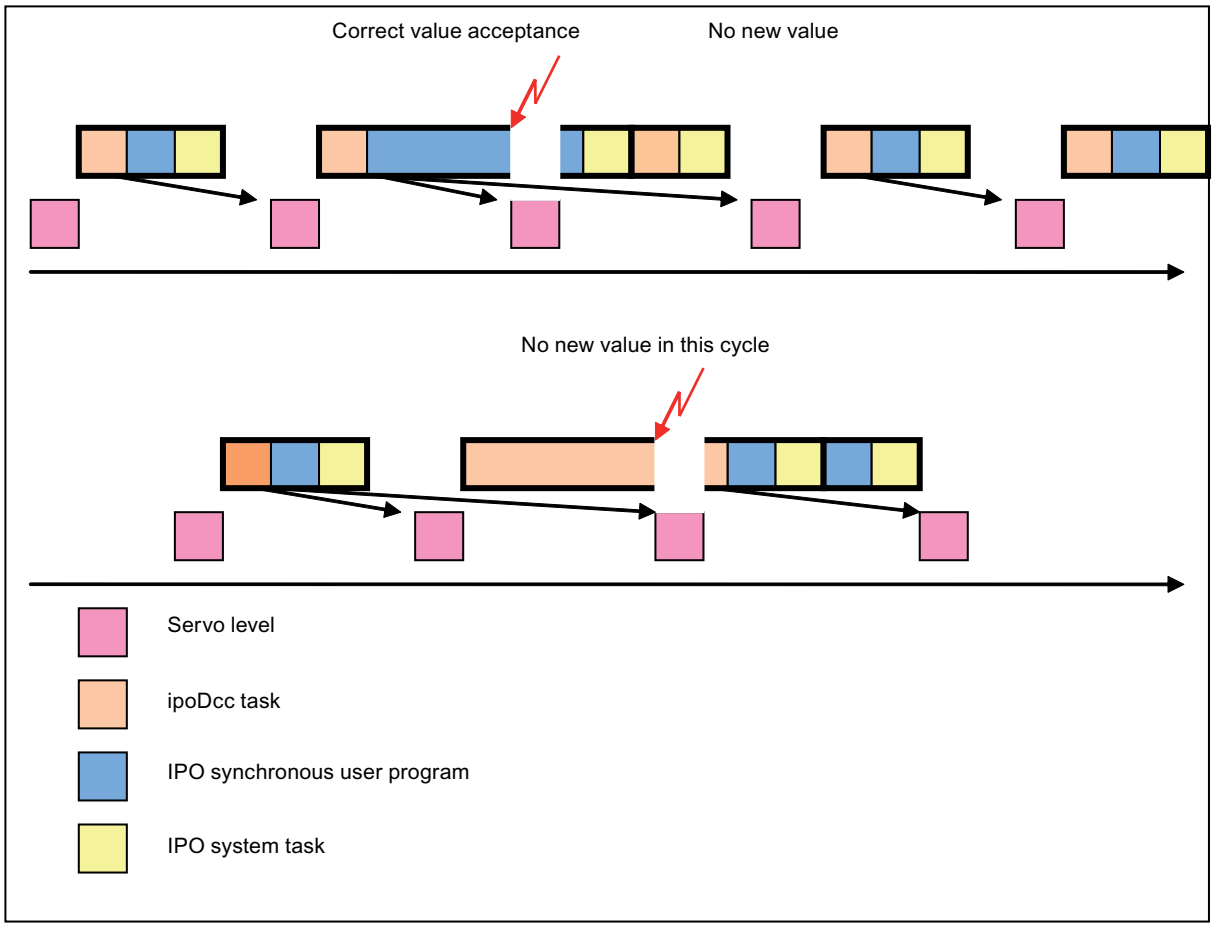

Figure 4-156 Overflow in the execution context with other tasks

Note

To ensure an isochronal data transfer between the ipoDCC task in the IPO level and the servoDCC in the servo level, the ipoDcc task in the IPO level considered by itself should not already cause a level overflow. If this is the case, the higher-priority task does not have available any updated values for the transfer of the values from the lower-priority level. The updated values are then transferred only after the next cycle of the lower-priority levels.

Data for blocks from a higher-priority level

Description

If an access is made to the output values from a lower-priority level, the values must be transferred from a dedicated cycle clock of the higher-priority level in order to guarantee the isochronism of input values.

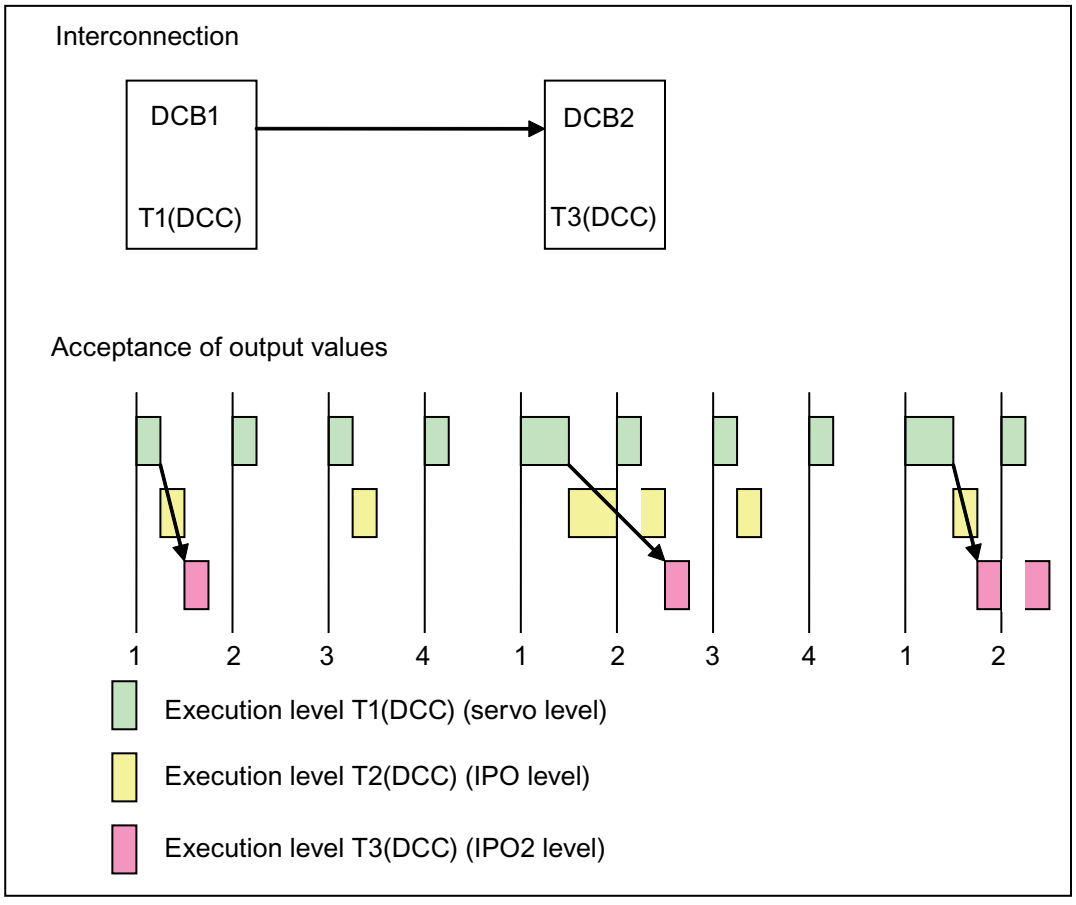

Figure 4-157 Data transfer from a higher-priority level

Interconnection of blocks with variables

Interconnection with variables

Overview of the interconnection possibilities with variables

In addition to the possibility of interconnecting blocks, a PIN can also be interconnected to an external variable. In this way, you can establish a connection with the I/O, the technology objects, a user program and an HMI.

The following user variables can be interconnected with blocks:

- **I/O variables**.
- **System variables**
- The following **user variables** can be interconnected with DCC:
  - Global device variables
  - Variables in the interface of a source

Interconnection of technology objects

- Interconnection using system variables and cyclic interface
- System functions of TOs cannot be called directly from DCCs.

Interconnect PIN with variables

You can interconnect the various inputs and outputs of a block in the DCC editor. The description of the DCC editor contains detailed information.

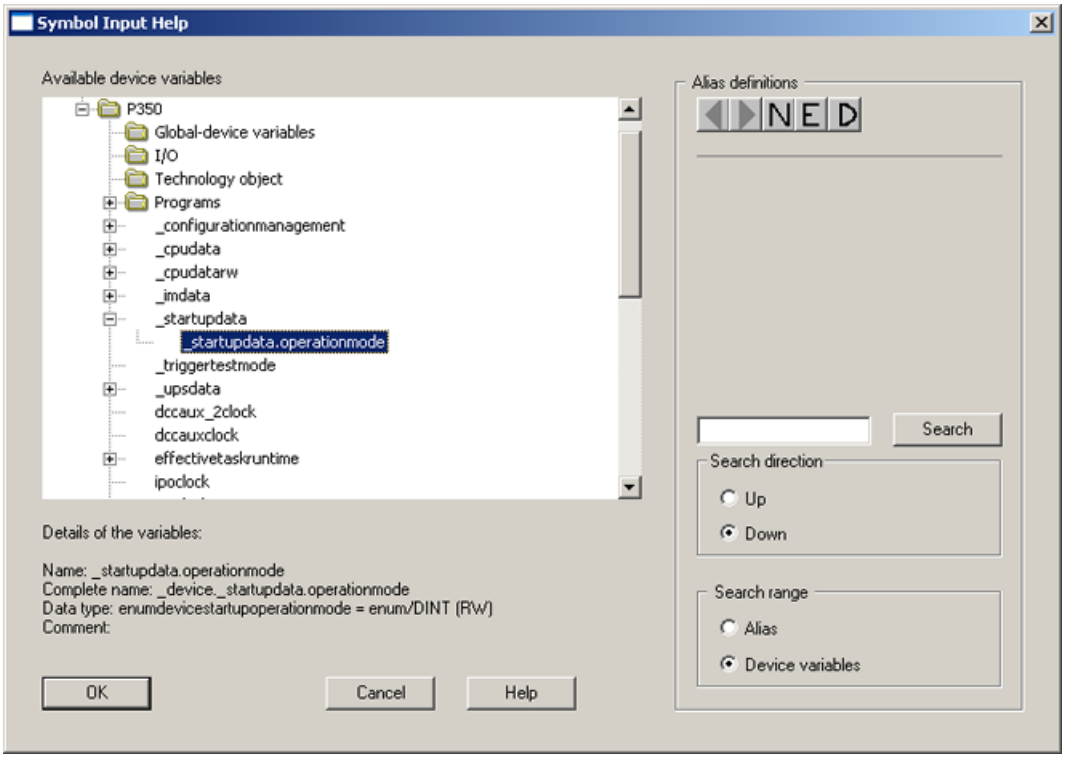

Figure 4-158 Interconnection of user variables in the DCC editor

Note

There are no restrictions as to how often an output can be interconnected to a variable. The output value of the most recently calculated block is always effective.

Behavior for FPU exceptions

Description

DCC Tasks exhibit the following behavior for FPU (Floating-Point Unit) exceptions:

Exception	Description	SIMOTION response
Invalid Operation	Invalid operation (e.g. 0/0, INF/ INF, INF - INF, SQRT(-1)	Device switches to STOP mode.
Division by Zero	Division by zero	Device switches to STOP mode.
Overflow	The absolute result of an operation is larger than abs(+/-- Nmax)	Device switches to STOP mode.
Underrun	The absolute result of an operation is less than abs(+/-- Nmax)	The result is 0.
Inexact	The result cannot be represented exactly.	The result is rounded.

See Error during operations with floating-point numbers (FPU exceptions) (Page 1257).

4.2.7.9 Include drive I/O

Assigning the drive I/O symbolically

Description

As of V4.2, the drive I/O can be assigned symbolically to the I/O variables. For more information, refer to Assigning I/O variables via the address list (Page 1202).

Terminal modules TM15 and TM17 High Feature

Description

The TM15 and TM17 High Feature terminal modules must be evaluated isochronously by the SIMOTION motion control system. Details for the timing can be obtained from the TM15 / TM17 High Feature Terminal Modules Commissioning Manual.

Terminal modules TMxx, TB30 and onboard I/Os on SIMOTION D or CX32/CX32-2 and CU3xx/ CU3xx-2

Description

TM31, TM41, TM15 DI/DO, TB30 and the onboard I/Os operate free-running (not isochronous) for SINAMICS.

The updating cycle is specified by the following drive parameters with 4 ms as default setting:

- p4099 for TM31, TM41 and TM15 DI/DO or
- p0799 for the onboard I/O

The accesses are performed in a SINAMICS background task (for example, every 4 ms). Access time to the inputs and outputs within the set updating cycle can vary from cycle to cycle; this means that the system merely ensures that within each cycle an update is made with a possible fluctuation range in accordance with the updating cycle. This can be influenced using the setting for p4099 or p0799.

Note

The following figure only provides a schematic presentation of the times and does not provide information on the absolute amount.

The I/O produces the following timing:

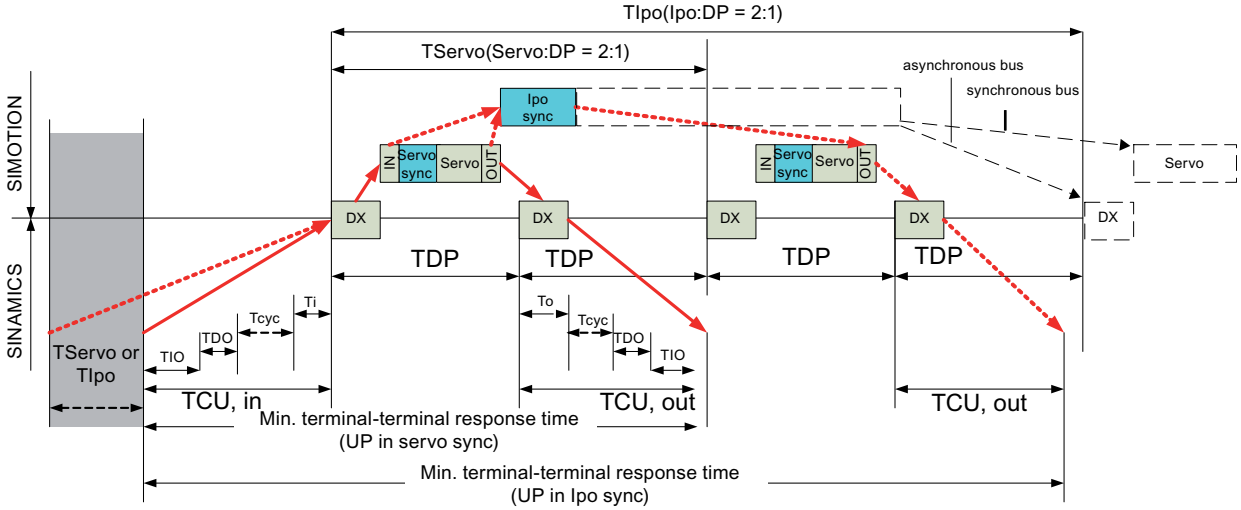

Figure 4-159 I/O Timing

Legend

- T_{DP}: Clock cycle PROFIBUS (see setting in HW Config)
- T_i: Latch time of the inputs for isochronous PROFIBUS (see setting in HW Config for the drive)
- T_o: Delay of the outputs for isochronous PROFIBUS (see setting in HW Config for the drive)
- T_{IO}: Module-specific signal delay (corresponds to a DRIVE-CLiQ cycle + the input delay time for digital input or the load-dependent output delay time for digital outputs)
- T_{cyc}: Updating cycle in the SINAMICS (p4099 or p0799 parameter)
- Servo: SIMOTION servo cycle clock; multiple of T_{DP} (see cycle clock settings for SIMOTION)
- IPO: SIMOTION IPO-cycle clock; multiple of the servo cycle clock (see cycle clock settings for SIMOTION)
- T_{DQ}: DRIVE-CLiQ clock cycle (for V4.1, always corresponds to the current controller cycle clock)

- UP: User program
- Output time on the CU: $T_{CU\_out} = T_O + T_{cyc} + T_{DQ} + T_{IO}$
- Read in time on the CU: $T_{CU\_in} = T_i + T_{cyc} + T_{DQ} + T_{IO}$

The figure shows all times that affect the terminal-terminal response time. Worst case values should be used for the dashed times, thus:

- The set updating cycle T_{cyc} (= maximum time for the access time)
- The time T_{servo} or T_{IPO} in the gray area. Depending on the time the input event occurs the maximum terminal-terminal reaction time can be up to one position control or IPO cycle clock longer than the minimum terminal-terminal reaction time.

The gray area shows the range in which the input event is acquired and processed with the next call of the user program (UP). The size of this range depends on whether the user program runs in the servo-synchronous task or IPO-synchronous task.

Note

Please note that a reduction of the update cycle leads to higher utilization of the SINAMICS closed-loop control or the SIMOTION D, which may result in a reduction in the quantity frame for drives, terminal modules, etc., under certain circumstances.

It is possible to access I/O components in the SINAMICS drive unit from the SIMOTION user program:

- As of V4.2, this can be carried out by means of symbolic assignment of the I/O variable to the SINAMICS I/O. SIMOTION automatically configures the required BICO interconnections and telegrams
- In V4.1, use can be made of this function with special telegrams (39x)
- In earlier versions, the I/O components are inserted in the PROFIdrive message frame as I/O PZD (process data) using a BICO interconnection (refer to the SIMOTION D Commissioning and Hardware Installation Manual, section "Message frame configuring for onboard I/O and drive objects").

The timing depends on which I/O component is accessed. The following table specifies the maximum delay times. To determine the terminal-terminal times, the values for the "terminal → user program" and "user program → terminal" must be added.

Note

The dashed line areas in the **IO Timing** graphic for the IPO synchronous task only apply for PROFINET IO. Analogously the times for PROFINET IO are presented in the following table in the **UP in IPOsynchronous task** column. For PROFIBUS DP in the line **OUT** T_{IPO} must be replaced by T_{Servo}. The dotted line area is irrelevant for PROFIBUS as the servo cannot run there over multiple bus cycles.

			Maximum delay times		
I/O module			**UP in servo-synchronous task**	**UP in iposynchronous task**	**T_{cyc}**
TM31, TM41, TM15 DI/O	Out	UP → terminal	$T_{DP} + T_{CU\_out}$	$T_{IPO} + T_{DP} + T_{CU\_out}$	p4099
	In	Terminal → UP	$T_{Servo} + T_{CU\_in}$	$T_{IPO} + T_{CU\_in}$	
TB30	Out	UP → terminal	$T_{DP} + T_o + T_{cyc} + T_{IO}$	$T_{IPO} + T_{DP} + T_o + T_{cyc} + T_{IO}$	p4099[3)]
	In	Terminal → UP	$T_{Servo} + T_i + T_{cyc} + T_{IO}$	$T_{IPO} + T_i + T_{cyc} + T_{IO}$	
Onboard I/O SIMOTION D, CX32, CX32-2, CU3xx, CU3xx-2	Out	UP → terminal[1)]	75 µs	75 µs	p0799[4)]
		UP → terminal[2)]	$T_{DP} + T_o + T_{cyc}$	$T_{IPO} + T_{DP} + T_o + T_{cyc}$	
	In	Terminal → UP	$T_{Servo} + T_i + T_{cyc}$	$T_{IPO} + T_i + T_{cyc}$	

1) Access to SIMOTION D integrated drives in conjunction with standard telegram 39x for the DO1. Without the standard message frame, the same timing behavior applies as for CX32 or CX32-2.

2.) Access to CX32, CX32-2 as well as via external PROFIBUS or PROFINET IO on CU3xx and CU3xx-2

3) For isochronous operation, T_{cyc} = max (T_{DP}, p4099)

4) For isochronous operation, T_{cyc} = max (T_{DP}, p0799)

Further information

You can also find more information on this topic:

- In the SIMOTION D410/D410-2 and D4x5/D4x5-2 Commissioning Manuals
- In an FAQ on the Utilities & Applications CD under FAQs
- On the Internet at http://support.automation.siemens.com/WW/view/de/27585482.

4.2.7.10 Time for SIMOTION and SINAMICS

SIMOTION time (real-time clock)

All SIMOTION devices have an integrated real-time clock. All events on a module (alarms, messages, etc.) are "time-stamped" based on the time shown by this real-time clock.

Setting the SIMOTION time of day

How to set the clock from SIMOTION SCOUT:

1. Select the SIMOTION device in the project navigator
2. Then select the **Target system > Set time of day** menu.

Alternatively, the clock can be set using the RTC system function block.

Synchronizing SINAMICS time of day

SINAMICS system runtime (operating hours counter)

With the SINAMICS Integrated of a SIMOTION D, controller extensions and the SINAMICS S120 control units, faults and warnings are "time-stamped" on the basis of the system runtime. This means that events are recorded by default on the basis of operating hours rather than a particular time of day or date.

System runtime

The entire system runtime is displayed in CU parameter r2114.

- r2114[0] shows the system runtime in milliseconds. After reaching 86,400,000 ms (24 hours), the value is reset.
- r2114[1] shows the system runtime in days.

The counter value is saved when the power is switched off. After the drive unit has been switched on, the counter continues to run with the value stored when the power was last switched off.

As a result, the drive displays the system runtime from 00:00:00 on 01.01.1992 in both the alarm window in SIMOTION SCOUT and the diagnostic buffer for entries.

If faults and warnings need to be "time-stamped" based on a time of day, "Time stamp operating hours" needs to be changed to "Time stamp UTC format" as described below.

Requirements

Telegram 39x is required for the time synchronization. If the automatic PROFIdrive telegram setting is selected for the control unit, this telegram is used automatically.

If the telegrams are specified manually, telegram 39x must be set up (see Section Telegram configuration (Page 1212)).

So that drive units can be synchronized with the SIMOTION time, they must support telegram 39x and the UTC time format.

For precise time synchronization, the drive unit must also be operated via an isochronous/ equidistant bus on SIMOTION. The SINAMICS Integrated for SIMOTION D and the CX32/CX32-2 controller extension always have an isochronous/equidistant connection.

The following control units support time synchronization:

- SINAMICS Integrated of the SIMOTION D
- CX32/CX32-2 controller extensions
- SINAMICS S120, CU310, CU310-2, CU320, CU320-2 control units, connected via PROFIBUS or PROFINET

Procedure

Proceed as follows to convert the SINAMICS clock to UTC format and to synchronize this with the SIMOTION clock:

1. Select the SIMOTION device in the project navigator.
2. Select the **Edit > Object Properties** menu.
3. Select the **Settings** tab.
4. Activate the option **Perform time synchronization with SINAMICS drive units**.
5. Confirm with OK.

Note

This setting is automatically activated for new projects as of V4.2 and applies for all drive units connected to the SIMOTION device. The SINAMICS clock is automatically synchronized with the SIMOTION clock for all drive units with configured telegram 39x.

The first time synchronization is performed after the SIMOTION device has reached the RUN operating state.

To compensate for deviations between the SIMOTION and SINAMICS clocks, the time of day is automatically resynchronized at regular intervals.

Using the system variable **_driveStates.allClocksSynchronized** on the SIMOTION device, the user program can query whether the automatic time synchronization is activated (=YES) or deactivated (=NO).

Before the first synchronization, alarms and messages are stored with the time stamp valid in the SINAMICS at this time, all subsequent alarms and messages with the synchronized time.

The first time synchronization after switching on is entered with the status of the operating hours counter and the time (UTC time, synchronized with SIMOTION) in the diagnostic buffer of the drive (e.g. SINAMICS Integrated).

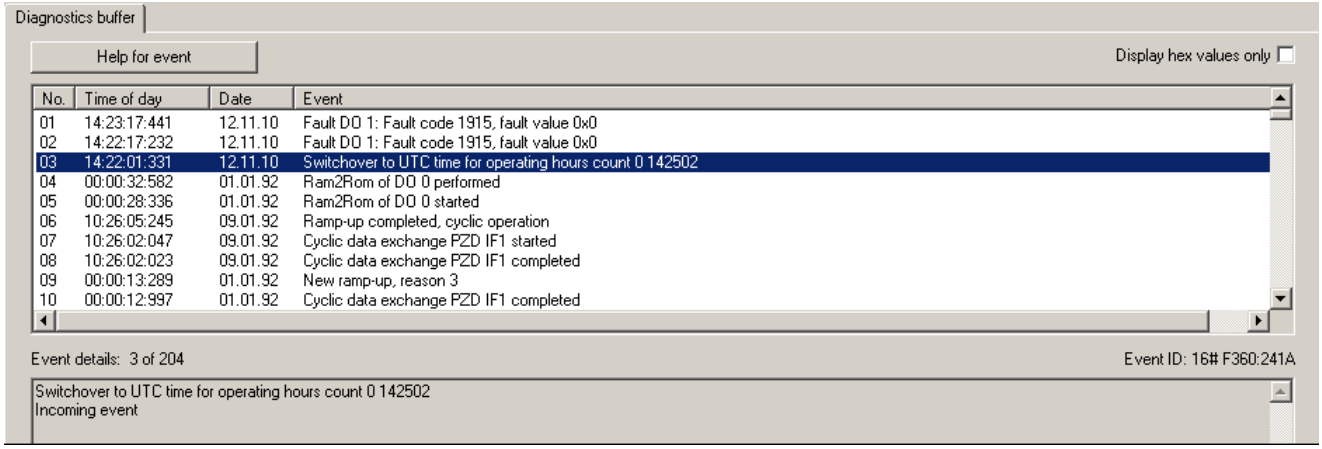

Figure 4-160 SINAMICS time synchronization diagnostic buffer entry

Error correction

If problems occur during the time synchronization, this may be due to faulty configuration information (Fast IO configuration) when symbolic assignment is deactivated.

For further information, see Section Message frame configuration (Page 1212).

Compensation of runtime deviations

To compensate for deviations between the SIMOTION and SINAMICS clocks, the time of day is automatically resynchronized at regular intervals.

The following behavior must be taken into consideration when setting the SIMOTION time:

- "Time/date to be set" is after "Time/date on SINAMICS":
  Time and date are corrected on the SINAMICS.
- "Time/date to be set" is before "Time/date on SINAMICS":
  The SINAMICS clock must be stopped until the SINAMICS "Time/date" has caught up with "Time/date to be set".

Adopting this procedure ensures that the sequence of SINAMICS diagnostic buffer entries remains the same, even when the runtime differences are aligned.

The SINAMICS clock operates with a resolution of 1 ms. A synchronization accuracy of 1 ms can be achieved for all bus cycle clocks that can be divided exactly by 1 ms (e.g. 1 ms, 2 ms, 3 ms, etc.).

Due to system considerations, a slightly lower synchronization accuracy is achieved for all bus cycle clocks that cannot be divided exactly by 1 ms (e.g. 1.25 ms).

If the drive unit does not have an isochronous/equidistant connection on SIMOTION, this can result in runtime differences of milliseconds (depending on the set cycle clock ratios).

Resetting the time

Requirement:

- SIMOTION D4xx-2: As of SIMOTION V4.3
- SINAMICS S120: As of SINAMICS firmware version V4.5

A threshold value is defined using the CU parameter 3109 and is effective as follows:

- In the case of negative time jumps less than the threshold value (p3109), the time is halted (for details, see "Compensation of runtime deviations").
- In the case of negative time jumps greater than the threshold value (p3109), the time is reset.
  The factory setting of p3109 is 100 ms
  This means that in the case of negative time jumps greater than 100 ms, the time is reset.
  The factory setting is configured so that normal runtime deviations (drift of the quartzes) are below the threshold value.
  If the SIMOTION clock is reset by more than 100 ms, this is interpreted as a "specific reset of the time" and the time of the drives is also immediately reset.

If the real-time clock is reset by more than 60 seconds, a diagnostic buffer entry is also made in the drive:

Time correction (reset) by <correction value> seconds

After a re-synchronization (negative time gap greater than the threshold value), the CU parameter r3107 shows:

- In r3107[0..1] the UTC time after the synchronization
- In r3107[2..3] the UTC time before the synchronization

The milliseconds are in indices [0] and [2] and the days in [1] and [3].

Note

The diagnostic buffer entries are not converted to the new time when the time is changed.

4.2.8 Programming Execution System/Tasks/System Cycle Clocks

4.2.8.1 Execution system

Introduction to the execution system

All programs are executed in the SIMOTION device execution system. The execution system provides a series of execution levels with various execution properties.

Programs must therefore be assigned to the execution levels in order to be executed. To this end, programs of the source files are assigned to one or more tasks.

This defines the sequence in which they are to be executed.

Note

Before programs can be assigned to the execution levels the ST/MCC/LAD/FBD sources must be translated.

Execution levels and tasks

Execution levels define the chronological sequence of programs in the execution system. Each execution level contains one or more tasks.

A task provides the execution framework for the programs. You can assign one or more user programs to each task and specify their order within the task.

Besides user program tasks there are also several system tasks, the contents and execution sequence of which you cannot influence.

The table shows the execution levels with their tasks that are available for the user programs (user program tasks).

You can use task control commands to influence the execution system.

Table 4-78 Execution levels in SIMOTION

Execution level	Description
Time-controlled	Cyclic tasks, automatically restarted once assigned programs have been executed.
• SynchronousTasks	Tasks are started periodically, synchronous with specified system cycle clock. • ServoSynchronousTask: synchronous with the position control cycle clock (as of SIMOTION Kernel V4.0) • ServoSynchronousTask_fast: Synchronous with Servo_fast (Version 4.2 of SIMOTION Kernel and higher) as an option • IPOsynchronousTask: Synchronous with interpolator cycle clock IPO • IPOsynchronousTask_fast: Synchronous with interpolator cycle clock IPO_fast (Version 4.2 of SIMOTION Kernel and higher) as an option • IPOsynchronousTask_2: Synchronous with interpolator cycle clock IPO_2 • Synchronous tasks for the Tcontrol technology package: – PWMsynchronousTask: Synchronous to the PWM cycle clock InputSynchronousTask_1: Synchronous with cycle clock Input1 – InputSynchronousTask_2: Synchronous with cycle clock Input2 – PostControlTask_1: Synchronous with cycle clock Control1 – PostControlTask_2: Synchronous with cycle clock Control2
• TimerInterruptTasks	Tasks are started periodically in a fixed time frame. This time frame must be a multiple of interpolator cycle clock IPO.
Interrupts	Sequential tasks, executed once after start and then terminated.
• SystemInterruptTasks	Started when a system event occurs: Detailed description • ExecutionFaultTask: Error processing a program • PeripheralFaultTask: Error on I/O • TechnologicalFaultTask: Error on the technology object • TimeFaultBackgroundTask: BackgroundTask timeout • TimeFaultTask: TimerInterruptTask timeout
• UserInterruptTasks	Started on edge trigger when a user-defined event occurs.
Round robin	MotionTasks and BackgroundTasks share the free time remaining after execution of the higher-priority system and user tasks. The proportion of the two levels can be assigned.

Execution level	Description
• MotionTasks	Sequential tasks, executed once after start and then terminated. Start takes place: • Explicitly via a task control command in a program assigned to another task. • Automatically when RUN mode is attained if the corresponding attribute was set during task configuration. The priority of a MotionTask can be increased temporarily using the system function WAITFORCONDITION (see **Let MotionTask wait until a condition is satisfied**).
• BackgroundTask	Cyclic task, restarted automatically once the assigned programs have been executed; task cycle time depends on runtime.
StartupTask	Task is executed once when there is a transition from STOP or STOP U mode to RUN mode. SystemInterruptTasks are started by their triggering system event.
ShutdownTask	Task is executed once when there is a transition from RUN mode to STOP or STOP U mode. STOP or STOP U mode is reached by: • Corresponding mode selector switch position • Corresponding system function of the SIMOTION device • Alarm (fault) with corresponding error response SystemInterruptTasks and PeripheralFaultTasks are started by their triggering system event.
For information on behavior of sequential and cyclic tasks: • For the initialization of local program variables, refer to the Initialization of local program variables depending on the task execution behavior (Page 1418) table. • In the event of execution errors in the program, see Processing errors in programs (Page 1256) section. For information about options for accessing the process image and I/O variables, see the *Important properties for direct access and process image* section, which can be found in the various programming manuals.	

Task start sequence

When the StartupTask is completed, RUN mode is reached.

The following tasks are then started:

- SynchronousTasks
- TimerInterruptTasks
- BackgroundTask
- MotionTasks with startup attribute.

Note

The sequence in which these tasks are first started after RUN mode has been reached does not conform to the task priorities.

Configure execution system

Specifications for the configuring

When configuring the execution system, you assign the programs you want to execute in each task. In so doing, you specify the following:

- Priority with which the programs are executed
- Execution behavior (sequential, cyclical)
- Initialization behavior of local program variables

Assignment of a program to one or more tasks can only be performed after compilation and must occur before the program is loaded onto the target system.

When you have assigned a program to one or more tasks, you can establish the connection to the target system, download the program to the target system, and start it.

See also

Configure execution system (Page 1345)

Assigning programs to the execution levels/tasks (Page 1345)

Assigning programs to the tasks

In the *Execute sample program* section, you set up a task assignment using the sample program. The basic procedure is as follows:

1. Select the SIMOTION device in the project navigator, and select the **Target system > Configure execution system** menu command.
   The configuration window for the execution system of the SIMOTION device opens.
2. Select the task to be configured.
3. Select the **Program assignment** tab, and assign the desired programs to the task.
   See Section "Assigning programs to the execution levels / tasks (Page 1345)".
4. Select the Task configuration tab and make any additional settings, such as:
   - The local data stack size in the Area limit for dynamic data field, see SIMOTION ST Programming Manual
   - Error response to program error
   - Time watchdogs for cyclic tasks
   - Start behavior of MotionTasks

   See the detailed description for the relevant task in Section "Description of the user program tasks (Page 1314)".

Effect of the task execution behavior on the variable initialization

Time for the initialization of local program variables

The execution behavior of the task (sequential or cyclic) determines the initialization of local variables in the assigned programs. These descriptions also apply to instances of function blocks that were declared as local variables in the programs.

A summary of all variable types and their time of initialization can be found in the "Time of the variable initialization" chapter which can be found in the various Programming Manuals.

Table 4-79 Initialization of local program variables according to task execution behavior

Execution behavior	Tasks	Initialization of local program variables
Sequential (non-cyclic)	MotionTasks, UserInterruptTasks, SystemInterruptTasks, StartupTask, ShutdownTask.	After start, sequential tasks are executed once and then terminated. On each start, all local variables of the assigned programs are initialized. The time for data initialization is included in the task runtime. Behavior with compiler option "Only create program instance data once": • The local variables of the assigned programs will only be initialized once (during the download). See Download of changed sources in RUN (Page 1656) and Influence of the compiler on variable initialization (Page 1419). • Setting is possible so that the initialization of local variables is performed for every STOP - RUN transition, see Initialization of data during a STOP - RUN transition (Page 1664).
Cyclic	BackgroundTask, SynchronousTasks, TimerInterruptTasks	Cyclic tasks are automatically restarted upon completion, and the values of static local variables of the assigned programs (declared in VAR/ END_VAR) are retained. • Static variables are initialized once only during the transition from STOP to RUN. • Temporary variables (declared in VAR_TEMP / END_VAR) are initialized every time the task is started. This one-time initialization of static variables is not included in the task runtime. Behavior with compiler option "Only create program instance data once": • The local variables of the assigned programs will only be initialized once (during the download). See Download of changed sources in RUN (Page 1656) and Influence of the compiler on variable initialization (Page 1419). • Setting is possible so that the initialization of local variables is performed for every STOP - RUN transition, see Initialization of data during a STOP - RUN transition (Page 1664).

Assigning initial values to unit variables

Unit variables and global device variables are not initialized during the transition from STOP or STOPU mode to RUN mode (see the "Time of the variable initialization" chapter which can be found in the various Programming Manuals).

If you nevertheless want to assign initial values to these variables, use the StartupTask to do so. For information about the initialization for a STOP - RUN transition and the pragma BlockInit_OnDeviceRun (ST) or pragma lines (MCC and LAD/FBD), see also Initialization of data during a STOP - RUN transition (Page 1664).

Note

The task start sequence is not defined after the transition to RUN mode (refer to the **Task start sequence** section).

Correct initial value assignment is not ensured if a task other than the StartupTask is used.

Use multiple VAR_GLOBAL, VAR_GLOBAL RETAIN blocks

Description

You can create multiple VAR_GLOBAL, VAR_GLOBAL RETAIN blocks in the interface and implementation area of a UNIT (as of V4.1).

In the interface area and in the implementation area you can specify multiple declaration blocks in any sequence. Each of these blocks will be versioned separately. Changes within a block (whether direct or indirect via data type change) thus result in reinitialization of these blocks when reloading. Thus the (RETAIN) data retain works block-by-block.

New blocks can be added on the end and the changed sources can be reloaded in the RUN, without influencing the existing data blocks. If in one source section (statement applies separately for interface and implementation) a block is added in front of an existing block of the same type (RETAIN or not RETAIN) then all the subsequent blocks change and will be reinitialized at download. Thus download in the RUN after such a change is not possible.

Via the functions _saveUnitDataSet /_loadUnitDataSet and _exportUnitDataSet / _importUnitDataSet, the unit data block information can be saved. If when reading a data set one or multiple blocks are missing this can be detected on the return code, the remaining blocks however will be read. See also General information on saving data sets from the user program (Page 1522) and Data backup and data initialization from user program - functions and instructions (Page 1573).

Loss of retain data due to initialization

This data can be saved first in SCOUT via the "Save variables" function and read in again via the "Restore variables" function, see Online help.

Alternatively you can also use the _exportUnitDataSet (Page 1528) and _importUnitDataSet (Page 1531) system functions in the application.

Influence of the compiler on variable initialization

Compiler option "Only create program instance data once"

The compiler option can be set on each source and thus overwrites the global setting. It works regardless of the creation language and consequently it can also be used in LAD/FBD and MCC.

The compiler option controls how the instance data must be created in a PROGRAM contained in a source. Instance data of a PROGRAM are formed by the content of the VAR declaration block.

Generally, the following is valid: A program can be hooked into the execution system once and only once per task.

If "Only create program instance data once" is not set (DEFAULT), then the following behavior applies:

- The program cannot be called from a different LAD.
- The instance data of a program will be created separately for each task to which the program is assigned.
- The data initialization of the instance data is executed with the start of the TASK; (sequential task with task start, cyclic tasks for the STOP-RUN transition)
- Instance data of PROGRAMs in sequential tasks can be changed in RUN mode (if a loading is possible in principle).

Activation of the compiler option "Only create program instance data once" (also when using a program in different tasks) causes the following:

- Instance data of programs compiled in this manner will only be created once. The instance data is in the source, where the PROGRAM is declared.
- Each time a PROGRAM created in this manner is used, the same data is involved. This affects the assignment to (possibly multiple) tasks and the call in other PROGRAMS or function blocks.
- The data initialization is executed according to the rules of global data initialization (see download settings on the project) with the download of the source / of the code in which the program is declared. See also Download of changed sources in RUN (Page 1656).

NOTICE
Changed behavior for the data initialization when "Only create program instance data once" has been selected. With sequential tasks, data initialization is no longer performed with a task start or for cyclic tasks with the STOP - RUN transition, but generally only during a download. If necessary, the data must now be initialized by the application in the StartUp task or at the beginning of the programs in sequential tasks. An initialization during a STOP - RUN transition is possible • With a pragma BlockInit_OnDeviceRun (ST) or pragma line (MCC and LAD/FBD) • As of V4.2 using the dialog **Properties > Settings** via the context menu on the device. See Initialization of data during a STOP - RUN transition (Page 1664). For information on the influence of the compiler option in conjunction with the download in RUN, see Download of changed sources in RUN (Page 1656). If several tasks are assigned to one program, the same data is used as the basis for all of them.

Initialization of variables during a STOP - RUN transition

For information about the initialization for a STOP - RUN transition and pragma BlockInit_OnDeviceRun, see Initialization of data during a STOP - RUN transition (Page 1664).

Compiler option "Permit language extensions" (for non-IEC conformity)

The compiler option can be set on each source and thus overwrites the global setting. It works regardless of the creation language and consequently it can also be used in LAD/FBD and MCC.

The compiler option allows the following:

- Direct bit access, bit addressing for bit string variables (except data type BOOL)
- Read and write access to the input parameter (VAR INPUT) from function blocks outside the function block.
- Permissible call "program in program".

A program can be called within a different program, like a global FB instance within a program organization unit, such as calling "myprog" within a different program, within a different FB, but not within a function.

Global availability of the instance data is a prerequisite for "program in program". This can be satisfied either in that the PROGRAM does not have any instance data, or by using the compiler option "Only create program instance data once" when compiling the PROGRAM that will be called (see **Only create program instance data once**).

Note

If you do not set the compiler options, then the behavior remains unchanged compared to V4.0 (corresponds to DEFAULT).

Re-initialization of variable blocks

In VAR_GLOBAL, VAR_GLOBAL RETAIN blocks (interface and implementation sections of the source/unit):

- `BlockInit_OnChange := true`; causes (IMPLEMENTATION only) a reinitialization of the data to be executed with the values specified in the source when changes are made to the block structure for the download in RUN.
- With MCC and LAD/FBD, as of V4.2 the behavior can be set in the declaration tables using pragma lines.

This pragma is also applicable in VAR declarations of PROGRAMs. However, it will only work if the "Only create program instance data once" compiler option is selected.

See also Download of changed sources in RUN (Page 1656).

Marking HMI relevant data

As standard, the following applies for the HMI relevance of retentive unit variables (VAR_GLOBAL RETAIN) and non-retentive unit variables (VAR_GLOBAL):

- Unit variables declared in the interface section are available for operator control and monitoring (OCM).
  OCM addresses are generated for the variables contained therein. Changes have an effect on the HMI consistency.
- Unit variables declared in the implementation section are not exported to HMI devices. Changes have no effect on the HMI consistency.

Marking data as "non-HMI-relevant data"

You can mark individual declaration blocks in the interface section as non-HMI-relevant.

- In the SIMOTION ST programming language:
  Via the pragma `{ HMI_Export := FALSE; }` at the start of the declaration block (see the following example).
- In the SIMOTION MCC and SIMOTION LAD/FBD programming languages (as of V4.2):
  Via a pragma line in the declaration table.

OCM addresses are then no longer generated for the variables contained therein. For SIMOTION devices as of version V4.1, changes in this declaration block have no effect on the HMI consistency.

Example

```
VAR_GLOBAL
    { HMI_Export := FALSE; }
    x : INT;
    y : INT;
END_VAR
```

Marking data as "HMI-relevant data"

You can mark individual declaration blocks in the interface section as non-HMI-relevant.

- In the SIMOTION ST programming language:
  Via the pragma `{ HMI_Export := TRUE; }` at the start of the declaration block (see the following example).
- In the SIMOTION MCC and SIMOTION LAD/FBD programming languages (as of V4.2):
  Via a pragma line in the declaration table.

OCM addresses are then generated for the variables contained therein. Changes to this declaration block have an effect on the HMI consistency.

Example

```
VAR_GLOBAL
    { HMI_Export := TRUE; }
    x : INT;
    y : INT;
END_VAR
```

HMI address space and HMI consistency

The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.

Within the HMI address space, the variables are arranged in the following order:

- Retentive unit variables (VAR_GLOBAL RETAIN) of the interface section
- Retentive unit variables (VAR_GLOBAL RETAIN) of the implementation section
- Non-retentive unit variables (VAR_GLOBAL) of the interface section
- Non-retentive unit variables (VAR_GLOBAL) of the implementation section

Within these segments, the variables are arranged according to order of their declaration.

Note

For SIMOTION devices as of version V4.1:

Only HMI-relevant unit variables of the interface and implementation section are assigned to the HMI address space.

For SIMOTION devices up to version V4.0:

The following unit variables are assigned to the HMI address space:

- HMI-relevant **and non-HMI-relevant** unit variables of the interface section.
- HMI-relevant unit variables of the implementation section.

If variables of an HMI-relevant declaration block lie outside the HMI address space (64 KB), the compiler issues information 32050 that variables are not visible for the HMI. The first variable of the declaration block that exceeds the limit of the HMI address space is specified in this information.

Note

If variables are inserted in non-HMI-relevant declaration blocks, the HMI can still access SIMOTION variables even when the consistency check is activated.

A new compilation of the HMI project and a new transfer of the HMI project to an HMI device are then not necessary.

Exception for SIMOTION devices up to version V4.0:

HMI consistency is only retained when you enter or change variables in the following areas:

- In non-HMI-relevant declaration blocks of the **implementation section**
- In the **last declaration block** for non-retentive unit variables (VAR_GLOBAL) **of the interface section** when the following two conditions are satisfied:
  - This declaration block is marked as non-HMI-relevant.
  - No declaration blocks for non-retentive unit variables are marked as HMI-relevant in the implementation section.

  If the last condition is satisfied, you can add any number of declaration blocks for non-retentive unit variables (VAR_GLOBAL) at the **end of the interface section**, if they are marked as non-HMI-relevant.

See also HMI (Human Machine Interface) connection (Page 1611) and HMI variables in one unit (Page 1690).

For detailed information on the behavior of HMI-relevant data, see *SIMOTION ST Programming Manual*, Section Variables and HMI devices.

Task status

Querying and meaning of the task status

The task status can be queried using the function _getStateOfTaskId (Page 1437). This function requires the *TaskId* as an input parameter and returns a value of data type DWORD.

The table shows the possible combinations of task statuses in hex representation and as symbolic constants. Task status combinations are possible and are displayed as the sum of the hexadecimal values.

Table 4-80 Task statuses and their meaning

Symbolic constant	Hex notation	Symbolic constant
TASK_STATE_INVALID	16#0000	The task does not exist.
TASK_STATE_STOP_PENDING	16#0001	Task has received signal to stop; it is in a state between TASK_STATE_RUNNING and TASK_STATE_STOPPED. Actions may be performed until the task has stopped.
TASK_STATE_STOPPED	16#0002	Task stopped (e.g. using _resetTaskID (Page 1439) function), completed or not yet started.
TASK_STATE_RUNNING	16#0004	Task running, e.g.: • using _startTaskID (Page 1441) function, • As an active cyclic task
TASK_STATE_WAITING	16#0010	Task waiting due to _waitTime function or WAITFORCONDITION.
TASK_STATE_SUSPENDED	16#0020	Task suspended by function _suspendTaskid (Page 1442).
TASK_STATE_WAIT_NEXT_CYCLE	16#0040	TimerInterruptTask waiting for start trigger.
TASK_STATE_WAIT_NEXT_INTERRUPT	16#0080	SystemInterruptTask or UserInterruptTask is waiting for the triggering event to occur.
TASK_STATE_LOCKED	16#0100	Task locked by function *_disableScheduler*.

Combinations of task statuses

_getStateOfTaskId (Page 1437) often delivers a return value in the form of combinations found in the *Keywords for the declaration of static and temporary variables* table, depending on the task status named by the source file section. These combinations are generated by an OR logic operation. Frequent combinations are listed in the table.

Table 4-81 Frequently occurring task status combinations

Combination	Hex notation	Meaning
TASK_STATE_WAITING OR TASK_STATE_RUNNING	16#0014	Task running but currently waiting, for example, because of *_waitTime* or WAITFORCONDITION.
TASK_STATE_SUSPENDED OR TASK_STATE_RUNNING	16#0024	Task running but currently suspended by _suspendTaskid (Page 1442).
TASK_STATE_WAIT_NEXT_CYCLE OR TASK_STATE_RUNNING	16#0044	TimerInterruptTask running, but currently waiting for its start trigger.
TASK_STATE_WAIT_NEXT_CYCLE OR TASK_STATE_SUSPENDED OR TASK_STATE_RUNNING	16#0064	TimerInterruptTask running but currently waiting for its start trigger and suspended by _suspendTaskid (Page 1442).
TASK_STATE_WAIT_NEXT_INTERRUPT OR TASK_STATE_RUNNING	16#0084	SystemInterruptTask or UserInterruptTask running, but currently waiting for its triggering event.
TASK_STATE_WAIT_NEXT_INTERRUPT OR TASK_STATE_SUSPENDED OR TASK_STATE_RUNNING	16#00A4	SystemInterruptTask or UserInterruptTask running, but currently waiting for its triggering event, and is suspended by *_suspendTaskid*.
TASK_STATE_LOCKED OR TASK_STATE_RUNNING	16#0104	Task running but currently locked by *_disableScheduler*.

Other combinations are possible.

Example of the task status in use

In the following example, the task status of a MotionTask is queried to decide whether it can be started. The relevant bits of the return value are evaluated for this. If the result is positive, the MotionTask is started.

Table 4-82 Example of a query whether a MotionTask can be started

```
ret_dword := _getStateOfTaskId (id := _task.motionTask_1);
    IF (ret_dword AND
        (TASK_STATE_STOPPED OR TASK_STATE_STOP_PENDING)
        ) <> 0 THEN
        // MotionTask can be started.
        ret_dword := _restartTaskId (id := _task.motionTask_1);
    ELSE
        ; // MotionTask cannot be started.
    END_IF;
```

For an example with MCC: See Section "Parameter overview for the task state" in the MCC Programming Manual.

Waiting in MotionTask for a condition to be satisfied

Syntax of the condition of the EXPRESSION

The following applies for programming in ST. For MCC, definition of the wait condition is executed directly in the commands.

You can use the WAITFORCONDITION command in a MotionTask to wait for a condition to be satisfied (e.g. an event to occur). The MotionTask in which the statement is called is kept in TASK_STATE_WAITING status until the condition is satisfied.

When the VAR_IN_OUT in/out parameter is used, you can enable a time watchdog for WAITFORCONDITION.

This condition is formulated in the form of an EXPRESSION.

The expression is a special type of function declaration (for information on the syntax, see the **Expressions** section in the ST Programming Manual):

- The data type of the return value can be defined as BOOL and is not specified explicitly.
- The use of the VAR_IN_OUT in/out parameter and the VAR_INPUT input parameter is possible.

An expression can only be declared in the implementation section of the unit.

Optionally, local (temporary) variables can be declared in the declaration section. No other declarations (e.g. of input parameters or constants) are possible.

The following can be accessed in the statement section:

- Local variables for the expression
- Unit variables
- Global device variables, I/O variables, and the process image

An expression of the BOOL data type must be assigned to the expression identifier in the statement section of the expression (see **Expressions** section in the ST Programming Manual).

Note

The statement section of the expression cannot contain any function calls or loops.

Syntax of the WAITFORCONDITION statement

The following syntax is used to call the command for a waiting MotionTask subject to an expression:

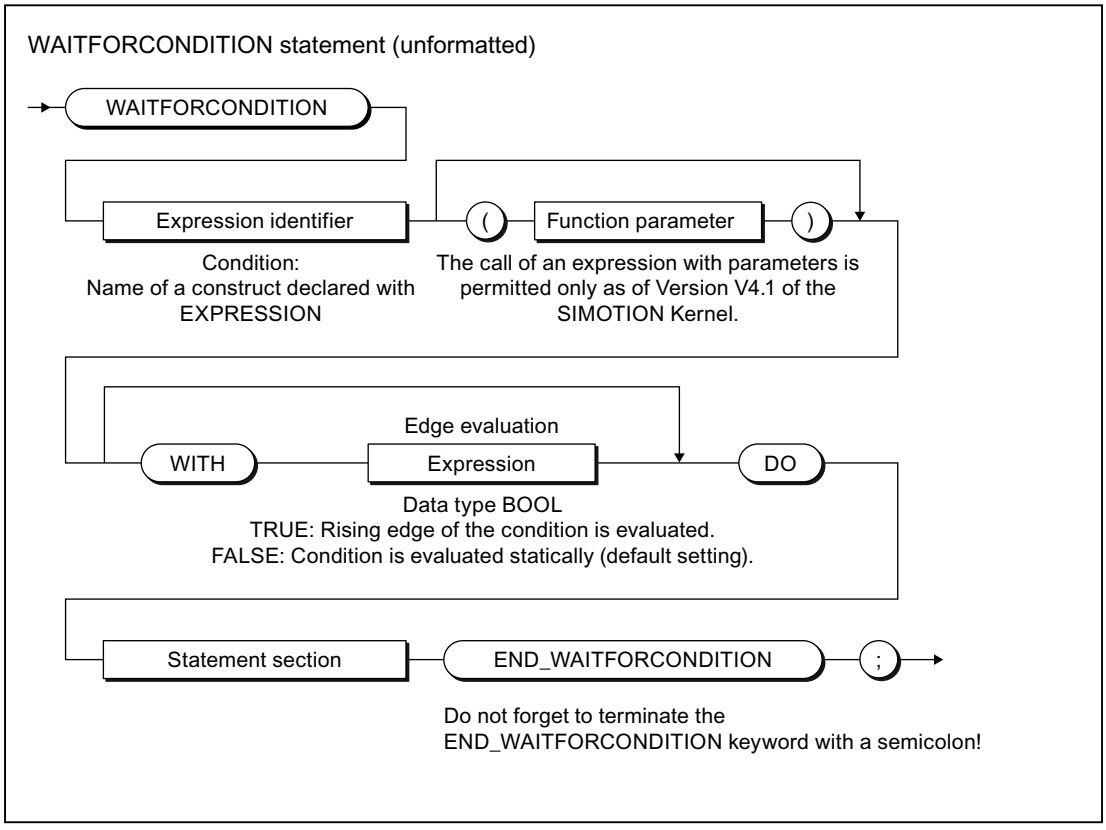

Figure 4-161 Syntax: WAITFORCONDITION statement

Expression identifier is a construct declared with EXPRESSION; its value defines (together with *WITH edge evaluation*, if necessary) whether the condition is considered as satisfied.

The *WITH edge evaluation* sequence is optional. *Edge evaluation* is an expression of data type BOOL; it determines how the value of *expression identifier* is interpreted:

- *Edge evaluation* = TRUE: The rising edge of *expression identifier* is interpreted; i.e. the condition is satisfied when the value of *expression identifier* **changes** from FALSE to TRUE.
- *Edge evaluation* = FALSE: The static value of *expression identifier* is evaluated; i.e. the condition is satisfied when the value of *expression identifier* **is** TRUE.

If is not specified, the default setting is FALSE, i.e. the static value of *expression identifier* is evaluated.

The statement section must contain at least one statement (empty statements also possible).

Effect of the WAITFORCONDITION statement

The WAITFORCONDITION statement sets the task that called it to the TASK_STATE_WAITING state until the condition (expression) is TRUE.

The priority of the task is increased if the expression is true. The priority is higher than for UserInterruptTasks and lower than for SystemInterruptTasks, i.e. the MotionTask has its turn before the other task in the round-robin execution level, as well as before the UserInterruptTasks and TimerInterruptTasks.

The increased task priority applies to all statements between the WAITFORCONDITION command and the END_WAITFORCONDITION command. The END_WAITFORCONDITION command ends the increased task priority.

The statement section must contain at least one empty statement.

Please note the following when using the WAITFORCONDITION command:

- The command is used to wait for an event in a MotionTask. If it is programmed within another task, it is ignored.
- There is no time watchdog in a MotionTask.
  Therefore, make sure that the condition does actually become true. Otherwise, the MotionTask would always be in the wait state and this would produce a timeout error.
- As of V4.1 a time watchdog for WAITFORCONDITION can be programmed in a Motion Task.
- The WAITFORCONDITION ... END_WAITFORCONDITION structure may not be nested.
- Within the round-robin level, the waiting task is the next to be executed when the event occurs, as long as it is not hindered by higher-priority tasks (such as alarms).
- The time slice of the active task in the round robin level is interrupted.
- For the behavior in the event of task interruption, see *_suspendTaskid*).
- The expression is checked in the IPO cycle clock with high priority.

Task priorities (Page 1307)

MotionTasks (Page 1316)

Example of use of WAITFORCONDITION

The following example assumes that the *feeder* program is running in a MotionTask. The option **Activation after StartupTask** is selected for this MotionTask.

The assignment of programs to tasks is performed in SIMOTION SCOUT (see **Assigning programs to the execution levels / tasks**).

Table 4-83 Example for use of the WAITFORCONDITION condition

```
INTERFACE
 USEPACKAGE CAM;
 PROGRAM feeder;
END_INTERFACE

IMPLEMENTATION
    // Condition for WAITFORCONDITION in MotionTask_1
    EXPRESSION automaticExpr
        automaticExpr := IOfeedCam; // Digital input
    END_EXPRESSION
    // feeder (MotionTask_1)
    PROGRAM feeder
        VAR
            retVal : DINT;
    END_VAR ;
    retVal := _enableAxis(axis := realAxis,
        enableMode := ALL,
        servoCommandToActualMode := INACTIVE,
        nextCommand := WHEN_COMMAND_DONE,
        commandId := _getCommandId() );
        // Wait for automatic start
    WAITFORCONDITION automaticExpr WITH TRUE DO
        retVal := _pos(axis := realAxis,
            positioningMode := RELATIVE,
            position := 500,
            velocityType := DIRECT,
                                    velocity:=300,
            positiveAccelType := DIRECT,
            positiveAccel:= 400,
            negativeAccelType := DIRECT,
            negativeAccel := 400,
            velocityProfile:= TRAPEZOIDAL,
                                    mergeMode:=IMMEDIATELY,
                                    nextCommand:=WHEN_MOTION_DONE,
            commandId:= _getCommandId() );
            // Reduce priority after WAITFORCONDITION
    END_WAITFORCONDITION;
    retVal := _disableAxis(axis := realAxis,
    disableMode := ALL,
    servoCommandToActualMode := INACTIVE,
    nextCommand := WHEN_COMMAND_DONE,
    commandId := _getCommandId() );
    END_PROGRAM
END_IMPLEMENTATION
```

Example for time verification via FB

Example of using WAITFORCONDITION with time verification via FB (as of V4.1)

The following example shows time monitoring of the *expressions* (WAITFORCONDITION). The bonding of the expression at the call point to instance data of a calling function block inclusive time monitoring is presented alongside. This is a TON type reference variable. The call is executed within the expression with query of the output.

```
INTERFACE
    VAR_GLOBAL
        v1, v2 : INT;
        t1, t2 : TIME;
        Evaluation: INT;
    END_VAR
    PROGRAM Test_1;
END_INTERFACE
IMPLEMENTATION
    EXPRESSION mcccont1
        VAR_IN_OUT
            v : INT;
            t : TON;
        END_VAR
        t();
        mcccont1 := v > 100 or t.q ;
    END_EXPRESSION
    FUNCTION_BLOCK waitfb
        VAR_IN_OUT
            refpar1 : INT;
            refpar2 : TIME;
        END_VAR
        VAR_TEMP
            expr_timeout : TON;
        END_VAR
        expr_timeout(pt := refpar2, IN := TRUE);
        // Set monitoring time and
        //activate timer
        Evaluation: = 0;
        WAITFORCONDITION mcccont1(v := refpar1, t := expr_timeout ) DO
           Evaluation: = 100; //statement
            IF (expr_timeout.q) THEN
                // Error handling feasible, if Time-Out
                Evaluation: = 20005;
            END_IF;
        END_WAITFORCONDITION;
        expr_timeout( IN := FALSE);
        ;
    END_FUNCTION_BLOCK
    PROGRAM test_1
        VAR
            my_waitfb1 : waitfb;
        END_VAR
        my_waitfb1 (refpar1 :=v1, refpar2:=t1);
        //Wait until V1>100 and time
    END_PROGRAM
END_IMPLEMENTATION
```

The call of the waitfb type instance can then be executed at any point with different variables in each case. These global variables are then updated by cyclic tasks:

```
my_waitfb_1(refpar1 := v1, refpar2:=t1); //Wait until V1>100 and
time t1 not elapsed

my_waitfb_2(refpar1 := v2, refpar2:=t1);
```

Example for using WAITFORCONDITION with time monitoring directly in non-cyclic task / Motion Task

Description

Example of time monitoring of the expression (WAITFORCONDITION).

The call is executed directly in a MotionTask.

The time monitoring is type TON, with call within the expression and query of the output.

```
INTERFACE
    TYPE
        eDiagType : (TIMEOUT, COUNTER_REACHED, NOTHING);
    END_TYPE
    VAR_GLOBAL
        eDiag   : eDiagType := NOTHING;
        v1      : INT  := 0;
        t1      : TIME := T#0d_0h_0m_3s_0ms;
    END_VAR
    PROGRAM testExpression;
    PROGRAM increaseV1;
END_INTERFACE
IMPLEMENTATION
    EXPRESSION expr
        VAR_IN_OUT
            v : INT;
            t : TON;
        END_VAR
        t();
        expr := v > 500 OR t.q;
    END_EXPRESSION
                        //MotionTask
    PROGRAM testExpression
        VAR_TEMP
            expr_timeout : TON;
        END_VAR
                       // Set monitoring time, and activate timer
expr_timeout(pt := t1, IN := TRUE);
                      //Wait until v1 > 500 or time t1 has elapsed
        WAITFORCONDITION expr(v := v1, t := expr_timeout) DO
            IF (expr_timeout.q) THEN
                      // Error handling
                      // Time t1 has elapsed without v1 > 500 becoming true
                eDiag := TIMEOUT;
                … ;
            ELSE
                      // Good case,  v1 > 500
                eDiag := COUNTER_REACHED;
                 … ;
            END_IF;
        END_WAITFORCONDITION;
    END_PROGRAM
                       //BackgroundTask
    PROGRAM increaseV1
        v1 := v1 + 1;
    END_PROGRAM
END_IMPLEMENTATION
.....
```

You can update v1 in any cyclical tasks.

Making tasks wait a defined period

Place task in the wait state

You can place a task in the TASK_STATE_WAITING status for a specific period of time (see Task status (Page 1424)). To do so, use the *_waitTime* function. This places the calling task in the wait state for the specified period.

Note

A task that is in the wait state does not (or hardly) requires any CPU time. The only load on the target system is the periodic check to establish whether the wait time has expired. This check takes place in the IPO cycle clock.

The call of *_waitTime (timeValue := T#0ms)* in a MotionTask temporarily inactivates these and returns the program control to the scheduler. This is recommended, for example for longer loops if the program control will knowingly be transferred to the next round robin task (also possible in BackgroundTask).

Note

The function should be used in MotionTasks only; using it in cyclic tasks may lead to time monitoring errors!

- With SynchronousTasks: You can configure whether the time watchdog is suspended. Time monitoring is active by default.
  With IPOsynchronousTask, additionally take the following into account: UserInterruptTasks will no longer be started by their triggering event!
- With other cyclic tasks (BackgroundTask, TimerInterruptTasks): Time monitoring is always active.

In cyclic tasks, use the timer system function blocks (see *Timers* section) to implement waiting times.

Use an expression of data type TIME as an input parameter, the return value of data type DINT is always 0.

For more information on the function (syntax), refer to the description of the **_waitTime** function.

The following sample program puts the MotionTask to which it is assigned in the wait state for ten seconds:

Table 4-84 Example of _waitTime function

```
INTERFACE
    PROGRAM waitTime;
END_INTERFACE

IMPLEMENTATION
    PROGRAM waitTime
        VAR
            retVal :DINT;
        END_VAR;
        retVal := _waitTime(timeValue := T#10s);
    END_PROGRAM
END_IMPLEMENTATION
```

4.2.8.2 Task control commands

Overview of the task control commands

The commands listed in the table are available for task control.

Table 4-85 Task control commands in SIMOTION ST

Task control command	Meaning
_startTaskId (Page 1441)	Starts a MotionTask that is in the state TASK_STATE_STOPPED; its startup code is executed. Can only be applied to MotionTasks. Command must not directly follow *_resetTaskId*. Use *_restartTaskId* instead.
_resetTaskId (Page 1439)	Resets a MotionTask to TASK_STATE_STOPPED. Can only be applied to MotionTasks. *_startTaskId* must not directly follow this command. Use *_restartTaskId* instead.
_restartTaskId (Page 1439)	Resets a MotionTask to TASK_STATE_STOPPED and restarts it; the startup code for this MotionTask is executed. Can only be applied to MotionTasks.
_suspendTaskId (Page 1442)	The task in question will be suspended (set to TASK_STATE_SUSPENDED), for cyclic tasks time monitoring will be suspended. Cannot be used on SynchronousTasks, StartupTask, or ShutdownTask.
_resumeTaskId (Page 1440)	The relevant task, which is located in the TASK_STATE_SUSPENDED state, is resumed. For cyclic tasks, time monitoring is activated again. Cannot be used on SynchronousTasks, StartupTask, or ShutdownTask.

Task control command	Meaning
_getStateOfTaskId (Page 1437)	Queries the state of the relevant task.
_retriggerTaskIdControlTime (Page 1441)	The monitoring time is reset once for the relevant task.

The task is specified for these functions via a unique TaskId (Page 1436).

An example of a task control command can be found in Section "Example for using a task control command (Page 1437)".

See the SIMOTION MCC Programming Manual (Chapters "Incoming message" and "Outgoing message") for programming functions in MCC.

See also Task status (Page 1424).

Commands for controlling the scheduler

In addition, SIMOTION devices provide system functions for controlling the scheduler. These are listed in the table (for a description, see the List Manuals for SIMOTION devices):

Table 4-86 Commands for controlling the scheduler

Task control command	Meaning
_disableScheduler()	Prevents all user program tasks (except SynchronousTasks) from being loaded until *_enableScheduler* is called. It does not, however, affect system tasks. **Note**: The time monitoring for cyclic tasks is **not** suspended. **Note**: This command also prevents exchanging of SystemInterruptTasks and UserInterruptTasks!
_enableScheduler()	Cancels the effect of *_disableScheduler*.

TaskId

Tasks are specified via the associated TaskId.

You can obtain the TaskId for a task (data type StructTaskId) as follows:

- As _task.*name* variable (e.g. _task.motionTask_1). Explanation of terms:
  - _task
    Predefined name space for TaskId, see Section "Name spaces" in the SIMOTION ST Programming Manual. The identifier for the name space is separated by a period from the following identifier.
  - *name*
    The identifier of the task as specified in the execution system (e.g. motionTask_1).
- With the _getTaskId (*name*) function, see _getTaskId (Page 1444) function.
  name is the identifier of the task as assigned in the execution system.

You can use the _checkEqualTask function to check whether a TaskId belongs to a particular task (see _checkEqualTask (Page 1445) function).

Note

The _checkEqualTask and _getTaskId functions may only be called in the short form, i.e. with a complete listing of all parameter values, but without specification of the formal parameters.

The _checkEqualTask and _getTaskId functions and variables of the form _task.*name* must not be used in libraries.

Example for using a task control command

The following example requires that the following assignments have been made in SIMOTION SCOUT:

- The *myStart* program is assigned to the StartupTask.
- The *myMotion* program is assigned to MotionTask_1.

After controller startup (transition from STOP to RUN), the StartupTask runs automatically. The *myStart* program is executed in this task.

The *_startTaskId* task control command is used in the *myStart* program to start MotionTask_1. In MotionTask_1, the *myMotion* program is executed.

```
INTERFACE
    PROGRAM myStart;
    PROGRAM myMotion;
END_INTERFACE

IMPLEMENTATION
    PROGRAM myStart
        VAR
            RetDWord : DWORD;
        END_VAR

        RetDWord := _startTaskid (_task.motionTask_1);
        // Start MotionTask_1
    END_PROGRAM

    PROGRAM myMotion
        ;// Here, commands in the program, e.g. axis commands
    END_PROGRAM
END_IMPLEMENTATION
```

_getStateOfTaskId function

Description

This functions returns the state of the relevant task. The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function can be applied to all tasks except StartupTask and ShutdownTask.

See also Section "Task status (Page 1424)". An example is also provided of how to decide if a MotionTask can be started, based on the task status, see Example for use of the task status (Page 1425).

Declaration

```
_getStateOfTaskId (
             { id     : StructTaskId // TaskId
             }
             ) : DWORD
```

Input parameter

id (optional)

Data type: StructTaskId

Default: TaskId of the current task in which the function is called.

TaskId of the task to be controlled, see TaskId (Page 1436).

Return value

Data type: DWORD

Status of the task is displayed as an OR operation on the following values, see also Task status (Page 1424):

16#0000	Task does not exist or Task ID is invalid TASK_STATE_INVALID
16#0001	Task in transition from running to stopped TASK_STATE_STOP_PENDING
16#0002	Task stopped TASK_STATE_STOPPED
16#0004	Task running TASK_STATE_RUNNING
16#0010	Task waiting TASK_STATE_WAITING
16#0020	Task suspended TASK_STATE_SUSPENDED
16#0040	TimerInterruptTask waiting for its start trigger TASK_STATE_WAIT_NEXT_CYCLE
16#0080	SystemInterruptTask or UserInterruptTask waiting for the occurrence of an initiating event TASK_STATE_WAIT_NEXT_INTERRUPT
16#0100	Task locked (by _disableScheduler) TASK_STATE_LOCKED

_resetTaskId function

Description

The function resets a MotionTask to TASK_STATE_STOPPED. The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function is only applicable to MotionTasks.

The _startTaskId (Page 1441) function must not directly follow this function. Use the _restartTaskId (Page 1439) function instead.

Declaration

```
_resetTaskId (
         id    : StructTaskId    // MotionTasks only
         ) : DWORD
```

Input parameter

id

Data type: StructTaskId

For the TaskId of the task to be controlled, see TaskId (Page 1436) – MotionTasks only.

Return value

Data type:	DWORD
0	No error
16#FFFF_FFFE	TaskId does not refer to a MotionTask
16#FFFF_FFFF	TaskId is invalid

_restartTaskId function

Description

The function resets a MotionTask to TASK_STATE_STOPPED and restarts it; its data is initialized. The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function is only applicable to MotionTasks.

To prevent this function from being used to stop a running MotionTask, its status can be queried and evaluated, see _getStateOfTaskId (Page 1437) function and the Example for use of the task status (Page 1425).

Declaration

```
_restartTaskId (
         id    : StructTaskId  // MotionTasks only
         ) : DWORD
```

Input parameter

id

Data type: StructTaskId

For the TaskId of the task to be controlled, see TaskId (Page 1436) – MotionTasks only.

Return value

Data type:	DWORD
0	No error
16#FFFF_FFFE	TaskId does not refer to a MotionTask
16#FFFF_FFFF	TaskId is invalid

_resumeTaskId function

Description

The function resumes a task that is in the TASK_STATE_SUSPENDED state. This state has been achieved using the _suspendTaskId (Page 1442) function. The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function is applicable to MotionTasks, BackgroundTask, TimerInterruptTasks, UserInterruptTasks, SystemInterruptTasks.

In the case of cyclic tasks (BackgroundTask, TimerInterruptTasks), the time watchdog for the task is enabled again.

Declaration

```
_resumeTaskId (
         id    : StructTaskId
         ) : DWORD
```

Input parameter

id

Data type: StructTaskId

TaskId of the task to be controlled, see TaskId (Page 1436).

Return value

Data type:	DWORD
0	No error
16#FFFF_FFFE	TaskId refers to an illegal task
16#FFFF_FFFF	TaskId is invalid

_retriggerTaskIdControlTime function

Description

The function resets the monitoring time once for the relevant task. The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function is applicable to MotionTasks, BackgroundTask, TimerInterruptTasks, UserInterruptTasks, SystemInterruptTasks.

Declaration

```
_retriggerTaskIdControlTime (
                    { id        : StructTaskId
                    }
                ) : DWORD
```

Input parameter

id (optional)

Data type:	StructTaskId
Default:	TaskId of the current task in which the function is called.

TaskId of the task to be controlled, see TaskId (Page 1436).

Return value

Data type:	DWORD
0	Function executed normally.
Not equal to 0	Function not executed normally.

_startTaskId function

Description

The function starts a MotionTask that is in the TASK_STATE_STOPPED state; its data is initialized. The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function is only applicable to MotionTasks.

It has no effect on MotionTasks in the following states:

- TASK_STATE_RUNNING
- TASK_STATE_WAITING
- TASK_STATE_SUSPENDED

Before using the function, the state of the MotionTask can be queried and evaluated, see _getStateOfTaskId (Page 1437) function and Example for use of the task status (Page 1425).

It must not directly follow the _resetTaskId (Page 1439) function. Use the _restartTaskId (Page 1439) function instead.

Declaration

```
_startTaskId (
         id    : StructTaskId    // MotionTasks only
         ) : DWORD
```

Input parameter

id

Data type: StructTaskId

TaskId of the task to be controlled, see TaskId (Page 1436) – MotionTasks only.

Return value

Data type:	DWORD
0	No error
16#FFFF_FFFE	TaskId does not refer to a MotionTask
16#FFFF_FFFF	TaskId is invalid

_suspendTaskId function

Description

The function suspends the relevant task (sets it to TASK_STATE_SUSPENDED). The task is specified by means of a project-wide unique TaskId (see TaskId (Page 1436)).

The function is applicable to MotionTasks, BackgroundTask, TimerInterruptTasks, UserInterruptTasks, SystemInterruptTasks.

In the case of cyclic tasks (BackgroundTask, TimerInterruptTasks), the time watchdog for the task is stopped.

The task and its time monitoring are resumed using the _resumeTaskId (Page 1440) function.

Declaration

```
_suspendTaskId (
             id        : StructTaskId
         ) : DWORD
```

Input parameter

id

Data type: StructTaskId

TaskId of the task to be controlled, see TaskId (Page 1436).

Return value

Data type:	DWORD
0	No error
16#FFFF_FFFE	TaskId refers to an illegal task
16#FFFF_FFFF	TaskId is invalid

Interruption of the evaluation of a condition for WAITFORCONDITION

When the wait condition of a WAITFORCONDITION statement in a MotionTask is checked, the task status is not taken into account automatically.

You have programmed the wait condition for WAITFORCONDITION statement, e.g. wait for overtravel of an initiator, in an EXPRESSION. The associated MotionTask is now interrupted with _suspendTaskId before the wait condition is satisfied. Subsequently the condition is temporarily satisfied, e.g. through manual overtravel of an initiator. After _resumeTaskId, the MotionTask is executed as if the condition had been satisfied in the normal process.

However, you can avoid this by additionally querying the task status in the EXPRESSION.

```
// Condition for WAITFORCONDITION statement in MotionTask_1
EXPRESSION automaticExpr
    automaticExpr := IOfeedCam AND        // Digital input
        (task_status = (TASK_STATE_RUNNING OR TASK_STATE_WAITING));
END_EXPRESSION
```

_getTaskId function

Description

The function generates a project-wide unique TaskId (Page 1436) from the task name (as in the execution system). This TaskId can be assigned to a variable of data type StructTaskId and used as an input parameter in the following functions:

- Task control commands (Page 1435)
- Functions for runtime measurement of tasks (Page 1446)

Note

This function must not be used in libraries.

This function may only be called in the short form, i.e. with a complete listing of all parameter values, but without specification of the formal parameters.

Declaration

```
_getTaskId (  // Only the short form is permitted
         name    : Task_Name  // Name of the task
         ) : StructTaskId
```

Input parameter

name (only short form permitted)

Name of task as defined in the execution system.

Return value

Data type: StructTaskId

Return value contains the TaskId of the task.

_checkEqualTask function

Description

This function indicates whether a TaskId (Page 1436) is associated with a specified task.

Note

This function must not be used in libraries.

This function may only be called in the short form, i.e. with a complete listing of all parameter values, but without specification of the formal parameters.

Declaration

```
_checkEqualTask (  // Only the short form is permitted
        id     : StructTaskId,  // TaskId
        Name   : TaskName       // Name of the task
    ) : BOOL
```

Input parameter

id

(only short form permitted)

Data type: StructTaskId

TaskId to be checked, e.g. TSI#taskId.

Name

(only short form permitted)

Data type: TaskName

Name of a task, as defined in the execution system.

Return value

Data type: BOOL

The return value indicates whether the TaskId is associated with the specified task:

TRUE: TaskId is associated with the specified task.

FALSE TaskId is not associated with the specified task.

4.2.8.3 Functions for runtime measurement of tasks

Functions for runtime measurement of tasks - overview

The functions for runtime measurement are permissible for all tasks. However, the measurement is not supported by the IPOsynchronousTask, the ServosynchronousTask and the ShutdownTask. The functions for runtime measurement of tasks supply the runtime in ms.

The following runtimes can be measured:

- The maximum runtime of the task since the last STOP-RUN transition, see _getMaximalTaskIdRunTime (Page 1446) function
- The minimum runtime of the task since the last STOP-RUN transition, see _getMinimalTaskIdRunTime (Page 1447) function
- The runtime from the preceding task pass, see _getCurrentTaskIdRunTime (Page 1448) function
- The average task runtime from the last ten preceding passes, see _getAverageTaskIdRunTime (Page 1449) function

The task is specified for these functions via a unique TaskId.

Note

You can also use the Track Trace to determine the runtime of tasks. For detailed information regarding the Task Trace, see the Task Trace function manual.

Functions for accurate runtime determination

You can use the following system functions to measure the time since the system started with µs precision. Thus, you can measure the time precisely for sections within the application in order, for example, to optimize the application.

- Function _getInternalTimeStamp (Page 1451)
- _getTimeDifferenceOfInternalTimeStamps function (Page 1451)

See also

Task runtimes (Page 1358)

_getMaximalTaskIdRunTime function

Description

The _getMaximalTaskIdRunTime function provides the maximum runtime of the task since the last STOP-RUN transition, including all interruptions by higher-priority tasks. The task is specified by means of a project-wide unique task ID, see description in the section Overview of the task control commands (Page 1435).

The following functions do not interrupt the measurement:

- _suspendTaskId (Page 1442)
- _disableScheduler (see List Manuals for SIMOTION devices)

The determined runtime is a multiple of the position control cycle clock; for runtimes less than the position controller cycle, T#MIN (= T#0ms) is returned as measured value.

The function is permitted for all tasks. However, the measurement is not supported by the IPOsynchronousTask and the ShutdownTask. Measured value T#MIN (= T#0ms) is returned when called with these tasks.

Declaration

```
_getMaximalTaskIdRunTime (
                { id  : StructTaskId
                }
            ) : TIME
```

Input parameter

id (optional)

Data type: StructTaskId

Default: TaskId of the current task in which the function is called.

TaskId of the task whose runtime should be measured, see description in the section Overview of the task control commands (Page 1435).

Return value

Data type:	TIME
T#MIN (= T#0ms = T#1ms * UDINT#0)	Measurement is not supported or is not yet finished.
Greater than T#MIN and less than T#MAX	Greatest runtime that has occurred.
T#MAX (= T#49d_17h_2m_47s_295ms = T#1ms * UDINT#16#FFFF_FFFF)	TaskId is invalid

_getMinimalTaskIdRunTime function

Description

The _getMinimalTaskIdRunTime function provides the minimum runtime of the task since the last STOP-RUN transition, including all interruptions by higher-priority tasks. The task is specified by means of a project-wide unique task ID, see description in the section Overview of the task control commands (Page 1435).

The following functions do not interrupt the measurement:

- _suspendTaskId (Page 1442)
- _disableScheduler (see List Manuals for SIMOTION devices)

The determined runtime is a multiple of the position control cycle clock; for runtimes less than the position controller cycle, T#MIN (= T#0ms) is returned as measured value.

The function is permitted for all tasks. However, the measurement is not supported by the IPOsynchronousTask and the ShutdownTask. Measured value T#MIN (= T#0ms) is returned when called with these tasks.

Declaration

```
_getMinimalTaskIdRunTime (
                { id  : StructTaskId
                }
            ) : TIME
```

Input parameter

id (optional)

Data type: StructTaskId

Default: TaskId of the current task in which the function is called.

TaskId of the task whose runtime should be measured, see description in the section Overview of the task control commands (Page 1435).

Return value

Data type:	TIME
T#MIN (= T#0ms = T#1ms * UDINT#0)	Measurement is not supported or is not yet finished.
Greater than T#MIN and less than T#MAX	Minimum runtime that has occurred.
T#MAX (= T#49d_17h_2m_47s_295ms = T#1ms * UDINT#16#FFFF_FFFF)	TaskId is invalid

_getCurrentTaskIdRunTime function

Description

The _getCurrentTaskIdRunTime function provides the runtime from the preceding pass of the task, including all interruptions by higher-priority tasks. The task is specified by means of a project-wide unique task ID, see description in the section Overview of the task control commands (Page 1435).

The following functions do not interrupt the measurement:

- _suspendTaskId (Page 1442)
- _disableScheduler (see List Manuals for SIMOTION devices)

The determined runtime is a multiple of the position control cycle clock; for runtimes less than the position controller cycle, T#MIN (= T#0ms) is returned as measured value.

The function is permitted for all tasks. However, the measurement is not supported by the IPOsynchronousTask and the ShutdownTask. Measured value T#MIN (= T#0ms) is returned when called with these tasks.

Declaration

```
_getCurrentTaskIdRunTime (
                { id  : StructTaskId
                }
            ) : TIME
```

Input parameter

id (optional)

Data type: StructTaskId

Default: TaskId of the current task in which the function is called.

TaskId of the task whose runtime should be measured, see description in the section Overview of the task control commands (Page 1435).

Return value

Data type:	TIME
T#MIN (= T#0ms = T#1ms * UDINT#0)	Measurement is not supported or is not yet finished.
Greater than T#MIN and less than T#MAX	Runtime that occurred during the preceding pass.
T#MAX (= T#49d_17h_2m_47s_295ms = T#1ms * UDINT#16#FFFF_FFFF)	TaskId is invalid

Function _getAverageTaskIdRunTime

Description

This _getAverageTaskIdRunTime function provides an average runtime of the task from the last ten preceding cycles, including all interruptions by higher-priority tasks. The task is specified by means of a project-wide unique task ID, see description in the section Overview of the task control commands (Page 1435).

The following functions do not interrupt the measurement:

- _suspendTask (Page 1442)
- _disableScheduler (see List Manuals for SIMOTION devices)

The determined runtime is a multiple of the position control cycle clock; for runtimes less than the position controller cycle, T#MIN (= T#0ms) is returned as measured value.

The function is permitted for all tasks. However, the measurement is not supported by the IPOsynchronousTask and the ShutdownTask. Measured value T#MIN (= T#0ms) is returned when called with these tasks.

Declaration

```
_getAverageTaskIdRunTime (
                { id  : StructTaskId
                }
            ) : TIME
```

Input parameter

id (optional)

Data type	StructTaskId
Default:	TaskID of the task for which runtime is to be measured, as defined in the execution system.

TaskId of the task whose runtime should be measured, see description in the section Overview of the task control commands (Page 1435).

Return value

Data type:	TIME
T#MIN (= T#0ms = T#1ms * UDINT#0)	Measurement is not supported or is not yet finished.
Greater than T#MIN and less than T#MAX	Average of runtimes that have occurred.
T#MAX (= T#49d_17h_2m_47s_295ms = T#1ms * UDINT#16#FFFF_FFFF)	TaskId is invalid

Functions for the precise runtime measurement of tasks

Description

With the following system functions you can measure the time since system start with µs precision. Thus for sections within the application you can measure the time precisely, in order to optimize the application.

You can use the following functions:

- Function _getInternalTimeStamp (Page 1451)
- _getTimeDifferenceOfInternalTimeStamps function (Page 1451)

Function _getInternalTimeStamp

Description

The _getInternalTimeStamp function supplies a specific internal time stamp as UDINT. You can set a time stamp, e.g. at the start and at the end of a task. You can then use the two time stamps as parameters t1 and t2 of the _getTimeDifferenceOfInternalTimeStamp (Page 1451) function.

Note

The function is suitable for the measurement of short times (e.g. performance optimization of algorithms). In the case of extended measurements, there may be differences of the real time and the expired system cycle clocks. These differences can vary for different CPU types.

Declaration

```
_getInternalTimeStamp ()     : UDINT;
```

Input parameter

None

Return value

Data type: UDINT

Internal time stamp.

_getTimeDifferenceOfInternalTimeStamps function

Description

The _getTimeDifferenceOfInternalTimeStamps function supplies a time value from two internal time stamps (UDINT return value). Both time stamps must be generated via the _getInternalTimeStamp (Page 1451) function.

Note

When calling the function, pay attention to the order of the parameters t1 and t2 for the internal time stamp. The numeric values of the time stamp are not significant for this.

Declaration

```
_getTimeDifferenceOfInternalTimeStamps (
        t1  : UDINT,  // Internal time stamp 1
        t2  : UDINT   // Internal time stamp 2
    ): UDINT;         // Time difference in µs
```

Input parameter

t1

Data type: UDINT

Internal time stamp 1.

The start time of the interval to be measured, created with _getInternalTimeStamp function.

t2

Data type: UDINT

Internal time stamp 2.

The end time of the interval to be measured, created with _getInternalTimeStamp function.

Return value

Data type: UDINT

Time difference in µs.

Application

With this function you can measure, for example, the runtimes of code sections or communication times in an IPOsynchronous task.

4.2.8.4 Functions for message programming (AlarmS)

General information for the message programming

You can send messages configured in SIMOTION SCOUT of the AlarmS type (e.g. error messages) to logged-on display devices and check their status.

In particular, you can:

- Send a message that does not require acknowledgment, see _alarmSId (Page 1453) function.
- Send a message that requires acknowledgment, see _alarmSqId (Page 1456) function.
- Check the status of a message and its acknowledgment, see _alarmScId (Page 1459) function.
- List all pending alarms, see _getPendingAlarms (Page 1462) function (as of V4.1).

- Set messages to "outgoing", see _resetAlarmId (Page 1463) and _resetAllAlarmId (Page 1464) functions (as of V4.1).
- Acknowledge messages, see _acknowledgeAlarmSqId (Page 1466) and _acknowledgeAllAlarmSqId (Page 1467) functions (as of V4.4).

The message is specified for these functions using a unique AlarmId. For more information about the AlarmId, see the following section (Page 1453).

Examples of message programming are included in Programming messages. (Page 1563)

See the SIMOTION MCC Programming Manual (Chapters "Incoming message" and "Outgoing message") for programming functions in MCC.

AlarmId

Messages are specified via the associated AlarmId.

You can obtain the AlarmId (data type StructAlarmId) for a configured message name in the following way:

- As variable _alarm.*name*. Explanation of terms:
  - _alarm
    Predefined name space for AlarmId, see Section "Name spaces" in the SIMOTION ST Programming Manual. The identifier for the name space is separated by a period from the following identifier.
  - *name*
    Identifier of the message as configured in SIMOTION SCOUT.
- With the _getAlarmId (*name*) function, see _getAlarmId (Page 1461) function.
  name is the identifier of the message as configured in SIMOTION SCOUT.
  This function may only be called in the short form, i.e. with a complete listing of all parameter values, but without specification of the formal parameters.

Note

The _getAlarmId function and variables of the form _alarm.*name* must not be used in libraries.

_alarmSId function

Description

When a level change occurs in the triggering signal (Sig), the function generates a message that does not require acknowledgment and that is sent to all display devices logged on to receive such signals. The message to be generated is specified by means of a project-wide, unique AlarmId, see AlarmId (Page 1453).

As option, associated values can be appended:

- Independent of the SIMOTON kernel version:
  One associated value of the general data type ANY_NUM or ANY_BIT
- As of version V4.5 of the SIMOTION kernel:
  Several associated values are possible. They are passed in an ARRAY [0..11] OF BYTE.

A maximum of 40 messages can be processed simultaneously.

Declaration

```
_alarmSId (
         Sig    : BOOL
         Ev_Id  : StructAlarmId
         { sd   : ANY_NUM, ANY_BIT, ARRAY [0..11] OF BYTE
         }
         )  : DWORD
```

Input parameter

Sig

Data type: BOOL

The signal triggering the message is interpreted as follows:

If the signal represents a rising edge – relative to the last call with this AlarmId – an incoming message is generated. An incoming message is also generated if the signal state is TRUE on the first call with this message name.

If the signal represents a falling edge – relative to the last call with this AlarmId – an outgoing message is generated.

Ev_Id

Data type: StructAlarmId

AlarmId of the message to be generated, see AlarmId (Page 1453).

sd (optional)

Data type:	ANY_NUM, ANY_BIT (independent of the kernel version) ARRAY [0..11] OF BYTE (as of kernel V4.5)
Default:	0

Associated value:

Associated values must be specified when associated values have been defined during the message configuring in SIMOTION SCOUT.

- Independent of the SIMOTON kernel version:
  One associated value possible, all elementary data types are permissible.
  Variables or previously defined identifiers for constants belonging to one of the permitted data types are possible.
  Values can be entered, but it is not recommended. The format is determined only by the numerical value, which is particularly problematic for floating-point values. If a value is nonetheless specified directly, use the typed literal notation string for constants. A warning is generated if non-typed numerical values are entered.
- As of version V4.5 of the SIMOTION kernel:
  A maximum of 12 associated values of data type BYTE (or SINT, USINT) are possible; they are passed in an ARRAY [0..11] OF BYTE.
  Associated values with data types that comprise several bytes (e.g. WORD, DINT, REAL) are possible; they reduce the number of possible associated values. The user must ensure that their values are stored in the permissible array elements in accordance with the Big Endian byte order. The AnyType_to_BigByteArray (Page 1492) function can be used for this purpose.

During compilation, a check cannot be performed with the data types of the associated values configured in the message.

Return value

Data type: DWORD

The return value informs the user about the result of the call.

The specified values can be represented as an OR operation between the ALARMS_ERROR constants and the DSC_SVS_DEVICE_ALARMS_xxx constants.

16#0000	No error For an incoming message, an entry is made in the message list. For an outgoing message, an entry was deleted from the message list.
16#8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID
16#8002	Loss of messages due to overflow (no more space in the message list). All 40 entries of the message list are occupied. Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_ENTRY_USED

16#8003	Loss of messages due to overflow (signal not yet sent, signal overflow). Send buffer for notification of the clients is still occupied by the last event. Entry is not made in the message list. Error may also occur if function calls come quickly one after the other with rising and falling edge. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_SIGNAL_USED
16#8004	Double message, message rejected (call with incoming or outgoing message for the second time in succession). Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_CALL
16#8005	No display device registered (message is entered into the list anyway). ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_NOT_USED
16#8006	Message name is already being processed in a lower-priority level. Does not occur for SIMOTION. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_IN_USE
16#8007	No job has been started yet with this message name (first call with Sig = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_FIRST_CALL
16#8008	Message name already assigned. Does not occur for SIMOTION. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_SFC_TYP
16#8009	Internal error ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_INTERNAL_ERROR
16#8010	Entry was rejected; message acknowledgment memory full. Only for _alarmSqId ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_NO_ENTRY

Example

See Example of message generation (Page 1566), Example of messages with several associated values (as of kernel V4.5) (Page 1567).

_alarmSqId function

Description

When a level change occurs in the triggering signal (Sig), the function generates a message that requires acknowledgment and that is sent to all display devices logged on to receive such signals. The message to be generated is specified by means of a project-wide, unique AlarmId, see AlarmId (Page 1453).

As option, associated values can be appended.

- Independent of the SIMOTON kernel version:
  One associated value of the general data type ANY_NUM or >ANY_BIT
- As of version V4.5 of the SIMOTION kernel:
  Several associated values are possible. They are passed in an ARRAY [0..11] OF BYTE.

A maximum of 40 messages can be processed simultaneously.

Declaration

```
_alarmSqId (
         Sig    : BOOL
         Ev_Id  : StructAlarmId
         { sd   : ANY_NUM, ANY_BIT, ARRAY [0..11] OF BYTE
         }
         )  : DWORD
```

Input parameter

Sig

Data type: BOOL

The signal triggering the message is interpreted as follows:

If the signal represents a rising edge – relative to the last call with this message name – an incoming message is generated. An incoming message is also generated if the signal state is TRUE on the first call with this message name.

If the signal represents a falling edge – relative to the last call with this message name – an outgoing message is generated.

If no signal is generated with falling edge, an alarm of type SQ remains in the message buffer, even if it has been acknowledged using _acknowledgeAllAlarmSqId.

Ev_Id

Data type: StructAlarmId

AlarmId of the message to be generated, see AlarmId (Page 1453).

sd (optional)

Data type:	ANY_NUM, ANY_BIT (independent of the kernel version) ARRAY [0..11] OF BYTE (as of kernel V4.5)
Default:	0

Associated value

Associated values must be specified when associated values have been defined during message configuring in SIMOTION SCOUT.

- Independent of the SIMOTON kernel version:
  One associated value possible, all elementary data types are permissible.
  Variables or previously defined identifiers for constants belonging to one of the permitted data types are possible.
  Values can be entered, but it is not recommended. The format is determined only by the numerical value, which is particularly problematic for floating-point values. If a value is nonetheless specified directly, use the typed literal notation string for constants. A warning is generated if non-typed numerical values are entered.
- As of version V4.5 of the SIMOTION kernel:
  A maximum of 12 associated values of BYTE (or SINT, USINT) data type is possible; they are passed in an ARRAY [0..11] OF BYTE.
  Associated values with data types that comprise several bytes (e.g. WORD, DINT, REAL) are possible; they reduce the number of possible associated values. The user must ensure that their values are stored in the permissible array elements in accordance with the Big Endian byte order. The AnyType_to_BigByteArray (Page 1492) function can be used for this purpose.

During compilation, a check cannot be performed with the data type of the associated value configured in the message.

Return value

Data type: DWORD

The return value informs the user about the result of the call.

The specified values can be represented as an OR operation between the ALARMS_ERROR constants and the DSC_SVS_DEVICE_ALARMS_xxx constants.

16#0000	No error For an incoming message, an entry is made in the message list. For an outgoing message, an entry was deleted from the message list.
16#8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID
16#8002	Loss of messages due to overflow (no more space in the message list). All 40 entries of the message list are occupied. Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_ENTRY_USED

16#8003	Loss of messages due to overflow (signal not yet sent, signal overflow). Send buffer for notification of the clients is still occupied by the last event. Entry is not made in the message list. Error may also occur if function calls come quickly one after the other with rising and falling edge. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_SIGNAL_USED
16#8004	Double message, message rejected (call with incoming or outgoing message for the second time in succession). Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_CALL
16#8005	No display device registered (message is entered into the list anyway). ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_NOT_USED
16#8006	Message name is already being processed in a lower-priority level. Does not occur for SIMOTION. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_IN_USE
16#8007	No job has been started yet with this message name (first call with Sig = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_FIRST_CALL
16#8008	Message name already assigned. Does not occur for SIMOTION. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_SFC_TYP
16#8009	Internal error ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_INTERNAL_ERROR
16#8010	Entry was rejected; message acknowledgment memory full. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_NO_ENTRY

Example

See Example of message generation (Page 1566), Example of messages with several associated values (as of kernel V4.5) (Page 1567).

_alarmScId function

Description

The function displays the status of a message and its acknowledgment status. The message is specified by means of a project-wide, unique AlarmId, see AlarmId (Page 1453).

Alarms that do not have to be acknowledged are always treated as acknowledged in "incoming" status.

Declaration

```
_alarmScId (
         Ev_Id    : StructAlarmId
         )    : DWORD
```

Input parameter

Ev_Id

Data type: StructAlarmId

AlarmId of the relevant message, see AlarmId (Page 1453).

Return value

Data type: DWORD

The return value informs the user about the result of the call and the status of a message. The constant values and symbolic constants below can be used with equal priority.

First check for errors:

16#8000	Filter for errors ALARMS_ERROR
16#8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID

Second check for message status:

16#0000	Outgoing message, not acknowledged (a).
16#0001	Incoming message, not acknowledged (b). ALARMS_STATE
16#0010	There is no message for this message name. Three options: 1. Message never triggered 2. Message triggered via _alarmSId, but also sent 3. Message triggered via _alarmSqId, sent and acknowledged at the display device
16#0101	Incoming message, acknowledged (c). ALARMS_STATE OR ALARMS_QSTATE

Messages (a) ... (b) imply _alarmSqId.

Message (c) implies _alarmSqId and _alarmSId.

Example

See Checking the error number and status of a message (filtering return values) (Page 1569).

_getAlarmId function

Description

The _getAlarmId function generates the AlarmId (Page 1453) of the message from a configured, application-specific message name. This AlarmId can be assigned to a variable of data type StructAlarmId and used as an input parameter in the following functions:

- _alarmSId (Page 1453) function
- _alarmSqId (Page 1456) function
- _alarmScId (Page 1459) function
- _resetAlarmId (Page 1463) function
- _acknowledgeAlarmSqId (Page 1466) function

Note

This function must not be used in libraries.

This function may only be called in the short form, i.e. with a complete listing of all parameter values, but without specification of the formal parameters.

Declaration

```
_getAlarmId (  // Only the short form is permitted
        Al_Name : Alarm_Name // Name of the message
        ) : StructAlarmId
```

Input parameter

Al_Name

This is a message name configured specifically for the application that is created when the message is configured in SIMOTION SCOUT.

Return value

Data type: StructAlarmId

The return value contains the AlarmId of the configured message, see AlarmId (Page 1453).

Function _getPendingAlarms

Description

The _getPendingAlarms provides information on the pending alarms. It provides:

- The number of entries in the message list (maximum of 40 entries).
- For each entry in the message list:
  - The AlarmId (Page 1453) of the message
  - The message type:
    Message that does not require acknowledgement generated with the _alarmSId (Page 1453), or
    Message that requires acknowledgement generated with the _alarmSqId (Page 1456).
  - The status of the message: "Incoming" or "Outgoing".

The function is available for SIMOTION devices as of version V4.1.

Declaration

```
_getPendingAlarms ()  :StructRetGetPendingAlarms
```

Input parameter

None

Return value

Data type: StructRetGetPendingAlarmState

The return value is a structure of data type *StructRetGetPendingAlarmState*.

It comprises the following:

- A numberOfPendingAlarms component: UINT
  This provides information on the number of entries in the message list.
- An alarm component: ARRAY [0..39] OF StructPendingAlarmState
  This provides information about the state of the individual messages in the list (maximum of 40 entries).
  The state of the individual messages is a structure of data type *StructPendingAlarmState*. It comprises the following:
  - An Id component: StructAlarmId
    This provides information about the project-wide, unique AlarmId (Page 1453) of the message
  - A _type component: EnumAlarmIdType
    This provides information about the message type (requires acknowledgement or not)
  - A state component: EnumAlarmIdState
    This provides information about the message state (incoming or outgoing)

Data types

```
TYPE
  EnumAlarmIdType  : (
    ALARM_S ,   // Message that does not require acknowledgement
    ALARM_SQ ); // Message that requires acknowledgement
  EnumAlarmIdState : (
    INCOMING_ALARM ,   // Incoming message
    OUTGOING_ALARM );  // Outgoing message
  StructPendingAlarmState    : STRUCT
    Id     : StructAlarmId;
    _type  : EnumAlarmIdType;
    state  : EnumAlarmIdState;
  END_STRUCT;
  StructRetGetPendingAlarmState : STRUCT
    numberOfPendingAlarms  : UINT;
    alarm  : ARRAY [0..39] OF StructPendingAlarmState;
  END_STRUCT;
END_TYPE
```

_resetAlarmId function

Description

The _resetAlarmId function sets a message to "outgoing". The message is specified by means of a project-wide, unique AlarmId, see AlarmId (Page 1453).

If this is a message that requires acknowledgment that has been generated with the _alarmSqId (Page 1456) function, the following applies:

- A message that has not been acknowledged must also be acknowledged, e.g.
  - Via the HMI or SIMOTION SCOUT.
  - With the _acknowledgeAlarmSqId (Page 1466) or _acknowledgeAllAlarmSqId (Page 1467) functions.
- An already acknowledged message is deleted.

A message that does not require acknowledgment that has been generated with the _alarmSId (Page 1453) function is deleted:

The function is available for SIMOTION devices as of version V4.1.

Declaration

```
_resetAlarmId (
        Id  : StructAlarmId
        ) : UDINT
```

Input parameter

Id

Data type: StructAlarmId

AlarmId of the message that is to be set to "outgoing", see AlarmId (Page 1453).

Return value

Data type	UDINT
The return value informs the user about the result of the call.	
16#0000_0000	No error Message could be acknowledged without errors.
16#0000_8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID
16#0000_8002	Loss of messages due to overflow (no more space in the message list). All 40 entries of the message list are occupied. Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_ENTRY_USED
16#0000_8003	Loss of messages due to overflow (signal not yet sent, signal overflow). Send buffer for notification of the clients is still occupied by the last event. Entry is not made in the message list. Error may also occur if function calls come quickly one after the other with rising and falling edge. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_SIGNAL_USED
16#0000_8005	No display unit registered (message is entered into the list anyway). ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_NOT_USED
16#0000_8007	No job has been started yet with this message name (first call with Sig = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_FIRST_CALL
16#0000_8009	Internal error. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_INTERNAL_ERROR
16#0000_8010	Entry was rejected; message acknowledgment memory full. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_NO_ENTRY

_resetAllAlarmId function

Description

The _resetAllAlarmId function sets all messages to "outgoing".

For messages that require acknowledgment that have been generated with the _alarmSqId (Page 1456) function, the following applies:

- Messages that have not been acknowledged must also be acknowledged, e.g.
  - Via the HMI or SIMOTION SCOUT.
  - With the _acknowledgeAlarmSqId (Page 1466) or _acknowledgeAllAlarmSqId (Page 1467) functions.
- Already acknowledged messages are deleted.

Messages that do not require acknowledgment that have been generated with the _alarmSId (Page 1453) function are deleted:

The function is available for SIMOTION devices as of version V4.1.

Declaration

```
_resetAllAlarmId  () : UDINT
```

Input parameter

None

Return value

Data type	UDINT
The return value informs the user about the result of the call.	
16#0000_0000	No error Message could be acknowledged without errors.
16#0000_8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID
16#0000_8002	Loss of messages due to overflow (no more space in the message list). All 40 entries of the message list are occupied. Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_ENTRY_USED
16#0000_8003	Loss of messages due to overflow (signal not yet sent, signal overflow). Send buffer for notification of the clients is still occupied by the last event. Entry is not made in the message list. Error may also occur if function calls come quickly one after the other with rising and falling edge. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_SIGNAL_USED
16#00008005	No display unit registered (message is entered into the list anyway). ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_NOT_USED

16#0000_8007	No job has been started yet with this message name (first call with Sig = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_FIRST_CALL
16#0000_8009	Internal error. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_INTERNAL_ERROR
16#0000_8010	Entry was rejected; message acknowledgment memory full. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_NO_ENTRY

_acknowledgeAlarmSqId function

Description

The _acknowledgeAlarmSqId function acknowledges a message that requires acknowledgment that has been generated with the _alarmSqId (Page 1456) function. The message is specified by means of a project-wide, unique AlarmId, see AlarmId (Page 1453).

This enables the user, for example, to acknowledge a message via the signal of an I/O input and the call of the function.

The function is available for SIMOTION devices as of version V4.4.

Declaration

```
_acknowledgeAlarmSqId (
        Id  : StructAlarmId
        ) : DWORD
```

Input parameter

Id

Data type: StructAlarmId

AlarmId of the message that is to be acknowledged, see AlarmId (Page 1453).

Return value

Data type DWORD

The return value informs the user about the result of the call.

16#0000_0000	No error Message could be acknowledged without errors.
16#0000_8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID

16#0000_8002	Loss of messages due to overflow (no more space in the message list). All 40 entries of the message list are occupied. Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_ENTRY_USED
16#0000_8003	Loss of messages due to overflow (signal not yet sent, signal overflow). Send buffer for notification of the clients is still occupied by the last event. Entry is not made in the message list. Error may also occur if function calls come quickly one after the other with rising and falling edge. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_SIGNAL_USED
16#0000_8005	No display unit registered (message is entered into the list anyway). ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_NOT_USED
16#0000_8007	No job has been started yet with this message name (first call with Sig = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_FIRST_CALL
16#0000_8009	Internal error. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_INTERNAL_ERROR
16#0000_8010	Entry was rejected; message acknowledgment memory full. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_NO_ENTRY

_acknowledgeAllAlarmSqId function

Description

The _acknowledgeAllAlarmSqId function acknowledges all messages that require acknowledgment that have been generated with the _alarmSqId (Page 1456) function.

This enables the user, for example, to acknowledge all messages via the signal of an I/O input and the call of the function.

The function is available for SIMOTION devices as of version V4.4.

Declaration

```
_acknowledgeAllAlarmSqId  () : DWORD
```

Input parameter

None

Return value

Data type	DWORD
The return value informs the user about the result of the call.	
16#0000_0000	No error Message could be acknowledged without errors.
16#0000_8001	Message name not permitted. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID
16#0000_8002	Loss of messages due to overflow (no more space in the message list). All 40 entries of the message list are occupied. Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_ENTRY_USED
16#0000_8003	Loss of messages due to overflow (signal not yet sent, signal overflow). Send buffer for notification of the clients is still occupied by the last event. Entry is not made in the message list. Error may also occur if function calls come quickly one after the other with rising and falling edge. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_LAST_SIGNAL_USED
16#0000_8005	No display unit registered (message is entered into the list anyway). ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_EVENT_ID_NOT_USED
16#0000_8007	No job has been started yet with this message name (first call with Sig = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) Entry is not made in the message list. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_IV_FIRST_CALL
16#0000_8009	Internal error. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_INTERNAL_ERROR
16#0000_8010	Entry was rejected; message acknowledgment memory full. ALARMS_ERROR OR DSC_SVS_DEVICE_ALARMS_NO_ENTRY

4.2.9 Programming of general standard functions

4.2.9.1 Programming of general standard functions - overview

SIMOTION provides a series of standard functions you can call in your sources to solve common tasks.

Note

Some of the following standard functions can only be called in short form, i.e. with a complete list of all parameter values, but without specifying the formal parameters:

- Result := function name (1st parameter value, 2nd parameter value)
  instead of
- Result := function name (formal parameter1 := 1st parameter value, etc.)

This is noted in the description of each function.

For information about the general data types (e.g. ANY_INT, ANY_BIT), see **Elementary data types**, General data types table in the ST programming manual.

Using the command library

The command library is a tab in the project navigator. It contains the available system functions, system function blocks, and operators.

You can use a drag-and-drop operation to move these elements from the command library:

- To the window of the ST editor
- To a network of the LAD/FBD editor
- To the system function call command of the MCC editor

Comparison of the system functions for SIMOTION and SIMATIC

You can find a comparison of the SIMATIC S7 and SIMOTION system functions on the Utilities & Applications CD under FAQs.

4.2.9.2 Numeric standard functions

Special features of a numeric function

Every numeric standard function has an input parameter. The result is always the return value. The general numeric, the logarithmic and the trigonometric standard functions each specify a group of numeric standard functions through the function name and the data type.

General numeric standard functions

General numeric standard functions are used for:

- Calculation of the absolute value of a variable
- Calculation of the square root of a variable
- Truncating a variable to its integer part

Table 4-87 General numeric standard functions

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
ABS	in	ANY_NUM	ANY_NUM[1]	Absolute value
SQRT	in	ANY_REAL	ANY_REAL[1]	Square root
TRUNC	in	ANY_REAL	ANY_INT	Truncation of value to integer part (0 direction)

[1] Data type of input parameter *in*.

The following table shows possible general numeric standard function calls and their results:

Table 4-88 General numeric standard function calls

Call	Result
`Result := ABS (-5);` `Result := ABS (in := -5);`	`5`
`Result := SQRT (81.0);` `Result := SQRT (in := 81.0);`	`9.0`
`Result := TRUNC (-3.141_59);` `Result := TRUNC (in := -3.141_59);`	`-3`

Logarithmic standard functions

Logarithmic standard functions are the functions for the calculation of an exponential value or a logarithm.

Table 4-89 Logarithmic standard functions

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
EXP	in	ANY_REAL	ANY_REAL[1]	e^x (e function)
EXPD	in	ANY_REAL	ANY_REAL[1]	10^x
EXPT	in1	ANY_REAL[2]	ANY_REAL[3]	Exponentiation (see also Operator ** in **Arithmetic expressions** in the ST programming manual)
	in2	ANY_REAL		

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
LN	in	ANY_REAL	ANY_REAL[1]	Natural logarithm
LOG	in	ANY_REAL	ANY_REAL[1]	Common logarithm

1 Data type of input parameter *in*.

2 The input parameter *in1* must be greater than zero.
Exceptions as of SIMOTION Kernel V4.1:
– If *in2* is an integer, *in1* can also be less than zero.
– If *in2* is positive, *in1* can also be equal to zero.
The following applies up to SIMOTION Kernel V4.0: If *in1* is equal to zero, an error message can be caught with ExecutionFaultTask.

3 Data type of input parameter *in1*.

The following table shows possible logarithmic standard function calls and their results:

Table 4-90 Logarithmic standard function calls

Call	Result
`Result := EXP (4.1);` `Result := EXP (in := 4.1);`	`60.3403 ...`
`Result := EXPD (3.0);` `Result := EXPD (in := 3.0);`	`1_000.0`

`Result := EXPT (2.0,4.0);`
`Result := EXPT (in1 := 2.0, in2 := 4.0);`
`Result := 2.0 ** 4.0;`
	`16.0`

`Result := LN (2.718_281);` `Result := LN (in := 2.718_281);`	`1.0`
`Result := LOG (245);` `Result := LOG (in := 245);`	`2.389_166`

Trigonometric standard functions

The trigonometric standard functions shown expect and calculate variables of angles in radians.

Table 4-91 Trigonometric standard functions

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
ACOS	in	ANY_REAL	ANY_REAL[1 2]	Arc cosine (main value)
ASIN	in	ANY_REAL	ANY_REAL[1 2]	Arc sine (main value)
ATAN	in	ANY_REAL	ANY_REAL[1 2]	Arc tangent (main value)
COS	in	ANY_REAL[2]	ANY_REAL[1]	Cosine (radian measure input)
SIN	in	ANY_REAL[2]	ANY_REAL[1]	Sine (radian measure input)
TAN	in	ANY_REAL[2]	ANY_REAL[1]	Tangent (radian measure input)

1 Data type of input parameter *in*.

2 Radian angle

The following table shows possible trigonometric standard function calls and their results:

Table 4-92 Trigonometric standard function calls

Call	Result

`PI := 3.141592; //PI is a variable!`
`Result := SIN (PI / 6);`
`Result := SIN (in := PI / 6);`
	`0.5`

`Result := ACOS (0.5);` `Result := ACOS (in := 0.5);`	`1.047_197 //equals PI/3`

Bit string standard functions

Each bit string standard function has two input parameters:

- in (data type ANY_BIT):

Bit string to be manipulated by bit shift operations

- n (data type USINT):
  - Number of places to be rotated for ROL and ROR
  - Number of places to be shifted for SHL and SHR

The result is always the return value. The following table shows the function names and the data types of the two input parameters and of the return value.

Table 4-93 Bit string standard functions

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
ROL	in n	ANY_BIT USINT	ANY_BIT[1]	The bit string in parameter *in* is **left-rotated** through the number of places specified by the content of parameter *n*.
ROR	in n	ANY_BIT USINT	ANY_BIT[1]	The bit string in parameter *in* is **right-rotated** through the number of places specified by the content of parameter *n*.
SHL	in n	ANY_BIT USINT	ANY_BIT[1]	The bit string contained in parameter *in* is **left-shifted** and replaced by 0, as specified by the content of parameter *n* [2].

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
SHR	in n	ANY_BIT USINT	ANY_BIT[1]	The bit string contained in parameter *in* is **right-shifted** and replaced by 0, as specified by the content of parameter *n* [2].
[1] Data type of input parameter *in* [2] Only the five least-significant bits of the parameter in are evaluated, for example: SHL (16#FFFF_FFFF,32) = 16#FFFF_FFFF SHR (16#FFFF_FFFF,32) = 16#FFFF_FFFF				

1 Data type of input parameter *in*.

2 Only the five least-significant bits of the parameter in are evaluated, for example:
SHL (16#FFFF_FFFF,32) = 16#FFFF_FFFF
SHR (16#FFFF_FFFF,32) = 16#FFFF_FFFF

Note

If numerical values are used as input parameters, the smallest possible data type is assumed (for example, BOOL if 1, BYTE if 2).

The following table shows possible bit string standard function calls and their results.

Table 4-94 Examples of bit string standard function calls

Call	Result
`Result := ROL (2#1101_0011, 5);` `// 1st parameter corresponds to 211 decimal`	`2#0111_1010` `(= 122 decimal)`
`Result := ROR (2#1101_0011, 2);` `// 1st parameter corresponds to 211 decimal`	`2#1111_0100` `(= 244 decimal)`
`Result := SHL (2#1101_0011, 3);` `// 1st parameter corresponds to 211 decimal`	`2#1001_1000` `(= 152 decimal)`
`Result := SHR (2#1101_0011, 2);` `// 1st parameter corresponds to 211 decimal`	`2#0011_0100` `(= 52 decimal)`
`Result := SHL (1, 3);` `// 1st parameter data type BOOL`	`2#0000_0000` `(= 0 decimal)`
`Result := SHL (2, 3);` `// 1st parameter data type BYTE`	`2#0001_0000` `(= 16 decimal)`

4.2.9.3 Access to bits in bit strings

_getBit function

Description

This function reads the bit string variable and returns the value of the specified bit.

Note

The access to bits of an I/O variable or system variable can be interrupted by other tasks. There is therefore no guarantee of consistency.

Access to I/O variables of the BOOL data type is consistent.

Declaration

```
FUNCTION _getBit (
        in  : ANY_BIT,  // Bit string variable
        n   : USINT     // Number of the bit
    ) : BOOL
```

Input parameter

in

Data type ANY_BIT

Bit string variable

n

Data type USINT

Number of the bit for which the value is to be output

Permissible values:		
	[0..7]	For BYTE
	[0..15]	For WORD
	[0..31]	For DWORD

When specifying impermissible values, the function supplies the return value FALSE.

Return value

Data type: BOOL

Value of the bit

Example

```
myBit := _getBit (
                in  := myBitString,
                n   := 5);
```

The user variable *myBit* contains bit 5 of the user variable *myBitString*.

Direct bit access

You can also access an individual bit of a bit string variable by specifying the number of the bit as constant separated by a point behind the variable. The number of the bit must be specified as a constant of the ANY_INT data type, see also SIMOTION ST Programming and Operating Manual.

To be able to use this option, you must activate the "Permit language extensions" compiler option (Page 1419), see also SIMOTION ST Programming and Operating Manual.

```
FUNCTION f : VOID
    VAR CONSTANT
        BIT_7 : INT := 7;
    END_VAR
    VAR
        dw : DWORD;
        b  : BOOL;
    END_VAR
    b := dw.BIT_7; // Access to bit number 7
    b := dw.3;     // Access to bit number 3
//  b := dw.33;    // Compilation error:
//  Bit offset not permitted for the data type!
END_FUNCTION
```

Note

The access to bits of an I/O variable or system variable can be interrupted by other tasks. There is therefore no guarantee of consistency.

_setBit function

Description

The function reads the specified bit string variable and returns its value. The specified bit is set to the prespecified Boolean value (TRUE or FALSE).

To change a bit value to a variable with this function, reassign the return value to this variable.

Example:

```
myVar := _setBit (in := myVar, n := 2, value := TRUE);
// Bit 2 is set to the value 1 in the myVar variable.
```

Note

A function call is generally executed in 3 steps:

- Read the input variables
- Function execution
- Result assignment

The execution sequence can be interrupted by other tasks. This also applies to the _setBit function.

When you use the function to modify bits of a variable, limit all function calls for the same variable to one task, e.g. BackgroundTask, IpoSynchronousTask, MotionTask_x.

The use for I/O variables (address list) is not recommended because interruptions by other accesses to the I/O variables are possible, e.g. access to lower-level BOOL variable declared in the address list, update of the process image. This can result in undesirable data corruption.

Declaration

```
FUNCTION _setBit (
        in      : ANY_BIT,    // Bit string variable
        n       : USINT,      // Number of the bit
      { value   : BOOL        // Value of the bit
        }
    ) : ANY_BIT
```

Input parameter

in

Data type: ANY_BIT

Bit string variable

n

Data type: USINT

Number of the bit for which the value is to be set.

Permissible values: [0..7] For BYTE
[0..15] For WORD
[0..31] For DWORD

If illegal values are specified (without an additional message), the unchanged value of the bit string variable is returned.

value (optional)

Default setting: TRUE

Value assigned to the bit to be set

Return value

Data type: ANY_BIT
Data type of input parameter *in*.
Value of the bit string variable with modified bit.

Example

```
myBitString := _setBit (
                    in    := myBitString,
                    n     := 5,
                    value := FALSE);
```

Bit 5 of the *myBitString* user variable is set to FALSE (logic 0).

Direct bit access

You can also access an individual bit of a bit string variable by specifying the number of the bit as constant separated by a point behind the variable. The number of the bit must be specified as a constant of the ANY_INT data type, see also SIMOTION ST Programming and Operating Manual.

To use this option, you must activate the "Permit language extensions" compiler option (Page 1419), see also SIMOTION ST Programming and Operating Manual.

```
FUNCTION f : VOID
    VAR CONSTANT
        BIT_7 : INT := 7;
    END_VAR
    VAR
        dw : DWORD;
        b  : BOOL;
    END_VAR
    b  := 1;
    dw.BIT_7 := b; // Write to bit number 7
    dw.3     := b; // Write to bit number 3
//  dw.33    := b; // Compilation error:
//  Bit offset not permitted for the data type!
END_FUNCTION
```

Note

When you set or reset multiple bits of a variable, limit all function calls for the same variable to one task, e.g. BackgroundTask, IpoSynchronousTask, MotionTask_x.

The use for I/O variables (address list) is not recommended because interruptions by other accesses to the I/O variables are possible, e.g. access to lower-level BOOL variable declared in the address list, update of the process image. This can result in undesirable data corruption.

_toggleBit function

Description

This function reads the specified bit string variable and returns its value, whereby the specified bit is inverted.

Change the specified bit in the variable by assigning the return value to the variable again.

Note

A function call is generally executed in 3 steps:

- Read the input variables
- Function execution
- Result assignment

The execution sequence can be interrupted by other tasks. This also applies to the _setBit function.

When you use the function to modify bits of a variable, limit all function calls for the same variable to one task, e.g. BackgroundTask, IpoSynchronousTask, MotionTask_x.

The use for I/O variables (address list) is not recommended because interruptions by other accesses to the I/O variables are possible, e.g. access to lower-level BOOL variable declared in the address list, update of the process image. This can result in undesirable data corruption.

Declaration

```
FUNCTION _toggleBit (
        in  : ANY_BIT,  // Bit string variable
        n   : USINT,    // Number of the bit
    ) : ANY_BIT
```

Input parameter

in

Data type: ANY_BIT

Bit string variable

n

Data type: USINT

Number of the bit whose value is to be inverted (set from TRUE to FALSE or from FALSE to TRUE).

Permissible values:		
	[0..7]	For BYTE
	[0..15]	For WORD
	[0..31]	For DWORD

If illegal values are specified (without an additional message), the unchanged value of the bit string variable is returned.

Return value

Data type: ANY_BIT
Data type of input parameter *in*.
Value of the bit string variable with inverted bit

Example

```
myBitString := _toggleBit (
                    in  := myBitString,
                    n   := 5);
```

Bit 5 of the *myBitString* user variable is inverted.

Direct bit access

You can also access an individual bit of a bit string variable by specifying the number of the bit as constant separated by a point behind the variable. The number of the bit must be specified as a constant of the ANY_INT data type, see also SIMOTION ST Programming and Operating Manual.

To be able to use this option, you must activate the "Permit language extensions" compiler option (Page 1419), see also SIMOTION ST Programming and Operating Manual.

```
FUNCTION f : VOID
    VAR CONSTANT
        BIT_7 : INT := 7;
    END_VAR
    VAR
        dw : DWORD;
        b  : BOOL;
    END_VAR
    b  := 1;
    dw.BIT_7 := NOT dw.BIT_7; // Write to bit number 7
    dw.3     := NOT dw.3;     // Write to bit number 3
//  dw.33    := NOT dw.33;    // Compilation error:
//  Bit offset not permitted for the data type
END_FUNCTION
```

Note

When you set or reset multiple bits of a variable, limit all function calls for the same variable to one task, e.g. BackgroundTask, IpoSynchronousTask, MotionTask_x.

The use for I/O variables (address list) is not recommended because interruptions by other accesses to the I/O variables are possible, e.g. access to lower-level BOOL variable declared in the address list, update of the process image. This can result in undesirable data corruption.

4.2.9.4 Bit operations on numeric data types

The following functions enable bit operations on numeric data types. Each bit of the return value is generated from the corresponding bits of the input parameters.

Table 4-95 Bit operators on numeric data types

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
_NOT	in	ANY_INT	ANY_INT[1]	Bit-by-bit negation
_AND	in1 in2	ANY_INT[32] ANY_INT[32]	ANY_INT[43]	Bit-by-bit conjunction (AND operation): A bit of the return value is only 1 when all the corresponding bits of the input parameters are 1, otherwise 0.
_OR	in1 in2	ANY_INT[32] ANY_INT[32]	ANY_INT[4]	Bit-by-bit disjunction (OR operation): A bit of the return value is only 1 when at least one of the corresponding bits of the input parameters is 1, otherwise 0.
_XOR	in1 in2	ANY_INT[32] ANY_INT[32]	ANY_INT[43]	Bit-by-bit exclusive disjunction (exclusive OR operation): A bit of the return value is only 1 when exactly one of the corresponding bits of the input parameters is 1, otherwise 0.

1 Data type of the input parameter.

2 It must be possible to convert the data types of in1 and in2 implicitly to a common general ANY_INT data type.

3 Smallest common data type to which the input parameters can be converted implicitly.

4.2.9.5 String processing

Functions for the string editing

The following functions enable the processing of variables of data type STRING.

Table 4-96 Functions for the string processing

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
CONCAT	in1 in2	STRING[254] STRING[254]	STRING[254]	Attaches string in2 to string in1[1]. Error flags: TSI#ERRNO := 1, if LEN (in1) + LEN (in2) > 254
DELETE	in l p	STRING[254] INT INT	STRING[254]	Deletes l character(s) from string in, starting at position p[2 4 6]. Error flags: TSI#ERRNO := 2, if l < 0, p < 1, p > LEN (in)

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
FIND	in1 in2	STRING[254] STRING[254]	INT	Returns the position at which string in2 begins in string in1. Result is 0 if string in2 is not contained in string in1. Error flags: None
INSERT	in1 in2 p	STRING[254] STRING[254] INT	STRING[254]	Inserts string in2 in string in1, starting at position p[1 2 5 7]. Error flags: TSI#ERRNO := 2, if p < 0, p > LEN (in1) TSI#ERRNO := 1, if LEN (in1) + LEN (in2) > 254
LEFT	in l	STRING[254] INT	STRING[254]	Returns the first l characters in string in[2 3]. Error flags: TSI#ERRNO := 2, if l < 0
LEN	in	STRING[254]	INT	Returns the number of characters in string in. Error flags: None
MID	in l p	STRING[254] INT INT	STRING[254]	Returns l characters from string in, starting at position p[2 3]. Error flags: TSI#ERRNO := 2, if l < 0, p < 1, p > LEN (in)
REPLACE	in1 in2 l p	STRING[254] STRING[254] INT INT	STRING[254]	Replaces l characters from string in1 with string in2, starting at position p[2 4 7]. Error flags: TSI#ERRNO := 2, if l < 0, p < 1, p > LEN (in1) TSI#ERRNO := 1, if LEN (in1) + LEN (in2) - l > 254
RIGHT	in l	STRING[254] INT	STRING[254]	Returns the last l characters in string in[2 3]. Error flags: TSI#ERRNO := 2, if l < 0

1 If LEN (in1) + LEN (in2) > 254: String is truncated.

2 If l < 0 or p < 0: Empty string is returned.

3 If l = 0 or p = 0: Empty string is returned.

4 If l = 0 or p = 0: String in or in1 remains unchanged.

5 If p = 0: String in1 is attached to string in2.

6 If p > LEN(in) : String in remains unchanged.

7 If p > LEN(in1): String in2 is attached to string in1.

Table 4-97 Examples for calls of the functions for the string processing

Call	Result
`A := CONCAT (in1 := 'ASTRING', in2 := '123');`	`'ASTRING123'.`

`A := DELETE (in1 := 'ASTRING', l := 2, p := 4);`

	`'ASTRING'.`
	`''.`

For information about conversion functions for STRINGs, see Functions for the conversion of numeric data types to STRING data type (Page 1490).

Error analysis during the string editing

Description

Errors which occur during string functions are stored separately for each task in the Taskstartinfo. It is therefore implemented in the task context and can then be subsequently queried accordingly in the same task, e.g. BackgroundTask.

```
Variable:TSI#ERRNO : DINT
```

Value 0 indicates free of errors. For the string functions, the errors in P (position in the string) and L (number of characters) are stored separately from the violation of the maximum string length with different values.

- Value 0: for free of errors
- Value 1: for violation of the maximum string length
- Value 2: for p or l outside the value range

Note

TSI#ERRNO cannot be used to examine the string length (applies to DINT_TO_STRING, UDINT_TO_STRING, REAL_TO_STRING, and LREAL_TO_STRING).

In this case, the 0 error code will be set in TSI#ERRNO (string length exceeded).

You must, therefore, ensure that the string you enter is long enough or should check the length in the user program prior to conversion.

Resetting of the TSI#ERRNO value:

- The error remains in Taskstartinfo until you explicitly reset the content of TSI#ERRNO.
- The value of TSI#ERRNO is only rewritten in the case of an error when executing a new string function.
  A correctly executed string function does not overwrite any error ID present in TSI#ERRNO.
- The error ID is reset when the task is restarted.
  Cyclic execution of a task (e.g. IpoSynchronousTask, BackgroundTask) does not overwrite the error ID. The error ID is retained, as is the content of local variables.

Table 4-98 Example

```
VAR
    A : STRING [254];
END_VAR

A := DELETE (in := 'ASTRING', l:= -1, p := 4);
// Result is an empty string
IF (TSI#ERRNO = 2)THEN  // Error during string processing
    // l < 0, p < 1, p > LEN (in)
   A := 'ERROR';
END_IF;
```

4.2.9.6 Standard functions for data type conversion

Functions for the conversion of numeric data types and bit data types

Explicit conversion is always required if information could be lost, for example, if the value range is decreased or the accuracy is reduced, as is the case for conversion from LREAL to REAL.

The compiler outputs warnings when it detects conversions associated with loss of precision.

Note

The type conversion result may cause errors when the program is running, the error response set in the task configuration will then be triggered, see Execution errors in programs (Page 1256).

Special attention is required when converting DWORD to REAL. The bit string from DWORD is taken unchecked as the REAL value. You must make sure that the bit string in DWORD corresponds to the bit pattern of a normalized floating-point number in accordance with IEEE. To do this, you can use the _finite (Page 1503) and _isNaN (Page 1504) functions.

Otherwise, an error can be triggered (FPU exception (Page 1257)) as soon as the REAL value is first used for an arithmetic operation (for example, in the program or when monitoring in the symbol browser).

Explicit data type conversion is performed using standard functions which are listed in the following table.

- **Input parameter**
  Each function for the conversion of a data type has exactly one input parameter named *in*.
- **Return value**
  The result is always the return value of the function. The respective conversion rule is specified in the following table.
- **Names**
  As the data types of the input parameter and the return value come from the respective function name, they are not listed separately in the following table: For example, with the BOOL_TO_BYTE function, the data type of the input parameter is BOOL and the data type of the return value is BYTE.

Table 4-99 Functions for converting numeric data types and bit data types

Function name	Conversion rule	Implicitly possible
BOOL_TO_BYTE	Accept as least significant bit and fill the rest with 0.	Yes
BOOL_TO_DWORD	Accept as least significant bit and fill the rest with 0.	Yes
BOOL_TO_WORD	Accept as least significant bit and fill the rest with 0.	Yes
BOOL_VALUE_TO_DINT	Accept Boolean value as DINT value (0 or 1).	No
BOOL_VALUE_TO_INT	Accept Boolean value as INT value (0 or 1).	No
BOOL_VALUE_TO_LREAL	Accept Boolean value as LREAL value (0.0 or 1.0).	No
BOOL_VALUE_TO_REAL	Accept Boolean value as REAL value (0.0 or 1.0).	No
BOOL_VALUE_TO_SINT	Accept Boolean value as SINT value (0 or 1).	No
BOOL_VALUE_TO_UDINT	Accept Boolean value as UDINT value (0 or 1).	No
BOOL_VALUE_TO_UINT	Accept Boolean value as UINT value (0 or 1).	No
BOOL_VALUE_TO_USINT	Accept Boolean value as USINT value (0 or 1).	No
BYTE_TO_BOOL	Accept the least significant bit.	No
BYTE_TO_DINT	Accept bit string as least significant byte and fill the rest with 0.	No
BYTE_TO_DWORD	Accept bit string as least significant byte and fill the rest with 0.	Yes
BYTE_TO_INT	Accept bit string as least significant byte and fill the rest with 0.	No

Function name	Conversion rule	Implicitly possible
BYTE_TO_SINT	Accept bit string as SINT value.	No
BYTE_TO_UDINT	Accept bit string as least significant byte and fill the rest with 0.	No
BYTE_TO_UINT	Accept bit string as least significant byte and fill the rest with 0.	No
BYTE_TO_USINT	Accept bit string as USINT value.	No
BYTE_TO_WORD	Accept bit string as least significant byte and fill the rest with 0.	Yes
BYTE_VALUE_TO_LREAL	Interpret bit string as USINT value and accept this value.	No
BYTE_VALUE_TO_REAL	Interpret bit string as USINT value and accept this value.	No
DINT_TO_BYTE	Accept the least significant byte as bit string.	No
DINT_TO_DWORD	Accept bit string.	No
DINT_TO_INT	Accept the 2 least significant bytes as INT value.	No
DINT_TO_LREAL	Accept value.	Yes
DINT_TO_REAL	Accept value (accuracy may be lost).	No
DINT_TO_SINT	Accept the least significant byte as SINT value.	No
DINT_TO_UDINT	Accept value as bit string.	No
DINT_TO_UINT	Accept the 2 least significant bytes as UINT value.	No
DINT_TO_USINT	Accept the least significant byte as USINT value.	No
DINT_TO_WORD	Accept the 2 least significant bytes as bit string.	No
DINT_VALUE_TO_BOOL	FALSE (0), if DINT value = 0; else TRUE (1).	No
DWORD_TO_BOOL	Accept the least significant bit.	No
DWORD_TO_BYTE	Accept the least significant byte as bit string.	No
DWORD_TO_DINT	Accept bit string as DINT value.	No
DWORD_TO_INT	Accept the 2 least significant bytes as INT value.	No
DWORD_TO_REAL	Accept bit string as REAL value (validity check of the REAL number is not carried out!). Note the important information at the start of this section!	No
DWORD_TO_SINT	Accept the least significant byte as SINT value.	No
DWORD_TO_UDINT	Accept bit string as UDINT value.	No
DWORD_TO_UINT	Accept the 2 least significant bytes as UINT value.	No
DWORD_TO_USINT	Accept the least significant byte as USINT value.	No
DWORD_TO_WORD	Accept the 2 least significant bytes as bit string.	No
DWORD_VALUE_TO_LREAL	Interpret bit string as UDINT value and accept this value.	No
DWORD_VALUE_TO_REAL	Interpret bit string as UDINT value and accept this value (accuracy can be lost).	No
INT_TO_BYTE	Accept the least significant byte as bit string.	No
INT_TO_DWORD	Accept bit string as least significant word (2 bytes) and fill the rest with 0.	No
INT_TO_DINT	Accept value.	Yes
INT_TO_LREAL	Accept value.	Yes
INT_TO_REAL	Accept value.	Yes
INT_TO_SINT	Accept the least significant byte as SINT value.	No
INT_TO_USINT	Accept the least significant byte as USINT value.	No
INT_TO_UDINT	Accept bit string as least significant word (2 bytes) and fill the rest with 0.	No
INT_TO_UINT	Accept bit string as UINT value.	No

Function name	Conversion rule	Implicitly possible
INT_TO_WORD	Accept bit string.	No
INT_VALUE_TO_BOOL	FALSE (0), if INT value = 0; else TRUE (1).	No
LREAL_TO_DINT	Round off to next integer[1].	No
LREAL_TO_INT	Round off to next integer[1].	No
LREAL_TO_REAL	Accept value (accuracy may be lost).	No
LREAL_TO_SINT	Round off to next integer[1].	No
LREAL_TO_UDINT	Round off value to next integer[1].	No
LREAL_TO_UINT	Round off value to next integer[1].	No
LREAL_TO_USINT	Round off value to next integer[1].	No
LREAL_VALUE_TO_BOOL	FALSE (0), if LREAL value = 0.0; else TRUE (1).	No
LREAL_VALUE_TO_BYTE	Round off value to next integer[1] and accept value as bit string.	No
LREAL_VALUE_TO_DWORD	Round off value to next integer[1] and accept value as bit string (only for positive numbers[2])	No
LREAL_VALUE_TO_WORD	Round off value to next integer[1] and accept value as bit string.	No
REAL_TO_DINT	Round off to next integer[1].	No
REAL_TO_DWORD	Accept bit string.	No
REAL_TO_INT	Round off to next integer[1].	No
REAL_TO_LREAL	Accept value.	Yes
REAL_TO_SINT	Round off to next integer[1].	No
REAL_TO_UDINT	Round off value to next integer[1].	No
REAL_TO_UINT	Round off value to next integer[1].	No
REAL_TO_USINT	Round off value to next integer[1].	No
REAL_VALUE_TO_BOOL	FALSE (0), if REAL value = 0.0; else TRUE (1).	No
REAL_VALUE_TO_BYTE	Round off value to next integer[1] and accept value as bit string.	No
REAL_VALUE_TO_DWORD	Round off value to next integer[1] and accept value as bit string.	No
REAL_VALUE_TO_WORD	Round off value to next integer[1] and accept value as bit string.	No
SINT_TO_BYTE	Accept bit string.	No
SINT_TO_DINT	Accept value.	Yes
SINT_TO_DWORD	Accept bit string as least significant byte and fill the rest with 0.	No
SINT_TO_INT	Accept value.	Yes
SINT_TO_LREAL	Accept value.	No
SINT_TO_REAL	Accept value.	No
SINT_TO_UDINT	Accept bit string as least significant byte and fill the rest with 0.	No
SINT_TO_UINT	Accept bit string as least significant byte and fill the rest with 0.	No
SINT_TO_USINT	Accept bit string.	No
SINT_TO_WORD	Accept bit string as least significant byte and fill the rest with 0.	No
SINT_VALUE_TO_BOOL	FALSE (0), if SINT value = 0; else TRUE (1).	No
StructAlarmId_TO_DINT	Accept bit string.	No
UDINT_TO_BYTE	Accept the least significant byte as bit string.	No
UDINT_TO_DINT	Accept bit string.	No
UDINT_TO_DWORD	Accept bit string.	No
UDINT_TO_INT	Accept the 2 least significant bytes as INT value.	No

Function name	Conversion rule	Implicitly possible
UDINT_TO_LREAL	Accept value.	Yes
UDINT_TO_REAL	Accept value (accuracy may be lost).	No
UDINT_TO_SINT	Accept the least significant byte as SINT value.	No
UDINT_TO_UINT	Accept the 2 least significant bytes as UINT value.	No
UDINT_TO_USINT	Accept the least significant byte as USINT value.	No
UDINT_TO_WORD	Accept the 2 least significant bytes as bit string.	No
UDINT_VALUE_TO_BOOL	FALSE (0), if UDINT value = 0; else TRUE (1).	No
UINT_TO_BYTE	Accept the least significant byte as bit string.	No
UINT_TO_DINT	Accept value.	Yes
UINT_TO_DWORD	Accept bit string as least significant word (2 bytes) and fill the rest with 0.	No
UINT_TO_INT	Accept bit string.	No
UINT_TO_LREAL	Accept value.	No
UINT_TO_REAL	Accept value.	Yes
UINT_TO_SINT	Accept the least significant byte as SINT value.	No
UINT_TO_UDINT	Accept value.	Yes
UINT_TO_USINT	Accept the least significant byte as USINT value.	No
UINT_TO_WORD	Accept bit string.	No
UINT_VALUE_TO_BOOL	FALSE (0), if UINT value = 0; else TRUE (1).	No
USINT_TO_BYTE	Accept bit string.	No
USINT_TO_DINT	Accept value.	No
USINT_TO_DWORD	Accept bit string as least significant byte and fill the rest with 0.	No
USINT_TO_INT	Accept value.	Yes
USINT_TO_LREAL	Accept value.	No
USINT_TO_REAL	Accept value.	No
USINT_TO_SINT	Accept bit string as SINT value.	No
USINT_TO_UDINT	Accept value.	Yes
USINT_TO_UINT	Accept value.	Yes
USINT_TO_WORD	Accept bit string as least significant byte and fill the rest with 0.	No
USINT_VALUE_TO_BOOL	FALSE (0), if USINT value = 0; else TRUE (1).	No
WORD_TO_BOOL	Accept the least significant bit.	No
WORD_TO_BYTE	Accept the least significant byte as bit string.	No
WORD_TO_DINT	Accept bit string as least significant word (2 bytes) and fill the rest with 0.	No
WORD_TO_DWORD	Accept bit string as least significant word (2 bytes) and fill the rest with 0.	Yes
WORD_TO_INT	Accept bit string as INT value.	No
WORD_TO_SINT	Accept the least significant byte as SINT value.	No
WORD_TO_UDINT	Accept bit string as least significant word (2 bytes) and fill the rest with 0.	No
WORD_TO_UINT	Accept bit string.	No
WORD_TO_USINT	Accept the least significant byte as USINT value.	No
WORD_VALUE_TO_LREAL	Interpret bit string as UINT value and accept this value.	No
WORD_VALUE_TO_REAL	Interpret bit string as UINT value and accept this value.	No

[1] If the distance to the two next integers is the same: Round off to next even integer.

[2] The LREAL_VALUE_TO_DWORD function behaves the same as the LREAL_TO_UDINT function. Consequently only positive numbers are converted. If a floating-point number with sign is to be converted to a bit string, the combination of LREAL_TO_DINT and DINT_TO_DWORD must be used.

Functions for converting date and time data types

The following standard functions are available for date and time data types.

For information about arithmetic expressions with date and time data types, see "Arithmetic expressions" in the SIMOTION ST Programming Manual.

Table 4-100 Standard functions for date and time

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
CONCAT_DATE_TOD	in1 in2	DATE TIME_OF_DAY	DATE_AND_TIME	Combine DATE and TIME_OF_DAY to DATE_AND_TIME (DT).
DATE_AND_TIME_TO_TIME_OF_DAY or DT_TO_TOD	in	DATE_AND_TIME	TIME_OF_DAY	Accept time of day.
DATE_AND_TIME_TO_DATE or DT_TO_DATE	in	DATE_AND_TIME	DATE	Accept date.
INT_TO_TIME	in	INT	TIME	Accept value as time (unit is ms) The function does not return any useful results for negative values.
REAL_TO_TIME	in	REAL	TIME	Round off to unsigned integer component and accept the value as indication of time (in ms).
TIME_TO_INT	in	TIME	INT	Accept time (unit is ms) as value.
TIME_TO_REAL	in	TIME	REAL	Accept time (unit is ms) as value.
TIME_TO_UDINT	in	TIME	UDINT	Accept time (unit is ms) as value.
UDINT_TO_TIME	in	UDINT	TIME	Accept value as time (unit is ms). The function does not return any useful results for negative values.

Functions for the conversion of enumeration data types

You can obtain the numeric value of an enumeration data type element with the ENUM_TO_DINT function. When calling the function, you specify the data type of the enumeration element by placing the identifier of the data type and the character # in front of the identifier of the enumeration element (*enum_type#enum_value*).

Table 4-101 Standard functions for date and time

Function name	Input parameter		Return value	Description
	Name	Data type	Data type	
ENUM_TO_DINT	in	any enumeration data type	DINT	Supplies the numeric value of the enumeration element

All user-defined enumeration data types organize the values in ascending order starting with 0.

Enumeration data types that are defined as system data types (e.g. of the SIMOTION devices or technology objects), deviate from this. You will find the values in the relevant List Manuals (reference lists).

Conversions between BYTE and STRING

Description

The implicit conversion from BYTE to STRING and from STRING to BYTE enables:

- A byte to be written to a string or
- A byte to be read from a string (ASCII format, 1 byte per character).

Note

Strings are interpreted as ARRAY[1...stringsize].

Conversion from BYTE to STRING

The conversion is performed through direct assignment of the byte to string element n:

```
mySTring[n] := myByte;
```

Rules:

1. If n > len(myString) and n < maxlen(myString), the length of the string is adjusted.
   All characters between myString[len(myString)] ... myString[n] are assigned the value "0".
2. If n > maxlen(myString), TSI#ERRNO is set to value 1 (maximum string length exceeded) and myString remains the same.

Conversion from STRING to BYTE

The conversion is performed through direct assignment of string element k to the byte:

```
myByte := myString[k];
```

Rule

1. If k > len(myString), TSI#ERRNO is set to value 2 (value exceeds the valid range) and myByte is assigned the value 0.

Applications

- Read out of internal variable and, if required, conversion from INT to STRING or DINT to STRING.
- Direct output of STRING on HMI, e.g. WIN CC Op.
- Conversion of STRING to ARRAY OF BYTE and thus output on HMI.

Functions for the conversion of numeric data types to STRING data type

Description

The following functions are used for the conversion of numbers to strings for the purpose of displaying numbers of the DINT/UDINT/REAL/LREAL data types.

Explicit data type conversion is performed using standard functions which are listed in the following table.

- Input parameter
  Each function for the conversion of a data type has exactly one input parameter named *in*.
- Return value
  The result is always the return value of the function.

Rules for the conversion from DINT/UDINT/REAL/LREAL to STRING

- Values are written left-justified in the STRING as decimal number or real number.
- If signs are present, they are written in front of the numerals.
- If the string length is not sufficient, the numeric sequence is truncated on the right (violation of the string length).
- With the conversion to STRING, the number representation is decimal.

Rules for the conversion from STRING to DINT/UDINT/REAL/LREAL

1. Leading white spaces are not taken into account; blanks and tabs are recognized as white spaces.
2. Conversion stops at the end of the string or at the first character that is not a numeral.
3. The function uses the "." as decimal character. If you use a "," as decimal character, the numbers after the comma are not taken into account.
   Example:
   - 1.1 -> STRING_TO_REAL -> 1.1
   - 1.1 -> STRING_TO_REAL -> 1.0

4. If the string does not contain a valid number or the value range is violated, TSI#ERRNO is set to value 3 (invalid number representation) and 0.0 (REAL/LREAL) output.
5. Leading zeros are omitted.

Function	Example	Description
DINT_TO_STRING	myString:=DINT_TO_STRING(myDint) myString := DINT_TO_STRING(mySint)	Observe rules
UDINT_TO_STRING	myString:=UDINT_TO_STRING(myUDint) myString:=UDINT_TO_STRING(myUsint)	
STRING_TO_DINT	myDin t:= STRING_TO_DINT(myString)	A valid number has the form [white space [sign][digits] Decimal numbers are required for conversion from STRING. Octal and hexadecimal notation is not supported.
STRING_TO_UDINT	myUDint:=STRING_TO_UDINT(myString)	
REAL_TO_STRING	myString := REAL_TO_STRING(myReal)	Observe rules
LREAL_TO_STRING	myString := LREAL_TO_STRING(myLReal)	
STRING_TO_REAL	myReal := STRING_TO_REAL(myString)	A valid number has the form [white space [sign][digits][digits][{ e I E } [sign]digits].
STRING_TO_LREAL	myLReal := STRING_TO_LREAL(myString)	

Application

- An HMI fetches texts from the file system (recipe memory) and loads the text via a sequence into the run-time system of SIMOTION (unit variable).
- The data is saved with _saveUnitDataSet or _exportUnitDataSet in the run-time system. Extension of the STRINGs with current SIMOTION data (e.g. actual position).
- The text is output via the serial interface (e.g. ET200).

4.2.9.7 Conversion between any data types and defined byte order

General

Variables of any data type (elementary data types, standard data types of technology packages and devices, and user-defined data types) can be converted to the defined big endian or little endian byte order, and vice versa, using the functions specified below:

- To byte arrays of the big endian or little endian type:
  AnyType_to_BigByteArray function, AnyType_to_LittleByteArray function (Page 1492)
- From byte arrays of the big endian or little endian type:
  BigByteArray_to_AnyType function, LittleByteArray_to_AnyType function (Page 1494)
- To the same data type with big endian or little endian byte order:
  TO_BIG_ENDIAN function, TO_LITTLE_ENDIAN function (Page 1496)
- From the same data type with big endian or little endian byte order:
  FROM_BIG_ENDIAN function, FROM_LITTLE_ENDIAN function (Page 1498)

For further information (e.g. for the ordering of the byte arrays, application example) see Converting between any data types and byte arrays (marshalling) (Page 1593).

These functions are commonly used to create defined transmission formats for data exchange between various devices (see also Communication functions (Page 1596)).

AnyType_to_BigByteArray function, AnyType_to_LittleByteArray function

Description

The functions convert a variable of any data type (elementary data types, user-defined data types, system data types of technology packages, and devices) to a byte array.

- For AnyType_to_BigByteArray:
  Big endian-type byte array (most significant byte at low memory address)
- For AnyType_to_LittleByteArray:
  Little endian-type byte array (least significant byte at low memory address)

The array index of the first element to be occupied in the array is an optional constant offset (default = 0). It must fall within the array limits.

When an ST source file is compiled, a check is made to determine whether the offset falls within the array limits and whether the variable can be displayed completely in the byte array (between the offset and the upper array limit).

Only those byte array elements that are covered by variables to be converted are occupied with values. Other elements of the byte array remain unchanged.

Note

Where possible, the function call and the processing of the result should be made in the same task.

If the function call and the processing of the result are made in different tasks, they must be synchronized using appropriate means (e.g. _testAndSetSemaphore (Page 1512), _releaseSemaphore (Page 1513)). Otherwise data consistency is not guaranteed and undefined values can result.

If the return value of the function should be assigned to a global variable that is evaluated in a higher priority task, the following procedure is recommended (also for simple data types):

1. Conversion to a temporary variable.
2. Assign the temporary variable to the global target variable.

Note

Each variable of data type BOOL (including variables that are components within a structured data type) occupies one byte in the byte array.

For the big endian and little endian byte order as well as the use of the functions, see Converting between any data types and byte arrays (marshalling) (Page 1593).

Declaration

```
FUNCTION AnyType_to_BigByteArray (
        anydata : ANY,         // Any data type
        { offset  : DINT         // Only constants permitted
        }
        ) : ARRAY [..] OF BYTE       // Big endian
FUNCTION AnyType_to_LittleByteArray (
        anydata : ANY,         // Any data type
        { offset  : DINT         // Only constants permitted
        }
        ) : ARRAY [..] OF BYTE  // Little endian
```

Input parameter

anydata

Data type: ANY

Variable of any data type.

The following data types are permitted:

- Elementary data types (ANY_ELEMENTARY)
- User-defined data types (UDT)
- System data types of technology packages and devices

The following data types are **not** permitted:

- Technology object data types
- Object-oriented interfaces
- Structures with overlapping memory areas (STRUCT OVERLAP)
  Components within these structures are, however, permitted.

offset (optional)

Data type: DINT

Default 0

Constant, specifies the first element to be assigned in the array.

Return value

Data type: ARRAY [..] OF BYTE

- For AnyType_to_BigByteArray:
  In big endian order (most significant byte at low memory address)
- For AnyType_to_LittleByteArray:
  In little endian order (least significant byte at low memory address)

BigByteArray_to_AnyType function, LittleByteArray_to_AnyType function

Description

The functions convert a byte array to a variable of any data type (elementary data types, user-defined data types, system data types of technology packages and devices, data types of technology objects).

- For BigByteArray_to_AnyType
  Big endian-type byte array (most significant byte at low memory address)
- For LittleByteArray_to_AnyType
  Little endian-type byte array (least significant byte at low memory address)

The array index of the first element to be evaluated in the array is an optional constant offset (default = 0). It must fall within the array limits.

When an ST source file is compiled, a check is made to determine whether the offset falls within the array limits and whether the byte array (between the offset and the upper array limit) completely covers the variable.

Note

Where possible, the function call and the processing of the result should be made in the same task.

If the function call and the processing of the result are made in different tasks, they must be synchronized using appropriate means (e.g. _testAndSetSemaphore (Page 1512), _releaseSemaphore (Page 1513)). Otherwise data consistency is not guaranteed and undefined values can result.

If the return value of the function should be assigned to a global variable that is evaluated in a higher priority task, the following procedure is recommended (also for simple data types):

1. Conversion to a temporary variable.
2. Assign the temporary variable to the global target variable.

Note

One byte from the byte array is assigned to each variable of data type BOOL (including variables that are components within a structured data type).

For the big endian and little endian byte order as well as the use of the functions, see Converting between any data types and byte arrays (marshalling) (Page 1593).

Declaration

```
FUNCTION BigByteArray_to_AnyType (
    byteArray : ARRAY [..] OF BYTE, // Big endian
    { offset  : DINT        // Only constants permitted
    }
    ) : ANY
```

```
FUNCTION LittleByteArray_to_AnyType (
    byteArray : ARRAY [..] OF BYTE, // Little endian
    { offset  : DINT        // Only constants permitted
    }
    ) : ANY
```

Input parameter

byteArray

Data type: ARRAY [..] OF BYTE

- For BigByteArray_to_AnyType
  In big endian order (most significant byte at low memory address)
- For LittleByteArray_to_AnyType
  In little endian order (least significant byte at low memory address)

offset (optional)

Data type: DINT

Default 0

Constant, specifies the first element to be assigned in the array.

Return value

Data type: ANY

Any data type.

The following data types are permitted:

- Elementary data types (ANY_ELEMENTARY)
- User-defined data types (UDT)
- System data types of technology packages and devices

The following data types are **not** permitted:

- Technology object data types
- Object-oriented interfaces
- Structures with overlapping memory areas (STRUCT OVERLAP)
  Components within these structures are, however, permitted.

Note

The marshalling function result may cause errors when the program is running, the error response set in the task configuration will then be triggered, see Execution errors in programs (Page 1256).

Proceed with caution when converting byte arrays to the general ANY_REAL data type or to structures that contain this data type. The bit string from the byte array is taken unchecked as the ANY_REAL value. You must make sure that the bit string of the byte array corresponds to the bit pattern of a normalized floating-point number in accordance with IEEE 754. To do this, you can use the _finite (Page 1503) and _isNaN (Page 1504) functions or the IS_VALID (Page 1505) function.

Otherwise, an error can be triggered (FPU exception (Page 1257)) as soon as the ANY_REAL value is first used for an arithmetic operation (for example, in the program or when monitoring in the symbol browser).

TO_BIG_ENDIAN function, TO_LITTLE_ENDIAN function

Description

The functions store a variable of any data type (elementary data types, user-defined data types, system data types of technology packages, and devices) in a variable of the same byte array data type. Whereby, elementary data types that comprise several bytes are stored as follows:

- For TO_BIG_ENDIAN:
  In big endian byte order (most significant byte at low memory address)
- With TO_LITTLE_ENDIAN:
  In little endian byte order (least significant byte at low memory address)

To use this function, you must activate the "Permit language extensions IEC61131-3rd Edition" compiler option, see SIMOTION ST Programming and Operating Manual.

Note

Where possible, the function call and the processing of the result should be made in the same task.

If the function call and the processing of the result are made in different tasks, they must be synchronized using appropriate means (e.g. _testAndSetSemaphore (Page 1512), _releaseSemaphore (Page 1513)). Otherwise data consistency is not guaranteed and undefined values can result.

If the return value of the function should be assigned to a global variable that is evaluated in a higher priority task, the following procedure is recommended (also for simple data types):

1. Conversion to a temporary variable.
2. Assign the temporary variable to the global target variable.

Note

Each variable of data type BOOL (including variables that are components within a structured data type) occupies one byte in the byte array.

For information about big endian and little endian byte ordering, see Converting between any data types and byte arrays (marshalling) (Page 1593).

Declaration

```
FUNCTION TO_BIG_ENDIAN (
        in  : ANY,        // Any data type
        )   : ANY       // Big endian
FUNCTION TO_LITTLE_ENDIAN (
        in  : ANY,        // Any data type
        )   : ANY       // Little endian
```

Input parameter

in

Data type: ANY

Variable of any data type.

The following data types are permitted:

- Elementary data types (ANY_ELEMENTARY)
- User-defined data types (UDT)
- System data types of technology packages and devices

The following data types are **not** permitted:

- Technology object data types
- Object-oriented interfaces
- Structures with overlapping memory areas (STRUCT OVERLAP)
  Components within these structures are, however, permitted.

Return value

Data type: ANY

The same data type as the *in* input parameter.

- For TO_BIG_ENDIAN:
  Elementary data types that comprise several bytes to the big endian byte order (most significant byte at low memory address)
- For TO_LITTLE_ENDIAN:
  Elementary data types that comprise several bytes to the little endian byte order (least significant byte at low memory address)

FROM_BIG_ENDIAN function, FROM_LITTLE_ENDIAN function

Description

The functions store a variable of any data type (elementary data types, user-defined data types, system data types of technology packages and devices, data types of technology objects) in a variable of the same data type. Whereby, elementary data types in the input parameter that comprise several bytes have the following byte order:

- For FROM_BIG_ENDIAN:
  The big endian byte order (most significant byte at low memory address)
- For FROM_LITTLE_ENDIAN:
  The little endian byte order (least significant byte at low memory address)

To use this function, you must activate the "Permit language extensions IEC61131-3rd Edition" compiler option, see SIMOTION ST Programming and Operating Manual.

Note

Where possible, the function call and the processing of the result should be made in the same task.

If the function call and the processing of the result are made in different tasks, they must be synchronized using appropriate means (e.g. _testAndSetSemaphore (Page 1512), _releaseSemaphore (Page 1513)). Otherwise data consistency is not guaranteed and undefined values can result.

If the return value of the function should be assigned to a global variable that is evaluated in a higher priority task, the following procedure is recommended (also for simple data types):

1. Conversion to a temporary variable.
2. Assign the temporary variable to the global target variable.

Note

One byte from the byte array is assigned to each variable of data type BOOL (including variables that are components within a structured data type).

For information about big endian and little endian byte ordering, see Converting between any data types and byte arrays (marshalling) (Page 1593).

Declaration

```
FUNCTION FROM_BIG_ENDIAN (
    in : ANY // Any data type, big endian
    )  : ANY
FUNCTION FROM_LITTLE_ENDIAN (
    in : ANY // Any data type, little endian
    )  : ANY
```

Input parameter

in

Data type: ANY

Any data type.

- For FROM_BIG_ENDIAN
  Elementary data types that comprise several bytes to the big endian byte order (most significant byte at low memory address)
- For FROM_LITTLE_ENDIAN
  Elementary data types that comprise several bytes to the little endian byte order (least significant byte at low memory address)

The following data types are permitted:

- Elementary data types (ANY_ELEMENTARY)
- User-defined data types (UDT)
- System data types of technology packages and devices

The following data types are **not** permitted:

- Technology object data types
- Object-oriented interfaces
- Structures with overlapping memory areas (STRUCT OVERLAP)
  Components within these structures are, however, permitted.

Return value

Data type: ANY

The same data type as the *in* input parameter.

4.2.9.8 Combining bit-string data types

General information for combining bit-string data types

The following functions enable several bit-string data-type variables to be combined into a higher-level data-type variable.

The inverse functions are implemented as function blocks, see Separating bit-string data types (Page 1630).

_BYTE_FROM_8BOOL function

Description

This function combines eight variables of data type BOOL into one variable of data type BYTE.

Declaration

```
FUNCTION _BYTE_FROM_8BOOL (
       { bit0,          // Least significant bit
         bit1, bit2, bit3, bit4, bit5, bit6,
         bit7 : BOOL   // Most significant bit
         }
    ) : BYTE
```

Input parameter

bit0 (optional)
...
bit7 (optional)

Data type: BOOL
Default FALSE

Up to eight variables of data type BOOL which are to be combined into a variable of data type BYTE

bit0: Least significant bit
...
bit7: Most significant bit

Return value

Data type: BYTE
Byte formed by combining input parameters.

_WORD_FROM_2BYTE function

Description

This function combines two variables of data type BYTE into one variable of data type WORD.

Declaration

```
FUNCTION _WORD_FROM_2BYTE (
       { byte0,           // Less significant byte
         byte1   : BYTE   // More significant byte
         }
    ) : WORD
```

Input parameter

byte0 (optional)
byte1 (optional)

Data type: BYTE
Default BYTE#0

Up to two variables of data type BYTE, which are to be combined into a variable of data type WORD

byte0: Less significant byte
byte1: More significant byte

Return value

Data type: WORD
Word formed by combining input parameters.

_DWORD_FROM_2WORD function

Description

This function combines two variables of data type WORD into one variable of data type DWORD.

Declaration

```
FUNCTION _DWORD_FROM_2WORD (
       { word0,          // Less significant word
         word1 : WORD    // More significant word
         }
    ) : DWORD
```

Input parameter

word0 (optional)
word1 (optional)

Data type: WORD
Default WORD#0

Up to two variables of data type WORD, which are to be combined into a variable of data type DWORD

word0: Less significant word
word1: More significant word

Return value

Data type: DWORD
Double word formed by combining input parameters.

_DWORD_FROM_4BYTE function

Description

This function combines four variables of data type BYTE to one variable of data type DWORD.

Declaration

```
FUNCTION _DWORD_FROM_4BYTE (
       { byte0          // Least significant byte
         byte1, byte2,
         byte3 : BYTE   // Most significant byte
         }
    ) : DWORD
```

Input parameter

byte0 (optional)
byte1 (optional)
byte2 (optional)
byte3 (optional)

Data type: BYTE
Default BYTE#0
Up to four variables of data type BYTE, which are to be combined into a variable of data type DWORD
byte0: Least significant byte
...
byte3: Most significant byte

Return value

Data type: DWORD
Double word formed by combining input parameters.

4.2.9.9 Conversion of technology object data types

AnyObject_to_Object function

Description

The function converts variables of a hierarchical TO data type (driveAxis, posAxis, followingAxis) or of the general ANYOBJECT type to a compatible TO data type.

You will find examples and additional information in Conversion of TO data types (Page 1242).

Declaration

```
FUNCTION AnyObject_to_Object (
        in    : ANYOBJECT
    ) : ANYOBJECT
```

Input parameter

in

Data type: ANYOBJECT

Variable of a TO data type (or ANYOBJECT) or a TO instance

Return value

Data type: ANYOBJECT

Value is TO#NIL, if type conversion is not possible

4.2.9.10 Functions for verification of floating-point numbers

_finite function

Description

The function checks whether the input parameter complies with the bit pattern for infinite in accordance with IEEE 754.

In combination with the _isNaN (Page 1504) function, it is used in particular to check whether bit strings converted to floating-point numbers correspond to the bit pattern of a normalized floating-point number in accordance with IEEE 754.

This prevents the error response specified during task configuration from being triggered (see "Execution errors in programs" (Page 1256)) as soon as an invalid floating-point number is used

for an arithmetic operation for the first time (for example in the program or when monitoring in the symbol browser).

Declaration

```
_finite (
        in : ANY_REAL
     ) : BOOL
```

Input parameter

in

Data type: ANY_REAL
Variable to be checked

Return value

Data type:	BOOL
FALSE	Bit pattern for infinite in accordance with IEEE 754
TRUE	No bit pattern for infinite in accordance with IEEE 754, i.e. valid floating-point number within the value range or invalid bit pattern (NaN Not a Number)

Example

```
var_real := DWORD_TO_REAL (var_dword);
IF NOT _finite (var_real) OR _isNaN (var_real) THEN
    ; // Error handling
ELSE
    var_real := SQRT (var_real);
END_IF;
```

_isNaN function

Description

The function verifies whether the input parameter corresponds to an invalid bit pattern of a floating-point number in accordance with IEEE 754 (is Not a Number NaN).

In combination with the _finite (Page 1503) function, it is used in particular to check if bit strings converted to floating-point numbers correspond to the bit pattern of a normalized floating-point number in accordance with IEEE 754.

This prevents the error response specified during task configuration from being triggered (see "Execution errors in programs" (Page 1256)) as soon as an invalid floating-point number is used

for an arithmetic operation for the first time (for example in the program or when monitoring in the symbol browser).

Declaration

```
_isNaN (
         in : ANY_REAL
      ) : BOOL
```

Input parameter

in

Data type: ANY_REAL
Variable to be checked

Return value

Data type:	BOOL
FALSE	Valid bit pattern or bit pattern for infinite in accordance with IEEE 754
TRUE	Invalid bit pattern in accordance with IEEE 754 (NaN Not a Number)

Example

```
var_real := DWORD_TO_REAL (var_dword);
IF NOT _finite (var_real) OR _isNaN (var_real) THEN
    ; // Error handling
ELSE
    var_real := SQRT (var_real);
END_IF;
```

IS_VALID function

Description

The function checks whether the input parameter complies with the bit pattern of a normalized floating-point number in accordance with IEEE 754.

This prevents the error response specified during task configuration from being triggered (see "Execution errors in programs" (Page 1256)) as soon as an invalid floating-point number is used for an arithmetic operation for the first time (for example in the program or when monitoring in the symbol browser).

To use this function, you must activate the "Permit language extensions IEC61131-3rd Edition" compiler option, see SIMOTION ST Programming and Operating Manual.

Declaration

```
IS_VALID (
        in : ANY_REAL
     ) : BOOL
```

Input parameter

in

Data type: ANY_REAL

Variable to be checked

Return value

Data type:	BOOL
FALSE	Bit pattern for infinite in accordance with IEEE 754 or invalid bit pattern (NaN Not a Number)
TRUE	Valid floating-point number within the value range

Example

```
var_real := DWORD_TO_REAL (var_dword);
IF IS_VALID (var_real) THEN
    var_real := SQRT (var_real);
ELSE
    ; // Error handling
END_IF;
```

4.2.9.11 Functions for selection

SEL function

Description

Binary selection

The return value is one of the input parameters in0 or in1, depending on the value of input parameter g.

Declaration

```
FUNCTION SEL (
        g    : BOOL,
        in0  : ANY,
        in1  : ANY
        ) : ANY
```

Input parameter

g

Data type: BOOL

Selection of the input parameter in0 or in1

in0, in1

Data type: ANY

The input parameters in0 and in1 must either be of the same data type or must be convertible to a common data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

Return value

Data type: ANY

Selected input parameter

in0 If g = 0 (FALSE)

in1 If g = 1 (TRUE)

The data type corresponds to the common data type of the input parameters in0 and in1.

MUX function

Description

Expandable multiplex function

The return value is one of the *n* input parameters in0 to in*n*-1, depending on the value of input parameter k.

Note

This description is not relevant to LAD/FDB. The corresponding function is described in the SIMOTION LAD/FDB Programming Manual.

Declaration

```
FUNCTION MUX (
        k       : ANY_INT,
        in0     : ANY,
        ...
        inn-1   : ANY
        ) : ANY
```

Input parameter

k

Data type: ANY_INT

Selection of the input parameter in0 to in*n*-1.

The value range depends on the number n of the input parameters in0...in*n*-1: 0 ≤ k ≤ *n*-1.

If illegal values are specified, input parameter in0 will be selected.

in0

...

in*n*–1

Data type: ANY

The number n of the input parameters in0 and in*n*-1 may vary.

All input parameters in0 and in*n*-1 must either be of the same data type or must be convertible to a common data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

If *n* formal parameters in0 to in*n*-1 are specified when calling the function, this must be done in ascending, uninterrupted order; for four input parameters, for example, the identifiers of the formal parameters are: in0, in1, in2, in3.

Return value

Data type: ANY

Input parameter in*m* if input parameter k has the value *m*.

The data type corresponds to the common data type of the input parameters in0 to in*n*-1.

MAX function

Description

Expandable maximum function

The return value is the maximum value of *n* input parameters in0 to in*n*-1.

Note

This description is not relevant to LAD/FDB. The corresponding function is described in the SIMOTION LAD/FDB Programming Manual.

Declaration

```
FUNCTION MAX (
        in0    : ANY_ELEMENTARY,
        ...
        inn-1  : ANY_ELEMENTARY
        ) : ANY_ELEMENTARY
```

Input parameter

in0
...
in*n*–1

Data type: ANY_ELEMENTARY

The number n of the input parameters in0 and in*n*-1 may vary.

All input parameters in0 and in*n*-1 must either be of the same data type or must be convertible to the most powerful data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

If *n* formal parameters in0 to in*n*-1 are specified when calling the function, this must be done in ascending, uninterrupted order; for four input parameters, for example, the identifiers of the formal parameters are: in0, in1, in2, in3.

Return value

Data type: ANY_ELEMENTARY

Maximum of the input parameters

The data type corresponds to the most powerful data type of the input parameters in0 to in*n*-1.

MIN function

Description

Expandable minimum function

The return value is the minimum value of *n* input parameters in0 to in*n*-1.

Note

This description is not relevant to LAD/FDB. The corresponding function is described in the SIMOTION LAD/FDB Programming Manual.

Declaration

```
FUNCTION MIN (
        in0    : ANY_ELEMENTARY,
        ...
        inn-1  : ANY_ELEMENTARY
        ) : ANY_ELEMENTARY
```

Input parameter

in0
...
in*n*–1

Data type: ANY_ELEMENTARY

The number n of the input parameters in0 and in*n*-1 may vary.

All input parameters in0 and in*n*-1 must either be of the same data type or must be convertible to the most powerful data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

If *n* formal parameters in0 to in*n*-1 are specified when calling the function, this must be done in ascending, uninterrupted order; for four input parameters, for example, the identifiers of the formal parameters are: in0, in1, in2, in3.

Return value

Data type: ANY_ELEMENTARY

Minimum of the input parameters

The data type corresponds to the most powerful data type of the input parameters in0 to in*n*-1.

LIMIT function

Description

Limiting function

The input parameter *in* is limited to values between the lower limiting value *mn* and the upper limiting value *mx*.

The function value is calculated as follows with the MIN (Page 1509) and MAX (Page 1508) selection functions:

```
LIMIT = MIN (MAX (in, mn), mx)
```

Declaration

```
FUNCTION LIMIT (
        mn  : ANY_ELEMENTARY,
        in  : ANY_ELEMENTARY,
        mx  : ANY_ELEMENTARY
        ) : ANY_ELEMENTARY
```

Input parameter

mn

Data type: ANY_ELEMENTARY

Lower limiting value

All input parameters must either be of the same data type or must be convertible to the most powerful data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

in

Data type: ANY_ELEMENTARY

Value to be limited

All input parameters must either be of the same data type or must be convertible to the most powerful data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

mx

Data type: ANY_ELEMENTARY

Upper limiting value

All input parameters must either be of the same data type or must be convertible to the most powerful data type by implicit conversion (see "Elementary data type conversion" in the SIMOTION ST Programming Manual).

Return value

Data type: ANY_ELEMENTARY

MIN (MAX (in, mn), mx)

The data type corresponds to the most powerful data type of the input parameters.

4.2.9.12 Consistent access to global variables of derived data types (UDT)

General

When accessing **global** variables of derived data types (see **User-defined data types (UDT)** in the ST programming manual), the user is responsible for ensuring data consistency when multiple tasks access the same user variables (I/O variables, system variables, system variables of technology objects, global device variables, and global unit variables, see **Variable model** in the programming manuals).

Note

Consistent data access is always ensured within a task.

You can work with semaphores to ensure that global variables of derived data types (UDT) are written and read consistently.

A global variable of data type DINT serves as a semaphore. Use the following functions to change and test the status of the semaphore:

- _testAndSetSemaphore (Page 1512)
- _releaseSemaphore (Page 1513)

Consistent data access to global variables is ensured under the following conditions:

1. All tasks signal access to global variables by setting a semaphore.
2. All tasks access global variables only when the semaphore is enabled.

For more information on consistent data access and semaphores, refer to "Consistent reading and writing of variables (semaphores)" (Page 1570).

_testAndSetSemaphore function

Description

This function checks whether the semaphore is set.

The semaphore is always set when the function ends. Additional calls of this function (even from other programs) return a value of FALSE until the _releaseSemaphore (Page 1513) function is called.

Declaration

```
_testAndSetSemaphore     (
                          sema    : DINT
                         ) : BOOL
```

Input parameter

sema

Data type DINT

Sema is a **global** variable of the DINT data type; it serves as semaphore. It must not be indexed. If it is an element of an array, the index must be specified when compiling (e.g. a[2]).

Return value

Data type: BOOL

This return value determines whether the semaphore is set:

TRUE	The semaphore was successfully set/assigned by this call. If TRUE, the semaphore must be released again after completion of the critical code section by calling the **_releaseSemaphore** function so it can be assigned at another location.
FALSE	The semaphore was already set/assigned by another program.

Example

See Example: Consistent data access with semaphores (Page 1572).

_releaseSemaphore function

Description

This function releases the semaphore. The next call of the _testAndSetSemaphore (Page 1512) function (even from different programs) results in a return value of TRUE.

Declaration

```
_releaseSemaphore     (
                       sema    : DINT
                       ) : VOID
```

Input parameter

sema

Data type: DINT

Sema is a **global** variable of the DINT data type; it serves as semaphore. It must not be indexed. If it is an element of an array, the index must be specified when compiling (e.g. a[2]).

Return value

none

Example

See Example: Consistent data access with semaphores (Page 1572).

4.2.9.13 Access to system variables and inputs/outputs

General information on accessing system variables and inputs/outputs

The _getSafeValue and _setSafeValue functions allow a special error response for access to system variables, configuration data, or I/O variables. It is possible to specify a different response from what has been configured in the event of an error (see Access errors to system variables and configuration data, as well as I/O variables for direct access (Page 1258)).

The system functions _getSafeValue and _setSafeValue require a lot of execution time. Therefore, only use them when necessary, e.g. in an IF statement, to wait for the restart of a TO.

With V4.1 and higher, you can also specify a "replacement value" or "last value" for accesses to system variables and config data (V4.1.3 and higher) in the event of an error (e.g. TO is in restart). The configuration data restartInfo.behaviorInvalidSysvarAccess is relevant for this. See System variables (Page 1245) or Configuration data (Page 1249).

The _getInOutByte function enables direct read access to individual I/O bytes by specifying the address.

See also

Access errors to system variables and configuration data, as well as I/O variables for direct access (Page 1258)

System variables (Page 1245)

Configuration data (Page 1249)

_getSafeValue function

This function reads the specified system variable (or configuration data element) or I/O variable and returns the value in another variable.

When this function is used (instead of a variable assignment), the transition to STOP mode can be prevented if an error occurs when accessing system variables, configuration data or I/O variables (e.g. while restarting a technology object, or in the event of an I/O failure).

Note

Runtime of the function

- Up to SIMOTION Kernel V4.3
  The runtime can be very long. Therefore, this function is not suitable for use in fast cyclic tasks.
- As of SIMOTION Kernel V4.4
  The runtime has been optimized. Access from synchronous user tasks is possible.

Specifying the error response

You can control the error response using the *accessmode* parameter:

- CONFIGURED (default): The error response defined by *restart.behaviorInvalidSysvarAccess* is used, see Access errors to system variables and configuration data, as well as I/O variables for direct access (Page 1258).
- NO_CHANGE:
  - System variables and configuration data:
    Variable is not read and the value remains undefined, see System variables (Page 1245).
  - I/O variables:
    With read access (to inputs or outputs): The last valid value is applied.
- DEFAULT_VALUE: Substitute value or limit value is read.
- STOP_DEVICE: SIMOTION device switches to STOP mode. When a transition to STOP mode occurs, the ExecutionFaultTask is not started.

You can use the return value to determine whether the access was successful.

Declaration

```
_getSafeValue (
         variable      : ANY,        //System variable,
                                     // Configuration data or
                                     // I/O variable
         accessMode    : EnumAccessMode,
         getValue      : ANY
         )             : EnumSetAndGetSafeValue
```

Input parameter

variable

Data type: ANY

System variable, configuration data item or I/O variable to be read.

accesssMode

Data type: EnumAccessMode

Response when an error occurs during read access.

```
TYPE EnumAccessMode : (
// Response as configured:
    CONFIGURED  // System variables and config data:
                // Behavior depends on config data item
                // restartInfo.behaviorInvalidSysvarAccess
                // For I/O variables:
                // Strategy specified during creation
                // of the I/O variables
// Different response than configured:
    NO_CHANGE      // For system variables and
                   // configuration data: Variable
                   // do not read.
                   // For I/O variables: Accept
                   // last available (valid)
                   // value.
    DEFAULT_VALUE  // Configured value or
                   // Substitute value for I/O variables
    STOP_DEVICE    // Device switches to STOP mode.
END_TYPE
```

getvalue

Data type: ANY

Name of the variable to which the current value of the system variable (or configuration data item) or I/O variable is written.

The following applies for the data type:

- It must be the same as the data type of the variable to be read, or
- The data type of the variable to be read must be able to be converted to this data type by means of implicit type conversion.

Return value

Data type: EnumSetAndGetSafeValue

The return value indicates whether the access was successful.

```
TYPE EnumSetAndGetSafeValue : (
 // Access successful:
 OK            // Access was successful.
 // Access error:
, NO_CHANGE  // For system variables and configuration data: Variable was
             // not read, last value
             // For I/O variables: Last
             // available (valid) value was
             // accepted.
, DEFAULT_VALUE    // Only for I/O variables:
                   // Substitute value was accepted.
, INVALID_VALUE    // Only for configuration data:
                   // Configuration data item was
                   // not read, default value is returned,
                   // impermissible parameter
                   //(accessMode = DEFAULT_VALUE).
, NO_ACCESS )      // Only for configuration data:
                   // Configuration data item was
                   // not read, default value is returned
END_TYPE
```

See also

Errors when accessing system data with _get/_setSafeValue (Page 1295)

_setSafeValue function

The function behaves differently as of V4.1.3. It writes the specified value to the system variable, configuration data item or I/O variable and there is an option for it to return the currently written value in another variable. The response in the event of a fault can be specified differently from the configured response.

When this function is used (instead of a variable assignment), the transition to STOP mode can be prevented if an error occurs when accessing system variables, configuration data or I/O variables (e.g. while restarting a technology object, or in the event of an I/O failure).

Note

Runtime of the function

- Up to SIMOTION Kernel V4.3
  The runtime can be very long. Therefore, this function is not suitable for use in fast cyclic tasks.
- As of SIMOTION Kernel V4.4
  The runtime has been optimized. Access from synchronous user tasks is possible.

Specifying the error response

You can control the error response using the *accessmode* parameter:

- CONFIGURED (default): The error response specified in *restart.behaviorInvalidSysvarAccess* is used, see Errors when accessing system variables and configuration data as well as I/O variables for direct access (Page 1258).
- NO_CHANGE:
  - System variables and configuration data:
    Value is not written and remains unchanged or retains the last available value.
  - I/O variables:
    With write access (to outputs): The value is written to the variable. However, it will not be active at the output until the output becomes available again.
- DEFAULT_VALUE: Substitute value or limit value is written.
- STOP_DEVICE: SIMOTION device switches to STOP mode. When a transition to STOP mode occurs, the ExecutionFaultTask is not started.
- Value range for variable

The value is restricted to the value range and is not affected by the accessMode parameter.

You can use the return value to determine whether the access was successful.

Declaration

```
_setSafeValue (
        variable     : ANY,         //System variable,
                                   // Configuration data or
                                   // I/O variable
        value        : ANY,
        accessMode   : EnumAccessMode,
        setValue     : ANY
         ) : EnumSetAndGetSafeValue
```

Input parameter

variable

Data type: ANY

System variable, configuration data item or I/O variable to be written.

value

Data type**:** ANY

Value to be written to the system variable (or configuration data item) or I/O variable. The value data type must be the same as the data type of the variable to be written to, or it must be able to be converted to this data type by means of implicit type conversion.

accessMode

Data type: EnumAccessMode

Response when an error occurs during write access:

```
TYPE EnumAccessMode : (
 // Response as configured:
     CONFIGURED       // System variables and config data:
                       // Behavior depends on config data item
                       // restartInfo.behaviorInvalidSysvarAccess
                       // For I/O variables:
                       // Strategy specified during creation
                       // of the I/O variables
 // Different response than configured:
    , NO_CHANGE        // For system variables and
                       // configuration data: Current value
                       // Is not written.
                       //For I/O variables
                       // The value transferred in the
                       // parameter is written to the
                       // written. It is not active at the output
                       // until the output is
                       // again available.
, DEFAULT_VALUE
                       // For system variables and config data:
                       // Variable is not described.
                       // For I/O variables:
                       // Variable is described with the
                       // substitute value specified
                       // when creating the variable.
, STOP_DEVICE )        // Device goes into STOP
                       // mode
END_TYPE
```

setvalue

Data type: ANY

Name of a variable to which the current value of the system variable, configuration data item, or I/O variable is written.

The following applies for the data type:

- It must be of the same data type as the variable to be written, or
- The data type of the variable to be written must be able to be converted to this data type by means of implicit type conversion.

If, for example, 100 is to be written, but only 90 was entered, *setValue* is given a value of 90.

Return value

Data type: EnumSetAndGetSafeValue

The return value indicates whether the access was successful.

```
TYPE EnumSetAndGetSafeValue : (
 // Access successful:
 OK                // Access was successful.
 // Access error:
, NO_CHANGE        // For system variables and config data:
                   // Value is not written.
                   // For I/O variables: The value transferred
                   // in the parameter was
                   // written. It is not active at the output
                   // until the output is
                   // again available.
, DEFAULT_VALUE    // For system variables: Limitation
                   // active, limit value was
                   // written.
                   // For I/O variables: Substitute value was
                   // written. It is not active at the output
                   // until the output is
                   // again available.
, NO_ACCESS )     // Only for configuration data and system variables:
                   // Value of the configuration data item was
                   // not changed,
                   // Configuration data item
                   // not available).
END_TYPE
```

Errors when accessing system data with _get/_setSafeValue (Page 1295)

_getInOutByte function

This function enables direct read access to individual I/O bytes through specification of the input/output address.

In the event of an access error, the PeripheralFaultTask is not called; rather a corresponding value is returned in the functionResult component of the return value.

If an I/O variable (for direct access or the process image of the cyclic task) (see **Direct access and process image of the cyclical tasks** in the ST Programming Manual) is defined for the specified I/O address and a replacement value is specified, this replacement value is returned in the event of an access error.

Evaluation of the return value can determine, for example, whether an input or an output is assigned to the address in the hardware.

Note

The runtime of this function can be very long. Therefore, this function is not suitable for use in fast cyclic tasks.

Declaration

```
_getInOutByte (
            mode          : EnumInOutDirection,
            logAddress    : DINT
         )                 : StructRetGetInOutByte
```

Input parameters

mode

Data type: EnumInOutDirection

Specifies whether logAddress is used to access the input or output.

```
TYPE EnumInOutDirection : (
      IN            // Access to input
 ,    OUT )        // Access to output
END_TYPE
```

logAddress

Data type: DINT

Logic address of input or output

Return value

Data type: StructRetGetInOutByte

Function call result and read byte value

```
TYPE StructRetGetInOutByte : STRUCT
    functionResult    : DINT;    // Result of the
                                 // function call
    value            : BYTE;     // Value of byte read
 END_STRUCT;
END_TYPE
```

Possible values of functionResult (result of function call):

0	No error, access okay.
16#FFFF_FFFA	Not enough memory available
16#FFFF_FFFE	Access error
16#FFFF_FFFF	Input/output not available

4.2.9.14 Backing up data from the user program

General information on saving data sets from the user program

The functions below are for:

- Saving, loading, or initializing the following values:
  - Non-retentive or retentive global unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit)
  - Non-retentive or retentive global device variables (declared via project navigator)

  Data backup is performed by selecting the relevant function
  - Binary: The backed-up data set can no longer be read after the version ID of the data segment has been changed.
  - In XML format: The backed-up data set can be read after the version ID of the data segment has been changed.
- Managing the data set in which the values are backed up

The values are backed up in a data set that is identified uniquely by specifying the storage location, the name of the unit, and a data set number.

The application of these functions - in particular, the step enabling condition - is described in detail in Data backup and initialization from user program (Page 1573).

As well as saving retentive variables as individual data sets, it is also possible to back up all the retentive data to the memory card using the _savePersistentMemoryData function. For more information, see the *System Functions/Variable Devices* Parameter Manual.

_saveUnitDataSet function

Description

The values of the following variables are saved as a binary data set:

- Non-retentive or retentive global unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit, LAD/FBD unit)
- Non-retentive or retentive global device variables (declared via project navigator)

You can select the location at which the data set will be stored:

- Temporary data storage (RAM disk), erased in the event of a power failure
- Permanent data storage (memory card) is retained if there is a power failure

Pay attention to consistency of the data to be backed up, see Consistent reading and writing of variables (semaphores) (Page 1570).

When calling this function in short form, all parameters (including all optional parameters) must be specified.

The "Save variables" and "Restore variables" SCOUT functions can be used to retain data sets saved with _saveUnitDataSet, even if there is a change of version or data segments have been

changed. For additional information, refer to the SIMOTION SCOUT Configuration Manual or the online help.

Declaration

```
_saveUnitDataSet (
            unitName        : STRING,
            id              : UDINT,
            storageType     : EnumDeviceStorageType,
          { path            : STRING,
            overwrite       : BOOL,
            nextCommand     : EnumNextCommandMode,
            dataScope       : EnumDeviceDataScope,
            kindOfData      : EnumDeviceKindOfData,
            }
        ): StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit, LAD/FBD unit) whose unit variables will be saved.

The name must be indicated in lower case and inside single quotation marks (e.g. 'st_unit1').

If '_device' is specified, the global device variables will be saved.

id

Data type: UDINT

Number of the data set under which the variable values are saved (maximum of 1_000_000 data sets per unit).

storageType

Data type: EnumDeviceStorageType

Location at which the data is saved.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        //  is retained if there is a power failure
    USER_STORAGE )
        // with path specification
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING
Default: ' ' (empty string)
Destination path, if storageType = USER_STORAGE.
Only the default value may be specified. Otherwise, an error message is output.

overwrite (optional)
Data type: BOOL
Default: FALSE
If TRUE, existing data set is overwritten.

nextCommand (optional)
Data type: EnumNextCommandMode
Default: IMMEDIATELY
Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

dataScope (optional)
Data type: EnumDeviceDataScope
Default _INTERFACE

```
TYPE EnumDeviceDataScope : (
    _INTERFACE,
        // Interface section
    _IMPLEMENTATION,
        // Implementation section
    _INTERFACE_AND_IMPLEMENTATION )
        // Interface and implementation section
END_TYPE
```

If unitName = '_device' is specified, only the values _INTERFACE or _INTERFACE_AND_IMPLEMENTATION are permissible for dataScope.

kindOfData (optional)
Data type: EnumDeviceKindOfData
Default NO_RETAIN_GLOBAL
Specification of whether non-retentive or retentive global variables will be saved.

```
TYPE EnumDeviceKindOfData : (
    NO_RETAIN_GLOBAL,
        // Non-retentive variables
    _RETAIN,
        // Retentive variables
    ALL_GLOBAL )
        // Retentive and non-retentive variables
END_TYPE
```

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A functionResult : EnumDeviceUnitDataSetCommand component.
  This supplies information on errors and the current state.
- A handle : UDINT component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

Table 4-102 Data type return value

```
TYPE
  EnumDeviceUnitDataSetCommand: (
    DONE,       // Execution or start successful
    ACTIVE,                 // Being processed
    INTERNEL_ERROR,         // Internal error
            // (please call the hotline)
    COMMAND_FAILED,         // Command cannot be executed
    NO_COMMAND_BUFFER_AVAILABLE,  // Command buffer full
    COMMAND_NOT_FOUND,      // Command (handle) not found
    DATASET_ID_NOT_VALID,   // Data set number is invalid
    READ_ERROR,             // Data read error
                            // (defective storage medium)
    NO_STORAGE_AVAILABLE,   // No memory space available
    ACCESS_DENIED,          // Access denied
                            // (missing write/read rights)
    DATASET_ALREADY_EXISTS, // File already exists
    DATASET_NOT_FOUND,      // Data set not found
    UNIT_NOT_FOUND,         // Unit not found
            // (e.g. ST source file, MCC unit) not available
    VERSION_MISSMATCH,      // Incorrect version ID
            // of the data area to be imported
    DATA_INCOMPLETE,    // Incomplete import of the data
    SYMBOL_INFORMATION_NOT_AVAILABLE,
            // Symbol information not available
            //(Activate the OPC-XML export at the program source)
    DATA_MISMATCH,      // Data area to be imported
                        // is not contained in the data set
    DATA_INCOMPATIBLE )
            // Data set contains additional data segments or
            // selected data segments are missing in the data set

  StructRetUnitDataSetCommand  : STRUCT
    functionResult : EnumDeviceUnitDataSetCommand;
    handle : UDINT;
  END_STRUCT;
END_TYPE
```

For information about data backup, see "Data backup and data initialization from user program" (Page 1573)

_loadUnitDataSet function

Description

The values of the following variables are loaded from a binary data set saved with _saveUnitDataSet (Page 1522):

- Non-retentive or retentive global unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit, LAD/FBD unit)
- Non-retentive or retentive global device variables

The data set can only be loaded if the version codes of all the data segments to be loaded (e.g. non-retentive and retentive variables of the interface section of the unit) have remained unchanged since the data set was saved. For data segments and their version ID, see Section "Version ID of global variables and their initialization during download" in the Programming Manuals, e.g. SIMOTION ST.

A subset of the data segments backed up in the data set can be loaded (e.g. if the version codes of some data segments have changed).

When calling this function in short form, all parameters (including all optional parameters) must be specified.

The "Save variables" and "Restore variables" SCOUT functions can be used to retain data sets saved with _saveUnitDataSet, even if there is a change of version or data segments have been changed. For additional information, refer to the SIMOTION SCOUT Configuration Manual or the online help.

Declaration

```
_loadUnitDataSet (
            unitName        : STRING,
            id              : UDINT,
            storageType     : EnumDeviceStorageType,
          { path            : STRING,
            nextCommand     : EnumNextCommandMode,
            dataScope       : EnumDeviceDataScope,
            kindOfData      : EnumDeviceKindOfData,
            }
        ): StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit), whose unit variables will be loaded.

The name must be indicated in lower case and inside single quotation marks (e.g. 'st_unit1').

If '_device' is specified, the global device variables will be loaded.

id

Data type: UDINT

Number of the data set from which the variable values are loaded (maximum of 1_000_000 data sets per unit).

storageType

Data type: EnumDeviceStorageType

Location at which the data is saved.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        // is retained if there is a power failure
    USER_STORAGE )
        // with path specification,
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING

Default: '' (empty string)

Destination path, if storageType = USER_STORAGE.

Only the default value may be specified. Otherwise, an error message is output.

nextCommand (optional)

Data type: EnumNextCommandMode

Default: IMMEDIATELY

Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

dataScope (optional)

Data type: EnumDeviceDataScope

Default _INTERFACE

Specification of the section whose unit variables are to be saved.

```
TYPE EnumDeviceDataScope : (
    _INTERFACE,
        // Interface section
    _IMPLEMENTATION,
        // Implementation section
    _INTERFACE_AND_IMPLEMENTATION )
        // Interface and implementation section
END_TYPE
```

If unitName = '_device' is specified, only the values _INTERFACE or _INTERFACE_AND_IMPLEMENTATION are permissible for dataScope.

kindOfData (optional)

Data type: EnumDeviceKindOfData
Default NO_RETAIN_GLOBAL

Specification of whether non-retentive or retentive global variables will be loaded.

```
TYPE EnumDeviceKindOfData : (
    NO_RETAIN_GLOBAL,
        // Non-retentive variables
    _RETAIN,
        // Retentive variables
    ALL_GLOBAL )
        // Retentive and non-retentive variables
END_TYPE
```

If retentive and non-retentive variables are stored in the saved data set, it is possible to load retentive or non-retentive variables selectively.

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A *functionResult* : EnumDeviceUnitDataSetCommand. component.
  This supplies information on errors and the current state.
- A *handle* : UDINT component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

For further information on data types StructRetUnitDataSetCommand and EnumDeviceUnit-DataSetCommand, see Section **Return value** of the _saveUnitDataSet (Page 1525) function.

For information about data backup, see "Data backup and data initialization from user program" (Page 1573)

_exportUnitDataSet function

Description

The values of the following variables are exported in XML format as a data set:

- Non-retentive global unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit or LAD/FBD unit)
- Retentive global unit variables of the interface or the implementation section of a unit

You can select the location at which the data set will be stored:

- Temporary data storage (RAM disk), erased in the event of a power failure
- Permanent data storage (memory card) is retained if there is a power failure

Non-retentive or retentive global device variables can only be backed up with the _saveUnitDataSet (Page 1522) function.

Make sure the symbol information of the unit variables in the SIMOTION device is available for the relevant unit. Therefore, activate the **Permit OPC-XML** option in the local settings of the compiler at the program source, see Section "Local settings of the compiler" in the Programming Manuals, e.g. SIMOTION ST.

Pay attention to consistency of the data to be exported, see Consistent reading and writing of variables (semaphores) (Page 1570).

The exported data set can also be imported with the _importUnitDataSet (Page 1531) function if the version ID of the data area (e.g. retentive variables of the interface section of the unit) has changed (e.g. by a change to the data structure).

When calling this function in short form, all parameters (including all optional parameters) must be specified.

Declaration

```
_exportUnitDataSet (
            unitName        : STRING,
            id              : UDINT,
            storageType     : EnumDeviceStorageType,
          { path            : STRING,
            overwrite       : BOOL
            nextCommand     : EnumNextCommandMode,
            dataScope       : EnumDeviceDataScope,
            kindOfData      : EnumDeviceKindOfData,
            }
        ): StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit), whose unit variables will be exported.

The name must be indicated in lower case and inside single quotation marks (e.g. 'st_unit1').

Specifying '_device' (for exporting global device variables) is not permissible here (only possible with _saveUnitDataSet (Page 1522)).

id

Data type: UDINT

Number of the data set under which the variable values are saved (maximum of 1_000_000 data sets per unit).

storageType

Data type: EnumDeviceStorageType

Location at which the data is saved.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        //  is retained if there is a power failure
    USER_STORAGE )
        // with path specification
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING

Default: ' ' (empty string)

Destination path, if storageType = USER_STORAGE.

Only the default value may be specified. Otherwise, an error message is output.

overwrite (optional)

Data type: BOOL

Default: FALSE

If TRUE, existing data set is overwritten.

nextCommand (optional)

Data type: EnumNextCommandMode

Default: IMMEDIATELY

Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

dataScope (optional)

Data type: EnumDeviceDataScope

Default _INTERFACE

Specification of the section whose unit variables will be exported.

```
TYPE EnumDeviceDataScope : (
    _INTERFACE,
        // Interface section
    _IMPLEMENTATION,
        // Implementation section
    _INTERFACE_AND_IMPLEMENTATION )
        // Interface and implementation section
END_TYPE
```

kindOfData (optional)

Data type: EnumDeviceKindOfData

Default NO_RETAIN_GLOBAL

Specification of whether non-retentive or retentive global variables will be exported.

```
TYPE EnumDeviceKindOfData : (
    NO_RETAIN_GLOBAL,
        // Non-retentive variables
    _RETAIN,
        // Retentive variables
    ALL_GLOBAL )
        // Retentive and non-retentive variables
END_TYPE
```

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A *functionResult* : EnumDeviceUnitDataSetCommand component.
  This supplies information on errors and the current state.
- A *handle* : UDINT component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

For further information on data types StructRetUnitDataSetCommand and EnumDeviceUnit-DataSetCommand, see Section **Return value** of the _saveUnitDataSet (Page 1525) function.

For information about data backup, see "Data backup and data initialization from user program" (Page 1573)

_importUnitDataSet function

Description

The values of the following variables are imported from a data set that was exported with _exportUnitDataSet (Page 1528).

- Non-retentive global unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit or LAD/FBD unit)
- Retentive global unit variables of the interface or the implementation section of a unit

Make sure the symbol information of the unit variables in the SIMOTION device is available for the relevant unit. Therefore, activate the **Permit OPC-XML** option in the local settings of the compiler at the program source, see Section "Local settings of the compiler" in the Programming Manuals, e.g. SIMOTION ST.

The data set can also be imported if the version code of a data segment to be loaded has changed since the data set was saved (e.g. non-retentive variables of the interface section of the unit):

- Variables that no longer exist are ignored.
- The value of added variables remains unchanged.

- In the case of a variable with a changed data type, the value is transferred if it can be converted to the new data type; otherwise the value of the variable is retained.
- The returned value of the function is DATA_INCOMPLETE.

To avoid unwanted values in variables, you can initialize the relevant data segments before importing the data set with the _resetUnitData function (see List Manual for the system functions of the SIMOTION devices).

For data segments and their version ID, see Section "Version ID of global variables and their initialization during download" in the Programming Manuals, e.g. SIMOTION ST.

A subset of the data segments exported in the data set can be imported.

When calling this function in short form, all parameters (including all optional parameters) must be specified.

Declaration

```
_importUnitDataSet (
            unitName        : STRING,
            id              : UDINT,
            storageType     : EnumDeviceStorageType,
          { path            : STRING,
            nextCommand     : EnumNextCommandMode,
            dataScope       : EnumDeviceDataScope,
            kindOfData      : EnumDeviceKindOfData,
            }
        ): StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit), whose unit variables will be imported.

The name must be indicated in lower case and inside single quotation marks (e.g. 'st_unit1').

Specifying '_device' (for importing global device variables) is not permissible here (only possible with _loadUnitDataSet (Page 1526)).

id

Data type: UDINT

Number of the data set under which the variable values are saved (maximum of 1_000_000 data sets per unit).

storageType

Data type: EnumDeviceStorageType

Location at which the data is saved.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        //  is retained if there is a power failure
    USER_STORAGE )
        // with path specification
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING

Default: ' ' (empty string)

Destination path, if storageType = USER_STORAGE.

Only the default value may be specified. Otherwise, an error message is output.

overwrite (optional)

Data type: BOOL

Default: FALSE

If TRUE, existing data set is overwritten.

nextCommand (optional)

Data type: EnumNextCommandMode

Default: IMMEDIATELY

Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

dataScope (optional)

Data type: EnumDeviceDataScope

Default _INTERFACE

Specification of the section whose unit variables will be imported.

```
TYPE EnumDeviceDataScope : (
    _INTERFACE,
        // Interface section
    _IMPLEMENTATION,
        // Implementation section
    _INTERFACE_AND_IMPLEMENTATION )
        // Interface and implementation section
END_TYPE
```

kindOfData (optional)

Data type: EnumDeviceKindOfData

Default NO_RETAIN_GLOBAL

Specification of whether non-retentive or retentive global variables will be imported.

```
TYPE EnumDeviceKindOfData : (
    NO_RETAIN_GLOBAL,
        // Non-retentive variables
    _RETAIN,
        // Retentive variables
    ALL_GLOBAL )
        // Retentive and non-retentive variables
END_TYPE
```

If retentive and non-retentive variables are stored in the exported data set, it is possible to import retentive or non-retentive variables selectively.

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A *functionResult* : EnumDeviceUnitDataSetCommand component.
  This supplies information on errors and the current state.
- A *handle* : UDINT. component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

For further information on data types StructRetUnitDataSetCommand and EnumDeviceUnit-DataSetCommand, see Section **Return value** of the _saveUnitDataSet (Page 1525) function.

For information about data backup, see "Data backup and data initialization from user program" (Page 1573)

_deleteUnitDataSet function

Description

A single data set containing the stored values of the following variables is deleted:

- Backed-up non-retentive or retentive unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit)
- Backed-up non-retentive or retentive global device variables.
- Exported non-retentive or retentive unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit)

When calling this function in short form, all parameters (including all optional parameters) must be specified.

Declaration

```
_deleteUnitDataSet (
            unitName       : STRING,
            id             : UDINT,
            storageType    : EnumDeviceStorageType,
          { path           : STRING,
            nextCommand    : EnumNextCommandMode,
            }
        ): StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit); the name must be written in lower case and placed inside single quotation marks (e.g. 'st_unit1').

If '_device' is specified, a data set for global device variables will be deleted.

id

Data type: UDINT

Number of the data set to be deleted (maximum of 1_000_000 data sets per unit).

storageType

Data type: EnumDeviceStorageType

Location from which the data set is to be deleted.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        //  is retained if there is a power failure
    USER_STORAGE )
        // with path specification
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING

Default: ' ' (empty string)

Destination path, if storageType = USER_STORAGE.

Only the default value may be specified. Otherwise, an error message is output.

nextCommand (optional)

Data type: EnumNextCommandMode
Default: IMMEDIATELY
Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A *functionResult* : EnumDeviceUnitDataSetCommand component.
  This supplies information on errors and the current state.
- A *handle* : UDINT component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

For further information on data types StructRetUnitDataSetCommand and EnumDeviceUnit-DataSetCommand, see Section Return value of the _saveUnitDataSet (Page 1525) function.

For information about data backup, see "Data backup and data initialization from user program" (Page 1573)

See also

_deleteAllUnitDataSets function (Page 1539)

_getStateOfUnitDataSetCommand function

Description

It returns the state of the functions for data backup.

Declaration

```
_getStateOfUnitDataSetCommand (
            handle  : UDINT
        ) : EnumDeviceUnitDataSetCommand
```

Input parameter

handle

Data type: UDINT

Handle of the data backup function for which the state is to be checked. You received this handle as a component of the return value of the data backup function.

Return value

Data type: EnumDeviceUnitDataSetCommand

This supplies information on errors and the current state.

For further information on the EnumDeviceUnitDataSetCommand data type, see Section **Return value** of the _saveUnitDataSet (Page 1525) function.

For information about data backup, see "Data backup and data initialization from user program" (Page 1573).

_checkExistingUnitDataSet function

Description

A check is performed to determine whether the specified data set containing the stored values of the following variables is available on the storage medium:

- Backed-up non-retentive or retentive unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit)
- Backed-up non-retentive or retentive global device variables.
- Exported non-retentive or retentive unit variables of the interface section of a unit (e.g. ST source file, MCC unit)

When calling this function in short form, all parameters (including all optional parameters) must be specified.

Declaration

```
_checkExistingUnitDataSet (
            unitName       : STRING,
            id             : UDINT,
            storageType    : EnumDeviceStorageType,
          { path           : STRING,
            nextCommand    : EnumNextCommandMode,
            }
        ) : StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit); the name must be written in lower case and placed inside single quotation marks (e.g. 'st_unit1').

If '_device' is specified, a data set for global device variables will be checked (possible as of Version 3.2 of the SIMOTION Kernel).

id

Data type: UDINT

Number of the data set (max. 1_000_000 data sets per unit).

storageType

Data type: EnumDeviceStorageType

Location at which the data is stored.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        //  is retained if there is a power failure
    USER_STORAGE )
        // with path specification
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING

Default: ' ' (empty string)

Destination path, if storageType = USER_STORAGE.

Only the default value may be specified. Otherwise, an error message is output.

nextCommand (optional)

Data type: EnumNextCommandMode

Default: IMMEDIATELY

Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A *functionResult* : EnumDeviceUnitDataSetCommand component.
  This supplies information on errors and the current state.
- A *handle* : UDINT component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

For further information on data types StructRetUnitDataSetCommand and EnumDeviceUnit-DataSetCommand, see Section Return value of the _saveUnitDataSet (Page 1525) function.

For information about data backup, see "Data backup and data initialization from user program" (Page 1573).

_deleteAllUnitDataSets function

Description

All data sets containing stored values for the following variables are deleted.

- Backed-up non-retentive or retentive unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit)
- Backed-up non-retentive or retentive global device variables.
- Exported non-retentive or retentive unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit)

When calling this function in short form, all parameters (including all optional parameters) must be specified.

Declaration

```
_deleteAllUnitDataSets (
            unitName       : STRING,
            storageType    : EnumDeviceStorageType,
          { path           : STRING,
            nextCommand    : EnumNextCommandMode,
            }
        ) : StructRetUnitDataSetCommand
```

Input parameter

unitName

Data type: STRING

Name of the unit (e.g. ST source file, MCC unit); the name must be written in lower case and placed inside single quotation marks (e.g. 'st_unit1').

If '_device' is specified, all data sets for global device variables will be deleted (possible as of Version 3.2 of the SIMOTION Kernel).

storageType

Data type: EnumDeviceStorageType

Location from which the data set is to be deleted.

```
TYPE EnumDeviceStorageType : (
    TEMPORARY_STORAGE,
        // Temporary data storage (RAM disk),
        // is deleted if there is a power failure
    PERMANENT_STORAGE,
        // Permanent data storage (memory card),
        //  is retained if there is a power failure
    USER_STORAGE )
        // with path specification
        // (only default permissible)
END_TYPE
```

path (optional)

Data type: STRING

Default: ' ' (empty string)

Destination path, if storageType = USER_STORAGE.

Only the default value may be specified. Otherwise, an error message is output.

nextCommand (optional)

Data type: EnumNextCommandMode

Default: IMMEDIATELY

Advance to next command

```
TYPE EnumNextCommandMode : (
    IMMEDIATELY,
        // Immediately
    WHEN_COMMAND_DONE )
        // After completion or abort of the command
END_TYPE
```

Return value

Data type: StructRetUnitDataSetCommand

The return value is a structure of data type StructRetUnitDataSetCommand. It comprises the following:

- A *functionResult* : EnumDeviceUnitDataSetCommand component.
  This supplies information on errors and the current state.
- A *handle* : UDINT component.
  This provides the possibility, by means of the _getStateOfUnitDataSetCommand (Page 1536) function of checking the current state of a data backup function (especially useful with step enabling condition IMMEDIATELY).

For further information on data types StructRetUnitDataSetCommand and EnumDeviceUnit-DataSetCommand, see Section **Return value** of the _saveUnitDataSet (Page 1522) function.

For information about data backup, see "Data backup and data initialization from user program".

4.2.9.15 Functions for commandId

CommandID overview

Description

A CommandId is transferred every time a command is issued. This is saved on the command and represents a reference to the issued command.

A command is thus uniquely identifiable and traceable using the CommandId.

Note

If the CommandId is not assigned for the command call, the default value of the parameter takes effect with (0.0).

Further information

Further information can be found at Command execution diagnostics (Page 1239), Transition and step enabling conditions (Page 1233) and Using the commandId parameter correctly (Page 1680).

_getCommandId function

Description

This function supplies a project-wide unique commandId, which can be used for explicit identification of commands.

A commandId is always produced, there is no error feedback.

Declaration

```
_getCommandId ( ) : CommandIdType
```

Input parameters

None

Return value

Data type: CommandIdType

Project-wide unique CommandId for tracking the command status

```
TYPE
 CommandIdType : STRUCT
    SystemId_low        : UDINT;    // Lower-order part
    SystemId_high       : UDINT;    // Higher-order part
 END_STRUCT
END_TYPE
```

See also

Using the commandId parameter correctly (Page 1680)

_getSyncCommandId function

Description

This function supplies the user with a project-wide unique syncCommandId. This ID can be transferred to system functions BEGIN_SYNC and _startSyncCommands (see Parameter Manuals for SIMOTION devices) to start motion sequences synchronously.

A syncCommandId is always produced, there is no error feedback.

Declaration

```
_getSyncCommandId ( ) : CommandIdType
```

Input parameter

None

Return value

Data type: CommandIdType

Project-wide unique syncCommandId for tracking the command status.

```
TYPE
 CommandIdType : STRUCT
    SystemId_low        : UDINT;    // Lower-order part
    SystemId_high       : UDINT;    // Higher-order part
 END_STRUCT
END_TYPE
```

See also

Using the commandId parameter correctly (Page 1680)

4.2.9.16 Defining the waiting time

_waitTime function

Description

This function interrupts the task triggering this function until the time specified in the call has expired.

Note

The function should be used in MotionTasks only; using it in cyclic tasks may lead to time monitoring errors!

- With SynchronousTasks: You can configure whether the time watchdog is suspended. Time monitoring is active by default.
  With IPOsynchronousTask, additionally take the following into account: UserInterruptTasks will no longer be started by their triggering event!
- With other cyclic tasks (BackgroundTask, TimerInterruptTasks): Time monitoring is always active.

In cyclic tasks, use the system function blocks Timers (Page 1627) to implement wait times.

The _waitTime function is always executable, its return value = 0.

For information on how you can make a task wait for a certain time, see Making tasks wait a defined period (Page 1434).

Declaration

```
_waitTime (
        timeValue    : TIME    // Wait time
        ) : DINT               // Always = 0
```

Input parameter

timeValue

Data type: TIME

Indicates the time interval during which task processing is interrupted.

Return value

Data type: DINT

Is always 0.

See also

Time allocation in the round robin execution level (Page 1373)

Wait times in cyclic tasks (Page 1679)

4.2.9.17 Device-specific functions

_getDeviceId function

Description

The function reads the hardware ID of the SIMOTION device from its hardware information block. You specify the type of ID to be read as input parameter when calling the function.

Declaration

```
_getDeviceId (
              idType : EnumDeviceIdType
             ) : StructRetGetDeviceId
```

Input parameter

idType

Data type: EnumDeviceIdType

Specification of the ID to be read

```
TYPE EnumDeviceIdType : (
    SERIAL_NUMBER ,    // CPU serial number
    HW_TYPE ,          // Module type
    SPECIFIC_NUMBER ,  // Special OEM number
    ORDER_ID )         // Order number of the module
END_TYPE
```

Return value

Data type: StructRetGetDeviceId

The return value is a structure of data type StructRetGetDeviceId. It comprises the following:

- A *functionResult* component: DINT.
  This provides information on errors.
- An *id* component: STRING[254]
  This contains the read hardware ID of the memory card.

```
TYPE
  StructRetGetDeviceId : STRUCT
    functionResult : UDINT; // Error status
        // 16#00000000 : No error
        // 16#FFFF80C3 : Information not available
        // 16#FFFF8090 : Incorrect transfer parameter
        // 16#FFFF8099 : Internal error
    id : STRING[254];       // Read-out hardware ID
  END_STRUCT;
END_TYPE
```

_getMemoryCardId function

Description

The function reads the hardware ID of a memory card from its hardware information block. You specify the type of ID to be read as input parameter when calling the function (at present only serial number possible).

Declaration

```
_getMemoryCardId (
                  idType : EnumMemoryCardIdType
                 ) : StructRetGetMemoryCardId
```

Input parameter

idType

Data type: EnumMemoryCardIdType

Specification of the ID to be read

```
TYPE EnumMemoryCardIdType : (
    MEMORY_CARD_SERIAL_NUMBER ) // Memory card serial number
END_TYPE
```

Return value

Data type: StructRetGetMemoryCardId

The return value is a structure of data type StructRetGetMemoryCardId. It comprises the following:

- A *functionResult* component: DINT.
  This provides information on errors.
- An *id* component: STRING[254]
  This contains the read hardware ID of the memory card.

```
TYPE
  StructRetGetMemoryCardId : STRUCT
    functionResult : UDINT; // Error status
        // 16#0000_0000 : No error
        // 16#FFFF_FFFD : Internal error
        // 16#FFFF_FFF8 : Incorrect parameter
    id : STRING[254];       // Read-out hardware ID
  END_STRUCT;
END_TYPE
```

Note

Any leading "S" in the memory card serial number will be ignored and not returned in the return value. For determining the license key in the Web License Manager, it is irrelevant whether or not the serial number is specified with a leading "S".

_setDeviceErrorLED function

Description

The function sets the **Underlicensing of technology/option objects** error on the SIMOTION device. The corresponding LED flashes in red on the SIMOTION device (see Manual of the SIMOTION device).

Declaration

```
_setDeviceErrorLED ( ) : DINT
```

Input parameter

None

Return value

Data type:	DINT
16#0000_0000	No error
16#FFFF_FFFD	Internal error

_setDriveObjectSTW function

Description

The _setDriveObjectSTW system function can be used to set individual bits of the CU_STW control word for drive object 1 (DO1) of the drive unit. This control word is part of the manufacturer-specific PROFIdrive telegrams 390 ff (telegrams 39x) for the control unit of the drive unit.

No bits can be set that have been reserved for the communication between the SIMOTION device and the drive unit or for other purposes.

This function is available in the SIMOTION device as of version V4.1 SP2.

Declaration

```
_setDriveObjectSTW (
            logAddress  : DINT;
            STW1BitMask : UINT;
            STW1BitSet  : UINT
           ) : DINT
```

Input parameter

logAddress

Data type DINT

Logical base address of the send telegram for the drive object.

STW1BitMask

Data type UNIT

Bit mask for selecting the affected bits in the CU_STW control word of the send telegram.

Bits that are operated autonomously in the connection to the drive object of SIMOTION (e.g. for the synchronization, fault handling, etc.) cannot be accessed by this function (see the table below for the assignment and reservation of the bits in the CU_STW).

Bits that can be accessed via the function: 16#007E = 2#0000_0000_0111_1110.

STW1BitSet

Data type UNIT

Bit-coded value for writing in the CU_STW control word of the send telegram. Only those bits selected via STW1BitMask are written.

Return value

Data type: DINT

The return value informs the user about the result of the call.

16#0000_0000	Request successfully completed • Bits have been written in the control word • Bits in STW1 were already in the defined state
16#FFFF_8090	Job aborted Logical address is not available
16#FFFF_8091	Job aborted Addressed drive object does not support the function
16#FFFF_8093	Job aborted STW1BitMask contains bits blocked for the function
16#FFFF_809F	Job aborted Internal error, function cannot be executed, e.g. function called on SIMOTION devices of version V4.1 or V4.1 SP1

Bit assignment and reservation in CU_STW of the 39x telegrams

Bit	Name	Meaning	Access right
12-15	MLZ	Dyn. master sign-of-life	SIMOTION FW
11	-	Reserved - system	Reserved
10	DAG	Demand from AG	SIMOTION FW
9	-	Reserved - system	Reserved
8	-	Reserved - system	Reserved
7	FACK	Fault acknowledge	_resetDriveObjectFault

Bit	Name	Meaning	Access right
6	-		_setDriveObjectSTW
5	-		_setDriveObjectSTW
4	-		_setDriveObjectSTW
3	-		_setDriveObjectSTW
2	-		_setDriveObjectSTW
1	PING	Start pulse for time synchronization	_setDriveObjectSTW
0	SYN	Dyn. synchronization flag for system time cycle	SIMOTION FW

4.2.9.18 Determine the memory size of a variable or of a data type

_sizeOf function

Description

The function returns the memory size in bytes required for a variable or data type:

- By default, the return value is determined at the time of compilation. The function can then be used in constant expressions (e.g. during initialization).
- Exception - only as of Version 4.2 of the SIMOTION kernel:
  In the case of an ARRAY with a dynamic length (i.e. the index limits are not declared), the return value is determined during runtime.

Declaration

```
_sizeOf (
         in  : ANY  // Identifier of the data type or
                    // of the variables
         )   : DINT
```

Input parameter

in

Data type: ANY

Identifier of the variable or data type, whose size is to be determined.

Return value

Data type: DINT

Required memory size in bytes.

The memory size is specified taking account of the natural layout, i.e. in accordance with the assignment possibilities of the data types in the memory. Therefore, the effective size is determined, which is required for the use of the data type in an ARRAY.

The actual required size may be less.

Example

```
TYPE
    a_type  : STRUCT
        a   : LREAL;    // 8 bytes
        b   : BOOL;     // 1 byte
    END_STRUCT;
END_TYPE
//...
x := _sizeOf (in := a_type);    // Returns value 16
```

_firstIndexOf function

Description

This function returns the lower index limit for an ARRAY (variable or data type):

- In the case of an ARRAY with a defined length (i.e. the index limits are declared), the return value is determined at the time of compilation. The function can then be used in constant expressions (e.g. during initialization).
- Only as of Version V4.2 of the SIMOTION kernel:
  In the case of an ARRAY with a dynamic length (i.e. the index limits are not declared), the return value is determined during runtime.

Note

The function must not be used for variables of the STRING data type or directly on this data type. The function then returns the value 1.

Declaration

```
_firstIndexOf (
        in  : ARRAY [..] OF ANY  // Identifier of the ARRAY
                                 // (Data type or variable)
        )   : DINT
```

Input parameter

in

Data type: ARRAY [..] OF ANY

Identifier for the ARRAY (variable or data type) whose lower index limit is to be determined

Return value

Data type: DINT

Lower index limit

Example

```
TYPE
    array_1  : ARRAY [5..29] OF DINT;
    string_1 : STRING[80];
END_TYPE
// ...
x := _firstIndexOf (in := array_1);      // Returns value 5
y := _firstIndexOf (in := string_1);     // Returns value 1
```

_lastIndexOf function

Description

This function returns the upper index limit for an ARRAY (variable or data type):

- In the case of an ARRAY with a defined length (i.e. the index limits are declared), the return value is determined at the time of compilation. The function can then be used in constant expressions (e.g. during initialization).
- Only as of Version V4.2 of the SIMOTION kernel:
  In the case of an ARRAY with a dynamic length (i.e. the index limits are not declared), the return value is determined during runtime.

Note

The function must not be used for variables of the STRING data type or directly on this data type. The function then returns the last index permitted for indexed access (**not** the currently assigned length of the string).

Declaration

```
_lastIndexOf (
        in  : ARRAY [..] OF ANY  // Identifier of the ARRAY
                                 // (Data type or variable)
        )   : DINT
```

Input parameter

in

Data type: ARRAY [..] OF ANY

Identifier for the ARRAY (variable or data type) whose upper index limit is to be determined

Return value

Data type: DINT

Upper index limit.

Example

```
TYPE
    array_1  : ARRAY [5..29] OF DINT;
    string_1 : STRING[80];
END_TYPE
// ...
x := _lastIndexOf (in := array_1);      // Returns value 29
y := _lastIndexOf (in := string_1);     // Returns value 80
```

_lengthIndexOf function

Description

This function returns the number of array elements for an ARRAY (variable or data type):

- In the case of an ARRAY with a defined length (i.e. the index limits are declared), the return value is determined at the time of compilation. The function can then be used in constant expressions (e.g. during initialization).
- Only as of Version V4.2 of the SIMOTION kernel:
  In the case of an ARRAY with a dynamic length (i.e. the index limits are not declared), the return value is determined during runtime.

Note

The function must not be used for variables of the STRING data type or directly on this data type. The function returns the usable length of the string (identical with the return value of the _lastIndexOf function.

Declaration

```
_lengthIndexOf (
        in  : ARRAY [..] OF ANY  // Identifier of the ARRAY
                                 // (Data type or variable)
        )   : DINT
```

Input parameter

in

Data type: ARRAY [..] OF ANY

Identifier of the ARRAY (variable or data type) for which the number of array elements is to be determined

Return value

Data type: DINT

Number of array elements

The following applies:
_lengthIndexOf (*array name*) := _lastIndexOf (*array name*) - _firstIndexOf (*array name*) +1

Example

```
TYPE
    array_1 : ARRAY [5..29] OF DINT;
END_TYPE
// ...
x := _lengthIndexOf (in := array_1);      // Returns value 25
```

LOWER_BOUND function

Description

This function returns the lower index limit for an ARRAY (variable or data type):

- In the case of an ARRAY with a defined length (i.e. the index limits are declared), the return value is determined at the time of compilation. The function can then be used in constant expressions (e.g. during initialization).
- Only as of Version V4.2 of the SIMOTION kernel:
  In the case of an ARRAY with a dynamic length (i.e. the index limits are not declared), the return value is determined during runtime.

To use this function, you must activate the "Permit language extensions IEC61131-3rd Edition" compiler option, see SIMOTION ST Programming and Operating Manual.

Note

The function must not be used for variables of the STRING data type or directly on this data type. The function then returns the value 1.

Declaration

```
LOWER_BOUND (
        arr   : ARRAY [..] OF ANY  // Identifier of the ARRAY
                                   // (Data type or variable)
        { dim : UDINT          // ARRAY dimension
        }                      // (Only constant value 1 permitted)
        )     : DINT
```

Input parameter

arr

Data type: ARRAY [..] OF ANY

Identifier for the ARRAY (variable or data type) whose lower index limit is to be determined

dim (optional)

Data type: UDINT

Default setting: 1

ARRAY dimension (only constant value 1 permitted)

It may be specified only when a variable was passed in *arr*.

Return value

Data type: DINT

Lower index limit

Example

```
TYPE
    array_1  : ARRAY [5..29] OF DINT;
    string_1 : STRING[80];
END_TYPE
// ...
x := LOWER_BOUND (arr := array_1);      // Returns value 5
y := LOWER_BOUND (arr := string_1);     // Returns value 1
```

UPPER_BOUND function

Description

This function returns the upper index limit for an ARRAY (variable or data type):

- In the case of an ARRAY with a defined length (i.e. the index limits are declared), the return value is determined at the time of compilation. The function can then be used in constant expressions (e.g. during initialization).
- Only as of Version V4.2 of the SIMOTION kernel:
  In the case of an ARRAY with a dynamic length (i.e. the index limits are not declared), the return value is determined during runtime.

To use this function, you must activate the "Permit language extensions IEC61131-3rd Edition" compiler option, see SIMOTION ST Programming and Operating Manual.

Note

The function must not be used for variables of the STRING data type or directly on this data type. The function then returns the last index permitted for indexed access (**not** the currently assigned length of the string).

Declaration

```
UPPER_BOUND (
        arr   : ARRAY [..] OF ANY  // Identifier of the ARRAY
                                   // (Data type or variable)
        { dim : UDINT          // ARRAY dimension
        }                      // (Only constant value 1 permitted)
        )     : DINT
```

Input parameter

arr

Data type: ARRAY [..] OF ANY

Identifier for the ARRAY (variable or data type) whose upper index limit is to be determined

dim (optional)
Data type: UDINT
Default setting: 1
ARRAY dimension (only constant value 1 permitted)
It may be specified only when a variable was passed in *arr*.

Return value

Data type: DINT
Upper index limit.

Example

```
TYPE
    array_1  : ARRAY [5..29] OF DINT;
    string_1 : STRING[80];
END_TYPE
// ...
x := UPPER_BOUND (arr := array_1);      // Returns value 29
y := UPPER_BOUND (arr := string_1);     // Returns value 80
```

4.2.9.19 Determination of the logical address for an I/O variable

Function _getLogicalAdressOfIoVariable

Description

The function determines the start address of an I/O variable for direct access or process image of the cyclical tasks.

This function is especially useful if a symbolic assignment of the I/O variables to the addresses (Page 1197) is performed. Some functionalities, such as the evaluation of alarms or TSI, require the knowledge of the logical address for an I/O variable in advance.

When using the function, the standard rules for using I/O variables apply.

Note

Every change in the address list for I/O (e.g. changes to the I/O addresses, new I/O variables) requires a recompilation of all program sources which contain this function.

Declaration

```
_getLogicalAddressOfIoVariable (
                in : <IO_VARIABLE> // Identifier of an I/O variable
            ) : DINT
```

Input parameter

in

Data type: <IO_VARIABLE>

Identifier of an I/O variable for direct access or the process image of the cyclical tasks. The I/O variable must be defined in the address list of the detail view.

With arrays of I/O variables, the specification of a constant index is permitted.

Return value

Data type: DINT

Logical start address of the I/O variable. It is returned in the following value ranges:

- For I/O variables for inputs: 16#0000 .. 16#FFFF
- For I/O variables for outputs: 16#7000_0000 .. 16#7000_FFFF

4.2.9.20 Copy areas of arrays

_ArrayCopy function

Description

The function copies an area of an array (copy source) to any location of another array of the same base data type (copy target). This area is specified by:

- Specification of the area length to be copied (number of array elements to be copied)
- Optional specification of the area start to be copied within the copy source.
- Optional specification of the area start to be written within the copy target.

The base data type of the copy source and the copy target must be identical; the index specifications may, however, differ. For information about the base data type and the index specification: see SIMOTION ST Programming and Operating Manual.

The copy target may also be identical with the copy source; the correct copy sequence of the array elements is selected automatically.

Note

If the area to be copied or written lies completely or partially outside the array limits of the copy source or copy target, the following applies: The array limits determine the maximum number of copied array elements.

If the compiler already determines that no array elements are copied (return value = 0), a warning will be issued.

The function can be interrupted by other tasks. The consistency of the copy target so cannot be guaranteed.

Declaration

```
_ArrayCopy (
        Dest   : ARRAY [..] OF ANY  // Copy target
        Source : ARRAY [..] OF ANY  // Copy source
        Length : DINT    // Number of array elements to be copied
        { DestIndex   : DINT  // Start of the area to be written
          SourceIndex : DINT  // Start of the area to be copied
         }
         )     : DINT
```

In-out parameter

Dest

Data type: ARRAY [..] OF ANY

Copy target.

Array into which the area is to be copied.

The copy source and the copy target must be arrays of the same base data type, although they can have different index specifications. For information about the base data type and the index specification: see SIMOTION ST Programming and Operating Manual.

Source

Data type: ARRAY [..] OF ANY

Copy source.

Array from which the area is to be copied.

The copy source and the copy target must be arrays of the same base data type, although they can have different index specifications. For information about the base data type and the index specification: see SIMOTION ST Programming and Operating Manual.

Input parameter

Length

Data type: DINT

Length of the area to be copied (number of array elements to be copied)

DestIndex (optional)

Data type: DINT

Default setting: 0

Start of the area within the copy target into which the copied array elements are written (index of the copy target into which the first copied array element is written).

The value must lie within the declared array limits of the copy target.

SourceIndex (optional)

Data type: DINT

Default setting: 0

Start of the area to be copied within the copy source (index of the first copied array).

The value must lie within the declared array limits of the copy source.

Return value

Data type: DINT

Number of copied array elements

For a successful and error-free execution of the function, the return value represents the length of the area to be copied.

Example

```
VAR
    src_array  : ARRAY [6..36] OF DINT;
    dest_array : ARRAY [0..25] OF DINT;
    copy_length : DINT := 15;
END_VAR
// ...
ret := _ArrayCopy (
        Dest        := dest_array,
        Source      := src_array,
        Length      := copy_length,
        DestIndex   := 20,
        SourceIndex := 10);
IF ret = copy_length THEN
    ; // Copy successful
ELSE
    ; // Error handling
END_IF;
```

4.2.9.21 Display the intermediate results for "program status"

_trcVal function

Description

The function extends the display options for the "Program status" (Page 4949) diagnostic function for the SIMOTION ST programming language

By default, the program status shows only the values for simple variables of elementary data types. The intermediate results of formulas can also be displayed with the _trcVal function. To do this, pass the expression to be displayed as actual parameter to the _trcVal function.

The "Program status" display window shows the return value for each _trcVal function call in the form: "`_TRCVAL = ...`".

Note

If the _trcVal function is used for variables that cannot be displayed in the "Program status" (e.g. no simple variable), the compiler issues an error message.

The function cannot be used for enumerations.

For information about the "Program status" diagnostic function, see SIMOTION ST Programming and Operating Manual (Page 4951).

Declaration

```
_trcVal (
        in  : ANY_ELEMENTARY
        )   : ANY_ELEMENTARY
```

Input parameter

in

Data type: ANY_ELEMENTARY

The expression to be displayed in the "Program status".

Return value

Data type: ANY_ELEMENTARY

The same data type as the *in* input parameter.

Example

In the following example, the intermediate results from the calculation of the distance between two points in the Cartesian coordinate system are displayed in the "Program status".

```
VAR
    Distance,
    x_koord0, x_koord1,
    y_koord0, y_koord1,
    z_koord0, z_koord1 : LREAL;
END_VAR
// ...
Distance := SQRT (_trcVal (_trcVal (x_koord1 - x_koord0)**2) +
                  _trcVal (_trcVal (y_koord1 - y_koord0)**2) +
                  _trcVal (_trcVal (z_koord1 - z_koord0)**2));
```

The function return value is displayed six times in the form "`_TRCVAL = ...`" in the "program status". The sequence of the display corresponds to the sequence of occurrence in the _trcVal function in the formula.

4.2.9.22 Creating general references

REF function

Description

The function returns the reference for a variable (address information). This can, for example, be assigned to a variable declared as reference to the data type of the passed actual parameter (REF_TO).

Note

Note for instances of function blocks passed as in/out parameter (VAR_IN_OUT):

- The REF function cannot be used for static variables (VAR) of function blocks imported from technology packages or device-independent libraries.

The restriction does not apply to class instances.

To use this function, you must activate the "Permit object-oriented programming" compiler option, see SIMOTION ST Programming and Operating Manual.

Declaration

```
REF (
    in  : ANY
    )   : REF_TO ANY
```

Input parameter

in

Data type: ANY

The variable for which the reference should be formed

The following are permitted:

- Retentive and non-retentive unit variables or instances of classes or function blocks or their elements declared as such.
- In methods within classes or function blocks:
  - Static variables (VAR) of the higher-level class or function block (including instance variables for classes or function blocks).
  - The THIS keyword. It permits access to the instance variable of the higher-level class or function block.
- In function blocks:
  - Static variables (VAR) of the function block (including instance variables of classes or function blocks).
  - The THIS keyword. Permits access to the instance variable of the function block.

The variable must be able to be read and written.

Not permitted are:

- Variables of technology object data types
- Variables of object-oriented interfaces
- Variables of general references
- Retentive local variables within classes or function blocks
- I/O variables
- Global device variables
- Constants

Return value

Data type: REF_TO ANY

Reference to the variable.

The data type is "Reference to the data type of the input parameter *in*".

4.2.9.23 Additional available system functions

In SIMOTION additional system functions are available that are introduced, for example, by the SIMOTION devices and technology objects. The following table lists provides an overview of where these functions are described.

Table 4-103 Overview of additional system functions and system function blocks in SIMOTION ST

System function	Description
System functions of technology objects	SIMOTION Cam Technology Package, System Functions List Manual (reference list) SIMOTION TControl Technology Package List Manual (reference list) Additionally see the function manuals on the technology objects
System functions of SIMOTION devices	List Manual of the SIMOTION devices (reference list)
System functions for controlling axes in accordance with the PLCopen standard	SIMOTION Cam Technology Package, System Functions List Manual (reference list)
Standard functions for controlling I/O modules and drive components	List Manual for the corresponding I/O module and drive component (reference list)

4.2.9.24 Application of certain system functions

Programming messages

General

You can use the following functions to program messages, e.g. error messages, or check their status:

- _alarmSId (generation of a message without acknowledgment)
- _alarmSqId (generation of a message with acknowledgment)
- _alarmScId (query about message status)

However the prerequisite is an application-specific configured message name.

Note

You can use the *_writeAndSendMessage* function to make user-defined entries in the diagnostic buffer. For a description of this function, refer to the List Manuals for SIMOTION devices.

See also General information for the message programming (Page 1452).

Overview of the functions

The functions described here can be used in libraries.

During each call, **_alarmSId** generates a **message that does not require acknowledgment**. The message is triggered according to a signal and an associated value can be appended to it. The message is transferred to all display devices registered for this purpose.

During each call, **_alarmSqId** generates a **message that requires acknowledgment**. The message is triggered according to a signal and an associated value can be appended to it. The message is transferred to all display devices registered for this purpose and can be acknowledged at these devices.

Note

No display device registered

If no display device is registered, the acknowledgment status of an Alarm_SQ is not reset when there is a new "incoming" message from the same alarm instance.

In this status, an Alarm_SQ is no longer displayed by the _getPendingAlarms() function.

Therefore, use _alarmScId() to read the status of the message.

You use the following as input signals for the functions:

1. The signal that triggered the message:
   This is interpreted as follows:
   - If the signal represents a rising edge – relative to the last call with this message name – an incoming message is generated. An incoming message is also generated if the signal state is TRUE on the first call with this message name.
   - If the signal represents a falling edge – relative to the last call with this message name – an outgoing message is generated.
2. The message to be compiled:
   It is specified via a unique, project-wide AlarmId (Page 1453).
3. Optional associated values provided they have been specified in the message configuration.
   - Independent of the SIMOTON kernel version:
     One associated value of the general data type ANY_NUM or ANY_BIT possible
   - As of version V4.5 of the SIMOTION kernel:
     A maximum of 12 associated values of BYTE (or SINT, USINT) data type is possible; they are passed in an ARRAY [0..11] OF BYTE.
     Associated values with data types that comprise several bytes (e.g. WORD, DINT, REAL) are possible; they reduce the number of possible associated values. The user must ensure that their values are stored in the permissible array elements in accordance with the Big Endian byte order. The AnyType_to_BigByteArray function can be used for this purpose.

The **_alarmScId** function queries the status of a message and its acknowledgment status. The relevant message is specified via a unique AlarmId (Page 1453).

For information about the formal structure of functions, see:

- _alarmSId function (Page 1453).
- _alarmSqId function (Page 1456).
- _alarmScId function (Page 1459).

For message names configured application-specifically, see online help.

Note

You should only generate an outgoing message after an incoming one, otherwise an error message is output.

The associated value (optional) must be a variable of an elementary data type. Avoid the use of constant values in the function call!

Buffer management of AlarmS

Description

A message list with 40 buffer areas is available for the AlarmS messages. Incoming messages are entered with their ID in this message list. For each outgoing message, an incoming message with the same ID must exist in the message list.

For each of the total 40 list entries there is also a send buffer. This send buffer is used to organize the notification of the registered client (HMI or SIMOTION SCOUT).

Message list and send buffer

Message list and send buffer are used as follows:

Return value		Meaning
Return values for incoming message (function call with rising edge *sig*)		
	16#8002	All entries in the message list are already occupied. Message entry is not made in the message list.
	16#8003	There is still an outgoing message with this ID in the message list and the send buffer is still occupied. Message entry is not made in the message list.
	16#8004	There is already an incoming message for this ID in the message list. Message entry is not made in the message list.
	16#0000	A message with this ID has not been found in the message list and the send buffer is no longer occupied. • ID of the message is entered in the message list. • The associated send buffer is occupied. • The system function returns with return value 16#0000. • The registered clients will be notified. • The send buffer is released again after the successful notification of the clients. • The ID of the message remains as incoming message in the message list.
Return values for outgoing message (function call with falling edge *sig*)		

Return value		Meaning
	16#8003	There is still an incoming message for this ID in the message list and the send buffer is still occupied. Message entry is not made in the message list.
	16#8004	There is already an outgoing message for this ID in the message list. Message entry is not made in the message list.
	16#8007	An incoming entry has not been found for the ID. Message entry is not made in the message list.
	16#0000	An incoming message for the ID has been found in the message list and the send buffer is no longer occupied. • The entry in the message list will be overwritten with the outgoing message. • The associated send buffer is occupied. • The system function returns with return value 16#0000. • The registered clients will be notified. • The send buffer is released again after the successful notification of the clients. • The entry in the message list will be deleted.

Example of message generation

The example in the table checks the temperature and generates an incoming message with one associated value which does not have to be acknowledged (e.g. *Temperature too high, incoming*), if the temperature is too high. If the temperature drops below the maximum value specified, an outgoing message is generated (the incoming message disappears).

The message named *SCOUT_alarm_name* has been configured in SIMOTION SCOUT, as for example: `Temperature too high: @1I%2d@ degrees.` A status variable prevents the same message from being repeated. The *handleAlarm* program is assigned to the BackgroundTask.

This example is independent of the SIMOTON kernel version.

Example of message generation

```
INTERFACE
  PROGRAM handleAlarm;
END_INTERFACE

IMPLEMENTATION
  PROGRAM handleAlarm
    VAR
      retVal         : DWORD;         // Return value
      temperature    : INT;           // Status to be queried
      maxTemperature : INT  := 60;    // Signal comparison value for status
      mySignal       : BOOL := FALSE; // Signal yes/no
    END_VAR
    //...
```

Example of message generation

```
    IF temperature > maxTemperature THEN
      IF mySignal = FALSE THEN
        // Incoming message, does not require acknowledgment
        retVal := _alarmSId (
            Sig   := TRUE,
            Ev_id := _alarm.SCOUT_alarm_name,
            sd    := temperature);
        mySignal := TRUE;
      END_IF;
    ELSE
      IF mySignal = TRUE THEN
        // Outgoing message, does not require acknowledgment
        retVal := _alarmSId (
            Sig   := FALSE,
            Ev_id := _alarm.SCOUT_alarm_name,
            sd    := temperature);
        mySignal := FALSE;
      END_IF;
    END_IF;
    //...
  END_PROGRAM
END_IMPLEMENTATION
```

Example of messages with several associated values (as of kernel V4.5)

As of version V4.5 of the SIMOTION kernel, several associated values can be specified for message configuring.

The _alarmSId (Page 1453) and _alarmSqId (Page 1456) functions are passed the associated value in an ARRAY FIELD [0..11] OF BYTE.

Associated values in the ARRAY [0..11] OF BYTE

The following table shows which array elements in the ARRAY [0..11] OF BYTE are assigned the associated value of a specific data type, as well as the addressing of the associated values in the message configuring.

The following applies to an associated value with a data type comprising several bytes:

- It must be stored in consecutive array elements. The first index must be divisible by the number of bytes assigned to the data type.
- It must be stored in the array with big endian byte order (most significant byte at low memory address). The AnyType_to_BigByteArray (Page 1492) function can be used for this purpose.

Table 4-104 Ordering of the associated values in the ARRAY [0..11] OF BYTE and access to the message configuring

Data type	Access to the associated values depending on the index of the byte array											
	[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]
BOOL	@1B...	@2B...	@3B...	@4B...	@5B...	@6B...	@7B...	@8B...	@9B...	@10B...	@11B...	@12B...
BYTE, USINT	@1Y...	@2Y...	@3Y...	@4Y...	@5Y...	@6Y...	@7Y...	@8Y...	@9Y...	@10Y...	@11Y...	@12Y...
WORD, UINT	@1W...		@2W...		@3W...		@4W...		@5W...		@6W...	

Data type	Access to the associated values depending on the index of the byte array											
	[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]
INT	@1I...		@2I...		@3I...		@4I...		@5I...		@6I...	
DWORD, UDINT	@1X...				@2X...				@3X...			
DINT	@1D...				@2D...				@3D...			
REAL	@1R...				@2R...				@3R...			
LREAL	@1O...											
Combination examples												
Example 1	@1W...		@3Y...	@4Y...	@2R...							
Example 2	@1X...				@3I...		@7Y...	@8Y...	@3R...			
Example 3	@1W...		@3Y...	@4Y...	@5Y...				@3R...			

For example, an associated value of the INT data type can be stored with indexes [4] and [5] in the array elements. During the message configuring, access is made to this associated value with `@3I...`, i.e. with the format code `%4d` (decimal number with at least 4 digits), the output of this associated value is configured with `@3I%4d@`.

Example

In the message configuring, a *SCOUT_alarm* message is configured with five associated values:

- One associated value of DWORD data type
- One associated value of INT data type
- Two associated values of BYTE data type
- One associated value of REAL data type

The associated values are placed in ARRAY [0..11] OF BYTE passed to the _alarmSId (Page 1453) and _alarmSqId (Page 1456) functions in accordance with combination example 2 in the above table. The message text can, for example, be configured as follows:

```
Value 1 @1X%6X@, value 2 @3I%5d@, value 3 @7Y%2X@, value 4 @8Y%2X@,
value 5 @3R%8.2f@
```

The following program example shows how the associated values are written in big endian byte order in an ARRAY [0..11] OF BYTE and passed to the _alarmS function. For information about big endian byte ordering, see Converting between any data types and byte arrays (marshalling) (Page 1593).

Table 4-105 Example of message programming with several associated values

```
PROGRAM alarm_example
  VAR
    alarm_array : ARRAY [0..11] OF BYTE;
    value_1     : DWORD := 100;
    value_2     : INT   := -10;
    value_3     : BYTE  := 1;
    value_4     : BYTE  := 2;
    value_5     : REAL  := 3.14;
    ret_val     : DWORD;
  END_VAR
```

```
  alarm_array := AnyType_to_BigByteArray (anydata := value_1, offset := 0);
  alarm_array := AnyType_to_BigByteArray (anydata := value_2, offset := 4);
  alarm_array := AnyType_to_BigByteArray (anydata := value_3, offset := 6);
  alarm_array := AnyType_to_BigByteArray (anydata := value_4, offset := 7);
  alarm_array := AnyType_to_BigByteArray (anydata := value_5, offset := 8);
  // Incoming message
  ret_val := _alarmSId (Sig   := TRUE,
                        Ev_id := _alarm.SCOUT_alarm,
                        sd    := alarm_array);
END_PROGRAM
```

Checking the error number and status of a message (filtering return values)

_alarmSId and _alarmSqId functions

The return value of the _alarmSId (Page 1453) and _alarmSqId (Page 1456) functions contains the error number and thus indicates whether an error occurred during execution. As with most system functions, return value = 0 indicates error-free execution.

_alarmScId function

However, the return value of the _alarmScId (Page 1459) function indicates both the error number and the status of a message. Therefore, proceed as follows when checking the status with these functions:

1. First, filter the return value with the constant ALARMS_ERROR (= 16#8000).
   This enables you to determine whether an error occurred while the function was being executed. The filter and the error numbers are selected such that they are true when combined in an AND operation.
2. If no error has occurred, you can evaluate the status of the message.

You can find a complete listing of error numbers and message states in the description of the _alarmScId function (Page 1459).

Consequently, you can check for errors when the *_alarmScId function* is called (the retVal (Page 1459) variable of data type DWORD contains the return value of the function) as follows:

Example of error and status check with the _alarmScId function

```
retVal := _alarmScId (Ev_id := _alarm.SCOUT_alarm_name);
// Error check here
IF (retVal AND ALARMS_ERROR) <> 0 THEN
    // Condition satisfied, therefore an error has occurred.
    // Error number check
    IF retVal = (ALARMS_ERROR OR
        DSC_SVS_DEVICE_ALARMS_ILLEGAL_EVENT_ID) THEN
        ; // Message number not permitted.
    END_IF;
ELSE
    // Condition not satisfied, therefore no error has occurred.
    // Check of the message and acknowledgment state
    IF retVal = 16#0000 THEN
        ; // Outgoing message, not acknowledged
    ELSIF retVal = ALARMS_STATE THEN
        ; // Incoming message, not acknowledged
    ELSIF retVal = 16#0010 THEN
        ; // Message not available
    ELSIF retVal = (ALARMS_QSTATE OR ALARMS_STATE) THEN
       ; // Incoming message, acknowledged
    END_IF;
    //...
END_IF;
```

Note

You can use constant values and symbolic constants on an equal footing to check for errors, see _alarmScId function (Page 1459).

Consistent reading and writing of variables (semaphores)

Consistent data access

All accesses to variables of elementary data types (see Section *Elementary data types*) are managed consistently by the system. The system ensures that these variables do not change while you are processing them.

When accessing **global** variables of derived data types (see Section *User-defined data types (UDT)*), the user is responsible for ensuring data consistency when multiple tasks access the same variables (symbolic I/O variables, system variables of SIMOTION devices, system variables of technology objects, global device variables and unit variables, see Section *Variable model*).

Access to **local** variables of derived data types are always consistent, since they can only be used inside the program (or function or function block) in which they are defined.

Note

Consistent data access is always ensured within a task.

Semaphores

To ensure consistent reading and writing of global variables, you work with semaphores.

A global variable (e.g. *semaA*) of data type DINT is used as a semaphore. If the variable is an element of an array, the index must be specified when compiling (e.g. a[2]).

Use the following functions to change and test the status of the semaphore:

- _testAndSetSemaphore (sema : DINT) : BOOL
  This function is used to check whether the semaphore is set:
  - Return value TRUE: The semaphore is enabled.
  - Return value FALSE: The semaphore is set.

  When the function is ended, the semaphore is always set. Additional calls of this function (even from other programs) return a value of FALSE, until the _releaseSemaphore (semaA) function is called.
- _releaseSemaphore (sema: DINT) : VOID

For information on the formal structure of functions, see Section *Working with variables*.

The semaphore is released.

Consistent data access to global variables is ensured under the following conditions:

1. All tasks signal access to global variables by setting a semaphore.
2. All the tasks only access global variables when the semaphore is released.

Example: Consistent data access with semaphores

The example in the table illustrates the use of semaphores in a program that reads data and a program that writes data.

Table 4-106 Example for ensuring consistent access to global variables using semaphores

```
IMPLEMENTATION
    VAR_GLOBAL
        myArray : ARRAY [0..1] OF DINT;
        semaA : DINT;
    END_VAR

    PROGRAM Writer
        // Consistent writing of variables
        IF _testAndSetSemaphore(sema := semaA) THEN
            myArray[0] := 18;
            myArray[1] := 19;
            _releaseSemaphore(sema := semaA);
            // The semaphore must be released in the TRUE
            // branch of the query; this ensures that
            // it is only released when it has been
            // reset.
        ELSE
            ; // Error handling
        END_IF;
        // _releaseSemaphore(sema := semaA);
        // The release would be incorrect at this point;
        // the semaphore would always be released.
    END_PROGRAM
    PROGRAM Reader
        VAR
            var0        : DINT;
            var1        : DINT;
        END_VAR

        // Consistent reading of variables
        IF _testAndSetSemaphore(sema := semaA) THEN
            var0 := myArray[0];
            var1 := myArray[1];
            _releaseSemaphore(sema := semaA);
            // The semaphore must be released in the TRUE
            // branch of the query; this ensures that
            // it is only released when it has been
            // reset.
        ELSE
            ; // Error handling
        END_IF;
        // _releaseSemaphore(sema := semaA);
        // The release would be incorrect at this point;
        // the semaphore would always be released.
    END_PROGRAM

END_IMPLEMENTATION
```

Data backup and initialization from user program

Data backup and data initialization from user program - functions and instructions

From a user program, it is possible to save, load, or initialize the values of the following variables in data sets:

- Non-retentive or retentive unit variables of the interface or implementation section of a unit (e.g. ST source file, MCC unit).
- Non-retentive or retentive global device variables.

Various functions are available for this:

- _saveUnitDataSet (Page 1522): The values are stored as a binary data set.
- _loadUnitDataSet (Page 1526): The values are loaded from a binary data set saved with *_saveUnitDataSet*.
  Loading the data set is only possible if since saving the data set the version IDs of all data segments to be loaded have remained unchanged.
  Please also pay attention to the note below.
- _exportUnitDataSet (Page 1528): The values are exported in XML format as ZIP archive (file name *.dat).
- _importUnitDataSet (Page 1531): The values are imported from a data set that was exported in XML format as ZIP archive (file name *.dat) with *_exportUnitDataSet*.
  Importing the data set is also possible if, since the data set was saved, the version ID of a data segment to be loaded has changed:
  - Variables that no longer exist are ignored.
  - The value of added variables remains unchanged.
    You can, for example, initialize the relevant data segments with *_resetUnitData* before importing a data set to avoid unwanted values in variables.
  - In the case of a variable with a changed data type, the value is transferred if it can be converted to the new data type; otherwise the value of the variable is retained.
- _deleteUnitDataSet (Page 1534): A single data set is deleted.
- _checkExistingUnitDataSet (Page 1537): A check determines whether the specified data set exists on the storage medium.
- _deleteAllUnitDataSets (Page 1539): All data sets are deleted.
- _resetUnitData: The values of the variables are initialized, see *System Functions of Devices* List Manual.

For data segments and their version ID, see Section "Version ID of global variables and their initialization during download" in the Programming Manuals, e.g. SIMOTION ST.

The description for *_resetUnitData* can be found in the List Manual (reference list) for the system functions of the SIMOTION devices.

The input parameters (Page 1574) and the return value (Page 1575) of the functions are explained in detail in the following sections.

NOTICE
Data loss possible If the data structure of a data segment is changed in a unit or in the global device variables, the following applies to loading the project into the SIMOTION device: • All temporarily backed-up data sets are deleted. • None of the binary data sets that have been permanently saved (with *_saveUnitDataSet*) can be read for this data segment any longer.

Up to 16 data backups can run simultaneously on a device.

The number of data sets that can be saved - up to 1_000_000 - depends on the available memory space.

Pay attention to consistency of the data to be backed up or exported, see Consistent reading and writing of variables (semaphores) (Page 1570).

Note

You can upload data sets saved with *_saveUnitDataSet* or *_exportUnitDataSet* from the SIMOTION device. Use the **Save variables** function in SIMOTION SCOUT. The data sets saved with *_saveUnitDataSet* are automatically converted to XML format.

You can use the **Restore variables** function to download these data sets and variables back to the SIMOTION device. For this purpose select the relevant SIMOTION device in the project navigator and select the function from the context menu. For more information, refer to the SIMOTION SCOUT Configuration Manual.

This makes it possible, for example, to obtain the data saved with *_saveUnitDataSet*, even if it is initialized by a project download or if it becomes unusable (e.g. due to a SIMOTION version change).

Input parameters

The most important parameters are briefly outlined below. For a more detailed description of the individual functions and their parameters, refer to Backing up data from the user program (Page 1522).

- *unitName*: Name of the unit (e.g. ST source file, MCC unit)
  If '*_device*' is specified, the data backup function is applied to global device variables (possible with _saveUnitDataSet).
- *id*: Data set number
  Specifying a data set number as an index enables several versions of the unit variables to be saved and then downloaded selectively.
  id < 1_000_000

- *storageType*: Specifying the storage location allows you to select the following:
  - TEMPORARY_STORAGE: Data is saved to the RAM disk (deleted after a power failure).
  - PERMANENT_STORAGE: Data is saved to a memory card (and retained after a power failure).

  Note also the additional information on the Storage location and memory requirement (Page 1576).
- *nextCommand*: Step enabling condition
  Specifying the step enabling conditions enables you to select from the following options:
  - Execute next command in the ST source file immediately (IMMEDIATELY).
  - Wait until command is done (WHEN_COMMAND_DONE).

  Note also the additional information on the Step enabling condition (Page 1577).
- *dataScope*
  It enables the section of the unit to which the data backup function is applied to be selected.
  - _INTERFACE: Function is applied to the interface section of a unit.
  - _IMPLEMENTATION: Function is applied to the implementation section of a unit.
  - _INTERFACE_AND_IMPLEMENTATION: Function is applied to the interface and implementation section of a unit.

  If *unitName* = '*_device*' is specified, only the values _INTERFACE or _INTERFACE_AND_IMPLEMENTATION are permissible for *dataScope*.
- *kindOfData*:
  It permits selection of whether the data backup function will be applied to retentive or retentive global variables.
  - NO_RETAIN_GLOBAL: Function is applied to non-retentive global variables.
  - _RETAIN: Function is applied to retentive global variables.
  - ALL_GLOBAL: Function is applied to retentive and non-retentive global variables.

  If retentive and non-retentive variables are stored in a data set, it is possible to load or import retentive or non-retentive variables selectively.

Return value

The return value is a structure of data type *StructRetUnitDataSetCommand*. It comprises the following:

- A *functionResult* component: *EnumDeviceUnitDataSetCommand*
  This supplies information on errors and the current status.
- A *handle* component: UDINT
  This allows you to check the current status of a data backup function by means of the *_getStateOfUnitDataSetCommand* function (this is required for step enabling condition IMMEDIATELY).

Storage location and memory requirement

You define the storage location with input parameter *storageType*:

- TEMPORARY_STORAGE: Data sets are saved to the RAM disk.
- PERMANENT_STORAGE: Data sets are saved to the Memory Card (under \USER\SIMOTION \USER_DIR\).

The number of data sets that can be saved depends on the available memory space at the respective memory location. Information on the available memory space can be obtained by means of the Device diagnostics, **System utilization** tab (see online help).

Note

Do not fill the entire available memory space with data sets! Otherwise, it will no longer be possible to download a project to the target system or copy RAM to ROM if project data is increased!

You can estimate the required memory space for binary data sets (saved with _saveUnitDataSet (Page 1522)) with the following information:

- Elementary data types occupy their natural data width on the memory (see Table *Bit widths and value ranges of the elementary data types* in Chapter *Elementary data types*; data type BOOL occupies 1 byte).
- Additional memory space is required due to:
  - Adaptation of the memory addresses to word or double-word boundaries
  - Consistency information (approx. 100 bytes per data set)
  - Usual supplementary data of a file system (e.g. sector headers, directory, occupy whole sectors only)

For data sets exported in XML format (with _exportUnitDataSet (Page 1528)), the memory requirement is much higher and cannot be ascertained in this way.

Step enabling condition

General information

The step enabling condition is indicated in input parameter *nextCommand*.

- **Synchronous call**
  The function is called with parameter *nextCommand* := WHEN_COMMAND_DONE. The next command in the program source when the function has been completed.
  The return value contains the result of the executed function in its *functionResult* component (see example).
  This procedure is mainly used in sequential tasks (e.g. MotionTasks).
- **Asynchronous call**
  The execution of this function may take quite a long time. Therefore, the time watchdog might respond in connection with cyclic tasks (e.g. BackgroundTask).
  For this reason, the function can also be executed asynchronously by setting parameter *nextCommand* := IMMEDIATELY. In this case, the function is started, and then the next command in the source is immediately processed.
  From the return value you can see:
  - If the start was successful (component *functionResult* = DONE)
  - A handle for further status query (*handle* component)

  If the command start was successful, you must check the current status of the data backup function using the _getStateOfUnitDataSetCommand (Page 1536) function and the handle until the result is something other than ACTIVE (see example).

Example of a synchronous call (in sequential tasks)

The data backup function _loadUnitDataSet (Page 1526) is called with the step enabling condition WHEN_COMMAND_DONE.

```
VAR_GLOBAL
    ds_ret : StructRetUnitDataSetCommand;
    error  : BOOL := FALSE;
END_VAR

PROGRAM save_data_seq
    // Program is assigned to a sequential task.
    // Function is executed synchronously:
    ds_ret := _loadUnitDataSet (
            unitName := 'ds3',
            id := 1,
            storageType := TEMPORARY_STORAGE,
            nextCommand := WHEN_COMMAND_DONE);
    // Function completed, evaluate result
    IF (ds_ret.functionResult <> DONE) THEN
        error := TRUE;    // Fehler
    END_IF;
END_PROGRAM
```

Example of an asynchronous call (in cyclic tasks)

The data backup function _saveUnitDataSet (Page 1522) is called with the step enabling condition IMMEDIATELY. The _getStateOfUnitDataSetCommand (Page 1536) is then called until the _saveUnitDataSet function has been completed

```
VAR_GLOBAL
    error : BOOL := FALSE;
    ds_rslt      : EnumDeviceUnitDataSetCommand;
    ds_ret       : StructRetUnitDataSetCommand;
    cmd_busy     : BOOL := FALSE;
    cmd_done     : BOOL := FALSE;
END_VAR

PROGRAM save_data_cycl
    // Program is assigned to a cyclic task.
    IF NOT cmd_busy THEN
        cmd_busy := TRUE;
        // Function is executed asynchronously:
        ds_ret := _saveUnitDataSet (
                unitName := 'ds1',
                id := 1,
                storageType := TEMPORARY_STORAGE,
                overwrite   := TRUE,
                nextCommand := IMMEDIATELY);
        IF (ds_ret.functionResult <> DONE) THEN
            cmd_busy := FALSE;
            error := TRUE; // Start of the function has failed
            // (e.g. too many services)
        END_IF;
    ELSE
        // Function is running, wait for result:
        ds_rslt := _getStateOfUnitDataSetCommand (
                handle := ds_ret.handle);
        IF (ds_rslt <> ACTIVE) THEN
            cmd_busy := FALSE;
            IF (ds_rslt = DONE) THEN
                cmd_done := TRUE;
                // Function terminated successfully
            ELSE
                error := TRUE;
                // Function has failed
            END_IF;
        END_IF;
    END_IF;
END_PROGRAM
```

Accessing files from a user program (as of V4.4)

As of version 4.4 of the SIMOTION Kernel, the user can access the file system of the SIMOTION device via a program. The user can access the permanent storage medium (e.g. the memory card) or the temporary storage medium (e.g. the RAM disk) and read or write files. The user can also manage the files (e.g. copy, rename and delete).

The user can only use selected areas of the file system on the applicable storage medium so that SIMOTION function is not impaired. These areas are addressed by symbolic names.

The following sections describe how to:

- read or write files (Page 1579), and
- manage files (Page 1589).

Note

Memory cards are not designed to be rewritten an unlimited number of times. With this in mind, you should avoid writing user data from the application to the memory card cyclically. Depending on the system, a write operation from the application may trigger one or more write operations on the memory card. Therefore, we recommend you adopt a conservative approach in terms of the number of writing processes. In other words, do not perform more than 100,000 write access instances from the user program over the estimated service life of the application.

Never switch off a SIMOTION device during write accesses to the memory card. If the SIMOTION device is switched off during write accesses, this can result in destruction of the data and, in the worst case, damage the file system (FAT Table = table of contents) on the memory card.

Follow the instructions in the section "Recommended method of handling CF cards" in Commissioning and Hardware Installation Manual SIMOTION D4x5-2.

Reading and writing files from a user program (as of V4.4)

As of version 4.4 of the SIMOTION Kernel, it is possible to read and write files from a user program. These files can be on the permanent storage medium (e.g. memory card) or the temporary storage medium (e.g. RAM disk). The following function blocks are provided for this purpose. Their functionality and use is described below.

Brief description of function blocks

- _filehandle function block
  See the information about "Filehandle" in this section.
- _fileOpen function block
  This function block opens the file specified in the parameters STORAGETYPE, LOCATION and FILENAME and links them to the instance of the _filehandle function block transferred in the HANDLE parameter.
  For information about the STORAGETYPE, LOCATION and FILENAME parameters, see "General information about the storage locations of a file" in the following section (Page 1589).
  Specify using the OPENFILE parameter whether the file should only be opened with write authorization or with read and write authorization. A file can either be opened multiple times for read-only access or only once exclusively for read and write access.
  If a file that is not present is opened for read and write, it is created with a fixed length (as well as the path, if not present). The fixed length is specified in the FILESIZE parameter. If the file already exists under the specified path, this parameter is ignored.
  A maximum of five files can be opened at the same time.

- _fileSetPosition function block
  This function block determines the position within an open text file.
  This file is identified via the _filehandle function block instance transferred in the HANDLE parameter.
  The position is specified relative to the FILEPOSITION parameter (FILEPOSITIONOFFSET parameter).
- _fileRead function block
  This function block reads binary data from the current position of the open file and copies it to an ARRAY OF BYTE (BUFFER parameter).
  The file to be read is identified via the _filehandle function block instance transferred in the HANDLE parameter.
  The number of bytes to be read is specified in the DATALENGTH parameter. The BUFFERPOSITION parameter specifies the index of the ARRAY OF BYTE from which the data is copied into the array.
- _fileWrite function block
  This function block copies binary data from an ARRAY OF BYTE (BUFFER parameter) and writes it into the open file from the current position.
  The file to be written is identified via the _filehandle function block instance transferred in the HANDLE parameter.
  The number of bytes to be written is specified in the DATALENGTH parameter. The BUFFERPOSITION parameter specifies the index of the ARRAY OF BYTE from which the data is copied from the array.
- _fileReadLn function block
  This function block reads data from the current position up to the end of line (CR/LF - $0D$0A) from the open text file and copies it into a string (LINE parameter).
  The text file to be read is identified via the _filehandle function block instance transferred in the HANDLE parameter.
- _fileWriteLn function block
  This function block writes a string (LINE parameter) into the open text file from the current position and ends the line with CR/LF ($0D$0A).
  The text file to be written is identified via the _filehandle function block instance transferred in the HANDLE parameter.
  The written data is visible in the WRITTENLINE parameter.
- _fileClose function block
  This function closes the open file and releases the system resources.
  The file to be closed is identified via the _filehandle function block instance transferred in the HANDLE parameter.
  If the file was open for read and write access, potential changes are saved on the storage medium.

The syntax of these function blocks is described in detail in the "System Functions/Variables Devices" List Manual (reference list) and in the online help (see index).

Operation of the function blocks

The interfaces of the function blocks behave in accordance with the PLCopen specification "Technical Specification, Function blocks for motion control, Version 1.1".

The rules described in the "SIMOTION PLCopen Blocks" Function Manual in Chapter "General rules for the PLCopen FB interface" apply for the PLCopen function blocks.

The function blocks work asynchronously, i.e. after calling an instance of these function blocks, they are processed in the background.

1. They declare an instance of the function block, and class this instance in a program which is integrated into a cyclic task (e.g. BackgroundTask).
   As long as the value is set to FALSE in the EXECUTE input parameter, the instance of the function block is not executed.
2. A positive edge in the EXECUTE input parameter starts the function block. The BUSY output parameter is set to TRUE.
   As long as the job is being processed, then BUSY = TRUE. Further positive edges in the EXECUTE input parameter are then ignored and an instance of the function block can no longer be called.
   The instance of the function block is processed in the background.
3. When the job is finished, BUSY is set to FALSE.
   - If execution was successful, the DONE output parameter is set to TRUE.
   - If execution completed with errors, the ERROR output parameter is set to TRUE and the cause of error is displayed in the ERRORID output parameter.

   Only one of the three output parameters BUSY, DONE or ERROR can have the value TRUE at any one time.
4. A negative edge in the EXECUTE input parameter resets the DONE and ERROR output parameters to FALSE.
   If the negative edge occurs at EXECUTE while a job is active (BUSY = TRUE), the running job is not aborted. After the job has finished, the DONE or ERROR output parameters are, however, only in TRUE status for one cycle time.

The instances of the function blocks can also be called in sequential tasks (e.g. MotionTasks). However, the user must ensure the cyclic execution. Refer to the information in "Basic procedure for reading and writing files" later in this section.

Filehandle

Filehandle is an instance of the _filehandle function block. It is transferred to the function blocks for open, read, write and close, and identifies the file to be read or written uniquely. It provides the system resources to access the file system and its structure.

Calling an instance of the _fileOpen function block links the filehandle to a file in the file system The system resources are assigned.

The location at which the instance of the _filehandle function block has been declared determines its initialization behavior and therefore the life of the system resources. See also the section "Initialization of instances of function blocks (FBs)" in the SIMOTION ST Programming Manual.

The system resources are released again by closing the file with an instance of the _fileClose function block.

Note

- Accesses to the storage medium are buffered. For this reason, e.g. for write accesses, only once the file has been closed successfully with an instance of the _fileClose function block can it be ensured that the data have been written in full to the storage medium.
- If the instance of the _filehandle function block is declared as a static variable that is saved in the user memory of the task, the following applies:
  On transition to STOP mode, an existing job is processed first before the system resources are released. On rapid transition to RUN mode, it may therefore be the case that the system resources are still assigned.
  For information about variables in the user memory of the task, see section "Memory areas of the variable types" in the SIMOTION ST Programming Manual.

A separate call of an instance of the _filehandle function block provides information about the associated filehandle and the storage medium (available memory and number of open files).

The syntax of the _filehandle function block is described in detail in the "System Functions/ Variables Devices" List Manual (reference list) and in the online help (see index).

Basic procedure for reading and writing files

For an asynchronous call in a cyclic task (e.g. BackgroundTask)

The following basic procedure is recommended:

1. Declare instances of the _filehandle, _fileOpen and _fileClose function blocks and the other necessary function blocks.
2. Provide a start signal. For this purpose declare, e.g. a unit variable of data type BOOL with initialization value FALSE.
3. Call the instance of the _fileOpen function block first. Assign these values to the following parameters:
   - HANDLE: the instance of the _filehandle function block.
   - EXECUTE: the start signal.
   - STORAGETPYE, LOCATION and FILENAME: as per the file in the file system.
     See "General information about the storage locations of a file" in the next section (Page 1589).
   - OPENFILE: READONLY or READWRITE.
4. Call the required instances of the function blocks to read write or position. Assign these values to the following parameters:
   - HANDLE: the instance of the _filehandle function block.
   - EXECUTE: the DONE output parameter of the preceding instance.

5. Release the system resources. To do so, call the instance of the _fileClose function block. Assign these values to the following parameters:
   - HANDLE: the instance of the _filehandle function block.
   - EXECUTE: the DONE output parameter of the preceding instance.
6. Assign the program to a cyclic task in the execution system (e.g. BackgroundTask).
7. In RUN operating mode, assign the value TRUE to the start signal at the required time. Execution starts. The instances of the function block are processed sequentially in the background.

The following examples 1 and 2 explain this procedure.

For a synchronous call in a sequential task (e.g. MotionTask)

In order to use the function blocks in sequential tasks, proceed in a similar way as for asynchronous execution.

However, the user must ensure the cyclic execution, e.g through the following procedure:

1. Include each used instance of a function block in a loop (e.g. REPEAT ... END_REPEAT).
2. Also include a call of the system function _waitTime (Page 1543) with the parameter timeValue = T#0s in each of these loops.
   This ensures that the next MotionTask is executed. Also refer to information on "Cyclic MotionTasks" in Section "Time allocation in the round robin execution level" (Page 1373).
3. Use a suitable expression with the output parameters BUSY, DONE or ERROR as an abort condition for the loop.

Assign the program to a sequential task in the execution system (e.g. StartupTask, MotionTask).

This procedure is explained in the following example 3.

Examples

Example 1: Create file and write line (asynchronous call)

This example shows how to create a file and write a line in the file.

The program is called in a cyclic task (e.g. BackgroundTask). A positive edge at the bWrite variable starts execution.

```
INTERFACE
    PROGRAM WriteLineToFile;
    VAR_GLOBAL
        bWrite : BOOL := FALSE;
    END_VAR
END_INTERFACE

IMPLEMENTATION
  PROGRAM WriteLineToFile
    VAR
        myFilehandle    : _filehandle;
        myOpenFileFB    : _fileOpen;
        myWriteLnFileFB : _fileWriteLn;
        myCloseFileFB   : _fileClose;
    END_VAR

    myOpenFileFB (
        EXECUTE  := bWrite,
        STORAGETYPE := CARD,
        LOCATION := USERFILES,
        FILENAME := 'MyData/file_name.txt',
        OPENFILE := READWRITE,
        FILESIZE := 512,
        HANDLE   := myFilehandle);

    myWriteLnFileFB (
        EXECUTE := myOpenFileFB.DONE,
        LINE    := 'This is the text that is written.',
        HANDLE  := myFilehandle);

    myCloseFileFB (
        EXECUTE := myWriteLnFileFB.DONE,
        HANDLE  := myFilehandle);
  END_PROGRAM
END_IMPLEMENTATION
```

Example 2: Open file and read line (asynchronous call)

This example shows how to open an available file and read a line from a specific position.

The program is called in a cyclic task (e.g. BackgroundTask). A positive edge at the bRead variable starts execution.

```
INTERFACE
    PROGRAM ReadLineFromFile;
    VAR_GLOBAL
        bRead : BOOL := FALSE;
    END_VAR
END_INTERFACE

IMPLEMENTATION
  PROGRAM ReadLineFromFile
    VAR
        myFilehandle   : _filehandle;
        myOpenFileFB   : _fileOpen;
        myReadLnFileFB : _fileReadLn;
        mySetFilePosFB : _fileSetPosition;
        myCloseFileFB  : _fileClose;
        lineBuffer     : STRING[254];
    END_VAR

    myOpenFileFB (
        EXECUTE  := bRead,
        STORAGETYPE := CARD,
        LOCATION := USERFILES,
        FILENAME := 'MyData/file_name.txt',
        HANDLE   := myFilehandle);

    mySetFilePosFB (
        EXECUTE := myOpenFileFB.DONE,
        FILEPOSITION := BEGINNING_OF_FILE,
        FILEPOSITIONOFFSET := 12,
        HANDLE  := myFilehandle);

    myReadLnFileFB (
        EXECUTE := mySetFilePosFB.DONE,
        HANDLE  := myFilehandle,
        LINE    => lineBuffer);

    myCloseFileFB (
        EXECUTE := myReadLnFileFB.DONE,
        HANDLE  := myFilehandle);
  END_PROGRAM
END_IMPLEMENTATION
```

Example 3: Create file and write lines (synchronous call)

This example shows how to create a file and write some lines in the file.

The program is called in a sequential task (e.g. StartupTask, MotionTask). A positive edge at the bWrite variable starts execution.

```
INTERFACE
    PROGRAM writeFile_From_MotionTask;
    VAR_GLOBAL
        bWrite : BOOL := FALSE;
    END_VAR
END_INTERFACE

IMPLEMENTATION
  FUNCTION_BLOCK write

Managing files from a user program (as of V4.4)

Files can be managed from a user program (e.g. copy, rename and delete) as of version 4.4 of the SIMOTION Kernel. The files can be on the permanent storage medium (e.g. memory card) or the temporary storage medium (e.g. RAM disk). The following function blocks are provided for this purpose. Their functionality and use is described below.

Brief description of function blocks

- _fileCopy function block
  This function block creates a copy of a file.
  The file to be copied is specified by the SOURCESTORAGETYPE, SOURCELOCATION and SOURCEFILENAME parameters.
  The copy destination is specified by the DESTINATIONSTORAGETYPE, DESTINATIONLOCATION and DESTINATIONFILENAME parameters.
- _fileRename function block
  This function block renames a file inside a directory.
  The file to be renamed is specified by the STORAGETYPE, LOCATION and FILENAME parameters.
  Enter the new file name in the NEWFILENAME parameter without specifying the path.
- _fileDelete function block
  This function block deletes a file from a folder.
  The file to be deleted is specified by the STORAGETYPE, LOCATION and FILENAME parameters.
  The file must not be open. If necessary, the _fileClose function block must be used first.
- _directoryPathDelete function block
  This function block deletes a folder including all sub-folders and their contents.
  The folder to be deleted is specified by the STORAGETYPE, LOCATION and DIRECTORYPATHNAME parameters.
- _getStateOfFile function block
  This function block provides status information about a file or a folder (e.g. size and modified date).
  The file or the folder is specified by the STORAGETYPE, LOCATION and FILENAME parameters.

The syntax of these function blocks is described in detail in the "System Functions/Variables Devices" List Manual (reference list) and in the online help (see index).

General information about the storage locations of a file

For the above function blocks and the _fileOpen (Page 1579) function block, a file is specified in the file system via three entries and the associated parameters.

1. The storage medium (e.g. STORAGETYPE parameter).
   The following values are permissible:
   - RAMDISK: temporary, non-retentive storage medium, e.g. RAM disk.
   - CARD: permanent storage medium, e.g. memory card.

   Note

   Files that have been created using the above function blocks or the _fileOpen function block on the temporary storage medium (e.g. RAM disk) are not copied to the permanent storage medium (e.g. memory card) using the "Copy RAM to ROM" SIMOTION SCOUT function.

2. The location on the storage medium (e.g. LOCATION parameter).
   The files are stored in the selected folders on the storage medium. These folders are selected via symbolic names. This ensures that the SIMOTION functions are not affected.
   The following values (symbolic names) are permitted:
   - USERFILES
     Corresponds to path: '\USER\SIMOTION\HMI\USERFILES'
   - USERLOG
     Corresponds to path: '\USER\SIMOTION\HMI\USERLOG'
   - USERDATASETS
     Corresponds to path: '\USER\SIMOTION\USER_DIR\UPP\UNITDS'
     All data and sub-folders in this folder are deleted when the following SIMOTION SCOUT function is used: "Delete user data on card" when the unit data sets checkbox is activated.
   - USERWEB
     Corresponds to path: '\USER\SIMOTION\HMI\FILES'
   - USERTEMP
     Corresponds to path: '\USER\SIMOTION\USER_DIR\USERTEMP'
     All data and sub-folders in this folder are deleted when the following SIMOTION SCOUT function is used: "Delete user data on card"

   Any folder structure can be created beneath the specified folder.

3. The path and the file name (e.g. FILENAME parameter)
   This allows files to be accessed in any folder tree beneath the folders selected using LOCATION.
   Permissible characters for file name and path:
   - All displayable characters from the ASCII character set are permitted as name of the file and sub-folders, except the following symbols:
     '"'($22), '*'($2A), '/'($2F), ':'($3A), '<'($3C), '>'($3E), '?'($3F), '\'($5C), '|'($7C).
   - The following symbols may be used as separator between the folder name and file name:
     '/'($2F), '\'($5C).

Operation of the function blocks

The function blocks are designed for asynchronous calls.

For information about this functionality, see the previous section (Page 1579).

Basic procedure to manage files

The following basic procedure is recommended:

1. Declare instances of the required function blocks.
2. Provide a start signal. For this purpose declare, e.g. a unit variable of data type BOOL with initialization value FALSE.
3. Call the required instances of the function blocks sequentially. Assign the following values to the EXECUTE parameter:
   - For the first instance: the start signal.
   - For the subsequent instances: the DONE output parameter of the preceding instance in each case.
4. Assign the program to a cyclic task in the execution system (e.g. BackgroundTask).
5. In RUN operating mode, assign the value TRUE to the start signal at the required time. Execution starts. The instances of the function block are processed sequentially in the background.

Example

This example demonstrates the following file management operations:

1. Rename a file
2. Copy the file from the permanent storage medium (e.g. memory card) to the temporary storage medium (e.g. RAM disk)
3. Delete the original file from the permanent storage medium

The program is called in a cyclic task. A positive edge at the bStart variable starts execution.

```
INTERFACE
    PROGRAM fileSystemOperation;
    VAR_GLOBAL
        bStart : BOOL := FALSE;
    END_VAR
END_INTERFACE

IMPLEMENTATION
  PROGRAM fileSystemOperation
    VAR
        myDeleteFileFB     : _fileDelete;
        myRenameFileFB     : _fileRename;
        myCopyFileFB       : _fileCopy;
        myGetStateOfFileFB : _getStateOfFile;
    END_VAR

    myRenameFileFB (
            EXECUTE  := bStart,
            STORAGETYPE := CARD,
            LOCATION := USERFILES,
            FILENAME := 'MyData/file_name.txt',
            NEWFILENAME := 'new_name.txt');

    myCopyFileFB (
            EXECUTE := myRenameFileFB.DONE,
            SOURCESTORAGETYPE := CARD,
            SOURCELOCATION    := USERFILES,
            SOURCEFILENAME    := 'MyData/file_name.txt',
            DESTINATIONSTORAGETYPE := RAMDISK,
            DESTINATIONLOCATION    := USERFILES,
            DESTINATIONFILENAME    := 'MyTemplates/file.txt');

    myGetStateOfFileFB (
            EXECUTE  := myRenameFileFB.DONE,
            STORAGETYPE := CARD,
            LOCATION := USERFILES,
            FILENAME := 'MyData/new_name.txt');

    IF myGetStateOfFileFB.FILEEXISTING = YES THEN
        myDeleteFileFB (
                EXECUTE  := myGetStateOfFileFB.DONE,
                STORAGETYPE := CARD,
                LOCATION := USERFILES,
                FILENAME := 'MyData/new_name.txt');
    END_IF;
  END_PROGRAM
END_IMPLEMENTATION
```

Converting between any data types and byte arrays (marshalling)

Conversion of variables of any data type to byte arrays, and vice versa, is frequently used to create defined transmission formats for data exchange between different devices (see also section Communication functions (Page 1596)).

Variables of any data type (elementary data types, standard data types of technology packages and devices, and user-defined data types) can be converted to byte arrays, and vice versa, using the following functions:

- AnyType_to_BigByteArray (Page 1492)
- AnyType_to_LittleByteArray (Page 1492)
- BigByteArray_to_AnyType (Page 1494)
- LittleByteArray_to_AnyType (Page 1494)

For all functions, an offset can be specified optionally for the first element to be assigned or evaluated in the byte array.

A distinction is made as to:

- Conversion direction (to or from byte arrays)
- Byte order in the array (see table):
  - Big endian: Most significant byte at low memory address (Motorola, SUN Sparc, SIMATIC S7)
  - Little endian: Least significant byte at low memory address (Intel, DEC Alpha)

Table 4-107 Examples of byte order (big endian and little endian)

Address	Number 34677374 = 16#2_11_22_7E (data type UDINT)		Character string "Byte" (data type DWORD)	
	Big endian	Little endian	Big endian	Little endian
2#...11	16#7E = 126	16#02 = 2	16#65 = "e"	16#42 = "B"
2#...10	16#22 = 34	16#11 = 17	16#74 = "t"	16#79 = "y"
2#...01	16#11 = 17	16#22 = 34	16#79 = "y"	16#74 = "t"
2#...00	16#02 = 2	16#7E = 126	16#42 = "B"	16#65 = "e"

Note

TO data types cannot be converted. See section “Conversion of technology object data types” (Page 1503) for conversion of TO data types.

If structures and arrays are to be converted, consistency is guaranteed only at the elementary variable level. Any higher level of consistency must be ensured by the user (see the following sections:

- "Consistent reading and writing of variables (semaphores)" (Page 1570) and
- Consistent access to global variables of derived data types (UDT) (Page 1512).

The following data types are not portable convertible, i.e their transmission formats are not defined across systems. Conversions between SIMOTION devices are possible without any restrictions:

- Time types: For transmission format, see Table
- Enumerators (enumeration data types)

When converting these data types, the compiler outputs a warning (16013).

Table 4-108 Transmission formats of time data types for marshalling functions

Data type	Transmission format
TIME	Time specification, in ms (UDINT)
TIME_OF_DAY (TOD)	Time of day starting with TOD#0:0:0 in ms (UDINT)
DATE	Number of days since DATE#1992_01_01 (UDINT). DATE#1992_01_01 corresponds to 1
DATE_AND_TIME (DT)	Summary of TOD and DATE in the order specified.

Note

The marshalling function result may cause errors when the program is running, the error response set in the task configuration will then be triggered, see Execution errors in programs (Page 1256).

Proceed with caution when converting byte arrays to the general ANY_REAL data type or to structures that contain this data type. The bit string from the byte array is taken unchecked as the ANY_REAL value. You must make sure that the bit string of the byte array corresponds to the bit pattern of a normalized floating-point number in accordance with IEEE 754. To do this, you can use the _finite (Page 1503) and _isNaN (Page 1504) functions or the IS_VALID (Page 1505) function.

Otherwise, an error can be triggered (FPU exception (Page 1257)) as soon as the ANY_REAL value is first used for an arithmetic operation (for example, in the program or when monitoring in the symbol browser).

Table 4-109 Example of marshalling function use

```

Communication functions

Available functions

ST provides the following functions for communication over non-configured connections:

- _Xsend, see Parameter description for _Xsend (Page 1597)
- _GetStateOfXCommand, see Parameter description for _GetStateOfXCommand (Page 1599)
- _Xreceive, see Parameter description for _Xreceive (Page 1599)
- _tcpsend, see Communication via Ethernet with TCP/IP protocol (Page 1603)
- _tcpreceive
- _udpsend, see Communication via Ethernet with UDP protocol (Page 1604)
- _udpreceive

These communication functions are used to send and receive data:

- Between SIMOTION devices
- Between SIMOTION and SIMATIC S7 devices
  (S7-300, S7-400, M7-300, M7-400, etc.).
- Via acyclic communication; see also Acyclic communication with the drive (Page 1604).

The dual functions **_Xsend** and **_Xreceive** enable transparent transmission of data packets that are sent coordinately by the user program of the client and received coordinately by the user program of the server.

Further information

Additional information is also available in the **Communication System/Configuration Manual** or in Acyclic communication with the drive (Page 1604).

The program on the receiving device recognizes whether it is the data packet to be received on the basis of a user-definable integer appended to the data packet. The data exchange is only successful if the user program accepts and does not reject the data packet.

The sent data is in the form of byte sequences in an array, i.e. the data has no logical structure. SIMOTION devices can send or receive up to 200 bytes at once; the actual user data length depends on the communication peer.

You can check the status of an XSend or XReceive request with the **_GetStateOfXCommand** command.

Parameter description for _Xsend

The _Xsend function sends a data packet with transparent data to a communication peer. For the detailed syntax of the parameters, refer to the List Manual for the SIMOTION devices.

An overview is provided below:

- You can choose between two communication modes (*communicationMode* parameter): The connection is or is not retained after the data transmission.
- The *address* parameter specifies the destination address of the communications peer. The parameter is of data type *StructXSendDestAddr*. The following table lists the meaning of the individual components.

Table 4-111 Structure of destination address

Parameter (data type)	Meaning/values	Values	
deviceId (USINT)	Point of the connection	SIMOTION C230-2, C240, C240 PN	**1** for X8 **2** for X9
		SIMOTION P350, P350-3	**1** for X101 **2** for X102
		SIMOTION D410 DP	**1** for X21
		SIMOTION D410-2 DP	**2** for X21 **1** for X24
		SIMOTION D410-2 DP/PN	**2** for X21
		SIMOTION D4x5, D4x5-2	**1** for X126 **2** for X136
remoteSubnetIdLength (USINT)	Length of the subnet dialog box	**0** for MPI, PROFIBUS	
remoteStaddrLength (USINT)	Length of the station address (station number) of the destination system.	**1** for MPI, PROFIBUS	
nextStaddrLength (USINT)	Length of the router address	**0** for MPI, PROFIBUS	
remoteSubnetId (ARRAY [0..5] OF USINT)	Subnet mask	(Irrelevant for MPI, PROFIBUS)	
remoteStaddr (ARRAY [0..5] OF USINT)	Station address of the target system (actual destination address)	Station number for MPI, PROFIBUS, e.g. remoteStaddr[0] = 25	
nextStaddr (ARRAY [0..5] OF USINT)	Router address	(Irrelevant for MPI, PROFIBUS)	

Additional parameters of the _Xsend function are:

- The receiver identifies the data packet from the **job identifier** (*messageId* parameter) that you append to the data packet.
- You can select between two **modes of data transmission** (*nextCommand* parameter): synchronous or asynchronous.
  - During synchronous data transmission, the program waits until the receiver acknowledges receipt of the data packet before resuming execution. This happens automatically on receipt of the data packet.
  - During asynchronous data transmission, the program is resumed immediately after the command is issued. You can check the status of the command with *_GetStateOfXCommand*
- The mandatory **CommandId** parameter is used for internal command detection in ST. The parameter value should be saved to a local variable (data type *CommandIdType*) with the _getCommandId (Page 1541) function. This variable can be used as a parameter value.
- The **data packet** (*data* parameter) involves a list containing 200 entries of 1 byte each. The list does not have to be this long if the amount of data you are sending is less than the maximum.

- The **data length** (*dataLength* parameter) is used to specify the actual length of the data packet to be transmitted.
- You can determine whether the command was successfully executed (return value = 0) on the basis of the **return value**.
  If a return value other than 0 is returned, an error has occurred (see the command syntax in the List Manual for the SIMOTION devices).

Parameter description for _Xreceive

The *_Xreceive* function is used to receive transparent data sent by a communication peer with *_Xsend*.

Below is a brief overview of the function parameters (see also the section on system functions in the List Manual for the SIMOTION devices):

- You identify the anticipated data packet from the **job identifier** (*messageId* parameter) appended by the sender.
- As when sending data, you can choose between two **modes of data reception** (*nextCommand* parameter): synchronous or asynchronous.
  - During synchronous data receipt, the program waits until the data packet has arrived before it resumes execution. Receipt of the data packet is then acknowledged automatically to the sender.
  - During asynchronous data transmission, the program is resumed immediately after the command is issued. You can check the status of the commands with *_GetStateOfXCommand*.
- The mandatory **CommandId** parameter is used for internal command detection in ST. The parameter value should be saved to a local variable (data type *CommandIdType*) with the _getCommandId (Page 1541) function. This variable can be used as a parameter value.
- The **return value** is a structure:
  - You can determine whether the command was successfully executed (functionResult = 0) on the basis of the *functionResult* element.
    If a value other than 0 is returned, an error has occurred (see the command syntax in the List Manual for the SIMOTION devices).
  - The *dataLength* element represents the data length of the data packet received.
  - The *data* element represents the data packet received (array of up to 200 entries of one byte each).

Parameter description for _GetStateOfXCommand

You can check the status of an *_Xsend* or *_Xreceive* command with the _GetStateOfXCommand function.

Below is a brief overview of function parameters (see also documentation for the technology functions):

- The status query can tell which command is involved by the mandatory *commandId* parameter uniquely assigned to each send and receive function (see information about this parameter for *_Xsend* and *_Xreceive* above).
- The return value consists of an error number (zero when command execution is okay, otherwise greater than zero) and the status of the command being checked (see command syntax in the system functions for the SIMOTION devices).

Communication between SIMOTION and SIMATIC S7 devices

You must consider the following for communication between SIMOTION and SIMATIC S7 devices:

- Communication is only possible with *_Xsend* and *_Xreceive*.
- The maximum volume of data that can be transmitted in one packet is limited to 76 bytes. If you transmit larger data packets, an error message is output.
- The SIMOTION interface must be connected to the **MPI interface** of the SIMATIC S7 devices. The baud rate on the SIMOTION interface must be set to correspond to the baud rate of the SIMATIC S7device. For example, the baud rate for an SIMATIC S7-300 must be configured to 187.5 Kbits/s (see documentation for the relevant SIMATIC S7 devices).

Note

The parameters for the *_Xsend* and *_Xreceive* commands have different names in the SIMOTION system are in some cases have a different meaning than those you used in your previous SIMATIC S7 system. You will find a comparison in the following tables.
The *_GetStateOfXCommand* command does not exist in an SIMATIC S7 system, thus eliminating the need for comparison.

Table 4-112 Comparison of the parameters for _Xsend in SIMATIC S7 and SIMOTION devices

SIMATIC S7 device (parameters for SFC 65 X_SEND)	SIMOTION device (parameters for _Xsend)
REQ (Request to activate, data type BOOL)	– (Not available)
DEST_ID (MPI station number of the communications peer)	address (Destination address of the communication peer as a structure of data type StructXSendDestAddr)
CONT (Keep connected, Boolean value TRUE or FALSE)	communicationMode (Keep connected, enum. value M_TRUE or M_FALSE)
– (Not available)	nextCommand (Data transmission mode, enum values for synchronous and asynchronous)
REQ_ID (Job identifier, value of data type DWORD)	messageId (Job identifier, value of data type UDINT)

SIMATIC S7 device (parameters for SFC 65 X_SEND)	SIMOTION device (parameters for _Xsend)
SD (Variable address for sent data, value of data type ANY pointer, max. 76 bytes long)	data (Data packet to be sent, one-dim. array with max. 200 values of data type USINT)
– (Not available)	dataLength (Data length of data packet to be sent in bytes, value of data type UDINT)
– (Not available)	commandId (Internal command identifier, see description in parameter description above)
BUSY (Activation status, values of data type BOOL)	– (Not available)
<Return value> (= 0, if no error occurred; <> 0, if error occurred; see SIMATIC S7 documentation)	<Return value, (= 0, if no error occurred; <> 0, if error occurred; see Parameter Manual for the SIMOTION devices)

Table 4-113 Comparison of the parameters for _Xreceive in SIMATIC S7 and SIMOTION devices

SIMATIC S7 device (parameters for SFC 66 X_RCV)	SIMOTION device (parameters for _Xreceive)
EN_DT (Enable Data Transfer, data type BOOL)	– (Not available)
REQ_ID (Job identifier, value of data type DWORD)	messageId (Job identifier, value of data type UDINT)
– (Not available)	nextCommand (Data transmission mode, enum values for synchronous and asynchronous)
– (Not available)	commandId (Internal command identifier, see description in parameter description above)
RD (variable address for received data, value of data type ANY pointer, max. 76 bytes long)	<Return value, data structure element> (Received data packet; an array of up to 200 entries of 1 byte each)
– (Not available)	<Return value, dataLength structure element> (Data length of received data package)
<Return value> (= 0, if no error occurred; <> 0, if error occurred; see SIMATIC S7 documentation)	<Return value, functionResult structure element> (= 0, if no error occurred; <> 0, if error occurred; see Parameter Manual for the SIMOTION devices)

Example of send and receive program

The following figures show the source text for the send and receive program.

Table 4-114 Example of send program

```

Communication via Ethernet with TCP/IP protocol

For SIMOTION devices with Ethernet interface, communication via the TCP/IP protocol is also possible.

The following table lists the individual steps to establish communication between a sender (client) and a receiver (server):

Table 4-116 Communication steps of a TCP/IP connection and the corresponding system functions

Communication steps		System function
Establish the connection		
1	Receiver (server) waits for communication request.	_tcpOpenServer
2	Sender (client) requests connection establishment to the receiver.	_tcpOpenClient
3	Receiver (server) has established communication request.	
Communicating		
4	Sender sends data to the receiver.	_tcpSend
5	Receiver receives data from the sender.	_tcpReceive
Terminating communication connection		
6	Sender does not send any more data and closes the connection.	_tcpCloseConnection
7	There is no further connection required.	_tcpCloseServer

The system functions are described in detail in the List Manual for the SIMOTION devices, in the chapter on system functions.

Note

A sender or receiver can be a client as well as a server when establishing a connection.

There must be at least one client and one server to establish TCP/IP connection.

The client-server relationship is only valid until the connection is established. After connection is established, both communication peers are equivalent, i.e. each of the two can send or receive or close the connection at any point of time.

For detailed information, please refer to the *Frequently Asked Questions* (FAQs) on *SIMOTION Utilities & Applications* (DVD2 - CD_14).

Communication via Ethernet with UDP protocol

For SIMOTION devices with Ethernet interface, communication via the UDP protocol is also possible.

- The *_udpSend* function sends a data packet to a communication peer which is specified with IP address and port number.
  The data to be sent is transferred to the function as ARRAY [0..1399] OF BYTE.
- The *_udpReceive* function is used to receive a data packet which a communication peer has sent with *_udpSend*.
  The received data is stored in a variable of data type ARRAY [0..1399] OF BYTE, whose identifier is transferred to the function as parameter.

The system functions are described in detail in the Parameter Manual for the SIMOTION devices, in the chapter on system functions.

A detailed description is available in the FAQs on *SIMOTION Utilities & Applications* (DVD2 - CD_14).

Acyclic communication with the drive

Overview

PROFIdrive drive units are supplied with control signals and setpoints by the controller and return status signals and actual values. These signals are normally transferred cyclically (i.e. continuously) between the controller and the drive.

For SINAMICS S110/S120, configure the axis message frames for data exchange (see Setting up addresses and message frames - overview (Page 1211)).

As well as offering cyclic data exchange, PROFIdrive drive units have an acyclic communication channel. In particular, this is used for reading and writing drive parameters (e.g. error codes, warnings, controller parameters, motor data, etc.).

As a result, data can be transferred on an "acyclic" as opposed to a "cyclic" basis when required. Acyclic reading and writing of parameters for PROFIdrive drives is based on the DP V1 services "Read data set" and "Write data set".

The acyclic DP V1 services are transferred in parallel to the cyclic communication via PROFIBUS or PROFINET. The PROFIdrive profile specifies precisely how these basic mechanisms are used for read/write access to parameters of a PROFIdrive-compliant drive.

The PROFIdrive standard states that "pipelining" of jobs on PROFIdrive drives is not supported. This means:

- Only one "Write/read data set" can be performed at any one time on a drive unit (e.g. SINAMICS S110/S120 control unit or the SINAMICS Integrated of a SIMOTION D).
- However, if several PROFIdrive drive units are connected to a controller, a job can be processed for each of these drive units at the same time. In this case, the maximum total number of jobs will depend on the controller (maximum of eight jobs simultaneously with SIMOTION).

For acyclic data exchange with SINAMICS drives, this means you will have to coordinate the write/read jobs with each other (buffer management). An interlock must be set to prevent the application or different parts of the application from sending overlapping jobs to the same PROFIdrive drive unit.

Additional references

Additional information on how to use DP V1 services can be found in the *SIMOTION Communication* System Manual.

SIMOTION Utilities & Applications also has a DP V1 library with functions that are capable of performing coordination tasks commonly associated with acyclic communication. The library not only coordinates access to the system functions (_ReadRecord/_WriteRecord/_readDriveParameter/_writeDriveParameter/, etc.), but also expands the range of functions for frequently required tasks, e.g. the reading of faults and alarms from the drive unit.

SIMOTION Utilities & Applications is part of the scope of delivery of SIMOTION SCOUT.

The following functions are available in the DP V1 library:

- Buffer management (coordination of a number of parallel DP V1 services)
- StartUp (function for coordinating the power-up of the SINAMICS drive with SIMOTION)
- TimeSync (applicative time synchronization: Transfer of SIMOTION time of day to the SINAMICS drives)
- SetActIn (activating/deactivating objects in SIMOTION and SINAMICS)
- RwnPar (reading and writing of drive parameters)
- GetFault (reading errors and warnings from the drive)

Available functions (Page 1596)

Synchronous start

On synchronous start, several commands are started within an IPO cycle clock or IPO_2 cycle clock.

Follow these steps:

1. First, obtain a unique SyncCommandId from the system. You will need this SyncCommandId as a unique designation for the synchronized commands.
   For this purpose, use the _getSyncCommandId() system function.
2. Enclose the commands to be executed synchronously between the BEGIN_SYNC(SyncCommandId) and END_SYNC() functions. This defines them for synchronized start.
   All motion commands are permissible within the structure BEGIN_SYNC/END_SYNC. The value IMMEDIATELY must be transferred as the nextCommand parameter.
3. The synchronous start itself occurs with the _startSyncCommand (SyncCommandId) function. The commands defined for the synchronized start are processed in parallel.

See sample program.

Note

Synchronous start for motion commands is only ensured if the following conditions are satisfied:

1. Commands included in a synchronous start must act on various technology objects.
2. The technology objects involved must be in the same execution level (IPO or IPO_2).
3. When you use the Synchronous Start command in MCC, you must generate the UserInterruptTask_1 since this is called in the event of an error. You can program an error response in this task, see UserInterruptTasks (Page 1338).

The task controller is temporarily shut down during the synchronous start. It is not restarted until the following conditions are met:

- All single-axis commands and synchronous operation and cam commands in the branches have been started
- All basic commands in the branches have been completed

Start interruptions by other tasks (except SynchronousTasks) are thus prevented. This can cause a timeout to occur in cyclic tasks (BackgroundTask, TimerInterruptTasks). This error can be detected and caught by programming the TimeFaultBackgroundTask or TimeFaultTask appropriately.

The BEGIN_SYNC, END_SYNC, and *_startSyncCommand* functions are system functions of SIMOTION devices; for more information, refer to the parameter manual for the relevant SIMOTION device.

Note

Synchronous start is often used in conjunction with the WAITFORCONDITION construct. In this case, the system waits for a condition to be fulfilled before the synchronized start. The *_startSyncCommand* function must not occur within the WAITFORCONDITION construct.

Table 4-117 Sample program for synchronized start of two axes with WAITFORCONDITION

```
INTERFACE
    USEPACKAGE cam;
    PROGRAM sync_motion;
END_INTERFACE

IMPLEMENTATION

    EXPRESSION wait_sync_expression
        wait_sync_expression := TRUE;
    END_EXPRESSION

    PROGRAM sync_motion
        VAR
            ret_val : DINT;
            sync_id : CommandIdType;
        END_VAR

        sync_id := _getSyncCommandId();
        BEGIN_SYNC(sync_id);
        (* Positioning axis ('Pos') *)
        ret_val := _pos    (axis := Axis_1,
                    positioningMode := ABSOLUTE,
                    position := 100,
                    mergeMode := IMMEDIATELY,
                    nextCommand := IMMEDIATELY,
                    commandId := _getCommandId() );
        (* Positioning axis ('Pos') *)
        ret_val := _pos    (axis := Axis_2,
                    positioningMode := ABSOLUTE
                    position := 50
                    mergeMode := IMMEDIATELY
                    nextCommand := IMMEDIATELY,
                    commandId := _getCommandId() );
        END_SYNC();

        WAITFORCONDITION wait_sync_expression DO
            ;
        END_WAITFORCONDITION;

        ret_val := _startSyncCommands(sync_id);
        // Here in the event of an error Start of the UserInterruptTask
        IF (_ret_val <> 0) THEN
            _startTaskId(_task.UserInterruptTask_1);
        END_IF;

    END_PROGRAM
END_IMPLEMENTATION
```

To check the correct completion of the synchronous start, you can query whether the commands of the two axes started in the previous example have been completed without error.

The following MCC sample program shows a synchronous start with two axes and subsequent query of the group variable _MccRetSyncStart. This is not equal to 0 when a command within the synchronous start had a return value not equal to 0.

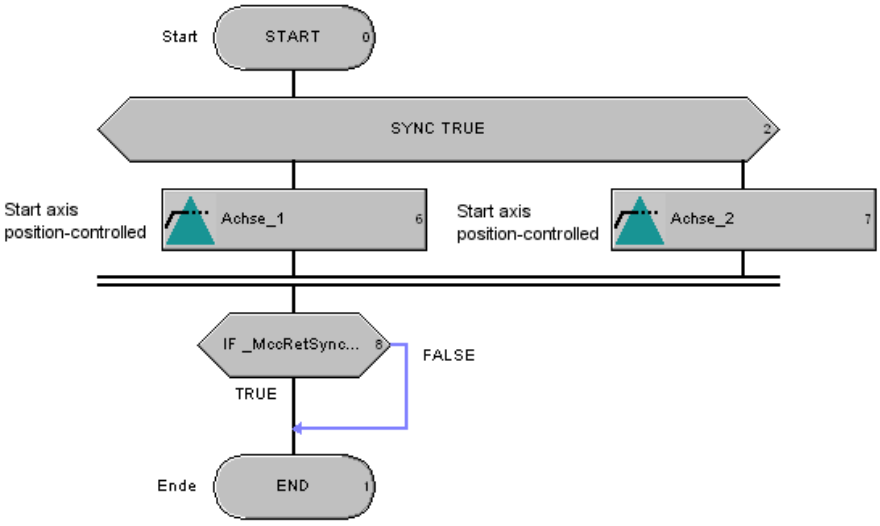

Figure 4-162 MCC synchronous start

The following is the section from the appropriate ST program (generated here via export from MCC unit)

Table 4-118 ST synchronous start

```
(* Synchronous start ('StartSync') *)
_MccCommand1 := _getCommandId();
_MccCommand2 := _getCommandId();

_MccSync := _getSyncCommandId();
BEGIN_SYNC(_MccSync);
    (* Start axis position-controlled ('Move') *)
    _MccRetDINT_1:=_move(axis:=Achse_1, velocityType:=DIRECT,
        velocity:=v_blue, moveTimeOutType:=WITHOUT_TIME_LIMIT,

(*  ('EndIf') *)
END_IF;
```

4.2.9.25 HMI (Human Machine Interface) connection

Interface between HMI and SCOUT or SIMOTION

SIMOTION allows communication with HMI devices (operator devices for the end user), e.g. with operator panels.

If one or more SIMOTION devices are connected on the PROFIBUS or PROFINET, the HMI device can display variables, messages and alarms of the SIMOTION devices. Likewise, you can initiate functions programmed using the HMI device and a program in the SIMOTION device.

The WinCC flexible software package is available for implementing such tasks on the HMI device. You can use WinCC flexible to read and write to system variables and unit variables declared in the interface section. See also HMI variables in one unit (Page 1690).

Note

If you would like to use a SIMOTION module as DP slave on an HMI, you must make the following settings in HW Config for the object properties of the relevant DP interface:

1. Select the **Operating mode** tab.
2. Select **DP Slave** as the setting.
3. Activate the Option **Programming, status/control or other PG functions and non-configured communication connection possible**.

SIMOTION also provides an OPC server. You can use this server to access process data with non-proprietary HMI software. The configuration software for WinCC flexible allows direct access to the symbolic variables of a SIMOTION device. Likewise, this is possible via OPC. For this purpose,

the configuration data of WinCC flexible must be located in the same project as the SIMOTION devices.

Note

- Variables that are meant to be available in HMI must always be created as unit variables in the interface section of a source.
- HMI tags can only be linked to SIMOTION variables of a simple data type (e.g. DINT). Other variables such as ANYOBJECT or configuration data cannot be linked.

Further information about WinCC flexible

Notes on the configuration with WinCC flexible can be found:

- In the online help for WinCC flexible
- In the online help for SCOUT when WinCC flexible is integrated in SCOUT

Further FAQs are also available online at:

http://support.automation.siemens.com/WW/view/en/28767398

http://support.automation.siemens.com/WW/view/en/23751257

Additional information on the topics below is available in the FAQs in SIMOTION Utilities & Applications:

- Time synchronization SIMOTION
- WinCC/WinCCFlexible
- SIMOTION and HMI (parallel work on SIMOTION and HMI projects)

Examples of HMI configurations can be found among the standard applications contained within the Applications section on SIMOTION Utilities & Applications.

- Examples of HMI implementation

See also HMI variables in one unit (Page 1690).

Alarms

Everything that is displayed in the alarm list in SCOUT can also be displayed in WinCC flexible with the appropriate configuration, except SINAMICS alarms!

All SIMOTION and SINAMICS alarms function with OPC Alarm&Event.

The present mechanism is as follows:

When the HMI project is generated, the SCOUT texts (axis names, axis alarms, Alarm_S, etc.) are synchronized with the HMI, whereby each technology object has a number.

Therefore, when an alarm occurs the TO number, alarm number, coefficient, etc. are signaled and the HMI then writes the TO number, alarm text with coefficient, time stamp, etc.

With WinCC flexible, warning and error messages of the technology objects (axes, output cams, measuring inputs, etc.) are output directly on the HMI and are acknowledged by the operator. The AlarmS concept also provides a method for configuring and programming user messages. User messages are configured in SIMOTION SCOUT; messages are called and acknowledged

during runtime by calling the appropriate system commands. OPC supports the same message mechanisms. For the OPC export, an additional OPC alarm/event must be activated.

Consistent data access with HMI devices (example)

HMI devices can also access user data of the SIMOTION device consistently. The following example includes an ST program on the SIMOTION device (see example) and an application (Visual Basic program) on the HMI device (see example).

The user requests consistent read access to user variables (including arrays) from within the HMI application (in this case, Visual Basic; but it could also be Visual C++ ...). An uneven value is written to the consistencyFlag variable. The SIMOTION user program then copies the data. The HMI application waits until the SIMOTION user program confirms that it has completed copying the data by writing an even value to the *consistencyFlag* variable. Then, the HMI reads out this variable consistently, since no changes have been made in the meantime.

The ST program can be assigned to a cyclic task; it may be necessary to take the IPOsynchronousTask if, for example, axis positions and velocities are to be read at the same time (as a snapshot).

Examples:

Table 4-119 ST program for consistent data access from HMI devices

```
INTERFACE
    VAR_GLOBAL
        consistencyFlag : DINT;
        myDint    : DINT;
        myArray : ARRAY[0..10] OF LREAL;
    END_VAR
    PROGRAM OPC_Prog;
END_INTERFACE

IMPLEMENTATION
    PROGRAM OPC_Prog
        IF (consistencyFlag MOD 2) = 1 THEN
            myDint := 99;
            myArray[0] := 0.0;
            myArray[1] := 1.0;
            myArray[10] := 10.0;
            consistencyFlag := consistencyFlag + 1;
        END_IF;
    END_PROGRAM
END_IMPLEMENTATION

4.2.10 Programming of general system function blocks

4.2.10.1 Overview of the function blocks

ST contains a series of system function blocks that you can use in your ST source files without having to declare them beforehand. You only have to create an instance and assign the necessary parameters.

Overview of system function blocks

Below is an overview of all system function blocks implemented in the system. You will find definitions and a further specification in the following sections.

Table 4-121 System function blocks

Collective term	Name	Input parameter		Output parameter	
	Definition	Name	: Type	Name	: Type
Bistable function blocks (Page 1617)	**SR**[1] Priority set	S1 R	: BOOL; : BOOL;	Q1	: BOOL;
	RS[1] Priority reset	SR1	: BOOL; : BOOL;	Q1	: BOOL;
Edge detection (Page 1619)	**R_TRIG**[1] Rising edge	CLK	: BOOL;	Q	: BOOL;
	F_TRIG[1] Falling edge	CLK	: BOOL;	Q	: BOOL;

[1] These function blocks require a repeated call (e.g. in a cyclic task).					

Comparison of the system function blocks for SIMOTION and SIMATIC

You can find a comparison of the SIMATIC S7 and SIMOTION system function blocks in the 2_FAQ directory on the Utilities & Applications CD.

4.2.10.2 Bistable elements (set flip-flop)

Description

In ST you can use system function block SR to set/reset the flip-flop (priority set) and system function block RS to reset/set the flip-flop (priority reset).

Bistable function block SR (priority set)

The stored value can be obtained at output Q1. Output Q1 is 1 when S1 is 1. If S1 and R are equal to 0, output Q1 does not change.

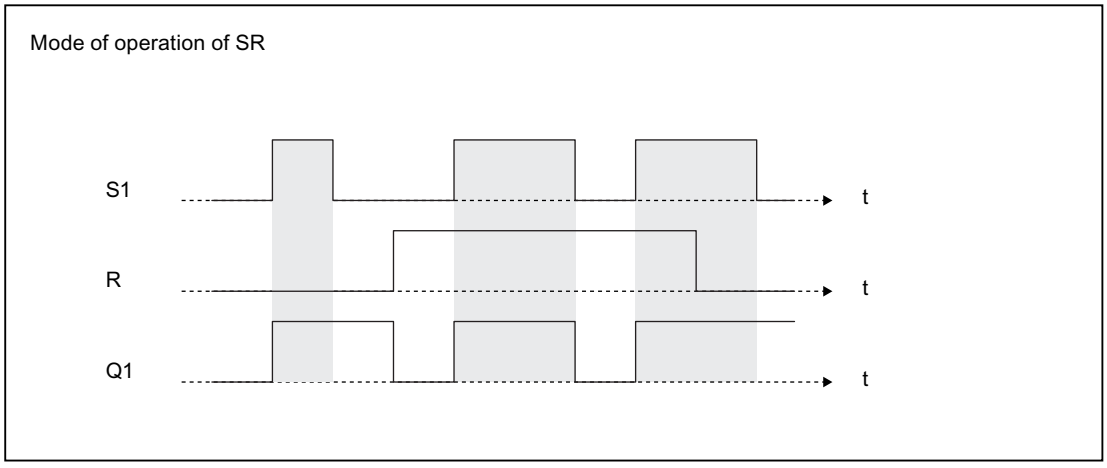

Figure 4-163 Mode of operation of the SR bistable function block

Program code of the SR bistable function block

```
FUNCTION_BLOCK SR

    VAR_INPUT
        S1, R    : BOOL;
    END_VAR

    VAR_OUTPUT
        Q1       : BOOL;
    END_VAR

    Q1 := S1 OR (NOT R AND Q1);

END_FUNCTION_BLOCK
```

Table 4-122 Call parameters for SR

Identifier	Parameter	Data type	Description
S1	Input	BOOL	Set
R	Input	BOOL	Reset
Q1	Output	BOOL	Signal state

Bistable function block RS (priority reset)

The stored value can be obtained at output Q1. Output Q1 is 0 when R1 is 1. If R1 and S are equal to 0, output Q1 does not change.

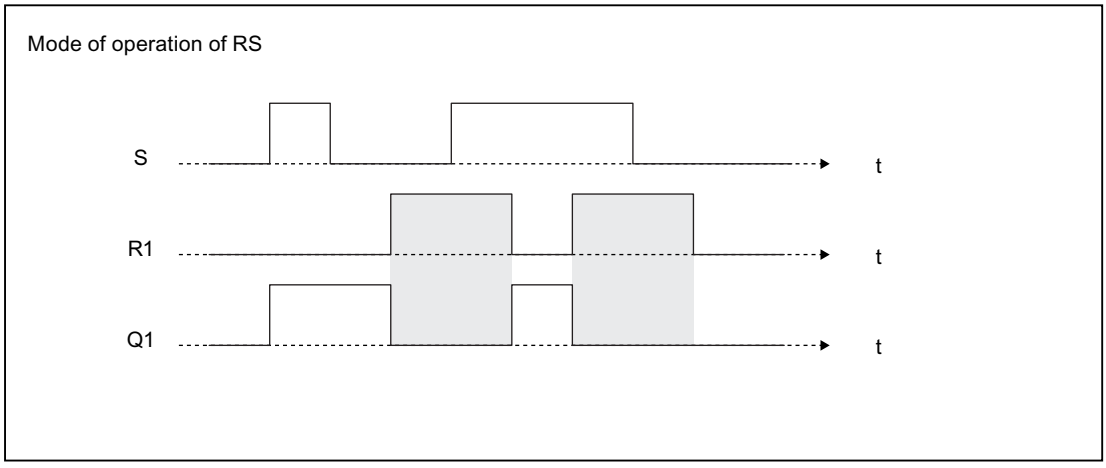

Figure 4-164 Mode of operation of the RS bistable function block

Program code of RS bistable function block

```
FUNCTION_BLOCK RS

    VAR_INPUT
        R1, S      : BOOL;
    END_VAR

    VAR_OUTPUT
        Q1         : BOOL;
    END_VAR

    Q1 := NOT R1 AND (S OR Q1);

END_FUNCTION_BLOCK
```

Table 4-123 Call parameters for RS

Identifier	Parameter	Data type	Description
S	Input	BOOL	Set
R1	Input	BOOL	Reset
Q1	Output	BOOL	Signal state

4.2.10.3 Edge detection

Description

System function block R_TRIG can be used to detect a rising edge; F_TRIG can detect a falling edge. You can use this function, for example, to set up a sequence of your own function blocks.

Detection of rising edge R_TRIG

If a rising edge (R_TRIG, Rising Trigger), i.e. a status change from 0 to 1 is present at the input, 1 is applied at the output for the duration of one cycle.

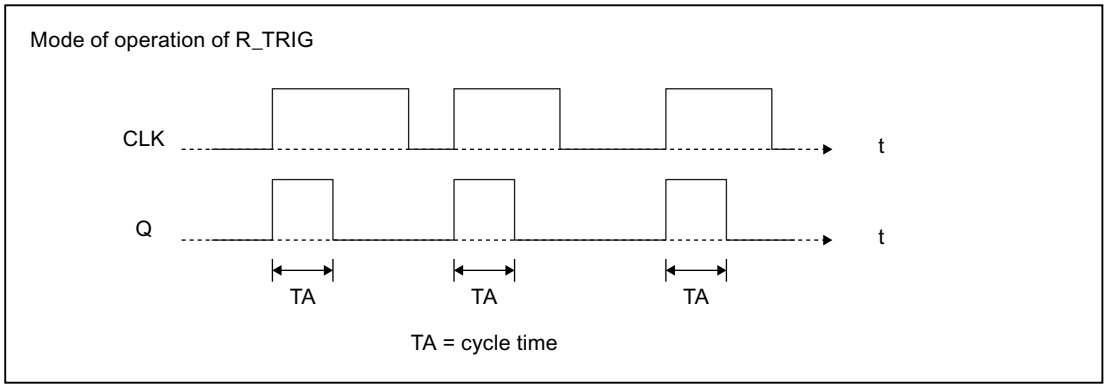

Figure 4-165 Mode of operation of R_TRIG (rising edge) function block

Program code for function block R_TRIG (rising edge)

```
FUNCTION_BLOCK R_TRIG

    VAR_INPUT
        CLK     : BOOL;
    END_VAR

    VAR_OUTPUT
        Q       : BOOL;
    END_VAR

    VAR
        M       : BOOL := 0;
    END_VAR

    Q := CLK AND NOT M;
    M := CLK;

END_FUNCTION_BLOCK
```

Table 4-124 Call parameters for R_TRIG

Identifier	Parameter	Data type	Description
CLK	Input	BOOL	Input for edge detection
Q	Output	BOOL	Status of edge

Detection of falling edge F_TRIG

When a falling edge (F_TRIG, falling trigger), i.e. a status change from 1 to 0, occurs at the input, the output is set to 1 for the duration of one cycle time.

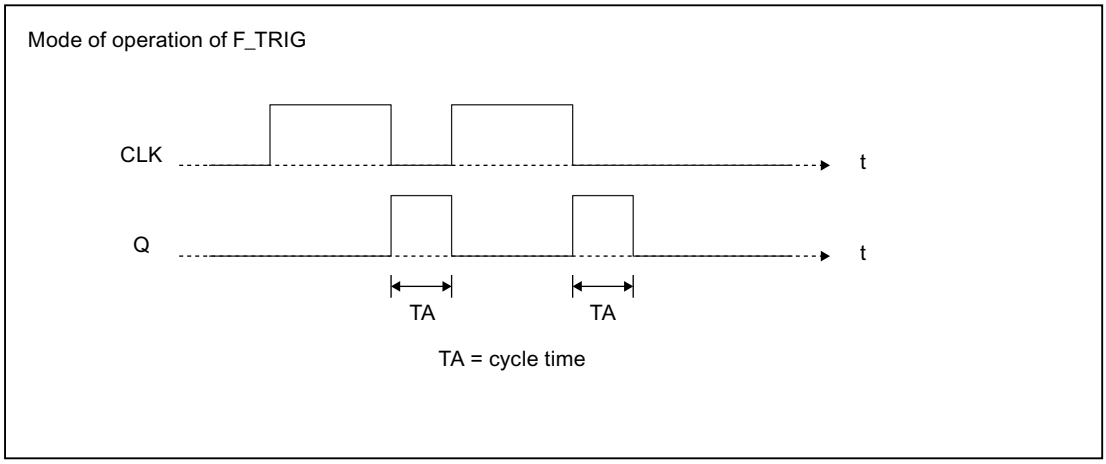

Figure 4-166 Mode of operation of F_TRIG (falling edge) function block

Program code for function block F_TRIG (falling edge)

```
FUNCTION_BLOCK F_TRIG

    VAR_INPUT
        CLK  : BOOL;
    END_VAR

    VAR_OUTPUT
        Q    : BOOL;
    END_VAR

    VAR
        M    : BOOL    := 1;
    END_VAR

    Q := NOT CLK AND NOT M;
    M := NOT CLK;

END_FUNCTION_BLOCK
```

Table 4-125 Call parameters for F_TRIG

Identifier	Parameter	Data type	Description
CLK	Input	BOOL	Input for edge detection
Q	Output	BOOL	Status of edge

4.2.10.4 Counters

General information on counters

ST provides a series of system function blocks for counters that you can use in your ST program.

CTU up counter

Description

The CTU counter allows you to perform upward counting operations:

- If the input is R = TRUE when the FB is called up, then the CV output is reset to 0.
- If the CU input changes from FALSE to TRUE (0 to 1) when the FB is called (rising edge), then the CV output is incremented by 1.
- Output Q specifies whether CV is greater than or equal to comparison value PV.

The CV and PV parameters are both INT data types, which means that the maximum counter value possible is 32_767 (= 16#7FFF).

User interface prototype

```
FUNCTION_BLOCK CTU
    VAR_INPUT
        CU    : BOOL;        // Count:
        R     : BOOL;        // Reset
        PV    : INT;         // Comparison value
    END_VAR

    VAR_OUTPUT
        Q     : BOOL;        // Status
        CV    : INT;         // Counter value
    END_VAR

    // ... (Code)

END_FUNCTION_BLOCK
```

Input parameter

CU

Data type: BOOL

Count up if value changes from FALSE to TRUE (rising edge)

R

Data type: BOOL

TRUE: Reset the counter to 0

PV

Data type: INT

Comparison value

Output parameter

Q

Data type: BOOL

Status of counter (CV ≥ PV)

CV

Data type: INT

Counter value

CTU_DINT up counter

The method of operation is the same as for the CTU up counter (Page 1622) except for the following:

The CV and PV parameters are both DINT data types, which means that the maximum counter value possible is 2_147_483_647 (= 16#7FFF_FFFF).

Table 4-126 Parameters for CTU_DINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (rising edge)
R	Input	BOOL	Reset the counter to 0
PV	Input	DINT	Comparison value
Q	Output	BOOL	Status of counter (CV ≥ PV)
CV	Output	DINT	Counter value

CTU_UDINT up counter

The method of operation is the same as for the CTU up counter (Page 1622) except for the following:

The CV and PV parameters are both UDINT data types, which means that the maximum counter value possible is 4_294_967_295 (=16#FFFF_FFFF).

Table 4-127 Parameters for CTU_UDINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (rising edge)
R	Input	BOOL	Reset the counter to 0
PV	Input	UDINT	Comparison value

Identifier	Parameter	Data type	Description
Q	Output	BOOL	Status of counter (CV ≥ PV)
CV	Output	UDINT	Counter value

CTD down counter

The CTD counter allows you to perform downward counting operations.

- If the LD input = TRUE when the FB is called, then the CV output is reset to start value PV.
- If the CD input changes from FALSE to TRUE (from 0 to 1) when the FB is called (= positive edge), then the CV output is decremented by 1.
- Output Q specifies whether CV is less than or equal to 0.

The CV and PV parameters are both INT data types, which means that the minimum counter value possible is –32_768 (= 16#8000).

Table 4-128 Call parameters for CTD

Identifier	Parameter	Data type	Description
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (rising edge)
LD	Input	BOOL	Reset the counter to start value
PV	Input	INT	Start value of counter
Q	Output	BOOL	Status of counter (CV ≤ 0)
CV	Output	INT	Counter value

CTD_DINT down counter

The method of operation is the same as for the CTD down counter (Page 1624) except for the following:

The CV and PV parameters are both DINT data types which means that the minimum counter value possible is –2_147_483_648 (= 16#8000_0000).

Table 4-129 Call parameters for CTD_DINT

Identifier	Parameter	Data type	Description
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (rising edge)
LD	Input	BOOL	Reset the counter to start value
PV	Input	DINT	Start value of counter
Q	Output	BOOL	Status of counter (CV ≤ 0)
CV	Output	DINT	Counter value

CTD_UDINT down counter

The method of operation is the same as for the CTD down counter (Page 1624) except for the following:

The CV and PV parameters are both UDINT data types, which means that the minimum counter value possible is 0.

Table 4-130 Call parameters for CTD_UDINT

Identifier	Parameter	Data type	Description
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (rising edge)
LD	Input	BOOL	Reset the counter to start value
PV	Input	UDINT	Start value of counter
Q	Output	BOOL	Status of counter (CV = 0)
CV	Output	UDINT	Counter value

CTUD up/down counter

The CTUD counter allows you to perform both upward and downward counting operations.

- Reset the CV count variable:
  - If the input is R = TRUE when the FB is called up, then the CV output is reset to 0.
  - If the LD input = TRUE when the FB is called, then the CV output is reset to start value PV.
- Count:
  - If the CU input changes from FALSE to TRUE (0 to 1) when the FB is called (rising edge), then the CV output is incremented by 1.
  - If the CD input changes from FALSE to TRUE (from 0 to 1) when the FB is called (= rising edge), then the CV output is decremented by 1.
- Counter status QU or QD:
  - Output Q specifies whether CV is greater than or equal to comparison value PV.
  - Output QD specifies whether CV is less than or equal to 0.

Table 4-131 Parameters for CTUD

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (rising edge)
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (rising edge)
R	Input	BOOL	Reset the counter to 0 (up counter)
LD	Input	BOOL	Reset the counter to PV start value (down counter)
PV	Input	INT	Comparison value (for up counter) Start value (for down counter)
QU	Output	BOOL	Status as up counter (CV ≥ PV)
QD	Output	BOOL	Status as down counter (CV ≤ 0)
CV	Output	INT	Counter value

CTUD_DINT up/down counter

The method of operation is the same as for the CTUD up/down counter (Page 1625) except for the following:

The CV and PV parameters are both DINT data types.

Table 4-132 Parameters for CTU_DINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (rising edge)
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (rising edge)
R	Input	BOOL	Reset the counter to 0 (down counter)
LD	Input	BOOL	Reset the counter to PV start value (down counter)
PV	Input	DINT	Comparison value (for up counter) Start value (for down counter)
QU	Output	BOOL	Status as up counter (CV ≥ PV)
QD	Output	BOOL	Status as down counter (CV ≤ 0)
CV	Output	DINT	Counter value

CTUD_UDINT up/down counter

The method of operation is the same as for the CTUD up/down counter (Page 1625) except for the following:

The CV and PV parameters are both UDINT data types.

Table 4-133 Parameters for CTU_UDINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (rising edge)
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (rising edge)
R	Input	BOOL	Reset the counter to 0 (up counter)
LD	Input	BOOL	Reset the counter to PV start value (down counter)
PV	Input	UDINT	Comparison value (for up counter) Start value (for down counter)
QU	Output	BOOL	Status as up counter (CV ≥ PV)
QD	Output	BOOL	Status as down counter (CV = 0)
CV	Output	UDINT	Counter value

4.2.10.5 Timers

Description

Timers are elements in your program used to execute and monitor time-driven processes. ST provides a series of system function blocks that you can access with ST. You can use timers in your program to do the following:

- Set waiting times
- Enable monitoring times
- Generate pulses
- Measure times

TP pulse

With a signal state change from 0 to 1 at the IN input, time ET is started. Output Q remains at 1 until elapsed time ET is equal to programmed time value PT. As long as time ET is running, the IN input has no effect.

The following figure illustrates the mode of operation of the TP pulse timer.

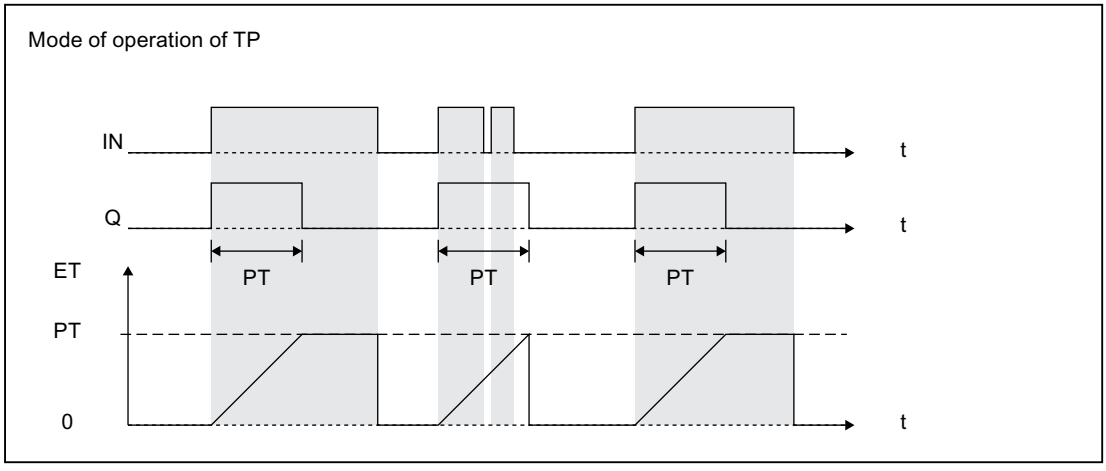

Figure 4-167 Mode of operation of the TP pulse

The following table shows the call parameters.

Table 4-134 Call parameters for TP

Identifier	Parameter	Data type	Description
IN	Input	BOOL	Start input
PT	Input	TIME	Duration of pulse
Q	Output	BOOL	Status of time
ET	Output	TIME	Elapsed time

TON ON delay

With the signal state change from 0 to 1 at the IN input, time ET is started. The output signal Q only changes from 0 to 1 if the time ET = PT has elapsed and the input signal IN still has a value of 1, i.e. the output Q is switched on with a delay. Input signals of shorter durations than that of programmed time PT do not appear at the output.

The following figure illustrates the mode of operation of the TON ON delay timer.

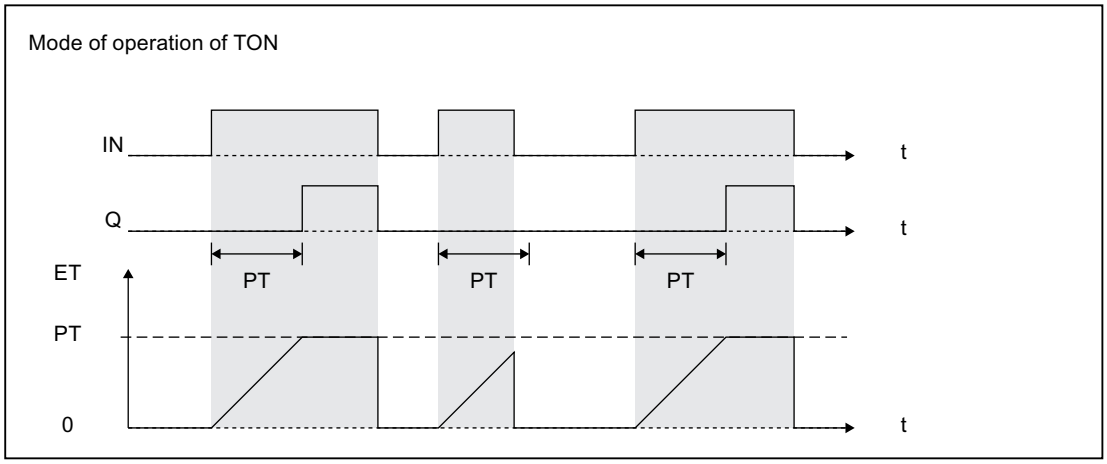

Figure 4-168 Mode of operation of the TON ON delay

The following table shows the call parameters.

Table 4-135 Call parameters for TON

Identifier	Parameter	Data type	Description
IN	Input	BOOL	Start input
PT	Input	TIME	Duration for which the rising edge at input IN is delayed
Q	Output	BOOL	Status of time
ET	Output	TIME	Elapsed time

Example

```
VAR
    Mytimeout : TON;
END_VAR

Mytimeout (PT := T#2s, IN := TRUE);
IF (mytimeout.Q) THEN
    ; //Time has expired
END_IF;
```

TOF OFF delay

With a signal state change from 0 to 1 at start input IN, state 1 appears at output Q. If the state at the start input changes from 1 to 0, then time ET is started. If a change occurs at input IN from 0 to 1 before time ET has elapsed, then the timer operation is reset. A start is initiated again when the state at input IN changes from 1 to 0. Only after the duration ET = PT has elapsed does output Q adopt a signal state of 0. This means that the output is switched off with a delay.

The following figure illustrates the mode of operation of the TOF OFF delay timer.

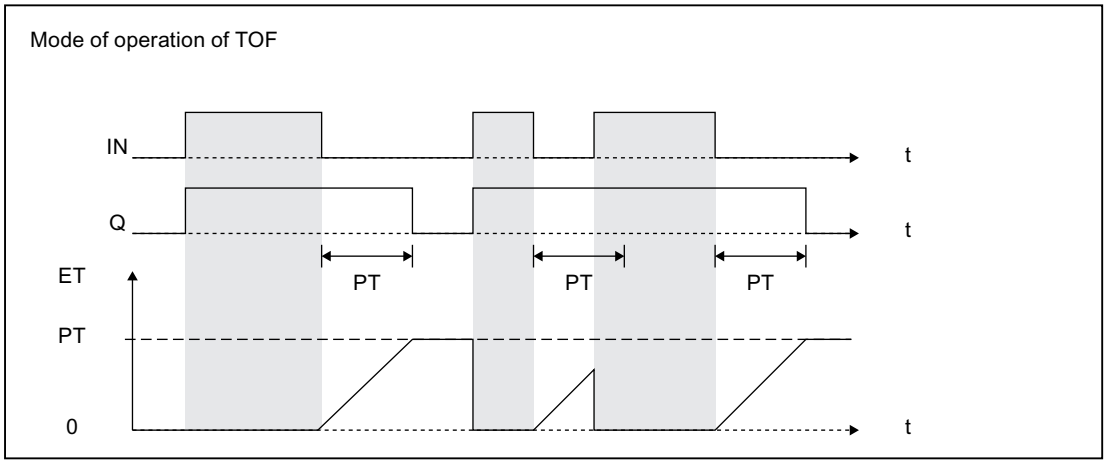

Figure 4-169 Mode of operation of the TOF OFF delay timer

The following table shows the call parameters.

Table 4-136 Call parameters for TOF

Identifier	Parameter	Data type	Description
IN	Input	BOOL	Start input
PT	Input	TIME	Period for which the falling edge at input IN is delayed
Q	Output	BOOL	Status of time
ET	Output	TIME	Elapsed time

Real-time clock RTC

The rising edge on SET sets the real-time clock to the value of PDT; PDT is copied to CDT. If READ is set to TRUE, then the current system time is read and is available at output CDT.

Table 4-137 Call parameters for the RTC

Identifier	Parameter	Data type	Description
SET	Input	BOOL	Set time, default FALSE
READ	Input	BOOL	Read time, default FALSE

Identifier	Parameter	Data type	Description
PDT	Input	DT	Value to which the real-time clock is to be set, default DT#0001-01-01-0:0:0 If the value is less than the default value of the SIMOTION device real-time clock, the real-time clock will be set to its default value (e.g. with C2xx: DT#1994-01-01-00:00:00)
CDT	Output	DT	Current system time

The granularity for setting the real-time clock is 1 ms; the accuracy depends on the position control cycle clock.

4.2.10.6 Splitting bit-string data types

General information for splitting bit-string data types

The following functions enable a variable of a bit string data type to be split into multiple variables of a lower-level data type.

The inverse functions are implemented as functions, see Combining bit-string data types (Page 1499).

_BYTE_TO_8BOOL function block

Description

This function splits a variable of data type BYTE into eight variables of data type BOOL.

User interface prototype

```
FUNCTION_BLOCK _BYTE_TO_8BOOL
    VAR_INPUT
        bytein : BYTE;
    END_VAR
    VAR_OUTPUT
        bit0,               // Least significant bit
        bit1, bit2, bit3, bit4, bit5, bit6,
        bit7 : BOOL;        // Most significant bit
    END_VAR
    // ... (Code)
END_FUNCTION_BLOCK
```

Input parameter

bytein

Data type: BYTE

Variable of data type BYTE to be split into eight variables of data type BOOL.

Output parameter

bit0
...
bit7

Data type: BOOL

Eight variables with the individual bits of the input parameter

bit0: Least significant bit

...

bit7: Most significant bit

_WORD_TO_2BYTE function block

Description

This function splits a variable of data type WORD into two variables of data type BYTE.

User interface prototype

```
FUNCTION_BLOCK _WORD_TO_2BYTE
    VAR_INPUT
        wordin : WORD;
    END_VAR
    VAR_OUTPUT
        byte0,           // Less significant byte
        byte1 : BYTE;    // More significant byte
    END_VAR
    // ... (Code)
END_FUNCTION_BLOCK
```

Input parameter

wordin

Data type: WORD

Variable of data type WORD to be split into two variables of data type BYTE.

Output parameter

byte0
byte1

Data type: BYTE

Two variables with the individual bytes of the input parameter

byte0: Less significant byte
byte1: More significant byte

_DWORD_TO_2WORD function block

Description

This function splits a variable of data type DWORD into two variables of data type WORD.

User interface prototype

```
FUNCTION_BLOCK _DWORD_TO_2WORD
    VAR_INPUT
        dwordin : DWORD;
    END_VAR
    VAR_OUTPUT
        word0,           // Less significant word
        word1 : WORD;    // More significant word
    END_VAR
    // ... (Code)
END_FUNCTION_BLOCK
```

Input parameter

dwordin

Data type: DWORD

Variable of data type DWORD to be split into two variables of data type WORD.

Output parameter

word0
word1

Data type: WORD

Two variables with the individual words of the input parameter

word0: Less significant word
word1: More significant word

_DWORD_TO_4BYTE function block

Description

This function splits a variable of data type DWORD into four variables of data type BYTE.

User interface prototype

```
FUNCTION_BLOCK _DWORD_TO_4BYTE
    VAR_INPUT
        dwordin : DWORD;
    END_VAR
    VAR_OUTPUT
        byte0,           //  Least significant byte
        byte1, byte2,
        byte3 : BYTE;    // Most significant byte
    END_VAR
    // ... (Code)
END_FUNCTION_BLOCK
```

Input parameter

in

Data type: DWORD

Variable of data type DWORD to be split into four variables of data type BYTE.

Output parameter

byte0
byte1
byte2
byte3

Data type: BYTE

Four variables with the individual bytes of the input parameter

byte0: Least significant byte

...

byte3: Most significant byte

4.2.10.7 Emulation of SIMATIC S7 commands

General

The following function blocks are interface-compatible with the commands for the SIMATIC S7 counters and timers; see the reference manual SIMATIC Statement List (STL) for S7-300/400.

Note

You should generally use the function blocks in accordance with IEC 61131-3 (**counters** and **timers**).

See also

General information on counters (Page 1622)

Timers (Page 1627)

_S7_COUNTER function block

User interface prototype

```
FUNCTION_BLOCK _S7_COUNTER
    VAR_INPUT
        CU: BOOL;
        CD: BOOL;
        PV : INT;
        S: BOOL;
        R : BOOL;
    END_VAR
    VAR_OUTPUT
        Q : BOOL;
        CV : INT;
    END_VAR;
    // ... (Code)
END_FUNCTION_BLOCK
```

Input parameters

CU

Data type: BOOL

Count up (with edge)

CD

Data type: BOOL

Count down (with edge)

PV

Data type: INT

Preset value

S

Data type: BOOL

Set preset value (with edge)

R

Data type: BOOL

Reset counter (static)

Output parameters

Q

Data type: BOOL

Counter status

CV

Data type: INT

Counter value

_S7_TIMER function block

This function block is used to emulate SIMATIC S7 time functions.

User interface prototype

```
FUNCTION_BLOCK _S7_TIMER
    VAR_INPUT
        T_TYPE : WORD;

4.2.11 SIMOTION memory concept (in the target device)

4.2.11.1 Overview of the memory in the target device

Memory types

SIMOTION has a staggered memory management concept. A distinction is made in the target device between the DRAM (RAM disk and RAM) and the SRAM/NVRAM. The data (TOs, units and TPs) in the DRAM are lost when the device is switched off whereas the SRAM/NVRAM can retentively store smaller data quantities. A removable data medium (CF card or memory card) is also available as ROM.

RAM disk

The RAM disk is a virtual memory that can be controlled in the same way as a hard disk, but can be accessed much faster. A fixed memory area is reserved for the RAM disk in the DRAM of the target device. After the download, the RAM disk contains the hardware and device configuration, technology packages (TP), configuration data of the technology objects, and the program units. With **Copy RAM to ROM**, the contents of the RAM disk are written to the ROM (on the card). During an upload, the data is loaded from the RAM disk to the programming device. You can display the utilization of the RAM disk in the device diagnostics under System utilization (ONLINE only).

RAM

User data (user RAM) and system data (system RAM) are stored in the RAM. The user RAM contains the TO Current data memory, the TO Next memory of the technology objects (for more information, see Changing system variables and configuration data online (Page 1640)) and is also used to store technology packages, units (variables and code). During power-up or download, the data is loaded from the RAM disk to the RAM.

The user RAM containing the TPs and units can be divided into a data memory (e.g. variables) and a code memory (compiled user programs) for clarity. Retain variables are saved retentively (powerfail-proof) in the SRAM/NVRAM.

The kernel, kernel data and further settings such as communication settings, cycle clock settings and the contents of the diagnostic buffer are stored in the system RAM.

You can display the utilization of the RAM in the device diagnostics under System utilization (ONLINE only).

ROM (CF card or memory card)

Data is saved retentively on the memory card (ROM). To do this, you must execute the command **Copy RAM to ROM**. The data saved last with Copy RAM to ROM is loaded from the ROM to the RAM disk during power-up and from there to the RAM. You can display the utilization of the CF/ memory card in the device diagnostics under System utilization (ONLINE only).

SRAM/NVRAM (retentive data - non-volatile data)

Data is saved retentively and in a powerfail-proof manner in the SRAM/NVRAM. The data is loaded from the SRAM/NVRAM to the RAM during power-up. You can display the allocation of the SRAM/NVRAM in the device diagnostics under System utilization (retentive data, ONLINE only).

Non-volatile data available in SIMOTION devices:

Non-volatile data	Contents
Kernel data	Last operating mode
	IP parameters (IP address, subnet mask, router address)
	DP parameters (PROFIBUS DP address, baud rate)
	Diagnostics buffer
Retain variables	Variables in the interface or implementation section of a unit declared with VAR_GLOBAL RETAIN
	Local variables in programs, function blocks or classes declared with VAR RETAIN. As of SIMOTION Kernel version V4.5
	Global device variables set with the "RETAIN" attribute
Retain TO	Absolute encoder offset
DCC blocks	SAV blocks and user-defined blocks with retain behavior

The user program can use the "_savePersistentMemoryData" system function to save the contents of non-volatile data to the memory card. This prevents the retain variables and the absolute encoder position from being lost if, for example, a component is replaced (for more details, see the *System Function/Variables* List Manual).

The following graphic shows the general structure of the memory in the target device

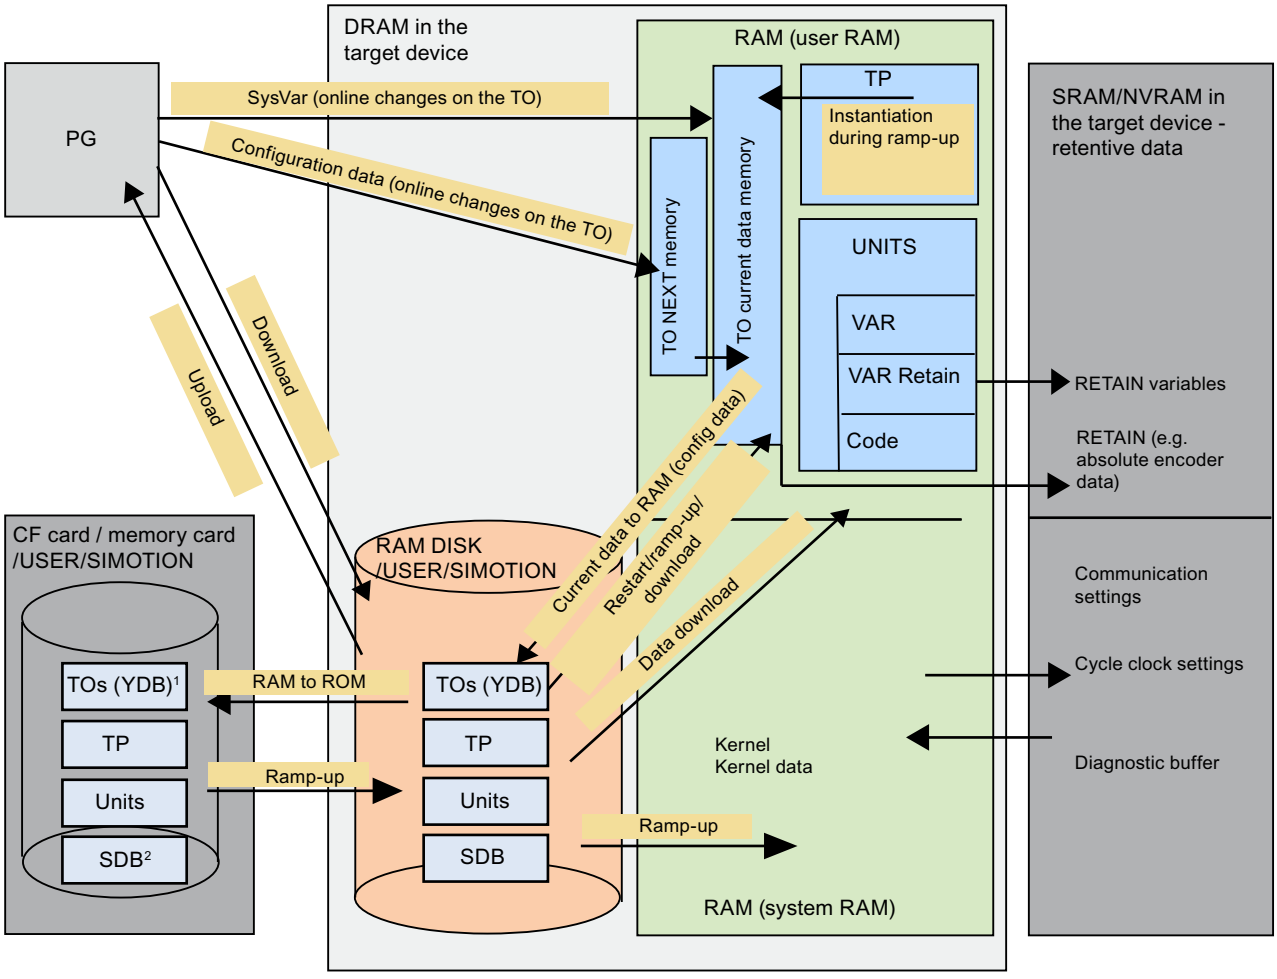

Figure 4-170 Memory concept, general representation

[1] YDBs contain the configuration data of technology objects, such as system variables, configuration data or alarms.

[2] SDBs are system data blocks

See also

Overview of the data download (Page 1643)

Copy RAM to ROM (Page 1676)

Download in RUN (Page 1655)

4.2.11.2 Memory access

Power-up of the target device

The data of the TOs, technology packages, units and further data is transferred from the ROM via the RAM disk to the USER RAM during a power-up. The TO data is loaded to the TO current data memory, the technology packages (TP) and units to the USER-RAM. The individual TOs are instantiated and assigned the appropriate values. Communication settings, cycle clock settings, and the content of the diagnostic buffer (if available) are transferred from the SRAM/NVRAM to the system RAM, along with the retain data.

Note

IP and DP parameters in non-volatile data

If there is configuration data on the memory card, the IP and DP parameters are loaded from the memory card during ramping up and used by the SIMOTION device. The addresses defined in the configuration data are used to go online. During ramping up, the IP and DP parameters on the memory card are also written to the non-volatile data. If the SIMOTION device is then powered up with a CF card with no configuration, the IP and DP parameters are retained in the non-volatile data and are used by the device. This means the SIMOTION device can continue to go online if a configuration has been loaded with SIMOTION SCOUT at least once or if the SIMOTION device is powered up with a memory card containing a configuration.

Power On and overall reset

Data (configuration data, default values of system variables) is loaded from ROM (memory card) into the RAM disk and then into the TO current data memory. During the memory reset operation, the RAM and the retentive data in the SRAM/NVRAM, except for the communication configuration (baud rates, network addresses, etc.), are deleted prior to the power-up. In addition, the unit data is deleted during the memory reset and are then reloaded from the ROM during power-up.

Restarting a technology object

Data of the TO (configuration data, default values of system variables, cams) is loaded from RAM disk into the TO current data memory.

STOP - RUN transition

There is no access to any of the various memories during the transition from STOP to RUN.

Download to the target device

During a download from the programming device to the target device, the data is first written to the RAM disk and then from there to the RAM, with optional data initialization. See also Overview of the data download (Page 1643) and Separate initialization of source and TO data during a download (Page 1655).

Additional data (e.g. sources) can be included in the download to the target device.

This data is required for

- Online object comparison (e.g. additional properties)
- Various detailed comparisons (e.g. ST source file comparison)
- "Load to PG" function (complete upload to offline project)
- Synchronization with online objects

In order to be able to load sources or additional data of a project to the PG, this must be specified in the project under **Options > Settings > Download > Store additional data on the target device**.

Changing system variables and configuration data online

If you change the values of system variables, the system variable values are effective immediately in the TO current data memory. New configuration data values are initially stored in the Next memory. Immediately effective configuration data is transferred automatically to the TO current data memory. Configuration data that only becomes active following a RESTART on the technology object (set the *restartactivation* system variable to ACTIVATE_RESTART) is only written to the TO current data memory after the RESTART.

To save the configuration data changed online to the offline project, you must first transfer the content of the TO current data memory to the RAM disk with the menu command **Target system > Copy current data to RAM**.

The configuration in SCOUT is then no longer consistent with the configuration in the target device as the data of the RAM disk is used for the consistency check. Read the data from the RAM disk with the menu command **Target system > Load > Load to PG** (only for the configuration data) to re-establish a consistent system state. To ensure that the configuration is saved on the CompactFlash card or memory card with protection against power failure, execute the menu command **Target system > Copy RAM to ROM**. This menu command can also be used to implicitly execute the **Copy current data to ROM** and **Load to PG** functions.

As of V4.2, configuration data is completed during ramp-up using parameter values of the SINAMICS drive (adaptation). For more detailed information, see "Adaptation" under Symbolic assignment - introduction (Page 1189). When "Copy current data to RAM" or "Copy RAM to ROM" is executed, adapted values are detected and "Load to PG" is automatically preselected as well.

Note

Copy current to RAM does not transfer the values of the system variables to the RAM memory. This means that "Save to memory card (Copy RAM to ROM)" or "Save in the engineering project (Load to PG)" is not possible.

So that values of system variables can also be saved in the engineering project and on the memory card, the default value of system variables must be changed OFFLINE and then loaded to the target device per download and saved.

For information on how TOs, variables and programs behave during a download in RUN, see Download in RUN (Page 1655)

Backing up non-volatile SIMOTION data

You have the following options for backing up non-volatile SIMOTION data on the memory card:

- In the user program:
  The "_savePersistentMemoryData" system function allows the user program to back up the content of non-volatile SIMOTION data on the memory card. This ensures that the retain variables and the absolute encoder position are backed up in the event that a spare part is used.
- Using the switch/pushbutton (service selector switch or DIAG pushbutton the SIMOTION D) or IT DIAG.

Backing up non-volatile SINAMICS data

As of SINAMICS FW version V4.5, the backup of the non-volatile SINAMICS data (NVRAM data) is carried out by setting the CU parameter p7775 to the value 1. The data is stored on the CF card under /USER/SINAMICS/DATA/NVRAM/PMEMORY.ACX.

- For SIMOTION D4xx-2 with SINAMICS Integrated and CX32-2 controller extension
- For SINAMICS drives (e.g. S120) with CU310-2 or CU320-2 control units

Restoring non-volatile SIMOTION data

SIMOTION data backed up on a CompactFlash card with _savePersistentMemoryData is restored in the following cases:

1. After an overall reset
2. By selecting a switch position on SIMOTION D
3. SRAM content lost due to a discharged battery. In this case, the entire contents of the SRAM are restored from the file.

If, after a module has been replaced, retain data is available on the module, it is accepted and remains valid as long as the TO name or unit name is consistent. Otherwise, this data is invalid.

This means that once a module has been replaced, if the project is not consistent with the saved retain data, you should proceed as described in 1 or 2.

The backed-up data in the USER/SIMOTION/PMEMORY.XML file is copied back to the SRAM/NVRAM when the controller is being ramped up.

System variable device.persistentDataPowerMonitoring.persistentDataState indicates the state of the non-volatile SIMOTION data after ramp-up. The FROM_RAM state indicates that the non-volatile SIMOTION data has not been lost and has been downloaded from the SRAM/NVRAM.

Table 4-138 State of non-volatile data after ramp-up (persistentDataState system variable)

State	Meaning
FROM_RAM (1)	Non-volatile SIMOTION data in the SIMOTION device is used
FROM_FILE (2)	Non-volatile SIMOTION data restored from the backup file

State	Meaning
FROM_BACKUP (3)	Non-volatile SIMOTION data is restored from the backup copy of the backup file
INVALID (4)	Data in the non-volatile SIMOTION data and in the backup file / backup copy of backup file is invalid or not available/deleted. The SIMOTION device has copied the default settings to the non-volatile SIMOTION data and used this data to power up.

Restoring non-volatile SINAMICS data

The restoration of the SINAMICS-non-volatile data

- Is performed automatically in the event of a module replacement:
  A module replacement is detected on the basis of the serial number.
- Can be performed manually:
  Restore can be initiated manually by setting the CU parameter p7775 to 2.

4.2.12 Downloading data to the target device

4.2.12.1 Overview of the data download

Description

You have to download the project data that you have created with the SCOUT to the target system. The target system can contain several CPUs (SIMOTION controllers or drives). The project data contains the programs (ST, MCC, LAD/FBD and DCC) that you have created and compiled, the hardware configuration and the technology objects (with their technology packages) that you have created and parameterized.

You must reload a project to the target system, if you have:

- Created or changed programs
- Changed definitions of global variables or symbolic I/O variables
- Made changes to the execution system
- Changed technology object configurations

Download requirements

The following conditions must be met before the project can be downloaded to the target system:

- All cables must be plugged in and the interfaces configured
- All program sources are compiled (Project > Save and compile changes) or the program sources will be compiled automatically before the download.
- The project has been checked for consistency (Project > Check consistency)
- The system status is ONLINE (menu: Project > Connect to target system)

Note

The processing work increases with the size of the project. Plan the required components first in order to avoid any download errors. Note the technical specifications for the relevant device, technology object, communications interface, etc.

If an error occurs, transfer of data to the target system is aborted. The **Target system output** tab in which the transfer sequence and any errors are logged indicates the possible cause of the error.

Note

If a power failure occurs on the SIMOTION device during the download (RAM2ROM), a message will appear in the diagnostics buffer: Starting lockout set, after you have switched to RUN mode. Go online again and carry out the download once more.

In earlier versions, this can lead to various faults that cannot be corrected by the system. Unexplainable error messages may appear.
If this happens:
Go online again and carry out the download once more.

Download scope

You can either download the entire project or perform a download for a specific device.

- Downloading a project to the target system (all target devices) (Page 1647)
- Downloading CPU/drive unit to target device (Page 1650)
- Downloading a program subset and single units (sources) to the target device (Page 1652)

Operating state

You can perform a download in the STOP mode, and also in the RUN mode.

Additional download options in OFFLINE mode

Additional functions in OFFLINE mode are also available for transferring the project data in SCOUT to the memory card:

- Download direct to memory card or hard disk, see Download direct to memory card or hard disk (Page 1671)
- Device Update Tool, see Downloading using the device update tool (Page 1673).

4.2.12.2 Save and compile

The project must be saved and compiled first before the download. SIMOTION SCOUT distinguishes three commands in the main project menu that act differently when saving and compiling:

- Save; the project is saved to the hard disk
- Save and compile changes
- Save and recompile all

In addition, there is the following command in the context menu of a source, a device and a library:

- Accept and compile (a single source)

Save

The project is saved to the hard disk. The changes are accepted into the project. No other processes, such as compilation or consistency checking, are initiated for the project.

Save and compile changes

On this command, the whole project is searched for changes. If a source is found which has been changed or has no compilation results, this and any linked sources are compiled and saved (e.g. during an FB call). Therefore only the changes are compiled. Use this command for day-to-day operations within a SCOUT version.

Save and recompile all

All sources of the entire project are recompiled with this command. DCC libraries are also recompiled.

The **Save and recompile all** command is suitable if you are entirely sure that all the old data from older SCOUT versions has been removed and should be replaced with new compilation results. It consists of the following steps:

- Project-wide deletion of all compilation results
- Recompilation of all objects (except libraries, see also AUTOHOTSPOT)

Use this command if you specifically want to convert a project from an earlier SCOUT version to a later one. All the error correction and optimization features are accepted into the new SCOUT as part of the process, Thus, the compilation results in SCOUT and SIMOTION RT can become inconsistent. The project navigator and object comparison then display the objects as "inconsistent" in ONLINE mode. You need to load the whole project to the target system in order to debug it.

Accept and compile

The Accept and compile command compiles the changes of the individual source and accepts them in the project. The data, together with the project, is only saved to the hard disk if you select **Save**, **Save and compile changes** or **Save and recompile all**.

Comparison of compilation results in the project and in SIMOTION RT

Before SIMOTION SCOUT V4.0, compilation results were compared on the basis of their time stamp. As of V4.0, SCOUT uses a hash function to compare compilation results. A hash function compares larger amounts of data based on the hash code. Compilation results are only displayed as "consistent" if their hash code is the same in both the project and SIMOTION RT. The hash code is only deemed to be the "same" if code and compiler (note the SCOUT version) are the same.

Information about errors

Detailed information about transfer and compilation errors is output during the compilation of single sources (OFFLINE **Compile/Check Output** and ONLINE **Target System Output**). Double-clicking the error message in the detail window causes the cursor to jump to the error location in the source. Correct the errors, for example, by:

- Changing the configuration of the technology objects
- Changing the programs

Repeat the steps as often as required until no more errors are displayed.

Note

You have the option to output detailed error information even for project-wide compilation (with Save and (re)compile all). To do this, execute **Options > Settings > Compiler > Create detailed message log during compilation of the project/devices**

4.2.12.3 Editing a project with a more recent SCOUT version

Opening a converted project

The project was opened and edited with a more recent SCOUT version, and saved in the current project format. This can cause inconsistencies in online mode for objects that were not edited. It suffices to compile the project to avoid this problem. Click **Yes** to compile the project immediately. If you click **No**, you have the possibility to resolve the inconsistencies subsequently with the **Save and compile changes** function.

4.2.12.4 Performing a consistency check

Checking the project for consistency and compiling the project

Before you download the project to the target system, the program sources must be compiled without error and the consistency ensured. In this process, I/O addresses or TO configurations are checked, for example.

1. Select the **Project > Save and compile changes** menu.
   SIMOTION SCOUT compiles all changed sources.
   Further information about saving and compiling the project can be found in Save and compile (Page 1645).
2. Select the **Project > Consistency check** menu.
   SIMOTION SCOUT checks, for example, whether all technology objects have been configured and that the sources have been compiled without errors. Prior to a download, a consistency check can be performed automatically if the corresponding option is selected under **Options > Download > Check consistency before loading**.
   During the download, a consistency check is always performed in the target system. If download errors occur, their possible causes are displayed by entries in various output windows (ONLINE in the **Target System Output** window) of the detail view.

Note

SINAMICS components for the consistency check

SINAMICS components are considered only for a cross-project consistency check. For the consistency check on the device, e.g. on the SIMOTION D4x5-2, the SINAMICS component (SINAMICS Integrated or Controller Extensions) is not checked.

4.2.12.5 Downloading a project to the target system (all target devices)

During a project download, the entire project is loaded to all devices that are connected online (you can tell which devices these are from the green or red/green plug icons in the project navigator). This loads data to all devices selected in the **Target Device Selection** dialog. This includes all devices which are located below a SIMOTION device (e.g. SINAMICS Int, external PROFIBUS/PROFINET slaves). If you go offline with a specific device prior to running the download, data will not be downloaded to that device. If you change the selection in the **Target Device Selection** dialog after going online, this does not affect the download at first (device remains connected).

Note

You can only perform a project download for all devices connected ONLINE and their subordinate drive units, in the STOP operating state.

You cannot download to drives that cannot be configured in SCOUT, such as MASTERDRIVE or 611U.

Note

Project change (downloading a new project to the target system)

Delete the user data on the CF card before downloading the new project.

We also recommend that you reset the controller to the factory settings.

The procedure is described in the Commissioning Manuals.

Procedure

1. Click the **Download project to target system** button. The **Download to Target System** dialog box is displayed.

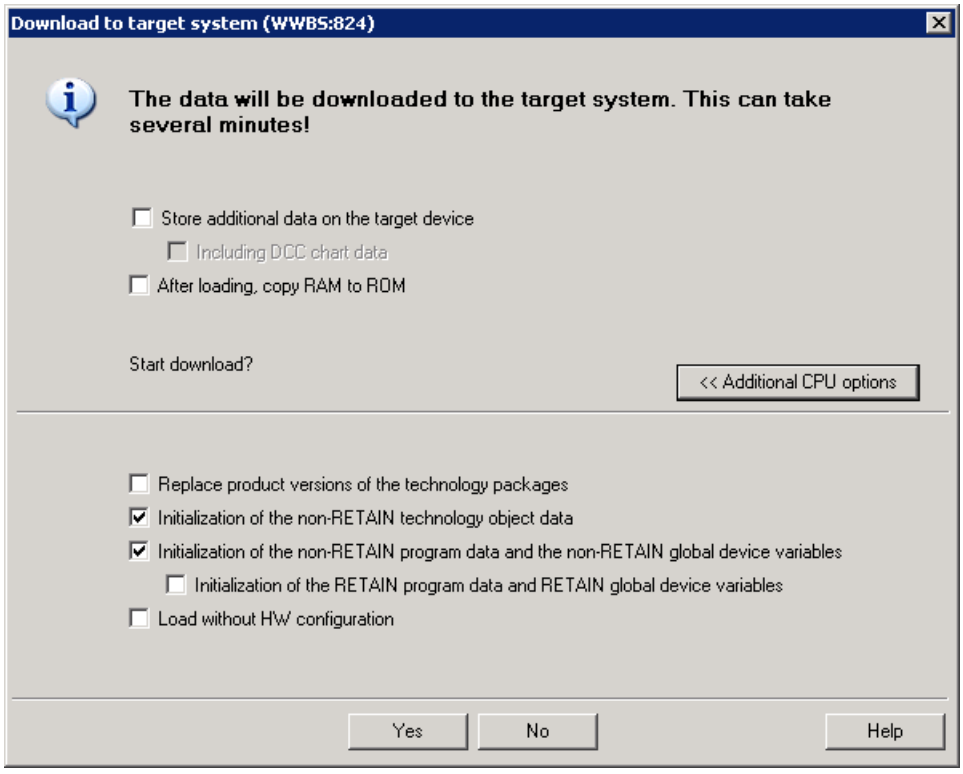

Figure 4-171 Download to target system

You can select the following options depending on the device:

- **Store additional data on the target device**; you can use this option to store supplementary data (e.g. program sources) on the target device.
  - **Including DCC chart data**
    With DCC, it is possible to store graphical chart data in addition to the supplementary data that enables a functional chart to be uploaded, meaning that the chart in question is in the full source text and can, therefore, be edited further.
  - For further information, see also Project download - settings in the SCOUT online help.
- **After loading, copy RAM to ROM**; copies RAM to ROM after the download for all target devices.
  After the download, the data is copied from RAM to ROM for all target devices. The loaded configuration is then stored retentively on the memory card.

Click **Additional CPU options** to display the following options:

- **Replace product versions of the technology packages**; this loads the technology package versions selected in the Select technology packages dialog to the target system. See also Downloading the selected product version of the technology packages (Page 1654).
- **Initialization of the non-RETAIN technology object data** (see Separate initialization of source and TO data during a download (Page 1655))
- **Initialization of the non-RETAIN program data and the non-RETAIN global device variables** - only effective in STOP mode
  - **Initialization of the RETAIN program data and RETAIN global device variables** (see Separate initialization of source and TO data during a download (Page 1655))
- **Load without HW configuration** (see Download without HW Config information (Page 1667))

The global settings are made at **Options > Settings > Download**.

Accepting or rejecting settings

- Click **Yes** to start the download or **No** to cancel the download.

The additional options are also active when they are not visible. The settings with which the last download was performed are then used. The only exception is the **Replace product versions of the technology packages** option which is only active for one action.

For drive units, you can only select **After loading, copy RAM to ROM** and **Supplementary data... incl. DCC chart data**.

Troubleshooting possible errors from older SCOUT versions:

If an error occurs when using projects from older SCOUT versions that can be reproduced in those versions, the error status can be resolved for the affected device and the project re-downloaded using the **Save and recompile all** command. If necessary, run **Delete user data on card** first.

Error messages:

- "IOM configuration inconsistent" (although there is no overlap of I/O variables).
- "UPP transfer of the source failed"

See also

Save and compile (Page 1645)

4.2.12.6 Downloading CPU/drive unit to target device

Description

In addition to a project download, you can also selectively load data to each CPU / drive unit. The standard procedure is the download in STOP mode. You can also perform a download in RUN operating state. For further information, see Download in RUN (Page 1655).

Procedure

1. First select the device to which you want to load the data in the project navigator (device must be ONLINE).
2. Click the **Download CPU / drive unit to target system**
   or
   right-click the device in the project navigator and perform **Target device > Download** in the context menu.
3. The **Download** dialog box is displayed. The contents depend on the device for which you want to download data.

Loading the CPU to the target device

A download can be performed for the entire CPU (without drive unit) but also separately for individual related download units.

- Download CPU without drive unit
- Download all technology objects of the CPU
- Download all programs of the CPU

You can select the following options:

- **Store additional data on the target device**; you can use this option to store supplementary data (e.g. program sources) on the target device.
  - **Including DCC chart data**
    With DCC, it is possible to store graphical chart data in addition to the supplementary data that enables a functional chart to be uploaded, meaning that the chart in question is in the full source text and can, therefore, be edited further.
  - For further information, see also Project download - settings in the SCOUT online help.
- **Copy RAM to ROM after download**
  After the download, the data is copied from RAM to ROM for the selected target device. The loaded configuration is then stored retentively on the memory card**.**
- **Perform download during RUN**; enables a download to be performed in RUN mode.
  Click **Additional CPU options** to display the following options:
- **Replace product versions of the technology packages**; this loads the technology packages selected in the Select Technology Packages (Page 1654)dialog to the target device.

- **Initialization of the non-RETAIN technology object data** - only effective in STOP mode (see Separate initialization of source and TO data during a download (Page 1655))
- **Initialization of the non-RETAIN program data and the non-RETAIN global device variables** - only effective in STOP mode
  - **Initialization of the RETAIN program data and RETAIN global device variables** (see Separate initialization of source and TO data during a download (Page 1655))
- **Load without HW configuration** (see Download without HW Config information (Page 1667))

You set the global default under **Options > Settings > Download** or **CPU download**.

The additional options are also active when they are not visible. The settings with which the last download was performed are then used. The only exception is the **Replace product versions of the technology packages** option which is only active for one action.

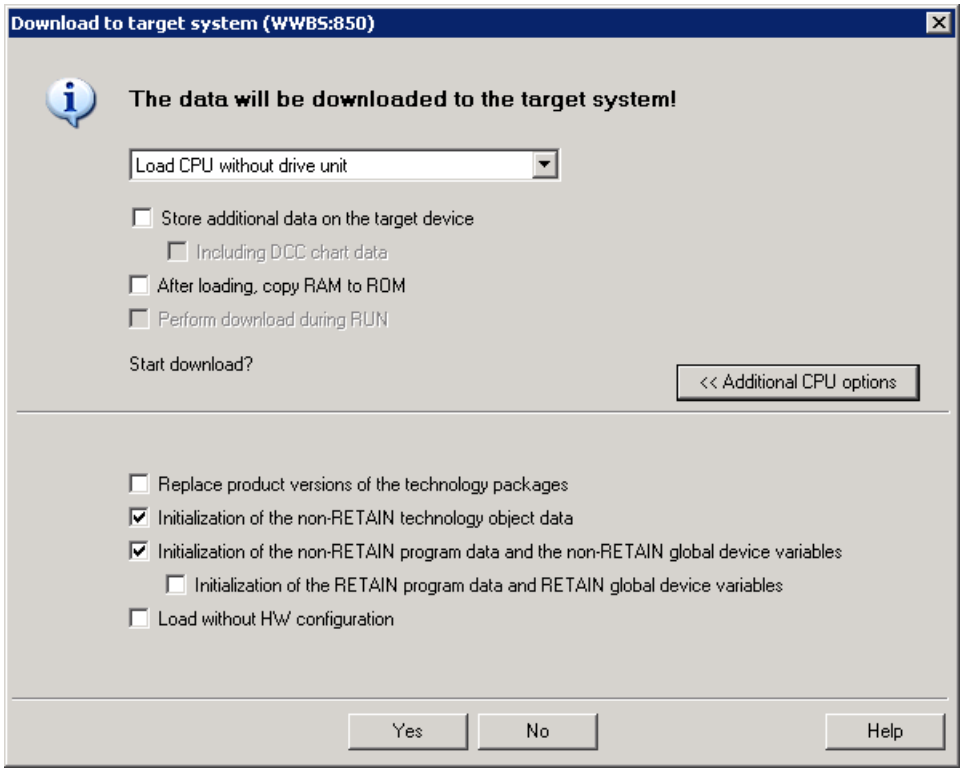

Figure 4-172 Download to CPU / drive unit

Accepting or rejecting settings

- Click **Yes** to start the download or **No** to cancel the download.

Downloading the drive to the target device

For drives, you can only download the drive data (parameterization, etc.) to the drive unit.

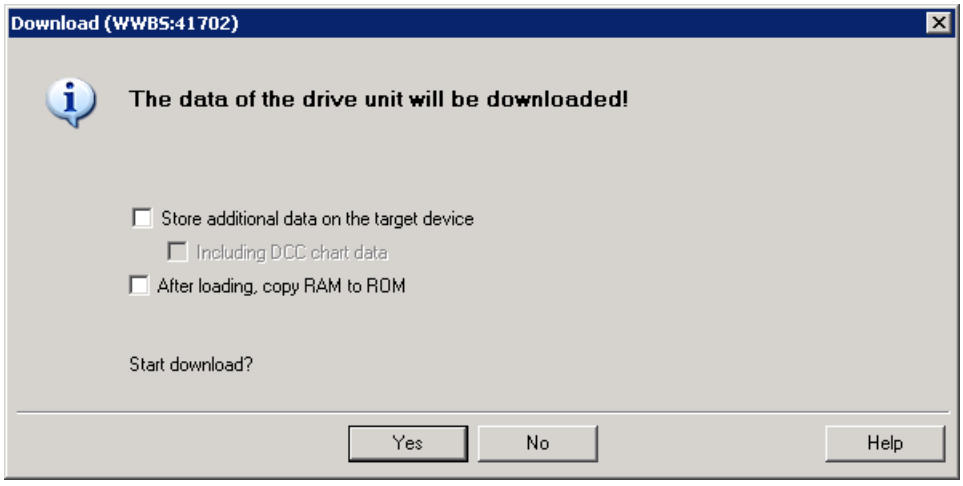

Figure 4-173 Download to drive unit

By default, the download is performed in STOP. After a successful download, the CPU can be restored to its previous status.

You can select the following options:

- **Store additional data on the target device**; you can use this option to store supplementary data (e.g. program sources) on the target device.
  - **Including DCC chart data**
    With DCC, it is possible to store graphical chart data in addition to the supplementary data that enables a functional chart to be uploaded, meaning that the chart in question is in the full source text and can, therefore, be edited further.
- **After loading, copy RAM to ROM**; copies RAM to ROM to the selected device once the download is complete.

See also

Download of changed technology objects (Page 1668)

4.2.12.7 Downloading a program subset and single units (sources) to the target device

Download of selected units

As of SIMOTION V4.4, you can download a single of several units to the SIMOTION device in the RUN and STOP states.

You no longer have to download all units that have been displayed as inconsistent, but can download a specific program subset. This enables, for example, two users who are connected online to target device at the same time with SCOUT to download separate program subsets independently.

To do this, right-click the unit in online mode and execute **Download...** in the context menu.

Note

The selective download is not possible for DCC charts.

When downloading a subset, the system ensures that the project as a whole is available again in a consistent state. For this purpose, it may be necessary to download additional units for the selection. This operation must be confirmed in a dialog box.

Note the following applications in this respect:

- You change the interface of a unit and this interface is used by a second unit. This unit is then also downloaded.
  Example: You change the signature of a function.
- You load only a subset of the changed units. After checking the dependency, independent units can be downloaded as a subset.
- You are referencing a library that has not been downloaded, in a unit that you want to download, or you change the interface of a library used in the unit. The library is downloaded with the unit.
- You delete a program (POU) of a unit that is called from the execution system. When downloading the unit, the execution system must also be downloaded.
- If programs have been downloaded to the controller that are not in the project, these programs are removed from the controller during a complete download. If you only load a subset, then programs are only deleted when there are no longer any dependencies.
  If the programs that have not been removed reference the programs that are to be downloaded (uses), then the behavior of these programs may be changed.
  Therefore, perform a detailed comparison to display the programs online and offline.

Selective download not possible

A selective download is not possible for the following reasons:

- If the relevant CPU has not been compiled error-free or the consistency check is not error-free.
- If an I/O variable has been changed in the address list.
- If a global device variable has been inserted, deleted, renamed or changed structurally (e.g. data type changed, length of the array changed); a change of the initial value does not prevent the download.
- If a TO has been inserted, deleted, renamed or changed structurally.
- If technology packages have to be loaded.
- If DCC is affected, see above.
- If tasks have been activated, deactivated for an execution system, or the cycle clocks have been changed.

4.2.12.8 Downloading the selected product version of the technology packages

Description

As of Version V4.2, you can select the product version of technology packages within a particular version (service packs and hotfixes). **Replace product versions of the technology packages** is used to download the selected technology package versions to the target system. This enables you to overwrite newer or older versions of the technology package in the target system. Further information can be found at Selecting or replacing technology packages in the SCOUT online help.

How to load a specific version of a technology package to the target system

1. Right-click a SIMOTION device in the project navigator and then click **Select Technology Packages**.
   The dialog opens.
2. Select the technology package you want to update.
3. Select the version under TP version and Version. Hotfix versions can also be selected here as of V4.2.
4. Click **OK** to close the dialog and accept these settings.
5. Go online with the device and click **Download project to target system** or **Download CPU to target system**.
   The dialog opens.
6. First click **Additional options** and select **Replace product versions of the technology packages**, then click **OK.**
7. The technology package is downloaded to the target system, even if a technology package already exists there.
   The SCOUT's detail view shows the loading process for the technology packages.

Boundary conditions for replacing technology packages

- If no technology package version is selected in the **Select Technology Packages** dialog, the latest technology package of the appropriate firmware version is downloaded to the target system.
- If you are performing an upload, the versions of the technology packages already present in the target system are uploaded too, entered on the device, and appear in the **Select Technology Packages** dialog.
- Technology package versions are exported and imported at the same time.
- If the version selected is not already on the PG/PC, an error message is output.

4.2.12.9 Separate initialization of source and TO data during a download

Description

As of V4.1.2, you can initialize non-RETAIN and RETAIN data of programs (units) and global device variables as well as non-RETAIN and technology objects separately via two settings. The data is initialized together at the first or complete download of the project. During servicing or if you only want to reload programs (units, sources) or technology objects, you can initialize the data separately.

- Initialization of the non-RETAIN technology object data; only non-RETAIN data can be initialized for TOs. This does not affect the program data (variable values).
- Initialization of the non-RETAIN program data (variables) and the non-RETAIN global device variables The RETAIN program data and RETAIN global device variables can also be initialized. This does not affect the technology object data. The global device variables are initialized together with the settings for the program data (variable values).

The initialization only takes effect in the STOP operating state.

To make the settings, see Downloading CPU/drive unit to target device (Page 1650).

The "Time of variable initialization" section in the programming manuals contains general information on variable initialization.

4.2.12.10 Download in RUN

General information for downloading in RUN

Perform download in RUN

As for a download in STOP, all selected changes are always downloaded in RUN. Therefore, only manageable changes should be made for a download in RUN. You can load an entire target device or even just parts of the target device.

A number of issues presented below must be noted for a successful download in RUN

Allowing a download in RUN

Settings in SCOUT

1. In SCOUT, select **Enable download / copy RAM to ROM during RUN** under **Options > Settings > CPU download**. This activates the option **Perform download during RUN** in the **Download to target system** dialog.
2. Click the option **Perform download during RUN**.

Download of changed sources in RUN

Change to sources – general

If a source (unit) contains several programs, FBs or FCs (POUs), then the entire unit is always loaded.

A unit can generally be exchanged in RUN. At the time of transfer, neither code (of the programs, FBs or FCs) nor the data (variables) of this unit may be used in a task.

Units are loaded at the cycle control point.

At this point in time, all cyclic tasks are restarted. As no source is accessed at the time, no source is therefore blocked in cyclical tasks for exchange in RUN.

If Motion Tasks are also used and they have been started at the time of exchange, the system determines at the cycle control point which POUs are currently accessed and blocks the applicable units from exchange in RUN.

Several seconds are spent attempting to load the changed units simultaneously at the cycle control point. If that is not possible, the process is terminated.

Options for download in RUN:

- The number of cyclic tasks in which programs (POUs) can be loaded in RUN is limited to four.
- If the number of sources (units) and relevant tasks is too high for time or volume reasons, the sum of the changes cannot be processed (loaded). This problem is displayed in the output window and the complete set of changes is not transferred to the sequence. The old data remains effective.

Dependencies on other sources

SIMOTION applies the unit concept, so that you can access the global variables, data types, functions (FCs), function blocks (FBs), and programs of other source files.

You can connect to other program sources to use their exported components by using a USES instruction in ST sources or via the **Connections** tab on the declaration tables of MCC and LAD/FBD sources.

Changes to connected sources also affect download in RUN. Additional units may have to be loaded.

If units depend on another changed unit, these units must also be compiled before download. They may use data or POUs that have been changed. On download, these units must only be exchanged if data or POUs are used.

As of SIMOTION SCOUT V4.4, the dependencies between the units are taken into account. Only called (used) POUs require the unit to be replaced. There are therefore significantly fewer dependencies compared to older SCOUT versions. This behavior applies to all supported RT versions that are processed using SIMOTION SCOUT V4.4.

In projects that have been converted from older versions of SCOUT, the feature is only available after full re-compilation using SCOUT V4.4. Execute the function **Save and recompile all** on the **Project** menu for this purpose. Note that recompilation in this case creates an online inconsistency.

In the event of a simple change to the code of a POU and in the event of any changes to the data in the implementation part of a unit, only the modified unit has to be replaced. Please note that data changes in RUN are only possible if the data is initialized (see Changes to the data declaration (Page 1659)).

Reduction of dependencies between the units

In the Engineering System, individual parameters of the units are checked for changes as of SIMOTION SCOUT V4.4.

The decision regarding whether changes in a used unit are relevant to your unit reduces the dependencies and therefore the necessary number of units to be replaced.

The following parameters are changes when a unit is used:

- Data declarations (if data from the unit is used)
- POU interfaces of used POUs (if POUs from the unit are used)
  - The following is checked for FUNCTION, FUNCTION_BLOCK and PROGRAM: Return value, VAR_INPUT and VAR_IN_OUT
  - For FUNCTION_BLOCK and PROGRAM the following are also checked: VAR and VAR_OUTPUT

Example 1

If the code of unit_2 is only processed in the BackgroundTask, the modified unit_2 can be replaced at time t4. However, as unit_1 has started a call for code (POU) from unit_2 that at time t4 has not yet returned, unit_2 cannot be replaced at this point in time.

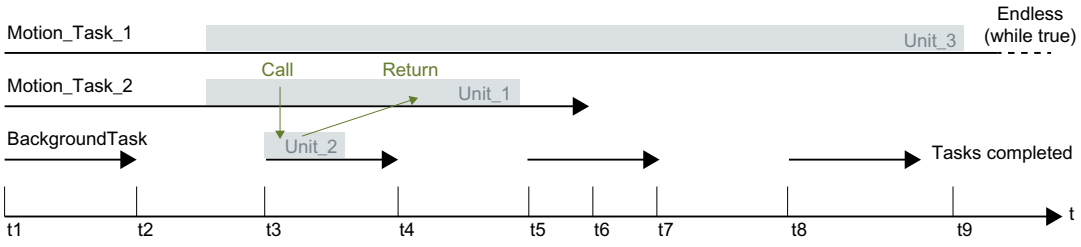

Figure 4-174 Dependencies on other sources – example 1

Unit_2 can be replaced at time t7 at the earliest.

A unit also cannot be replaced for as long as it is being processed by a MotionTask. In the example, unit_3 in the endless MotionTask can never be replaced.

The Motion_Task_1 can be stopped explicitly by the user to allow replacement to take place.

Example 2

In unit ST_2, data (data types and variables) and POUs (programs, functions, function blocks) used by ST_1 are indicated via the interface area:

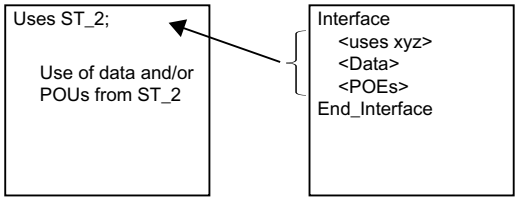

Figure 4-175 Dependencies on other sources – example 2

A change to the interface area of ST_2 has an impact on ST_1:

- ST_1 must also be re-compiled
- If ST_2 is to be replaced (loaded), ST_1 must also be replaced. Replacement depends on the scope of the change (see above) and the method for checking dependencies.

If, for example, a program is running in a cyclic task in ST_2 and a program is running in an endless MotionTask in ST_1, the unit ST_2 cannot be replaced in RUN. Unit ST_1 would also have to be replaced.

System unit of the execution system

Also note the system unit of the execution system in addition to the user units to be loaded This system unit primarily implements the execution system configuration and is therefore the connecting element between the programs and the tasks.

In the event of the following changes, the system unit must also be replaced:

- Changes to the program assignment and the size of the local data stacks in the execution system
- Changes to the data declaration of programs that are used in the execution system (PROGRAM container)
  (This point does not apply if the following compiler option is not selected for the unit that provides the program: "Create program instance data only once")
- Where a UserInterruptTask has been configured with condition on a global variable of a unit (from the interface area), if the interface (data structure of exported POUs) of this unit changes.

Where the system unit of the execution system is replaced, no task may be running simultaneously (long-running tasks and endless MotionTasks are problematic).

As of SIMOTION SCOUT V4.4, the Engineering System checks whether changes in the interface area of a user unit only related to the interfaces of the published programs or to the conditions of UserInterruptTasks. Only then is a change of the system unit of the execution system necessary, which must then be loaded and replaced. This procedure applies to all RT versions.

Changes to the data declaration

Changes to the following variables declarations are generally not permitted for a download in RUN, and the download in RUN is terminated. At the time of loading, the current values would otherwise have to be saved for all variables and, after the new variable structure had been created, the existing current values would have to be set as active again. This is not possible during the short period of loading.

If applicable measures are taken (permit initialization of the current variable values), download in RUN can, however, generally be performed anyway:

- Changes in VAR_GLOBAL blocks.
  Remedy: Permit initialization via compiler pragma BlockInit_OnChange or pragma lines in the declaration tables, see Recommended settings for download of changed sources in RUN (as of SIMOTION V4.1) (Page 1661).
- Changes in VAR blocks by programs (program instance data) that are used in cyclic tasks. The program instance data of the cyclic task is retained over the run of the tasks and therefore cannot be changed.
  Remedy: Permit initialization via compiler pragma BlockInit_OnChange or pragma lines in the declaration tables and additionally set the compiler option "Only create program instance data once" at the unit that declares the program (PROGRAM). See Recommended settings for download of changed sources in RUN (as of SIMOTION V4.1) (Page 1661).

The following variables declarations can always be changed:

- VAR_TEMP in programs and FBs, as well as all declaration blocks in FCs
- The program instance data of non-cyclic tasks (MotionTasks), as they are reinitialized on every start.
  (This only applies if the compiler option "Only create program instance data once" has not been activated for these programs (PROGRAM).)

Programmer notes for download of changed sources in RUN

Appropriate programming for download of changed sources in RUN

Use appropriate programming to enable a download of changed units in RUN mode.

- When structuring the units, ensure that data and POUs that are used both by cyclic and by sequential tasks are stored in separate units. This reduces the number of dependencies.
- Use the USES instruction (connection to other program sources to use their exported components) where possible in the implementation section and not in the interface section. This ensures there are fewer dependencies between the units, as USES instructions are not inherited in the connected source. Fewer units are affected, even at the compile stage. Changes therefore have an impact on fewer units. For more information, see "*USES statement in an importing unit*" in the *ST programming manual*.
- Configure the size of the local data stack in the task configuration for large sources (see Configure execution system (Page 1345) and Setting size of local data stack (Page 1685)):
  Take into account a reserve for download in RUN to avoid changes in the execution system. For example, additional storage may be required on the local data stack as the result of a change (e.g. for new local variables and function parameters).

In addition, for new variables:

- An additional variables declaration block may be used in the interface and implementation section of a unit with new declarations for TYPE and global variables. The variables declaration block must be introduced after the pre-existing declaration sections.
- Instead of using an additional variables declaration block, you can also create a new UNIT with the new data and then link it with USES (in the implementation section). This is also possible in MCC and LAD/FBD.

In addition, when using MotionTasks:

- Create units in accordance with how tasks and programs are assigned to one another. This minimizes dependencies and increases programming clarity.
  Negative example: One unit contains two programs. One of the two is assigned to the BackgroundTask and the other to a MotionTask.
  Download in RUN in this and other units is not possible while the MotionTask is active.
- If the program of the modified unit is assigned to a MotionTask: Provide options so that the MotionTask is not active when you want to replace the unit:
  - Avoid continuous loops in MotionTasks! For example, instead of a WHILE loop, use the *_restartTaskId* function.
  - Make provision for an operator function (such as single clock mode) so that you can reset one MotionTask, several MotionTasks, or all MotionTasks. MotionTasks can also be reset via SCOUT as of V4.1.2 (see Manage MotionTasks via SCOUT (as of V4.1.2) (Page 1666)).
- Store the program parts in their own units, if the units run permanently or are called ad hoc. This is particularly advantageous in the case of MotionTasks. A sequential control system in MCC, for example, is a permanently running program part.
  These called program parts can be replaced as long as they are not being accessed.

Error messages if download is not possible

Description

Error messages are output during the download if a change is not possible in RUN, e.g. UPP change in RUN not possible (UPP = User Program Processing). UPP indicates that an error has occurred when a user program is loaded. The old program is retained in the controller, the change is rejected.

Any changes made to the source in the SCOUT project can be easily undone by reloading the current data on the controller to the Engineering System. This ensures the SCOUT project is consistent online once more.
Requirement: Supplementary data have previously been loaded at the same time.

See Loading data from the target device to the programming device (PG)/PC (Page 1673).

Recommended settings for download of changed sources in RUN (as of SIMOTION V4.1)

Overview of settings

Download in RUN can be further improved by the following settings:

- Set the compiler switch "Create program instance data only once"
  The system unit of the execution system is then not affected by changed instance data of a program.
- Use the "BlockInit_OnChange := True;" compiler pragma or as of SCOUT V4.2, an appropriate pragma line in the declaration tables (MCC, LAD/FBD) to allow changed variables to be initialized for download in RUN.

Compiler option "Only create program instance data once"

Description

The program data instantiation and the storage of the program instance data are important in the context of download in RUN.

Compiler option "Only create program instance data once" is set (preferable for download in RUN)

- Instance data associated with programs compiled in this way is created just once, even if the program is used in multiple tasks. The instance data is then in the source or in the program code (for diagnostic purposes, this data is in the symbol browser for the unit and no longer under the execution system).
  If several tasks are assigned to one program, the same instance data is used as the basis for all of them.
  This setting has advantages for a download in RUN as the system unit of the execution system remains unchanged with changed instance data of a program.
- Local program variable data initialization is performed for sequential and cyclic tasks once when the source (unit) is downloaded and the CPU ramps up.
- A compiler pragma or the device properties can be adjusted so that the local variables are initialized on each STOP-RUN transition. See Initialization of data during a STOP - RUN transition (Page 1664).
- Where instance data has been changed, a program within a cyclic or sequential task can even be downloaded in RUN while other tasks (cyclic or sequential) are active.
  Requirement: Allow initialization by compiler pragma BlockInit_OnChange or pragma lines in the declaration tables

NOTICE
Changed behavior for data initialization Changed behavior for the data initialization when "Only create program instance data once" has been selected (see above).

Information on which tasks can run sequentially or cyclically can be found under Execution levels / tasks (Page 1301).

Compiler option "Only create program instance data once" is not activated (default)

- The instance data of all programs is in a central memory area (for diagnostic purposes, this data is in the symbol browser for the execution system). If several tasks are assigned to the same program, then separate program instance data will be created for each task.
  If instance data of a program has been changed, all non-cyclic tasks must be terminated (via central storage in the system unit of the execution system) for activation to be successful. This gives rise to restrictions for download in RUN.
- The data initialization of local program variables is performed:
  - For non-cyclic tasks, at start of task.
  - For cyclic tasks, at STOP-RUN transition.
- A program within a non-cyclic task can also be downloaded in RUN (as long as this task and other non-cyclic tasks are not active) even if the instance data is changed, as the program data is initialized at the start of the task.

Setting of the compiler option

- For the global default of the compiler settings for the program sources, activate **Only create program instance data once** under **Options > Settings > Compiler**.
- For the local setting, when inserting a program source, select **Only create program instance data once** under Compiler in the **Insert xxx** or **Properties** dialog of the source (xxx = ST, MCC, LAD, FBD unit).
  The local settings overwrite the global settings.
  The compiler switch must be placed in RUN before a download (i.e. the source must have been loaded previously with a download in STOP).

See also Influence of the compiler on variable initialization (Page 1419).

Compiler pragma for re-initialization of program instance data for download in RUN

Description

Pragma lines in the declaration tables or the pragma "{BlockInit_OnChange := TRUE;}" in ST sources can initiate a re-initialization of the data with the default values specified in the source in the event of changes to the block structure during a download in RUN.

The pragma can be used in the following cases:

- Changes to TYPE and global variables (VAR_GLOBAL) in the interface and implementation section of a unit
  (alternatively an additional variable block can also be used)
- Changes to instance data of programs (VAR)
  (when the “Only create program instance data once” option is active)

Changes made in VAR_GLOBAL blocks in the INTERFACE section may affect other sources, which will then also need to be loaded. This applies to sources which import the amended source via USES (ST) or are linked with the changed source in the declaration table (MCC, LAD/FBD) and

access variables or POUs of this source. By contrast, only the changed source is affected during the download where changes are made in VAR_GLOBAL blocks in the IMPLEMENTATION section.

Where changes are made in VAR_GLOBAL blocks in the INTERFACE section, any MotionTasks which may be running prevent download in RUN despite the pragmas mentioned above (for details of how to avoid this, see Manage MotionTasks via SCOUT (as of V4.1.2) (Page 1666)).

The pragma may only be placed at the beginning of a block.

Example of the syntax of BlockInit_OnChange:

```
VAR_GLOBAL
    {BlockInit_OnChange := TRUE;}
    Interface_Var_Global1 : INT;
    Interface_Var_Global2 : REAL;
END_VAR
```

NOTICE
Unexpected behavior after initializing data areas in RUN
Initializing data areas in RUN can cause unexpected behavior, as any saved values from the previous task cycle are no longer available.

In LAD/FDB and MCC, initialization can be activated in the declaration tables by inserting pragma lines (context menu); see the relevant LAD/FDB and MCC Programming Manuals. The pragma can be set and deleted as required at any time (see also *Adding pragma lines in variable definition* in the MCC and LAD/FBD Programming Manuals).

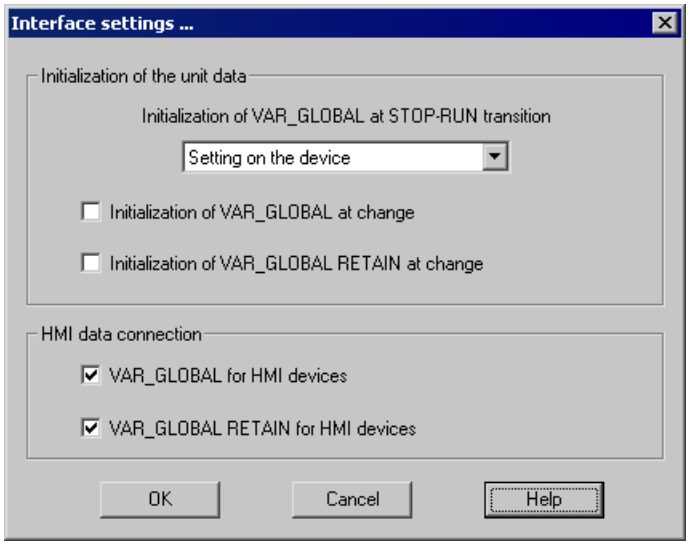

Figure 4-176 Pragma settings for unit variables (interface section)

Example

If it is not possible to perform a download in RUN because of a change to a VAR block within the program, the pragma can be subsequently set in the VAR block. Following compilation, a download in RUN will be possible, because the VAR block will have been reinitialized.

The pragma can be removed again prior to the next download. Where this is not the case, however, re-initialization in RUN is only performed in the event of a further change in the VAR block.

Simple changes to the pragma (add/delete) can be loaded in RUN at any time. You are not required to stop sequential tasks.

Initialization of data during a STOP - RUN transition

Description

If the "Only create program instance data once" compiler option has been activated, data initialization for program variables only occurs during a download or when the CPU is started.

You can set the configuration so that global unit variables (in the interface and implementation section) and program variables are also initialized during a STOP-RUN transition. The initialization is performed immediately before the start of the StartupTask. You therefore always have the ability to perform an initialization of the variables during a STOP-RUN transition:

- As of V4.2 via the Device properties dialog.
- As of V4.1.2 with the compiler pragma "BlockInit_OnDeviceRun" in the Units (ST) or pragma lines in the declaration tables of the sources or programs/charts (MCC and LAD/FBD).

Initialization via the Device properties dialog (as of V4.2)

The **Initialization of the non-RETAIN global variables (VAR_GLOBAL and global device variables) and program variables (VAR) at the transition from STOP to RUN** option in the Properties dialog of a device enables you to trigger initialization immediately before the StartupTask is started.

This global setting can be overwritten locally with a compiler pragma or a pragma line (see below).

Always / never initialize data in ST sources

In ST sources, the initialization can be influenced during a STOP-RUN transition using the compiler pragma "BlockInit_OnDeviceRun" at the start of the variable blocks.

If you use this pragma, the setting on the device is no longer valid for the applicable variable block.

If you set this pragma to "ALWAYS" in the VAR_GLOBAL block or in the VAR block of programs, the variables are initialized at each STOP - RUN transition. The setting is only valid for the variable block in which the pragma is used.

Set the pragma with the "DISABLE" setting to prevent initialization at the STOP - RUN transition in a targeted way.

The compiler issues a warning when the pragma is used at a position where it has no effect.

See also Section "Controlling compiler with attributes" in the SIMOTION ST Programming and Operating Manual.

Example of "always" initialize:

```
VAR
      {BlockInit_OnDeviceRun := ALWAYS;}
      Test_1 : REAL;
      Test_2 : REAL;
  END_VAR
```

Example of "never" initialize (even if, in the device settings, the option "Initialization of the non-RETAIN global variables (VAR_GLOBAL and global device variables) and program variables (VAR) at the transition from STOP to RUN " is active):

```
  VAR_GLOBAL
      {BlockInit_OnDeviceRun := DISABLE;}
      Test_1 : REAL;
      Test_2 : REAL;
  END_VAR
```

Always / never initialize data in MCC or LAD/FBD sources

In MCC or LAD/FBD sources and/or the associated programs/charts, the initialization during a STOP - RUN transition can be influenced by inserting a pragma line in the declaration table. Click the "Pragmas" button and select the appropriate setting under "Initialization ... at the transition from STOP to RUN".

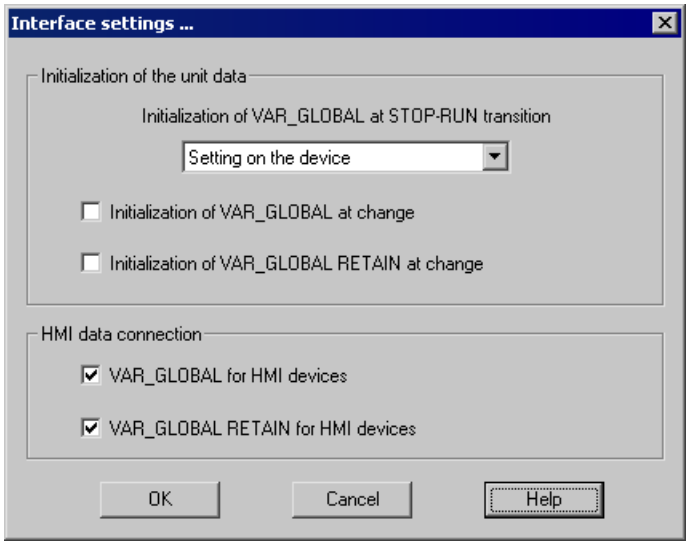

Figure 4-177 Pragma settings for unit variables (interface section)

The default value of "Setting on the device" means:

- As of V4.2: The setting made on the SIMOTION device applies.
- Up to V4.1: Variables are not initialized.

See also section "Adding pragma lines in variable definition" in the MCC Programming and Operating Manual or in the LAD/FBD Programming and Operating Manual.

Download in RUN before programs in Motion Tasks

Description

If you have made changes to sources and want to reload these using download in RUN, an active MotionTask may prevent a change-over time from being found for the interchange of the sources.

Make provision for an operator function (such as single clock mode) so that you can reset one MotionTask, several MotionTasks, or all MotionTasks.
MotionTasks can also be reset via SCOUT as of V4.1.2.

Manage MotionTasks via SCOUT (as of V4.1.2)

Description

You can control MotionTasks from SCOUT even without having created a user program.

In this way you can test programs and directly affect the execution of MotionTasks. To perform a download in RUN, you can terminate MotionTasks individually via SCOUT and restart them after download.

Switching on debug mode and controlling MotionTasks

Requirement

To control MotionTasks, you must be ONLINE and switch to debug mode.

1. Right-click the relevant device and execute **Operating mode** in the context menu.
2. Then select the **Debug mode** option in the **Operating mode** dialog, read the safety instructions, accept these by clicking the option and then clicking **OK**.

Procedure

1. After you have activated the debug mode, call up the device diagnostics via **Target system > Device diagnostics**.
2. Select a MotionTask on the **Task status tab** and right-click it.
   A context menu is displayed.
3. Select **Disable task start** if you want to block the start of the MotionTask. This prevents the task from restarting (TASKSTART_LOCKED in task status).
4. Select **Reset task** if you want to set the task in the STOPPED state. A download in RUN can be performed in this state.

5. Select **Enable task start** if you want to release the start of the task. You can then restart the task from the program or via SCOUT.
6. Select **Start task** if you want to start the MotionTask.

After executing the task control commands, it takes some time before the display in SCOUT is refreshed. You can also click the **Update (F5)** button.

Controlling several MotionTasks simultaneously

1. Select the desired tasks by holding down the Ctrl key and clicking the left mouse button. The tasks are selected.
2. Click the **Control MotionTasks** button and select the corresponding command in the context menu that appears.

Note

The task control commands depend on the system task control commands. You can read the task status in the **Task runtimes** tab under **Task status**.

Behavior when changing the operating mode

If all tasks are enabled when leaving the debug mode, the CPU retains its operating state.

The system displays the following behavior if you intentionally or unintentionally exit the **Debug mode** operating mode and at least one task is disabled.

- If you exit the debug mode before all tasks are enabled, the CPU switches to STOP and the disabling is canceled.
- If you go OFFLINE before all tasks are enabled, the CPU goes into STOP and the disables are cancelled. If you go ONLINE, the CPU switches to process mode again (debug mode is canceled).
- A RUN - STOP - RUN transition does not affect the task status. If the task was disabled before the start, it is also disabled for the start.
- The CPU goes into STOP if SCOUT unintentionally loses communication to the controller. SCOUT goes OFFLINE at the same time.

Download without HW Config information

Download with inconsistent HW Config

As of V4.1.2, it is also possible to perform a download with inconsistent HW Config. In the event of significant changes to the hardware configuration, the download is still canceled and the HW Config also has to be loaded.

The following parameter changes require a download with HW Config

- Logical addresses
  - Address moved in HW Config
  - Adding separate slots to DP nodes or to existing nodes
- Telegram length
  - Telegram length changed
- Cycle clock settings
  - DP cycle time and PN send cycle clock changed

Note

The settings for the telegram length, address and data types are adapted in HW Config in the **DP Slave Properties** dialog box in the **Configuration** tab.
The cycle clock settings are made in the **Isochronous operation** tab.

Setting download without HW Config

You can select this additional option in **Additional CPU options** in the **Load to target system** and **Load to CPU/drive unit** dialogs. You can preset the additional option in **Options > Settings > Download**.

Download of changed technology objects

Description

You can reload changes in the configuration data and system variables of a TO you made offline in RUN (using restart and effective immediately). If necessary, a TO restart is performed after the download.

Downloading TOs

It is possible to download a changed TO under the following circumstances or prerequisites:

- Only technology objects whose structure is retained can be downloaded (see below)
- A download is also performed when a technology object is used by a program, e.g. axis is enabled. If necessary, TO alarms are then output.
- The substitute values of the TO supplied during the download are returned according to the setting of "restart.behaviorInvalidSysvarAccess" (LAST_VALUE, DEFAULT_VALUE). If a restart is performed during a download of TOs, access errors from the user program may occur. The reaction of the CPU or the return value then depends on the settings of the configuration data item "restart.behaviorInvalidSysvarAccess". If this configuration data item is set to STOPPED, the CPU goes to STOP. For more information, refer to System variables (Page 1245).

- If the change to a TO cannot be loaded during the download or an error occurs, the original configuration is retained or re-established (situation as prior to the download).
- The technology objects are loaded in succession and take effect immediately.

Behavior when loading multiple TOs

If you are loading a group of TOs and one of the TOs cannot be downloaded:

- The configuration for already loaded TOs remains active
- The download for the technology object that could not be loaded is rejected.
- The download for the TOs not yet loaded continues

Permitting a TO restart

Before the download is performed, you can use an option to select whether a RESTART of the TOs is to be permitted or not. In this way, you can directly influence a TO RESTART. A RESTART is then executed independently of the setting in the TO in configuration data element RestartCondition.

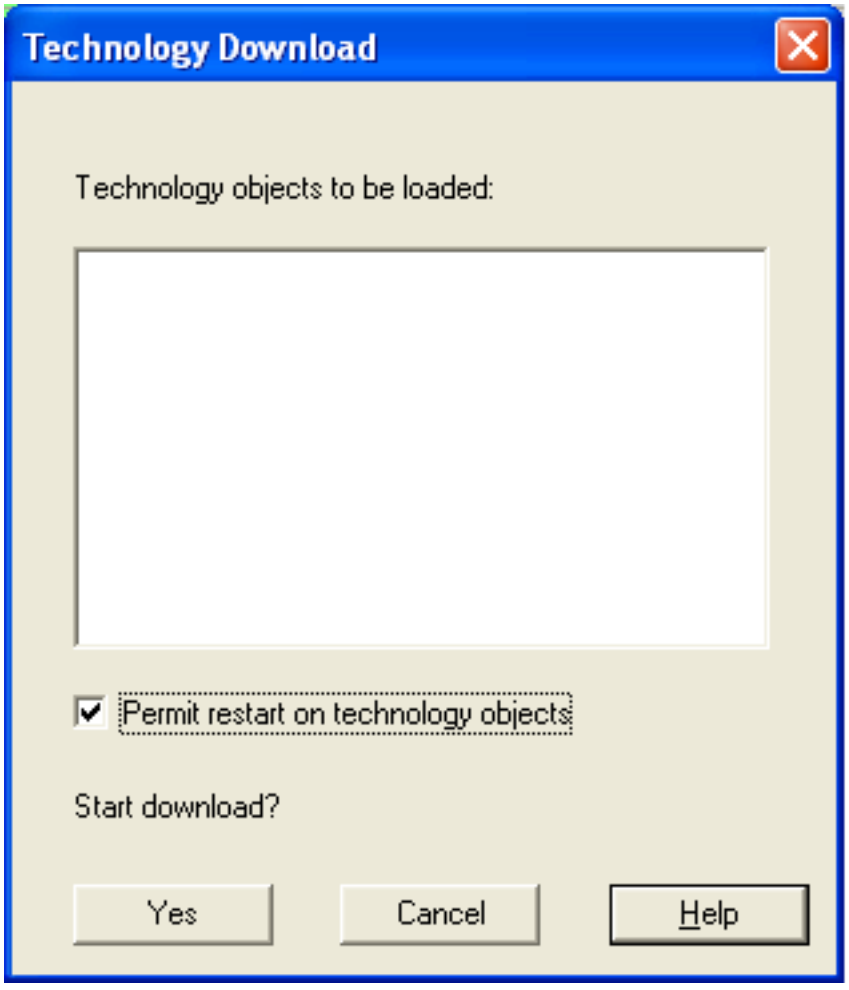

Figure 4-178 TO overview for download

The **Permit restart on technology objects** option is selected by default. If you deselect the option, this setting is saved for further downloads with this project. With configuration data that can only be changed via restart, the TO then behaves as though the download would not have functioned.

Changeable parameters that allow a download in RUN

Configuration data that can be changed via a download always acts on the structure of the TO. In addition, changes to units, interconnections, alarm configuration, and profiles also act on the structure of a TO in such a way that a download in RUN is no longer possible.

In view of this, you are able to change the following data for a download in RUN:

- Immediately effective configuration data
- Configuration data effective at a restart
- System variables

In the expert list of the TOs, the **Effectiveness** column allows you to recognize whether the change in a configuration data item takes effect immediately, requires a restart or is possible only with a download (in STOP). This applies to the configuration data in ONLINE as well as OFFLINE mode.

Copying RAM to ROM in RUN (as of V4.2)

Description

If you have performed a download in RUN, you can also save the changes on the memory card in a powerfail-safe manner.

The Copy RAM to ROM option can be selected beforehand in the download dialog. After a download, this is also possible by means of a separate function (using the **Copy RAM to ROM** button in the toolbar or in the device context menu under Target device).

To preset the option in the download dialog, select **Options > Settings > CPU download**. Here, it can also be specified whether or not the actual values of the TO configuration data are transferred to RAM before the copy RAM to ROM operation.

Note

During "Copy RAM to ROM in RUN", CPU utilization must not be at a critical level (see device diagnostics) as this function generates additional load.

Download with RAM2ROM in RUN in projects with older runtime versions (< V4.1) is not possible and is actively prevented.

Inconsistent TO after a download in RUN

If a TO configuration data element has been changed in the application, it may be the case that the corresponding TO is displayed as inconsistent after a download in RUN.

Scenario with the following settings:

- **Download > Copy RAM to ROM**
- **Settings > CPU download > Accept actual values when copying RAM to ROM**

The configuration data changed by the application will then be in the current data memory. The above settings ensure they are copied from current memory to the RAM and then to the memory card (ROM).
The configured values in the project and the values in the RAM are therefore different and the TO is displayed as inconsistent in the project navigator.

You will then be able to proceed as follows:

- Ignore TO inconsistency
- Analyze the TO inconsistency by means of a project comparison.
- Load the online TO configuration data to the programming device using **Load to PG**.
- Load the offline TO configuration data by performing a download to the device.

See also Copy RAM to ROM (Page 1676).

4.2.12.11 Download direct to memory card or hard disk

With **Load to File System**, you can save the executable project data from SCOUT to the hard disk of the PC/PG or directly to the memory card using a card adapter.

Two methods of saving are available:

- With the "Save normally" option, the user directory is created containing the SIMOTION and SINAMICS subdirectories.
- The "Save compressed" option creates the same content in the form of a Zip file that can be used, for example, for loading via SIMOTION IT Diag.

The loading to the memory card can be viewed the same as a download with subsequent copying of RAM to ROM. This function is very useful, for example, during series commissioning.

Note that the non-volatile data saved on the memory card is overwritten with **Load to file system**. If required, back up the non-volatile data first as described in Memory access (Page 1640).

Procedure

To save the data, SCOUT must be in OFFLINE mode and the device must have been selected in the project navigator for this function to be available.

- Perform **Edit > Load to file system** or **Load to file system** using the context menu of the CPU to save the data of a device on a memory card / CF card or locally on a hard disk.

SCOUT does not automatically recognize the connected read and storage media automatically. The storage/read device must be explicitly selected using **Select target**. An executable project is produced when the project data is saved.

Note

When you save data (either to hard disk or CF card), a USER directory is created automatically so that you can copy data directly to the ROOT directory of a CF card.

⚠ CAUTION

Data loss on the memory card

If you perform **Load to file system**, then the **OEM** folder on the memory card is also deleted. This data is not restored for OEM applications that are not known in the engineering system (are not installed there). You must copy the data manually to the card.

Loading data from the hard disk to the card

You can copy the data from the hard disk to the CF card. As of V4.2, only the contents of the following directories are deleted or overwritten:

- \USER\SIMOTION\RT_DIR
  The subdirectory UPP can be backed up as of version 4.4.
  To do this, check the box "Restore the retentive unit global variables on the device". If the program sources with the compiler option "Permit OPC-UA / -XML (load symbols to RT)" have been compiled, retentive data can be restored by this method. See section "Retaining retentive data" in the "Basic Functions for Modular Machines" Function Manual.
- \USER\SINAMICS\DATA\RT_DIR

The user data in the directories listed below is retained.

Examples of user data saved on the card:

- Backing up retain data (non-volatile data saved using _savePersistentMemoryData) stored in the directory:
  - user\simotion\pmemory.xml
- Backing up IT DIAG user files, settings (e.g. trace.xml), task trace data, log files, and Java files (classes, archives, user file system, etc.), stored in the following directories:
  - user\simotion\hmicfg
  - user\simotion\hmi
- Backing up unit data (data saved on the CF card using _saveUnitDataSet/ _exportUnitDataSet), stored in the following directory:
  - user\simotion\user dir\<unitname>

Note

The stored data must match the firmware of the card. If, for example, you load an old configuration to a card with the latest firmware, you receive error messages during ramp-up.

4.2.12.12 Downloading using the device update tool

Description

SIMOTION offers a convenient solution when updating SIMOTION devices or SIMOTION projects for machine manufacturers and machine operators. Upgrading does not simply mean updating to a higher firmware version; it is a general term for switching to a defined configuration, e.g. a project update. It is also possible to return (restore) to a previous configuration. Update or restore procedures can easily be performed on SIMOTION devices in situ or remotely. The data can be imported to a SIMOTION device via a portable, handy storage medium (e.g. memory stick) or a communication connection.

Note

The firmware of connected SINAMICS drives will only be updated if the automatic firmware update function has been set in parameter p7826 (on every drive unit to be updated).

Detailed information can be found under Updating SIMOTION devices.

4.2.12.13 Retaining retentive data during download

Retentive unit variables and retentive local variables are retained when a download is performed provided that no changes are made to the data blocks.

Please also note the relevant information in section "Retaining retentive data" in the "Modular Machines" Function Manual.

Reorganization of the retentive memory

If the size of the retentive data blocks changes in the new configuration, fragmentation of the retentive memory may make it impossible to perform the download.

The following applies as of version V4.5 of the SIMOTION Kernel:

- The device must be restarted manually
- The retentive memory will then be reorganized.
  The values of the retentive global unit variables are retained if the symbol information is saved in the device. For this purpose, the compiler option "Permit OPC-UA / -XML (load symbols to RT)" must be activated for all relevant program sources during compilation.
- Please also note the relevant information in section "Retaining retentive data" in the "Modular Machines" Function Manual.

The following applies up to version V4.4 of the SIMOTION Kernel:

- You must perform a memory reset on the device.
  The retentive data is lost.

4.2.12.14 Loading data from the target device to the programming device (PG)/PC

With **Load to PG**, the data is loaded from the target device to the PG/PC. In this way, the currently loaded project can be loaded from the target device with all settings to the local hard disk.

Sources or additional data of a project can only be loaded to a programming device when they have previously been loaded to the target system. **Options > Settings > Download > Store additional data on the target device** must have been set in the project for this.

The menu item **Load to PG** is only active when you are ONLINE and a device has been selected.

Note

This function is not suited to restore the original project in SIMOTION SCOUT. Use the **Target system > Load > Copy archived project from card to PG/PC** function for this purpose.

The function is more suited to restore an archived original project, see the following Section "Loading with an existing original project".

Further information on the archiving of a project and saving of the archived project on the memory card can be found in the Online help.

Load to PG with available original project (maintenance scenario)

You are placing commissioned equipment into service, along with a project, or loading the archived project from the memory card of the controller. The project is not consistent online, but is essentially the same as the project that will run on the target device. You can use **Load to PG** when performing the upload to create online consistency between the SCOUT project and the CPU. Afterwards, possible errors are searched for and changes downloaded to the target device.

Note

Objects in the OFFLINE project will be overwritten. As a result, objects which are only present OFFLINE will be deleted. If you want to still be able to access the OFFLINE project after the upload, click **Save before loading to PG** to save the current version of the OFFLINE project. You can retain the OFFLINE project again by exiting the project after the upload without saving it.

Alternative: Archive the OFFLINE project first or save it under another name.

Please note that various functions (e.g. program status) remain inactive and cannot be used until the uploaded objects are saved with the project.

The offline and online projects can also be aligned using the comparison functions (project comparison).

Procedure where there is an existing project

1. Perform **Target system > Load > Load CPU / drive unit to PG**.
   The **Load to PG** dialog box is displayed.
2. Select the option **Load target device to PG** if you want to load all the project data from the target device to the programming device. Note the information in the dialog box.
3. Select the option **Save before loading to PG** if you want to save the project on your PG before uploading.
4. Select the option **Overwrite available libraries** if you want to overwrite the libraries of the project available locally on your programming device.

Only load configuration data to PG

1. Select the **Only load configuration data to PG** option if you want to load the configuration data from the RAM to the programming device.

Transfer current data to RAM

If you want to load the amended configuration data in the current data memory of the target device to the RAM before loading to the programming device, select the **Transfer current data to RAM** checkbox. If you do not transfer the current data to the RAM, it is not loaded to the programming device.

As of V4.2, configuration data is completed during ramp-up using parameter values of the SINAMICS drive (adaptation). For more detailed information, see **Adaptation** under Symbolic assignment - introduction (Page 1189). When "Load to PG" is executed, adapted values are detected and "Transfer current data to RAM" is automatically preselected as well.

Loading to the programming device via a project comparison (object granular)

- With the project comparison functionality, you can also load the data for individual objects to the programming device. For more detailed information, please refer to the online help on project comparison or the sections relating to project comparison in the SIMOTION manual.

See also

Overview of the data download (Page 1643)

4.2.12.15 Copy current data to RAM

Description

Use **Copy current data to RAM** to copy the current configuration data, changed during the RUN mode, to the RAM. Depending on the data item, changes to the configuration data during RUN take effect in different ways (e.g. immediately or after a restart of the technology object).

After the restart on the technology object, the changed configuration data is stored in the current data memory. To copy the values from the current data memory to the RAM, you must execute this function explicitly. Only after copying is the data in the RAM, and is then uploaded at the next ramp-up and takes effect. See also Overview of the memory in the target device (Page 1637).

Note

So that the project data in SCOUT is consistent with the project data in the target system if configuration data has been changed online, you must perform an upload to the PG/PC (menu **Target system > Load > Configuration data to PG**).

Adaptation of configuration data

When SIMOTION devices ramp up, reference variables, along with drive and encoder data for SINAMICS S120 (SINAMICS Integrated), are transferred automatically for the configuration data of the SIMOTION technology objects "TO axis" and "TO external encoder". Therefore, this data no longer has to be entered in SIMOTION. The adapted data is located in the current data memory. When **Copy current data to RAM** is executed, these values are added to the RAM. This makes the technology object inconsistent online. To resolve this inconsistency, you also need to load the configuration data to the PG. This is detected in the dialog and the appropriate preselections are made. If you have changed configuration data online yourself, this will also be loaded to the PG. For more detailed information on adaptation, see Symbolic assignment - introduction (Page 1189).

Transferring current data to RAM

1. Select **Target system > Copy current data to RAM**.
   The **Copy current data to RAM** dialog opens. The dialog indicates whether the configuration data has been changed as a result of adaptation.
2. Select one of the following options:
   – Copy RAM to ROM
   – Load to PG
3. Click **Yes** to trigger the copying process and any options selected.

For more setting options to trigger **Copy current data to RAM** select:

- **Load to PG** dialog
- **Options > CPU download >Copy RAM to ROM > Transfer current values to RAM**

See also

Copy RAM to ROM (Page 1676)

4.2.12.16 Copy RAM to ROM

Description

Select **Copy RAM to ROM** to save the project from the volatile memory (RAM) to the retentive memory (ROM) of the memory card. A power failure must be avoided when writing to the memory card.

For a detailed description, see Overview of the memory in the target device (Page 1637).

Possible errors when copying from RAM to ROM

Errors can occur when copying from RAM to ROM Possible causes:

- An access error has occurred.
- Rotating measurement (p1960) is activated.

- Insufficient storage space is available. Check the memory card and restart the action.
- The ramp up of the drive unit has not yet completed, check the operating state of the diagnostic overview.

Note

Check the entries in the diagnostic buffer and the **target system output**.

Copying RAM to ROM with adapted configuration data

When SIMOTION devices ramp up, reference variables, along with drive and encoder data for SINAMICS S120 (SINAMICS Integrated), are transferred automatically for the configuration data of the SIMOTION technology objects "TO axis" and "TO external encoder". Therefore, this data no longer has to be entered in SIMOTION. The adapted data is located in the current data memory, **not** in the RAM.

When **Copy RAM to ROM** is executed, the system detects whether values have been adapted. **Copy current data to RAM** and **Load configuration data to the PG** are also preselected in order to back up this configuration data to the memory card (ROM) and to carry out alignment with the engineering project as well. See also Copy current data to RAM (Page 1675).

See also

Copying RAM to ROM in RUN (as of V4.2) (Page 1670)

4.2.12.17 Deleting user data on the memory card

You will need to delete the user data on the memory card, for example:

- If you want to save a different (new) project to the memory card and, therefore, delete any user data relating to an "old project" (e.g. unit data sets) which might be stored on the memory card.
- If you want to delete the technology packages on the memory card, e.g.:
  - If you want to use a smaller technology package (e.g. CAM instead of CAM_EXT)
  - To force an upgrade of the technology package **within a version** in line with a new hotfix or service pack

    Note

    User data does not have to be deleted in the event of a change of version. In such cases, the technology packages on the memory card are always updated.

- You can delete the user data with SIMOTION SCOUT. As of V4.2, you can select which data you want to delete.

This means you can still access the SIMOTION module online with your PG/PC. The licenses on the memory card are retained.

Deleting user data

1. In SIMOTION SCOUT, open the project you want to edit.
2. Go online with the module.
3. Select the module in the project navigator and then select **Target system > Delete user data on card**.
   The **Delete user data on card** dialog appears. You can select which data you want to delete in this dialog:
   - Project data (programs, technology objects, TPs, SINAMICS Integrated, etc.)
   - Unit data sets
   - Non-volatile data (overall reset)
   - Archived project
4. Activate the options which you want to delete.
5. Click **OK** to delete the data.

Note

Non-volatile data and unit data sets may only be deleted together with project data.

4.2.13 Error sources and efficient programming

4.2.13.1 Error sources during programming

Error sources during programming

Explanations of the most important error sources associated with programming are provided below. The section also provides you with solution possibilities for eliminating these error sources.

Checking data types when assigning arithmetic expressions

In arithmetic expressions, the result is always calculated in the largest number format contained in the expression.

An expression value can only be assigned to a variable in the following cases:

- The calculated expression and the variable to be assigned are of the same data type.
- The data type of the calculated expression can be implicitly converted to the data type of the variable to be assigned.

Therefore, if you want to assign an expression to a variable:

- Ensure that the variable is of a large enough data type.
- Perform an explicit data type conversion for that part of the expression that is too large (see Functions for the conversion of numeric data types and bit data types (Page 1483)). However, as a result information could be lost, for example, if the value range is decreased or the accuracy is reduced, as is the case for conversion from LREAL to REAL.
- If applicable, specify the data type explicitly for numbers (e.g. UINT#127, if the number 127 is to be of data type UINT instead of USINT).

Checking start of functions in cyclic tasks every time

Technology object functions, such as functions for positioning axes, should only be started in cyclic tasks if they are not already running. Otherwise, the commands in your program are executed every time the cycle is repeated.

You can program a condition for the technology object function start in cyclic tasks, e.g. depending on the contents of an auxiliary variable, which is set when the command is executed.

Table 4-139 Example for correct TO function start in a cyclic task

```
//...
IF myStart = 0 THEN       // If auxiliary variable has not yet been set
    myStart := 1;        // Set auxiliary variable (function started)
    myCommandID := _getCommandId ();
    myFC := _pos (axis := myAxis, // Execute function
             position        := position_1,
             nextCommand     := IMMEDIATELY,
             commandID       := myCommandID);
END_IF;
//...
IF myAxis.positioningState.actualPosition = position_1 THEN
    myStart := 0;         // Reset auxiliary variable, if
                          // function execution required.
END_IF;
//...
```

Wait times in cyclic tasks

If you link command transitions to conditions when using system functions in cyclic tasks, e.g. for the *_pos* command, a timeout can occur, causing a CPU stop.

This can occur in any system function where the *nextCommand* parameter assumes a value other than IMMEDIATELY, e.g. the value WHEN_MOTION_DONE.

The timeout occurs if the cycle time configured in SIMOTION SCOUT is exceeded as a result of a step enabling condition or programmed wait times, e.g. using *_waitTime*.

Note

Do not use commands with wait times in cyclic tasks, e.g. *_waitTime*.

Use only input parameter **nextCommand := IMMEDIATELY** for system functions in cyclic tasks.

Using the commandId parameter correctly

All TO commands must contain a parameter for command identification, see **Function parameters of technology functions.**

Prior to calling the appropriate command you can obtain a project-wide unique command ID with the command *_getCommandId*. Save the command ID in a local variable and use it as a parameter in the technology object command; alternatively, use the function call in *commandId:=_getCommandId()* directly as a parameter.

Note

If the CommandId is not assigned for the command call, the default value of the parameter takes effect with (0.0).

The CommandID is not only used by TO commands.

You must use this unique command ID to check the status of the motion command, e.g. to check the status of a positioning motion with *_getStateOfAxisCommand*. The system can only uniquely identify a motion command from its command ID!

Table 4-140 Example of using a TO function with command identification

```
//...
VAR
    myCommandID                 : commandIdType;
    myState                     : StructRetCommandState;
END_VAR
//...
myCommandID := _getCommandId ();
// Save unique ID
myFC := _pos (axis := myAxis,
// Execute function with ID
             position           := position_1,
             nextCommand     := IMMEDIATELY,
             commandID          := myCommandID);
myState := _getStateOfAxisCommand (axis:=myAxis,
             commandID          := myCommandID);
// Status check
IF myState.commandIdState = WAITING_FOR_SYNC_START THEN
    ;
//...
END_IF;
//...
```

CommandID overview (Page 1541)

Locating errors (ST programs)

The following error message can occur during compilation:

Error 7000, 7010, 7011, or 7014 in Line ...

A syntax error has occurred. Possible causes:

- *Incorrectly terminated control structures (e.g. END_IF missing)*
- *Statements not terminated with ;*
- *Missing parentheses*

First, check the specified line to see whether the error actually occurred there, i.e. perhaps you have not terminated a control structure, or have omitted a semicolon at the end of a line, or a parenthesis is missing.

If you cannot find any of the specified errors, you must locate the error:

1. Comment out the program block-by-block before the line containing the error message, i.e. enclose the selected section between the character pair (* and *). The line with the error message must not be commented out.
2. Recompile the program.
3. If an error message still appears after steps 1 and 2, the commented-out section is too small. Expand it until the error message disappears.
4. When the error message no longer appears, the error is contained in the commented-out section. Now reduce the size of the commented-out section line by line and recompile the program each time until the error message appears again. The last enabled line is the line with the error message.

Note

You can consult a list of all compiler error messages in the appendix of the ST Programming Manual.

Errors on download

If an error message occurs when your program is downloaded, the log is held in the SIMOTION SCOUT detail view. Look for the error cause in the log. Check your hardware configuration or the program, e.g. for addresses that do not exist.

For more information about hardware configuration and addressing, refer to the SIMOTION SCOUT configuration manual.

Error messages during the download that contain the abbreviation UPP (User Program Processing) occur when a user program is being processed, e.g. when changes cannot be performed in RUN.

CPU does not switch to RUN

If the CPU switches back to STOP mode immediately after you have started your programs, check the device diagnostics and alarm window in SCOUT. The causes of the STOP are entered in the diagnostics buffer. The alarms of the technology objects that can also cause a CPU STOP are displayed in the Alarms window.

CPU goes to STOP

Description

If the CPU changes to STOP mode then check the device diagnostics and the alarm window in the SCOUT. The causes of the STOP are entered in the diagnostics buffer. The alarms of the technology objects that can also cause a CPU STOP are displayed in the Alarms window.

Possible reasons, why a CPU can go into STOP are:

- Incorrect direct I/O access
- Configuration data access or system variable access to TO if in RESTART (as of V4.1, however, substitute values for system variables are possible; see System variables (Page 1245))
- Missing PeripheralFaultTask (if there is incorrect access to the process image)
- Missing TechnologicalFaultTask (if there are errors on the technology object)
- Processing error in the programs (or missing ExecutionFaultTask)
- Monitoring time overflow of the IPO/servo tasks
- Monitoring time overflow of the BackgroundTask
- Monitoring overflow of a TimerInterruptTask
- Sign-of-life monitoring Simotion - drive
- Technology object alarms with STOP response (e.g. 20001)
- Set mode using system variable

Displaying and changing the operating mode

Use the device system variable *modeOfOperation* to display or change the current operating mode.

Syntax example

```
modeOfOperation  :EnumDeviceModeOfOperation  //readable, writable,
immediately effective
EnumDeviceModeOfOperation:
    [
     _STOP |
     _RUN
    ]
```

For example, with this, you can switch a SIMOTION CPU that has gone into STOP into RUN again from a local HMI by writing the device system variables.

Detailed information about the system variable *modeOfOperation* can be found in the *System Functions/Variables of the Devices* Manual or in the online help.

See also

Execution errors in programs (Page 1256)

Access errors to system variables and configuration data, as well as I/O variables for direct access (Page 1258)

SystemInterruptTasks (Page 1334)

Possible errors in technology objects (Page 1281)

Checking and setting system clocks

Often, incorrectly set system cycle clocks (servo cycle clocks, interpolator cycle clocks, PWM cycle clock) cause the SIMOTION device to go into STOP mode.

Check the runtimes of the SynchronousTasks (ServoSynchronousTask, ServoSynchronousTask_fast, IPOsynchronousTask, IPOsynchronousTask_fast, IPOsynchronousTask_2, tasks for the TControl technology package). It could be that the user programs or system programs for individual tasks need more time than is set in the system cycle clocks in SIMOTION SCOUT.

Also try to minimize the runtime of the SynchronousTasks. Shift the programs to MotionTasks as much as possible, and split up your programs accordingly, if necessary.

Make sure there is an integer ratio between individual tasks. Otherwise, low-priority SynchronousTasks will not be started at periodic intervals.

Deactivate unnecessary tasks.

Note

The system tasks for the TControl technology package can be disabled in the system cycle clock settings window.

Refer to the online help for information about how to check the device diagnostics, interpret the alarm window and check/change your system clocks.

System functions and a Task Trace are available for checking the runtimes. The Task Trace can be used to graphically display the sequence of individual tasks and user events (generated per program command); see Task Trace function manual.

See also Isochronous data processing (Page 1385) , Functions for message programming (AlarmS) (Page 1452).

Comparing REAL or LREAL variables

When you compare REAL variables or LREAL variables (also corresponding system variables, e.g. axis position) with one another, you should never use "=". Because of the different internal number representation, the compared numbers are never identical. Instead, you should evaluate, for example, the direction of motion and use ">" or "<" or the system variable for "Position window reached".

Sequential task is interrupted

Description

Sequential tasks (MotionTasks) can assume different states, including TASK_STATE_WAITING. The status can be read out in the diagnostics display of the CPU.

If you do not know why the task is waiting, you must carry out an extensive search to identify the point in the program at which the task is waiting on a condition.

You use the following functions to find these points:

- Display program run function
- Display code position (e.g. line of an ST source file) that runs a MotionTask

For detailed information refer to Section *Program run* in the *ST programming manual*.

Checking for range violations

Range violations, i.e. the violation of range limits for a data type, are not signaled by the compiler. Therefore, if you use variables in arithmetic operations, you should always check for possible range violations.

Table 4-141 Example of checking for a range violation

```
PROGRAM myRange
    VAR
        a,b  : SINT := 100;
        c: SINT;
    END_VAR

    c := a + b;
    // If c is outside range, then exit program.
    IF (a > 0) AND (c < a) AND (c < b) OR
       (a < 0) AND (c > a) AND (c > b) THEN
       // Range violation
       RETURN;
    ELSE
        ; // OK
    END_IF;
END_PROGRAM
```

Setting size of local data stack

When configuring the execution system, set the size of the reserved local data stack for each task in the *Task configuration* tab, see Description of the respective user program task (Page 1314).

Use the "Program structure" function to obtain information about the memory requirements of a program with all called program organization units (FCs and FBs) on the stack, see the SIMOTION ST Programming Manual. You will also find information on the memory requirement of variables on the local data stack in this manual.

During configuration, ensure that there is sufficient spare. For example, temporary additional storage may be required on the local data stack during downloading in RUN.

The download operation will be aborted with an error message if the reserved local data stack exceeds the available memory space in the RAM.

The program will be aborted during execution if the reserved local data stack is insufficient for program execution.

In the event of an error, check the following:

- RAM utilization in the device diagnostics
- The sources (programs, etc.) for large data structures (arrays, structures), e.g. using the cross-reference list
- Size of local data stack for the task

See also

Specifications for the configuring (Page 1417)

Sources of errors during multitasking

The main sources of errors during multitasking are:

- Using FB instances in different tasks
- Using global variables in different tasks

Using FB instances and global variables in different tasks carries the risk of this data not being processed correctly. If global variables are used in different tasks, a change of task and processing in a different task may cause an unwanted change in the value, for example.

4.2.13.2 Efficient programming

Efficient programming - overview

The following discrepancy always occurs in many control systems and/or the associated programming environments:

- Well structured and concise user programs with special emphasis on modifiability and expandability do not perform optimally with regard to runtime.
- On the other hand, runtime-optimized programs are difficult to expand or modify.

The following description provides information for runtime-optimizing programming and for change-optimizing programming. Depending on the task or with local optimizations, you should focus on one of these options.

Runtime-optimized programming

The following description contains information about runtime-optimized programming. Note that instructions for runtime-optimizing programming are often at odds with the rules of structured programming.

Optimizing access to inputs and outputs

Access to the process image of cyclic tasks is significantly faster than direct access to inputs or outputs (see Direct access and process image of the cyclic tasks in the ST Programming Manual). Therefore, you should assign an I/O variable to the process image of the task in which the variable is used. In addition to quicker access, another advantage of this is that the I/O variable will be consistent during the entire runtime of the task.

Optimizing access to system variables

It takes considerably longer to access system variables (see System variables (Page 1245)) than to access variables that are stored in the dynamic memory (local variables, non-retentive unit variables).

Therefore, only a few instances of direct access to system variables are possible in high-speed cyclic tasks (e.g. SynchronousTasks). For this reason, when a system variable is accessed many times, it is recommended that you copy the entire system variable structure at the beginning of a cycle (program in the cyclic task) to a local variable of the corresponding system data type. Then access this variable during the program cycle.

The data types for declaring the local variables can be found in the List Manuals for SIMOTION technology objects (TOs).

Optimal variable declaration

Arrange the variables within a declaration block (e.g. VAR/END_VAR) in order of ascending size. This enables you to make optimal use of the memory space.

Initialize variables with values other than 0 only when necessary. Variable initialization at the start of a task or POU requires time. This is especially the case for temporary variables and variables of programs that are assigned to sequential tasks.

Optimizing access to function block parameters

When creating function blocks (FBs) that are to process values, you can select one of two methods. You can assign input variables in the FB with VAR_INPUT, process the variables there, and assign the results to output parameters with VAR_OUTPUT.

If a large data volume is to be transferred to the FB, it can be faster to use in/out parameters (VAR_IN_OUT) than to use input and output parameters (VAR_INPUT and VAR_OUTPUT). Parameters can be transferred more quickly because copying is eliminated, however, it could take longer to access the variable from the FB under certain conditions.

Note

When you access unit variables or global device variables with in/out parameters, note that other tasks can access these variables at the same time.

Optimizing program structure

Make sure that your ST source files and the POUs they contain are structured clearly and concisely. However, avoid modularizing your source files too much, since it takes longer to access functions and variables of imported units than functions and variables within a unit.

Optimizing the execution system

Assign the IPOsynchronousTask to a single program only. This reduces the risk of a timeout during runtime.

Use functions that are executed synchronously in MotionTasks only. (During synchronous processing, the next command is not executed until processing of the pending command satisfies a condition, e.g. it is complete.)

Make sure that not too many MotionTasks are active simultaneously.

For more efficient programming of cyclic tasks (primarily the BackgroundTask) go to sequence controlled programming. This means you consciously control the program flow via case decisions and only run through the portions of code that are relevant in the current status (e.g. via CASE statement).

Moreover edge triggered program instead of level-triggered programming is recommended.

Do not run through the relevant code cyclically (if the level of the condition is TRUE) but rather just once. This is done by querying the satisfied condition on rising edge (new status of the condition is TRUE, the old status on the other hand was FALSE).

Use of USEPACKAGE for multiple technology packages

Syntax for the use of "USEPACKAGE" for several technology packages

If you want to use more than one technology package simultaneously, you can select it again using the following syntax. See also Using technology functions in a program (Page 1223).

Table 4-142 Formal description

```
usepackagestatement ::= 'USEPACKAGE' packagelist ';'
packagelist         ::= packageentry {',' packageentry }
packageentry        ::= simplepackname | namespacepackname
simplepackname      ::= packagename
namespacepackname ::= packagename 'AS' namespaceident
//packagename and namespaceident must be valid identifiers
```

Change-optimized programming

The following description contains information about change-optimized programming.

For information about downloading in RUN, please see Download of changed sources in RUN (Page 1656) .

Notes on the draft program

Description

Useful notes on the following, for example:

- How best to structure the program
- How best to use the different tasks (MotionTask, BackgroundTask, IPO task, etc.)
- How best to divide your program between the different tasks

can be found in the application guidelines for SIMOTION.

You can find the application guidelines for SIMOTION in **SIMOTION Utilities & Applications**, which is included in the scope of delivery of SIMOTION SCOUT (under **Documentation > Application guidelines for SIMOTION**).

Generic programming

Description

Program axes in arrays and loops. This offers advantages, especially when new axes are being added or errors corrected (only once in the loop and not separately for each axis), and results in a more compact code. The readability is significantly improved.

With MCC and LAD/FDB sources, program initialization can also be activated using a pragma line in the declaration tables ("BlockInit_OnChange" pragma).

You can also information on axis arrays under **Documentation > Application guidelines for SIMOTION** in the section titled **Generic programming** in SIMOTION Utilities & Applications, which is part of the SIMOTION SCOUT scope of delivery.

Declaring retentive variables in one unit

Declare all retentive variables in the interface section in one single unit. This has the following advantage:

- It enables you to make optimal use of limited memory space.
- The variables are only initialized if the interface section in this unit has been changed.
- As of V4.1 you can also use multiple declaration blocks, see Use multiple VAR_GLOBAL, VAR_GLOBAL RETAIN blocks (Page 1419) .

HMI variables in one unit

Declare variables that are exported to HMI devices (see HMI (Human Machine Interface) coupling (Page 1611)). In the case of larger projects or strictly delimited software modules, a separate HMI unit per module is appropriate.

- The HMI project (e.g. WinCC flexible) must only be downloaded again if the interface section of this unit has been changed.
- You also have the option of disabling the consistency check during commissioning (**Options > Settings > Download**), though you do so at your own risk. Please note that, as there is no check for inconsistencies (e.g. for valid hardware addresses), access to processes may go unmonitored.
- You can also mark HMI relevant data, see Marking HMI relevant data (Page 1422).

See also HMI (Human Machine Interface) connection (Page 1611).

Using device global variables versus unit global variables

Description

Use of global unit variables in sources is preferable to use of device global variables (via the project navigator).

Benefits:

- Variable structures can be used.
- Initialization (initial values) of the variables for the STOP-RUN transition is possible (via program in StartupTask)
- For newly created global unit variables a download in RUN is also possible (in a new declaration block)

Procedure

1. Define unit-global variables in a source file in the interface section.
   Retain variables and HMI variables should likewise each be declared in a separate source file or declaration block (see above).
2. Assign the program with the initialization of the variables to the StartupTask.
   The variables will be set to a defined initial value in the startup.

Parameter | I/O symbols | Structures | Enumerations | Connections

	Structure name	Element name	Data type	Array length	Initial value
1	MyStruct	IntValue	INT		0
2		RealValue	REAL		0.0
3		BitValue	BOOL		FALSE
4					

Figure 4-179 Example of the declaration of structures in an MCC source file

Parameter | I/O symbols | Structures | Enumerations | Connections

	Name	Variable type	Data type	Array length	Initial value
1	m	VAR_GLOBAL CONSTANT	INT		16
2	BitArray	VAR_GLOBAL	BOOL	m	16(False)
3	IntArray	VAR_GLOBAL	INT	m	16(0)
4	ReadArray	VAR_GLOBAL	REAL	m	16(0.0)
5	StructVar	VAR_GLOBAL	MyStruct		
6					

Figure 4-180 Example of the declaration of parameters in an MCC source file

Table 4-143 Example declaration and program in an ST source file (unit)

```
INTERFACE
    //global types
    TYPE
       MyStruct : STRUCT
                   Intvalue : INT;
                   Realvalue: REAL;
                   Bitvalue : BOOL;
                  END_STRUCT
    END_TYPE
    //global constants
    VAR_GLOBAL CONSTANT
        n : INT := 0;
        m: INT := 15;
    END_VAR
    //global variables
    VAR_GLOBAL
        Bitarray : ARRAY [n..m] OF BOOL := [16 (FALSE)];
        Intarray : ARRAY [0..15] OF INT := [16 (0)    ];
        Realarray: ARRAY [0..15] OF REAL:= [16 (0.0)  ];
        StructVar: MyStruct;
    END_VAR
    //programs
    PROGRAM Init;
    //end of the interface
END_INTERFACE

IMPLEMENTATION
 PROGRAM Init
  ////////////////////////////////////////////////
  //initialization of the variables during startup//
  ////////////////////////////////////////////////
  StructVar.Intvalue :=0;
  StructVar.Realvalue:=0;
  StructVar.Bitvalue :=FALSE;
 END_PROGRAM
END_IMPLEMENTATION
```

The program is then assigned to the StartupTask.

Whenever unit global variables are to be used in a different source, the sources that contain the declaration must be combined (USES). See also **Connection to other program sources or to libraries** in the MCC Programming Manual or **Use of the USES statement in the interface or implementation section of an importing unit** in the ST programming manual.

Centralized starting and resetting of MotionTasks

To enhance programming clarity, program starting and resetting of MotionTasks in one centralized location.

4.2.14 Appendix

4.2.14.1 Symbolic constants

The following table presents names of reserved constants that you must not use for individual variable names.

Table 4-144 Symbolic constants of the Taskstartinfo

Symbolic constant	Data type	Value
_SC_ALARM_CONFIGURATION	UDINT	404
_SC_ARRAY_BOUND_ERROR_READ	UDINT	502
_SC_ARRAY_BOUND_ERROR_WRITE	UDINT	503

Table 4-148 Symbolic constants for invalid values of selected data types

Symbolic constant	Data type	Meaning
STRUCTALARMID#NIL	StructAlarmId	Invalid AlarmId
STRUCTTASKID#NIL	StructTaskId	Invalid TaskId
TO#NIL	ANYOBJECT	Invalid technology object

4.2.14.2 Identifiers with defined meaning in SIMOTION

This section contains an alphabetical listing of identifiers with a predefined meaning in SIMOTION. The list contains:

- The reserved and protected identifiers of the SIMOTION ST (Structured Text) programming language
- The reserved and protected identifiers of other programming languages
- The general standard functions and standard function blocks with the associated data types
- The functions for task control, runtime measurement and message programming with the associated data types
- The system functions and system variables of SIMOTION devices with their associated data types
- The technology object data types
- The system functions, system variables (and configuration data) of technology packages

The response when using this identifier is different, e.g.:

- Compiler error with reserved identifiers
- Possible masking and resulting inability to obtain the identifiers
  Under certain circumstances, the compiler may not issue a warning if, for example, the associated technology package is not imported.

4.2.14.3 Assignment types for symbolic assignment

Interface types of the technology objects

Description

SIMOTION technology objects and SINAMICS objects provide interfaces and assignment types for symbolic assignment; these are described in detail below.

Only interfaces of the same type can be assigned.

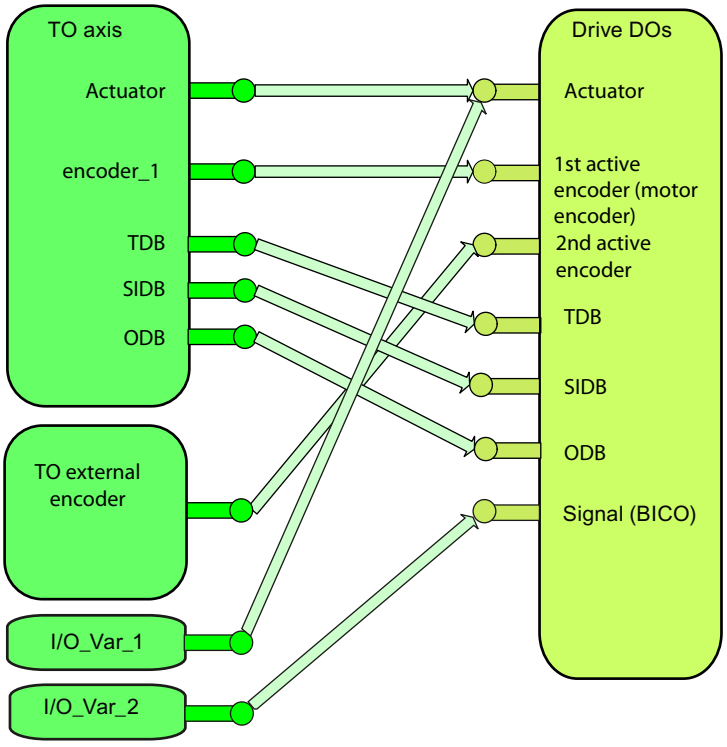

Figure 4-181 Example TO - DO assignment

Assignment types for the Axis TO

Assignment partner designation	Assignment type	Description
Actuator	• ActorProfidrive • ActorOnboard • WordOutput	Axis setpoint interface • Via PROFIdrive message frame • Onboard • Analog output for hydraulics
Technology data	TDB	Technology data on the axis
Safety data	SIDB	Safety data on the axis
encoder_<n>	BitInput	Encoder interface of the nth encoder
StatusExternalZeroMark	BitInput	External zero mark status of a digital drive. For incremental encoders
Homing output cam	BitInput	Homing output cam
HomingOutputCamPassive-Homing	BitInput	Homing output cam for passive homing
Ready status detection	BitInput	Ready status detection for analog sensor
Error status detection	BitInput	Error status detection for analog sensor
Update counter	BitInput	Update counter, analog sensor
Positive reversing cam	BitInput	Positive reversing cam
Negative reversing cam	BitInput	Negative reversing cam

Assignment partner designation	Assignment type	Description
HW limit switch positive	BitInput	Hardware limit switch positive
HW limit switch negative	BitInput	Hardware limit switch negative
Q-valve	WordOutput	Q output for hydraulics, Q-valve
Q-valve enable	BitOutput	Enable bit for Q-valve
P-valve	WordOutput	F output for hydraulics, P-valve
P-valve enable	BitOutput	Enable bit for P-valve
Pressure sensor	Wordinput	Pressure sensor
Digital input	BitInput	Digital input for fast switching to pressure control

Assignment types for the External Encoder TO

Assignment partner designation	Assignment type	Description
encoder_1	• sensorPROFIdrive • sensorOnboard • wordInput • dwordInput	Encoder interface of the encoder
StatusExternalZeroMark	bitInput	External zero mark status of a digital drive. For incremental encoders
Homing output cam	bitInput	Homing output cam
HomingOutputCamPassive-Homing	bitInput	Homing output cam for passive homing
Ready status detection	bitInput	Ready status detection for analog sensor
Error status detection	bitInput	Ready status detection for analog sensor
Update counter	bitInput	Update counter, analog sensor
Measuring input		Measuring input input for local measuring

Assignment types for the Output Cam TO

Assignment partner designation	Assignment type	Description
Output	• bitOutput • bitOutputWithTi-meStamp	Output cam output

Assignment types for the Measuring Input TO

Assignment partner designation	Assignment type	Description
Input	bitInputWithTimeStamp	Measuring input input

Assignment types for the TControl TO

The following interface types are available on the TO sensor:

Assignment partner designation	Assignment type	Description
Temperature input	wordInput	Analog input, temperature
PWM signal	bitInput	Output, PWM signal
PWM signal_2	bitInput	Output, PWM signal_2

Assignment types for the Sensor TO

The following interface type is available on the TO sensor:

Assignment partner designation	Assignment type	Description
Analog sensor	wordInput	Analog input

SINAMICS interface types

Description

The various SINAMICS DOs offer the following I/O interfaces to SIMOTION interfaces.

DO servo, vector, and TM41 (drive DOs)

Name	Interface type	Description
Actor	actorProfidrive	Axis setpoint interface (via PROFIdrive message frame)
Encoder_1	sensorPROFIdrive	Encoder 1 on the drive
Encoder_2	sensorPROFIdrive	Encoder 2 on the drive
Bico_iw.<BICO> Bico_id.<BICO>	wordInputDriveParameter	Additional parameter transferred via BICO interconnection (input side)
Bico_qw.<BICO> Bico_qd.<BICO>	dwordInputDriveParameter	Additional parameter transferred via BICO interconnection (output side)
For information on interfaces, see: TM41 inputs/outputs in the SCOUT online help.		

Encoder DO

Name	Interface type	Description
encoder	sensorPROFIdrive	PROFIdrive encoder interface
Bico_iw.<BICO> Bico_id.<BICO>	wordInputDriveParameter	Additional parameter transferred via BICO interconnection (input side)

Name	Interface type	Description
Bico_qw.<BICO> Bico_qd.<BICO>	dwordInputDriveParameter	Additional parameter transferred via BICO interconnection (output side)
For information on interfaces, see: Encoder DO in the SCOUT online help.		

DO TM15/TM17 High Feature

Name	Interface type	Description
DI_<n> MI_<n> DO_<n> CAM_<n>	bitInput bitInputWithTimeStamp bitOutput bitOutputWithTimeStamp	Interfaces for DIs, DOs, measuring inputs, output cams for terminals X520, X521, X522; interface type depends on terminal configuration TM15: 24 channels, TM17: up to 16 channels
DI_0_15 DI_16_23 DO_0_15 DO_16_23	_wordInputInterfaceType wordOutputInterfaceType	Group interfaces for replacement values (Wordinput, Wordoutput)
For information on interfaces, see: TM17 inputs/outputs TM15 inputs/outputs in the SCOUT online help.		

DO control unit

Name	Interface type	Description
DI_<n>	bitInput	Digital inputs of the control unit with SIMOTION D, CX32/CX32-2, and SINAMICS S110/S120 control units
DI_<n> MI_<n> DO_<n> CAM_<n>	bitInput bitInputWithTimeStamp bitOutput bitOutputWithTimeStamp	Bidirectional digital inputs/outputs DI interfaces (bidirectional digital input) Measuring input input DO interfaces (bidirectional digital output) Output of output cam for the terminals
DI_0_15 DO_0_15	_wordInputInterfaceType _wordOutputInterfaceType	Group interfaces for replacement values (Wordinput, Wordoutput)
Bico_iw.<BICO> Bico_id.<BICO>	wordInputDriveParameter	Additional parameter transferred via BICO interconnection (input side).
Bico_qw.<BICO> Bico_qd.<BICO>	wordOutputDriveParameter	Additional parameter transferred via BICO interconnection (output side)
For information on interfaces, see: Control Unit CU320 inputs/outputs in the SCOUT online help.		

Additional SINAMICS DO (such as TM31, TB30, and TM15 DI/DO)

Name	Interface type	Description
Interfaces depending on the standard message frame		
Bico_iw.<BICO>	WordInputDriveParameter	Additional parameter transferred via BICO interconnection (input side). The number of interconnectable parameters depends on the message frame used.
Bico_qw.<BICO>	WordOutputDriveParameter	Additional parameter transferred via BICO interconnection (output side). The number of interconnectable parameters depends on the message frame used.

Interfaces in standard message frames

Description

Standard message frames are standardized and transfer a set number of interfaces with certain properties.

They contain the following interfaces:

Standard message frame 1

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_A	WORD	Actor interface, speed setpoint A, 16 bits
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_A	WORD	Actor interface, actual speed value A, 16 bits

Standard message frame 2

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2

Standard message frame 3

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2

Standard message frame 4

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
encoder_2.Gn_STW	WORD	Encoder 2, control word
encoder_2.Gn_ZSW	WORD	Encoder 2, status word
encoder_2.Gn_XIST1	DWORD	Encoder 2, act. position val. 1
encoder_2.Gn_XIST2	DWORD	Encoder 2, act. position val. 2

Standard message frame 5

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word

Name	Data type	Description
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
actor.XERR	DWORD	Actor interface, position deviation
actor.KPC	DWORD	Actor interface, position controller gain factor

Standard message frame 6

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
actor.MOMRED	WORD	Actor interface, torque reduction
actor.MELDW	WORD	Actor interface, message word
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
encoder_2.Gn_STW	WORD	Encoder 2, control word
encoder_2.Gn_ZSW	WORD	Encoder 2, status word
encoder_2.Gn_XIST1	DWORD	Encoder 2, act. position val. 1
encoder_2.Gn_XIST2	DWORD	Encoder 2, act. position val. 2

SIEMENS message frame 101

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
actor.MOMRED	WORD	Actor interface, torque reduction
actor.MELDW	WORD	Actor interface, message word

SIEMENS message frame 102

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits

Name	Data type	Description
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
actor.MOMRED	WORD	Actor interface, torque reduction
actor.MELDW	WORD	Actor interface, message word
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2

SIEMENS message frame 103

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
actor.MOMRED	WORD	Actor interface, torque reduction
actor.MELDW	WORD	Actor interface, message word
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
encoder_2.Gn_STW	WORD	Encoder 2, control word
encoder_2.Gn_ZSW	WORD	Encoder 2, status word
encoder_2.Gn_XIST1	DWORD	Encoder 2, act. position val. 1
encoder_2.Gn_XIST2	DWORD	Encoder 2, act. position val. 2

SIEMENS message frame 105

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
actor.MOMRED	WORD	Actor interface, torque reduction
actor.MELDW	WORD	Actor interface, message word

Name	Data type	Description
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
actor.XERR	DWORD	Actor interface, position deviation
actor.KPC	DWORD	Actor interface, position controller gain factor

SIEMENS message frame 106

Name	Data type	Description
actor.STW1	WORD	Actor interface, control word 1
actor.NSOLL_B	DWORD	Actor interface, speed setpoint B, 32 bits
actor.STW2	WORD	Actor interface, control word 2
actor.ZSW1	WORD	Actor interface, status word 1
actor.NIST_B	DWORD	Actor interface, actual speed value B, 32 bits
actor.ZSW2	WORD	Actor interface, status word 2
actor.MOMRED	WORD	Actor interface, torque reduction
actor.MELDW	WORD	Actor interface, message word
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
encoder_2.Gn_STW	WORD	Encoder 2, control word
encoder_2.Gn_ZSW	WORD	Encoder 2, status word
encoder_2.Gn_XIST1	DWORD	Encoder 2, act. position val. 1
encoder_2.Gn_XIST2	DWORD	Encoder 2, act. position val. 2
actor.XERR	DWORD	Actor interface, position deviation
actor.KPC	DWORD	Actor interface, position controller gain factor

Standard message frame 81

Name	Data type	Description
encoder_1.STW2	WORD	Control word 2
encoder_1.ZSW2	WORD	Status word 2
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2

Standard message frame 82

Name	Data type	Description
encoder_1.STW2	WORD	Control word 2
encoder_1.ZSW2	WORD	Status word 2
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
encoder_1.NIST_A	WORD	Encoder 1, actual speed value A, 16 bits

Standard message frame 83

Name	Data type	Description
encoder_1.STW2	WORD	Control word 2
encoder_1.ZSW2	WORD	Status word 2
encoder_1.Gn_STW	WORD	Encoder 1, control word
encoder_1.Gn_ZSW	WORD	Encoder 1, status word
encoder_1.Gn_XIST1	DWORD	Encoder 1, act. position val. 1
encoder_1.Gn_XIST2	DWORD	Encoder 1, act. position val. 2
encoder_1.NIST_B	DWORD	Encoder 1, actual speed value B, 32 bits

Structure of message frame extension TDB

Name	Data type	Description
M_ADD	WORD	Additional torque
M_LIMIT_PLUS	WORD	Positive torque limit
M_LIMIT_MINUS	WORD	Negative torque limit
M_ACTUAL	WORD	Current torque

Structure of message frame extension SIDB

Name	Data type	Description
S_ZSW1B	WORD	Safety status word
S_SPEED_LIMIT	DWORD	Velocity limit signal

Designations for interface types

Description

The following assignment types have been defined for SIMOTION:

Axis and encoder interface types

Table 4-149 Axis interface types

Name under ST nomenclature	Name in the address list
_actorProfidriveInterfaceType	ActorProfidrive
_actorOnboardInterfaceType	ActorOnboard
_wordOutputInterfaceType	WordOutput

Table 4-150 Encoder interface types

Name under ST nomenclature	Name in the address list
_sensorProfidriveInterfaceType	SensorProfidrive
_sensorOnboardInterfaceType	SensorOnboard
_wordInputInterfaceType	WordInput
_dwordInputInterfaceType	DWordInput

Table 4-151 Data blocks (extended communication)

Name under ST nomenclature	Name in the address list
_tdbInterfaceType	TDB
_sidbInterfaceType	SIDB

Output cam, measuring input

Name in ST naming scheme of the output cam assignment types	Name in the address list
_bitOutputInterfaceType	BitOutput
_bitOutputWithTimeStampInterfaceType	BitOutputWithTimeStamp

Name in ST naming scheme of the measuring input assignment types	Name in the address list
_bitInputWithTimeStampInterfaceType	BitInputWithTimeStamp

Standard I/O interfaces

Name under ST nomenclature	Name in the address list
_bitInputInterfaceType	BitInput
_bitOutputInterfaceType	BitOutput
_byteInputInterfaceType	ByteInput
_byteOutputInterfaceType	ByteOutput
_wordInputInterfaceType	WordInput
_wordOutputInterfaceType	WordOutput

Name under ST nomenclature	Name in the address list
_dwordInputInterfaceType	DWordInput
_dwordOutputInterfaceType	DWordOutput

SINAMICS parameter interface types

Name under ST nomenclature	Name in the address list
_wordInputDriveParameterInterfaceType	WordInputDriveParameter
_dwordInputDriveParameterInterfaceType	DWordInputDriveParameter
_wordOutputDriveParameterInterfaceType	WordOutputDriveParameter
_dwordOutputDriveParameterInterfaceType	DWordOutputDriveParameter

Syntax of the assignments

You can also enter the symbolic assignments for the I/O variable using text fields in the address list and TO configuration dialogs (in addition to the buttons for calling the assignment dialog). The syntax required for this purpose is specified in the table below.

Table 4-152

Interconnection target	Syntax
Onboard I/Os of SIMOTION D4x5/ D4x5-2, terminal X122/X132 (SINAMICS Integrated);	<device>.<DO_name>.<interface_name> [<terminal_name>] **Example of D4x5-2:** SINAMICS_Integrated.Control_Unit.DO_8 [DI/DO 8, X122.9] -> Digital output "DO_8" on "SINAMICS_Integrated" device, "Control_Unit" drive object, terminal "X122.9", pin designation "DI/DO 8"
Onboard I/Os of SIMOTION D4x5-2, terminal X142	<device>.<<interface_name> **Example:** D455-2, X142: D455.CAM_6 [DI/DO 6, X142.12] -> Output with output cam quality "CAM_6" on "D455" device, terminal "X142.12", pin designation "DI/DO 6"
Onboard I/Os of SINAMICS S120 CU3xx and CX32/32-2 controller extension	<device>.<DO_name>.<interface_name> [<terminal_name>] **Example:** SIMOTION_CX32.Control_Unit.DI_1 [DI 1, X122.2] S120_CU320.Control_Unit.DI_1 [DI 1, X122.2] -> Digital input "DI_1" on "SIMOTION_CX32" or "S120_CU320" device, "Control_Unit" drive object, terminal "X122.2", pin designation "DI 1"

Interconnection target	Syntax
TM15, TM17, TM41	<device>.<DO_name>.<interface_name> [<terminal_name>] **Examples:** TM15: SINAMICS_Integrated.TM15.MI_8 [DI/DO 8, X521.2] -> Input with measuring input quality "MI_8" on "SINAMICS_Integrated" device, "TM15" drive object, terminal "X521.2", pin designation "DI/DO 8" TM41: SINAMICS_Integrated.TM41.AI_0 [AI 0, X523] -> Analog input "AI_0" on "SINAMICS_Integrated" device, "TM41" drive object, terminal "X523", pin designation "AI 0"
TB30, TM31, TM15 DI/DO	<device>.<DO_name>.<interface_name> [<terminal_name>] **Examples:** TB30: SINAMICS_Integrated.TB30.AI_0 [AI 0, X482.1, X482.2] -> Analog input "AI_0" on "SINAMICS_Integrated" device, "TB30" drive object, terminals "X482.1" and "X482.2", pin designation "AI 0" TM31: SINAMICS_Integrated.TM31.DI_2 [DI 2, X520.3] -> Digital input "DI_2" on "SINAMICS_Integrated" device, "TM31" drive object, terminal "X520.3", pin designation "DI 2" TM15 DI/DO: SINAMICS_Integrated.TM15DIDO.DO_23 [DI/DO 23, X522.9] -> Digital output "DO_23" on "SINAMICS_Integrated" device, "TM15DIDO" drive object, terminal "X522.9", pin designation "DI/DO 23"
SINAMICS free message frame extensions	<device>.<DO_name>.BICO_xx.<parameter_number> with (xx = IW, QW, ID, QD) for interconnection to a parameter in the same drive object (DO), to which the message frame is addressed <device>.<DO_name>. BICO_xx.<DO_name2>#<parameter_number> for interconnection to a parameter in drive object (DO) <DO_name2>, whereby the message frame is configured for DO <DO_name>
Message frame components	<device>.<DO_name>.<interface_name>.<subinterface_name> **Examples:** SINAMICS_Integrated.Axis_Red.actor.STW1 SINAMICS_Integrated.Axis_Blue.actor.ZSW1 SINAMICS_Integrated.Axis_Red.encoder_1.Gx_ZSW

Interconnection target	Syntax
Message frame of the infeed unit	If the automatic message frame determination is activated, the message frame for the infeed is specified automatically (PROFIdrive message frame 370). You can now create two I/O variables in WORD format via symbolic assignment in the address list for the status and control words (ZSW1/STW1) of the infeed. You require these I/O variables for the **FB _LineModule_control** for the control of the line module. For further information refer to the *Standard Function for SINAMICS S120 Line Modules* Function Manual
Onboard I/Os of SIMOTION C	<device>.<interface_name> **Examples:** C240_1.AnalogActor_3 [ANALOG/STEPPER 3, X2] C240_1.Encoder_2 [ENCODER 2, X4] C240_1.DI_0 [I 0, X1.28] C240_1.DO_7 [Q7, X.19] C240_1.M1 [M1, X1.26] C240_1.B2 [B2, X1.23]

4.3 Output Cams and Measuring Inputs

4.3.1 Preface

This **document** is part of the
System and Function Descriptions documentation package.

Scope

This manual is valid for SIMOTION SCOUT in conjunction with the SIMOTION Cam, Path or Cam_ext technology package for product version V4.5.

Chapters in this manual

This manual provides information about the functions, operation, command execution, and technology alarms of the technology objects.

- **Output Cam technology object** (part I)
  Functions and operation
- **Cam Track technology object** (part II)
  Functions and operation
- **TO measuring input** (part III)
  Functions and operation
- **Index**
  Keyword index for locating information

4.3.1.1 SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.5:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

4.3.1.2 Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

https://support.industry.siemens.com/cs/ww/en/view/109479653

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

4.3.2 Fundamental safety instructions

4.3.2.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life caused by machine malfunctions caused by incorrect or changed parameterization

Incorrect or changed parameterization can cause malfunctions on machines that can result in injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

4.3.2.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

4.3.2.3 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

4.3.3 Output Cam TO - Part I

4.3.3.1 Overview of Output Cam TO

General information about the Output Cam TO

The **Output Cam** technology object

- Generates position-dependent switching signals
- Can be assigned to positioning axes, synchronous axes, path axes or external encoders
- The axes can be real or virtual.

Different switching signals distinguish different types of output cam:

- **Software cam**
  Switching signals are used internally in the user program by evaluating the relevant **state** system variable.
- **Hardware cam**
  Switching signals are output **externally** on I/O devices by assigning a digital output to the Output Cam TO. For example, digital output modules from the ET 200 I/O system can be used for the cam output.

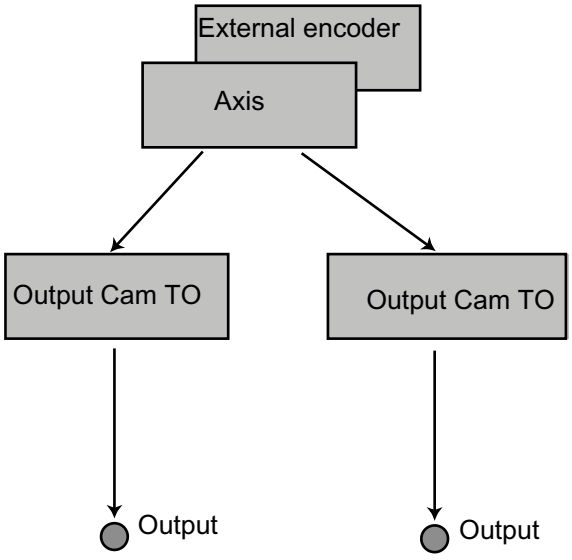

Figure 4-182 Interconnection options for the output cam TO

A range of output cam types with different switching behaviors are available.

- **Position-based cam**
  The switching signal is supplied between the switch-on position and the switch-off position.
- **Time-based cam**
  The switching signal is supplied for a specified time period after the switch-on position is reached.
- **Unidirectional output cam**
  The switching signal is supplied when the axis reaches the switching position and is then reset by the user.
- **Counter cam**
  Counter cams are not a separate output cam type, but rather position-based or time-based type cams. Counter cams can be configured so that they are output for every switching or for every nth switching. They can only be programmed and activated in the user program.
- **Cam output types**
  While output cams are usually output in the IPO cycle clock or the position control cycle clock, high-speed output cams provide better output accuracy than the position control cycle clock because the switching edges are positioned within the position control cycle clock.

Functionality

It is possible to define an **effective direction** for the Output Cam TO, i.e. the output cam is only active when the direction of motion of the axis is the same as the effective direction.

The output cam can be calculated in servo cycles, IPO cycles, or IPO_2 cycles.

Note

With modules D435-2 DP/PN, D445-2 DP/PN, and D455-2 DP/PN, cam calculation can be performed in Servo_fast or IPO_fast. For more information, see the chapter Second servo cycle clock (Servo_fast) in the Motion Control Basic Functions manual.

The reference values of the output cam depend on the axis type or the external encoder:

Table 4-153 Reference to the actual or set position

Technology object	Reference to actual position possible	Reference to set position possible
Real drive axis	-	-
Real position axis	X	X
Real synchronized axis	X	X
Virtual axes	-	X
External encoder	X	-

Possible configuration of the cams with actual value reference:

- **Reference to the actual value on the encoder without considering Ti**. Reference to the actual position in the controller before the position filter.
- **Reference to the actual value after the position filter**. Reference to the actual position in the controller after the position filter.
- **Reference to the actual value on the encoder. Ti is taken into account**. Reference to the actual value on the encoder module / drive. The transmission time Ti from the encoder module / drive to the controller is taken into account by the system.

Possible configuration of the cams with setpoint reference:

- **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoints will already have been reached at the end of this IPO cycle, e.g. if a setpoint is calculated for the IPO cycle clock with the virtual axis and also displayed at the end of the cycle. Reference is made directly to the setpoint applicable at the end of the cycle.
- **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoint calculated in the interpolator will be output completely in the following cycle and the calculated position setpoint will therefore be reached at the end of the following cycle.
- **Reference to the setpoint on the drive**. Calculation of the cam switch points according to the setpoint output with the current settings on the drive.

In this case, the output cam functionality can be applied to axes or external encoders with or without modulo properties.

The output cam is also effective for axes that have not been homed.

The Output Cam technology object is assigned to exactly one output during configuration. Output can be achieved via:

- Onboard I/O
- Drive I/O (e.g. TB30, TM31, TM1x)
- SIMOTION C centralized I/O
- Distributed I/O; PROFIBUS DP IO (e.g. ET 200M) and PROFINET IO (e.g. ET200xP TM Timer DI/DQ)

However, the output must not be in the process image.

The switching accuracy is dependent on the following:

- Output accuracy of the I/O
- How the output cam is allocated in the task system
- How constant delay times are compensated

Several Output Cam TOs can be connected to the same output (see Chapter **Logical operation**). Alternatively, the Cam Track TO can be used for this purpose.

Example

Lines of glue are applied to a wooden board. The output cams are assigned to an external encoder. Output cams assigned to outputs Q 0 to Q 4 are switched on and off at specified positions.

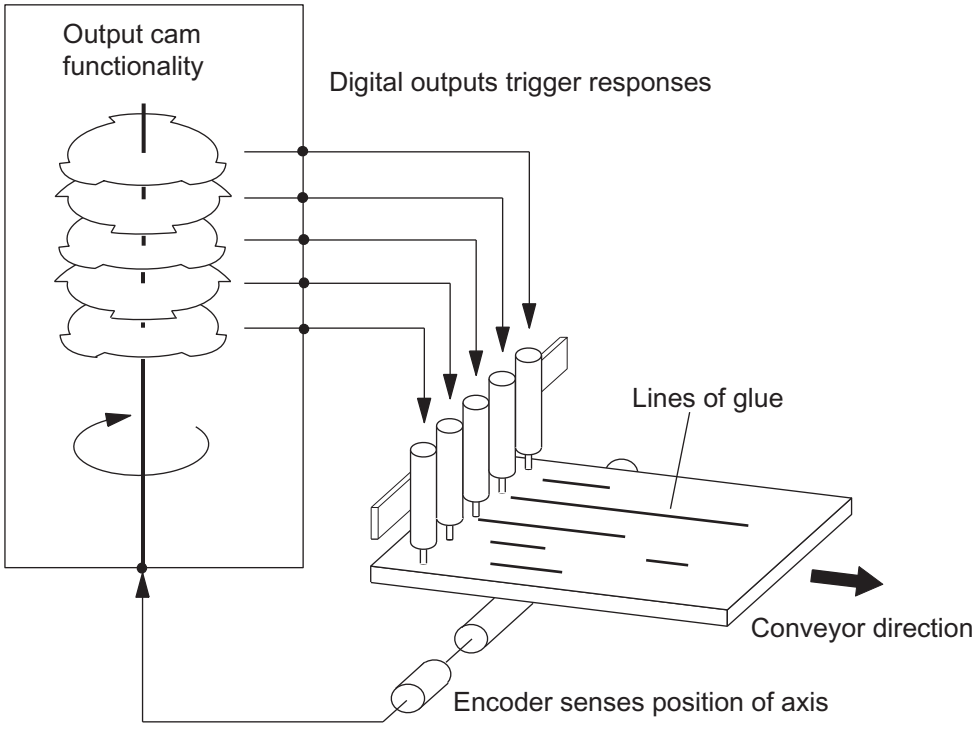

Figure 4-183 Example of an electronic cam control

See also

Logical operation (Page 1822)

Comparison of Output Cam TO and Cam Track TO

Depending on the application, it may be practical to use either the Cam Track TO or one or more Output Cam TOs. The table below should help you to decide which TO should be used in which case.

Table 4-154 Comparison of Output Cam TO and Cam Track TO

Features	Output Cam TO	Cam Track TO
Availability	• As of Version 1.0	• As of Version V3.2
Supported output cams	• Position-based cam • Time-based output cam • Unidirectional output cam • Counter cam • Exact time setting of an output, exact time output cams (as of V4.1)	• Position-based cam • Time-based output cam • Time-based cam with maximum ON length
Several output cams on one output	• Via logical operation (AND/OR)	• Maximum 32 output cams of the same type in one track • No cam track logical operations (AND/OR)
Different types of output cam on one output	• Via AND/OR	• Not available
Output cam definition	• Related to axis • Via system variables	• Related to cam track (cam track can be mapped as required on axis) • Via system-variables array
Hysteresis	• Available	• Available
Effective direction	• Available	• Not available
Derivative-action times	• Separate for power ON/power OFF	• Separate for power ON/power OFF
Deactivation time for time-based cam	• As of Version V3.2	• As of Version V3.2
Activation/deactivation types	• Active immediately	• Start and stop mode parameterizable
Types of output	• Cyclic	• Cyclic • Once
Output cam status	• System variable	• Status of single output cams over one array of byte
Output cam enable	• Via_enableOutputCam	• via_enableCamTrack • Validity of single output cams configurable via system variables

Features	Output Cam TO	Cam Track TO
Performance	• Depends on number of single output cams	• When 5 or more output cams are used in one output cam track instead of 5 single output cams, the output cam track performs better. This performance advantage amounts to at least a factor of 2 for 32 single output cams.
MCC command available	• Available	• Available (V4.0 and higher)

4.3.3.2 Output cam TO basics

Output cam type

Software cam

Switching signals are used **internally** in the user program by evaluating the relevant **state** system variable.

Hardware cam

Description

Switching signals are output **externally** on I/O devices by assigning a digital output to the Output Cam TO.

The following can be used as digital outputs:

- Onboard outputs (SIMOTION C, D, ...)
- Centralized I/O (SIMOTION C)
- Distributed I/O via PROFIBUS DP (e.g. ET 200M) and PROFINET IO (e.g. ET 200S, ET200xP TM Timer DI/DQ)
- Drive I/O (for example, TM15 and TM17 High Feature Terminal Modules)

Hardware for output cams

Cam output on cam output (I/O channel is configured as CAM)

- SIMOTION D410-2
- SIMOTION D4x5-2
- TM15, TM17 High Feature
- PROFINET IO (e.g. ET200xP TM Timer DI/DQ)

Cam output on high-speed output with direct access (I/O channel is configured as DO)

- SIMOTION D4xx / D4x5-1
- SIMOTION C240, C240 PN

Cam output on standard output (I/O channel is configured as DO)

- SIMOTION C/D/CX onboard I/O
- SINAMICS onboard I/O
- TM15, TM15 DI/DO, TM17 High Feature, TM31, TM41, TB30
- Standard DO (SIMATIC ET200, ...)
- PROFINET IO (e.g. ET200xP TM Timer DI/DQ)

For more information, see cam output types. (Page 1811)

Position-based cam

Direction-neutral switching

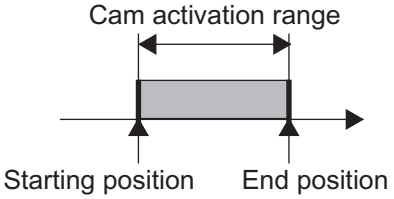

Figure 4-184 Position-controlled output cam with start position less than end position

Limits imposed by start and end positions

The output cam is activated:

- Axis position is within the switch-on area
- Axis position value is shifted into the switch-on area of the output cam
  The position value of the interconnected object can change abruptly, for example, when it is homed or when its coordinate system is shifted with the **_redefinePosition** command.

The output cam is switched off:

- When the axis position is outside the start or end position
- When the axis position value is shifted outside the switch-on area
- When commands are issued that deactivate the output cam, e.g. **_disableOutputCam**, **_setOutputCamState**, and **_resetOutputCam**

Switch-on area

The switch-on area of the output cam is defined from the start position to the end position in a positive counting direction, i.e. within a range between the start position and the end position. If the end position is greater than the start position, the switch-on area is defined by the start and end positions (see figure above).

The switch-on area is outside the area between the end and start positions if the end position is less than the start position (see figure below).

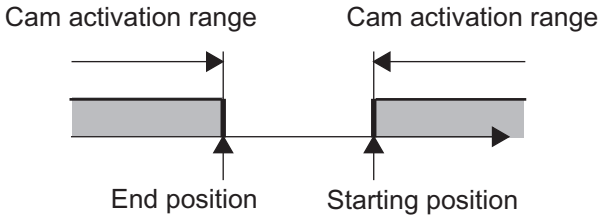

Figure 4-185 Position-controlled output cam with end position less than start position

Note

This definition of the switch-on area is possible for all modulo and non-modulo axes.

ON duration

The ON duration of the output cam depends on the velocity at which the axis traverses the output cam length.

Direction-dependent switching

The output cam is activated:

- When the axis position is between the start and end positions, and the axis is moving in the programmed effective direction

The output cam is switched off:

- When the axis position is outside the start or end position
- When the motion direction is not the same as the assigned effective direction
- When the axis position value is shifted outside the switch-on area
- When commands are issued that deactivate the output cam, e.g. **_disableOutputCam**, **_setOutputCamState**, and **_resetOutputCam**

Time-based output cam

Direction-neutral switching

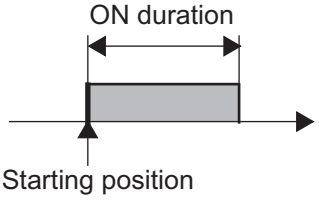

Figure 4-186 Time-controlled output cam

Limits imposed by starting position and ON duration

The output cam is switched on:

- At the starting position.
  If the starting position is overrun again during the ON duration, the time-based cam is not switched on again. It is not possible to retrigger a time-based cam.

The output cam is switched off:

- When the assigned time period expires
- When commands are issued that deactivate the output cam, e.g. **_disableOutputCam**, **_setOutputCamState** and **_resetOutputCam**

Output cam length

The output cam length is dependent on the velocity at which the assigned axis traverses during ON duration of the output cam.

Direction-dependent switching

The output cam is switched on:

- At the starting position if the traversing direction is the same as the effective direction

The output cam is switched off:

- When the assigned time period expires
- When commands are issued that deactivate the output cam, e.g. **_disableOutputCam**, **_setOutputCamState** and **_resetOutputCam**

A change of direction will not lead to the output cam being switched off if the time-based cam has already been activated.

Unidirectional output cam

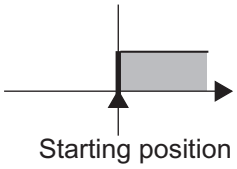

Figure 4-187 Unidirectional output cam

Limits imposed by starting position

The output cam is switched on:

- At the starting position if the axis is moving in the programmed effective direction

The output cam is switched off:

- By the **_disableOutputCam**, **_setOutputCamState** and **_reset** commands

Note

The unidirectional output cam does not switch unless the starting position is explicitly crossed, e.g. by setting the actual value.

An end position is not defined for the unidirectional output cam. The output cam signal depends solely on the switching criteria when the output cam is crossed over. The unidirectional cam can be reset via the program (e.g. by calling up the system function **_enableOutputCam** again).

Counter cam

For a counter cam, it can be specified whether the output cam is to be output **every** time it switches or every **nth** time it switches.

Note

Counter cams can only be configured for position-based and time-based cams. A counter cam is used via the **_setOutputCamCounter** system function.

Counter cams can only be defined in the user program. In configuring the output cam, the output cam type **cannot** be defined as counter cam.

Every counter cam has a starting count value and a current count value.

The current count value for the output cam is reduced by 1 every time the output cam switches. If the current count reaches 0, the output cam is output (**state** system variable and output cam output). At the same time, the current count value is reset to the starting count value. If the current count value does not reach 0, the output cam output is suppressed. The default setting of the starting count value and current count value is 1. The starting count value and current count value are programmed by means of the **_setOutputCamCounter**. The current count values can be scanned with the **counterCamData.actualValue** and **counterCamData.startValue** system variables. No resetting of the values by the system takes place, e.g. after **_enableOutputCam** or **_disableOutputCam**.

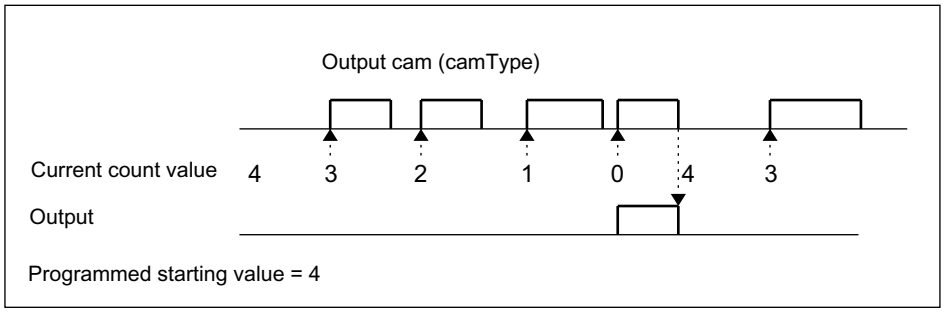

Figure 4-188 Example of a counter cam

Cam output types

The cam calculations are performed in the processing cycle clock (IPO or IPO_2 cycle clock or in the servo cycle clock). For the possible setting of Servo_fast or IPO_fast, see Section Second servo cycle clock (Servo_fast) in the SIMOTION Runtime Basic Functions manual.

The temporal resolution of the cam output depends on the hardware used and the setting in the configuration. In standard applications, the setting is undertaken using screen forms. The configuration data can also be set via the expert list.

The possible setting options for cam output are described below:

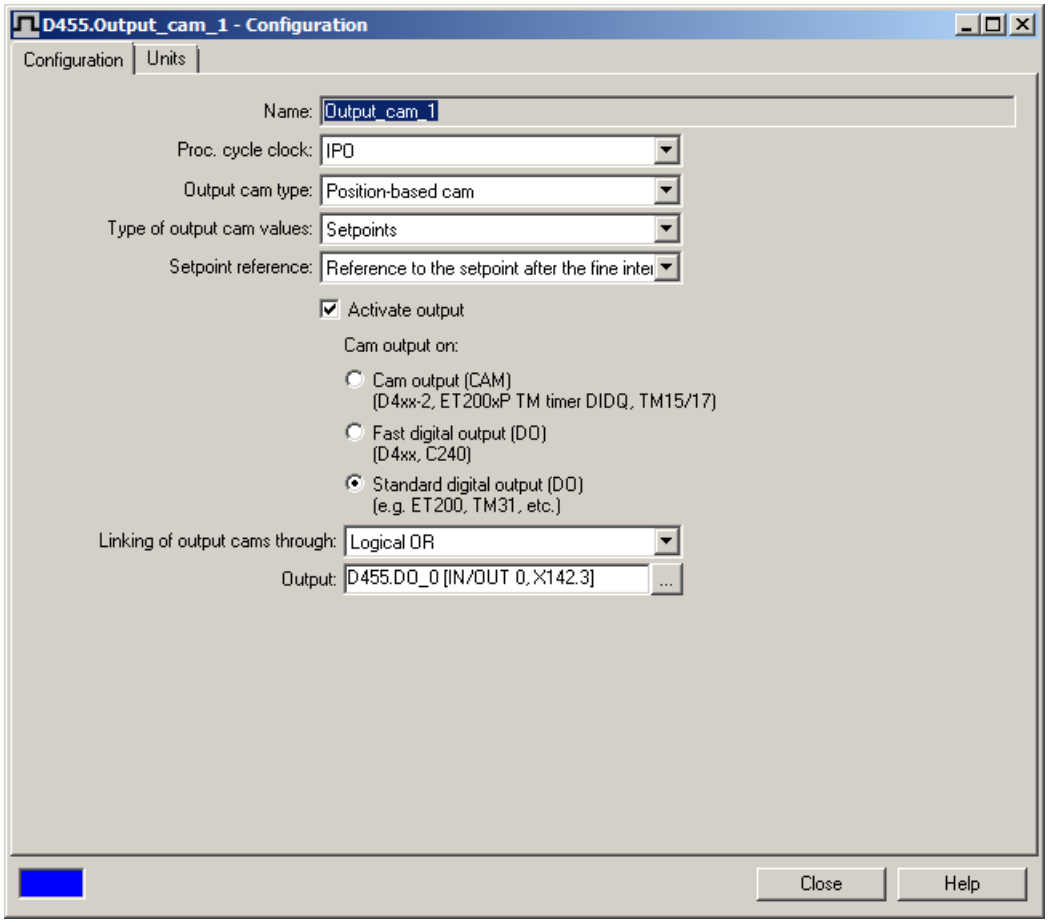

Figure 4-189 Output cam configuration using the example of a position-based cam

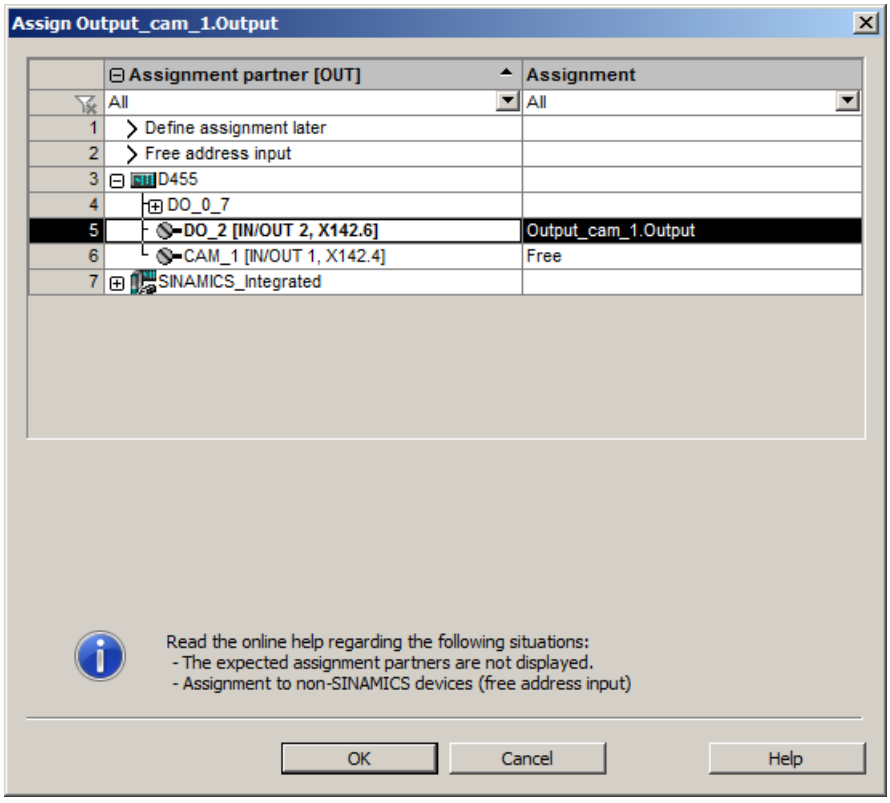

Figure 4-190 Assignment dialog

Symbolic assignment is activated by default in projects as of V4.2 (**Project > Use symbolic assignment**)

Cam output (CAM)

The cam output is performed on the basis of an internal time stamp. The temporal resolution of the cam output depends on the hardware used. In the case of D4x5-2 and the TM17 High Feature, the resolution is 1 µs.

Hardware supported

- SIMOTION D410-2
- SIMOTION D4x5-2 (X142)
- TM15, TM17 High Feature
- ET200xP TM Timer DI/DQ

The I/O channel must be configured as CAM.

SIMOTION D410-2

The digital inputs/outputs are used for the cam output in the D410-2. The digital inputs/outputs can be used as the cam output (CAM) from the user program.

As of the editorial deadline of this documentation, the output cam resolution for D410-2 was not yet certain. The information can be found at the following website Additional information about the SIMOTION D manuals (http://support.automation.siemens.com/WW/view/en/27585482).

SIMOTION D4x5-2 onboard outputs (interface X142)

The D4x5-2 onboard outputs can be used as cam output (CAM) from the user program. The D4x5-2 onboard outputs are permanently assigned to SIMOTION. The X142 I/Os are configured using HW Config.

The X142 configuration screen form can be accessed directly from the project navigator in SIMOTION SCOUT.

With SIMOTION D4x5-2, output cams are output at the X142 interface with a resolution of 1 µs.

TM15 / TM17 High Feature Terminal Modules

The TM15 and TM17 High Feature Terminal Modules can be used to set up cam outputs (CAM) within the SIMOTION Motion Control system. The Terminal Modules are connected directly to SIMOTION D or CX32/CX32-2 via DRIVE-CLiQ for this purpose.

Alternatively, TM15 and TM17 High Feature can be connected to a SINAMICS S120 CU320/ CU320-2/CU310/CU310-2 Control Unit with higher-level SIMOTION C, P or D.

Output cams on the TM15 operate with DRIVE-CLiQ cycle-clock resolution (typically 125 µs). Output cams on the TM17 High Feature have a resolution of 1 µs.

If current controller cycle clocks other than 125 µs are used, the parameter calculations of the drive must be taken over into the PG and the Fast IO configuration must be recreated when using cam outputs on TM15/TM17 High Feature. (For more information, see chapter Current controller cycle clocks <> 125 µs / use of output cams and measuring inputs in the TM15 / TM17 High Feature Terminal Modules Commissioning Manual).

ET200xP TM Timer DI/DQ

The digital inputs/outputs are used for the cam output in ET200xP TM Timer DI/DQ. The digital inputs/outputs can be used as the cam output (CAM) from the user program. Output cams on the ET200xP TM Timer DI/DQ have a resolution of 1 µs.

High-speed digital output (DO)

The cam output is performed via onboard outputs of the SIMOTION CPU. The output is via a hardware timer and the cam output is achieved with a resolution with respect to time < servo cycle clock.

The time that it takes for the axis to reach the output cam switching position with reference to the processing cycle is calculated by linear extrapolation. Calculated from the beginning of the 1st position control cycle, the output cam function is triggered by a hardware time when this time is reached.

Hardware supported

The onboard I/O of the following CPUs is used:

- SIMOTION D4x5 (interface X122, X132), 8 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as **DO**)
- SIMOTION D410 (interface X121), 4 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as **DO**)
- SIMOTION C240, C240 PN (interface X1), 8 high-speed cam outputs

SIMOTION D410/D4x5 onboard outputs

Output cams are output via **a high-speed digital output (DO).**

- Up to and including SIMOTION V4.1 SP5, all D410/D4x5 onboard I/Os configured as digital outputs are exclusively available to SIMOTION
- As of SIMOTION V4.2, D410/D4x5 onboard I/Os configured as digital outputs can be switched over to SINAMICS using BICO interconnection (channel granular)

Standard digital output (DO)

The output cam calculations are performed in processing cycles (IPO or IPO_2 cycle clock or servo cycle clock).

Actual cam output is performed in servo cycles. The temporal resolution of the cam output is usually reduced by the output cycle of the I/O used.

Therefore the resolution

- with standard I/O (e.g. ET 200) depends on the cycle time of the bus system (PROFIBUS DP / PROFINET IO)
- with TM15 / TM17 depends on the cycle time of the bus system (PROFIBUS Integrated / PROFIBUS DP / PROFINET IO)
- with TM15 DI/DO, TM31, TM41, TB30 depends on the configured sampling time
  - cu.p0799 (CU inputs/outputs sampling time) for the TB30 and onboard outputs
  - p4099 (TMxx inputs/outputs sampling time) for TM15 DI/DO, TM31 and TM41

Hardware supported

- Onboard outputs (SIMOTION D, Controller Extension CX, SINAMICS Control Unit CU3xx)
- Centralized I/O (SIMOTION C)
- Distributed I/O via PROFIBUS DP/PROFINET I/O (e.g. ET 200, ET200xP TM Timer DI/DQ)
- Drive I/O TM15, TM15 DI/DO, TM17 High Feature, TM31, TM41, TB30

Configuration data of cam output types in expert list

Table 4-155 Setting options for cam output

Selection in configuration screen	Setting in expert list
Cam output (CAM) (D4xx-2, ET200xP TM Timer DIDQ, TM15/17)	OcaBaseCfg.outputType = [1] TIME_STAMP OcaBaseCfg.hwTimer = [91] NO
High-speed digital output (DO) (D4xx, C240)	OcaBaseCfg.outputType = [0] STANDARD OcaBaseCfg.hwTimer = [173] YES
Standard digital output (DO) (Standard DO, e.g. ET200, TM31)	OcaBaseCfg.outputType = [0] STANDARD OcaBaseCfg.hwTimer = [91] NO

Output cams on **cam output (CAM)** or on **high-speed digital output (DO)** are also referred to below as high-speed, hardware-supported output cams.

Note

Further information and the output accuracy for high-speed output cams is described in the PM21 Catalog and in the respective product brief or commissioning/equipment manuals.

Configuring cams on SIMOTION D4xx onboard (Page 1835)

Exact time setting of an output, exact time output cams (as of V4.1)

You can switch a high-speed output cam On/Off at an exact time within an execution cycle (position control, IPO cycle) via the **timeOffset** parameter of the **_setOutputCamState** system function.

Enter an offset of the switching edge in the configured unit (e.g. s) of the Output Cam TO in the **timeOffset** parameter. The reference point of the offset is the start of the next execution cycle of the Output Cam TO. You can read out the value of the time offset (system-dependent execution time between the execution cycle and the output cycle) in the **tOutput** system variable. The time in **tOutput** is the earliest possible time to switch the output cam. The **timeOffset** is added to this time.

Features

- The offset must be less than the cycle time of the processing cycle clock. The offset is limited automatically and a technological alarm is output when the cycle time is exceeded.
- It is possible to switch on or off within one cycle.
- When this function is used, there is a dependency on the processing cycle clock and the set cycle clock times.
- The offset is valid for every output cam type. If only switched once, the unidirectional output cam type is recommended.
- The offset can only be stated if the output cam TO on the outputs is configured with a time stamp (cam output (CAM)).
- For output cams without time stamp (e.g. C240-2 onboard output cams), **tOutput** (time stamp) is set to 0.0.

- If multiple activation or deactivation signal edges are output within one cycle, the most recently written values apply.
- The start of the output cycle is shifted with respect to the beginning of the processing cycle by the value output in the **tOutput** system variable and the specified **timeOffset**.

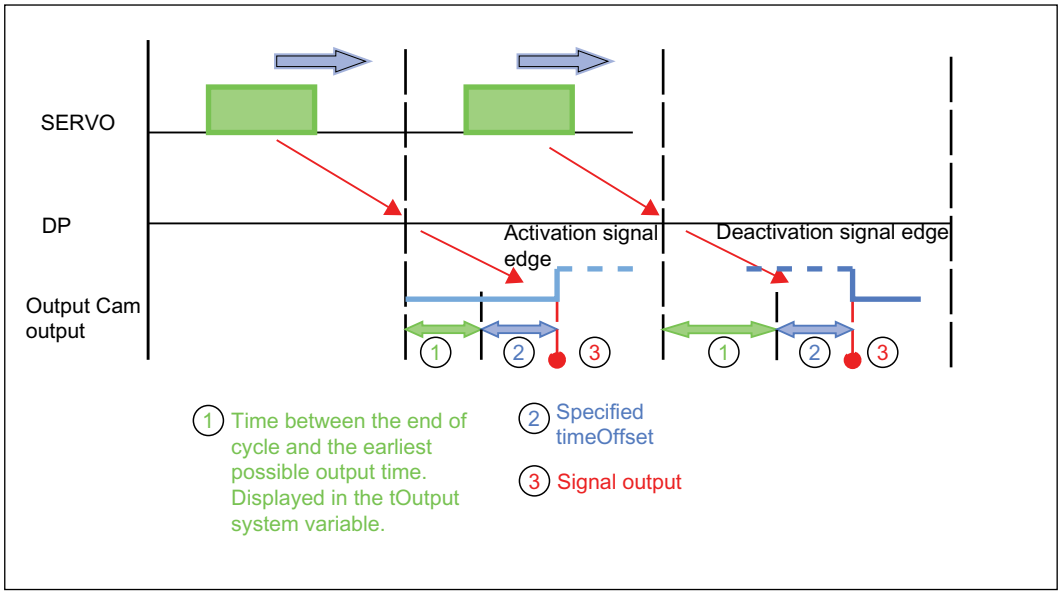

Figure 4-191 Exact-time output setting for DP:POSITION CONTROL=1:1

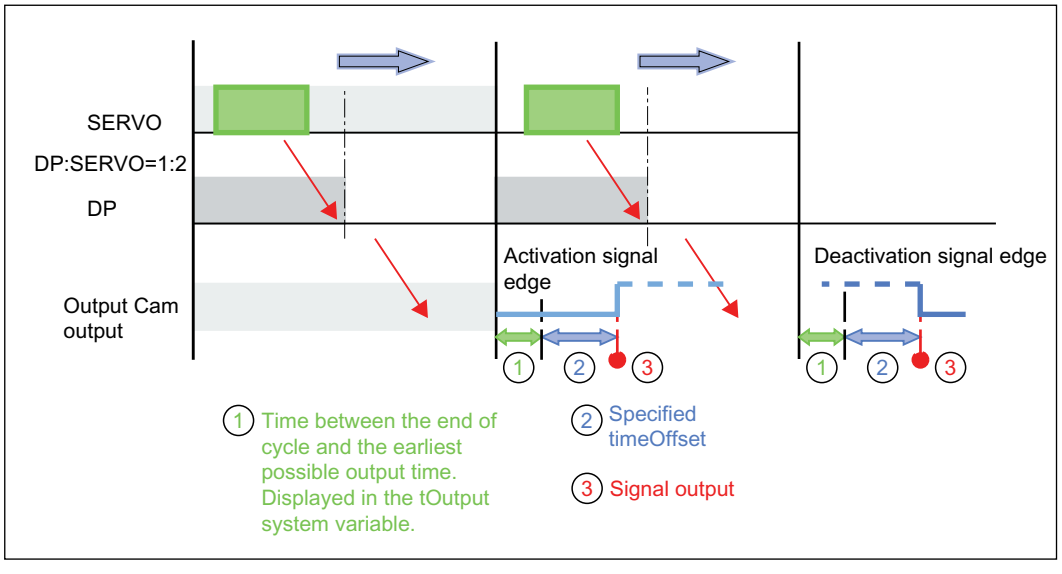

Figure 4-192 Exact-time output setting for DP:POSITION CONTROL=1:2

Cam parameters

Reaction, effective direction

Behavior

The following diagram shows output cam behavior when switching on and off, without hysteresis, activation, or deactivation time.

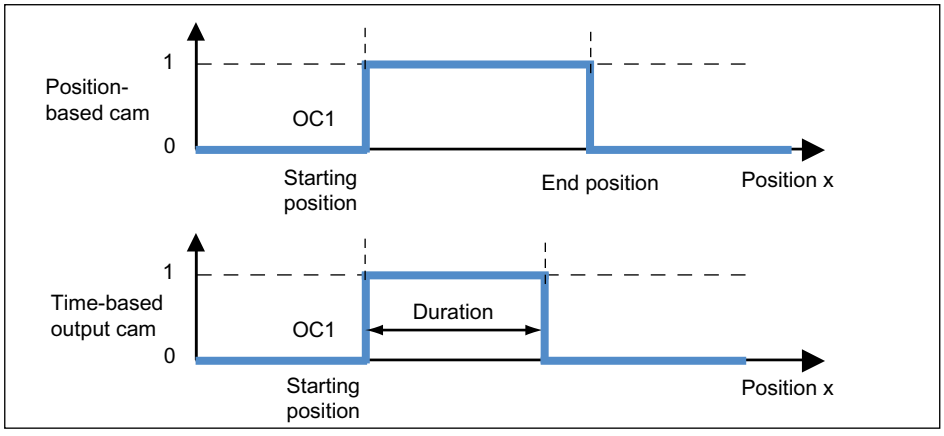

Figure 4-193 Output cam behavior when switching on/off

The switching action depends on the position only (position setpoint or actual position).

Effective direction

You can define a default effective direction when you activate output cams. The output cam only switches when the motion direction and effective direction are identical.

Options:

Table 4-156 Effective direction and behavior

Effective direction	Behavior
Positive	The output cam is activated only in positive direction of motion.
Positive and negative	The output cam is activated independent of the direction of motion.
Negative	The output cam is activated only in negative direction of motion.
Last programmed direction of rotation	With this setting, the output cam switches for the last programmed direction of rotation. If no direction of rotation has been previously programmed, the default setting is used.

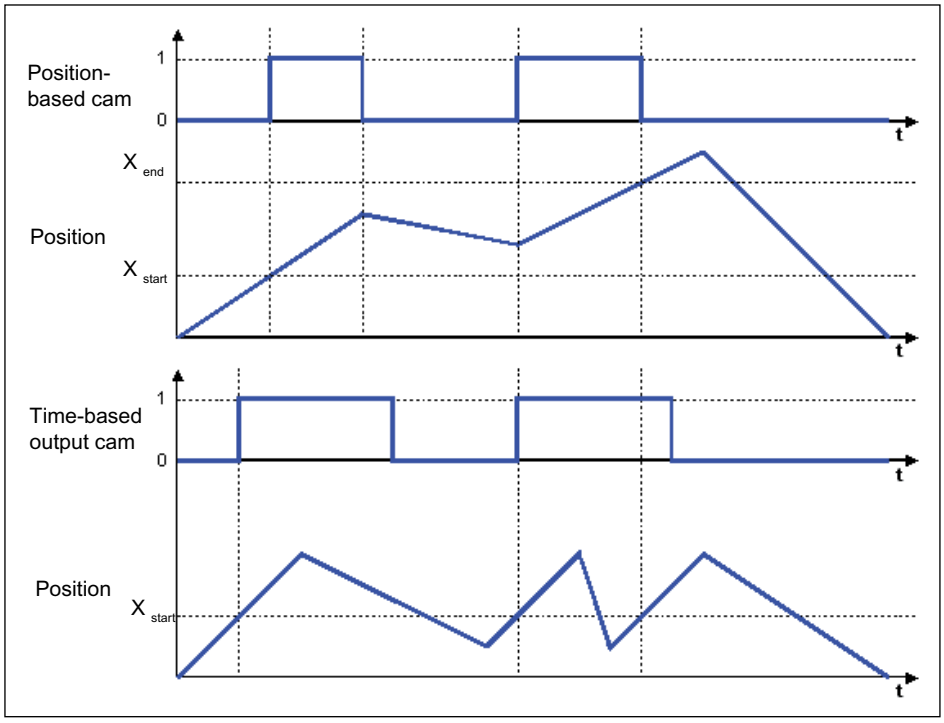

Figure 4-194 Positive effective direction and output cam switching behavior

Hysteresis

If the actual position value tends to fluctuate due to mechanical influences, specification of a **hysteresis** prevents the output cam from unintended switch status changes.

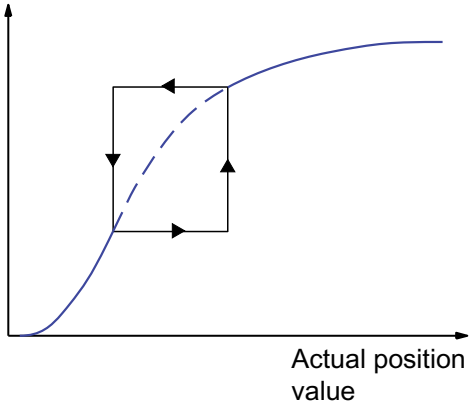

Figure 4-195 Hysteresis

Hysteresis range conditions

- Hysteresis is not activated until the direction has been reversed.
- The direction of motion is not redefined within the hysteresis.

- Within the hysteresis, the switching state of position-based cams is not changed.
- If modified switching conditions for the output cam are detected when the output cam is outside the hysteresis range, this current switching state is set.

Example: position-based cam hysteresis

Output cam configuration:
output cam type: position-based cam; switch-on position, 20 mm; switch-off position, 200 mm; hysteresis, 20 mm; effective direction: positive

Axis positions:
0 mm -> 100 mm -> 10 mm -> 50 mm -> 0 mm -> 150 mm -> 0 mm

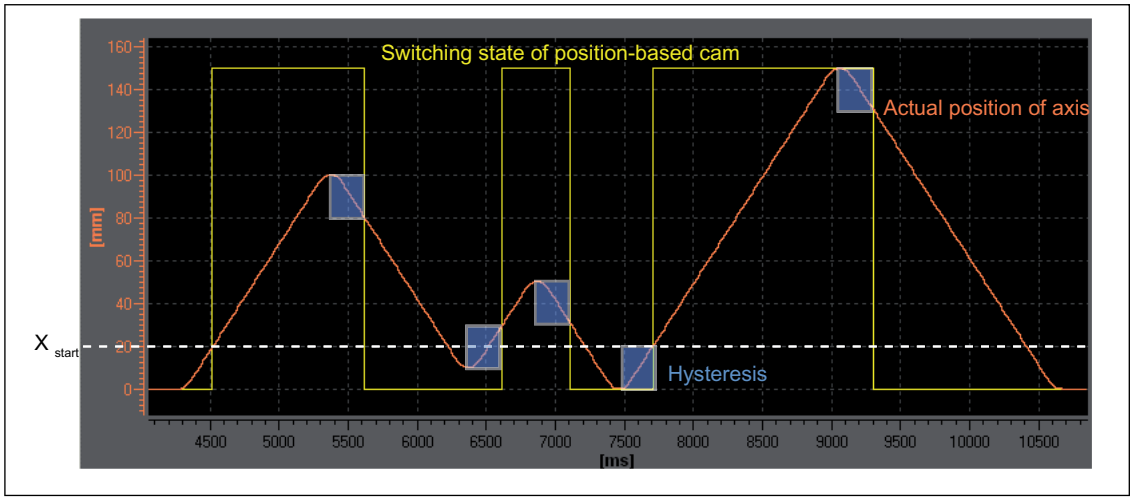

Figure 4-196 Hysteresis range (height of blue sections) and behavior of a position-based cam, positive effective direction

Output cam's second switch-on point is moved to position 30 mm, due to hysteresis (see figure above).

Example: time-based cam hysteresis

Output cam configuration:
output cam type: time-based cam; switch-on position, 40 mm; ON duration, 0.5 s; hysteresis, 20 mm; effective direction: positive

Axis positions:
0 mm -> 100 mm -> 20 mm -> 60 mm -> 30 mm -> 80 mm -> 10 mm -> 150 mm

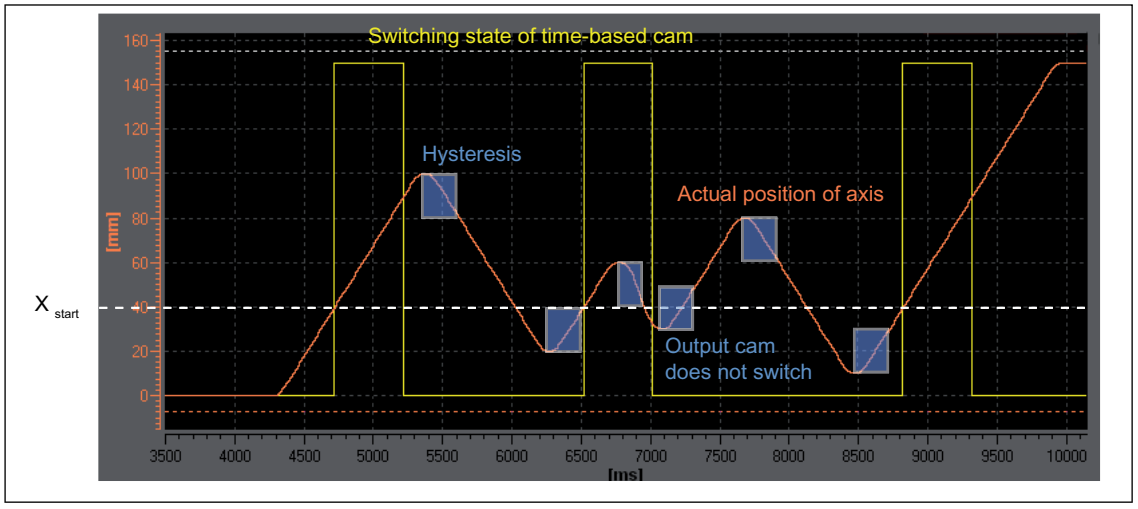

Figure 4-197 Hysteresis range (height of blue sections) and behavior of a time-based cam, positive effective direction

Time-based cam switches off only after ON duration has expired, not after change of direction.

Time-based cam with a start position within the hysteresis range is not output (see figure above).

Hysteresis range

The upper limit of the hysteresis range is set at 25% of the working range for a linear axis, and 25 % of the rotary axis range for a rotary axis. If you violate this maximum setting, an error message is issued. In practice, a lower setting is used for the hysteresis range.

- **Path-controlled output cam**
  The hysteresis becomes active after direction reversal is detected. If only a positive or only a negative effective direction has been parameterized for an output cam, the output cam does not switch off after a reversal of direction until it has left the hysteresis.
- **Time-based cam**
  The switching behavior of a time-based cam is determined by the ON duration, not by the hysteresis. This means that an entered hysteresis range has no influence on the ON duration of an output cam. It only has an influence on the switch-on time (start position).

Note

If a time-based cam's start position lies within the hysteresis, it is **not** output.

Derivative-action times (activation/deactivation time)

To compensate for the switching times of digital outputs and connected switching elements, or of propagation delays, it is possible to specify **actuation times**. Actuation times are calculated from the sum of all delay times and can be specified separately for activation and deactivation edges as an actuation time at the activation edge (activation time) or an actuation time at the deactivation edge (deactivation time).

The activation/deactivation times of the TO outputCam are dynamically compensated by means of the derivative-action times. In this way, output cams are dynamically shifted depending on the actual velocity.

For example, a valve that should open at 200°, with an activation time of 0.5 s

- Must be controlled at 195° at a velocity of 10°.
- Must be controlled at 190° at a velocity of 20°.

This dynamic shift takes place automatically by means of the Output Cam TO.

Settings for the activation and deactivation times can contain positive or negative values.

A negative activation time must be entered if the output cam is to be switched before the programmed start of the output cam.

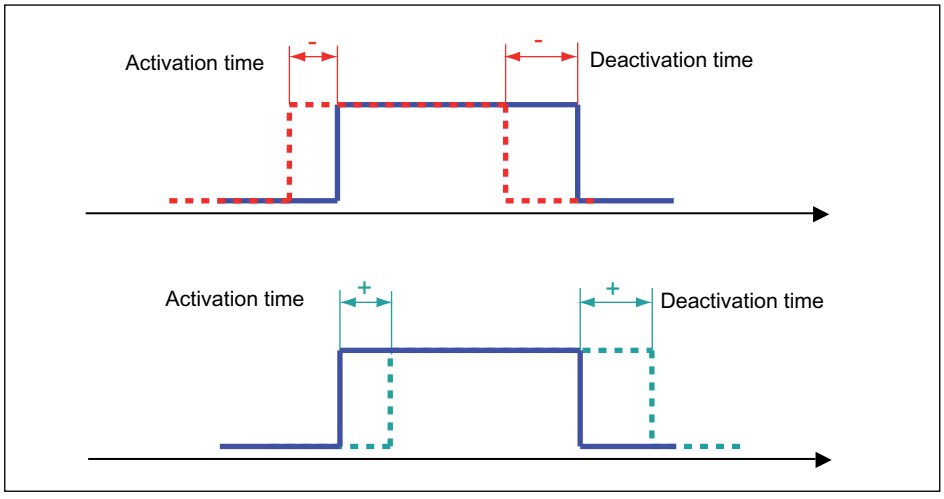

Figure 4-198 Switching behavior at varying actuation times

Note

The time of output for the output cam in the controller is relevant for calculation of the dynamic adjustment. If velocity changes up to signal output, these changes are no longer taken into account.

Dead times, e.g. PROFIBUS DP communication times, output delay times on digital outputs, etc., are taken into account in the actuation time.

Long actuation times exceeding one modulo cycle may lead to heavy fluctuation of the switching position of actual value output cams (actual value curve). Here, setpoint output cams should be used or the actuation time should be considerably less than one modulo cycle.

The system takes into account the specified actuation times when the output cams are calculated and managed. The switching positions of the output cams are calculated taking into account the activation time and deactivation time in relation to the present velocity. If, allowing for actuation times, the output cam was switched, then the system deems this operation to have occurred, and it does not switch the output cam again even if any subsequent current velocity changes occur.

The dynamic actuation of modulo axes can be greater than one modulo length. However, the number of switching operations is not collected by the system, i.e. for actuation times longer than one modulo length, a switching operation cannot take place in each modulo cycle. One switching operation is active in the system at any given point in time. A switching operation is completed when the output cam is switched off.

Actuation times and cycle clock settings

A change of cycle clock settings does not have to be taken into account for the actuation time settings (activation/deactivation time). These are, for example:

- Changing the Servo/IPO/IPO_2 clock settings (for example, from "1/1/1 ms" to "2/2/2 ms").
- Change of processing cycle clock of the TO outputCam (setting: Servo cycle clock, IPO cycle clock, IPO_2 cycle clock).

Deactivation time for time-based cam

Deactivation time is also taken into account in setting a time-based cam.

Deactivation time must be:

- Deactivation time ≤ activation time + ON duration

Activation and deactivation times can vary independently of the I/O and can, therefore, influence the ON duration of the time-based cam.

To achieve compatibility with older software versions (<V3.2), deactivation time for time-based cams can be activated or deactivated in the **Defaults** window, by means of the **Use deactivation time** checkbox.

See also

Determining derivative-action times for output cams (dead time compensation) (Page 1833)

Logical operation

Through a setting in the **LogAdress.logicOperation** configuration data element you can specify whether the output cam is connected to the output using an AND or OR operation.

That is, all ORed output cams will be grouped and then logically linked at the output with the output cams linked by AND logic.

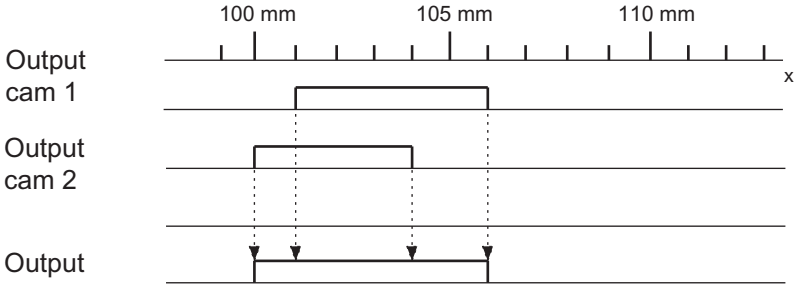

Figure 4-199 OR operation of two output cams

Note

If hardware output cams are configured, you can configure an I/O variable in the symbol browser for monitoring.

See also

Output cam configuration (Page 1826)

Simulation

Operation can be simulated by means of the simulation commands on the output cam. The output cam status is then not output to the hardware output. In simulation mode, a hardware cam behaves as a software cam. It is then only used for programming purposes.

If an active output cam is switched to simulation mode (**_enableOutputCamSimulation**), the output cam status remains the same, and only the control of the output is reset or interrupted.

Inversion

The inversion of single output cams is available and is set on the **_enableOutputCam** command by a parameter (**invertOutput**).

Configure Units

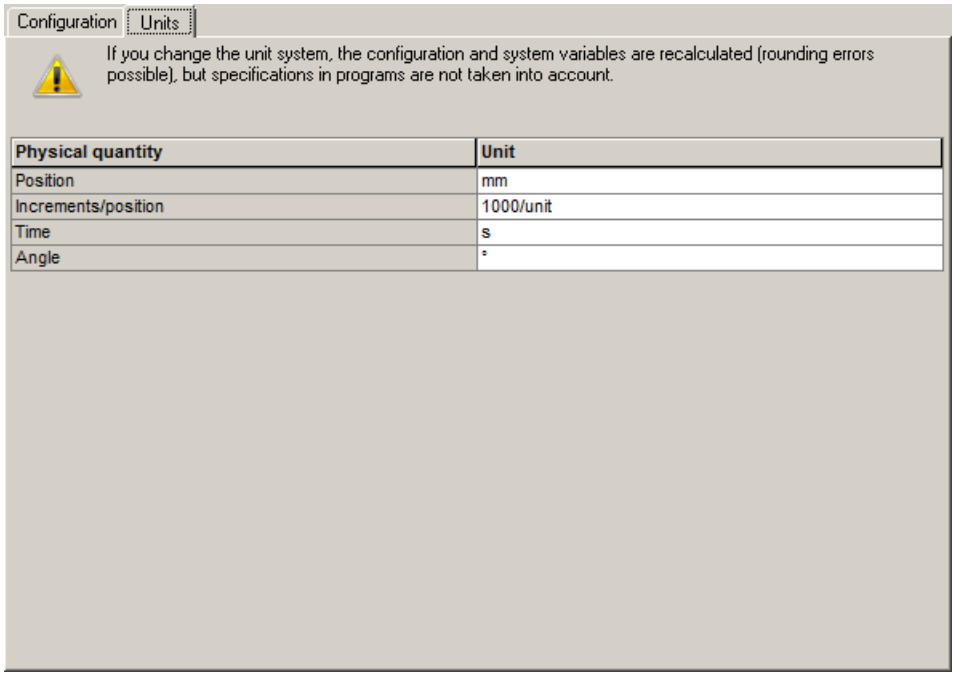
You can define the basic units for each technology object. The same physical variables can have different units in different technology objects. These are converted:

How to configure the units:

1. In the project navigator, open the context menu for the technology object.
2. In the context menu, select **Expert > Configure units**. The **Configure Units** window appears in the working area.
3. Select the **unit** for the **physical variables**. These units are used for the technology object, e.g. s for time units.

or

1. In the project navigator, open the **Configuration** under the TO.
2. Select the **Units** tab.



You can set the following parameters:

Field/button	Meaning/instruction
Table with units	
Physical variable column	Shows the physical variable. The physical variables which are used by the TO are available for the configuration.
Unit column	Displays and configures the unit. A drop-down list for selecting the unit appears when you click on the cell.
Toolbar	
	Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display
Close	Button for closing the dialog.
Help	Button for opening the online help for the dialog.

4.3.3.3 Configuring the Output Cam technology object

Insertion of Output Cam

Note

Before you insert an output cam, the axis (position or synchronous axis) or external encoder to which the output cam is assigned has to be created.

If the cam is output to a TM15/TM17 High Feature or ET200xP TM Timer DI/DQ, the module must be added and configured before cam configuration.

To insert a new output cam:

1. In the project navigator, highlight the **OUTPUT CAMS** folder under the relevant axis or external encoder.
2. Select **Insert > Technology object > Output cam** or double-click **Insert output cam** in the project navigator under the axis or external encoder in the OUTPUT CAMS folder. The **Insert output cam** window appears.
3. Enter a **name** for the output cam. You can also enter a **comment**.
   Names must be unique throughout the project and must comply with ST syntax conventions. For this reason, all the existing output cams are displayed under **Available output cams**.
4. Confirm with **OK**. In the working area, the window for the configuration is displayed and the created output cam TO is shown in the project navigator.

Parameterize Output Cam technology object

General information about configuration data and system variables

Two data classes are distinguished when parameterizing a TO.

Configuration data defines the principal functionality of a TO. They are set within the object configuration framework with the SCOUT engineering system and are not normally changed during runtime.

System variables provide status data of the TO for the user program and a parameterization interface on the TO. System variables can be changed during runtime.

Note

You will find more information on technology objects in the *SIMOTION Runtime Basic Functions functional description*.

To parameterize an output cam:

1. In the project navigator under the folder **OUTPUT CAMS**, find the output cam TO that you want to parameterize. Double-click the output cam TO to display the associated objects.
2. Double-click Configuration or Default in the project navigator. The window appears on the workspace.
   - **Configuration**:
     Define the **configuration data** of the output cam here. This includes, for example, output cam type.
   - **Default**:
     Define the output cam defaults of the **system variables** here. This includes, for example, the effective direction.
3. Change the configuration data and output cam defaults.
4. Click **Close** to accept the changes.
5. Repeat steps 2 to 4 for all objects in which you want to change the configuration data and output cam defaults.

See also

Output cam configuration (Page 1826)

Defining output cam defaults (Page 1831)

Using the expert list for output cams

For standard SIMOTION applications, necessary parameters (configuration data and system variables) are parameterized into the Output Cam technology object directly in screen forms or are defined automatically.
It may be necessary to change automatically defined parameters for special SIMOTION applications. These configuration data and system variables can only be displayed and changed in the expert list.

Note

You will find more information on working with the expert list in the *SIMOTION Runtime Basic Functions functional description*.

Output cam configuration

In the **Configuration** window, define the configuration data values for the output cam.

Double-clicking in the project navigator below the output cam on the **Configuration** element displays the window in the working area.

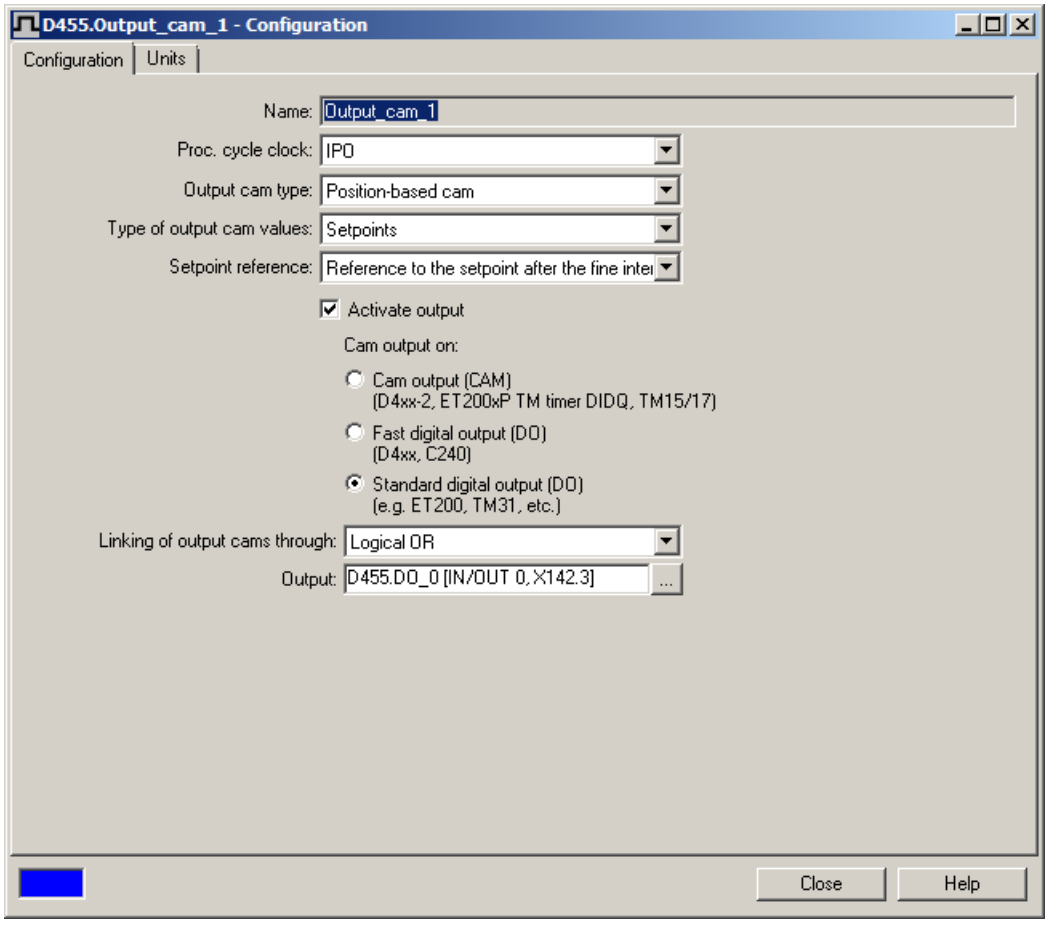


Figure 4-200 Output cam configuration using the example of a position-based cam

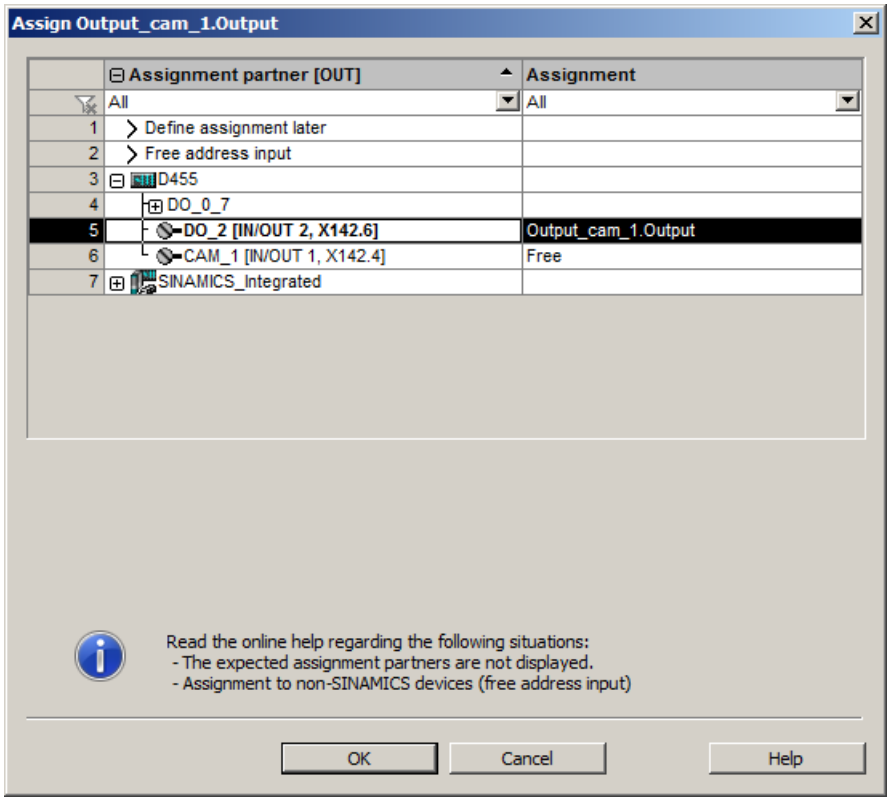

Figure 4-201 Assignment dialog

You can set the following parameters:

Table 4-157 Output cam configuration data

Field/button	Meaning/information
Name	The name of the created output cam is displayed here.
Output cam type	Choose **Output cam type** to select the type of output cam. **Position-based cam** (default value)The switching signal is active when the position of the axis lies between two markers (start and end position). **Time-based cam** The switching signal is on for a specific period of time after reaching the switching position (start position). **Uni-directional output cam** The switching signal changes when the axis reaches the switching position (start position). The output cam remains switched on even if the start position is overtraveled several times. The output cam must be explicitly reset.

Field/button	Meaning/information
Processing cycle clock	Choose **Processing cycle clock** to select the system cycle clock used to update the output cam signal at the output or in the system variables. The cam calculations are performed in IPO or IPO_2 cycles or in servo cycles. The processing cycle clock is set in the configuration by means of the **OcaBaseCfg.taskLevel** configuration data element. **IPO** (default value) The output cam signal is updated in the interpolator cycle clock. **IPO_2** The output cam signal is updated in the interpolator cycle clock 2. The IPO_2 cycle clock length is at least twice that of the IPO. **Servo** The output cam signal is updated in servo cycles. **The following configurations of the processing cycle clock are possible:** • Axis in IPO cycles and output cam in IPO_2 cycles • Output cam in servo cycles and axis in IPO or IPO_2 cycles For the possible setting of IPO_fast and Servo_fast with D435-2, D445-2 and D455-2, see Section Second servo cycle clock (Servo_fast) in the SIMOTION Runtime Basic Functions Manual. **Note:** • It is not possible to configure the axis in the servo cycle clock and the output cam in the IPO or IPO_2 cycle clock. • It is not possible to configure the axis in the IPO cycle clock and the output cam in the IPO_2 cycle clock if it is a setpoint output cam. • It is not possible to configure the axis in the IPO_2 cycle clock and the output cam in the IPO cycle clock.
Type of output cam value	Select the position value that is the reference for the output cam during processing.
Actual value reference	Select the following settings here depending on the type of the output cam values: • **Reference to the actual value on the encoder without considering Ti**. Reference to the actual position in the controller before the position filter. • **Reference to the actual value after the position filter**. Reference to the actual position in the controller after the position filter. • **Reference to the actual value on the encoder. Ti is taken into account**. Reference to the actual value on the encoder module / drive. The transmission time Ti from the encoder module / drive to the controller is taken into account by the system.
Setpoint reference	Select the following settings here depending on the type of the output cam values: • **Reference to the setpoint before the fine interpolator**. The cam switch points are calculated as if the setpoints will already have been reached at the end of this IPO cycle, e.g. if a setpoint is calculated for the IPO cycle clock with the virtual axis and also displayed at the end of the cycle. Reference is made directly to the setpoint applicable at the end of the cycle. • **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoint calculated in the interpolator will be output completely in the following cycle and the calculated position setpoint will therefore be reached at the end of the following cycle. • **Reference to the setpoint on the drive**. Calculation of the cam switch points according to the setpoint output with the current settings on the drive.

Field/button		Meaning/information
Activate output		Activate the checkbox if the output cam signal is to be applied to a digital output. Parameters are displayed.
Cam output on		
	Cam output (CAM)	If the output checkbox is activated and the cam output (CAM) radio button selected, the cam output is on the basis of an internal time stamp. The temporal resolution of the cam output depends on the hardware used. In the case of D4x5-2 and the TM17 High Feature, the resolution is, for example, 1 µs. Supported hardware: • SIMOTION D410-2 • SIMOTION D4x5-2 (X142) • TM15, TM17 High Feature • ET200xP TM Timer DI/DQ The I/O channel must be configured as **CAM**. For more details, see cam output types. (Page 1811) **Note** Cam output (CAM) or high-speed digital output (DO) are also known as high-speed, hardware-supported output cams.
	High-speed digital output (DO)	If the output checkbox is activated and the "High-speed digital output (DO)" radio button selected, the output cam is output via onboard outputs of the SIMOTION CPU. The output is via a hardware timer and the cam output is achieved with a resolution with respect to time < servo cycle clock. The time that it takes for the axis to reach the output cam switching position with reference to the processing cycle is calculated by linear extrapolation. Calculated from the beginning of the 1st position control cycle, the output cam function is triggered by a hardware time when this time is reached. Supported hardware: The onboard I/O of the following CPUs is used: • SIMOTION D4x5 (interface X122, X132), 8 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as **DO**) • SIMOTION D410 (interface X121), 4 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as **DO**) • SIMOTION C240, C240 PN (interface X1), 8 high-speed cam outputs For more details, see cam output types. (Page 1811) **Note** Cam output (CAM) or high-speed digital output (DO) are also known as high-speed, hardware-supported output cams.
	Standard digital output (DO)	If the output checkbox is activated and the "Standard digital output (DO)" radio button selected, the output cam is output in the servo cycle clock. The temporal resolution of the cam output is usually reduced by the output cycle of the I/O used. Supported hardware: • Onboard outputs (SIMOTION D, Controller Extension CX, SINAMICS Control Unit CU3xx) • Centralized I/O (SIMOTION C) • Distributed I/O via PROFIBUS DP/PROFINET I/O (e.g. ET 200, ET200xP TM Timer DI/DQ) • Drive I/O TM15, TM15 DI/DO, TM17 High Feature, TM31, TM41, TB30 For more details, see cam output types. (Page 1811)

Field/button	Meaning/information
Logical operation (Page 1822)	You can assign several TO output cams to an output. Select the logical link of the output cam signal with the output. During the operation, all output cam signals are first grouped together with the logical operation OR. The result of this operation is then combined with the output cam signals to which a logical AND was assigned.
Output	The output can be symbolically assigned via the assignment dialog (see Chapter Symbolic assignment (as of V4.2) in the SIMOTION Runtime Functions Manual) using the ... button in the Output field (symbolic assignment is activated by default in projects as of V4.2). If symbolic assignment is not active or if the CPU version is < V4.2, a physical output is assigned by entering the HW address and bit number in the Output field. Enter the logical HW address of the output to which the output cam signal is to be applied. Only the output cam signal may be present at this address. If other objects are already using this output, an error occurs that is reported following a download to the target system. The logical HW address must be located outside the process image and therefore be greater than 63. For more details, see cam output types. (Page 1811)
...	Button for opening the assignment dialog (see Section Symbolic assignment (as of V4.2) in the SIMOTION Runtime Basic Functions Manual). Select a parameter or an address in the Assign dialog.
	Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display

Defining output cam defaults

You can define the defaults for every output cam. These values are stored in system variables and can be changed by programs.

Double-clicking in the project navigator below the output cam on the **Defaults** element displays the window in the working area.

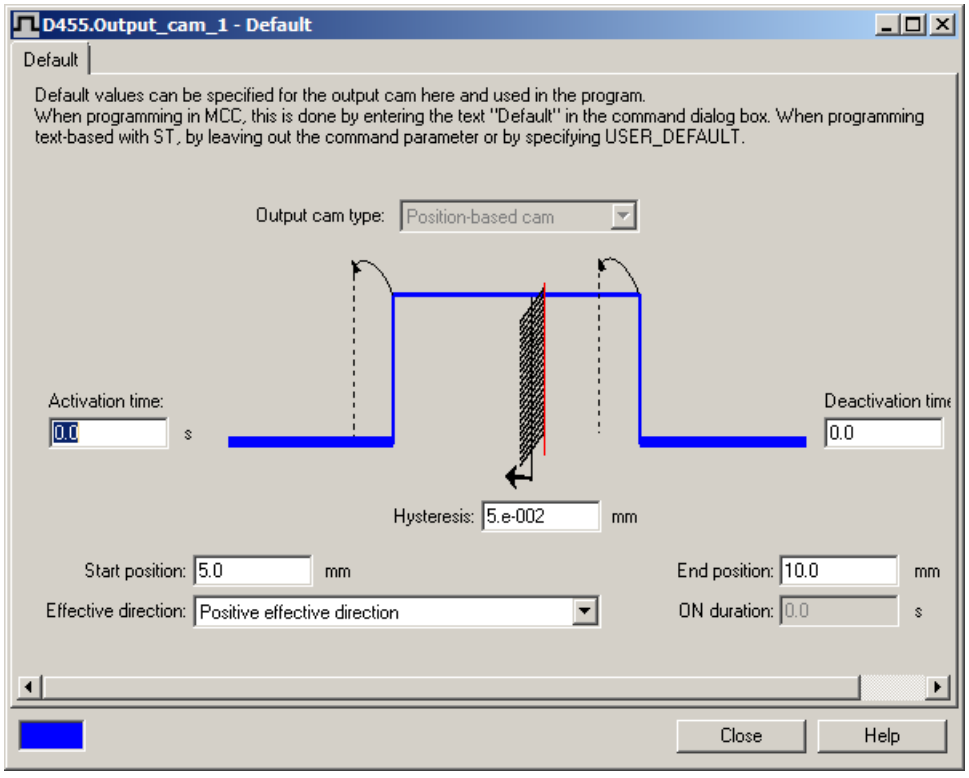

Figure 4-202 Output cam defaults, position-based cam example

You can set the following parameters:

Table 4-158 Defining output cam defaults

Field/Button	Significance/Note
Output cam type	**Output cam type** displays the type of output cam selected in the Configuration window.
Activation time See also the **Actuation times (activation/deactivation time)** section.	Enter the **activation time** here. The output cam switching time is set to the point when the start position is reached, plus this period. The output cam position is adapted dynamically. This allows you to compensate for propagation delays. If a negative value is entered as an activation time, the switching signal is activated before the start position is reached.
Using deactivation time	Activate the checkbox if you want to use a deactivation time when working with time-based cams. If this checkbox is deactivated, you cannot enter a time. In this respect, the time-based cam is compatible with older software versions (<V3.2).
Deactivation time	Enter the **deactivation time** here. The output cam switch-off time is set to the point when the end position is reached, plus this period. The output cam position is adapted dynamically. This allows you to compensate for propagation delays. If a negative value is entered as a deactivation time, the switching signal is activated before the end position is reached.
Hysteresis	Enter a range for the **hysteresis** here. The output cam does not change its switching state in this defined range around the switching position even under changed switching conditions. This prevents a repeated change of the switching state.
Start position See also the **Output cam types** section.	Enter the start position of the output cam. For path-controlled output cams this is the left switching position.

Field/Button	Significance/Note
End position	Enter the end position of the output cam. For path-controlled output cams this is the right switching position.
Effective direction	Enter the **effective direction** for the output cam. The output cam is active only if the current direction of motion of the axis corresponds to the parameterized effective direction. **Positive and negative effective direction (both)** Output cam switches in both directions of motion **Last programmed effective direction (effective)** Output cam switches only in the last programmed effective direction **Negative effective direction (negative)** Output cam switches only for negative direction of motion **Positive effective direction (positive)** Output cam switches only for positive direction of motion
ON duration	Enter the ON duration for time-controlled output cams here. After the axis has passed the switch-on position, the time-based cam output remains on for the ON duration.

Reaction, effective direction (Page 1817)

Hysteresis (Page 1818)

Determining derivative-action times for output cams (dead time compensation)

Depending on the system and the device, there is a certain time between the setting of a cam output by the program and the actual reaction of the actuator (e.g. solenoid valve). This time is called dead time and depends, for example, on the load-dependent delay times of a digital output, the switching properties of a valve, etc. Usually the exact value for the dead time is not known and can therefore be determined empirically through measurements.

In order that an output cam switches at the correct time, the dead time must be compensated by specifying a derivative-action time, which offsets the cam output by the dead time. Whereby it must be taken into account that the derivative-action times for switching an actuator on and off are usually different.

The empirical determination of the dead times using a difference measurement as an example.

Note

The procedure applies not only to output cams, but also to cam tracks. However, with cam tracks you can only specify a derivative-action time for the entire cam track.

Example

Lines of glue are to be applied to a product at a defined position and with a fixed length. The glue output is controlled by an output cam or a cam track. The glue is output from the start of output cam (switch-on point) to the end of output cam (switch-off point). The offset of the begin and end of output cam with respect to the velocity can be observed on the length and position of the glue line on the product (see figure). The figure below shows the line of glue for two velocities (v_1, v_2) with $v_2 > v_1$.

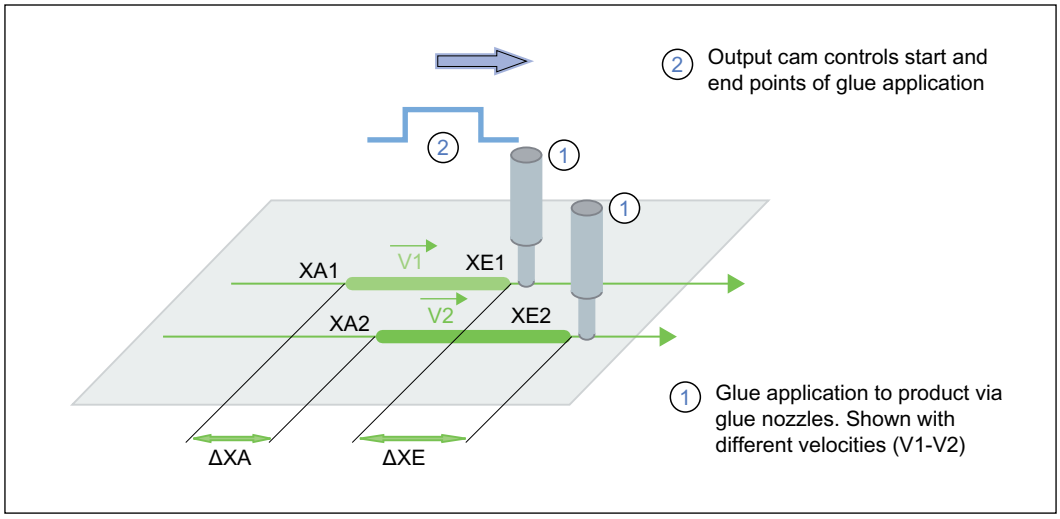

Figure 4-203 Offset of the output of output cam through dead times (dead time compensation)

Procedure:

1. Set all actuation times for start of output cam (activation time) and end of output cam (deactivation time) to 0.
2. Define the velocities for which the positions are to be determined. You should select two velocities that correspond to velocities that occur during production (e.g. minimum and maximum velocity).
3. Start the application and determine the start positions (x_{A1} and x_{A2}) and end positions (x_{E1} and x_{E2}) of the line of glue for the velocities v_1 and v_2.

   Note

   To increase the accuracy, you can perform several comparison measurements and use the average measured values.

4. You can determine the actuation times for the output of output cam using the following formula.
   $\mathbf{t_{activation} = \Delta s/\Delta v = (x_{A2}-x_{A1})/(v_2-v_1)}$
   $\mathbf{t_{deactivation} = \Delta s/\Delta v = (x_{E2}-x_{E1})/(v_2-v_1)}$

5. Enter the calculated actuation times as **activationtime** for the start of output cam and as **deactivationtime** for the end of output cam. Note that the actuation time must be entered as a negative when the output time is to be before the programmed output cam switching time.
6. After you have determined the activation time and the deactivation time for the output of output cam, you should perform a control measurement and check the result.

Note

Depending on the application, it may be, e.g. with eccentric presses, that there is no linear relationship between dead time and velocity (e.g. non-linear response of an applied brake). You have to dynamically adapt the dead time to the respective velocity for these applications. This can be implemented in the application with a user program. After the actuation time has been changed, you have to activate the output cam again with **_enableOutputCam** or the cam track with **_enableCamTrack**.

Derivative-action times (activation/deactivation time) (Page 1820)

Configuring cams on SIMOTION D4xx onboard

Output cams and cam tracks can be configured for standard outputs, or as high-speed, hardware-based output cams / cam tracks.

Cams can be configured on SIMOTION D4xx onboard as follows:

1. In the project navigator, switch to the Control Unit via **SINAMICS_Integrated > Control_Unit.**
2. Double-click **Inputs/outputs** below the control unit. The window appears on the workspace.
3. Switch to the **Bidirectional digital inputs/outputs** tab.
4. Click the **button** to switch between the input and output for the digital inputs/outputs (**DO8 to DO15**). In each case, switch the DI/DO to the output you wish to use as the output of output cam. The designation at the terminal strip of DI or DO switches to DO. Outputs of the output cam can only be used if they have been defined as an output. DO 8 is configured as an output in the diagram. For the output, select the **DO (SIMOTION)** setting.

Note

Mixed use of the SIMOTION D4xx DI/O as high-speed outputs (of output cams) and inputs of measuring inputs is possible.

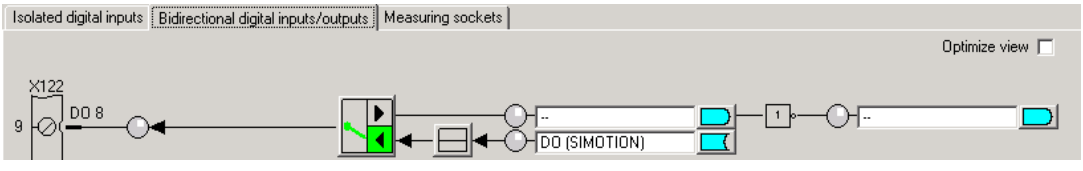

Figure 4-204 SIMOTION D4xx digital inputs/outputs

5. Click **Close**.
6. Insert a new output cam or a new cam track or use an existing one.
7. Parameterize the TO Output Cam / Cam Track
8. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
9. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used. Should you wish to configure a high-speed output cam, select the **Activate output** check box and select the **High-speed digital output (DO)** radio button.
10. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address.
11. Click **OK** to close the window and select **Project > Save**.

To determine the logical hardware address for outputs on SIMOTION D4xx onboard (only if symbolic assignment is not activated)

1. In the project navigator, below the SIMOTION D device, select **SINAMICS_Integrated > Communication > Telegram configuration**.
2. Double-click Configuration and, in the window which appears, select the tab **IF1: PROFIdrive PZD telegram**. The components are displayed there with address range (input/output data).

3. Select SIEMENS telegram 390, 391 or 392 as telegram type. A maximum of eight output cams can be configured for each telegram. The number of DI/DO is limited to eight, i.e. only two output cams can be configured for telegram 392 if you are already using six measuring inputs. Therefore consider whether you also want to use measuring inputs during the telegram selection.

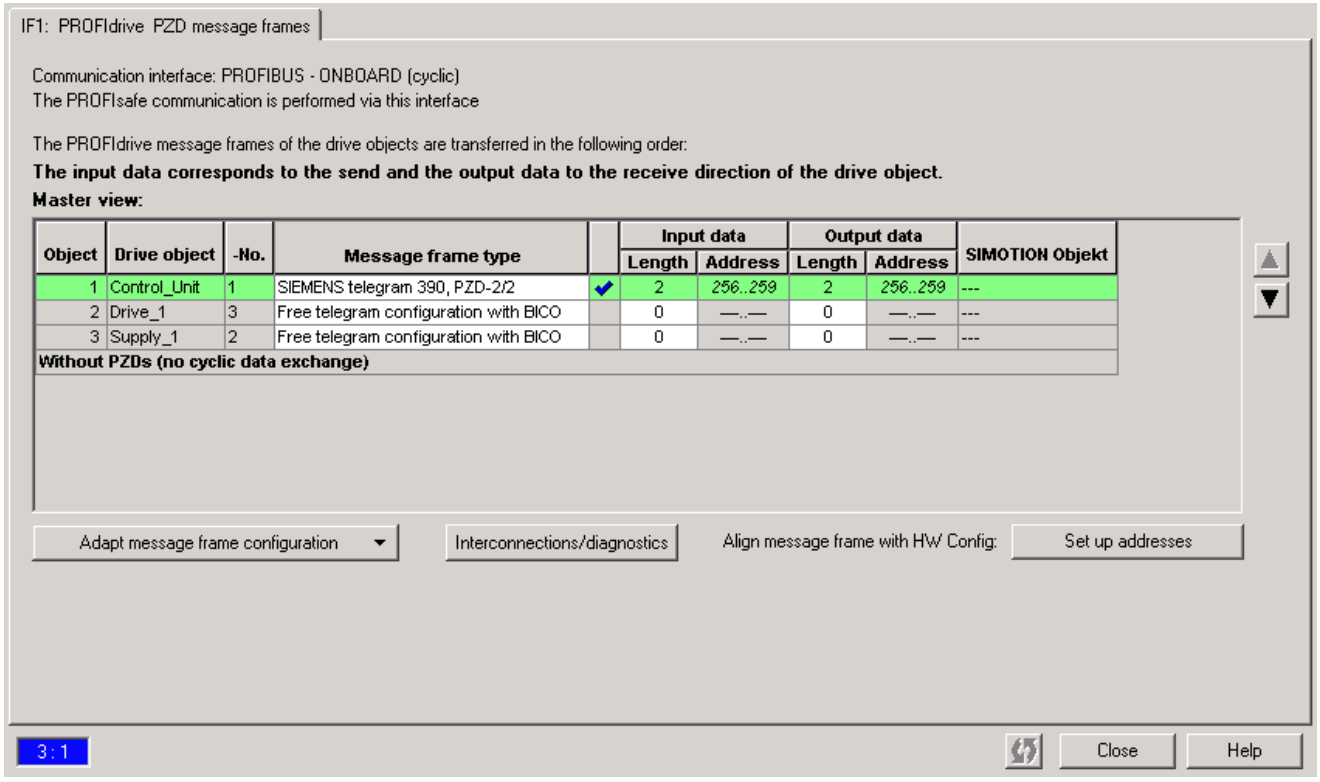

Figure 4-205 Determining the hardware address of the components

4. Before you determine the hardware address, an alignment between HW Config and SIMOTION SCOUT, with respect to the address, must be performed. If this has not been performed or you have changed the addresses, click on **Set up addresses**. If there are question marks in the fields instead of I/O addresses, you must also perform an alignment.
5. Now calculate the hardware address by adding the base output address (first value of the output data) of the Control Unit to the offset (for example 298 + 3 = 301). The offset always has the value **3**. Enter this calculated address under Measuring input > Configuration > Input (e.g. PI 301.1)."]
6. The onboard measuring inputs in the expert list of the Control Unit must be set in parameters 680[0] to 680[5] (e.g. 680[0] -> [1] DI/DO 9 (X122.8/X121.8))." You will find the bit number in the following table. The inputs are set in parameters 680.0 to 680.7 of the Control Unit, e.g. bit 1 in parameter 680[0].

Table 4-159 Bit numbers for D410 and D4x5

Output D4x5	Output D410	Bit number
X122.7 (DI/DO 8)	X121.7 (DI/DO 8)	Bit 0
X122.8 (DI/DO 9)	X121.8 (DI/DO 9)	Bit 1
X122.10 (DI/DO 10)	X121.10 (DI/DO 10)	Bit 2

Output D4x5	Output D410	Bit number
X122.11 (DI/DO 11)	X121.11 (DI/DO 11)	Bit 3
X132.7 (DI/DO 12)	-	Bit 4
X132.8 (DI/DO 13)	-	Bit 5
X132.10 (DI/DO 14)	-	Bit 6
X132.11 (DI/DO 15)	-	Bit 7

Note

In the case of versions earlier than V4.2, when using 39x telegrams, the onboard D4x5 outputs are to be assigned exclusively to SIMOTION. During a consistency check in SIMOTION SCOUT, no check is made as to whether the entered HW address actually belongs to a **high-speed digital output (DO)**.

Configuring output cams on SIMOTION D410-2

1. In the project navigator, switch to the **Control Unit** via **SINAMICS_Integrated > Control_Unit**.
2. Double-click **Inputs/outputs** below the control unit. The window appears on the workspace.
3. Switch to the **Bidirectional digital inputs/outputs** tab.
4. Click the button to switch between the input and output for the digital inputs/outputs (**DO 8 to DO15**). In each case, switch the DI/DO to the output you wish to use as the output of output cam. The designation at the terminal strip switches to DO. Cam outputs must always be defined as outputs so that they can be used. DO 8 is configured as an output in the diagram. For the output, select the **Output cam (SIMOTION)** setting.

   Note

   Mixed use of the SIMOTION D410-2 DI/DO as high-speed (output cam) outputs and inputs of measuring inputs is possible.

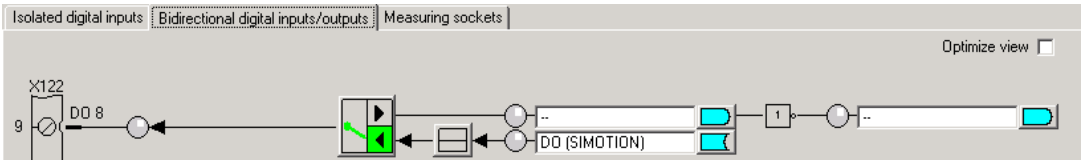

Figure 4-206 Digital inputs/outputs onboard

5. Click Close.

6. Insert a new output cam or a new cam track or use an existing one.
7. Parameterize the TO Output Cam / Cam Track
8. Double-click Configuration below the output cam or the cam track in the project navigator. The Configuration window appears in the working area.
9. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used. Should you wish to configure a high-speed output cam, select the **Activate output** checkbox and select the **Output cam output (CAM)** radio button.
10. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address.
11. Click OK to close the window and select **Project > Save** from the menu.

Configuring cams on SIMOTION D4x5-2 onboard

With SIMOTION D4x5-2 the outputs on the interface X142 are used for cam output

1. The **Inputs/outputs X142** entry in the project navigator can be used to open the configuration screen in HW Config.
2. For the selected I/O channel, select **Output cam** as the function.

Note

If you do not use symbolic assignments (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual), you must note the logical address. (see Figure I/O Properties) This address must be configured at the TO output cam

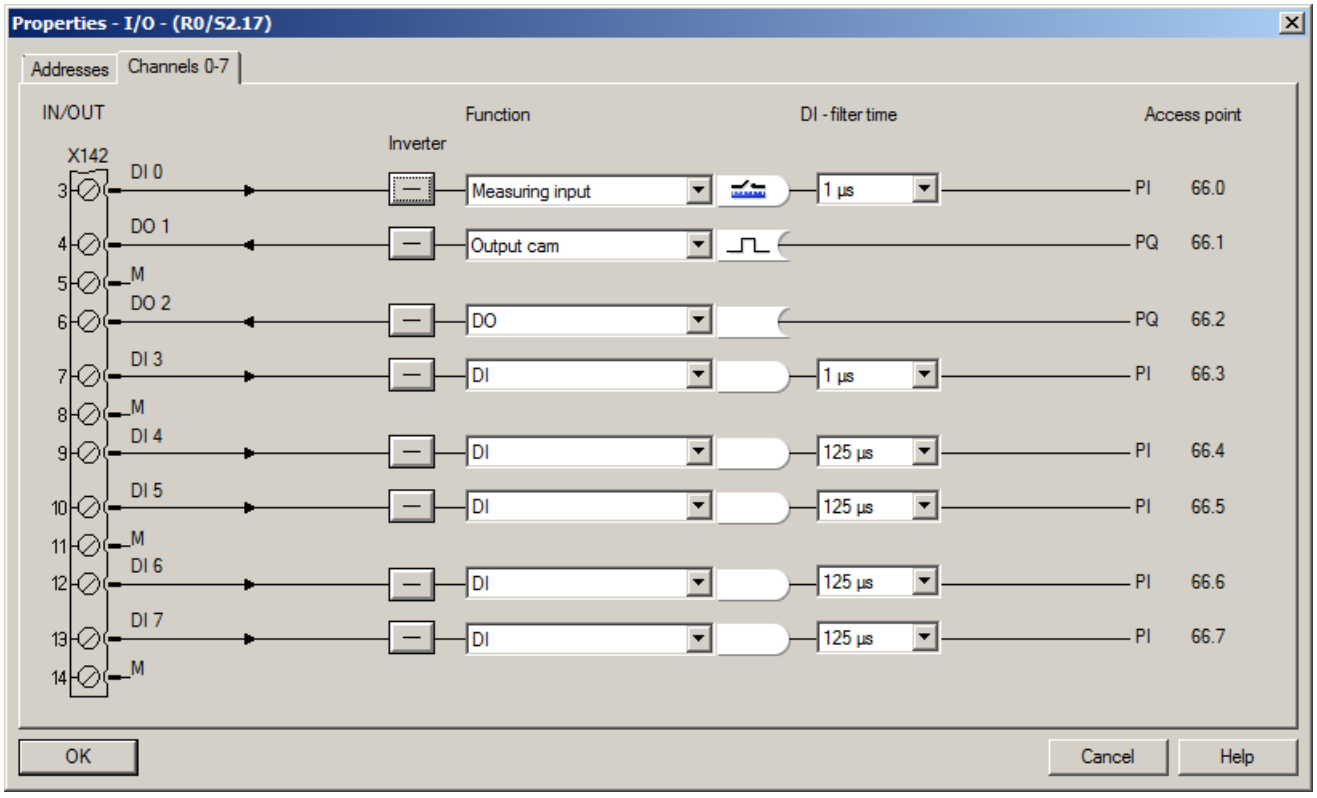

Figure 4-207 I/O Properties

3. Click OK.
4. Insert a new output cam or a new cam track or use an existing one.
5. Parameterize the TO Output Cam / Cam Track
6. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
7. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used.
   If you would like to configure a high-speed output cam, select the Activate output check box and select the output cam output (CAM) radio button.

8. Assignment of an output to an output cam/cam track is supported as of V4.2 using symbolic assignment or by entering the HW address.
9. Click OK to close the window and select **Project > Save** from the menu.

Configuring an output cam on a TM15/TM17 High Feature

1. In the project navigator, below the input/output component (TM15/TM17) that you want to use, double-click the entry **Inputs/outputs.** The **Bidirectional Digital Inputs/Outputs** window is displayed.
2. For the selected I/O channel, select **Output cam** as the function.

   Note

   If you do not use symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual), you must note the offset (e.g. 3.1).

3. Insert a new output cam or a new cam track or use an existing one.
4. Parameterize the TO Output Cam / Cam Track
5. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
6. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used.
   If you would like to configure a high-speed output cam, select the **Activate output** check box and select the **Cam output (CAM)** radio button.
7. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address.
8. Click OK to close the window and select **Project > Save** from the menu.

To determine the logical hardware address for TM15/TM17 High Feature outputs (only if symbolic assignment is not activated)

1. In the project navigator, below the SIMOTION device or the SINAMICS drive unit
   - for SIMOTION D, select: **SINAMICS_Integrated > Communication > Telegram configuration**
   - for SINAMICS S/G drive unit (position axis only): **Communication > Telegram configuration**
2. Double-click **Telegram configuration** and, in the window that opens, select tab **IF1: PROFIdrive PZD telegram**. The components are displayed there with the address ranges (e.g. TM17 output data 304 to 315).

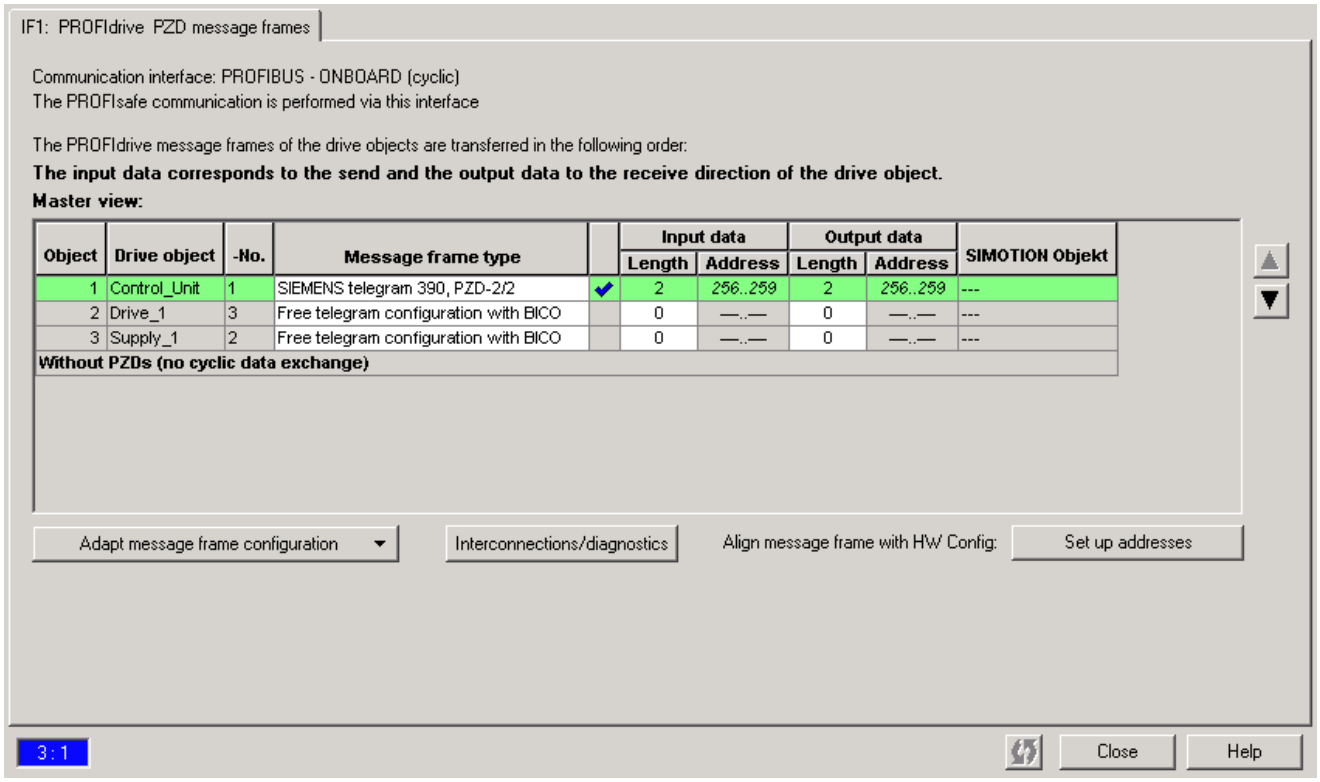

Figure 4-208 Determining the hardware address of the components

3. Before you determine the hardware address, an alignment between HW Config and SIMOTION SCOUT, with respect to the address, must be performed. If this has not been performed or you have changed the addresses, click on **Set up addresses**. If question marks are entered in the fields instead of I/O addresses, either alignment has not yet taken place, or the address is not recognized by SIMOTION SCOUT. In this case, you must perform an alignment.
4. Now calculate the HW address by adding the base output address (first value of the address range) of the TM to the offset (e.g. 304 + 3 = 307).
5. The bit number is defined by means of the offset. For example, a 3.1 offset of an output cam on DO 1 results in a bit number of 1.

Configuring cams on SIMATIC ET200SP and ET200MP

Overview

Description

You can configure TO output cam on the ET200SP technology module TM Timer DIDQ 10x24V and ET200MP technology module TM Timer DIDQ 16x24V.

- Configuration on the ET200SP technology module TM Timer DIDQ 10x24V is possible both using Step7 in connection with SIMOTION SCOUT Classic and with SIMOTION SCOUT TIA in connection with the TIA Portal. Further information can be found in the section Configuring output cams to TM Timer DIDQ 10x24V (Page 1843).
- Configuration on the ET200MP technology module TM Timer DIDQ 16x24V is only possible using SIMOTION SCOUT TIA in connection with the TIA Portal. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA.

Further information

Further information on the functions of the TM Timer DIDQ technology modules can be found in the SIMATIC ET 200SP Technology Module TM Timer DIDQ 10x24V and SIMATIC S7-1500/ET 200MP Technology Module TM Timer DIDQ 16x24V.

Configuring output cams on TM Timer, using DIDQ 10x24V as example

Description

You can configure TO output cams on the ET200SP technology module TM Timer DIDQ 10x24V in SIMOTION SCOUT or SIMOTION SCOUT TIA in connection with the TIA Portal. The configuration in the TIA Portal is described in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA. The configuration in SIMOTION SCOUT in connection with Step7 is described below:

In order to parameterize the ET200SP TM Timer DIDQ 10x24V with Step7 in connection with SIMOTION SCOUT Classic, a Hardware Support Package (HSP) for Step7 is required. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA in the section on hardware and software requirements.

For the TM Timer DIDQ technology module, the digital outputs are used for the cam output. Irrespective of whether you work with SIMATIC STEP 7 or SIMOTION SCOUT, the parameterization is always performed in HW Config:

Parameterization of TM Timer DIDQ in HW Config

1. Open the HW configuration in SIMOTION SCOUT or SIMATIC STEP 7.
2. Select the header module (IM) with the TM Timer DIDQ in HW Config.
   The TM Timer DIDQ appears in the detail view.
3. To open the context menu, select the TM Timer DIDQ with the right mouse key

4. Select object properties.
   You can view or change the following properties in the object properties:
   - General
   - Addresses
   - Identification
   - Parameters
5. Open the tab **Parameter** > **DQ0 / DI0**
6. Set the parameter value **Configuration DQ/DI group** to **Use input/output individually**.

   Note

   With this setting, the DQ0 channels can be interconnected as cam output CAM or DI0 as measuring input MI under SIMOTION SCOUT.

7. Press **OK** to close the dialog.
8. Open the menu **Station** > **Save and Compile**.

Note

The technology modules and the individual channels may only be reparameterized in offline state. All changes only take effect after saving, compiling and subsequent download of your changed user project to the controller. The download can be performed in HW Config via **Target system** > **Download to module** or in SCOUT via **Load CPU / drive unit to target device**.

Parameterization of CAM in SCOUT

1. Insert a new output cam or a new cam track or use an existing one.
2. Parameterize the TO Output Cam/Cam Track.
3. Double-click Configuration below the output cam or the cam track in the project navigator. The Configuration window appears in the working area.
4. Activate the selection box **Activate output** and select the option **Cam output (CAM).**

5. Assignment of an output to an output cam/cam track is supported as of V4.2 using symbolic assignment or by entering the HW address.

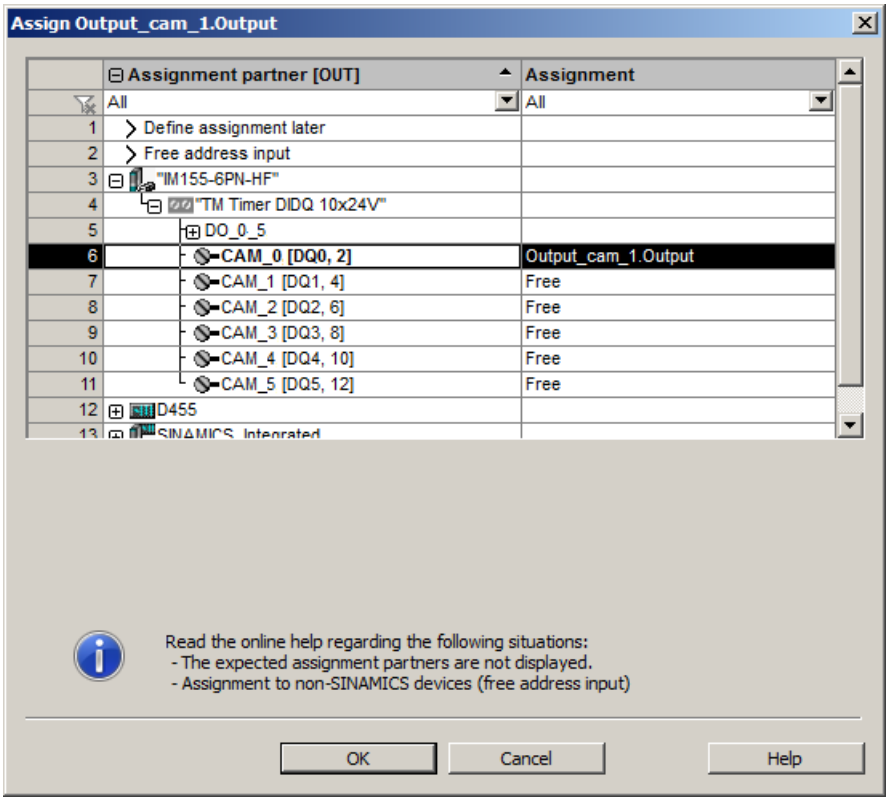

Figure 4-209 Assigning a cam output by means of symbolic assignment

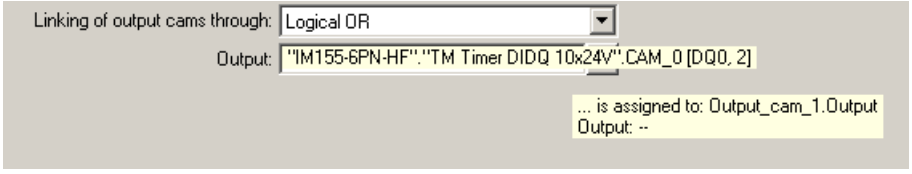

Figure 4-210 Assigning a cam output by entering the HW address

6. Click OK to close the window and select **Project** > **Save**.

Configuring cams on SIMOTION C240

1. Insert a new output cam or a new cam track or use an existing one.
2. Parameterize the TO Output Cam / Cam Track
3. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
4. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used. If you would like to configure a high-speed output cam, select the **Activate output** check box and select the **High-speed digital output (DO)** radio button

5. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address. During a consistency check in SIMOTION SCOUT, no check is made as to whether the entered HW address actually belongs to a **high-speed digital output (DO)**.
6. Click OK to close the window and select **Project > Save** from the menu.

HW enable for Output Cam TO

You can make the output of output cams dependent on a hardware-supported enable (only for TM17 High Feature).

Because hardware enables are mainly used for output cam tracks, this function is described under Cam Track TO (Page 1909).

4.3.3.4 Programming/references of Output Cam TO

Programming

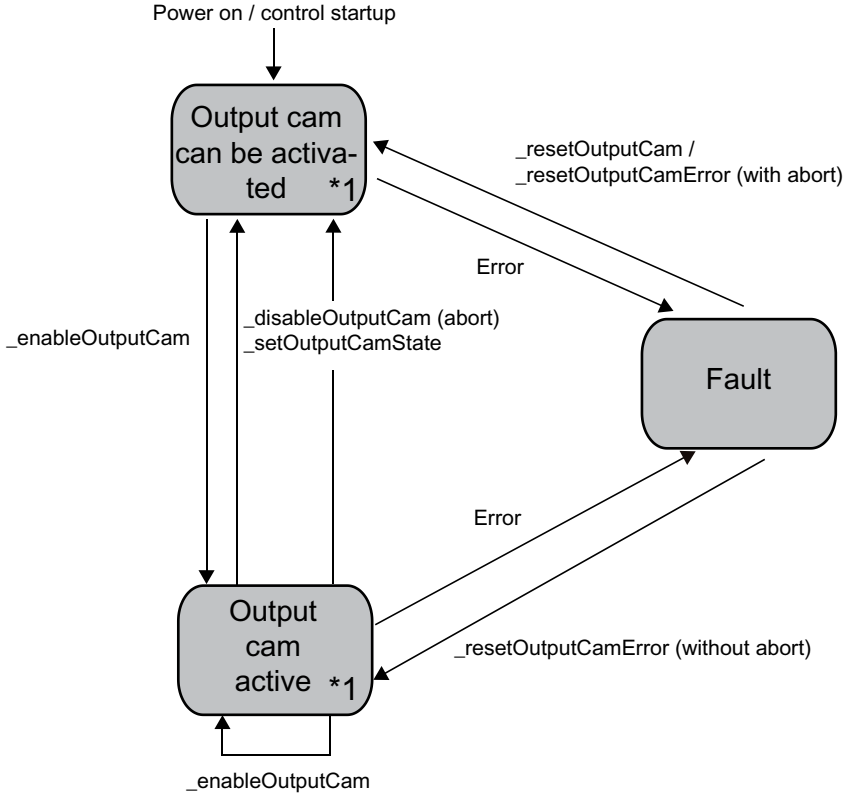

Figure 4-211 Programming and execution model for Output Cam technology object

***1** The following commands are effective in the TO states **can be activated** and **active**:

- **_disableOutputCamSimulation**
- **_enableOutputCamSimulation**

The simulation commands are modal / act in parallel and do not replace any existing _enableOutputCam commands.

Commands

The Output Cam technology object can be addressed in the user program using the following commands:

Table 4-160 Output Cam TO system functions

Commands	Description	Application
_enableOutputCam	Activate output cam	Output cam analysis is activated. If the switching condition for the output cam is fulfilled, the output or **state** system variable is set.
_disableOutputCam	Deactivate output cam	Output cam analysis is deactivated. If the switching condition for the output cam is fulfilled, the output or **state** system variable is not set. Controlled output cams are reset immediately.
_enableOutputCamSimulation	Activate simulation mode. This function simulates an output cam by disconnecting the output.	Values are calculated, but not forwarded to the hardware. Hardware output cams act as software cams. The output cam remains internally active, the status is retained, the output of output cam is not switched. If an active output cam is switched to simulation mode, the output cam status remains the same, and only the control of the output is reset or interrupted.
_disableOutputCamSimulation	The output cam is reset from simulation mode.	The output of output cam is switched according to the output cam status and the signal inversion.
_setOutputCamState	Deactivate the output cam function and set the output cam status to the specified value.	This is used if the output should not be controlled by the output cam TO. **Example:** A glue nozzle is controlled by the output cam TO (applying glue dots). As a service function, it should also be possible to rinse the nozzle while constantly controlling it. This is achieved via **_setOutputCamState**.
_resetOutputCamError	Reset error on output cam TO.	E.g. acknowledge configuration errors after entering correct values.
_setOutputCamCounter	Change starting count for a counter cam.	Output cam is output on every nth switching operation.
_resetOutputCam	This function sets the output cam to an initial state. Pending errors are deleted. Modified configuration data is reset on request.	Create initial state of output cam TO.

Commands	Description	Application
_resetOutputCamConfigDataBuffer	This function deletes the configuration data collected in the buffer since the last activation without activating it.	Changing configuration data in the RUN state discards the accumulated modifications.
_getStateOfOutputCamCommand (V3.2 and higher)	This function returns the execution state of a command.	Check whether the output cam switching has already taken place, i.e. whether the command ID is still available or has already been deleted.
_bufferOutputCamCommandId (V3.2 and higher)	This function enables **commandId** and the associated command status to be saved beyond the execution period of the command. The **commandId** parameter is used to define the command for which the respective status is to be saved. The maximum number of saveable command status is specified in the **decodingConfig.numberOfMaxBufferedCommandId** configuration data element.	Subsequent check of how command was terminated, e.g. error-free or number of error that occurred.
_removeBufferedOutputCamCommandId (V3.2 and higher)	This function ends saving of **commandId** and the associated command status beyond the execution period of the command.	Explicit deletion of previously saved command IDs.

For further information on the system functions, please refer to the *SIMOTION TP CAM Reference Lists*.

Process Alarms

You can predefine local alarm responses via SIMOTION SCOUT.

Note

For more information, refer to the *Motion Control Technology Objects Basic Functions* functional description.

How to configure the alarm response:

1. Double-click **Execution system** in the project navigator below the SIMOTION device. The execution system opens.
2. In the execution level tree, select **SystemInterruptTasks > TechnologicalFaultTask**.
3. Then click the **Alarm Response** button in the displayed window. The **Alarm Response** window appears. You can configure the alarm response for every TO here.

A system variable **error** indicates that a technology alarm has been generated. The response to the alarm is displayed in the **errorReaction** variable.

Table 4-161 Possible alarm responses

Alarm Response	Description	Application
NONE	No response	-
DECODE_STOP	Command processing is aborted, the output cam function remains active. Execution on the technology object can continue after **_resetOutputCam** or **_resetOutputCamError**.	The Output Cam TO can only be reactivated after the error has been acknowledged.
OUTPUTCAM_DISABLE	Command processing is aborted, current output cam function is aborted. Execution on the technology object can continue after **_resetOutputCam** or **_resetOutputCamError**.	The Output Cam TO can only be reactivated after the error has been acknowledged.

Output Cam TO menus

Output cam menu

Grayed-out menu functions cannot be selected. The menu is only active if an output cam window is active in the working area.

You can select the following functions:

Table 4-162 Output cam TO menu

Function		Significance/Note
Close		Select **Close** to close the configuration window for the output cam that is open in the working area.
Characteristics		Select **Properties** to display the properties of the output cam highlighted in the project navigator.
Configuration		Select **Configuration** to determine the configuration data (for example output cam type) of the output cam.
Default		Select **Default** to define the default settings of the system variables (e.g. effective direction) for the output cam.
Expert		
	Expert list	Select **Expert list** to open the expert list for the highlighted output cam. The configuration data and system variables can be displayed and changed in this list.
	Configure units	Select **Configure units** to open the **Configure units of the object** window in the working area. You can configure the units used for the selected object here.

Output cam context menu

Grayed-out functions in the context menu cannot be selected.

You can select the following functions:

Table 4-163 Output cam context menu

Function		Significance/Note
Open configuration		Select **Open configuration** to display the window for configuring the output cam in the working area. Enter the configuration data (for example, output cam type) for the output cam in this window.
Expert list		Select **Expert list** to open the expert list for the highlighted output cam. The configuration data and system variables can be displayed and changed in this list.
Cut		Select **Cut** to remove the selected object and save it to the clipboard.
Copy		Select **Copy** to copy the selected object. It is stored in the clipboard.
Paste		Select **Paste** to insert the output cam stored in the clipboard.
Delete		Select **Delete** to delete the highlighted output cam. The entire data of the output cam is deleted permanently.
Rename		Use **Rename** to rename the object selected in the project navigator. Note that with name changes, name references to this object are not adapted.
Expert		
	Insert script folder	**Insert script folder** enables you to insert a folder below the TO. You can create scripts in this folder in order to, for example, automate the configuration.
	Import object	**Import object** imports the data of a SIMOTION object from another project which was previously created with a selective XML export. You cannot import the entire project, only the data of the SIMOTION object.
	Save project and export object	**Save project and export object** exports selected data of the selected object in XML format. This data export can then be reimported into other projects. Only the data of the selected object, not the entire project, is exported.
Print		Select **Print** to print the configuration of the output cam. All system variables and configuration data with the associated values are printed.
Print preview		Select **Print preview** to open the preview of the output cam data to be printed.
Default		Select **Default** to define the default setting of the system variables (e.g. effective direction) of the output cam.
Properties		Select **Properties** to display the properties of the output cam highlighted in the project navigator.

4.3.4 Cam Track TO - Part II

4.3.4.1 Overview of TO Cam Track

General information about Cam Track TO

Cam tracks allow several output cams to be output as a track on one output.

The **Cam Track** technology object

- Generates position-dependent switching signals
- Can be assigned to positioning axes, synchronous axes or external encoders
- The axes can be real or virtual.

Different switching signals distinguish different types of output cam on the cam track:

- **Software cam**
  Switching signals are used **internally** in the user program by evaluating the relevant **state** system variable.
- **Hardware cams**
  Switching signals are output **externally** on I/O by assigning a digital output to the cam track TO. For example, digital output modules from the ET 200 I/O system can be used for cam track output.

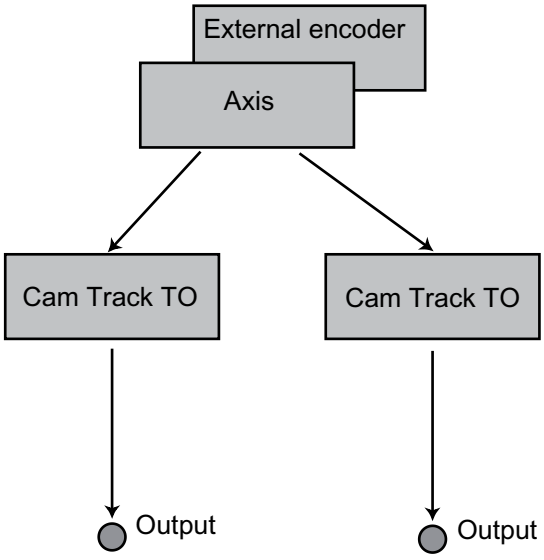

Figure 4-212 Interconnection options for the cam track TO

A range of output cam types with different switching behaviors are available on a cam track:

- **Position-based cam**
  The switching signal is supplied between the switch-on position and the switch-off position.
- **Time-based cam**
  The switching signal is supplied for a specified time period after the switch-on position is reached.
- **Time-based cam with maximum ON length**
  A maximum ON length can be defined for time-based cams. This means that the time-based cam is deactivated once it has covered the maximum length, even though the parameterized time has not yet expired.
- **High-speed/accurate output cam (hardware-based output cam)**
  Although output cams are usually output in IPO cycles or the servo cycles, high-speed output cams achieve output accuracy that is better than the servo cycle clock because the switching edges are output within servo cycles.

Functionality

Cam track functionality

- Cam tracks allow up to 32 output cams to be configured within one TO and allow, for example, the switching point for all output cams to be shifted collectively.
- The switching of several output cams is dependent on the same setpoint/actual value, and they are output on one output.
- Any number of cam tracks can be used per axis. The only restriction placed on this number is the system performance.
- The cam track can be calculated in servo cycles, IPO cycles, or IPO_2 cycles.
- All output cams on one track are of the same type (position or time-based cams).
- Cam tracks can be activated once or cyclically.
- Various modes are available for activating and deactivating cam tracks, e.g. **active immediately**, **next track cycle**, etc.
- Cam track output can be inverted.
- The status of each single output cam (controlled/not controlled) can be read over one array of byte.
- Single output cams on a cam track can also be defined as valid/invalid.
- In connection with the TM17 High Feature terminal module, the cam track output can be controlled via a high-speed hardware enabling signal.

Reference to axis

The reference values of the cam track depend on the axis type or the external encoder:

Table 4-164 Reference to the actual or set position

Technology object	Reference to actual position possible	Reference to set position possible
Real drive axis	-	-
Real position axis	X	X
Real synchronized axis	X	X
Virtual axes	-	X
External encoder	X	-

Possible configuration of the cam tracks with actual value reference:

- **Reference to the actual value on the encoder without considering Ti**. Reference to the actual position in the controller before the position filter.
- **Reference to the actual value after the position filter**. Reference to the actual position in the controller after the position filter.
- **Reference to the actual value on the encoder. Ti is taken into account**. Reference to the actual value on the encoder module / drive. The transmission time Ti from the encoder module / drive to the controller is taken into account by the system.

Possible configuration of the cam tracks with setpoint reference:

- **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoints will already have been reached at the end of this IPO cycle, e.g. if a setpoint is calculated for the IPO cycle clock with the virtual axis and also displayed at the end of the cycle. Reference is made directly to the setpoint applicable at the end of the cycle.
- **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoint calculated in the interpolator will be output completely in the following cycle and the calculated position setpoint will therefore be reached at the end of the following cycle.
- **Reference to the setpoint on the drive**. Calculation of the cam switch points according to the setpoint output with the current settings on the drive.

In this case, the cam track functionality can be applied to axes or external encoders with or without modulo properties.

The cam track is also effective for axes that have not been homed.

The cam track is defined independently of the axis. The cam track is mapped on the axis via an axis reference position, once the track is activated. This enables cam tracks to be operated in a particularly flexible way (e.g. relative output of a cam track on the basis of a measured edge on the measuring input, cam track offset, etc.).

Output on one output

The cam track TO is assigned to one output only during configuration. Output can be achieved via:

- Onboard I/O
- Drive I/O (for example TB30, TM31, TM1x)
- SIMOTION C centralized I/O
- Distributed I/O; PROFIBUS DP I/O (e.g. ET 200M)

However, the output must not be in the process image.

The switching accuracy is dependent on the following:

- Output accuracy of the I/O
- How the cam track is allocated in the task system
- How constant delay times are compensated

Comparison of Output Cam TO and Cam Track TO

Depending on the application, it is practical to use either the Cam Track TO or one or more Output Cam TOs. The table below should help you to decide which TO should be used in which case.

Table 4-165 Comparison of Output Cam TO and Cam Track TO

Features	Output Cam TO	Cam Track TO
Availability	• As of Version 1.0	• As of Version V3.2
Supported output cams	• Position-based cam • Time-based output cam • Unidirectional output cam • Counter cam • Exact time setting of an output, exact time output cams (as of V4.1)	• Position-based cam • Time-based output cam • Time-based cam with maximum ON length
Several output cams on one output	• Via logical operation (AND/OR)	• Maximum 32 output cams of the same type in one track • No cam track logical operations (AND/OR)
Different types of output cam on one output	• Via AND/OR	• Not available
Output cam definition	• Related to axis • Via system variables	• Related to cam track (cam track can be mapped as required on axis) • Via system-variables array
Hysteresis	• Available	• Available
Effective direction	• Available	• Not available
Derivative-action times	• Separate for power ON/power OFF	• Separate for power ON/power OFF
Deactivation time for time-based cam	• As of Version V3.2	• As of Version V3.2
Activation/deactivation types	• Active immediately	• Start and stop mode parameterizable
Types of output	• Cyclic	• Cyclic • Once
Output cam status	• System variable	• Status of single output cams over one array of byte
Output cam enable	• Via_enableOutputCam	• via_enableCamTrack • Validity of single output cams configurable via system variables
Performance	• Depends on number of single output cams	• When 5 or more output cams are used in one output cam track instead of 5 single output cams, the output cam track performs better. This performance advantage amounts to at least a factor of 2 for 32 single output cams.
MCC command available	• Available	• Available (V4.0 and higher)

4.3.4.2 TO Cam Track basics

Cam track features

A cam track has parameters that are valid for the track as a whole, and parameters that can be configured for each single output cam on a track.

Track data

Track data is valid for all output cams on a track and is, therefore, configured for the cam track as a whole.

- **Output cam type**
  Position-based, time-based, etc.
- **Cam track start**
  Always defined from "0"
- **Track length**
  Cam track start to cam track end
- **Hysteresis**
  Even if the switching conditions change, the output cam does not change its switching state in this defined range around the switching position.
- **Actuation times**
  Actuation times can be specified to compensate for the switching times of digital outputs and connected switching elements.
- **Axis reference position**
  Cam tracks are defined independently of the axis. The axis reference position is used to define how the cam track is mapped on the axis, or from which axis position the cam track should be output.
- **Cyclic or non-cyclic activation mode**
  If the cam track is output non-cyclically, it will have to be reactivated after execution.
- **Start mode and stop mode**
  Start mode or stop mode can be used, for example, to define whether a cam track will be output immediately or not until the next track cycle.

Output cam data

Output cam data can be configured separately for each single output cam on a cam track.

- **Output cam parameters**:
  Depending on output cam type, start position, end position, ON duration, maximum ON length.
- **Validity of single output cam**
  Single output cams on a defined cam track can be parameterized as "invalid." This output cam is completely suppressed and is not output. It also has no status indication.

Example of a cam track definition

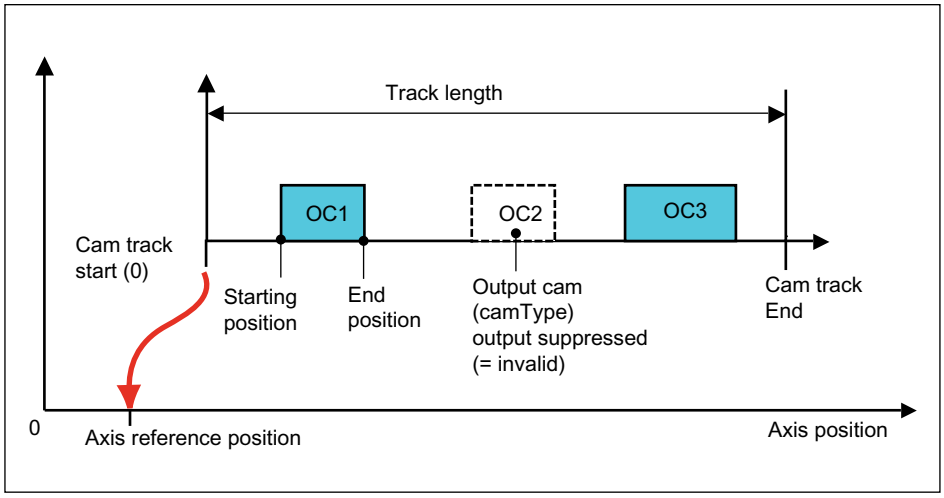

Figure 4-213 Definition of a cam track with 3 output cams

Output cam types of the single output cams on a track

The following chapter provides an overview of the output cam types within a cam track. All output cams on a cam track are always of the same output cam type.

Software cam (Page 1856)

Hardware cam (Page 1856)

Position-based cam (Page 1857)

Time-based cam (Page 1858)

Time-based cam with maximum ON length (Page 1859)

Cam output types (Page 1860)

Software cam

Switching signals are used **internally** in the user program by evaluating the relevant **state** system variable.

Hardware cam

Description

Switching signals are output **externally** on I/O devices by assigning a digital output to the Cam Track TO.

The following can be used as digital outputs:

- Onboard outputs (SIMOTION C, D, ...)
- Centralized I/O (SIMOTION C)

- Distributed I/O via PROFIBUS DP (e.g. ET 200M) and PROFINET IO (e.g. ET 200S, ET200xP TM Timer DI/DQ)
- Drive I/O (for example, TM15 and TM17 High Feature Terminal Modules)

Hardware for cam track

Cam output on cam output (I/O channel is configured as CAM)

- SIMOTION D410-2
- SIMOTION D4x5-2
- TM15, TM17 High Feature
- ET200xP TM Timer DI/DQ

Cam output on high-speed output with direct access (I/O channel is configured as DO)

- SIMOTION D4xx / D4x5-1
- SIMOTION C240, C240 PN

Cam output on standard output (I/O channel is configured as DO)

- SIMOTION C/D/CX onboard I/O
- SINAMICS onboard I/O
- TM15, TM15 DI/DO, TM17 High Feature, TM31, TM41, TB30
- Standard DO (SIMATIC ET200, ...)
- PROFINET IO (e.g. ET200xP TM Timer DI/DQ)

Position-based cam

Switching behavior

Position-based cams on a cam track switch independently of the direction of motion, i.e. they always have a positive and negative effective direction.

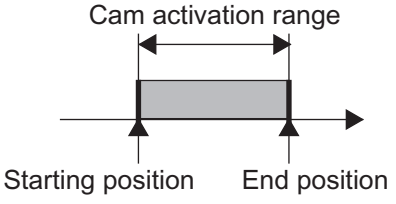

Figure 4-214 Position-controlled output cam with a starting position less than the end position

Limits imposed by starting and end positions

The cam is activated:

- if the axis position is within the activation range
- if the axis position value is shifted into the activation range of the output cam
  The position value of the interconnected object can change abruptly, for example, when it is homed or when its coordinate system is shifted with the **_redefinePosition** command.

The output cam is switched off:

- if the axis position is outside the starting or end position
- if the position value is shifted outside the activation range
- via commands that deactivate the output cam, e.g. **_disableCamTrack**, **_setCamTrackState**, **_resetCamTrack**

Cam activation range

The activation range of the output cam is defined from the start position to the end position in a positive direction of motion, i.e. in the range between the starting position and end position. If the end position is greater than the starting position, the activation range is defined by the starting and end positions (see figure above).

The activation range is outside the range between the end and starting positions if the end position is less than the starting position (see figure below).

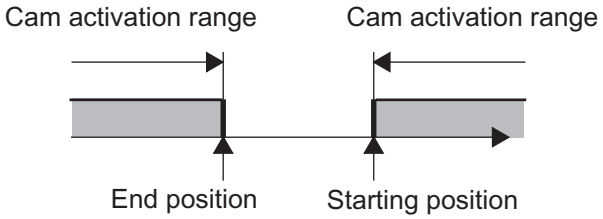

Figure 4-215 Position-controlled cam with an end position less than the starting position

Note

This definition of the activation range is possible for all modulo and non-modulo axes.

ON duration

The ON duration of the output cam depends on the velocity at which the axis traverses the output cam length.

Time-based output cam

Switching behavior

Time-based cams on a cam track switch independently of the direction of motion, i.e. they always have a positive and negative effective direction.

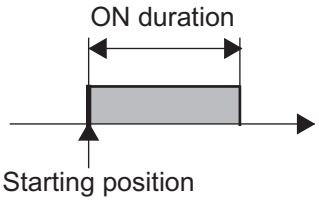

Figure 4-216 Time-controlled output cam

Limits imposed by starting position and ON duration

The output cam is switched on:

- At the starting position.
  If the starting position is overrun again during the ON duration, the time-based cam is not switched on again. It is not possible to retrigger a time-based cam.

The output cam is switched off:

- When the assigned time period expires
- When commands are issued that deactivate the output cam, e.g. **_disableOutputCam**, **_setOutputCamState** and **_resetOutputCam**

Output cam length

The output cam length is dependent on the velocity at which the assigned axis traverses during ON duration of the output cam.

Time-based cam with maximum ON length

Additional limits imposed by maximum ON length

A maximum ON length can also be defined for time-based cams on cam tracks. This means that the time-based cam is deactivated once it has covered the maximum length, even though the parameterized time has not yet expired.

This is the case if, for example, glue dots should be applied to a workpiece and the amount of glue should be independent (constant time -> time-based cam) of the throughput rate.

To avoid the time-based cam still being controlled after the end of the workpiece at high sweep rates, the ON duration can be limited by a maximum ON length (related to the start position of the output cam). This prevents a glue dot being placed adjacent to the workpiece.

The maximum ON length is effective in both traversing directions of the axis, and the cam track's switch-on position is the reference position.

Parameters of a time-based cam with maximum ON length

Every time-based cam on a track has three parameters

- Start of output cam (SOC)
- ON time (t)
- Maximum ON length (Lmax)
  This always relates to the dynamically adjusted start of output cam SOC, i.e. the assigned activation time **is** taken into account. The output cam is then traversed over the maximum ON length, **without** taking into account the deactivation time (see the **Actuation times (activation time/deactivation time** section).

Example of a cam track which controls glue application

In the following example, a cam track with three output cams is used to control the application of glue onto a workpiece. No glue may be applied outside of the predefined areas.

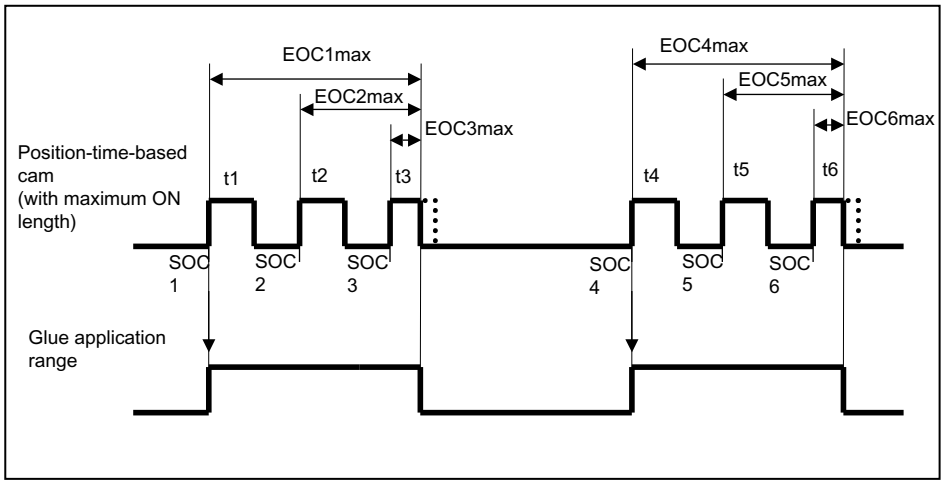

Figure 4-217 Control of glue application via a cam track, based on a time-based cam with maximum ON length

- The start of output cam (here, SOC1 and SOC4) is used to exactly define the start of glue application.
- The ON time (t) is used to ensure that the same amount of glue is applied, independent of the axis speed.
- The maximum ON length Lmax is used to ensure that no glue is applied outside of the defined area. In the example, the output cam ON durations t_3 and t_6 are limited by the maximum ON length.

Cam output types

The cam calculations are performed in the processing cycle clock (IPO or IPO_2 cycle clock or in the servo cycle clock). For the possible setting of Servo_fast or IPO_fast, see Section Second servo cycle clock (Servo_fast) in the SIMOTION Runtime Basic Functions manual.

The temporal resolution of the cam output depends on the hardware used and the setting in the configuration. In standard applications, the setting is undertaken using screen forms. The configuration data can also be set via the expert list.

The possible setting options for cam output are described below:

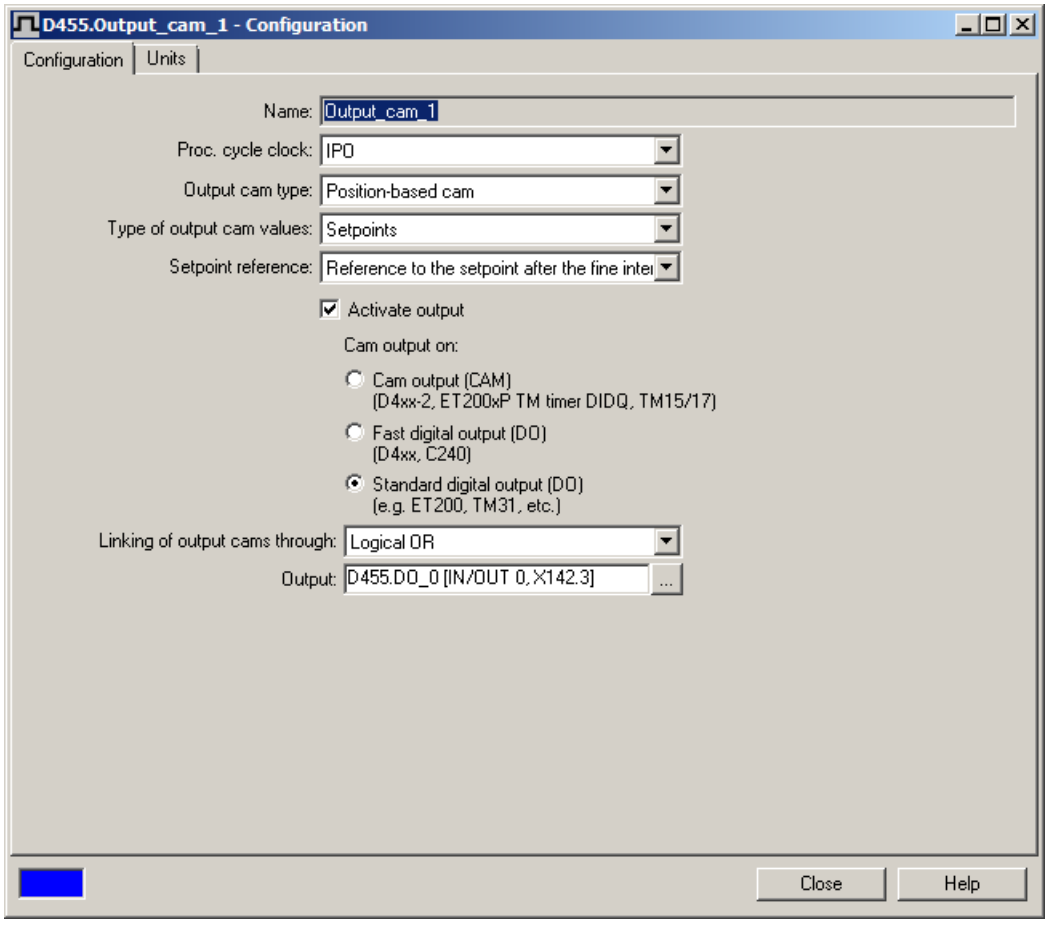

Figure 4-218 Output cam configuration using the example of a position-based cam

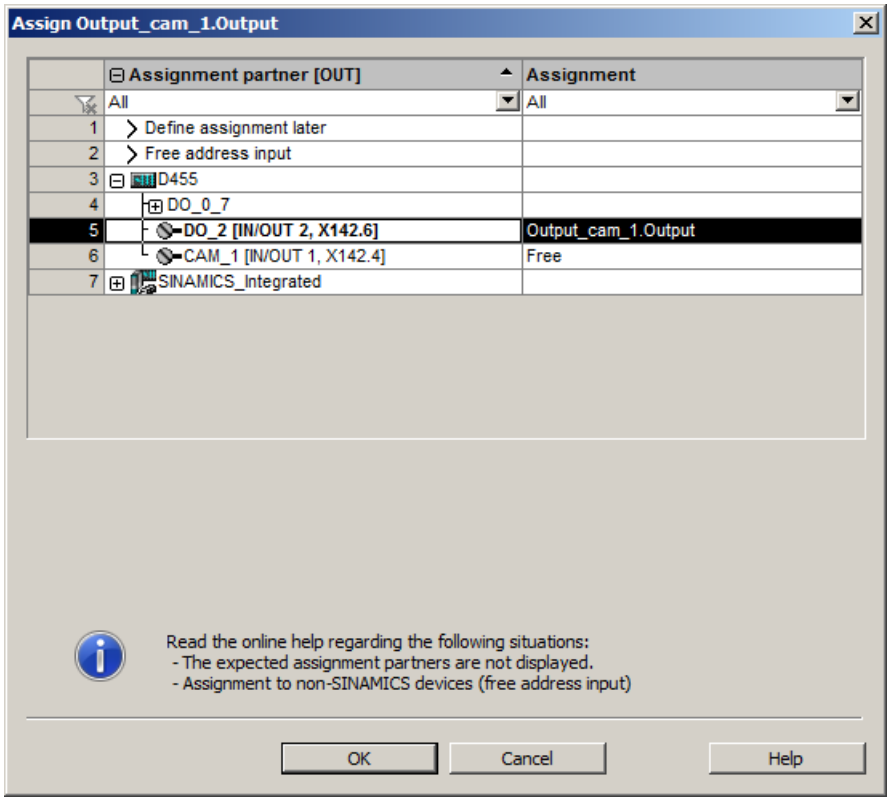

Figure 4-219 Assignment dialog

Symbolic assignment is activated by default in projects as of V4.2 (**Project > Use symbolic assignment**)

Cam output (CAM)

The cam output is performed on the basis of an internal time stamp. The temporal resolution of the cam output depends on the hardware used. In the case of D4x5-2 and the TM17 High Feature, the resolution is 1 µs.

Hardware supported

- SIMOTION D410-2
- SIMOTION D4x5-2 (X142)
- TM15, TM17 High Feature
- ET200xP TM Timer DI/DQ

The I/O channel must be configured as CAM.

SIMOTION D410-2

The digital inputs/outputs are used for the cam output in the D410-2. The digital inputs/outputs can be used as the cam output (CAM) from the user program.

As of the editorial deadline of this documentation, the output cam resolution for D410-2 was not yet certain. The information can be found at the following website Internet link (http://support.automation.siemens.com/WW/view/en/27585482).

SIMOTION D4x5-2 onboard outputs (interface X142)

The D4x5-2 onboard outputs can be used as cam output (CAM) from the user program. The D4x5-2 onboard outputs are permanently assigned to SIMOTION. The X142 I/Os are configured using HW Config.

The X142 configuration screen form can be accessed directly from the project navigator in SIMOTION SCOUT.

With SIMOTION D4x5-2, output cams are output at the X142 interface with a resolution of 1 µs.

TM15 / TM17 High Feature Terminal Modules

The TM15 and TM17 High Feature Terminal Modules can be used to set up cam outputs (CAM) within the SIMOTION Motion Control system. The Terminal Modules are connected directly to SIMOTION D or CX32/CX32-2 via DRIVE-CLiQ for this purpose.

Alternatively, TM15 and TM17 High Feature can be connected to a SINAMICS S120 CU320/ CU320-2/CU310/CU310-2 Control Unit with higher-level SIMOTION C, P or D.

Output cams on the TM15 operate with DRIVE-CLiQ cycle-clock resolution (typically 125 µs). Output cams on the TM17 High Feature have a resolution of 1 µs.

If current controller cycle clocks other than 125 µs are used, the parameter calculations of the drive must be taken over into the PG and the Fast IO configuration must be recreated when using cam outputs on TM15/TM17 High Feature. (For more information, see chapter Current controller cycle clocks <> 125 µs / use of output cams and measuring inputs in the TM15 / TM17 High Feature Terminal Modules Commissioning Manual).

ET200xP TM Timer DI/DQ

The digital inputs/outputs are used for the cam output in ET200xP TM Timer DI/DQ. The digital inputs/outputs can be used as the cam output (CAM) from the user program. Output cams on the ET200xP TM Timer DI/DQ have a resolution of 1 µs.

High-speed digital output (DO)

The cam output is performed via onboard outputs of the SIMOTION CPU. The output is via a hardware timer and the cam output is achieved with a resolution with respect to time < servo cycle clock.

The time that it takes for the axis to reach the output cam switching position with reference to the processing cycle is calculated by linear extrapolation. Calculated from the beginning of the 1st position control cycle, the output cam function is triggered by a hardware time when this time is reached.

Hardware supported

The onboard I/O of the following CPUs is used:

- SIMOTION D4x5 (interface X122, X132), 8 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as **DO**)
- SIMOTION D410 (interface X121), 4 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as **DO**)
- SIMOTION C240, C240 PN (interface X1), 8 high-speed cam outputs

SIMOTION D410/D4x5 onboard outputs

Output cams are output via **a high-speed digital output (DO).**

- Up to and including SIMOTION V4.1 SP5, all D410/D4x5 onboard I/Os configured as digital outputs are exclusively available to SIMOTION
- As of SIMOTION V4.2, D410/D4x5 onboard I/Os configured as digital outputs can be switched over to SINAMICS using BICO interconnection (channel granular)

Standard digital output (DO)

The output cam calculations are performed in processing cycles (IPO or IPO_2 cycle clock or servo cycle clock).

Actual cam output is performed in servo cycles. The temporal resolution of the cam output is usually reduced by the output cycle of the I/O used.

Therefore the resolution

- with standard I/O (e.g. ET 200) depends on the cycle time of the bus system (PROFIBUS DP / PROFINET IO)
- with TM15 / TM17 depends on the cycle time of the bus system (PROFIBUS Integrated / PROFIBUS DP / PROFINET IO)
- with TM15 DI/DO, TM31, TM41, TB30 depends on the configured sampling time
  - cu.p0799 (CU inputs/outputs sampling time) for the TB30 and onboard outputs
  - p4099 (TMxx inputs/outputs sampling time) for TM15 DI/DO, TM31 and TM41

Hardware supported

- Onboard outputs (SIMOTION D, Controller Extension CX, SINAMICS Control Unit CU3xx)
- Centralized I/O (SIMOTION C)
- Distributed I/O via PROFIBUS DP/PROFINET I/O (e.g. ET 200, ET200xP TM Timer DI/DQ)
- Drive I/O TM15, TM15 DI/DO, TM17 High Feature, TM31, TM41, TB30

Configuration data of cam output types in expert list

Table 4-166 Setting options for cam output

Selection in configuration screen	Setting in expert list
Cam output (CAM) (D4xx-2, ET200xP TM Timer DIDQ, TM15/17)	OcaBaseCfg.outputType = [1] TIME_STAMP OcaBaseCfg.hwTimer = [91] NO
High-speed digital output (DO) (D4xx, C240)	OcaBaseCfg.outputType = [0] STANDARD OcaBaseCfg.hwTimer = [173] YES
Standard digital output (DO) (Standard DO, e.g. ET200, TM31)	OcaBaseCfg.outputType = [0] STANDARD OcaBaseCfg.hwTimer = [91] NO

Output cams on **cam output (CAM)** or on **high-speed digital output (DO)** are also referred to below as high-speed, hardware-supported output cams.

Note

Further information and the output accuracy for high-speed output cams is described in the PM21 Catalog and in the respective product brief or commissioning/equipment manuals.

Cam track parameters

Track length

The **camTrackLength** system variable is used to parameterize the track length. The track length is calculated from the start of the cam track (always 0) to the end of the cam track. Usually, the output cams of the cam track are located within the track length. The track length must not be 0. When track length = 0, an error is reported when the cam track of a non-modulo axis is activated. If track length = 0 for a modulo axis during cam track activation, the cam track length is set to the axis modulo length.

Effective direction and behavior

The following diagram shows output cam behavior on switching on and off, without hysteresis, activation or deactivation time.

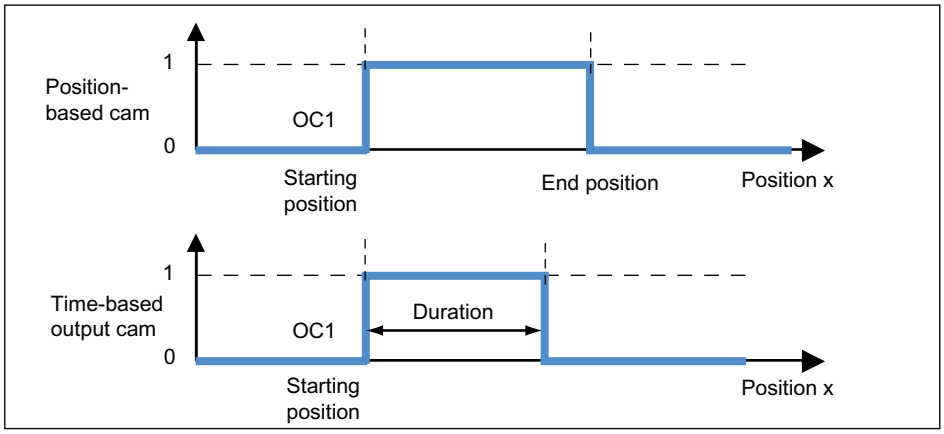

Figure 4-220 Output cam behavior on switching on/off

The switching characteristic depends only on the position (position setpoint or actual position). The cams on a cam track switch independently of the direction of motion, i.e. they always have

a positive and negative effective direction. A position-based cam can be output **repeatedly** on changing the direction of movement. Time-based cams are output **once only**.

Hysteresis

If the actual position value tends to fluctuate due to mechanical influences, specification of a **hysteresis** prevents the output cam from unintended switch status changes.

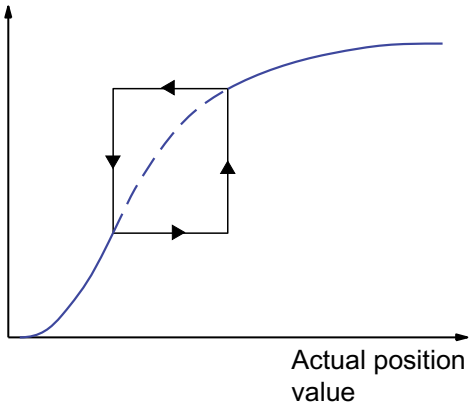

Figure 4-221 Hysteresis

Conditions for the hysteresis range

- Hysteresis is not activated until the direction has been reversed.
- The direction of motion is not redefined within the hysteresis.
- Within the hysteresis, the switching state of position-based cams is not changed.
- If modified switching conditions for the output cam are detected when the output cam is outside the hysteresis range, this current switching state is set.

Example: position-based cam hysteresis

Cam track configuration (only one output cam configured):
Output cam type: position-based cam; switch-on position, 20 mm; switch-off position, 200 mm; hysteresis, 20 mm; effective direction: both

Axis positions:
0 mm -> 100 mm -> 10 mm -> 50 mm -> 0 mm -> 150 mm -> 0 mm

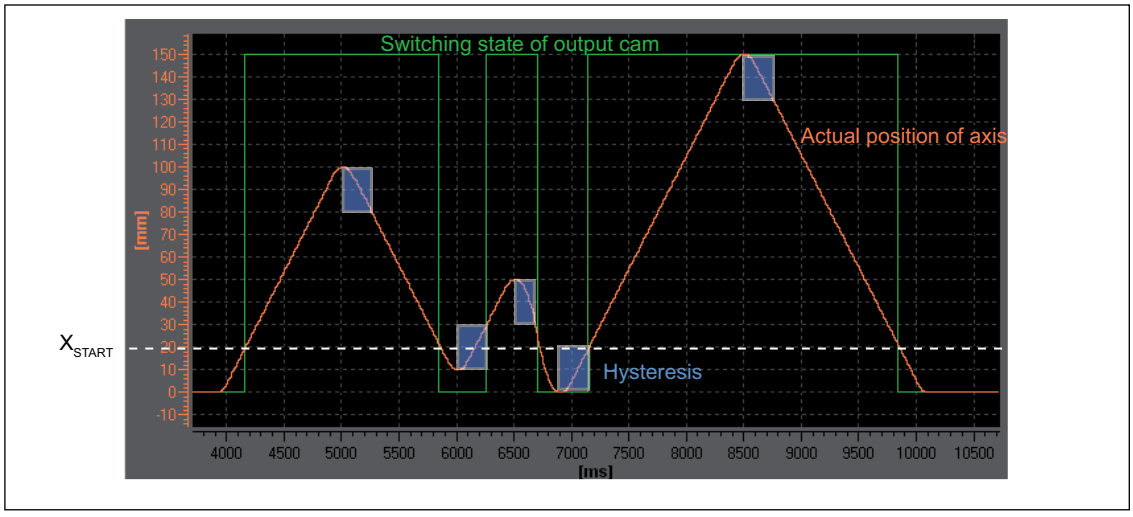

Figure 4-222 Hysteresis range (height of blue sections) and behavior of a cam track with a position-based cam, effective direction in both directions.

As the cam track switches in both directions, the output cam does not switch off after the first reversal of direction. The second switch-on point is moved to position 30, due to active hysteresis.

Example: time-based cam hysteresis

Cam track configuration (only one output cam configured):
Output cam type: time-based cam; switch-on position, 40 mm; ON duration, 0.5 s; hysteresis, 20 mm; effective direction: both

Axis positions:
0 mm -> 100 mm -> 20 mm -> 50 mm -> 30 mm -> 80 mm -> 10 mm -> 150 mm

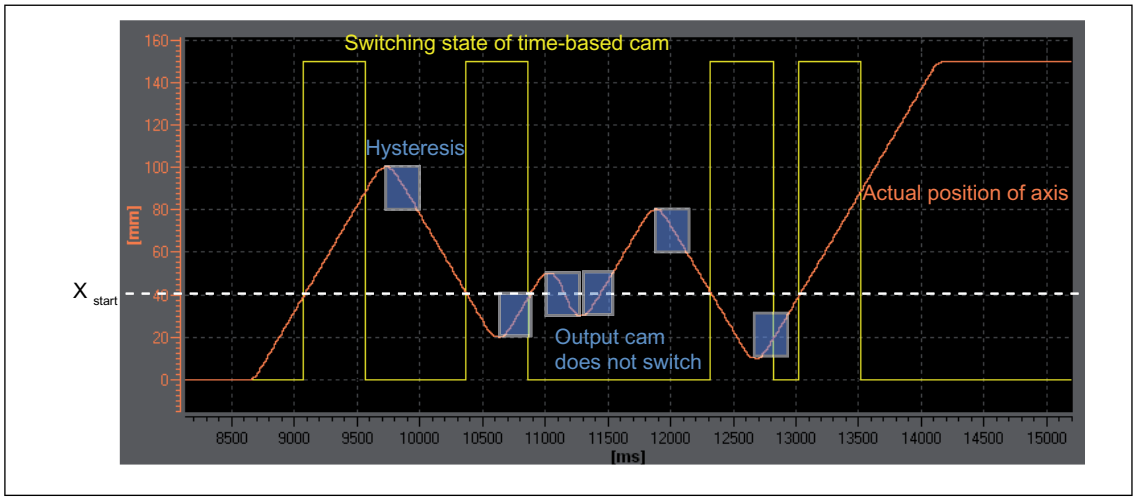

Figure 4-223 Hysteresis range (height of blue sections) and behavior of a cam track with one time-based cam, no effective direction.

Time-based cam switches off only after ON duration has expired, not after change of direction.

Time-based cams with a start position within the hysteresis range are not output (see figure above).

Hysteresis range

The upper limit of the hysteresis range is set at 25% of the working range for a linear axis, and 25 % of the rotary axis range for a rotary axis. If you violate this maximum setting, an error message is issued. In practice, a lower setting is used for the hysteresis range.

- **Path-controlled output cam**
  The hysteresis becomes active after direction reversal is detected. The output cam switches off once the hysteresis has been left and the position is located outside of a defined output cam.
- **Time-based cam**
  The switching behavior of a time-based cam is determined by the ON duration, not by the hysteresis. This means that an entered hysteresis range has no influence on the ON duration of an output cam. It only has an influence on the switch-on time (start position).
- **Time-based cam with maximum ON length**
  The maximum ON length switches off the output cam once the hysteresis has been left and the maximum ON length has been exceeded.

Note

If a time-based cam's start position lies within the hysteresis, it is **not** output.

Derivative-action times (activation time/deactivation time)

To compensate for the switching times of digital outputs and connected switching elements, or of propagation delays, it is possible to specify **actuation times**. Actuation times are calculated from the sum of all delay times and can be specified separately for activation and deactivation edges as an actuation time at the activation edge (activation time) or an actuation time at the deactivation edge (deactivation time).

The activation/deactivation times of the output cam are dynamically compensated by means of the derivative-action times. In this way, output cams are dynamically shifted depending on the actual velocity.

For example, a valve that should open at 200°, with an activation time of 0.5 s

- Must be controlled at 195° at a velocity of 10°.
- Must be controlled at 190° at a velocity of 20°.

This dynamic shift takes place automatically by means of the TO camTrack.

Settings for the activation and deactivation times can contain positive or negative values.

A negative activation time must be entered if the output cam is to be switched before the programmed start of the output cam.

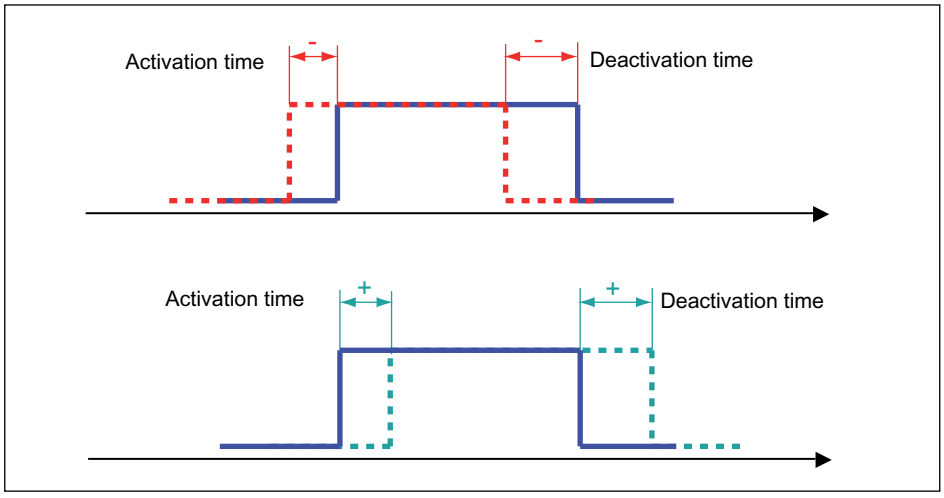

Figure 4-224 Switching behavior at varying actuation times

Note

The time of output for the output cam in the controller is relevant for calculation of the dynamic adjustment. If velocity changes up to signal output, these changes are no longer taken into account.

Dead times, e.g. PROFIBUS DP communication times, output delay times on digital outputs, etc., are taken into account in the actuation time.

Long actuation times exceeding one modulo cycle may lead to heavy fluctuation of the switching position of actual value output cams (actual value curve). Here, setpoint output cams should be used or the actuation time should be considerably less than one modulo cycle.

The system takes into account the specified actuation times when the output cams are calculated and managed. The switching positions of the output cams are calculated taking into account the activation time and deactivation time in relation to the present velocity. If, allowing for actuation times, the output cam was switched, then the system deems this operation to have occurred, and it does not switch the output cam again even if any subsequent current velocity changes occur.

The dynamic actuation of modulo axes can be greater than one modulo length. However, the number of switching operations is not collected by the system, i.e. for actuation times longer than one modulo length, a switching operation cannot take place in each modulo cycle. One switching operation is active in the system at any given point in time. A switching operation is completed when the output cam is switched off.

Actuation times and cycle clock settings

A change of cycle clock settings does not have to be taken into account for the actuation time settings (activation/deactivation time). These are, for example:

- Changing the Servo/IPO/IPO_2 cycle clock settings (for example, from "1/1/1 ms" to "2/2/2 ms").
- Change of processing cycle clock of the cam track TO (setting: Servo cycle clock, IPO cycle clock or IPO_2 cycle clock).

Deactivation time for time-based cam

Deactivation time is also taken into account in setting a time-based cam.

Deactivation time must be:

- Deactivation time ≤ activation time + ON duration

Activation and deactivation times can vary independently of the I/O and can, therefore, influence the ON duration of the time-based cam.

Cam track activation

The **_enableCamTrack** command activates the cam track. On activation, the defaults are transferred to the system variables. If you explicitly want to use other values, these must be transferred with the command.

The following parameters are transferred via the _enableCamTrack command:

- Cam track data
- Output cam data

If you do not transfer any new data when activating the command, the defaults are used.

Cam track deactivation

Cam tracks are deactivated automatically or via a command.

Automatic deactivation

Automatic cam track deactivation is only possible when the configuration data octBaseCfg.keepEnabledOutOfTrackRange has been set to **NO**. In this case deactivation occurs on exiting the domain of the cam track, i.e. the track start (in a negative direction) or the track end (in a positive direction). It is not possible to reverse the direction of movement repeatedly within the track length. Output cams can therefore be output repeatedly. Automatic deactivation is set as default. As of V4.1 you can set the deactivation via the configuration data.

Note

In the cam track **Configuration** window, you can configure the automatic deactivation via **Leave non-cyclic activated cam track active in the axis range**.

Deactivation via command

The **_disableCamTrack** command is used to deactivate the cam track.

You can parameterize the deactivation time for the **_disableCamTrack** command (see Section **Start mode and stop mode**).

Leave cam track active in the axis range (as of V4.1)

Non-cyclic activated cam tracks are deactivated per default when the cam track length is exited. So that the non-cyclic cam track remains active over the entire axis range (also outside of the cam track length), you must set the configuration data **octBaseCfg.keepEnabledOutOfTrackRange** to **YES**. When the cam track length is exited, the non-cyclic cam track remains active and is deactivated, for example, via command.

Note

In the cam track **Configuration** window, you can deselect the automatic deactivation via **Leave non-cyclic activated cam track active outside of the track range**.

Features

- Valid for modulo axes and non-modulo axes
- With modulo axes, the cam track is only switched in the appropriate modulo range of the axis, and **not** in every modulo range. This also ensures a clear assignment when cam track lengths ≥ modulo length.
- Value=**NO**: Non-cyclic cam track is only active within the cam track length.
  If the axis or external encoder moves out beyond the cam track length, the cam track is deactivated. Returning to this length triggers new switching operations.
- Value=**YES**: Non-cyclic cam track is active over the entire axis range, also after leaving the cam track length If the axis or external encoder moves out beyond the cam track length and then back into the cam track range, the configured output cams switch again.

Example

There is a linear axis (non-modulo axis) with a traversing range of -1000 mm to 1000 mm and a cam track with a track length of 200 mm (-100 mm to 100 mm). The cam track is to remain active over the entire axis range and the cam track is to be activated non-cyclically.

After the cam track is exited (2), it remains active and is switched again after the reversal of direction (3) (see figure below).

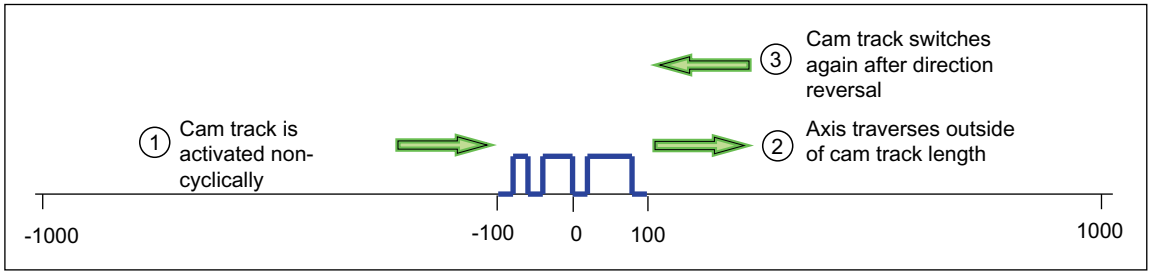

Figure 4-225 Leaving cam track active over the entire axis range

Start mode and stop mode

Start mode and stop mode are used to parameterize behavior on activation or deactivation of a track.

Start mode

The start mode (**startMode**) is used to define when the cam track should become effective after activation, or how tracks should be changed.

The mode is defined either as part of the cam track configuration in the **Default** window, or directly as a default setting using the **_enableCamTrack** command.

Table 4-167 Types of start mode

Start mode	Description
Effective immediately (default) (IMMEDIATELY)	Track becomes active immediately. If an output cam (or time-based cam) is defined or active at the current position of the old track, the output is aborted. The new track is enabled without delay (as quickly as possible). This enables high-speed exchange of cam tracks. If an output cam is already controlled and new data from the exchanged cam track continues to control the track signal, the track signal is not interrupted.
Immediately when cam track output inactive (IMMEDIATELY_BY_CAM_TRACK_OUTPUT_INACTIVE)	Changeover is made to the new cam track if no single output cam is active (any longer) on the old cam track. An active (output) single output cam on the old cam track is still output completely. If a changeover to the new track has not been made at the start position of a single output cam on the new track, this output cam is not output. Only after the tracks have been exchanged are the subsequent output cams on the new track output.
With next track cycle (NEXT_CAM_TRACK_CYCLE)	Track does not become active until the next track cycle, after either the axis reference position (in the positive traversing direction) or the end position of the cam track (in the negative traversing direction). The cam track end of the old track equals the axis reference position of the new track. Immediately the first output cam on the new track switches, a changeover is made to the new track. Up to that point, a time-based cam on the old track is output. The previous cycle is processed according to the previous command, the next cycle according to the **_enable** command. This allows the next track to be enabled, although another track is currently being processed. It is necessary to use this mode if the enable must occur before the start of the new cam track, for example, if the first output cam lies at the very start, but an output cam at the very end of an old (inactive) track is not to be enabled by mistake.
Last programmed value (EFFECTIVE)	The last programmed stop mode is active. If a stop mode is not programmed, the user default setting is used.

Changing cam track output on the basis of the selected start mode

The effect of the start mode on cam track output is shown in the following table for two cam tracks. The examples refer to activation of the same cam track with new or modified data.

Table 4-168 Start mode examples

Mode	Description	Display on cam track output
	One cam track with different data is given. • Cam track 1 (A to C) active cam track. • Cam track 2 (1 to 3) is activated.	Effective immediately (IMMEDIATELY)	• New cam track becomes active immediately. • Cam track output becomes inactive. • Output cams 1, 2 and 3 are output.	Cam track output inactive (IMMEDIATELY_BY_CAM_TRACK_OUTPUT_INACTIVE)	• New cam track becomes active at a cam track output of zero. • Output cam A on the active track is output completely. • Output cams 2 and 3 are output. • Output cam 1 is not output.	
With next track cycle (NEXT_CAM_TRACK_CYCLE)	• Cam track is exchanged at the axis reference position of the new cam track. • Example 1, position-based cam: Position-based cam of the old track is terminated. • Example 2, time-based cam: New cam track becomes active with the first output cam of the new track, at the latest. Up to that point, time-based cams remaining from the old cam track are still output.	
Stop mode

The stop mode (**stopMode**) is used to define the behavior of the cam track on deactivation.

The mode is defined either as part of the cam track configuration in the **Default** window, or directly as a default setting using the **_disableCamTrack** command.

Table 4-169 Types of stop mode

Stop mode	Description
Effective immediately (default) (IMMEDIATELY)	Track is deactivated immediately. If an output cam (or time-based cam) is defined or active at the current position of the track, the output of output cam is aborted.
Immediately when cam track output inactive (IMMEDIATE-LY_BY_CAM_TRACK_OUTPUT_IN-ACTIVE)	If no single output cam is active (any longer), the active cam track is stopped. An active (output) single output cam is still output completely.
At end of cam track (BY_CAM_TRACK_END)	Track is deactivated at its end. Immediately the final output cam on the track switches, the track is deactivated. Up to that point, a time-based cam on the track is output.
Last programmed value (EFFEC-TIVE)	The last programmed start mode is active. If a start mode is not programmed, the user default setting is used.

Output activation mode

Cam tracks can be output in a cyclic or non-cyclic mode. This setting is also transferred when activating the cam tracks (**_enableCamTrack**)

Cyclic output

The **CYCLIC** setting in the **activationMode** parameter is used to predefine the activation mode for cyclic output of the cam track.

The cam track's track length is mapped from the start position and continued/repeated **cyclically**. The cam track switches after the axis reference position and remains active until it is switched off with **_disableCamTrack**.

Non-cyclic output

The **NO_CYCLIC** setting in the **activationMode** parameter is used to predefine the activation mode for non-cyclic output of the cam track.

The cam track is mapped from the start position, output **once only** and terminated automatically after reaching the end position or remains active in the axis range. The performance depends on the value of the configuration date **octBaseCfg. keepEnabledOutOfTrackRange**.

Example of cyclic and non-cyclic output

A cam track is mapped onto a modulo axis. The figure shows a representation of the different activation modes.

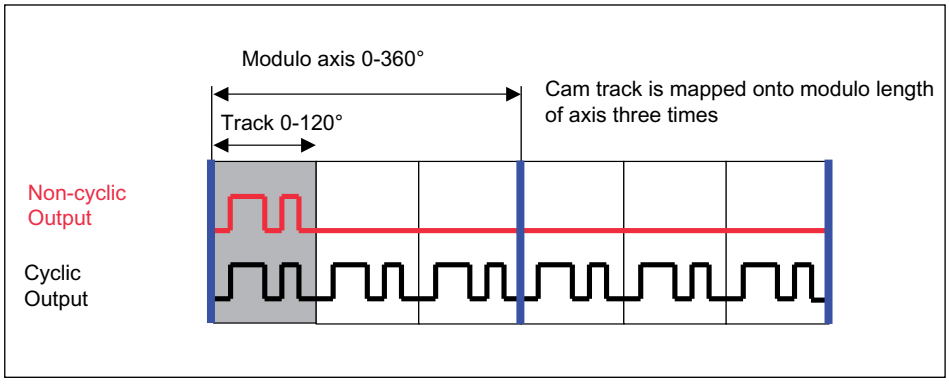

Figure 4-226 Example of cyclic and non-cyclic output on a modulo axis

Axis reference position and cam track offset

Cam tracks are defined independently of the axis. Output cams are not calculated according to the defaults until they are mapped onto the axis. The (**enableCamTrack.axisReferencePosition**) axis reference position is used to define from which position on the axis the cam track should be output. The axis reference position value can be negative or positive. The cam track is always output relative to this position data.

The axis reference position enables you to offset the cam track on the axis as you wish, and therefore to define when the output should take place (see figure in Section **Cam track features**).

A cam track is mapped to the axis range **exactly once**, beginning with the **axis reference position specified** in the enable command. This axis reference position represents the beginning of the cam track (applies for modulo and non-module axes). Upon activation, the cam track is executed once (NO_CYCLIC) or continued cyclically (CYCLIC).

Simulation

Operation can be simulated by means of the simulation commands on the cam track. The cam track status is then not output to the hardware output. In simulation mode, hardware cams behave as software cams. They are then only used for programming purposes.

If an active cam track is switched to simulation mode (**_enableCamTrackSimulation**), the output cam status remains the same, and only the control of the output is reset or interrupted.

Configure Units

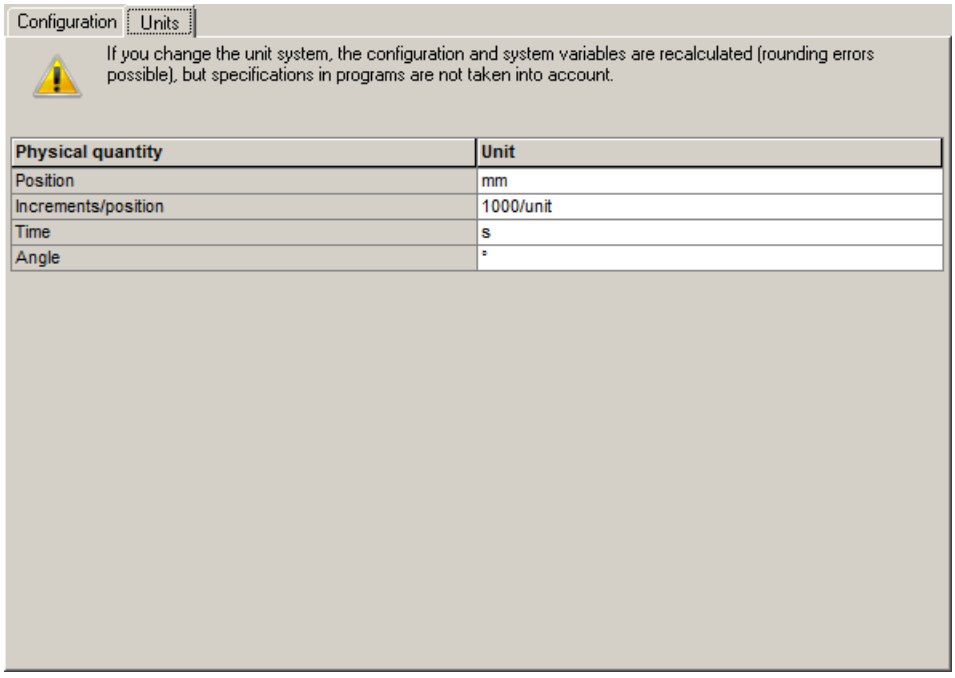
You can define the basic units for each technology object. The same physical variables can have different units in different technology objects. These are converted:

How to configure the units:

1. In the project navigator, open the context menu for the technology object.
2. In the context menu, select **Expert > Configure units**. The **Configure Units** window appears in the working area.
3. Select the **unit** for the **physical variables**. These units are used for the technology object, e.g. s for time units.

or

1. In the project navigator, open the **Configuration** under the TO.
2. Select the **Units** tab.



You can set the following parameters:

Field/button	Meaning/instruction
Table with units	
Physical variable column	Shows the physical variable. The physical variables which are used by the TO are available for the configuration.
Unit column	Displays and configures the unit. A drop-down list for selecting the unit appears when you click on the cell.
Toolbar	
	Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display
Close	Button for closing the dialog.
Help	Button for opening the online help for the dialog.

Mapping a cam track onto an axis

The cam track is defined independently of the axis. On activation, the cam track is mapped onto the axis. Only then are the switching states of the output cams calculated.

See also

Basics of cam track mapping (Page 1877)

Mapping output cams onto the cam track (Page 1877)

Mapping onto negative axis positions (e.g. linear axes) (Page 1878)

Relation of track length, modulo length and activation mode in mapping (Page 1879)

Basics of cam track mapping

- Conversion and mapping of the track onto the axis is identical for modulo and non-modulo axes. Certain points must be noted when mapping onto negative reference positions (see Section **Mapping onto negative axis positions (e.g. linear axes)**).
- The track length can be longer than, shorter than or equal to the modulo length of the axis. Based on this relationship, the switching states of the output cams may differ when they are mapped onto the axis.
- The positions of single output cams always relate to the cam track, not to the axis position. Only on activation of the cam track and entry of the axis reference position is a relationship to the axis position created (start of cam track output).
- If the cam track is activated and the axis rotates negatively, the track will also travel in a negative direction. There is no conversion on the basis of the direction of rotation (see figure). If a cam track should always be output in a positive direction, irrespective of the axis direction, this must be solved in the application.

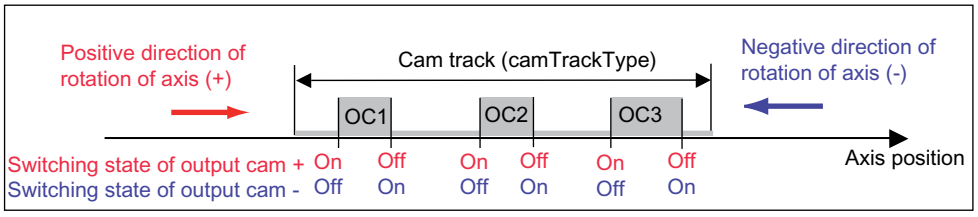


Figure 4-227 Cam track in positive and negative direction, depending on axis direction

- Cam tracks defined outside of the track length limits are mapped or converted during mapping onto the track range.

Mapping output cams onto the cam track

The **_enableCamTrack** command is used to map the starting and end positions of the output cam individually onto the cam track (not onto the axis). Output cams, which have been defined outside of the track range, are converted to this track. Negative starting and end-position values are also converted to the cam track.

"Unfavorable" starting and end-position default settings for output cams, e.g. output cam position outside of the track range, can lead to output cams being shifted, or new output cams being created. This must be taken into account when mapping the cam track onto the axis.

Note

After converting the cam track onto the axis, the effective output cam length is always shorter than or equivalent to the track length. No output cams are defined outside of the track length.

For standard applications, and in the interests of clear programming, automatic conversion of output cams should be avoided. This can be achieved by only defining output cams, which lie within the track length.

Mapping example

A cam track with three output cams (OC1 - OC3) is provided. The end position of output cam OC2 and the entire output cam OC3 are defined outside of the track length. After being mapped onto the axis, OC3 is converted to the track length and mapped to position OC3*. A new output cam OC4* arises from partial output cam OC2.

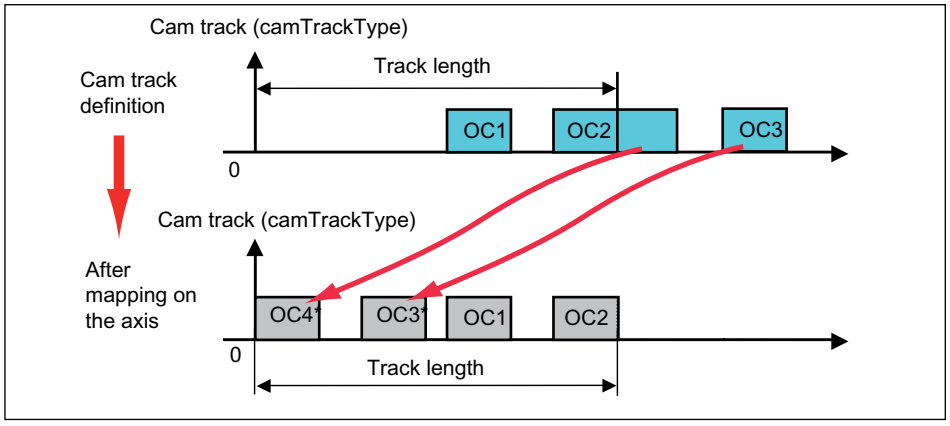

Figure 4-228 Parts of cam track lie outside of the track length

Mapping onto negative axis positions (e.g. linear axes)

Output cams on the cam track are always predefined positively. If you want to output output cams at negative axis positions, the cam track output start must be set in the negative range by means of the axis reference position.

Example of a linear axis with negative axis position

- Range of linear axis: -1000 mm to +1000 mm (non-modulo axis)
- Output of output cam at axis position: -100 mm to -200 mm
- Cam track length: 2000 mm
- Definition of the output cam on the track: SOC=800 mm; EOC=900 mm

By mapping the cam track via the axis reference position, the output cam OC1 can be output at a negative axis position.

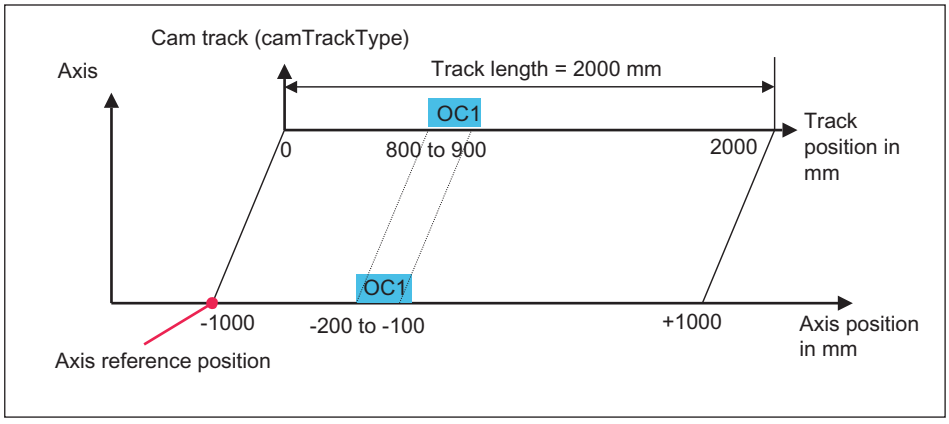

Figure 4-229 Linear axis with output of output cam at negative axis position

Please note that during cyclic output (CYCLIC), cam tracks are continued cyclically even with non-modulo axes, and thus the cam track can be output multiple times to different axis positions.

If a cam track is to remain switched on permanently and only output at one axis position, we recommend the following setting: cam track length ≥ axis traversing range.

This setting prevents the cam track from being continued cyclically in the case of cyclic output of a cam track after execution of the track range (in the figure: axis position - 1000 to +1000).

In the above figure, for example, the cam track would be continued cyclically

- in the positive range from axis position 1000 to 3000; 3000 to 5000 etc
- In the negative range from axis position -1000 to -3000; -3000 to -5000 etc.

.

The same behavior applies also for non-modulo rotary axes.

Relation of track length, modulo length and activation mode in mapping

In conventional output-cam output (comparable to mechanical cam controllers), the track length corresponds to the modulo length of the axis and cyclic output takes place.

With electronic cam controllers, the track length can be shorter or longer than the modulo length of the axis, therefore offering a greater degree of flexibility.

- Track length (tl) < modulo length (m) (integer ratio m to tl)
  Track length is output n-fold (n = m/tl) on modulo length.
- Track length (tl) > modulo length (m) (integer ratio tl to m)
  Output takes place on every nth rotation (n = tl/m). Output always takes place after the first quadrant. If the output takes place differently, a greater track length must be defined and the output cam placed accordingly.
- Non-integer division ratios lead to the cam track being dislocated on every axis rotation.

Use of cyclic output with track length = n x modulo length

If the track length is n times the modulo length, cyclic output allows a repetitive output of output cam to be easily achieved on every nth rotation (e.g. an air nozzle, which is always activated in the same angular range on every nth rotation).

Use of cyclic output with track length = 1/n x modulo length

A cycle scan rate is described using the example of a packaging machine with variable product lengths.

A cam controller controls/triggers all machine functions through a machine cycle of 0-360° (fed from left-hand area, see figure below). The product lengths may vary and are always mapped at 360°.

The machine cycle is subdivided into four identical operation steps at an operating station (right-hand area). The output cam is output cyclically for the operating station, with the track length = 1/4 modulo length of axis. The output cams on a cam track define the operating steps for one of the four identical feeds.

The advantage of this solution is that the product defaults are set in mm of the blister length and calculation/mapping at 360° only has to take place once. In this example, one machine cycle is used for four purposes. The same outputs are required for one use. Therefore, the same configuration does not have to be performed four times. Rather, the repetition factor n is calculated into the track length of the cyclically active track.

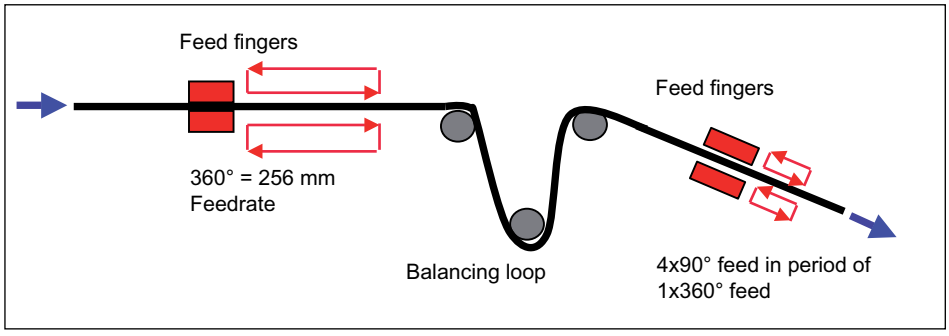

Figure 4-230 Packaging machine with reduced cycle

Example of a modulo axis with cyclic output

Table 4-170 Example of a modulo axis with cyclic output and track length < modulo length

Cam track data/Explanation	Representation
• Modulo length: 360° • Track length: 0-120° • Output cam defaults: SOC=10°, EOC=20° Output cam is output cyclically every 10-20°, 130-140°, 250-260°, etc. If the direction of movement is reversed at 50°, for example, the 10-20° output cam will be output again.	
Example of a modulo axis with non-cyclic output

The example (following table) below shows a modulo axis with non-cyclic output, **next-track-cycle** start mode, and varying enable positions and axis reference positions.

- **Enable A, axis reference position 0°, positive direction of rotation:**
  output cam A is output.
  If the cam track is not exited, output cam A switches multiple times when the direction is reversed. The cam track output is terminated on exiting the cam track.
- **Enable A, axis reference position 240°, negative direction of rotation:**
  output cam C is output during the next cycle.
- **Enable B, axis reference position 120°, positive direction of rotation:**
  output cam B is output.
- **Enable C, axis reference position 240°, positive direction of rotation:**
  output cam C is output.

Table 4-171 Example of a modulo axis with non-cyclic output and track length < modulo length

Cam track data/Explanation	Representation
• Modulo length: 360° • Track length: 0-120° • Output cam defaults: SOC=10°, EOC=20° • Start mode: with next track cycle	
Cam track operating behavior

Changes made to the configuration and defaults of cam tracks or their associated axes during operation affect the cam track, which is active at that time. This section briefly describes the most important changes.

An explanation of how you can determine the status of single output cams and cam tracks is also provided.

The values of system variables are stored in the **userdefault** array. This array is transferred on using **_enableCamTrack** to activate a cam track. These defaults are configured during cam track configuration or other values can be written to them dynamically in the user program.

See also

Changing output cams on a cam track during runtime (Page 1882)

Changing the track length during operation (Page 1882)

Changing the axis configuration when a cam track is active (Page 1883)

Calling up the status of cam tracks and single output cams (Page 1883)

Changing output cams on a cam track during runtime

Changing start and end positions of an output cam

The start and end positions of single output cams can only be changed by transferring the new single positions to the **userdefault** array and using **_enableCamTrack** to activate the changed array.

Validity of single output cams on a track

You can define whether single output cams on a track are valid or invalid. This enables you to define whether single output cams should be output or not. If existing output cams are to be activated on an already active cam track, the relevant **userdefault.singleCamSettings.cam.cam[0-31].validity** system variable can be set with the value **YES** or **NO**, and the **_enableCamTrack** system function must be executed.

When parameterizing the cam track in SIMOTION SCOUT, validity can be set during configuration in the **Default** window and the **Output cam data** tab (see the **Defining cam track defaults** section).

Disabling or enabling valid output cams of a cam track without reactivation via _enableCamTrack (as of V4.1)

Valid output cams of a cam track can be quickly disabled or enabled via the **enableValidCam** system variable without reactivation of the cam track via **_enableCamTrack**.

Default setting of the **enableValidCam** system variable is **0xFFFFFFFF**, i.e. all valid output cams are enabled. By setting the bit of the relevant output cam, e.g. Bit_0 for output cam 0, the valid output cam is enabled with **1** and disabled with **0** (e.g. only output cam 0 is disabled with **0xFFFFFFFE**).

Properties of enableValidCam:

- Value of **enableValidCam** is retained with reactivation by **_enableCamTrack**
- During system ramp-up or with **_resetCamtTrack**, **enableValidCam** is set to the default setting 0xFFFFFFFF.
- Invalid output cams cannot be enabled via **enableValidCam**.
- System variable takes effect immediately without activation of the cam track.

Changing the track length during operation

The **userdefault.camTrackLength** system variable can be used to change the track length of an active cam track during operation. Changes to a track length do not become effective until the cam track is reactivated (**_enableCamTrack**). The track length of the cam track that is already active remains unchanged unless it is overridden by the changed cam track.

Example of a changed track length

- 360° track length is changed to 400° and the new track is activated.
- Output cam defaults: SOC=310°, EOC=30°

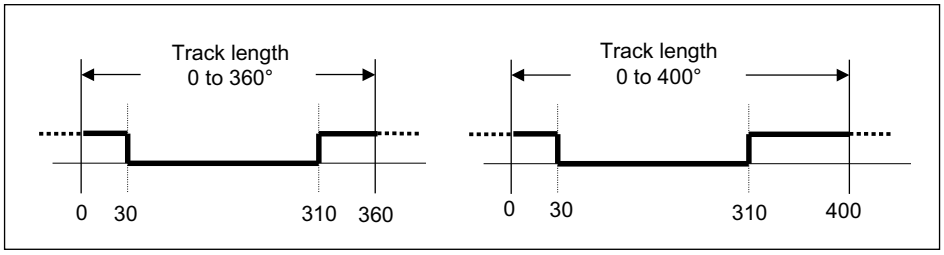

Figure 4-231 Changed track length with an effect on switching states

Changing the axis configuration when a cam track is active

Changing the axis configuration for an assigned, active cam track affects cam track behavior.

Changing modulo length

Changing the modulo length of an axis does not affect the definition or behavior of a cam track when it is enabled.

If the modulo length of an axis is changed, the conversion of the cam track on that axis is not automatically adjusted. If necessary, when changing the modulo length, you must deactivate the active cam track and activate it again, so that the axis can be mapped according to the new modulo length.

Output-cam output is aborted if the modulo length on an axis is changed and the axis is restarted.

Redefine axis

If the axis position is changed during operation, e.g. with **_redefinePosition**, the cam track is aborted and restarted. The change is interpreted as a skip in the modulo range. The cam track is mapped onto the new modulo range of the axis.

Calling up the status of cam tracks and single output cams

You can detect the status of single output cams and cam tracks at any time via system variables, and use the status in the user program.

Table 4-172 Status and position of cam tracks and single output cams

System variable	Meaning	Description
control	Functional status of Cam Track TO	The variable displays the state of the cam track. For example, it can be active, inactive or waiting for the next cam track cycle.
state	Output status	The variable displays if cam track output is in an ON or OFF state.

System variable	Meaning	Description
singleCamState	Status of single output cam	The **singleCamState** system variable is used to read out the status of single output cams. The variable consists of a 32-bit array, in which the lowest bit (bit0) represents output cam 0.
camTrackPosition	Position of the cam track	The **camTrackPosition** system variable is used to read out the actual position of a cam track operation within a cam track cycle. The cam track position is required, because the actual track position of a cam track cannot be determined by means of the axis position of a modulo axis (as, for example, the track length could be longer than the modulo range of the axis). The detected value always lies between the start (always "0") and end (defined by the cam track length) of the track.

Inverting a cam track

If the application requires, you can invert the cam track's activation level. The Cam Track TO retains its positive logic. The cam track switches at level 1 or high.

You can set the inversion via the **OctTechnologicalCfg.invertOutput** configuration data element or in the **Configuration** window of the cam track. The TO must be restarted in order for a change to be made.

Effect of cam track parameters on mapping

This chapter uses examples to explain the effect of configuration changes on cam track mapping onto an axis.

See also

Basic mapping of a simple cam track (Page 1884)

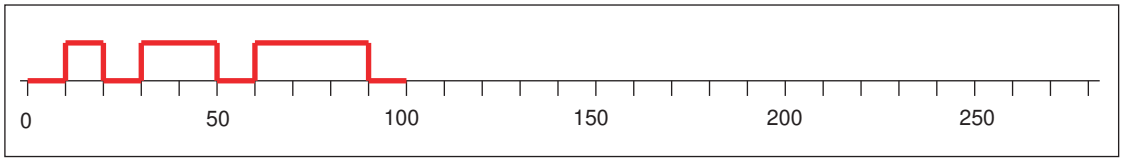
Advanced mappings with shifted output cam positions (Page 1886)

Basic mapping of a simple cam track

One cam track with the following data is given.

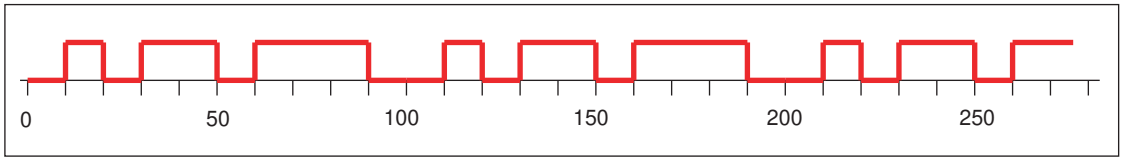
- Three position-based cams (10-20; 30-50; 60-90)
- Activation mode: Non-cyclical cam track activation
- Start mode and stop mode: Effective immediately

- Track length: 100
- All other user-default variables are the default setting unless another setting is mentioned explicitly.

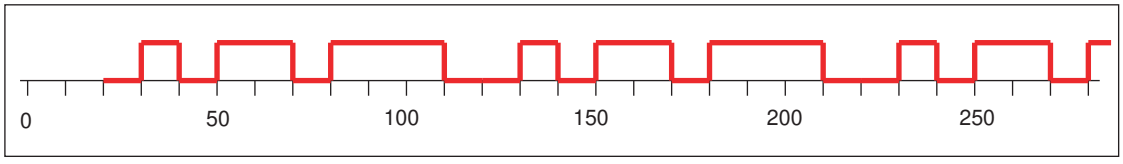


Display of given cam track with modified axis reference position, activation mode, and track length

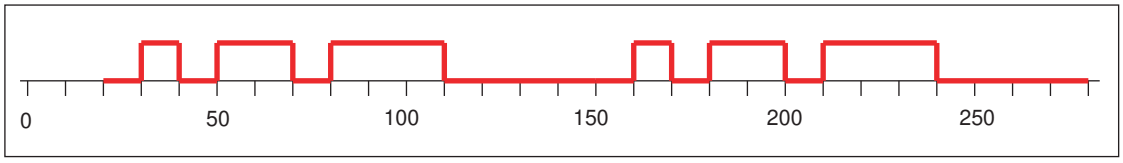
- Activation mode: Cyclic



- Activation mode: Cyclic
- Axis reference position: 20



- Activation mode: Cyclic
- Axis reference position: 20
- Track length: 130



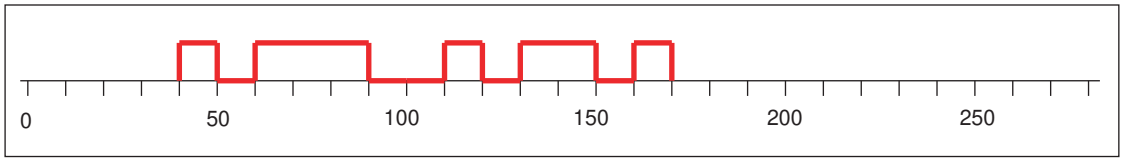
The following applies:

- A change of axis reference position causes a change in the cyclic and non-cyclic mode. The cam track is offset once.
- A track length change only affects the cyclic mode and causes an offset in the cam track cycle.

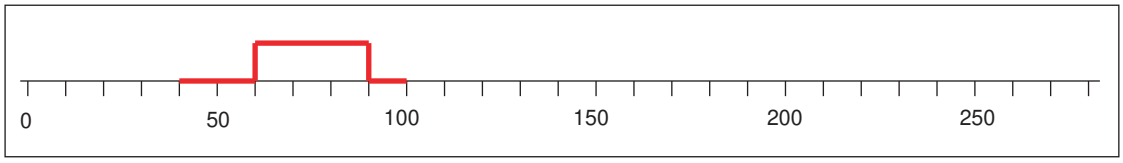
Display of given cam track with modified start/stop mode

- Start mode: Effective immediately
- Position of axis on which _enableCamTrack occurs: 40
- Position at which _disableCamTrack occurs: 170

- Activation mode: Cyclic



- Start mode: Immediate for inactive output cam track output
- Position of axis on which _enableCamTrack occurs: 40

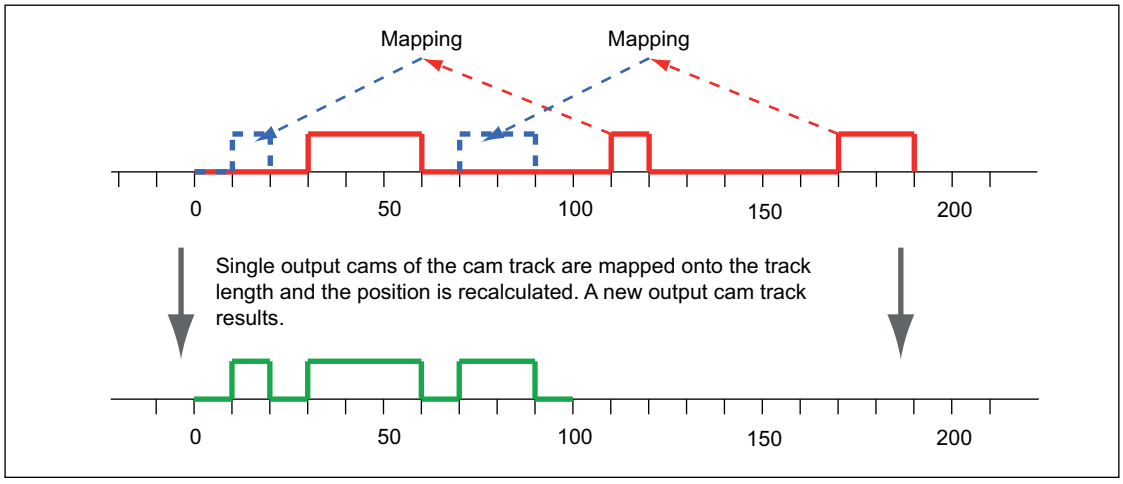


Advanced mappings with shifted output cam positions

The following chapter presents examples of a cam track with shifted single cams, i.e. when they are mapped onto the axis, single cams are shifted to another position if they are defined outside the track length.

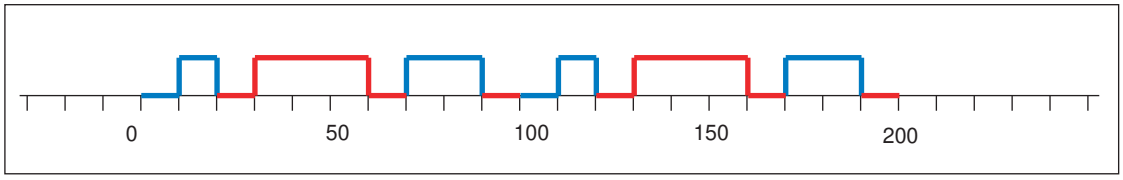
One cam track with the following data is given.

- Three position-based cams (30-60; 110-120; 170-190)
- Track length: 100
- Axis reference position: 0
- All other user-default variables are the default setting unless another setting is mentioned explicitly.

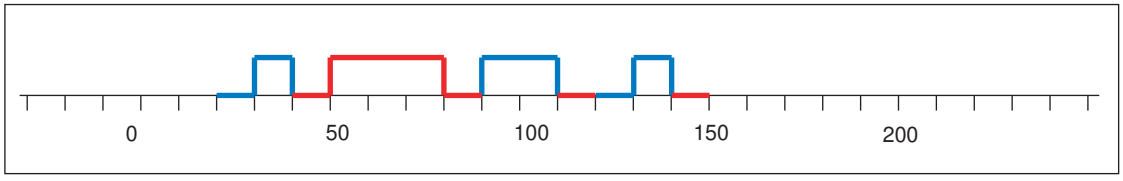


Display of given cam track with modified activation mode and axis reference position

- Activation mode: Cyclic



- Mode: Cyclic
- Axis reference position: 20
- Position at which _disableCamTrack occurs: 150



4.3.4.3 Configuring the TO Cam Track

This chapter describes typical operations used when working with the Cam Track technology object.

See also

Inserting cam tracks (Page 1887)

Parameterizing the Cam Track technology object (Page 1888)

Using expert list for cam tracks (Page 1889)

Configuring a cam track (Page 1889)

Defining cam track defaults (Page 1893)

Determining derivative-action times for cam tracks (dead time compensation) (Page 1907)

Using HW enable for cam tracks (Page 1909)

Inserting cam tracks

Note

Before you insert a cam track, the axis or external encoder to which the cam track is assigned has to be created.

If the cam is output to a TM15/TM17 High Feature or ET200xP TM Timer DI/DQ, the module must be added and configured before cam track configuration.

To insert a cam track:

1. In the project navigator, highlight the **OUTPUT CAMS** folder under the relevant axis or external encoder.
2. Select **Insert > Technology object > Cam track** or double-click **Insert cam track** in the project navigator under the axis or external encoder in the OUTPUT CAMS folder. The **Insert cam track** window appears.
3. Enter a **name** for the cam track. You can also enter a **comment**.
   Names must be unique throughout the project. For this reason, all the existing output cam tracks are displayed under **Available cam tracks**.
4. Confirm with **OK**. In the working area, the window for the configuration is displayed and the created cam track TO is shown in the project navigator.

Parameterizing the Cam Track technology object

General information about configuration data and system variables

Two data classes are distinguished when parameterizing a TO.

Configuration data defines the principal functionality of a TO. They are set within the object configuration framework with the SCOUT engineering system and are not normally changed during runtime.

System variables provide status data of the TO for the user program and a parameterization interface on the TO. System variables can be changed during runtime.

Note

You will find more information on technology objects in the *SIMOTION Runtime Basic Functions* functional description.

To parameterize a cam track

1. In the project navigator under the **OUTPUT CAMS** folder, find the cam track technology object (TO) that you want to parameterize. Double-click the cam track TO to display the associated objects.
2. Double-click **Configuration** or **Default** in the project navigator. The window appears on the workspace.
   - **Configuration** (see chapter **Configuring a cam track**):
     Define the values for the **configuration data** of the cam track here. This includes, for example, output cam type.
   - **Default** (see chapter **Defining cam track defaults**):
     Define the cam track defaults of the **system variables** here. This can include, for example, cam track and output cam data.
3. Changing configuration data and defaults

4. Click **Close** to accept the changes.
5. Repeat steps 2 to 4 for all objects in which you want to change the configuration data and defaults.

Using expert list for cam tracks

Parameters required for standard SIMOTION applications (configuration data and system variables) are parameterized in the Cam Track TO directly by means of screen forms or are defined automatically.
It may be necessary to change automatically-defined parameters for special SIMOTION applications. These configuration data and system variables can only be displayed and changed in the expert list.

Note

You will find more information on working with the expert list in the *SIMOTION Runtime Basic Functions* functional description.

Configuring a cam track

In the **Configuration** window, define the configuration data values for the cam track.

Double-clicking in the project navigator below the cam track on the **Configuration** element displays the window in the working area.

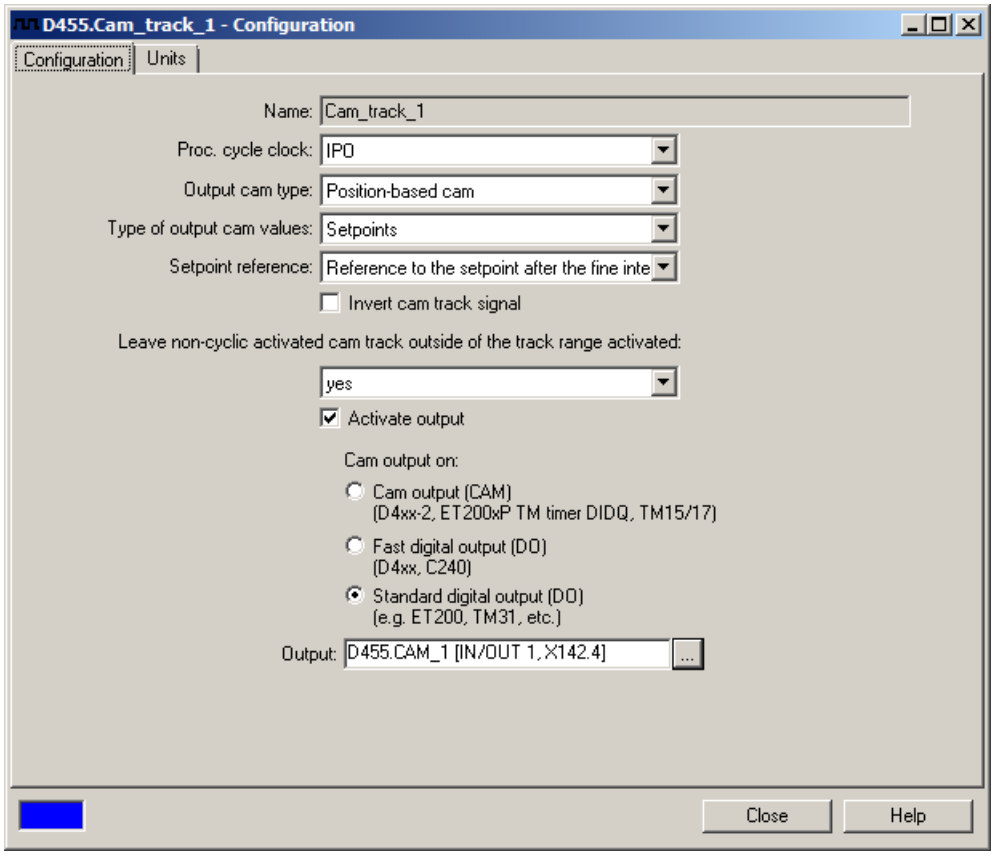


Figure 4-232 Output cam configuration using the example of a position-based cam

You can set the following parameters:

Table 4-173 Cam track configuration data

Field/button	Meaning/information
Name	The name of the created cam track is displayed here.
Output cam type (See Chapter **Output cam types of the single output cams on a track**)	Choose the type of output cam used on the track in **Output cam type**. **Position-based cam** (default value) The switching signal is active when the position of the axis lies between two markers (start and end position). **Time-based cam** The switching signal is on for a specific period of time after reaching the switching position (start position). **Time-based cam with maximum ON length** A maximum ON length can also be defined for time-based cams. This means that the time-based cam is deactivated once it has covered the maximum length, even though the parameterized time has not yet expired.

Field/button	Meaning/information
Processing cycle clock	Choose **Processing cycle clock** to select the system cycle clock used to update the output cam signal at the output or in the system variables. The cam calculations are performed in IPO or IPO_2 cycles or in servo cycles. The processing cycle clock is set in the configuration by means of the **OctBaseCfg.taskLevel** configuration data. **IPO** (default value) The output cam signal is updated in the interpolator cycle clock. **IPO_2** The output cam signal is updated in the interpolator cycle clock 2. The IPO_2 cycle clock length is at least twice that of the IPO. **Servo** The output cam signal is updated in servo cycles. **The following configurations of the processing cycle clock are possible:** • Axis in IPO cycles and output cam in IPO_2 cycles • Output cam in servo cycles and axis in IPO or IPO_2 cycles For the possible setting of IPO_fast and Servo_fast with D435-2, D445-2 and D455-2, see Section Second servo cycle clock (Servo_fast) in the SIMOTION Runtime Basic Functions Manual. **Note:** • It is not possible to configure the axis in the servo cycle clock and the output cam in the IPO or IPO_2 cycle clock. • It is not possible to configure the axis in the IPO cycle clock and the output cam in the IPO_2 cycle clock if it is a setpoint output cam. • It is not possible to configure the axis in the IPO_2 cycle clock and the output cam in the IPO cycle clock. **Note:** When the Servo:IPO ratio is ≠ 1:1, then the greatest possible accuracy for the calculation is reached for "output cams related to position value" when the **servo cycle clock** is set as the processing cycle clock for the cam track TO.
Type of output cam value	Select the position value that is the reference for the output cam during processing.
Actual value reference	Select the following settings here depending on the type of the output cam values: • **Reference to the actual value on the encoder without considering Ti**. Reference to the actual position in the controller before the position filter. • **Reference to the actual value after the position filter**. Reference to the actual position in the controller after the position filter. • **Reference to the actual value on the encoder. Ti is taken into account**. Reference to the actual value on the encoder module / drive. The transmission time Ti from the encoder module / drive to the controller is taken into account by the system.
Setpoint reference	Select the following settings here depending on the type of the output cam values: • **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoints will already have been reached at the end of this IPO cycle, e.g. if a setpoint is calculated for the IPO cycle clock with the virtual axis and also displayed at the end of the cycle. Reference is made directly to the setpoint applicable at the end of the cycle. • **Reference to the setpoint after the fine interpolator**. The cam switch points are calculated as if the setpoint calculated in the interpolator will be output completely in the following cycle and the calculated position setpoint will therefore be reached at the end of the following cycle. • **Reference to the setpoint on the drive**. Calculation of the cam switch points according to the setpoint output with the current settings on the drive.

Field/button		Meaning/information
Activate output		Activate the checkbox if the output cam signal is to be applied to a digital output. Parameters are displayed.
Cam output on		
	Cam output (CAM)	If the output checkbox is activated and the cam output (CAM) radio button selected, the cam output is on the basis of an internal time stamp. The temporal resolution of the cam output depends on the hardware used. In the case of D4x5-2 and the TM17 High Feature, the resolution is, for example, 1 µs. Supported hardware: • SIMOTION D410-2 • SIMOTION D4x5-2 (X142) • TM15, TM17 High Feature • ET200xP TM Timer DI/DQ The I/O channel must be configured as **CAM**. For more details, see cam output types. (Page 1811) **Note** Cam output (CAM) or high-speed digital output (DO) are also known as high-speed, hardware-supported output cams.
	High-speed digital output (DO)	If the output checkbox is activated and the "High-speed digital output (DO)" radio button selected, the output cam is output via onboard outputs of the SIMOTION CPU. The output is via a hardware timer and the cam output is achieved with a resolution with respect to time < servo cycle clock. The time that it takes for the axis to reach the output cam switching position with reference to the processing cycle is calculated by linear extrapolation. Calculated from the beginning of the 1st position control cycle, the output cam function is triggered by a hardware time when this time is reached. Supported hardware: The onboard I/O of the following CPUs is used: • SIMOTION D4x5 (interface X122, X132), 8 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as DO) • SIMOTION D410 (interface X121), 4 high-speed cam outputs, as of V4.1 (the I/O channel must be configured as DO) • SIMOTION C240, C240 PN (interface X1), 8 high-speed cam outputs For more details, see cam output types. (Page 1856) **Note** Cam output (CAM) or high-speed digital output (DO) are also known as high-speed, hardware-supported output cams.
	Standard digital output (DO)	If the output checkbox is activated and the "Standard digital output (DO)" radio button selected, the output cam is output in the servo cycle clock. The temporal resolution of the cam output is usually reduced by the output cycle of the I/O used. Supported hardware: • Onboard outputs (SIMOTION D, Controller Extension CX, SINAMICS Control Unit CU3xx) • Centralized I/O (SIMOTION C) • Distributed I/O via PROFIBUS DP/PROFINET I/O (e.g. ET 200, ET200xP TM Timer DI/DQ) • Drive I/O TM15, TM15 DI/DO, TM17 High Feature, TM31, TM41, TB30 For more details, see cam output types. (Page 1856)

Field/button	Meaning/information
Output	The output can be symbolically assigned via the assignment dialog (see Chapter Symbolic assignment (as of V4.2) in the SIMOTION Runtime Functions manual) using the ... button in the Output field (symbolic assignment is activated by default in projects as of V4.2). If symbolic assignment is not active or if the CPU version is < V4.2, a physical output is assigned by entering the HW address and bit number in the Output field. Enter the logical HW address of the output to which the output cam signal is to be applied. Only the output cam signal may be present at this address. If other objects are already using this output, an error occurs that is reported following a download to the target system. The logical HW address must be located outside the process image and therefore be greater than 63. For details see Cam output types (Page 1811)
	Button for opening the assignment dialog (see Chapter Symbolic assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual). Select a parameter or an address in the Assign dialog.
	Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display

Defining cam track defaults

You can define defaults for every cam track. These values are stored in system variables and can be changed by programs.

Double-clicking in the project navigator below the cam track on the **Defaults** element displays the window in the working area.

See also

Track data (Page 1894)

Output cam data (Page 1896)

Track data

The defaults for the track system variables, e.g. track length, are displayed in the **Track Data** tab.

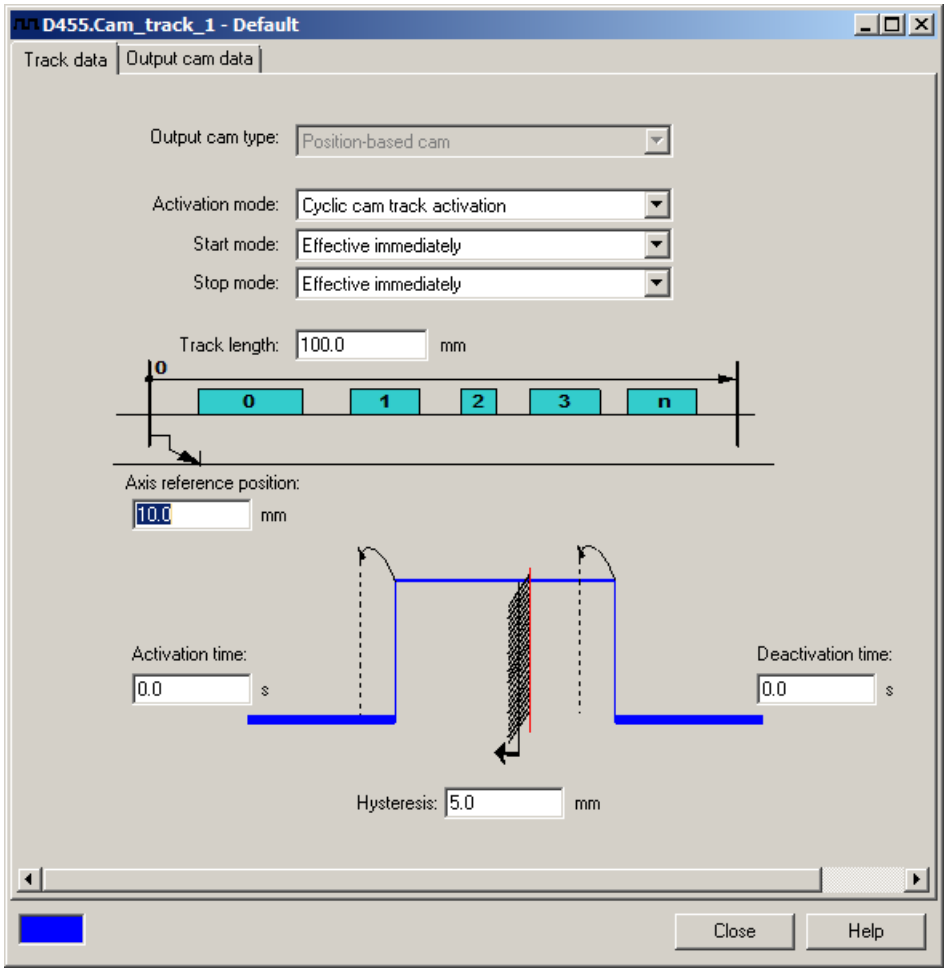

Figure 4-233 Cam track data using the example of a position-based cam

You can set the following parameters:

Table 4-174 Defaults for cam track data

Field/Button	Significance/Note
Output cam type	**Output cam type** displays the type of output cam selected for the cam track in the **Configuration** window.
Activation mode (See the **Output activation mode** section)	Cam tracks can be output in a cyclic or non-cyclic mode. **Cyclic cam track activation** The cam track's track length is mapped from the axis reference position and continued/repeated cyclically. **Non-cyclic cam track activation** Cam track is mapped from the axis reference position, output once, and terminated automatically after exiting the cam track or remains active in the axis range. This setting depends on the value of the **octBaseCfg.disableOutOfTrackRange** configuration data element.

Field/Button	Significance/Note
Start mode (See the **Start mode and stop mode** section)	The start mode (**startMode**) is used to define when the cam track should become effective after activation, or how tracks should be changed. **Last programmed value** The last programmed start mode is active. If a start mode is not programmed, the user default setting is used. **Effective immediately** Track becomes active immediately. If an output cam (or time-based cam) is defined or active at the current position of the old track, the output is aborted. The new track is enabled without delay (as quickly as possible). This enables high-speed exchange of cam tracks. **Immediately with inactive cam track output** Changeover is made to the new cam track if no single output cam is active (any longer) on the old cam track. An active (output) single output cam on the old cam track is still output completely. **With next track cycle** The track becomes active at the next track cycle. Immediately the first output cam on the new track switches, a changeover is made to the new track. Up to that point, a time-based cam on the old track is output.
Stop mode (See the **Start mode and stop mode** section)	The stop mode (**stopMode**) is used to define the behavior of the cam track on deactivation. **Last programmed value** The last programmed stop mode is active. If a stop mode is not programmed, the user default setting is used. **Effective immediately** Track is deactivated immediately. If an output cam (or time-based cam) is defined or active at the current position of the track, the output of output cam is aborted. **Immediately with inactive cam track output** If no single output cam is active (any longer), the active cam track is stopped. An active (output) single output cam is still output completely. **At cam track end** Track is deactivated at its end. Immediately the final output cam on the track switches, the track is deactivated. Up to that point, a time-based cam on the track is output.
Track length	Enter the track length. The track length is calculated from the start of the cam track to the end of the cam track.
Axis reference position (See the **Cam track features** section)	The axis reference position is used to define how the cam track is mapped on the axis, or from which axis position the cam track should be output.
Axis modulo length (See the **Relation of track length, modulo length, and activation mode** section)	The modulo length of the axis, which the cam track is linked to, is displayed here. The modulo length does not have to be identical to the track length. To change the modulo length of the axis, you must work through the axis wizard. It is only displayed when the axis is configured as a modulo axis.
Activation time (See the **Actuation times (activation time/deactivation time)** section)	Enter the **activation time** here. The output cam switching time is set to the point when the start position is reached, plus this period. The output cam position is adapted dynamically. This allows you to compensate for propagation delays. If a negative value is entered as an activation time, the switching signal is activated before the start position is reached.

Field/Button	Significance/Note
Deactivation time	Enter the **deactivation time** here. The output cam switch-off time is set to the point when the end position is reached, plus this period. The output cam position is adapted dynamically. This allows you to compensate for propagation delays. If a negative value is entered as a deactivation time, the switching signal is activated before the end position is reached.
Hysteresis (See the **Hysteresis** section)	Enter a range for the **hysteresis** here. The output cam does not change its switching state in this defined range around the switching position even under changed switching conditions. This prevents a repeated change of the switching state.

Output cam data

The defaults for system variables of single output cams on a track, e.g. starting and end position, are displayed in the **Output Cam Data** tab.

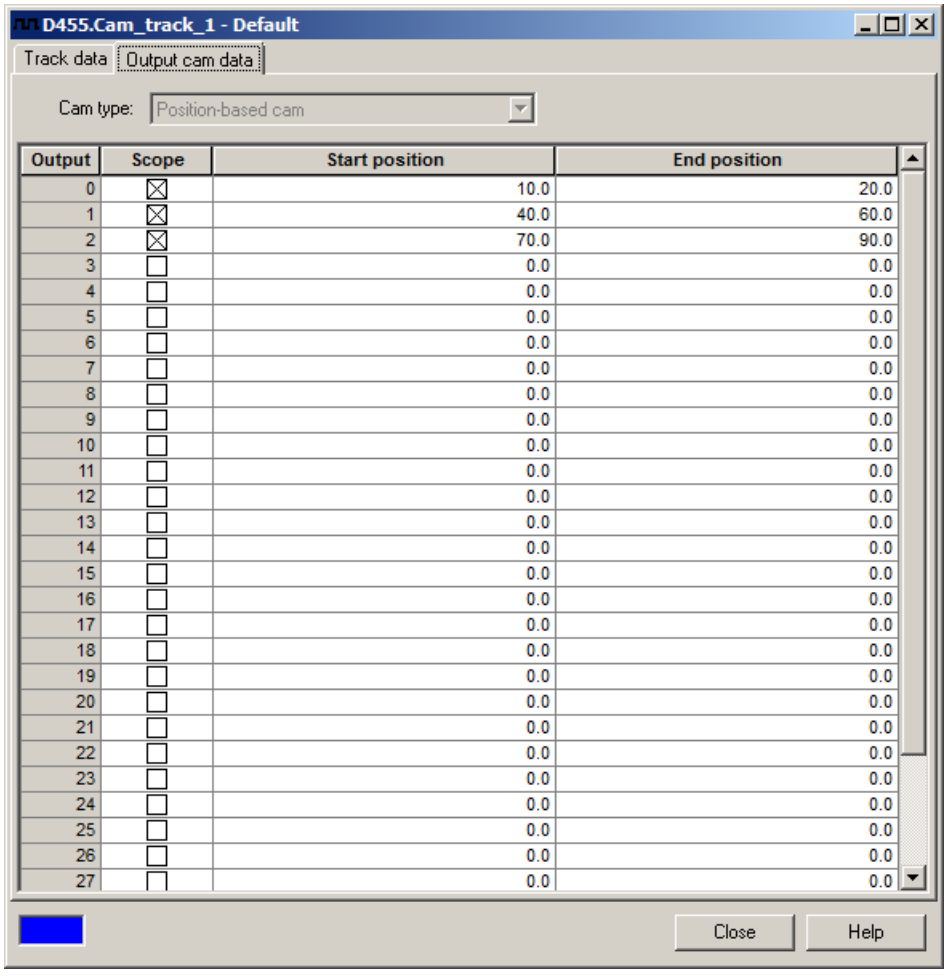

Figure 4-234 Cam track output cam data, position-based cam example

You can set the following parameters:

Table 4-175 Cam track output cam data defaults

Field/Button	Meaning/Note
Output cam (cam-Type)	The output cam number (0 - 31) is displayed here. Each track can have up to 32 output cams.
Validity	Select this checkbox, if you want to set the output validity of single output cams on a track. If the box is activated, the output cam will be output, along with the track. If it is not activated, the output cam is not output.
Starting position	Enter the starting position of the output cam.
End position	Enter the end position of the position-based cam here.
Last programmed ON duration (See Section **Time-based cam**)	Enter the ON duration for time-based cams here. The output cam switches off once the parameterized time has expired.
Max. ON length (See Section **Time-based cam with maximum ON length**)	Enter the maximum ON length for time-based cams with maximum ON length here.

Configuring cam tracks on SIMOTION D4xx onboard

Output cams and cam tracks can be configured for standard outputs, or as high-speed, hardware-based output cams / cam tracks.

A cam track can be configured on SIMOTION D4xx onboard as follows:

1. In the project navigator, switch to the Control Unit via **SINAMICS_Integrated > Control_Unit.**
2. Double-click **Inputs/outputs** below the control unit. The window appears on the workspace.
3. Switch to the **Bidirectional digital inputs/outputs** tab.
4. Click the **button** to switch between the input and output for the digital inputs/outputs (**DO8 to DO15**). In each case, switch the DI/DO to the output you wish to use as the output of output cam. The designation at the terminal strip of DI or DO switches to DO. Outputs of the output cam can only be used if they have been defined as an output. DO 8 is configured as an output in the diagram. For the output, select the **DO (SIMOTION)** setting.

Note

Mixed use of the SIMOTION D4xx DI/O as high-speed outputs (of output cams) and inputs of measuring inputs is possible.

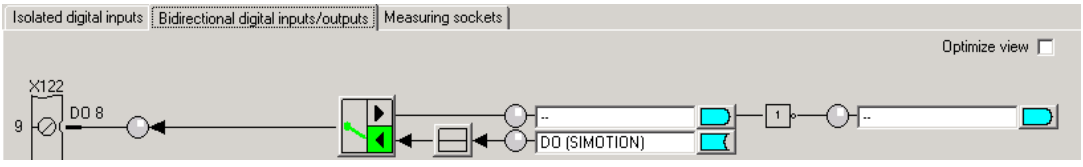

Figure 4-235 SIMOTION D4xx digital inputs/outputs

5. Click **Close**.
6. Insert a new output cam or a new cam track or use an existing one.
7. Parameterize the TO Output Cam / Cam Track
8. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
9. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used. Should you wish to configure a high-speed output cam, select the **Activate output** check box and select the **High-speed digital output (DO)** radio button.
10. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address.
11. Click **OK** to close the window and select **Project > Save**.

To determine the logical hardware address for outputs on SIMOTION D4xx onboard (only if symbolic assignment is not activated)

1. In the project navigator, below the SIMOTION D device, select **SINAMICS_Integrated > Communication > Telegram configuration**.
2. Double-click Configuration and, in the window which appears, select the tab **IF1: PROFIdrive PZD telegram**. The components are displayed there with address range (input/output data).

3. Select SIEMENS telegram 390, 391 or 392 as telegram type. A maximum of eight output cams can be configured for each telegram. The number of DI/DO is limited to eight, i.e. only two output cams can be configured for telegram 392 if you are already using six measuring inputs. Therefore consider whether you also want to use measuring inputs during the telegram selection.

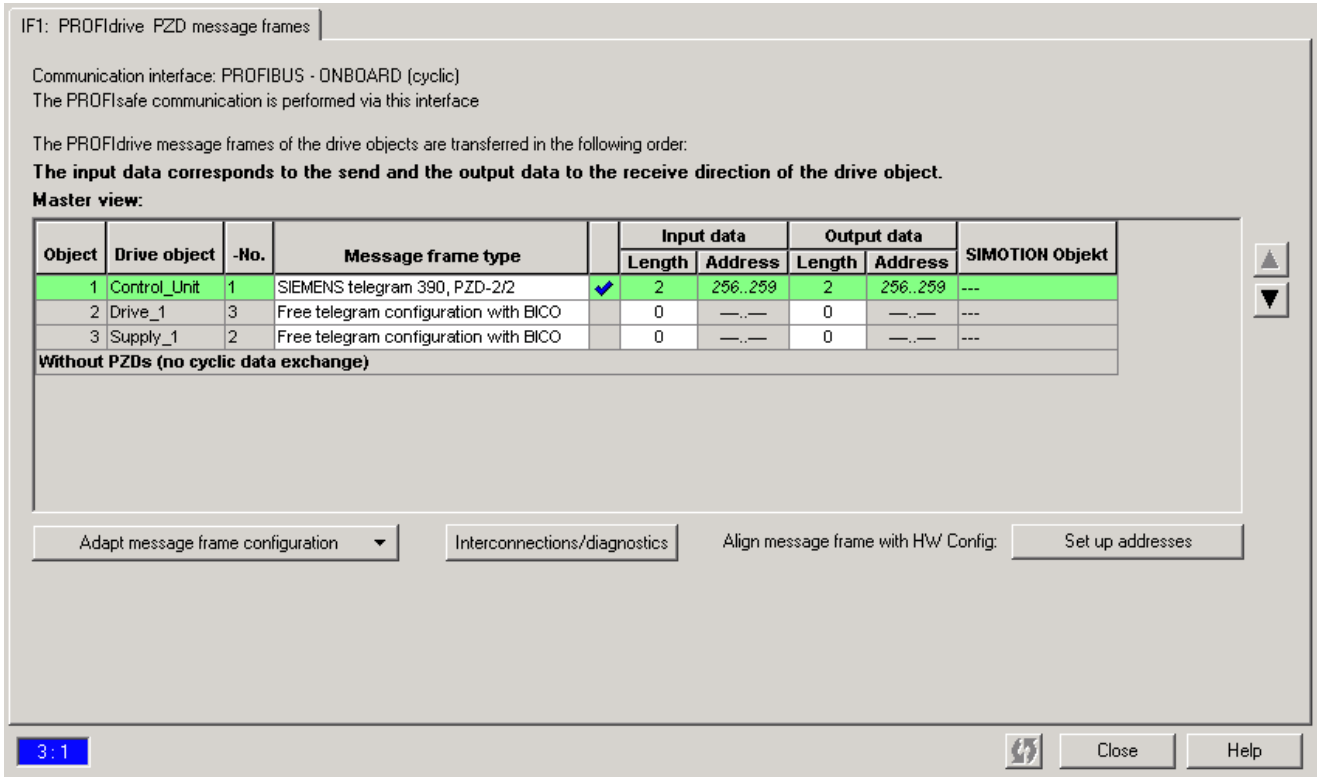

Figure 4-236 Determining the hardware address of the components

4. Before you determine the hardware address, an alignment between HW Config and SIMOTION SCOUT, with respect to the address, must be performed. If this has not been performed or you have changed the addresses, click on **Set up addresses**. If there are question marks in the fields instead of I/O addresses, you must also perform an alignment.
5. Now calculate the hardware address by adding the base output address (first value of the output data) of the Control Unit to the offset (for example, 256 + 3 = 259). The offset always has the value **3**.
6. You will find the bit number in the following table.

Table 4-176 Bit numbers for D410 and D4x5

Output D4x5	Output D410	Bit number
X122.7 (DI/DO 8)	X121.7 (DI/DO 8)	Bit 0
X122.8 (DI/DO 9)	X121.8 (DI/DO 9)	Bit 1
X122.10 (DI/DO 10)	X121.10 (DI/DO 10)	Bit 2
X122.11 (DI/DO 11)	X121.11 (DI/DO 11)	Bit 3
X132.7 (DI/DO 12)	-	Bit 4
X132.8 (DI/DO 13)	-	Bit 5

Output D4x5	Output D410	Bit number
X132.10 (DI/DO 14)	-	Bit 6
X132.11 (DI/DO 15)	-	Bit 7

Note

In the case of versions earlier than V4.2, when using 39x telegrams, the onboard D4x5 outputs are to be assigned exclusively to SIMOTION. During a consistency check in SIMOTION SCOUT, no check is made as to whether the entered HW address actually belongs to a **high-speed digital output (DO)**.

Configuring cam track on the SIMOTION D410-2

1. In the project navigator, switch to the **Control Unit** via **SINAMICS_Integrated > Control_Unit**.
2. Double-click **Inputs/outputs** below the control unit. The window appears on the workspace.
3. Switch to the **Bidirectional digital inputs/outputs** tab.
4. Click the button to switch between the input and output for the digital inputs/outputs (**DO 8 to DO15**). In each case, switch the DI/DO to the output you wish to use as the output of output cam. The designation at the terminal strip switches to DO. Cam outputs must always be defined as outputs so that they can be used. DO 8 is configured as an output in the diagram. For the output, select the **Output cam (SIMOTION)** setting.

   Note

   Mixed use of the SIMOTION D410-2 DI/DO as high-speed (output cam) outputs and inputs of measuring inputs is possible.

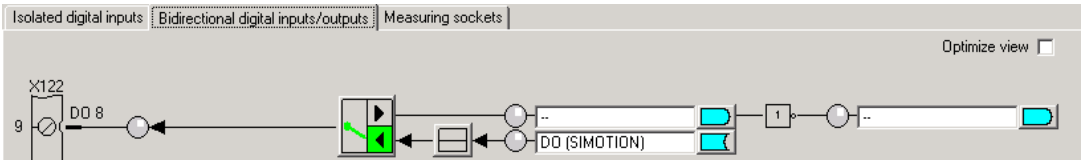

Figure 4-237 Digital inputs/outputs onboard

5. Click Close.
6. Insert a new output cam or a new cam track or use an existing one.
7. Parameterize the TO Output Cam / Cam Track
8. Double-click Configuration below the output cam or the cam track in the project navigator. The Configuration window appears in the working area.
9. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used. Should you wish to configure a high-speed output cam, select the **Activate output** checkbox and select the **Output cam output (CAM)** radio button.

10. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address.
11. Click OK to close the window and select **Project > Save** from the menu.

Configuring cam tracks on SIMOTION D4x5-2 onboard

With SIMOTION D4x5-2 the outputs on the interface X142 are used for cam output

1. The **Inputs/outputs X142** entry in the project navigator can be used to open the configuration screen in HW Config.
2. For the selected I/O channel, select **Output cam** as the function.

Note

If you do not use symbolic assignments (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual), you must note the logical address. (see Figure I/O Properties) This address must be configured at the TO output cam

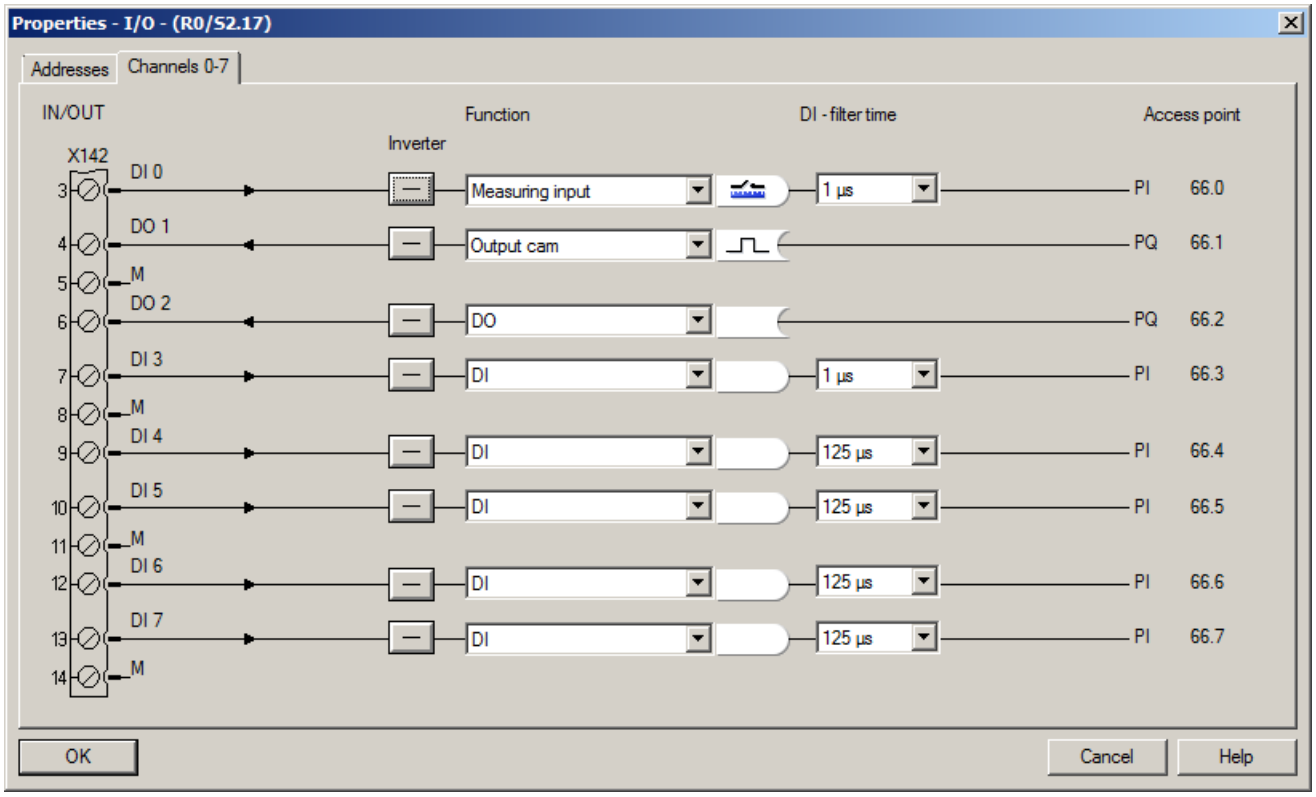

Figure 4-238 I/O Properties

3. Click OK.
4. Insert a new output cam or a new cam track or use an existing one.
5. Parameterize the TO Output Cam / Cam Track

6. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
7. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used.
   If you would like to configure a high-speed output cam, select the Activate output check box and select the output cam output (CAM) radio button.
8. Assignment of an output to an output cam/cam track is supported as of V4.2 using symbolic assignment or by entering the HW address.
9. Click OK to close the window and select **Project > Save** from the menu.

Configuring cam tracks on a TM15/TM17 High Feature

1. In the project navigator, below the input/output component (TM15/TM17) that you want to use, double-click the entry **Inputs/outputs.** The **Bidirectional Digital Inputs/Outputs** window is displayed.
2. For the selected I/O channel, select **Output cam** as the function.

   Note

   If you do not use symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual), you must note the offset (e.g. 3.1).

3. Insert a new output cam or a new cam track or use an existing one.
4. Parameterize the TO Output Cam / Cam Track
5. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
6. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used.
   If you would like to configure a high-speed output cam, select the **Activate output** check box and select the **Cam output (CAM)** radio button.
7. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address.
8. Click OK to close the window and select **Project > Save** from the menu.

To determine the logical hardware address for TM15/TM17 High Feature outputs (only if symbolic assignment is not activated)

1. In the project navigator, below the SIMOTION device or the SINAMICS drive unit
   - for SIMOTION D, select: **SINAMICS_Integrated > Communication > Telegram configuration**
   - for SINAMICS S/G drive unit (position axis only): **Communication > Telegram configuration**
2. Double-click **Telegram configuration** and, in the window that opens, select tab **IF1: PROFIdrive PZD telegram**. The components are displayed there with the address ranges (e.g. TM17 output data 304 to 315).

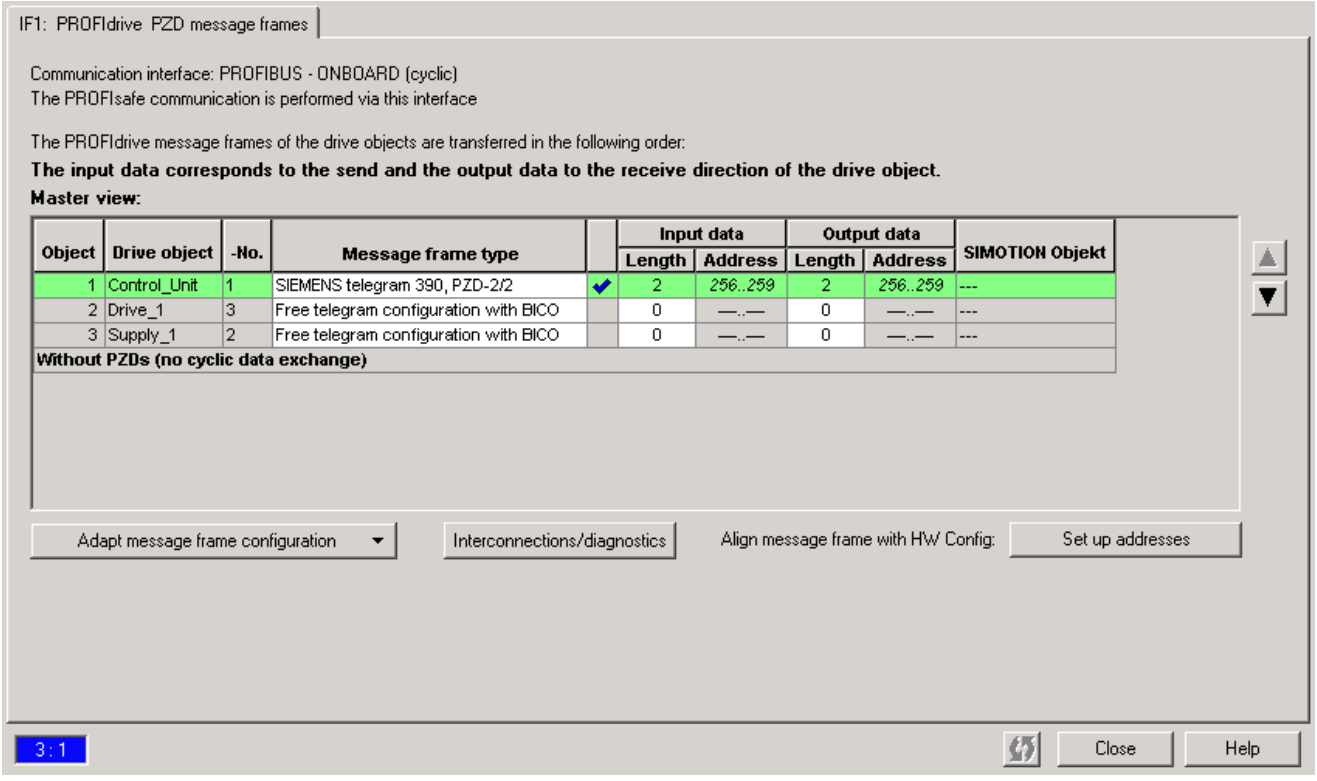

Figure 4-239 Determining the hardware address of the components

3. Before you determine the hardware address, an alignment between HW Config and SIMOTION SCOUT, with respect to the address, must be performed. If this has not been performed or you have changed the addresses, click on **Set up addresses**. If question marks are entered in the fields instead of I/O addresses, either alignment has not yet taken place, or the address is not recognized by SIMOTION SCOUT. In this case, you must perform an alignment.
4. Now calculate the HW address by adding the base output address (first value of the address range) of the TM to the offset (e.g. 304 + 3 = 307).
5. The bit number is defined by means of the offset. For example, a 3.1 offset of an output cam on DO 1 results in a bit number of 1.

Configuring a cam track on SIMATIC ET200SP and ET200MP

Overview

Description

You can configure TO cam track on the ET200SP technology module TM Timer DIDQ 10x24V and ET200MP technology module TM Timer DIDQ 16x24V.

- Configuration on the ET200SP technology module TM Timer DIDQ 10x24V is possible both using Step7 in connection with SIMOTION SCOUT Classic and with SIMOTION SCOUT TIA in connection with the TIA Portal. Further information can be found in the section Configuring output cams to TM Timer DIDQ 10x24V (Page 1904).
- Configuration on the ET200MP technology module TM Timer DIDQ 16x24V is only possible using SIMOTION SCOUT TIA in connection with the TIA Portal. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA.

Further information

Further information on the functions of the TM Timer DIDQ technology modules can be found in the SIMATIC ET 200SP Technology Module TM Timer DIDQ 10x24V and SIMATIC S7-1500/ET 200MP Technology Module TM Timer DIDQ 16x24V.

Configuring a cam track on TM Timer, using DIDQ 10x24V as example

Description

You can configure TO output cam tracks on the ET200SP technology module TM Timer DIDQ 10x24V in SIMOTION SCOUT or with SIMOTION SCOUT TIA in connection with the TIA Portal. The configuration in the TIA Portal is described in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA. The configuration in SIMOTION SCOUT in connection with Step7 is described below:

In order to parameterize the ET200SP TM Timer DIDQ 10x24V with Step7 in connection with SIMOTION SCOUT Classic, a Hardware Support Package (HSP) for Step7 is required. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA in the section on hardware and software requirements.

For the TM Timer DIDQ technology module, the digital outputs are used for the cam output. Irrespective of whether you work with SIMATIC STEP 7 or SIMOTION SCOUT, the parameterization is always performed in HW Config:

Parameterization of TM Timer DIDQ in HW Config

1. Open the HW configuration in SIMOTION SCOUT or SIMATIC STEP 7.
2. Select the header module (IM) with the TM Timer DIDQ in HW Config.
   The TM Timer DIDQ appears in the detail view.
3. To open the context menu, select the TM Timer DIDQ with the right mouse key.

4. Select object properties.
   You can view or change the following properties in the object properties:
   - General
   - Addresses
   - Identification
   - Parameters
5. Open the tab **Parameter** > **DQ0 / DI0**
6. Set the parameter value **Configuration DQ/DI group** to **Use input/output individually**.

   Note

   With this setting, the DQ0 channels can be interconnected as cam output CAM or DI0 as measuring input MI under SIMOTION SCOUT.

7. Press **OK** to close the dialog.
8. Open the menu **Station** > **Save and Compile**.

Note

The technology modules and the individual channels may only be reparameterized in offline state. All changes only take effect after saving, compiling and subsequent download of your changed user project to the controller. The download can be performed in HW Config via **Target system** > **Download to module** or in SCOUT via **Load CPU / drive unit to target device**.

Parameterization of CAM in SCOUT

1. Insert a new output cam or a new cam track or use an existing one.
2. Parameterize the TO Output Cam/Cam Track.
3. Double-click Configuration below the output cam or the cam track in the project navigator. The Configuration window appears in the working area.
4. Activate the selection box **Activate output** and select the option **Cam output (CAM).**

5. Assignment of an output to an output cam/cam track is supported as of V4.2 using symbolic assignment or by entering the HW address.

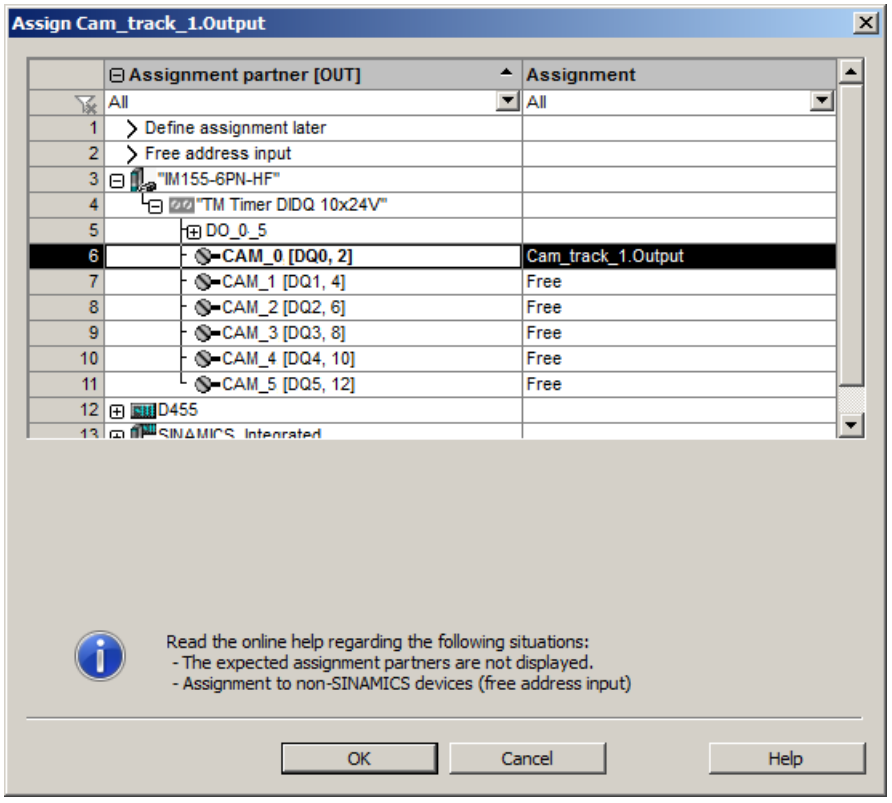

Figure 4-240 Assigning a cam output by means of symbolic assignment

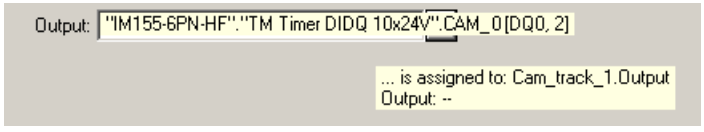

Figure 4-241 Assigning a cam output by entering the HW address

6. Click OK to close the window and select **Project** > **Save**.

Configuring cam tracks on SIMOTION C240

1. Insert a new output cam or a new cam track or use an existing one.
2. Parameterize the TO Output Cam / Cam Track
3. Double-click **Configuration** below the output cam or the cam track in the project navigator. The **Configuration** window appears in the working area.
4. For high-speed, hardware-supported output cams, you can achieve an output accuracy exceeding the servo cycle clock based on the hardware used. Should you wish to configure a high-speed output cam, select the **Activate output** check box and select the **High-speed digital output (DO)** radio button

5. Assignment of an output to an output cam/cam track is supported as of V4.2 either by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address. During a consistency check in SIMOTION SCOUT, no check is made as to whether the entered HW address actually belongs to a **high-speed digital output (DO)**.
6. Click OK to close the window and select **Project > Save** from the menu.

Determining derivative-action times for cam tracks (dead time compensation)

Depending on the system and the device, there is a certain time between the setting of a cam output by the program and the actual reaction of the actuator (e.g. solenoid valve). This time is called dead time and depends, for example, on the load-dependent delay times of a digital output, the switching properties of a valve, etc. Usually the exact value for the dead time is not known and can therefore be determined empirically through measurements.

In order that an output cam switches at the correct time, the dead time must be compensated by specifying a derivative-action time, which offsets the cam output by the dead time. Whereby it must be taken into account that the derivative-action times for switching an actuator on and off are usually different.

The empirical determination of the dead times using a difference measurement as an example.

Note

The procedure applies not only to output cams, but also to cam tracks. However, with cam tracks you can only specify a derivative-action time for the entire cam track.

Example

Lines of glue are to be applied to a product at a defined position and with a fixed length. The glue output is controlled by an output cam or a cam track. The glue is output from the start of output cam (switch-on point) to the end of output cam (switch-off point). The offset of the begin and end of output cam with respect to the velocity can be observed on the length and position of the glue line on the product (see figure). The figure below shows the line of glue for two velocities (v_1, v_2) with $v_2 > v_1$.

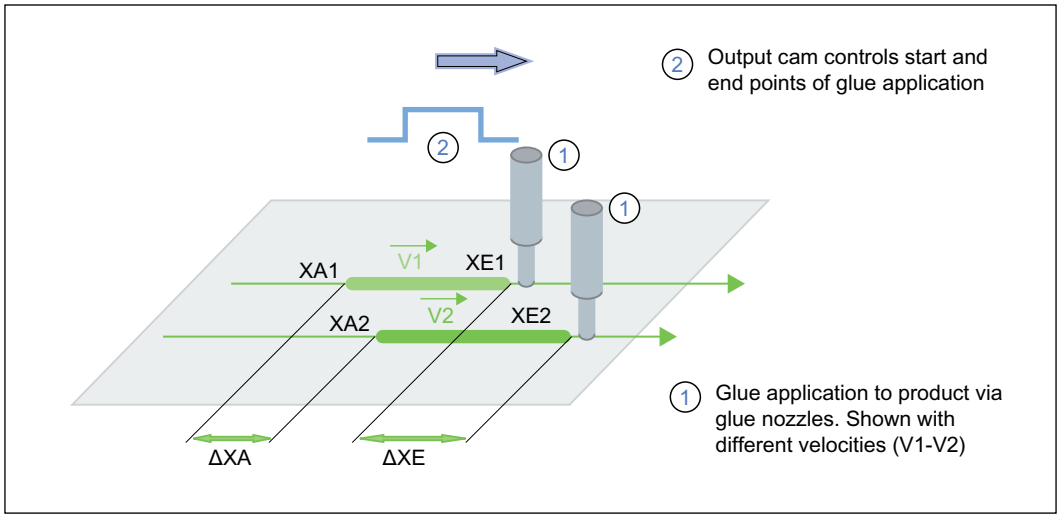

Figure 4-242 Offset of the output of output cam through dead times (dead time compensation)

Procedure:

1. Set all actuation times for start of output cam (activation time) and end of output cam (deactivation time) to 0.
2. Define the velocities for which the positions are to be determined. You should select two velocities that correspond to velocities that occur during production (e.g. minimum and maximum velocity).
3. Start the application and determine the start positions (x_{A1} and x_{A2}) and end positions (x_{E1} and x_{E2}) of the line of glue for the velocities v_1 and v_2.

   Note

   To increase the accuracy, you can perform several comparison measurements and use the average measured values.

4. You can determine the actuation times for the output of output cam using the following formula.
   $\mathbf{t_{activation} = \Delta s/\Delta v = (x_{A2}-x_{A1})/(v_2-v_1)}$
   $\mathbf{t_{deactivation} = \Delta s/\Delta v = (x_{E2}-x_{E1})/(v_2-v_1)}$

5. Enter the calculated actuation times as **activationtime** for the start of output cam and as **deactivationtime** for the end of output cam. Note that the actuation time must be entered as a negative when the output time is to be before the programmed output cam switching time.
6. After you have determined the activation time and the deactivation time for the output of output cam, you should perform a control measurement and check the result.

Note

Depending on the application, it may be, e.g. with eccentric presses, that there is no linear relationship between dead time and velocity (e.g. non-linear response of an applied brake). You have to dynamically adapt the dead time to the respective velocity for these applications. This can be implemented in the application with a user program. After the actuation time has been changed, you have to activate the output cam again with **_enableOutputCam** or the cam track with **_enableCamTrack**.

Using HW enable for cam tracks

You can make the output of cam tracks dependent on a hardware-supported enable (only for TM17 High Feature). The cam track is, for example, output cyclically on the TM17 High Feature. The enable signal (level or edge-controlled) triggers output of the cam track at the output of the TM17 High Feature.

A measuring input TO can be configured to implement an edge-controlled enable at the enable input of the TM17 High Feature. In this case, the cam track is only enabled at the output of the TM17 High Feature once the configured measuring signal occurs.

A hardware enable can be configured for Cam Track TOs, as well as Output Cam TOs. The procedure to be used is described below using the example of a Cam Track TO. Subject to any stated restrictions, this procedure is also used for Output Cam TOs.

In the case of edge-controlled HW enable of a cam output, the input bit **actualInputState** of the assigned "Measuring input" does not provide its terminal level but the level of the enable signal.

Note

You will find more information on the hardware enable in the *Terminal Modules TM15 / TM17 High Feature* Commissioning Manual.

See also

Absolute level-controlled (TM17 High Feature) (Page 1910)

Absolute edge-controlled (TM17 High Feature) (Page 1911)

Setting (overriding) the enable via a program (Page 1912)

Relative edge-controlled (Page 1912)

Absolute level-controlled (TM17 High Feature)

Required configuration for level-controlled HW enable

- Cam track TO or output cam TO is configured
- Digital output on TM17 High Feature parameterized for cam track output, and level-triggered enable input set at this output. The appropriate enable input for the enable signal is parameterized automatically.
- Digital output configured for cam track output (HW address)
- Cam track TO or output cam TO must be active.

Level-controlled enable procedure

For cam tracks with a level-controlled enable, output cams are output for as long as the cam track is active in the TO (set with the **_enableCamTrack** command) and as long as a hardware enable signal, which has been parameterized on the TM17 High Feature, is present. This means that a cam track can also be output multiple times with a continuous enable signal. An output cam, which is already active, is still output even if the enable is deactivated.

An output cam cannot be controlled until a hardware enable signal is present at the TM17 High Feature. If the enable takes place within an output cam, it is no longer output. Subsequent output cams are however output. This can be assigned parameters in the track enable of the TO (see Chapter **Start mode and stop mode**).

It is also possible to operate the output with inverted logic, i.e. the enable input on the TM17 High Feature can be operated inversely and then works in LOW-active mode.

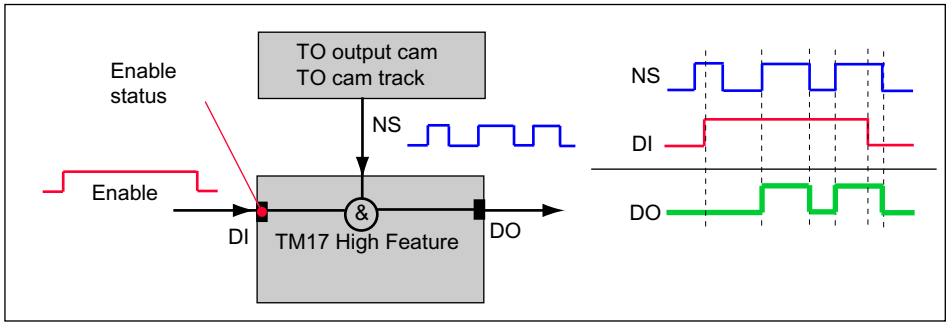

Figure 4-243 Schematic representation of a level-controlled HW enable

Note

With level-controlled HW enables, the **state** system variable does not indicate the status of the output (DO), but rather the status of the cam track signal (C-TS).

Determining the status of the enable

You can determine the status of the enable via the I/O area of the digital input for the enable signal. You will find more information in the *Terminal Modules TM15 / TM17 High Feature* Commissioning Manual.

Absolute edge-controlled (TM17 High Feature)

Required configuration for edge-controlled HW enable

- TO camTrack or TO outputCam is configured.
- Digital output on TM17 High Feature parameterized for cam track output, and edge-triggered enable input set at this output. The appropriate enable input for the enable signal is parameterized automatically.
- TO measuringInput configured (measuring range, edge, operating mode of measurement once).
- TO measuringInput is interconnected to the Enable input for the enabling signal.
- Digital output on the TO configured for cam track output (HW address)
- TO camTrack or TO outputCam must be active.

Evaluating edges for the measurement

For the measuring input, only the measurement once mode is permitted with the following edge detection:

- Rising edge
- Falling edge
- Both edges

A measuring of **both edges, first rising** and **both edges, first falling** and the **cyclic measuring** mode is not supported.

Edge-controlled enable procedure

In the case of edge-controlled HW enable inputs, the cam track is output when the track is active (**_enableCamTrack** command set) and the configured edge has been detected by the configured measuring input at the TM17 High Feature input. This edge enables the hardware gate for outputting the active cam track. The edge is detected in the configured measuring range (if configured) or with **_enableMeasuringInput** (without measuring range) on the measuring input.

The measuring range operates with the IPO/IPO_2 or position control cycle clock and the enable input (measuring input) resolution at 1us. The enable signal position can be evaluated in the usual way using the measuring input.

An output cam cannot be controlled until a hardware enable signal is present at the TM17 High Feature (edge). If the enable takes place within an output cam, it is no longer output. Subsequent output cams are, however, output.

As soon as a new measurement job is transmitted (measuring input activated) or a new measuring range begins, the enable for the active output is reset.

To achieve quick response times, the cam track is continually output by the TO (cyclic cam track output), i.e. all output cams are transmitted to the TM17 High Feature.

In principle, non-cyclic cam track output is possible (e.g. if a hardware enable is coupled to a software enable). The cam track is then only output once after the HW enable.

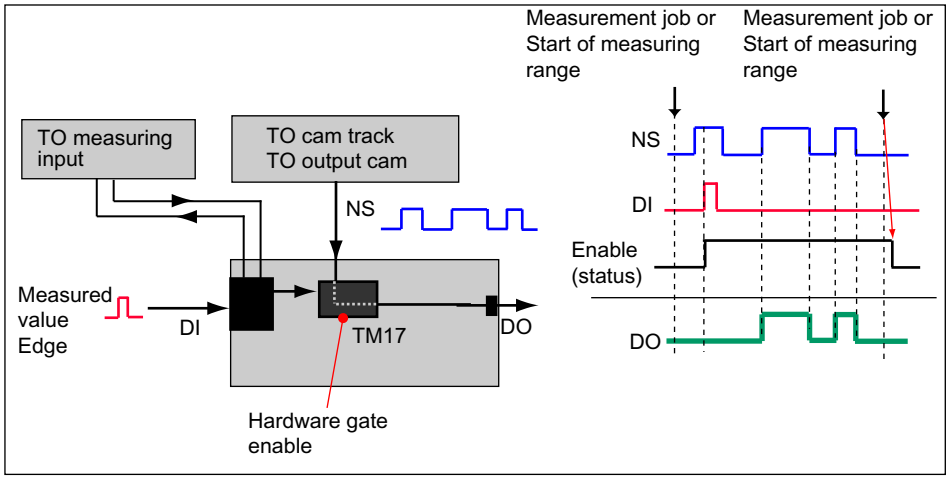

Figure 4-244 Schematic representation of an edge-controlled HW enable

Note

With an edge-controlled HW enable, the **state** system variable does not indicate the status of the output (DO), but rather the status of the cam track signal (C-TS).

Determining the status of the enable

You can determine the status of the enable via the I/O area of the digital input for the enable signal. You will find more information in the *Terminal Modules TM15 / TM17 High Feature* Commissioning Manual.

Setting (overriding) the enable via a program

It is possible to set the HW input of the enable for the cam track via a SW enable signal. For this, you have to access the HW input directly via its address in the user program and set the bit.

- **Level-controlled:**
  Enable is set for as long as the bit is set (functions as enable input). This can be achieved by logically ORing the software enable and enable input (i.e. the enable can also be active "outside of" the software enable, if the enable input is active).
- **Edge-controlled:**
  Enable is set for as long as the bit is set, irrespective of the measurement jobs measuring input TO.
  If the measured-value edge is detected at the enable input during software enable, the enable will remain active even after the software enable has been canceled until a new measurement job / new measuring range occurs.

Relative edge-controlled

You can use the user program to implement a relative, edge-controlled enable input for a cam track.

Follow the steps outlined below:

1. Configure the cam track.
2. Configure a measuring input that detects the measured result for exchanging the cam track (e.g. position of a workpiece edge).
   The measuring input can be connected, for example, to a drive via PROFIBUS DP, a SIMOTION CPU, or a TM15/TM17 High Feature. Unintended edges apparent during measuring can be hidden using the measuring range.
3. Depending on the measured position, the configured cam track can be activated with **_enableCamTrack** in the user program and the detected position can be calculated via the axis reference position. Cam track output then occurs relative to the measured position.

Note that output cams cannot be output immediately after the measurement has taken place, due to data transfer times (for example bus runtimes).

This must be taken into account as follows in your application:

- A certain time interval should be left between the measurement and output of the first output cam.
- The edge-detecting sensor should be positioned in the machine accordingly.

4.3.4.4 Programming/References of TO Cam Track

Programming

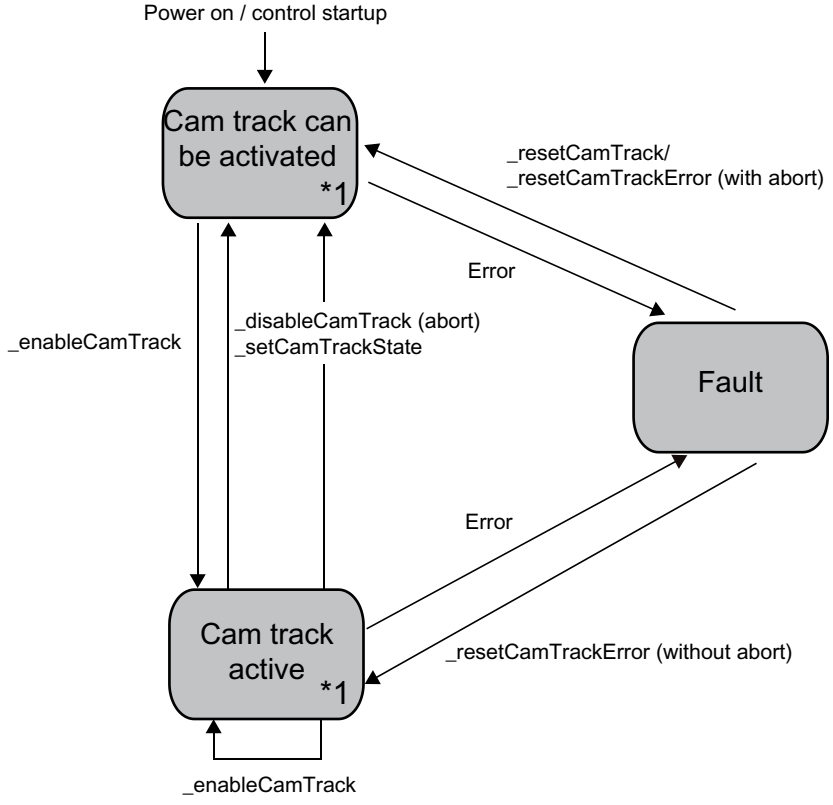

Figure 4-245 Programming and execution model for the Cam Track TO

***1** The following commands are available in the technology object states **can be activated** and **active**:

- **_disableCamTrackSimulation**
- **_enableCamTrackSimulation**

The simulation commands are modal/act in parallel and do not replace any existing _enableCamTrack commands.

Commands

The Cam Track technology object can be addressed in the user program using the following commands:

Table 4-177 Cam Track TO system functions

Commands	Description	Application
_enableCamTrack	Activates cam track execution	Cam track evaluation is activated. If the switching condition for the output of output cam is fulfilled, the output or **state** system variable is set. It is also effective for axes that have not been homed.
_disableCamTrack	Deactivates cam track execution	Cam track evaluation is deactivated. If the switching condition for the output of output cam is fulfilled, the output or **state** system variable is not set.
_enableCamTrackSimulation	This function simulates a cam track by disconnecting the output. The cam track remains internally active, the status is retained, the cam track output is not switched.	Values are calculated, but not forwarded to the hardware. Hardware output cams act as software cams. The cam track remains internally active, the status is retained, the cam track output is not switched. If an active cam track is switched to simulation mode, the output cam status remains the same, and only the control of the output is reset or interrupted.
_disableCamTrackSimulation	The cam track is reset from simulation mode. The cam track output is switched according to the cam track status and the signal inversion.	The output of output cam is switched according to cam track status and signal inversion.
_setCamTrackState	This function deactivates the cam track function and sets the cam track status to the specified value.	This is used if the output should not be controlled by the cam track TO. **Example:** A glue nozzle is controlled by the cam track TO (applying glue dots). As a service function, it should also be possible to rinse the nozzle while constantly controlling it. This is achieved via **_setCamTrackState**.

Commands	Description	Application
_resetCamTrack	This function switches the cam track to an initial state. Pending errors are deleted. Modified configuration data is reset on request.	Creating initial state of cam track TO
_resetCamTrackError	Resets cam track errors. It is terminated with a negative acknowledgment for any errors that cannot be acknowledged at this point.	E.g. acknowledging configuration errors after entering correct values.
_getCamTrackErrorNumberState	Readout of error number status.	Check for occurrence of an error with the specified error number
_getStateOfCamTrackCommand	This function returns the execution state of a command.	Check whether or not cam track switching has already taken place (i.e. the command ID is still available or has already been deleted)
_resetCamTrackConfigDataBuffer	Changed configuration data is collected and stored in a buffer, and is activated with this command in the RUN configuration. This function deletes the configuration data collected in the buffer since the last activation without activating it.	Changing configuration data in the RUN state discards the accumulated modifications.
_bufferCamTrackCommandId	This function enables **commandId** and the associated command status to be saved beyond the execution period of the command. The **commandId** parameter is used to define the command for which the respective status is to be saved. The maximum number of savable command states is specified in the **decodingConfig.numberOfMaxBufferedCommandId** configuration data element.	Subsequent check of how command was terminated, e.g. error-free or number of error that occurred.
_removeBufferedCamTrackCommandId	This function ends the saving of **commandId** and the associated command status beyond the execution period of the command.	Explicit deletion of previously saved command IDs.

For further information on the system functions, please refer to the *SIMOTION TP CAM Reference Lists*.

Process Alarms

You can predefine local alarm responses via SIMOTION SCOUT.

Note

For more information, refer to the *Motion Control Technology Objects Basic Functions* functional description.

How to configure the alarm response:

1. Double-click **Execution system** in the project navigator below the SIMOTION device. The execution system opens.
2. In the execution level tree, select **SystemInterruptTasks > TechnologicalFaultTask**.
3. Click the **Alarm Response** button in the window that then opens. The **Alarm Response** window appears. You can configure the alarm response for every TO here.

A system variable **error** indicates that a technology alarm has been generated. The response to the alarm is displayed in the **errorReaction** variable.

Table 4-178 Possible alarm responses

Alarm Response	Description	Application
NONE	No response	-
DECODE_STOP	Command processing is aborted, the cam track function remains active. Execution on the technology object can continue after **_resetOutputCam** or **_resetOutputCamError**.	The Cam Track TO can only be reactivated after the error has been acknowledged.
CAMTRACK_DISAB LE	Command processing is aborted, current cam track function is aborted. Execution on the technology object can continue after **_resetCamTrack** or **_resetCamTrackError**.	The Cam Track TO can only be reactivated after the error has been acknowledged.

TO Cam Track menus

Cam track menu

Grayed-out menu functions cannot be selected. The menu is only active if a Cam Track TO window is active in the working area.

You can select the following functions:

Table 4-179 Cam track TO menu

Function		Significance/Note
Close		Select **Close** to close the configuration window for the cam track that is open in the working area.
Properties		Select **Properties** to display the properties of the cam track highlighted in the project navigator.
Configuration		Select **Configuration** to determine the configuration data (e.g. output cam type) of the cam track.
Default		Select **Default** to define the defaults of the system variables (e.g. track data and output cam data) of the cam track.
Expert		
	Expert list	Select **Expert list** to open the expert list for the highlighted cam track. The configuration data and system variables can be displayed and changed in this list.
	Configure units	Select **Configure units** to open the **Configure units of the object** window in the working area. You can configure the units used for the selected object here.

Cam track context menu

Grayed-out functions in the context menu cannot be selected.

You can select the following functions:

Table 4-180 Cam track TO context menu

Function		Significance/Note
Open configuration		Select **Open configuration** to display the window for configuring the cam track in the working area. Enter the configuration data for the cam track in this window.
Expert list		Select **Expert list** to open the expert list for the highlighted cam track. The configuration data and system variables can be displayed and changed in this list.
Cut		Select **Cut** to remove the selected object and save it to the clipboard.
Copy		Select **Copy** to copy the selected object. It is stored in the clipboard.
Paste		Select **Paste** to insert the cam track stored in the clipboard.
Delete		Select **Delete** to delete the selected cam track. The entire data of the cam track is deleted permanently.
Rename		Use **Rename** to rename the object selected in the project navigator. Note that with name changes, name references to this object are not adapted.
Expert		
	Insert script folder	**Insert script folder** enables you to insert a folder below the TO. You can create scripts in this folder in order to, for example, automate the configuration.
	Import object	**Import object** imports the data of a SIMOTION object from another project which was previously created with a selective XML export. You cannot import the entire project, only the data of the SIMOTION object.
	Save project and export object	**Save project and export object** exports selected data of the selected object in XML format. This data export can then be reimported into other projects. Only the data of the selected object, not the entire project, is exported.
Print		Select **Print** to print the data of the cam track. All system variables and configuration data with the associated values are printed.
Print preview		Select **Print preview** to open the preview of the output cam data to be printed.
Default		Select **Default** to define the system variables (e.g. track data and output cam data) of the cam track.
Properties		Select **Properties** to display the properties of the cam track highlighted in the project navigator.

4.3.5 Measuring Input TO - Part III

4.3.5.1 Overview of Measuring Input TO

General information about the Measuring Input TO

The **Measuring Input** technology object is used for fast, accurate measurement of actual positions. This is achieved with hardware support (e.g. measuring input on the associated drive unit).

Measurement jobs are activated and configured using the functions of the Measuring Input TO.

Local and global measuring inputs

Depending on the hardware platform, local and global measuring inputs are available for the measuring tasks. Local measuring inputs are axis-related and are mainly implemented in the drive. The actual position value is measured.
Global measuring inputs can be freely assigned to the axes and add an internal time stamp to the measurement result for more precise determination of the axis positions.

Assignment to axes and encoders

The measuring input TO can be assigned to the following axes/encoders:

- Position, synchronized, or path axes
- External encoders
- Virtual axes (only global measuring inputs)

Note

It is not possible to assign a measuring input to speed-controlled axes.

Measurement once

A measurement job is started by a program command. When a signal edge is detected at the measuring input, the current position (for virtual axes, either setpoint or actual value, as required) is stored temporarily. When the current system cycle clock finishes (either Servo cycle clock or interpolator cycle clock), this value is available in a system variable for further processing in low-priority tasks.

Cyclic measurement (global measuring inputs only)

A measurement job is started by a program command. Up to two edges can be detected for each processing cycle clock of the measuring input TO (with onboard measuring inputs of SIMOTION D, CX32, CX32-2, CU310, CU310-2, CU320, CU320-2 max. of two edges for every three position control cycle clocks). These are stored in system variables and remain available until they are overwritten by more recent measurements. The measured values are detected continuously/ cyclically until the program command is deactivated. Cyclic measuring is only possible with global measuring inputs.

Measuring range

By specifying a measuring range, the validity of the measurement can be restricted to this range; the measurement will only be activated when the position lies within the measuring range.

One measuring input for more than one axis (as of V4.0)

By creating a measuring input with the "monitoring measuring input" property, measurements can be made with one measuring input simultaneously on more than one axis/external encoder.

4.3.5.2 Fundamentals of Measuring Input technology object

Measuring input types - local and global measuring inputs

Depending on the hardware platform (measuring input type), local and global measuring inputs are available for the measuring tasks. Compared to local measuring inputs, global measuring inputs have a greater range of functions and enable measurements to be made faster. During the configuration of a Measuring Input TO, you must consider which functions (measurement, interconnection options) are to the used. Depending on the requirements, you have to configure a local or a global measuring input.

Local measuring inputs

At a signal edge on the respective input, the actual values of a SIMOTION C230-2, C240, D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2 or on the drive (for example, SIMODRIVE 611U, MASTERDRIVES MC, SINAMICS) of a connected encoder are acquired with positional accuracy in order to determine lengths or distances. The device on which the measuring system is available, is used for the measuring.

The assignment of inputs is not fixed depending on the hardware and is performed in the SCOUT engineering system during configuration of the Measuring Input TO symbolically or via the HW address.

Local measuring inputs refer to the respective drive. Configuration usually takes place via drive parameters.

Global measuring inputs

With a signal edge at the relevant input, the current actual values of one or more encoders are measured using time stamp functionality with positioning accuracy in order to provide information for determining lengths or distances (possible with any encoders included in the project).

Each measurement result is assigned a very precise "internal" time stamp which is then used to determine the corresponding actual position in SIMOTION.

The assignment of inputs is not fixed depending on the hardware and is performed in the SCOUT engineering system during configuration of the Measuring Input TO symbolically or via the HW address.

Global measuring inputs support extended functionalities

- More than one measuring input on one axis/encoder, whereby these can be active simultaneously.
- More than one measuring input is assigned to one measuring input (monitoring measuring input).
  With this functionality, one measuring input can have a functional effect on more than one measuring input and therefore on more than one axis/external encoder.
- Cyclic measuring
- Measuring on virtual axes
- should be configured on the respective device. (I/O channel is configured as measuring input (**MI)**).

- can be assigned on the SIMOTION-CPU to an axis TO or external encoder TO.
- Configuration by way of symbolic assignment is possible.

If current controller clock cycles <> 125 µs are used, the parameter calculations of the drive must be taken over into the PG and the Fast IO configuration must be recreated when using global measuring inputs (for further information, see chapter entitled Current controller clock cycles <> 125 µs / use of output cams and measuring inputs in the TM15 / TM17 High Feature Terminal Modules Commissioning Manual)

Time stamp functionality

With global measuring inputs, a time value (time stamp) is stored with each measurement. In this way, the exact axis position can still be determined even with different propagation delays between the time of the measurement to the evaluation.

Hardware for measuring inputs

Description

Global measuring inputs are only supported by certain hardware (measuring inputs) (see table below).

Hardware for local and global measuring inputs

The following table provides an overview of which hardware supports local and which hardware supports global measuring inputs.

Table 4-181 Hardware for local and global measuring inputs

Hardware (measuring inputs)	Local measuring inputs	Global measuring inputs
TM15, TM17 High Feature	-	X
SIMOTION C240/C240 PN (B1-B4)	-	X
SIMOTION C230/C240 (M1, M2)	X	-
SIMOTION D4xx	X	X (as of V4.1)
SIMOTION D410-2	X	X
SIMOTION D4x5-2	X (X122/X132 only)	X (X122/X132/X142)

ET200MP TM Timer DI/DQ 16x24V	8	-	X

Interconnections

The Measuring Input TO can be linked to all technology objects, such as Axis TO (positioning axis, following axis, path axis) and External Encoder TO.

A TO, such as an Axis TO, can be interconnected simultaneously with several Measuring Input TOs. The assignment can be configured.

With local measuring inputs, the measuring input TO is assigned symbolically or if <V4.2 as part of its configuration. The configuration specifies the number of the measuring input to be used and the number of the encoder on the assigned axis.

(See also Local measuring (Page 1950))

With global measuring inputs, the HW address is used for assignment to the measuring input.

(See also Overview (Page 1951))

With V4.2 and higher, **global measuring inputs** can also be configured with symbolic assignments. Address handling is thereby no longer required.

Measuring input connection options

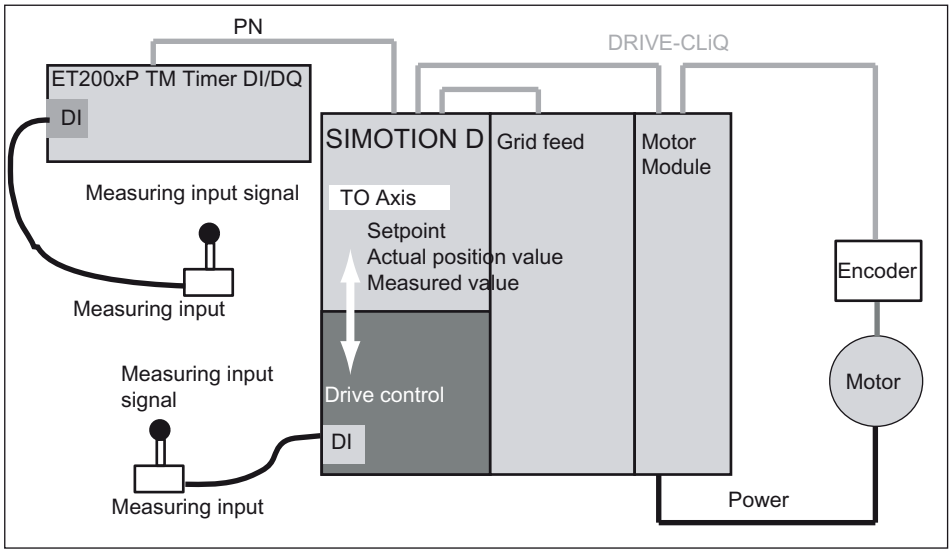

Figure 4-249 Connection of measuring input to ET200xP TM Timer DIDQ

Several Measuring Input TOs on one axis/encoder (as of V3.2)

Several Measuring Input TOs can be assigned to an Axis TO or an External Encoder TO. The number of measuring inputs is determined according to the functionality (local or global).

Local measuring inputs

For local measuring input (see Hardware for measuring inputs (Page 1920)) the following applies:

- Only **two** measuring inputs can be configured per axis TO or external encoder.
- Only **one** measuring input can be active on an axis TO or external encoder.

Global measuring inputs

For global measuring inputs (see Hardware for measuring inputs (Page 1920)) the following applies:

- **More than one** measuring input can be configured per axis TO or external encoder.
- **More than one** measuring input can be active simultaneously on an axis TO or external encoder.

As far as interconnections of measuring input TOs are concerned, **one** local measuring input can be configured on an onboard measuring input and **one** or **more** global measuring inputs can be configured and simultaneously active on measuring inputs of C240/C240 PN (B1-B4), D4xx, D410-2, D4x5-2 (X122/X132/X142), CX32, CX32-2, CU310/310-2/320/320-2 and TM15/TM17 High Feature, ET200xP TM Timer DI/DQ.

Measuring input types - local and global measuring inputs (Page 1919)

More than one measuring input TO on a single measuring input (C230-2/C240 only)

It is possible to assign more than one measuring input to a single measuring input (onboard inputs C230-2/C240 (M1-M2)). In this case, however, it must be ensured that only one measuring input is active at any one time.

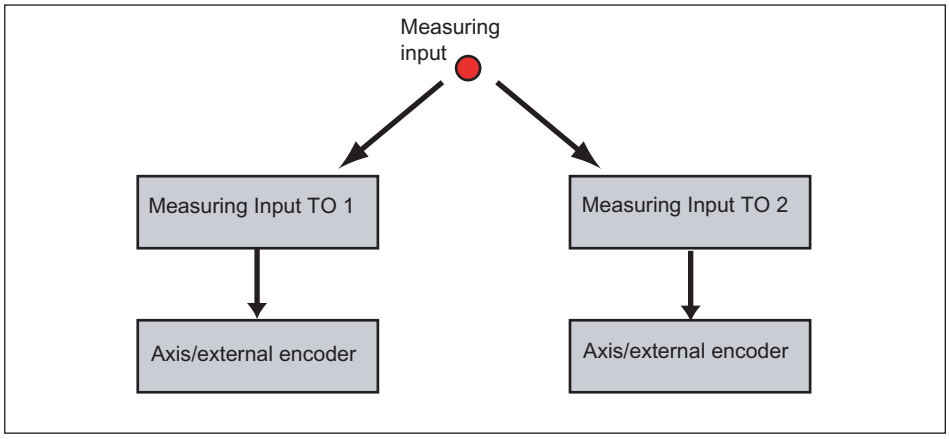

Figure 4-251 Interconnection of more than one measuring input with a single C230-2/C240 (M1-M2) onboard input

Measuring one measurement event on several axes - Listening measuring input (V4.0 and later)

With the "Monitoring measuring input" function, the measurement event of a measuring input can also be measured simultaneously by several Measuring Input TOs. To do so, an original measuring input (hereinafter referred to only as measuring input) is configured on a HW input. Additional Measuring Input TOs can be configured as monitoring measuring inputs and interconnected with the Measuring Input TO. The monitoring Measuring Input TOs "listen in" on the measurement event of the Measuring Input TO.

The monitoring Measuring Input TOs can also be assigned to other axes / external encoders. With this functionality, one measuring input can have a functional effect on several axes / external encoders.

The "listening in" property on the Measuring Input TO is set with the configuration data element **inputAccess**:=TO_INTERFACE.

Note

An event can only be measured on more than one axis/external encoder at the same time if the measuring input TO is configured as a global measuring input (see Hardware for measuring inputs (Page 1920)). Only these inputs have the necessary time stamp functionality.

Procedure

One measuring input is interconnected with one measuring input, as usual. This measuring input is the **original** measuring input. The measuring process is activated and the measurement events are measured on this measuring input. The monitoring measuring inputs are connected internally to the measuring input via an interconnection interface, and the measurement events are communicated simultaneously.

The activation and deactivation of the measurement, as well as the configuration of a measuring range can only take place on the measuring input. Activation and deactivation commands issued on the monitoring measuring input are not executed and are returned with errors. Technology alarm 40011 is issued.

Functionality

- Activation and deactivation of the measuring process on the measuring input only. These commands are not active on the monitoring measuring input.
- Measuring range and edge selection are only available on the measuring input.
- The monitoring measuring input must be configured correctly at the time of the measurement (measuring input cycle clock, system number).
- A monitoring measuring input does not have its own measuring input and cannot perform any measurements of its own.
- The processing cycle clocks of the measuring input and the monitoring measuring input do not have to have the same setting. However, accuracy is lost if the measuring input TO is assigned to the IPO and the monitoring TO measuring input is assigned to IPO_2, and IPO and IPO_2 are configured differently.

The following must be considered when interconnecting more than one measuring input:

- The measuring input and the monitoring measuring input are interconnected with one axis TO or external encoder.
- A measuring input can be interconnected with **more than one** monitoring measuring input **on the output side**.
- A measuring input has **no interconnection on the input side**.
- A monitoring measuring input can only be interconnected with **one** measuring input **on the input side**.
- A monitoring measuring input has **no interconnection on the output side**.
- An axis TO or an external encoder can be interconnected with more than one measuring input, including a mixture of measuring inputs and monitoring measuring inputs. Depending on the hardware (see Chapter **More than one measuring input on one axis/encoder (as of V3.2)**), more than one measuring input may be active simultaneously.

- Local measuring inputs (onboard I/O from SINAMICS and C2xx) cannot be used for the measuring input. Only global measuring inputs can be used (see Hardware for measuring inputs (Page 1920)).
- Only single-stage interconnections are possible.

Note

You will find more information on interconnections in the *SIMOTION Runtime Basic Functions* function manual.

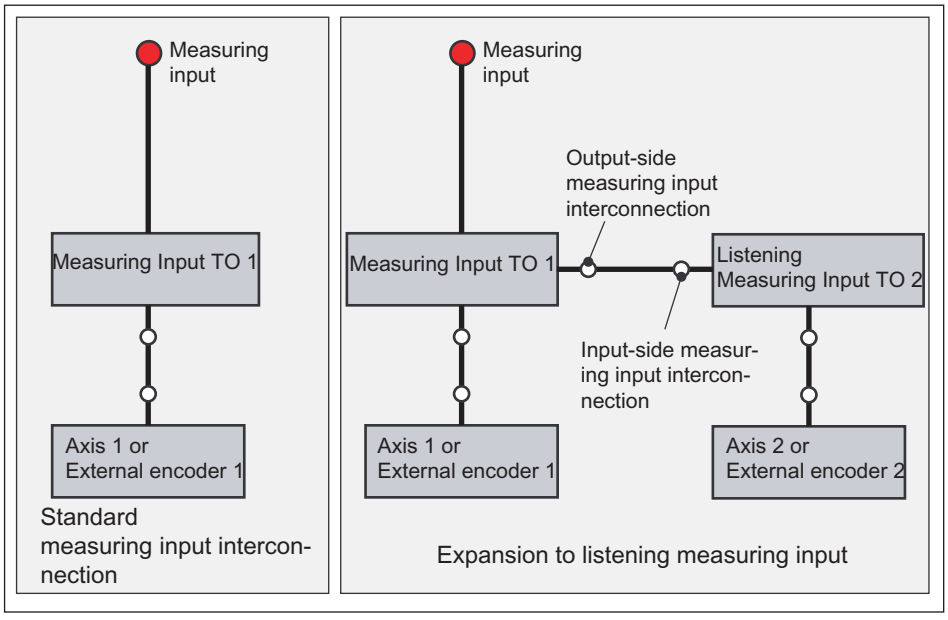

Figure 4-252 Interconnecting monitoring measuring inputs

Measuring input types - local and global measuring inputs (Page 1919)

Measurement

The measuring process is divided into one-time and cyclic measurement modes. The operating mode is distinguished using two separate program commands.

Table 4-183 Overview of one-time and cyclic measurement functions

Measurement once	Cyclic measurement (global measuring inputs only)
As of version V1.0	As of Version V3.2
Call up with **_enableMeasuringInput** command.	Call up with **_enableMeasuringInputCyclic** command.
Measurement jobs must be issued individually for each measurement.	Measuring is activated just once and runs cyclically until deactivated with **_disableMeasuringInput**.

Measurement once	Cyclic measurement (global measuring inputs only)
Several interpolation cycle clocks between two measurements	Up to two edges can be measured in each processing cycle clock of the measuring input TO (IPO interpolation cycle clock, IPO_2 interpolation cycle clock or position control cycle clock). The minimum distance between two measurements in SIMOTION D410-2, D4x5, D4x5-2 (X122/X132) onboard, CX32, CX32-2 and CU310/310-2/320/320-2 is 3 position control cycle clocks. The measured values must be read from the user program before they can be overwritten by a new measurement.
Supported by: For hardware for local and global measuring inputs, see Hardware for measuring inputs (Page 1920)	**Supported by:** For hardware for global measuring inputs, see Hardware for measuring inputs (Page 1920) (excluding TM15)
Optional measuring range is possible.	One measuring range can be defined as of V4.0. Prior to V4.0, measuring range for TO cannot be configured (must be solved in the application).

One-time measurement

In one-time measurement mode, the measured result must be waited for. On its occurrence, the measuring process is terminated.

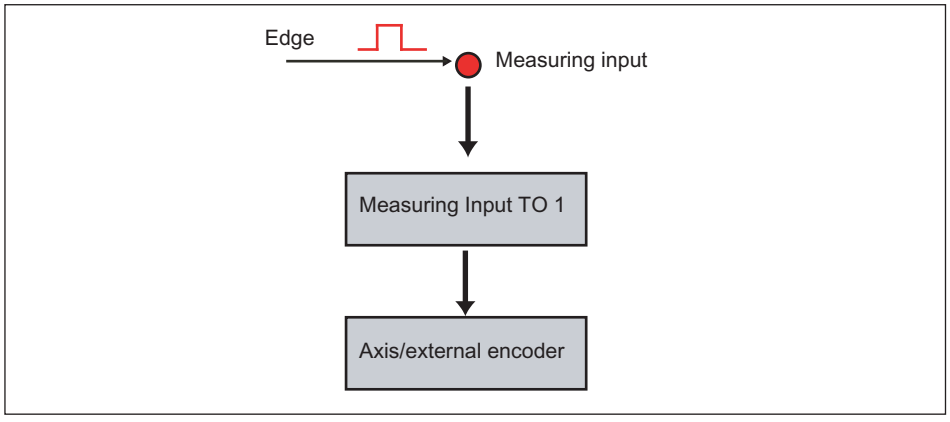

Figure 4-253 TO measuring input, one-time measurement

Measurement process

A measurement is activated by the **_enableMeasuringInput** program command. The **enableCommand** variable indicates the execution status of this command.

The **control** system variable indicates whether the measuring function is active. If, for example, a positive measured edge has been selected and the measuring input is deflected, i.e. a measuring event occurred, the system variable cannot assume the value ACTIVE until the measuring input is no longer deflected.

The **state** variable is set to the value WAITING_FOR_TRIGGER. A rising edge (from 0 to 1) or a falling edge (from 1 to 0) triggers the measuring function. The **measuredEdgeMode** parameter can be used to select which type of edge will be acquired. Acquisition of both measured edges can also be activated by means of a measurement job, in which case you can specify in the command which edge will be acquired first, for example, first the rising edge and then the falling edge.

The drive must be capable of evaluating the signal edge (rising, falling, or both edges) selected by SIMOTION at the measuring input.

When the measurement result is received, the measurement position is stored. Once the measurement has been made, the **state** variable is set to TRIGGER_OCCURED, and the measured values can be evaluated using the **measuredValue1** and **measuredValue2** variables for two measured edges.

Activation/deactivation of measurement job

The measurement job remains active until the measurement result has been obtained or until the job is terminated by a command (e.g. **_disableMeasuringInput**).

The measuring process must be reactivated for each new measurement.

The measuring accuracy depends on the accuracy of the hardware used. It lies in the range of microseconds.

Table 4-184 Storing the measurement results in the system variables

Edges per processing cycle of the TO measuring input	measuredValue1	measuredValue2	Remark
Rising edge	First rising edge	---	Only the first rising edge is acquired (each new edge requires a new measurement job).
Falling edge	First falling edge	---	Only the first falling edge is acquired (each new edge requires a new measurement job).
Both edges	Chronologically the first edge	Chronologically the second edge	The hardware used must provide the possibility of evaluating the edge selected with SIMOTION (rising, falling, or both edges) at the measuring input (e.g. for SIMOTION D, SINAMICS S120 CU320(-2), TM1x).
Both edges, rising edge first	First rising edge	First falling edge	TM1x; D4xx, D4xx-2 (X122/X132), CX32, CX32-2, CU320, CU320-2: The minimum distance of the first edge to be measured from the previous edge must be several servo cycles so that the first edge can be acquired. D4x5-2 (X142): No restrictions With hardware support, the "false" first edge is ignored.
Both edges, falling edge first	First falling edge	First rising edge	

Cyclic measurement (as of V3.2)

In cyclical measurement, up to two edges can be measured per processing cycle of the measuring input TO IPO interpolation cycle clock, IPO_2 interpolation cycle clock, and servo cycle clock in the case of TM17 High Feature, D4x5-2 (X142) and C240 (B1-B4).

In the case of D435-2 DP/PN, D445-2 DP/PN, and D455-2 DP/PN, it is also possible to configure a processing cycle clock in Servo_fast or IPO_fast for the measuring input.

In the onboard measuring inputs of D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2, CU310/310-2/320/320-2, the minimum duration between two measurements is three servo cycles. Measuring signals in between are not detected.

Measurements are taken cyclically, until they are terminated with a command.

The measured values must be read from the user program in good time before they are overwritten by a new measurement.

Note

Cyclic measuring is only possible with global measuring inputs (see Hardware for measuring inputs (Page 1920)(excluding TM15)).

You are not prevented from also using local measuring inputs for cyclic measuring during configuration. However, this is a pure software solution, and only unique measuring processes are cyclically collected. The minimum time between two measurements is therefore much longer than with cyclic measuring with global measuring inputs.

When cyclic measurement is activated with local measuring inputs (command **_enableMeasuringInputCyclic**), as of V4.2 **Note 40014** is output stating that during cyclic measuring with local measuring inputs, results may be lost if they are not spaced sufficiently.

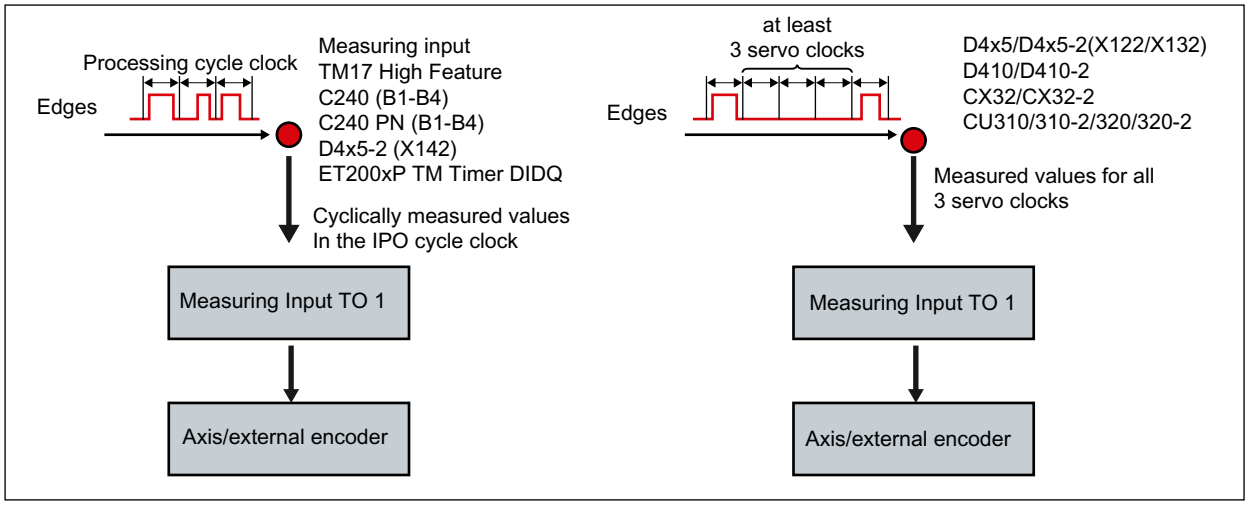

Figure 4-254 Measuring input TO, measuring operation cyclic measurement (example processing cycle clock IPO, no cycle clock scaling IPO:Servo, IPO = Servo)

Measurement process

A measurement is activated by the **_enableMeasuringInputCyclic** program command. The **cyclicMeasuringEnableCommand** variable indicates the execution status of this command.

The **control** system variable indicates whether the measuring function is active. Measuring begins on activation of the program command.

The **userdefault.measurededgecyclicMode** system variable is used to select which type of edge should be acquired. Up to two edges can be measured per processing cycle of the measuring input TO (e.g. IPO interpolation cycle clock, IPO_2 interpolation cycle clock, or position control cycle clock).

The measured values are taken over in the measurement equipment at time Ti and placed in the telegram to the control. After that, the measurement equipment is ready again. In the telegram, two edges per servo can be transmitted to the control. These are provided in a buffer and processed by the measuring input TO in its processing cycle clock.

With cyclic measuring, the **state** variable remains in the WAITING_FOR_TRIGGER state even after the arrival of events, as waiting is continued for further events. Increases on the **countermeasuredvalue1/2** event counter indicate that a measurement event has occurred.

When the measurement event occurs, the measurement position is stored. After successful measurement, the measured values are stored in the **measuredValue1** and **measuredValue2** system variables and can be evaluated. The measured values must be read from the user program before they can be overwritten by a new measurement. For example, if polling is being performed in the IPO-synchronous task, up to two edges can be evaluated per IPO cycle clock.

Table 4-185 Archiving measurement results in the system variables within an IPO cycle clock

Edges per processing cycle of the measuring input TO	measuredValue1	measuredValue2	Description
Rising and falling	First rising edge	First falling edge	- If both edges are to be measured, the measured values of the rising edges are in **measuredValue1**; those of the falling edge in **measuredValue2**, irrespective of the order in which they occur.
Rising only or falling only	First edge	Second edge	-
One edge only	First edge	-	-
More than two edges	First edge	Second edge	- Error status is synchronously reported with the **error** system variable, and the 40009 TO alarm is output.

If the measuring equipment only reports one value in a position control cycle, only one value will be forwarded to the TO and this overwrites the one matching **measuredValue** and increments the counter.

The error condition "more than two edges" signaled via system variable and TO alarm can only occur if scaling of the servo down to the processing cycle clock of the measuring input TO is configured, that is, if more than two edges arrive within one TO processing cycle but across several servo cycles. If more than two edges occur within one servo cycle, the additional edges are already discarded in the measuring equipment. The technology object does not contain any information about this.

counterMeasuredValue system variable

The **counterMeasuredValue1** and **counterMeasuredValue2** counter variables are defined for the **measuredValue1** and **measuredValue2** system variables and are automatically incremented by a value of one for each measuring input. In this way, new events can be traced

immediately, e.g. even if the position value happens to be identical with the previous measurement.

Measuring events can also be read out from tasks that are not synchronous with the processing cycle clock. A measuring event that is not fetched from the user program in time can be detected by larger increments in the counting variables.

The counting variable counterMeasuredValue1 is incremented by "1" each time a new measurement input has been made in **measuredValue1**.

The counting variable counterMeasuredValue2 is incremented by "1" each time a new measurement input has been made in **measuredValue2**.

Measured values lost due to too many edges per unit time cannot be indicated via **measuredValue1** and **measuredValue2**. They are therefore also not counted in the counting variables **counterMeasuredValue1** and **counterMeasuredValue2**.

Counter variables are reset on power-up, reset, restart, and on first activation of cyclic measuring. Counter variables are not reset if cyclic measuring was already active and, for example, only a parameter was changed with the **_enableMeasuringInputCyclic** command.

Activation/deactivation of measurement job

The measurement job remains active until it is deactivated with the **_disableMeasuringInput** command.

See also

Measuring input types - local and global measuring inputs (Page 1919)

Lost edges during cyclic measurement

Lost edges

Lost edges are edges that did exist at the measuring input (after filtering) and were also to be acquired according to the configuration (e.g. only rising edges), but were not signaled via the system variables **measuredValue1** and **measuredValue2**.

Lost edges do not result in incrementation of the counting variables **counterMeasuredValue1** and **counterMeasuredValue2**.

Edges that are filtered out, for example, at X142 via the settable digital filter do not exist for the measuring input logic.

Edges that are not "seen," for example, because the sensor is dirty, are not acquired in any way.

Measured values

Measured values are only acquired for the edges that are also to be calculated according to the configuration of the measuring input TO, that is, optionally

- 2 rising edges,
- 2 falling edges or
- one rising and one falling edge.

During parameterization, generate "only rising edges," that is 2 print marks (comprising 2 rising and 2 falling edges) in total 2 measured values.

Edges can be lost in 2 ways:

1. D4x5-2 (X142), TM17 High Feature and C240 (B1-B4) can acquire up to 2 measured values per position control cycle. If more edges occur that would result in a measured value, these will already be lost in the measuring equipment.
2. Possible scaling of "servo cycle clock" down to "TO processing cycle clock" can result in the measurement hardware communicating the measured values to the measuring input TO, but these not all being made available to the user interface. Only the system variables **measuredValue1** and **measuredValue2** exist.
   Example:
   X142: Servo cycle clock = 1 ms; processing cycle clock measuring input TO in the IPO = 2 ms.
   2 x 2 edges occur in the 2 servo cycles within one IPO cycle.
   ⇒ Of the 2 x 2 edges, only the **first** two edges are entered as measured values

In the case of the onboard measuring inputs of D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2,

CU310/310-2/320/320-2, the minimum period between two measurements is 3 position

control cycles. Measuring signals in between are not detected.

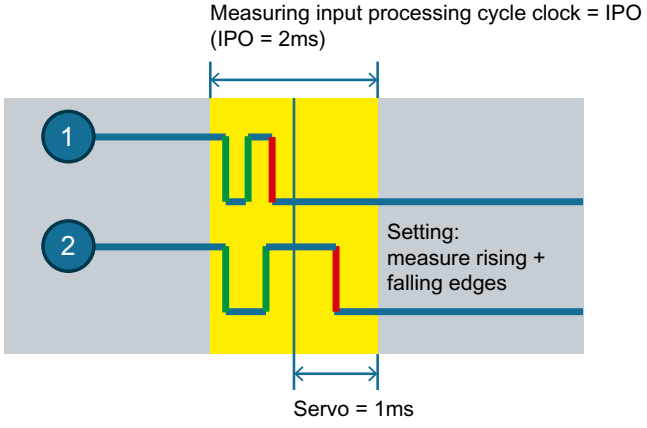

Figure 4-255 (1): Edge lost in measurement hardware(2): Edge lost due to cycle clock scaling

Case 1: Loss of edges in measuring equipment

Edges that result in more than 2 measured values per position control cycle are lost in the measuring equipment. Loss of these edges is not signaled via system variable **error** and TO alarm 40009.

In the case of X142 and ET200xP TM Timer DI/DQ, there is a separate edge counter LEC for lost edges.

Case 2: Loss of edges due to scaling of servo cycle clock down to TO processing cycle clock

Only if the "servo cycle clock" is scaled down to "TO processing cycle clock," can lost edges be signaled via TO alarm.

Example:

Processing cycle clock measuring input TO in the IPO = 2 ms

Servo cycle clock = 1 ms

In this case, the measuring input can transfer up to 2 measured value per 1 ms to the TO (that is, up to 4 in total). The TO can, however, provide the user program with only the first two measured values via the system variables **measuredValue1** and **measuredValue2**. **counterMeasuredValue1** and **counterMeasuredValue2** are each incremented by "1".

In this case, the error condition is signaled synchronously via system variable error and TO alarm 40009 is output.

Behavior of the count variables counterMeasuredValue1/2

Lost edges can result in the counters counterMeasuredValue1 and counterMeasuredValue2 diverging.

Example: Measurement of rising and falling edges

Processing cycle clock measuring input TO	Edges	counterMeasuredValue1	counterMeasuredValue2
N		:	:
N+1		6	6
N+2		6	6
N+3	rising-falling	7	7
N+4	rising	8	7
N+5	falling	8	8
N+6	rising-falling-*rising*	9	9
N+7	falling	9	10
N+8	rising-falling-*rising*	10	11
N+9	falling	10	12
N+10	rising-falling-*rising*	11	13
N+11	falling	11	14

**Italics: Edge is lost*

Hardware-specific aspects

X142 and ET200xP TM Timer DI/DQ / Lost Edge Counter

X142 and ET200xP TM Timer DI/DQ have a counter for lost edges (Lost Edge Counter). Up to 7 lost edges are recorded in one counter. The counter value is transmitted cyclically and can be symbolically interconnected in the controller. (LEC). Because the LEC only counts lost edges, for

example, only the not measured "rising" edges are counted in measuring mode "only rising edges."

The LEC only counts the edges that are lost on the X142 or ET200xP TM Timer DI/DQ. Edges lost due to scaling of the servo cycle clock down to TO processing cycle clock are not acquired by the LEC.

The edges lost on the measuring equipment are only signaled via the LEC. That is, they are not signaled via system variable/TO alarm.

Via an I/O variable, it is possible to access LEC symbolically and evaluate it in the user program.

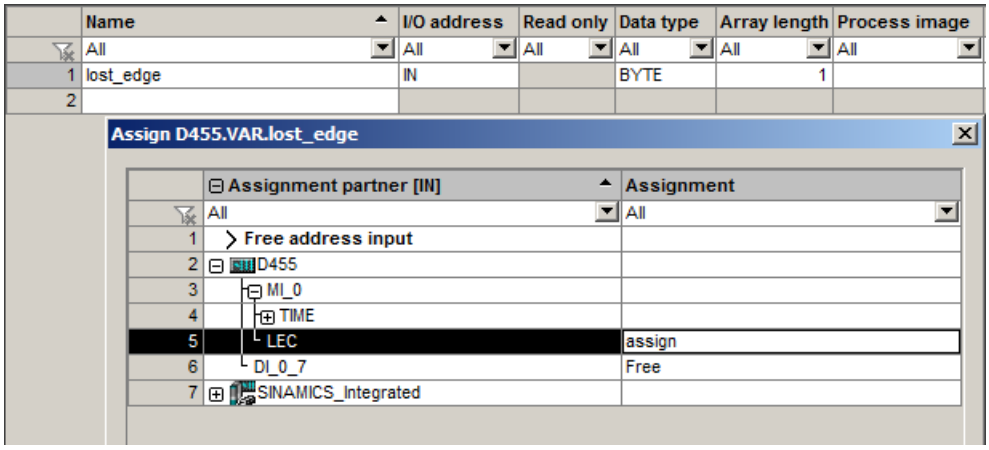

Figure 4-256 Accessing I/O variables on LEC

The value in LEC is automatically reset during cyclic measurement, und the current measured values taken over from the measuring equipment to be transmitted to the controller and the measuring equipment is automatically reactivated for the next cycle.

If the servo cycle clock is scaled down to the TO processing cycle clock, the value must be fetched in good time; otherwise, it will be overwritten.

Example:

Measuring input processing cycle clock: IPO = 2 ms

Servo/bus cycle clock: 1 ms

⇒ the I/O variable assigned to the LEC must be evaluated in the servo-synchronous user task.

TM17 High Feature

If no edges are measured in a cycle, the TM17 High Feature can measure up to 4 edges in the following cycle. In this case, the 3rd and, if necessary, 4th edges are buffered (buffering of up to 2 edges).

In the following cycle, the buffered edges are transferred first, even if new edges have been acquired; these new edges are buffered again.

You will find further information in chapter *System behavior during cyclic measurement* in the Terminal Modules TM15 / TM17 High Feature Commissioning Manual.

Measurement activation times

Various response times (e.g., effects of propagation delays) must be taken into account in the application for the measuring function, depending on the axis/external encoder connection (Onboard C2xx, PROFIBUS axis), the drive used (611U, MASTERDRIVES MC, SINAMICS), and the execution level (IPO/IPO_2, or position control cycle clock).

The measuring process is started with **_enableMeasuringInput** or **_enableMeasuringInputCyclic** in the user program.

The runtime up to the evaluation of the measured edge at the HW input is dependent on the configuration. In order to detect the measured edge correctly, you must ensure in the user program that **_enableMeasuringInput** or **_enableMeasuringInputCyclic** have been executed prior to this runtime.

Utilities & applications

The SIMOTION Utilities & Applications contains examples of and help for SIMOTION. It serves to support SIMOTION users and clarify SIMOTION applications.

SIMOTION Utilities & Applications includes, for example, a tool to estimate:

- The time elapsed from activating the **_enableMeasuringInput** and **_enableMeasuringInputCyclic** command to the measuring input job becoming effective in the drive
- The minimum time between two measurement jobs
- Derivative action time when applying a measuring range (fine range)

The SIMOTION Utilities & Applications is shipped with the SIMOTION SCOUT software package.

Measuring range

A measuring range (system variable **userdefault.measuringRangeMode**) can be predefined for a measurement job. This can either be valid for the whole range, or restricted by entering a measuring range start and end.

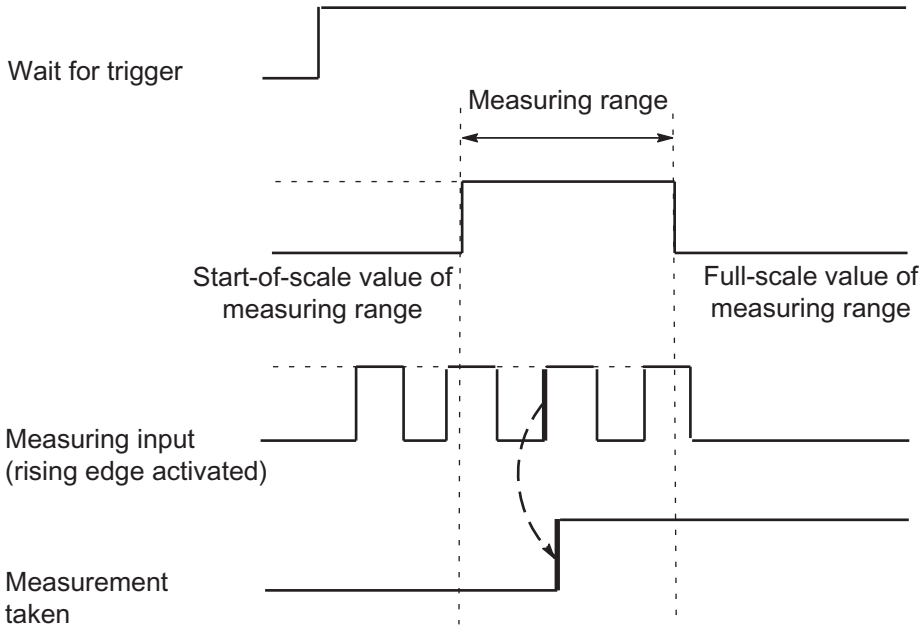
Note

The measuring range can be used for single measurement and, as of V4.0, for cyclic measurement. If a measuring range is required for cyclic measurement (prior to V4.0), this can be implemented in the application.

A user program in the IPO-synchronous task can detect up to two edges in each IPO cycle clock. If an "unintended edge" is detected, it simply has to be rejected.

Measuring process with measuring range

When measuring with a measuring range, initially, **_enableMeasuringInput** or **_enableMeasuringInputCyclic** simply records the measurement job in the system. The measurement will then be triggered only when the axis position lies within the measuring range. Measuring is only valid within this range.



Wait for trigger
Measuring range
Start-of-scale value of measuring range
Full-scale value of measuring range
Measuring input (rising edge activated)
Measurement taken

Figure 4-257 Measuring in the measuring range

The time that elapses after reaching the start of the measuring range on the axis (mechanics) until the measured edge is evaluated at the HW input is dependent on the configuration. In order to activate the measuring function on reaching the desired start of the measuring range on the axis (mechanics), you must preset the start of the measuring range with the **_enableMeasuringInput** or **_enableMeasuringInputCylic** command, depending on the axis velocity and response time.

This procedure is the same for the end of the measuring range. Here, it is important that the measuring function is deactivated as soon as the end of the measuring range on the axis (mechanics) is crossed.

If no measured edge is detected in the measuring range during a single measurement, the measuring job is aborted and a TO alarm is triggered. During cyclic measuring, each measurement result in the measuring range is reported. However, a TO alarm is not output if no measured edge is detected in the measuring range.

During cyclic measuring, the measurement remains active for modulo and non-modulo axes even after the measuring range is exited, and even over several modulo cycles. The measurement is only terminated with **_disableMeasuringInput**.

For non-modulo axes, the sequence in which the start and end of the measuring range are specified is irrelevant. If the start of the measuring range is greater than the end of the measuring range value, the two values are exchanged.

If the start of the measuring range is greater than the end of the measuring range in a modulo axis, the measuring range is extended from the start of the measuring range over the modulo transition of the axis to the end of the measuring range.

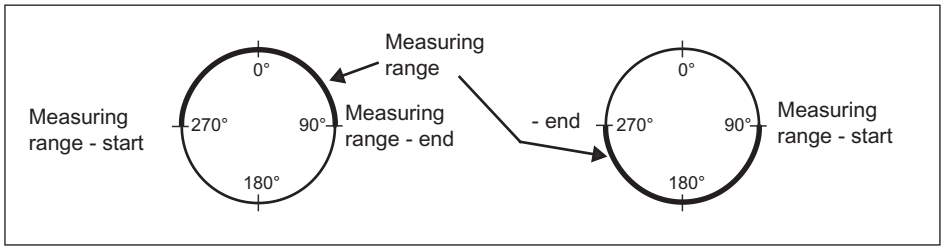


Figure 4-258 Measuring range for modulo axes for the measuring input

Dynamic measuring range

The measuring range can also be switched on or off dynamically. An activation time is allowed for this purpose when switching on or off.

The activation time can be specified by means of the **measuringRange.activationTime** configuration data element.

This time can be used, for example, to compensate for the runtimes during activation via PROFIBUS and the drive.

The following applies here:

- Activation of the measuring range and consideration of the activation time are performed on a position control granular basis.
- This means that the accuracy depends on the position control cycle clock.

- The runtime should be taken into consideration: Position control DP cycle clock activation in the drive (i.e. the position of the position control cycle clock in relation to the DP cycle clock as well).
- The actual position of the encoder is not evaluated directly, instead the filtered actual position is evaluated (see Actual value system).

Configure Units

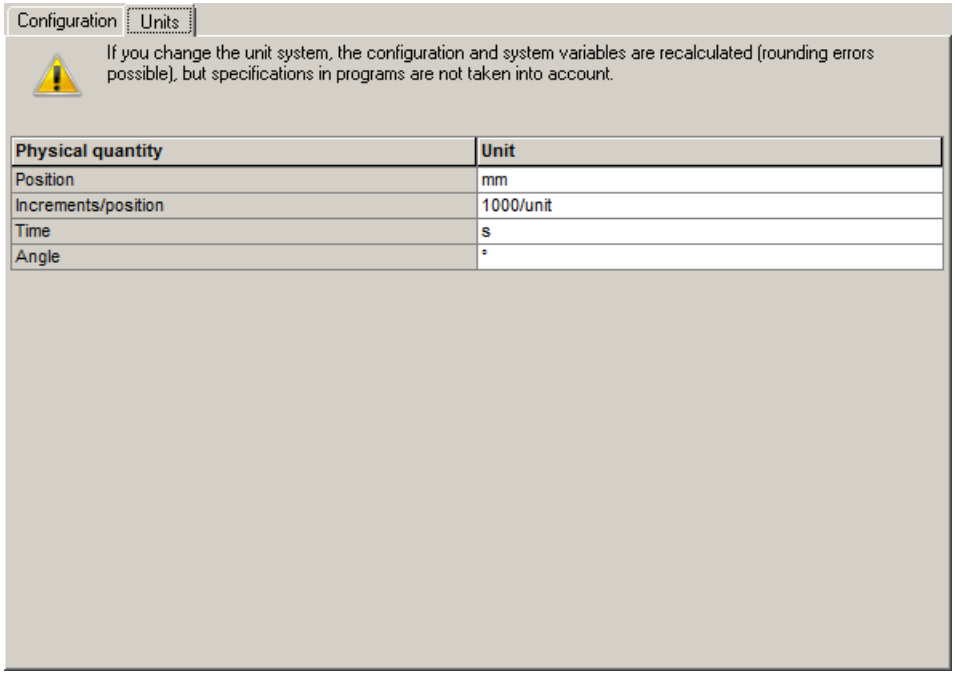
You can define the basic units for each technology object. The same physical variables can have different units in different technology objects. These are converted:

How to configure the units:

1. In the project navigator, open the context menu for the technology object.
2. In the context menu, select **Expert > Configure units**. The **Configure Units** window appears in the working area.
3. Select the **unit** for the **physical variables**. These units are used for the technology object, e.g. s for time units.

or

1. In the project navigator, open the **Configuration** under the TO.
2. Select the **Units** tab.



You can set the following parameters:

Field/button		Meaning/instruction
Table with units		
	Physical variable column	Shows the physical variable. The physical variables which are used by the TO are available for the configuration.
	Unit column	Displays and configures the unit. A drop-down list for selecting the unit appears when you click on the cell.
Toolbar		
		Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display
	Close	Button for closing the dialog.
	Help	Button for opening the online help for the dialog.

Simulation

This function activates the measuring input simulation (**simulation**=active). **Measured result arrived** is set and allocated to the programmed measured value as a measured result.

If the simulation mode is active on the measuring input, the simulated measured value is entered in **Measuredvalue1** using the function **_enableMeasuringInput** (trigger), and **state**=trigger_occured is set.

4.3.5.3 Configuring the Measuring Input technology object

Inserting Measuring Inputs

Note

Before you insert a measuring input, the hardware must be configured and the axis or external encoder to which the measuring input cam is assigned has to be created.

To insert a new measuring input

1. In the project navigator, highlight the **MEASURING INPUTS** folder under the relevant axis or external encoder.
2. Select **Insert > Technology Objects > Measuring Input** , or double-click **Insert Measuring Input** in the project navigator at the axis or external encoder entry in the MEASURING INPUTS folder. The **Insert Measuring Input** window appears.

3. Enter a **name** for the measuring input. You can also enter a **comment**.
   Names must be unique throughout the project. For this reason, all the inserted measuring inputs are displayed under **Available measuring inputs**.
4. Confirm with **OK**. In the working area, the window for the configuration is displayed and the measuring input created is shown in the project navigator.

Parameterization of the Measuring Input technology object

General information about configuration data and system variables

Two data classes are distinguished when parameterizing a TO.

Configuration data defines the principal functionality of a TO. They are set within the object configuration framework with the SCOUT engineering system and are not normally changed during runtime.

System variables provide status data of the TO for the user program and a parameterization interface on the TO. System variables can be changed during runtime.

Note

You will find more information on technology objects in the *SIMOTION Runtime Basic Functions* functional description.

To parameterize a measuring input:

1. In the project navigator under the **MEASURING INPUTS** folder, find the measuring input technology object (TO) that you want to parameterize. Double-click the measuring input to display the associated objects.
2. Double-click **Configuration** or **Default** in the project navigator. The window appears on the workspace.
   - **Configuration** (see chapter **Configuring a measuring input**):
     Define the **configuration data** of the measuring input here. This includes, for example, the processing cycle clock.
   - **Default** (see chapter **Measuring input defaults**):
     Define the measuring input defaults of the **system variables** here. These include the edge, start of measuring range, and end of measuring range.
3. Change configuration data and measuring input defaults.
4. Click **Close** to accept the changes.
5. Repeat steps 2 to 4 for all objects in which you want to change the configuration data and defaults.

Measuring Input Configuration (Page 1942)

Measuring input defaults (Page 1947)

Use Expert List for Measuring Inputs

Parameters required for standard SIMOTION applications (configuration data and system variables) are parameterized into the output cam technology object directly by means of screen forms or are defined automatically.
It may be necessary to change automatically defined parameters for special SIMOTION applications. These configuration data and system variables can only be displayed and changed in the expert list.

Note

You will find more information on working with the expert list in the *SIMOTION Runtime Basic Functions* functional description.

Measuring Input Configuration

Measuring Input Configuration

In the **Configuration** window, define the configuration data values for the measuring input.

Double-clicking in the project navigator below the measuring input on the **Configuration** element displays the window in the working area.

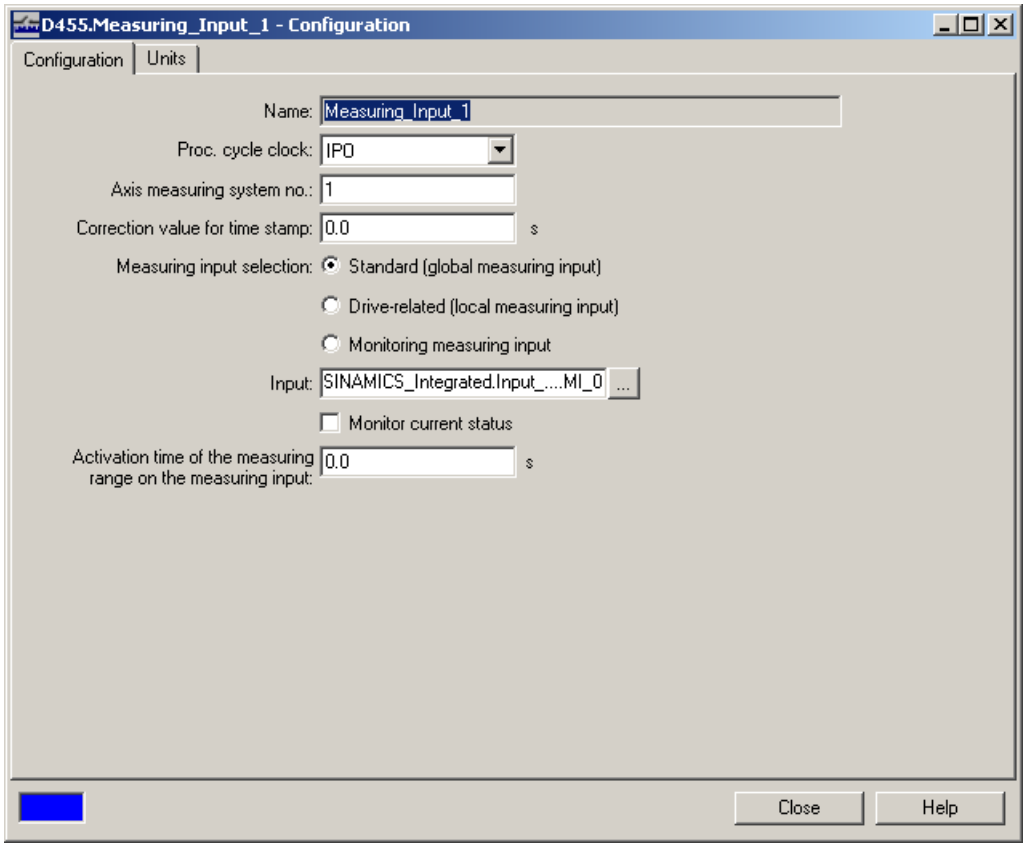

Figure 4-259 Global measuring input

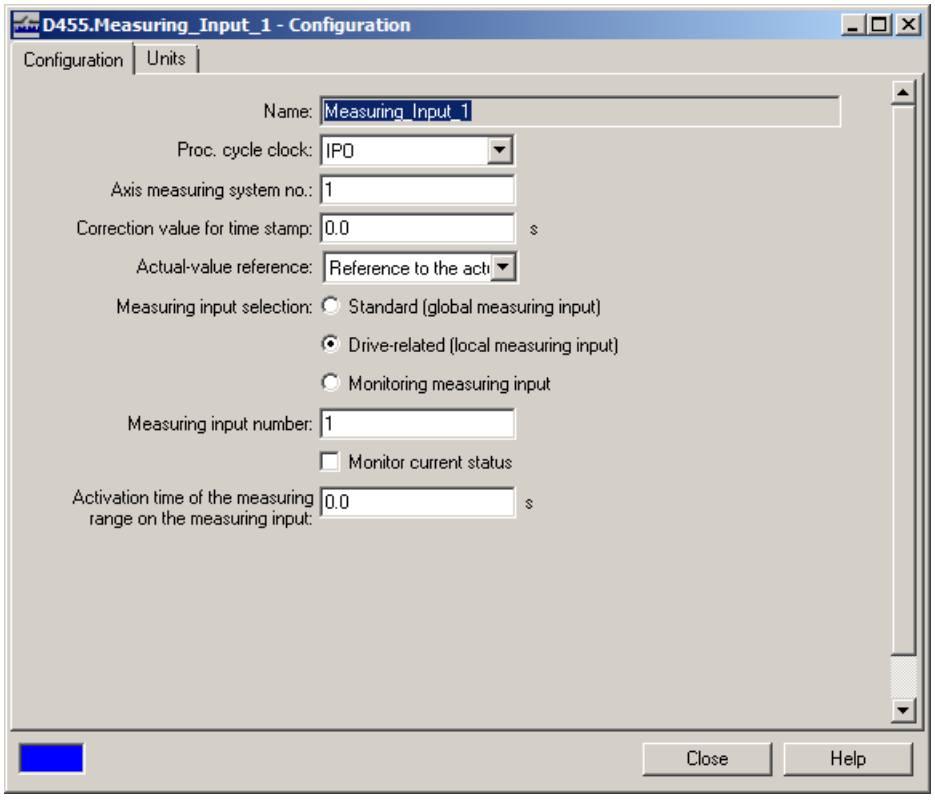

Figure 4-260 Local measuring input

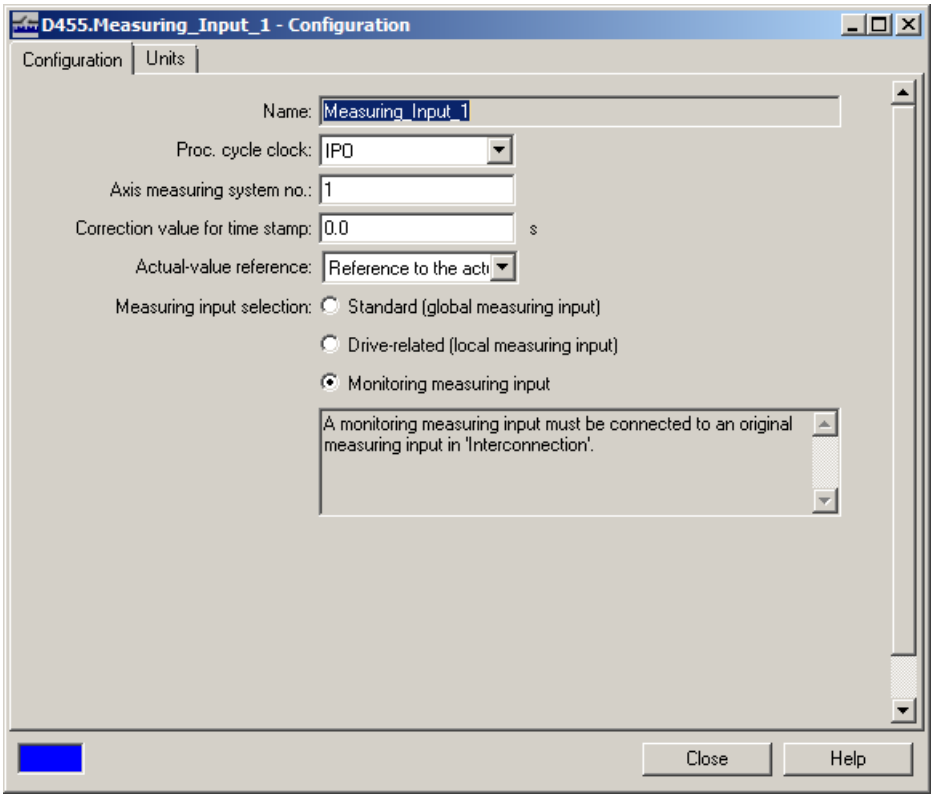

Figure 4-261 Monitoring measuring input

You can set the following parameters:

Table 4-186 Measuring input configuration data

Field/button	Meaning/information
Name	The name of the created measuring input is displayed here.
Processing cycle clock	Use this to select the system cycle during which the measurement result is interpolated and stored in the system variables. **IPO** (Default value) The measurement result is refreshed in interpolation cycles. **IPO_2** Measurement result is refreshed in the interpolation cycle clock 2. The IPO_2 cycle clock length is at least twice that of the IPO. **Servo** The measurement result is refreshed in position control cycles. For the possible setting of IPO_fast and Servo_fast with D435-2, D445-2 and D455-2, see Section Second servo cycle clock (Servo_fast) in the SIMOTION Runtime Basic Functions Manual.

Field/button	Meaning/information
Axis measuring system no.	Under **Axis measuring system no.**, enter the number of the encoder system used on the measuring input (if the axis has more than one encoder). Encoder system 1 is the default setting. An encoder system can be assigned to several measuring inputs. **Note:** With global measuring inputs, please note that measurement is not based on the encoder which is active for the control/Ipo, but on the axis measuring system set on the measuring input. **Note:** With virtual axes, the axis measuring system number is irrelevant because only setpoints are measured.
Time stamp correction value (Page 1946)	Enter the correction time for the evaluation of the time stamp. The correction value will be saved in the configuration data element **TimeStampConfig.correctionTime**. Each measuring result is assigned a time stamp. **Delay times can be corrected in the correction time**: • Delays that occur directly in the measuring input, e.g. the delay caused by mechanical deflection of the probe or the time required to generate the measuring signal before it is transferred to the measuring module; • Switching times in the sensing system, e.g. filter times at the input. When measuring actual values (reference to actual values at the encoder), the delays that occur between sensing of the measurement event and its communication to the SIMOTION system are automatically corrected by interpolation (delays based on bus and cycle clock system). **Special case: Measurement on virtual axis with reference to actual value of a real axis**: When measurements are taken on virtual axes, the actual value matches the setpoint and no delays occur. For example, if you program a measurement for the actual value of an axis in relation to a virtual axis (e.g. master axis), a correction value for the offset time must be taken into account so that the position can be calculated correctly. If the correction value is not taken into account, the measured value position can deviate with different cycle clock settings / velocities.
Actual value reference	Depending on the following settings, you select: • **Reference to the actual value on the encoder without considering Ti**. Reference to the actual position in the controller before the position filter. • **Reference to the actual value after the position filter**. Reference to the actual position in the controller after the position filter. • **Reference to the actual value on the encoder. Ti is taken into account**. Reference to the actual value on the encoder module / drive. The transmission time Ti from the encoder module / drive to the controller is taken into account by the system.
Measuring input selection	

Field/button		Meaning/information
	Standard (global measuring input), e.g. on the TM15/ TM17 module / C240 (B1-B4) or SIMOTION D onboard (See Chapter Overview (Page 1951))	Select the radio button if you want to configure a measuring input for global measuring. This functionality is available for hardware (see Hardware for measuring inputs (Page 1920)). With global measuring, the current actual values of one or more encoders are measured with positioning accuracy with a signal edge on the relevant input in order to determine lengths or distances from these (possible with any encoders existing in the project).
	Drive-related (local measuring input)	Click on the radio button if the measuring input is connected directly to the C230-2/C240, D4xx, D410-2, D410-2, D4x5-2 (X122/X132) or the drive. Measurements can be taken only on the device that has a measuring system. You still have to enter the name of the measuring input number.
	Monitoring measuring input	Select the radio button if you want to configure a monitoring measuring input. If the checkbox is selected, the measurement result of a measuring input TO that is interconnected on another HW input (see Hardware for measuring inputs (Page 1920)) is also measured by the measuring input configured as a monitoring measuring input (listening in on the measurement event). With this functionality, one measuring input can have a functional effect on several axes / external encoders. If you have configured a monitoring measuring input, you can now only select the processing cycle clock and axis measuring system number.
Input (global measuring input)		The output can be symbolically assigned via the assignment dialog using the ... button in the Input field (symbolic assignment is activated by default in the project as of V4.2). For more details, see cam output types. (Page 1811) If symbolic assignment is not active or if the CPU version < V4.2, a physical output is assigned by entering the HW address and bit number in the Input field. The logical HW address must be located outside the process image and therefore be greater than 63.
Measuring input number (local measuring input)		Enter the measuring input at the drive of the axis here. One input can be assigned to several measuring inputs. Input 1 is the default setting.
Monitor current status (measurement once)		If the checkbox is activated, short pulses (short position control cycle clock) will be suppressed at the measuring input. If the measuring input is activated, provided that rising edge is selected under **Edge**, the measuring input will only be activated when the measuring input was at signal status 0 for at least one position control cycle clock.
Activation time of the measuring range on measuring input		Enter an activation time, in seconds, for the activation and deactivation of the measuring range here. With this time, you can compensate, for example, the runtimes during activation via PROFIBUS and drive. The accuracy of the activation depends on the position control cycle clock.
...		Button for opening the assignment dialog. Select a parameter or an address in the Assign dialog.
		Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display

Time stamp correction value

When measuring with measuring inputs, the following should be taken into account when calculating the measurement positions from the measurement result and actual position of axis / external encoder:

- the filter time constant setting on the measuring input (e.g. TM17 smoothing filter),
- the delay times in the transmission section and sensors and
- with global measuring inputs also the Ti setting on axis / external encoder (depending on the actual value reference setting)

The hardware delay times on the measuring inputs can be found in the Manuals and can usually be ignored for values of much less than 125 µs (e.g. with SIMOTION D, SINAMICS Control Units, SIMOTION C240))

If the filter time can be parameterized for the hardware used (e.g. TM17 high feature: 1 µs or 125 µs), set the smallest possible value for the measuring inputs.

The delay times up to the measuring input, due to the transmission line and sensor technology, depend on the components used and are usually unknown. If these values are small, they can also be ignored.

With the setting "actual value reference - reference to the actual value at the encoder," the transmission time Ti of the system is considered. With the other settings, you must also consider the transmission time Ti for "global" measuring inputs. The value can be found in the properties of the SINAMICS drive unit in the HW Config.

Example of how to proceed:

- For SIMOTION D: in HW Config, double-click on **SINAMICS Integrated**
- Under **DP slave properties**, in the tab **Cycle synchronization** read off the value **Ti**

During the measuring input configuration of "global" measuring inputs, also enter the negated value of **Ti** as offset value of the time stamp (**TimeStampConfig.correctionTime**).

If measurements have to be performed with "very high" accuracy or the dead times caused by the filter time constant and delay times from the transmission line, BERO, converter, contacts, etc. cannot be ignored, we recommend the machine-specific determination of the dead times that really occur, through measurements or series of measurements.

Measurements with velocity-dependent displaced measuring results are an indication that the dead times have not been compensated or incorrectly compensated.

The procedure for **empirical/measuring technique determination** of dead times is similar to the process for determining dead times during cam output.

See also

Determining derivative-action times for output cams (dead time compensation) (Page 1833)

Measuring input defaults

You can define the defaults for every measuring input. These values are stored in system variables and can be changed by programs.

Double-clicking in the project navigator below the measuring input on the **Defaults** element displays the window in the working area.

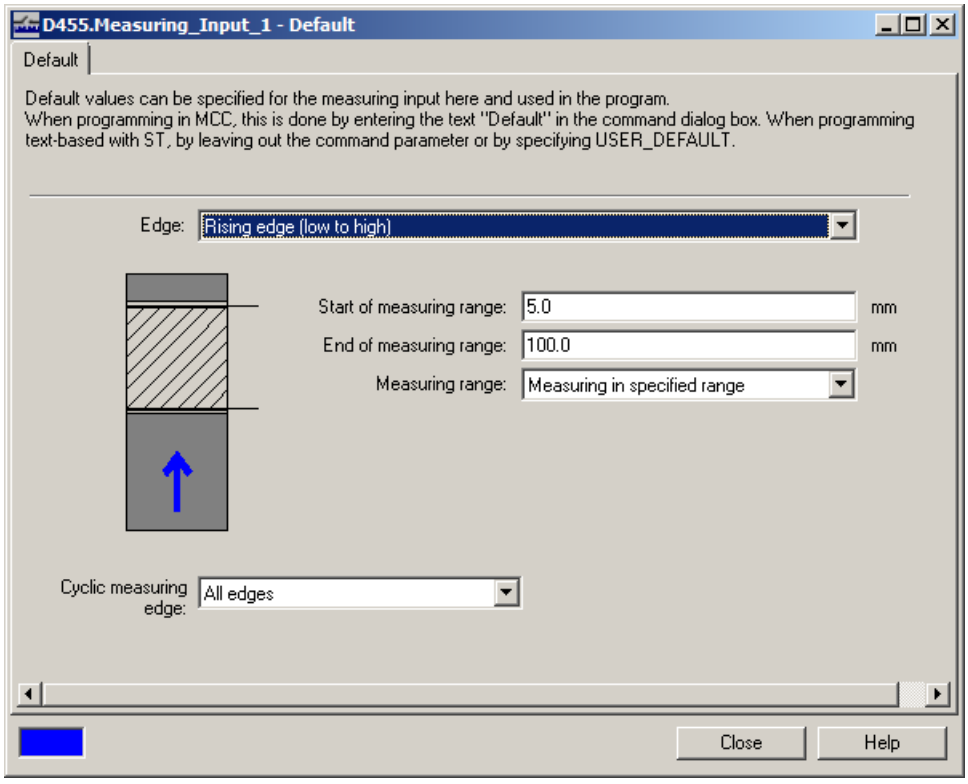

Figure 4-262 Measuring input defaults

You can set the following parameters:

Table 4-187 Measuring input defaults

Field/Button	Meaning/information
Edge (measurement once)	Under **Edge** you select the signal edge that starts the measurement when present at the measuring input and measures the actual position of the axis. The drive must be capable of evaluating the signal edge (rising, falling, or both edges) selected by SIMOTION at the measuring input. **Rising edge (low to high)** The actual position is recorded with the rising edge of the measuring input. **Falling edge (high to low)** The actual position is recorded with the falling edge of the measuring input. **Measure at both edges** The actual position is recorded using both the rising and falling edge of the measuring input. **Measure at both edges, starting with a rising edge (low to high)** The actual position is recorded using both the rising and falling edge of the measuring input, and measurement is begun at the first rising edge. **Measure at both edges, starting with a falling edge (high to low)** The actual position is recorded using both the rising and falling edge of the measuring input, and measurement is begun at the first falling edge.
Start of measuring range/ End of measuring range (measurement once) (See also Chapter **Measuring range**)	Enter the start and end of the measuring range here. If the start of the measuring range is greater than the end of the measuring range for modulo axes, the measuring range extends from the initial value through the modulo transition to the end value. For non-modulo axes the initial and end values are swapped in this case.
Measuring range (measurement once) (See also Chapter **Measuring range**)	Under **Measuring range** you can choose whether or not to apply the defined measuring range. **Measuring without specified range** The measuring input records the measured values in the entire traversing range. **Measuring in specified range** The measuring input only records the measured values within the measuring range defined by the start and end points.
Cyclic measuring edge (Page 1929)	The edges to be detected in cyclic measuring are selected here. Up to two edges can be acquired cyclically per measuring input processing cycle (IPO interpolation cycle, IPO_2 interpolation cycle, or servo cycle clock). Cyclic measuring is only possible with certain hardware (see Hardware for measuring inputs (Page 1920)). **All edges** Both rising and falling edges are measured. **Rising edges only** Only rising edges are measured. **Falling edges only** Only falling edges are measured.

Measuring range (Page 1936)

Local measuring

Introduction

With local measuring inputs, the measuring input is assigned as part of its configuration. The configuration specifies the number of the measuring input to be used and the number of the encoder on the assigned axis (PROFIdrive).

Local measuring on C230-2, C240 (not C240 PN)

With a signal edge at the relevant M1 or M2 input, the current actual values of one or more encoders connected to the onboard encoder interfaces (X3 to X6) are measured with positioning accuracy to determine lengths or distances.

The assignment of inputs is not fixed; the special use is activated in the SCOUT engineering system during configuration of the measuring input via the measuring input number.

Note

As the C240 PN has no onboard encoder interfaces, it has no local inputs of measuring inputs.

Local measurement on D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2, CU310, CU310-2, CU320 and CU320-2

If you connect a local measuring input TO to the measuring inputs of D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2 and CU310, CU310-2, CU320 and CU320-2, you will have to set the following parameters (PROFIdrive):

- Parameter p488 on the associated drive for one local measuring input
- Parameters p488 and p489 on the associated drive for two local measuring inputs
- Parameters p728.8 - p728.15 on the control unit as inputs for all DI/DO used as measuring inputs (these settings can also be made using a parameterization mask)

Local measuring on other drives (MASTERDRIVES MC, SIMODRIVE 611U, etc.)

With SIMOTION, the measuring input is assigned as part of its configuration. The configuration specifies the number of the measuring input to be used and the number of the encoder on the assigned axis.

Please refer to the documentation for the respective drive system for details of any additional settings which may be required.

Global measuring

Overview

Description

You can configure TO measuringInput on the ET200SP technology module TM Timer DIDQ 10x24V and ET200MP technology module TM Timer DIDQ 16x24V.

- Configuration to ET200SP technology module TM Timer DIDQ 10x24V is possible both using Step7 in connection with SCOUT Classic and with the TIA Portal in connection with SCOUT TIA. Further information can be found in the section Global measuring on TM Timer using DIDQ 10x24V as example (Page 1904).
- Configuration on the ET200MP technology module TM Timer DIDQ 16x24V is only possible using TIA Portal in connection with SCOUT TIA. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA.

Further information

Further information on the functions of the TM Timer DIDQ technology modules can be found in the SIMATIC ET 200SP Technology Module TM Timer DIDQ 10x24V and SIMATIC S7-1500/ET 200MP Technology Module TM Timer DIDQ 16x24V.

With global measuring, the current actual values of one or more encoders are measured with positioning accuracy with a signal edge on the relevant input in order to determine lengths or distances from these (possible with any encoders present in the project). Up to two edges can be measured for each position control cycle clock of the Measuring Input TO.

The assignment of the inputs is not fixed, and the special use is activated via the HW address when the Measuring Input TO is configured.

Note

Global measuring is only possible for measuring inputs with time stamp. Hardware for measuring inputs (Page 1920)

See also

Global measurement on D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2, CU310, CU310-2, CU320 and CU320-2 (Page 1957)

Configuring and interconnecting a listening Measuring Input TO (Page 1964)

Global measuring on TM15/TM17 High Feature

Description

Digital inputs are available for connection of measuring inputs on the TM15 and TM17 High Feature Terminal Modules. These can be used for one-off or cyclic measuring. Cyclic measuring is only supported by the TM17 High Feature.

Note

For more information about the Measuring Input TO on Terminal Modules, see the *TM15 / TM17 High Feature Terminal Modules* Commissioning Manual.

To configure a measuring input on a TM15/TM17 High Feature

1. In the project navigator, below the input/output component (TM15/TM17) that you want to use, double-click the entry **Inputs/outputs.** The **Bidirectional Digital Inputs/Outputs** window is displayed.
2. For the selected I/O channel, select measuring input as the function.

   Note

   If you do not use symbolic assignment (see Section Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual), you must note the offset (e.g. 3.1).

3. Insert a new measuring input or use an existing one.
4. Assign parameters to the measuring input TO.
5. Double-click **Configuration** below the measuring input in the project navigator. The **Configuration** window appears in the working area.
6. Activate the option **Standard (global measuring input)**. Assignment of an output to a measuring input is supported as of V4.2 by symbolic assignment (see Section Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions Manual) or by entering the hardware address. In order to assign a physical output, the HW address and bit number must be entered in the **Output** field.
7. Click **OK** to close the window and select **Project > Save**.

To determine the logical hardware address for a TM15/TM17 High Feature (only if symbolic assignment is not activated)

1. For TM15/TM17 modules, the hardware addresses result from the configured address range, and the bit numbers from the offset.
2. In the project navigator, below the input/output component (TM15/TM17) that you want to use, double-click the entry **Inputs/outputs.** The **Bidirectional Digital Inputs/Outputs** window is displayed**.**
3. Find the input that you want to use (**Measuring input** must be selected under **Function**) and note the offset (e.g. 3.0).

4. In the project navigator, below the SIMOTION device or the SINAMICS drive unit, select
   - For SIMOTION D:
     SINAMICS_Integrated > Communication > Telegram configuration
   - For the SINAMICS S120 drive unit:
     Communication > Telegram configuration
5. Double-click **Telegram configuration** and, in the window that opens, select the tab **PROFIdrive PZD telegrams.** The components are displayed there with the address ranges (e.g. TM17 input data 288...299).

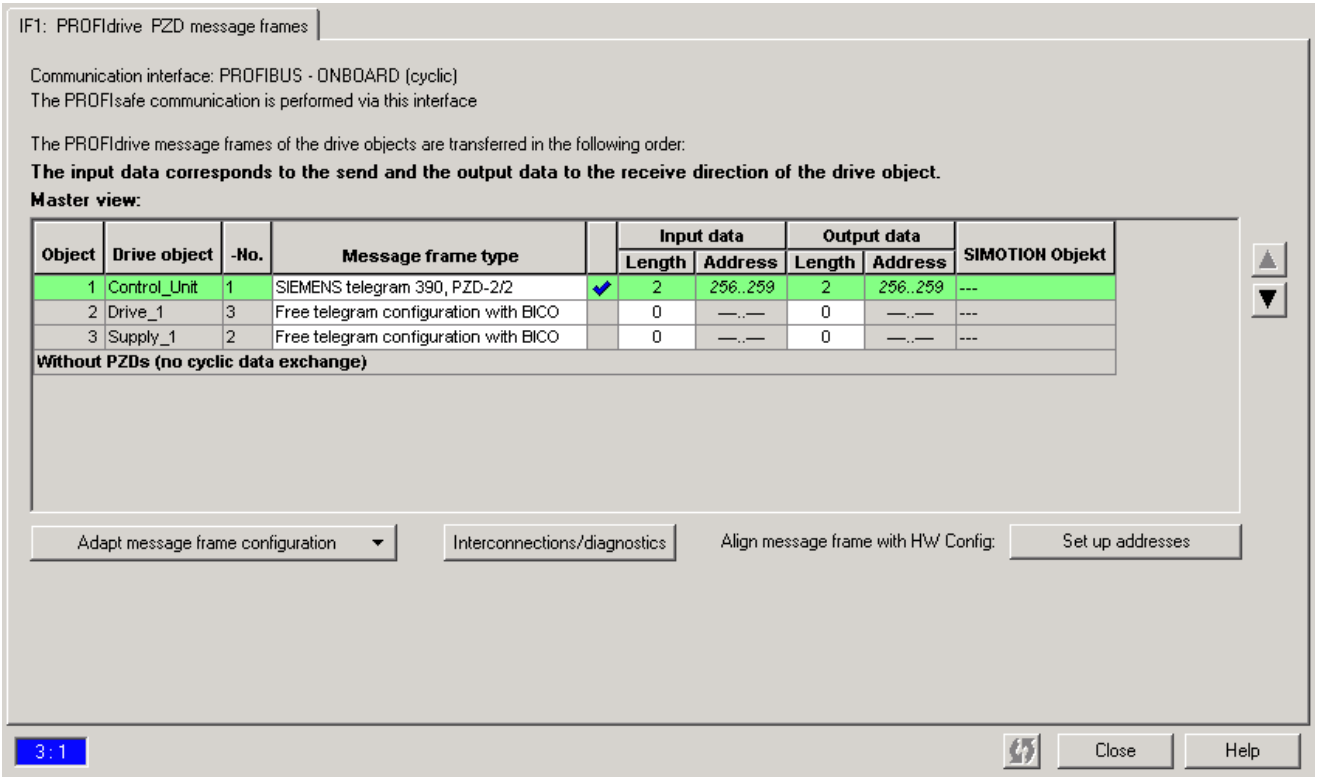

Figure 4-263 Determining the hardware address of the components

6. Before you determine the hardware address, an alignment between HW Config and SIMOTION SCOUT, with respect to the address, must be performed. If this has not been performed or you have changed the addresses, click on **Set up addresses**. If there are question marks in the fields instead of I/O addresses, you must also perform an alignment.
7. Now calculate the HW address by adding the base input address (first value of the address range) of the TM to the offset (for example 288 + 3 = 291).
8. The bit number is defined by means of the offset. For example, an offset of **3.0** results in a bit number of **0**.

Inserting Measuring Inputs (Page 1940)

Parameterization of the Measuring Input technology object (Page 1941)

Global measuring on SIMATIC ET200SP and ET200MP

Overview

Description

You can configure TO measuringInput on the ET200SP technology module TM Timer DIDQ 10x24V and ET200MP technology module TM Timer DIDQ 16x24V.

- Configuration to ET200SP technology module TM Timer DIDQ 10x24V is possible both using Step7 in connection with SCOUT Classic and with the TIA Portal in connection with SCOUT TIA. Further information can be found in the section Global measuring on TM Timer using DIDQ 10x24V as example (Page 1954).
- Configuration on the ET200MP technology module TM Timer DIDQ 16x24V is only possible using TIA Portal in connection with SCOUT TIA. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA.

Further information

Further information on the functions of the TM Timer DIDQ technology modules can be found in the SIMATIC ET 200SP Technology Module TM Timer DIDQ 10x24V and SIMATIC S7-1500/ET 200MP Technology Module TM Timer DIDQ 16x24V.

Global measuring on TM Timer, using DIDQ 10x24V as example

Description

You can configure TO measuring inputs on the ET200SP Technology Module TM Timer DIDQ 10x24V in SIMOTION SCOUT or SIMOTION SCOUT TIA in connection with the TIA Portal. The configuration in the TIA Portal is described in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA. The configuration in SIMOTION SCOUT in connection with Step7 is described below:

In order to parameterize the ET200SP TM Timer DIDQ 10x24V with Step7 in connection with SIMOTION SCOUT Classic, a Hardware Support Package (HSP) for Step7 is required. Further information can be found in the Commissioning Manual Technology Modules TM Timer DIDQ for SIMOTION SCOUT and SIMOTION SCOUT TIA in the section on hardware and software requirements.

For the TM Timer DIDQ technology module, the digital inputs are used for the measuring input. Irrespective of whether you work
with SIMATIC STEP 7 or SIMOTION SCOUT, the parameterization is always performed in HW Config:

Parameterization of TM Timer DIDQ in HW Config

1. Open the HW configuration in SIMOTION SCOUT or SIMATIC STEP 7.
2. Select the header module (IM) with the TM Timer DIDQ in HW Config.
   The TM Timer DIDQ appears in the detail view.
3. To open the context menu, select the TM Timer DIDQ with the right mouse key.

4. Select object properties.
   You can view or change the following properties in the object properties:
   - General
   - Addresses
   - Identification
   - Parameters
5. Open the tab **Parameter** > **DQ0 / DI0**
6. Set the parameter value **Configuration DQ/DI group** to **Use input/output individually**.

   Note

   With this setting, the DQ0 channels can be interconnected as cam output CAM or DI0 as measuring input MI under SIMOTION SCOUT.

7. Press **OK** to close the dialog.
8. Open the menu **Station** > **Save and Compile**.

Note

The technology modules and the individual channels may only be reparameterized in offline state. All changes only take effect after saving, compiling and subsequent download of your changed user project to the controller. The download can be performed in HW Config via **Target system** > **Download to module** or in SCOUT via **Load CPU / drive unit to target device**.

Parameterization of MI in SCOUT

1. Insert a new measuring input or use an existing one.
2. Assign parameters to the measuring input TO.
3. Double-click Configuration below the measuring input in the project navigator. The Configuration window appears in the working area.
4. Activate the measuring input selection **Standard (global measuring input)**.

5. Assignment of an output to an output cam/cam track is supported as of V4.2 using symbolic assignment or by entering the HW address.

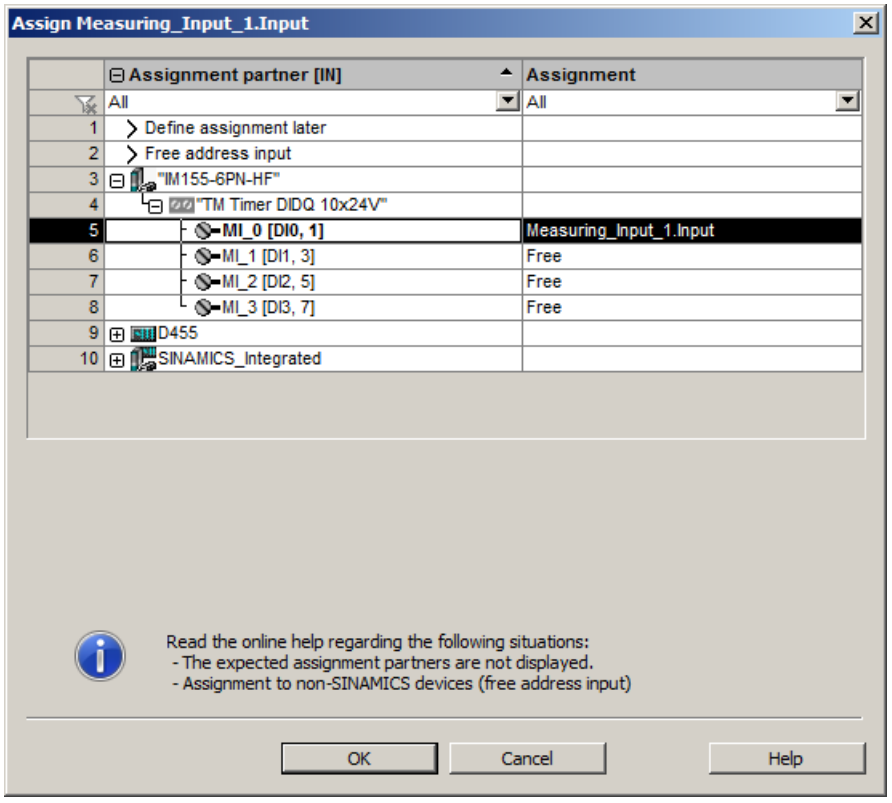

Figure 4-264 Assigning a measuring input by means of symbolic assignment

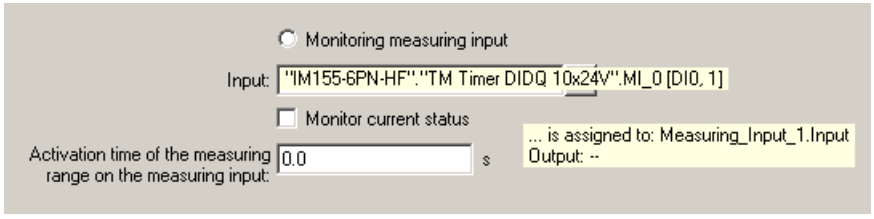

Figure 4-265 Assigning a measuring input by entering the HW address

6. Click OK to close the window and select **Project** > **Save**

Global measuring on C240/C240 PN (B1-B4)

The inputs B1-B4 are available for global measuring on the C240. These can be used for one-off or cyclic measuring.

Note

For more information about the measuring input on C240/C240 PN, refer to the *C2xx* Operating Instructions.

To configure a measuring input on a C240/C240 PN (B1-B4) (global measuring)

1. Insert a new measuring input (see **Inserting measuring inputs** section) or use an existing one.
2. Parameterize the measuring input (see the **Parameterization of the measuring input technology object** section)
3. Double-click **Configuration** below the measuring input in the project navigator.
   The **Configuration** window appears in the working area.
4. Activate the option **Standard (global measuring input)**. If symbolic assignment is not active or if the CPU version < V4.2, a physical input is assigned by entering the HW address and bit number in the Input field.
5. Enter the **HW address** and the **bit number**. The hardware address and the bit number can be ascertained in **HW Config** (e.g. 64.2 for the measuring input Pin 3 of connector X1).
6. Click **OK** to close the window and select **Project > Save**.

See also

Inserting Measuring Inputs (Page 1940)

Parameterization of the Measuring Input technology object (Page 1941)

Global measurement on D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2, CU310, CU310-2, CU320 and CU320-2

On D4xx, D410-2, D4x5-2, CX32, CX32-2, CU310, CU310-2 and CU320 you have digital inputs to connect to a global measuring input. These can be used for one-off or cyclic measuring.

If symbolic assignment is not active or if the CPU version < V4.2, the following applies:

The measurement results are transmitted by standard telegrams 391/392 and 393/396 (only D410-2/CU310-2/D4x5-2/CX32-2/CU320-2) and not via the axis telegram.

If a 39x telegram is set, the SINAMICS I/Os are interconnected automatically to this 39x telegram using BICO interconnections and are so available for SIMOTION.

Note

In the case of versions earlier than V4.2, when using 39x telegrams, the onboard D4x5 outputs are to be assigned exclusively to SIMOTION.

Inverting global measuring inputs

When selecting 39x telegram, inverting of the global measuring inputs is activated on Sinamics_Integrated, CX32, CX32-2 and S120 via parameters p490 and p2088[2].

The default assignment of p2088[2] is as follows:

- p2088[2].0 -> Inversion of DI/DO 8
- p2088[2].1 -> Inversion of DI/DO 9
- p2088[2].2 -> Inversion of DI/DO 10

- p2088[2].3 -> Inversion of DI/DO 11
- p2088[2].4 -> Inversion of DI/DO 12
- p2088[2].5 -> Inversion of DI/DO 13
- p2088[2].6 -> Inversion of DI/DO 14
- p2088[2].7 -> Inversion of DI/DO 15

If the default assignment of the digital inputs to PZD2 is changed in 39x telegram, this must be taken account of in p2088[2] correspondingly.

This is how you configure a measuring input on a measuring input of D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2, CU310, CU310-2, CU320, CU320-2

1. In the project navigator, switch to the **Control_Unit** entry under the control unit for the respective device.
2. Double-click **Inputs/outputs** below the control unit. The window appears on the workspace.
3. Select **Bidirectional digital inputs/outputs**.
4. Select via button  under **Further interconnections** parameters p2082 and the associated bit.
5. Insert a new measuring input (see Chapter **Inserting measuring inputs**) or use an existing one.
6. Assign parameters to the measuring input TO.
7. Double-click **Configuration** below the measuring input in the project navigator.
   The **Configuration** window appears in the working area.
8. Activate the option **Standard (global measuring input)**. Assignment of an output to a measuring input is supported as of V4.2 by symbolic assignment (see Chapter Symbolic Assignment (as of V4.2) in the SIMOTION Runtime Basic Functions manual) or by entering the hardware address. In order to assign a physical output, the HW address and bit number must be entered in the **Output** field.
9. Click **OK** to close the window and select **Project > Save**.

This is how you determine the logical hardware address for the onboard inputs of D4xx, D410-2, D4x5-2 (X122/X132), CX32, CX32-2, CU310, CU310-2, CU320, CU320-2 (only if no symbolic assignment is activated)

1. In the project navigator, select **Communication > Telegram configuration** under the SIMOTION or SINAMICS device.
2. Double-click **Telegram configuration** and, in the window that opens, select the tab **PROFIdrive PZD telegrams**. The components are displayed there with address range (input/output data).

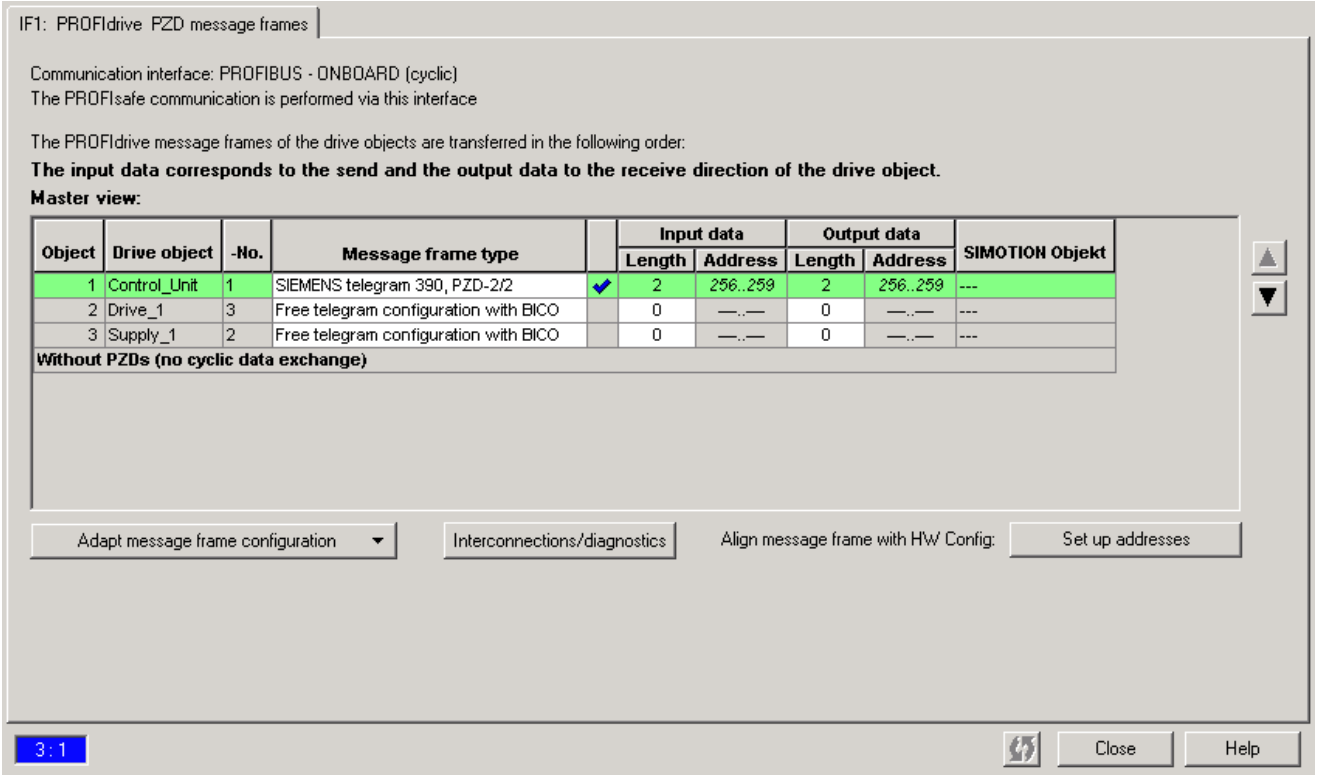

Figure 4-266 Control unit I/O addresses

3. Select the telegram type **SIEMENS telegram 391** (max. 2 measuring inputs), **392** (max. 6 measuring inputs) or 393/396 (max. 8 measuring inputs only D410-2/CU310-2/D4x5-2/ CU320-2). The message depends on the number of measuring inputs configured.
4. Before you determine the hardware address, an alignment between HW Config and SIMOTION SCOUT, with respect to the address, must be performed. If this has not been performed or you have changed the addresses, click on **Set up addresses**. If there are question marks in the fields instead of I/O addresses, you must also perform an alignment.
5. Now calculate the HW address by adding the base input address (first value of the input data) of the control unit to the offset (e.g. 256 + 3 = 301). The offset always has the value **3**.
6. You will find the bit number in the following table. The inputs are set in parameters 680.0 to 680.7 of the control unit, e.g. bit 1 in parameter 680.0.

Table 4-188 Bit numbers for D410, D4x5, D4x5-2 (X122/X132), CX32, CX32-2 CU310, CU320, CU320-2

Input D4x5, CU320	Input D4x5-2, CU320-2	Input D410, CU310, CX32	Input D410-2, CU310-2	Input CX32-2	Bit No.
-	X122.9 (DI/DO 8)	-	X121.7 (DI/DO 8)	X122.9 (DI/DO 8)	Bit 0
X122.8 (DI/DO 9)	X122.10 (DI/DO 9)	X121.8 (DI/DO 9)	X121.8 (DI/DO 9)	X122.10 (DI/DO 9)	Bit 1
X122.10 (DI/DO 10)	X122.12 (DI/DO 10)	X121.10 (DI/DO 10)	X121.10 (DI/DO 10)	X122.12 (DI/DO 10)	Bit 2
X122.11 (DI/DO 11)	X122.13 (DI/DO 11)	X121.11 DI/DO 11)	X121.11 (DI/DO 11)	X122.13 (DI/DO 11)	Bit 3
-	X132.9 (DI/DO 12)	-	X131.1 (DI/DO 12)	-	Bit 4
X132.8 (DI/DO 13)	X132.10 (DI/DO 13)	-	X131.2 (DI/DO 13)	-	Bit 5
X132.10 (DI/DO 14)	X132.12 (DI/DO 14)	-	X131.4 (DI/DO 14)	-	Bit 6
X132.11 (DI/DO 15)	X132.13 (DI/DO 15)	-	X131.5 (DI/DO 15)	-	Bit 7

Global measuring on D4x5-2 (X142)

Unlike (X122/X132), measuring inputs on measuring input D4x5-2 (X142) are configured in HW Config

Configuration of terminals and function as well as the fixed telegram's start address are configured in HW Config.

To configure a measuring input on an input of D4x5-2 (X142)

The dialog box for configuring the X142 can be opened via the input/output X142 in the project navigator. Alternatively, you can access the dialog to be configured via the HW Config by clicking **Open HW Configuration ...** in the device's context menu.

Slot X142 is shown in the detail view and in the station window of the respective D4x5-2 device. You can access the **Properties** dialog via the **Object properties...** context menu or by double-clicking on the X142 line.

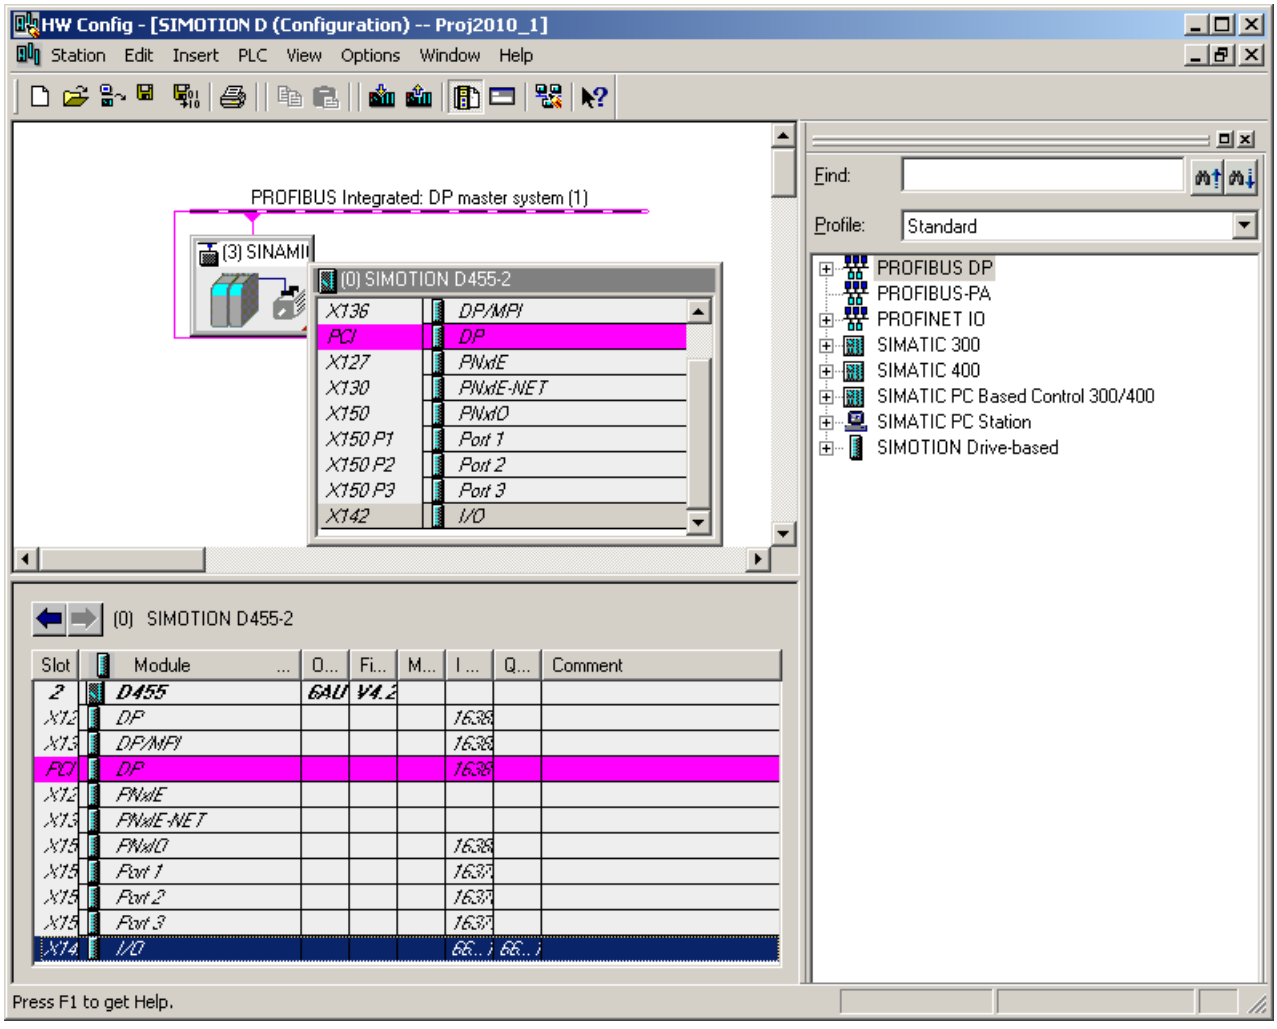

Figure 4-267 Display of D4x5-2 in HW Config

In the **Properties** dialog, you can manage **Addresses** and interconnect **Bidirectional digital inputs/outputs 0-7**.

Addresses

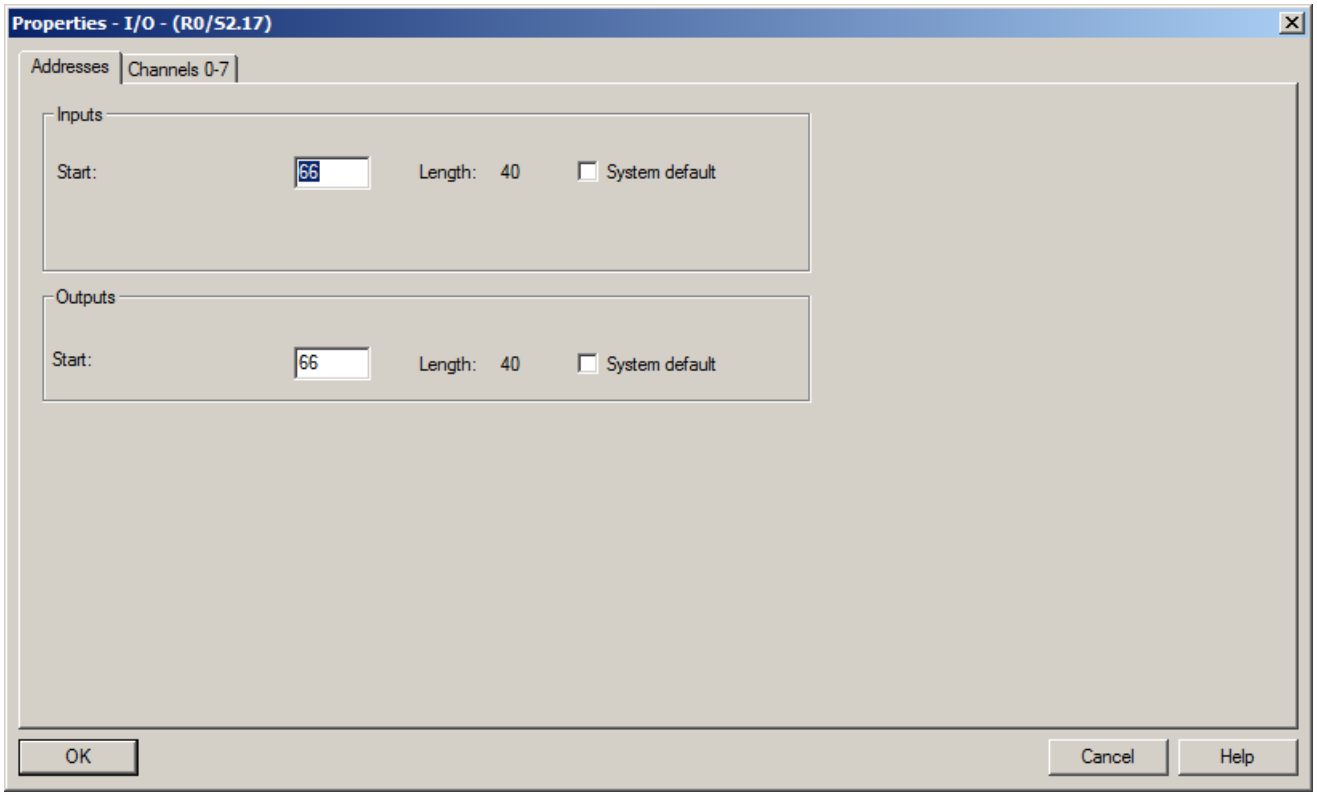

Figure 4-268 Manage addresses

Table 4-189 Addresses

Function		Description
Inputs		
	Start	Under **Start**, enter the start address of the digital inputs. Addresses >= 64 outside the process image are valid.
	Length	The **length** of the digital input address cannot be modified.
	System specification	With **System specification**, you can activate or deactivate the automatic setting of digital input addresses.
Outputs		
	Start	Under **Start**, you can enter the start address of the digital outputs. Addresses >= 64 outside the process image are valid.
	Length	The **length** of the digital output address cannot be modified.
	System specification	With **System specification**, you can activate or deactivate the automatic setting of digital output addresses.

Function		
	DI	Digital input.
	DO	Digital output.
	Output cam	Cam output.
	Measuring input	Measuring input input.
IN filter time		
	Filter time	The drop down list contains 1µs and 125µs values. Only available for **DI** and **measuring input** function.
	Set substitute value/keep last value	The selection options are available for the **DO** and **output cam** function.
Logical address		PI, PQ for output cam and measuring input. Note: Logical address is only required if you work without symbolic assignment.

Configuring and interconnecting a listening Measuring Input TO

With the "Monitoring measuring input" function, the measurement event of a measuring input can also be measured simultaneously by several Measuring Input TOs.

To configure and interconnect a monitoring measuring input:

1. Before you configure a monitoring measuring input, a measuring input must be configured on a measuring input with a HW address. This can be a measuring input (see Hardware for measuring input (Page 1920)). (see chapter Overview (Page 1951)).
2. Insert a new measuring input (see Inserting Measuring Inputs (Page 1940) section).
3. Double-clicking in the project navigator below the measuring input on the **Configuration** element displays the window in the working area.
4. Select **Monitoring measuring input**, and enter the **processing cycle clock** and the **system number** (see the **Measuring input configuration** section).
5. Double-clicking in the project navigator below the monitoring measuring input on the **Interconnections** element displays the window in the working area.
6. In the **EventIn** table row under the **Interconnected to output connectors** column, select the **EventOut** of the measuring input with which you want to interconnect the monitoring measuring input. The axis to which the monitoring measuring input is assigned is automatically displayed under **Reference**.

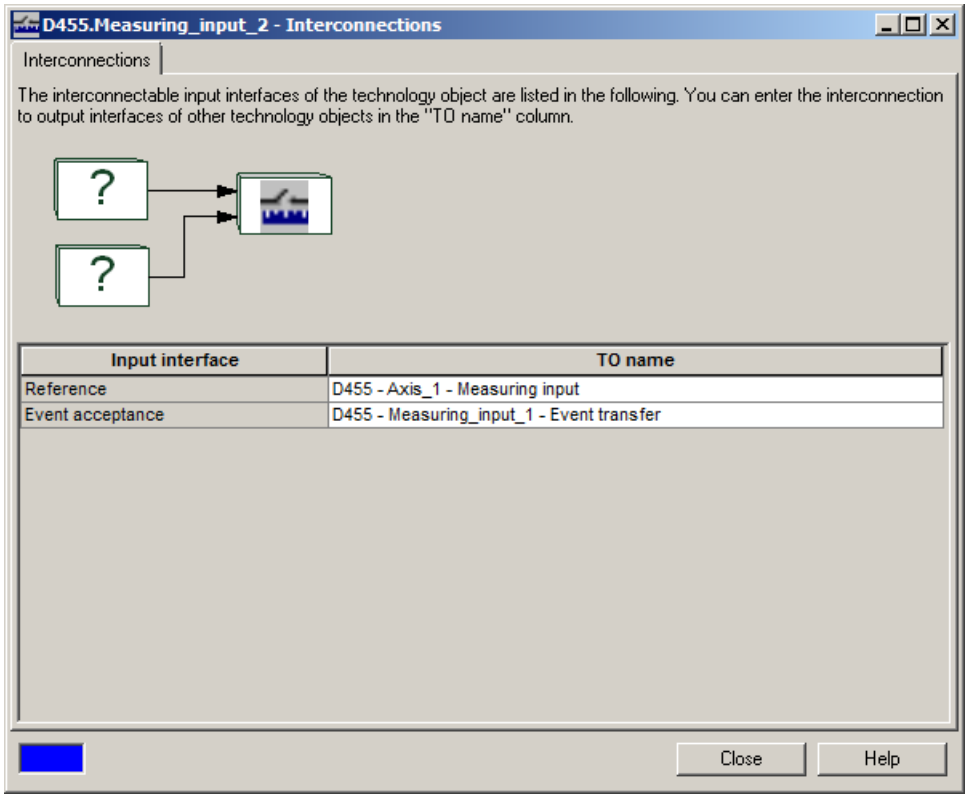

Figure 4-270 Interconnecting a monitoring measuring input

7. Click **Close**. The monitoring measuring input is configured and interconnected.

Measuring Input Configuration (Page 1942)

Measuring one measurement event on several axes - Listening measuring input (V4.0 and later) (Page 1925)

Measuring input with hardware enable (TM17 High Feature)

On the TM17 High Feature, hardware-based enable inputs can be configured for up to six measuring-input inputs. Measuring signals can only be detected at the assigned measuring input if an enable is present (this is a gate function).

Note

To be able to use an enable input it must be configured on the TM17 High Feature (see Section **Global measuring on the TM15/TM17 and C240 (B1-B4)**).

You will find more information on the hardware enable in the *Terminal Modules TM15 / TM17 High Feature* Commissioning Manual.

Required configuration for level-controlled HW enable

- Measuring input is configured.
- Digital input on TM17 High Feature parameterized for measuring input and level-triggered enable input set at this input. The appropriate enable input for the enable signal is parameterized automatically.
- Digital input configured for detecting measured values (HW address).
- Measuring input must be active.

Level-controlled enable procedure

The measuring input is activated with **_enableMeasuringInput** or **_enableMeasuringInputCyclic**. No measured values are forwarded to the TO in this state, as no enable signal is present yet (gate closed). Edges are forwarded to the TO by setting the enable (gate open).

Depending on the configured measuring range, measured edges are filtered by the TO in the measuring input processing cycle clock and by the TM17 High Feature with a resolution of several µs.

Edges are not detected if:

- The measuring process is terminated with **_disableMeasuringInput**.
- The edges fall outside the measuring range.
- No enable signal is present (gate closed).

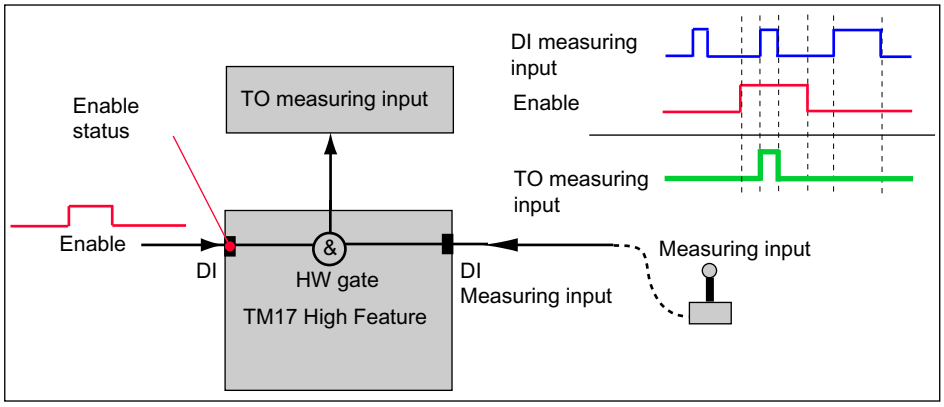

Figure 4-271 Schematic representation of HW enable on the measuring input

It is also possible to execute the enable with inverted logic, i.e. the enable input on the TM17 High Feature can be operated inversely and then works in LOW-active mode.

Overriding the enable

It is possible to override the measuring enable input with a software enable signal. To do this, you have to access the input directly via its address and set the bit. The enable is achieved, as long as the bit is set (functions as enable input).

Overview (Page 1951)

4.3.5.4 Measuring Input technology object programming/references

Programming

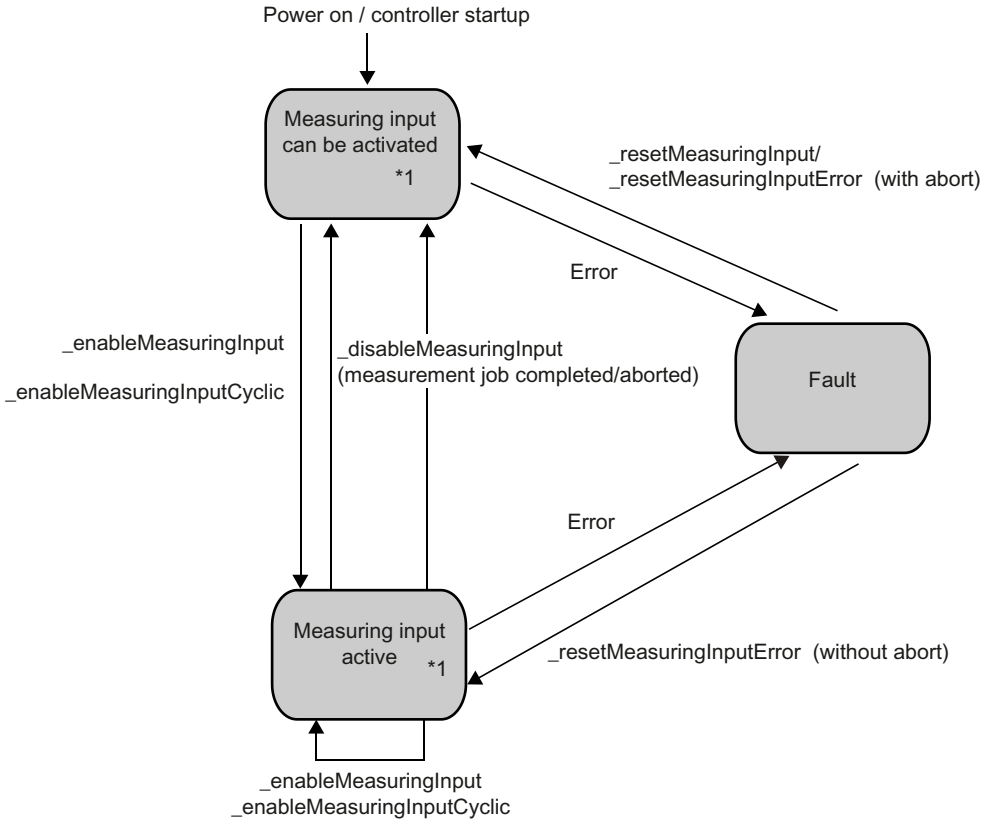

Figure 4-272 Programming and execution model for the Measuring Input TO

***1** The following commands are effective in the TO states **can be activated** and **active**:

- **_disableMeasuringInputSimulation**
- **_enableMeasuringInputSimulation**

Commands

The Measuring Input technology object can be addressed in the user program using the following commands:

Table 4-191 Measuring Input TO system functions

Commands	Description	Application
_enableMeasuringInput	Activate measurement job.	Measurement is activated. Measuring is terminated after the measuring process has been executed.
_enableMeasuringInputCyclic (V3.2 and higher)	This function activates a cyclical measurement job. The results of the last measurement are displayed in the system variables.	Cyclic measuring of axis/encoder positions by activating a measurement job once only
_disableMeasuringInput	Deactivate measurement job.	Measurement is terminated.
_enableMeasuringInputSimulation	Activates measuring input simulation. **Measured result arrived** is set and allocated to the programmed measured value as a measured result.	Simulation of a program run using default settings of programmed measured values
_disableMeasuringInputSimulation	Deactivate simulation mode.	-
_resetMeasuringInput	Reset measuring input.	Create initial state of measuring input.
_resetMeasuringInputError	Reset error on measuring input.	E.g. acknowledge configuration errors after entering correct values.
_resetMeasuringInputConfigDataBuffer	This function clears the configuration data collected in the buffer since the last activation without activating them.	Changing configuration data in the RUN state discards the accumulated modifications.
_getMeasuringInputErrorNumberState (V3.1 and higher)	Readout of error number status.	Check for occurrence of an error with the specified error number
_getStateOfMeasuringInputCommand (V3.2 and higher)	This function returns the execution state of a command.	Check whether or not measurement has already taken place (i.e. the command ID is still available or has already been deleted)
_bufferMeasuringInputCommandId (V3.2 and higher)	This function enables **commandId** and the associated command status to be saved beyond the execution period of the command. The **commandId** parameter is used to define the command for which the respective status is to be saved. The maximum number of saveable command statuses is specified in the **decodingConfig.numberOfMaxBufferedCommandId** configuration data element.	Subsequent check of how command was terminated (e.g. error-free or number of error that occurred)
_removeBufferedMeasuringInputCommandId (V3.2 and higher)	This function ends the saving of **commandId** and the associated command status beyond the execution period of the command.	Explicit deletion of previously saved command IDs

For further information on the system functions, please refer to the *SIMOTION TP CAM Reference Lists*.

Process Alarms

You can predefine local alarm responses via SIMOTION SCOUT.

Note

For more information, refer to the *Motion Control Technology Objects Basic Functions* functional description.

How to configure the alarm response:

1. Double-click **Execution system** in the project navigator below the SIMOTION device. The execution system opens.
2. In the execution level tree, select **SystemInterruptTasks > TechnologicalFaultTask**.
3. Then click the **Alarm Response** button in the displayed window. The **Alarm Response** window appears. You can configure the alarm response for every TO here.

A system variable **error** indicates that a technology alarm has been generated. The response to the alarm is displayed in the **errorReaction** variable.

Table 4-192 Possible alarm responses

Alarm Response	Description	Application
NONE	No response	-
DECODE_STOP	Command processing is aborted, the current measuring function remains active. Further processing on the technology object can continue after **_resetMeasuringInput** or **_resetMeasuringInputError**.	The TO measuring input can only be reactivated after the error has been acknowledged.
MEASURING_INPUT_DISABLE	Stop and abort of all commands. Further processing on the technology object can continue after **_resetMeasuringInput** or **_resetMeasuringInputError**.	The TO measuring input can only be reactivated after the error has been acknowledged.

Measuring input menus

Measuring Input technology object menu

Grayed-out menu functions cannot be selected. The menu is only active if a Measuring Input TO window is active in the working area.

You can select the following functions:

Table 4-193 Measuring input menu

Function		Significance/Note
Close		Select **Close** to close the configuration window for the measuring input that is open in the working area.
Properties		Select **Properties** to display the properties of the measuring input selected in the project navigator.
Configuration		Select **Configuration** to define the configuration data for the measuring input.
Default		Select **Default** to define the values for the system variables of the measuring input.
Expert		
	Expert list	Select **Expert list** to open the expert list for the selected measuring input. The configuration data and system variables can be displayed and changed in this list.
	Configure units	Select **Configure units** to open the **Configure units of the object** window in the working area. You can configure the units used for the selected object here.

Measuring input TO context menu

Grayed-out functions in the context menu cannot be selected.

You can select the following functions:

Table 4-194 Measuring input context menu

Function		Significance/Note
Open configuration		Select **Open configuration** to display the window for configuring the measuring input in the working area. Enter the configuration data of the measuring input in this window.
Expert list		Select **Expert list** to open the expert list for the selected measuring input. The configuration data and system variables can be displayed and changed in this list.
Cut		Select **Cut** to remove the selected object and save it to the clipboard.
Copy		Select **Copy** to copy the selected object. It is stored in the clipboard.
Paste		Select **Paste** to insert the measuring input stored in the clipboard.
Delete		Select **Delete** to delete the selected measuring input. The entire data of the measuring input is deleted permanently.
Rename		Use **Rename** to rename the object selected in the project navigator. Note that with name changes, name references to this object are not adapted.
Expert		
	Insert script folder	**Insert script folder** enables you to insert a folder below the TO. You can create scripts in this folder in order to, for example, automate the configuration.
	Import object	**Import object** imports the data of a SIMOTION object from another project which was previously created with a selective XML export. You cannot import the entire project, only the data of the SIMOTION object.
	Save project and export object	**Save project and export object** exports selected data of the selected object in XML format. This data export can then be reimported into other projects. Only the data of the selected object, not the entire project, is exported.
Print		Select **Print** to print the configuration of the measuring input. All system variables and configuration data with the associated values are printed.
Print preview		Select **Print preview** to open the preview of the measuring input data to be printed.

Function	Significance/Note
Default	Select **Default** to define the values for the system variables of the measuring input.
Properties	Select **Properties** to display the properties of the measuring input selected in the project navigator.

4.4 Additional technology objects

Preface

This **document** is part of the **Description of System and Functions** documentation package.

Validity range

This manual applies to SIMOTION SCOUT in association with the SIMOTION Cam or Cam_ext technology package from product version 4.4.

Chapters in this manual

The following is a list of chapters included in this manual along with a description of the information presented in each chapter.

- **Fixed Gearing** (Part I)
  Function of fixed gearing technology object
- **Addition Object** (Part II)
  Function of addition objects
- **Formula Object** (Part III)
  Function of formula objects
- **Sensor** (Part IV)
  Function of sensor technology object
- **Controller Object** (Part V)
  Function of controller objects
- **Temperature Controller** (Part VI)
  Function of temperature controllers
- **Index**
  Keyword index for locating information

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4.3:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Open source software

Third-party software - License conditions and copyright notes

Copyright notes for the third-party software contained in this product, in particular the open source software, as well as the applicable license conditions, can be found in the READ_OSS.ZIP file on the SIMOTION D CF card or in the corresponding firmware files.

Special note for resellers

The notes and the license conditions contained in the READ_OSS.ZIP file must be passed on to the purchaser in order to avoid the reseller and purchaser from violating the license conditions.

Source code availability

Some license terms of third-party software components used in this product may require us to provide you with the source code and other information for those components. You can find this information directly on or with the product (e.g. on mass storage devices, DVD). If this is not possible for technical reasons, Siemens will be happy to send you this OSS source code in exchange for reimbursement of the processing costs. Please contact the address provided at the end of this section.

4.4.1 Fundamental safety instructions

4.4.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

4.4.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

4.4.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

4.4.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

4.4.2 Part I - Fixed gearing

4.4.2.1 Overview of Fixed Gearing

Function overview

The **Fixed gear** technology object enables you to implement *fixed synchronous operation* (*without* synchronization/desynchronization) based on a specified gear ratio.

A Fixed gear converts an input variable into an output variable with a configured transmission ratio (gear ratio).

A Fixed gear is interconnected to a motion vector on the input side and the output side.

The basic functionality is the multiplication of the input vector by the configured gear ratio. The individual vector components are thereby multiplied by the gear factor.

Both absolute and relative synchronous operation, with or without offset are possible.

Offset changes, gear changes, and input changeovers are directly enabled.

An on-the-fly master value change is possible (direct transition).

No limiting operations, no transition phases, and no corrections (except the offset value) are taken into account.

You can connect the output interface to a position axis and activate the acceptance of the output values of the fixed gear on the axis with the TO functions _runpositionbasedmotionin or _runvelocitybasedmotionin.

Application

A **Fixed gear TO** can, for example, be used as follows:

- To make allowance for diameters in a master variable
- To implement a fixed gear ratio without clutch
- As a parallel gear on the master,
  slaves are "hung" or "unhung".
  Thus, the gear is always synchronous with the master.
  Example: A paper web also runs in synchronism with the master.

Interconnection

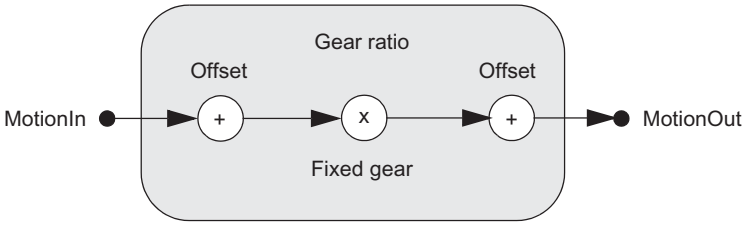

Figure 4-273 Fixed gear object model

A Fixed gear object has one input and one output.

The input vector is type MotionIn and the output vector type MotionOut. These vectors comprise the components distance (s), velocity (v) and acceleration (a).

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

Gear ratio

The **gear ratio** can be specified selectively as a rational value (LREAL) or as a ratio of two 32-bit numbers (DINT) in the form of a **numerator/denominator**.

The **gear ratio** can be changed using functions or commands.

Offset

An offset can be specified on both the input side and output side.

An offset only applies in position-related synchronous operation.

The offset is specified in the set user-defined unit.

It is possible to adjust the slave position by setting the master or slave offset. The difference between the two is as follows:

- **Master offset**: The gear ratio is included in the offset.
- **Slave offset**: The gear ratio is *not* included in the offset.

Units

Units can be set on the Fixed gear TO and they apply to both the input and output side.

Example: Axis 1 - Fixed gear - Axis 2

- The units are set to [mm] for axis 1.
- The units are set to [m] for the Fixed gear.
- The units are set to [m] for axis 2.

This means, for example, that a position of three millimeters on axis 1 corresponds to three meters on the input interface of the Fixed gear.

4.4.2.2 Configuring the fixed gearing

Creating fixed gearing

Fixed gearing technology objects are stored across-the-board for a device in the **TECHNOLOGY** folder. They can be interconnected with suitable technology objects of the device.

Proceed as follows

1. To create a new Fixed Gearing TO, double-click **Insert fixed gearing** under **TECHNOLOGY** in the project navigator.
   You can also copy an existing Fixed Gearing TO using the clipboard and insert it under another name.

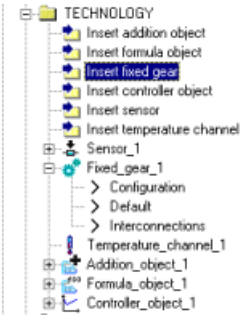

Figure 4-274 Representation of fixed gears in the project navigator

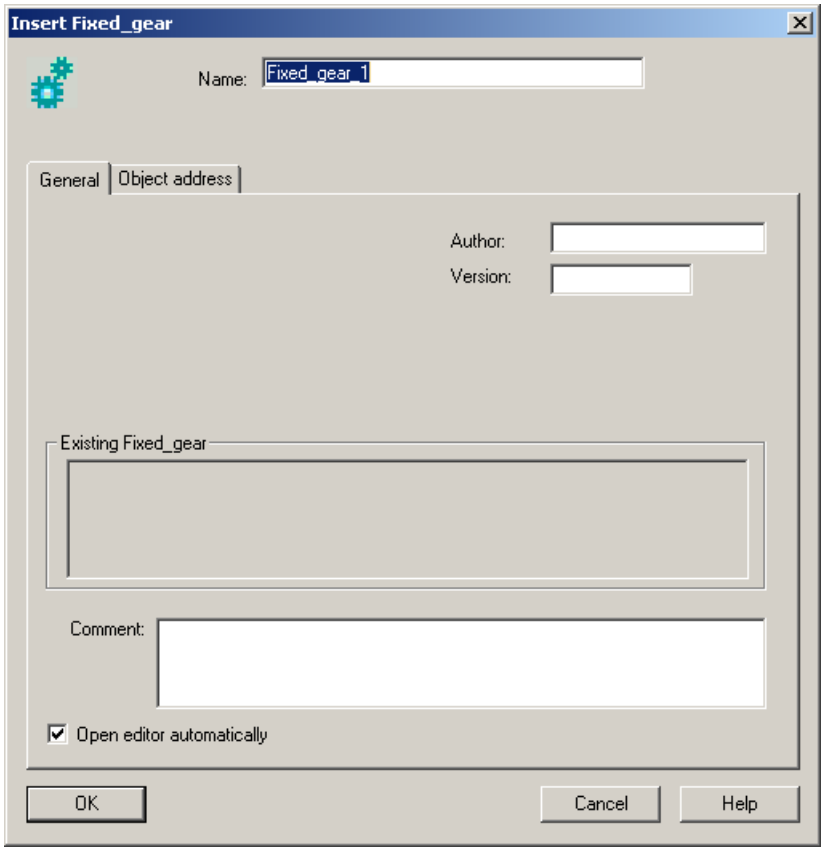

Figure 4-275 Inserting a fixed gear

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new fixed gear TO will be inserted under **TECHNOLOGY**.

Assigning parameters/defaults for fixed gearing

Proceed as follows

In the project navigator, double-click **Defaults** under the object.

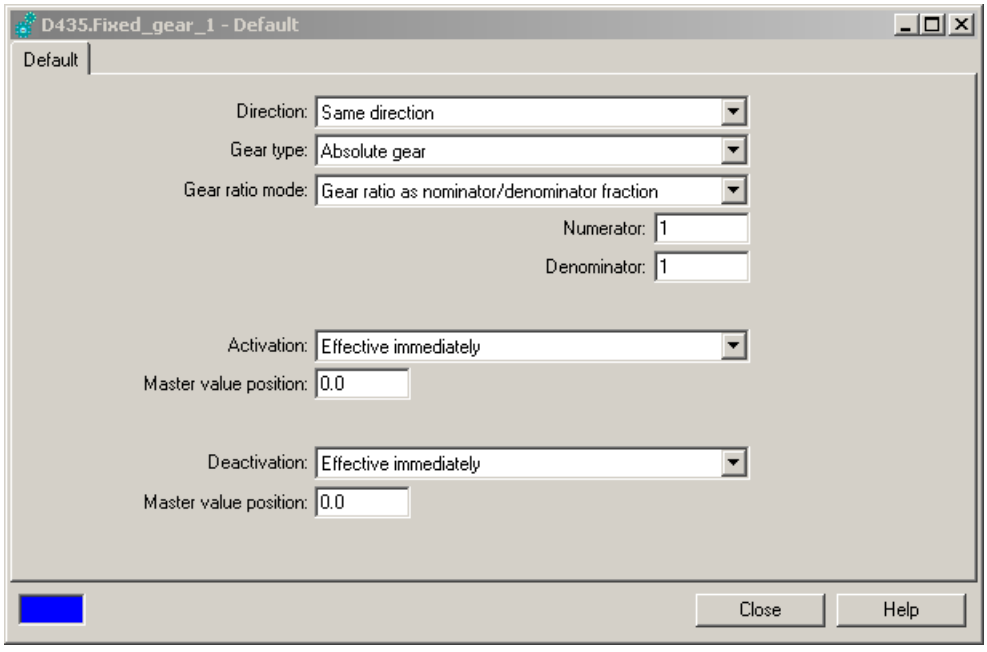

Figure 4-276 Fixed gear TO: Defaults

Fixed gearing - defaults

Specify the parameters (defaults) for calling the fixed gear in this window (**_enableFixedGearing** or **_disableFixedGearing**).

If you do not make any additional specifications during programming, these default values will be used.

You can set the following parameters:

Table 4-195 Fixed gear TO: Parameters that can be set for default purposes

Field/Button	Explanation/Instruction
Direction	Here, you specify the direction of the gearing.
Gear type	Here, you select the gear type (absolute or relative).
Gear ratio mode	Here, you specify the gear ratio mode. Depending on the selected mode, additional parameters are displayed as a rational value (`LREAL`) or as a ratio of two 32-bit numbers (`DINT`) in the form of a numerator/denominator.
Numerator	Here, you can enter the numerator of the gear ratio in the form of a numerator/denominator ratio.
Denominator	Here, you can enter the denominator of the gear ratio in the form of a numerator/denominator ratio.
Activation	Here, you specify the activation method for fixed synchronous operation.

Field/Button	Explanation/Instruction
Master value position	Here, you enter the position of the master value for activation.
Deactivation	Here, you specify the deactivation method for fixed synchronous operation.
Master value position	Here, you enter the position of the master value for deactivation.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION Reference Lists*.

See also

Function overview (Page 1975)

Overview of commands (Page 1983)

Configuring a fixed gearing

Procedure

In the project navigator, double-click **Configuration** under the object.

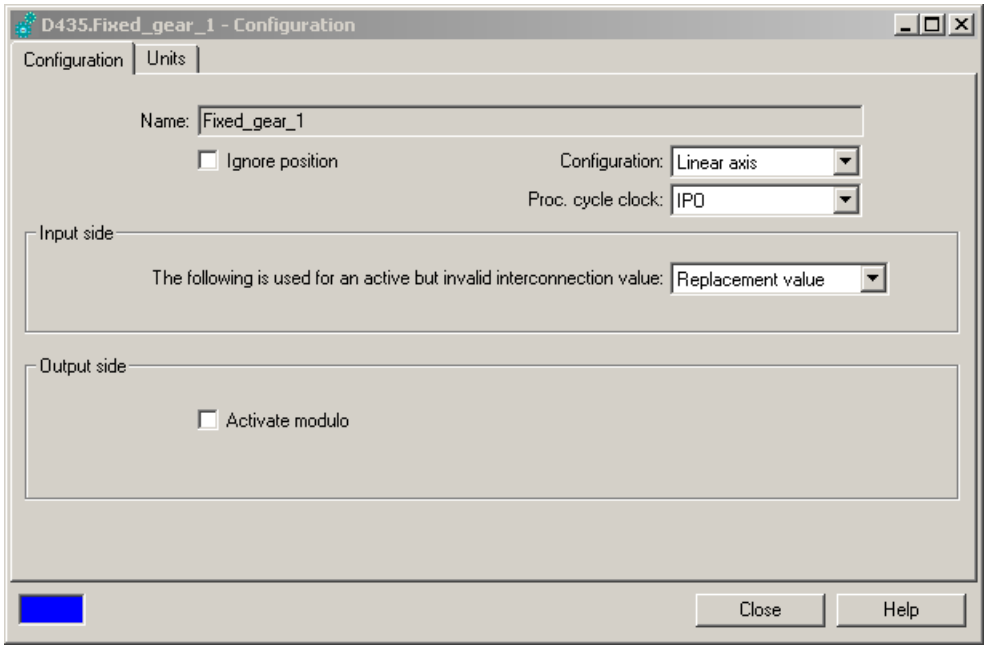

Figure 4-277 Configuring a fixed gearing

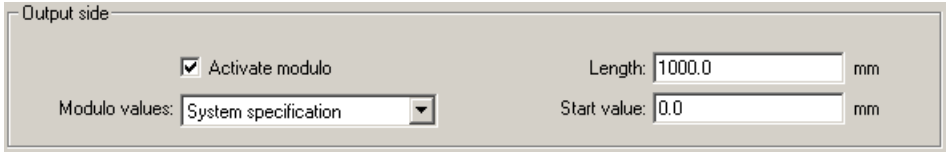

Figure 4-278 Configuring modulo properties of the output of a fixed gear

Fixed gearing - configuration

In this window, specify the configuration of the input and the output.

You can set the following parameters:

Field/Button	Explanation/instructions
Name	Display: name of the fixed gearing
Ignore position	If the check box is selected, the velocity will be used as the gearing basis.
Configuration	Here, you set the units: linear or rotary These apply to the output side. On the input side, the values are applied with their units, or are displayed without units.
Processing cycle clock	Here, you select the IPO cycle clock or IPO_2 cycle clock.
Input side	Here, you specify the validity of the input values or default values.
Output side	Here, you specify the modulo properties of the output. If the check box is selected, the parameters will be displayed.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION reference lists*.

See also

Function overview (Page 1975)

Overview of commands (Page 1983)

Gearing basis

The **gearing basis** (configuration data element **motionBase**) must be specified, i.e.,

- **Position** (POSITION):
  Multiplication of position, velocity, acceleration (s, v, a)
- **Velocity** (VELOCITY):
  Multiplication of velocity, acceleration (v, a)

All components are present in the output vector. When **Velocity** is specified as the gearing basis, the position component in the output vector is set to zero.

Any existing offset is applied to the variable specified by the motion basis.

Modulo properties

The output-side modulo setting is derived from the system or can be set using configuration data element **MotionOut.modulo**.

- The modulo setting is derived from the downstream TO with **system default** (**SYSTEM**) if this TO and its modulo properties can be uniquely determined. (A formula object, for example, does not have any modulo properties.)
- In all other cases, the modulo property set on the TO is used (**DIRECT**).

Interconnecting a fixed gearing

Procedure

1. In the project navigator, double-click **Interconnections** under the object.

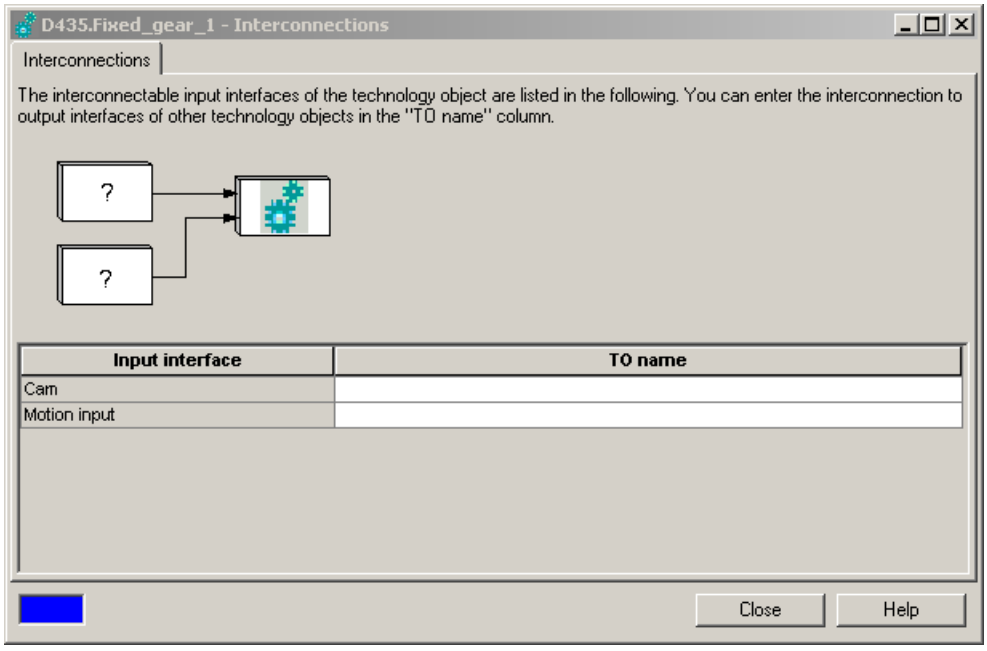

Figure 4-279 Interconnecting a fixed gearing

In this window, interconnect the input of the fixed gear (with axes, for example).

2. To do so, click in the corresponding input field and then select the desired object. (The objects must have already been created.)

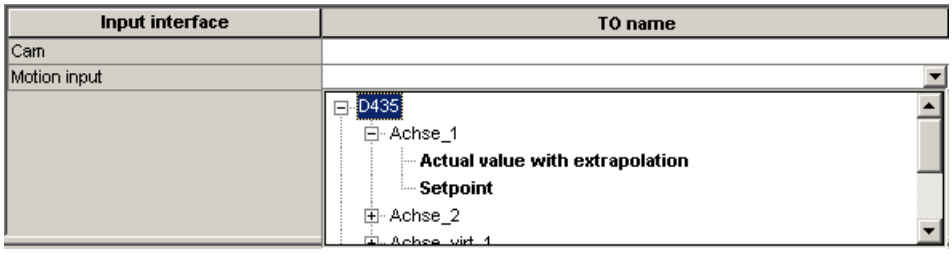

Figure 4-280 Interconnecting a fixed gear with an axis

Note

The interconnection with a cam profile is intended for a later software version and has no function in Version V3.2.

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

4.4.2.3 Programming fixed gearing/references

Programming

Overview of commands

Table 4-196 Fixed gearing TO: Overview of commands

Command	Functionality
_enableFixedGearMotionIn	Enabling/disabling of the input vector
_disableFixedGearMotionIn	
_enableFixedGearing	Activation/deactivation of fixed gear
_disableFixedGearing	
_setFixedGearingOffset	Set offset on the input side/output side
_setFixedGearMaster	Switch over master value
_resetFixedGear	Reset gear
_resetFixedGearError	Reset error
_resetFixedGearConfigDataBuffer	Delete collected configuration data
_bufferFixedGearCommandId	Store CommandId and command status temporarily
_removeBufferedFixedGearCommandId	Delete CommandId
_getStateOfFixedGearCommand	Read out command status
_getFixedGearErrorNumberState	Read out error number status

Note

For a complete list of all commands and their syntax, the system variables, and error messages, please see the SIMOTION Reference Lists.

Commands

Activation/deactivation of the input vector

Note

The interconnection interfaces on the input side are enabled/disabled separately from the functionality.

If the input values are inactive, the default values are applied.

- **_enableFixedGearMotionIn**: Use interconnected input values
- **_disableFixedGearMotionIn**: Disable interconnected input values;
  the default values will be used (**motionInDefault** and **motionOutDefault** system variables).

The commands are synchronous.

The input and the output are active following controller power-up, if they are interconnected. A status check is possible via the **motionIn.state** and **motionOut.state** system variables.

If the input and the output are not interconnected, an error is output. (The alarm is not generated until _enable...In.)

Enabling/disabling of fixed gearing

- **_enableFixedGearing**: Enable gearing functionality
  The command is synchronous.
  - The gearing is started with **_enableFixedGearing** without a transition function.
  - The gearing ratio is specified in the function parameter.
  - The **startPosition...** parameter acts only if **Position** is selected as the gearing basis.
- **_disableFixedGearing**: Disable gearing functionality
  - The gearing is started with **_disableFixedGearing** without a transition function.
  - The values of the interconnection values on the output side depend on the **motionOutBehaviourMode** parameter of the **_disableFixedGearing()** command.

The following can be set for **_disableFixedGearing**:

- Freeze value
- Define default value
- Input a value of "0.0"

Absolute or relative gearing

The fixed gearing can be set to absolute or relative gearing with the **gearingType** parameter of the **_enableFixedGearing** command.

- With *absolute synchronous operation* (**ABSOLUTE**), the input and output values are interpreted "absolutely", i.e., directly coupled.
- With *relative synchronous operation* (**RELATIVE**), the input and output are interpreted "relatively", i.e., coupled with an offset.

Direction

The gear ratio can be set to positive or negative (corresponding to a negative gear ratio) with the **direction** parameter of the **_enableFixedGearing** command.

- **POSITIVE** means that the axes are running in the same direction.
- **NEGATIVE** means that the axes are running in opposite directions.

Validity of input values or default values

The interconnected values are enabled/disabled using a command (**_enableFixedGearMotionIn**/**_disableFixedGearMotionIn**).

Configuration data element **MotionIn.behaviorByInvalidInterface** can be used to specify which of the following values is used if the interconnection values are enabled but invalid:

- Most recent valid value (**LAST_VALID_INTERFACE_VALUE**) or
- Replacement values (**DEFAULT_VALUE**)

(Following system startup, the most recent valid value is 0).

When the interconnection interface on the input side is disabled, the default value is applied.

Setting offset on the input side/output side

_setFixedGearingOffset: Shifts the gearing relative to the master value or slave value.

The offset can be changed over using the **activationMode** parameter of the **_setFixedGearingOffset** command. The changeover applies as follows:

- *For the next synchronous operation and all subsequent synchronous operations* if **DEFAULT_VALUE** is set
- *For the current synchronous operation only* if **ACTUAL_VALUE** is set
- *For the current synchronous operation and all subsequent synchronous operations* if **ACTUAL_AND_DEFAULT_VALUE** is set

An offset with reference to the current synchronous operation is retained only for the duration of the **_enableFixedGearing**, that is, the offset is directly assigned to the active **_enableFixedGearing** command.

The current offset is applied without a compensatory motion, i.e., it is applied directly.

Switch over master value

The active master can be switched over online by means of **_setFixedGearingMaster**.

System variables

The input and output values of a fixed gearing TO can be read out via system variables.

Table 4-197 Fixed gearing TO: System variables

System variable			Type	Description	Remark
motionIn			StructFixedGearMotionIn	input vector	The input vector must be interconnected. Can only be read
	value		StructMotionVector	Components of the input vector	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	
	state		EnumActiveInactive	Status	
	lastValidInterface value		StructMotionVector	Last valid values	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	
	validity		EnumInterfaceValueDefaultValue	Validity	
motionInDefault			StructMotionVector	Default values for input vector	
motionOut			StructFixedGearMotionOut	Output vector	
	value		StructMotionVector	Components of the output vector	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	
	fixedGearValue		StructMotionVector	Function result gearing	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	
motionOutDefault			StructMotionVector	Default values for output vector	Deactivate with function, see **_disable FixedGearing**

Local alarm response

Technological alarms

The standard technology object alarms, e.g., interconnection error, illegal parameter, are output.

Local responses

If an error occurs, the following local responses are possible:

- No response (**NONE**)
- Stop TO processing (**DISABLE**)
- Stop command decoding (**DECODE_STOP**)

The local reactions can be set under **TechnologicalFaultTask** in the alarm configuration.

Menus

Fixed gearing - menu

Grayed-out functions cannot be selected.

You can select the following functions:

Function		Meaning/Note
Close		Use this function to close the active window in the working area.
Properties		Properties displays the properties of the fixed gearing selected in the project navigator. You can enter the object name plus author and version in this window.

	Configure Units	This function opens the Configure Object Units window in the working area. You can configure the units used for the selected object here.
	Import object	Use Import object to open a window for the XML import. You can define the parameters for the XML import in this window.
	Save project and export object	Use Save project and export object to open a window for an XML export. You can define the parameters for the XML export in this window.

4.4.3 Part II - Addition object

4.4.3.1 Overview of Addition Object

Function overview

The **addition object** technology object enables you to add up to four input vectors for one output vector.

The input vectors are type MotionIn and the output vector is type MotionOut.

There are no limitations on the addition object. Transitional phases are not taken into account for non-continuous input signals.

Application

An **addition object** can, for example, be used as follows:

- For adding superimpositions/offsets in the main signal path, e.g., color register, cut-off register to the paper web

Interfaces

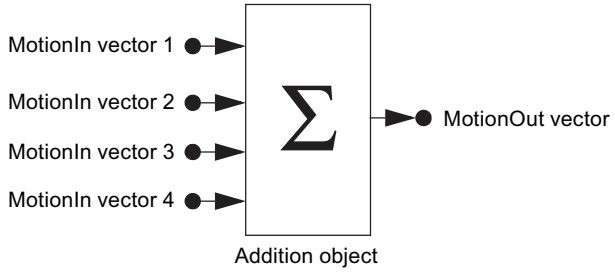

Figure 4-281 Object model for addition object

An addition object calculates the sum of the four input vectors.

The values of the respective input vectors are generated from the interconnection values, the most recent valid interconnection values, or the replacement values.

An interconnected input vector is activated/deactivated using a command; otherwise, the replacement value is applied.

The output vector can be activated or deactivated (frozen).

Interconnection

The first input must be interconnected, while the other inputs and the output may be interconnected.

The first input vector determines which technology variables are added up and are relevant in the output vector.

Non-interconnected input vectors can be specified by means of system variables from the user program.

The input vectors can be interconnected *once only* ('single point') and cannot be changed over; the output vector can be interconnected any number of times ('multi-point').

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

Modulo properties

The variables to be added can be modulo variables.

The output vector can be a modulo variable.

The input modulo lengths and the output modulo length can be different.

The modulo relationships can be specified in the addition object on the output side.

The output modulo length is derived from the output-side interconnection, or it can be directly specified (configuration setting).

Subtraction

Subtractions are possible for each input through configuration (inversion).

Units

Units can be set on the addition object, they apply to both the input and output side.

Example: Axis 1, 2 - Addition object - Axis 3

- The units are set to [mm] for axes 1 and 2.
- The units are set to [m] for the addition object.
- The units are set to [m] for axis 2.

This means, for example, that a position of three millimeters on axis 1 corresponds to three meters on the input interface of the addition object.

4.4.3.2 Configuring an Addition Object

Creating an addition object

Addition objects are stored across-the-board for a device in the **TECHNOLOGY** folder. They can be interconnected with suitable technology objects of the device.

Proceed as follows

1. To create a new addition object, double-click **Insert addition object** under **TECHNOLOGY** in the project navigator.
   You can also copy an existing addition object to the clipboard and then insert it under another name.

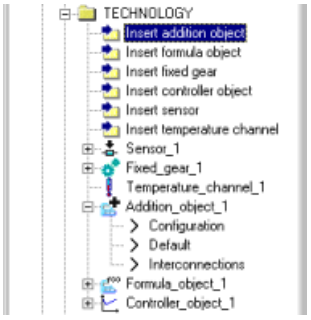

Figure 4-282 Representation of addition objects in the project navigator

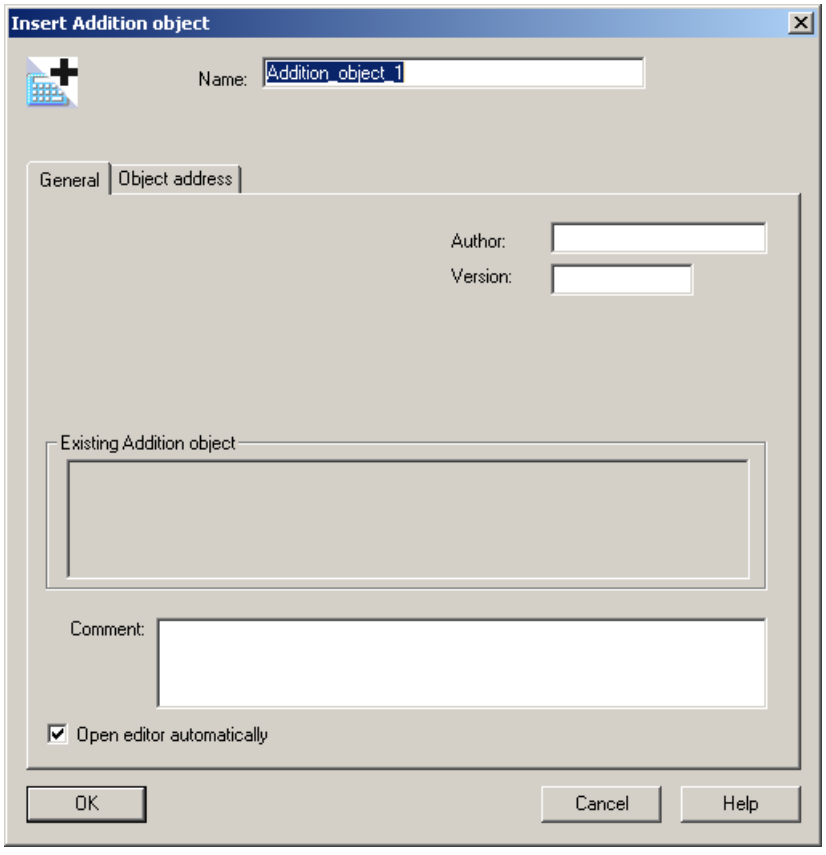

Figure 4-283 Inserting an addition object

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new addition object will be inserted under **TECHNOLOGY**.

Assigning parameters/defaults to an addition object

Procedure

In the project navigator, double-click **Defaults** under the object.

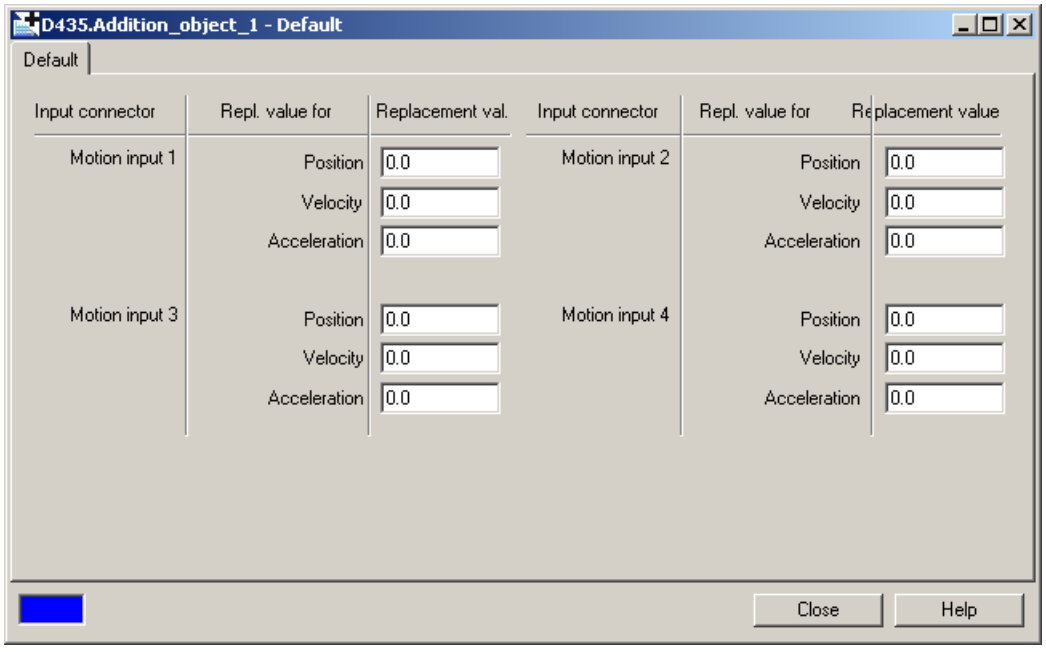

Figure 4-284 Addition object: Defaults

Specify the replacement values (defaults) for calling the addition object in this window (**_enableAdditionObject** or **_disableAdditionObject**).

Addition object - defaults

Specify the input default values (defaults) for calling the addition object in this window (_enableAdditionObject or _disableAdditionObject).

Field/Button	Explanation/instructions
Input connector	Motion inputs 1 to 4
Default value for	Input values are generated from the interconnected values, the most recent valid interconnected values, or the default values. Position, velocity, and acceleration can each be specified with default values.
Default value	Here, you enter the default values.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION reference lists*.

Configuring an addition object

Proceed as follows

In the project navigator, double-click **Configuration** under the object.

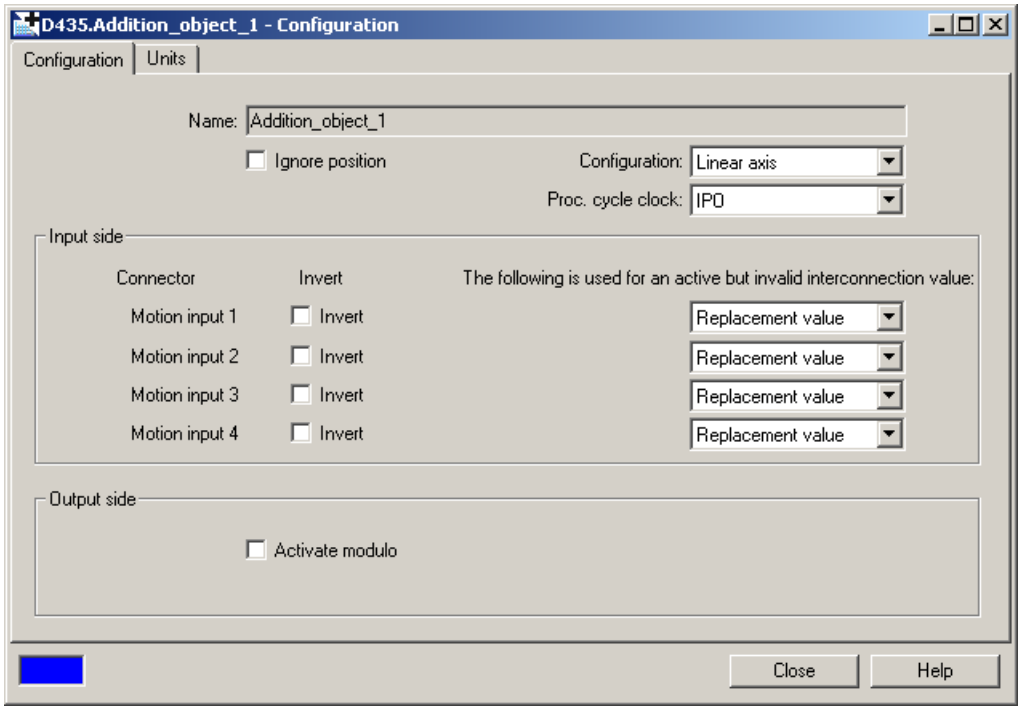

Figure 4-285 Configuring an addition object

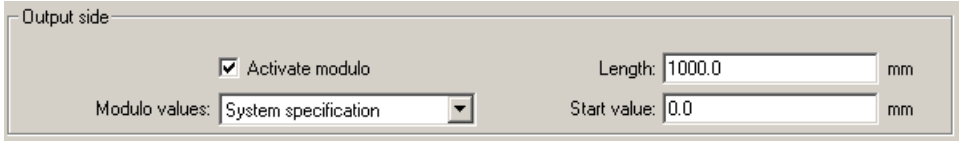

Figure 4-286 Configuring modulo properties of the output of an addition object

Addition object - configuration

In this window, specify the configuration of the inputs and the output.

You can set the following parameters:

Table 4-198 Addition object technology: Parameters that can be set for configuration purposes

Field/button	Meaning/instruction
Name	Display: name of addition object
Ignore position	If the check box is selected, the velocity will be used as the addition basis.
Configuration	Here, you set the units: linear or rotary
Processing cycle clock	Here, you select the IPO-, IPO_2, IPO_FAST, SERVO or SERVO_Fast cycle clock.
Input side	Here, you specify the input inversion and the validity of the input values/substitute values.
Output side	Here, you specify the modulo property of the output. If the check box is selected, the parameters will be displayed.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION reference lists*.

See also

Function overview (Page 1989)

Overview of commands (Page 1997)

Addition basis

The **addition basis** (configuration data element **motionBase**) must be specified, i.e.,

- **Position** (POSITION):
  Addition of position, velocity, acceleration (s, v, a)
- **Velocity** (VELOCITY):
  Addition of velocity, acceleration (v, a)

All input vectors are given the same addition basis.

Only the relevant vector components are then valid in the output vector. The other components are set to zero.

Comment:

A component can be added up selectively in the motion vector, e.g. torque, using a formula object.

Units

The following basic units are available for representing lengths:

- Linear
- Rotary
- No unit

The unit settings apply on the output side. On the input side, the values are added without consideration as to agreement of the units.

That is, all system variables acting on the output side have the configured unit, while all system variables acting on the input side are unitless.

Modulo properties

The output-side modulo setting is derived from the system or can be set using configuration data element **MotionOut.modulo**:

- The "Detect automatically" setting checks the uniqueness of the interconnection(s) on the output side.
  If a unique assignment is possible, the information is used for representing the output vector. If the object interconnected on the output side has a modulo representation, the output vector is already calculated in this modulo representation.
  If a unique assignment is not possible, no adaptation is performed; rather, an error/alarm is output.
- The "Determine from configuration" setting enables a modulo representation to be selected for the output vector itself.

Input inversion

Configuration data element **MotionIn#.invert** can be used to configure a signal inversion for each input prior to addition.

The inversion applies to position, velocity, or acceleration.

The input-side system variable (**motionIn#**) displays the inverted value or writes the value after inversion.

Interconnecting an addition object

Procedure

1. In the project navigator, double-click **Interconnections** under the object.

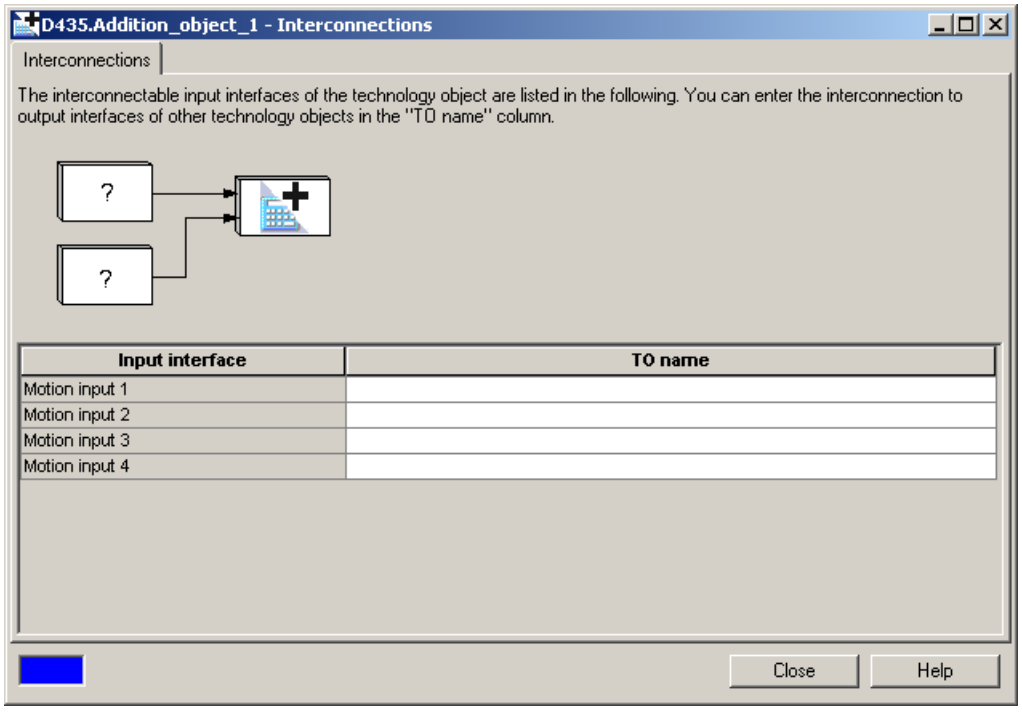

Figure 4-287 Interconnecting an addition object

In the displayed window, interconnect the inputs of the addition object (with axes, for example).

2. To do so, click in the corresponding input field and then select the desired object. (The objects must have already been created.)

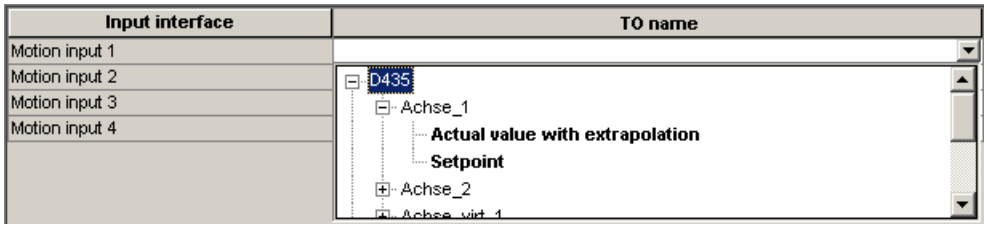

Figure 4-288 Interconnecting an addition object with axes

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

4.4.3.3 Programming an Addition Object/References

Programming

Overview of commands

Table 4-199 Addition object TO: Overview of commands

Command	Functionality
_enableAdditionObjectIn	Enabling and disabling input vectors
_disableAdditionObjectIn	
_changeEnableModeOfAdditionObject	Simultaneous switchover
_resetAdditionObject	Reset addition object
_resetAdditionObjectError	Reset error
_resetAdditionObjectConfigDataBuffer	Delete collected configuration data
_bufferAdditionObjectCommandId	Store CommandId and command status temporarily
_removeBufferedAdditionObjectCommandId	Delete CommandId
_getStateOfAdditionObjectCommand	Read out command status
_getAdditionObjectErrorNumberState	Read out error number status

Note

For a complete list of all commands and their syntax, the system variables, and error messages, please see the SIMOTION Reference Lists.

Commands

Enabling and disabling input vectors

- **_enableAdditionObjectIn**: Enable input vectors
- **_disableAdditionObjectIn**: Deactivate input vectors

The commands are synchronous.

All four input vectors can be enabled/disabled simultaneously with one command.

All of the inputs are always added.

Input values are generated from the interconnected values, the most recent valid interconnected values, or the default values.

- If interconnection values are not enabled, the default values are applied.
- If the interconnection interfaces on the input side are disabled, the most recent valid values or the default values are also used.

The inputs and the output are active following controller power-up if they are interconnected. (The status can be scanned using a system variable.)

If the inputs and the output are not interconnected, an error is output. (The alarm is not generated until _enable...In.)

Validity of input values or default values

Configuration data element **MotionIn#.behaviorByInvalidInterface** can be used to specify which of the following values is used if the interconnection values are enabled but invalid:

- Most recent valid value (**LAST_VALID_INTERFACE_VALUE**)

or

- Replacement values (**DEFAULT_VALUE**)

(Following system startup, the most recent valid value is 0).

System variables

The input and output values of an addition object can be read out via system variables.

Table 4-200 Addition object TO: System variables

System variable			Type	Description	Remark
motionIn1			StructAdditionObjectMotionIn	1. input vector	The first input must be interconnected.
	value		StructMotionVector	Components of 1st input vector	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	
	state		EnumActiveInactive	Status	
	lastValidInterface value		StructMotionVector	Last valid values

motionIn2Default			StructMotionVector	Default values for 2nd input vector	
motionIn3			StructAdditionObjectMotionIn	3. input vector	
motionIn3Default			StructMotionVector	Default values for 3rd input vector	
motionIn4			StructAdditionObjectMotionIn	4. input vector	
motionIn4Default			StructMotionVector	Default values for 4th input vector	

System variable			Type	Description	Remark
motionOut			StructAdditionObjectMotionOut	Output vector	
	value		StructMotionVector	Components of the output vector	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	
	additionResult		StructMotionVector	Function result addition	
		s	LREAL	Position	
		v	LREAL	Velocity	
		a	LREAL	Acceleration	

Local alarm response

Technological alarms

The standard technology object alarms, e.g. interconnection error or illegal parameter, are output.

Local reactions

If an error occurs, the following local responses are possible:

- No response (**NONE**)
- Stop TO processing (**DISABLE**)

The local reactions can be set under **TechnologicalFaultTask** in the alarm configuration.

4.4.4 Part III - Formula object

4.4.4.1 Overview of Formula Object

Function overview

The **formula object** technology object can be applied in the TO interconnection to LREAL and DINT scalars and to MotionIn and MotionOut motion vectors.

The components of a "generalized motion vector" can be modified individually, but the motion vector is interconnected as a whole.

The formula object is a *stand-alone* technology object, which can be interconnected with other technology objects.

Application

A **formula object** can be used between interconnected objects to modify scalar variables in the main signal path, e.g.:

- Superimposition of torque
- Superimposition of master velocity
- Modification of torque variables B+, B-
- Enabling of torque limitations
- Enabling of torque

Operations

The following operations can be performed (for a complete list, see "Available functions in formulas"):

- Manipulation of scalar variables within the TO interconnection
- Adding/subtracting
- Inverting (changing sign)
- Offsets
- Multiplication
- Division
- Switching, enabling (also using multiplication)
- Limiting (minimum, maximum)
- Logical operations (switch enable)

Interfaces and interconnection

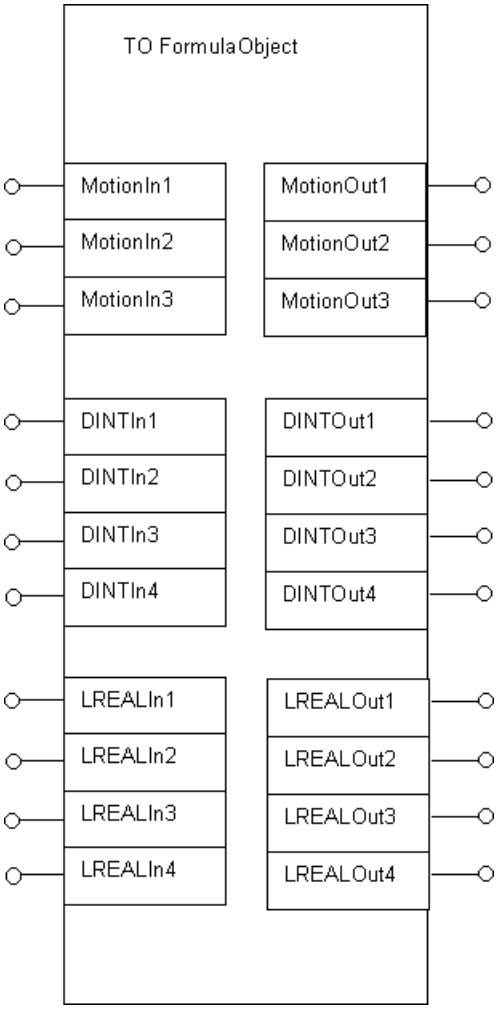

Figure 4-289 Object model for formula object

A formula object has the following inputs/outputs with different formats/types:

- 3 motion vectors/vector components
- 4 scalars `DINT`
- 4 scalars `LREAL`

The interconnection of each input/output is optional and occurs during configuration. However, a check is made to determine whether at least one input is connected (otherwise, an interconnection error is output).

The input interfaces are defined as local connectors, i.e. a device transition does not take place at the interfaces.

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

Definition

The formula must be defined in plain text (string with a maximum of 80 characters) with the **_defineFormula** command using (built-in) functions. (For details of possible functions, see "Available functions in formulas (formula operators)".)

In so doing, the associated formula number must be specified.

Mapping rules

The output value at time k can be calculated in relation to the inputs at time k and the outputs at time k-1:

$A_{i,k} = f\ (E_{1,k} \ldots E_{n,k}\ ,\ A_{1,k-1} \ldots A_{m,k-1})$

The following applies here:

- The order of calculation of individual formulas is not relevant.
- The assignment of a formula to an output can be changed online.
- Explicit conversions are not made.
- In the case of vectors, every component must be written to on the output side.
- The output values are retained, if the object is deactivated.
- The output values can be set (e.g. start value for integrator).
- The components of the vector are not kept consistent.

The instructions are calculated sequentially in each cycle.

Units

All scalar values are interpreted as unitless, i.e. all system variables are also unitless.

The following basic units are available for representing lengths (adjustable for vectors):

- Linear
- Rotary

The unit settings apply on the output side. On the input side, the values are used without consideration as to agreement of the units.

That is, all system variables acting on the output side have the configured unit, while all system variables acting on the input side are unitless.

Modulo properties

Modulo functionality is not taken into consideration in the formula object TO.

- Input values are used "as is".
- Output values are transmitted as calculated.

4.4.4.2 Configuring a Formula Object

Creating a formula object

Formula objects are stored across-the-board for a device in the **TECHNOLOGY** folder. They can be interconnected with suitable technology objects of the device.

Proceed as follows

1. To create a new formula object, double-click **Insert formula object** under **TECHNOLOGY** in the project navigator.
   You can also copy an existing formula object to the clipboard and then insert it under another name.

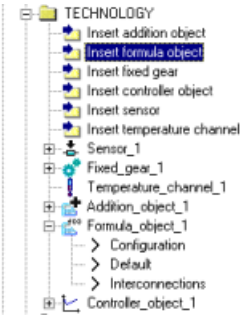

Figure 4-290 Representation of formula objects in the project navigator

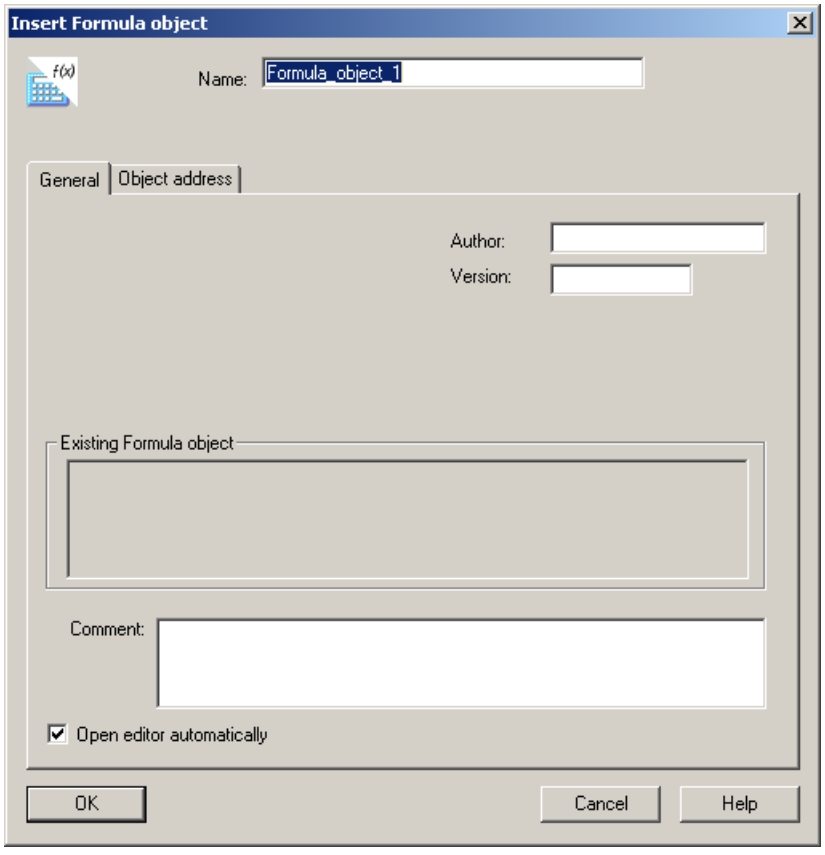

Figure 4-291 Inserting a formula object

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new formula object will be inserted under **TECHNOLOGY**.

Assigning parameters/defaults to a formula object

Proceed as follows

In the project navigator, double-click **Defaults** under the object.

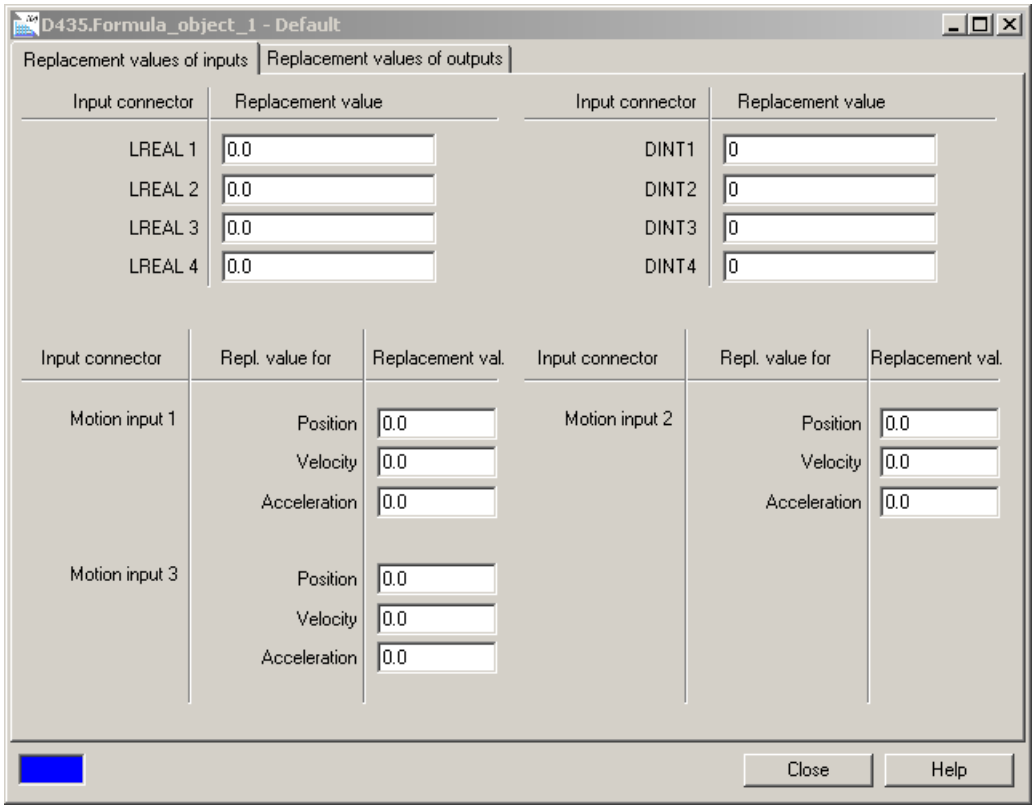

Figure 4-292 Formula object: Defaults

Formula object - defaults

Specify the input and output default values (defaults) for calling the formula object in this window (**_enableFormulaObjectIn** or **_disableFormulaObjectIn**).

You can set the following parameters:

Table 4-201 Formula object TO: Parameters that can be set for default purposes

Field/Button	Explanation/Instruction
Input connector/ Output connector	Motion input/output 1 to 3
Replacement value for	Input/output values are generated from the interconnected values, the most recent valid interconnected values, or the replacement values. Replacement values can be specified for each of the following input/output variables: • 3 motion vectors/vector components • 4 scalars DINT • 4 scalars LREAL
Replacement value	Here, you enter the replacement values.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION Reference Lists*.

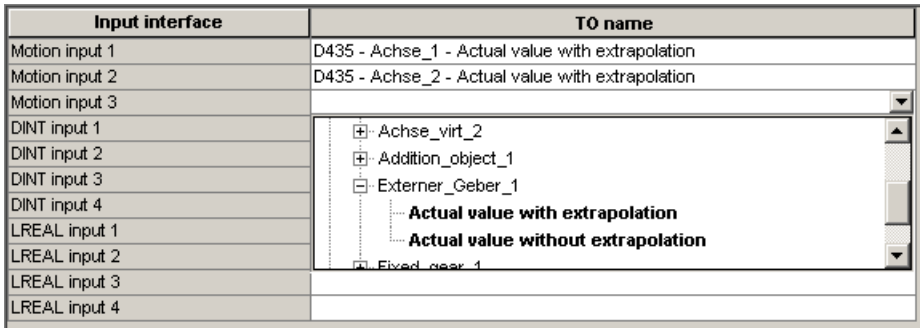

Figure 4-296 Interconnecting the scalar input of a formula object

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

Defining a formula

A formula is defined by programming it in the user program.

Definition

The formula must be defined in plain text (string with a maximum of 80 characters) with the **_defineFormula** command using (built-in) functions. (For details of possible functions, see "Available functions in formulas (formula operators)".)

In so doing, the associated formula number must be specified.

The formula syntax is checked when the formula is defined (on execution of command _defineFormula).

See also

Rules for definition of formulas (Page 2016)

4.4.4.3 Programming a Formula Object/References

Programming

Overview of commands

Table 4-203 Formula object TO: Overview of commands

Command	Functionality
_defineFormula	Define a formula
_setFormula	Simultaneous assignment/switchover of formulas to outputs
_enableFormulaObjectIn	Simultaneous activation of all inputs and formula assignment
_disableFormulaObjectIn	Simultaneous deactivation of all inputs
_enableFormula	Simultaneous activation/switching of formulas to outputs
_changeEnableModeOfFormulaObjectIn	Simultaneous activation/deactivation of selected inputs
_changeEnableOfFormula	Simultaneous activation/deactivation of selected formulas
_disableFormula	Simultaneous deactivation of formulas
_setFormulaObjectOutputValue	Selective setting of function values on outputs
_resetFormulaObject	Reset all output values
_resetFormulaObjectError	Reset error
_resetFormulaObjectConfigDataBuffer	Delete collected configuration data
_bufferFormulaObjectCommandId	Store CommandId and command status temporarily
_removeBufferedFormulaObjectCommandId	Delete CommandId
_getStateOfFormulaObjectCommand	Read out command status
_getFormulaObjectErrorNumberState	Read out error number status

Note

For a complete list of all commands and their syntax, the system variables, and error messages, please see the SIMOTION Reference Lists.

Commands

General

The following commands can be executed together in one IPO cycle clock:

- Formula number assignment
- Set output value
- Activate/deactivate

Defining a formula

A formula can be defined with **_defineFormula**.

The command is synchronous.

With **_defineFormula** it is also possible to influence individual components of the motion vector.

See "**Rules for definition of formulas**"

Assigning a formula

Formulas are assigned simultaneously to outputs with **_setFormula** (in one command because several formulas/all formulas are possible in one cycle clock).

Enabling inputs

- All inputs are enabled simultaneously with **_enableFormulaObjectIn ( )**.
  The inputs can be individually specified.

The inputs are active following controller power-up, if they are interconnected. (The status can be scanned using a system variable.)

If the inputs are not interconnected, an error is output. (The alarm is not generated until _enable...In.)

Enabling/disabling specific inputs

- Specific inputs are enabled/disabled simultaneously
  with **_changeEnableModeOfFormulaObjectIn ( )**.
  Input vectors can be enabled individually and are connected as a whole (with components s, v, a) when enabled.
  Input values are generated from the interconnected values, the most recent valid interconnected values, or the default values.

Validity of input values or default values

Configuration data element **MotionIn#.behaviorInvalidInterface** can be used to specify which of the following values is used if the interconnection values are enabled but invalid:

- Most recent valid value (**LAST_VALID_INTERFACE_VALUE**) or
- Replacement values (**DEFAULT_VALUE**)

(Following system startup, the most recent valid value is 0).

If the interconnection interfaces on the input side are disabled, the default values are applied.

Disabling inputs

- All inputs are disabled simultaneously with **_disableFormulaObjectIn ( )**.
  The inputs can be individually specified.

Enabling all formulas

_enableFormula ( ) enables the formula object.

It is possible to enable each input separately. It is, for example, possible to enable only the velocity component of a vector.

Enabling/disabling specific formulas

- Specific formulas are enabled/disabled simultaneously with **_changeEnableOfFormula ( )**.

Disabling all formulas

- Formulas are simultaneously disabled with **_disableFormula ( )**.
  The formulas can be specified individually using output assignment.

Setting function values on outputs

- **_setFormulaObjectOutputValue** can be used to assign function values to each possible output of the formula object.

  Note

  Only one disabled/inactive output can be set.

Example:

_setFormulaObjectOutputValue(MO1sValue=...) assigns a value to the s-component (position) of the motion interface 1 (MO: Motion Out)

Resetting outputs

- **_resetFormulaObject** sets all output values to zero and resets all formulas (formula number 0).

Rules for definition of formulas

The following rules apply when assigning formulas:

- The individual outputs are assigned to formulas in the formula object using formula numbers.
- The formulas can be assigned/changed over for a disabled output and an enabled output respectively.
- Formulas can be assigned simultaneously to multiple outputs, i.e. changeover of formulas in a command.
- It may be that new outputs will have to be enabled at the same time that formulas are changed over to outputs that have already been enabled.
  In other words, formulas can be changed over and inputs/outputs enabled on the basis of IPO-synchronous task commands that all take effect during the same IPO cycle.
- The formula in an output can be changed over online without having to reset or restart the entire formula object.
- Formulas that are not enabled can be written to.
- If a formula is not explicitly assigned to an output, the null formula is active (output = 0).

Formula numbers

The individual formulas in the Formula Object TO are identified using a formula number.

The formula numbers have values of 1 to n.

The formula numbers are assigned to the outputs. The formula calculation is enabled when the output is enabled.

The formula assigned to an output can be changed over during runtime by reassigning a formula number to an output.

The same formula number can be assigned to more than one output at a time and can thus be active a multiple number of times.

After controller power-up, the "null formula" (function value of 0) is assigned to the individual formula numbers.

Valid formula elements

The following elements can be used to define a formula:

- Literals (numbers and letters)
- Identifiers (variables)
- Basic operators
- Provided functions
- Nesting of expressions

Character set

The following characters are permissible:

- Numbers `0-9`
- Letters `a-z, A-Z`
- Special characters `+, -, *, /, (, ), _, #`

No distinction is made between upper and lower case letters.

Number types

Only integer and floating point number types are permitted:

- Integers (DINT) in decimal, octal, and hexadecimal notation
- Floating-point numbers (LREAL) in rational and exponential notation

Vector components are mapped onto these.

Identifier

Only defined symbols for input and output components are permitted as variables, e.g.:

- LI1 (LREALIn1)
- DI1 (DINTIn1)

Vectors are specified component by component because they refer to the components of the motion vector (s, v, a), e.g.:

- MI1.s (MotionIn1, position)
- MI1.v (MotionIn1, velocity)
- MI1.a (MotionIn1, acceleration)

Nesting of expressions

Expressions can be nested by using parentheses `( )`.

Implicit type conversions

- DINT to LREAL:
  In all (completed) expressions in which the highest address is a LREAL value
- DINT to LREAL:
  For function parameters of type LREAL
- DINT to LREAL:
  If the result of the instruction is a LREAL value

Explicit type conversions

- LREAL to DINT:
  Using LD( )

Data type ANY {DINT, LREAL} is implicitly specified for functions. Within a function, ANY is resolved into type DINT or LREAL. This conforms with the parameter assignment and/or the possible implicit type conversions.

Basic operators

In the case of basic operators, only those operators that require integer and/or floating point operand types are used.

Boolean operations/Boolean expressions are defined as functions in order to circumvent explicit type conversions.

- Unary operators:
  -(Negation) [DINT/LREAL]
- Binary operators:
  +, -, *, /, [DINT, LREAL], MOD [DINT]

Note

In contrast to the addition object, separate inversion of an input using configuration data is not possible in the formula object.

Available functions in formulas (formula operators)

Table 4-204 Formula object TO: Formula operators

Function	Description
Logic operators	
Logical **_AND** **AND**(DINT, DINT):DINT	Function for Boolean AND Result is 0 if either of the two parameters is 0; otherwise, it is 1
Logical **_OR** **OR**(DINT, DINT):DINT	Function for Boolean OR Result is 0 if both parameters are 0; otherwise, it is 1
Logical **_XOR** **XOR**(DINT, DINT):DINT	Function for Boolean XOR Result is 1 if one parameter is 0 and the other parameter is not 0; otherwise, result is 0
Logical **_NOT** **NOT**(ANY):DINT	Function for Boolean NOT Result is 1 if parameter is 0; otherwise, it is 0
Equal **EQ** **EQUAL**(DINT, DINT):DINT	Parameters are equal Result is 1 if parameters are identical; otherwise, it is 0
Not equal **LE** **LESS**(DINT, DINT):DINT	Parameters are not equal Result is 1 if parameter 1 is less than parameter 2; otherwise, result is 0
Arithmetic	

Function	Description
SIN(LREAL):LREAL **COS**(LREAL):LREAL **TAN**(LREAL):LREAL **ASIN**(LREAL):LREAL **ACOS**(LREAL):LREAL **ATAN**(LREAL):LREAL **LN**(LREAL):LREAL **LOG**(LREAL):LREAL TRUNC(LREAL):LREAL EXPT(LREAL, DINT):LREAL **ABS**(LREAL):LREAL **SQRT**(LREAL):LREAL	Arithmetic functions Result is the value of the mathematic operation In the event of an error, processing of the expression is aborted and the value is not updated.
Miscellaneous	
Maximum **MAX**(ANY, ANY):ANY	Maximum generation Result is the maximum of the two parameters
Minimum **MIN**(ANY, ANY):ANY	Minimum generation Result is the minimum of the two parameters
Limiting **LIMIT**(ANY, ANY, ANY):ANY	Limit • Parameter 1: Lower limiting value • Parameter 2: Value to be limited • Parameter 3: Upper limiting value Result is the limitation of parameter 2
Selection **SEL**(DINT, ANY, ANY):ANY	Selection function Parameter 1 <> 0 → Result = Parameter 2 Parameter 1 = 0 → Result = Parameter 3

System variables

The input and output values of an formula object can be read out via system variables.

Table 4-205 Formula object TO: System variables

System variable			Type	Description	Remark
motionIn1			StructFormula ObjectMotionIn	1. input vector	At least one input must be interconnected.

Local alarm response

Responses in the event of an error

The **error status** is displayed in the Formula Object TO if:

- An error is present in the overall object
- An individual error exists

Individual errors are also indicated at the output.

System variable **error** indicates the overall status. This variable is set if:

- The overall object is faulty
- Overall processing is halted
- An individual error exists

Intermediate results are not displayed.

Local reactions

If an error occurs, the following local responses are possible:

- No response (**NONE**)
- Stop processing of the specific formula (**STOP_SPECIFIC_FORMULA**)
- Stop all processing (**STOP_ALL_FORMULA**)
- Stop TO processing (**DISABLE**)

The local reactions can be set under **TechnologicalFaultTask** in the alarm configuration.

Response, e.g., for division by zero

The system performs a check to determine whether division by zero is present.

If yes:

- A technological alarm is triggered
- The output is disabled/frozen
- The formula must be restarted/enabled

Other technological alarms

The standard technology object alarms, e.g., interconnection error, illegal parameter, are output.

Menus

Formula object - menu

Grayed-out functions cannot be selected.

You can select the following functions:

Function	Meaning/Note
Close	Use this function to close the active window in the working area.
Properties	Properties displays the properties of the formula object selected in the project navigator. You can enter the object name plus author and version in this window.
Configuration	This function opens the configuration for the formula object selected in the project navigator. In this window, specify the configuration of the inputs and outputs.

Function	Meaning/Note
Factory setting (default)	This function opens the defaults for the formula object selected in the project navigator. Specify the input default values for calling the formula object in this window (**_enableFormulaObjectIn** or **_disableFormulaObjectIn**).
Interconnections	This function opens the interconnections for the formula object selected in the project navigator. In this window, interconnect the inputs of the formula object, e.g. to axes.
Expert	This function opens the submenu for the expert settings.
Expert list	This function opens the expert list for the formula object selected in the project navigator. The configuration data and system variables can be displayed and changed in this list. See Basic functions - expert list

Function		Meaning/Note
	Import object	Use Import object to open a window for the XML import. You can define the parameters for the XML import in this window.
	Save project and export object	Use Save project and export object to open a window for an XML export. You can define the parameters for the XML export in this window.

4.4.4.4 Example

A real axis 1 is to be linked to a virtual axis 2 via a formula object.

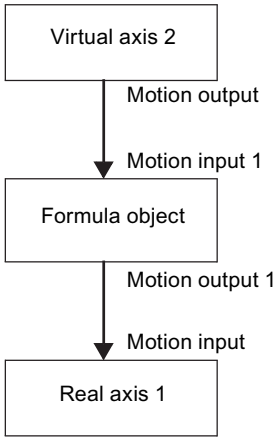

Figure 4-297 Linking two axes via a formula object

Procedure

1. Create all objects.
2. Interconnect motion input 1 of the formula object with the motion output of virtual axis 2.

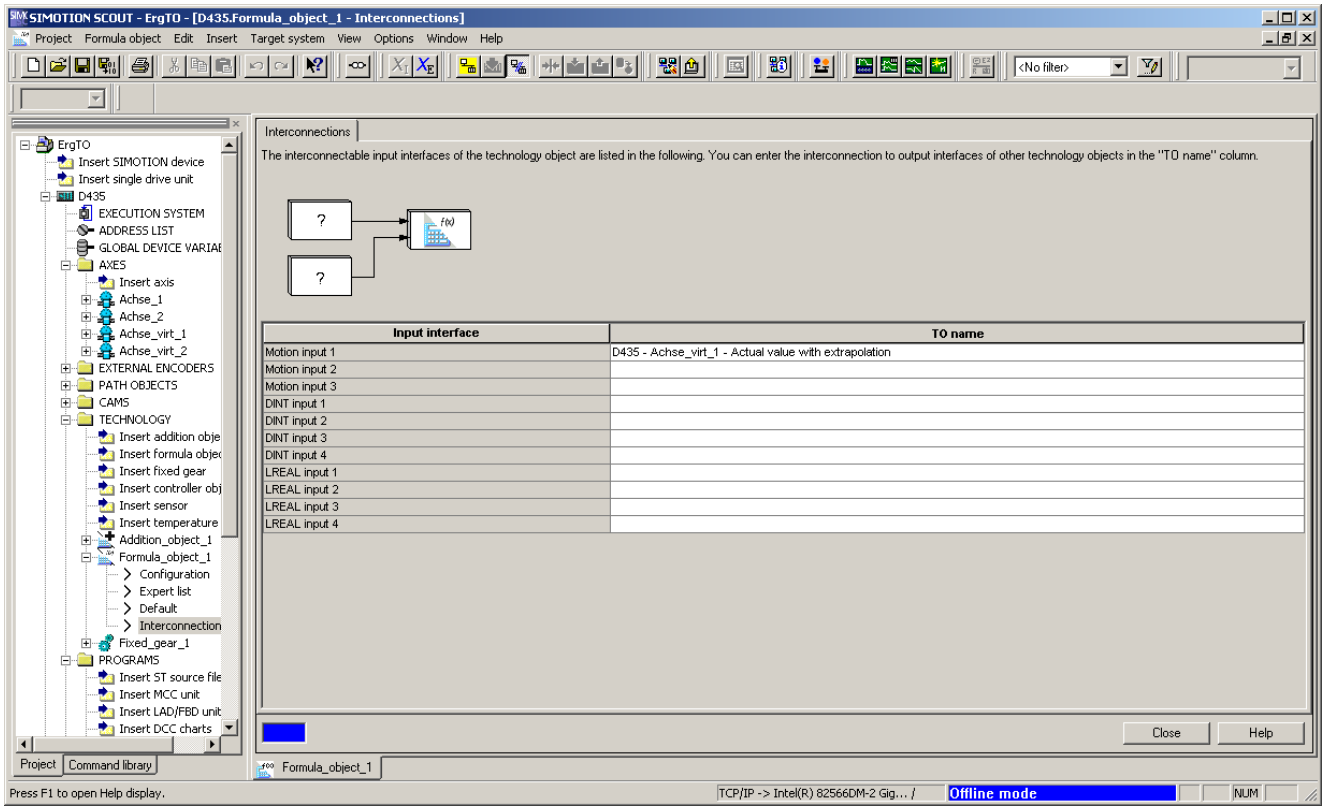

Figure 4-298 Example of interconnection: Formula_object_1 -> Axis_virt_2

3. Interconnect the motion input of axis 1 with the motion output of the formula object.

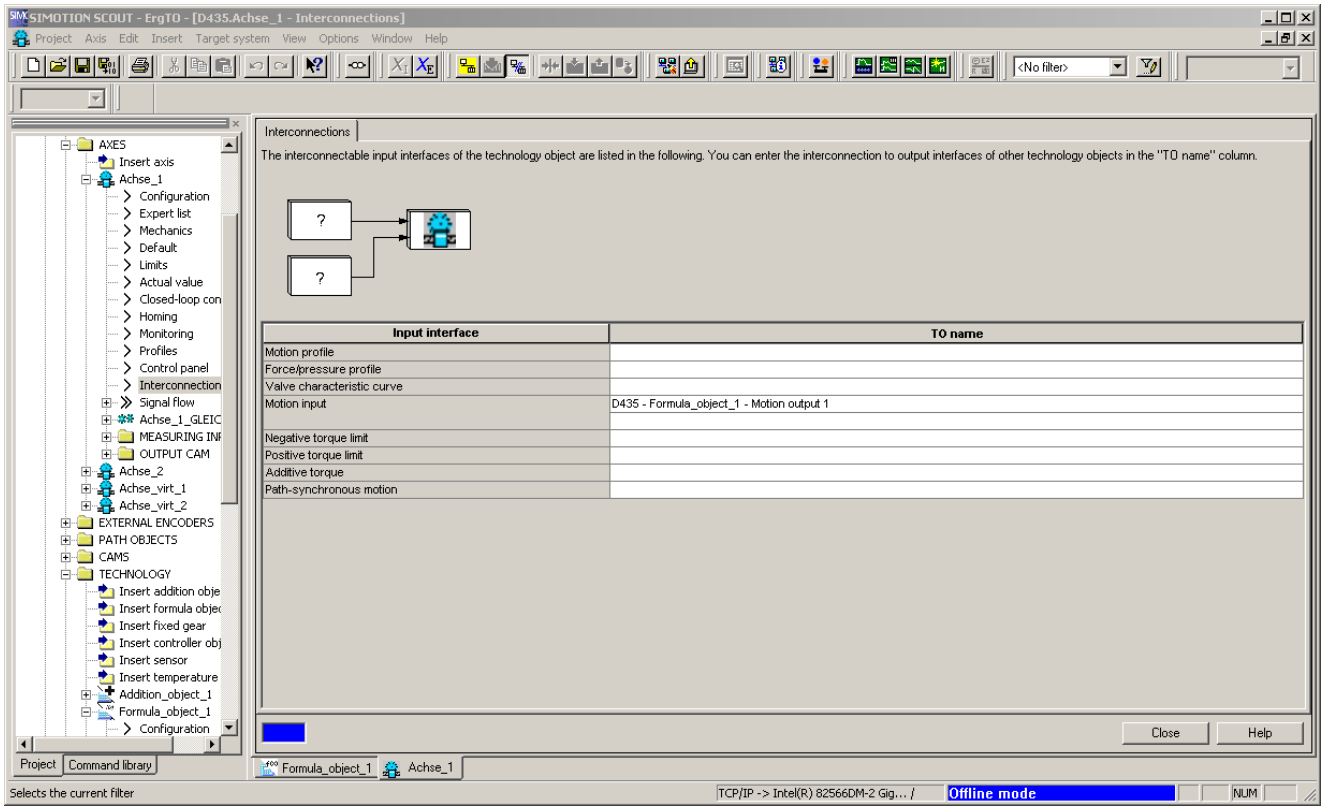

Figure 4-299 Example of interconnection: Axis_1 -> Formula_object_1

4. Use the **_defineFormula** command to influence the components of the motion vector.

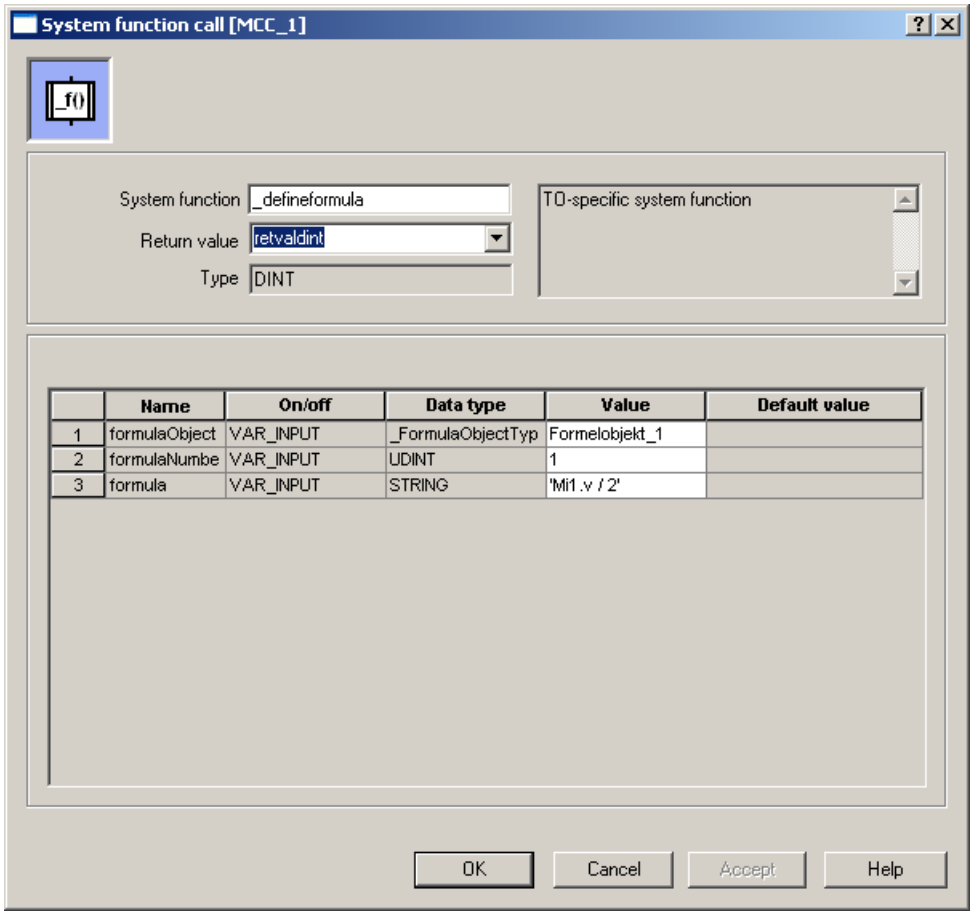

Figure 4-300 Example of calling **_defineFormula** to change a component

The abbreviation "Mi1.v" stands for MotionIn1.value.v (velocity).

5. The **_enableFormula** command activates the formula object; it is also possible to activate each input separately.
   Only the velocity component of the vector is to be activated here.

	Name	On/off	Data type	Value	Default value
1	formulaObject	VAR_INPUT	_FormulaObjectTyp	Formula_object_	
2	MO1s	VAR_INPUT	EnumActiveNoChan	...	DO_NOT_CHANGE
3	MO1v	VAR_INPUT	EnumActiveNoChan	ACTIVE	DO_NOT_CHANGE

13	LO3	VAR_INPUT	EnumActiveNoChan	...	DO_NOT_CHANGE

Figure 4-301 Example of calling **_enableFormula** with a component

6. The formula is assigned to the outputs with the **_setFormula** command.

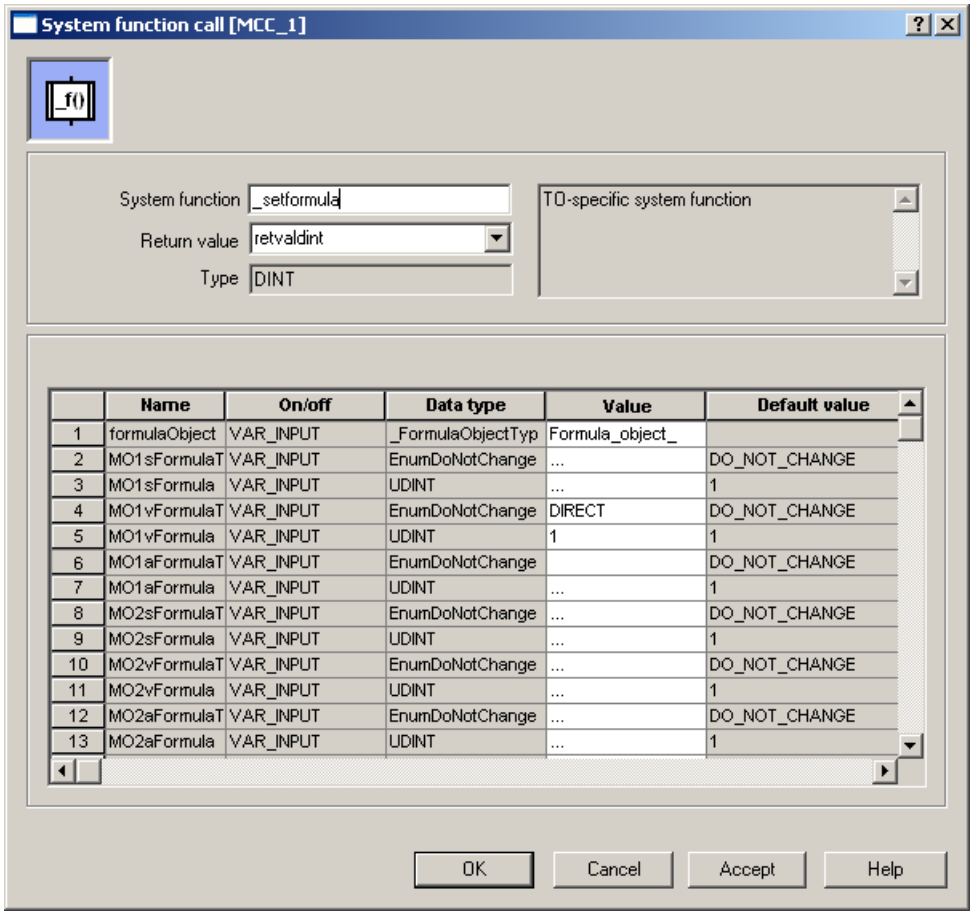

Figure 4-302 Example of calling **_setFormula** with a component

7. Use the **_runVelocityBasedMotionIn** command to activate the motion input of axis 2.

4.4.5 Part IV - Sensor

4.4.5.1 Overview of Sensor

Function overview

The **sensor** TO can be used to record scalar measured values.

The sensor TO reads out a value from the I/O and supplies an actual value as an output signal in standardized formats.

Application

A **sensor TO** can be used to acquire and prepare scalar measured values.

Interfaces

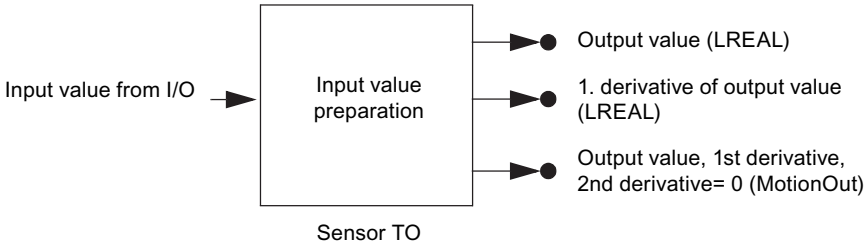

Figure 4-303 Object model for sensor TO

A sensor TO has one input for reading an I/O value and three outputs.

The first output provides the output value, the second output provides its first derivative, and the third output provides the output value as well as its first and second derivatives in the form of a motion vector.

The acceleration component in the motion vector is always 0 (see image).

Interconnection

The input value is obtained from the I/O.

The interfaces are optional and incorporated during configuration.

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

Preprocessing

The input value is preprocessed according to the configuration.

The following preprocessing steps can be performed:

- Format adaptations for a wide range of input formats
- Signal monitoring
- Linear signal normalization
- Signal filtering
- Signal differentiation

Input value

The input value and the input value preparation can be activated or deactivated (**_enableSensor** or **_disableSensor**).

When the input value ifs deactivated, it can be specified whether the value is retained or replaced by a zero value, default value, or direct value.

The sensor TO enables up to 32-bit values to be read in from the I/O interface (adjustable). Functions for adaptation to different input formats are possible.

Output value

At the output, it is possible to select whether the prepared input value, the last value, or the default value is output.

The output value can be read.

The sensor TO is active after power-up.

The output value can be interconnected to a **motion vector**:

- The value to the position component (s)
- The derived value to the velocity component (v)
- The value of the acceleration component (a) is zero.

The output values are zero after the TO has powered up.

Units

Units are taken into account (SI units).

The following units are available as of V3.2:

- Force: [N] (newton)
- Distance: [mm] (millimeter)
- Temperature: [°C]
- Angular degrees: [°]
- Voltage: [V] (volt)
- Current: [A] (ampere)
- Unitless [---, %] (normalized variable)

Units can be set on the sensor TO, they apply at the input and output side.

4.4.5.2 Fundamentals of sensors

Function in principle

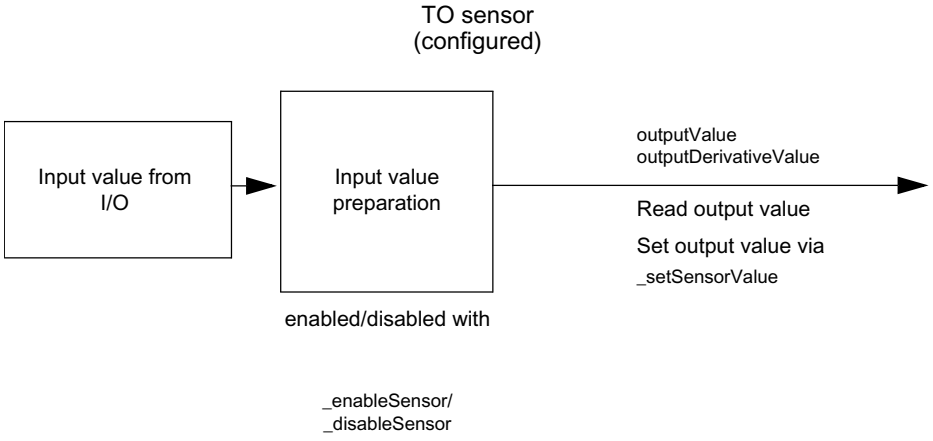

Figure 4-304 Function of sensor TO

The input value is read in from the I/O by the **TO sensor** and preprocessed according to configuration.

The output value is made available directly and as a derived value.

Measured value

The sensor TO enables values to be read in from the I/O interface (up to 32 bits, adjustable).

The **sensor.analogSensorDriverInfo** configuration data element can be used to adapt the input to different input formats.

logAddress	Logical address of the communication module used
resolution	Number of relevant bits (INT32, resolution ADU)
format	Format of the actual value
minValue	Minimum digitized measured value
maxValue	Maximum digitized measured value
errorToleranceTime	Tolerance time for which an error has to be present before an alarm is triggered

Function in detail

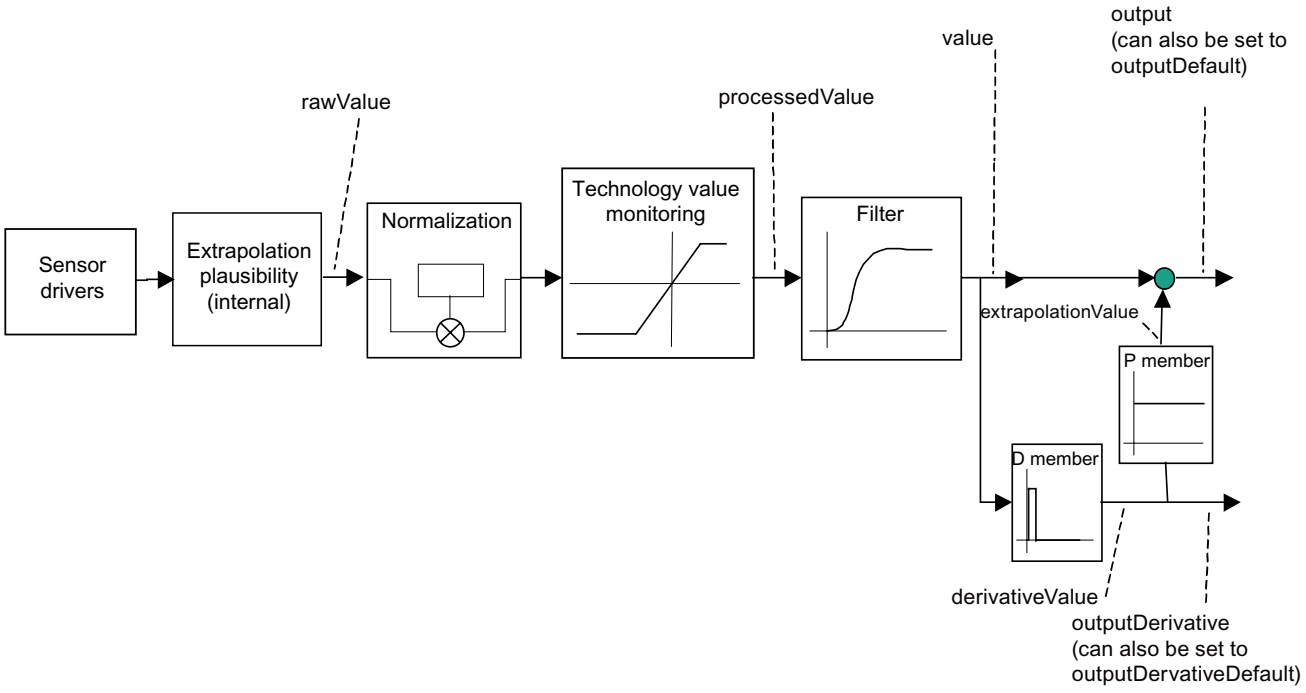

Figure 4-305 Description of functions of sensor TO

Normalization of the input variable

The signals are normalized linearly (configuration data element **sensor.conversiondata._type** =LINEAR).

Configuration data elements **sensor.conversiondata.factor** and **sensor.conversiondata.offset** can be used to specify (linear) normalization.

⚠ WARNING

Weighting factor for analog sensors

The scaling or conversion in the value of the configuration data **ConversionData.factor** for the position of the analog sensor has changed in SIMOTION V4.4.

As of V4.4, the following applies:

If the unit system is configured for inches, then the values are entered directly in inches and are therefore no longer converted from mm to inches. This can result in a higher velocity being detected (by a factor of 25) if the axis is working in inches.

The following applies to SIMOTION < V4.4:

Values are entered in mm and then converted to inches (1 inch corresponds to around 25 mm). Please check the values entered for **ConversionData.factor** in older projects and correct them if necessary.

Raw value monitoring

A permissible raw value range is specified for monitoring of the raw value output by the module. The raw values may fall outside the range for a defined period of time. All values outside the range are regarded as errors, and the raw values are limited.

The permissible raw value range and the time window can be specified in configuration data item **sensor.AnalogsensorDriverInfo.minValue/maxValue**.

The monitoring status is indicated in the **monitorings.rawvalue** system variable.

Technology value monitoring

The technology value is monitored and limited with respect to the limits specified in the **sensor.range** configuration data element.

The monitoring status is indicated in the **monitorings.value** variable.

Filter

A PT1 function is inserted in the signal path for smoothing the output value.

The filter can be switched on and off with the **sensor.filter** configuration data element.

Differentiation

The derivative of the output value is generated by numerical differentiation.

The filtered value is used for this purpose.

Applying the derived value to the output value

The derived value can be applied to the output value with weighting (P element).

The weighting value is specified as a factor and not as an extrapolation time.

The weighting value setting can be made in the **extrapolation.factor** configuration data element.

4.4.5.3 Configuring sensors

Creating a sensor object

Sensor technology objects are stored across-the-board for a device in the **TECHNOLOGY** folder. They can be interconnected with suitable technology objects of the device.

Proceed as follows

1. To create a new sensor TO, double-click **Insert sensor** under **TECHNOLOGY** in the project navigator.
   You can also copy an existing sensor TO using the clipboard and insert it under another name.

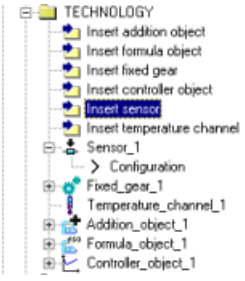

Figure 4-306 Representation of sensors in the project navigator

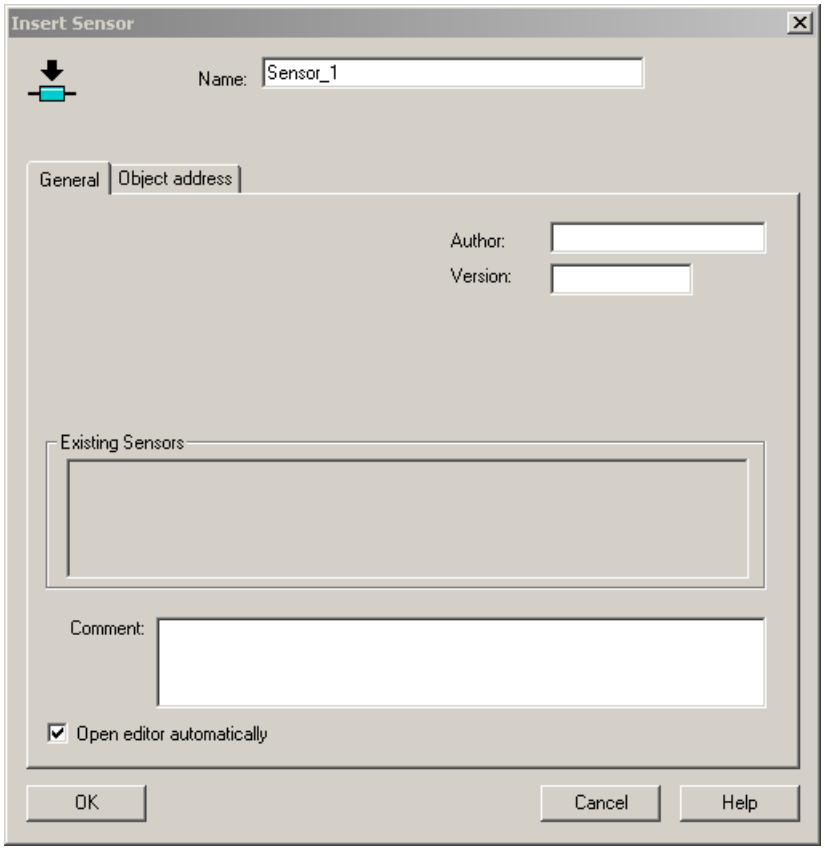

Figure 4-307 Inserting a sensor TO

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new sensor TO will be inserted under **TECHNOLOGY**.

Configuring a sensor

Procedure

In the project navigator, double-click **Configuration** under the object.

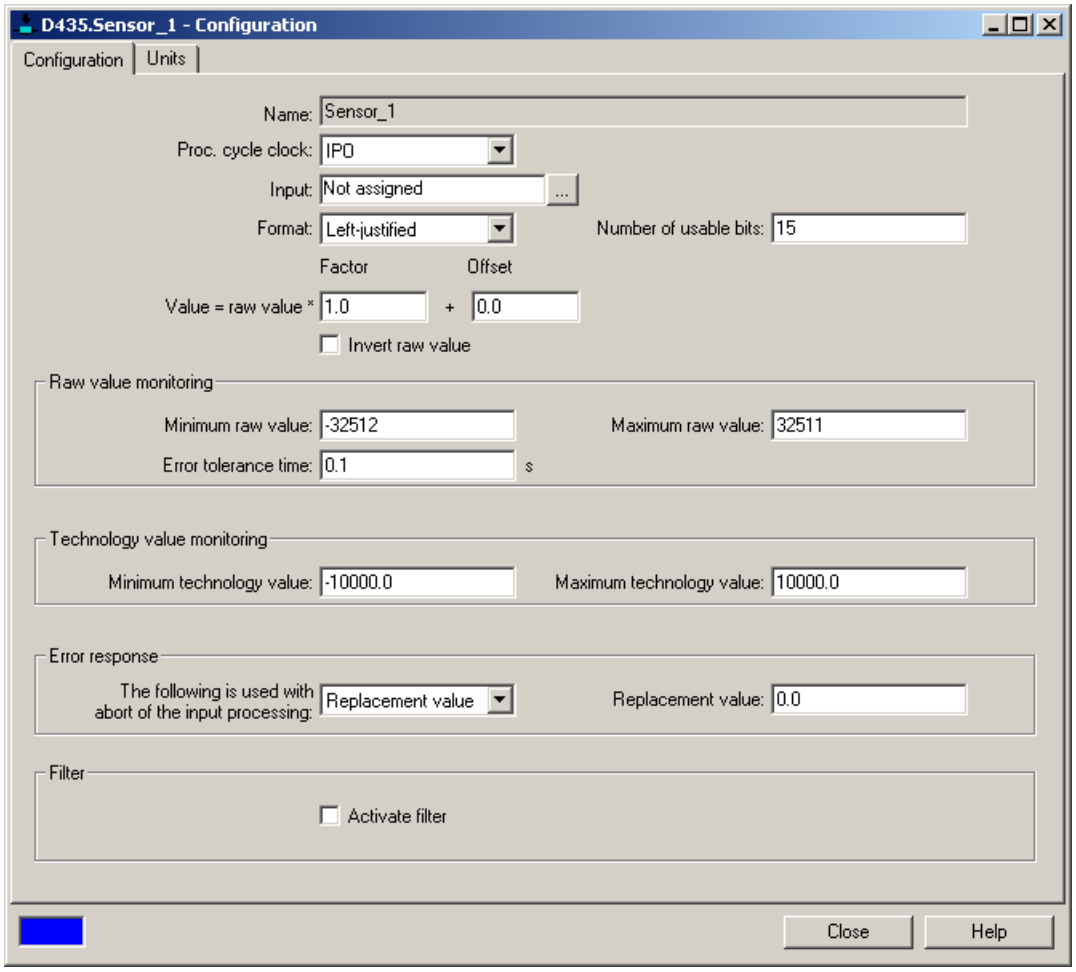

Figure 4-308 Configuring a sensor

Sensor - configuration

Define the properties of the sensor in this window.

You can set the following parameters:

Table 4-206 Sensor TO: Parameters that can be set for configuration purposes

Field/button	Meaning/instruction
Name	Display: name of sensor
Input	The input can be symbolically assigned to the analog signal via the assignment dialog (see the Chapter entitled Symbolic Assignment (from V4.2 onward) in the Motion Control Basic Functions manual) and by using the ... button in the Input field (symbolic assignment is activated by default in projects as of V4.2).
Format	Here, you select the binary format.
Number of usable bits	Here, you enter the number of data bits.
Processing cycle clock	Here, you select the IPO-, IPO_2, Servo, Servo_fast or IPO_servo cycle clock. For the possible setting IPO_fast, see the chapter entitled Second position control cycle clock (Servo_fast) in the Motion Control Basic Functions manual.
Raw value monitoring	Here, you enter the values for raw value monitoring. A permissible raw value range is specified for monitoring of the raw value output by the module. The raw values may fall outside the range for a defined period of time. All values outside the range are regarded as errors, and the raw values are limited.
Technology value monitoring	Here, you enter the values for **Technology Value Monitoring**. The technology value is monitored and limited with respect to the limits specified.
Error response	Here, you select the response in the event of an error.
Filter	Here, you switch the filter on or off. A PT1 function is inserted in the signal path for smoothing the output value. The derived value is generated from the filtered value.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION reference lists*.

Programming

Overview of commands

Table 4-207 Sensor TO: Overview of commands

Command	Functionality
_enableSensor	Enabling/disabling input processing in a sensor TO
_disableSensor	
_resetSensor	Reset sensor
_resetSensorError	Reset error
_resetSensorConfigDataBuffer	Delete collected configuration data
_bufferSensorCommandId	Store CommandId and command status temporarily
_removeBufferedSensorCommandId	CommandId and delete
_getStateOfSensorCommand	Read out command status
_getSensorErrorNumberState	Read out error number status

Note

For a complete list of all commands and their syntax, the system variables, and error messages, please see the SIMOTION Reference Lists.

Commands

Enabling/disabling the sensor TO

The input value of the sensor TO is active after power-up, and thus does not have to be enabled specifically.

The option exists to disconnect the I/O value and specify a default value.

Activating/deactivating input processing in a sensor TO

- **_enableSensor**:
  Enables the input processing
- **_disableSensor**:
  Disables the input processing
  A value setting is not cyclically overwritten.
  The **valueBehaviorMode** parameter can be used to set one of the following functions:
  - Retain the last value (LAST_VALUE)
  - Use the default value (DEFAULT_VALUE)
  - Output the zero value (ZERO_VALUE)

System variables

The input and output signals of the sensor TO are represented using system variables.

Table 4-208 Sensor TO: System variables

System variable	Type	Description	Remark
rawValue	LREAL	Value before linearization	Can only be read
processedValue	LREAL	Value after linearization and limiting	Can only be read
value	LREAL	Technological output value (value after filtering)	Can only be read
derivedValue	LREAL	Differential technological output value	Can only be read
extrapolationValue	LREAL	Extrapolation value	Can only be read
outputDefault	LREAL	Specification for output value	Read/write
outputDerivativeDefault	LREAL	Specification for derivative of output value	Read/write
output	LREAL	Output value	Can only be read
outputDerivative	LREAL	Derivative of output value	Can only be read
motionOut	StructMotionVector	Motion vector	Can only be read
monitorings	StructSensorMonitorings	Monitoring states of sensor TO:	Can only be read
rawValue	EnumLimitExceededOk	Raw value monitoring	
value	EnumLimitExceededOk	Technology value monitoring	
control	EnumActiveInactive	Operational status	Read-only
error	EnumYesNo	Technological alarm on the sensor TO	Read-only
errorReaction	EnumSensorErrorReaction	Active reaction to technological alarm	Read-only
activationModeChanged ConfigData	EnumToActivationModeSet ConfigData	Activation of modified configuration data	Read/write
restartActivation	EnumToRestartActivation	Perform a TO restart	Read/write

Local alarm response

Technological alarms

The standard technology object alarms, e.g. interconnection error or illegal parameter, are output.

Local reactions

If an error occurs, the following local responses are possible:

- No response (**NONE**)
- Stop command decoding (**DECODE_STOP**)
- Cancel input processing and set defined value (**CONFIGURED_OUTPUT_VALUE)**
  You can use configuration data element **ValueOut.outputValueErrorBehaviorMode** to specify whether:
  - The last value is retained (LAST_VALUE)
  - The zero value (ZERO_VALUE) is applied
  - The default value is applied (DEFAULT_VALUE)

  (default: LAST_VALUE)

4.4.6 Part V - Controller object

4.4.6.1 Overview of Controller Object

Function overview

The **Controller object** technology object enables you to prepare and control scalar variables.

Application

A controller object can be used as:

- Universal PIDT1 controller for scalar controlled variables,
  can also be used as a PI or P controller

Interfaces

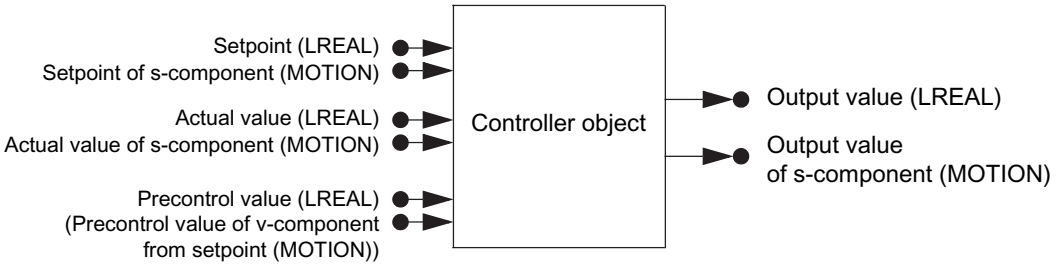

Figure 4-309 Object model for controller object

Each controller object has a setpoint input, actual value input, and precontrol value input.

The inputs are each configurable as a scalar input or as an input for a component of a motion vector.

The output provides the output value as a scalar or as a component of a motion vector.

Interconnection

The interfaces are optional and incorporated during configuration.

The input vectors can be interconnected *once only* ('single point'); the output vector can be interconnected any number of times ('multi-point').

Note

For additional information, please refer to the following manuals:

Function Manual *Motion Control Basic Functions*, "Interconnection of Technology Objects"

Function Manual *Motion Control Technology Objects Axis, Electric/Hydraulic, External Encoder*, "Traversing using Motion Vectors"

Activation/Deactivation

All inputs and the controller object can be activated and deactivated independently of one another.

Output

An activated controller object writes the controller value to the output, provided another behavior is not specified for an error occurrence.

A valid controller output value cannot be overwritten on the output side in the case of an active controller object.

The output value is readable and can be written via **_disableControllerObject**.

Units

Units are taken into account (SI units).

- The following units are available as of V3.2:
  - Force: [N] (newton)
  - Torque: [N] (newton meter)
  - Distance: [m] (meter)
  - Velocity: [m/s] (meters per second)
  - Temperature: [°C]
  - Angular degrees: [°]
  - Unitless [---] (normalized variable)
- The following units are used for controller variables:
  - K_R: [manipulated variable/controlled variable]
  - T_n, T_v: [s] (seconds)

4.4.6.2 Fundamentals of Controller Object

Description of function

Universal PIDT1 controller for scalar controlled variables

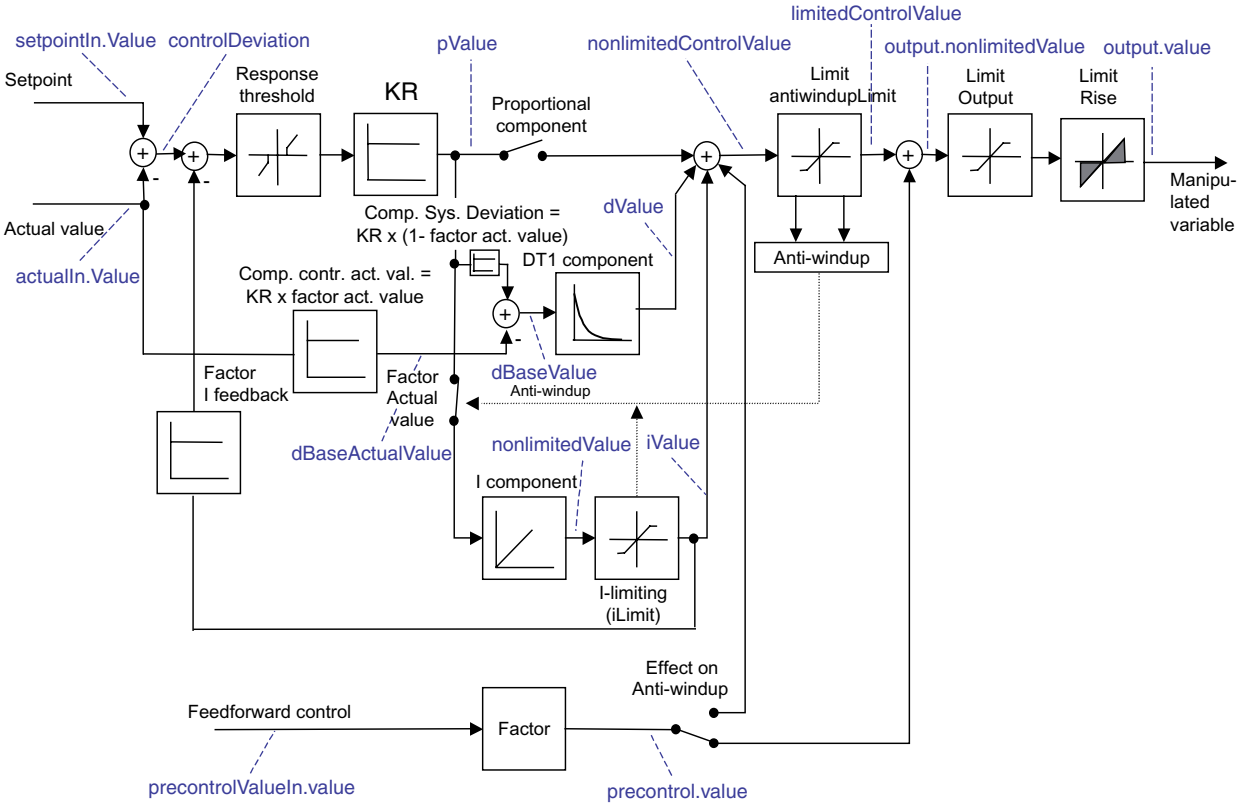

Figure 4-310 Controller object as PIDT1 controller

The controller is designed for systems which can be controlled by the PID algorithm. The control response can be improved by the precontrol function.

Feedforward control is based on a factor (the **precontrol.factor** configuration data item) which is proportional to the actuating signal.

All controller components can be connected and disconnected individually and independently of one another. As a result, the controller can also be employed as a P, PI, PD, and I controller.

In each case, the D and I components are disconnected by setting the associated T_v or T_n controller parameters to zero.

As the proportional gain is upcircuit of all components, the P component is connected via a supplementary parameter (`pmode`).

The upper and lower limits of the actuating signal and the integrator are adjustable. When the selected limits are reached, the signal and integrator are limited and displayed.

Configuration data element **precontrol.addupMode** can be used to indicate whether the feedforward control occurs before or after the anti-windup limiting (default: after).

The response threshold value for control deviation can be specified.

The I component can be fed back with a weighting factor.

It is possible to select whether the D component is generated from the system deviation or directly from the actual value, i.e. the D component from the system deviation and the actual value can be weighted to each other.

The D component is calculated by a differentiator with smoothing.

The I value can be limited.

The I value can be preassigned.

The integrator can be stopped.

The integrator can be stopped using anti-windup, i.e. if the integrator or actuating signal limits are active (configurable), an increment of the integrator is prevented.

P component, I component, and D component are added and limited according to the setting.

The output signal can be limited in value and rise (configuration data elements **output.Limit** and **outputDerivativeLimiting**).

Active limiting operations are indicated.

Limitation and increase limitation of the output value are active:

- For an active controller
- If the output value is set (e.g. with _disableControllerObject)

4.4.6.3 Configuring a Controller Object

Creating a controller object

Controller objects are stored across-the-board for a device in the **TECHNOLOGY** folder. They can be interconnected with suitable technology objects of the device.

Proceed as follows

1. To create a new controller object, double-click **Insert controller object** under **TECHNOLOGY** in the project navigator.
   You can also copy an existing controller object to the clipboard and then insert it under another name.

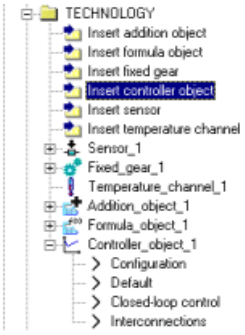

Figure 4-311 Representation of controller objects in the project navigator

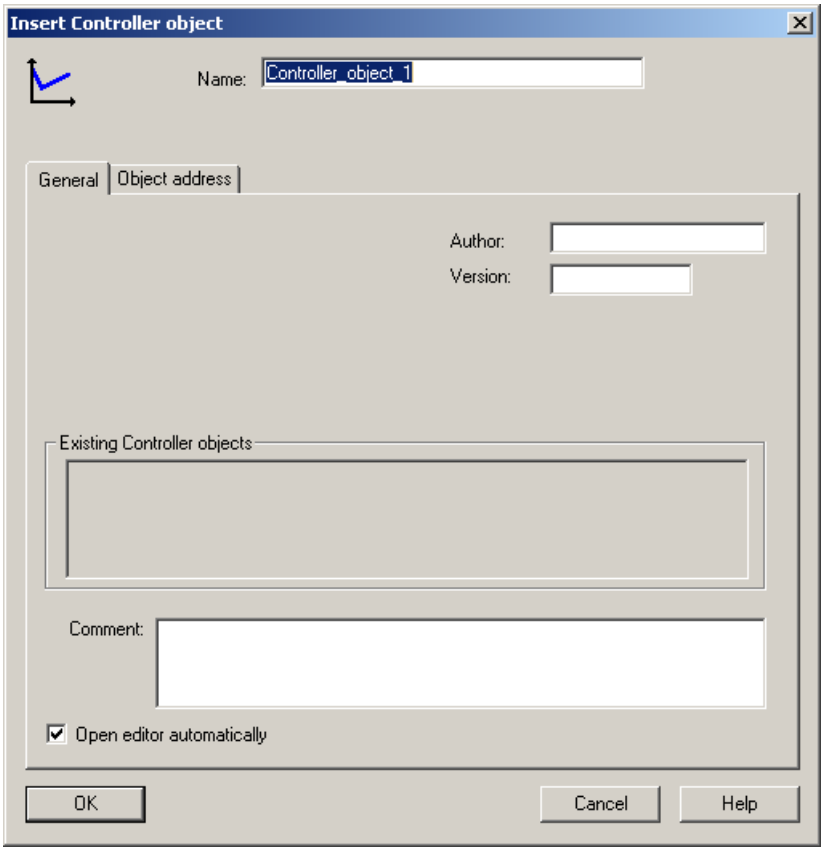

Figure 4-312 Inserting a controller object

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new controller object will be inserted under **TECHNOLOGY**.

Assigning parameters/defaults to a controller object

Proceed as follows

In the project navigator, double-click **Defaults** under the object.

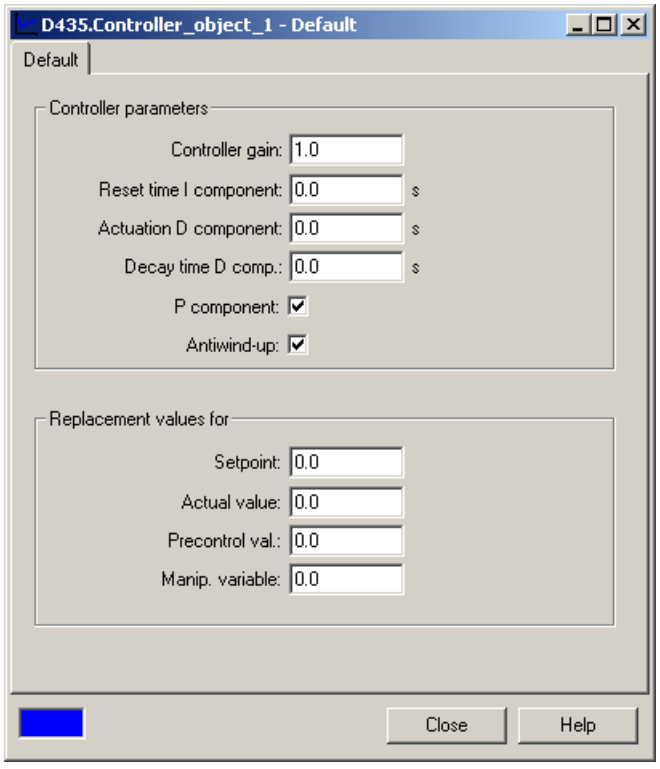

Figure 4-313 Controller object: Defaults

Controller object - defaults

Specify the parameters (defaults) for calling the controller object in this window (**_enableControllerObject** or **_disableControllerObject**). If you do not make any additional specifications during programming, these default values will be used.

You can set the following parameters:

Table 4-209 Controller object TO: Parameters that can be set for default purposes

Field/Button	Explanation/instructions
Controller parameters	Here, you enter the parameters for the controller.
Default value for	Default values can be specified individually for the **setpoint**, **actual value**, **precontrol value**, and **manipulated variable**. Here, you enter the default values.

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION reference lists*.

Configuring a controller object

Proceed as follows

In the project navigator, double-click **Configuration** under the object.

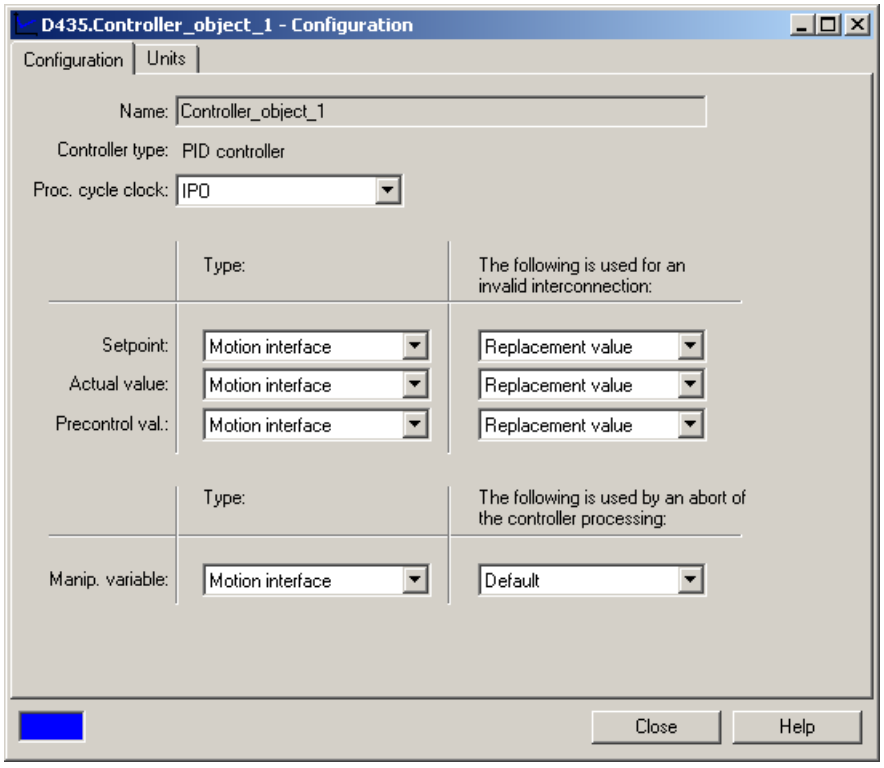

Figure 4-314 Configuring a controller object

Controller object - configuration

Define the properties of the controller inputs in this window.

You can set the following parameters:

Table 4-210 Controller object TO: Parameters that can be set for configuration purposes

Field/button	Meaning/instruction
Name	Display: Name of controller object
Controller type	Display: Controller type

Field/button	Meaning/instruction
Processing cycle clock	Here, you select the IPO-, IPO_2, Servo, Servo_fast or IPO_servo cycle clock.
Type	For **setpoint**, **actual value** and **precontrol value** you can specify whether the LREAL interface or the MOTION interface is connected on the input side. (Configuration data item **setpointIn/actualValueIn/precontrolValueIn._type**) When using the LREAL interfaces, the replacement values are used as input values. (System variables setpointDefault/actualValueDefault/precontrolvalueDefault). For the **manipulated variable**, you can specify whether the LREAL interface or the MOTION interface is connected on the output side. (Configuration data item **outputInterface._type**)
Applicable in the case of an invalid interconnection:	For each **setpoint**, **actual value** and **precontrol value**, you can specify whether the replacement value or the most recent valid value is to be used if the interconnection value is active, but invalid. (Configuration data item **setpointIn/actualValueIn/precontrolValueIn.behaviorByInvalidInterface**)
The following is applied if controller processing is aborted:	For the **manipulated variable**, you can specify whether the replacement value, the last valid value or zero must be output when controller processing is aborted by an alarm. (Configuration data item **outputValueErrorBehaviorMode**)

For additional information on the meaning of parameters and their permissible value ranges, please see the *SIMOTION reference lists*.

4.4.6.4 Programming a Controller Object/References

Programming

Overview of commands

Table 4-212 Controller object TO: Overview of commands

Command	Functionality
_enableControllerObject	Enabling/disabling a controller
_disableControllerObject	
_enableControllerObjectIn	Activating/deactivating interconnection interfaces on the input side
_disableControllerObjectIn	
_setControllerObjectPIDControl	Set controller parameters
_resetControllerObject	Reset controller object
_resetControllerObjectError	Reset error
_resetControllerObjectConfigDataBuffer	Delete collected configuration data
_bufferControllerObjectCommandId	Store CommandId and command status temporarily
_removeBufferedControllerObjectCommandId	Delete CommandId
_getStateOfControllerObjectCommand	Read out command status
_getControllerObjectErrorNumberState	Read out error number status

Note

For a complete list of all commands and their syntax, the system variables, and error messages, please see the SIMOTION Reference Lists.

Commands

Enabling/disabling interconnection interfaces on the input side

The input-side interconnection interfaces can be enabled or disabled using commands **_enableControllerObjectIn**/**_disableControllerObjectIn**.

- If the inputs are enabled, the input values are used.
  If an interconnection error occurs when interfaces are enabled, configuration data element **behaviorByInvalidInterface** can be used to specify whether the most recent valid value (LAST_VALID_INTERFACE_VALUE) or the default value (DEFAULT_VALUE) is used.
- If the inputs are disabled, the default values are used.
  (The values are applied cyclically or updated when a change occurs.)
  Actual value (parameter **actualValueIn**), setpoint (parameter **setpointIn**), and manipulated variable (parameter **precontrolValueIn**) can be enabled or disabled with a command.

Activating/deactivating a controller

- **_enableControllerObject**: Enables the controller object
  The controller is inactive after TO power-up and is enabled using the command.
  The controller object and interconnections are active.
  The controller parameters must be set in the configuration.
  The following values are active after power-up.
  - When the controller is first enabled, the configuration and defaults values are used first. The values last set are displayed in system variable **pidControllerEffective**.
  - When the controller is next enabled, the currently set values are active.
- **_disableControllerObject**: Disables the controller object
  The **valueBehaviorMode** parameter can be used to set one of the following functions:
  - Retain the last value (LAST_VALUE)
  - Use the default value (DEFAULT_VALUE)
  - Output the zero value (ZERO_VALUE)

Local alarm response

Technological alarms

The standard technology object alarms, e.g. interconnection error or illegal parameter, are output.

Local reactions

If an error occurs, the following local responses are possible:

- No response (**NONE**)
- Stop command decoding (**DECODE_STOP**)
- Abort of command processing (**CONTROLLER_STOP**)
  The **outputValueErrorBehaviorMode** configuration data element can be used to set one of the following functions:
  - Retain the last value (LAST_VALUE)
  - Use the zero value (ZERO_VALUE)
  - Use the default value (DEFAULT_VALUE)

  (default: LAST_VALUE)
- Deactivation of controller (**DISABLE_CONTROLLER**)

	Expert list	This function opens the expert list for the controller object selected in the project navigator. The configuration data and system variables can be displayed and changed in this list. See Basic functions - expert list
	Configure Units	This function opens the Configure Object Units window in the working area. You can configure the units used for the selected object here.
	Import object	Use Import object to open a window for the XML import. You can define the parameters for the XML import in this window.
	Save project and export object	Use Save project and export object to open a window for an XML export. You can define the parameters for the XML export in this window.

4.4.7 Part VI - Temperature controller

4.4.7.1 Overview of Temperature Controller

Function overview

The **temperature channel** technology object provided in SIMOTION allows you to configure temperature controllers that cover all basic functions of temperature control, from actual value measurement and closed-loop control right through to generation of the actuating signal, including identification of temperature control systems and calculation of the resulting channel parameters.

Application

The **temperature channel** technology object is specifically optimized for temperature control tasks in machines, e.g., for plastics processing machines. It can be configured as a heating channel, a cooling channel, or a combination heating/cooling channel.

4.4.7.2 Fundamentals of Temperature Controller

Principles of operation for a temperature controller (temperature channel TO)

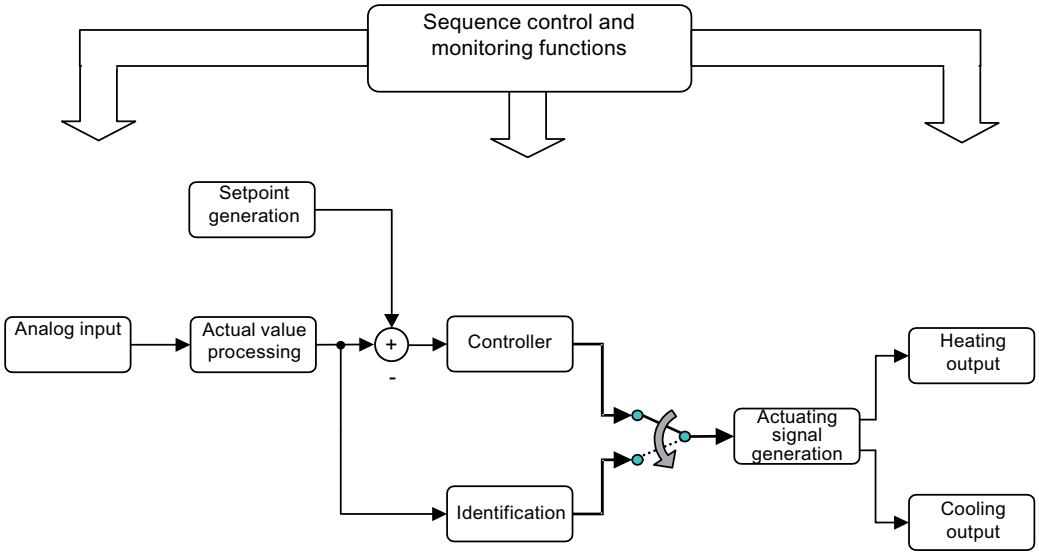

Figure 4-319 Signal processing of the temperature channel

The actual value measured (and linearized according to the sensor characteristic curve) at the analog input is filtered during actual value processing and subjected to a plausibility test to compensate for signal disturbances or sensor errors. This smoothed and tested signal is then processed further, either during closed-loop control or during system identification.

The current system deviation is determined in the controller using the setpoint specified during setpoint generation. For an optimal closed-loop response, different parameter sets are used for

heating and cooling, and the system switches from one parameter set to the other according to the sign of the actuating signal.

The analog actuating signal calculated by the controller or used for system identification is pulse-length modulated during actuating signal generation and routed to the digital outputs for heating and/or cooling.

Note

Temperature controllers with nonexistent physical modules cannot be loaded.

Functional scope

The following table provides an overview of the main functions of the **Temperature Channel** technology object.

Table 4-213 Temperature controller (temperature channel TO) Functional scope

Function	Content
Controller	
Control process	The temperature channel controllers normally operate as DPID controllers. Another type of temperature channel controller provides additional tuning options. Main features of the ADVANCED controller type: • Sampling time adaptation • Parameter adaptation • Control zone • Stop and hold cycles Additional features include: • High level of dynamic response and control performance • Robustness with regard to disturbance variables
Configurable channel structure	You can configure the temperature channel for closed-loop control as a **heating system**, a **cooling system**, or a **combination heating/cooling system**. Separate parameters are used for heating and cooling.
Operating modes	For each temperature channel, one of the following operating modes can be selected: • Inactive • Rules • Actual value acquisition and output of the manual manipulated variable value • Actual value acquisition and output of a manipulated variable value of 0 • Identification (of system parameters for self tuning) In Inactive mode, actual value acquisition does not take place, and a manipulated variable value of 0 is output.
Actual value acquisition and processing	

Function	Content
Actual value plausibility check	Each new actual value is checked for plausibility and corrected before appropriate filtering is applied. Values outside of the tolerance range are considered to be outliers, which, if they occur frequently, can cause error messages to be generated. A plausibility check is carried out, implausible actual values are filtered out and the expected actual value is extrapolated.
Actual value filtering	Filtering takes place separately for the actual control value and the actual display value. A low-pass filter (PT1 function) is used for actual value filtering. Parameters can be assigned for the time constant, or the time constant can be calculated by self-tuning. This ensures that the "smoothed" actual display value is free of the short dips that can be caused, for example by disturbance signals.
Actuating signal preparation and output	
Digital, pulse-length modulated actuating signal	An actuating signal is calculated by the controller as a percent value (in reference to the connected heating/cooling power, +100% to -100%) and output to manipulated variable processing. From this actuating signal, the manipulated variable processing derives a digital, pulse-length modulated signal that is output to the power switch by means of the corresponding output module.
Response times	Because the switching cycle of mechanical relays is supposed to be kept to a minimum, actuating signal pulses that are too small are suppressed by the response time (minimum switch-on duration). Operating (ON) times that are less than the response time or components that are truncated by PWM quantization are not output; rather, they are summed up over several manipulated variable cycles until the specified response time is reached. Conversely, large actuating signal pulses (close to 100 %) can lead to very short turn-off times. If a minimum switch-off duration (e.g., 5%) is specified, these types of pulses are always output at 100%, and the difference relative to 100% is subtracted again from the current manipulated variable during the next output cycle.
Output of manual manipulated variable value	Output of manual manipulated variable value is an operating mode in which a definable manipulated variable value (manual manipulated variable value) is output (manual manipulated variable mode).
Calculation of average manipulated variable value	In closed-loop control mode, the temperature channel calculates an average manipulated variable value, which is read out by the operator or the application and can be used as a substitute manipulated variable value.
Identification	
System identification	In Identification mode, the temperature of the controlled system is changed by specifying a constant manipulated variable value. Process parameters are determined from the time delay and the rate of temperature change. System identification is only possible for a heating controller.

Function	Content
Calculation of parameters	Appropriate temperature channel parameters for the control system can be calculated from the process parameters.
Monitoring and alarm functions	
Actual value monitoring by definition of tolerance bands	The actual values of each channel are monitored for adherence to an inner and outer tolerance band. The inner and outer tolerance bands can be defined independently as absolute or relative tolerance bands: • In an absolute tolerance band, there is no relationship between the limit values and the setpoint; the limit values are fixed. • The relative tolerance band is always defined in relation to the current setpoint, and it changes whenever the setpoint changes. Response when tolerance bands are violated: • When the inner tolerance band is violated, an alarm (warning) is output. When the outer tolerance band is violated, the system reaction can be set separately for the upper and lower tolerance thresholds in the alarm configuration.
Plausibility check	The control loop plausibility check can detect errors in the control loop (sensor-controller-heating), thus preventing hazardous situations from occurring. The control loop plausibility check is only active in *Control* mode. In the case of a control loop plausibility error, an alarm is generated and the output is set to zero.
Gradient monitoring	Temperature changes in the controlled system can be monitored for adherence to maximum gradient values. Repeated violation of the maximum gradients is signaled by means of a system variable and an alarm.
Gradient check for the parameters	All parameters are checked to ensure that they agree mutually and do not exceed limit values.
Alarm functions	If errors occur or if activated monitoring functions respond, corresponding alarms are triggered by the temperature channel. The reaction of the operator/application to an alarm depends on the situation. In the case of serious errors, the temperature channel will react automatically in advance (local response) in order to avoid a dangerous situation (e.g., by outputting a manipulated variable value of "0" at the heating output).

4.4.7.3 Configuring the Temperature Controller

Creating a temperature controller

Temperature controllers (**temperature channel** TOs) are stored globally for all devices in the **TECHNOLOGY** folder.

Proceed as follows

1. To create a new temperature controller (temperature channel TO), double-click **Insert temperature channel** under **TECHNOLOGY** in the project navigator.
   You can also copy an existing **Temperature Channel** TO using the clipboard and insert it under another name.

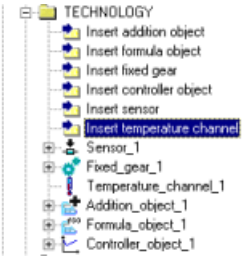

Figure 4-320 Representation of temperature controllers in the project navigator

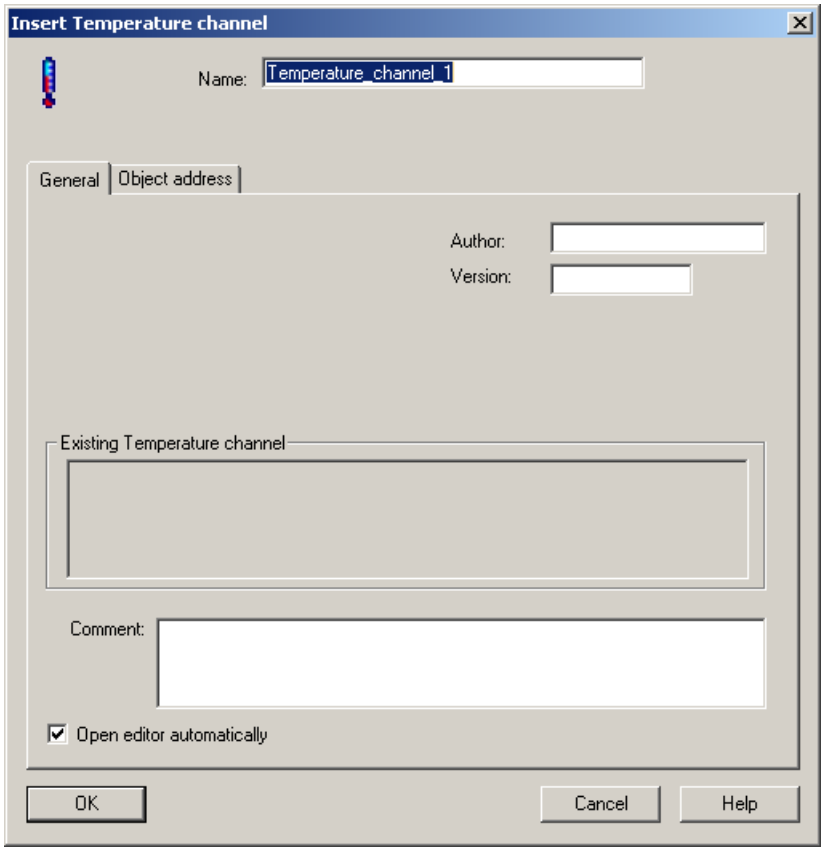

Figure 4-321 Inserting a temperature channel TO

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new temperature channel TO will be inserted under **TECHNOLOGY**.

Configuring the temperature controller in the expert list

Via the expert list, all configuration data and system variables for the temperature controller (**temperature channel** TO) can be displayed and changed in a list.

The configuration data of the **Temperature Channel** TO is already assigned and needs only to be adjusted for your configuration.

Note

The **Temperature Channel** TO can only be configured in the expert list.

For additional information, see the Function Manual *Motion Control Basic Functions*, "Expert List"

Configuring a temperature controller

Default values are already assigned to the parameters of a Temperature Channel TO (configuration data and system variables). The Temperature Channel TO uses these configuration data during power-up.

For each Temperature Channel TO, you can make changes to the configuration and parameter assignment of the following elements:

- Analog Input
- Controller
- Digital outputs

Operating parameters (.generalParameter)

Setting the operating mode for a temperature channel (.generalParameter.operatingMode)

Via the expert list, you can set the operating mode that the selected temperature channel is to assume automatically during the first power-up.

Table 4-214 Temperature controller (temperature channel TO) Operating modes (first power-up)

Configuration parameter	Description
Inactive No actual value acquisition, output of 0	The channel is not active, that is, no actual value measurement takes place, and a manipulated variable value of "0" is output. This is the default operating mode.
Control Control to a particular setpoint	In this operating mode, the predefined setpoint **generalParameter.setpoint** is used for control.
Measuring and manual output Actual value acquisition and output of the manual manipulated variable value	In this operating mode, the actual value is measured, and a manual manipulated variable value **generalParameter.manualOutputValue** is specified as the manipulated variable value.

Configuration parameter	Description
Measuring and output zero Actual value acquisition and output of 0	In this operating mode, the actual value is measured, and a manipulated variable value of "0" is output.
Identification System identification	This operating mode starts system identification, during which a constant manipulated variable value is specified, and the temperature of the controlled system is changed. Process parameters used to calculate appropriate channel parameters are determined from the delay and the rate of temperature change.

Setting the temperature setpoint (.generalParameter.setpoint)

The temperature setpoint for closed loop control mode is specified in this parameter.

Note

If **Control** mode (.generalParameter.operatingMode) is the default setting for the channel, then the system is controlled to this setpoint immediately following initial startup.

Setting the manual manipulated variable value (.generalParameter.manualOutputValue)

In this parameter, you specify the manual manipulated variable value for the selected channel. The manual manipulated variable value is output if you have assigned **Measuring and Manual Output** mode in **generalParameter.operatingmode**.

The manual manipulated variable value **manualOutputValue** can have a value ranging from +100% to -100%.

- **Heating controller: from 0% to 100%**
  (0: no heating power, 100: full heating power)
- **Heating/cooling controller: from -100 % to 100%**
  (-100: full cooling power, 100: full heating power)
  If the manual manipulated variable value is to be output at the cooling output of a heating/cooling controller, then it must have a negative value.
- **Cooling controller: from 0% to 100%**
  (0: no cooling power, 100: full cooling power)

Configuration data for the analog input

Here, you set the address of the analog input and specify the input handling of the actual values.

Entering the address (.input.device)

The address for this input must match the address of the analog input in the hardware configuration data.

Defining the sampling time ratio (.input.analog)

All actual values are read in during an input cycle that is dependent on the controller cycle and are then checked.

The ratio between the sampling time of actual value handling and the sampling time of the controller or identification is critical for optimal filtering of the actual values. For this reason, the sampling time ratio is user-defined.

Note

To filter out disturbances during actual value acquisition, the actual value must be measured more quickly than the controller cycle clock, so that smoothing (PT1 function) can occur. The larger and more frequent the disturbances, the larger the sampling time ratio should be.

Setting parameters for filtering of actual values (.input.analog.filterParameter)

Here, you specify the settings for smoothing of actual values. Not every input value is evaluated as it appears: Rather, a value that is filtered with a PT1 function is calculated.

Actual value handling.

The following functions are performed for each actual value during input handling:

1. Read in all measured actual values during a cycle that is generally dependent on the controller cycle.
2. Use a plausibility test followed by actual value filtering to check for disturbances and smooth the actual value
3. Tolerance tests of the current actual value are then carried out.

Defining time constants (controlTimeConstant, displayTimeConstant)

Actual value filtering takes place separately for the actual control value and the actual display value. For this reason, you can specify the following time constants:

- Time constant for filtering of the actual control value (control input filter)
- Time constant for filtering of the actual display value (display input filter).

A PT1 function is used for actual value filtering. This ensures that the "smoothed" actual display value is free of the short dips that can be caused, for example, by disturbance signals.

Parameters can be assigned for the time constants, or the time constants can be calculated by self-tuning. The time constant of the display input filter is greater than the time constant of the control input filter. The actual display value undergoes a more intense smoothing operation. The actual value smoothed with the display input filter is made available in system variable **TOTCx.actualInputData.displayValue**.

Setting the initialization value of the maximum and minimum measured actual display value (input.analog.displayValueParameter)

The current actual display value - as well as the maximum and minimum actual display values that are likewise calculated during the actual value processing - are always available for display and data recording.

The maximum and minimum actual display values determined during runtime can be reset via the system functions **_setTControllerInputDisplayValueParameter** and **_resetTController**.

Parameters for the actual value plausibility check (.input.analog.gradientCheckParameter)

Each new actual value is checked for plausibility before filtering is applied. The main purpose of the actual value plausibility check is to filter out short-term disturbances (outliers), as such disturbances can have a particularly negative effect on the controller performance due to the differential components in the control algorithm.

Activating/deactivating check mode

The plausibility check can be activated (ACTIVE) or deactivated (INACTIVE) with the **checkMode** parameter. The default setting for the plausibility check is INACTIVE.

Entering the number of tolerated violations

Here, you enter the number of violations of maximum gradients to be tolerated. All values outside the range of the maximum positive and maximum negative actual value gradients are considered to be violations.

If the number of tolerated violations is exceeded in direct succession, an alarm is generated.

Specifying the maximum positive and negative gradients

When you specify the maximum positive and maximum negative actual value gradients, you set the range of the actual value gradients. The input signal change is checked to determine whether it is within the specified value range.

Actual value monitoring by defining tolerance bands (.input.analog.limitCheckParameter)

The actual values of each channel are monitored for adherence to an inner and outer tolerance band.

Defining the inner and outer tolerance bands

The actual control value is checked for tolerance violation. For this purpose, you can assign parameters to each control channel for an inner and an outer tolerance band.

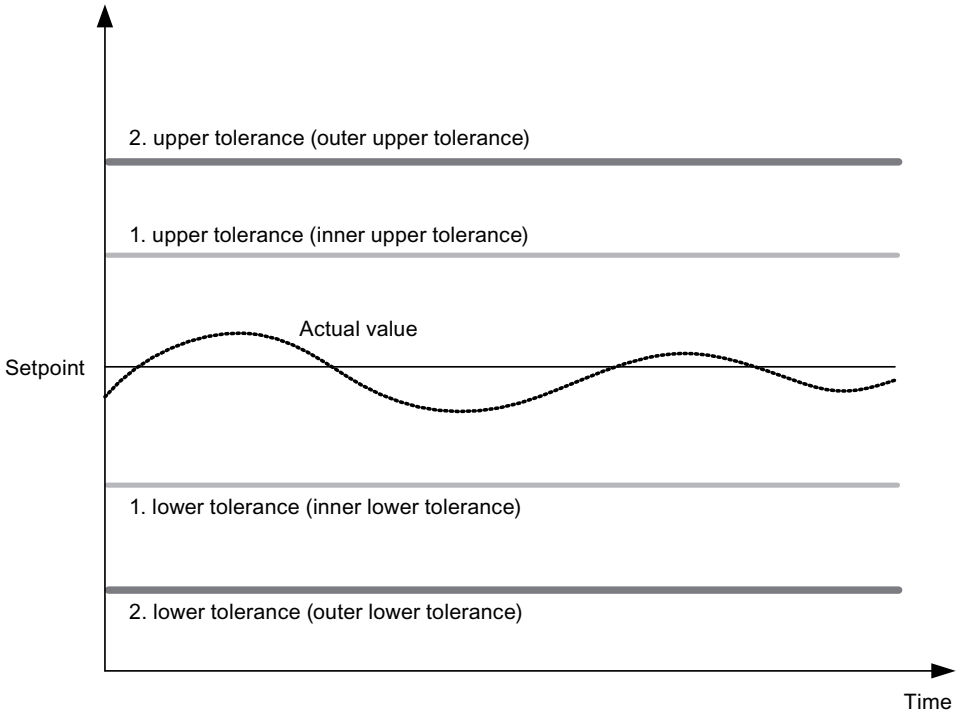

Figure 4-322 Inner and outer tolerance bands

The inner tolerance band is nested inside the outer tolerance band.

If the:

- Inner limit (1st tolerance band) is crossed, a warning (TO alarm) is output. There is no local reaction from the channel.
- Outer limit (2nd tolerance band) is also crossed, an error (TO alarm) is displayed, triggering a local reaction from the channel (for example, a heating output is reduced to 0% when the outer upper tolerance limit is exceeded).

Absolute or relative tolerance band

It is possible to parameterize an upper (**upperLimitValue**) and a lower (**lowerLimitValue**) limit value in each case for the inner and outer tolerance bands. Via **lowerLimitMode** and **upperLimitMode**, the limits can be set to apply as an absolute limit value or as a relative deviation from the current setpoint.

For an absolute tolerance band, the limit values are not dependent on the setpoint; they are fixed. A relative tolerance band is always defined in relation to the current setpoint, and thus it changes relative to changes in the setpoint.

In the case of relative tolerance, if a setpoint step change occurs, the tolerance limit that is further away from the new setpoint is corrected in parallel to the actual value to prevent an unwanted tolerance violation.

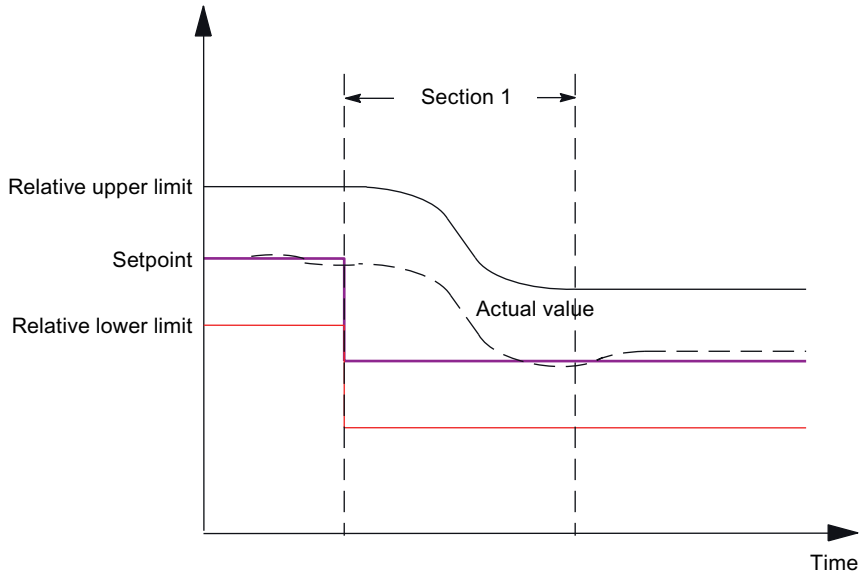

Figure 4-323 Correction of the relative tolerance band

If a relative tolerance band is configured and a setpoint step change occurs during control mode, the tolerance band check is corrected until the actual value has reached the new setpoint. Once this occurs, the tolerance check is once again active.

Tolerance violations

If the actual value is outside of a tolerance band, this means that one of the tolerance limits has been violated. The following mechanisms are used to indicate a tolerance violation:

- TO alarm sent to the application and alarm message on the HMI device
- Display in the **actualInputLimitCheckData** system variable

(See Reference List for temperature channel TO)

Tolerance band monitoring:

Tolerance band monitoring is reset under the following conditions:

- Modification of data for tolerance band monitoring
- Reset of the temperature controller
- Stop/Run
- Power supply off/on

Under these conditions, a relative tolerance band is corrected to the setpoint.

Configuration data for the controller

You set the configuration data in the **controller** data element.

Controller structure

You can configure the controller structure for **heating systems**, **cooling systems**, or **combination heating/cooling systems**.

Heating systems or cooling systems

For heating systems and cooling systems, there is only one controller, the primary controller.

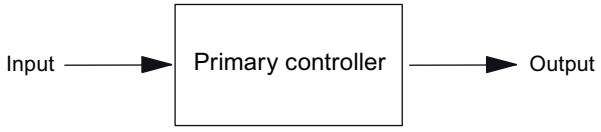

Figure 4-324 Controller structure for heating or cooling controller

- For **heating systems**, the primary controller works in a **positive effective direction**. Temperatures that are too low cause a rise in the output value.
- For **cooling systems**, the primary controller works in a **negative effective direction**. Temperatures that are too high cause a rise in the output value.
- If a control system can only be heated or cooled, only **one parameter set must be entered for a controller**.

Combination heating/cooling systems

Combination heating/cooling systems have two controllers:

- The **primary controller** works in a positive effective direction (**heating controller**). Temperatures that are too low cause a rise in the output value.
- The **secondary controller** works in a negative effective direction (**cooling controller**).
- If a control system can be both heated and cooled, then the **controller parameters must be entered for two controllers**.

During switchover phases, 0% is output at both outputs.

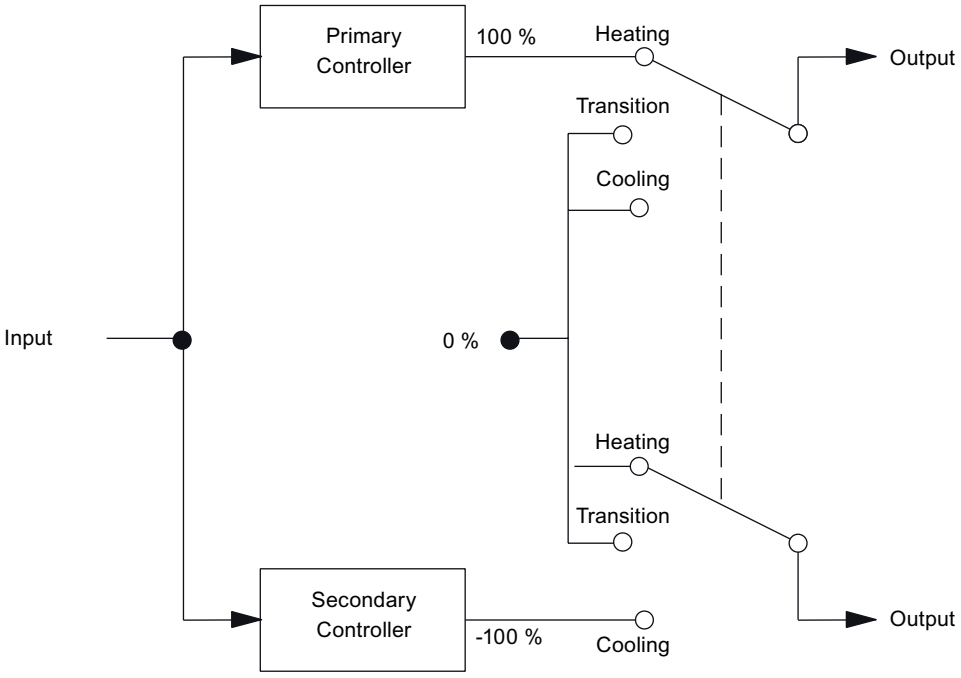

Figure 4-325 Controller structure for combined heating/cooling controllers

Controller parameters

The controller parameters depend on the controller structure:

- A dedicated heating controller uses a parameter set for heating and a dedicated cooling controller uses a parameter set for cooling (for example **controller.standard.DPIDParameter**).
- A combined heating/cooling controller uses two separate parameter sets, one for heating and one for cooling:
  The first parameter set is for heating, and the second parameter set is for cooling (for example, **controller.standard.DPIDParameter** - parameters for a heating controller and **controller.standard.DPIDParameterSecondary** - parameters for a cooling controller).

Selecting the controller type

You can specify the controller type under **controller.type**.

You can select between two DPID controllers that are especially designed to meet the requirements of temperature control systems:

- Standard DPID controller (**STANDARD**)
- Advanced DPID controller (**ADVANCED**)

ADVANCED controller

The ADVANCED controller provides additional tuning options while control mode is in operation (sampling time and parameter adaptation), as well as an assignable control zone:

- **Sampling time adaptation**
  If the absolute value of the system deviation increases sharply, the sampling time is reduced in the possible range by means of sampling time adaptation.
- **Parameter adaptation**
  Adaptation of the controller parameters for each operating point has advantages relating to control performance and dynamic response.
  Parameter adaptation can be especially optimized for:
  - Continuous processes (extruders)
  - Batch processes (injection molding machines, blow molding)
- **Control zone**
  The control zone improves the dynamic response of the control and reduces overshoots. Maximum cooling occurs above the control zone to be defined, and maximum heating takes place below the control zone. Within the control zone, the actuating signal calculated by the controller is output.

The following overview figure shows how a DPID controller operates:

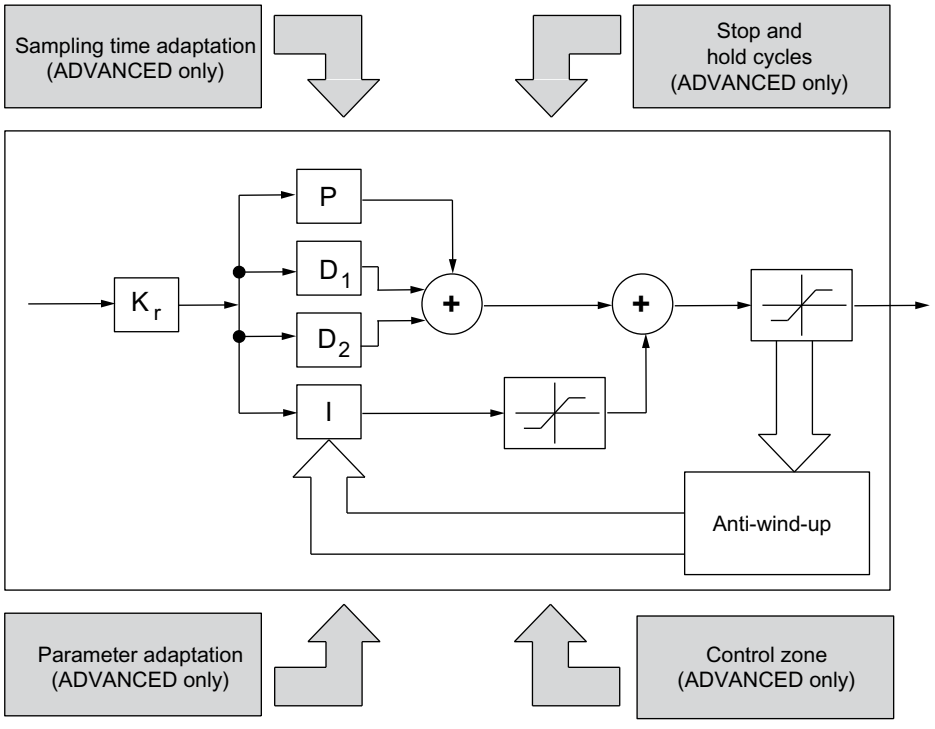

Figure 4-326 Stop and hold cycles for both controller types, plus control zone for ADVANCED

Both controller types have the following features in common:

- **Separate parameter sets for heating and cooling**
  For optimal control performance, the DPID controller uses separate parameter sets for heating and cooling. The controller switches from one parameter set to the other according to the sign of the actuating signal ("+" for heating and "–" for cooling). This also changes the controller sampling time.
- **Anti windup for the I component**
  Anti windup prevents rise of the I component when the actuating signal reaches its limit. If the manipulated variable output is limited, the calculation of the I component is stopped.
- **Stop and hold cycles** (ADVANCED controller type only)
  In operation, the D component is, for example, temporarily switched off to ensure a bumpless parameter transition during the switchover from a heating controller to a cooling controller (for combination controllers) or in the event of a setpoint jump. This behavior is performed by the technology object and cannot be specified.
- **Average manipulated variable value**
  During the control process, an average manipulated variable value is calculated. In settled state, this manipulated variable value can be used to switch temporarily from closed-loop control mode over to output mode without causing a large change in the current working temperature.

DPID parameters (.controller.standard.DPIDParameter[Secondary])

The following DPID parameters are available for the **ADVANCED** and **STANDARD** controller types:

- **Gain (K_R)**
  The gain corresponds to the proportional-action coefficient of the controller and is then calculated as **P = K_R * control deviation** (see the figure titled "Stop and hold cycles for both controller types, plus control zone for ADVANCED").
  You can select values between the controller limit values for **minimum controller gain** (.limits.controller.minGain) and **maximum controller gain** (.limits.controller.maxGain).
- **Switch I component on/off**
  With this parameter, you can switch the integral component of the controller on or off.
- **Reset time**
  With the reset time, you set the I component of the controller.
- **Actuation time**
  With the first order actuation time, you set the D component of the controller, and with the second-order actuation time, you set the D2 component. If you enter a value of 0, the respective D component is switched off. In this way, you can implement a P controller or a PI controller.
- **Start value of integrator following RESET**
  With this start value, you specify the initialization value of the I component when (re)starting the SIMOTION device. The initialization value is also activated by the **_resetTController** system function.

Controller cycle parameter (.controller.standard)

The dynamic response of the controlled system determines the length you must set for the controller cycle time. To control rapid temperature changes, the controller cycle time must be shorter than for control of slower temperature changes.

There are two speed classes (**.execution.executionlevel**) for both the heating and the cooling controller for the controller cycle time **n** (with n = 1, 2, etc.). T_1 and T_2 depend on specific task settings in SIMOTION SCOUT:

- High-speed controllers: n * T_1
- Slow controllers: n * T_2 (with $T_2 > T_1$)

Note

If you specify a controller cycle time that is not within the time base, the controller cycle time is rounded up to the next time-base increment. For slow controllers, the cycle time must not < T_2.

Parameters and sampling time adaptation (.controller.advanced.processModeParameter)

This adaptation type can only be adjusted for the **ADVANCED** controller type. It is determined by the system features.

While the controller is in operation, the controller parameters of adaptive controllers are constantly being adapted. This adaptation has a stronger effect on the DISCONTINUOUS process type than on the CONTINUOUS process type. This affects the following parameters:

- Gain
- Reset time
- Actuation time
- Controller cycle time

Control zone parameters (.controller.advanced.controlRangeParameter)

You can only make control zone parameter settings for the **ADVANCED** controller type.

The control zone is a band on either side of the current setpoint that is formed by a value for the upper limit and a value for the lower limit.

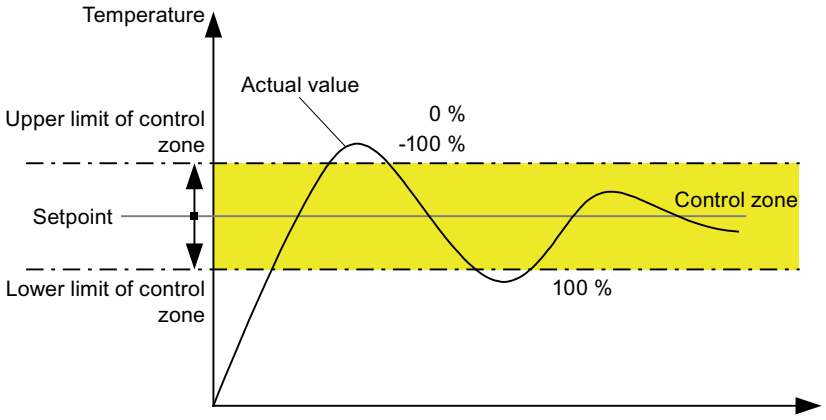

Figure 4-327 Control zone

If the actual value falls outside of the control zone, the controller responds as follows:

- If the actual value falls below the control zone, the controller outputs heat at the maximum manipulated variable value.
- If the actual value exceeds the control zone, the controller outputs a manipulated variable value of 0% (heating controller) or it cools on the basis of the maximum manipulated variable value.

Controller plausibility check (.controller.standard.upper/lowerPlausibilityParameter[Secondary])

Control loop plausibility is used to detect failure of final controlling elements.

The **controller plausibility is violated** if in a specified temperature range (within the upper and lower temperature limits) and starting from a particular output capacity (the lower manipulated variable value limit) a minimum rise of the actual value is **not achieved** within a specified time (delay time). A violation of the controller plausibility is displayed in the **ActualDPIDData.plausibilityState** system variable. Two separate temperature ranges can be distinguished to increase the sensitivity of this monitoring process.

For the primary controller, there are two parameter sets, which are handled separately. If a secondary controller is present, there are two additional parameter sets for this controller.

Configuration data for identification

Identification is available only for dedicated heating systems. The parameters are determined according to the inflectional tangent method.

Identification method (.identification.actualIdentificationType)

Once the system parameters are identified, they can be used to determine appropriate controller parameters for each controller type (ADVANCED or STANDARD). The two methods described below can be used for identification:

- With the **standard tangent method**, the system is activated with a constant, definable actuating signal until it reaches a static equalization. The system parameters determined are time delay (T_U), rise time/equalization time (T_A), and system gain (K_S).
- With the **modified tangent method**, the system is excited with the maximum actuating signal (100 %) until the inflection point is detected. The system parameters determined are delay (T_U) and the maximum temperature rise S_{max}(100 %) with reference to a 100 % actuating signal. With these parameters, only a simplified determination of the system parameters is possible. The advantage of the modified tangent method as compared to the standard tangent method is a considerably shorter identification time.

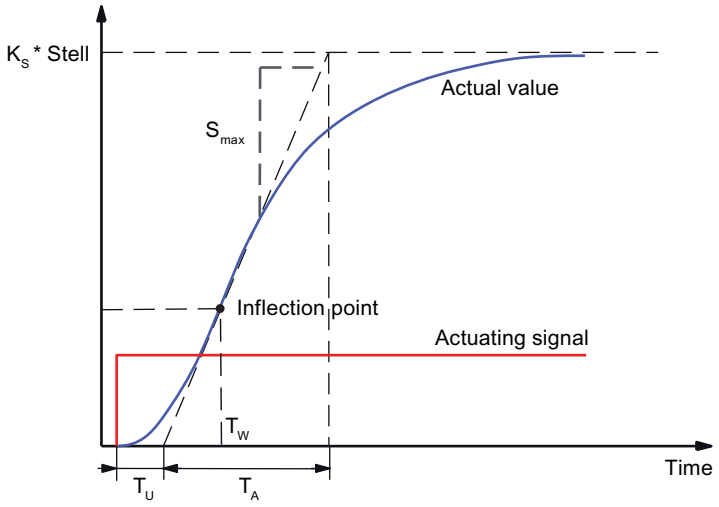

Figure 4-328 Tangent method

Note

The basic functions of the closed-loop control (such as actual value acquisition and actuating signal output) are also used for self-tuning.

The phases of self-tuning are monitored in relation to the runtime, and self-tuning is aborted with an alarm if the time limit is exceeded.

If self-tuning is called at a too high basic cycle clock, it might happen that the internal limit for the temperature rise of 5°C/basic cycle clock is exceeded. In this case, self-tuning goes on running and the determines values for the set basic cycle clock. The following alarm is issued: 30014 "Selected controller sampling time too small for the measured temperature rise".

The sampling time of the identification corresponds to the controller sampling time which can be set with the **.controller.maxControllerCyle** configuration data element.

The following times apply for both methods:

SETTING_UP	10 * max. controller sampling time
SEARCH STARTPOINT	Maximum equalization time

HEATING	5 times maximum delay time
SEARCH INFLECTIONPOINT	Maximum equalization time

Additionally for the standard tangent method:

SEARCH ENDPOINT	Maximum equalization time

Table 4-215 Temperature controller (temperature channel TO) Operating modes (identification)

Variable type	Description
Self-tuning enable (.available)	If self-tuning is available for a heating channel, then you set the AVAILABLE parameter value. If you set the NON_AVAILABLE parameter value, the required program section for self-tuning of a Temperature Channel technology object will not be loaded.
Start mechanism (.transitionMode)	You use the start mechanism to specify whether the temperature controller should switch automatically to the heating phase once the start conditions have been satisfied (AUTOMATICALLY) or whether it should wait for an explicit start command (BY_COMMAND) before switching. **Note:** For interaction with the **TControl** function object, you must set the BY_COMMAND value (any other value will be automatically overwritten by the **TControl** function object with BY_COMMAND).
Start conditions (.startCondition)	Before the heating phase is entered, the actual value must have attained a stable idle state. You set the idle state using the waiting time (.waitingTime) and the tolerated temperature change during the waiting time (.permissableTemperatureChange).
Minimum step size of actual value/setpoint (.minimumStepSize)	Before the heating phase is entered, a check is performed to determine whether the temperature difference between the current actual value and the setpoint to which the system is to be heated for parameter identification is at least as large as the configured minimum step size (.minimumStepSize). If it is not, then self-tuning is aborted.

Output handling of measured values

General

An actuating signal is calculated by the controller as a percent value (-100% to +100%, with reference to the connected heating/cooling capacity).

This value is then used to derive a digital, pulse-length modulated signal that is output to the power switch by means of the corresponding output module.

Actuators of temperature controlled systems are usually digitally-controlled mechanical or solid-state relays with no-voltage releasing magnets that are used to switch on and off electrical strip-

type heaters or heat-exchanger units (valves for liquid coolants, such as water, or a fan for air cooling).

These actuators are activated by means of separate pulse-width modulated, digital outputs for the heating circuit and the cooling circuit.

Output value/control signal

Generation of the actuating signal converts the analog actuating signal to a proportional switch-on time within the controller cycle clock separately for the heating output and the cooling output.

For pulse-length modulation, an actuating signal of 100 % corresponds to a control output being activated all the time. Smaller actuating signals are converted to proportional switch-on times within an manipulated variable cycle clock.

The low pass behavior of the temperature controlled systems has a smoothing effect on this pulsated characteristic if the manipulated variable cycle clock is sufficiently small in relation to the system time constants (manipulated variable cycle clock < 1/10 system time constant, for example sampling time).

The accuracy of the manipulated variable resolution depends on the quantization resolution of the on-time as compared to the manipulated variable cycle clock. Resolutions between 1% and 5% are a good compromise between the system load for identifying the manipulated variable and a reasonable control resolution.

Clocked actuating signal output

The controller outputs the complete actuating signal in one block at the beginning of each controller cycle clock. This might result in a saw-tooth temperature characteristic.

The "stroke of the saw-tooth" can be minimized by outputting in several blocks, e.g. 8 blocks at intervals of 250 ms instead of 1 block at intervals of 2 s. (V4.0 and higher)

The number of blocks can be set via the **numberOfOutputCycles** configuration data element (default: 1).

Making settings for pulse-width modulation (.output.out[Secondary])

Specifying output parameters for pulse width modulation

You specify output parameters for pulse width modulation (upper and lower threshold values for the manipulated variable value) to avoid insufficient switching intervals for the output of a dedicated heating or cooling controller or for the cooling output of a combined heating/cooling controller.

- The following applies to all manipulated variable values that exceed the upper threshold: The controller outputs the maximum manipulated variable (100%).
- The following applies to all manipulated variable values that fall below the lower threshold: The controller outputs the minimum manipulated variable value (0%).

Here, the missing absolute manipulated variable values are summed up and the corresponding switching correction is made.

Specifying the address and number of the digital output

Heating controllers and cooling controllers have a digital output for which you must enter an address.

A combination heating/cooling controller has two digital outputs that operate between 0% and 100%, depending on the manipulated variable value. Parameters of the first digital output are assigned for heating and parameters of the second digital output are assigned for cooling. You must enter addresses for both digital outputs.

Note

The address for this digital output must match the address of the corresponding digital output in the hardware configuration data.

Specification of limit values

You can specify the following types of limit values:

- General limit values (.limits.general)
- Controller limit values (.limits.controller)
- Limit values of the system to be controlled (.limits.process)

System cycle clocks and execution speed

Activation in the execution system and setting the cycle clocks

The Temperature Channel TO utilizes dedicated tasks in the execution system. These must be enabled through selection of **Use system tasks for TControl** when the temperature channels are used.

1. Call the configuration window **System Cycle Clocks** in SCOUT via **EXECUTION SYSTEM > Expert > Set system cycle clocks**.
2. Display the settings for the TControl system tasks via key **TControl**.
3. Activate the **Use system tasks for TControl** checkbox.

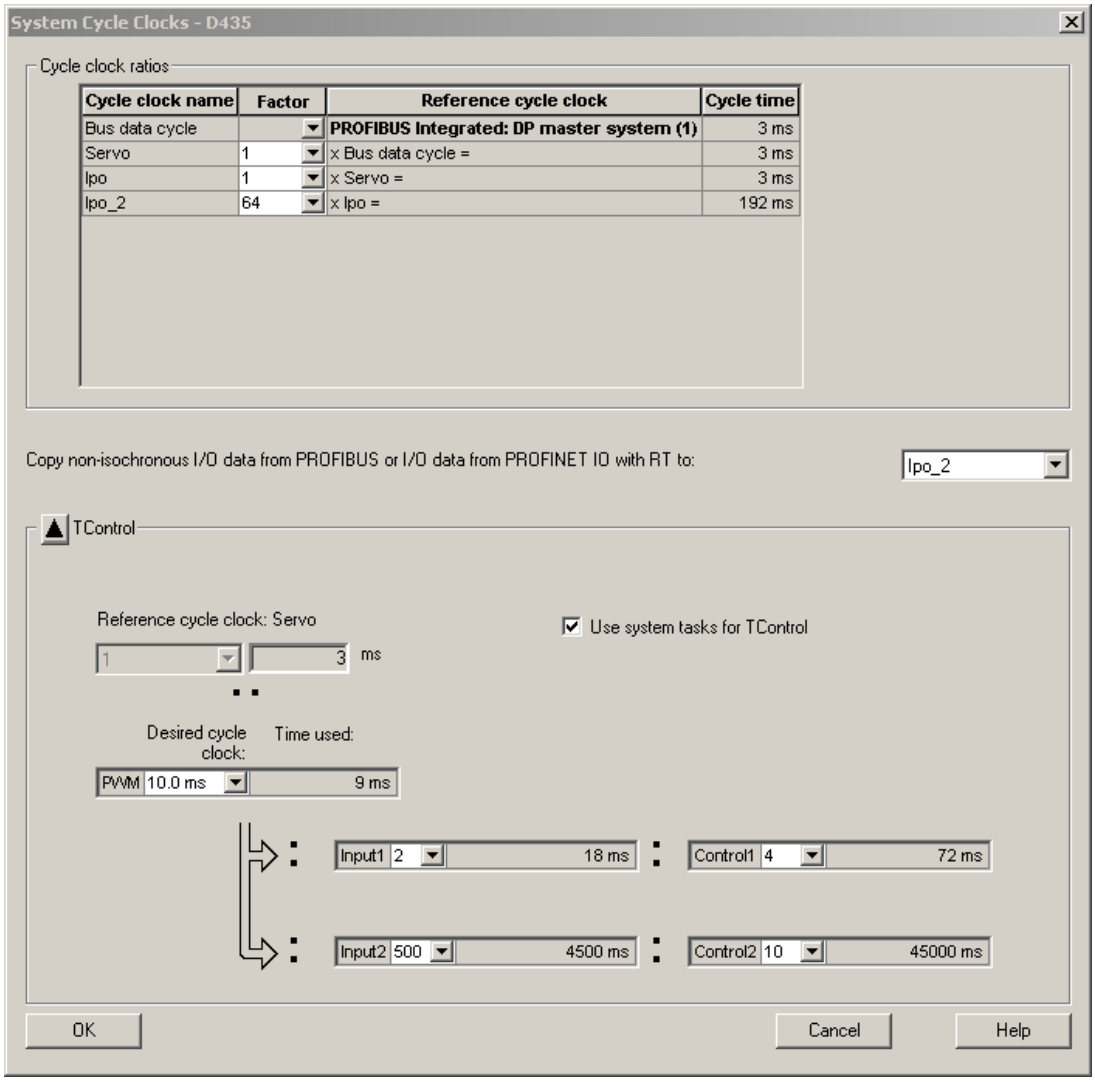

Figure 4-329 System cycle clocks for temperature control

Table 4-216 Temperature controller (temperature channel TO) Meaning of temperature channel tasks

Task	Description
TCInput_Task_1	Actual-value acquisition
TCTask_1	Temperature control
TCPWM_Tasks	Pulse width modulation (PWM) cycle clock time at digital output

Speed classes

Two classes of speed are available depending on which pulse width modulation (**PWM**) is selected.

The speed class specifies the time base to be used as the basis for the controller cycle time. The speed class can be set via configuration data element **controller.execution.executionlevel**.

Table 4-217 Temperature controller (temperature channel TO) Assignment of speed classes

Speed class	classification
FAST (T_1)	Input 1 = Read actual values
	Control 1 = Controller cycle
SLOW (T_2)	Input 2 = Read actual values
	Control 2 = Controller cycle

These times define the cyclical task start times (system time base) for pulse width modulation, controller and actual-value processing.

Controller sampling time

The following configuration data from the **expert list** are available for this purpose:

Table 4-218 Temperature controller (temperature channel TO) Description of configuration data elements

Configuration parameter	Description
controller.standard. cycleParameter	This time defines the actual call time of the controller. The time you set must exceed the time configured under Control1 if you have selected the FAST speed class or, if you have selected the SLOW class speed, the time configured under Control2. The controller will automatically round the values to an integer multiple of Control1/Control2.
Input.analog.relation ControllerCycle-toInputCycle	Ratio between controller and actual-value processing. The ratio set should match the ratio between Input1 and Control1/Input2 and Control2. The actual-value processing is faster by the set factor.

Distribution of actuating signal output

The actuating signal is output on the basis of a specific distribution. As a result, not all controllers are included in the same cycle clock, thereby minimizing peaks in terms of the system load. This is achieved by delaying the controller call within a controller sampling time. In the case of two controllers, for example, the first controller will be called immediately, but the second will only be called once 50% of the sampling time has elapsed. If the ratio is smaller than the number of controller channels, then several controllers will have to be processed at the same time. For example, in the case of 4 channels and a ratio of 3: The first controller will be processed at the beginning, the second once 33% of the time has elapsed, the third once 66% has elapsed and the fourth at the beginning.

Example:

In the example below, 43 channels need to be configured with a cycle time of 1.008 s.

Make the following settings in the expert list:

ContollerCycleTime	1.008 s

Make the following settings in the "System Cycle Clocks" dialog:

Servo cycle clock	Selection 1	3 ms
PWM - Task [1]:	10 ms	Rounded to: 9 ms
System time base of actual-value acquisition (Input 1):	Distribution ratio 2	9 ms (PMV) * 2 --> 18 ms
System time base of controller (Control 1):	Distribution ratio 4	18 ms (Input 1) * 4 --> 72 ms

[1] Set integer multiple of the basic cycle clock. If you specify a controller cycle time that is not within the time base, the controller cycle time is rounded up to the next time-base increment (in the example: 9 ms). This is valid for all controller instances.

The ControllerCycleTime is always rounded up to an integer multiple of Control1.

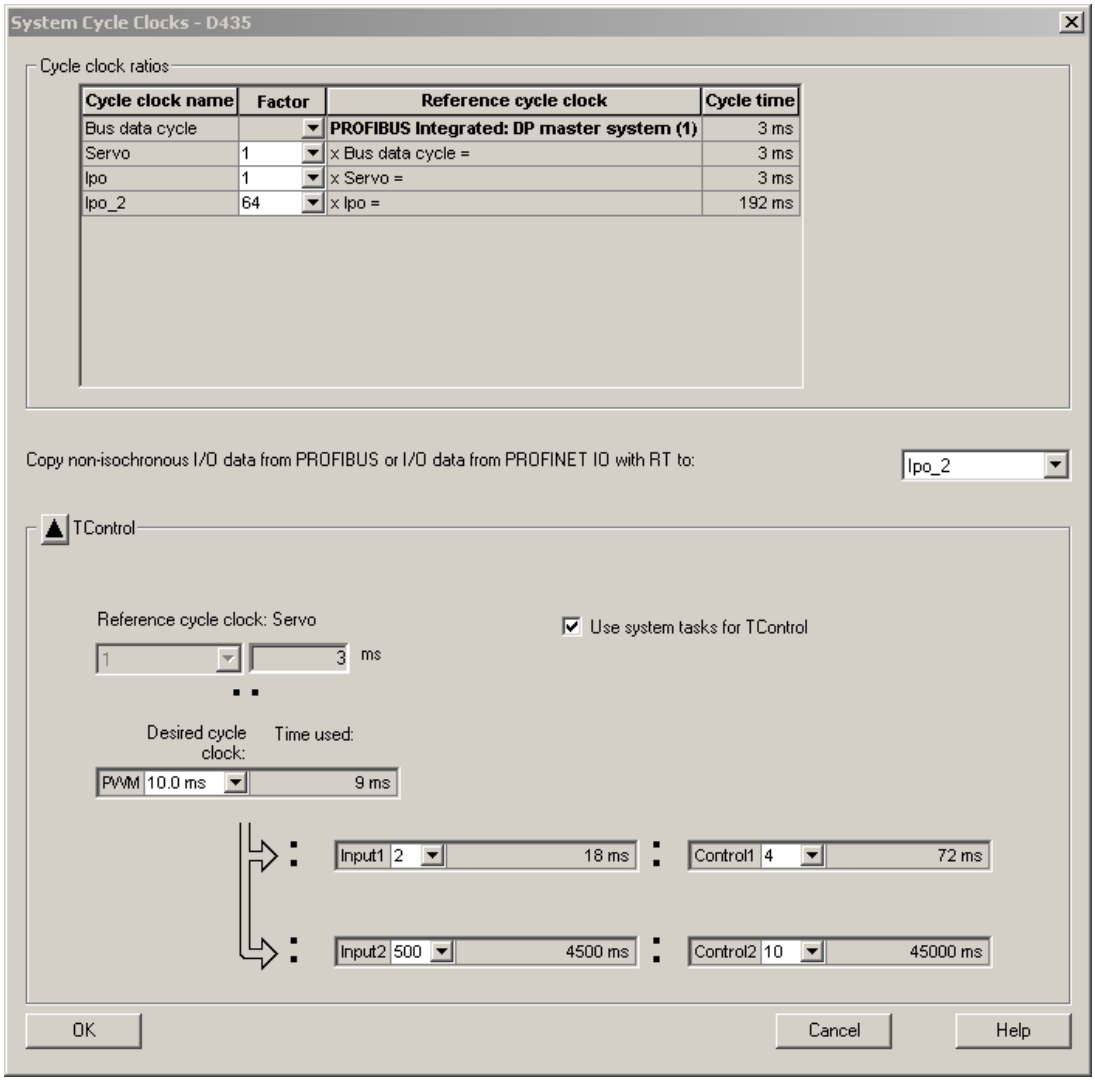

Figure 4-330 System cycle clocks for temperature control

Resulting distribution slices:

Number of distribution slices = ControllerCycleTime/Control1_Time

Number of distribution slices = 1,008 s/72 ms = 14

Thus, the 43 channels are distributed across 14 time slices (three or four channels will always switch at the same time).

Signs of life for temperature channels

Unless **TControl** was activated via the **Use system tasks for TControl** checkbox in the execution system when creating a temperature channel, you will not be notified in automatic mode that this temperature channel *is not being processed*.

Each temperature channel has a sign of life via the **lifeSign** system variable (V4.0 and higher). The sign of life is counted up in each cycle and can be evaluated via the user program.

Nevertheless, there is no checking carried out by the system.

TO	Technology object

4.5 Communication

Foreword

Foreword

Content

This document is part of the **System and Function Descriptions** documentation package.

Scope of validity

This manual is valid for SIMOTION SCOUT product version V5.4:

- SIMOTION SCOUT V5.4 (engineering system of the SIMOTION product family)
- The software configuration is described in this manual based on SIMOTION SCOUT and SIMATIC STEP 7 version V5.x. The described theoretical principles apply to SIMOTION SCOUT and, usually, also to SIMOTION SCOUT TIA.
  Information on configuration in the Engineering Framework Totally Integrated Automation Portal (SIMOTION SCOUT in the TIA Portal) is find in the SIMOTION SCOUT TIA Configuration Manual.

Sections in this manual

This manual describes the communications possibilities for SIMOTION systems.

- **Communications functions and services overview**
  General information about the communications possibilities provided by SIMOTION.
- **PROFIBUS**
  Information about the DPV1 communication, and the setup and programming of the communication between SIMOTION and SIMATIC devices.
- **PROFINET IO**
  Information about configuring PROFINET with SIMOTION

- **Ethernet introduction (TCP/IP and UDP connections)**
  Information about the setup and programming of the Ethernet communication between SIMOTION and SIMATIC devices.
- **Routing - communication across network boundaries**
  General information about routing
- **SIMOTION IT**
  General information about the IT and Web functions provided by SIMOTION.
- **PROFIsafe**
  General information on configuring failsafe controllers.
- **PROFIdrive**
  Description of the PROFIdrive profile.
- **Index**
  Keyword index for locating information

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

4.5.1 Fundamental safety instructions

4.5.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

4.5.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

4.5.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

4.5.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

4.5.2 Introduction

4.5.2.1 The communications subject in the SIMOTION documentation

Overview

You can find information on the subject of communication in the individual Manuals, in the Programming Manuals and in this Communication Manual.

Communication manual

This Communication Manual provides, in particular, information that is important for the communication of SIMOTION devices with devices that are not part of the SIMOTION family, especially SIMATIC devices.

This manual contains explanations of the required configuration steps that must be performed on both communication partners in order to obtain an error-free, functioning communication relationship.

Therefore, this manual deals very intensively with the settings and the programming of the SIMATIC S7 stations as communication partners of the SIMOTION devices.

Product manuals and programming manuals

The product manuals deal with the subject of communication from the point of view of the devices themselves, i.e. with respect to the electrical properties of the available interfaces as well as the setting options with the SIMOTION SCOUT engineering system.

You will also find further information in the manuals entitled **Modular Machine Concepts** and **Base Functions**, which are part of the SIMOTION documentation package.

There is no information here how the partner stations are set.

4.5.3 Overview of the communication functions and services

4.5.3.1 Network options

Introduction

As an integral part of "Totally Integrated Automation" (TIA), the SIMOTION and SIMATIC network solutions provide the necessary flexibility and performance characteristic for the communication requirements of your application, irrespective of how simple or complex it is.

Note

This section provides a general description of the communication functions and services included in Siemens' automation technology. This does not necessarily imply that all functions mentioned also are available for SIMOTION. You will find details concerning the functions supported by SIMOTION in chapters 4 - 8.

SIMOTION and SIMATIC networks for all applications

The SIMOTION products support a variety of network options. With these network solutions, you can combine the SIMOTION devices in accordance with the requirements of your application.

For further optimization of the network solutions, SIMOTION products provide integrated communication services and functions to extend the performance capability of the network protocol.

Note

Appropriate protective measures (among other things, IT security, e.g. network segmentation) are to be taken in order to ensure safe operation of the system. You can find more information on Industrial Security on the Internet at:

www.siemens.de/industrialsecurity.

PROFINET

Overview

PROFINET is based on the open Industrial Ethernet standard for industrial automation for company-wide communication and extends the capability for data exchange of your automation components through to the office environment, so that your automation components, even the distributed field devices and drives, can be connected to your local area network (LAN).

Because PROFINET connects all levels of your organization – from the field devices through to the management systems – you can perform the plant-wide engineering using normal IT standards. As for all solutions based on Industrial Ethernet, PROFINET supports electrical, optical and wireless networks.

As PROFINET is based on Industrial Ethernet and not implemented as a derived form of "PROFIBUS for Ethernet", PROFINET can utilize the previously installed Ethernet-compatible devices. Even if PROFINET is not a master/slave system, the PROFINET IO and PROFINET CBA communication services provide the functionality required by automation systems:

- With PROFINET IO, you can connect distributed field devices (e.g. digital or analog signal modules) and drives directly to an Industrial Ethernet subnet.
- PROFINET CBA (Component-Based Automation) supports modular solutions for machine and plant construction. You define your automation system as autonomous components, whereby each component consists of independent, self-contained tasks.

Both communication services provide real-time functionality to make PROFINET a real-time implementation. PROFINET also enables the simultaneous existence of the real-time communication of your automation process and your other IT communication, at the same time in the same network, without the real-time behavior of your automation system being impaired.

The PROFIsafe profile communicates with the fail-safe devices via the PROFINET subnet for further support of fail-safe or "safety-relevant" applications.

Industrial Ethernet

Overview

As Industrial Ethernet provides a communication network for the connection of command levels and cell levels, you can extend the data exchange capability of your automation components into the office environment with Industrial Ethernet.

Industrial Ethernet is based on the standards IEEE 802.3 and IEEE 802.3u for communication between computers and automation systems and enables your system to exchange large data volumes over long distances.

PROFIBUS

Overview

PROFIBUS is based on the standards IEC 61158 and EN 50170 and provides a solution with open field bus for the complete production and process automation. PROFIBUS provides fast, reliable data exchange and integrated diagnostic functions. PROFIBUS supports manufacturer-independent solutions with the largest third-party manufacturer support worldwide. A variety of transmission media can be used for your PROFIBUS subnet: electrical, optical and wireless.

PROFIBUS provides the following communication services:

- PROFIBUS DP (Distributed Peripherals) is a communication protocol that is especially suitable for production automation.
  PROFIBUS DP provides a fast, cyclic and deterministic exchange of process data between a bus DP master and the assigned DP slave devices. PROFIBUS DP supports isochronous communication. The synchronized execution cycles ensure that the data is transmitted at consistently equidistant time intervals.
- PROFIBUS PA (Process Automation) expands PROFIBUS DP to provide intrinsically safe data and power transmission according to the IEC 61158-2 standard.
- PROFIBUS FMS (Fieldbus Message Specification) is for communication on the cell level, where the controllers communicate with one another. Automation systems from different manufacturers can communicate with one another by means of PROFIBUS FMS.
- PROFIBUS FDL (Fieldbus Data Link) has been optimized for the transmission of medium-sized data volumes to support error-free data transmission on the PROFIBUS subnet.

In addition, PROFIBUS uses profiles to provide communication options for the needs of specific applications, such as PROFIdrive (for the motion control) or PROFIsafe (for fail-safe or "safety-relevant" applications).

MPI (Multi-Point Interface)

Overview

MPIs are integrated interfaces for SIMOTION and SIMATIC products (SIMOTION devices, SIMATIC S7 devices, SIMATIC HMI as well as SIMATIC PC and PG).

MPI provides an interface for PG/OP communication. In addition, MPI provides simple networking capability using the following services: communication via global data (GD), S7 communication and S7 basic communication.

The electric transmission medium for MPI uses the RS 485 standard, which is also used by PROFIBUS.

Point-to-point communication (PtP)

Overview

SIMOTION devices can be programmed so that they exchange data with another controller in the network. Even if the point-to-point communication is not considered as a subnet, the point-to-point connection provides serial transmission (e.g. RS232 or RS485) of data between two stations, e.g. with a SIMATIC controller or even with a third-party device that is capable of communication.

CP modules (e.g. a CP340) or ET200 modules can be used for point-to-point communication to read and write data between two controllers. Point-to-point communication thus represents a powerful and cost-effective alternative to bus solutions, particularly when only a few devices are connected to the SIMOTION device.

Point-to-point communication provides the following capabilities:

- Using standard procedures or loadable drivers to adapt to the protocol of the communication partner
- Using ASCII characters to define a user-specific procedure
- Communication with other types of devices, such as operator panels, printers or card readers

Additional references

You will find additional references concerning point-to-point communication in the descriptions of the CP or ET200 modules.

4.5.3.2 Communications services (or network functions)

Introduction

SIMOTION and SIMATIC devices support a set of specific communication services, which control the data packets that are transmitted via the physical networks. Each communication service defines a set of functions and performance characteristics, e.g. the data to be transferred, the devices to be controlled, the devices to be monitored and the programs to be loaded.

Communication services of the SIMOTION and SIMATIC products

Communication services, also often referred to as network functions, are the software components that utilize the physical hardware of the networks. Software interfaces (e.g. S7 system functions) in the end device (e.g. SIMOTION device, SIMATIC S7 device or PC) provide access to the communication services. However, a software interface does not necessarily have all of the communication functions for the communication service. Such a service can be provided in the respective end system with different software interfaces.

Communicating with SIMATIC

For the communication functions of the SIMATIC controllers, refer to the SIMATIC documentation.

- SIMATIC S7-1500, ET 200MP, ET 200SP communication (https://support.industry.siemens.com/cs/ww/en/view/59192925)
- SIMATIC communication with SIMATIC (https://support.industry.siemens.com/cs/ww/en/view/25074283)

PG/OP communication services

Overview

PG/OP services are the integrated communication functions with which SIMATIC and SIMOTION automation systems communicate with a programming device (e.g. STEP 7) and operator control and monitoring system. All SIMOTION and SIMATIC networks support the PG/OP communication services.

S7 communication services

Overview

S7 communication services provide data exchange using communication system function blocks (SFBs) and communication function blocks (FBs) for configured S7 connections.

All SIMOTION devices and SIMATIC S7 devices have integrated S7 communication services that allow the user program in the controller to initiate the reading or writing of data. These functions are independent of specific networks, allowing you to program S7 communication via any network (MPI, PROFIBUS, PROFINET or Industrial Ethernet).

For transferring data between the controllers, you must configure a connection between both controllers. The integrated communication functions are called up by the SFB/FB in the application. You can transfer up to 64 KB of data between SIMOTION and SIMATIC S7 devices.

You can access data in the controller with your HMI device, programming device (PG), or PC as the S7 communication functions are integrated in the operating system of the SIMOTION devices and SIMATIC S7 devices. This type of peer-to-peer link does not require any additional connection equipment. (However, if you configure a connection to one of these devices, you can access the data via the symbolic names.)

Note

SFBs may not be used with SIMOTION.

S7 basic communication services

Overview

S7 basic communication services provide data exchange using communication system functions (SFCs) for non-configured S7 connections. These SFCs (e.g. X_GET or X_PUT) read or write the data to a SIMATIC controller, so that small data volumes can be transferred via an MPI subnet to another S7 station (S7 controller, HMI or PC).

The SFCs for the S7 basic communication do not communicate with stations in other subnets. You do not need to configure connections for the S7 basic communication. The connections are established when the user program calls the SFC.

Note

You can only use the S7 basic communication services via an MPI connection between SIMATIC S7-300, S7-400 or C7-600 controllers.

"Global data" communication service

Overview

In addition to the other options for the network communication, you can configure a 'global data' communication connection (GD) to provide cyclic data transmission between SIMATIC controllers that are connected to an MPI network. The data exchange runs as part of the normal process image exchange, as the global data communication is integrated in the operating system of the SIMATIC controller.

As the global data communication is a process for transferring data, the receipt of the global data is not acknowledged. A publisher (data source) sends the data to one or several subscriber(s) (data sink) and subscribers receive the data. The publisher does not receive an acknowledgement from the subscribers that they have received the transmitted data.

Note

You can only use the global data communication via an MPI connection between SIMATIC S7-300, S7-400 or C7-600 controllers.

GD communication does not require any special programming or program blocks in your STEP 7 user program. The operating systems of the individual controllers process the global data exchange. Using STEP 7, you configure a global data (GD) table with the source path of the data to be transmitted to the subscribers. This GD table is downloaded with the hardware configuration for both the publisher and the subscribers.

Global data is not available for SIMOTION.

PROFINET communication services

Overview

PROFINET provides the following communication services:

- You can connect I/O devices and drives via a Ethernet physics to the SIMOTION or SIMATIC controller with the communication service PROFINET IO. The user program executed in the controller can process the input and output data of the I/O devices with PROFINET IO. You configure the addressing for PROFINET IO in STEP 7 or SIMOTION SCOUT.
- With PROFINET CBA, you can define your automation system as autonomous subunits or components. These components can be PROFINET IO, PROFIBUS DP or third-party devices or subnets.

If you want to use the PROFINET CBA communication services for a component-based solution, configure the SIMATIC controllers and the I/O devices in individual components in STEP 7. Then configure the communication between the various components with SIMATIC iMAP.

Both PROFINET IO and PROFINET CBA communication services provide the real-time communication required by automation systems.

Note

PROFINET CBA is only available for SIMATIC devices, not for SIMOTION devices.

Industrial Ethernet communication services

Overview

Industrial Ethernet is based on the IEEE 802.3 and IEEE 802.3u standards and connects the automation systems with your business system, so that you also have access to the data in the office.

Industrial Ethernet provides the following communication services:

- The ISO transfer provides services for transmitting data via connections that support error-free data transmission. The ISO transfer is only possible with STEP7.
- TCP/IP allows you to exchange contiguous data blocks between the controllers and computers in PROFINET or Industrial Ethernet networks. With TCP/IP, the controller transmits contiguous data blocks.
- ISO-on-TCP (RFC 1006) supports error-free data transmission. For SIMOTION only when going though SCOUT ONLINE. If the communication is performed from the user program, an RFC must be programmed.
- UDP (User Datagram Protocol) and UDP multi-cast provide simple data transmission without acknowledgment. You can transmit related data blocks from one station to another, such as between a SIMOTION and SIMATIC controller, a PC or a third-party system.
- Information technology (IT) communication allows you to share data using standard Ethernet protocols and services (such as FTP, HTTP and e-mail) via PROFINET or Industrial Ethernet networks.

PROFIBUS communication services

Overview

PROFIBUS provides the following communication services:

- PROFIBUS DP (Distributed Peripherals) supports the transparent communication with the distributed I/O. The SIMOTION/STEP 7 user program accesses the distributed I/O in the same manner as it accesses the I/O on the central rack of the controller (or the PLC). PROFIBUS DP enables the direct communication with the distributed I/O. PROFIBUS DP complies with the EN 61158 and EN 50170 standards.
- PROFIBUS PA (Process Automation) facilitates the direct communication with process automation (PA) instruments. This includes cyclic access to I/O, typically with a PLC master, as well as acyclic access to the potentially large set of device operating parameters, typically with an engineering tool such as Process Device Manager (PDM). PROFIBUS PA complies with the IEC 61158 standard.
- PROFIBUS FMS (Fieldbus Message Specifications) enables the transmission of structured data (FMS variables). PROFIBUS FMS complies with the IEC 61784 standard.
- PROFIBUS FDL (Fieldbus Data Link) has been optimized for the transmission of medium-sized data volumes to support error-free data transmission on the PROFIBUS subnet. PROFIBUS FDL supports the SDA function (Send Data with Acknowledge).

Note

SIMOTION devices only support the PROFIBUS DP communication service.

For fail-safe communication, SIMOTION and SIMATIC devices use the PROFIsafe profile for PROFIBUS DP.

SIMOTION devices use the PROFIdrive profile for communication between SIMOTION devices through to the connected drives.

You can find a comparison of the SIMATIC S7 and SIMOTION system functions in the 2_FAQ directory on the Utilities & Applications CD.

Time-of-day synchronization via NTP

Introduction

To ensure that all components throughout the system have the same time of day, they must be synchronized to a time of day and one component must be the time generator for all the others. One possibility is to synchronize the time of day via an NTP server.

For NTP, the device sends time of day queries in regular time intervals to the NTP server in the subnet. A router must be used if the NTP server is located outside the subnet. The most accurate time of day is determined based on the responses and used to synchronize the station time of day. NTP has the advantage that the synchronization is also performed over subnet limits.

NTP time-of-day synchronization properties

- The NTP server is configured at the PN/IE interface of the controller. The PN interface via which communication with the time-of-day server actually takes place is determined on the basis of the IP address configured in the TCP/IP stack.
  - X7 with C240
  - X130 with D4x5
  - X127 with D410
  - X1 with P320-4
- Up to four servers can be configured as time generator.
- NTP does not support any automatic adjustment between summer and winter time.
- Time zones cannot be set. UTC (Universal Time Coordinated) is always transferred. It is identical with GMT (Greenwich Mean Time).

Configuring NTP in SIMOTION SCOUT

Introduction

The NTP time-of-day synchronization of a SIMOTION CPU can be configured in HW Config.

Procedure

How to configure the NTP time-of-day synchronization:

1. Click the PN/IE-NET interface (for D4x5 X130) in the HW Config for the SIMOTION CPU.
2. Select the time-of-day synchronization tab in the displayed dialog.
3. Activate the "Activate time-of-day synchronization in NTP" checkbox.

4. Enter the IP addresses for as many as four NTP servers. A router must be used when the IP address lies outside the subnet of the SIMOTION controller.
5. Enter the refresh interval.

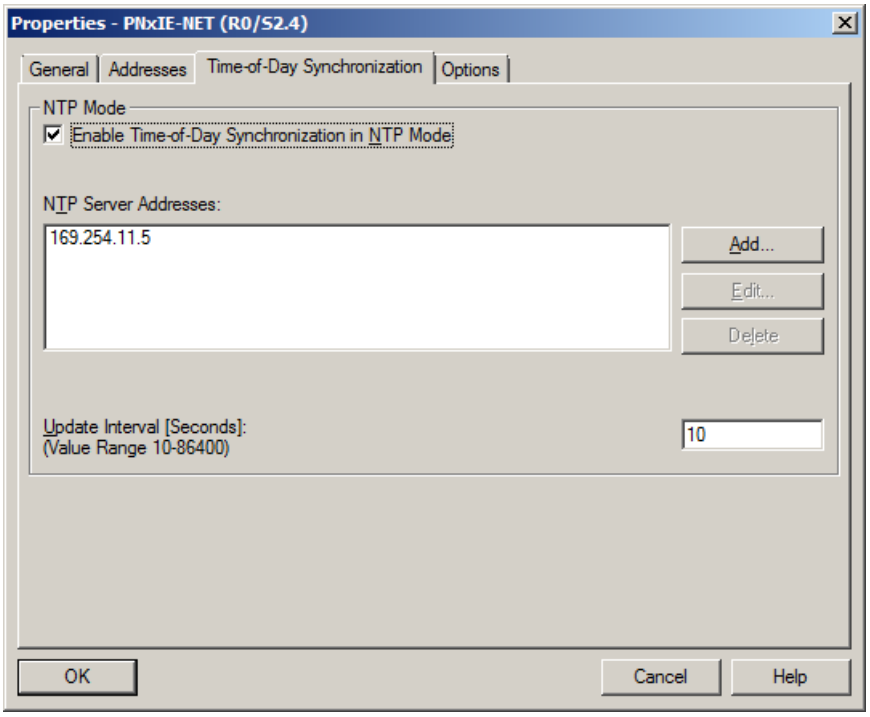

Figure 4-331 Time-of-day synchronization via NTP in HW Config

4.5.3.3 Additional services for the exchange of information

In addition to supporting the standard communication networks, SIMOTION and SIMATIC also provide additional means for sharing information via networks.

Sharing data with other applications via OPC (OLE for Process Control)

With OPC, Windows applications can access process data so that it is easy for devices and applications from different vendors to be combined with each other. OPC not only provides an open, manufacturer-independent interface, but also an easy-to-use client/server configuration for the standardized data exchange between applications (e.g. HMI or office applications) that do not require a specific network or protocol.

The OPC server provides interfaces for connecting the OPC client applications. You configure the client application for access to data sources, e.g. addresses in the memory of a PLC. Because several different OPC clients can access the same OPC server at the same time, the same data sources can be used for any OPC-compliant application.

In addition to OPC servers, SIMATIC NET also provides applications for configuring and testing OPC connections: Advanced PC Configuration (APC) and OPC Scout (used to test and commission an OPC application or OPC server). You use these tools to connect SIMOTION and SIMATIC S7 products to other OPC-compliant applications.

The SIMATIC NET OPC servers support the following communication services:

- PROFINET IO (by means of PROFINET or Industrial Ethernet subnet)
- PROFINET CBA (by means of PROFINET or Industrial Ethernet subnet)
- TCP/IP (by means of PROFINET or Industrial Ethernet subnet)
- PROFIBUS DP (by means of PROFIBUS subnet)
- PROFIBUS FMS (by means of PROFIBUS subnet)
- S7 communication
- S5compatible communication

Using information technology (IT) for sharing data in an office environment

SIMOTION and SIMATIC use standard IT tools (such as e-mail, HTTP Web server, FTP and SNMP) with PROFINET and Industrial Ethernet networks to expand the data-sharing capabilities into the office environment.

For SIMOTION devices, the corresponding functions are made available through SIMOTION IT, see SIMOTION IT Ethernet-based HMI and Diagnostic Functions.

4.5.4 PROFIBUS DP

4.5.4.1 PROFIBUS DP communication

Overview of PROFIBUS DP communication

Description

PROFIBUS DP (Decentralized Peripherals) is designed for fast data exchange at the field level. The communication is performed between a class 1 PROFIBUS DP master (e.g. a SIMOTION controller) and PROFIBUS DP slaves (e.g. a SINAMICS S120 drive). The data exchange with decentralized devices is mainly performed cyclically (DP V0 communication). In this case, the central controller (SIMOTION controller) reads the input information cyclically from the slaves and writes the output information cyclically to the slaves. Moreover, diagnostics functions are made available through the cyclic services. The following figure shows the data protocol on PROFIBUS DP.

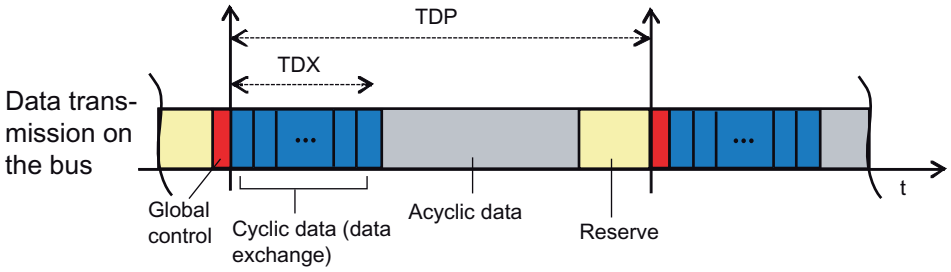

Figure 4-332 Data protocol on PROFIBUS DP

4.5.4.2 Cyclical data exchange between a SIMOTION and SIMATIC controller.

Description of cyclical SIMOTION and SIMATIC controller data exchange

The following section describes the options for having a SIMOTION and a SIMATIC controller communicating with one another via PROFIBUS DP.

There are various possibilities:

- A SIMOTION controller is connected to a PROFIBUS DP master system of a SIMATIC controller as a PROFIBUS DP slave.
- A SIMATIC controller is connected to a PROFIBUS DP master system of a SIMOTION controller as a PROFIBUS DP slave.
- A master-master communication is used between SIMOTION and SIMATIC controls.

Linking as DP slave

For linking as a DP slave, there are two options:

- The controller is connected to the DP master as a "standard" DP slave by means of a GSD file. This is essential if the two controllers are in different projects.
- The controller is connected to the DP master as a so-called I slave (intelligent DP slave). For this purpose, the two controls must be located in one project.

The two options are supported by SIMOTION and SIMATIC controllers.

Note

You will find further information on cyclic data exchange with controllers in the SIMATIC FAQs.

- Linking a S7-400 CPU to a non-Siemens master as a DP slave (https://support.industry.siemens.com/cs/ww/en/view/13091565)
- DP linking CPU 315-2DP (slave) and S7-400 (master) (https://support.industry.siemens.com/cs/ww/en/view/6518822)

Linking a SIMOTION controller to a SIMATIC controller as a PROFIBUS DP slave

Linking by means of a GSD file

Procedure

The GSD files for the various SIMOTION hardware platforms are automatically also installed by the SIMOTION SCOUT installation.

If there is no SIMOTION SCOUT on the engineering PC, the GSD files must first be installed in STEP7 HW Config. You will find the corresponding GSD files on the SIMOTION SCOUT DVD "Add-on" in the respective device directory under Firmware and Version.

Table 4-219 GSD file

Device	Name of the GSD file
SIMOTION C	Si0480aa.gsd
SIMOTION D	Si0280ab.gsd (This file can be used for all SIMOTION D)
SIMOTION P	Si0380fa.gsd

After the GSD files have been installed by selecting **Options > Install GSD file...** in the menu, the corresponding SIMOTION devices will appear in the Hardware Catalog under **PROFIBUS DP >**

Additional FIELD DEVICES > PLC > SIMOTION. These can be inserted into a DP master system from there.

Note

On SIMOTION controllers that are linked to a higher-level controller via a GSD file (separate projects), access is not possible with SIMOTION SCOUT and the access point S7ONLINE via a routed connection.

The alternative access point **DEVICE** in the SIMOTION SCOUT must be used for this! This also has the advantage of being able to go online simultaneously with the two projects to SIMATIC (S7ONLINE) and SIMOTION controller (DEVICE). However, it is not possible to go online to the SINAMICS_Integrated of a SIMOTION D controller if the link with the SIMOTION has already been routed. Only one network transition can be configured (e.g. PC/PG <Ethernet> S7-CPU <PROFIBUS> SIMOTION, but not <PROFIBUS_Integrated> SINAMICS_Integrated in addition).

Note

It is possible to access SINAMICS drives that are linked to a controller via a GSD file with SIMOTION SCOUT (or STARTER) via a routed connection with the exception of the SINAMICS_Integrated drive.

To do this, it is possible to set a network transition point using the S7 subnet ID with the setting **Target device > Online access ...**. Through a network node it is also possible to route to drives that have been inserted as single drives.

Linking using an I slave

Requirement

- STEP 7 and SIMOTION SCOUT must have been installed on the engineering PC.
- The SIMATIC and SIMOTION controllers must be in the same project.

If these requirements are fulfilled, the SIMOTION controller can also be connected to the PROFIBUS DP master system of the higher-level SIMATIC as an I slave.

Procedure

It is recommended that the SIMOTION station is first completely configured as DP slave before it is placed on the DP line of the SIMATIC CPU as an I slave.

Below you will find a description of the procedure for a SIMOTION C. The procedure is identical apart from the selection of the SIMOTION platform.

1. Configuring a station as a DP slave, e.g. SIMOTION C2xx
   Double-clicking on the desired PROFIBUS interface (e.g. DP2/MPI) in HW Config opens its properties. Select the **DP slave** option from the **Operating Mode** tab.
2. Configuring the local I/O addresses
   You can set the local I/O addresses and the diagnostics address on the **Configuration** tab.
3. Switch to the configured SIMATIC station that is to be DP master for the SIMOTION.

4. Creating an I slave
   Drag the station type "C2xx/P3xx/D4xx/D4xx-2-I-Slave" from the **Hardware catalog** window, "Preconfigured stations" folder, and drop it on the DP master system of the SIMATIC controller.
5. Linking an I-slave
   Double-click the I slave proxy to open the properties window. On the **Link** tab, assign the station that is to represent the intelligent DP slave (I slave). This displays all the stations that are already available in the project and that are potential link partners.

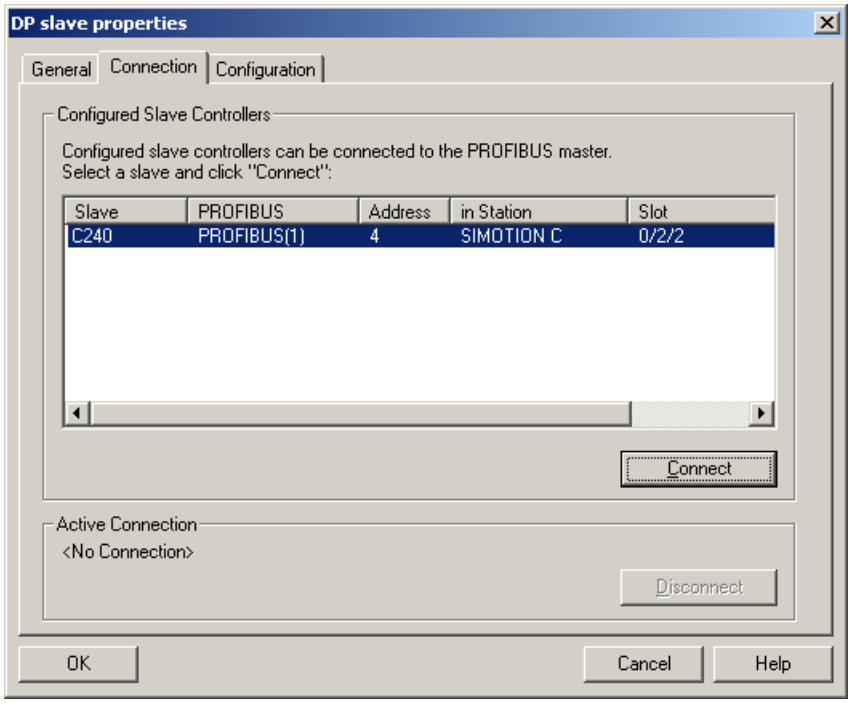

Figure 4-333 I-slave properties

6. Select the appropriate SIMOTION and click **Connect**. The configured SIMOTION station is now connected as intelligent DP slave to the SIMATIC.

7. Select the **Configuration** tab and assign the addresses:

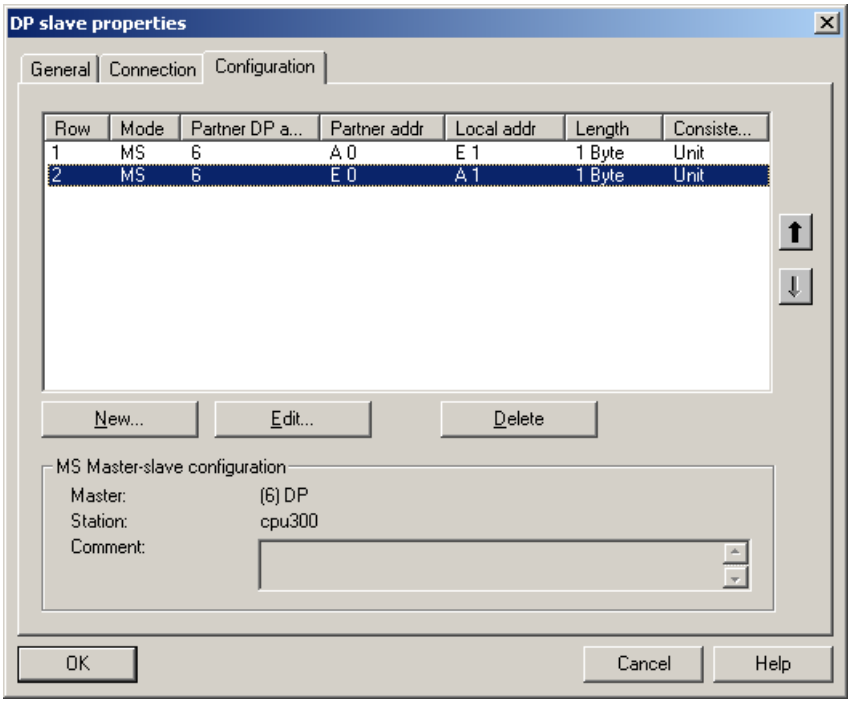

Figure 4-334 Properties - configuration

– For the data exchange with the DP master via I/O areas, select the **MS** (Master-Slave) mode

Note

For direct data exchange with a DP slave (slave-to-slave data exchange broadcast) or DP master (master-to-master data exchange broadcast), it would be necessary to select DX mode (Direct Data Exchange) mode here.

8. Confirm the settings by clicking **OK**.

Configuration of the SIMOTION station as intelligent DP slave on the SIMATIC station is now complete and data can be exchanged via the specified I/O addresses.

Linking a SIMATIC controller to a SIMOTION controller as a PROFIBUS DP slave

Linking by means of a GSD file

Procedure

The GSD files for the various SIMATIC stations must first be installed in STEP 7 HW Config.

Note

You will find the corresponding GSD files in Product Support: PROFIBUS GSD files for SIMATIC.

After the GSD files have been installed by selecting **Options > Install GSD file...** in the menu, the corresponding SIMATIC devices will appear in the Hardware Catalog under **PROFIBUS DP > Additional FIELD DEVICES > PLC > SIMATIC**. These can be inserted into a DP master system from there.

Note

SIMATIC controllers that have been connected to a higher-level controller by means of a GSD file, cannot be accessed with STEP 7 via a routed connection.

See also

PROFIBUS GSD files: SIMATIC (https://support.industry.siemens.com/cs/ww/en/view/113652)

Linking using an I slave

Requirements

- STEP 7 and SIMOTION SCOUT must have been installed on the engineering PC.
- The SIMATIC and SIMOTION controllers must be in the same project.

If these requirements are fulfilled, the SIMATIC controller can also be connected to the PROFIBUS DP master system of the SIMOTION controller as an I slave.

Procedure

It is recommended that the SIMATIC station is first completely configured as a DP slave before it is placed on the DP line of the SIMOTION as an I slave.

Below you will find a description of the procedure for a CPU 315-2 D. The procedure is identical apart from the selection of the CPU types, also for an S7-400.

1. Configure a station, for example, with the CPU 315-2 DP, as DP slave. Double-click on line 2.1 (interface) in the configuration table and select the DP slave option in the **Operating mode** tab.
2. You can set the local I/O addresses and the diagnostics address in the **Configuration** tab.
3. Switch to the configured SIMOTION station that is to be DP master for the SIMATIC.
4. Drag the appropriate station type, CPU 31x or CPU 41x, from the **Hardware Catalog** window (folder of already configured stations) and drop it on the symbol for the DP master system of the SIMOTION station.

5. Double-click the I slave proxy to open the properties window. On the **Link** tab, assign the station that is to represent the intelligent DP slave (I slave). This displays all the stations that are already available in the project and that are potential link partners.

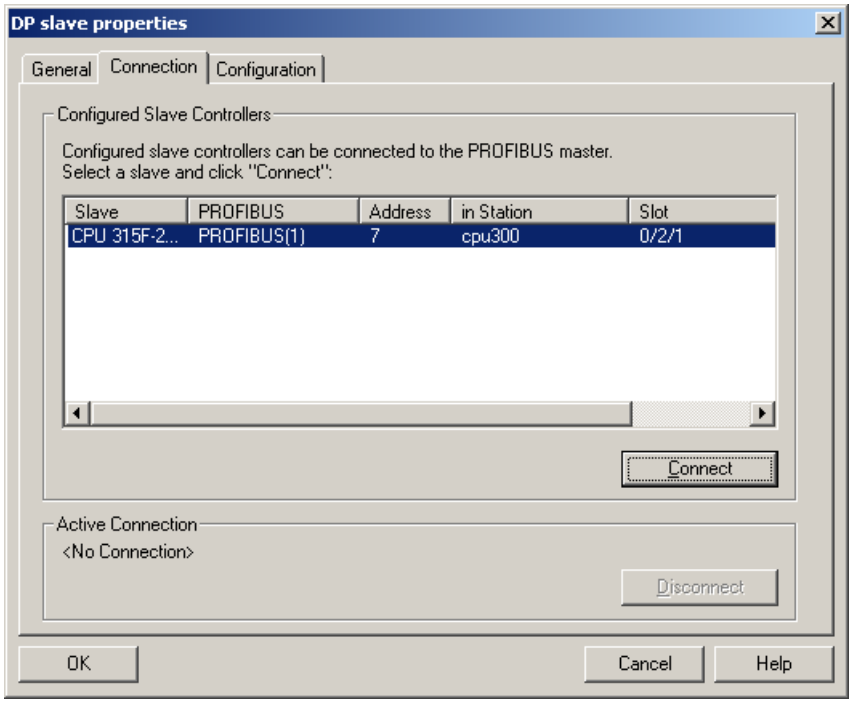

Figure 4-335 Properties - link

6. Select the appropriate S7 station and click **Connect**. The configured S7 station is now connected as intelligent DP slave to the SIMOTION.

7. Select the **Configuration** tab and assign the addresses:

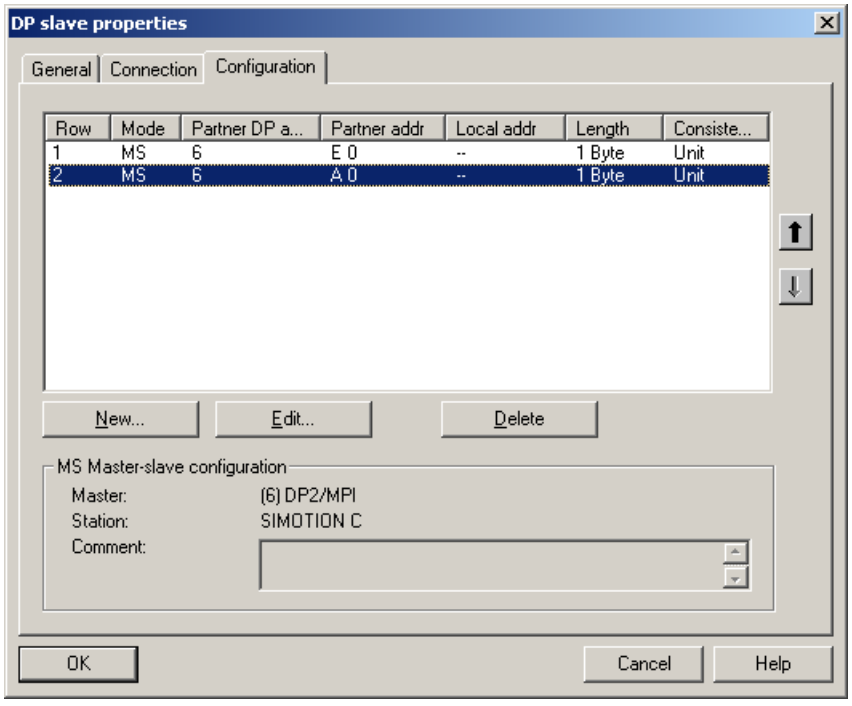

Figure 4-336 Configuration - address selection

– For the data exchange with the DP master via I/O areas, select the **MS** (Master-Slave) mode

Note

For direct data exchange with a DP slave (slave-to-slave data exchange broadcast) or DP master (master-to-master data exchange broadcast), it would be necessary to select DX mode (Direct Data Exchange) mode here.

8. Confirm the settings by clicking **OK**.

The configuration of the SIMATIC station as intelligent DP slave on the SIMOTION station is now completed and data can be exchanged via the specified I/O addresses.

CPU-CPU communication using the S7 basic communication via PROFIBUS

Introduction

CPU-CPU communication

CPU-CPU communication using the S7 basic communication between a SIMATIC and a SIMOTION controller, is set up using the SFC65 (XSEND) and SFC66 (XRECEIVE) system functions on the SIMATIC side and the _Xsend() and _Xreceive() system functions on the SIMOTION side. This application communication is effected via PROFIBUS, or MPI.

Table 4-220 CPU-CPU communication

Protocol	SIMATIC device	Function	SIMOTION device	Function
PROFIBUS	S7-300 CPU S7-400 CPU	SFC65 (XSEND) SFC66 (XRCV)	SIMOTION C SIMOTION D SIMOTION P	_Xsend _Xreceive

PROFIBUS addresses are assigned in HW Config. This must also be passed as a parameter when the system function _Xsend() is called. That is, the parameters that are important for communication are determined by the user and passed in the function call. It is not necessary to configure the communication link in NetPro.

Note

For further information, refer to the online help of each system function.

You will find additional information in the FAQ for SIMATIC communication:

- CPU-CPU communication with SIMATIC controllers (https://support.industry.siemens.com/cs/ww/en/view/20982954)
- S7 basic communication (https://support.industry.siemens.com/cs/ww/en/view/28866132)

SIMOTION functions

The SIMOTION functions for a PROFIBUS connection are explained in more detail below.

System functions Xsend() and Xreceive()

Table 4-221 Xsend()

```
RetVal_PB_Senden:=
    _xsend(
          communicationMode := PB_Senden_CommunicationMode,
          address := PB_Senden_Address,
          messageID := PB_Senden_MessageID,
          nextCommand := PB_Sender_NextCommand,
          commandID := PB_Senden_CommandID,
          data := PB_Sende_Daten,
          datalenght := PB_Sende_Daten_Laenge
          );
```

Example of the call of the SIMOTION function _xsend

If the SIMATIC S7 station and the SIMOTION device communicate via PROFIBUS, the _xsend function is called on the SIMOTION side for sending purposes.

Note

Application transmission and reception via S7 basic communication (_Xreceive() or _Xsend()) is only possible on a PROFIBUS interface of the SIMOTION controller if the **Programming, status/ force, or other PG functions and non-configured communication connections possible** option is set.

The "communicationmode" parameter informs the called function of what is to happen to the connection after the successful data transfer. The function data type can assign the ABORT_CONNECTION or HOLD_CONNECTION values. If ABORT_CONNECTION is assigned to the parameter, the connection will be removed after the data transfer. The HOLD_CONNECTION value is used to parameterize the function so that the connection will be retained after a successful data transfer.

The address parameter contains a structure of the StructXsendDestAddr data type, which also consists of various parameters. This structure contains all the information about the communication partner address of the SIMOTION device.

Parameter structure "StructXsendDestAddr

The individual parameters of the structure are listed and explained in the following.

The deviceid parameter is used for the respective SIMOTION hardware. The physical connection point is specified with the parameter. For example, the value 1 is entered for interface X8 for a SIMOTION C2xx. The value 2 is entered for interface X9. If a SIMATIC S7 station is connected to X101 of a SIMOTION P, the value 1 is assigned in the deviceid parameter. The value 2 is written in the deviceid parameter for the X102 interface. For the SIMOTION D, the value 1 is entered for the X126 interface and the value 2 for the X136 interface in the deviceid parameter.

Because no subnet mask is specified for communication via MPI or PROFIBUS, a value of 0 is pre-assigned to the remotesubnetidlength parameter. Consequently, the assignment of the remotesubnetid parameter is irrelevant.

The value 1 is set in the remotestaddrlength parameter for the MPI or PROFIBUS communication.

The nextstaddrlength parameter specifies the length of the router address. As a router is not used for the MPI or PROFIBUS communication between the SIMATIC S7 station and the SIMOTION device, the value 0 is assigned for this parameter. Consequently, the nextstaddr parameter is also irrelevant (see below).

The following remotesubnetid parameter identifies the subnet mask and has, as already mentioned above, no significance for the communication via MPI or PROFIBUS.

The remotestaddr parameter specifies the actual destination address. The parameter is an array. However, only the first index is used for the MPI or PROFIBUS communication. The other five indices have no significance.

The nextstaddr parameter is used to specify the router address. The same applies for this parameter as for the remotesubnetid parameter. Its assignment is also irrelevant for the communication via MPI or PROFIBUS.

The messageid parameter is assigned by the user for the identification of the SIMOTION on the receive side. The value entered enables an assignment on the SIMATIC S7 station via the REQ_ID parameter. The value can be fetched there from the messageid parameter.

The behavior of this function with respect to the advance when called is parameterized with the nextcommand parameter. There are two setting options: IMMEDIATELY and WHEN_COMMAND_DONE. With the first value, the advance is immediately and with the second value, after completion of the command.

When the function is called, a system-wide unique number is assigned in the commandid parameter to allow tracking of the command status.

The send data is specified with the data variable when the function is called.

The datalength parameter specifies the length of the data to be transferred from the send area.

The return value of the _xsend function to the user program is of data type DINT. The various return values indicate any problems that occurred during the execution of the function. There is also a confirmation when the data has been successfully sent.

Table 4-222 Xreceive()

```
RetVal_PB_Empfangen:=
    _xreceive(
          messageID := PB_Empfangen_MessageID,
          nextCommand := PB_Empfangen_NextCommand,
          commandID := PB_Empfangen_CommandID
          );
```

Call example of the SIMOTION _xreceive function

The example shows the use of the _xreceive function. The function is used when data from a SIMATIC S7 station is to be received via PROFIBUS.

The messageid parameter is transferred to the _xreceive function for the identification of the S7 station from which the data is to be received. The entered value is that what was assigned on the S7 page in the REQ_ID parameter of the corresponding _xsend system function.

The behavior of this function with respect to the advance when called is parameterized with the nextcommand parameter. There are two setting options: IMMEDIATELY and WHEN_COMMAND_DONE. With the first value, the advance is immediately and with the second value, after completion of the command.

When the function is called, a system-wide unique number is assigned in the commandid parameter to allow tracking of the command status.

The structure returned from the function to the user program contains the functionresult, datalength and data parameters. The receive status can be queried via the functionresult parameter. The datalength parameter returns the number of received useful data bytes after a successful call of the _xreceive function. The received useful data can be accessed via the data parameter.

4.5.5 PROFINET IO

4.5.5.1 PROFINET IO overview

PROFINET IO

In machine construction, there is a clear trend toward distributed machine concepts and mechatronic solutions. This increases the demands on the drive networking. A large number of drives and shorter cycle times as well as the use of IT mechanisms are increasingly gaining in importance.

The two successful solutions, PROFIBUS DP and Ethernet, are combined under PROFINET IO. PROFINET IO is based on many years of experience with the successful PROFIBUS DP and combines the normal user operations with the simultaneous use of innovative Ethernet technology concepts. This ensures the smooth migration of PROFIBUS DP into the PROFINET IO world.

PROFIBUS DP is a bus system where only one node can have "send" access to the bus at any one time (half-duplex operation). PROFINET IO uses the switching technology which is also found with Ethernet. This involves separating all the network segments, thereby enabling sending and receiving to be performed on all lines at the same time (full-duplex operation). In this way, the network can be used much more efficiently through the simultaneous data transfer of several nodes. The bandwidth has also been increased to 100 Mbps.

Note

Detailed descriptions on the subject of PROFINET can be found in the *SIMATIC PROFINET System Description* System Manual.

Application model

During the development of PROFINET IO, special emphasis was placed on the protection of investment for users and device manufacturers. The application model is retained for the migration to PROFINET IO. Compared with PROFIBUS DP, the process data view remains unchanged for:

- I/O data (access to the I/O data via logical addresses)
- Data records (storage of parameters and data) and
- Connection to a diagnostic system (reporting of diagnostic events, diagnostics buffer)

This means that the familiar view for access to the process data is used in the user program. Existing programming know-how can continue to be used. This also applies to device profiles, such as PROFIdrive, which is also available with PROFINET IO.

The engineering view also has a familiar "look and feel". The engineering of the distributed I/O is performed in the same way and with the same tools, as already used for PROFIBUS.

PROFINET IO system

A PROFINET IO system consists of an IO controller and the IO devices assigned to it.

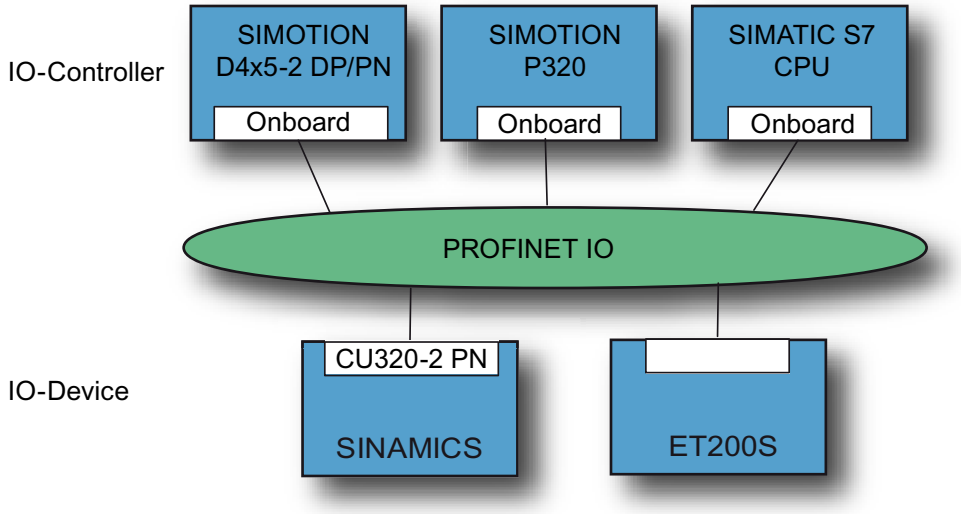

Figure 4-337 PROFINET overview IO Controller - IO Device

IO controller

The PROFINET IO controller has the same functions as the PROFIBUS DP master. The IO controller of, for example, a D4x5-2 DP/PN with onboard PROFINET interface exchanges data cyclically with the I/O devices assigned to it (PROFINET IO devices), such as the SINAMICS S120.

IO device

Distributed field devices such as I/O components (e g. ET200) or drives (e.g. SINAMICS S120 with CU320-2 PN) are referred to as IO devices. The function is comparable to a PROFIBUS DP slave.

See also

Creating an IO device (Page 2213)

PROFINET interface

Overview

PROFINET IO is based on Switched Ethernet full-duplex operation and a transmission bandwidth of 100 Mbit/s.

PROFINET devices have one or more PROFINET interfaces (Ethernet controller/interface). The PROFINET interfaces have one or more ports (physical connections).

PROFINET devices that have interfaces with several ports also have an integrated switch. PROFINET devices with two ports at one interface allow you to establish a system with a linear or ring topology. PROFINET devices with three and more ports at one interface are also suitable for establishing tree topologies.

Transmission medium

You can set the transmission medium in STEP 7 for the ports of a PN interface. **Full duplex with 100 Mbps** is the default setting at all ports. When ports are interconnected, the partner port must use the same transmission medium. **Automatic settings** is recommended as the setting for ports because this will ensure harmonized settings between ports and partner ports.

RT classes

RT classes for PROFINET IO

Description

PROFINET is based on the Ethernet standard. This means that all standard Ethernet-based protocols (e.g. HTTP, FTP, TCP, UDP, IP, etc.) can be transferred via the PROFINET network.

In addition to the protocols associated with the types of office-based applications known throughout the world, PROFINET IO offers two protocols (transmission modes) adapted to the requirements of the automation sector. These are PROFINET IO with RT and PROFINET IO with IRT.

Both these transmission modes are optimized for cyclic IO communication within a network involving small amounts of data.

RT

PROFINET RT uses the option of prioritizing Ethernet telegrams (as described in the Ethernet standard). For more detailed information, see PROFINET IO with RT (Page 2116).

IRT

PROFINET IRT uses a time slot procedure (bandwidth reservation); i.e. 2 time slots occur. The IRT telegrams are transmitted in the first time slot; the standard Ethernet and RT telegrams in the second. By reserving the transmission bandwidth, the transmission of the IRT data is guaranteed for all load/overload situations. For all participating devices to know when the time slot begins, all the participating devices must be synchronized with PROFINET IRT.

In addition to the bandwidth reservation, a schedule for the cyclic telegrams is developed with consideration given to the topology. This makes it possible for the engineering system to determine the required bandwidth for each individual cable.

In addition to the synchronization of the transmission network with PROFINET IRT, the application can also be synchronized in the devices with IRT High Performance (isochronous application; e.g. position controller in SIMOTION or ServoSynchronousTask). This is an essential requirement for closing control loops across the network and isochronous switching of inputs and outputs in the network.

Note

Only PROFINET IRT High Performance is used for SIMOTION. Whenever PROFINET IRT is referred to in the rest of this document, this means IRT High Performance.

For more detailed information, see PROFINET IO with IRT (High Performance) (Page 2118).

Comparing RT and IRT

Table 4-223 The major differences between RT and IRT

Property	RT	IRT (High Performance)
Real-time class	Real-time class 1	Real-time class 3
Transfer mode	Prioritization of cyclic RT telegrams using the so-called VLAN tag.	Bandwidth reservation optimized by the engineering system on the basis of topology information
Determinism	No Send and receive time points of the cyclical RT data are not precise; they can be delayed by standard Ethernet telegrams.	Yes Transmission and receiving times for cyclic IRT data are precisely defined and guaranteed for all kinds of topologies.
Isochronous application	Not supported	Supported
Hardware support using special Ethernet controller	No	Special hardware necessary (e.g. SCALANCE X200 IRT)

Send clock and update time

Description

With PROFINET the send clock and update time are distinguished. The send clock is the basic cycle clock for cyclic communication. The update time indicates the cycle in which a device is supplied with data.

Send clock

This is the period between two successive intervals for IRT or RT communication. The send clock is the shortest possible transmit interval for exchanging data. The send clock therefore corresponds to the shortest possible update time. During this time, IRT data and non-IRT data (RT, TCP/IP) is transmitted. All devices within a sync domain work with the same send clock.

Update time

The update time can be configured separately for each IO device and determines the interval at which data is sent from the IO controller to the IO device (outputs) as well as from the IO device to the IO controller (inputs). The calculated/configured update times are always a multiple (2^n) of the send clock.

Relationship between the update time and send clock

The calculated update times are multiples (1, 2, 4, 8, ..., 512) of the send clock. The minimum possible update time thus depends on the minimum send clock for the IO controller that can be set and the efficiency of the IO controller and the IO device.

Adjustable send clocks and update times

Description

The table below describes the send clocks which can be set for SIMOTION devices with PROFINET IO, as well as the settable update times which are dependent on them and can be set for IRT and RT. Update times are obtained by multiplying the factor and the send clock. The adjustable send clocks are divided into two ranges: the "even" range and the "odd" range.

Note

The following versions generally relate to the use of the position control cycle clock with servo or IPO task, unless otherwise specified. When using the Servo_fast with Servo_fast or IPO_fast Task, other restrictions apply under certain circumstances. If Servo_fast and IPO_fast are used, then the PROFINET must be operated isochronously.

Table 4-224 Adjustable send clocks and update times when using servo or Servo_fast

Send clock		**Factors (update time = factor * send clock)**	
		RT	**IRT**
"Even" range	125 µs *Note 4)*	IO devices cannot be used with RT	1 *Note 2)*
	250, 500, 1,000 µs	1, 2, 4, 8, 16, 32, 64, 128, 256, 512	
	2,000 µs	1, 2, 4, 8, 16, 32, 64, 128, 256	
	4,000 µs	1, 2, 4, 8, 16, 32, 64, 128	
"Odd" range	375, 625, 750, 875, 1,125, 1,250 µs ... 3,875 µs (increment 125 µs)	Cannot be used in front of SIMOTION V4.4 IO devices with RT *Note 1*)	1
Note 1)	**Mixed operation RT / IRT with SIMOTION < V4.4** Send cycles from the "odd" range can be used only if there is no IO device in the IO systems involved in the sync domain. As soon as there are IO devices with RT in a sync domain, it is only possible to set send clocks from the "even" range.		

Send clock		Factors (update time = factor * send clock)	
		RT	IRT
Note 2)	**Settable factors and isochronous operation (isochronous application)** Some IO devices with IRT support the factors 2, 4, 8, and 16 in addition to factor 1. Where IO devices (e.g. ET200S IM151-3 PN HS, SINAMICS S120) are operated isochronously, it is usually only possible to set a factor of 1. In these cases, the mode for the update time must always be set to **Fixed factor** to ensure STEP 7 does not automatically adapt the update time. The update time than always matches the send clock.		
Note 3)	**Mixed operation RT / IRT as of SIMOTION V4.4** As of SIMOTION V4.4, send cycles from the "odd" range can be used only if there is no IO device with RT in the PROFINET IO systems involved in the sync domain. However, this mixed operation is only possible with SIMOTION D4x5-2 devices on the onboard PROFINET interface. The same factors are available as from the "even" range. The factors that can actually be set depends specifically on the set send clock. **Restriction of Shared Device with RT / IRT as of SIMOTION V4.4:** If a Shared Device is simultaneously used with PROFINET IO with RT and PROFINET IO with IRT, PROFINET IO with IRT can only be operated with send clocks from the "even" range.		
Note 4)	The send clock can only be used with D455-2 DP/PN on the onboard PROFINET interface together with Servo_fast as of SIMOTION V4.4. If this send clock is used, only the first port of the onboard PROFINET interface will be active, all other ports are deactivated and cannot be used.		

If there is no sync master configured in a PROFINET IO system (no PROFINET IRT), the send cycle clock for the respective PROFINET IO system can be set individually on the relevant IO controller. You can do this in the properties **<PROFINET Interface>** on the **PROFINET** tab under **Send cycle** or in the properties **PROFINET IO System** on the **Update time** tab. There is a default setting for the send clock of 1 ms. On the **IO cycle** tab, the down-scaling for the update time can be set via the mode **fixed factor** or **fixed update time** and the factor.

As soon as a sync master is configured in the PROFINET IO system, the send clock is defined under the sync domain properties. The IO controllers assigned to the sync domain take over this value. Update times can be set independently for each IO device.

Possible modes for setting the update time

- **Fixed factor**
  Fixed send clock down-scaling for the update time
- **Fixed update time**
  Update time is set
- **Automatic**
  STEP 7 automatically adjusts the down-scaling if the factor selected is too low

Note

It is recommended that you work with the **Fixed factor** setting.

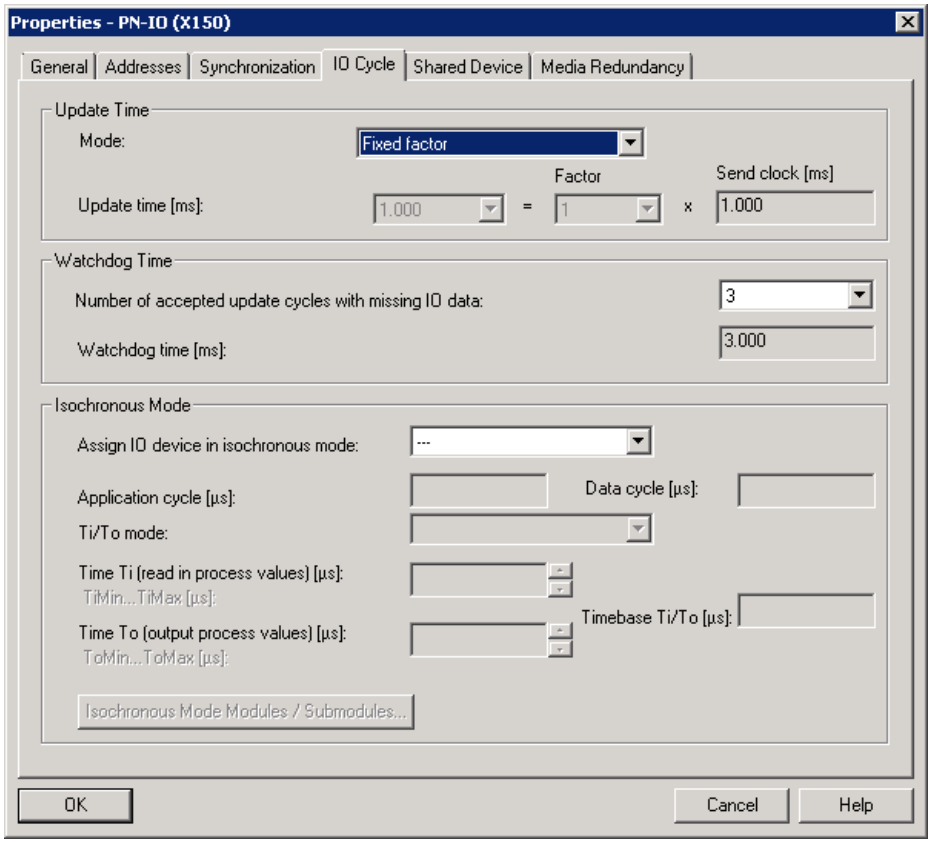

Figure 4-338 The influence of isochronous mode on setting the update time

PROFINET IO with RT

PROFINET IO with RT is the optimal solution for the integration of I/O systems without particular requirements in terms of performance and isochronous mode. This is a solution that uses standard Ethernet and commercially available industrial switches as infrastructure components. A special hardware support is not required.

Not isochronous

Although standard Ethernet and PROFINET IO with RT do not offer any synchronization mechanisms for devices, this does not mean that such arrangements are impossible. However, it does mean that isochronous data transmission is impossible, and there is no isochronous application for motion control as a result.

Data exchange

Communication via PROFINET IO with RT and IRT is based on the Ethernet frame and the MAC address. This means that cross-network communication via a router using RT and IRT is not possible. PROFINET IO message frames have priority over IT message frames in accordance with IEEE802.1Q. This ensures the availability of the real-time properties required in automation applications (e.g. for standard IOs).

Update time

The adjustable update time is in the range of 0.25 - 512 ms. The selected update time depends on the process requirements, the number of devices, and the amount of IO data. Given the improved performance offered by PROFINET compared to field buses, the bus cycle is generally no longer the variable which determines the system cycle.

Device replacement without removable data storage medium

Activate the "Support device replacement without removable data storage medium" checkbox if you want to use the module replacement (the devices connected to the IO controller) without the PG or removable data storage medium.

The IO device replacement is no longer assigned a device name from the removable data storage medium or the PG, but from the IO controller. The IO controller uses the configured topology and the neighboring relationships determined by the IO devices for this purpose.

Note

Device replacement without removable data storage medium

In order that the device replacement without removable data storage medium functions, the plant topology must be configured correctly. Use the topology editor for this purpose.

PROFINET IO with IRT - Overview

Overview

PROFINET IO with IRT satisfies communication requirements which go beyond the sending of standard signals. As far as IRT is concerned, the jitters which may still be encountered with RT during communication are significantly reduced by synchronizing the network.

A time-slot procedure is required at a level above that of the Ethernet network. One time slot is reserved for the IRT telegrams and another slot is reserved for the RT and IP-based telegrams, in which the standard Ethernet communication (NRT (optional)) also runs. This type of approach requires all devices involved in IRT communication to be synchronized.

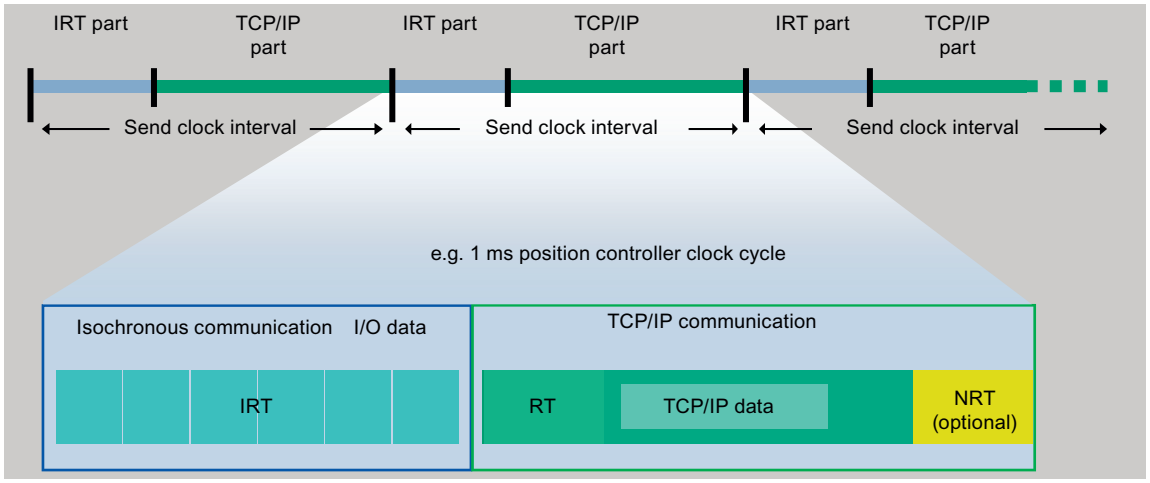

Figure 4-339 IRT Communication - Overview

See also IRT High Performance (Page 2118) with optimized bandwidth reservation and scheduled IRT communication.

For PROFINET IO with IRT, all IRT devices are synchronized on a shared sync master. See also Isochronous operation and isochronous mode with PROFINET (Page 2120).

PROFINET IO with IRT (High Performance)

The performance capability of motion control applications is significantly increased with PROFINET IO IRT (High Performance).

PROFINET is based on Ethernet technology, which is in turn based on point-to-point connections. Point-to-point connections support a significantly higher transmission rate when compared with arrangements based on parallel wiring. PROFINET uses 100 Mbps. Using this in conjunction with switching technology means that all connecting cables are decoupled from each other, enabling each cable to both transmit and receive at the same time.

Scheduling the telegram traffic for IRT High Performance enables data traffic to be optimized to a considerably higher degree, as only the bandwidth which is actually required is reserved.

IRT (High Performance) is particularly suitable for:

- The control and synchronization of axes via PROFINET IO
- A fast, isochronous I/O integration with short terminal-terminal times

Send clock

The send clocks that can be set are described in the table in Section Adjustable send clocks and update times (Page 2114).

The actual send clock that can be used depends on various factors:

- The process; communication should be no faster than required. This reduces the bus and CPU loads.
- The bus load (number of devices and the amount of IO data per device)

- The computing power available in the controller
- The supported send cycles on the PROFINET devices involved in a sync domain.

The supported send clocks can be found in the corresponding manuals of the respective SIMOTION controls.

Isochronous application

Isochronous data transmission and an application synchronized with the bus system satisfy the requirements associated with demanding motion control applications. This makes it possible to close control loops via the bus system and achieve minimum guaranteed response times (terminal-to-terminal time response). In addition, a high-performance and isochronous connection to the application with low load on the application CPU is ensured.

Unlike standard Ethernet and PROFINET IO with RT, transmission of telegrams for PROFINET IO with IRT High Performance is scheduled.

Time-scheduled data transmission

Scheduling is the specification of the communication paths and the exact transmission times for the data to be transferred. The bandwidth can be optimally utilized through communication scheduling and therefore the best possible performance achieved. This requires the network topology to be configured, with the engineering system automatically calculating the communication schedule from the configured topology (see also Topology (Page 2209)). The data relevant to PROFINET IO is transmitted by means of a download from HW Config to the IO controller. The highest determinism quality is achieved through the scheduling of the transmission times which is especially advantageous for an isochronous application connection.

Data exchange

PROFINET IO with IRT (high performance) only runs within a sync domain. These must not however be mixed in one IO system. In other words, a sync domain may consist of two or more IO systems which can all be synchronized with one another. Within the IO system, PROFINET IO with IRT (high performance) is then used.

Sync domain

A sync domain is a group of PROFINET devices synchronized to a common cycle clock. The sync slaves synchronize themselves with the cycle clock set by the sync master. The role of a sync master can assume a control system (IO controller) or a SCALANCE X200 IRT (IO device). A sync domain has just one sync master.

See also

Creating a sync domain (Page 2199)

Isochronous operation and isochronous mode with PROFINET

Description

PROFINET IO with IRT is based on Ethernet with a higher-level time-slot procedure. This arrangement requires all bus interfaces involved in communication to be synchronized. In the case of PROFINET IO with IRT High Performance, a sync master transfers a synchronization message frame to which all sync slaves synchronize themselves.

Sync master, slaves, and domain

The sync master and sync slave device roles are assigned during the configuration. An IO controller or SCALANCE 200 IRT switches can be assigned a sync master role.

A sync domain can comprise PROFINET devices with IRT High Performance. PROFINET devices with RT may also be located at the ends (spur lines), but not between two PROFINET IO devices with IRT (High Performance).

A line (network) may only comprise IRT High Performance, and these must always be connected to each other directly.

Compatibility

Communication between and through different sync domains via PROFINET IO with RT is possible.

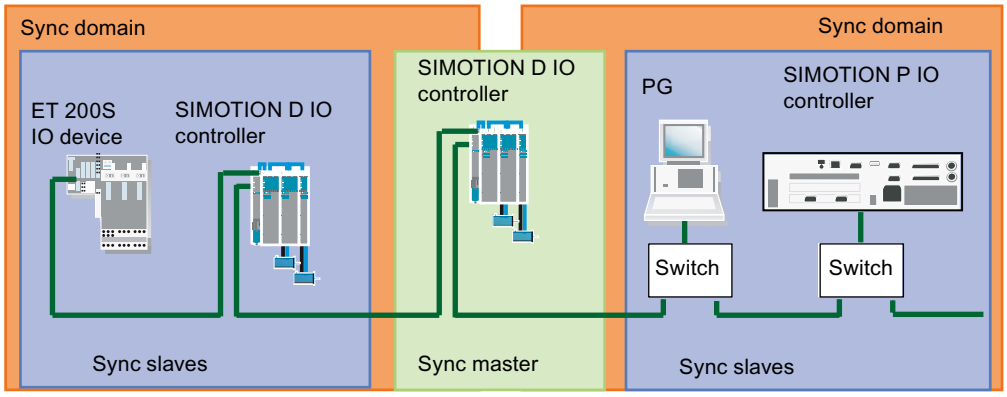

Figure 4-340 PROFINET isochronous mode

IRT-compatible switches, such as SCALANCE X204 IRT, are used in the structure. All devices involved in IRT communication are connected to each other directly. As the programming device in the center of the network is connected via a spur line, it does not interrupt the IRT path.

Isochronous applications with PROFINET (Page 2126)

Addressing of PROFINET IO devices

A globally unique MAC (Media Access Control) address is used for data exchange via Ethernet and forms part of the Ethernet telegram. The MAC address is linked to the hardware and cannot be modified.

Ethernet-based protocols such as HTTP (Web applications) or FTP (file transfer) use the IP protocol. Addressing is based on the IP address. This is a logical address, which can be assigned by the user.

PROFINET uses a device name (NameOfStation) to identify PROFINET devices, in addition to the two items of address information already known in connection with Ethernet. The device name is a string that fulfills the requirements of a DNS (Domain Name Service) name. This device name must be unique across the PROFINET network.

During the commissioning phase, each PROFINET device (identified via the MAC address) is assigned a device name once via the configuration tool and this is stored retentively in the PROFINET device (a process known as node initialization). A device is referenced in the configuration via the device name. If a device is replaced, e.g. because of a defect, the new device has another MAC address. If it is initialized with the same device name as the replaced device (e.g. by reconnecting a removable medium that stores the device name retentively), it can take over the function of the replaced device without any changes in the configuration.

Alternatively, the device can be initialized automatically by the controller on the basis of topology information. This is only possible if topology information (who is wired to whom) is stored in the engineering system. During ramp-up, the controller identifies the connected devices using the device names, before assigning the IP address defined in the engineering system to the device. The station can then be accessed via IP services. The IP address can be taken from a configured sequence of numbers or configured individually.

A PROFINET device has the following addresses by which it can be addressed:

- MAC address (part of the Ethernet telegram, stored on the device, and cannot be modified)
- IP address (IP-based communication such as engineering access, must be assigned to all devices)
- Device name (devices identified by the controller during ramp-up)

Assigning device names and IP addresses to IO devices (Page 2221)

Planning and topology for a PROFINET network

Planning guidance

Fundamental questions must be resolved before implementing the design of a PROFINET network. In this chapter, you will find broad guidelines to support you in defining requirements and creating planning documentation. Planning is an iterative process, i.e. some requirements influence each another and therefore necessitate changes in the overall plan.

Content of the planning documentation

Once the requirements have been specified and the planning process has come to an end, the following information should be available to you:

- System configuration
- Topology
- Selection of components
- Selection of transmission medium
- Connector selection
- Communication relationships
- Estimate of the data volumes to be transferred

Preliminary considerations and analysis during the planning stage

1. **Selecting the devices**
   Create a list of devices. The selection of devices is based, among other things, on the application class (conformance class), the time and communication requirements, the function, environmental influences, and the degree of protection.
2. **Position of the devices in the machine**
   The position of the devices in the machine has implications for the degree of protection, EMC, device dimensions and the cables used, e.g. whether fiber-optic cable should be used rather than copper cable. This in turn influences device selection.
3. **Defining the communication properties**
   The time requirements concerning the application (isochronous/cyclic) and communication via PROFINET must be defined, i.e. does communication take place in real-time (IRT/RT) or is it acyclic via TCP/IP or UDP/IP.

4. **Network planning (topology)**
   Specify the network topology (ring, star, line). Depending on the type of topology selected, the following must be taken into account: switches (with IRT capability), EMC, extent of network, WLAN (IRT not possible) and, if applicable, media redundancy MRP (possible with SIMOTION V4.3 and higher, and SINAMICS V4.5).
   - Set up your PROFINET in a point-to-point architecture where this is useful (for example, use a switch to branch off into a point-to-point topology downstream of a CPU).
   - In the case of PROFINET with IRT, a line structure with 64 IRT devices is permissible. The amount of data transmitted has certain implications. If longer message frame lengths are configured for each device, the possible number of devices per line may be reduced. However, this is detected early on during configuration with HW Config and signaled by means of an error message. The 64 IRT devices in the line are only applicable to PROFINET after V2.2.
   - Maintain a low interconnection depth for the switches. This will reduce the effect of a worst-case jitter scenario with RT communication.

Topology	
Star	If you connect communication nodes to a switch, you automatically create a star-shaped network topology. With this structure (unlike with other structures), if an individual PROFINET device fails, this does not automatically lead to the failure of the entire network. Only the failure of a switch causes the failure of devices downstream of the switch.
Tree	If you interconnect several star-shaped structures, you obtain a tree network topology.
Line	All the communication nodes are connected in series as a bus. If a switch fails, communication downstream of the failed switch is no longer possible. Devices with a 2-port switch must be used in order to set up a linear structure. Linear network structures require the least amount of cabling.
Ring	With V4.3 or higher, you can establish a ring topology for MRP or MRPD. For the ring topology you must define a redundancy manager and redundancy clients.

5. **Defining the communication relationships (logical assignment of partners)**
   Specify which communications partners are connected as well as the spatial and functional assignment of these partners.

6. **Defining the data volumes**
   Define the possible data volumes of the network nodes and those at the communication junctions.

   Note

   Communication within a PROFINET network should only be as fast as the technology of the system requires it to be and not as fast as technically possible.

7. **Defining the sending cycle and update time**
   The sending cycle is determined by the PROFINET device which has to be updated the most frequently. The update time is a multiple of the sending cycle and determines the PROFINET network load. The network load generated by PROFINET should always remain below 50% to allow reserve capacity for peak loads. Please note that the PROFINET network load increases in linear relation to the number of PROFINET devices and the sending cycle.

   Note

   Always configure the update times as required by the process, even if the bus system allows for a very large number of shorter update times. This reduces the PROFINET network load and the load on the PROFINET controller to what is strictly necessary.

8. **Checking the network load**
   In order to determine the network load, you must take into account the PROFINET network load as well as the network load generated by standard Ethernet devices. These can take the form of video cameras for monitoring the system or data servers for production data, for example. Ethernet devices with a low data volume such as engineering workstations or HMIs, for example, are normally non-critical. To prevent the PROFINET RT data stream from being compromised, you should, if necessary, adapt the network topology in cases where high network utilization by Ethernet nodes is anticipated. However, you also need to make sure you have sufficient bandwidth reserves for future expansion.

   Note

   Devices which exert a high IP load on the network should be located, where possible, in a separate area of the network. The diagnostics server and HMI server are examples of such devices.

9. **Connection to the company network**
   Various points must be considered if the automation system is to be connected to the company network. Normally, you should establish the connection via a router or a SCALANCE S with firewall to prevent unauthorized access. PROFINET IRT or RT communication via routers is not possible. You should only establish further connections (such as remote access or VPN, for example) in individual cases following consultation with the IT department.

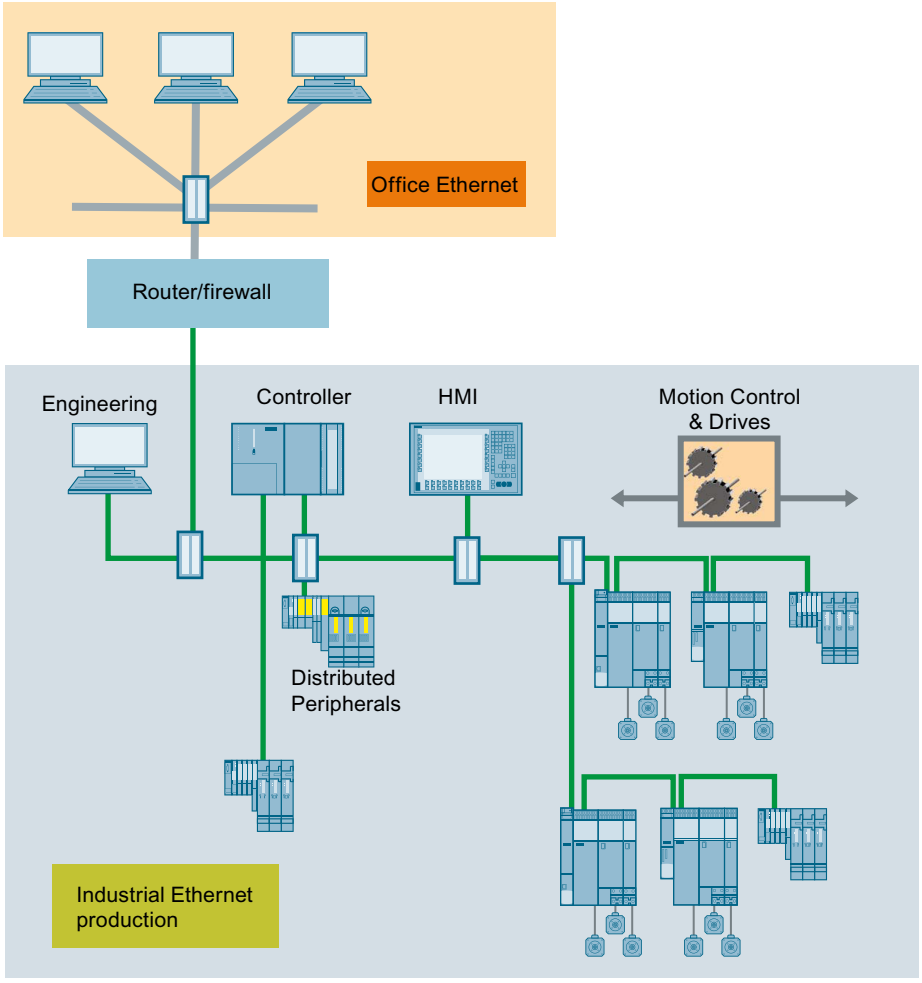

Figure 4-341 Optimized topology of a company network connection

Configuring the topology

Communication scheduling requires knowledge of the network topology. This includes information about interconnecting the individual devices to create a communication network.

Topology scheduling is only relevant for IRT High Performance. The topology editor that has been integrated in the hardware configuration enables user-friendly configuration of the network topology.

Isochronous applications with PROFINET

As with PROFIBUS, in the case of PROFINET IO with IRT High Performance the application can be synchronized with the transmission network's cycle clock. Distributed Motion Control applications and terminal-to-terminal response times of less than a millisecond require all PROFINET devices with IRT High Performance to be synchronized with a common time base.

Note

Isochronous mode for the application on the bus is only possible for PROFINET IO with IRT High Performance.

Configuration model for isochronous mode, V4.4 and higher

The configuration model for isochronous mode has changed as of V4.4. A selection must be made in the controller properties to specify whether isochronous IO devices are being operated. The isochronous task, the clock generator, must be selected. You can find a more detailed outline of the procedure for making settings in isochronous applications in the chapter titled Inserting and configuring the SINAMICS S120 (Page 2215)

Procedure

When configuring isochronous applications, proceed as follows in HW Config:

1. Set the synchronization role for the IO controller to **Sync Master**. For SIMOTION (controller) V4.2 or higher, the RT class is automatically set to **IRT** and **High Performance**.
   (Double-click in HW Config on the PN interface of the IO controller. You can set the **Synchronization role** in the **Synchronization** tab of the Properties window.)

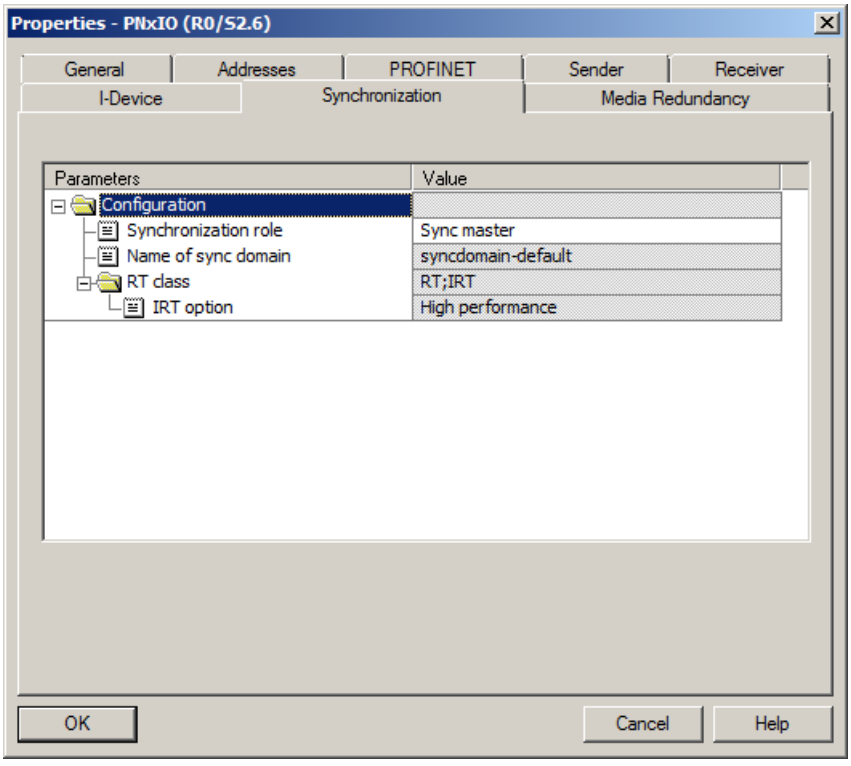

Figure 4-342 Setting the RT class

2. Set the synchronization role on the IO devices to **sync slave**. The RT class must be set to **IRT** and **High Performance**.
   (Double-click in HW Config on the PN interface of the IO devices. You can set the **Synchronization role** in the **Synchronization** tab of the Properties window.)

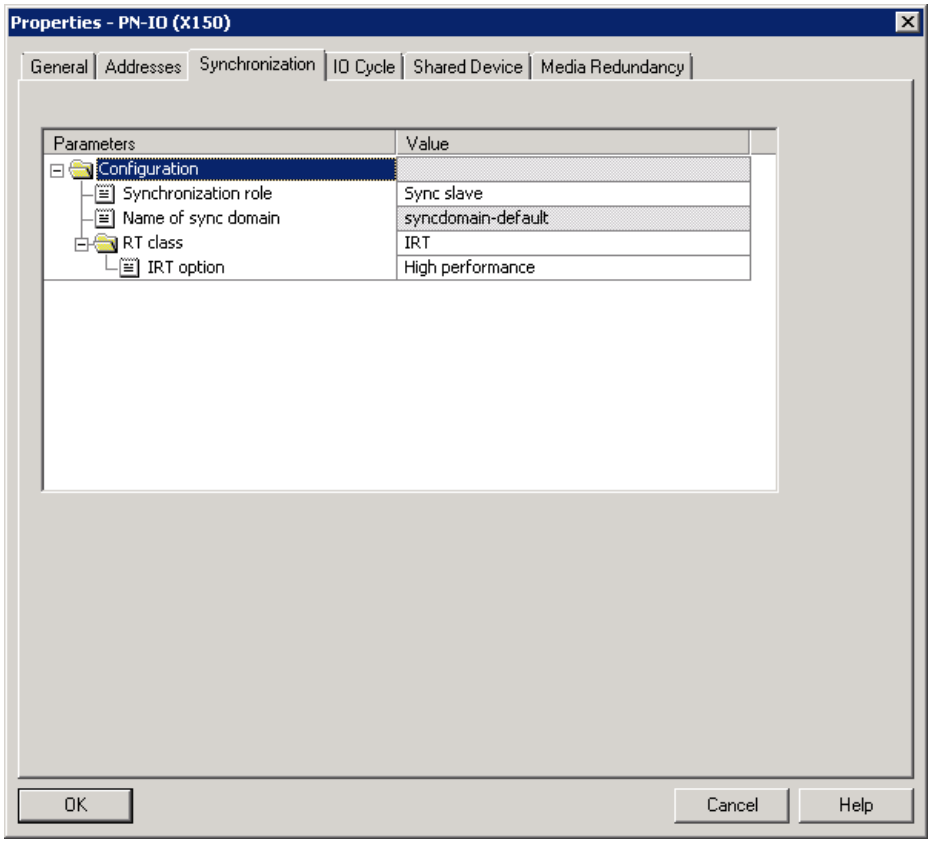

Figure 4-343 Setting IO device synchronization to sync slave and setting IRT High Performance.

3. Select the task (**Servo_fast** or **Servo**) in the **Isochronous tasks** tab in the controller properties. In general, **Servo** is used. The reference cycle clock is shown grayed out. The checkbox must be set for the following configurations:
   - Operation of isochronous IO devices (e.g. drives).
   - Configuration of exchange broadcast data. This is always isochronous.
   - Use of an iDevice with isochronous IO data.

   If two PN interfaces (e.g. X150 and X1400) of the controller are used with isochronous IO data, i.e. both checkboxes in the **Servo** field are activated, this is referred to as "coupled I/O" or "coupled IO systems". The two IO systems are then synchronized with one another.

Note

The checkbox must **not** be set if no isochronous IO data is configured. During compilation, inconsistent settings are displayed with an error message.

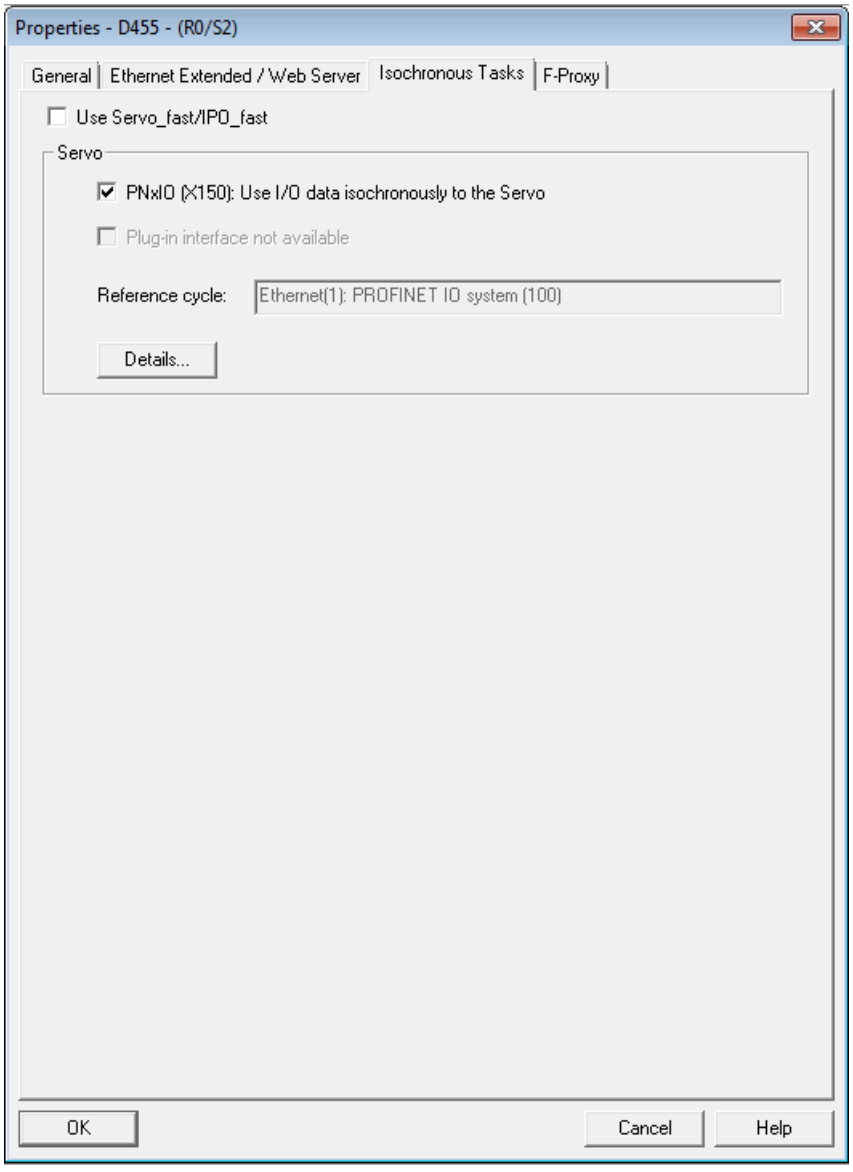

Figure 4-344 Isochronous IO devices are operated on the controller

Note

Servo_fast

If you activate Servo_fast, the other settings for Servo_fast are displayed in the dialog. You can then select **Details..** to enter further settings. If you have activated Servo_fast, you can also select Servo_fast as the reference cycle for the isochronous application (isochronous IO device).

The Servo_fast option is not available for all SIMOTION controllers and is not displayed for such controllers.

4. On the devices, set the **Update time** mode to **Fixed factor** and select the cycle clock (servo or Servo_fast) under **Assign IO device isochronously**. Here, you can select the cycle clock that was set under "Isochronous tasks" in the previous step. **Servo** is used in the example. (Double-click in HW Config on the PN interface of the IO devices. You can configure the settings in the **IO Cycle** tab of the Properties window.)

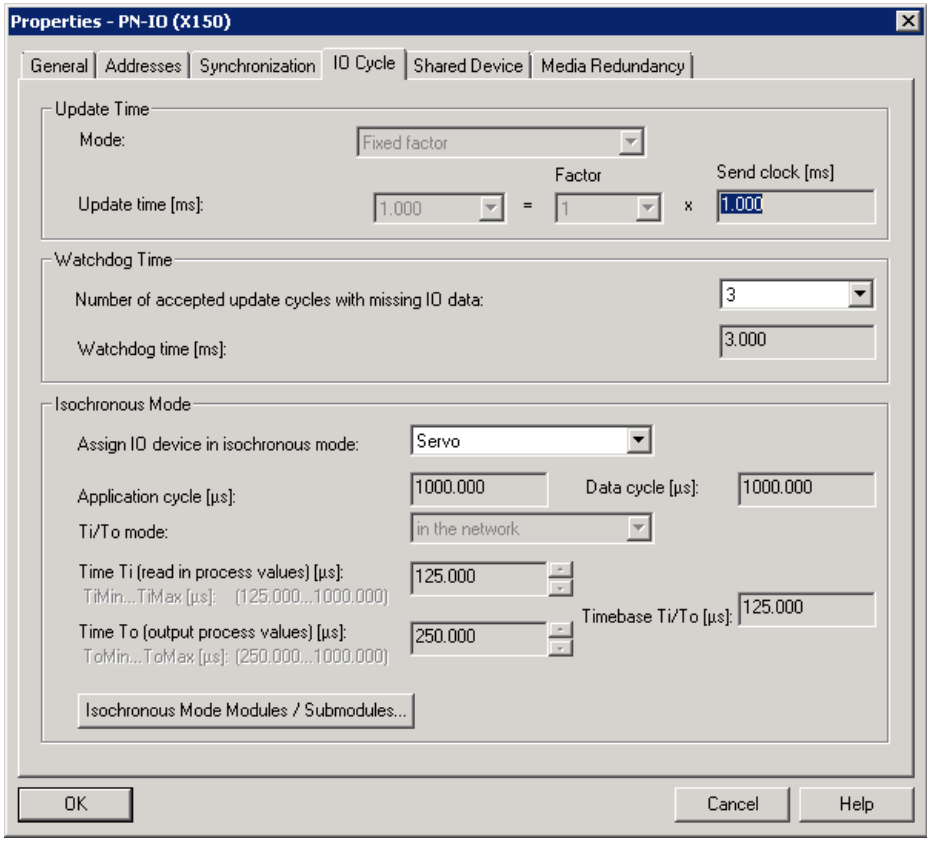

Figure 4-345 Assigning IO cycle parameters

Acyclic communication via PROFINET

Description

Similarly to PROFIBUS DP, it is also possible for PROFINET IO to operate acyclic communication (Base Mode Parameter Access). You will find a detailed description hereof under DP V1 communication (Page 2415).

Shared device

Shared device functionality

Large systems or systems spread out over a large area frequently make use of numerous IO controllers. It can, therefore, happen that sensors that are physically near one another must supply data to different IO controllers. Previously, this could be solved using multiple IO devices which were assigned to the different IO controllers. The shared device functionality makes it possible to divide up the submodules of an IO device between different IO controllers in order to save one or more interface modules.

Further application

Safety engineering is required in a system for certain system sections. Therefore, in addition to the standard CPU, an F-CPU is used which ensures that the critical system sections are shut down safely. With the shared device function, it is possible to assemble an IO device from F modules and standard modules and to assign the individual modules to either the F-CPU or the standard CPU accordingly.

The application with an F-CPU is described briefly in the PROFIsafe chapter (Page 2368).

Principle

Access to the submodules of the shared device is divided between the individual IO controllers. Each submodule of the shared device can be assigned exclusively to one IO controller. The individual submodules are assigned in HW Config.

iDevice

iDevice functionality

The PROFINET I device functionality is comparable with that of the I-slave for PROFIBUS, i.e. a SIMOTION CPU can accept the role of an IO device and thereby exchange data with a different IO controller.

Whereas with PROFIBUS an interface can be either a master or slave only, with PROFINET it is possible to be both an IO controller and IO device at the same time on a single PROFINET interface.

Shared iDevice (V4.4 or higher)

As of SIMOTION V4.4, an iDevice of the PN-IO interfaces can be operated with two higher-level controllers. This functionality is referred to as "shared iDevice" and is comparable with the shared device. A configuration example for a shared iDevice can be found in the chapter Shared iDevice and PROFIsafe (Page 2374).

PROFINET IO and I device (Page 2238)

4.5.5.2 Properties and functions of PROFINET IO with SIMOTION

Introduction

Requirement

To work with SIMOTION using PROFINET IO, you must have at least one PN interface available. This can either already be integrated within the controller or inserted via an (additional) option board.

Connection possibilities:

- SIMOTION D4x5 with Option Board CBE30
- SIMOTION D4x5-2 DP/PN
- SIMOTION D4x5-2 DP/PN with CBE30-2 (from V4.3)
- SIMOTION P350 PN or SIMOTION P320-4
- SIMOTION D410 PN/SIMOTION D410-2 DP/PN
- SIMOTION C240 PN

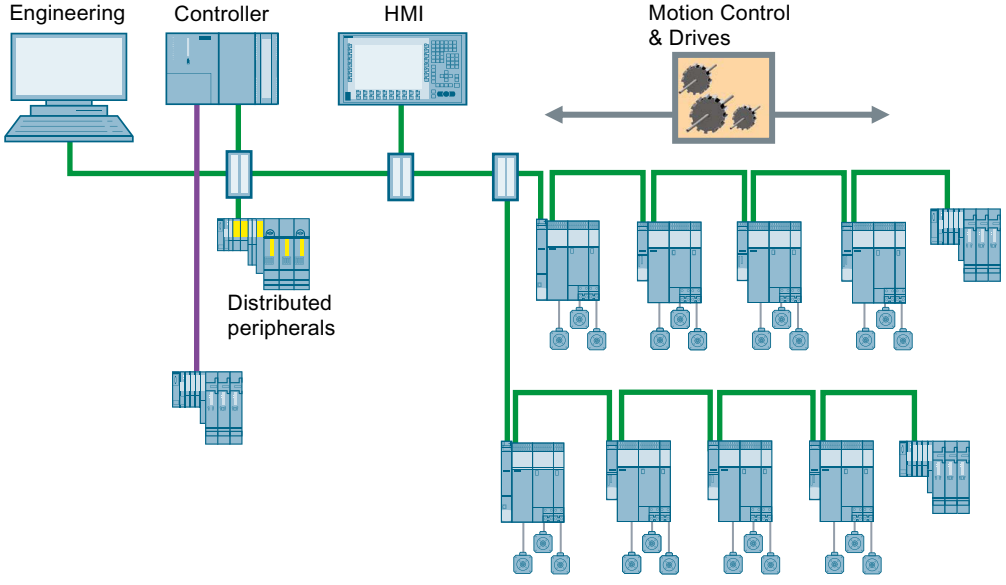

Figure 4-346 System topology with PROFINET

The SIMOTION controllers as PROFINET IO controllers support the simultaneous operation of:

- IRT High Performance - isochronous realtime Ethernet
  - Operation of IRT I/O (e.g. ET200S HS for IRT High Performance)
  - Operation of a SINAMICS S120 as an IRT IO device
  - Data exchange between IO controllers via IRT High Performance (e.g. distributed synchronous operation)
- RT - realtime Ethernet
  - Operation of RT - peripherals (e.g. ET 200S, ET 200pro)
  - ASi link via IE/AS interface link PN IO for the PROFINET IO gateway to AS interface
  - SINAMICS as RT IO device
- TCP/IP, UDP, HTTP, ... standard Ethernet services

Note

With a mixed operation of PROFINET IRT and PROFINET RT, one must be aware that the IRT IO devices have to be connected together directly; i.e. no IO devices which PROFINET IRT does not support are allowed to be connected between two IRT devices The IO device that is not IRT-compatible must be located at the end of the IRT line so that IRT operation is not interrupted.

Note

With SIMOTION SCOUT, it is possible to access a maximum of 10 nodes ONLINE simultaneously. If you have installed SIMATIC NET, it is possible to establish more connections. The exact number is based on the available resources of the network adapter.

Note

For a PROFINET IO device that is connected to a SIMOTION controller, max. submodule sizes are defined. This limit is especially important if a SIMATIC controller is configured as an I-device for a SIMOTION controller . Therefore, please note the possible quantity structures (Page 2162).

PROFINET V2.2/V2.3

SIMOTION SCOUT supports PROFINET V2.2 and is compatible with V2.3. Older versions are no longer supported as standard in the hardware and must be changed over.

When inserting SIMOTION controllers and/or SINAMICS drives, only PROFINET V2.2 versions are inserted in SIMOTION SCOUT. If you want to configure older versions, you need to explicitly add the hardware as PROFINET V2.1 in HW Config.

PROFINET V2.3 for SIMOTION D455-2 V4.4

SIMOTION D455-2 DP/PN supports PROFINET V2.3. In particular, the following functions are available:

- Fast Send Clock
  Isochronous mode with send clock ≥ 125 µs
- Dynamic Frame Packing (DFP)
  With DFP, the cyclic data of multiple IO devices is summarized in one Ethernet frame.

PROFINET V2.3 Performance Upgrade (Page 2175)

Cycles and cycle support

Cycle clock scaling with PROFINET IO on SIMOTION devices

Description (PROFINET IO with IRT High Performance)

An isochronous application (e.g. position controller) on an IO controller must be synchronized with the send clock for IRT High Performance. It can, however, be synchronized with a multiple of the send clock of the data. This multiple is designated as CACF (Controller Application Cycle Factor). Cycle clock scaling is configured in SCOUT with the execution system via **Expert > Set system cycle clocks** in the shortcut menu or via **Set system cycle clocks** from the shortcut menu of the highlighted SIMOTION controller in the project navigator.

Example: The data on the network is transferred with a send clock time of 1 ms. However, the servo should run with 2 msec. Therefore, the application cycle must be 2. For this purpose, set the ratio 2 at **Set system cycle clocks** for the servo.

The CACF is set on the IO device, see e.g. Inserting and configuring the SINAMICS S120 (Page 2215).

V4.2 and higher, two servo cycle clocks (servo, Servo_fast)

With V4.2 and higher, Servo_fast is introduced as a second position control cycle clock for fast applications. The second servo cycle clock enables you to operate two bus systems in different application cycle clocks (PROFINET and PROFIBUS). An assigned servo cycle clock and IPO cycle clock are available for each of the two application cycle clocks. This enables you to divide your application into a slow section (servo and IPO) and a fast section (Servo_fast and IPO_fast). If a Servo_fast is configured, it is linked to the send clock of PROFINET IRT at a ratio of 1:1. The servo cycle clock must be set as a multiple of Servo_fast (at least 2x Servo_fast). In this case, the CACF continues to be the factor between the send clock/Servo_fast and servo.

The functions described below mainly relate to configurations without the option of a second servo (Servo_fast).

Note

You can find a detailed description of the Servo_fast option in the *SIMOTION SCOUT Basic Functions Manual*, Chapter 6.

With V4.3 or higher, two PROFINET IO interfaces with different cycle clocks (SIMOTION D4x5-2 DP/PN with CBE30-2)

With V4.3 or higher, you can operate two PROFINET IO interfaces with different cycle clocks. With V4.2, it was only possible to operate one interface with PROFINET IO and one with PROFIBUS DP in different cycles (see above).

For the rules that apply when using Servo_fast, see Two PROFINET IO interfaces (Page 2144).

Description

Scaling to the send clock with SIMOTION controllers is possible in the case of PROFINET with IRT High Performance under the following conditions:

- The SINAMICS Integrated of a SIMOTION D and an isochronous DP master interface always run in accordance with the servo cycle clock.
- For a SIMOTION P350/C240, the isochronous DP master interface always runs simultaneously with the servo cycle clock.
- For drives (e.g. S120) which are connected via SINAMICS Integrated or as an external drive unit, the servo cycle clock must **always** be counted in the first send clock. This means that down-scaling is possible, although the position controller must be counted in a send clock.

The following general conditions apply to cycle clocks and cycle clock scalings for a SIMOTION controller

- The servo cycle clock/Servo_fast cycle clock is only synchronous with the send clock if the following conditions apply:
  - At least one IO device is operated isochronously.
  - At least one I-device is operated isochronously.
  - One controller-controller communication is configured.

Combinations of cycle clocks and cycle clock sources for PROFIBUS and PROFINET IO

- Servo can be scaled in integral multiples (1, 2, ...n) of the send clock.
- If a Servo_fast is configured, then the CACF = 1 for Servo_fast and Servo is also fixed and cannot be changed (not configurable).
- Cycle clocks for SINAMICS Integrated and isochronous DP master interfaces must run simultaneously with the servo cycle clock.

Cycle clock scaling for IO accesses

Description of PROFINET IRT data transmission

The following must be observed for cycle clock scaling (PROFINET and PROFIBUS):

- PROFINET IO IRT data is always read at the beginning of the servo cycle clock and written at the end of the servo cycle clock.
- PROFINET IO RT data is read at the beginning of the IPO or IPO2 cycle clock and written at the end of the IPO cycle clock.
- At the end of a IPOSynchronousTask, the process image is output with the next possible servo (Data Out) (= response-time-optimized). If the position control cycle clock is down-scaled to the IPO cycle clock (position control < IPO), this can lead to the data being output one or more position control cycle clocks earlier or later within an IPO cycle clock, if the I/O accesses are performed via the IPOSynchronousTask. This is the case if the runtime for the IPO cycle clock is not constant and, as a result, data is transmitted earlier or later on the bus with a faster position control cycle clock.
- At the end of the position control execution level, the process image of the ServoSynchronousTask is output with the next possible bus cycle clock (= response-time-optimized).
- If the PROFINET cycle clock is down-scaled to the position control cycle clock (PROFINET <= servo), the data is always output in the first PROFINET cycle clock.
- For PROFIBUS, the data is always output with the first bus clock cycle, since the servo priority class must always be finished with the first bus clock cycle. In case of a different runtime of the servo priority class in the individual cycles, the terminal-terminal time may vary as a result.

If an always constant response time is to be achieved instead of a response-time-optimized behavior, the following must be set:

- For PROFIBUS:
  - A reduction ratio servo: IPO = 1 : 1 so that the I/O accesses from the IPOSynchronousTask are always implemented in isochronous mode.
  - Comment: IO accesses from the ServoSynchronousTask are always isochronous for PROFIBUS
- For PROFINET:
  - A reduction ratio bus clock cycle: Servo: IPO = 1 : 1 : 1 so that the I/O accesses from the IPOSynchronousTask are always implemented in isochronous mode
  - A reduction ratio bus clock cycle: servo = 1 : 1 so that the I/O accesses from the ServoSynchronousTask are always implemented in isochronous mode

Note

With I/O access, cycle clock down-scaling can result in an offset (fixed dead time) for the IPO of a send cycle clock.

Bus cycle clocks that can be adjusted for cycle clock scaling to SIMOTION devices

Overview of the possible bus cycles

	PROFIBUS[2)]	PROFINET IRT High Performance	PROFINET IRT High Performance	Servo Servo_fast
	Minimum	Minimum	Maximum	Minimum
SINAMICS S120 CU310-2 PN	1.0 ms	0.25 ms	4.0 ms	0.25 ms
SINAMICS S120 CU320-2 PN	1.0 ms	0.25 ms	4.0 ms	0.25 ms
SINAMICS S110 CU305 PN	1.0 ms	1.0 ms	4.0 ms	1.0 ms
SINAMICS S120 CU320-2 DP with CBE20	1.0 ms	0.25 ms	4.0 ms	0.25 ms
SINAMICS S120 CU320-2 PN with CBE20	1.0 ms	0.25 ms	4.0 ms	0.25 ms

D445/D445-1	1.0 ms	0.5 ms	4.0 ms	0.5 ms
D445-2 DP/PN	1.0 ms	0.25 ms	4.0 ms	0.25 ms[1)]
D455-2 DP/PN	1.0 ms	0.125 ms	4.0 ms	0.125 ms [1)]
P350-3	1.0 ms	0.25 ms	4.0 ms	0.25 ms
P320-3	-	0.25 ms	4.0 ms	0.25 ms
P320-4 PN	-	0.25 ms	4.0 ms	0.25 ms
P320-4 DP/PN	1.0 ms	0.25 ms	4.0 ms	0.25 ms
ET200S High Speed	-	0.25 ms	4.0 ms	0.25 ms
ET200SP High Speed	-	0.125 ms	4.0 ms	0.125 ms

1) Explanation:

- 0.5 ms in conjunction with SINAMICS S120 (incl. SINAMICS Integrated/CX32-2)
- 0.25 ms in conjunction with SERVO_fast and IPO_fast (D455-2 DP/PN: 0.125 ms)

2) Explanation:

- The specifications apply to "external" PROFIBUS interfaces and not to PROFIBUS Integrated for SIMOTION D. PROFIBUS Integrated for SIMOTION D: minimum 0.5 ms

3) Explanation:

- 1 ms when using the TO axis and the integrated drive control

Cycle scaling with PROFINET IO

As of V4.3, it is possible to down-scale the PROFIBUS cycle to the position control cycle. Down-scaling is only permitted if PROFINET with IRT has not been configured. It is also possible to down-scale the PROFINET send cycle to the PROFIBUS cycle. For example, PROFINET send cycle = 0.5 ms and PROFIBUS cycle = position control cycle = 1 ms.

The PROFIBUS cycle can be operated relative to the PROFINET send cycle at a ratio of 1:1 to 16:1. The table below shows the possible ratio settings for the system cycles based on the DP cycle of the SINAMICS_Integrated or PROFINET send cycle.

Table 4-225 Ratios of the system cycles (when one servo is used)

Cycle name	Adjustable factors	Reference cycle
PROFIBUS DP bus cycle	1, 2, 3, 4, 6, 8, 10, 12, 14, 16	PROFINET IO send cycle
Servo	As of V4.3: 1, 2, 3, 4, 8[1)] V4.2: 1	PROFIBUS DP bus cycle
IPO	1, 2, 3, 4, 5, 6	Servo
IPO_2	2, 3, 4, 5, ..., 64	IPO

1) Always "1" if PROFINET with IRT has been configured

Table 4-226 Ratios of system cycles (two servos)

Cycle name	Adjustable factors	Reference cycle
Servo_fast	1	Send cycle of the onboard PROFINET IO interface (X150)
IPO_fast	1, 2, 4	Servo_fast
Servo	1	PROFIBUS DP bus cycle and send cycle of the optional second PROFINET IO interface (CBE30-2)
IPO	1, 2, 4	Servo
IPO_2	2, 3, 4, 5, ... 64	IPO

Ratios of the system cycles when using Servo_fast and Servo

- PROFIBUS DP bus cycle = N x send cycle of the onboard PROFINET IO interface X150
  N = 2, 4, 8, 16, 32, 64 (N = 2 only for send cycles > 250 µs)
  (for < V4.4: N = 2, 4, 8, 16 for all send cycles)
- Send cycle of an optional second PROFINET IO interface (CBE30-2) = PROFIBUS DP bus cycle
- IPO ≥ IPO_fast

Cycles with SINAMICS_Integrated (<500 µs)

Introduction

As of SIMOTION SCOUT/SIMOTION SCOUT TIA V4.5, SINAMICS_Integrated for drives on SIMOTION D4x5-2 can use bus cycles of less than 500 µs. It supports cycles between 250 µs and 375 µs. SINAMICS_Integrated remains assigned to the servo cycle. Servo_fast is not supported.

Supplementary conditions

The supplementary conditions for deployment of cycles < 500 µs are listed below.

PROFIBUS and Servo_fast

- External PROFIBUS interfaces cannot be used isochronously
- Since a factor of 4 between Servo and Servo_fast is prescribed for cycles of ≤ 250 µs, Servo_fast with 125 µs cannot be used in parallel to SINAMICS_Integrated with 250 µs.
- Because the Servo cycle must be a multiple of the Servo_fast cycle, Servo_fast cannot be used:
  - Servo_fast > 250 µs: N = 2, 4, 8, 16, 32, ...
  - Servo_fast ≤ 250 µs: N = 4, 8, 16, 32, ...

Number of axes

With regard to utilization, SINAMICS_Integrated is subject to the same restrictions as those applicable to an external SINAMICS drive.

If the SINAMICS_Integrated is operated with a DP Integrated cycle clock of 250 µs or 375 µs, the resultant utilization is higher in comparison to a cycle clock of ≥ 500 µs. Depending on the utilization situation (e.g. by deployed ALMs, CXs, TMs), this can result in a reduction in the number of axes (e.g. from six to five servo drives).

The higher utilization can result in a reduction of the quantity structure for vector and V/f-controlled drives.

CBE30

CBE30 supports a minimum send cycle of 500 µs. The SINAMICS_Integrated can only be operated with 250 µs if no isochronous communication is configured for the CBE30. If the CBE30 operates isochronously (assignment to the Servo), the Servo has a minimum cycle of 500 µs.

Task system and time response

Overview of SIMOTION task system and system cycle clocks

Overview

If IRT data is transmitted via the bus using PROFINET IO, the cycle clock execution times fall between reading and writing the data (e.g. axis data), depending on which task in the execution system the application is executed in. You can find examples of applications in different tasks (execution levels) in the chapters that follow.

BackgroundTask, MotionTask, and IPOSynchronousTask

MotionTask/BackgroundTask

The data is transmitted via the bus using PROFINET IO with IRT High Performance, and accepted by the communication interface at the start of the position control cycle clock. The logic signals are generally evaluated in a MotionTask or BackgroundTask. Here, a distinction is made as to which machine function is activated; for example, "position-controlled traversing of axis". The traversing profile required is counted in the next IPO cycle clock. Based on the position setpoints determined here, the speed setpoints for controlling the axis are calculated in the next position control cycle clock. These are transmitted to the drive in the next cycle, via PROFINET IO with IRT High Performance.

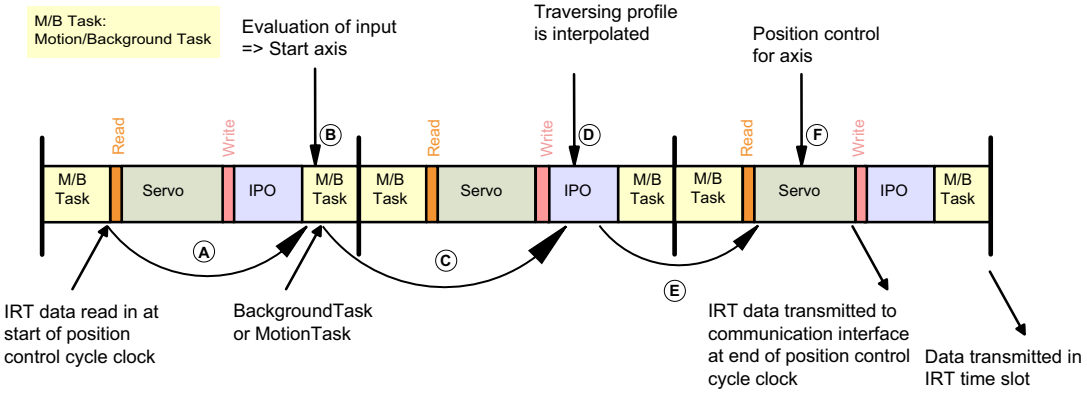

Figure 4-347 Logic evaluation for an axis in the BackgroundTask or MotionTask

Constraints

The option of a second servo clock is not activated, i.e. no Servo_fast and IPO_fast. The bus cycle clock, servo clock and IPO cycle clock are set to a 1:1:1 ratio. Other ratios may result in longer response times. With a 1:1:2 ratio, the IPO execution may be extended to two position control cycle clocks, which can lead to the response time increasing by one position control cycle clock.

Additionally, the BackgroundTask may be processed over several position control cycle clocks, meaning that the system is unable to make sure the data is evaluated in the first position control cycle clock. This may also lead to an increased response time.

Assigning the variables to a process image has an impact on the response time as well. The process images are made available to other tasks or to the communication interface at the end of the respective task, rather than after the variables are updated.

IPOSynchronousTask

In order to optimize the time response and enable synchronous triggering of actions (e.g. starting axes simultaneously), in the IPOSynchronousTask it is possible to process the part of the application that triggers axis commands. If this option is used, it is counted before the IPO. In this way, the axis command can be issued before the IPO is executed, and the resulting position setpoint then calculated in the IPO. Based on this, the speed setpoint for the drive is calculated in the next position control cycle clock. Once the position control cycle clock has finished, the data is passed on to the communication interface and transmitted in the next PROFINET IRT send clock. Unlike processing in a MotionTask/BackgroundTask, where the response time equals the maximum BackgroundTask runtime + one IPO cycle clock + one position control cycle clock, in this case you can be assured that the response time will be one IPO cycle clock + one position control cycle clock until new data is output.

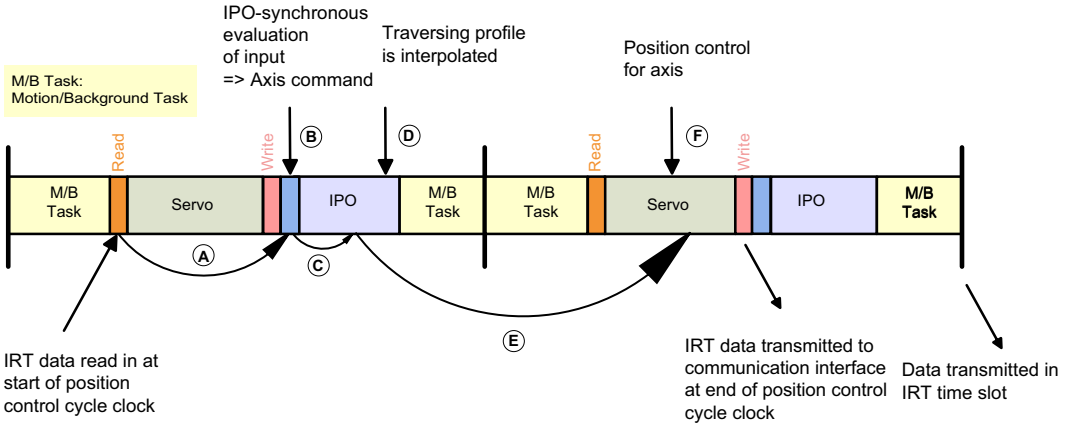

Figure 4-348 Logic evaluation for an axis in the IPOSynchronousTask

ServoSynchronousTask

ServoSynchronousTask

It is possible to optimize the time response even further and reduce the response time to one servo cycle clock. This option can be used for high-speed actual-value synchronous operations, e.g. flying knife/shear. Within this context, the part of the application that triggers axis commands for selected axes is processed in the ServoSynchronousTask. Additionally, the IPO part of the system for the axes involved is counted before the position controller in the servo task. In this way, the speed setpoints may be transmitted as soon as the next IRT time slot.

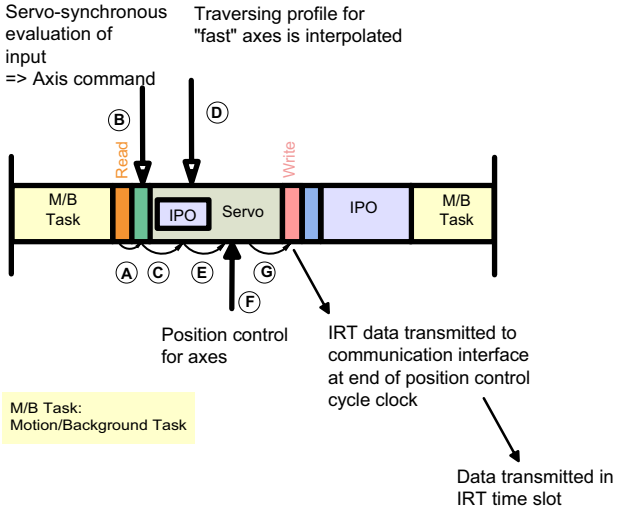

Figure 4-349 Logic evaluation for an axis in the ServoSynchronousTask

Boundary conditions

Using this function increases the CPU load and, therefore, the position control cycle clock; for this reason it should only be used when necessary.

Activating

This feature must be activated explicitly for the axes in SIMOTION SCOUT as part of axis configuration.

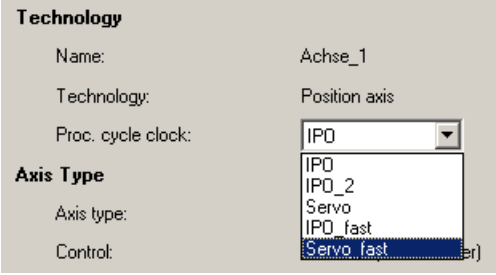

Figure 4-350 Determining the processing cycle clock for the axis

If the option of a second servo cycle clock is configured, then the axis can also be assigned to the Servo_fast processing cycle clock if this is linked to the faster bus.

Position control

The position controller responds within one position control cycle clock. The data is read out from the communication interface at the start of the position control cycle clock. The position controller is counted in the position control cycle clock. The new speed setpoints are copied to the communication interface at the end of the position control cycle clock and, therefore, transmitted in the next IRT time slot.

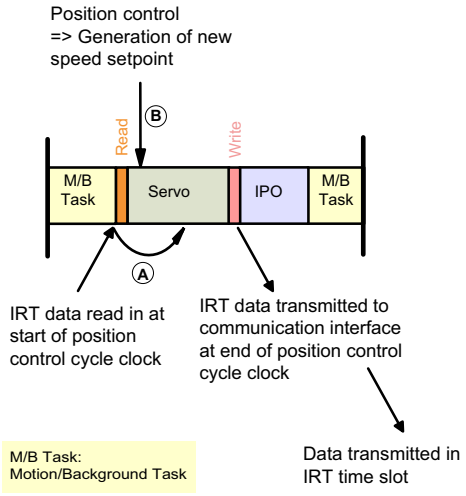

Figure 4-351 Position control time response with ServoSynchronousTask

Fast I/O processing in the ServoSynchronousTask

Fast I/O processing in the ServoSynchronousTask

The evaluation of quick I/Os – e.g. ET200S High Speed – is performed in the ServoSynchronousTask. resulting in a system response time of one cycle. Due to the terminal-terminal response, there is a delay of Ti + servo cycle clock + To.

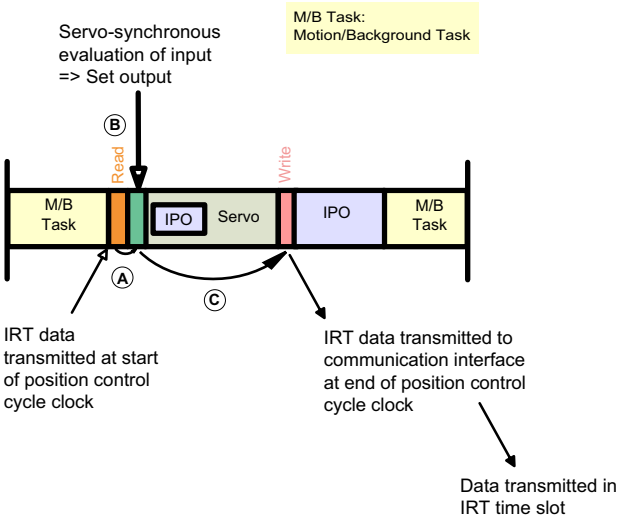

Figure 4-352 Fast IOs in the ServoSynchronousTask

If the **second servo clock** is configured, the fast I/O processing can also be performed in the Servo_fast clock (i.e. in the ServoFastSynchronousTask). This requires the I/O peripherals to be configured on the faster bus.

SIMOTION controllers with two PROFINET IO interfaces

Two PROFINET IO interfaces

SIMOTION controllers with two PROFINET IO interfaces

With the SIMOTION D4x5-2 DP/PN controllers, optionally a second PROFINET IO interface is available in addition to the onboard PROFINET interface (X150) with the Ethernet communication board (CBE30-2, X1400).

The CBE30-2 can only be operated in D4x5-2 DP/PN control units. It is impossible to use it in D4x5-2 DP control units.

Application description

A detailed application description explaining how to operate two different PROFINET networks on one SIMOTION controller at the same time is available to download in the Service and Support Portal.

Basic rules for using two PN IO interfaces

Introduction

The following rules must be considered in use of two **isochronous** PROFINET interfaces. The most important basic rules for the PN interfaces and the use of Servo_fast are sorted thematically there.

Definition of isochronous PN interfaces

A PN interface is isochronous (i.e. assigned to servo or Servo_fast) if the following conditions apply.

- The PN interface is the IO controller and one of the IO devices is isochronous.
- The I-device is configured isochronously.
- Controller-controller data exchange broadcast is configured.

Note

IO controller and I-device cannot simultaneously be configured isochronously (IRT) on a PN interface. One PN interface can be configured as the IRT controller and the second PN interface as the IRT I-device.

If a PN interface is configured as IRT and does not meet the conditions for isochronous operation, it will work **asynchronously** with respect to the Servo or Servo_fast clocks and therefore also asynchronously with respect to the second isochronous PN interface.

General rules when using the onboard PN interface (X150) and CBE30-2 PN interface (X1400)

- A higher-level, isochronous controller must always be connected via the CBE30-2 PN interface. This applies both to controller-controller data exchange broadcast communication and to I-device communication with a higher-level controller.
- Lower-level isochronous drives or IO devices should be connected via the onboard PN interface.
- Both PN interfaces can be configured as a PROFINET IO I-device and/or as an IO controller.
- If a PN interface is used as an IRT I-device, it cannot be configured as a redundant sync master. Only the sync slave and sync master roles are possible.

Constraints on Sync master and Sync slave

- The CBE30-2 PN interface can be configured as the sync master, sync slave, or redundant sync master.
- The onboard PN interface can only be configured as the sync master.
- In the Sync domain of the onboard PN interface, there must be no redundant sync master if the CBE30-2 is configured as a Sync slave or IRT I-device.

Failsafe I/Os for using two PN interfaces

An F-CPU can only be connected to one of the two PN interfaces, because fail-safe I/O transfer areas can only be configured either on the I-device on the onboard PN interface **or** on the CBE30-2 PN interface (I-device F proxy).

The PROFIsafe telegrams are routed to the following drives:

- Drives on the SINAMICS Integrated and CX32-2
- Drives on the external PROFIBUS
- Drives on the onboard PROFINET interface (X150 interface)
- Drives on the CBE30-2 (X1400 interface)
  The maximum quantity structure for PROFIsafe on PROFINET is therefore not increased by using a second PROFINET interface.

Use of Servo_fast

For the use of Servo_fast, the following rules apply.

- If Servo_fast is not used, either one or both PN interfaces can be assigned to the servo.
- If Servo_fast is used, the onboard PN interface is assigned to Servo_fast and the CBE30-2 PN interface can be assigned to the servo.

Constraints on the use of Servo_fast

- Only the onboard PN interface can be assigned to Servo_fast.
- If Servo_fast is used, only one CACF=MACF=1 (Controller Application Cycle Factor=Master Application Cycle Factor) is permitted Servo and Servo_fast, i.e. the servo clock is taken over from the set send clock in HW Config and does not have to be set especially.
  The following applies:
  - Servo clock = send clock CBE30-2 PN interface X1400
  - Servo_fast cycle clock = send clock onboard PN interface X150
- The onboard PN interface can only be operated as the sync master (not sync slave or redundant sync master).
  This means that **no** controller-controller data exchange broadcast can be configured between the two SIMOTION controllers if the onboard PN interfaces of both SIMOTION controllers are assigned to Servo_fast.
- The onboard PN interface can be an IRT IO controller but not an IRT I-device if assigned to Servo_fast.
- If the Servo_fast is used, it is essential that isochronous IO devices are assigned to it.

Constraints on the clock ratio and cycle time of servo/Servo_fast

- Rules for the cycle clock ratio **servo = N * Servo_fast**
  - Servo_fast > 250 µsec: N = 2, 4, 8, 16, 32, ...
  - Servo_fast <= 250 µsec: N = 4, 8, 16, 32, ...(For 32: Servo_fast = 125 µs, Servo = 4000 µs)
- The minimum send clock for Servo_fast depends on the SIMOTION device (see also "Adjustable cycle clocks")
  - D455-2 DP/PN: 125 µs
  - Other: 250 µs
- The maximum send clock for the servo depends on the source of the IO data.
  - PROFINET is the source of the IO data: 4 ms
  - SINAMICS_Integrated or PROFIBUS is the source of the IO data: 8 ms

Applications for devices with two PROFINET IO interfaces

Applications for two PN IO interfaces

Possible applications

The PROFINET interface of a CBE30-2 can be used, for example, for the following applications:

- The second PROFINET interface is used
  - to increase the maximum number of connectable IO devices
  - to increase the available I/O address space
- IO devices are to be operated with different send cycle clocks and assigned different isochronous tasks (Servo and Servo_fast).
- IO devices should have an independent IP address range or NameOfStation. Devices with identical device configuration at the local interface can thus be connected to each other independently via the other interface in the plant network (e.g. higher-level network as the plant network; local network for machine module; identical machine modules; participants in the "local network" can be addressed independently of nodes in the "plant network").
- I-device and IO controller are to be operated isochronously at the same time.
  If one PROFINET interface is operated simultaneously as an I-device and IO controller, either only the I-device or the IO controller can be operated isosynchronously (i.e. with IRT). With two PROFINET interfaces, it is possible to operate a PROFINET IO controller and an I-device isosynchronously on a D4x5-2 DP/PN at the same time.

Application examples

There are, for example, the following applications for two PROFINET IO interfaces:

1. Increase the number of devices on PROFINET from 64 to 128, see Application 1 - increase in the maximum possible number of IO devices on PROFINET (Page 2149).
2. Fast and slow clock cycle for data to isochronous devices, see Application 2 - fast I/O processing and slower electrical drives on one module (Page 2150).
3. Distributed synchronous operation independent of isochronous devices, see Application case 3 - distributed synchronism over multiple devices and independent local systems (Page 2151).
4. The same project for the machine modules
5. Machine modules are individualized by assigning the IP address and NameOfStation on site, see Application 4 – Modular Machine: Independent IP address and NameOfStation for the iDevice and IO controller (Page 2152).
6. Two independent I-devices, see Application 5 - iDevice on both interfaces (Page 2154).

Application 1 - increase in the maximum possible number of IO devices on PROFINET

Description

The following functions are illustrated in the topology:

- Increased number of possible devices on SIMOTION D4x5 2 DP/PN by 2 subnets from 64 to up to 128.
- IRT and RT in each subnet

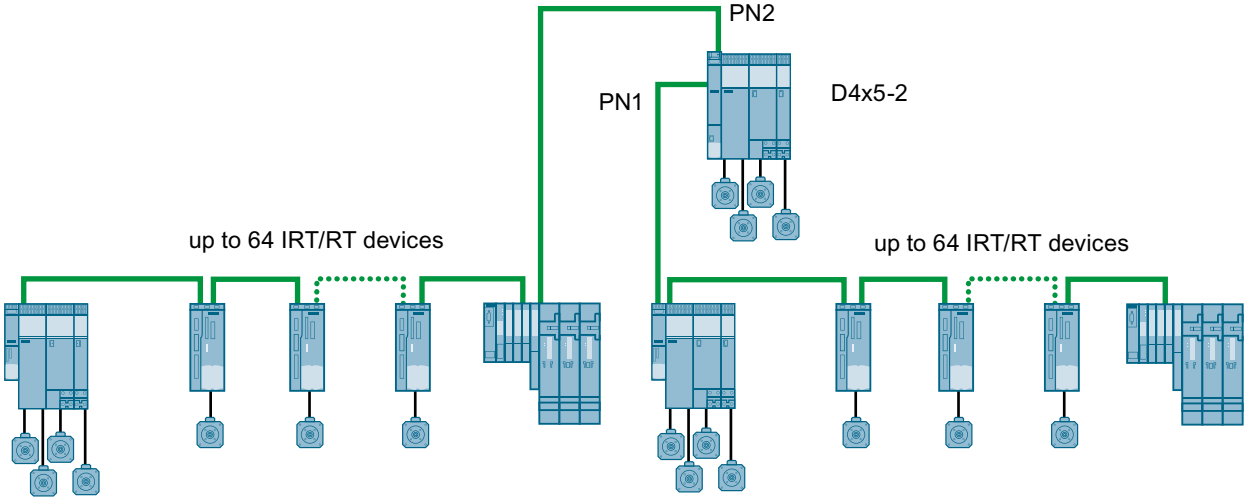

Figure 4-353 Application 1 for two PROFINET IO interfaces

PN1	Integrated PROFINET interface
PN2	CBE30-2

See also

Applications for two PN IO interfaces (Page 2148)

Application 2 - fast I/O processing and slower electrical drives on one module

Description

The following functions are illustrated in the topology:

- Fast I/O application and slower drive functions in one controller.
- Control of slower SINAMICS drives via PN2 (e.g. servo clock of 1 ms).
- Fast I/O processing (e.g. ET200S High Speed) via PN1 (e.g. Servo_fast clock of 250 µs).

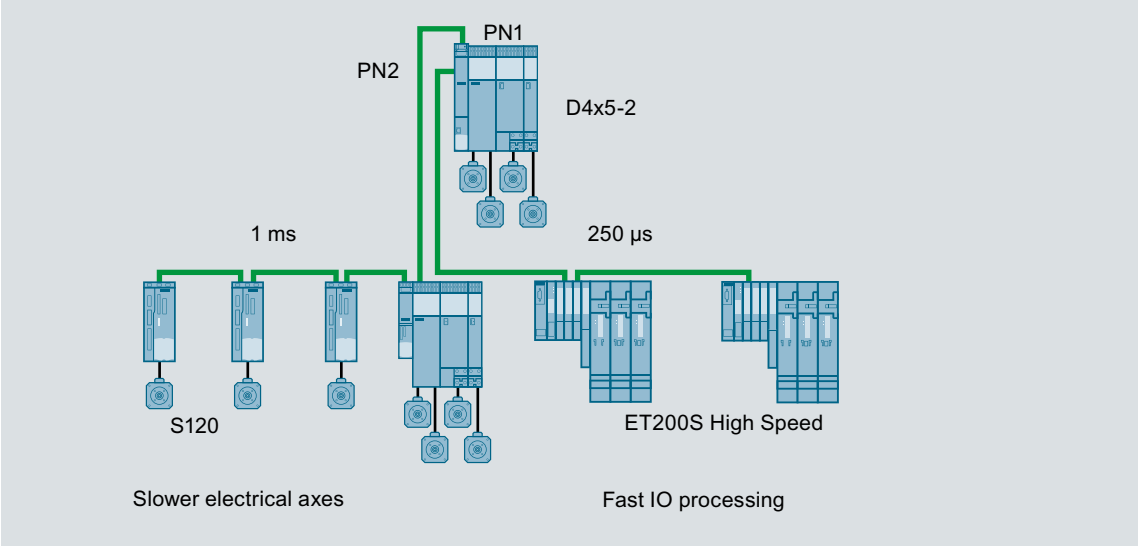

Figure 4-354 Application 2 for two PROFINET IO interfaces

PN1	Integrated PROFINET interface
PN2	CBE30-2

See also

Applications for two PN IO interfaces (Page 2148)

Application case 3 - distributed synchronism over multiple devices and independent local systems

Description:

The following functions are illustrated in the topology:

- Distributed synchronous operation via controller-controller communication between the SIMOTION controllers of different machine modules in subnet 1.
- Local I/O on each SIMOTION controller of a machine module in separate subnet independent of subnet 1.
  - Independent adjustable communication parameters (send clock, IRT, IP address, NameOfStation, etc.), adapted to the technical requirements.
  - Addresses can be set identically to the other modules, thus facilitating simpler establishment of modular machine concepts
- Use of Servo and Servo_fast

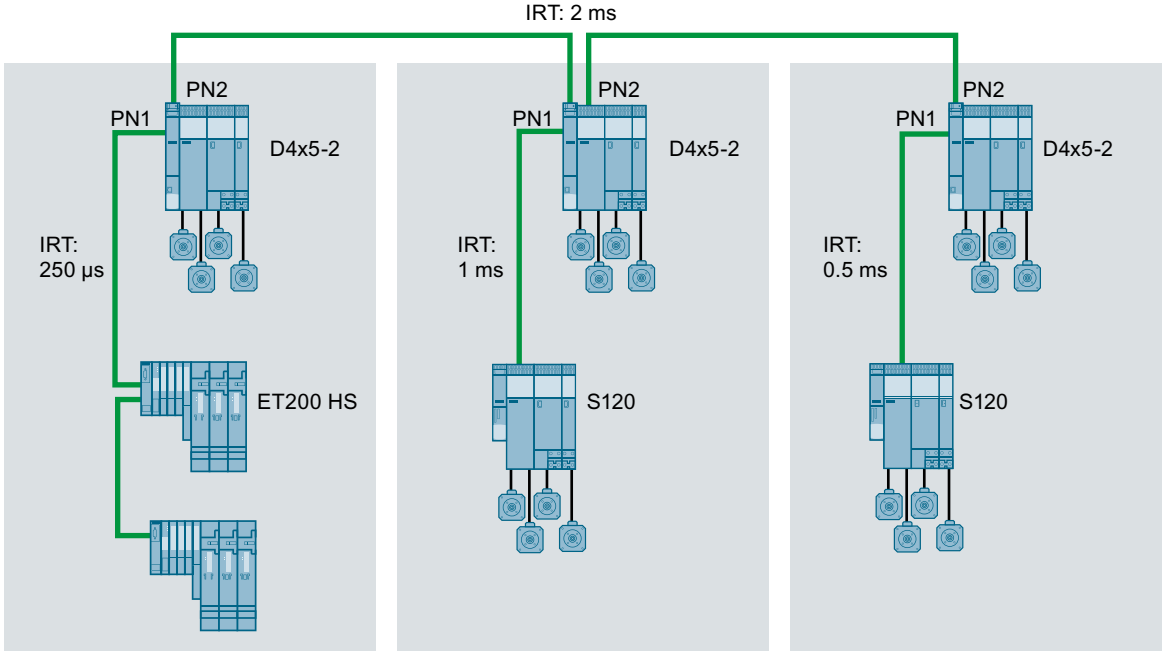

Figure 4-355 Application 3 for two PROFINET IO interfaces

PN1	Integrated PROFINET interface
PN2	CBE30-2

See also

Applications for two PN IO interfaces (Page 2148)

Application 4 – Modular Machine: Independent IP address and NameOfStation for the iDevice and IO controller

Description

The following functions are illustrated in the topology:

- 2 PN interfaces in the SIMOTION controllers disconnect the subnet of the base machine from the machine modules.
- IP address and NameOfStation of the interface of PN2 can be granted independently of IP address and NameOfStation of the interface of PN1.

  Note

  The IP addresses of the two PN interfaces must be in different IP subnets.

- IP addresses and NameOfStation of the PN interfaces that are operated as an IO controller can be identical in the different machine modules.
- In the base machine project the SIMOTION controllers are added as I devices via a GSD file (I device substitute).

- CBE30-2 as IRT I device and onboard PN interface as IRT IO controller.
- Distributed synchronous operation between the base machine controller and the IRT I devices.
  - Isochronous coupling of the subnets, if PN axes
  - IRT communication on iDevice and controller interface

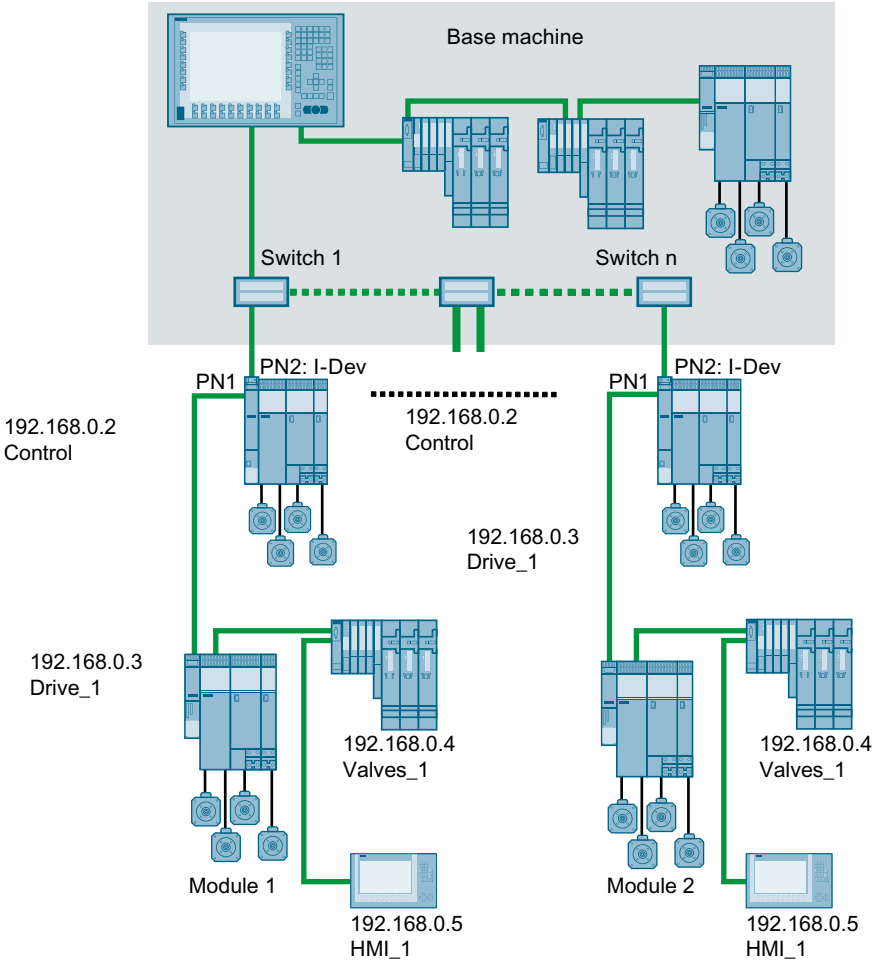

Figure 4-356 Application 4 for two PROFINET IO interfaces

PN1	Integrated PROFINET interface
PN2	CBE30-2

See also

Applications for two PN IO interfaces (Page 2148)

Application 5 - iDevice on both interfaces

Description

The following functions are illustrated in the topology:

- Distributed synchronous operation between higher-level controller and lower-level SIMOTION controllers via CBE30-2 as an IRT I device
- RT communication between additional higher-level controllers and lower-level SIMOTION controllers via onboard PN interfaces as an RT I device (e.g. for PROFIsafe, diagnostics, process value recording). IRT communication is not possible here.

Applications for two PN IO interfaces (Page 2148)

"Controlled" sync master

"Controlled" sync master

The "controlled" sync master synchronizes the PROFINET IRT cycle of the two PROFINET IO interfaces with the bus cycle of Servo/Servo_fast of the higher-level controller. The property "Controlled Sync Master" does not have to be explicitly configured. In the engineering, set "Sync Master" for this. The property "Controlled Sync Master" is automatically activated at the integrated PN interface if isochronous data has been configured on both PN interfaces, i.e. the send cycle clocks of both interfaces are synchronized to servo or Servo_fast.

A "controlled" sync master cannot be used together with a redundant sync master in a sync domain.

Application-specific synchronization is necessary analogously to PROFIBUS if the synchronization is lost and the system must be restarted.

Synchronization example with two PROFINET interfaces (IRT i device and IRT IO controller)

The following illustration shows the synchronization if the CBE30-2 is configured as an IRT I device for a higher-level controller and the onboard PN interface is configured as an IRT IO controller for the lower-level local peripherals.

Requirements for synchronization:

- CBE30-2 (X1400): Sync slave (synchronizes with the higher-level IO controller).
- Onboard PN interface (X150): "Controlled" sync master synchronizes the lower-level local peripherals.
- You can achieve application-specific synchronization with the _synchronizeDPInterfaces function, for example. See also *Clock generation and synchronization in PROFINET IO* in the Function Manual *Basic Functions for Modular Machines*.

  Note

  The application-specific synchronization can also be achieved in the StartupTask using the system function _enableDpInterfaceSynchronization.

- An example configuration can be found at Example configuration for "controlled" sync master (Page 2158).

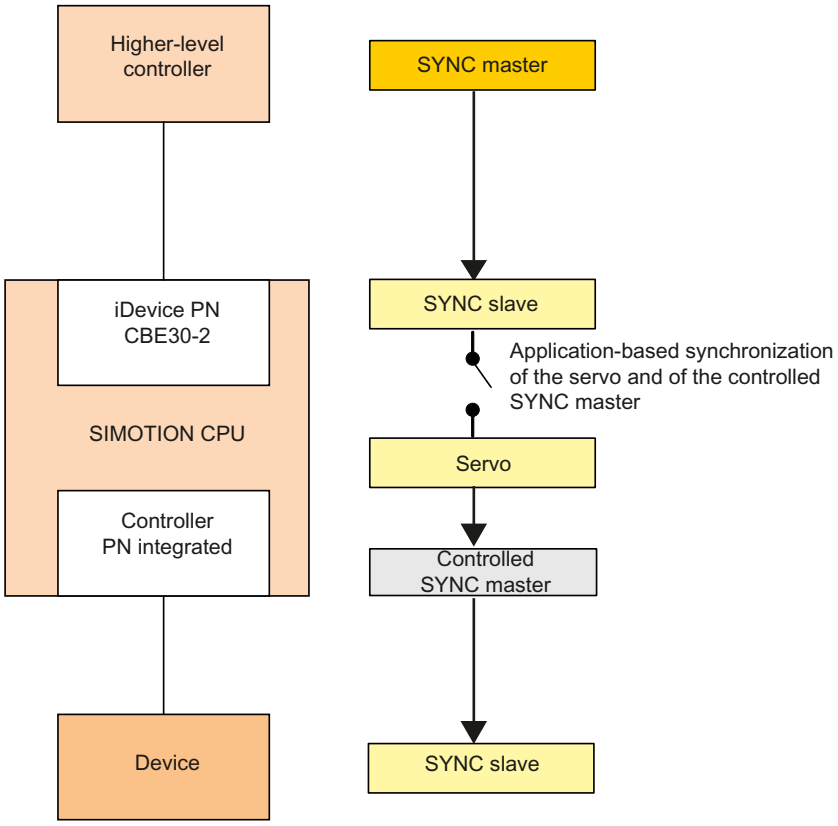

Figure 4-358 "Controlled" sync master

Synchronization example with two PROFINET interfaces (IRT IO controller on both interfaces)

The following illustration shows the synchronization if the CBE30-2 is configured as an IRT IO controller for direct controller-controller communication and the onboard PN interface is configured as an IRT IO controller for the lower-level local peripherals.

Requirements for synchronization:

- Onboard PN interface (X150): "Controlled" sync master synchronizes the lower-level local peripherals.
- CBE30-2 (X1400): Sync master (synchronizes the IO controller configured as a sync slave which is involved in direct data exchange) or sync slave (synchronizes with the IO controller configured as a sync master which is involved in direct data exchange).
- You can achieve application-specific synchronization with the _synchronizeDPInterfaces function, for example. See also *Clock generation and synchronization in PROFINET IO* in the Function Manual *Basic Functions for Modular Machines*.

Note

The application-specific synchronization can also be achieved in the StartupTask using the system function _enableDpInterfaceSynchronization.

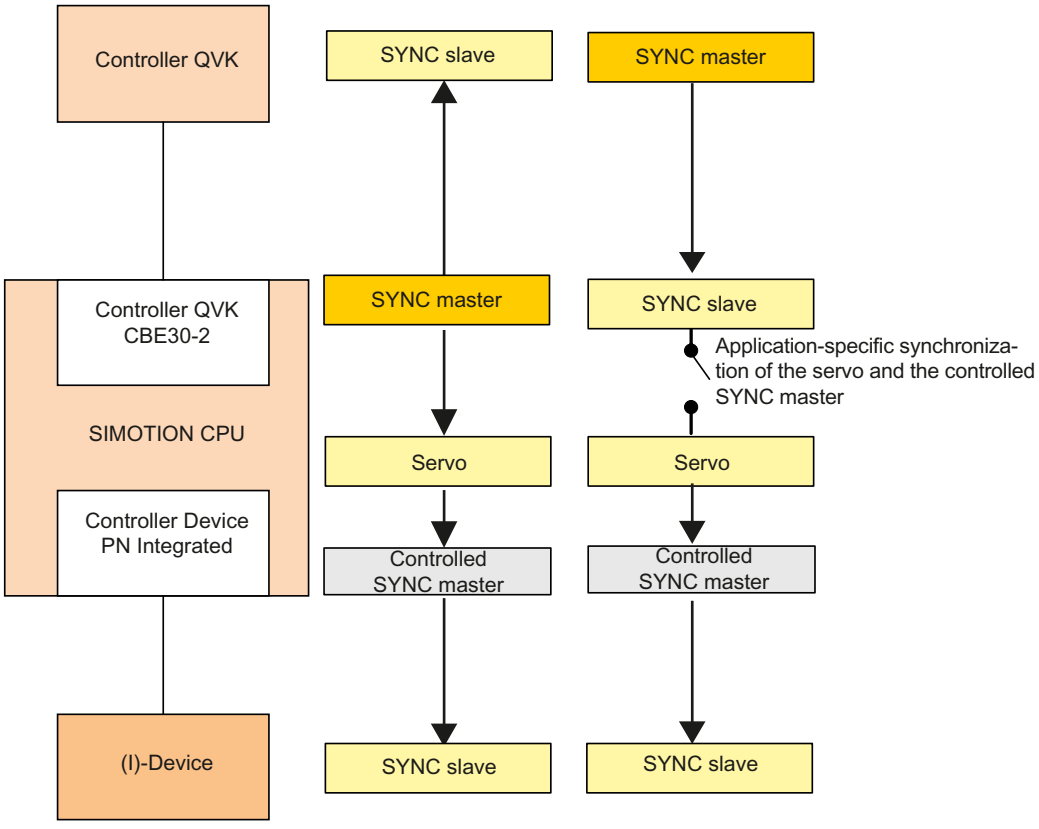

Figure 4-359 Controller direct data exchange with "controlled" sync master

Example configuration for "controlled" sync master

Distributed synchronous operation via two PROFINET interfaces

The example shows which application requires the use of two PROFINET interfaces for SIMOTION controllers. The PROFINET network "1" is configured as the MRPD ring for the distributed synchronous operation. The SIMOTION controller which has been configured as a sync master specifies the bus cycle clock as well as the servo and IPO cycle clock. The two other SIMOTION controllers are integrated into the MRPD ring as sync slaves via the CBE30-2 and synchronize with the sync master. Through their onboard PROFINET interface, they each set up their own PROFINET network and transmit the bus cycle clock as a "controlled" sync master to the lower-level local periphery (SINAMICS drives).

See also "Controlled" sync master (Page 2155) and Two PROFINET IO interfaces (Page 2144).

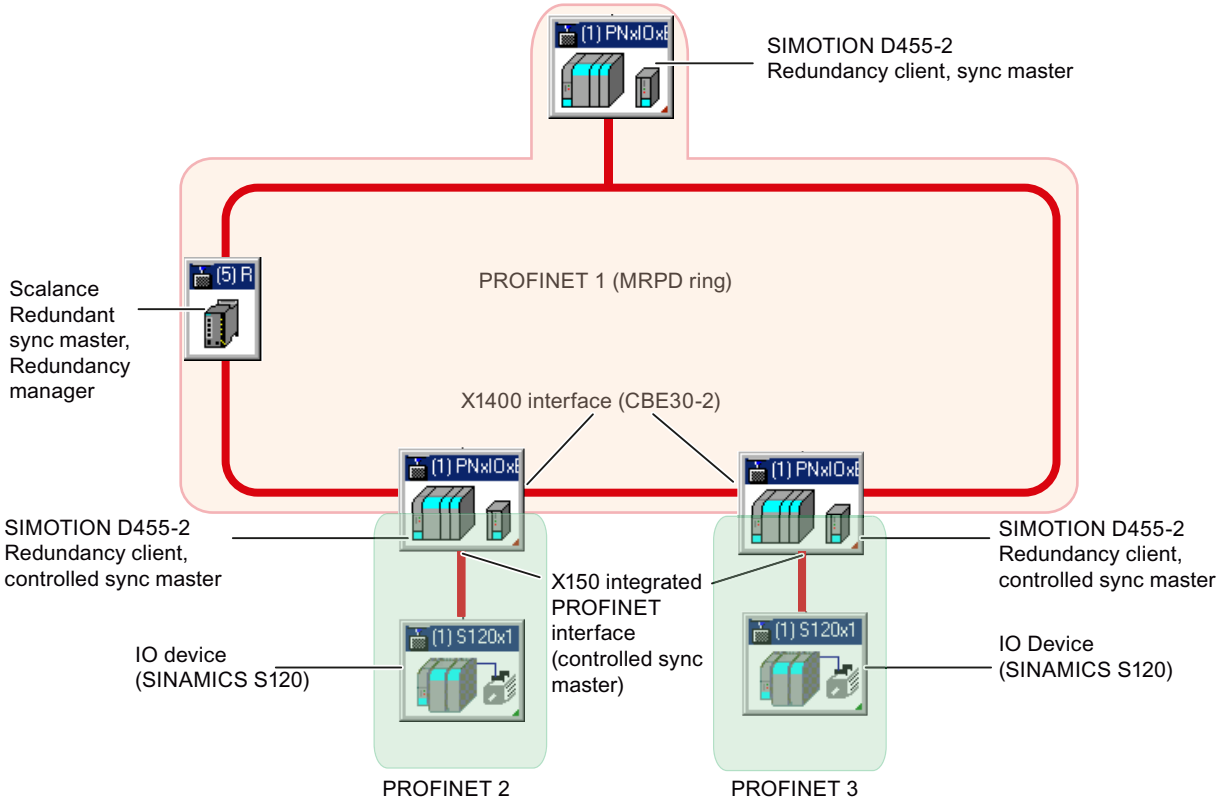

Figure 4-360 Example configuration for controlled sync master

If several sync domains are operated on a physical Ethernet, you should ensure that:

- either all sync domains have different names
- or configure this explicitly as the end of the sync domain at the ports that form the end of the sync domain.
  To do this click on the port that is to be the end of the sync domain and select **Properties** from the context menu. Choose the **Options** tab from the properties dialog box that appears. Activate the option **End of sync domain** and confirm with **OK**.

Relationship between sync domain and PROFINET IO systems

Introduction

The devices of several PROFINET IO systems can be synchronized by a single sync master, provided they are connected to the same Ethernet subnet and belong to a sync domain. Conversely, a PROFINET IO system may only belong to a single sync domain.

Devices with two PROFINET interfaces

The two PROFINET interfaces must belong to different sync domains. Synchronization of the two sync domains then takes place via a "controlled" sync master, see also "Controlled" sync master (Page 2155).

To find out how to create a second sync domain or change the name of an existing sync domain, go to Creating a sync domain (Page 2199).

Redundant sync master

Description

There are machines/plants that consist of two submachines / plant units. For such machines/ plants (complete systems), it may be that both submachines / plant units (subsystems) must be able to be operated synchronously, alone (separated) and in the complete system. This requires that a sync master is defined/configured on each subsystem. Only one sync master is permitted in the complete system. Consequently, a sync master is configured on one subsystem and a redundant sync master is configured on the other subsystem.

If the complete system is operated combined, either the sync master or the redundant sync master handles the synchronization of the complete system (depending on the switch-on sequence; for simultaneous switch-on, the sync master).

Applications

- Complete system (machine) with two subsystems (submachines)
  If it is necessary that a machine/plant consists of two subsystems and the complete system, as well as the two subsystems, must be operated synchronously independently of one another. See also Media redundancy for SIMOTION (Page 2166).
  Examples for the use of subsystems that are operated separately:
  - Part commissioning of the complete system.
  - Failure of the sync master and the first subsystem is permitted, but the second subsystem must continue to run on its own.
  - Shutdown of a subsystem by the user because it is not required for a process or is being serviced.
- Redundant sync master in the case of MRPD
  A redundant sync master is also possible in the case of a ring topology with media redundancy, see also Sample configurations for MRPD rings (Page 2171) and Information on PROFINET with MRPD (Page 2170). For this, an additional SCALANCE switch must be configured in the ring as a redundant sync master.

Special tandem machine application

An application example is a tandem configuration of a printing machine. For this special application, note the FAQ in the Service & Support portal (https://support.industry.siemens.com/cs/ww/en/view/109480700).

Limitations of use

- There can physically be up to a maximum of two additional modules between two sync masters.
- If the transmission link between the sync master and redundant sync master fails, leaving two subnets with one sync master each, both subnets remain synchronized with the remaining sync master in each case. This results in two independent synchronized subnets that drift apart due, among other things, to the temperature drift of the quartzes.
- Once the transmission link has been reestablished, the redundant sync master cannot synchronize with the sync master. The redundant sync master must be switched off and on again (power OFF/ON) before the synchronization can take place.
- If the plant section with the sync master fails as the result of a fault or shutdown, the other plant section with the redundant sync master will continue operating independently. The sync slaves assigned to the sync master will lose their synchronization and cease to operate.
- When both PN-IO interfaces operate isochronously, no redundant sync master is permitted in the sync domain for PN-IO.

Configuring the redundant sync master

1. Add a second SIMOTION module or a SCALANCE switch (if MRPD) and configure the PROFINET communication in accordance with your requirements.
2. Right-click on the PROFINET interface to open the **Properties - <PROFINET interface> -- (R0/S2.6)** dialog.
3. Select the **Sync master (redundant)** entry below **Synchronization role** on the **Synchronization** tab.

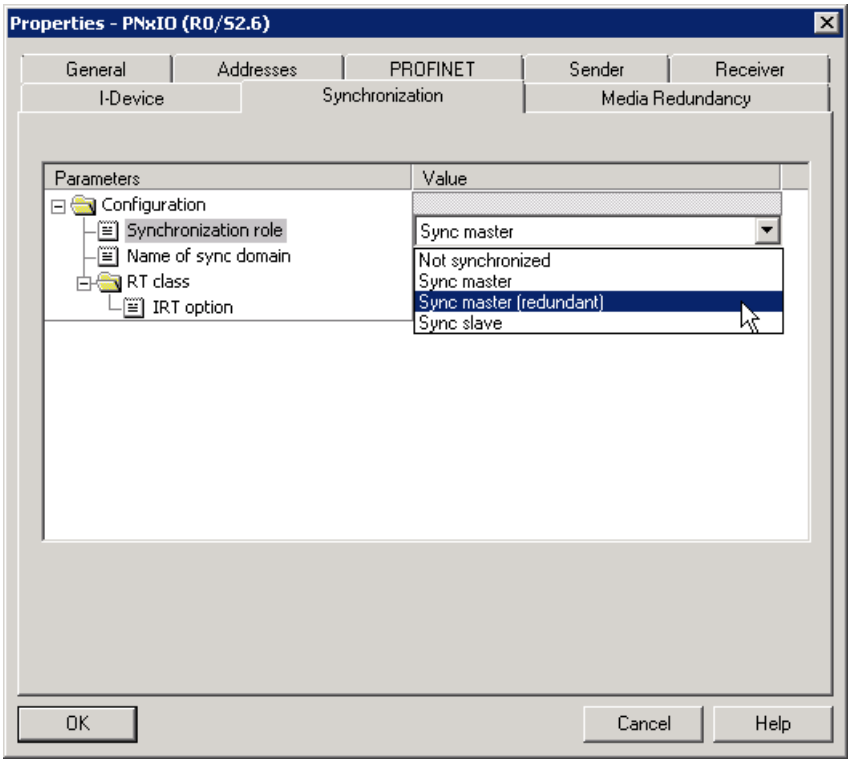

Figure 4-361 Configuring the redundant sync master

Deployment of a redundant sync master using the example of a machine with two machine parts.

The switchover behavior of the sync master and the redundant sync master is subject to several rules That must observed during the project creation and for applicative solutions.

- The topological design of the machine should provide the connection between the two machine parts via the sync master and the redundant sync master.
- If possible, no further device should be present between the sync master and the redundant sync master (e.g. IRT switch).

Supplementary conditions

- A wait time of 60 seconds must be observed for switching from the sync master to the redundant sync master. Only after this interval is it guaranteed that the redundant sync master has assumed its final status rather than the sync master resuming its role after a return.
- If the redundant sync master is switched on after the sync master, all sync slaves remain synchronized to the sync master.
- If the redundant sync master is switched on first and then the sync master after a wait time (> 60 seconds), all sync slaves remain synchronized to the redundant sync master.
- If both sync masters are switched on simultaneously, all sync slaves are synchronized to the sync master (this behavior is guaranteed only for an approximately equal startup time).
- If the connection between the sync master and the redundant sync master is interrupted, both sync masters accept their appropriate role and the topologically assigned sync slaves are synchronized accordingly.
- If the sync master and the redundant sync master are switched on simultaneously without a direct connection, the connection will be restored after a time > 60 seconds. The sync slaves remain synchronized to the sync master or the redundant sync master with which they are connected topologically. The two sync domains are not joined automatically. A diagnostic message will be generated.
- If the sync master is switched off, the redundant sync master handles the synchronization of the topologically-linked sync slaves. The sync slaves remain synchronized, i.e. no failure occurs.
- If the redundant sync master is switched off, the sync slaves connected topologically with the sync master remain synchronized.
- If the redundant sync master and sync master are separated and the redundant sync master has taken over the sync slaves, a combination (operation of the complete system) is only possible again after the complete machine has been shut down.

Quantity structures

The following maximum values apply to IO controllers of the SIMOTION platform.

A maximum of 64 communication relationships are possible; these can be divided up as follows:

- Connection of up to 64 IO devices.
- Maximum 64 RT IO devices.
- Maximum 64 IRT IO devices (High Performance).
- A maximum of up to 64 controller-controller data exchange broadcast relationships may be set up between SIMOTION controllers.
- If a SIMOTION controller has been configured as an I-Device, it also counts as an IO device; in other words, only another 63 IO devices can be connected to this controller.
- A SIMOTION controller can receive data from up to 64 other SIMOTION controllers as part of controller-controller data exchange broadcast yet can send data to any number of SIMOTION controllers.

- The IRT telegrams in controller-controller data exchange broadcast are broadcast telegrams. This is why any number of SIMOTION controllers can access the data of one SIMOTION controller.
- In controller-controller data exchange broadcast, the data volume also has to be considered. A data exchange broadcast only counts as a connection up to a certain data volume. Where a second telegram is required, data exchange broadcast does not require two connections.

Note

For MRPD, halve the quantity structures, since an MRPD IO device requires the resources of two IO devices. The same applies to controller-controller data exchange broadcast.

The IO area doubles if two PROFINET IO interfaces are used.

Mixed operation of IO devices and controller-controller data exchange broadcast

You can calculate the possible number of devices in mixed operation using the following formula:

```
RT + IRT High Performance IO device + data exchange broadcast frames
<= 64
```

Note

In a data exchange broadcast relationship, it is not the number of configured slots (lines on the **Receiver** tab - see Configuring the receiver (Page 2237)) that is intended for IRT High Performance direct communication configuration, but rather the number of Ethernet frames received for the data exchange broadcast. An Ethernet frame can contain up to 768 bytes of data exchange broadcast net data.

One slot has up to 768 bytes and 3,072 bytes of net data can be exchanged during data exchange broadcast (divided into 4 frames of 768 bytes each). The value will depend on the sizes of the slot chosen. This means a transmitter can receive more than one slot, although these must be transmitted within a single telegram.

Each sender sends its data exchange broadcast data in an Ethernet frame. Every other SIMOTION controller can read the data in this frame. This results in a counting connection to each transmitting SIMOTION controller.

For data exchange between an IO controller and an IO device, a frame has a useful data size of 1440 bytes for each transmitting SIMOTION controller.

During the compilation of the project, HW Config verifies the configured quality structure based on the formulas mentioned above.

Address space

A maximum of 4 KB each may be assigned for PROFINET IO data for the input and output data in the logical address space of an IO controller. The rest of the 16 KB large address space can be used, for example, for PROFIBUS data or diagnostic data.

Address space

A maximum of 4 KB each may be assigned for PROFINET IO data for the input and output data in the logical address space (IO address data) of an IO controller. As of SIMOTION V4.5, up to 6 KB can be used for SIMOTION D controllers. The rest of the 16 KB large address space can be used, for example, for PROFIBUS data or diagnostic data.

Definitions:

- IO address space:
  Logical addresses can be assigned in STEP 7 within this space.
- IO address data:
  Address space with assigned data.
- All logical addresses, i.e. diagnostic addresses as well, are included in the IO address space or the IO address data.
- The IO address data includes all logical addresses belonging to the IO system, i.e. I-Devices, slave-to-slave communication, and diagnostic addresses as well in the case of PROFINET (port submodules, for example).
- Only a check of the IO address data across all IO systems/DP systems is implemented in STEP 7 itself (including IO data + diagnostic addresses). The bus-specific check is carried out in the SIMOTION CPU-OM.

Example:

A 4-byte output module occupies 4 bytes of IO address data and can be assigned a logical address at any (free) location within the IO address space, e.g. 14000.

Size of the logical address space

	C240 / C240 PN	P3xx PN / P3xx DP/PN	D410-2 DP/PN	D4x5-2 DP/PN
CPU total [bytes]	4096	4096	16834	16834

Maximum quantity of IO address data

The maximum quantity of IO address data has been increased as of V4.5 from the current 4096 bytes to 6144 bytes for all PN/IO interfaces of SIMOTION D.

Segment	C240 / C240 PN	P3xx PN / P3xx DP/PN	D410-2 DP/PN	D4x5-2 DP/PN
DP ext. (per interface) [bytes]	1024	1024	1024	1024
DP_integrated [bytes]	-	-	512	4096
PROFINET (per interface) [bytes]	4096	4096	6144	6144

For each input and output per bus segment (DP system / IO system)

Submodule size from SIMOTION V4.4

In PROFINET, data for devices (and I-devices) and the controller-controller data exchange broadcast is structured in the form of submodules. Only data from a submodule can be read or written consistently when "non-synchronized" with PROFINET RT or IRT. The max. submodule size of SIMOTION controllers for PROFINET interfaces has been increased for the I-device and for the IO device from 254 bytes to 1024 bytes. The size of the submodule depends on the hardware and the PROFINET interface.

Maximum submodule size and consistency range

The following table defines the maximum submodule size, depending no the SIMOTION controller and the PROFINET interface. The submodule size stated applies to operation of a PROFINET interface with the following function:

- IO controller (the IO controller can operate IO devices with submodules up to the specified size)
- I-device (on the local I-device, submodules up to the specified size can be set up)

SIMOTION module	Onboard PROFINET interface [bytes]	CBE30-2 [bytes]
D455-2 DP/PN	1024	254
D445-2 DP/PN	1024	254
D435-2 DP/PN	1024	254
D425-2 DP/PN	1024	254
D410-2 DP/PN	1024	-
C240 PN	254	-
P320-4 PN	254	-
P320-4 DP/PN	254	-

Note

Controller-Controller data exchange broadcast

For controller-controller data exchange broadcast, the max. submodule size of 254 bytes is retained.

Rule for use of a SIMOTION or SIMATIC I-device on a SIMOTION IO controller

If a SIMOTION controller is configured as an IO controller and a SIMOTION or SIMATIC controller is configured as an I-Device in a project, submodules larger than 254 bytes can be used subject to the following constraints:

- The I-device must support submodules up to 1024 bytes.
- The IO controller must support submodules up to 1024 bytes.

Note

For SIMATIC controllers, a max. submodule size of 1024 bytes applies.

Potential problems when using interfaces with different consistency lengths

If, for example, you configure an I-Device that contains a submodule of 500 bytes in size on the onboard PROFINET interface of a SIMOTION D4x5-2, the I-Device, for example, cannot be operated on a SIMOTION C240 PN that is a higher-level controller. An error message is displayed in STEP 7, stating that the output/input net data length of 254 bytes has been exceeded.

Data exchange through the use of iDevices (Page 2258)

Media redundancy (MRP and MRPD)

Media redundancy for SIMOTION

Media Redundancy Protocol

It is possible to establish redundant networks via the so-called Media Redundancy Protocol (MRP). Redundant transmission links (ring topology) ensure that an alternative communication path is made available when a transmission link fails. The PROFINET devices that are part of this redundant network form an MRP domain.

Note

Devices that support MRP

An overview of all devices that support media and/or system redundancy can be found in the Support area (https://support.industry.siemens.com/cs/ww/en/view/67364686).

MRP (Media Redundancy Protocol for PROFINET RT, as of SIMOTION V4.3)

MRP guarantees media redundancy in the event of a problem in the ring. The switchover of the ring is performed by the Redundancy Manager.

The switchover times depend on the following parameters:

- The actual topology
- The devices used and
- The network load in the relevant network.

The typical reconfiguration time of the communication paths for TCP/IP and RT frames in the event of a fault is < 200 ms.

In most systems, the switchover time of MRP is far above the PROFINET update time for cyclic data, so that a failure for cyclic data is detected. The PROFINET connection therefore fails and is re-established after the switchover by the Redundancy Manager. In this way, an error can be corrected in the network, while the system continues to run *with bumps*.

The figures below show a sample topology with and without fault:

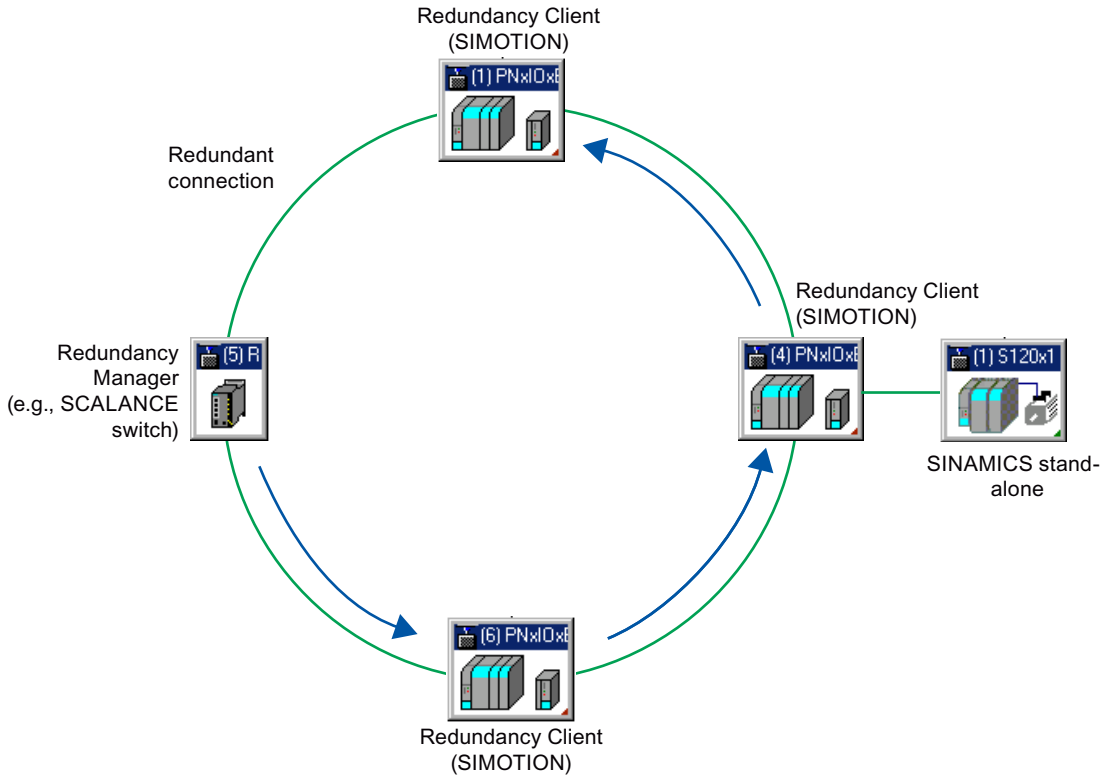

Figure 4-362 Ring topology for media redundancy without fault

After the occurrence of a fault, the Redundancy Manager reconfigures the communication of the ring. In contrast with MRPD, the PROFINET RT telegrams are only sent in one direction in the ring with MRP. Therefore, the redundant communication path is only closed by the redundancy manager in the event of a fault.

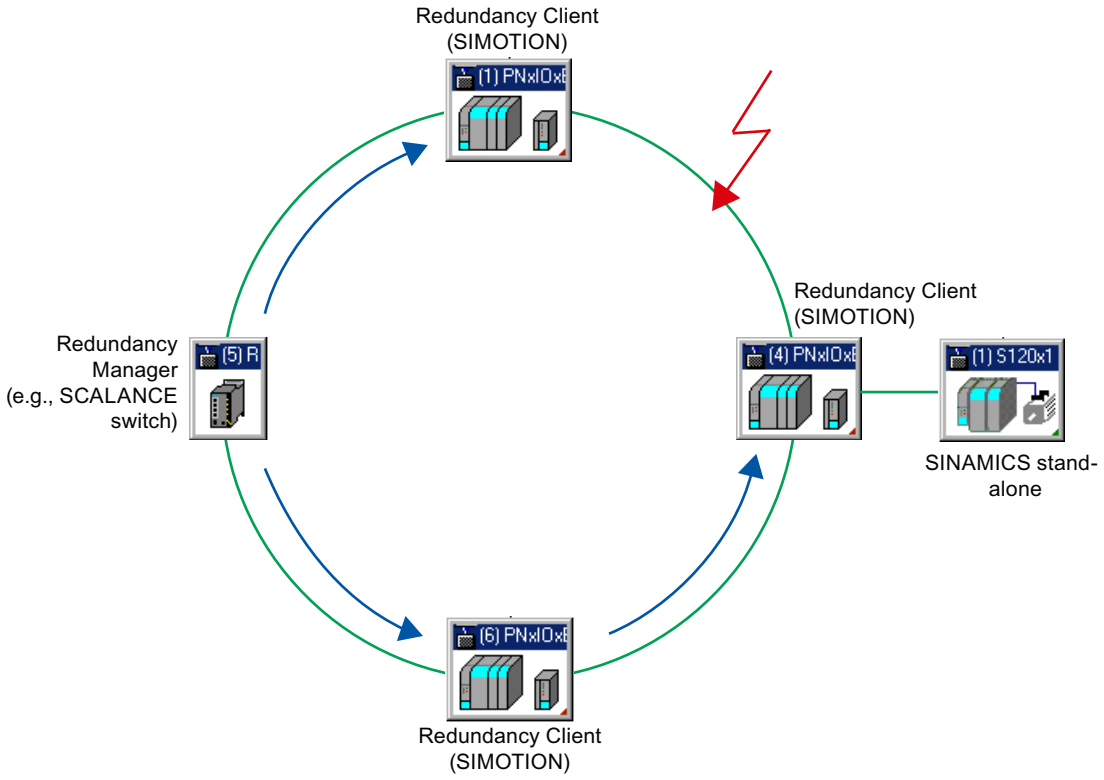

Figure 4-363 Ring topology for media redundancy with a fault

Ring ports

A SIMOTION controller / SINAMICS drive may only be inserted into an MRP ring as a node with MRP-capable ports. For SIMOTION D, the first two ports of the PROFINET IO interfaces are designed as ring ports.

These two ports are marked with an "R" in the module rack in HW Config.

Note

Only devices with MRP-capable ports may be inserted in an MRP ring. If MRP-capable ports are not used, the reconfiguration times can be in the multi-digit seconds range.

For SINAMICS S120 drives (SINAMICS S120 CU320-2/CU310-2), these are ports P1 and P2. However, they are not separately designated as ring ports in the HW Config.

MRPD (Media Redundancy for Planned Duplication) for PROFINET IRT, as of SIMOTION V4.3, SIMOTION SCOUT TIA V4.5

MRPD (Media Redundancy for Planned Duplication) is a method for smooth media redundancy with PROFINET IRT. MRPD also requires MRP.

The combination of MRP with MRPD provides smooth PROFINET operation for short cycle times in the event of a fault in the ring. MRPD is based on IRT and ensures bumpless operation by the sender sending the cyclic data in both directions which the recipient then receives twice. The

first received telegram is used by the recipient. The second telegram is discarded automatically. If the ring is interrupted at one position (e.g., through the failure of a ring node), receipt of the cyclic data via the uninterrupted side of the ring is still guaranteed. The following figure shows a sample configuration:

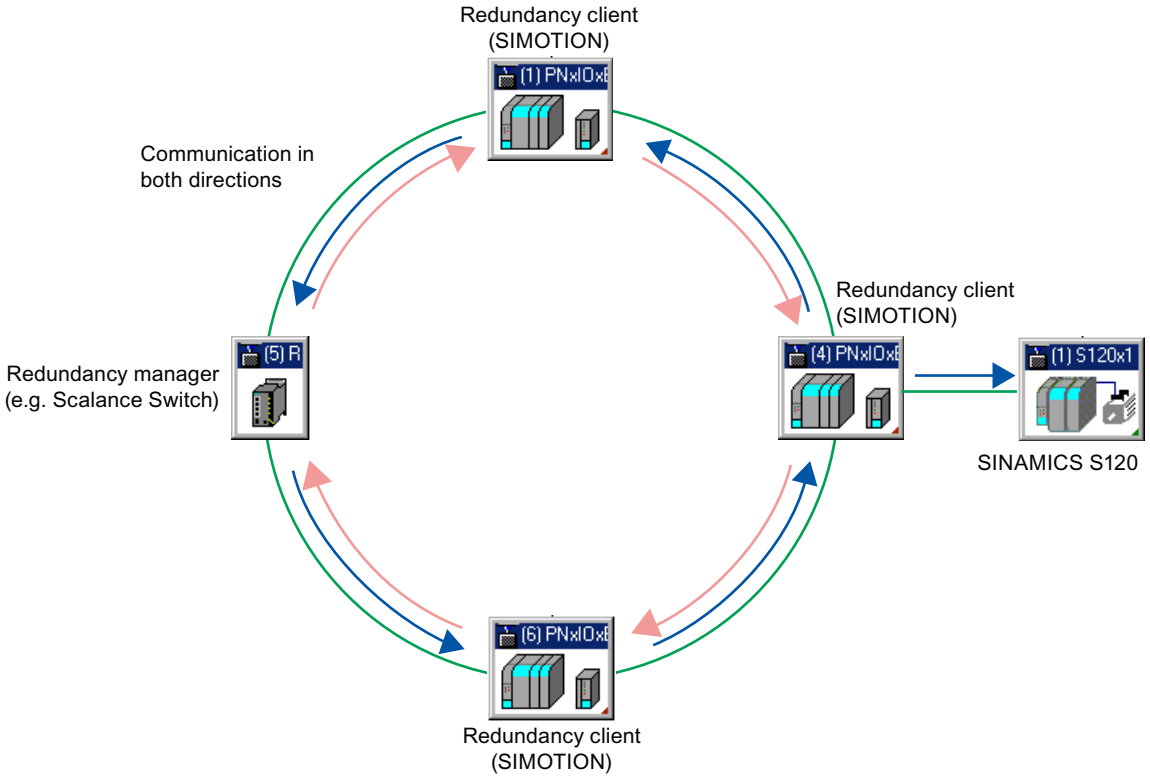

Figure 4-364 Ring communication in MRPD

Smooth media redundancy MRPD always requires the activation of MRP in the individual rings.

Note

Too high a network load or too rapid incoming/outgoing faults caused by delayed or continuous switchovers of the MRP, may lead to failure of the PROFINET connection even with activated MRPD.

Devices that support MRPD

Note

An overview of all devices that support media and/or system redundancy can be found in the Support area (https://support.industry.siemens.com/cs/ww/en/view/67364686).

If the device prevents MRPD, an **error message** is issued in HW Config:

- "The <xxxx> device does not support sync domain with MRPD area."

SIMATIC controllers, such as a SIMATIC 300 or an ET200, currently do not support MRPD.

Servo_fast, scaling down of cycle clocks to the servo at the PROFINET interface (Page 2207)

Redundant sync master (Page 2159)

Information on PROFINET with MRPD

Smoothness of MRPD

Delayed or incomplete switchovers of MRP/MRPD caused, for example, by a network load that is too high or the too rapid incoming/outgoing of faults, under unfavorable conditions, can lead to the PROFINET connection failing even with activated MRPD.

For example, in the event of two consecutive faults at various parts of the ring, smooth operation is only ensured when the two faults are separated by approx. three seconds (if a fault has "gone", an additional fault may "come" only after a short pause).

Operation of MRPD in conjunction with a redundant sync master

There can be a maximum of two Ethernet nodes between one sync master and one redundant sync master.

If the redundant sync master is used together with MRPD, it is recommended that the redundant sync master (e.g. a SCALANCE IRT switch) be connected directly to the sync master and the two nodes positioned in a common switch cabinet so that the cable connection between both nodes is protected.

The insertion or withdrawal of a connection in an MRPD ring does not have any effect on the synchronization. Only one sync master remains.

In case of an interruption in the distance between sync master and redundant sync master, the system initially continues to run smoothly, however faults may occur when you switch off and then restart the system if the devices between the sync master and the redundant sync master have too great a difference in ramp-up time.

The fault is that the sync domain breaks down into two sub-domains, and one part of the sync slave synchronizes to the sync master, and the other part synchronizes to the redundant sync master. The PN diagnosis "Remote mismatch / Peer PTCP mismatch 0x8008" is present.

If the sync master or the redundant sync master in an MRPD ring is switched off, all sync slaves remain synchronized, because unlike the line, all sync slaves retain their connection to the remaining sync master.

Configuration instructions

You must comply with the following rules to operate PROFINET IRT in connection with MRPD:

- The rules for configuring MRP and PROFINET IRT must be followed.
- All devices in the ring must support MRPD.

- If devices at the stub are in redundant communication via the ring, all devices at the stub must support up to the last MRPD node of the MRPD stub.
- Nodes in the stub that only communicate locally in the stub and not over the ring, do not have to support MRPD. They do, however, require the IRT property "StartupMode=Advanced" so you can operate them in a sync domain together with MRPD nodes. In V4.3, the devices described in Media redundancy for SIMOTION (Page 2166) have this IRT property.

See also

Media redundancy for SIMOTION (Page 2166)

Sample configurations for MRPD rings

MRPD configuration with a ring from SCALANCE switches

The ring consists of SCALANCE switches (redundancy manager and redundancy clients), SIMOTION controllers and IO devices at the stubs. In this configuration, several IO controllers can fail or be deactivated with their IO devices. The rest of the system continues to run smoothly. In addition, it is also possible for a SCALANCE switch to fail, or for the ring to be interrupted.

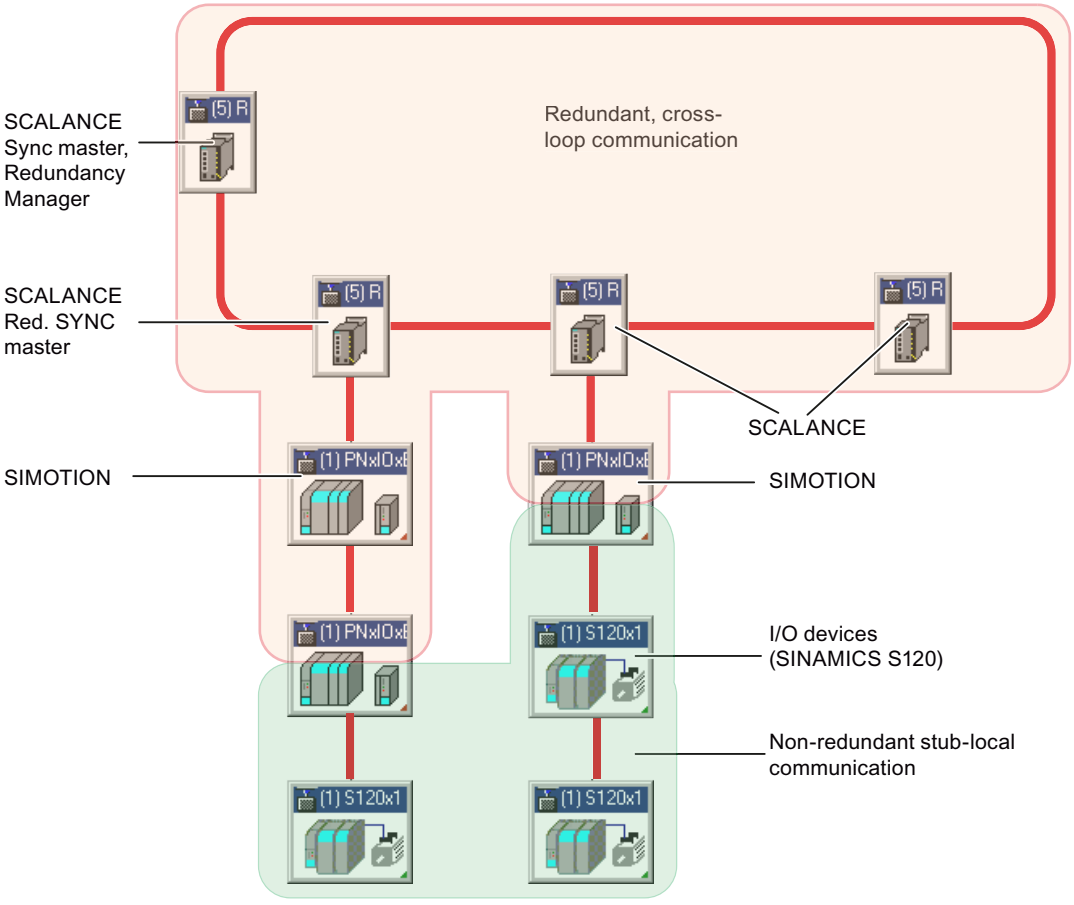

Figure 4-365 Ring configuration with SCALANCES

MRPD configuration with a ring from SIMOTION controllers and a SCALANCE switch

The ring contains a SCALANCE switch as a redundancy manager and SIMOTION controllers as redundancy clients. The SIMOTION controllers with their IO devices are connected with the ring via spur lines.

In this configuration, an IO controller can fail or can be deactivated with its IO devices (at the stub). The rest of the system continues to run smoothly.

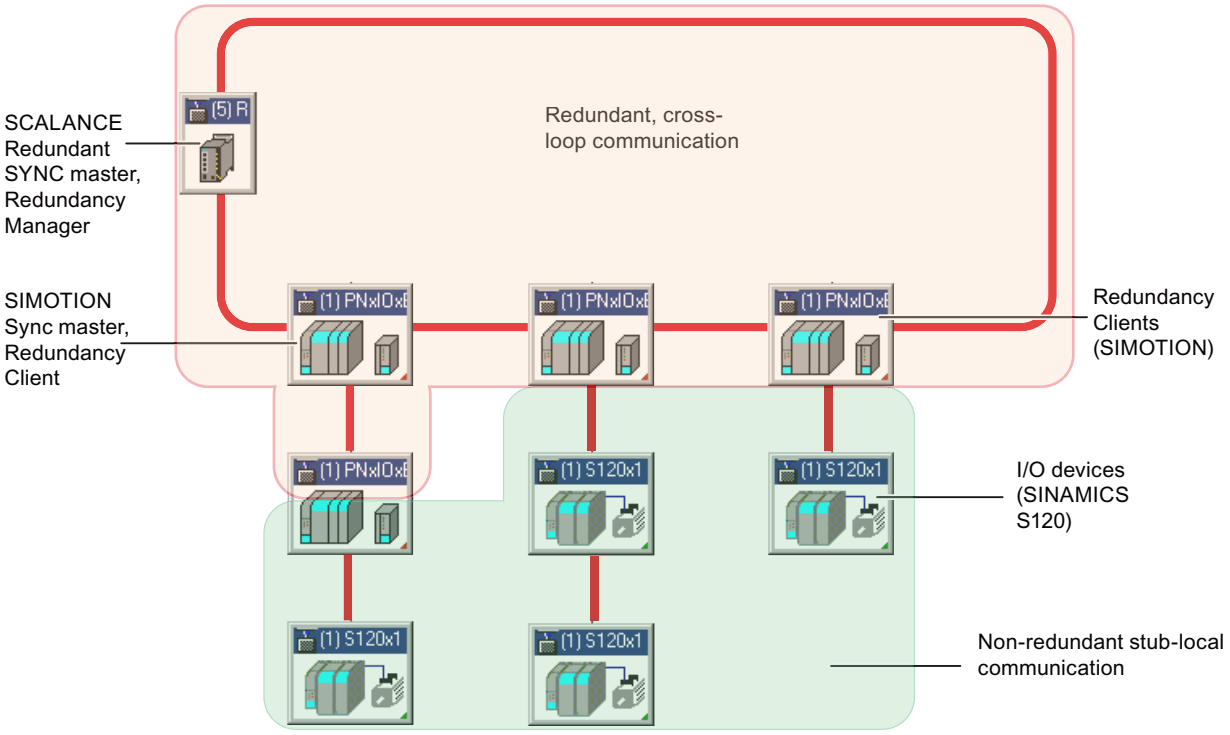

Figure 4-366 Ring configuration with SCALANCE and SIMOTION

MRPD configuration with SCALANCE, SIMOTION controller and SINAMICS I/O devices

The ring contains a SCALANCE switch, a SIMOTION controller and SINAMICS IO devices. An IO device can fail or can be deactivated. The rest of the system continues to run smoothly.

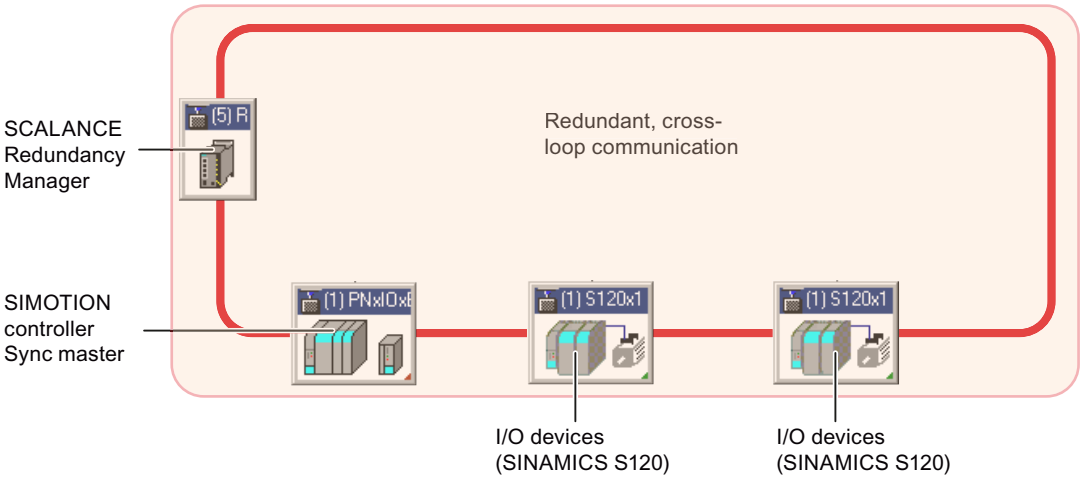

Figure 4-367 Ring configuration with SINAMICS I/O devices

Hierarchical multi-ring system

If, for example, the number of stations per ring or cycle times is exceeded, you can establish hierarchical multi-ring systems and divide the functionality into sub-rings. The sub-rings can continue to operate independently of each other.

For an example, see also Redundant sync master (Page 2159).

Use of Safety with MRRT

No smoothness for Safety via RT and shared device

MRRT offers no smooth redundancy for RT data (but only for IRT data).

In order to guarantee smooth media redundancy with Safety, the safety data within the MRRT ring must be transferred as IRT data. To make sure that this is the case, the SIMOTION controller F-proxy must be used for communication with the F-CPU. Please note that a direct connection must be established between the F-CPU and the SIMOTION controller. Either a free port or the second PROFINET interface, which is not part of the MRPD ring, can be used for this purpose. The

Safety RT data of the F-CPU is then transferred internally from the SIMOTION controller into the IRT data of the MRPD ring.

Note

The use of the shared device (the F-CPU communicates directly with the SINAMICS drive) is not recommended for MRPD, because the RT data deactivates temporarily in the event of a fault and so the PROFIsafe modules are passivated. Use of the I-device F-Proxy is recommended, because the PROFIsafe data is packed together in the IRT data.

Safety via I-device F-Proxy

When using the I-device F-Proxy, the safety data is transmitted from the F-Proxy to the drives in the MRPD ring via PROFINET IRT. The PROFIsafe communication between the F-CPU and the drives is thus also secured in case of a fault with the ring.

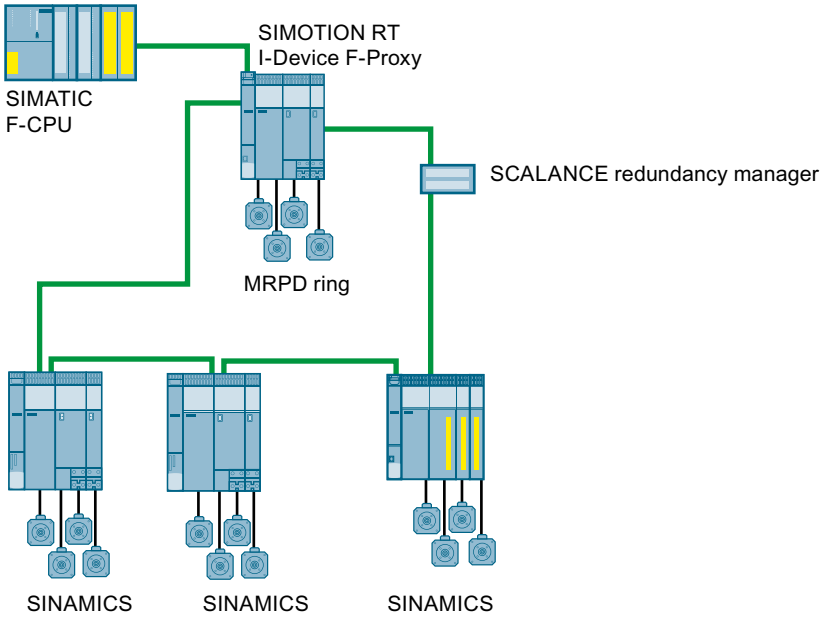

Figure 4-368 Safety via MRRT

In order for the safety data to be transferred smoothly, the communication paths between the F-CPU and the SIMOTION I-device F-Proxy may not go via the ring. As seen in the illustration above, the F-CPU should either be connected directly with an open port of the PN interface of the SIMOTION controller, which has been configured as an I-device F-Proxy, or the second PN interface be used as an I-device F-Proxy. For an exact description of how to configure an I-device F-proxy, please refer to section Principles of I device failsafe proxy (Page 2338).

You can find a description of how to configure Safety via PROFINET with an F-CPU in the FAQ (https://support.industry.siemens.com/cs/ww/en/view/50207350).

PROFINET V2.3 Performance Upgrade

Optimized data transfer / 125 µs PROFINET send clock

PROFINET V2.3 Performance Upgrade

All SIMOTION Control Units support PROFINET in accordance with the PROFINET International specification PN V2.3. The optional **Performance Upgrade** functionality that provides extended functional scope is available for SIMOTION D455-2 DP/PN.

- Minimum PROFINET send cycle clock 125 µs (Fast Send Clock)
- Optimization of data transfer (e.g. by Dynamic Frame Packing - DFP (Page 2176))
- Fast forwarding
- Fragmentation

Note

Validity

The PROFINET Performance Upgrade (Fast Send Clock 125 µs and Dynamics Frame Packing) is only approved for SIMOTION SCOUT TIA.

Note

You will find further information on this on the web site of the PI Organization (http://www.profibus.com) and the following technical specifications:

- Technical Specification for PROFINET, Version 2.3 – Date: October 2010, Order No.: 2.722
- Application Layer services for distributed I/O and distributed automation, Technical Specification for PROFINET, Version 2.3 – Date: October 2010, Order No.: 2.712

With optimized data transfer, the following options are possible:

- More devices can be operated with the same cycle time.
- The cycle time can be reduced for the same number of devices.

Requirements

General conditions for using the 125 µs send cycle:

- The 125 µs send cycle is supported only by the onboard PROFINET interface X150 in conjunction with Servo_fast / IPO_fast.
- Only one port can be used on X150; the other two ports must therefore be deactivated in the interface properties of X150 (the ports cannot be used for TCP/IP or UDP communication either).
- X150 can only be used as a PROFINET IO controller (not as an I-Device).
- No MRP/MRPD media redundancy (only one port is available on X150).
- Use of STEP 7 V14, V14; for other operating conditions, see also *Readme* for SIMOTION SCOUT V4.5.

Note

Quantity structures in the case of very short send cycles

When very short send cycles (125 µs, 250 µs) are used in a configuration with a large number of PROFINET devices, SIMOTION will be operating close to its upper performance limits. It is not possible to reliably predict all the restrictions applicable to the configuring of such systems. Only during runtime will it be possible to identify overload situations. Overload conditions will be indicated by appropriate messages (cycle violation, inconsistent data transmission). When you are using these very short cycle times, you should therefore restrict the number of devices to the absolute minimum necessary.

Components that can be used

The 125 µs send cycle is only supported by selected PROFINET nodes (e.g. by the ET 200SP I/O system). No SCALANCE switches are currently available for the 125 µs send cycle.

- SIMOTION D455-2 DP/PN as of V4.5

Note

For the PROFINET nodes that support a send cycle of 125 µs and the general conditions that have to be met, see the relevant product documentation.

Dynamic Frame Packing - DFP

Description

For PROFINET V2.2, a separate Ethernet frame is used for each IO device for the cyclic transfer of the IO data. This leads to a large overhead due to the Ethernet header, especially in the case of IO devices with a small amount of IO data.

With the PN V2.3 Performance Upgrade, SIMOTION D455-2 DP/PN supports Dynamic Frame Packing (DFP) via the onboard PROFINET interface X150. With Dynamic Frame Packing, the cyclic

data of multiple IO devices is summarized in one Ethernet frame. DFP significantly reduces the bandwidth required to exchange the cyclic data, especially in the case of IO devices with a small amount of IO data. This makes it possible to either operate more IO devices with the same cycle time or to reduce the cycle time in order to achieve a shorter response time.

In the outbound direction (from the IO controller to the last IO device), the Ethernet frame is automatically reduced. This is achieved by having each device remove its own data from the telegram when forwarding. In the inbound direction (from the last IO device to the IO controller), each IO device adds its own data to the Ethernet frame.

Dynamic Frame Packing is used automatically when send cycles < 250 µs are set and the requirements (see "Requirements" section) are met.

The figure below shows examples of how package groups can be formed. The IO devices (IO-D) with red backgrounds are automatically grouped into package groups.

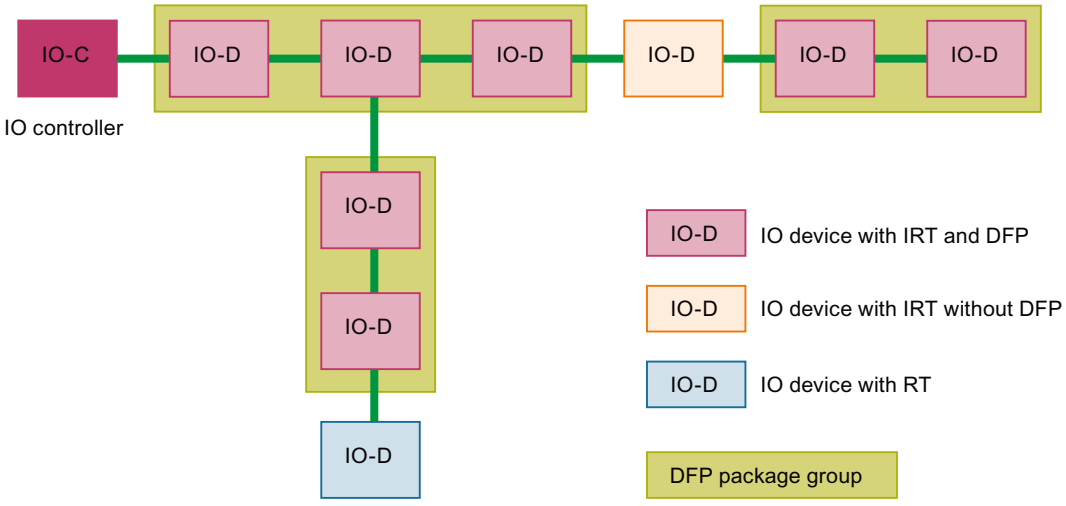

Figure 4-369 Example of DFP package group formation

Requirements

DFP can only be used with the following restrictions:

- DFP can be used only on the onboard PROFINET interface X150 of the SIMOTION D455-2 DP/PN and on the ET200SP High Speed IO-Devices.
- DFP is supported by SIMOTION only as an IO controller. The SIMOTION I-Device does not support DFP.
- A DFP device can be used as a shared device by a second IO controller. Whereby the shared device restrictions apply. One IO controller communicates with DFP via IRT; the other via RT.
- In the case of MRPD, the DFP devices must be present in a spur line. IO devices in the ring are not supported.
- IO devices that do not support DFP terminate a package group; i.e. the grouped IO devices must form a line with no gaps.
- A maximum of 63 IO devices can be packed in one group.
- The size of a package frame is limited to 128 bytes in the outbound direction and 256 bytes in the inbound direction.

4.5.5.3 Configuring PROFINET IO with SIMOTION

New features as of SIMOTION SCOUT V5.3

SINAMICS S210 drive with motion control in SIMOTION SCOUT TIA

SIMOTION SCOUT TIA supports the SINAMICS S210 drive system in conjunction with technology objects. The drive is commissioned in Startdrive or via the Web server and integrated in the project as GSD file. The data exchange is performed via telegrams.

See also

Technology objects with SIMOTION SCOUT TIA and SINAMICS S210 (https://support.industry.siemens.com/cs/ww/en/view/109759892)

Last versions

New as of SIMOTION SCOUT V5.2

Assign device names based on MAC addresses via system function (SIMOTION SCOUT / SIMOTION SCOUT TIA)

With the system function _assignNameOfStationToDevice(), you assign a device name (NameOfStation) to a PN device with a specific MAC address. You can implement modular machine concepts with this function.

System function _assignNameOfStationToDevice(). (Page 2282)

Automatic transfer of the F destination addresses (SIMOTION SCOUT / SIMOTION SCOUT TIA)

With function "Automatic transfer of the F destination addresses", you accept the F destination address configured in the hardware configuration for the Safety commissioning in the drive. The function is also available via scripting.

Transfer the F destination address (F_Dest_Add) (Page 2366)

Change of CRC-secured data of a PROFIsafe telegram is acquired (SIMOTION SCOUT TIA)

For plants and machines with comprehensive safety technology, it must be possible to detect changes to safety-related data quickly and precisely. As of V5.2, the F-Proxy Interconnection table is extended with the **CRC change** column. For each conversion action, changes are detected at the safety axes and displayed in the table.

Additional references

Detailed information and configuring examples specific to SIMOTION SCOUT TIA can be found in the *SIMOTION SCOUT TIA* Configuration Manual.

New in SIMOTION SCOUT as of V5.1

Configuration control for IO systems - machine tailoring (SIMOTION SCOUT TIA)

The configuration control for IO systems (machine tailoring) allows several specific versions or stages of a series machine to be generated from a single series machine project.

Configuration control for IO systems (Page 2287)

Additional references

Detailed information and configuring examples specific to SIMOTION SCOUT TIA can be found in the *SIMOTION SCOUT TIA* Configuration Manual.

New in SIMOTION SCOUT as of V4.5

VentorID, DeviceID for detecting wiring errors

Previously, if the wiring was incorrect, during the topology-based initialization of IO devices by the controller it was possible, for example, that the name of a SINAMICS drive was assigned to a SCALANCE switch. Before it initializes a device, the PN-IO controller now checks whether the device is of the expected type (VentorID/DeviceID).

Time-of-day synchronization

In order to synchronize the time of day of all the components in the system, the time of day can be synchronized via an NTP server.

NTP time-of-day synchronization (Page 2095)

SINAMCIS_Integrated cycle clock < 500µs

As of SIMOTION SCOUT / SIMOTION SCOUT TIA V4.5, SINAMICS_Integrated for drives on SIMOTION D4x5-2 can use bus cycles of less than 500 µs. It supports cycles of between 250 µs and 375 µs. SINAMICS_Integrated remains assigned to the servo cycle. Servo_fast is not supported.

SINAMICS_Integrated cycle clock (Page 2139)

Increasing the number of F-Proxy submodules to 128 safety axes

As of firmware version 4.5, a maximum of 128 F-Proxy submodules, and thus a maximum of 128 safety axes, can be configured for the SIMOTION D455-2. The maximum number of F-Proxy submodules **depends** on the configured PROFIsafe telegram.

Quantity structures I-Device-F-Proxy (Page 2342)

Increase in PN-IO address space

The IO address data (address space assigned to data) has been raised from 4K (in current version) to 6K for SIMOTION.

Quantity structures, address space (Page 2162)

Broadcast _udpReceive() and _udpSend()

A new checkbox "Permit broadcast _udpReceive/_udpSend" is provided, which allows you to configure whether the EDD network load filter should be deactivated if you want to perform Open User Communication with UPD broadcast (system functions _udpReceive() and _udpSend()).

Using broadcast communication (Page 2302)

Changes to PROFIenergy communication

PROFIenergy communication needs to be explicitly activated in SIMOTION SCOUT TIA for the SIMOTION I-Device in order to enable the PROFIenergy data sets. PROFIenergy communication is automatically activated in SIMOTION SCOUT and need not be set explicitly.

PROFIenergy communication (Page 2273)

Improvements in usability of isochronous tasks (SIMOTION SCOUT)

The Servo_fast cycle can be used as a reference cycle only if the Servo_fast box is checked. This selection is not available on SIMOTION controllers that do not support Servo_fast.

Overwriting of the existing PROFINET device name (SIMOTION SCOUT TIA)

Existing PROFINET device names are overwritten by the IO controller during the topology-based initialization routine. When IO devices were incorrectly initialized (due to a wiring error, for example) in previous software versions, it was necessary to reset the device names so that the devices could be reinitialized.

Address tailoring for series machines (SIMOTION SCOUT TIA)

The address tailoring function can be used to assign an IP address and a NameOfStation to IO controllers and IO devices by means of system functions at the commissioning stage. This feature allows a machine consisting of an IO controller and IO devices to be supplied with IP addresses and NameOfStation at the commissioning stage, and permits multiple instances of the machine to be commissioned on a single physical Ethernet without an engineering system.

Series machine projects - address tailoring (Page 2286)

Performance upgrade PN V2.3 (SIMOTION SCOUT TIA)

SIMOTION SCOUT TIA supports the performance upgrade PN V2.3. You can thus now configure send cycles of < 250 µs.

Optimized data transfer - performance upgrade (Page 2175)

Media redundancy MRPD (SIMOTION SCOUT TIA)

With this version and later, the MRPD functionality previously available only for SIMOTION SCOUT is now also available for SIMOTION SCOUT TIA.

Media redundancy (Page 2166)

SIMOTION controller as a shared I-Device (SIMOTION SCOUT TIA)

A SIMOTION I-Device can be operated as an IO device on two higher-level IO controllers. This functionality is known as shared I-Device.

Shared device on SIMOTION controller (SIMOTION SCOUT TIA)

It has been possible to configure a shared device for SIMOTION SCOUT as of version V4.2 of SIMOTION SCOUT. A shared device can now also be configured with SIMOTION SCOUT TIA. A typical application is a SIMOTION CPU as an automation CPU and an F-CPU for the safety application that is divided between the submodules of the SIMATIC ET200SP.

SINAMICS G120 as a shared device on the SIMOTION controller (SIMOTION SCOUT TIA)

SINAMICS G120 as a shared device only supports a fixed division of the subslots between the two sharing IO controllers. The shared device functionality is available only for the SINAMICS G120 GSD drives.

Update of GSD version to V2.32 (SIMOTION SCOUT TIA)

SIMOTION SCOUT TIA uses GSD version V2.32. A SIMOTION I-Device is exported as GSD V2.32 in SIMOTION SCOUT TIA. SIMOTION SCOUT utilizes GSD version V2.3.

Additional references

Detailed information and configuring examples specific to SIMOTION SCOUT TIA can be found in the *SIMOTION SCOUT TIA* Configuration Manual.

New in SIMOTION SCOUT as of V4.4

Shared iDevice

As of SIMOTION V4.4, an iDevice of the PN-IO interfaces can be operated with two higher-level IO controllers. This functionality is referred to as "shared iDevice" and is comparable with the shared device.

See also Shared iDevice and PROFIsafe (Page 2374)

PROFINET V2.3 Performance Upgrade

The Control Unit SIMOTION D455-2 DP/PN supports the PROFINET Performance Upgrade in accordance with the PROFINET specification V2.3. The PROFINET send clock can now be set to a minimum of 125 µs.

See also Performance Upgrade PN V2.3 (Page 2175)

Support for PROFIenergy

PROFIenergy is a data interface based on PROFINET. It allows loads to be shut down during idle time in a controlled, centralized manner, and irrespective of the manufacturer and device.

See also PROFIenergy (Page 2271)

Setting IP address and device name via user program

In the case of SIMOTION, the IP configuration can be set via the user program for the PN-IE and PN-IO interfaces.

See also Setting IP address and device name via UP (Page 2277)

Identification and maintenance (I&M) data

As of V4.4, SIMOTION supports the data sets 1-4 in addition to the I&M data set 0 (electronic rating plate) as a PROFINET iDevice.

See also I&M data (Page 2231)

PROFINET IO with IRT

As of SIMOTION V4.4, an additional configuration step has been added for the configuration of PROFINET IO with IRT. In the HW Config of the controller CPU, under **Object properties** in the **Isochronous tasks** tab, the setting is made as to whether the servo task is to be assigned to the PROFINET interface as the application level for the processing of isochronous data:

- If PROFINET IO devices with isochronous data are to be configured on PROFINET, the PROFINET interface must first be assigned to the servo under **Object properties** of the SIMOTION CPU in the **Isochronous tasks** tab (Use "..**I/O data isochronously to the servo**" checkbox). Only then can servo be assigned for the device in the **Object properties** of the PROFINET interface in the **I/O cycle** tab (**Assign I/O device isochronous** list box).
- If no devices are configured with isochronous data on the PROFINET interface, the PROFINET interface must also not be assigned to the SERVO.

As of SIMOTION V4.4, it is therefore also possible to configure the PROFINET interface of SIMOTION devices with IRT without the data being transferred isochronously. This means that the data is transferred synchronously via IRT on the bus, but the applications in SIMOTION and in the device do not accept the data isochronously. For example, an ET200HF can be configured with IRT, but the I/O data is not transferred isochronously to the physical input or output. Or a

SIMOTION I-device can be connected via IRT to a higher-level controller, but the input and output data of the I-device interface is not processed isochronously by the CPU.

Up to and including V4.3, SIMOTION always performed the communication with PROFINET IO with IRT isochronously to the servo, even if isochronous mode was not configured on any PROFINET IO device.

New in SIMOTION SCOUT as of V4.3

Media redundancy protocols MRP and MRPD

Via the so-called Media Redundancy Protocol (MRP or MRPD), it is possible to establish redundant networks, see Media redundancy for SIMOTION (Page 2166).

Second PROFINET I/O interface

With SIMOTION D4x5-2 DP/PN, is it possible to have two PROFINET I/O interfaces (integrated interface and CBE30-2) on one device, see Two PROFINET IO interfaces (Page 2144). If two interfaces are available, one interface can be operated in the servo cycle clock and the other interface in Servo_fast cycle clock (integrated interface).

Position control cycle clock and Servo_fast cycle clock

Position control cycle clock and Servo_fast both run via PROFINET (slow and fast bus cycle clock), see Servo_fast, scaling down of cycle clocks to the servo at the PROFINET interface (Page 2207).

Standard Ethernet interfaces

The standard Ethernet interfaces now include basic PROFINET services, Properties of the SIMOTION Ethernet interfaces (Page 2289).

More message frames for PROFIsafe

Additional message frames are provided for PROFIsafe, see also Message frames and signals in drive-based safety (Page 2332).

See also

New with SIMOTION SCOUT V4.2 or higher

IRT synchronization process

SIMOTION with IRT High Performance. With PROFINET IRT, this synchronization process is set automatically.

Controllers with integrated PN interface

With SIMOTION D4x5-2 DP/PN, new SIMOTION D controllers with integrated PN interfaces are available.

Isochronous operation for applications has been simplified.

The typical isochronous applications for Motion Control have been made much more straightforward. The Ti/To time constants can be calculated automatically for all IO devices. The configuration in HW Config has been enhanced to allow the object properties of isochronous tasks to be set to automatic on the controller.

iDevice

The I device functionality has been improved with the release of Step 7 V5.5. If SIMOTION SCOUT projects use a lower version than V4.2, certain points must be considered when upgrading. You can find more information in the I device chapter.

iDevice F-Proxy

Using the I device F-Proxy, you can produce a PROFIsafe configuration with an F host (F-CPU SIMATIC) on PROFINET with SIMOTION devices (SIMOTION D, SIMOTION P3xx, SIMOTION C240 PN) for the lower-level drives.

Second servo cycle clock (Servo_fast)

The second servo cycle clock enables you to operate two bus systems in different application cycle clocks in the case of SIMOTION D4x5-2 DP/PN. An assigned servo cycle clock and IPO cycle clock are available for each of the two application cycle clocks. This allows you to divide your application into a slow part (SINAMICS_Integrated with servo and IPO) and a fast part (IO devices on the PROFINET interface with Servo_fast and IPO_fast).

Procedure for configuring PROFINET IO with IRT High Performance

Procedure

The following steps need to be performed when configuring PROFINET IO with IRT High Performance:

1. Insert the SIMOTION module.
   Select the **Device** followed by the **Device version**. A PROFINET interface is already integrated in devices labeled with PN.
   - With SIMOTION C and SIMOTION P, you only select the SIMOTION version, e.g. V4.4.
   - With SIMOTION D, the modules have up to two PROFINET IO interfaces (onboard and CBE30-2) depending on the version. Depending on the version, select SIMOTION Version V4.4, the option module, and the SINAMICS drive and version.
     You can select the CBE30-2 option module for PROFINET here or enter it later in HW Config from the hardware catalog under **SIMOTION Drive-based > SIMOTION D4x5 xxx > 6AUxxxxxx > Vx.x SINAMICS > CBE30-x-PN-IO**.
2. Insert IO devices:
   Insert IO devices from the hardware catalog in HW Config into the IO system. The IO devices can be found in the hardware catalog under **PROFINET IO**.
3. Configure sync domain and specify send clock:
   Configure the PROFINET IO node as sync master (clock generator) and define the associated sync slaves. Specify the send clock.
4. Generate the topology:
   Define the topology, i.e. specify how the individual ports of the PROFINET devices (IO controller and IO device) are interconnected with one another. The topology only needs to be configured for PROFINET IO with IRT High Performance. If topology-based initialization is to be used, the topology will need to be configured for all PROFINET devices.
5. As an option, you can still configure the controller-controller data exchange broadcast:
   Specify which address areas are to be used for sending and receiving.

Inserting and configuring SIMOTION D

General information on inserting and configuring SIMOTION D

General information

You have created a project and want to configure a SIMOTION D using a PROFINET interface.

With SIMOTION D, the control units feature an onboard PROFINET interface (D410 PN, D410-2 DP/PN, D4x5-2 DP/PN) or an option module CBE30 for PROFINET (D4x5), depending on the version concerned.

With V4.3 or higher, you can use a CBE30-2 as a second PROFINET interface with SIMOTION D4x5-2 DP/PN.

You can select the CBE30-2 when inserting the SIMOTION D controller in the SIMOTION SCOUT project or, alternatively, you can insert the relevant version for the SIMOTION D controller later

in HW Config from the HW catalog. You will find the CBE30-2, for example, under **SIMOTION Drive-based > SIMOTION D4x5 xxx > 6AUxxxxxx > Vx.x SINAMICS > CBE30-x-PN-IO**

Implementing the PROFINET interface:

- Already integrated in the case of D410 PN, D410-2 DP/PN, and D4x5-2 DP/PN
- With D4x5-2 DP/PN, a second PROFINET interface can be implemented with a CBE30-2.
- Available as an option in the case of D4x5 (option module CBE30)

The procedure is explained in the following sections.

Inserting and configuring SIMOTION D4x5-2 DP/PN/D410 PN/D410-2 DP/PN

General information

You have created a project and want to configure a SIMOTION D4x5-2 DP/PN, SIMOTION D410 PN, or SIMOTION D410(-2) DP/PN using the internal PROFINET interface. The procedure for this will be explained using the example of a SIMOTION D4x5-2 DP/PN.

Procedure

1. Click on **Insert SIMOTION device** in the project navigator to open the device selection dialog box.
2. Select SIMOTION D under **Device** and click on a **Device version** e.g. D455-2 DP/PN.

3. Select the **SIMOTION Version**, e.g. **V4.4** and **SINAMICS S120 Integrated.**

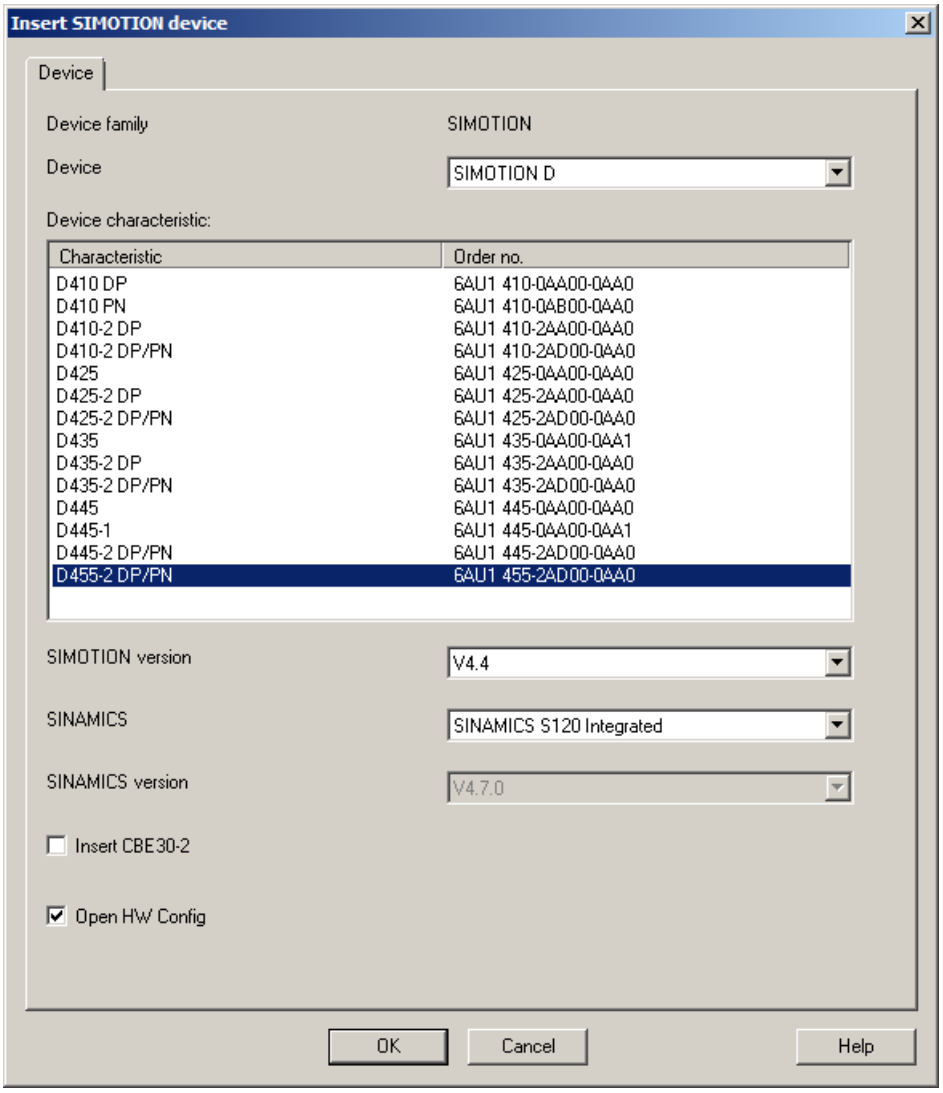

Figure 4-370 Inserting a SIMOTION device

4. Activate the **Open HW Config** check box to add e.g. an option module or an IO system.
5. Click **OK** to confirm.

6. The dialog box for creating a PROFINET subnet will be displayed. Create a new subnet using **New...** and enter the required **IP address** and **subnet mask**. Click **OK** to confirm.

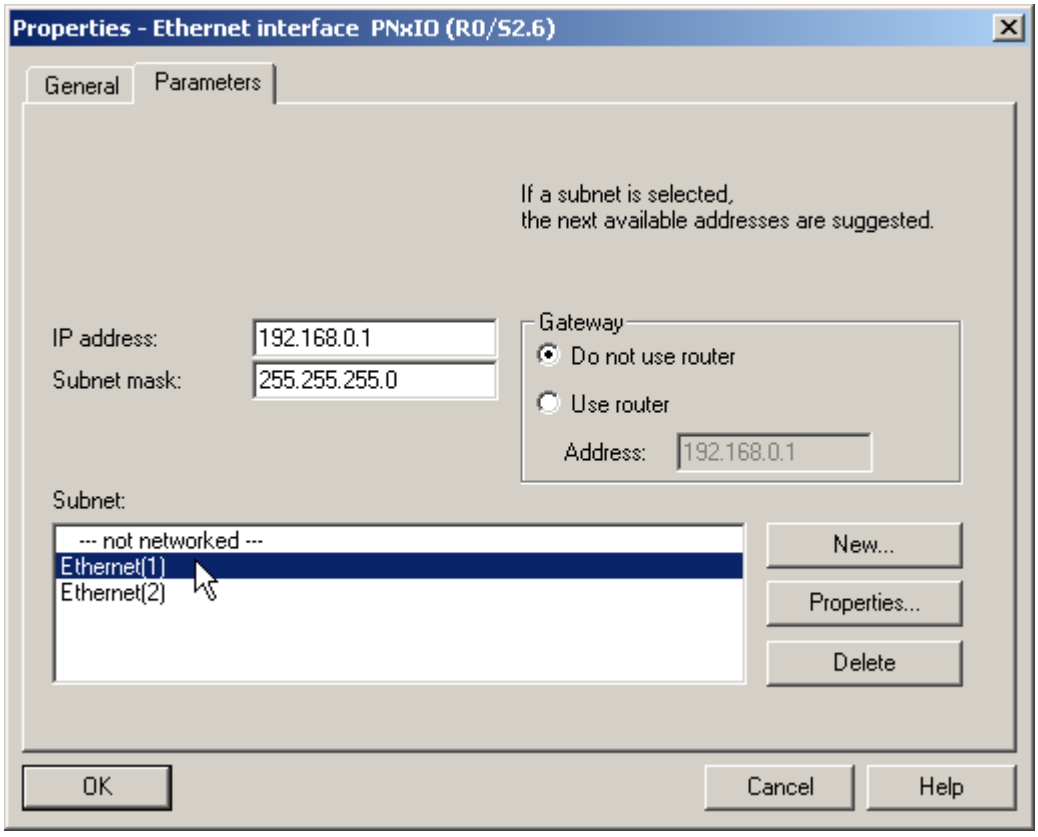

Figure 4-371 Creating a new Ethernet subnet

7. Select the PG/PC interface from the next dialog box and click OK to confirm. The device is inserted, HW Config opens, and the module with the configured PROFINET subnet is displayed.

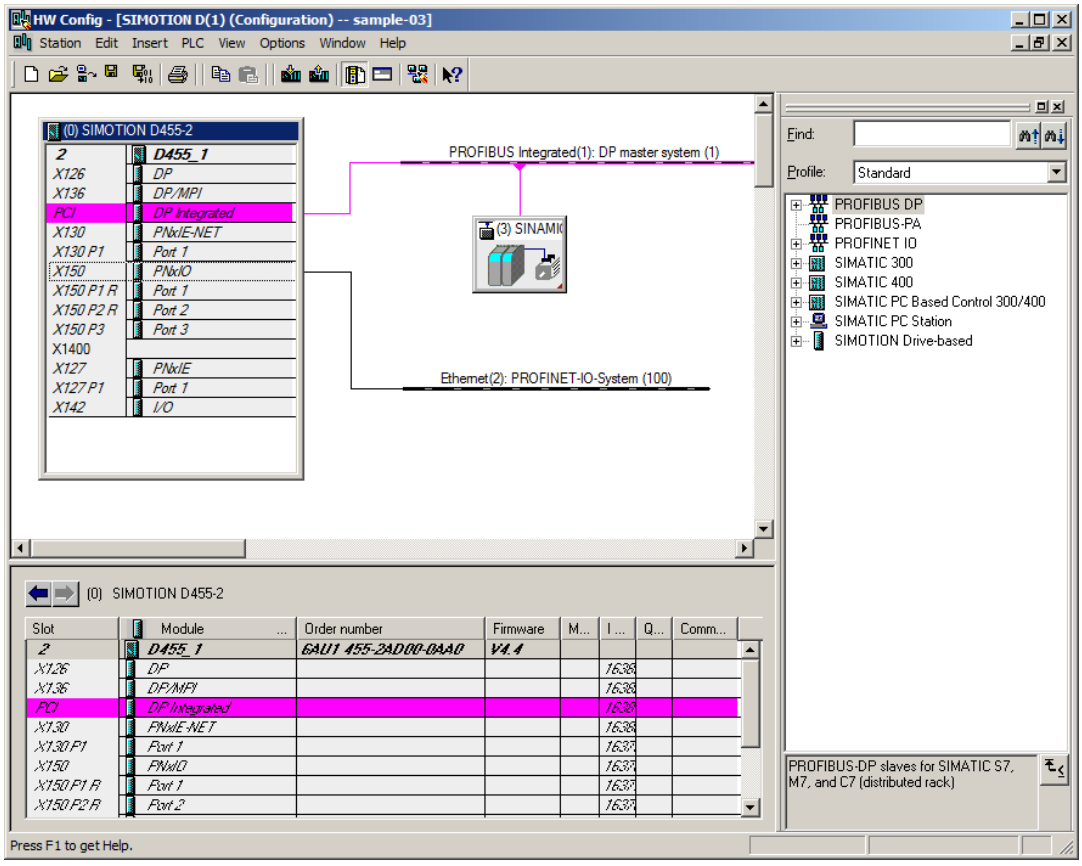

Figure 4-372 SIMOTION D455-2 DP/PN in HW Config

See also

Add and configure PROFINET interface CBE30-2 (Page 2191)

Insert and configure a SIMOTION D4x5-2 incl. CBE30-2

Requirement

You have already created a project and now want to insert a SIMOTION D4x5-2 with option module CBE30-2 for PROFINET.

Procedure:

1. Click on **Insert SIMOTION device** in the project navigator to open the device selection dialog box.
2. Select SIMOTION D under **Device** and click on the **Device version** e.g. D455-2 DP/PN.

3. Select the **SIMOTION Version**, e.g. **V4.4** and activate the option module **CBE30-2**.
   You can also insert the option module CBE30-2 in HW Config at a later point (see Add and configure PROFINET interface CBE30-2 (Page 2191)).

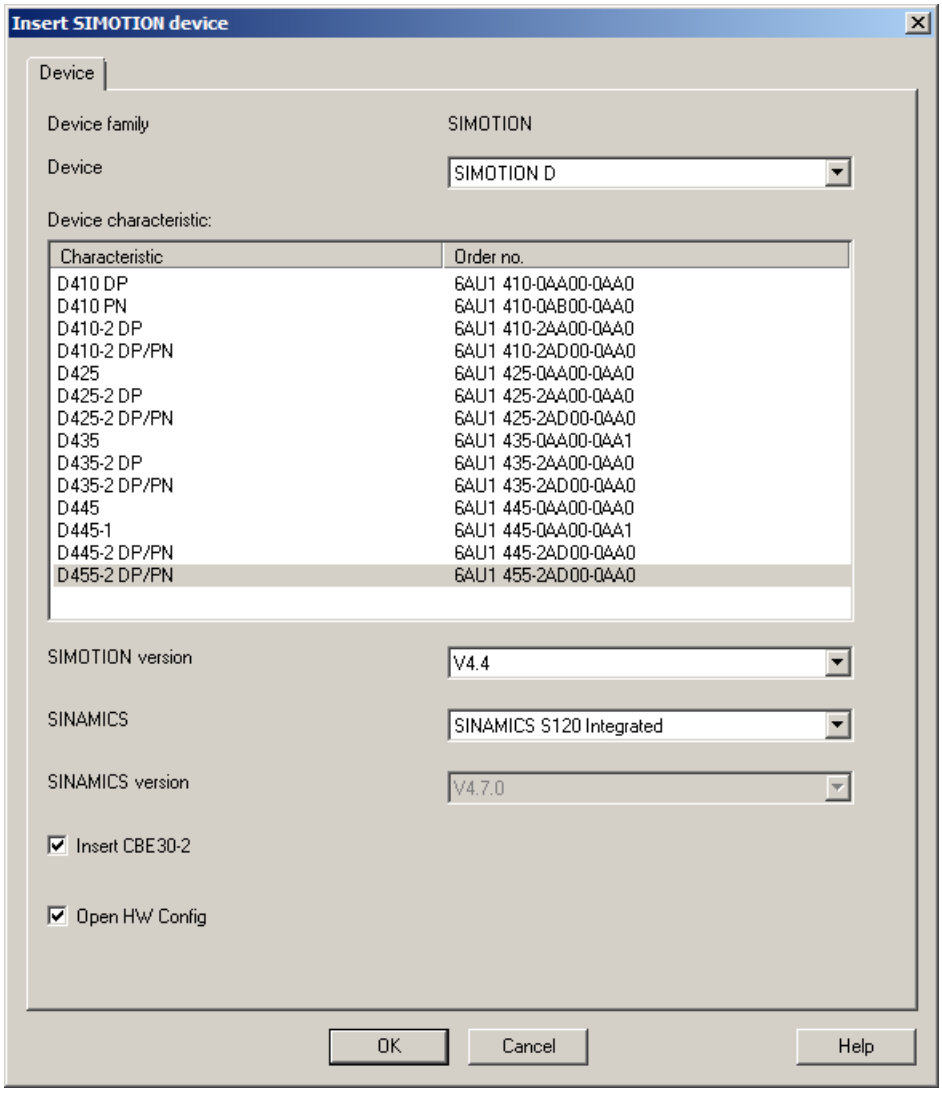

Figure 4-373 Creating a SIMOTION D4x5-2 with CBE30-2 for PROFINET

4. Activate the **Open HW Config** checkbox to insert an IO system, for example.

5. Click **OK** to confirm. The dialog box for creating a PROFINET subnet will be displayed. Create a new subnet using **New...** and enter the required **IP address** and **subnet mask**. Press **OK** to confirm.
6. Select the PG/PC interface from the next dialog box and click **OK** to confirm. The device is inserted, HW Config opens, and the module with the configured PROFINET subnet is displayed.

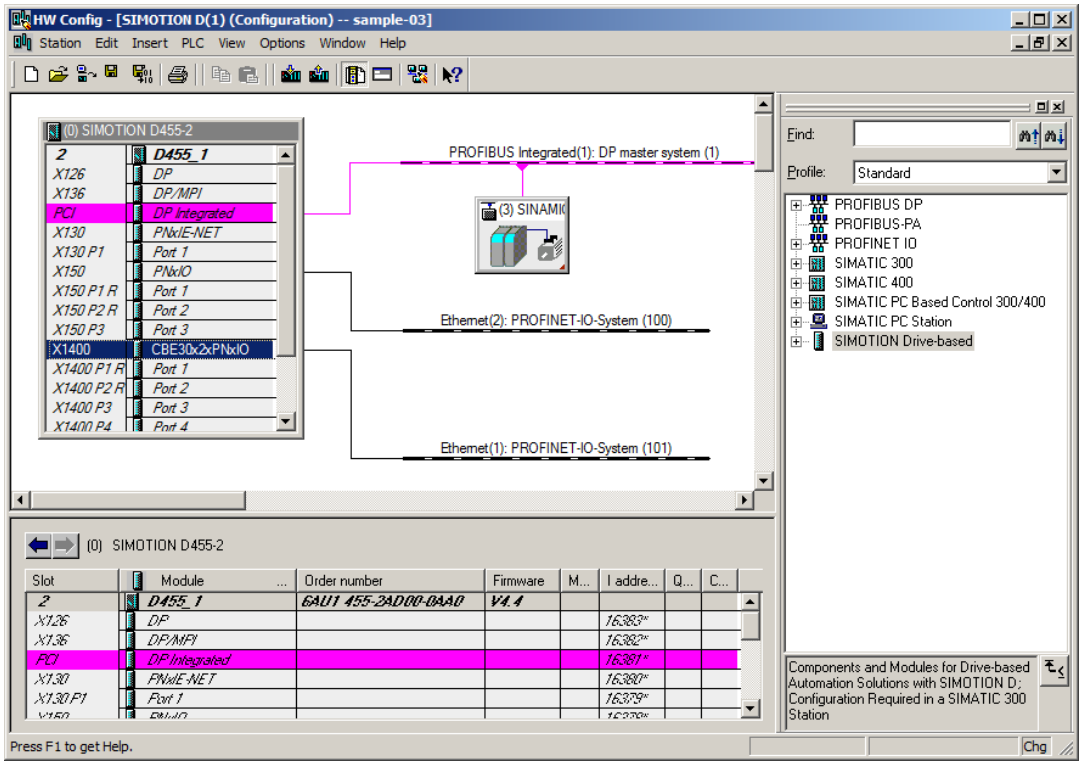

Figure 4-374 SIMOTION D4x5-2 in HW Config

Add and configure PROFINET interface CBE30-2

Requirement

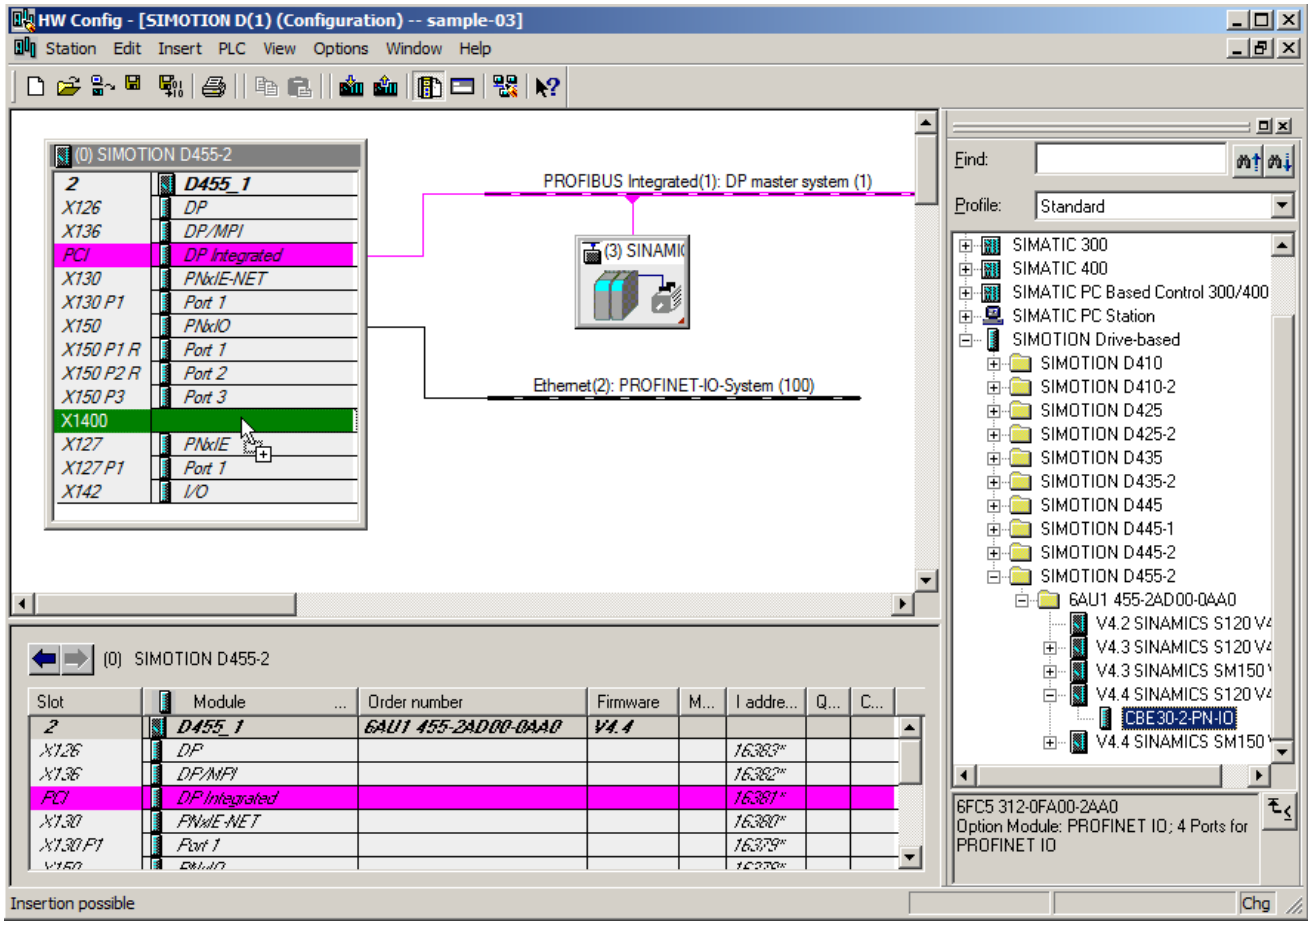
You have already created a project and inserted a SIMOTION D4x5-2 device.

When adding a device in SIMOTION SCOUT, you can add a CBE30-2 as standard. You can also insert the option module in HW Config at a later point.

Procedure

1. In the project navigator, double-click the module (in this case D455-2 DP/PN). HW Config is displayed with the corresponding module.
2. In the hardware catalog, select the appropriate option module under **SIMOTION Drive-based > SIMOTION D4x5-2 > 6AUxx > Vx.x SINAMICSxx > CBE30-x-PN-IO**. Note the CPU type and version.

3. Click PROFINET module CBE30-2-PN. As soon as the appropriate CBE30-PN is selected, the interface **X1400** in the rack turns green.

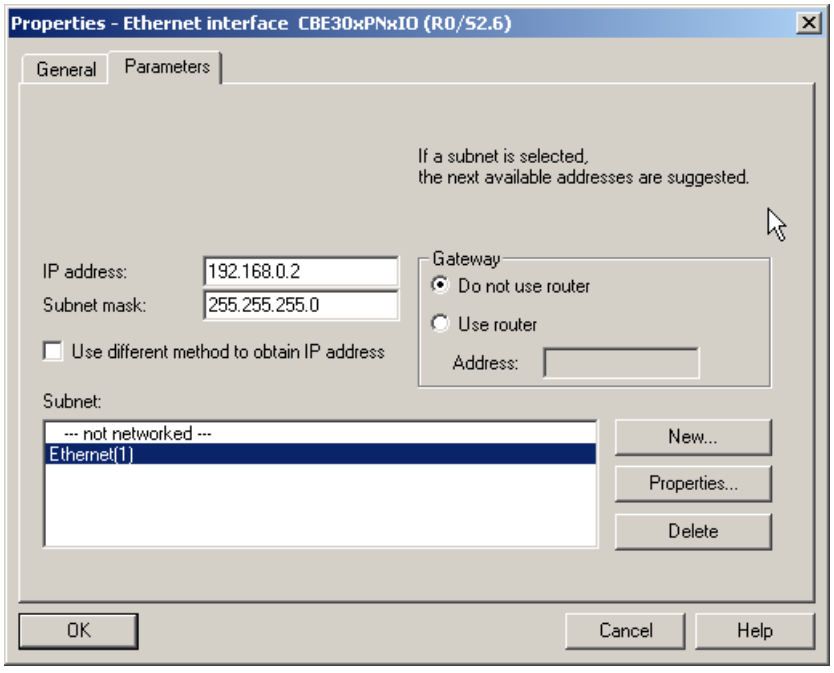


4. Drag the CBE30-2-PN to the corresponding interface of the SIMOTION module (X1400). The **Properties - Ethernet Interface CBE30-2-PN (R0/S2.6)** window opens.
5. Click **New** to create a new subnet. The **Properties – New subnet Industrial Ethernet** dialog box is displayed.

6. Click **OK** to confirm these entries. A new Ethernet subnet will be created, e.g. Ethernet(4).

Note

The IP addresses of the SIMOTION interfaces must be in different address areas.



7. Select the **subnet**.
8. Assign the required **IP address**.
9. Accept the settings by clicking **OK**.

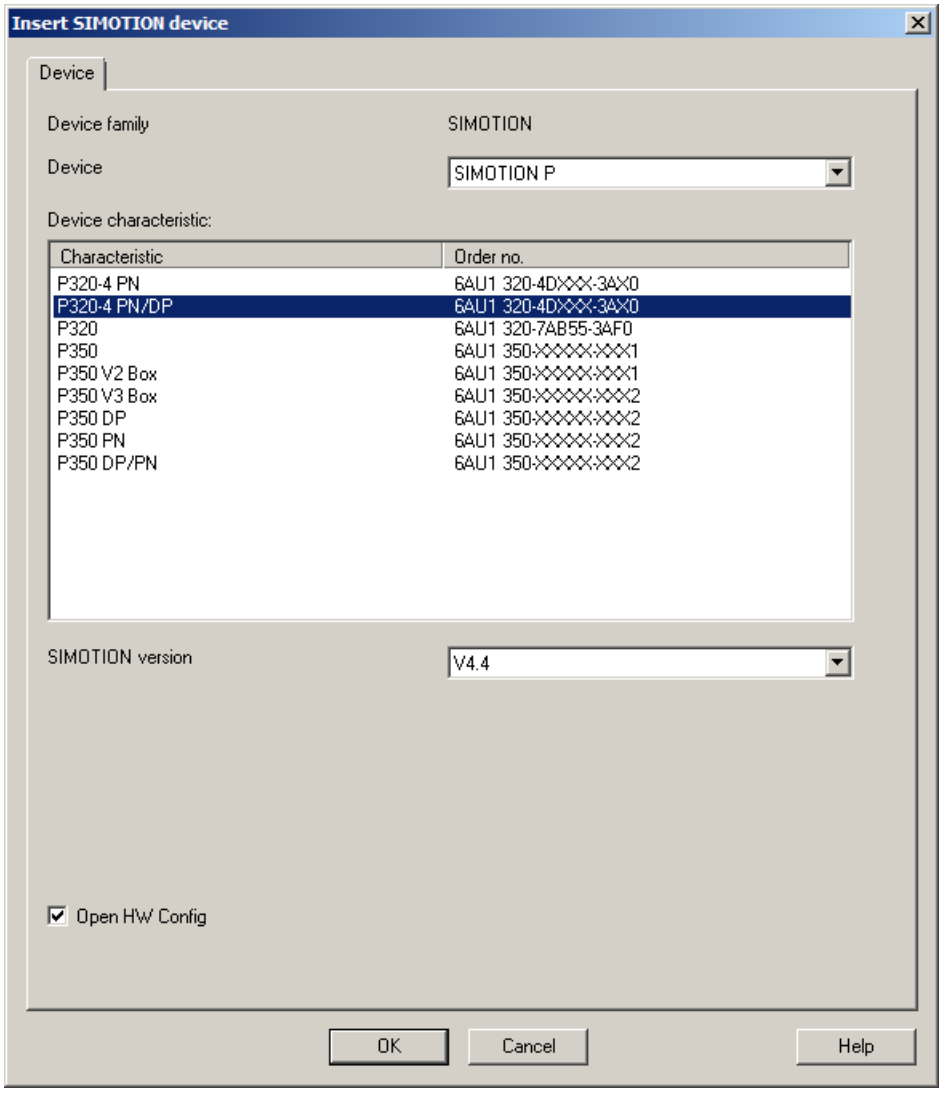
Adding and configuring SIMOTION P

Requirement

You have already created a project and want to insert a SIMOTION P with PROFINET. The procedure for this will be explained using the example of a SIMOTION P320.

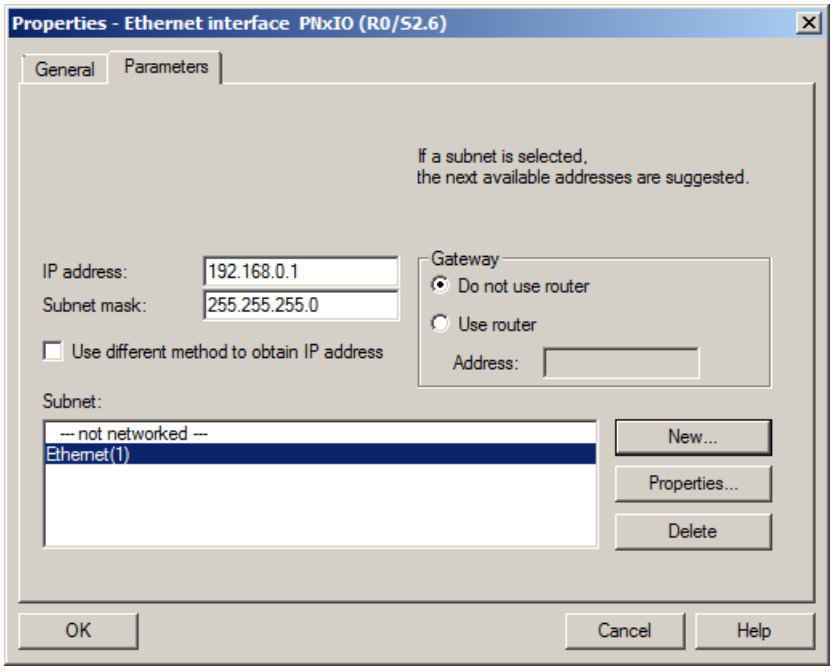
Procedure

1. Click on **Insert SIMOTION device** in the project navigator to open the device selection dialog box.
2. Under **Device**, select SIMOTION P, then click on a **Device version** (e.g. P320-4), and select the **SIMOTION Version**, e.g. V4.4.

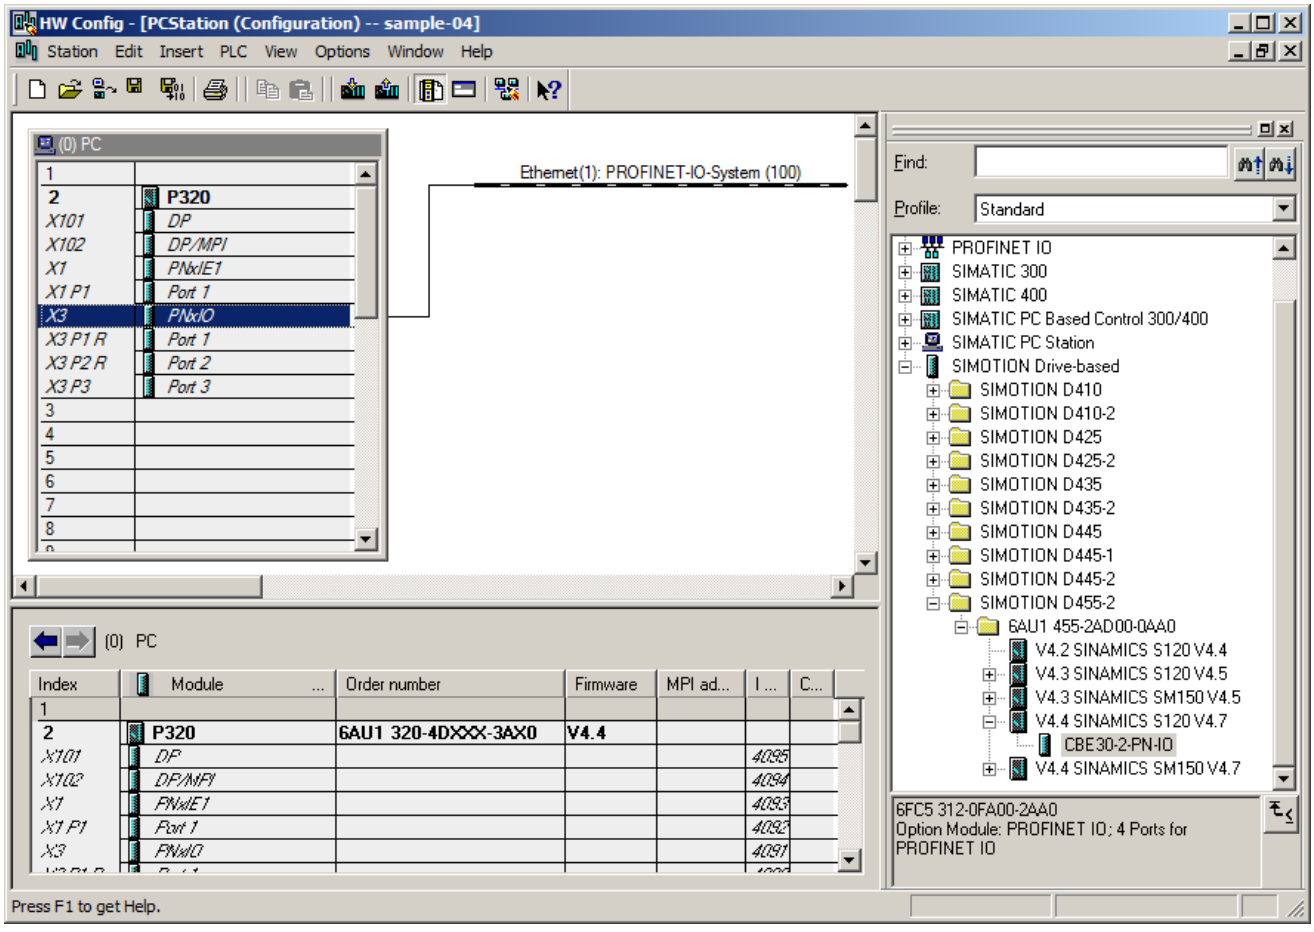


3. Activate the **Open HW Config** checkbox to insert an IO system, for example.
4. Click **OK** to confirm. The dialog box for creating a PROFINET subnet will be displayed.

5. Enter the required **IP address** and the **subnet mask** here. Click **OK** to confirm.



6. Select the PG/PC interface from the next dialog box and click **OK** to confirm.
   The HW Config opens and displays the module with the configured PROFINET subnet.



Adding and configuring SIMOTION C

Requirement

You have already created a project and now want to insert a SIMOTION C with PROFINET. The procedure for this will be explained using the example of a SIMOTION C240 PN.

Procedure

1. Click on **Insert SIMOTION device** in the project navigator to open the device selection dialog box.
2. Under Device, select **SIMOTION C**, then click on a **Device version** (e.g. **C240 PN**), and select the **SIMOTION version**, e.g. V4.4.

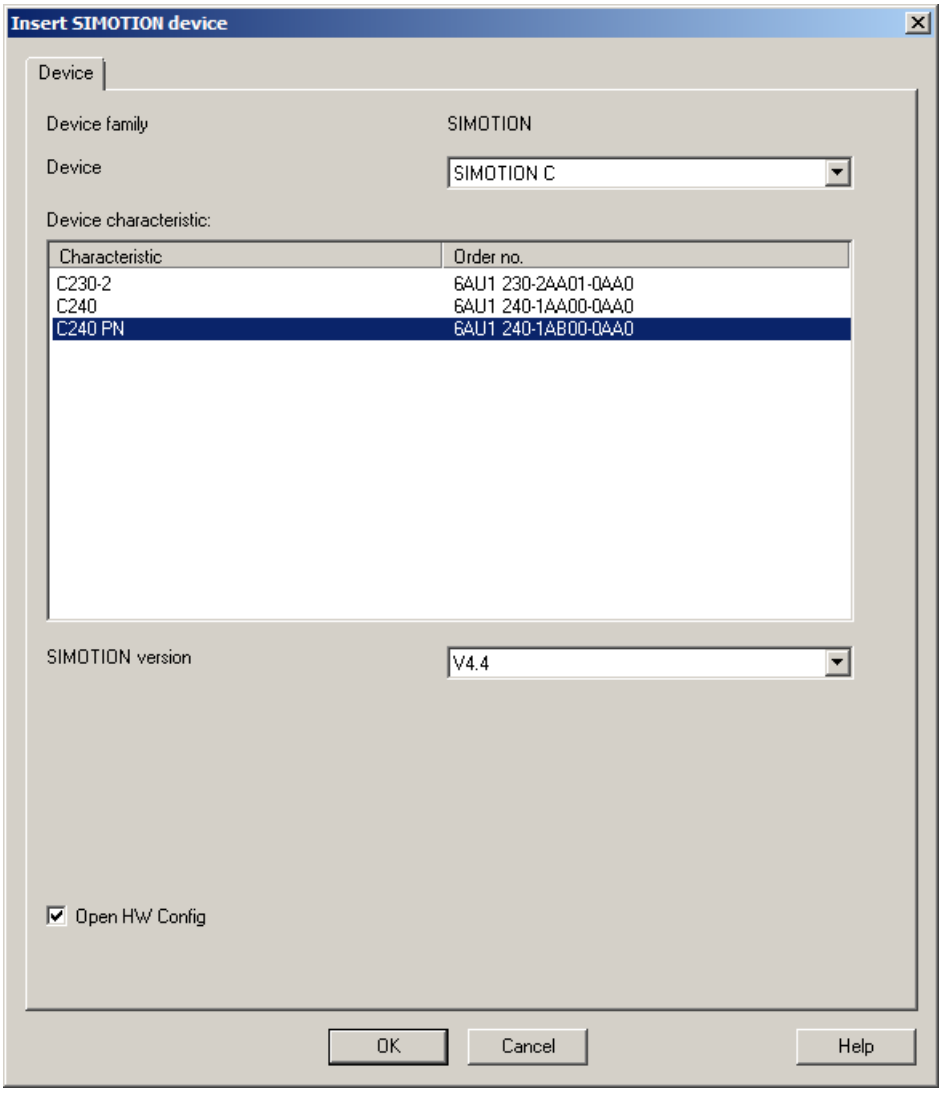


Figure 4-375 Creating a new C240 PN device

3. Activate the **Open HW Config** checkbox to insert an IO system, for example.

4. The dialog box for creating a PROFINET subnet will be displayed. Enter the required **IP address** and the **subnet mask** here. Click **OK** to confirm.

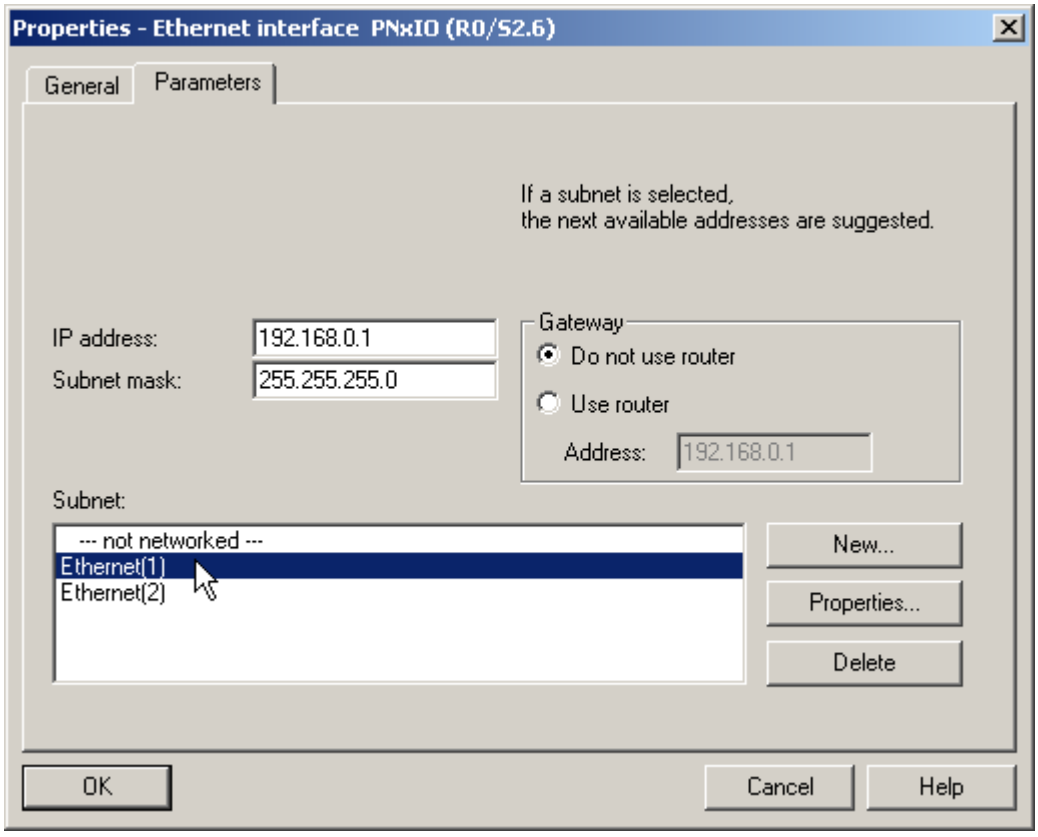

Figure 4-376 Creating a new Ethernet for C240 PN

5. Select the PG/PC interface from the next dialog box and click **OK** to confirm.
The HW Config opens and displays the module with the configured PROFINET subnet.

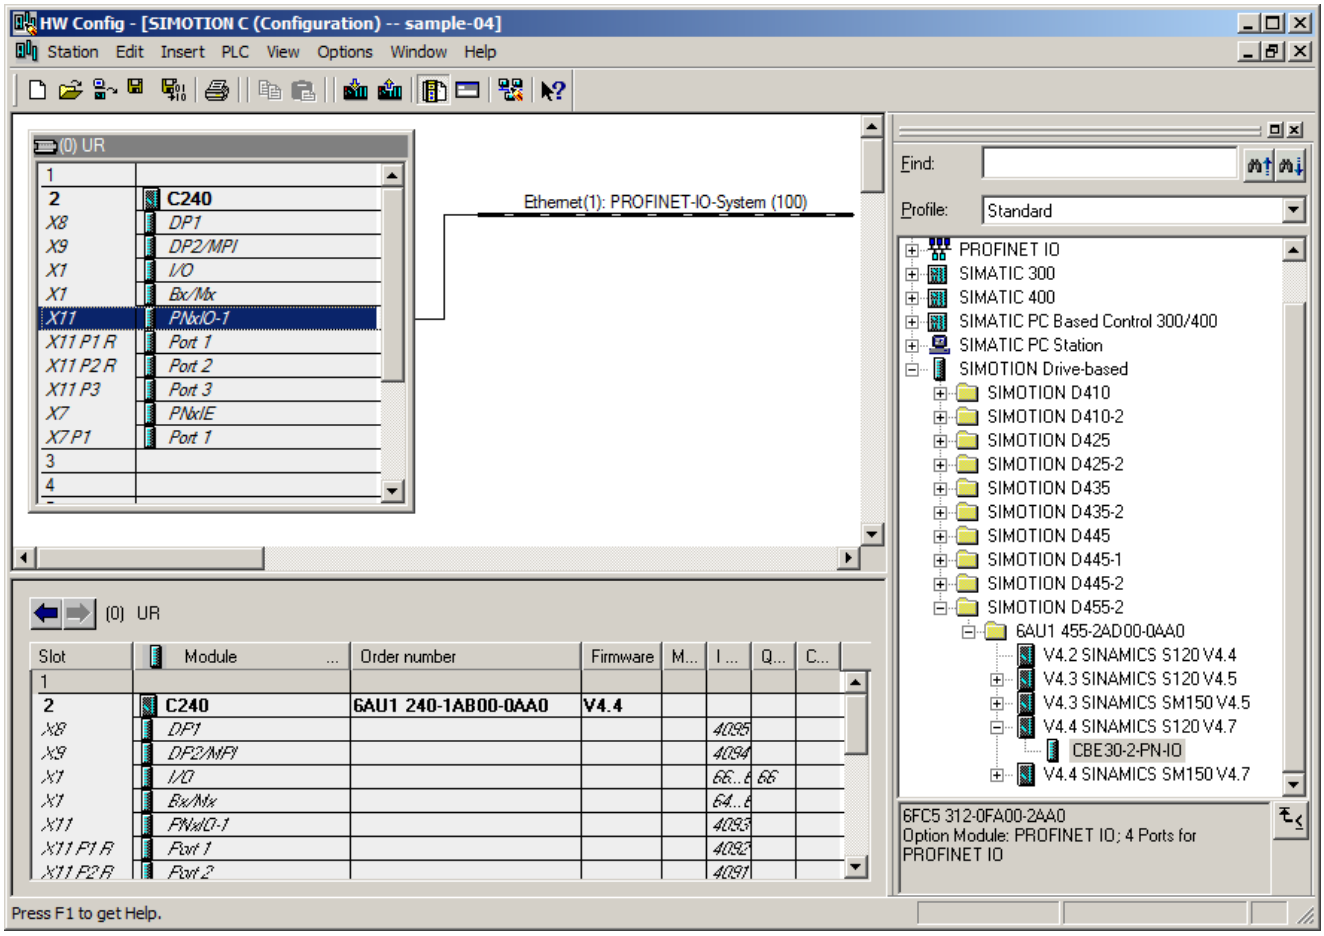

Figure 4-377 HW Config with PROFINET for C240 PN

Creating a sync domain

A sync domain is a group of PROFINET devices synchronized to a common cycle clock. One device has the role of the sync master (clock generator), all other devices have the role of sync slave.

Note

All devices that exchange data via PROFINET IRT must belong to a single sync domain and be directly connected to one another. The connection may not be interrupted by devices that do not support PROFINET IRT, because otherwise the synchronization information cannot be transferred.

Procedure

1. In HW Config, open the station with the PROFINET devices to be involved in IRT communication and select, for example, the PROFINET interface **PNxIO** in the case of a SIMOTION D455-2 DP/PN.
2. Select the **Edit > PROFINET IO > Domain Management** menu command. A dialog tab with the list of all the devices opens. A default sync domain is created and the devices are already assigned.
3. Select the station in the upper field and in the lower field double-click the device that is to be configured as the Sync-Master, e.g. SIMOTION D. This opens the Properties dialog box for the device.

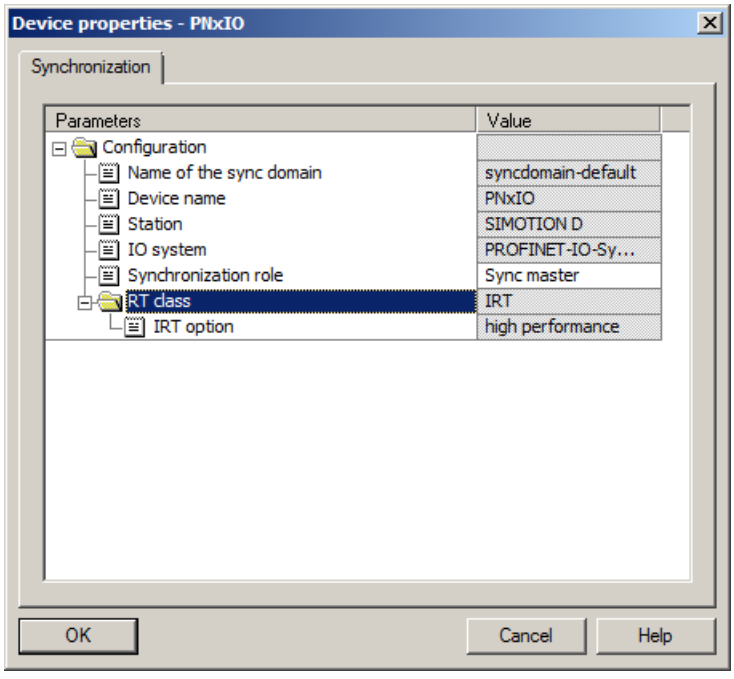

Figure 4-378 Selecting synchronization

4. Set the synchronization type to **Sync-Master**. IRT High Performance is the standard setting on SIMOTION controllers.
5. Confirm the settings by clicking **OK**.
6. Then, select all devices which are to be configured as sync slaves (keep the Ctrl key depressed and select the devices one after the other).
7. Then, click on the **Properties device** button.
8. Set the synchronization type to **Sync-Slave** in the dialog box.
9. Confirm the settings by clicking **OK**.

Note

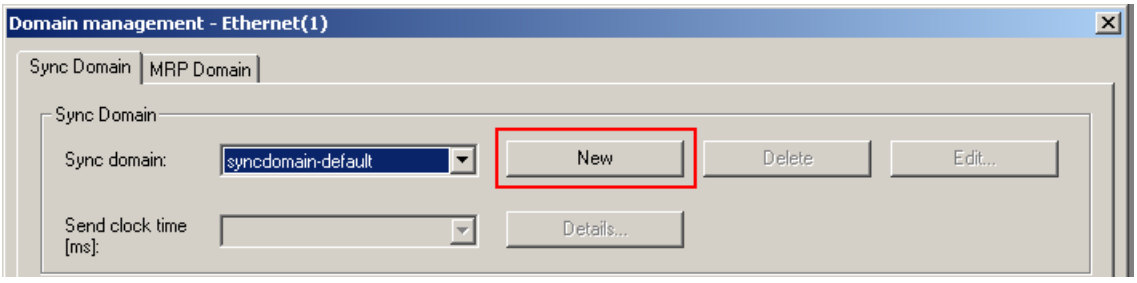
Any devices for which **not synchronized** is selected will not be involved in IRT communication, but will automatically take part in RT communication.

Creating a sync domain and changing the name of a sync domain

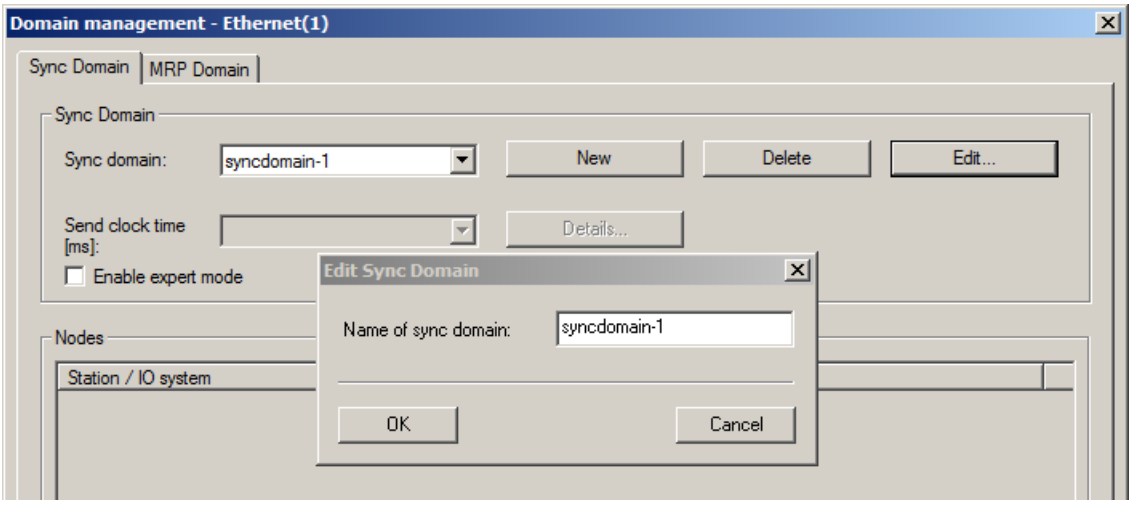
If you work with two PROFINET IO interfaces, they must be in different sync domains. The two sync domains must not have the same name.

To create a new sync domain and change the name of a sync domain, proceed as follows:

1. Open HW Config and right-click on a device of the sync domain.
2. In the shortcut menu, select **PROFINET IO Domain Management**.
   The dialog **Domain Management - PN-xxxx** opens.

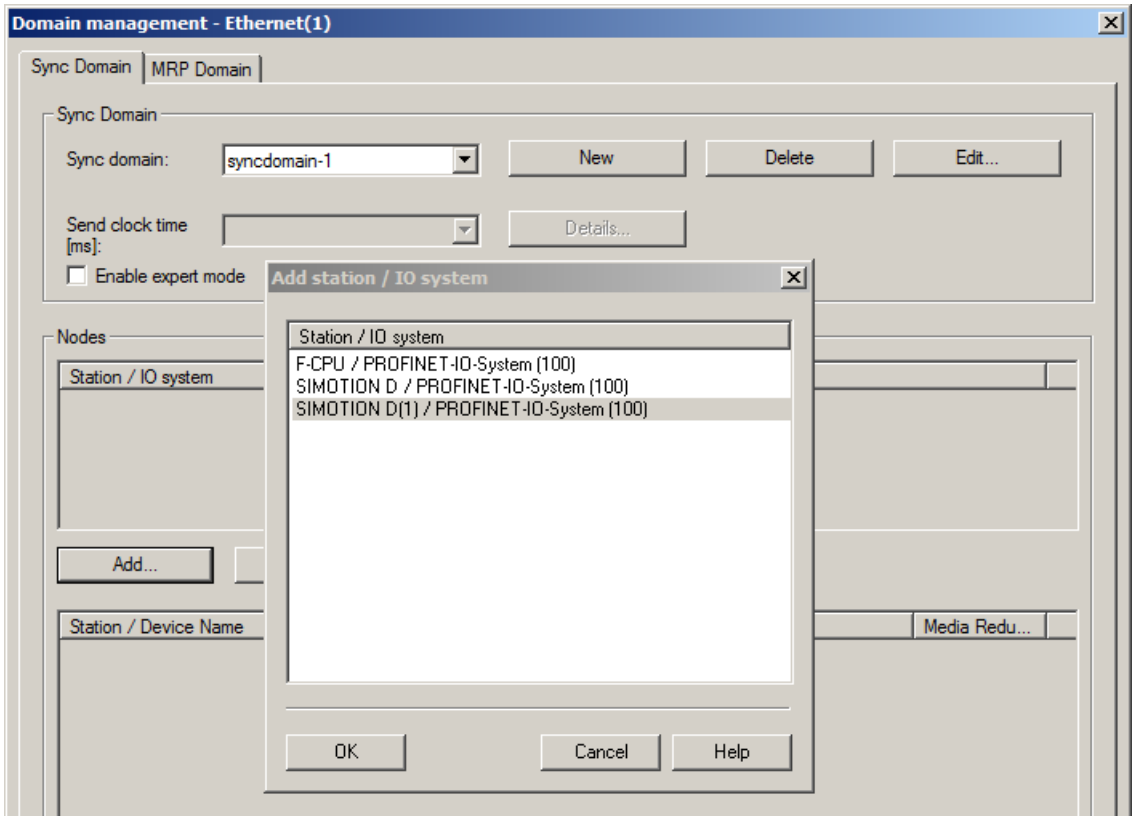


3. Click **New** to create a new sync domain.
4. Select the newly created sync domain in the **Sync Domain** drop-down list box.
5. Click the **Edit** button to open the **Edit Sync Domain** dialog box.



6. Enter a new name for the sync domain and click on **OK**.
   The name of the sync domain is changed.

7. Click on **Add** to add a station or an I/O system to the sync domain.



8. Click **OK** to add the station / IO system.

Defining send clock and refresh times

PROFINET RT and IRT are forms of cyclic communication; the basic clock is the send clock. The update time is a multiple (2^n) of the send clock and the devices are supplied with data in this cycle clock. Individual update times can be set for each device.

Note

With IRT High Performance, the devices are supplied with data during each sending cycle (sending cycle = update time). However, the data is only evaluated every nth cycle in the SIMOTION Servo cycle clock (Servo_fast runs scaled-down to the servo cycle clock) or SINAMICS_Integrated.

As far as SINAMICS_Integrated is concerned, the controller can be used to define an application cycle in such a way that it is only supplied with new data every n cycles.

Configuring a send clock for PROFINET IRT

1. In HW Config, open the **Domain Management** dialog box.

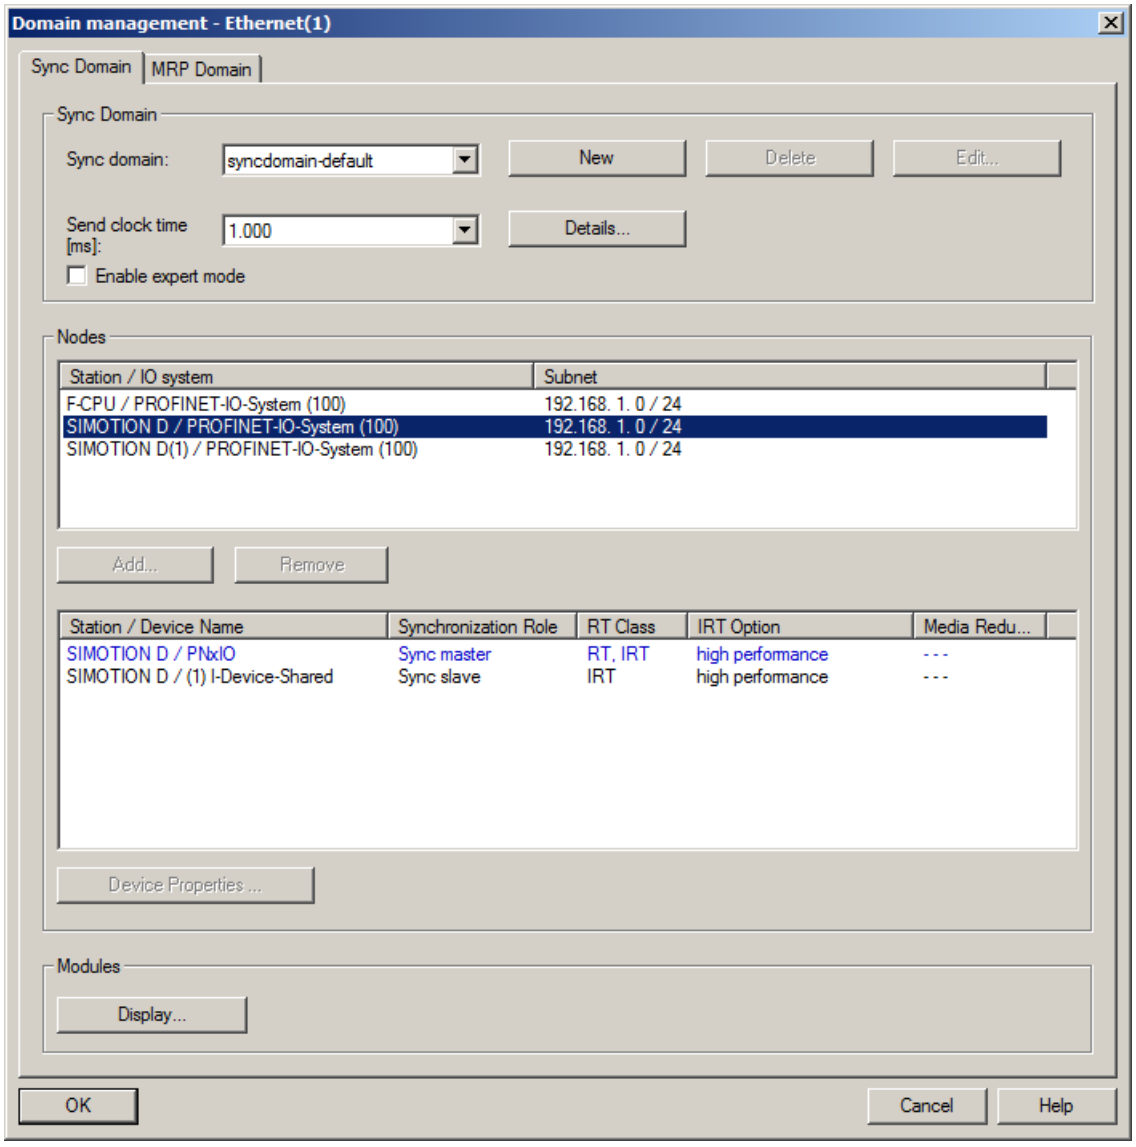


Figure 4-379 Domain Management

2. Select an appropriate send clock for the process. The transmission cycle clock is the smallest possible transmission interval. The send clock is preset to 1 ms.

Note

Communication should be no faster than required, irrespective of what the maximum communication speed may be. This will reduce the bandwidth requirement and the relieve the load that the devices need to support.

Configuring a send clock for PROFINET RT

1. Double-click on the PN interface. The **Properties** dialog box opens.
2. Switch to the PROFINET tab and select a **send clock**. The send clock can only be set if IO controllers and IO devices are not synchronized.

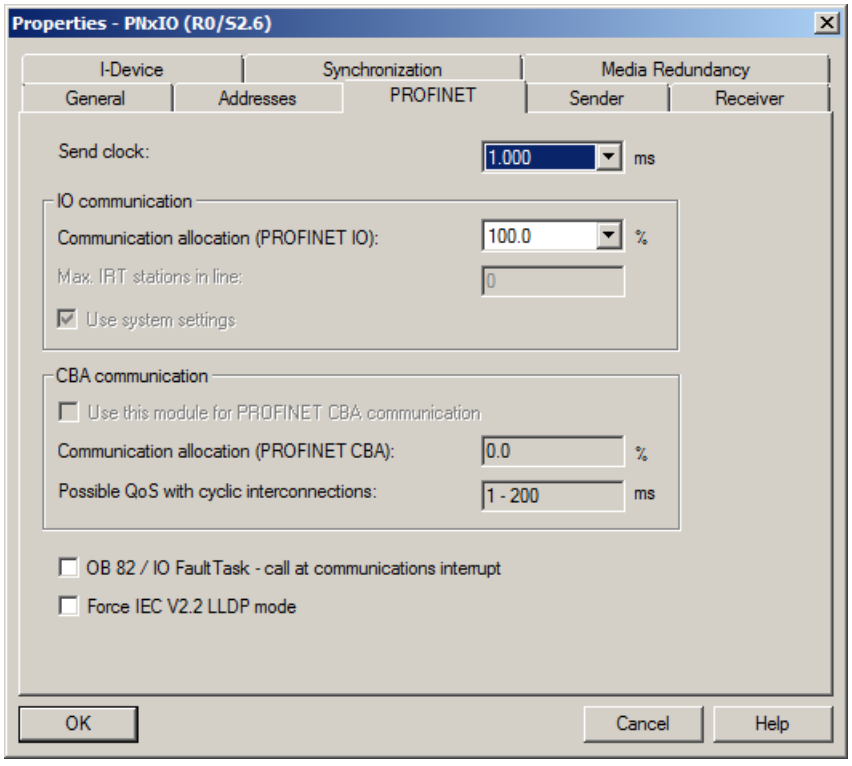

Figure 4-380 Configuring a send clock for PROFINET RT

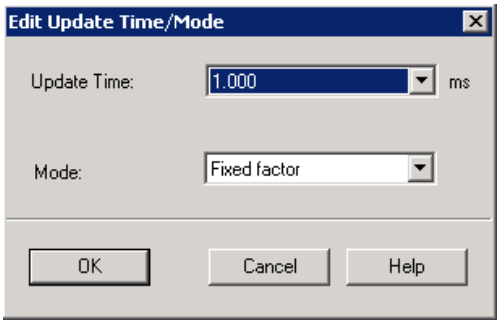
Defining the update times

The update times for the data exchange of the IO devices is set in the **Properties PROFINET IO System** dialog box.

1. Click the path for the PROFINET IO system in HW Config and select **Object properties** from the context menu. The dialog is displayed.
2. Switch to the **Update time** tab and highlight the respective IO device for which you want to set the update time.

3. Click **Edit**. You can select the refresh time in the **Edit refresh time** dialog.



4. Click **OK** to confirm.

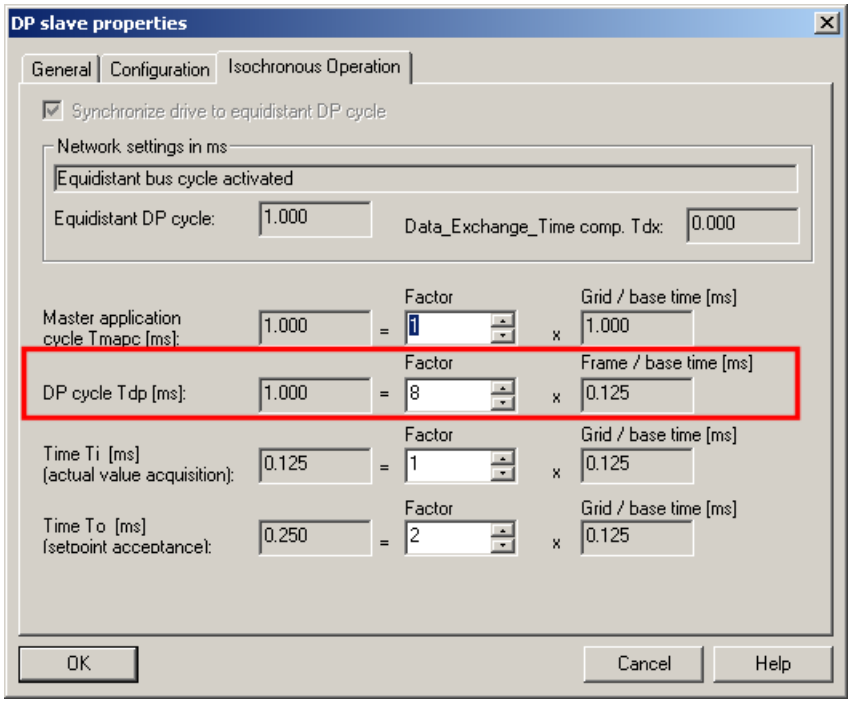
Ratio of PROFINET IRT send clock and DP cycle on SINAMICS_Integrated (SIMOTION D)

If a SINAMICS drive is being operated on a SIMOTION D via PROFINET IO IRT High Performance, the DP cycle of the SINAMICS_Integrated must be the same as the position control cycle clock. The DP cycle is set to 3 ms by default. In most cases, this will not be the same as the servo cycle clock selected for PROFINET applications. If the DP cycle does not correspond to the position control cycle clock, an error message is generated in SIMOTION SCOUT during the consistency check.

You set the DP cycle in the DP slave properties:

1. Double-click SINAMICS_Integrated in HW Config. The **DP slave properties** window appears.
2. Switch to the **Isochronous Operation** tab and activate the "Synchronize drive to equidistant DP cycle" checkbox.

3. Set the factor for **DP cycle Tdp**. The DP cycle must be the same as the position control cycle clock. For example, if the position control cycle clock is 1 ms, you will need to enter a factor of 8 (8 x [base time of 0.125 ms] = 1 ms).



4. Click **OK** to confirm.

When IO devices are operated on PROFINET the position control cycle clock must always correspond to the PROFIBUS cycle clock. The position control cycle clock and the PROFIBUS cycle clock can be scaled to the PROFINET cycle clock.

Example:

PROFINET send clock = 0.5 ms

PROFIBUS cycle clock = position control cycle clock = 1 ms

The PROFIBUS cycle clock can be operated relative to the PROFINET cycle clock at a ratio of 1:1 to 1:64 (max. 8 ms).

Servo_fast, scaling down of cycle clocks to the servo at the PROFINET interface

Cycle clock scaling to the Servo using Servo_fast

The second position control cycle clock enables you to operate two bus systems in different application cycle clocks. An assigned servo cycle clock and IPO cycle clock are available for each of the two application cycle clocks. This enables you to divide your application into slow and fast sections (Servo_fast and IPO_fast).

- The I/O on the fast bus system are used isochronously in the fast Servo_fast/IPO_fast.
- The I/O on the slow bus system are used isochronously in the slow Servo/IPO/IPO_2.
- Servo_fast is only intended to be used with fast IOs and drives.

Options available for isochronous use

For isochronous use, the application cycle is set in HW Config on the I/O module:

- The MAPC (Master Application Cycle) is set for DP slave. Only MAPC=1 is supported if you are also using PROFINET IO. All PROFIBUS devices run in the slow position control cycle clock. The master application cycle describes the reduction ratio between the DP cycle and the cycle of a higher-level controller, e.g. the servo clock of a SIMOTION controller.
- The CACF (Controller Application Cycle Factor) is set for I/O devices. In V4.2 or higher you can also select the position control cycle clock (Servo_fast) on I/O devices. If two servos are configured, only CACF = 1 is still allowed as a setting; i.e. send clock onboard PN interface = Servo_fast cycle clock, send clock CBE30-2 = servo clock. The servo must be scaled down to the Servo_fast at a factor of 2, 4, 8, 16, or 32 (as of SIMOTION V4.4).

The following settings are possible:

Product version	Property	Application cycle of the devices on		
		PROFINET IO Integrated (X150)	PROFINET IO (CBE30-2)	PROFIBUS DP
Before V4.2	1 position control cycle clock	--	--	Servo
Additionally for V4.2 or higher	2 servo clocks	Servo_fast	--	Servo
Additionally for V4.3 and higher	2 servo clocks	Servo_fast	Servo	Servo

Configuring the Servo_fast using the example of a D455-2 DP/PN

A precondition is that a D455-2 DP/PN must be configured with PROFINET IO system and PROFIBUS DP. In V4.3 or higher, you can also use a D455-2 DP/PN with two PN interfaces (onboard PN interface and CBE30-2).

1. In HW Config, select the SIMOTION device module, e.g. D455, and choose **Edit > Object properties** in the menu.
2. Activate the checkbox **Use Servo_fast/IPO_fast** on the **Isochronous Tasks** tab. Therefore the used PROFINET IO system is operated isochronously to the Servo_fast.

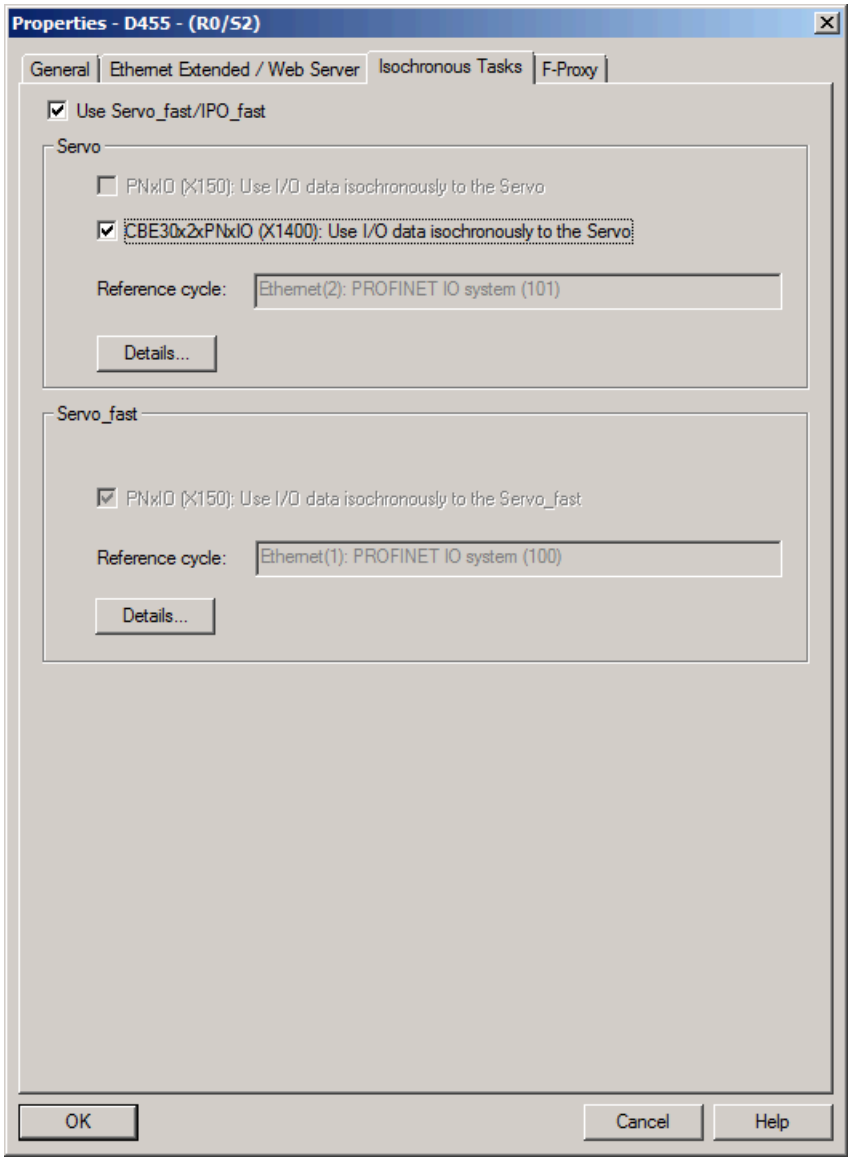


Figure 4-381 Configuring Servo_fast in HW Config

3. Click on the **Details...** button next to the **Servo** field.
4. On the **Isochronous operation** tab of the PROFIBUS DP, enter a factor for the DP cycle Tdp. The servo clock and DP cycle must always be configured the same when using PROFINET.

5. Confirm by selecting **OK** and save and compile the project in HW Config.
6. Switch to SIMOTION SCOUT and select **Set system cycle clocks** in the context menu of the SIMOTION CPU. This displays the values for the servo and for Servo_fast.

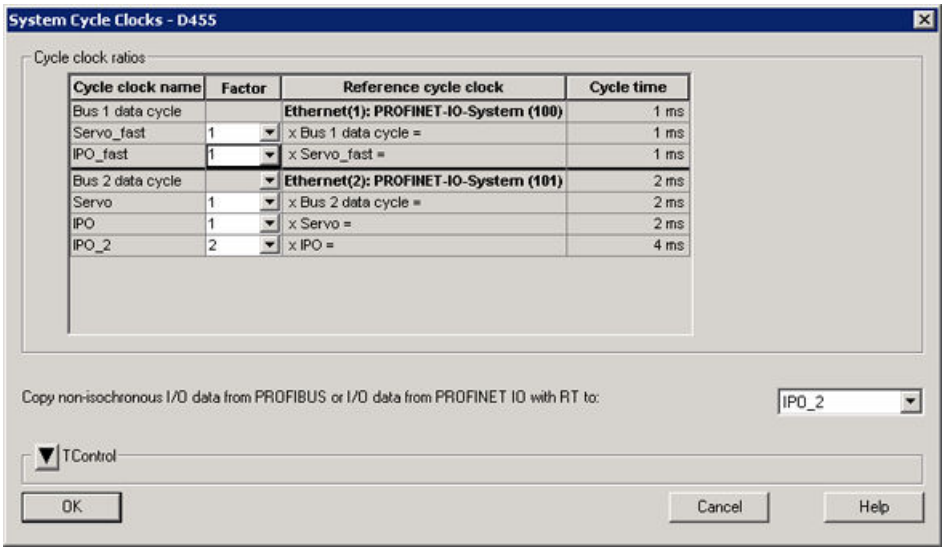

Figure 4-382 Servo and Servo_fast system cycle clocks

Note

For further information, refer to the *SIMOTION SCOUT Basic Functions* Function Manual.

Configuring a topology

Topology

Introduction

With IRT High Performance, the topology must be configured and settings made to determine which device is to be connected via which port to which other devices.

There are two options for defining the properties of the cables between the ports of the switches:

Using the topology editor (Page 2211)

Using the object properties (Page 2212)

Topology editor (graphical view)

Procedure

With the topology editor you have an overview of all ports in the project and can interconnect them centrally.

The topology editor is started with the **Edit > PROFINET IO > Topology** menu command in HW Config or NetPro (PROFINET device must be selected).

The topology editor offers the user two options for displaying the topology graphically (STEP7 V5.4 SP2 or higher) or in a tabular format. The graphic view is more suitable for situations involving interconnection.

Description

In the topology editor, you can:

- Interconnect ports
- Modify the properties of the interconnection
- Add passive components
- Arrange for an offline/online comparison to be displayed in online mode

Procedure

1. In SCOUT, double-click on the SIMOTION module in order to access HW Config.
2. Select the PROFINET module, e.g. PNxIO in the case of a D445-2 DP/PN.
3. Perform **Edit > PROFINET IO > Topology**. The topology editor opens.
4. Click **Graphical view** to bring the tab into the foreground.

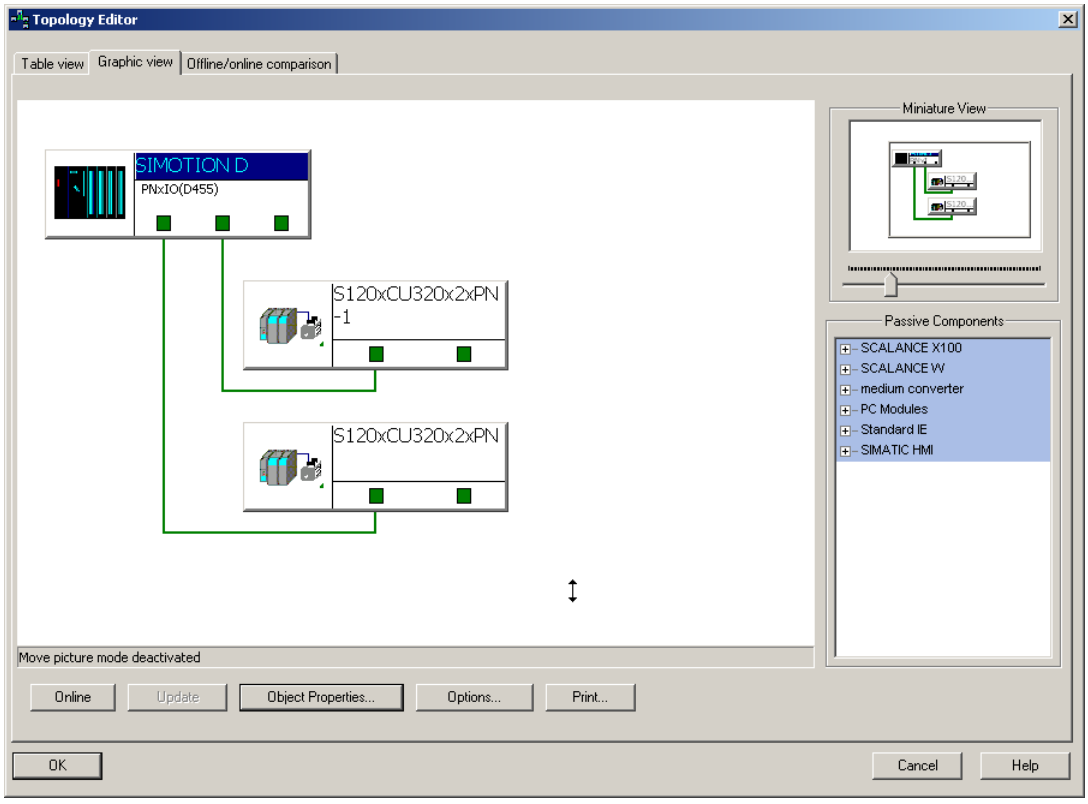

Figure 4-383 Topology editor (graphical view)

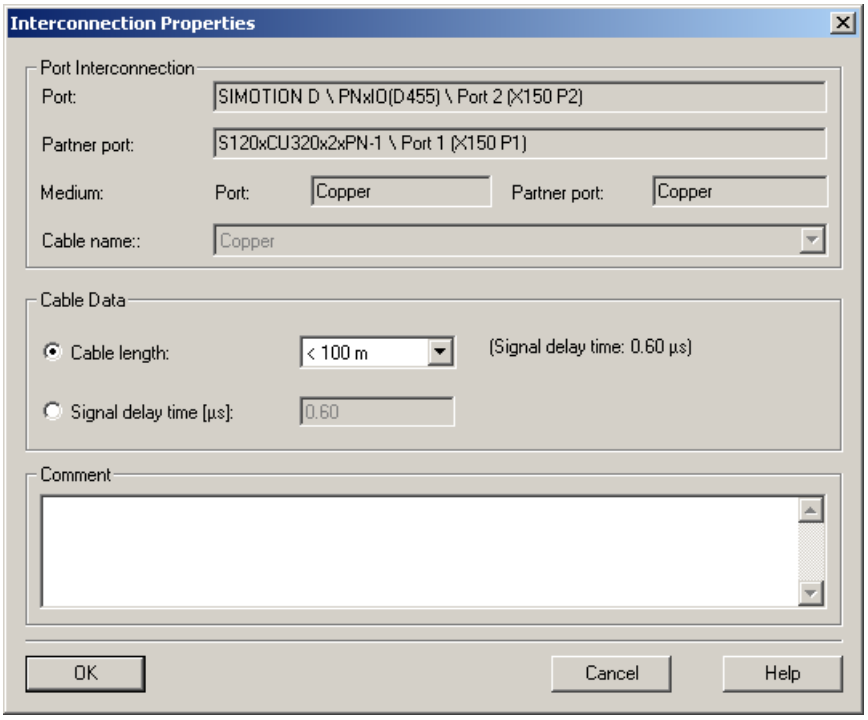
5. Establish connections between ports by pressing and holding down the left mouse button and drawing a line between the two ports to be connected. The **Interconnection Properties** window opens.
6. The port interconnection is displayed: You can configure the cable data: A cable length of <100 m is set as standard. This should not be modified under normal circumstances. Alternatively, you have the option of specifying a signal propagation delay; e.g. the latency time when using slip rings.



7. Click **OK** to confirm.

Offline/online comparison

When you switch to online mode, the topology in the editor is compared with the actual topology. Any components which are not recognized are highlighted by a question mark, while connections and components in RUN are highlighted in green.

Interconnecting ports via the topology editor (table view)

Procedure

Ports can be interconnected in the **Tabular view** of the topology editor.

The topology editor is started with the **Edit > PROFINET IO > Topology** menu command in HW Config or NetPro (PROFINET device must be selected).

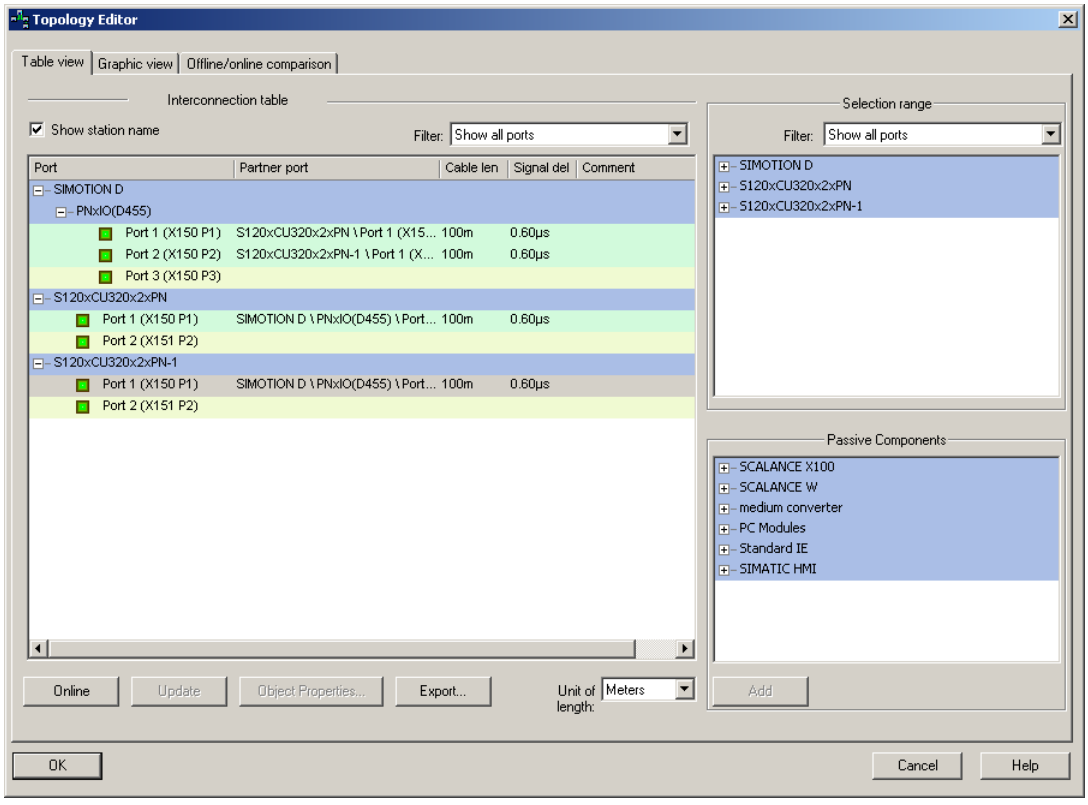


Figure 4-384 Topology editor

All configured PROFINET IO devices with their ports are listed in the interconnection table on the left-hand side. You can use the Filter dialog to select whether all ports, only the ports that have not yet been interconnected or only the ports that have already been interconnected are to be displayed.

Interconnecting ports in the tabular overview

1. To interconnect ports of different devices, select the port of a device that you want to interconnect in the right-hand field.
2. Drag this port to the desired port of a device in the interconnection table. The "Interconnection Properties" dialog opens.
3. Configure the cable data. A cable length of < 100 m should be set by default.
4. Confirm your entries with **OK**.

Interconnecting ports via object properties

Alternatively, a partner port can be selected via the properties of a port. Thus, the cable between two ports is defined and the properties of this cable can be edited.

Procedure

1. The dialog box is opened in HW Config by selecting a port on the module and selecting the **Edit > Object properties** menu command or double-clicking on the port.

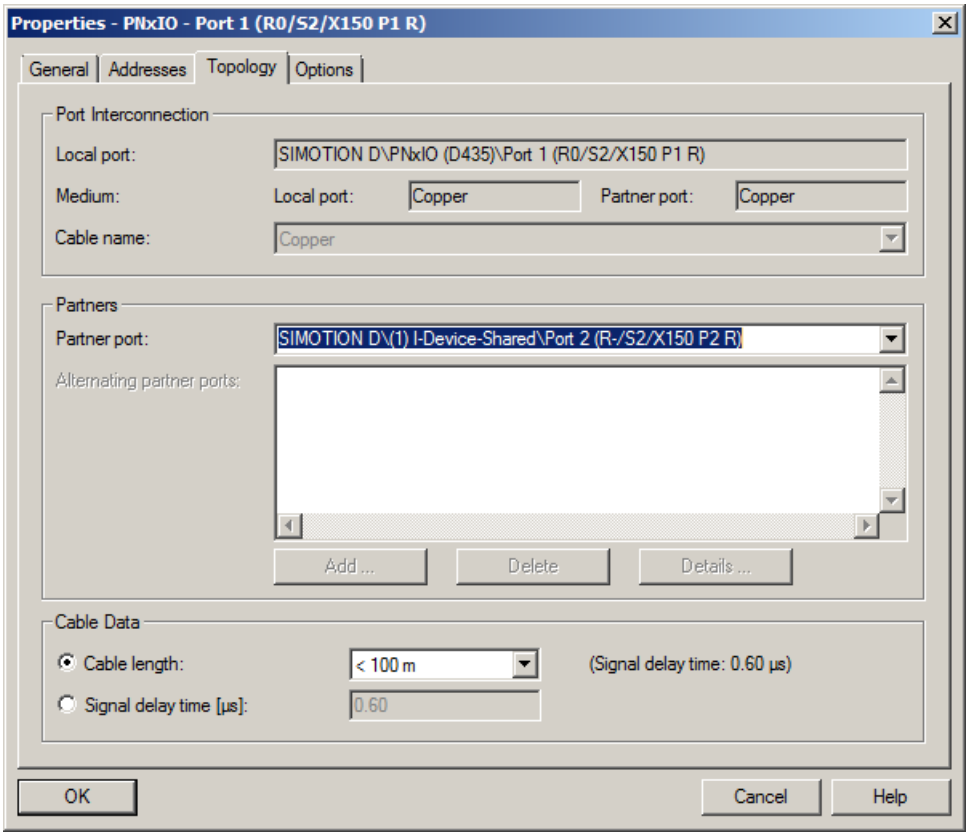

Figure 4-385 Object properties Topology

2. Then, select the **Topology** tab in the **Properties port...** dialog.
3. In the **Partner port** list, select the port with which you want to interconnect the currently selected port.
4. Confirm your entries with **OK**.

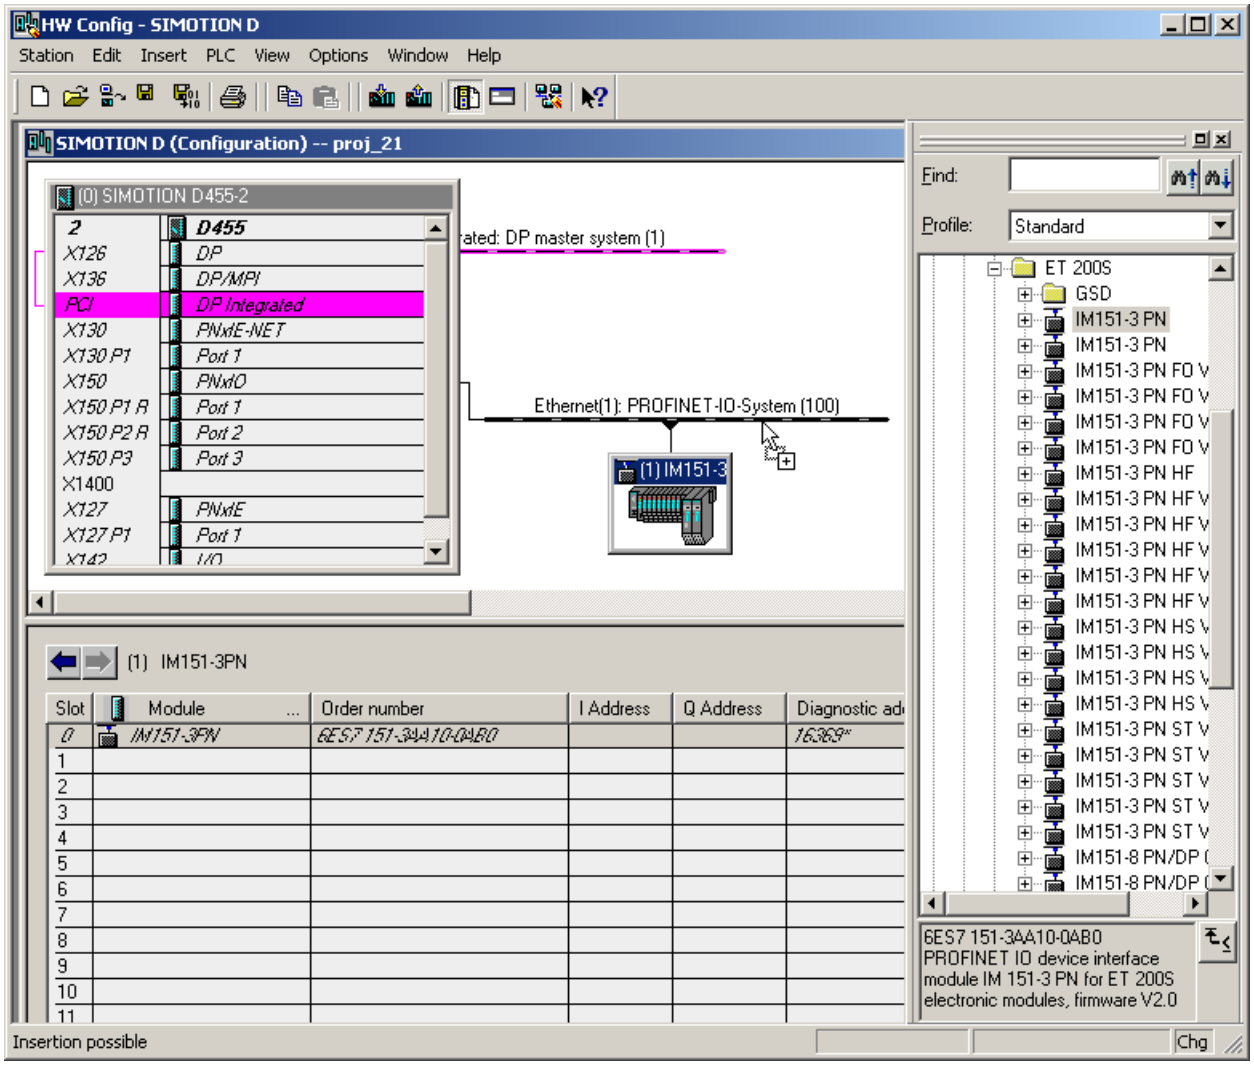
Creating an IO device

Requirement

You have already created a PROFINET IO system and configured a PROFINET IO module, e.g. SIMOTION D455-2 PN (see Inserting and configuring SIMOTION D4x5-2 DP/PN/D410 PN/D410-2 DP/PN (Page 2186)).

Procedure for PROFINET IO devices using the hardware catalog

1. Double-click the corresponding module in SIMOTION SCOUT to open HW Config.
2. Under PROFINET IO in the hardware catalog, select the module you wish to connect to the PROFINET IO system.
3. Drag the module to the path of the PROFINET IO system. The IO device is inserted.



4. Save and compile the settings in HW Config.

Procedure for third-party manufacturer PROFINET IO devices

1. Double-click the corresponding module to open HW Config.
2. Select the **Options > Install GSD files** menu command.
3. Select the GSD file to be installed in the **Install GSD Files** dialog box.
4. Click the **Install** button.
5. Close the dialog box by clicking the **Close** button.

6. Under PROFINET IO in the hardware catalog, select the module you wish to connect to the PROFINET IO system.
7. Drag the module to the path of the PROFINET IO system. The IO device is inserted.
8. Save and compile the settings in HW Config.

Inserting and configuring the SINAMICS S120

Requirement

You have inserted a SIMOTION D4x5-2 with integrated PROFINET interface in your project, a PROFINET IO subnet has already been created and the Sync-Master is configured.

Note

The configuration is almost identical for all SINAMICS S120 and SIMOTION D devices.

Procedure

1. Select **PROFINET IO > Drives > SINAMICS** in the HW Config hardware catalog. Then select the module, e.g. **SINAMICS S120 CU320-2 PN**.
2. Click the entry and drag the drive, e.g. **V4.4** , to the PROFINET IO subnet. The **Properties - Ethernet Interface SINAMICS-S120xCU320x2xPN** window opens.
   A suggested IP address will already be displayed here and the subnet will be selected.
3. Click **OK** to accept the setting.
4. In HW Config, select **Station > Save and Compile Changes**.

Setting a telegram in SIMOTION SCOUT

For V4.2 and higher, the telegrams are assigned automatically in SIMOTION SCOUT by means of symbolic assignment. For isochronous communication, a telegram must be configured (e.g. telegram 105) which enables the drive to be synchronized with PROFINET. The telegram is thus automatically set in SCOUT during the configuration of the drive unit and following the assignment of an axis.

1. If you have not yet configured a supply and drive, click **Configure drive unit** in the SCOUT project navigator and drive unit.
2. Run the drive unit configuration wizard.
3. After you have closed the wizard, click **Communication > Telegram configuration** under the drive unit in the project navigator. Tab **IF1: PROFIdrive PZD telegrams** contains a list of telegrams. A telegram is not yet configured following commissioning of the drive since the drive has not yet been symbolically assigned.
4. Therefore, insert a new axis TO and run through the axis wizard. In the wizard, interconnect the axis to the corresponding drive object of the S120 and a corresponding telegram will automatically be created (symbolic assignment).

5. Select **Project > Save and compile all** from the menu. This means that the addresses will be set up automatically with symbolic assignment. You can also trigger symbolic assignment of addresses using the menu item **Project > Set up addresses**.
6. Once the axis configuration process is complete, click **Communication > Telegram configuration** under the drive unit in the project navigator. Tab **IF1: PROFIdrive PZD telegrams** now lists the telegram for the drive (e.g. SIEMENS telegram 105).

Telegram in HW Config

Alternatively, you can assign the telegram in HW Config. This is only possible if the drive unit and the drive have already been configured in SCOUT. You will then be able to proceed as follows in HW Config.

Note

Symbolic assignment in SIMOTION SCOUT is recommended for telegram interconnection. For this purpose, make sure that a check mark is applied for **Project > Use symbolic assignment** in the menu.

If you are using the symbolic assignment, SIMOTION SCOUT is entirely responsible for managing the telegram between SIMOTION and the drive DOs. In other words, SIMOTION SCOUT independently creates telegrams that all contain the necessary signals according to the technological configuration. SIMOTION SCOUT automatically manages the positioning of signals in the telegram and its size; the user is no longer able to influence this process or make any changes.

1. Select the inserted SINAMICS drive and double-click the entry **SIEMENS / Standard telegram xx** in the lower table for the drive.
   The **Properties SIEMENS / Standard telegram xx** dialog box is called.
2. Select the corresponding telegram. After it is saved, the telegram can be also be selected in SCOUT, under **<"Drive_device_xx"> - Communication > Telegram configuration** in the project navigator. Alignment with HW Config is possible.

Settings for isochronous mode (V4.4 or higher)

For isochronous mode, the drive unit must be synchronized with the PROFINET cycle clock. You can make these settings at the PN interface of the drive unit and on the SIMOTION device (Sync-Master).

Settings on SIMOTION device (Sync-Master)

1. In HW Config, select the SIMOTION device module, e.g. D455, and choose **Edit > Object properties** in the menu.
2. Click the **Details...** button on the **Isochronous tasks** tab.
   This button only appears if you select the **...Assign I/O device isochronous** check box.

3. Select the **Automatic** setting in the **Details for servo** dialog box under **Ti/To mode**. The cycle clocks and time constants for all IO devices (Sync-Slaves) on the PROFINET are then calculated automatically by the system.

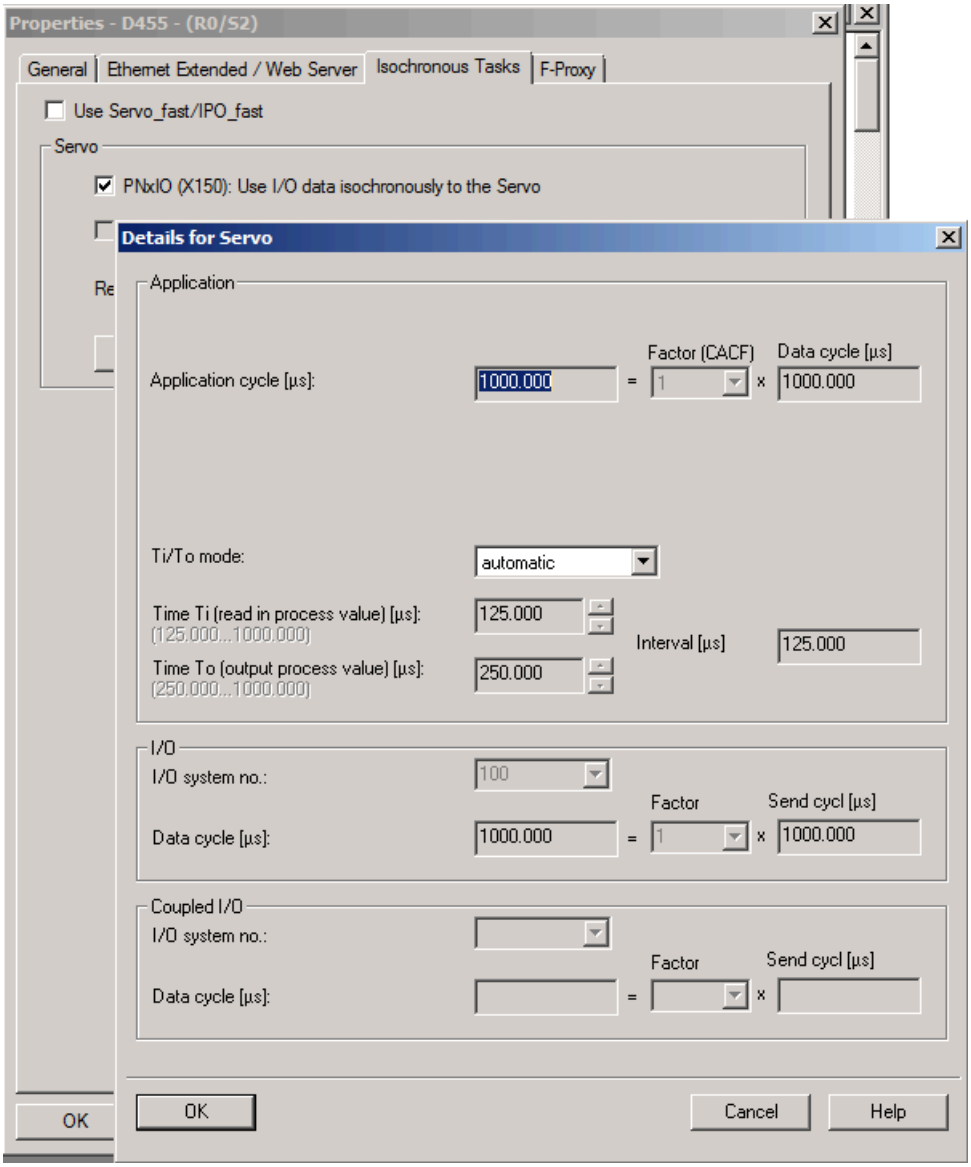


Figure 4-386 Configuring an isochronous task on the SIMOTION device.

4. Click **OK** to close both dialog boxes.

Settings on the SINAMICS drive (Sync-Slave)

1. Select the SINAMICS drive on the PROFINET IO system and double-click on the entry of the PROFINET interface in the lower table, e.g. PN-IO.
   The **Properties PN--IO** dialog box is displayed.
2. Select the **Servo** entry on the **IO cycle** tab under **Assign IO device isochronously**. The drive is operated isochronously. The time constants are calculated automatically.

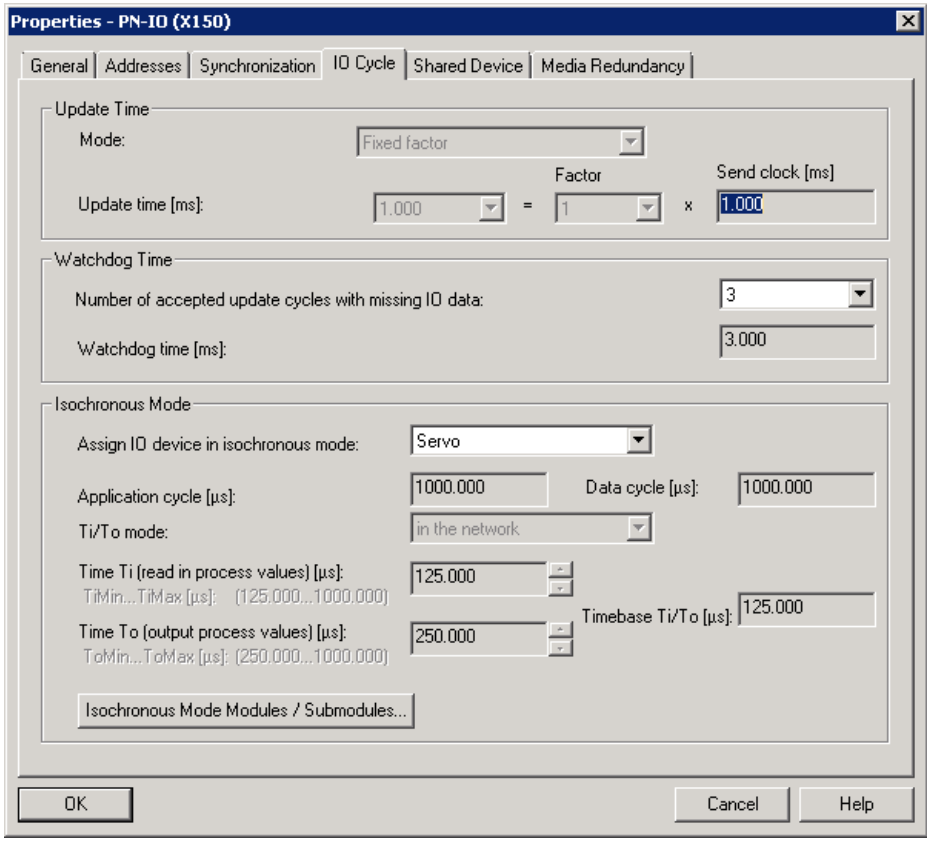

Figure 4-387 Configuring an isochronous task on the PROFINET IO device

3. You can see the current cycle clock in **Application cycle**. To configure cycle clock scaling, you need to configure down-scaling by selecting **Set system cycle clocks** in the **execution system**. This is required if the servo cycle clock should be slower than the PROFINET IRT send clock, for example. However, the servo cycle clock must already have been taken into account in the PROFINET IRT send clock.
4. If necessary, switch to the **Synchronization** tab to select the **Synchronization type**, **Sync slave** in this case. This can also be set under **Domain Management**.
5. Confirm the entries with **OK**.

Note

You must carry out further steps in order to include the drive in the sync domain (see Creating a sync domain (Page 2199)), load the IP address to the drive (see Assigning device names and IP addresses to IO devices (Page 2221)), and interconnect the ports (see Interconnecting ports via the topology editor (table view) (Page 2211)).

IP address and device name

Introduction

Devices and controllers have a fixed MAC address, a configurable IP address, and a device name. The IP address, subnet mask, and device name are defined within the Ethernet interface properties in the engineering software. This ensures the devices within the project have their own unique assignment. The device name is referred to as **NameOfStation** in accordance with the standards or, in the case of devices with multiple interfaces, **NameOfInterface**. The device name must be unique for the communication.

You can find the device name in the **Properties - Interface** dialog by double-clicking on the device or the controller. Click on **Properties** in the dialog to define the IP address. See also Add and configure PROFINET interface CBE30-2 (Page 2191).

Device name guidelines

In the case of an IO device, the device name is, for example, the drive name *Drive1*. In the case of controllers, the device name is the name of the PROFINET interface, e.g. *PNxIO* for an integrated interface of SIMOTION D. A controller can also have multiple interfaces and, therefore, multiple device names.

Device names are subject to certain syntax rules, i.e. they must always be DNS-compliant. For SIMOTION and SIMATIC, there are additional boundary conditions for the device names.

- Letters a-z and numbers 0-9 may be used.
- No German umlauts (ä, ö, ü)
- The special characters minus (-) and period (.) may be used
- No other special characters or spaces ! " § $ % & / ( ) = ? * ' _ : ; > < , # + | ~ \ }] [{
- The period is used for structuring, i.e. the device name can comprise several parts (labels)
  - Label.Label.Label.Label
  - Periods are used as separators.
  - A label must not begin with a hyphen (-) or a period (.)
  - A label must not exceed 63 characters
- The maximum total length of the name is 240 characters (including hyphen and period)
- The device name must start with a letter, but not with the character string "port-xyz-" (x, y, z = 0..9).
- **No** distinction is made between upper-case and lower-case letters. The configured device name can also contain upper-case letters but these will be saved on the device as lower-case letters.
- Up to SIMOTION SCOUT V4.3, the device name must not include hyphens (-), i.e. the name must comply with the ST naming convention. As of SIMOTION SCOUT V4.3, this restriction no longer applies.

Initialization of the controller and devices in online mode

As the controllers and devices do not have a device name or IP address when delivered, these will need to be assigned at the outset. When assigning addresses (i.e. the IP address and device name - a process also referred to as initialization), a distinction is made between controllers and devices. You can adopt different approaches when initializing devices and controllers.

Controller initialization

- Download the application
- Engineering software
  - HW Config, NetPro, SCOUT
  - Primary Setup Tool (PST)
  - PRONETA
- Via the application (the _setPnNameOfStation system function for SIMOTION (as of V4.4)

Note

When using engineering software for initialization, and particularly where larger systems are involved, you should establish direct connections with the device to ensure the device to be initialized is clearly identifiable. Alternatively, the Flash feature can be used, whereby devices can be identified by a flashing LED.

Device initialization

- Engineering software
  - HW Config, NetPro
  - SCOUT, STARTER
  - Primary Setup Tool (PST)
  - PRONETA
- Write to the MMC or CF card beforehand and then plug in.

Topology-based initialization for devices

Devices can also be initialized without an MMC or CF card. This method is known as topology-based initialization

Note

For topology-based initialization, the PN interface of the device must be in its factory setting.

See also

Creating an I device (Page 2245)

Assigning device names and IP addresses to IO devices

Introduction

You can only go online with the engineering software of a device (or controller) if it has been assigned an IP address in the engineering software. Devices must also be assigned a device name which is unique across the network. This enables the controller to identify the devices assigned to it.

You can specify the IP address in the **Properties - Ethernet interface....**dialog (double-click on the device to open this). Moreover, a default name is entered that you can modify. The default setting **Assign IP address through Controller** is active. In other words, when powering up, the controller identifies the devices assigned to it via the device names and then assigns the IP address defined in Engineering to them. We recommend leaving this function activated.

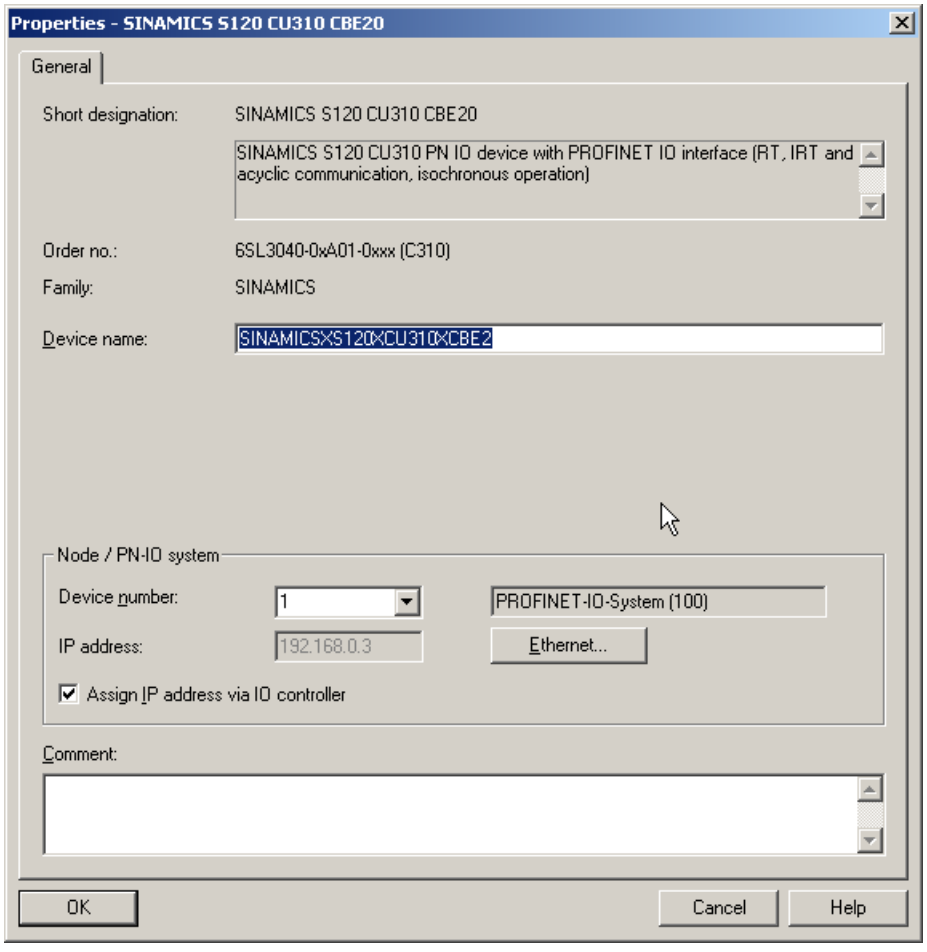

Figure 4-388 Properties SINAMICS S120

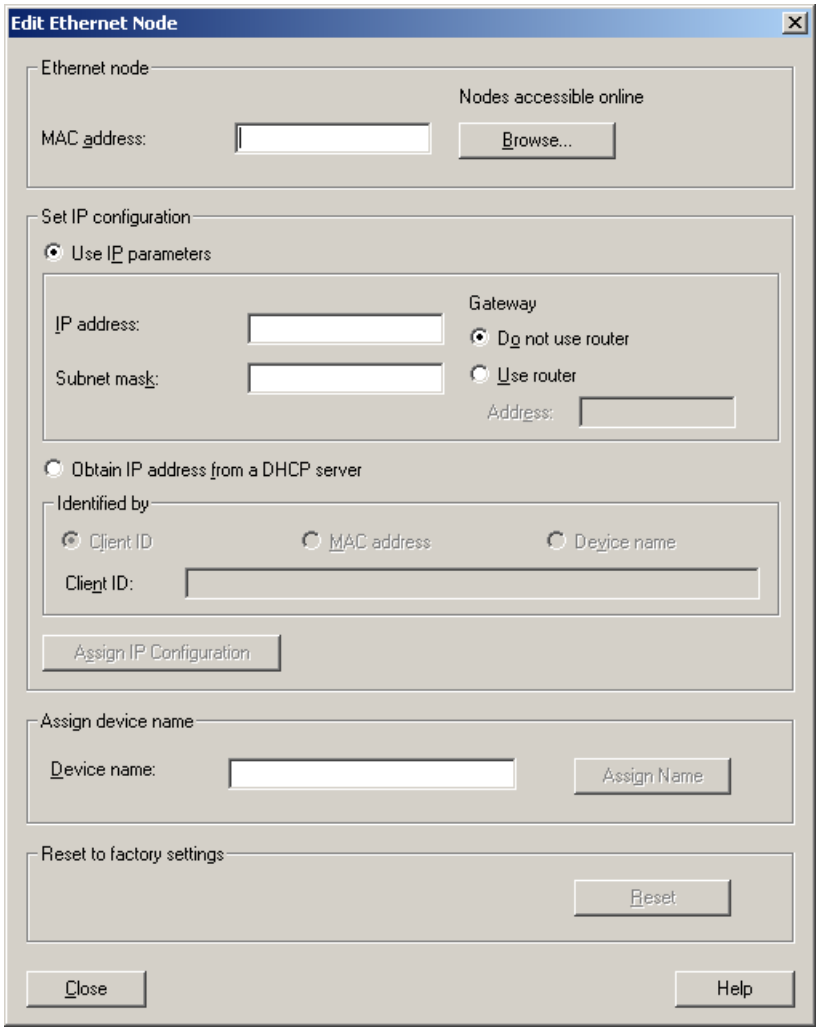
IO device initialization

Note

If you are connecting the programming device/PC directly to the device's PROFINET interface, you can use a patch or crossover cable. During commissioning, we recommend that the device to be initialized is connected directly to the programming device/PC.

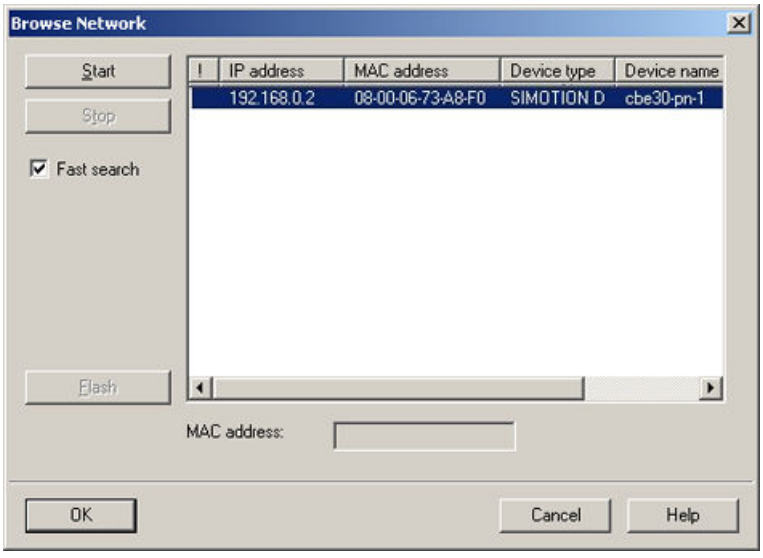
Alternatively, the Flash feature can be used, whereby the IO device can be identified by a flashing LED.

1. In HW Config or NetPro, select the **Target system - Ethernet - Edit Ethernet Node** menu item. The **Edit Ethernet node** dialog box is displayed.



2. Click the **Browse** button.

3. The **Browse Network** dialog box opens. The connected nodes are displayed.



4. Click the device to be initialized and confirm with **OK**.
5. Enter the IP address and subnet mask you specified in the **Properties – Ethernet interface ...** dialog.
6. The default setting (**Do not use router**) for the gateway remains unchanged.
7. Click on the **Assign IP configuration button**. The IP address is then assigned to the device online.
8. Enter the device name that you have defined in HW Config, see figure **Properties SINAMICS S120**.
9. Click on the **Assign Name** button. The device name is assigned to the device.

As an alternative, you can perform node initialization in SIMOTION SCOUT.

You can also perform the node initialization in SCOUT.

- In SCOUT, execute **Reachable nodes** and, in the dialog box displayed, right-click the device that you want to edit.
- Execute **Edit Ethernet nodes**. The corresponding dialog box is displayed.

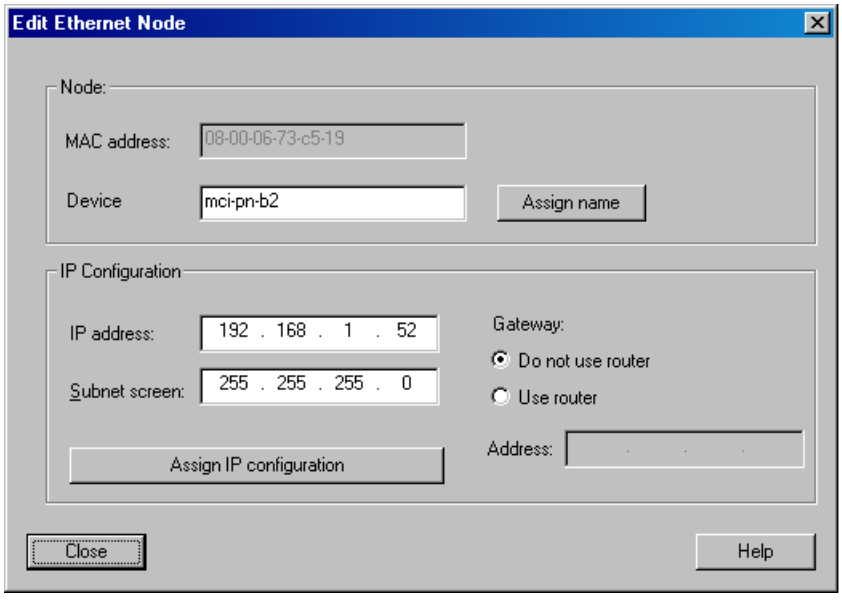


Figure 4-389 Edit Ethernet nodes

- Enter a device name, a subnet mask and an IP address.
- Confirm your entries.

The device name and IP address are transferred to the device and stored there.

Configuring media redundancy (V4.3 and higher)

Creating ring topology

Setting up ring topology

In order to use MRP, you must establish a ring topology. The ring nodes must support media/ system redundancy.

Note

Devices that support MRP

An overview of all devices that support media and/or system redundancy can be found in the Support area (https://support.industry.siemens.com/cs/ww/en/view/67364686).

To establish the ring, bring together the ends of the line topology into one device.

Requirement

You have created a project in SCOUT and added a SIMOTION module.

Setting up devices in HW Config

1. Open HW Config.
2. Set up a PROFINET IO system in the SIMOTION module.
3. Add a module, such as a SCALANCE switch, that can take the role of Redundancy Manager.
4. Then add the other required SIMOTION modules (or other modules). The modules assume the role of redundancy clients.

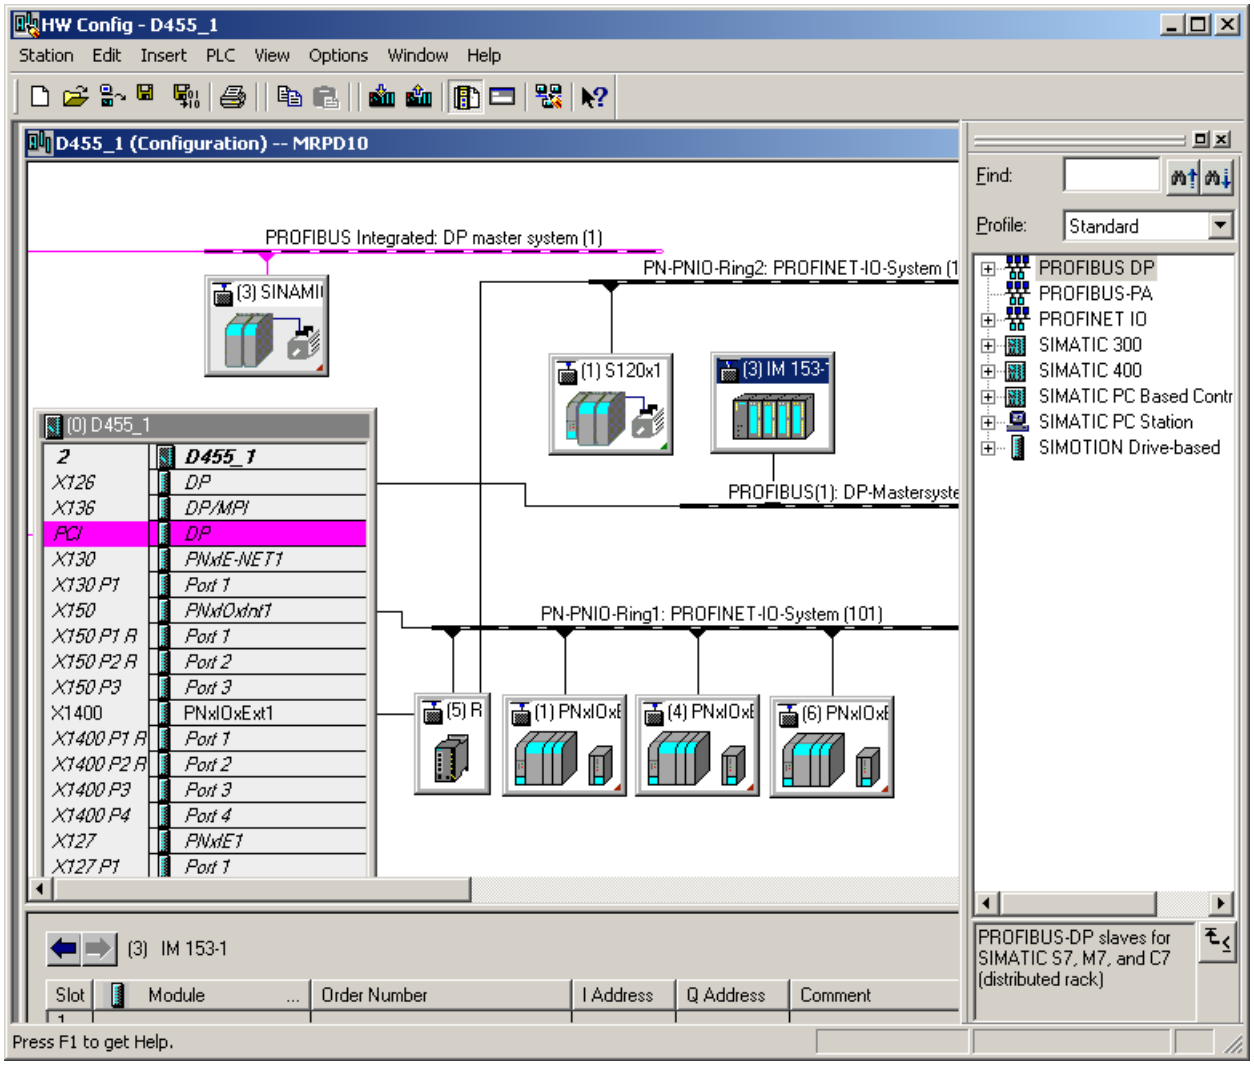

Figure 4-390 Ring project in HW Config

Establishing ring topology in the Topology Editor

1. Open the Topology Editor.
2. Interconnect the individual ports of the devices.
3. If necessary, change to graphic view to drag the connections with the mouse.
4. Connect the two end points of the line topology with each other in order to close the ring, e.g. the redundancy manager with a redundancy client.

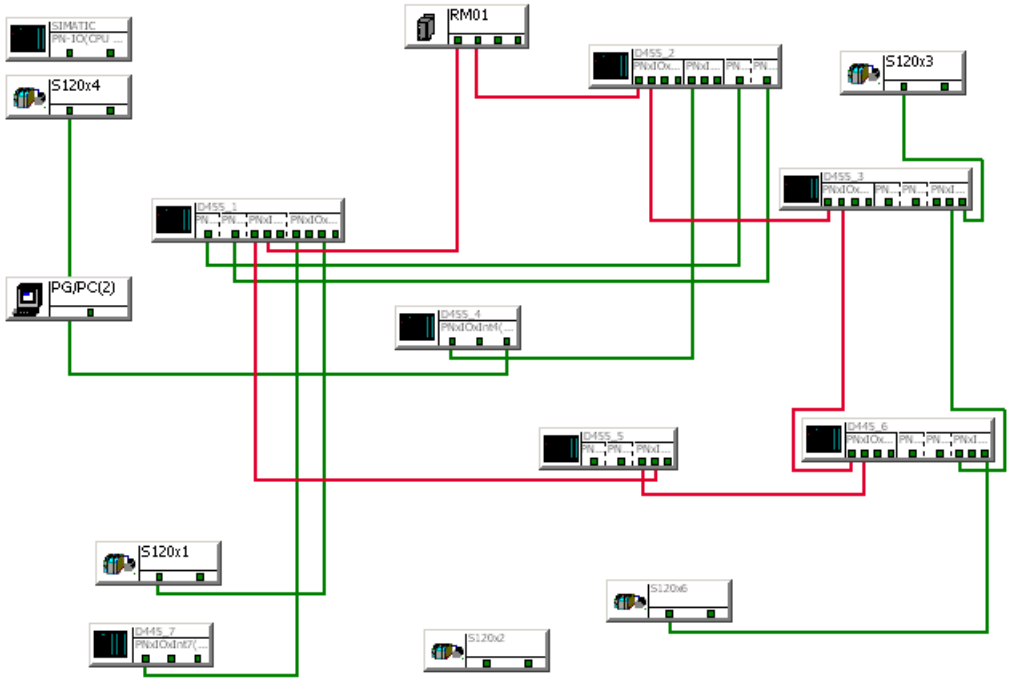

Figure 4-391 Ring topology in the Topology Editor

Setting up MRP domain

MRP domain

An MRP domain containing all ring nodes is required for media redundancy. If you are using several ring topologies, you must set up the corresponding number of MRP domains.

Setting up MRP domain

In order to set up an MRP domain, proceed as follows:

1. Select the PROFINET IO system in the working area of HW Config.
2. Go to **Edit > PROFINET IO > Domain Management**.
   The **Domain Management** dialog opens.

3. Switch to the **MRP domain** tab.

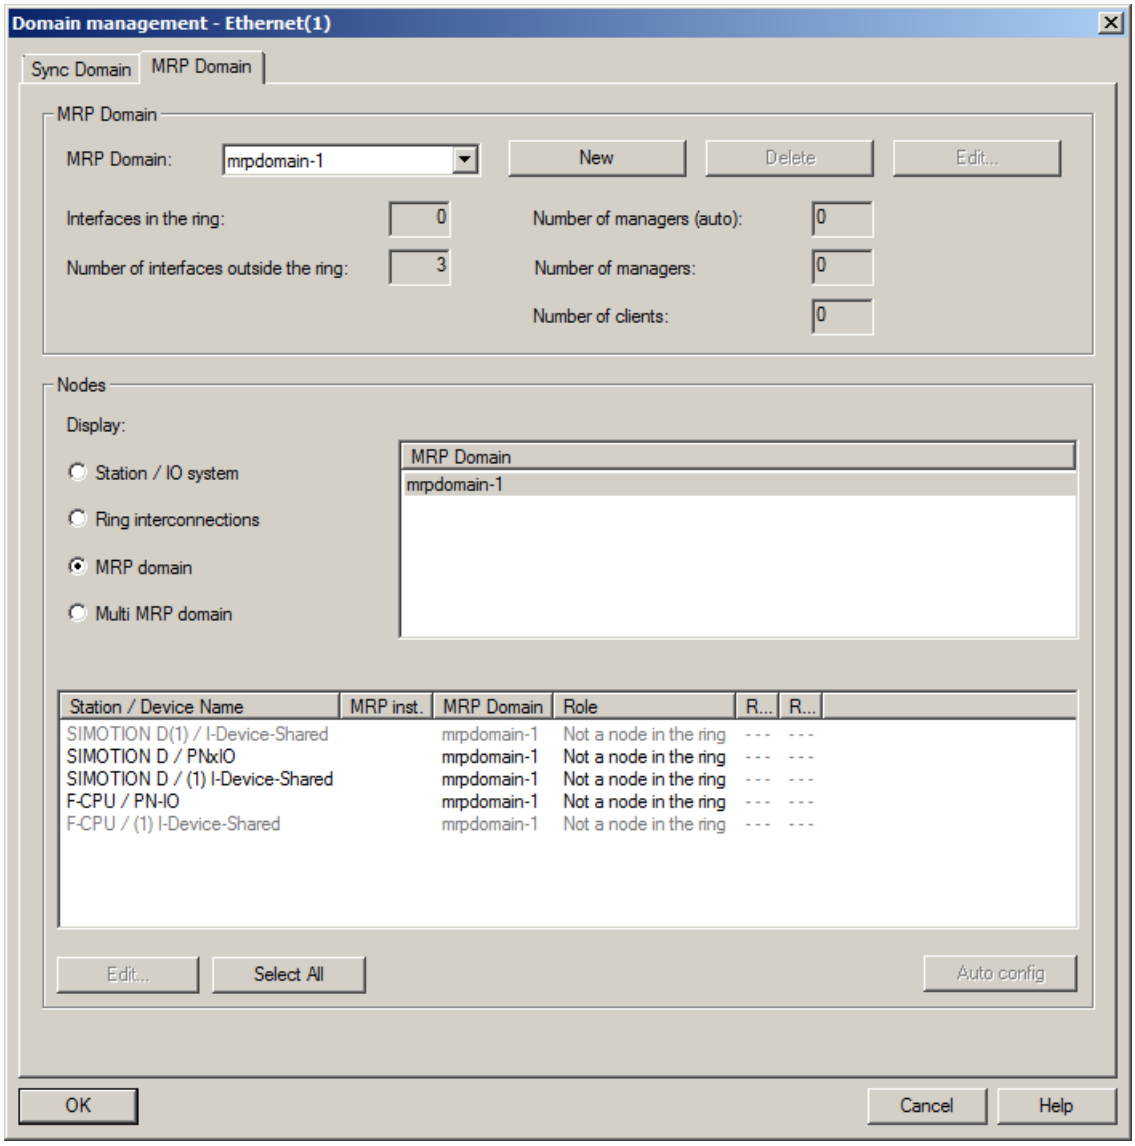

Figure 4-392 Domain Management MRP domain

4. Click **New** to create a new MRP domain. By default, the domain mrpdomain-1 will be created.

Assign the individual devices to the domain according to their roles.

1. Select the device under **Station/device name**and click on **Edit**.
   The "Edit Media Redundancy" dialog box opens.

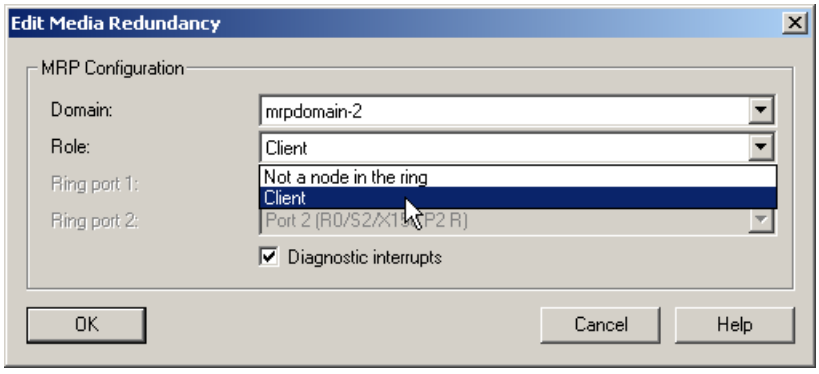

Figure 4-393 Edit media redundancy

2. Select the role intended for the device, e.g. Client, under **Role**.
3. Click OK to accept the settings.
4. Repeat the steps for all MRP domains and devices.

Result

The MRP domains have been created and the corresponding roles have been assigned to the members of the individual domains.

Configuring media redundancy

Entering settings for media redundancy

For media redundancy, you must assign the various roles and an MRP domain to the nodes.

Configure MRPD

If all participants within the MRP domain work in IRT mode (IRT with High Performance), MRPD is automatically activated for all nodes of the IRT domain that communicate via the ring.

Requirements

You have set up the devices in HW Config.

Procedure for the Redundancy Manager

To configure the Redundancy Manager, proceed as follows. Only SCALANCE switches can be Redundancy Managers.

1. Select the SCALANCE switch in the working area of HW Config.
2. Double-click on the PN interface in the detailed view; for example, on X1 in a SCALANCE switch.
   The **Properties - PN (xx)** dialog opens.

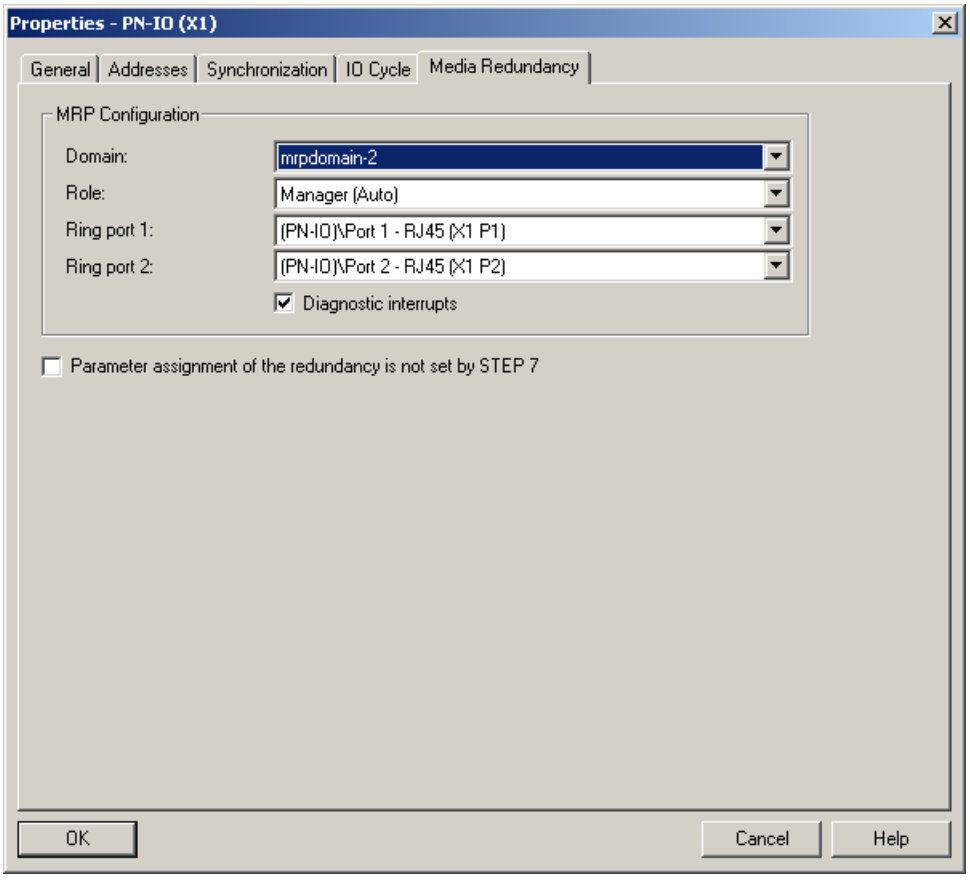

Figure 4-394 Properties Redundancy Manager

3. Switch to the **Media Redundancy** tab.
4. Select the MRP domain under **Domain**. If you are using only one domain, this is pre-assigned.
5. Under **Role** select the entry **Manager (Auto)**.
6. Under **Ring port 1** and **Ring port 2**, select the ports which are to be used in the ring (only with the SCALANCE switch).
7. Activate the **Diagnostic interrupts** option if you want to see ring communication faults in the diagnostics buffer and in the device diagnostics.

Procedure for the redundancy client

In order to configure devices as redundancy clients, proceed as follows:

1. Select the device in the work area of HW Config.
2. In the detailed view of the device, double-click on the interface line, e.g. on X1400 for a SIMOTION controller.
   The **Properties - Interface (xx)** dialog opens.

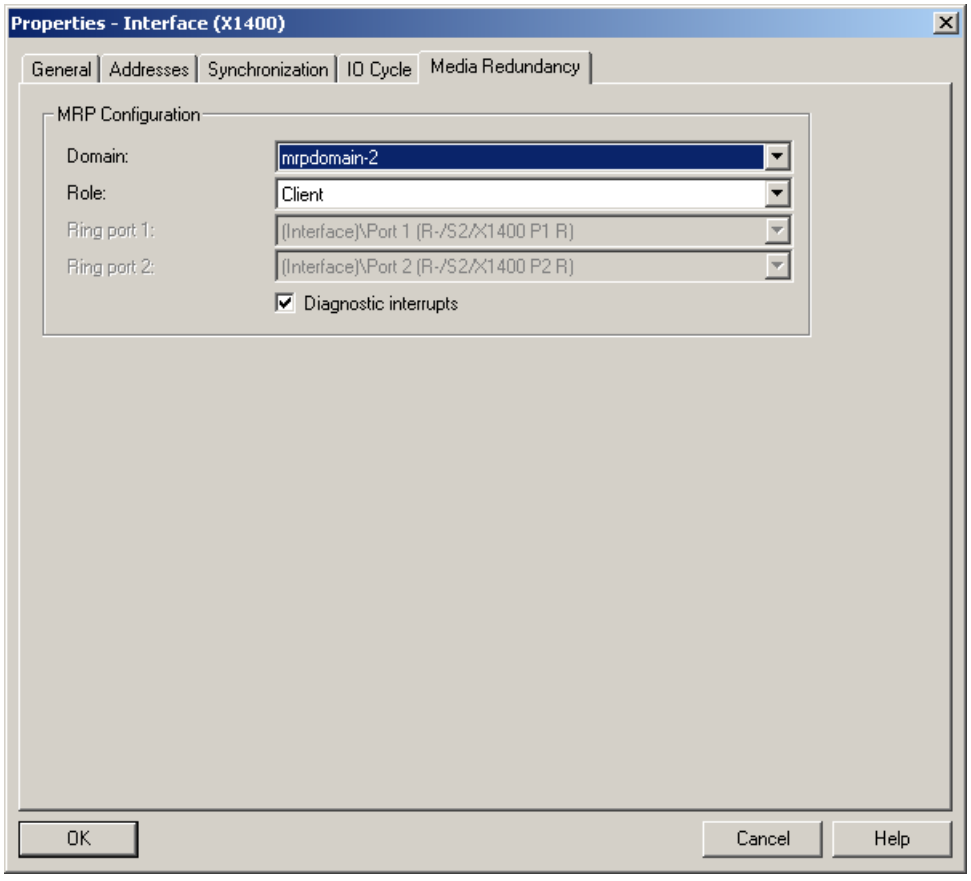

Figure 4-395 Properties of redundancy client

3. Switch to the **Media Redundancy** tab.
4. Select the MRP domain under **Domain**. If you are using only one domain, this is pre-assigned.
5. Activate the **Diagnostic interrupts** option if you want to see ring communication faults in the diagnostics buffer and in the device diagnostics.

Identification and maintenance (I&M) data

Introduction

For the identification and maintenance data (I&M), data structures are defined in PROFINET which can be implemented for all devices. These data structures are used to uniquely identify the IO device. The data set for the unique identification of an IO device, the identification and maintenance data set 0 (I&M0), is supported by all PROFINET IO devices. Further information can be stored in a standardized format as I&M 1-4 if required. As of V4.4, SIMOTION supports all I&M data.

PROFINET I-device I&M data

The I&M data is defined for a device (I-device in this case) and is readable and writable when the I-device is used by a higher-level controller. As of V4.4, SIMOTION supports the data sets 1-4 in addition to the I&M data set 0 (electronic rating plate) as a PROFINET I-device. Reading/writing via PROFINET data set services is supported. Access from the user program via the SIMOTION user interface is not possible.

I&M data sets:

- I&M0: Electronic rating plate
- I&M1: Location designation/Plant ID
- I&M2: Installation date
- I&M3: Description
- I&M4: Signature/additional information

Structure of the I&M data

The following description provides an overview of the I&M data structure. A detailed description can be found in the PROFINET specification.

- 0xAFF0 I&M0 (read) - electronic rating plate
  - Vendor ID (Unsigned16)
  - Order ID (VisibleString[20])
  - Serial Number (VisibleString[16])
  - Hardware Revision (Unsigned16)
  - Software Revision (“Vx.y.z”)
  - Revision Counter (Unsigned16)
  - Profile ID (Unsigned16)
  - Profile Specific Type (Unsigned16)
  - I&M Version (OctetString[2])
  - I&M Supported (Bit Sequence V2)
- 0xAFF1 I&M1 (read/write) - location designation/plant ID
  - Function (submodule’s function or task; “AKZ”; VisibleString[32])
  - Location (submodule’s location; “OKZ”; VisibleString[22])
- 0xAFF2 I&M2 (read/write) - installation date
  - Installation Date (date of installation or commissioning of a device or module; VisibleString[16])
- 0xAFF3 I&M3 (read/write) - description
  - Descriptor (allows storing any individual additional information and annotation; VisibleString[54])
- 0xAFF4 I&M4 (read/write) - signature disabled for PROFIsafe purposes, not changed by ResetToFactory
  - Signature ("security" code, e.g. for Safety; OctetString[54])

Constraints on the I-device I&M data

Please note the following constraints.

- The I&M 1-4 data can only be accessed if the option **Parameter assignment for the PN interface and its ports on the higher-level IO controller** has been activated on the **I-device** tab of the PN interface.
- In the case of a SIMOTION CPU with two PN-IO interfaces, each I-device has its own writable I&M data.

- The second SIMOTION PN-IO interface is a plug-in interface that has its own article number. Both I-devices, therefore, also have different I&M 0 data.
  - Onboard PN interface: SIMOTION CPU article number
  - CBE30-2 PN interface: CBE30-2 article number
- The rack for the I-device I&M data is the first subslot of the transfer areas (subslot 1000). The I&M 1-4 data can only be written via this subslot. The I&M data for the other subslots is also shown when reading.

Reading and writing I&M data

You can display the I&M data in SIMATIC Manager or in HW Config. If you have an online connection, you can also change the data.

Setting I&M data in SIMATIC Manager

The PG/PC is connected online with the SIMOTION I-devices. They are connected to the same physical Ethernet subnet.

1. Select the menu command **PLC > Display accessible nodes**.
2. Select the SIMOTION I-device that is found
3. Select menu command **PLC > Change module identification**. A window containing the I&M data appears.
4. Change the required I&M data. The **Take into account** checkbox must be activated for the change to be transferred to the module.
5. Click **OK** to confirm. The data is changed.

Changing I&M data in HW Config

1. In HW Config, double-click the SIMOTION I-device symbol in the working area.
   The **Properties window** is displayed.
2. You can view the I&M data in the **Identification** tab.
3. If you have an online connection, you can display a comparison of the offline and online data via the menu command **PLC > Load module identification**.
4. In order to change the data, you must activate the **Take into account** checkbox and confirm the new data with **OK**.

4.5.5.4 Configuring direct data exchange (data exchange broadcast) between IO controllers

Introduction

Introduction

I/O data areas can be exchanged cyclically between two or more SIMOTION controllers via IRT High Performance. This is also referred to as controller-controller data exchange broadcast. Controller-controller data exchange broadcast is only possible between SIMOTION controllers via PROFINET IO with IRT High Performance.

For data exchange to take place, the devices must be located in a common sync domain and configured accordingly as sync master and sync slaves.

Note

This function is not available for SIMATIC CPUs.

There are in fact two types of data exchange broadcast. One is automatically created by the system (e.g. distributed synchronous operation), while the other can be applied by the user in his or her application. You can configure this second type of data exchange broadcast.

Note

The user must not use the engineering tools to make changes (e.g. amending the address areas) to the data exchange broadcast which has been automatically configured by the system. Doing so will result in error states.

Note

The controller-controller data exchange broadcast can only be configured if all the SIMOTION controllers involved in slave-to-slave communication are together in one project. If this is not the case, alternatively the SIMOTION I-device can be used for cross-project data exchange broadcast.

Recommendation

We recommend, initially configure the send areas for all PROFINET devices and then the receive areas. Adopting this procedure will enable you to assign the previously defined send areas when defining the receive areas. This prevents invalid inputs.

Data volume

Approx. 3 KB (4 frames of 768 bytes each) can be transferred. 24 bytes are needed for each configured synchronous operation relationship. In other words, if 5 following axes were defined for one master axis, the system needs 5 * 24 bytes. The remaining data is available for application-specific data exchange broadcast. In controller-controller data exchange broadcast, the max. submodule size is limited to 254 bytes.

Note

An FAQ section on the subject of PROFINET configuration is provided in SIMOTION Utilities & Applications. SIMOTION Utilities & Applications is provided as part of the SIMOTION SCOUT scope of delivery.

This FAQ section deals with the subjects of distributed gearing and controller-controller data exchange broadcast (https://support.industry.siemens.com/cs/ww/en/view/38486079).

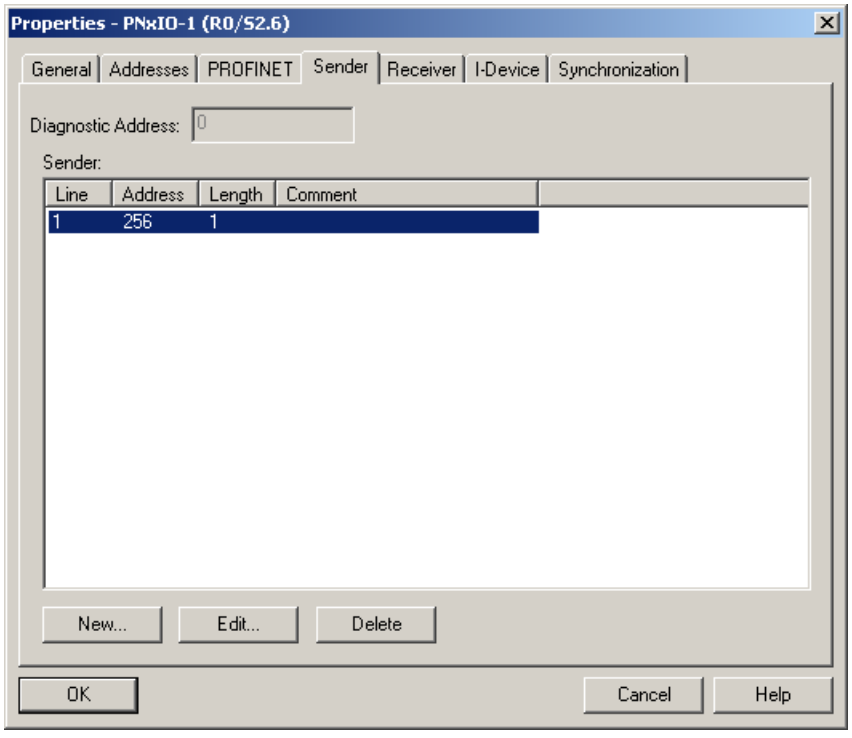
See also

Quantity structures (Page 2162)

Configuring the sender

Procedure

1. Open the Properties dialog of the PROFINET interface (double-click the corresponding row in the configuration table of HW Config).
2. Select the **Sender** tab.



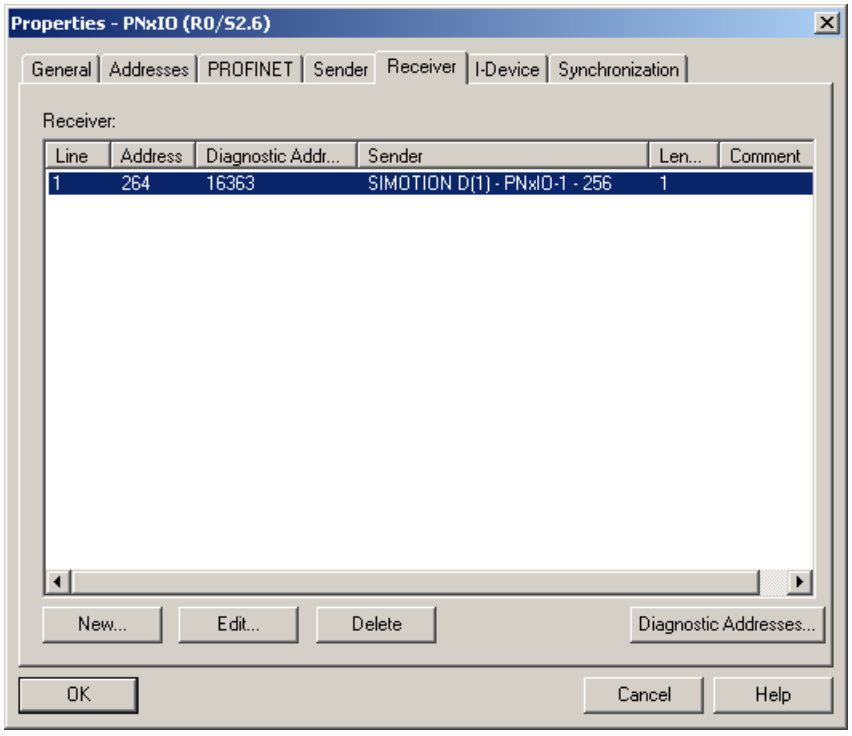
3. Click the **New** button.
4. Enter in the Properties dialog box of the sender, the start address from the I/O area and the length of the address area to be used for sending. Comment the data area so that you will be able to identify the data transmitted via this area later on. The maximum size of a variable is limited to 254 bytes (in the case of controller-controller data exchange broadcast).
5. Confirm the settings by clicking **OK**.
6. Repeat steps 3 to 5 for further send areas.
7. Change the preset diagnostics address for the send areas, if required.
8. Confirm your entries with **OK**.

Note

If a PROFINET interface of the SIMOTION controller is configured as a sender for controller-controller data exchange broadcast, this sender will have precisely one diagnostics address. This also applies if several slots are created for the data exchange broadcast.

Configuring the receiver

Procedure



1. Open the Properties dialog of the PROFINET interface (double-click the corresponding row in the configuration table of HW Config).
2. Select the **Receiver** tab.
3. Click the **New** button.
4. Click the **Assign sender** button in the **Properties receiver** dialog.
5. In the **Assign sender** dialog, select the data area of the desired node which is to be received by the local controller.
6. Confirm your selection with **OK**.
7. Enter in the Properties dialog of the receiver, the start address of the address area to be used for receiving. The length of the address area must not be changed as it is automatically adapted to the length of the send area. The configuration can only be compiled if the send and receive areas have identical lengths!

   Note

   Unlike the sender, each slot is assigned its own diagnostics address in the configuration of the receiver, through which the receiver can detect sender failure, for example. Click the Diagnostics addresses button if you want to edit this address.

8. Repeat steps 3 to 7 for further receive areas.
9. Confirm your entries with **OK**.

4.5.5.5 Configuring the iDevice

PROFINET IO and I device

Introduction

Up to SIMOTION 4.0, direct coupling (of SIMATIC and SIMOTION via PROFINET, for example) was only possible via TCP or UDP, or via additional hardware (PN/PN coupler, SIMATIC CP). With SIMOTION V 4.1.1.6 or higher, the direct coupling of controls - a familiar feature with PROFIBUS - has been introduced for PROFINET IO. It is possible, for example, to connect the SIMOTION as an I slave to the SIMATIC CPU via PROFIBUS. A similar function, referred to as "I-device", is also available for PROFINET IO. This supports data exchange between the controls via I/O areas, with the communication programming required for TCP or UDP being replaced by configuring and system functionality. In addition, the costs associated with the hardware solutions used previously no longer apply (PN/PN coupler, SIMATIC-CP).

The "I-device" (intelligent IO device) functionality of a controller enables exchange of data with an IO controller. Here the I-device is connected as an IO device to a higher-level IO controller. Communication can be established in both directions (bidirectional) via I/O areas using the I-device functionality. Further, this function allows both controls to operate in separate projects.

When operating as an I-device, a SIMOTION device can be used for data exchange with a SIMATIC station, for example. A SIMOTION device acting as an I-device may also be used as a feeder for a modular machine. Please see the *description of functions titled Motion Control basic functions for modular machines*.

Another application for a SIMOTION device acting as an I-device involves providing distributed synchronous operation beyond the limits of a project (see the *Motion Control Technology Objects Synchronous Operation, Cam* Function Manual).

Note

An I-device can only be created using SIMOTION V4.1.1.6 or higher.

Properties of an I-device

As well as performing the role of an IO device on a higher-level IO controller, an I-device can set up its own local PROFINET IO system with built-in local IO devices, thereby acting as an IO controller itself. Both these functions are implemented via the same PROFINET interface on the device.

With SIMOTION, the I-device is available for PROFINET IO with RT and IRT High Performance.

The following constraint applies to the options for combining functions:

Table 4-227 RT and IRT I-device combination options with SIMOTION

SIMOTION function	Possible additional functions			
	RT I-device	RT controller	IRT I-device	IRT controller
RT I-device		X	-	X
RT controller	X	-	X*	X*

SIMOTION function	Possible additional functions			
IRT I-device	-	X	-	-
IRT controller	X	X	-	

*Either an IRT I-device or an IRT controller

As with any other IO device, an I-device's PROFINET interface requires parameter assignment data in order to operate. With IO devices, this data is usually loaded via the associated IO controller in the form of parameter assignment data sets.

Two options are available for I-devices.

An I-device's interface and PROFINET interface ports can either be parameterized by the higher-level IO controller or by the I-device itself on a local level. The preferred option can be selected as part of the I-device's configuration.

- The higher-level IO controller does **not** need be used for parameterizing the PROFINET interface of the I-device.
  This option should be used if the I-device is to be operated as an RT I-device. The same interface can then additionally be operated as an RT controller or an IRT controller.
- The IO controller loads parameter assignment data sets for the PROFINET interface to the I-device.
  This option should be used if the I-device is to be operated as an RT I-device. The same interface can then also only be operated as an RT controller (IRT controller only possible on a second PROFINET interface).

If the I-device is being operated with IRT, the I-device's send clock must be set to match the send clock for the sync domain of the higher-level IO controller's PROFINET IO system. If the I-device is being operated with RT, the I-device's update time must be either set to match the send clock for the sync domain of the higher-level IO controller's PROFINET IO system, or down-scaled by a multiple of this send clock.

The table below contains details of the send clocks and update times which must be set, along with their possible combinations.

Send clocks/update times of an I-device
Higher-level IO controller and I-device with IRT, no local PROFINET IO system or local PROFINET IO system with IO devices with RT • I-device send clock: – Must be the same as the send clock for the higher-level IO controller. – To be set on the I-device in <PROFINET Interface> properties using the **Send clock** drop-down list box on the **PROFINET** tab
Higher-level IO controller with IRT and I-device with RT, local PROFINET IO system with IRT • I-device update time: – Must be an integral multiple of the send clock for the higher-level IO controller and the send clock for the IO controller on the I-device – To be set on the I-device proxy in <PROFINET Interface> properties, under **Update Time** on the **IO Cycle** tab

Higher-level IO controller and I-device with RT, no local PROFINET IO system • I-device update time: – Any of the possible update times for the I-device may be set. – To be set on the I-device proxy in <PROFINET Interface> properties, under **Update Time** on the **IO Cycle** tab
Higher-level IO controller and I-device with RT, local PROFINET IO system with IRT: • I-device update time: – Must be greater than or equal to the send clock for the IO controller in the I-device. This means that, for example, if an IRT controller with a 2 msec send clock is configured on the CPU of the RT I-device, the following condition applies to the higher-level controller: Update time of the higher-level controller for access to the I-device >= send clock on the CPU of the I-device. This means that update times of 2, 4, 8, ...ms are possible. – To be set on the I-device proxy in <PROFINET Interface> properties, under **Update Time** on the **IO Cycle** tab

The figure below shows how an I-device can be configured on a higher-level IO controller. The higher-level IO controller sets up a PROFINET IO system containing the I-device.. The I-device is able to set up a local PROFINET IO system. Each of these PROFINET IO systems can belong to its own sync domain. However, the I-device must only be assigned to one of the possible sync domains, as a PROFINET interface can only belong to a single sync domain.

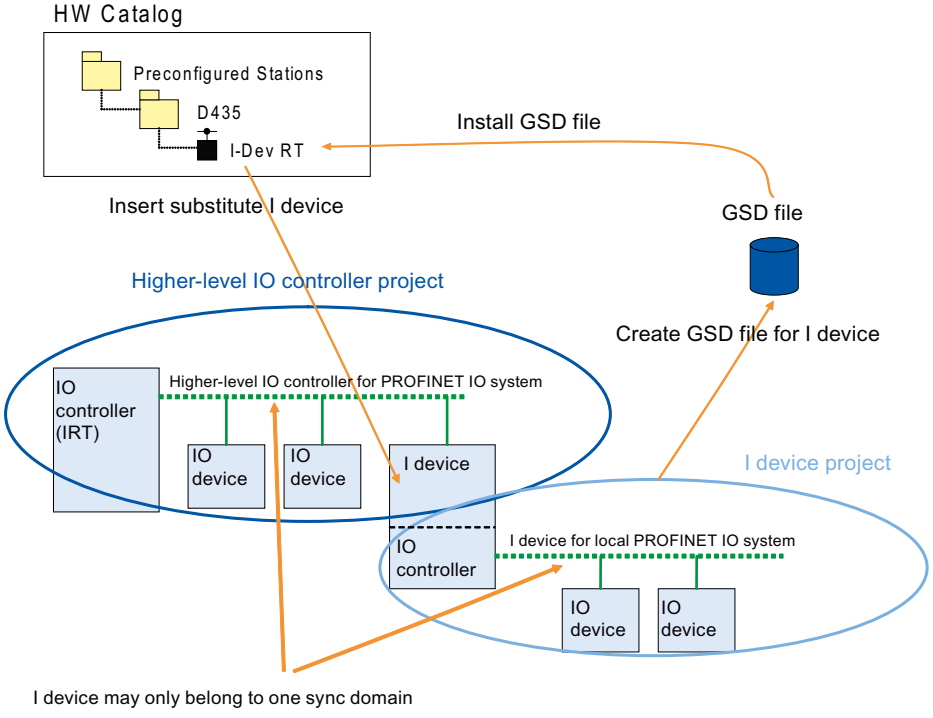


Figure 4-396 I-device configuration

Configuration procedure

- The I-device itself and the IO controller on which it is to be operated should be created in different projects.
- The PROFINET interface's I-device mode must be active for the I-device. In addition, the input and output ranges in the I-device must be configured for data exchange with the higher-level IO controller.
- After an I-device has been created and configured, a GSD file needs to be created and installed for its I-device proxy. The I-device proxy will then be available in the hardware catalog under "Preconfigured Stations."
- The next step involves inserting the I-device proxy from "Preconfigured Stations" in the hardware catalog into the higher-level IO controller's PROFINET IO system.

Since a manual process in the hardware catalog is required to create an I-device proxy, there is no automatic alignment between the project with the I-device and the corresponding I-device proxy in the GSD file. As a result, no subsequent modifications can be made to the I-device configuration. If a modification is made, however, a new GSD file will have to be created and installed. Where numerous modifications have subsequently been made to the configuration of a particular I-device, with multiple GSD files created and installed by the I-device, the version shown under "Preconfigured Stations" in the hardware catalog will always be the most recent one. The version will only be updated, however, if the identifier used for the I-device proxy when creating and installing the GSD file remains the same. Only the input and output addresses for data exchange may be modified in the project for the higher-level IO controller.

Since I-device connected to their higher-level IO controller and IO devices connected on the PROFINET IO system of a single I-device are connected via one and the same PROFINET interface, they will also be located in one and the same Ethernet subnet. This means that the device names and IP addresses of all these devices must be different from each other, and the subnet masks must be identical. It is particularly important to bear this in mind if the higher-level IO controller and the I-device are in different projects, as HW Config cannot check that device names, IP addresses, and subnet masks are consistent across different projects.

Device name (NameOfStation) for the I-device

As with all IO devices on PROFINET IO, a device name also has to be defined for the I-device in the configuration. As the device name (NameOfStation) for the I-device is set in the properties for its PROFINET interface, it is identical to the device name of the IO controller in the I-device. The name set is written to the GSD file for the I-device proxy when this file is created and installed.

When the I-device proxy is inserted into the PROFINET IO system of the higher-level IO controller, the device name previously assigned in the GSD file will be accepted into the configuration. The **device name will not be accepted** if you insert the GSD into the same project on a different IO controller. This is often the case with connections between a SIMOTION controller and a SIMATIC CPU. In this case the device name is automatically manipulated by the engineering system

(devicename"-1") and has to be manually adjusted to the original device name. Message 13:5144 ("There is already...") appears and must be confirmed.

Note

In all cases, it is important to ensure that the **device name in the configuration** of the higher-level **IO controller** is the **same** as the **device name** defined for the **I-device**. As a result, device names must not be amended after the higher-level IO controller has been added to the PROFINET IO system.

If the device names are different, the higher-level IO controller will be unable to identify the relevant I-device and, consequently, will not commence cyclic exchange of input/output data.

Applications of device names for the I-device

- Since a device name must not be used twice within an Ethernet subnet, any device name which already exists will be amended when an I-device proxy is inserted into the PROFINET IO system of its higher-level IO controller. In view of this, it is important to ensure that the device name previously assigned in the GSD file is not used at this stage.
- An I-device proxy can be used multiple times if multiple SIMOTION controllers with the same configuration are to be connected to a higher-level IO controller. You only have to ensure that each SIMOTION controller has a unique device name.

iDevice (Page 2131)

I device functionality with SIMOTION SCOUT V4.2 or higher

Description

With Step 7 5.5 or higher, SIMATIC CPUs can also be configured as I devices. The I device functionality of SIMOTION CPUs and SIMATIC CPUs has been consistently standardized. In the context of this standardization process, the GSD version has been set as V2.25. With SIMOTION projects that use a lower version than V4.2, the iDevice must therefore be re-exported / reinstalled and reintegrated into the project of the higher-level IO controller when upgrading to V4.2. If you edit projects without re-exporting and reinstalling the GSD file, a diagnostics buffer entry will be created on the CPU of the I device when establishing a connection via PROFINET.

Note

If you import, restore or insert a project that contains a module configured via a GSD file onto a computer, and then open with SIMOTION SCOUT, the GSD file used within it is installed automatically, if this is no longer present on the computer. The hardware catalog is not updated automatically and must be manually updated. Execute **Tools > Install catalog** in HW Config to do this.

Note

You can scan the logical address of a proxy iDevice using the function _getLogDiagnosticAddressFromDpStationAddress. The function _getnextlogaddress is not intended for this purpose.

Note

Boundary conditions for I device V4.2 or higher

STEP 7 V5.5 must be used for configuration on the higher-level IO controller, as this is the minimum version required to import the GSD file V2.25 file.

When upgrading older versions of the SIMOTION controller to V4.2, the iDevice becomes "incompatible" and it is absolutely essential to export/import the GSD file.

Below you will find a list of various scenarios which illustrate I device compatibility.

Use case 1: Old project involving SIMOTION devices lower than V4.2 without modification to the I device.

1. Open an old project involving SCOUT V4.2/Step 7 5.5. The project contains RT I devices for communication with a SIMATIC CPU.
2. Change the project, but do not make **any** changes to the I device configuration.
3. Compile the SIMOTION project, including HW Config, and save it as SIMOTION SCOUT V4.1.
4. The project can be reloaded without any problems.

Use case 2: Old project involving SIMOTION devices lower than V4.2 with modification to the I device interface.

1. Open an old project involving SCOUT V4.2/Step 7 5.5. The project contains RT I devices for communication with a SIMATIC CPU.
2. Change the project and make changes to the I device configuration. Changes are automatically implemented on the I device interface and an IO slot is added.
3. Create a new GSD from the iDevice.
4. Install the exported iDevice and replace it on the higher-level SIMATIC CPU.
5. Compile the SIMOTION project, including HW Config, and save it as SIMOTION SCOUT V4.1.
6. The project can be reloaded without any problems.

Use case 3: Higher-level SIMATIC CPU and SIMOTION I device lower than V4.2 and upgrade to V4.2.

1. Open the project with a SIMOTION CPU and higher-level SIMATIC CPU. The SIMATIC CPU communicates as a PN controller with the I device of the SIMOTION CPU.
2. Upgrade the SIMOTION CPU to SIMOTION V4.2.
3. Export the I device of the SIMOTION CPU.
4. Diagnostics addresses and station numbers have changed compared to what they were in the previous I device. If these are used as absolute values in system calls in the SIMOTION application, the application program will need to be adapted accordingly.
5. Delete the previous I device of the SIMOTION CPU in the project of the higher-level SIMATIC CPU. Make sure that the input and output addresses of the new I device are identical to those of the old I device, so that the previous S7 application can be used.
6. Import the new GSD file into the project of the higher-level SIMATIC CPU.
7. Compile the SIMOTION project, including HW Config, and save it as SIMOTION SCOUT V4.2. The project has now been upgraded to V4.2.

Use case 4: Higher-level SIMOTION CPU and several SIMOTION I devices lower than V4.2 and upgrade to V4.2.

1. Open the project with several SIMOTION CPUs as I devices and a higher-level SIMATIC CPU. The higher-level SIMOTION CPU communicates as a PN controller with the I device of the SIMOTION CPU.
2. Upgrade the SIMOTION CPUs to SIMOTION V4.2.
3. Diagnostics addresses and station numbers have changed compared to what they were in the previous I device. If these are used as absolute values in system calls in the SIMOTION application, the application program will need to be adapted accordingly.
4. Export the I device of the SIMOTION CPUs and import the GSD file into the project of the higher-level SIMOTION CPU.
5. Compile the SIMOTION project, including HW Config, and save it as SIMOTION SCOUT V4.2. The project has now been upgraded to V4.2.

Creating an I device

Requirement

You have already created a project and created a station with rack or a SIMOTION controller in HW Config (SIMATIC Manager or SIMOTION SCOUT). You have configured the PROFINET IO system and now want to configure the I-device.

Note

When configuring the I-device, pay attention to the possible settings for the RT class, see PROFINET IO and I device (Page 2238).

Procedure

1. Double-click on the PROFINET interface of the SIMOTION controller that you want to configure as an I-device. The **Properties** dialog box opens.
2. Switch to the **General** tab and, if necessary, change the device name. This must comply with the DNS conventions (Page 2277).
3. Switch to the **I-Device** tab.
4. Select the **I-device mode** check box.

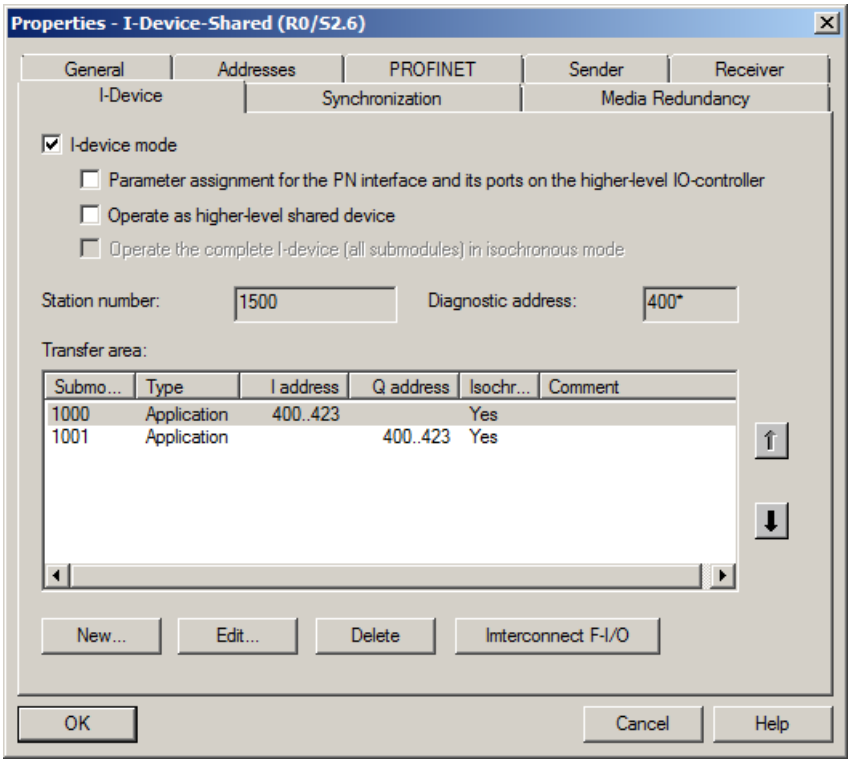

Figure 4-397 I-device properties dialog box

5. You have to activate different check boxes depending on whether I-device communication is to take place on the higher-level controller using RT or IRT.
   - **I-device using RT:**
     Select the **I-device mode** checkbox only.
   - **I-device using IRT**:
     If the I-device is to be operated on the higher-level IO controller isochronously, you also have to activate the **Parameter assignment for the PN interface and its ports on the higher-level IO controller** and **Operate the complete I-device (all submodules) in isochronous mode** checkboxes. This will also result in ports being created in the GSD file and parameter assignment data sets being loaded to the I-device's controller on start-up. If you do not select this check box cyclic communication between the higher-level IO controller and the I-device can only take place via RT. On the I-device proxy, this selection causes the **IO Cycle** tab to appear in the **Properties for the PROFINET interface** dialog box. It will then be possible to select the **Servo** entry under **Assign I-device in isochronous mode** on this tab so that the I-device can be operated isochronously. If an I-device is to be operated with IRT, the PN interface and its ports have to be parameterized on the higher-level IO controller and **Assign I-device isochronously** must be set.
6. You configure the **transfer areas** in the next step. Click **New**... each time to create the virtual subslots (input and output address transfer area), and configure these according to your requirements. By doing this, you are configuring the I/O range for the I-device via which data is exchanged with the higher-level IO controller. You do not need to configure any more settings in the **Sender** and **Receiver** tabs.
   Depending on the CPU used, the following settings are available for the transfer area type:
   - **Application**
   - **I/O**
   - **F-I/O**
     Note:
     You will find more information on the transfer area in the next section.
7. For the **transfer areas**, you can specify whether each individual area is to be operated isochronously, e.g. the fail-safe I/O cannot be operated isochronously. In order to select isochronous mode separately for each transfer area, the check box **Operate the complete I-device (all submodules) in isochronous mode** must be deactivated (from SIMOTION V4.4).
8. Click **OK** to accept these settings and save the project.
9. Continue by creating the I-device proxy (Page 2248).

Creating transfer areas for an I-device

How to create an application transfer area:

1. Select **Application** for an application transfer area. STEP 7 automatically assigns the values of the transfer area on the higher-level IO controller (slot and subslot); the fields cannot be edited.
2. Specify whether the transfer area is to be a local input or output transfer area. To do this, select the corresponding **Address type**. STEP 7 automatically assigns the address type of the higher-level IO controller. If the transfer area is to appear as an output in the higher-level IO controller, it must be an input in the I-device, and vice versa.

3. For isochronous application areas, activate the **Isochronous** checkbox.
4. As with any other submodule, a transfer area requires an address space in order to be addressed by the user program; specify the start address, length, and the process image of the input/output.
5. Enter further information in the comment area as required and click **OK** to close the dialog box.

How to create an F-I/O transfer area (or I/O transfer area):

1. Select **F-I/O** (or **I/O**) for an I/O transfer area. STEP 7 automatically assigns the values of the transfer area on the higher-level IO controller (slot and subslot); the fields cannot be edited.

   Note

   The I/O transfer areas are established automatically for the entire configured fail-safe I/O using the **Interconnect fail-safe I/O** button. You no longer have to set up each fail-safe I/O individually.

2. Now specify which modules/submodules of the I-device are to be made available to the higher-level IO controller as I/O transfer areas. Click the **Select I/O** button: The **I/O transfer area - Select I/O** dialog box opens.
3. Select a module/submodule and click **OK** to close the dialog.
4. As with any other submodule, a transfer area requires an address space in order to be addressed by the user program. You must, therefore, specify the start address of the input/output. The length is determined automatically from the selected module/submodule.
5. Enter further information in the comment area as required and click **OK** to close the dialog box.

See also

Insert the iDevice substitute in the higher-level IO controller (Page 2250)

Exporting the GSD file for the I device

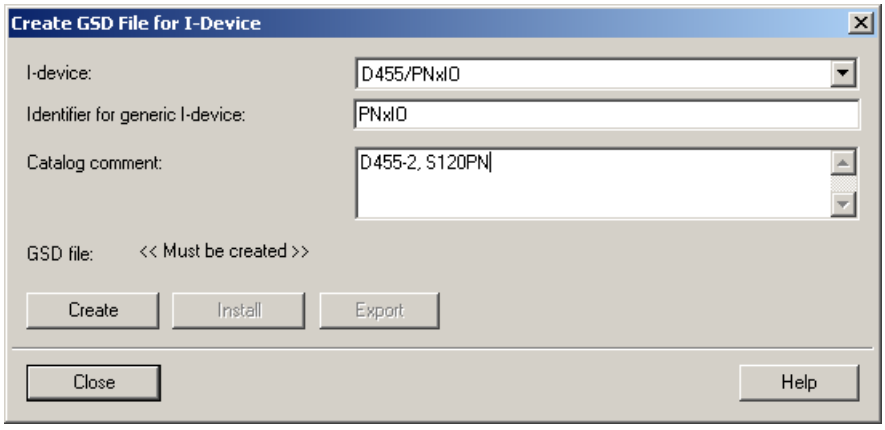
A GSD file must always be exported if an iDevice is to be used in a project on another PG/PC.

Requirement

You have already configured the module to be used as an I device.

1. First save the project.
2. Open HW Config and select **Extras > Create GSD file for iDevice...** from the menu. The **Create GSD file for I device** dialog opens.

3. Select the I device and enter a name for the substitute I device. The substitute I device will appear under this name in **Preconfigured Stations** in the HW catalog.



4. Click **Create** and then **Export**. The **Find folder** dialog opens.
5. Select the path in which the GSD file of the substitute I device is to be stored and click on **OK**.

Creating a substitute I device

There are two different ways of creating a substitute iDevice. The first, **Options > Install GSD files ...** , involves a previously exported GSD file. The second involves the **Create GSD file for I device** dialog.

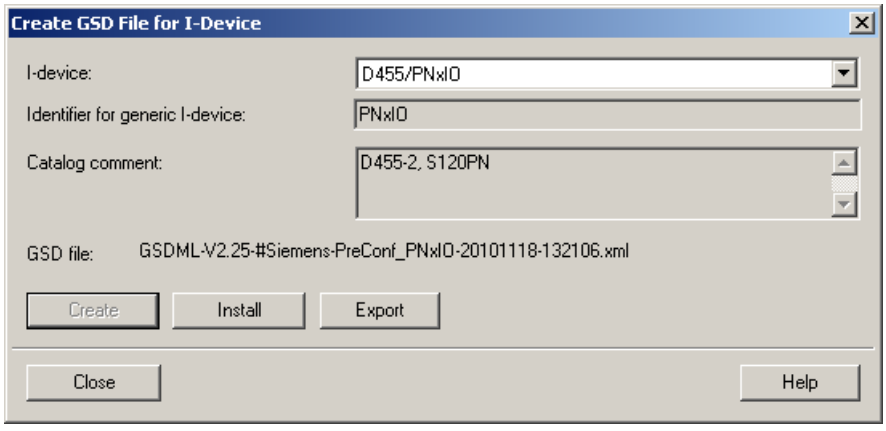
Requirement

You have already configured the module to be used as an I device and exported the GSD file from this.

Procedure 1:

1. First save the project.
2. Create an iDevice as described in Chapter Exporting the GSD file for the I device (Page 2247). There is no need to export the file; instead, it is installed immediately.

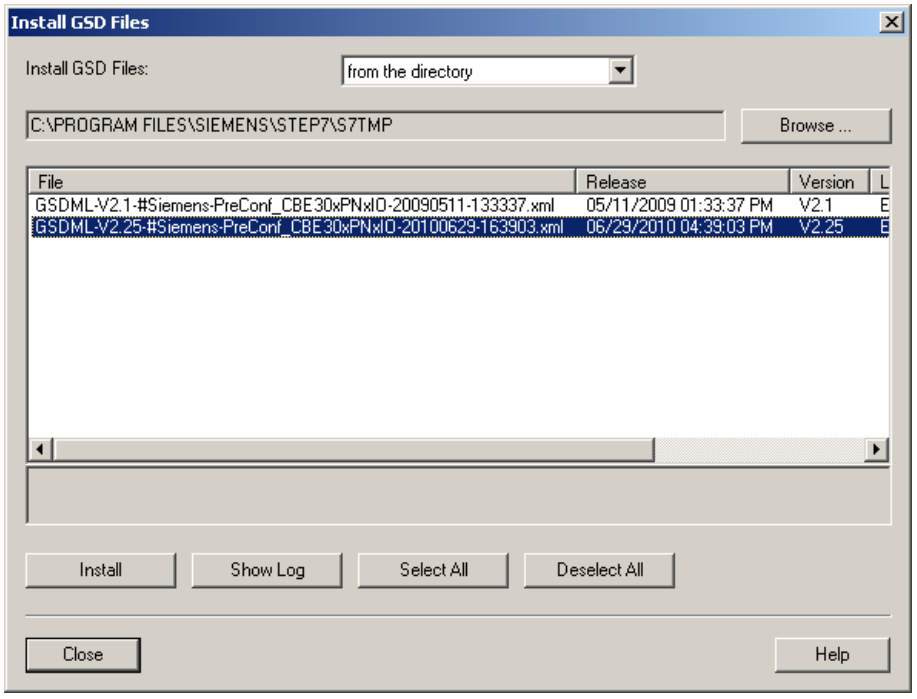
3. Click **Create** and then **Install**.



4. Click **Close**. The substitute I device will now be available under "Preconfigured Stations".

Procedure 2:

1. Select **Extras > Install GSD files....** . The "Install GSD files" dialog box opens.
2. Click **Browse...** . The **Find folder** dialog opens.
3. Select the path in which the GSD files of the substitute iDevice are stored and click on **OK.**



4. Select the required GSD files and click **Install**.
5. Click **Close**. The substitute I devices will now be available under "Preconfigured Stations".

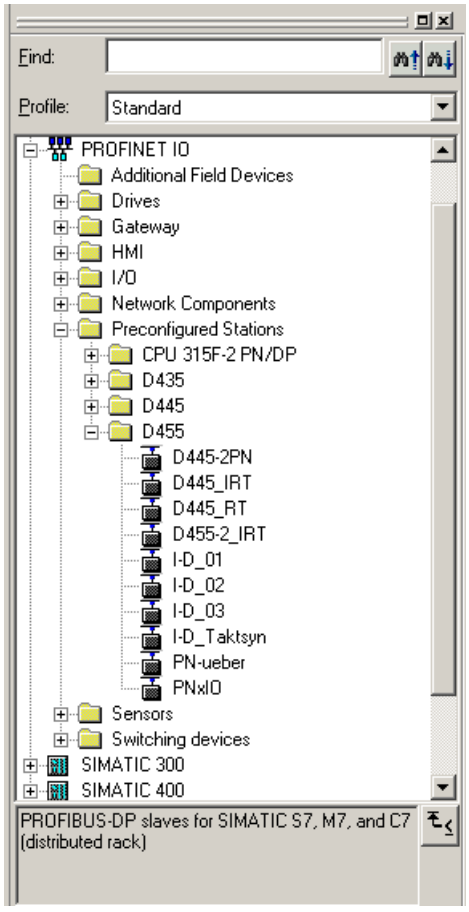


Figure 4-398 iDevice entry in the hardware catalog

Insert the iDevice substitute in the higher-level IO controller

Requirement

You have already created an I-device proxy. A project is open and an IO controller with a PROFINET IO system has already been configured.

Inserting an I-device proxy

1. Open the hardware catalog in HW Config.
2. Drag the relevant I-device proxy from the hardware catalog (**PROFINET IO > Preconfigured stations**) to the PROFINET IO system of the higher-level IO controller. The I-device proxy is displayed as a normal IO device on the PROFINET IO system. Depending on whether the option **Parameter assignment for the PN interface and its ports on the higher-level IO controller** has been selected for the I-device configuration, the PN interface and the individual ports of the I-device are also displayed here.

   Note

   Check whether the device name of the I-device proxy matches that of the PN interface of the corresponding controller. For more information, see the chapter PROFINET IO and I device (Page 2238).

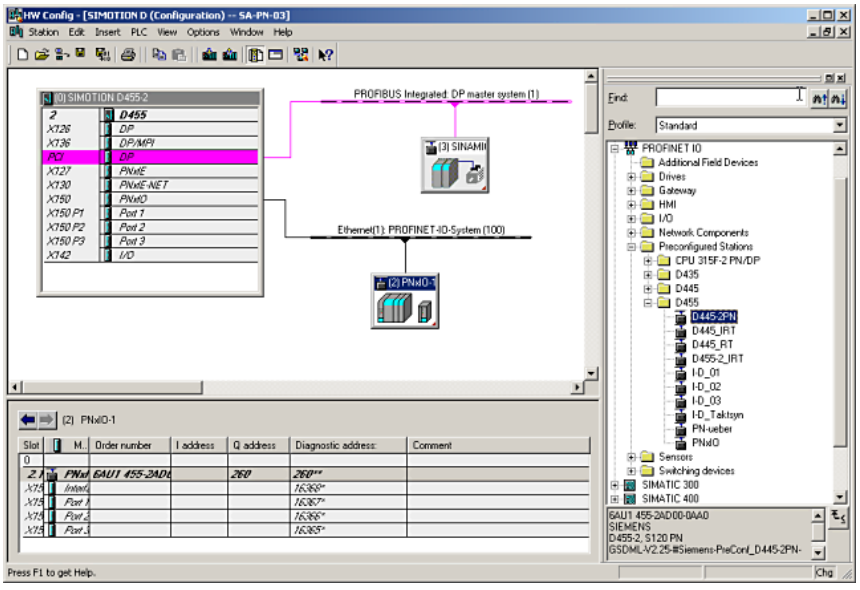

Figure 4-399 I-device on the IO controller

The number of submodules corresponds to the number of the configured submodules of the I-device in the GSD file. Modules and submodules (virtual subslots) cannot be deleted.

3. You can interconnect the I-device ports with the IO controller ports in the Topology Editor.

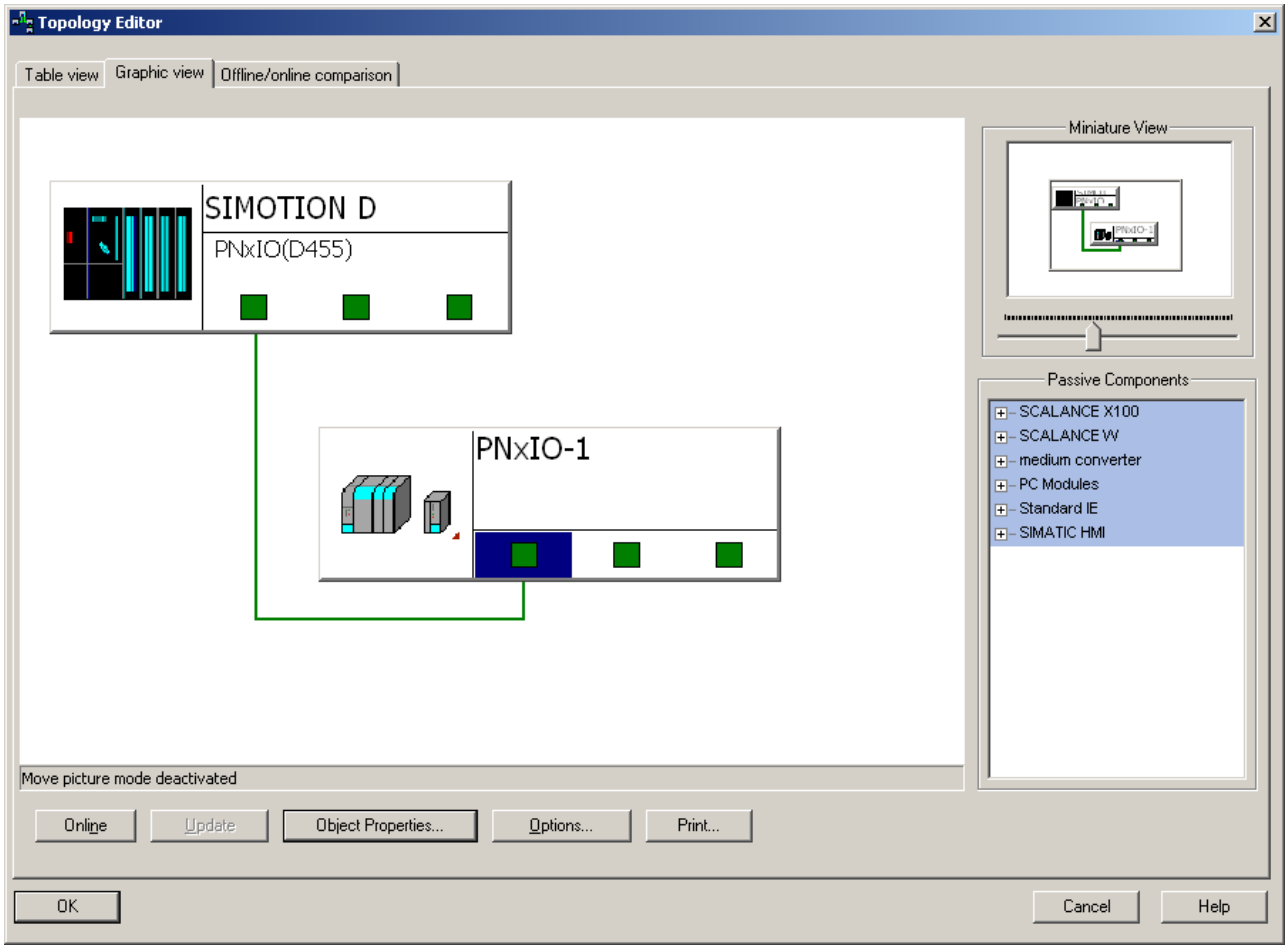

Figure 4-400 Interconnecting I-device ports

Assigning an IP address for the I-device proxy

1. Double-click the I-device to open the **Properties** dialog box. This displays how the IP address is assigned.
2. If the option **Obtain IP address using a different method** is activated for the SIMOTION controller that is configured as an I-device, **no** IP address will be saved in the project. Then the IP address must be assigned from the IO controller. If the option is **not** activated, then the IP address is already saved in the project.

Set synchronization role and isochronous mode for IRT I-device

1. Double-click on the PROFINET interface in the rack of the SIMOTION I-device to open its properties.
2. In the **Synchronization** tab, select **Sync-Slave** and **IRT** as synchronization role and RT class respectively.
3. Select Servo under **Assign IO device in isochronous mode** on the **IO Cycle** tab**.**

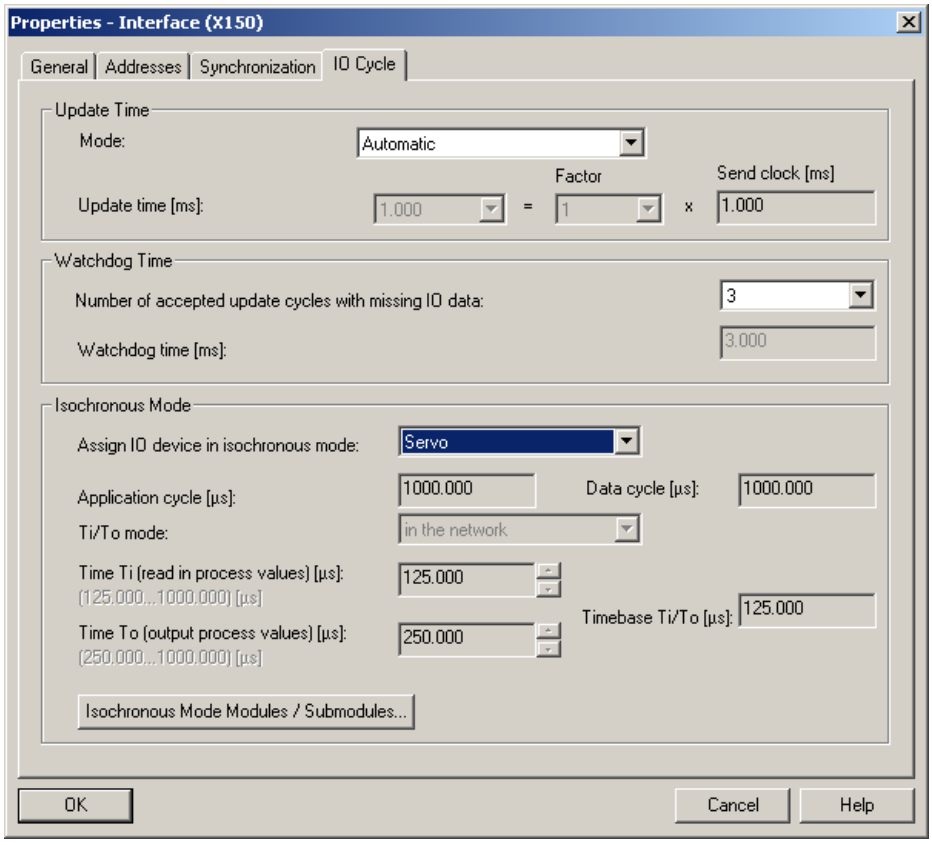

Figure 4-401 Setting isochronous mode on the I-device

Setting the update time and send clock

RT I-device

- The update time is to be set up for the RT I-devices. Double-click the PROFINET IO system and select the **Update time** tab in the **PROFINET subnet properties** dialog. Set the update time there.

IRT I-device

- The send clock needs to be set for IRT I-device. The setting made for the send clock in the I-device's project must be the same as for the send clock in the higher level IO controller's project. Set the send clock for the higher-level IO controller in HW Config using **Edit > PROFINET IO > Domain Management**.

See also

IP address and device name via UP/DCP (Mini-IP-Config) (Page 2277)

Deleting a substitute I device

The GSD files for the substitute I device can be found under "Preconfigured Stations" in the following directory:

<Program Files>\Siemens\Step7\S7DATA\GSD,
e.g. GSDML-V2.25-#Siemens-PreConf_**D455-2_IRT**-20100830-132044.xml.

Here, **D455-2_IRT** is the name of the substitute I device. You can delete the substitute I device by deleting the corresponding XML files. The substitute iDevices displayed under "Preconfigured Stations" are only updated when a new GSD file is created and installed or when the HW catalog is manually updated in HW Config.

Shared iDevice

Introduction

As of V4.4, the iDevice of the PN-IO interfaces can be operated with two higher-level IO controllers as a shared iDevice. The properties and configuration are comparable with a shared device. Configuration is similar to that of a shared device.

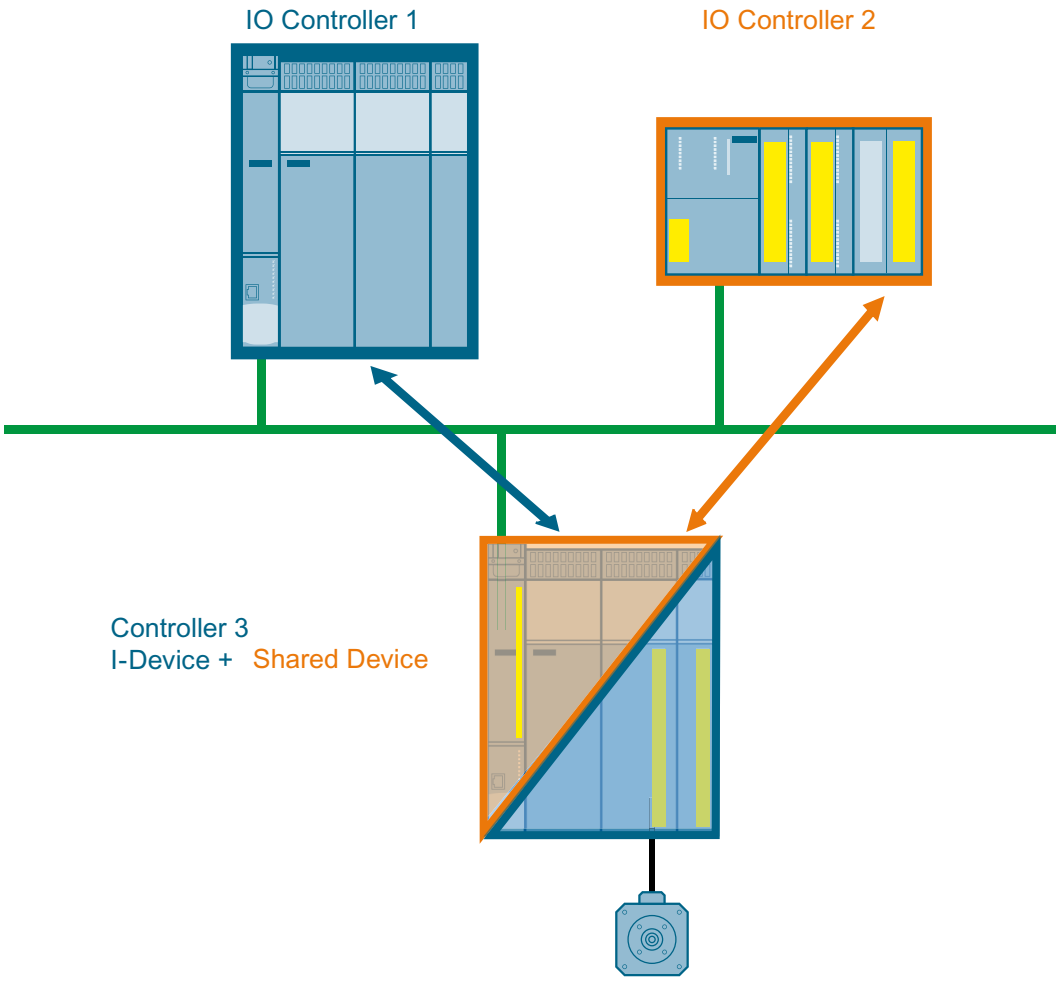

Figure 4-402 iDevice as a shared device

Boundary conditions

When using the shared iDevice, certain boundary conditions must be observed.

- Only one of the two higher-level IO controllers can communicate with the iDevice via PROFINET IRT. The interface module and the port submodule of the iDevice must be assigned to this IO controller.
- The second higher-level IO controller can only communicate with the iDevice via PROFINET RT.
- Each submodule of the iDevice can be assigned to one of the two IO controllers.

- Here a submodule can only be assigned to one of the two higher-level IO controllers.
- In the SIMOTION SCOUT the shared iDevice (shared master) appears only once in the project navigator.
  (The shared master: First device added directly to the network via drag&drop. The second device is created by copying the shared masters and clicking **Shared paste** in the context menu.)

Station failure and station reconnection

A shared iDevice communicates with two higher-level IO controllers which share the submodules of the iDevice. Using the diagnostic events "Partial station reconnection" and "Partial station failure", one can check on the CPU of the iDevice in an application-specific way whether only one or both higher-level IO controllers are connected to the iDevice. However, this is only possible if each submodule of the iDevice has also been assigned to one of the two IO controllers.

The establishment or removal of an application relationship between IO controller and iDevice is reported by opening the PeripheralFaultTask. A distinction can be thus made in an application-specific manner between the different cases using the reported event ID.

An overview of the evaluation with the PeripheralFaultTask can be found in the chapter Alarms on the IO controller (Page 2260).

Shared iDevice send clocks with IRT

If a shared iDevice is operated in connection with PROFINET IRT, then only "even" send clocks (125, 250, 500, 1,000, 2,000, 4,000 µsec) can be used on the higher-level IO controllers for PROFINET RT and IRT.

Background:
As only "even" send clocks are permitted for PROFINET RT and the shared iDevice physically represents a module, only "even" send clocks may also be set on the higher-level IO controller which communicates with the iDevice via PROFINET IRT.

Shared iDevice and PROFIsafe

The shared iDevice function can be used to implement a PROFIsafe configuration with the automation CPU and safety CPU. You can find more information on this subject from the chapter Shared iDevice and PROFIsafe (Page 2374) onward.

4.5.5.6 Loading the communication configuration

Loading the PROFINET IO configuration

Requirement

A PG/PC with which you can go ONLINE is connected.

Procedure

The configuration data must be loaded to all participating controllers once PROFINET IO configuration has been successfully completed.

1. In NetPro, select the Ethernet subnet and then select the **Target system > Loading in current project > Nodes on the subnet** menu command.

4.5.5.7 Communication connections between SIMOTION and SIMATIC

Communication connections overview

Description

The following options are available for establishing a communication connection between SIMOTION and SIMATIC:

- PROFINET RT (or IRT) via iDevice
- PROFINET RT (or IRT) via PN/PN coupler
- PROFINET RT via S7-300 CP as an IO device
- TCP/UDP user communication

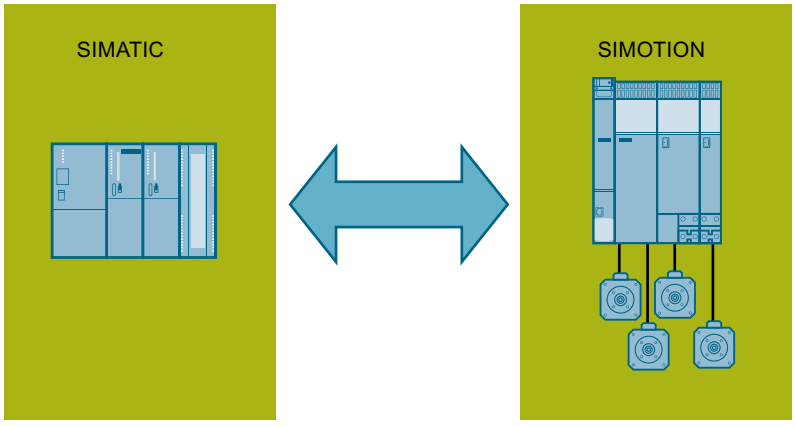

Figure 4-403 Data exchange between SIMOTION and SIMATIC

See also

Data exchange through the use of iDevices (Page 2258)

Data exchange through the use of iDevices

Description

With PROFINET IO/RT, data can be exchanged via an I-device.

Note

A PROFINET device connected to a SIMOTION CPU may have a maximum submodule size of 1,024 bytes.

This limit is especially important if a SIMATIC CPU is configured as an I-device for a SIMOTION CPU. Depending on the hardware and the PN interface, the submodule size may vary from 254 to 1024. Therefore, please note the possible quantity structures (Page 2162).

I-device FAQ

An FAQ section on the subject of coupling a PROFINET RT I-device between a SIMOTION control and a SIMATIC control is provided in SIMOTION Utilities & Applications. SIMOTION Utilities & Applications is provided as part of the SIMOTION SCOUT scope of delivery.

It looks at the following three application cases:

Case A: Two separate projects: SIMATIC and the SIMOTION as an I-device in a project; SIMOTION as a controller in a second, separate project

Case B: One project for all components

Case C: Multiple use of an I-device

For more detailed information on the configuration of I-devices, please refer to the chapter Configuring the iDevice (Page 2238).

Also note the FAQ for **Configuring RT communication between SIMATIC and SIMOTION (I-device)** I device FAQ (https://support.industry.siemens.com/cs/ww/en/view/38494882)

4.5.5.8 Diagnostic and alarm behavior

Device model for PROFINET

Definition of device model

The device model of PROFINET describes the structure of modular and compact field devices. Similar to a PROFIBUS DP slave, a PROFINET IO device is structured in a modular way. In this way, modules are attached to slots, and submodules to subslots. Channels are located on the modules and submodules, through which process signals can be read and output. In principle it is possible to divide one slot into further subslots, into which the submodules can be plugged.

Diagnostics levels for PROFINET

Diagnostics levels

Each occurring fault in an IO device is transmitted from it to the IO controller. The range and depth of information of a diagnosis can vary depending at which diagnostics level the diagnostics data is evaluated.

In principle there is the option of evaluating diagnostics information at the following levels of address.

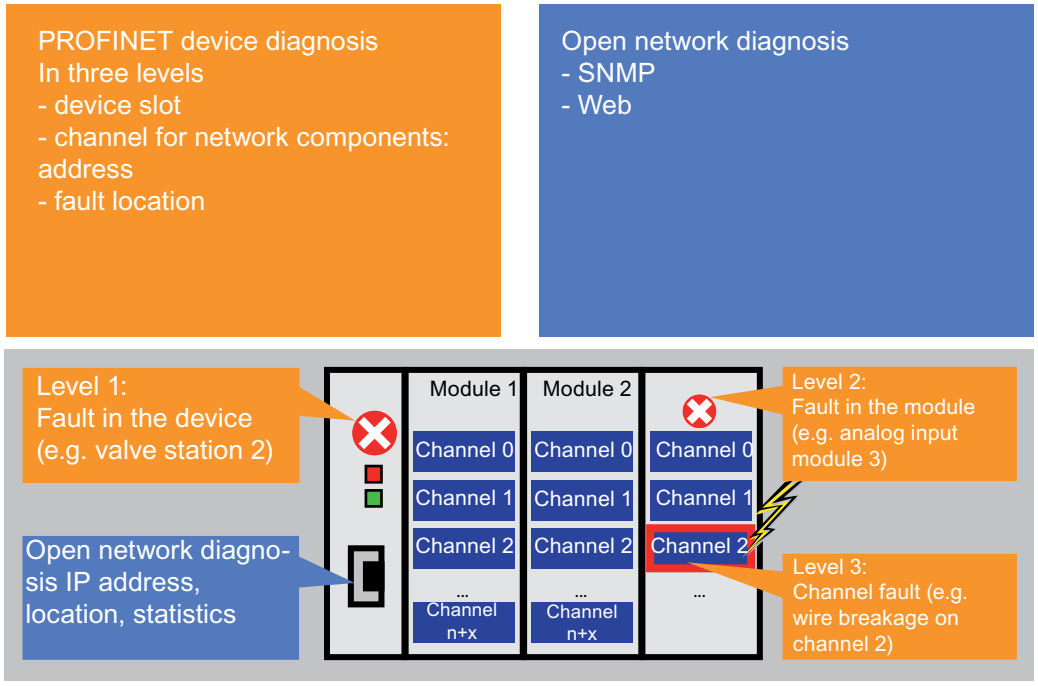

Figure 4-404 Diagnostics overview using the example of ET200

There is a group of standardized diagnostics data sets for PROFINET for each level of address with which the diagnostics information of the IO device can be read (e.g. via the SIMOTION system function _readRecord).

Note

You will find further information on the _readRecord system function in the online help or in the *"SIMOTION System Functions/Variables Devices List Manual"*.

You will find an overview of the data sets available with PROFINET, including the structure of data sets, from section 5 in the *Programming Manual "From PROFIBUS DP to PROFINET IO."* You can find the Programming Manual in the Service&Support portal as a download (https://support.industry.siemens.com/cs/ww/en/view/19289930).

Using TaskStartInfo

TaskStartInfo

In addition to the option of reading the diagnostics information of IO devices through standardized data sets, with SIMOTION the so-called "TaskStartInfo" can also be evaluated for fundamental fault diagnostics.

Important information on the start of each task in the execution system of the SIMOTION controller is saved in the "TaskStartInfo". The respective "TaskStartInfo" can be requested within a task (for diagnostics events that concern peripherals connected to the SIMOTION controller, this request must be made in the "PeripheralFaultTask").

In this process the event that occurs is reported through the system variable "TSI#interruptId" (e.g. CPU stop, process alarm, etc.). The system variable "TSI#eventClass" specifies whether the fault that occurs is appearing or disappearing. On this basis a more precise specification of the event is performed using the system variable "TSI#faultId" (e.g. channel diagnostics pending, station reconnection of an IO device with / without faults, etc.).

Note

Further information:

- Example application SIMOTION: Diagnose CPU stops and module statuses (https://support.industry.siemens.com/cs/ww/en/view/53705461).
- *Function Manual "SIMOTION Runtime Basic functions"* (section "Use Taskstartinfo").

Alarms on the IO controller

Description

A number of alarms are issued on the IO controller. Occurring alarms are listed with the corresponding EventID in the diagnostics buffer of SIMOTION. The following alarms are possible:

- Alarms for direct data exchange between IO controllers
- Station alarms reported by the PROFINET interface

The following table shows PROFINET IO alarms as they are represented in SIMOTION:

Alarm (TSI#InterruptId)	TSI#eventClass	TSI#faultId	Meaning
Station failure (_SC_STATION_DISCONNECTED (= 202))	16#39	16#CA	PROFINET IO system error: In this case there is only an incoming event; an outgoing event is represented on 16#38 - 16#CB for each IO device present.
		16#CB	Station failure of an IO device. Shared I-device: No submodule of the I-device is currently subscribed to by the higher-level IO controller.
		16#CC	IO device fault present. Channel diagnostics or manufacturer-specific diagnostics pending. **Note:** 16#39:16#CB is always used for the station failure; 16#38:16#CC is used for incoming with fault.
		16#F8	Partial station failure Shared I-device: Submodules of the I-device are partially subscribed to by the higher-level IO controller.
Station reconnection (_SC_STATION_RECONNECTED (= 203))	16#38	16#CB	An IO device has been reconnected with an error or warning. Shared I-device: All submodules of the I-device are currently subscribed to by the higher-level IO controller.
		16#CC	An IO device has been reconnected with an error or warning.
		16#CD	An IO device has been reconnected, but with an error: Set configuration <> actual configuration.
		16#CE	An IO device has been reconnected, but error during module parameterization.
		16#F8	Partial station reconnection Shared I-device: Submodules of the I-device are partially subscribed to by the higher-level IO controller.

Use of TaskStartInfo

Information about using the TaskStartInfo for the PeripheralFaultTask can be found in the *"SIMOTION Runtime Basic Functions"* Function Manual.

Alarms from the IO device to the IO controller

Description

The alarms are transferred using the PROFINET alarm mechanism from the IO device to its associated IO controller. The alarms are entered in the diagnostic buffer and can be evaluated using the PeripheralFaultTask. The following table shows how alarms are represented as PeripheralFaultTask.

Alarm (TSI#InterruptId)	TSI#eventClass	TSI#faultId	Meaning
Diagnosis (incoming)	16#39	16#42	Incoming diagnostic interrupt
Diagnosis disappears (outgoing) Multicast Communication Mismatch Port Data Change Notification Sync Data Changed Notification Isochronous Mode Problem Notification Network component problem notification (_SC_DIAGNOSTIC_INTERRUPT (=201))	16#38	16#42	Outgoing diagnostic interrupt
Process interrupt (_SC_PROCESS_INTERRUPT (= 200)	16#11	16#41	Process interrupt
Pull Alarm	16#39	16#51	PROFINET IO module has been removed or cannot be addressed.
		16#54	PROFINET IO submodule has been removed or cannot be addressed.
Plug Alarm Plug Wrong Submodule Alarm Return of Submodule Alarm (_SC_PULL_PLUG_INTERRUPT (=216))	16#38	16#54	PROFINET IO module or submodule has been inserted, module type OK (actual configuration = set configuration)
		16#55	PROFINET IO module or submodule has been inserted, but wrong module type (actual configuration <> preset configuration)
		16#56	PROFINET IO module or submodule has been inserted, but error during module parameterization
		16#58	IO status of a module has changed from BAD to GOOD
Status			Not Supported
Update			Not supported
Time data changed notification			Not supported
Upload and storage notification			Not supported
Pull module			Not supported
Manufacturer-specific			Not supported
Profile-specific			Not Supported

Alarm types indicated as "not supported" are acknowledged by the SIMOTION controller with "not supported" and not entered in the diagnostic buffer.

Use of TaskStartInfo

Information about using the TaskStartInfo for the PeripheralFaultTask is contained in the *SIMOTION Basic Functions* manual.

Transfer diagnostic data

The exact reason for the alarm is provided as diagnostic data. The _readDiagnosticData() function can be used to read out this data. The length is restricted to 240 bytes.

With V4.2 or higher, you can read out station/module diagnostic data of up to 65,535 bytes with the function block _readVariableDiagnosticData() and the user program.

Alarms for direct data exchange between IO controllers

Description

For PROFINET IO with IRT, communication monitoring takes place between IO controllers. If this establishes that IRT data is no longer being received (either there is no data arriving, or it is arriving too late) a station failure alarm is generated. If communication is re-established, a station reconnection alarm is generated. If IRT data arrives late on three occasions, a station failure alarm is reported.

Note

During communication monitoring, only the receiver slot is monitored.

The following table shows PROFINET IO alarms between IO controllers involved in direct data exchange as they are represented in SIMOTION:

Alarm (TSI#InterruptId)	TSI#eventClass	TSI#faultId	Meaning
Station failure (_SC_STATION_DISCONNECTED (= 202))	16#39	16#F3	The receiver in the direct data exchange is no longer receiving data.
Station reconnection (_SC_STATION_RECONNECTED (= 203)	16#38	16#F0	The transmitter in the direct data exchange has started up and is able to transmit.
		16#F1	The receiver in the direct data exchange has started up without errors and the receiver is receiving data again (all receiving areas are available).
		16#F2	The receiver in the direct data exchange has started up with errors and the receiver is receiving data again (at least one receiving area not available).

SINAMICS drives alarms

Description

In SINAMICS firmware Version 4.5 and higher, SINAMICS drives (S and G) have a PROFIBUS/ PROFINET diagnostics channel. Alarms can be forwarded to a higher-level control via this channel.

The drive is controlled via a TO

If the drive is controlled via a TO, drive alarms are issued via the alarm mechanisms of the technology object.

The drive is controlled directly by means of a user program

If you are controlling the drive directly by means of a user program, you must program the alarm response.

Alarms on the IO controller (Page 2260)

System functions for the diagnostics for PROFINET or PROFIBUS

Overview of system and diagnostics functions

The following table provides an overview of the various system and diagnostics functions for PROFINET IO. Differences with PROFIBUS DP are also indicated.

You will find detailed information about each of the functions in the reference list for functions *List Manual, SIMOTION system functions/variables for devices*.

Function	Note	PROFIBUS	PROFINET
_getStateOfSingleDpSlave()	The function determines the status of communication with a cyclic communications partner (device - PROFINET, slave - PROFIBUS, transmitter or receiver controller-controller data exchange broadcast - PROFINET).	Logical diagnostic address of the DP slave	Logical diagnostic address of the IO device
_getStateOfDpSlave()	_getStateOfDpSlave provides information concerning whether the PROFIBUS DP slave or the PROFINET IO device is activated or deactivated.	Logical diagnostic address DP slave	Logical diagnostic address of the IO device

Function	Note	PROFIBUS	PROFINET
_getStateOfAllDPStations()	The system function determines the status of the communication with cyclic communications partners (device - PROFINET, slave - PROFIBUS, transmitter or receiver controller-controller data exchange broadcast - PROFINET). In addition to the activation status, information on availability is also provided.	Logical diagnostics address of the interfaces	Logical diagnostics address of the interfaces 4.2 and higher With PROFINET IO devices, this system function forms a group signal from the modules present in the device. This means that the function can also tell the user program when modules have been removed or are faulty by using the device feedback values for this purpose.
_getStateOfIO()	This function provides the user program with information on the status of the DP stations, modules, and submodules. It also provides this information in detail for modules and submodules. The following are supported: • Interfaces such as PROFIBUS DP or PROFINET • Stations (slaves, devices), modules, or submodules This function provides a logical diagnostics address or logical I/O address to identified modules, and a list of assigned submodules.		
_getNextLogAddress()	All configured logical addresses of a segment can be determined using this function.	Logical diagnostics address	Logical diagnostics address
_readDiagnosticData() _getStateOfDiagnosticDataCommand()	This function is used to output diagnostic data for a DP slave via the user program. For PROFIBUS, the diagnostics for the slave are read out, i.e. the slave supplies the complete diagnostic information. The structure of the diagnostic data is described in IEC 61158-6-3. For PROFINET, the subslot-specific diagnostics are read (i.e. the data set 0x800A). The diagnostics for a subslot are supplied. The structure of the diagnostic data is described in IEC 61158-6-10.	Logical diagnostic address DP slave	Logical diagnostics address of the IO device, of the module/slot, or IO address of the channel/subslot

Function	Note	PROFIBUS	PROFINET
_readVariableDiagnosticData()	This function block is used to read out diagnostic data of a station or module via the user program. The diagnostics format for PROFINET IO V2.2 and PROFIBUS DP is described in the IEC 61158-6 standard.	-	Data records with a total length up to 4 KB can be read with the FB _readVariableRecord. This function can be used for PROFIBUS and PROFINET. Data sets up to 4 KB are returned from the device only with PROFINET.
_readDriveFaults() SINAMICS only (ET200FC, S120, etc.)	This function is used to read the current fault buffer entry in the drive.	Logical start address of drive (slot).	Each valid logical I/O address of the subslot concerned or diagnostics address of the PAP (for modules without cyclic data). **Note:** In the case of PROFINET, parameter access takes place via the MAP (Module Access Point) of a DO. The MAP submodule is the substitute DO and hosts the alarm channel along with one or more PAPs (Parameter Access Point). The PAP is a data record in the MAP submodule. MAP is displayed in the GSD file.

PROFINET device diagnosis in STEP 7

Device diagnosis in STEP 7

In SCOUT, HW Config can be used to perform an online device diagnosis via PROFINET. The diagnosis supplies not only the slot and the channel number, but also the error type. The diagnosis operates similar to that for PROFIBUS.

Procedure

1. Go online and open HW Config for the appropriate SIMOTION device.
2. Select **Target system > Diagnose, monitor/control Ethernet node**.
   HW Config searches for all network nodes. The **(Diagnosis) ONLINE** window opens and displays the network nodes.
3. Right-click the required node and select **Properties**. The detailed diagnosis is displayed. The associated fault is displayed here.

PROFINET IO and DS0 diagnostic interrupts

Diagnostic interrupt PROFINET IO maintenance concept

Description

A device or module of an automation system can essentially be in one of two states: either 'good' or 'failure.' With a view to increasing the availability of sensors/actuators, devices, and modules, these same components also supply information concerning necessary maintenance work in addition to these two states. This additional information includes details about the maintenance state, state of wear, and remaining life time, etc. This constitutes what is known as an 'extended maintenance concept'. The aim of the extended maintenance concept is to detect and eliminate potential faults early on - before they lead to production outages. For this purpose, the 'good' and 'failure' states are supplemented by states called 'maintenance required' and 'maintenance demanded'.

The above states can be depicted on the following maintenance state model.

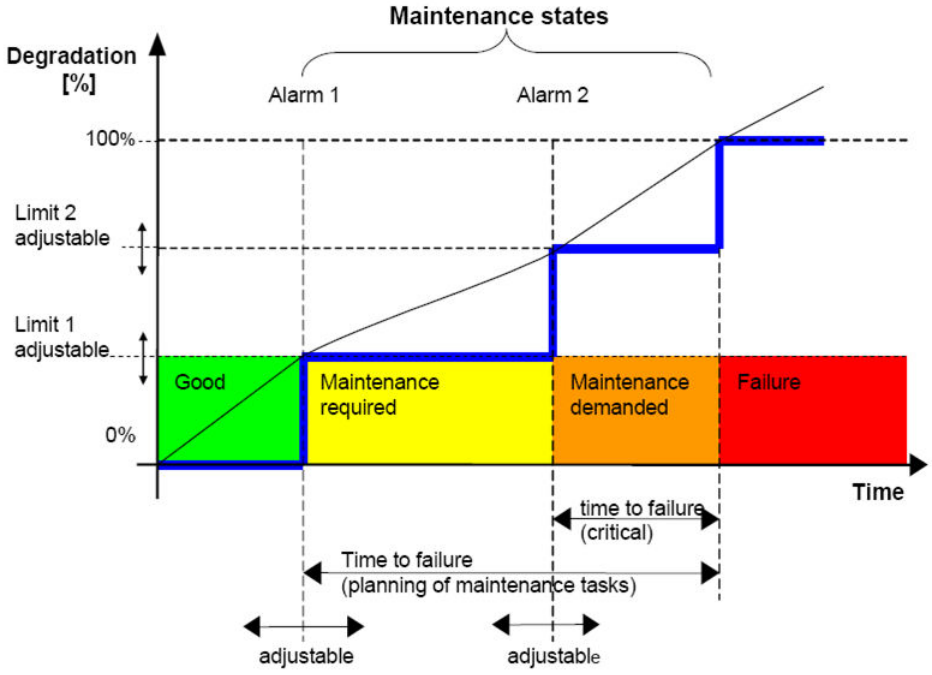

Figure 4-405 PROFINET IO maintenance state model

Maintenance state model

- Good (green): no action required
- Maintenance required (yellow): maintenance is to be scheduled
- Maintenance demanded (orange): maintenance is to be carried out
- Failure (red): fault

Device model for IO device

Description

The PROFINET IO device model stipulates that an IO device is to be divided into slots and subslots. A slot represents a module (= physical assembly) and a subslot represents a submodule (= physical subassembly).

Every submodule can be used for the following objects:

- Cyclic data (I/O interface useful data for process control)
- Alarms (e.g. diagnostic interrupt)
- Data sets
- Parameters
- Diagnostics

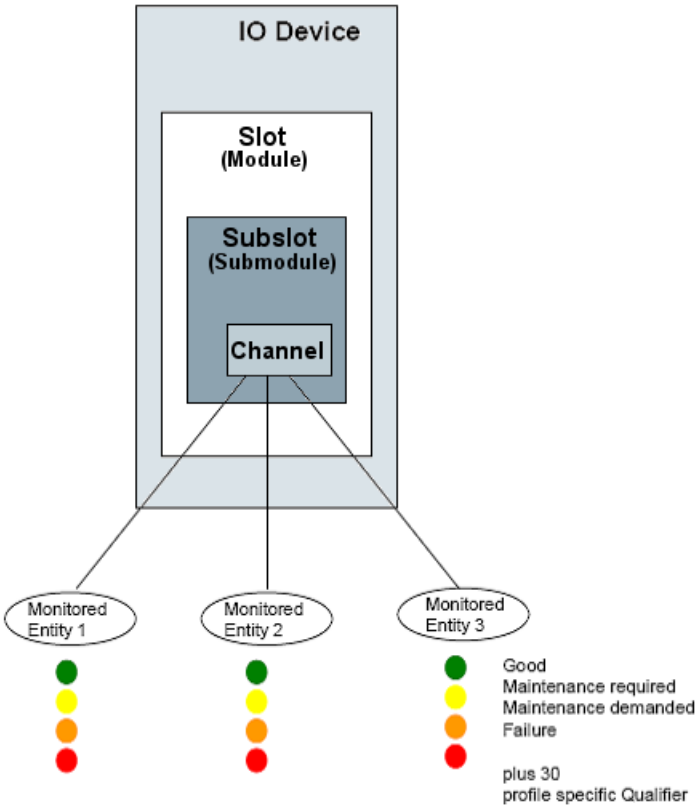

Figure 4-406 Classification of channel, diagnostic states and group information

In the PROFINET IO device model, channels are defined below submodules for the diagnostics. A channel is a logical substructure of a submodule. A submodule can contain up to 65,536 channels. Defined diagnostic functions (e.g. short-circuit, wire breakage, overtemperature) are monitored within the channels. A channel can also monitor several diagnostic functions in parallel.

This monitoring results in channel diagnostics. Several different sets of channel diagnostics can occur in a submodule at the same time. Channel diagnostics from different submodules can, of course, also occur. Channel diagnostics are signaled via a diagnostic interrupt. The diagnostic interrupt message is issued for each submodule in which channel diagnostics occur.

PROFINET IO and DS0 diagnostic interrupts

Description

If a diagnostics-related event occurs (e.g. failure or maintenance required) in an IO device, a diagnostic interrupt is generated and sent to the associated IO controller. The SIMOTION device acting as the IO controller then issues a diagnostic interrupt via the PeripheralFaultTask using TSI#interruptId = _SC_DIAGNOSTIC_INTERRUPT (= 201).

Data set 0 (DS0) for the diagnostic interrupt can be found under the TSI#InterruptId. Data set 0 (DS0) supplies the group states for the channels of a submodule.

Note

The DS0 contains only one selection of the possible diagnostics elements and is filled with all PROFINET-compliant I/O devices.

A diagnostic interrupt can occur as an incoming diagnostic interrupt with TSI#eventClass = 0x38, TSI#faultId = 0x42 and as an outgoing diagnostic interrupt with TSI#eventClass = 0x39, TSI#faultId = 0x42.

A diagnostic interrupt contains the following group states in data set 0 (DS0) in the form of the group bits below. The information relates to the sum total of all diagnostic functions of the channels within a submodule:

- Group failure: DS0.Byte0.Bit 0
- Group maintenance requirement: DS0.Byte1.Bit 7
- Group maintenance demand: DS0.Byte2.Bit7

The group bits are formed by the logical ORing of the respective individual bits of all diagnostic functions of the channels for a submodule. The three group bits are independent of each other and do not influence each other. The group bits are therefore set and/or reset independently of each other.

If just one modification is made to the maintenance states, individual maintenance requirements or maintenance demands are still pending in the submodule, and there are no faults, then an incoming diagnostic alarm is signaled and the following group bits are set accordingly in DS0: group maintenance requirement/group maintenance demand. If all maintenance states have disappeared and there is no failure, an outgoing diagnostic interrupt is signaled and the two group bits (group maintenance requirement/group maintenance demand) are set to 0. Normally, this means that the rule which applies is that an incoming diagnostic interrupt is signaled as soon as at least one of the group bits (group failure or group maintenance requirement or group maintenance demand) is set to 1. However, when all of the group bits (group failure or group maintenance requirement or group maintenance demand) are no longer set to 1, an outgoing diagnostic interrupt is signaled.

Explanation of the DS0 data set bits

Table 4-228 Table: DS0 byte 0

Bit	Description	Comment
Bit 0	Module Fault/OK	Group failure (diagnostics) for a submodule: • 0: No group failure (diagnostics) pending • 1: Group failure (diagnostics) pending
Bit 1	Internal error	Always 0
Bit 2	External error existent	Has the same content as bit 0
Bit 3	Channel error existent	Has the same content as bit 0
Bit 4	External auxiliary power missing	Always 0
Bit 5	Front connector missing	Always 0
Bit 6	Module not parameterized	Always 0
Bit 7	Wrong parameters in module	Always 0

Table 4-229 Table: DS0 byte 1

Bit	Description	Comment
Bit 0-3	Type class of module	3: Type class 3 is to be understood as a distributed I/O and as such also includes PROFINET IO.
Bit 4	Channel information existent	0: No readable channel information present 1: Readable channel information is present in the interrupt data of the diagnostic interrupt. The interrupt data can be read out using the _readDiagnosticData system function.
Bit 5	User information existent	0: No channel diagnostics or manufacturer-specific diagnostics available 1: At least one set of channel diagnostics and/or manufacturer-specific diagnostics is available
Bit 6	Diagnosis alarm from proxy	Always 0
Bit 7	Maintenance Required	Group maintenance requirement for a submodule: • 0: No group maintenance requirement pending • 1: Group maintenance requirement pending

Table 4-230 Table: DS0 byte 2

Bit	Description	Comment
Bit 0	-	Always 0
Bit 1	-	Always 0
Bit 2	-	Always 0
Bit 3	-	Always 0
Bit 4	-	Always 0

Bit	Description	Comment
Bit 5	-	Always 0
Bit 6	-	Always 0
Bit 7	Maintenance Demanded	Group maintenance demand for a submodule: • 0: No group maintenance demand pending • 1: Group maintenance demand pending

Table 4-231 Table: DS0 byte 3

Bit	Description	Comment
Bit 0	-	Always 0
Bit 1	-	Always 0
Bit 2	-	Always 0
Bit 3	-	Always 0
Bit 4	-	Always 0
Bit 5	-	Always 0
Bit 6	-	Always 0
Bit 7	-	Always 0

If detailed information on the channels of a submodule is required in the diagnostic interrupt, the interrupt data for the diagnostic interrupt must be read out and evaluated accordingly using the _readDiagnosticData system function.

Additional information

For more information, please refer to the FAQs in "SIMOTION Diagnostics Device Failure" and the SIMATIC "From PROFIBUS DP to PROFINET IO" Programming Manual.

4.5.5.9 PROFIenergy

Overview of PROFIenergy

Saving energy with PROFIenergy

PROFIenergy is a data interface based on PROFINET. It allows loads to be shut down during idle time in a controlled, centralized manner, and irrespective of the manufacturer and device. This means that the process is given only the energy it actually requires. As well as enabling non-operational states to be introduced, the interface also makes it possible to request consumption values and PROFIenergy statuses from the device. The majority of the energy is saved by the process itself; the PROFINET device only makes a small contribution to the saving potential.

Basic principles and functionality

The PROFINET devices are shut down using special commands in the user program of the PROFINET IO controller. No additional hardware is required; the PROFIenergy commands are interpreted directly by the PROFINET devices.

At the start and end of pauses, the plant operator activates or deactivates the pause function of the plant, after which the IO controller sends the PROFIenergy "START_Pause"/"END_Pause" command to the PROFINET devices. The device then interprets the content of the PROFIenergy command and switches to PROFIenergy mode PAUSE or back to READY TO RUN mode. Further PROFIenergy functions can be used to fetch device information.

PROFIenergy profile

Further information and the basic principles of the PROFIenergy profile can be found in the *Common Application Profile PROFIenergy; Technical Specification for PROFINET; Version 1.1; January 2012; Order No: 3.802*. This profile lists all possible measured values in table form, among other things.

Example of PROFIenergy with SIMOTION

PROFIenergy cell concept

As far as PROFIenergy is concerned, production plants are generally made up of independent cells. Each cell has a "head" controller, e.g. SIMOTION, which has a communication relationship with the higher-level controller. The higher-level energy management system (e.g. SIMATIC controller) communicates with the cell with the help of the PROFINET I-device functionality. In the example, cell 1 contains a SIMOTION controller which serves as a PROFIenergy controller for the lower-level devices (ET200, G120, and S120). At this point, SIMOTION is a PROFINET device for the higher-level, centralized energy management, but also a controller and PROFIenergy controller for its lower-level PN devices.

There may be several cells within a production plant. The higher-level controller records the state of the lower-level cells and shuts them down during idle time in a coordinated manner. A production plant can also consist of n cells.

In this example, the higher-level controller sends the PROFIenergy commands via the I-device interface to the SIMOTION controller. The SIMOTION controller evaluates these commands in the user program, responds with an appropriate PROFIenergy data set, and activates the relevant sensors and actuators. Please note that the interpretation and answering of the PE data sets must take place in the SIMOTION user program. A PROFIenergy library is available for SIMOTION for this purpose. This is described in more detail in the following chapters.

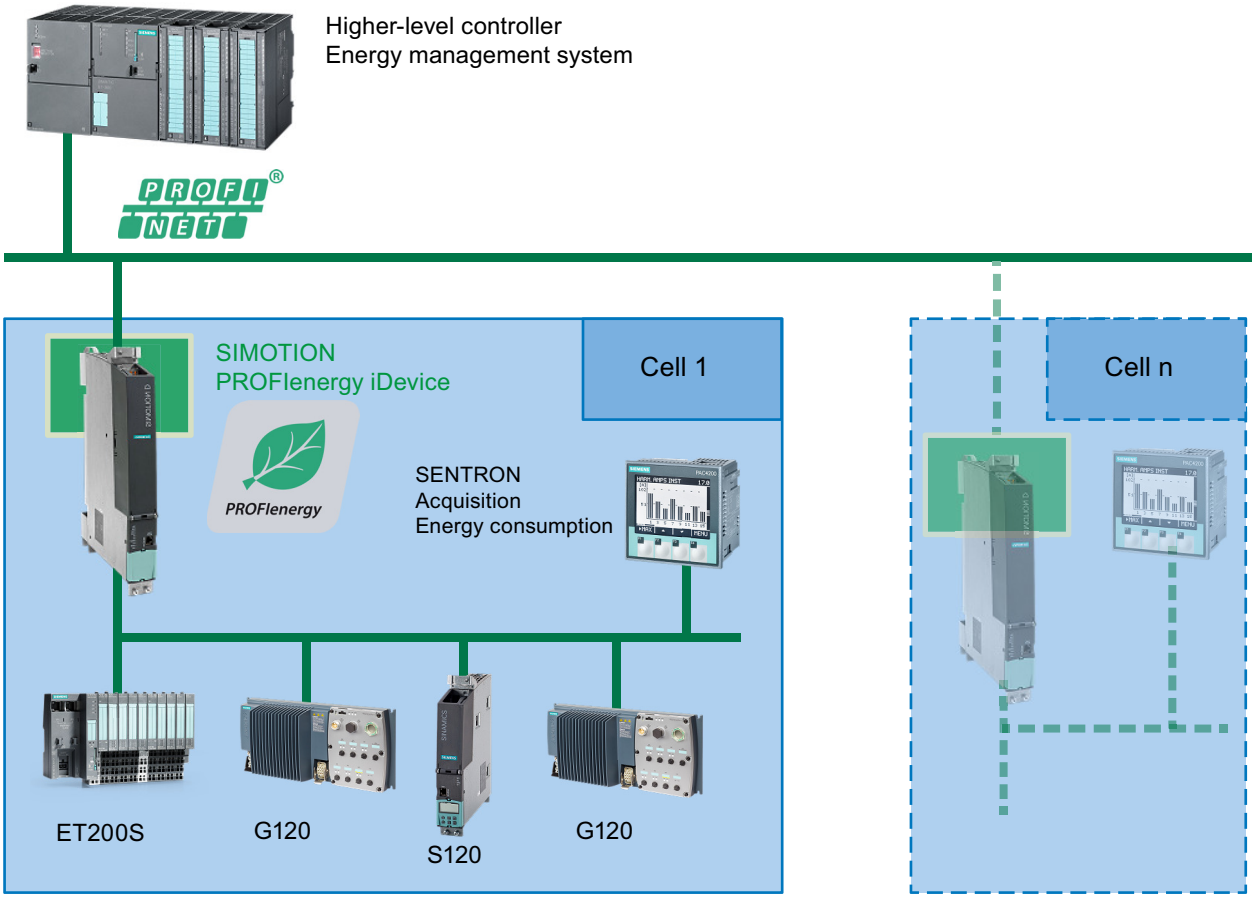

Figure 4-407 Schematic representation of the PROFIenergy cell concept

SIMOTION as PROFIenergy controller and PROFIenergy device

Basic principles of SIMOTION as PROFIenergy controller/device

SIMOTION controllers can control PROFIenergy states and read measured values when used with PROFIenergy-compatible devices (PROFINET devices, e.g. ET200S, S120, G120). SIMOTION controllers can also be operated via the I-Device interface as PROFIenergy devices, i.e. the SIMOTION controller can receive PROFIenergy data sets from the higher-level energy management system and respond to them (e.g. by supplying PROFIenergy measured values).

PROFIenergy telegrams are non-cyclic services and are further processed in data sets. SIMOTION uses the I-Device interface to provide the necessary non-cyclic services for the use of the PROFIenergy telegrams. In addition to the cyclic data, the higher-level PROFINET controller (e.g. S7 CPU) can also send non-cyclic data to SIMOTION in the form of data sets via the I-Device interface. The data set content from the non-cyclic I-device communication is made available for the SIMOTION applications. This data set content can be read by a user program as a receive buffer or written as a send buffer for the response. The processing and evaluation must take place in the user program.

Detailed description

As of SIMOTION V4.4, data sets can be received and sent via the I-device interface, which means that PROFIenergy data sets (commands) can be too. Two new SIMOTION system function blocks _receiveRecord() and _provideRecord() have been made available for this purpose. Data sets can be received by and sent to the higher-level IO controller by calling these system function blocks in the user program.

The interfaces, functionality, and handling of the new SIMOTION system functions are based on the existing SIMOTION system functions for reading/writing data sets, e.g. _readVariableRecord(), and on the corresponding system function blocks for the SIMATIC SFB73 and SFB74.

The system function blocks _receiveRecord() and _provideRecord() are used for non-cyclic communication between two IO controllers, whereby one of the two is functioning as an I-device. This means that non-cyclic data sets can be sent and received from the user program.

A short explanation of the function blocks can be found in the next chapter.

PROFIenergy communication - enabling data sets in the I-Device (as of V4.5)

PROFIenergy communication needs to be explicitly activated in SIMOTION SCOUT TIA for the SIMOTION I-Device in order to enable the PROFIenergy data sets. PROFIenergy data sets are enabled as standard for all "normal" data subslots as well as for F-Proxy subslots.

PROFIenergy communication is activated as standard in SIMOTION SCOUT and cannot be disabled. As a result, PROFIenergy data sets can always be used in SIMOTION SCOUT, but only in SIMOTION SCOUT TIA if the "Activate PROFIenergy communication" box is checked.

The following functions are active when PROFIenergy communication is activated:

- Reading and writing for PROFIenergy data sets via the application is enabled.
- The keywords for PROFIenergy are exported to the I-Device GSD.

Note

SIMOTION SCOUT TIA

The box can always be checked even if your application does not support PROFIenergy for the I-Device. For an I-Device that is to be certified, the box must be unchecked for all subslots of the I-Device for which a PROFIenergy application does not exist.

Activating PROFIenergy communication in the SIMOTION I-Device SIMOTION SCOUT TIA

The hardware is already configured and the operating mode PN interface of the SIMOTION controller is configured as an IO device. The transfer areas of the I-Device are already set up.

1. Click in the network view of TIA Portal on the SIMOTION controller.
2. In the Inspector window, select the "Properties > General" tab.
3. Select "PROFINET PN/IO interface > Operating mode > I-Device communication".
4. Click the entry for the transfer area, e.g. "Transfer area_1".

5. Check the "Activate PROFIenergy communication" box.
6. Look whether the box is checked for the other transfer areas that are to support PROFIenergy communication.

The I-Device can be exported and used for PROFIenergy communication.

Supported PROFIenergy functions and hardware

PROFIenergy is available as of SIMOTION V4.2 and SINAMICS V4.5.

SINAMICS S120 and SINAMICS G120 support the following PROFIenergy functionalities:

- PAUSE command
- Reading out two or three measured values
  - Active power P (MeasurementId = 34 in W)
  - Power factor cosφ (MeasurementId = 166, for G120 only)
  - Energy absorbed (MeasurementId = 200 in Wh)
- SINAMICS G120D-2 can also shut down encoders and I/Os.

Additional references

A detailed description of how to configure PROFIenergy communication in SIMOTION SCOUT TIA can be found in the *SIMOTION SCOUT TIA* Configuration Manual.

System function blocks _receiveRecord() and _provideRecord() for non-cyclic communication via the iDevice interface

Introduction

A SIMOTION controller uses these system function blocks to send and receive data sets via the iDevice interface. The user program must respond to a non-cyclic request. These system function blocks are used, among other things, to transfer PROFIenergy data sets.

Note

A detailed description of the system functions _provideRecord() and _receiveRecord() can be found in the online help and in the *SIMOTION System Functions/Variables Devices List Manual*.

_provideRecord()

The system function block _provideRecord() includes the following functionality:

- It checks cyclically (when mode=0) whether the iDevice has been sent a request to make a data set available.
- It makes the record data available to the higher-level controller.

_receiveRecord()

The system function block _receiveRecord() includes the following functionality:

- It checks cyclically whether the iDevice has been sent a request to receive a data set.
- It makes the data set available on the output parameters.
- It acknowledges receipt of the data by the higher-level controller.

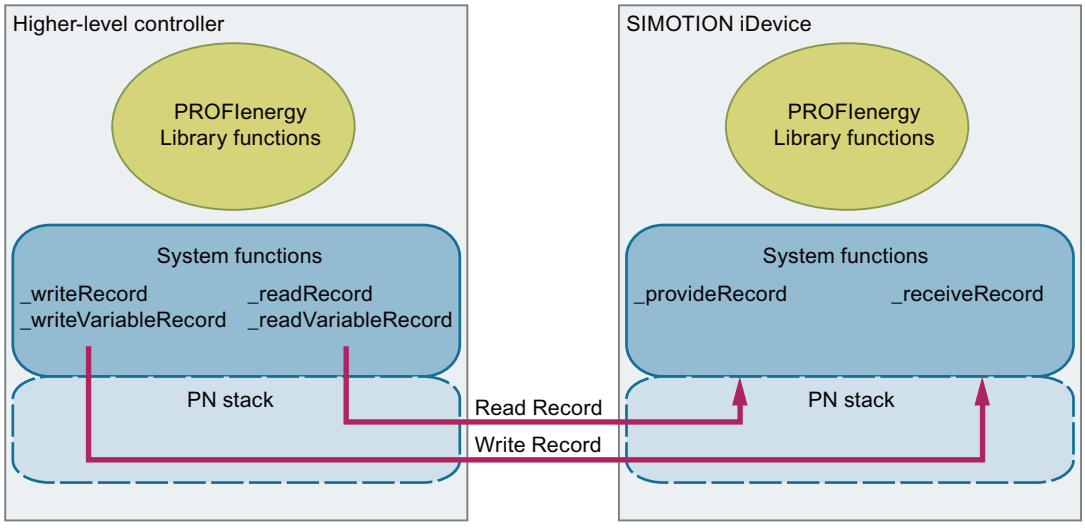

Figure 4-408 Read record and write record as iDevice

Function block for the SIMOTION PROFIenergy iDevice

PROFIenergy iDevice function block

A function block with an example application is available for decoding and coding the PROFIenergy data sets. This function block supports the following modes of operation:

- Forwarding the PROFIenergy commands from the higher-level controller to the lower-level PROFIenergy-compatible devices (e.g. ET200 or SINAMICS). Standard PROFIenergy function blocks that have already been implemented can be used in the user program (e.g. to read out the measured values).
- The PROFIenergy commands can be processed within the function blocks for a complete (production) cell; i.e. the PROFIenergy iDevice FB reflects the complete PROFIenergy functionality of a cell. As a prerequisite, there must be a SIMOTION CPU as the "head" controller. The shut-down and switch-on sequence for the individual PROFIenergy IO devices can be parameterized on the iDevice FB.

Download

The function block for the PROFIenergy iDevice with example application and comprehensive documentation can be found in the Support Portal (https://support.industry.siemens.com/cs/ww/en/view/58386840).

4.5.5.10 Series machine projects

IP address and device name via UP/DCP (Mini-IP-Config)

Description

It was previously only for I devices that SIMOTION supported the allocation of the IP address and device name (NameOfStation) from the user program or via the Discovery and Configuration Protocol (DCP). With SIMOTION V4.2 and Step 7 V5.5 or higher, this must be configured in HW Config and applies to all IO devices and IO controllers. To do this, you need to select the checkboxes for free allocation in the Properties of the Ethernet interface and the PROFINET interface. Previously in the case of SIMOTION, the IP configuration could only be set for the PN-IE interfaces via the user program; not for the PN-IO interfaces. As of V4.4, the IP address can be set from the user program for all PN interfaces.

A PN-IE/PN-IO interface is addressed in the system function via its diagnostics address (for the interface of the PN interface). You can also specify whether the IP configuration (device name, IP address) is to be set temporarily (until the power is next switched OFF/ON) or permanently (retained after the power is switched OFF/ON). If it is a temporary setting, the device name is deleted when the power is next switched OFF/ON and will contain a blank string.

With the new system functions, the IP addresses and the device names of the PN IE interfaces and the PN IO interfaces can be issued from the user program. An additional reboot is no longer necessary for the PN interfaces, as the set name does not also have to be activated via _activateNameOfStation.

This mechanism allows the IP addresses and device names to be adjusted without making changes to the project. The IP settings can be changed locally, especially for series machines.

New system functions as of V4.4

New system functions have been introduced as of SIMOTION V4.4 for assigning the IP address and device name. They expand the range of functions already available. The functionality of the existing system functions remains unchanged and they can still be used as before. You are advised to use the new system functions.

System functions up to V4.4	New system functions as of V4.4
_setNameOfStation/_activateNameOfStation	_setPnNameOfStation
_getActiveNameOfStation	_getPnNameOfStation
_getPnInterfacePortNeighbour	_getPnPortNeighbour (only PN IO interfaces)
_setIpConfig	_setPnIpConfig
_getIpConfig	_getPnIpConfig

Note

A detailed description of the system functions can be found in the online help and in the *SIMOTION System Functions/Variables Devices List Manual*.

Comparison of system functions for obtaining the IP address and device name via a different method

With the SIMOTION system functions, the following operations are possible:

	Assignment of device name via UP		Assignment of IP address via UP	
	(_setNameOfStation etc.)	(_setPnNameOfStation etc.) As of V4.4	(_setIPConfig/ _getIPConfig)	(_setPnIPConfig/ _getPnIPConfig) As of V4.4
PN IE interfaces	No	Yes	Yes	Yes
PN IO interfaces	Yes	Yes	No	Yes

Diagnostics when an error occurs

For the purpose of error diagnostics, a diagnostics buffer entry is created on the SIMOTION I device CPU if a DCP request to set the device name or IP address for the I device could not be carried out because the relevant checkboxes are not activated in HW Config.

Assigning the device name based on the MAC address (V5.2)

As of SIMOTION SCOUT V5.2, the device name can also be assigned based on the MAC address. The PN devices are named with the system function _assignNameOfStationToDevice() (Page 2282).

Configuring device names via system function

Introduction

The device name (NameOfStation or NameOfInterface) can be assigned via user program. This option must be explicitly enabled when configuring the hardware for this version.

Obtaining the device name using a different method

1. In HW Config, open the Properties dialog for the PROFINET interface.
2. Activate the **Obtain device name using a different method** checkbox on the General tab and confirm the selection by clicking **OK**.

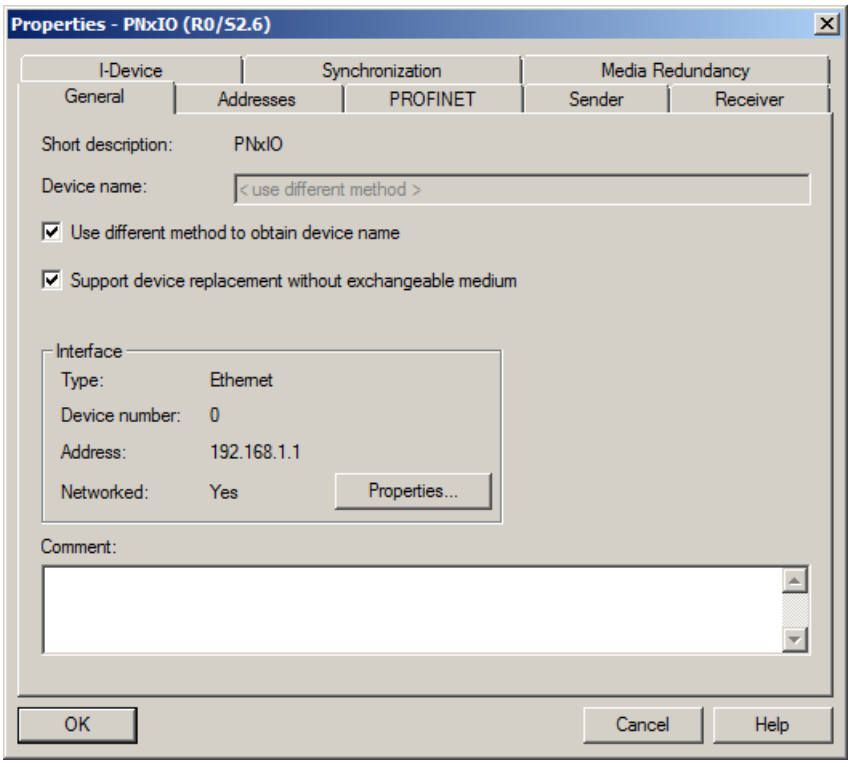

Figure 4-409 Obtaining the device name using a different method

Overview of the possible configuration methods

Configuration method		Response
Device name from project The option "Obtain device name using a different method" is **not** set.	System function **_setPnNameOfStation** or primary set-up tool via DCP	**The device name cannot be set.** The configured device name from the project is active. Following a restart, the device name from the project is still active.

Configuration method		Response
Device name not from project The option "Obtain device name using a different method" is set.	System function **_setPnNameOfStation** with parameter storeNameOfStationPermanent := YES	After fault-free performance of the system function, the set device name is active. Following a restart, the device name set by the system function is still active. **The device name from the project is no longer active.**
	System function **_setPnNameOfStation** with parameter storeNameOfStationPermanent := NO	After fault-free performance of the system function, the set device name is active. Following a restart, the device name set by the system function is no longer active. The device name contains an empty string. **The device name from the project is no longer active.**
	STEP7 / primary setup tool via DCP	The device name set via STEP7 / DCP is active. Following a restart, the device name set by STEP7 or the primary setup tool via DCP is still active. **The device name from the project is no longer active.**
	Through PROFINET controller via DCP (topology-based initialization)	**Before V4.5:** Following a restart, the device name set by the PROFINET controller is still active. Topology-based initialization only occurs when there is no existing device name (interface in factory setting). **The device name from the project is no longer active.** **As of V4.5 (only SIMOTION SCOUT TIA):** The device name set via DCP is active. The previous device name is overwritten.
	Through PRONETA via DCP with the "temporary" option (PRONETA supports the "temporary" option for tests)	Following a restart, the device name set by PRONETA is no longer active. The device name contains an empty string. **The device name from the project is no longer active.**
	System function **_assignNameOfStationToDevice**	**As of V5.2** The function block assigns the device name to an IO device with a specific MAC address. After error-free execution of the system function, the set device name is active. Following a restart, the device name set by the system function is still active.

Configuration method		Response
		The device name from the project is no longer active.

General information on device names

- If the setting "Use different method to obtain device name" is activated in the project, the last device name provided on the interface becomes active once the project is downloaded.
  This means:
  - The device name from the last project is active if a device name was configured in the previous project.
  - An empty string is set if the device name was in its factory setting (delivery state).
  - An empty string "" can be set via user program and DCP
  - A new device name can also be assigned via DCP and user program if a PROFINET connection (controller or I-Device) is active. Changing the name terminates the connection.
- In certain situations, the module is reset when downloading from SIMOTION SCOUT ("Target system reset" displayed in SCOUT log). This reset has the same effect on the NameOfStation as switching the power OFF/ON.

You will find an overview of the possible functions in the section IP address and device name via UP (Page 2277).

Note

If the option "Use different method to obtain device name" has been activated, the option "Use different method to obtain IP address" must also be activated.

Assigning the device name based on the MAC address

Initialization of PN devices with system function _assignNameOfStationToDevice()

With the system function _assignNameOfStationToDevice(), you assign a device name (NameOfStation) to a PN device with a specific MAC address. You can implement modular machine concepts with this function. During local commissioning, the technician assigns the device name directly for this plant extension based on the known MAC address, e.g. via the HMI. The HMI transfers the MAC address and the device name to the SIMOTION controller by means of variables.

Properties and supplementary conditions

- To set the IO device to a defined initial state, the system function resets the communication parameters of the IO device. Whereby, a permanent IP address is deleted, for example.
- The reset is performed via the ResetToFactory DCP service according to PN V2.3.
  If the IO device only supports PN V2.2 and rejects the ResetToFactory, only the PROFINET device name is assigned.

- No special characters such as umlauts, etc. are supported for the device name. **No** automatic conversion of the device name according to RFC 5890 is performed, for example, as in the TIA Portal.
- The device name is always set permanently. Temporary setting is not supported in contrast to the system function _setPnNameOfStation().

Configuring an IP address via system function

Introduction

The IP address can be assigned via user program. This option must be explicitly enabled when configuring the hardware for this version.

Obtaining the IP address using a different method

1. In HW Config, open the Properties dialog box for the PROFINET interface and click on the **Properties** button on the General tab.
2. Switch to the **Parameter** tab in the Properties dialog box that opens for the Ethernet interface.
3. Activate the **Use different method to obtain IP address** check box and confirm the selection by clicking **OK**.

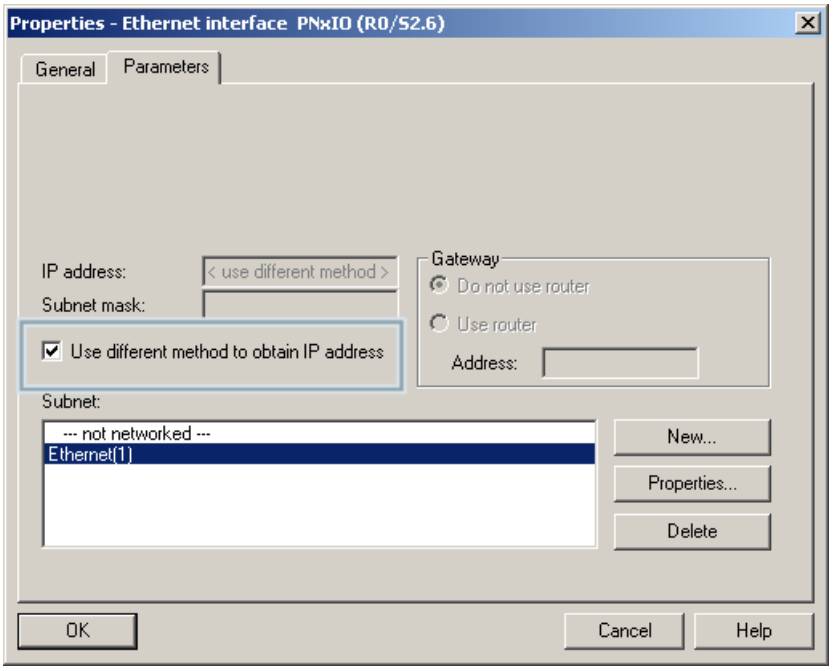

Figure 4-410 Obtaining the IP address using a different method

Overview of the possible configuration methods

Configuration method		Response
Project not present in the device	DCP (DCP BlockQualifier = permanent)	The IP address set via DCP is active. After a restart the IP address set via DCP is still active.
	DCP (DCP BlockQualifier = temporary)	The IP address set via DCP is active. After a restart the IP address 0.0.0.0 is active.
Project present in the device or not	Download project; in the project the "Obtain IP address using a different method" **option is not** set	The IP address loaded via the project is active. After a restart the IP address set via the project is still active.
	Download project; in the project the "Obtain IP address using a different method" option is set	The IP address last active on the interface is still valid. • The IP address from the last project, if a project with a valid IP address was previously loaded. • If a project with a valid IP address has not previously been loaded, then the IP address previously set via DCP / _setPnIPConfig or the default IP address as delivered.
Project present in the device The option "Obtain IP address using a different method" is **not** set	Opening of **_setPnIPConfig** to set an emergency IP address	The IP address loaded via the project is not temporarily overwritten by a so-called emergency IP address. Following a restart the IP address from the project is active again.
	DCP (DCP BlockQualifier = temporary or permanent) for setting an emergency IP address	
Project present in the device The option "Obtain IP address using a different method" is set	System function **_setPnIpConfig** with storeIp ConfigPermanent = YES	The IP address set via system function is active. After a restart the IP address set via the system function is still active.
	System function **_setPnIpConfig** with storeIp ConfigPermanent = NO	The IP address set via system function is active. After a restart the IP address 0.0.0.0 is active.
	STEP7 or primary setup tool via DCP (DCP BlockQualifier = permanent)	The IP address set via STEP7 / primary setup tool is active. After a restart the set IP address is still active.
	PROFINET controller via DCP (DCP BlockQualifier = temporary, only possible for PROFINET IO interfaces)	The IP address set via DCP is active. After a restart the IP address 0.0.0.0 is active.

General information on modifying the IP address

- If a PROFINET connection is active, DCP cannot be used to assign a new IP address. For safety reasons the setting of an IP address via DCP with a project present **in RUN and STOP operating state** is only permitted if **Obtain IP address using a different method** is set. If **Obtain IP address using a different method** is not set, the setting of an IP address is only permitted **in the STOP operating state**. This is intended to prevent an IP configuration set via a project, e.g. via the function "Edit Ethernet node," being changed easily from outside, by means of which a PROFINET communication of a SIMOTION device can be disrupted.
- An IP address can also be assigned via system function if a PROFINET connection (IO controller or I-device) is active. Changing the IP address via the system function leads to the breaking of the PROFINET connection.
- The IP address 0.0.0.0 can be set via the user program and DCP.
- In certain situations, the module is restarted when downloading with SIMOTION SCOUT ("Target system reset" displayed in SCOUT log). Such a restart has an impact on when IP addresses come into force.
- Emergency IP address:
  The emergency IP allows the user to temporarily overwrite the IP configured in the project via DCP or system function, e.g. in order to load a project with a corrected IP address if access is no longer possible via the IP address configured in the project. When downloading the new project, make sure that the emergency IP address assigned via "Edit Ethernet node" agrees with the IP address used in the project, because in certain cases SIMOTION performs restarts during downloading, and the IP address from the project subsequently becomes effective.

You will find an overview of the system functions in the chapter IP address and device name via UP (Page 2277).

ResetToFactorySettings via DCP

Description

A resetting of the device names or the IP address to the factory settings (ResetToFactorySettings) via DCP to one of the PN IO or PN IE interfaces sets the parameters as follows:

- IP address: 0.0.0.0
- NameOfStation: Blank string

Boundary condition

Due to security restrictions, DCP ResetToFactorySettings is only permitted when an iDevice is configured with **Parameter assignment for the PN interface and its ports on the higher-level IO controller** and, at the same time, **Use different method to obtain device name** and **Use different method to obtain IP address** are both set. The interface must not be used as an IO controller, i.e. no IO device is configured.

For an interface with a default IP address, the response after a ResetToFactory is as follows:

- When a ResetToFactorySettings is performed, the IP address is immediately set to 0.0.0.0.
- If the power is then switched OFF/ON, the IP address remains 0.0.0.0.
- The default IP address is not reactivated until the NVRAM is erased.

Reusable IO systems - Addresstailoring

Introduction

The Addresstailoring function assigns the IP address and NameOfStation for IO controllers and IO devices via system functions at commissioning time. This feature allows a machine consisting of an IO controller and IO devices to be supplied with IP addresses and NameOfStation, and permits multiple instances of the machine to be commissioned on a single physical Ethernet without the engineering system.

There is only one project (configuration and programs). It can be loaded onto machines of the same type without change. To integrate the machine in an existing network infrastructure, only limited customization is required for the on-site commissioning (IP address, NameOfStation). The user program assigns the IP address and the NameOfStation during the first controller startup.

Note

Addresstailoring can be configured only for SIMOTION SCOUT TIA.

Example of an automation solution

The following figure shows how an automation solution with a reusable IO system is loaded into various automation systems and one of these is then adapted on-site to the existing network infrastructure.

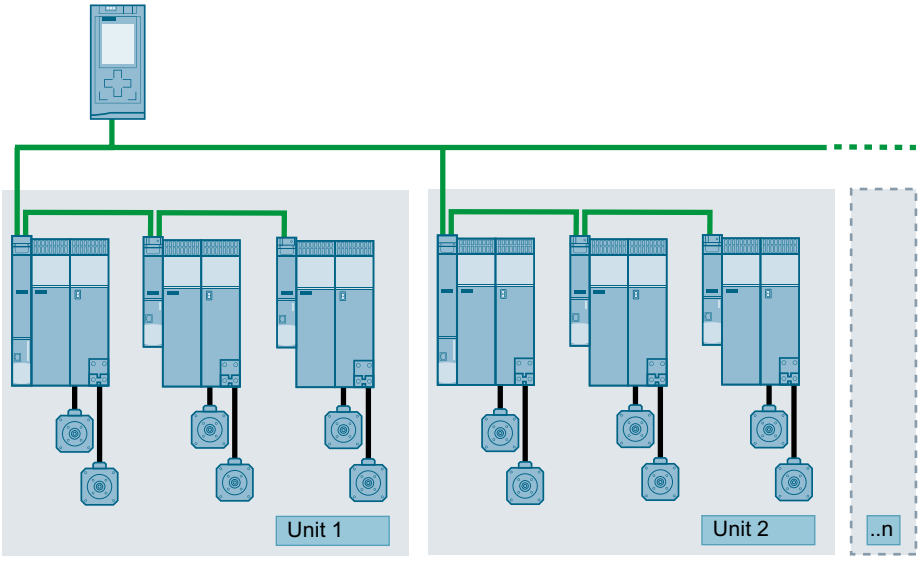

Figure 4-411 Addresstailoring: Series machine with the same units with a different name and IP address

Rules

The following rules apply to a reusable IO system:

- A series machine project consists of an IO controller and the associated IO devices. Consequently, configure only one CPU as IO controller and the associated IO devices in the series machine project.
- No IO device may be configured as shared device.
- If IRT is configured, all IO devices must belong to the same sync domain and the sync domain must not contain any further IO devices.

Alternatively to Addresstailoring via two PN interfaces

In the SIMOTION environment, under some circumstances, rather than using Addresstailoring, the same functionality can also be achieved by using the two PN interfaces. One PN interface is configured as I device and connected with the higher-level controller. The second PN interface is the IO controller for the IO devices. In this case, a second PN interface (e.g. CBE30-2) is required.

In the previously described configuration, the IO devices are located within a local network and so can have the same NameOfStation and IP address in all instances.

Additional references

Further information can be found in the *Basic Functions for Modular Machines Function Manual* and in the *online help for the TIA Portal*.

Configuration control for IO systems - Machinetailoring

Introduction

The configuration control for IO systems (Machinetailoring) allows several specific instances or configurations of the series machine to be generated from a single series machine project. The configuration of an IO system can vary flexibly for a specific application provided the real configuration can be derived from the configured configuration. The configured configuration (series machine project) so forms the superset of all derivable real configurations.

You can activate or deactivate a PROFINET IO system (IO devices, I devices) in a specific system. Different variants can be operated from a configured maximum configuration of an IO system. You prepare for a series machine project a modular system consisting of IO devices that can be adapted flexibly for the wide range of configurations via the configuration control.

Machinetailoring allows the following customizations to be made on-site (without engineering system):

- Variation of the number of associated modules (IO devices). This is also possible with restrictions with IRT (IRT node as leaf for the IRT node part in a line).

Note

Machinetailoring can be configured only for SIMOTION SCOUT TIA.

PROFINET IRT

Machinetailoring is possible for PROFINET IRT only when minor adaptations need to be made to the IRT devices of the master machine. Minor adaptation means that IRT IO devices are only bridged or individual branches and leaves are removed.

Example of an automation solution

The following figure shows an example from a series machine project how an instance can be created with a different number of IO devices. The IO devices in the middle and at the end can be optional.

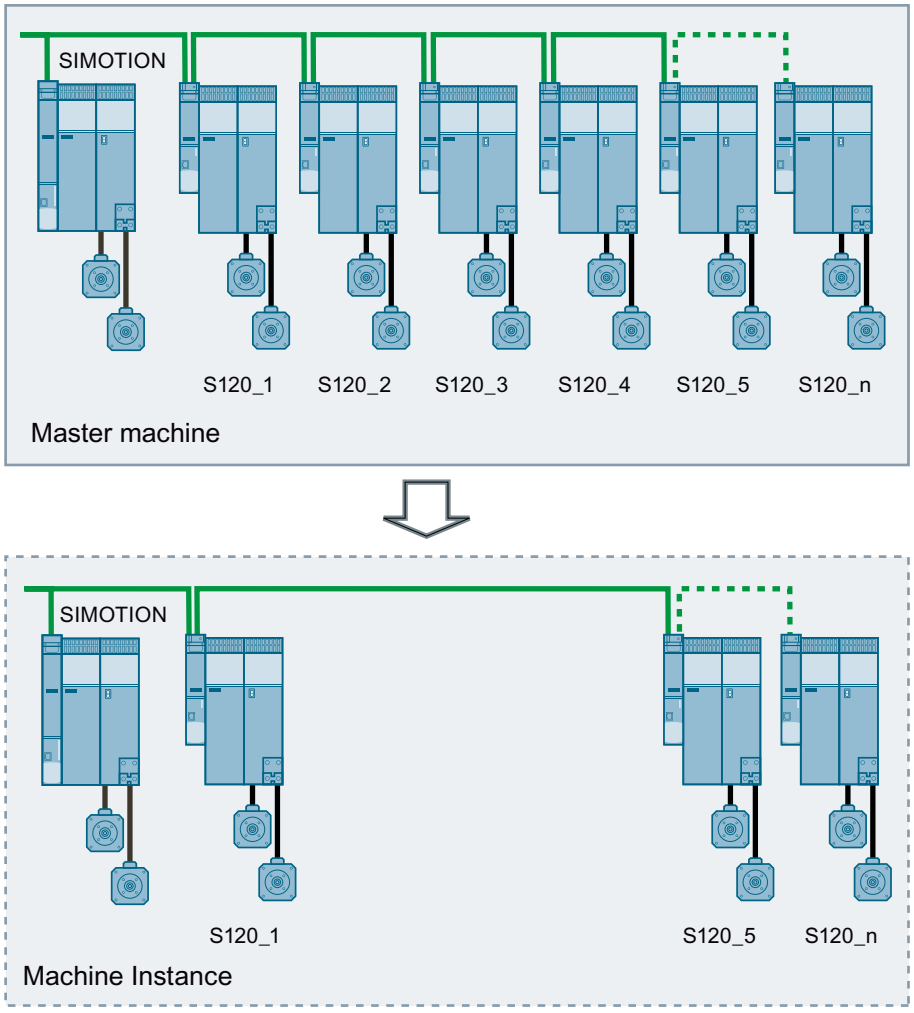

Figure 4-412 Instance of the machine with a different number of IO devices

Restrictions

- The number of optional IO devices in series is limited.
- The data exchange between IO controllers (controller-controller slave-to-slave communication) is possible only from the user program.
- Because it cannot be guaranteed that the optional IO devices actually exist in the machine instance, data exchange between IO devices is not meaningful.

Additional references

Further information can be found in the *Basic Functions for Modular Machines Function Manual* and in the *online help for the TIA Portal*.

4.5.6 Ethernet: General information (TCP and UDP connections)

4.5.6.1 Ethernet interfaces

Overview of Ethernet

Overview

Below is a description of how to configure TCP and UDP Ethernet connections between communications partners. TCP and UDP are based on Ethernet and the IP protocol.

Properties of the SIMOTION Ethernet interfaces

Ethernet interfaces

Depending on the device, SIMOTION has one or three onboard Ethernet interfaces, and one or two PROFINET IO interfaces. You can connect an Industrial Ethernet with a transmission rate of 10/100 Mbps or 1,000 Mbps to the RJ45 sockets with D4x5-2 DP/PN.

With several interfaces, TCP/IP timeout parameters can be set once for both interfaces. With several interfaces, the transmission rate/duplex can be set separately for the two interfaces. Utilities via TCP/IP and UDP are supported for both Ethernet interfaces, enabling S7 routing between all interfaces (including PROFIBUS DP). "Utilities via TCP" are not routed from one Ethernet interface to the other.

Alternatively, you can also connect an Industrial Ethernet through the onboard PROFINET interface of a SIMOTION D4x5-2 DP/PN (100 Mbit/s).

The MAC addresses of the Ethernet interfaces can be seen on the outside of the housing.

Note

Default gateway (network transition/router)

In a SIMOTION controller, only one of the existing Ethernet or PROFINET interfaces (onboard PN interfaces, CBE30-2...) can be configured as a default gateway (network transition/router). On the other Ethernet or PROFINET interfaces, the IP address and the subnet mask can be set. If more than one default gateway is configured on the SIMOTION controller, this will be output as an error message on the consistency check as of Step 7 V5.5 SP4. In older Step 7 versions, this check is is only made on the project download.

Converting standard Ethernet interfaces from V4.3 and higher

With SIMOTION V4.3, the standard Ethernet interfaces are marked as PN-IE interfaces:

- Determining neighborhood information via LLDP (Link Layer Discovery Protocol). To do so, use the system function _getPnPortNeighbour in SIMOTION.
- Via the Step7 diagnostic address, you can perform diagnostics from the user program for the Ethernet interface.
- You can assign the device name (NameOfStation) either via DCP or via the user program (see also IP address and device name (Page 2219)).
- You can assign the IP address either via DCP or via the user program.
- Provision of topology information via SNMP (Simple Network Management Protocol) (e.g. via the STEP7 Topology Editor, see also Topology editor (graphical view) (Page 2209)).
- You can configure a setpoint topology.
- Online diagnostics of the interface and ports via STEP7 device diagnostics.

The interfaces in HW Config are displayed as follows:

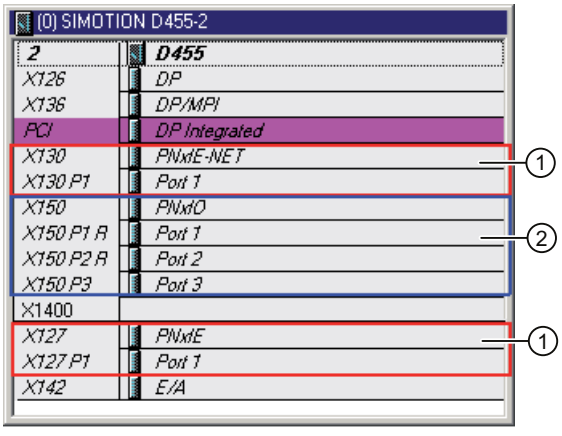

Figure 4-413 Ethernet interfaces in HW Config

①	Standard Ethernet interface with one port
②	PROFINET IO interface with three ports

See also

IP address and device name (Page 2219)

Topology editor (graphical view) (Page 2209)

Using the Ethernet interface

Using the Ethernet interface

- For communication with STEP 7, SIMOTION SCOUT, and SIMATIC NET OPC via a PG/PC
- For communication via UDP (User Datagram Protocol) with other components, e.g. other SIMOTION devices, SIMATIC devices, or PCs
- For communication via TCP (Transfer Control Protocol) with other components, e.g. other SIMOTION devices, SIMATIC S7 stations, or PCs
- For connecting SIMATIC HMI devices such as MP277, MP370, or PC-based HMIs
- For communication by means of SIMOTION IT Web server and SIMOTION IT OPC XML DA (no license required as of V4.2)
- For communication by means of SIMOTION VM (separate license required)

4.5.6.2 LCom communications library

LCom library

The **LCom** library is based on TCP and simplifies the use of both SIMOTION system functions and SIMATIC communication blocks in order to establish communication between multiple machines.

Note

You can find the LCom library on the SIMOTION SCOUT DVD "Documentation, Utilities & Applications". The DVD also contains an example project and comprehensive documentation for the library.

Types of control

The LCom library supports the following control types and combinations:

- SIMOTION ↔ SIMOTION
- SIMATIC ↔ SIMATIC
- SIMOTION ↔ SIMATIC

Functions

- The send and receive data must be of data type BYTE. Outside of the *FBLComMachineCom*, any user structures can be converted into an ARRAY OF BYTES via marshalling.
- Bi-directional operation
  - A logical point-to-point connection is established between two controls.
  - Each control can send and receive via a connection at the same time.
- Alignment of configuration settings between communications partners (e.g. send clock)
  - Assignment of communication parameters to the communications partner
  - Changing the configuration during operation
- Types of data transmission
  - Cyclic transmission (transmission at fixed periods of time)
  - Transmission when data is changed
  - One-off transmission
- Sending and receiving max. 64 kB useful data
- Acknowledgment and monitoring of received data
- Sign-of-life monitoring
- Time-of-day synchronization

4.5.6.3 TCP communication

Overview of TCP communication

Communication with TCP (Transfer Control Protocol)

Communication via TCP is connection-oriented, i.e. data can only be transferred once a connection to the communications partner has been established.

The main features of a communication connection are two end points. An end point is a controlled pair consisting of an IP address and a port. The port on the client may be the same as or different from the port on the server. Usually, one end point represents a server and the other end point a client.

The client-server relationship is only valid until the connection is established. After the connection is established, both communications partners are equivalent, i.e. each of the two can send or receive or close the connection at any point in time.

Principle of TCP communication (see figure)

- Server waits at port (1)
- Client announces connection request at this port (2). If a port is not announced on the server, there is a wait with TimeOut (system setting)

- Server creates internal communication port with connection announcement and releases server port for new connection. The internal communication port is identified via the connectionId (3)
- Possible to send/receive data via this connection not only from the client, but also from the server (4)
- Further connections can be established at the server port (5)
- An existing connection can be closed on the client or server side (6)
- Server port to establish connection is closed on the server side (7)

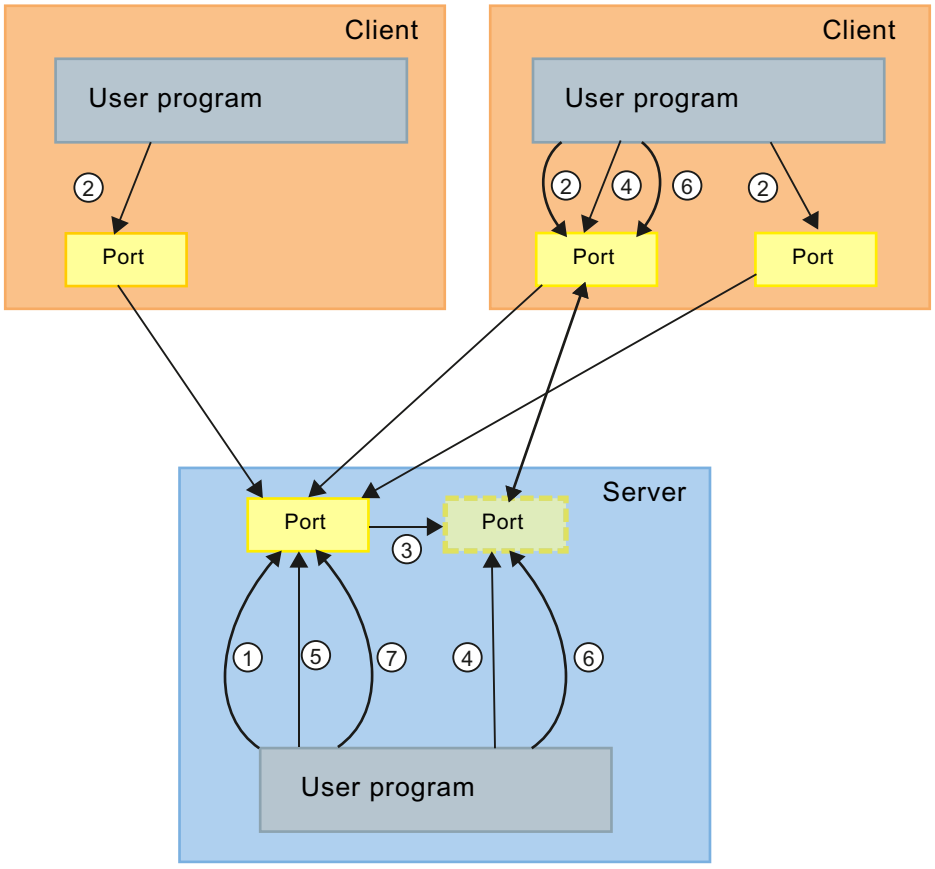

Figure 4-414 Schematic diagram showing TCP communication sequence

Principles of port assignment:

- The port number on the client can be the same as the port on the server.
- The port number on the client can be the different to the port on the server.

Data exchange between user program and TCP stack

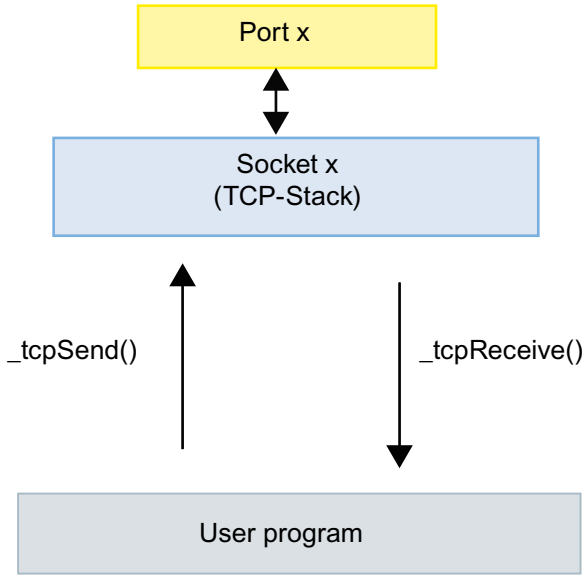

Figure 4-415 Data exchange between user program and TCP stack

Data packets

With TCP communication, the useful data received is buffered in the TCP stack and must be read out from here by the application. The size of the buffered useful data per connection depends on the control involved.

Table 4-232 Useful data and control

Control	Buffer size in bytes
SIMOTION	4096
SIMATIC	8192

The buffered useful data must be fetched promptly by the user program, otherwise it will not be possible for any other data to be received. However, by contrast none of the useful data is discarded, as TCP has a flow control facility. In this state, the communications partner does not send any additional data and alerts its application to this fact.

SIMOTION system functions for TCP communication

Overview of SIMOTION system functions

Maximum number of possible TCP connections

The table below contains examples of the number of possible communication connections for a SIMOTION CPU acting as a client. The values relate to a local network without any other external load sources, and a SIMOTION D435 acting as a server.

Table 4-233 Communication connections in relation to a SIMOTION CPU

SIMOTION CPU (client)	Number of communication connections
C2xx	45
D410	45
D410--2	45
D4x5	75
D4x5-2	75
P3x0	40

Function call

The SIMOTION system functions for TCP communication may only be called in the BackgroundTask or in a MotionTask. In the BackgroundTask, it should be noted that the system functions are executed asynchronously (nextCommand=IMMEDIATELY). In the MotionTask, however, the system functions can be executed synchronously (nextCommand=WHEN_COMMAND_DONE).

Note

To ensure reliable cyclic communication, you should use standard mechanisms such as those found in PROFIBUS DP or PROFINET IRT systems.

_tcpOpenServer() system function (Page 2296)

_tcpOpenClient() system function (Page 2297)

_tcpSend() system function (Page 2298)

_tcpReceive() system function (Page 2298)

_tcpCloseConnection() system function (Page 2299)

_tcpCloseServer() system function (Page 2300)

_tcpOpenServer() system function

Overview

This system function is used in order to initiate passive establishment of a connection.

Table 4-234 Call example

```
sRetValueTcpOpenServer := _tcpOpenServer(  //StructRetTcpOpenServer
   port        := 3456                     //UINT, 1024-65535
  ,backLog     := 5                        //DINT
  ,nextCommand := IMMEDIATELY              //EnumTcpNextCommandMode
);
```

To parameterize the function, the locally assigned SIMOTION port is transferred for the **port** parameter.

The maximum number of parallel connection requests for this port that are to be permitted from other controllers is also specified as a further parameter for **backLog**.

The behavior of this function with respect to the advance when called is also parameterized with the **nextCommand** parameter. There are two setting options: IMMEDIATELY and WHEN_COMMAND_DONE. With the first value the advance is immediate and with the second value it is after completion of the command.

When the _tcpOpenServer() function is called, the structure returned to the user program contains the following parameters.

The status of establishing the connection can be queried via the **functionResult** parameter.

The **connectionId** parameter is used as an (input) parameter for the call of the _tcpSend() and _tcpReceive() functions and assigns a unique TCP connection to these functions. This return value is referred to in the above call examples.

The **clientAddress** parameter returns the client IP address from which the connection is activated; this takes the form of an array.

The port number designated as the local port number of the client is specified in the **clientPort** parameter.

The port number is in the range 1024 to 65535.

_tcpOpenClient() system function

Overview

The _tcpOpenClient() system function is used to actively establish a connection.

Table 4-235 Call example

```
sRetValueTcpOpenClient :=_tcpOpenClient( // StructRetTcpOpenClient
   port           := 3456                // UINT, 1024-65535
  ,serverAddress  := au8ServerAddress    // ARRAY [0..3] OF USINT
  ,serverPort     := 3456                // UINT, 1024-65535
  ,nextCommand    := IMMEDIATELY         // EnumTcpNextCommandMode
  );
```

When called, the locally assigned SIMOTION port is transferred to the function for the **port** parameter.

The **serverAddress** parameter is the IP address of the communications partner, which is transferred in an array.

The port number designated as the local port number is transferred to the function in the **serverPort** parameter.

The port number is in the range 1024 to 65535.

The behavior of this function with respect to the advance when called is parameterized with the **nextCommand** parameter. There are two setting options: IMMEDIATELY and WHEN_COMMAND_DONE. With the first value, the advance is immediate and with the second value it is after completion of the command.

When the _tcpOpenClient() function is called, the structure returned to the user program contains the following parameters.

The status of establishing the connection can be queried via the **functionResult** parameter.

The **connectionId** parameter is used as an (input) parameter for the call of the _tcpSend(), _tcpReceive(), and _tcpCloseConnection() functions and assigns a unique TCP connection to these functions.

_tcpSend() system function

Overview

The _tcpSend() system function is used for sending data.

Table 4-236 Call example

```
i32RetValue := _tcpSend(                                    // DINT
   connectionId    := sRetValueTcpOpenClient.ConnectionId  // DINT
  ,nextCommand     := IMMEDIATELY                          // EnumTcpNextCommandMode
  ,dataLength      := 4096                                 // UINT, 0-4096
  ,data            := ab8SendData                          // ARRAY [0..4095] OF BYTE
 );
```

For the **connectionId** parameter, the **connectionId** return value of the _tcpOpenClient() or _tcpOpenServer() function is transferred, depending on whether the communication node that executes the function is a server or client.

The behavior of this function with respect to the advance when called is also parameterized with the **nextCommand** parameter. There are two setting options: IMMEDIATELY and WHEN_COMMAND_DONE. With the first value the advance is immediate and with the second value it is after completion of the command.

The **dataLength** parameter informs the function of the useful data length in bytes that has to be transferred (max. 4,096 bytes per function call).

The **data** parameter specifies the useful data area in which the send data that is to be transferred with the function is located.

The return value of the function to the user program is of data type DINT. The various return values indicate any problems that occurred during execution of the function. There is also a confirmation when the data has been successfully sent. Negative values in **functionResult** indicate a data transmission error. In this case, the connection must be closed by calling _tcpCloseConnection().

_tcpReceive() system function

Overview

The _tcpReceive() system function is used for receiving data.

Table 4-237 Call example

```
sRetValueTcpReceive := _tcpReceive(                          // StructRetTcpReceive
   connectionId     := sRetValueTcpOpenClient.connectionId  // DINT
  ,nextCommand      := IMMEDIATELY                          // EnumTcpNextCommandMode
  ,receiveVariable  := ab8ReceiveData                       // ARRAY [0..4095] OF BYTE
  );
```

For the **connectionId** parameter, the **connectionId** return value of the _tcpOpenClient() or _tcpOpenServer() function is transferred, depending on whether the communication node that executes the function is a server or client.

The behavior of the __tcpReceive() function with respect to the advance when called is also parameterized with the **nextCommand** parameter. There are two setting options: IMMEDIATELY and WHEN_COMMAND_DONE. With the first value, the advance is immediate and with the second value it is after completion of the command.

For each function call, up to 4,096 bytes of receive data can be read out from the TCP stack. Please note that it will not be possible to predict the sizes of the packets received. On the receiver side, you must take care to ensure that all user data is present before the evaluation and further processing. For this purpose, the **nextCommand** parameter should be set to IMMEDIATELY.

The **receiveVariable** parameter is used to inform the function of the user data area in which the receive data is to be stored. The received data is available in the **receiveVariable** parameter in the length **dataLength**, if the return value in the functionresult = 16#0. At the next function call, the **ReceiveVariable** parameter is overwritten with new data in the length **dataLength**.

When the _tcpReceive() function is called, the structure returned to the user program contains the following parameters. The receive status can be queried via the **functionResult** parameter. The **dataLength** parameter signals the number of received user data bytes once the _tcpReceive() function has been successfully called.

Negative values in **functionResult** indicate a data transmission error. In this case, the connection must be closed by calling _tcpCloseConnection().

_tcpCloseConnection() system function

Overview

The _tcpCloseConnection() function is used for closing a connection that has been actively established by the communication node executing the function (client).

Table 4-238 Call example

```
sRetValueTcpCloseConnection := _tcpCloseConnection(      // DINT
   connectionId := sRetValueTcpOpenClient.ConnectionId   // DINT
  );
```

The return value of the _tcpOpenClient() function is transferred at the **connectionId** parameter in order to clearly identify which connection is to be closed.

The return value of the function to the user program is of data type DINT and indicates any problems that occurred during execution of the function or signals if the connection has been closed successfully.

_tcpCloseServer() system function

Overview

The _tcpCloseServer() function is used for closing a connection that has been passively established by the communication node executing the function (server).

Table 4-239 Call example

```
sRetValueTcpCloseServer := _tcpCloseServer(port := 3456); //1024 - 65535
```

The server port is transferred at the **port** parameter.

The return value of the function to the user program is of data type DINT and indicates any errors that occurred during parameterization of the function or signals if the port has been closed successfully.

4.5.6.4 UDP communication

Overview of UDP communication

Communication with UDP (User Datagram Protocol)

UDP offers a method of sending and receiving data over Ethernet from the user program with a minimum use of protocol mechanisms. No information concerning the transferred data is returned in the case of communication via UDP. Communication takes place via ports on both the send and receive sides. Unlike TCP, you do not need to program any connection establishment or closing.

Principle of UDP communication

- For reception, in the command you address the port that you want to use on your component for the communication job.
- When sending data, you specify the IP address and port number of the target system, as well as the port number of the local control.
- You can specify whether the port should remain reserved on your end after the communication job has been executed.
  UDP is not a secured model. Therefore, data may be lost during transmission if it is not read from the buffer in good time. You must program a secured method of data transmission via your application, e.g. by acknowledging receipt of the data.

- At the very least, the following data is required for sending:
  - IP address of communications partner
  - "Own" port number
  - Port number of communications partner
- UDP is not a secured transfer protocol. You must program feedback concerning the success of data transmission in the user program yourself.

Data exchange between user program and UDP stack

The following figure shows the UDP communication model at the SIMOTION end.

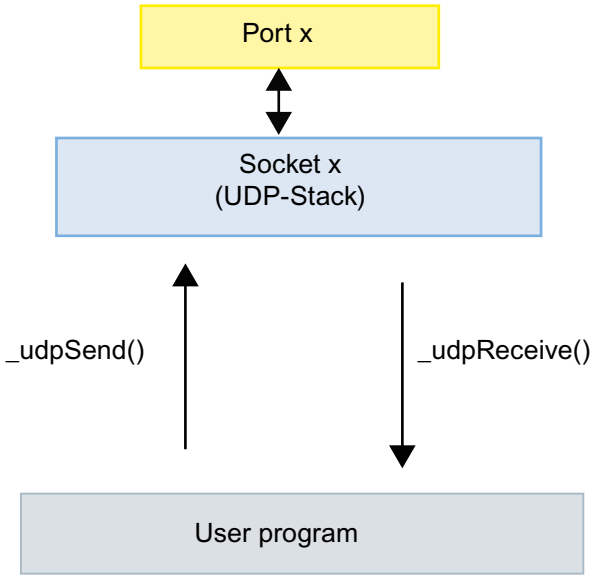

Figure 4-416 Data exchange between user program and UDP stack

With UDP communication, the useful data received is buffered in the UDP stack and must be read out from here by the application. The size of the buffered useful data per connection depends on the control involved. If the receive buffer is not read out on time, the received UDP telegrams will be lost once a new UDP telegram is received.

Table 4-240 Useful data and control

Control	Buffered useful data in bytes
SIMOTION	1,470 (SIMOTION V4.1 SP4 and higher) 1,400 (up to SIMOTION V4.1 SP3)
SIMATIC	Up to 2,048 (depending on CPU and communication via Ethernet CP or integrated Ethernet interface)

SIMOTION system functions for UDP communication

Overview of SIMOTION system functions

Function call

The SIMOTION UDP system functions may only be called in the BackgroundTask or in a MotionTask.

Data is sent via _udpSend(). If data is to be received on the SIMOTION side, the _udpReceive() function is used. The sections that follow describe the functions.

Note

To ensure reliable cyclic communication, you should use standard mechanisms such as those found in PROFIBUS DP or PROFINET IRT systems.

See also

_udpSend() system function (Page 2302)

_udpReceive() system function (Page 2304)

_udpAddMulticastGroupMembership() system function (Page 2305)

_udpDropMulticastGroupMembership() system function (Page 2306)

_udpSend() system function

Overview

The _udpSend() system function is used for sending data.

Table 4-241 Call example

```
i32RetValue :=_udpSend(
   sourcePort         := 3456                   //UINT, 1024 - 65535
  ,destinationAddress := au8DestinationAddress  //ARRAY[0..3] OF USINT
  ,destinationPort    := u16DestinationPort     //UINT, 1024 - 65535
  ,communicationMode  := CLOSE_ON_EXIT          //EnumUdpCommunicationMode
  ,dataLength         := u32DataLength          //UDINT
  ,data               := ab8SendData                //ARRAY[0..1469] OF BYTE
  );
```

When the _udpSend() function is called, the local port is transferred for the **sourcePort** parameter. The **destinationAddress** parameter is the IP address which is transferred in an array. The IP address can be configured and read out in HW Config.

The port of the communications partner is transferred as the **destinationPort**.

The user can use **communicationMode** to specify whether the communication resources are to be released after sending (CLOSE_ON_EXIT) or not released after sending (DO_NOT_CLOSE_ON_EXIT).

The **datalength** and **data** parameters specify the data length to be sent or the area where the send data is stored.

The status of the send job can be checked via the return value of the function.

Note

Up to SIMOTION 4.1 SP4, the length of the send data (data) was limited to 1,400 bytes.

Supplementary condition for UDP broadcast (as of V4.5)

If you want to use Open User Communication with UDP broadcast (_updSend(), _udpReceive()), you must configure this explicitly in SIMOTION SCOUT/SIMOTION SCOUT TIA. Broadcasts are filtered in the standard configuration in order to avoid potential network load problems. In other words, any broadcast that is not related to PROFINET services is discarded before it enters the TCP/IP stack. To enable UDP broadcasting, you must uncheck the box for the relevant network load filter.

You will be reminded during runtime by a corresponding error message that you need to check this box if you have programmed an _updSend() to a broadcast address.

Compatibility with older software versions

With older projects that you have upgraded to version V4.5 or set up as new projects in V4.5, the network load filter for UDP broadcasting is automatically active. If you want to communicate by UDP broadcast, you must check the box for use of UDP broadcast communication.

Activating communication with UDP broadcast in SIMOTION SCOUT

1. Click the SIMOTION controller in HW Config, e.g. D455.
2. Select "Object properties" from the context menu.
3. Check the box "Permit broadcast for _udpSend/_udpReceive" on the tab "Ethernet Extended / Web Server".

Activating communication with UDP broadcast in SIMOTION SCOUT TIA

1. Select the SIMOTION device in the network view in TIA Portal.
2. In the Inspector window, select the "Properties > General" tab and click "Web server/OPC/ Network protocols".
3. Check the box "Permit broadcast for _udpSend/_udpReceive".

Programming checkbox status (SIMOTION SCOUT only)

It is possible to set and read the checkbox value using the Step7 command interface and scripting functions. The attribute UDP_BROADCAST_ACTIVATE is used.

The following options are available for reading and setting the checkbox:

1. Directly using the Step 7 scripting mechanism for reading and writing.
2. External SCOUT scripting.
   If you are using a programming language that permits use of language-specific data types (e.g. LONG) (such as Visual Basic, MS Access), you can read and set the checkbox.
3. Internal SCOUT scripting.
   The VB script is used in this case. Only VARIANT data types are supported. In this case, the checkbox can only be set but not read if variables are not used.

Programming example for 1 and 2:

```
Private Sub CreateModule(Project As String, Station As String,
IOSystem As String, Value As String)
 Dim stationObj As S7Station
 Dim SimaticObj As New Simatic
 Dim Udp As String
 Dim io As Long
 Dim channel As Long

 Set stationObj = SimaticObj.Projects(Project).Stations(Station)
 Set cpuobj = stationObj.Racks(0).Modules(2)
 Set Udp = 1
 Call cpuobj.SetParameter("UDP_BROADCAST_ACTIVATE", 1, 0, 0)
‘ Writing
Call cpuobj.GetParameter("UDP_BROADCAST_ACTIVATE", Udp, io, channel)
‘ 'Reading
```

Programming example for 3:

```
Set oS7 = CreateObject("Simatic.Simatic")
oS7.Projects(PROJ.Name).Stations("SIMOTION
D").Racks(0).Modules(2).Putparameter "UDP_BROADCAST_ACTIVATE",1,0,0)
```

_udpReceive() system function

Overview

The _udpReceive() system function is called for receiving data.

Table 4-242 Call example

```
sRetValueUdpReceive :=_udpReceive(
   port               := 3456                  //UINT, 1024 - 65535
  ,communicationMode  := CLOSE_ON_EXIT         //EnumUdpCommunicationMode
  ,nextCommand        := IMMEDIATELY           //EnumNextCommandMode
  ,receiveVariable    := ab8ReceiveData               //ARRAY[0..1469] OF BYTE
  );
```

When the function is called, the local port is transferred for the **port** parameter.

In this case too, the user can use **communicationMode** to specify whether the communication resources are to be released after reception (CLOSE_ON_EXIT) or not released after reception (DO_NOT_CLOSE_ON_EXIT).

The behavior of this function with respect to the advance when called is parameterized with the **nextCommand** parameter. There are three setting options for this parameter: IMMEDIATELY, WHEN_COMMAND_DONE, and ABORT_CURRENT_COMMAND. With the first two values advance is either immediate or after completion of the command. With the third value, if the same port number as in the previous function call is transferred, the active function is aborted.

The **receiveVariable** parameter specifies the buffer in which the receive data is stored.

When the _udpReceive() system function is called, the structure returned to the user program contains the following parameters. The call status of the receive function can be queried in the **functionResult** parameter.

The **sourceAddress** parameter is an array that contains the IP address. The **sourcePort** parameter of the structure also contains the local port.

The number of received useful data bytes after a successful call of the _udpReceive() system function can be read out in the **dataLength** parameter.

Note

Up to SIMOTION 4.1 SP4, the length of the receive data (receiveVariable) was limited to 1,400 bytes.

Supplementary condition for UDP broadcast (as of V4.5)

If you want to use Open User Communication with UDP broadcast (_updSend(), _udpReceive()), you must configure this explicitly in SIMOTION SCOUT/SIMOTION SCOUT TIA. Please also read the section "Supplementary conditions for UPD broadcast" in chapter System function _udpSend() (Page 2302).

_udpAddMulticastGroupMembership() system function

Overview

This function is used to join a multicast group on a selected Ethernet interface.

A maximum of three multicast groups can be created on an Ethernet interface. These can occupy the same port or different ports.

```
myRetDINT :=
  _udpAddMulticastGroupMembership(
      multicastIPAddress :=
      ,interfaceIPAddress :=
      ,multicastPort :=
      // ,multicastTTL := 1
      // ,multicastLOOP := 1
      ,nextCommand :=
);
```

Note

In the case of UDP multicast communication, the _multicastPort must correspond to the destinationPort for function _udpSend.

Note

The UDP multicast functions (_updAddMulticastGroupMembership(), updDropMulticastGroupMembership()) can only be used on Ethernet interfaces. PROFINET interfaces are not supported.

_udpDropMulticastGroupMembership() system function

Overview

This system function is used to exit a multicast group on a selected Ethernet interface.

```
myRetDINT :=
  _udpDropMulticastGroupMembership(
      multicastIPAddress :=
      ,interfaceIPAddress :=
      ,multicastPort :=
      ,nextCommand :=
);
```

Note

The UDP multicast functions (_updAddMulticastGroupMembership(), updDropMulticastGroupMembership()) can only be used on Ethernet interfaces. PROFINET interfaces are not supported.

4.5.6.5 Services used

Communication services and port numbers used

Introduction

SIMOTION supports the protocols listed in the following table. The address parameters, the relevant communication layer as well as the communication role and the communication direction are specified for each protocol. This information allows you to match the security measures for the protection of the automation system to the protocols used.

Documentation of Ethernet services used

Protocol	Port number	Transport level	Role/direction	Function	Description
PROFINET protocols					
DCP Discovery and Configuration Protocol	Not relevant	Ethernet II and IEEE 802.1Q and Ethertype 0x8892 (PROFINET)	Server/ incoming Client/ outgoing	Accessible nodes, PROFINET discovery and configuration	DCP is used by PROFINET to determine PROFINET devices and to make basic settings.
LLDP Link Layer Discovery Protocol	Not relevant	Ethernet II and IEEE 802.1Q and Ethertype 0x88CC (PROFINET)	Server/ incoming Client/ outgoing	PROFINET Link Layer Discovery Protocol	LLDP is used by PROFINET to determine and manage neighborhood relationships between PROFINET devices.

MRP Media Redundancy Protocol	Not relevant	Ethernet II and IEEE 802.1Q and Ethertype 0x88E3 (PROFINET)	Server/ incoming Client/ outgoing	PROFINET media redundancy	MRP enables the control of redundant routes in a ring topology.
PTCP Precision Transparent Clock Protocol	Not relevant	Ethernet II and IEEE 802.1Q and Ethertype 0x8892 (PROFINET)	Server/ incoming Client/ outgoing	PROFINET send clock and time synchronization, based on IEEE 1588	PTCP enables a time delay measurement between RJ45 ports and, therefore, enables send clock synchronization and time synchronization.
PROFINET IO data	Not relevant	Ethernet II and IEEE 802.1Q and Ethertype 0x8892 (PROFINET)	Server/ incoming Client/ outgoing	PROFINET cyclic IO data transfer	The PROFINET IO telegrams are used to transfer IO data cyclically between the PROFINET IO controller and IO devices via Ethernet.
Internal protocol	34962 34963	UPD	Reserved	Reserved	The ports are reserved for PROFINET extensions.
PROFINET Context Manager	34964	UDP	IO device/ incoming IO Client/ outgoing	PROFINET connectionless RPC	The PROFINET Context Manager provides an endpoint mapper in order to establish an application relationship.
Connection-oriented communication protocols					
FTP	21	TCP	Server/ incoming	File Transfer Protocol	FTP is used to transfer files to the flash card. Password protection via Web server user management. The port can be deactivated.
Telnet	23	TCP	Server/ incoming		Used for internal debugging. Password protection via Web server user management. The port can be deactivated.

HTTP Hypertext Transfer Protocol	80	TCP	Server/ incoming	Hypertext Transfer Protocol	HTTP is used for communication with the internal SIMOTION Web server. Password protection via Web server user management. The port can be deactivated. You can modify the port number if desired.
RFC1006	102	TCP	Server/ incoming Client/ outgoing	ISO-on-TCP protocol	The protocol extension RFC1006 is used for communication with ES, HMI, OPC server, etc.
SNMP Simple Network Management Protocol	161	UDP	Server/ incoming	Simple Network Management Protocol	SNMP enables the reading out of network management data (MIBs) by SNMP clients.
HTTPS Secure Hypertext Transfer Protocol	443	TCP	Server/ incoming	Secure Hypertext Transfer Protocol	HTTPS is used to communicate with the internal CU Web server via Secure Socket Layer (SSL). Password protection via Web server user management. The port can be deactivated. You can modify the port number if desired.
Internal protocol	3844	TCP	Server/ incoming	System diagnostics	Diagnostic access for traces within the system.
Internal protocol	5188	TCP	Server/ incoming	Project download	Communication with SCOUT for downloading project data.
Internal protocol	8412	UDP	Server/ incoming Client/ outgoing	Trace	Port is used for trace functionality that must be synchronized over several devices. Cannot be switched off.

Internal protocol	44550	UDP	Server/ incoming Client/ outgoing	Trace	Port is used for trace functionality that must be synchronized over several devices. Cannot be switched off.
Reserved	49152...65 535	TCP UDP	-	-	Dynamic port area that is used for the active connection endpoint if the application does not specify the local port number.

Documentation of Ethernet services used

Deactivating PN interface ports in SIMOTION

Introduction

On SIMOTION CPUs as of Version 4.4, PN interface ports can be set to **Disable** in the engineering system. This prevents devices being connected without permission and also increases security with regard to accessing the system. The engineering system and the PN stack ensure that at least one port on each interface is not set to **Disable** to prevent the user locking him/herself out. The default setting is **Automatic settings**.

How to deactivate ports

1. In HW Config, double-click in the station on the port that you want to deactivate.
2. In the dialog box that opens, switch to the **Options** tab.
3. Under **Transmission media/Duplex**, select the item **disable**. The port is deactivated.

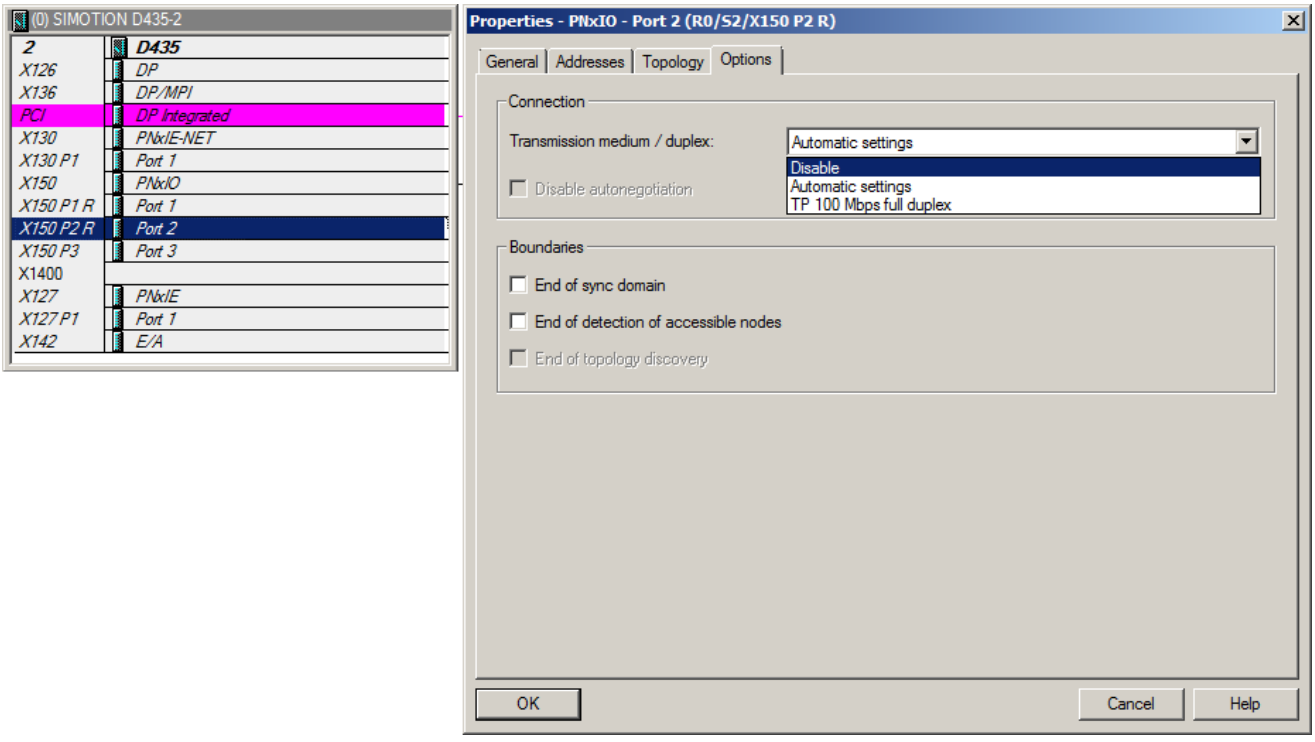

Figure 4-417 Deactivating PN ports on SIMOTION CPUs

4.5.7 Routing - communication across network boundaries

4.5.7.1 What does routing mean?

Introduction

Routing is the transfer of information from Network x to Network y.

There is a fundamental difference between intelligent, self-learning routing (e.g. IP routing in the Internet) and routing according to previously specified routing tables (e.g. S7 routing).

IP routing

IP routing is a self-learning routing procedure (which can also be performed manually), used exclusively in Ethernet communication networks which operate with the IP protocol, such as the Internet.

The function is performed by special routers that pass on the information to adjacent networks based on the IP address, when the IP address is not detected in the own network.

Note

IP routing is NOT supported by SIMOTION. Only S7 routing is possible between the interfaces of a SIMOTION controller.

S7 routing

S7 routing is a routing procedure based on previously configured routing tables, but which can also exchange information between different communication networks, e.g. between Ethernet, PROFIBUS and MPI. These routing tables can be created as interconnection tables in NetPro.

S7 routing does not work with the IP address, but with the so-called subnet IDs within the S7 protocol.

- Information transfer from Ethernet to MPI and vice versa
- Information transfer from Ethernet to PROFIBUS and vice versa
- Information transfer from MPI to PROFIBUS and vice versa
- Information transfer from Ethernet to Ethernet (SIMOTION V4.1.2 or higher, including PROFINET; CP343, CPU 315-2 PN/DP...)

CIDR Classless Inter-Domain Routing

Classless Inter-Domain Routing (CIDR) describes a process for a more efficient use of the existing 32-bit IP address space (IPv4). It was introduced to reduce the size of routing tables and utilize the available address areas more effectively. The CIDR (Classless Inter-Domain Routing) function includes subnetting and supernetting.

Subnetting refers to the splitting of an IP subnet into multiple subnetworks (by enlarging the subnet mask).

Supernetting refers to the compilation of multiple subnets into a joint IP subnet (by minimizing the subnet mask).

See also Relationships between subnet masks and IP addresses in relation to subnetting and supernetting (Classless Inter Domain Routing CIDR) (https://support.industry.siemens.com/cs/ww/en/view/2073614).

Note

CIDR is supported by all SIMOTION devices. In the case of SIMATIC devices, please refer to the notes in the manuals.

PG / PC assignment

Modification of the PG assignment may be required for S7 routing. You can do this now in the toolbar in SIMOTION SCOUT above the **Assign PG** button. This calls the properties window for PG assignment, where you modify the assignment and "activate" it (S7ONLINE access).

Note

You will find further notes on Ethernet/PROFINET and the settings required for routing in the *SIMOTION SCOUT Overview of Service and Diagnostics Options* product information as well as in the online help on this topic.

4.5.7.2 Configuration of S7 routing

S7 routing is configured in STEP 7 / SIMOTION SCOUT with the aid of the "NetPro" network configuration.

All stations contained in the network configuration can exchange information between one another. Connection tables must be created in NetPro for this purpose. The required routing tables are automatically generated during the compilation of the project, but must then be loaded to all the participating stations.

Establishing an online connection to the nodes in the project

Through S7 routing you can go to all the nodes in the project online.

This is how you establish an online connection from your PG/PC to the nodes in the project.

1. Insert a PG/PC station in NetPro.
2. Add a new interface.
3. Assign the new interface of the network card used to the PG/PC.
4. Make the assignment "active" (S7ONLINE access).
5. Compile NetPro and load the data into the routing devices by downloading it.

4.5.7.3 Routing for SIMOTION

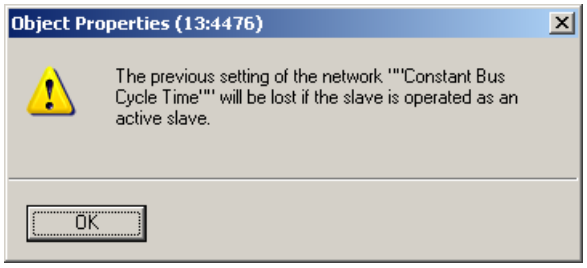
Definition

With routing you can, for example, access devices connected to subnets ONLINE via a PG/PC. S7 routing is supported by SIMOTION, i.e. information (engineering accesses) can be routed by a SIMOTION device from higher-level networks such as Ethernet and MPI to lower-level networks such as PROFIBUS or PROFINET/Ethernet (4.1.2 and higher).

Boundary conditions

The following boundary conditions must be taken into account in the "DP slave" mode when routing information on an isochronously operated PROFIBUS.

- The functions "Equidistant bus cycle" (requirement for isochronous applications) and "Active station" (requirement for routing to a lower-level network segment) mutually exclude each other.
- It is not possible to operate an active I slave on the isochronous bus.



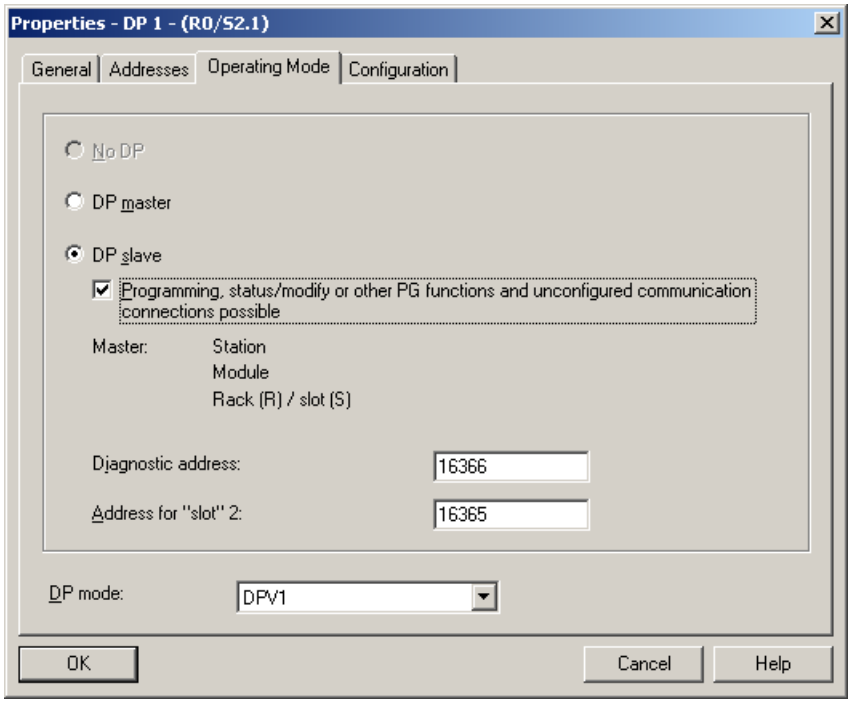


Figure 4-418 DP slave mode: Active station: Testing, commissioning, routing

The "Programming, status/control or other PG functions ..." check box must be activated if, for example, you frequently want to perform PG functions required for commissioning and testing via this interface, or if you want to access (S7 routing) SINAMICS drives on the cascaded, lower-level DP master interface of the SIMOTION controller with PG functions (e.g. STARTER).

If the "Programming, Status/Force or other PG functions..." option is activated, the interface becomes the active node on the PROFIBUS (i.e. the interface participates in the token rotation of the routing PROFIBUS). The following functions are then possible:

- Programming (e.g. loading)
- Test (status/control)
- S7 routing (I-slave as gateway)

The bus cycle time can be prolonged. Therefore, this option should not be activated for time-critical applications and when S7 routing and the client functionality are not required for the communication.

Note

When the "Programming, Status/Force or other PG functions ..." check box is not activated, the interface only operates as a server for cyclic data, i.e. S7 routing is not possible.

Note

If more than one gateway is used for the PG connection, all configured connection paths must also be physically connected. However, it is not possible to configure which of the configured connection paths is actually being used.

4.5.7.4 Routing with SIMOTION D (example of D4x5 with CBE30)

Routing between the different interfaces

The two standard Ethernet interfaces X120 and X130 of the SIMOTION D each form a separate subnet, all ports on the CBE30 also form a common subnet.

- S7 routing is possible to every interface.
  E. g. you can set up a connection from a PROFINET/Ethernet subnet to a PROFIBUS via S7 routing.
- IP routing from subnet to subnet is not supported. You can use an external IP router for this.

There are three options for connecting a PG/PC or HMI via S7 routing to a SIMOTION D with CBE30.

Note

The Ethernet interfaces X120 and X130 and the CBE30 must be in different subnets for S7 routing.

Engineering system to PROFINET (CBE30)

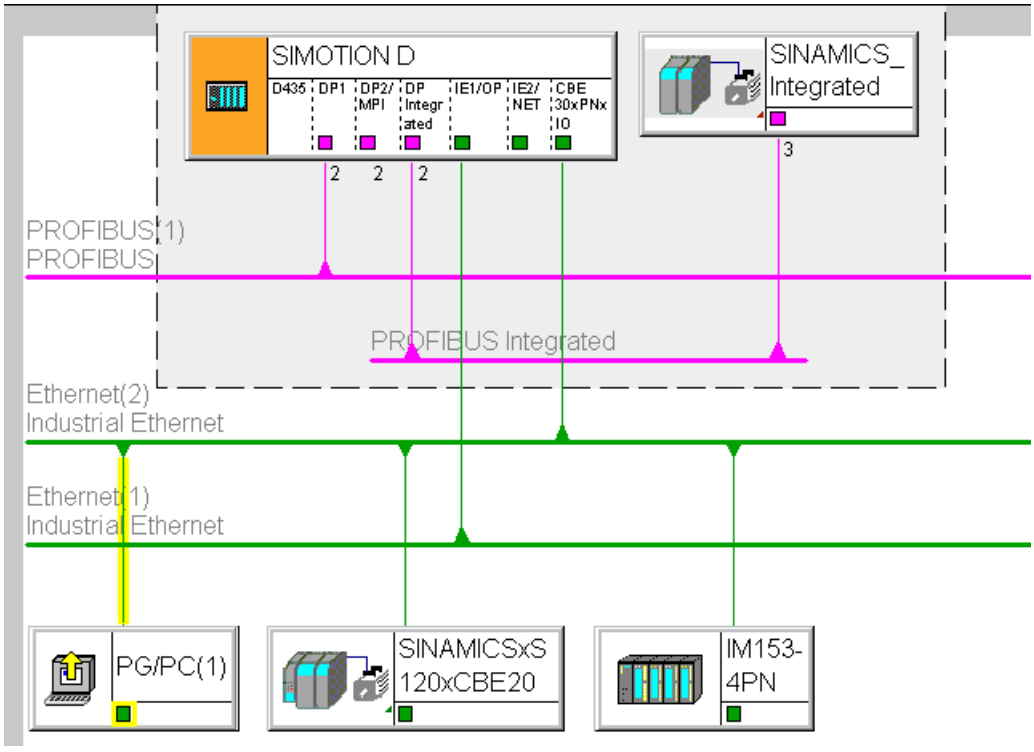

Figure 4-419 Example for PG/PC to CBE30

- S7 routing to the (master) PROFIBUS interfaces (only if configured)
- S7 routing to PROFIBUS Integrated
- S7 routing to the standard Ethernet interfaces ET1/ET2 (X120, X130) (V4.1.2 and higher)
- Access to the components on the same subnet (CBE30) via the switch functionality

Engineering system / HMI to PROFIBUS

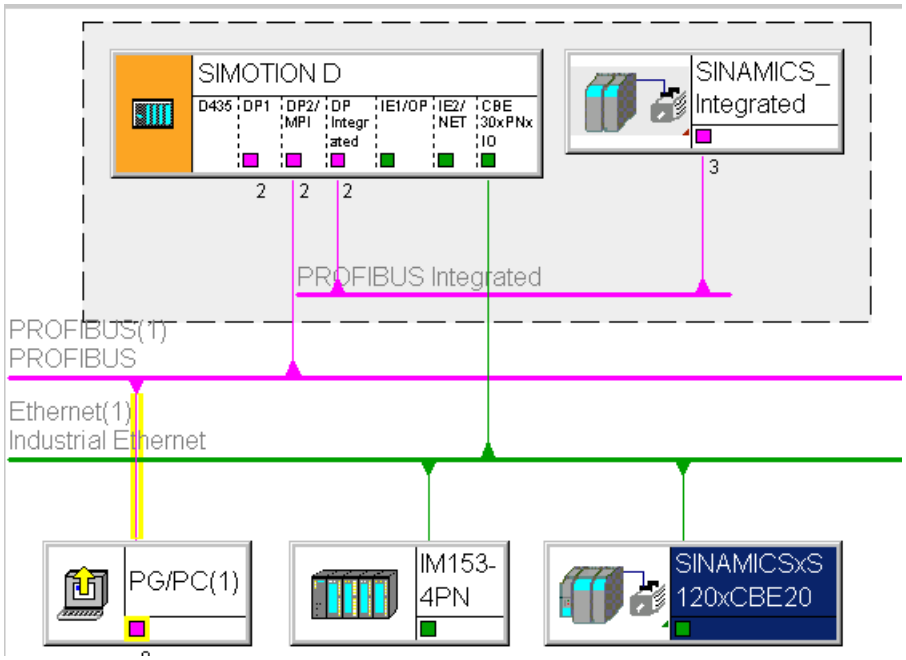

Figure 4-420 Example for PG/PC to PROFIBUS

- S7 routing to the other (master) PROFIBUS interfaces (only if configured)
- S7 routing to PROFIBUS Integrated
- S7 routing to the PROFINET interface (CBE30)
- S7 routing to X1400 on the CBE30
- S7 routing to the standard Ethernet interfaces (X120, X130) (V4.1.2 and higher)
- Access to nodes on the same network, e.g. HMI

Engineering system / HMI to Ethernet

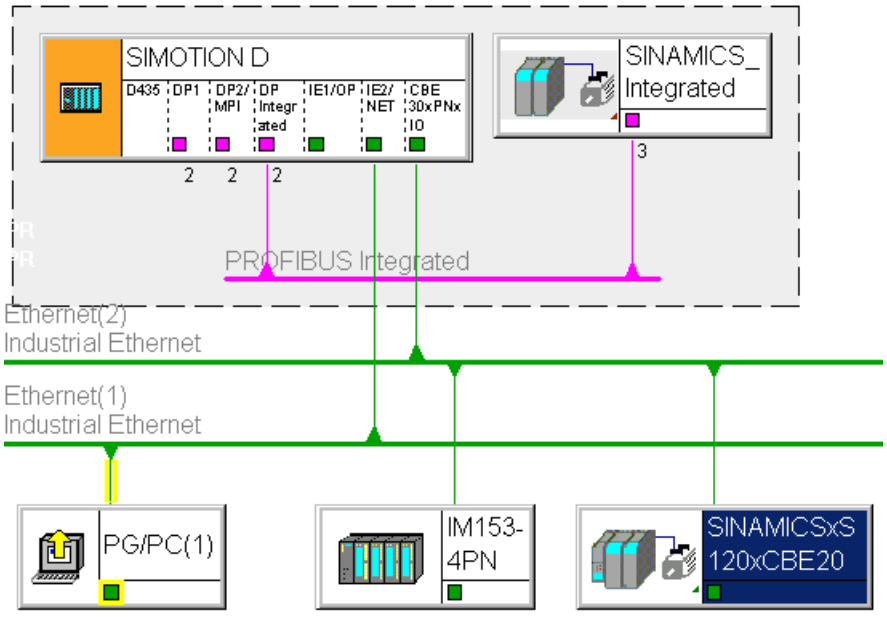

Figure 4-421 Example for PG/PC to Ethernet X120, X130

- S7 routing to the other (master) PROFIBUS interfaces (only if configured)
- S7 routing to PROFIBUS Integrated
- S7 routing to the PROFINET interface (CBE30)
- S7 routing to X1400 on the CBE30
- S7 routing between the Ethernet interfaces
- Access to nodes on the same network, e.g. HMI

4.5.7.5 Routing with SIMOTION D4x5-2 (example of D455-2 DP/PN)

Routing between the different interfaces

The two Ethernet interfaces of the D4x5-2 DP/PN (X127 P1 or X130 P1) each form a separate subnet.

The D4x5-2 DP/PN onboard PROFINET IO interface (X150, P1-P3) also forms a separate subnet. All ports of a PROFINET IO interface always belong to the same subnet.

- S7 routing is possible to every interface.
  E. g. you can set up a connection from a PROFINET/Ethernet subnet to a PROFIBUS via S7 routing.
- IP routing from subnet to subnet is not supported. You can use an external IP router for this.

There are therefore the following options for connecting a PG/PC or HMI device to a SIMOTION D using S7 routing.

Engineering system / HMI to PROFINET

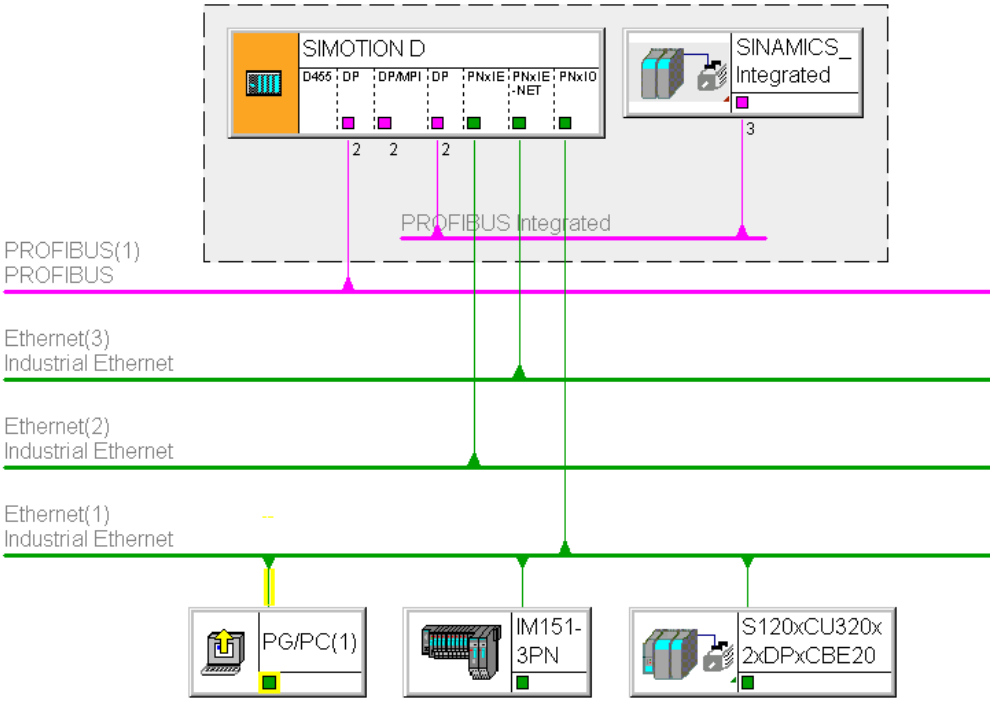

Figure 4-422 Example of PG/PC to PROFINET interface (PNxIO, X150)

- S7 routing to the (master) PROFIBUS interfaces (only if configured)
- S7 routing to the PROFIBUS Integrated
- S7 routing to the Ethernet interfaces PN/IE (X127 P1) and PN/IE-NET (X130 P1)
- Access to the components on the same subnet via the switch functionality of the PROFINET IO interface

Engineering system / HMI to PROFIBUS

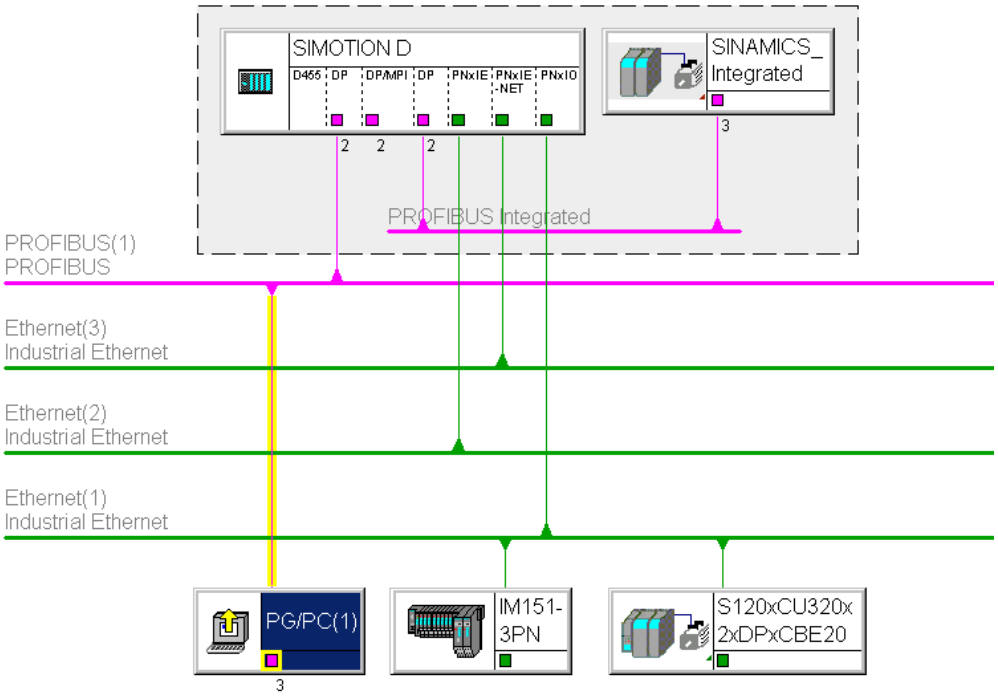

Figure 4-423 Example of PG/PC to PROFIBUS interface (DP, X126)

- S7 routing to the other (master) PROFIBUS interfaces (only if configured)
- S7 routing to the PROFIBUS Integrated
- S7 routing to the PROFINET interface (CBE30)
- S7 routing to the onboard PROFINET IO interface (X150, P1-P3)
- S7 routing to the Ethernet interfaces PN/IE (X127 P1) and PN/IE-NET (X130 P1)

Engineering system / HMI to Ethernet

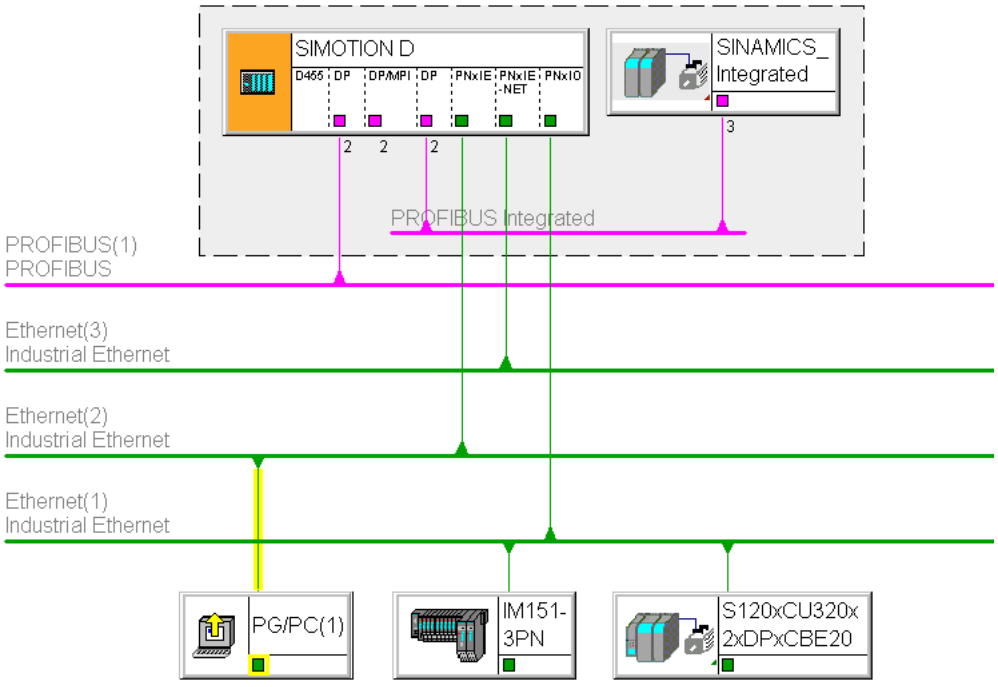

Figure 4-424 Example of PG/PC to Ethernet interface (PNxIE, X127)

- S7 routing to the other (master) PROFIBUS interfaces (only if configured)
- S7 routing to the PROFIBUS Integrated
- S7 routing to the PROFINET interface (CBE30)
- S7 routing to the onboard PROFINET IO interface (X150, P1-P3)
- S7 routing between the Ethernet interfaces

4.5.7.6 Routing for SIMOTION D to the SINAMICS integrated

All SIMOTION D controllers have a SINAMICS drive integrated: the so-called SINAMICS Integrated. As this is connected internally to the SIMOTION controller via PROFIBUS DP, S7 routing is imperative here to be able to access it. Here the telegrams have to be routed from the external interfaces of the SIMOTION controller to the internal PROFIBUS DP. Here, the internal PROFIBUS DP forms a separate subnet. This must be especially taken into account for the communication to several routing nodes.

4.5.7.7 Routing for SIMOTION P350

Description

S7 routing is possible:

- From PROFIBUS (IsoPROFIBUS board) on PROFINET subnet to MCI-PN board
- From PROFINET subnet to MCI-PN board on PROFIBUS (IsoPROFIBUS board)
- From SCOUT on SIMOTION P via softbus through the runtime on PN devices to the MCI-PN board and IsoPROFIBUS board
- From onboard Ethernet interfaces on PROFIBUS (IsoPROFIBUS board) and on PROFINET
- S7 routing between the Ethernet interfaces

IP routing is **not** possible via the P350 Ethernet interfaces.

Routing from PROFIBUS to PROFINET

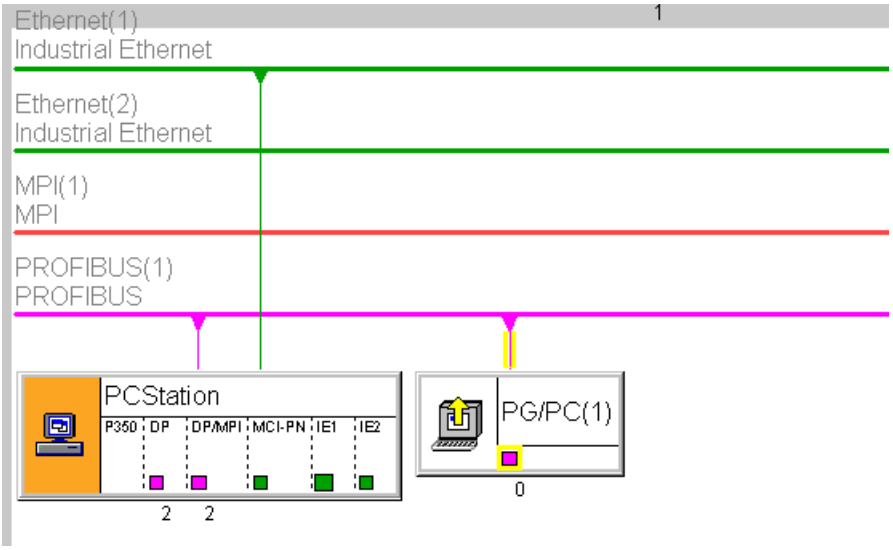

Figure 4-425 Example for P350 routing from PROFIBUS to PROFINET

Routing from PROFINET on PROFIBUS

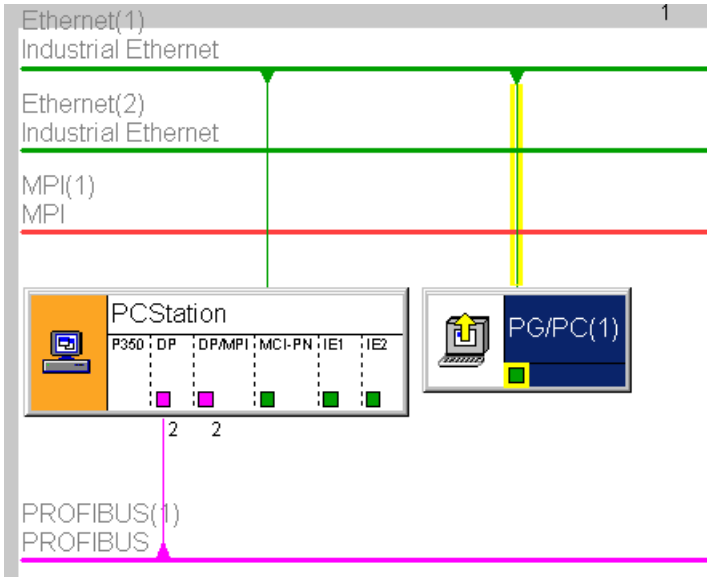

Figure 4-426 Example for P350 routing from PROFINET to PROFIBUS

4.5.7.8 Routing for SIMOTION P320

Description

S7 routing is possible:

- From the onboard Ethernet interface to the PROFINET subnet and the drive units or SIMOTION devices on the PROFINET subnet

Routing from Ethernet to PROFINET

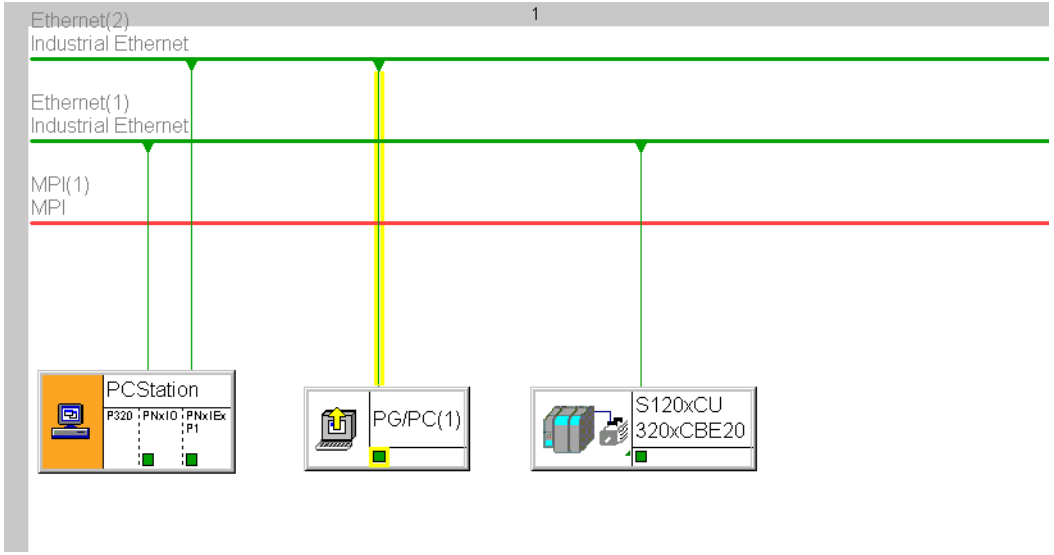

Figure 4-427 Routing for SIMOTION P320

4.5.8 SIMOTION IT

4.5.8.1 SIMOTION IT - overview

Description

SIMOTION IT provides the option of accessing this via standard web services (HTTP) and the integrated web server of the SIMOTION controllers.

Note

Appropriate protective measures (among other things, IT security, e.g. network segmentation) are to be taken in order to ensure safe operation of the system. You can find more information on Industrial Security on the Internet at:

www.siemens.de/industrialsecurity

This provides the following advantages.

- Location-independent open diagnosis / process monitoring
- Client device independent of the operating system (Windows, Linux, ...)
- Standardized communication interface for manufacturer-specific tools
- Independent of engineering system
- No version conflict between client application and SIMOTION RT (runtime)
- Series commissioning without engineering system

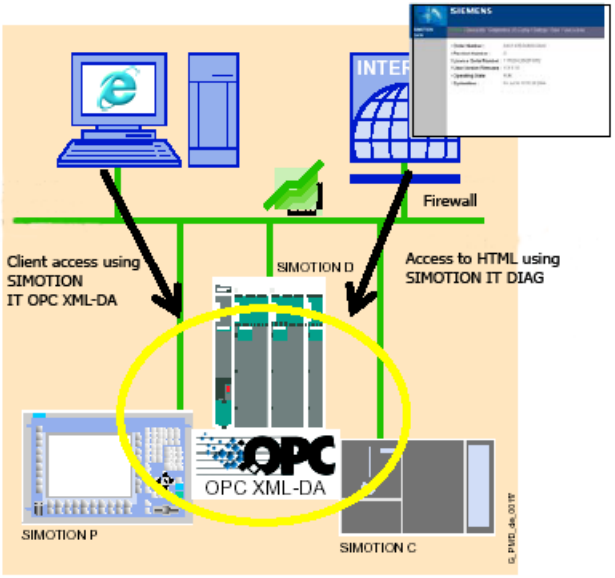

Figure 4-428 SIMOTION IT overview

SIMOTION IT provides the following service and diagnostics options via Internet technology:

- SIMOTION IT web server
- SIMOTION IT OPC XML DA
- Trace via SOAP
- File download using FTP (File Transfer Protocol)
- SIMOTION IT Virtual Machine

Further references

A detailed description of the SIMOTION IT products can be found in the *SIMOTION IT Ethernet-based HMI and Diagnostic Functions* product information on the SIMOTION SCOUT Documentation DVD.

Further information is available in the following manuals:

- *SIMOTION IT Diagnosis and Configuration, Diagnostics Manual*
- *SIMOTION – Jamaica*, Diagnostics Manual (Information on SIMOTION VM)

SIMOTION IT OPC XML DA (Page 2329)

4.5.8.3 SIMOTION IT web server

Description

The SIMOTION IT web server allows a PC to use any Internet browser to access the the web pages of the integrated web server of the SIMOTION controllers.

You will find a detailed description in the *SIMOTION IT Diagnostics and Configuration* Diagnostics Manual.

Standard diagnostic pages

SIMOTION provides the following standard diagnostic pages:

- **Start page**
- **Device Info/IP-Config**
  (information about the firmware, devices, device components, technology packages, and data of the SIMOTION device Ethernet interface)
- **Diagnostics**
  (CPU utilization, memory use, operating mode, display of task runtimes, trace for devices and system, service overview)
- **Message&Logs**
  (diagnostics buffer, SIMOTION alarms and Drives, syslog and userlog)
- **Machine Overview**
  (modules and topology of a machine as well as hardware configuration information)
- **Manage Config**
  (loading SIMOTION IT web server configurations, device updates, saving device data)
- **Settings**
  (setting the time zone, switching operating modes, changing the display of user-defined pages)
- **Files**
  (accessing the SIMOTION file system, uploading and downloading files, creating folders, and storing additional data, e.g. documentation)

Simplified standard pages

To enable the best possible display of HTML pages on devices such as cell phones or PDAs, a set of special pages is provided for version 4.1.3 and higher. These contain a simplified representation of information from the standard pages. The start page of the simplified standard pages can be reached at the address http://<IPAddr>/BASIC.

Configuration via WebCfg.xml

There are two files which can be used to configure SIMOTION IT web server:

- WebCfg.xml
- WebCfgFrame.xml

The WebCfg.xml configuration file is used to configure user-relevant settings in the web server. The WebCfgFrame.xml file contains the manufacturer's settings.

User-defined pages

The SIMOTION IT web server offers the option of integrating individually designed web pages. Two mechanisms are available for accessing SIMOTION variables:

- JavaScript libraries opcxml.js and appl.js
- MiniWeb Server Language (MWSL)

User-defined pages can be displayed in the "User's Area". For this purpose, they must be stored in the FILES folder of the SIMOTION file system.

Trace via SOAP

The WebTrace is almost identical to the SIMOTION SCOUT trace. The only difference is in output of the data format and in the number of signals that can be parameterized.

The "Trace via SOAP" function package enables SIMOTION variables to be written to a buffer. The values are packed in a file and can be retrieved asynchronously via an HTTP request. This interface can only be used by client applications.

The trace can be parameterized via a web interface and the recording viewed immediately using a TraceViewer.

Variable access

The variable access for the SIMOTION IT applications is implemented using a variable provider. The following variable providers currently exist.

- MiniWeb
- SIMOTION
- SIMOTION diagnostics
- UserConfig
- IT Diag

These variable providers allow access to the following variables:

- Device system variables
- TO system variables
- Global unit variables from the interface section
- TO configuration data
- Also global device variables and I/O variables as of 4.2
- Drive parameters
- Setting of the operating mode, execute RamToRom, execute ActiveToRom
- Technological alarms
- Diagnostics buffer

Secure HTTPS connection

The Secure Socket Layer protocol (SSL) enables encrypted data transmission between a client and the SIMOTION device. The Secure Socket Layer protocol forms the basis for HTTPS access. Encrypted access can take place via both SIMOTION IT OPC XML DA and the SIMOTION IT web server.

4.5.8.4 SIMOTION IT OPC XML DA

Description

The SIMOTION IT OPC XML DA server enables access via Ethernet to data and operating modes of the SIMOTION controller. As of V4.2, a separate license is no longer required for SIMOTION IT OPC XML DA.

OPC stands for open connectivity and refers to standardized software interfaces which enables the exchange of data between applications from different manufacturers in automation technology. With OPC XML DA, it is possible to communicate with a control using Ethernet-based standard message frames. Commands are transmitted via the SOAP (Simple Object Access Protocol) communication protocol.

A customer-specific application created on a client PC, which, for example, is programmed with the C#, Visual Basic, or Java programming language, uses the SIMOTION IT OPC XML DA services and properties:

- Open communication using HTTP, SOAP, OPC XML between client and SIMOTION device
- Uses the OPC XML DA 1.0 specification of the OPC Foundation
- Access to SIMOTION variables
  - Reading/writing
  - Cyclical reading of so-called "subscriptions"
  - Browsing
- Trace using SOAP; this function is an extension of the OPC specification
- Clients on any hardware with various operating systems (Windows, Linux, etc.)
- Creating client applications using C#, Java, C++. You must implement the application that you want to access on the SIMOTION OPC XML DA server yourself.
- Access protection with user groups, user ID, and password

The following figure is a schematic representation of access to the OPC XML DA server.

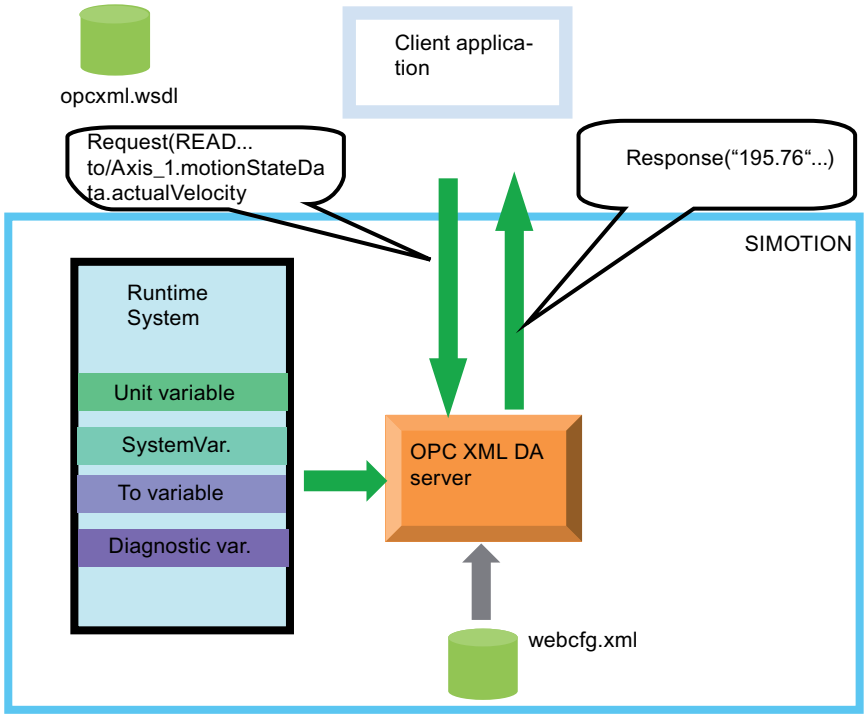

Figure 4-430 Access to the OPC XML DA server

4.5.9 PROFIsafe

4.5.9.1 Communication relationships for drive-based safety

Description

The drive-based safety functions in the drive can be controlled either by using safe terminals directly on the drive or from a fail-safe control (F control) via PROFIBUS/PROFINET.

The control signals for the drive-based safety functions, as well as the feedback relating to the safety function status, are safety-oriented and must be transmitted via a communication channel that is secured by means of the PROFIsafe protocol. The figure below contains a diagram providing a general overview of how interaction between the various control and drive processes works, as well as the communication relationships between them that are required for this purpose.

Signal flow for selecting and deselecting the drive-based safety functions and their signaling to the drive control process

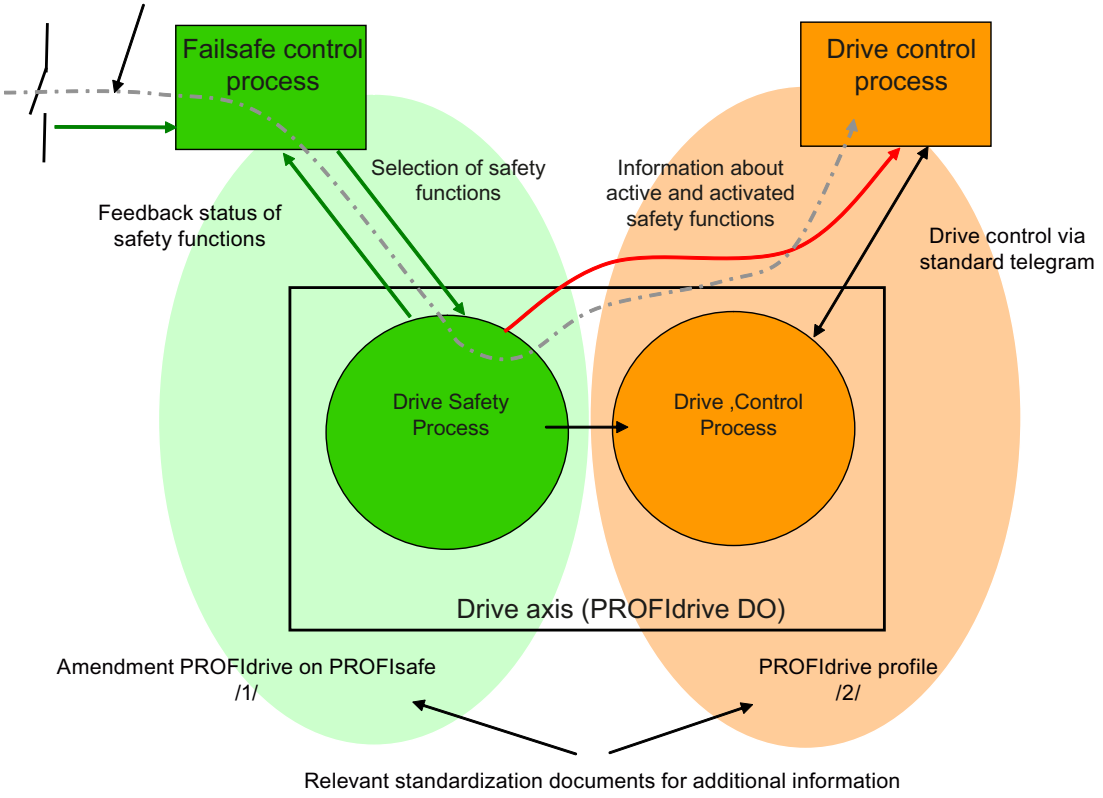

Figure 4-431 Communication relationships for drive-based safety

The "drive safety process" interfaces to the F control and drive control are PROFIdrive interfaces; their functions are defined in /1/ and /2/.

The F control introduces and monitors a drive-based safety function via the PROFIsafe-secured transmission channel between the F control and the drive (drive axis). The respective statuses of the drive-based safety functions in the drive also have repercussions on the drive interface to the drive control, since the drive priority switches between the drive control and drive safety process in the case of some drive-based safety functions.

In order for the F control and drive control to be coordinated effectively, therefore, an information channel from the "drive safety process" to the drive control is also required so that the drive control can respond to the required or activated drive-based safety functions accordingly.

4.5.9.2 Message frames and signals in drive-based safety

Description

Since SIMOTION does not have a safe logic function, it cannot attend to the F control process. Instead, this is carried out using a second controller featuring F functionality (usually a SIMATIC F-CPU). The image below shows how this setup works, using the example of a SINAMICS axis. A PROFIsafe-secured communication channel runs between the DO drive and the SIMATIC F-CPU. Standard telegram 30, consisting of a safety control word and status word (among other things), is normally available for this communication channel.

As of V4.3, the following PROFIsafe telegrams are available:

- Telegram 30
- Telegram 31
- Telegram 901
- Telegram 902 (from V4.4, can be used in SCOUT TIA in connection with the TIA Portal)
- Telegram 903 (as of V5.2)

With the user program on the F-CPU, the safety control word is used to select or deselect the configured drive-based safety functions in the drive (drive safety process). The feedback from the active safety functions is sent in the input data to the F-CPU, via the safety status word. A safe process in the drive is used to send the feedback from the active safety functions via a secured communication channel; therefore, the feedback may be used for activating protection zones and doors via the F-CPU.

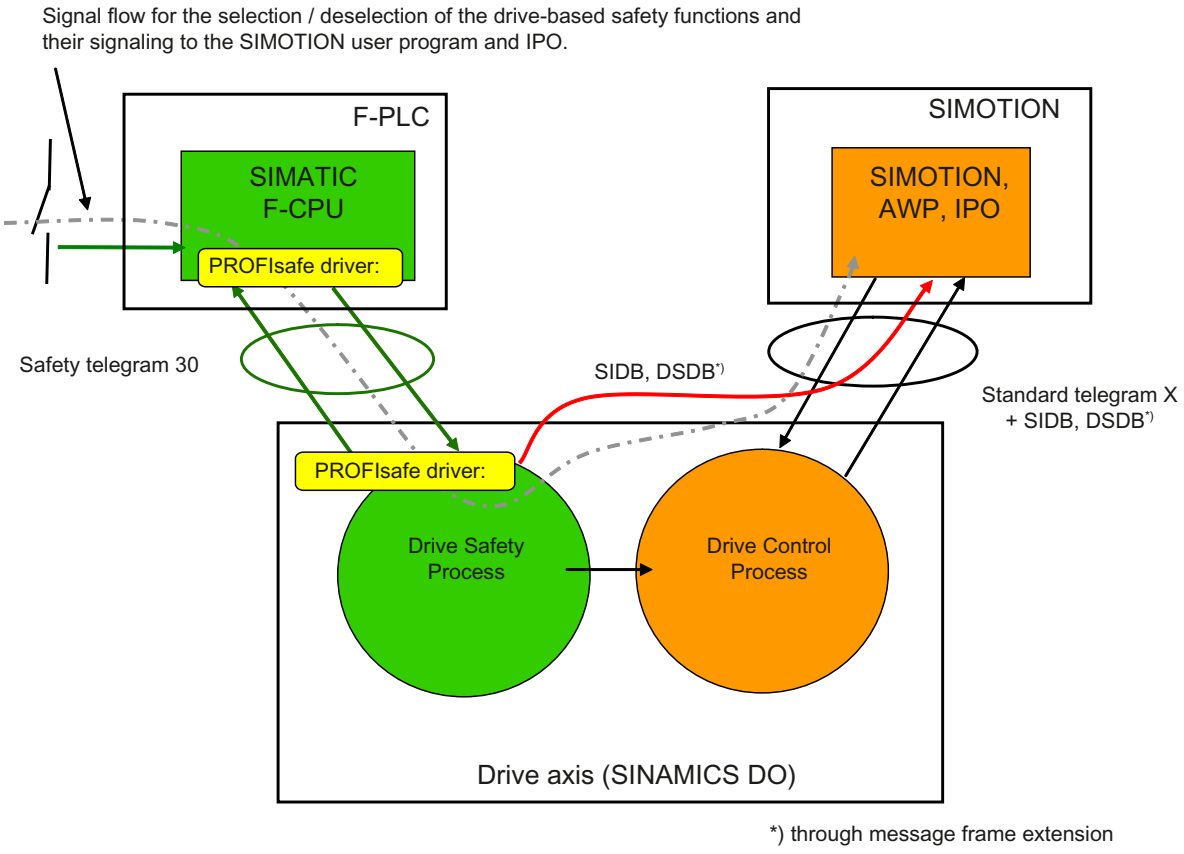

Figure 4-432 Messages and signals in drive-based safety

Safety information channel SIDB (up to V4.4) and DSDB (from SIMOTION V4.4)

In addition to controlling safety functions in the drive via the PROFIsafe channel, you have the option of transferring states and activation states of the drive-based safety functions from the drive to SIMOTION via a safety information channel (SIDB Safety Data Block). This has been expanded through the new standard DSDB (Drive Safety Data Blocks) from SIMOTION V4.4. The previous SIDB telegram extension block is replaced by two telegram extension blocks, DSDB1 and DSDB2. Instead of the previous single bico interconnections to bits in SINAMICS, interconnections are made to complete signals (bit blocks) with the new SC types. As a result, status information also becomes independent of the activated safety function (basic or extended functions). With DSDB the entire safety-oriented functionality configured on the drive is available on the TO. Configuration is automatic and uses the DSDB channel (Drive Safety Data Blocks).

Note

The Drive Safety Data Block is an extension of the PROFIdrive axis telegrams. Transfer according to PROFIdrive and is therefore not a secure safety telegram.

Note

Further information about SINAMICS Safety Integrated and the configuring with the TO axis can be found in Chapter **Support of the SINAMICS Safety Integrated functions** of the *TO Axis Function Manual*.

New in SIMOTION SCOUT as of V4.3 (Page 2183)

4.5.9.3 SIMOTION F proxy functions

Description

SIMOTION features integrated F-Proxy functionality for the purpose of PROFIsafe connection of integrated SIMOTION D drives, as well as SINAMICS drives that are controlled by SIMOTION but are in a different communication domain from the F-CPU, for example. The F proxy functionality enables transparent routing of safety message frames from the SIMOTION I slave or I device interface to the respective SIMOTION master or controller interface on which the drive is configured. Despite the SIMOTION routing function, PROFIsafe communication between the F-CPU and drive is secured, as the PROFIsafe drivers in the end points (F-CPU, drive) monitor communication securely.

In order to use F proxy functionality, the two paths of communication - from the F-CPU to SIMOTION and from SIMOTION to the drive - need to be configured separately.

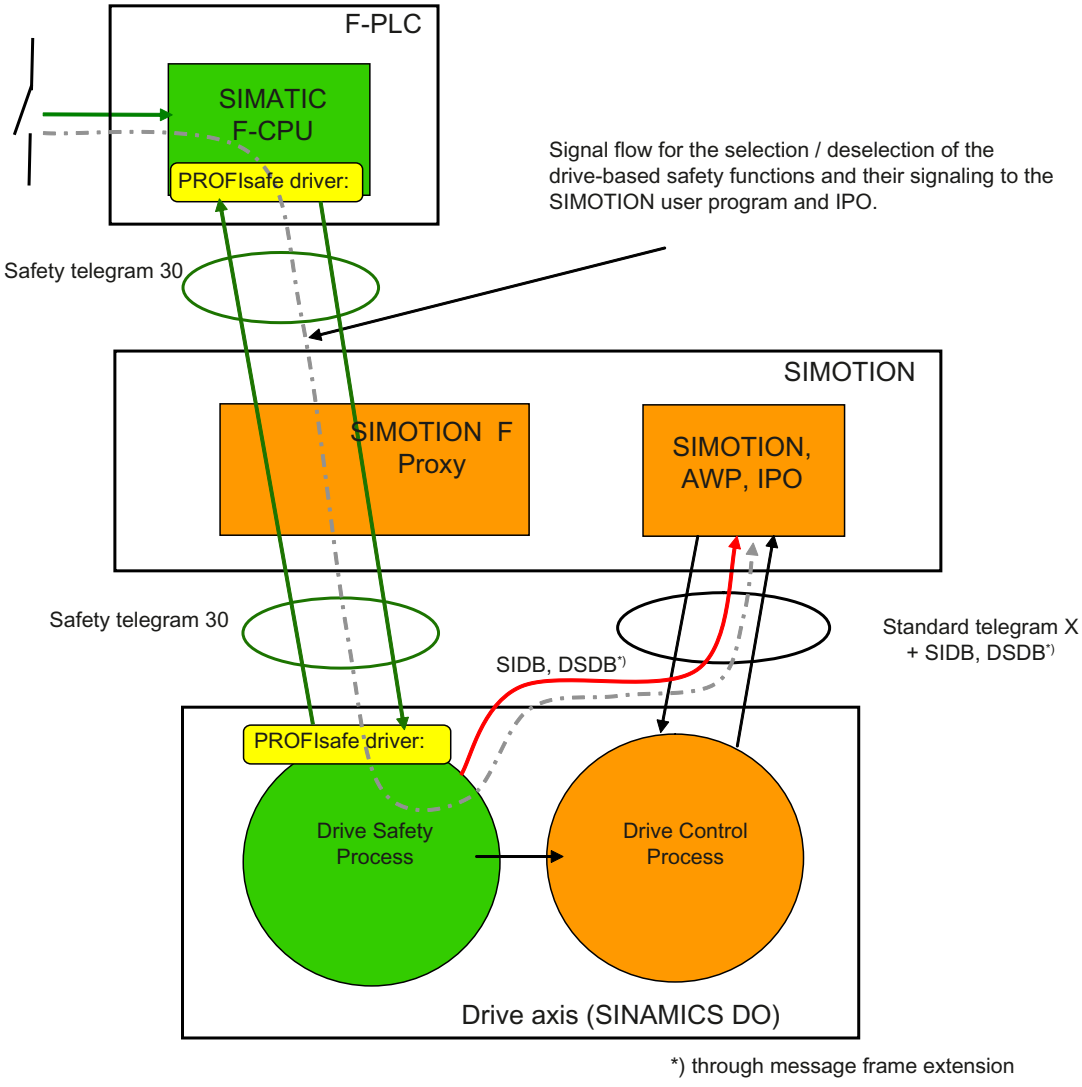

Figure 4-433 Routing the PROFIsafe channel with F proxy functionality

4.5.9.4 PROFIsafe properties for configuration

Mechanisms with PROFIsafe

Basically the PROFIsafe can communicate both via PROFINET and PROFIBUS. The I-device F-Proxy, the I-slave F-Proxy, the PROFINET shared device, and the PROFIBUS data exchange broadcast are available as mechanisms for PROFINET and PROFIBUS.

Note

Mixed operation is **not** supported for the PROFIsafe configuration. If, for example, in the case of a SINAMICS drive, the safety configuration for one axis is carried out via F-Proxy and those of the other axes are configured via shared device, this configuration will be rejected with a consistency error during compilation. The F-Proxy variants are recommended for the PROFIsafe configuration.

For all the mechanisms, the F data is managed by the F-CPU and the Motion Control data by the SIMOTION controller. The PROFIsafe communication properties required are set in the HW Config for the fail-safe parameters.

Note

For SIMOTION projects (RT version) < V4.2, secured PROFIsafe communication is only possible via PROFIBUS. Therefore, with SIMOTION devices < V4.2 with PROFIBUS and PROFINET interfaces, you can only implement PROFIsafe via the PROFIBUS interface and the Motion Control tasks (for example) via the PROFINET interface. Mixed operation (Motion Control via PROFINET and PROFIsafe via PROFIBUS) is, however, only possible with the integrated SIMOTION D drives. It is not permissible if you are using external drives (e.g.S120 CU320-2) on a SIMOTION controller.

Overview of failsafe parameters for PROFIsafe during configuration

To access the PROFIsafe dialog box, double-click the **PROFIsafe** entry in the drive rack in HW Config.

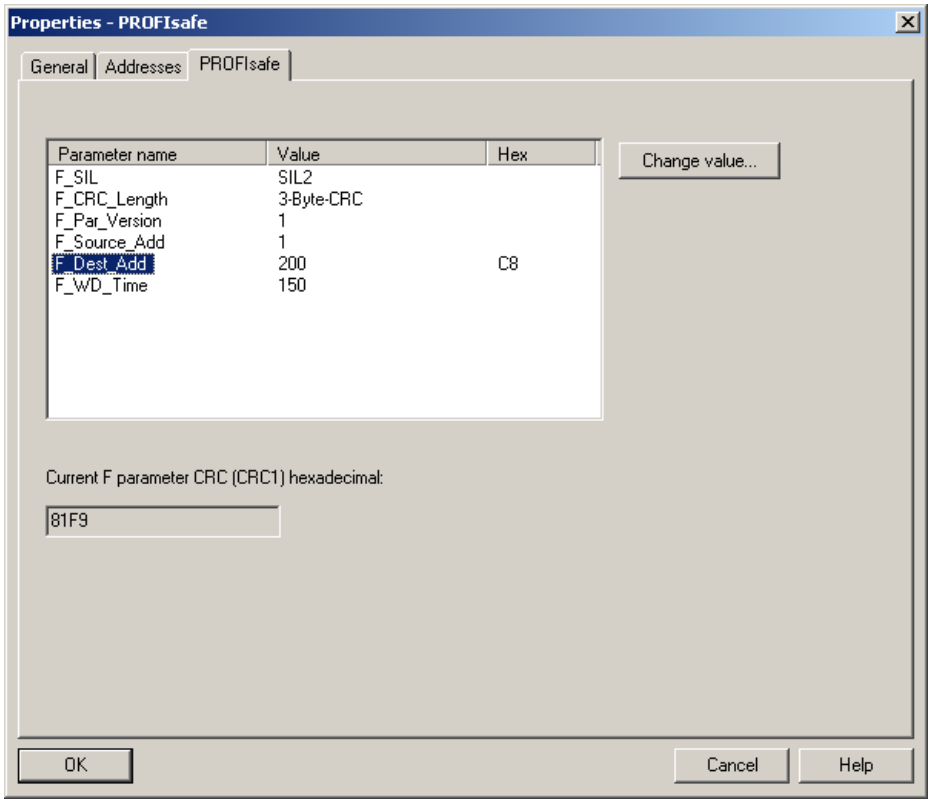

Figure 4-434 Properties of PROFIsafe using the example of I-device F-proxy

F_CRC_Length and F_Par_Version

Identifies not only the length of the failsafe useful data but also the PROFIsafe MODE.

- PROFIsafe V1-MODE
  F_CRC_Length = 2 to useful data length of 12 bytes
  F_CRC_Length = 3 from useful data length of 13 bytes
  F_Par_Version = 0
- PROFIsafe V2-MODE
  F_CRC_Length = 3 to useful data length of 12 bytes
  F_CRC_Length = 4 from useful data length of 13 bytes
  F_Par_Version = 1

Note

PROFIsafe V2 mode is not supported by all devices and/or firmware versions. Before configuration, find out which mode is available as of which version.

SINAMICS G120 CU240D DP F and SINAMICS G120 CU240S DP F only support V2 mode as of firmware version V3.2.

F_Dest_Add: 1-65534

F_Dest_Add determines the PROFIsafe destination address of the drive object.

Any value within the range is allowed, although it must be manually entered again in the Safety configuration of the drive in the SINAMICS drive unit and/or entered when configuring Safety Integrated (drive parameters p9610/p9810).

F_WD_Time: 10- 65535
A valid current safety telegram must be received from the F-CPU within the monitoring time. The drive will otherwise switch to the safe state.
The monitoring time should be of sufficient length to ensure not only that the communication functions tolerate telegram time delays, but also that the fault response is triggered as quickly as possible if a fault occurs (e.g. interruption of the communication connection).

For additional information on F Parameters, refer to the online help of the **PROFIsafe** dialog box.

4.5.9.5 PROFIsafe via PROFINET

Principles of I device failsafe proxy

Brief description

Using the I device F-Proxy you can produce a PROFIsafe configuration with an F host (F-CPU SIMATIC) on PROFINET with SIMOTION devices (SIMOTION D, SIMOTION P, SIMOTION C) for the lower-level drives. The routing of cyclic PROFIsafe data to SINAMICS Integrated and SINAMICS drives on external PROFIBUS or PROFINET is therefore possible.

You can also use the functionality of a shared iDevice for the iDevice F Proxy from SIMOTION V4.4 and higher. The iDevice interface can be shared between an F CPU and a SIMOTION controller. This means that an iDevice can communicate with two higher-level controllers as an IO device. At the same time, higher-level controllers can access certain modules, e.g. an F-CPU can access the F-Proxy submodules, using the shared device. You can find a configuration example in the Shared iDevice section and PROFIsafe (Page 2374).

Note

F-Proxy modules can be set up either on the CBE30-2 or on the integrated PROFINET interface.

A failsafe host communicates with the drives via the I device interface and an F-Proxy of a SIMOTION CPU. These drives may be located on PROFIBUS DP external, PROFIBUS DP integrated and the PROFINET IO system of the SIMOTION CPU. The SIMOTION CPU's communication segments feature SINAMICS S120/S110, incl. SINAMICS Integrated/CX32/CX32-2 and G120.

The higher-level project with the F-CPUs is the master project. There may be several F-CPUs in the master project. The lower-level projects with SIMOTION CPUs are designated as subprojects. All F slaves of all segments (PROFIBUS/PROFINET) which originate from SIMOTION are mapped by the F-Proxy as n F submodules in an F-Proxy module.

During configuration, a failsafe I device is produced as a substitute of a SIMOTION device with drives and imported into the F-CPU master project.

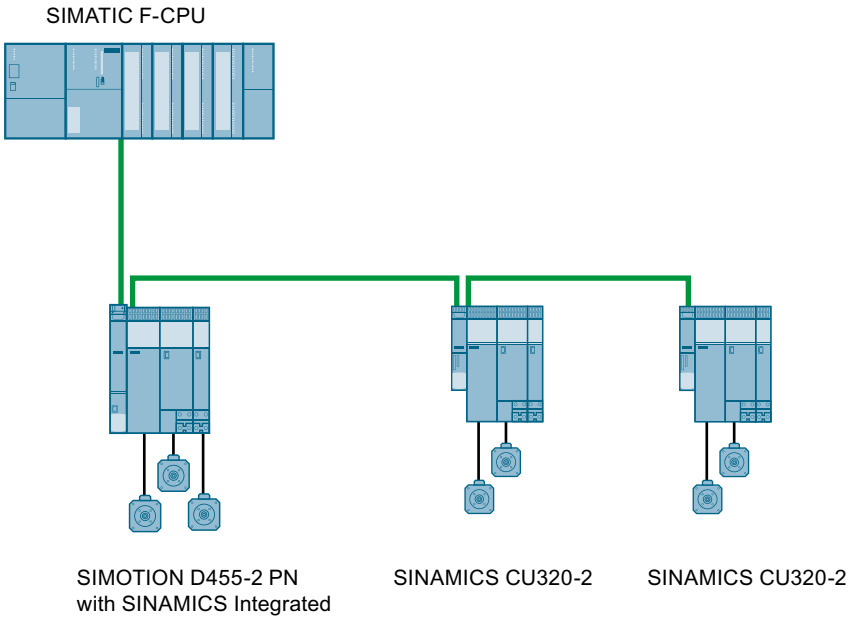

Figure 4-435 Example topology for F-CPU master with SIMOTION D and lower-level drives

Module/submodule structure

The submodules of the drive with the safety message frame are mapped to submodules of the PROFINET I device interface, regardless of whether the drive is connected to SIMOTION via PROFIBUS, integrated PROFIBUS, or PROFINET.

With an I device failsafe proxy, all failsafe proxy submodules of a SIMOTION device are depicted in one single module (module 2).

The diagram below shows an F-CPU as the master, to which a SIMOTION with integrated and lower-level drives is subordinate.

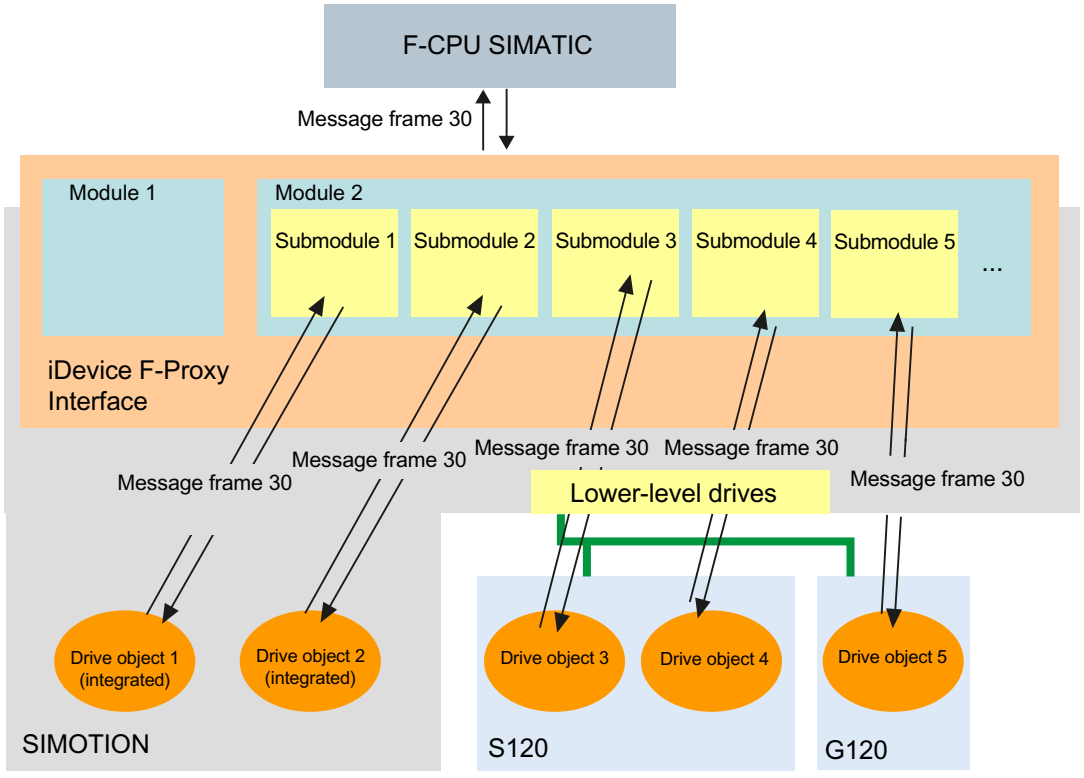

Figure 4-436 Master project with a sub-project as the I device failsafe proxy

Configuring I device failsafe proxy (Page 2348)

Supported devices and software requirements for I device failsafe proxy

Software requirement

- Step7 V5.5 or higher
- SINAMICS S120, V2.6 or higher
- SINAMICS G120, V3.2 or higher
- SIMOTION, V4.2 or higher
- S7 F configuration pack, V5.5 SP8 or higher (if using Safety/PROFIsafe)
- Valid from PROFIsafe V2

Supported devices

Drive units

- SINAMICS Integrated
- SINAMICS Controller Extension (CX32, CX32-2)
- SINAMICS devices on lower-level PROFIBUS
- SINAMICS devices on lower-level PROFINET

Devices with I-device F-proxy functionality

- SIMOTION D4xx, D4x5-2
- SIMOTION C240 PN
- SIMOTION P350-3, P320-3, P320-4
- F-CPU (List of supported F-CPUs (https://support.industry.siemens.com/cs/ww/en/view/44383954))

Table 4-243 The table shows which SIMOTION devices support the I-device F-Proxy and which SINAMICS devices can be accessed via the I-device F-Proxy.

Overview of devices capable of I-device F-proxy functions	
SIMOTION IO controller	
Controller Based	C240 PN
PC Based	P320-3 P350-3 P320-4

I-Device F-Proxy quantity structure and properties

Specific properties of I-Device F-Proxy

Acyclic services on the I-Device F-Proxy

The current I-Device interface does not support acyclic data transfer. The I-Device F-Proxy submodules do not have parameter access (Parameter Access Point PAP) and cannot convey alarms.

If an alarm channel is to be used, the drive must be operated on PROFINET and directly incorporated in SIMOTION and the F-CPU using the Shared Device function. Here the F data of the F-CPU and the Motion Control data are managed by SIMOTION.

Supported PROFIsafe SINAMICS telegrams

Telegrams 30, 31, 901, 902 and 903 are supported.

Note

Telegram 902 is available from V4.4 and can only be used in SCOUT TIA in connection with the TIA Portal.

Isochronous mode

The F-Proxy submodules on the SIMOTION CPU are RT and can be operated non-isochronously.

Supported lower-level bus systems

Drives on PROFIBUS integrated, PROFIBUS external and PROFINET external are supported. All these bus interfaces can also be routed via the I-Device F-Proxy at the same time.

Supported I-Device interfaces

All PROFINET-capable SIMOTION devices are supported.

Two F-CPUs via shared I-Device

If the power of a single F-CPU does not suffice for the number of safety axes, the safety axes can be distributed via the shared I-Device functionality to two F-CPUs.

Note

Because all F-Proxy axes must be configured on the I-Device of a single interface, the use of the second PN interface as I-Device for an additional F-CPU is not possible.

F-Proxy on PN-IO CBE30-2

For the operation with two PN-IO interfaces, the PN-IO CBE30-2 interface is provided for the higher-level communication, whereas the PN-IO integrated interface is provided for lower-level communication with "local" drives or fast IO.

Only the PN-IO integrated can be used for Servo_fast. This means, you must use the PN-IO CBE30-2 for safety communication to a higher-level F-CPU.

Note

F-Proxy modules can be configured either on the PN-IO CBE30-2 or on the PN-IO integrated. It is not possible to configure F-Proxy modules concurrently on the PN-IO CBE30-2 and on the PN-IO integrated.

Response times - Transmission time for I-Device F-Proxy

If data is transferred from the F-CPU via the I-Device F-Proxy, this extends the runtime for the SINAMICS drives via the I-Device F-Proxy by a maximum of 2 servo cycles per send direction. Use the servo cycle of the lower-level system as the servo cycle.

Supported number of F-Proxy submodules

A maximum of 128 I-Device submodules are supported. Of these, up to 64 submodules can be used for Safety by default. The other 64 submodules are available for standard IOs. The maximum number of 64 F-Proxy submodules can be configured **independently** of the PROFIsafe telegram for all SIMOTION CPUs.

Up to 128 F-Proxy submodules are supported (as of SIMOTION V4.5)

As of firmware version 4.5, a maximum of 128 F-Proxy submodules, and thus a maximum of 128 safety axes, can be configured for the SIMOTION D455-2. The maximum number of F-Proxy submodules **depends** on the configured PROFIsafe telegram.

In the following tables, the input/output data as well as the maximum number of F-Proxy submodules are shown depending on the PROFIsafe telegram and the SIMOTION CPU.

SINAMICS PROFIsafe telegrams

PROFIsafe telegram	F-Proxy submodules SIMOTION D455-2	F-Proxy submodules SIMOTION CPU (other)	Single telegram Input	Single telegram Output	Single telegram Total
30	128	64	6	6	12
31	128	64	8	8	16
901	89	64	14	10	24
902[1]	79	64	16	10	26
903	89	64	14	10	24

1) Can only be used in SCOUT TIA in connection with the TIA Portal.

Configuring more than 64 F-Proxy submodules

The following must be taken into account when configuring more than 64 F-Proxy submodules:

- A SIMOTION I-Device supports a maximum of 128 subslots. If, for example, 128 subslots are assigned to F-Proxy axes, no further user data can be configured on the I-Device interface (see table above).
- A SIMOTION I-Device supports a maximum of 1440 bytes of user data (including IOPS/CS user data qualifier). Depending on the selected Safety telegram and the number of F-Proxy axes, only limited (or no) space is available for user data in the I-Device.

PROFIsafe via PROFINET with an F-CPU

Description

A detailed description of how you can configure PROFIsafe with PROFINET in conjunction with a SIMATIC F-CPU can be found described in an FAQ.

See Actuating internal drive safety functions via SIMOTION and PROFINET with PROFIsafe (https://support.industry.siemens.com/cs/ww/en/view/50207350).

The diagram below shows a topology in schematic form in which the Safety drives are connected to the SIMOTION CPU via PROFINET and PROFIBUS DP.

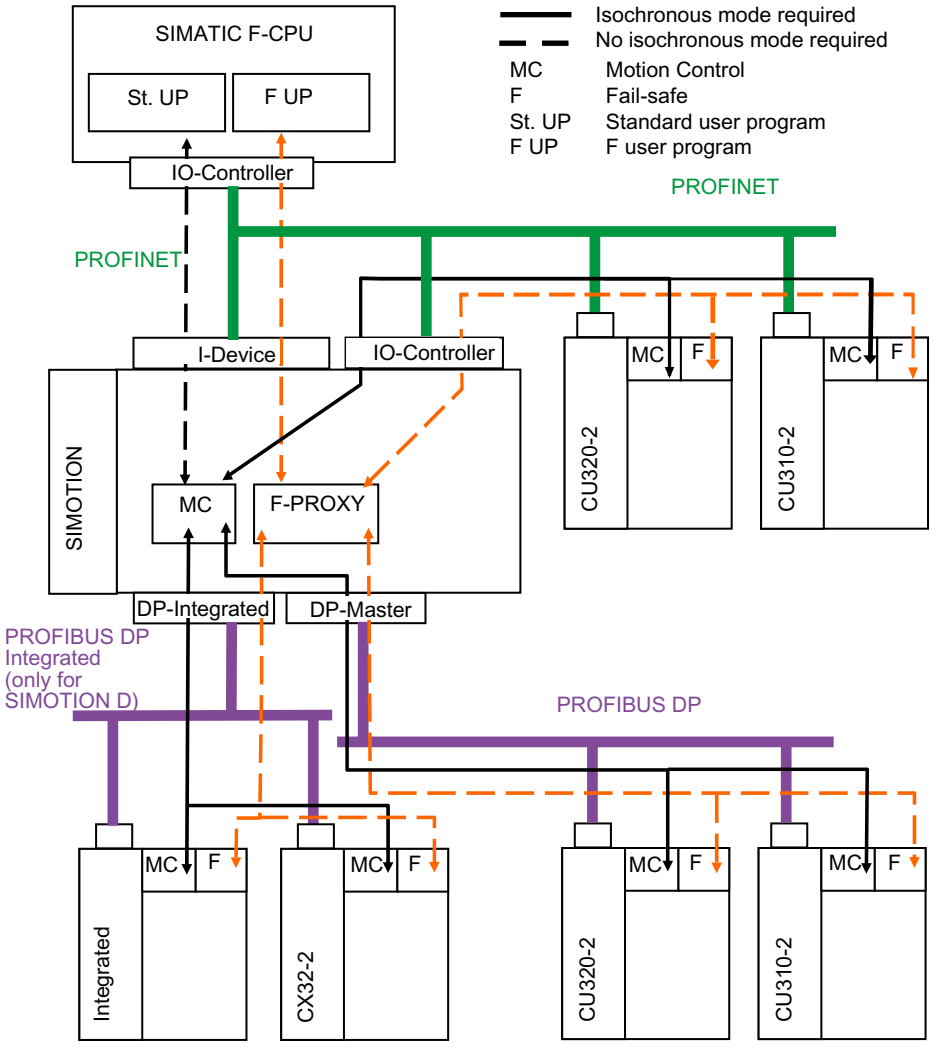

Figure 4-439 Topology for I device failsafe proxy for PROFIBUS and PROFINET drive units

Configuring I device failsafe proxy

Basic configuration process for I device failsafe proxy

Configuration requirements

A failsafe host communicates with the drives via the I device interface and an F-Proxy of a SIMOTION CPU. These drives may be located on PROFIBUS DP external, PROFIBUS DP integrated and the PROFINET IO system of the SIMOTION CPU.

Basic configuration process

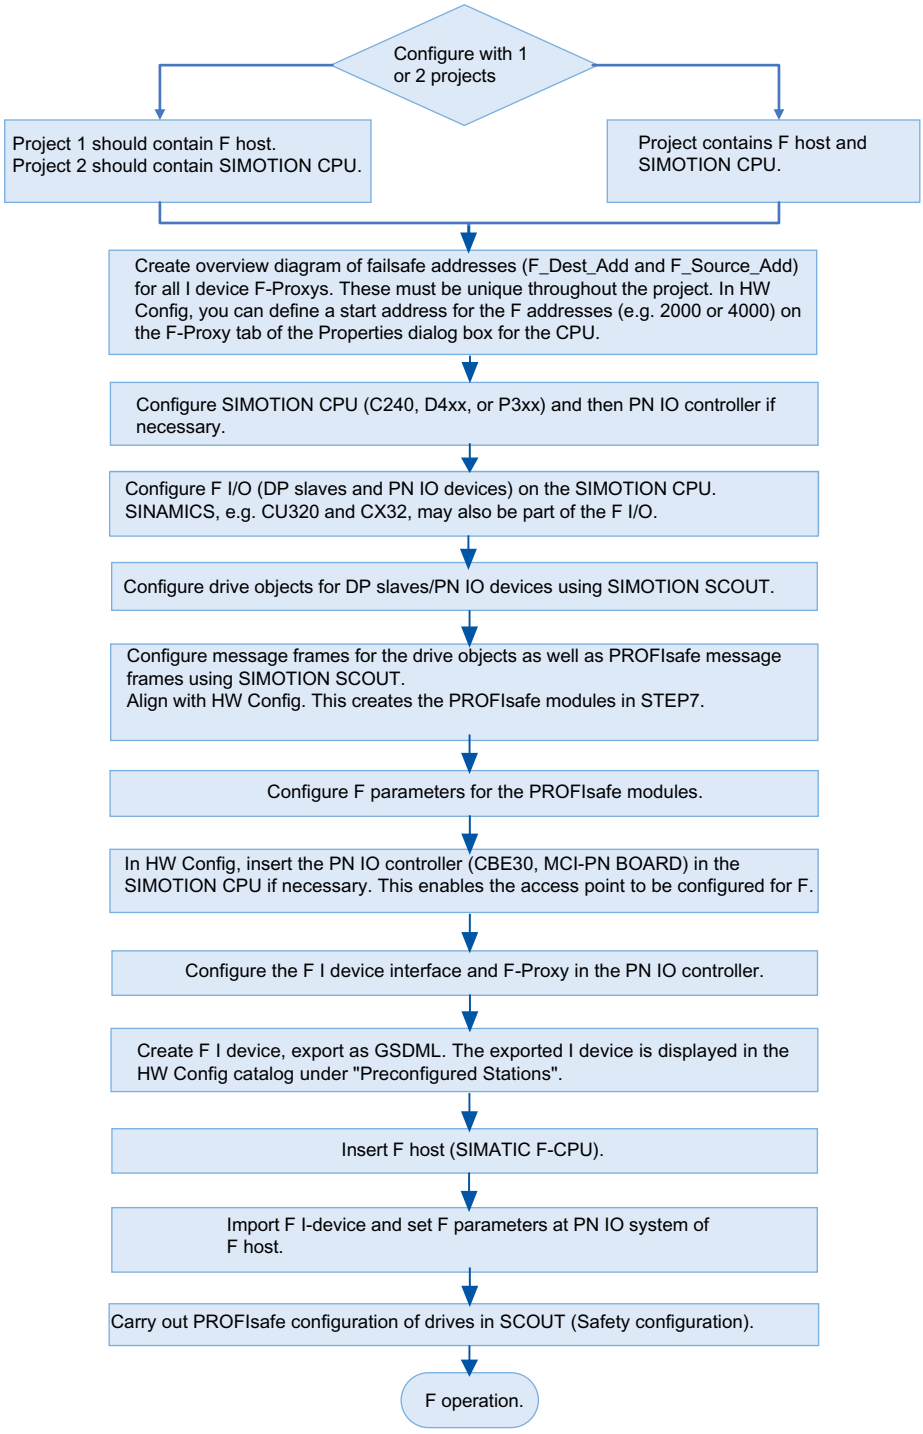

Figure 4-440 Basic configuration process for I device failsafe proxy

Configuration example for SIMOTION D435 and SINAMICS S120 via PROFINET

Configuration example for I device failsafe proxy

In the example below, you will configure a SIMATIC F-CPU 317F-2PN/DP V3.2. In addition, you will use a SIMOTION D435-2 DP/PN with a SINAMICS S120 CU320-2 PN, which is connected to the SIMOTION via the PN interface (CBE30-2). The exported I device F-Proxy of the lower-level SIMOTION CPU is then imported into the higher-level F-CPU. In the example, only one project is used in the configuration represented.

Configuring an I device F-Proxy

1. Create an overview diagram with the F-CPU, SIMOTION CPU and the drives intended to support PROFIsafe. In the example, there is just one SIMOTION CPU and a SINAMICS S120. Enter the start addresses of the CPU and the required drives into this overview diagram. The specified addresses are to be used later during configuration. The overview diagram is only required for larger projects.
2. Create a new project in SIMOTION SCOUT.
   You can find further information on configuration with PROFINET in the chapter Configuring PROFINET IO with SIMOTION (Page 2178).
3. Add a SIMOTION D435-2 DP/PN. The check box **Open HW Config** must be activated. Click **OK** to confirm. HW Config opens.
4. In HW Config, enter a start address for the F addresses of the F-Proxy under SIMOTION CPU. All F_Dest_Add for the lower-level drives then use this start address, making them easier to manage in the case of more extensive projects. If you use 4000 as a start address, for example, the first F_Dest_Add of the drive is allocated as 400, etc. Start address 2000 is used as standard.
5. Insert a CBE30 if necessary and configure the PROFINET network.
6. Add a SINAMICS S120 CU320-2 PN (e.g. V4.7) to HW Config and configure the interface.
7. Configure the drive unit in SIMOTION SCOUT with the help of the wizard. You should already be thinking here about selecting the appropriate safety functions in the drive; activate **Expanded Safety Functions via PROFIsafe**, for example.
8. Then insert a new TO axis and run through the axis wizard. In the wizard, you link the axis with the corresponding drive object of the S120, and a corresponding telegram (use symbolic assignment) is created automatically.
9. Save and compile the project.
10. After configuration, you have to select the PROFIsafe telegram. In the SIMOTION SCOUT project navigator, under the drive unit double-click on **<"Drive unit_xx"> - Communication > Telegram configuration**. The telegrams appear in the working area.

11. Mark the appropriate drive in the tab **IF1: PROFIdrive PZD telegram** of the telegram overview and in the bottom part of the window under **Adapt telegram configuration** select the entry **Add PROFIsafe**. The PROFIsafe telegram is added. Dependent on the drive, you can select from several telegrams.

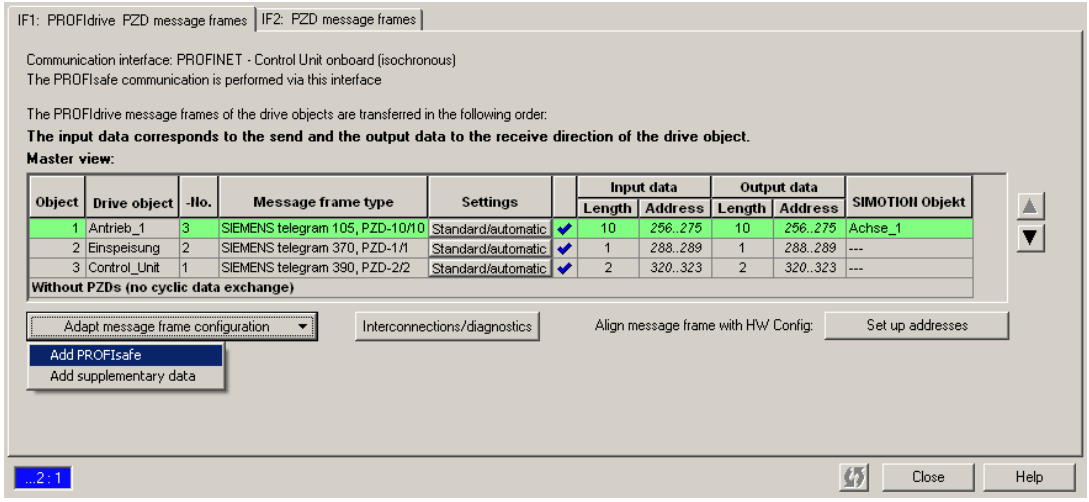

Figure 4-441 Adding PROFIsafe telegram

12. Save and compile the project.
13. Click on **Set up address** to run alignment between SIMOTION and HW Config. Configuration in SIMOTION SCOUT is completed by saving.
14. Move to HW Config and configure SYNC master and slave and an isochronous application.
15. Double-click in the SIMOTION D435 station overview on X1400 P1 and select the drive unit assignment in the **Topology** tab under **Partner port**. Click **OK** to confirm.

16. Double-click in the station on the PN IO interface to activate iDevice mode in the properties. In the **I device** tab, activate the check box **I device mode**. Click on **New...** and select the **Fail-safe I/O** entry in the dialog which opens under **Transfer area type**.

Note

In the **properties** dialog of the PN IO interface, you interconnect all the configured fail-safe I/Os directly (from STEP 7 V5.5 SP4). To do this, press the **Interconnect fail-safe I/O** button. The automatically generated transfer areas are displayed. You can then go straight on to Point 18.

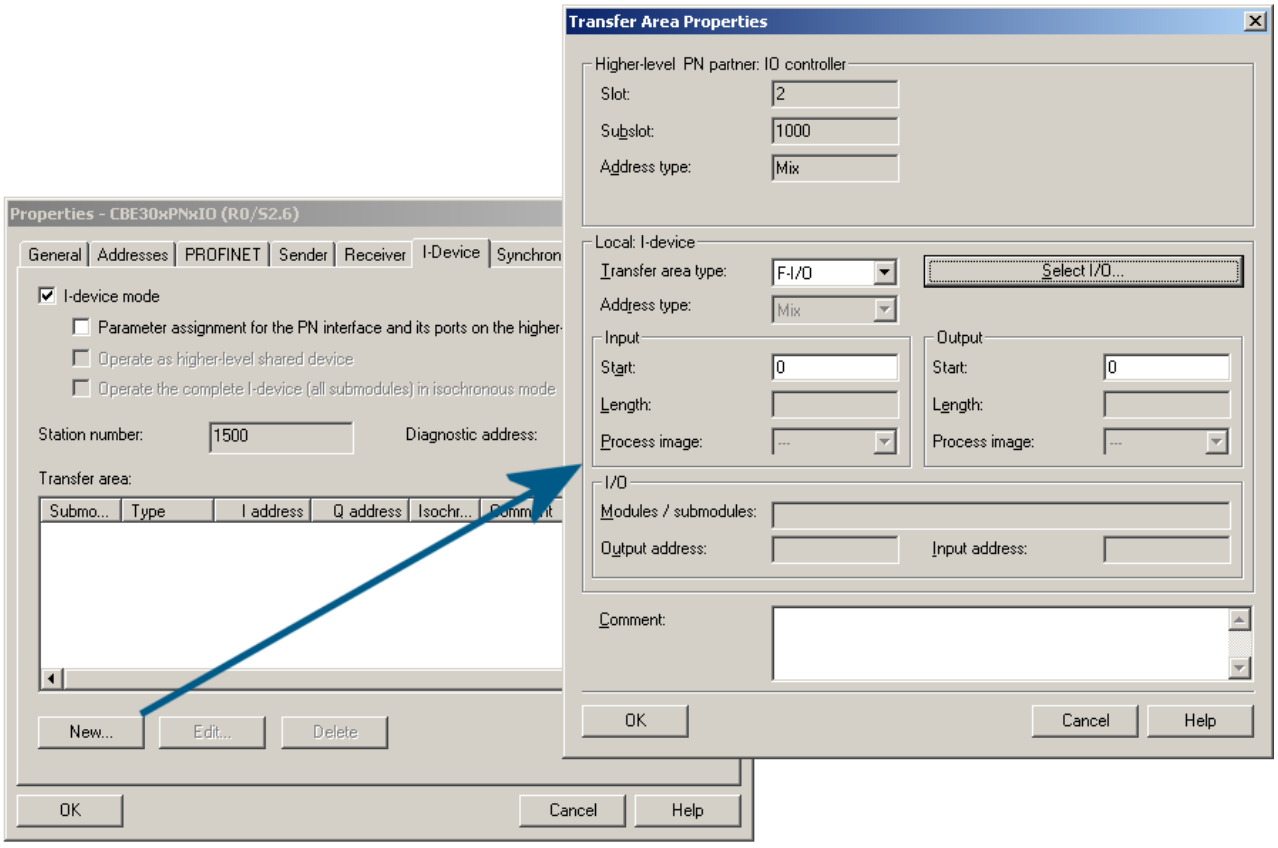

Figure 4-442 Properties of I device transfer area

17. Click on the **Select I/O** button and select the corresponding PROFIsafe channel in the dialog which opens. Confirm both dialogs with **OK**.
This completes configuration of the lower-level drive.

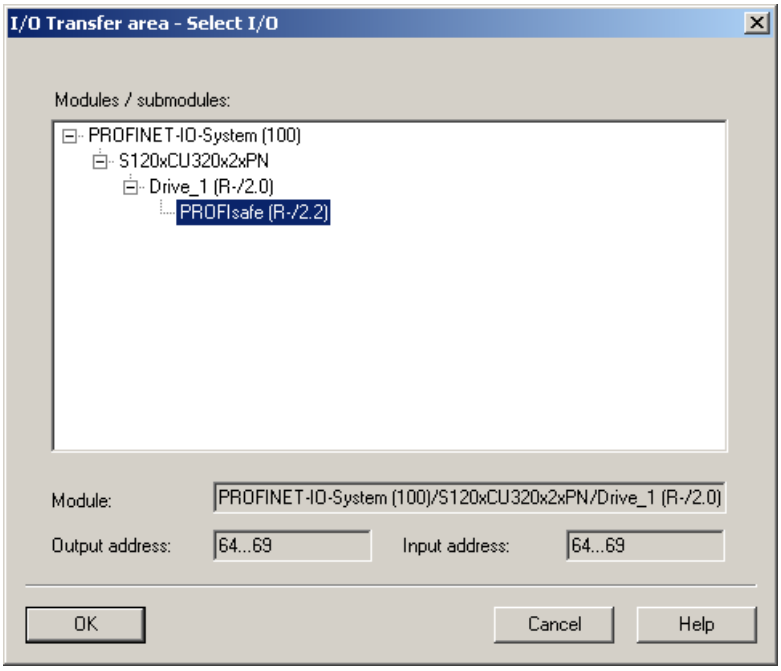

Figure 4-443 Selecting PROFIsafe channel of I/O

18. The transfer area must always contain two areas. You can either have two fail-safe I/O areas or you must define an application area for one fail-safe I/O area only. You should also refer to the iDevice chapter.

19. You can view the PROFIsafe settings for the drive unit. The detail view for the rack contains the entry **PROFIsafe**. Double-click on this to display the properties.
The **PROFIsafe** tab contains the F destination address under **F_Dest_Add**. This address must be unique within the entire project. If you are using several failsafe proxies, you must ensure that this address is only issued once. Change this value as required. The failsafe address is displayed in HW Config in the detail view in the station window under comments. This allows for clear assignment if using several participants.
The parameters F_CRC_Length=3-Byte-CRC and F_Par_Version=1 indicate PROFIsafe V2 mode. Please note these values because an I device F-Proxy configuration is only possible with this version and higher.
For more information about the fail-safe parameters, see PROFIsafe properties for configuration (Page 2336)

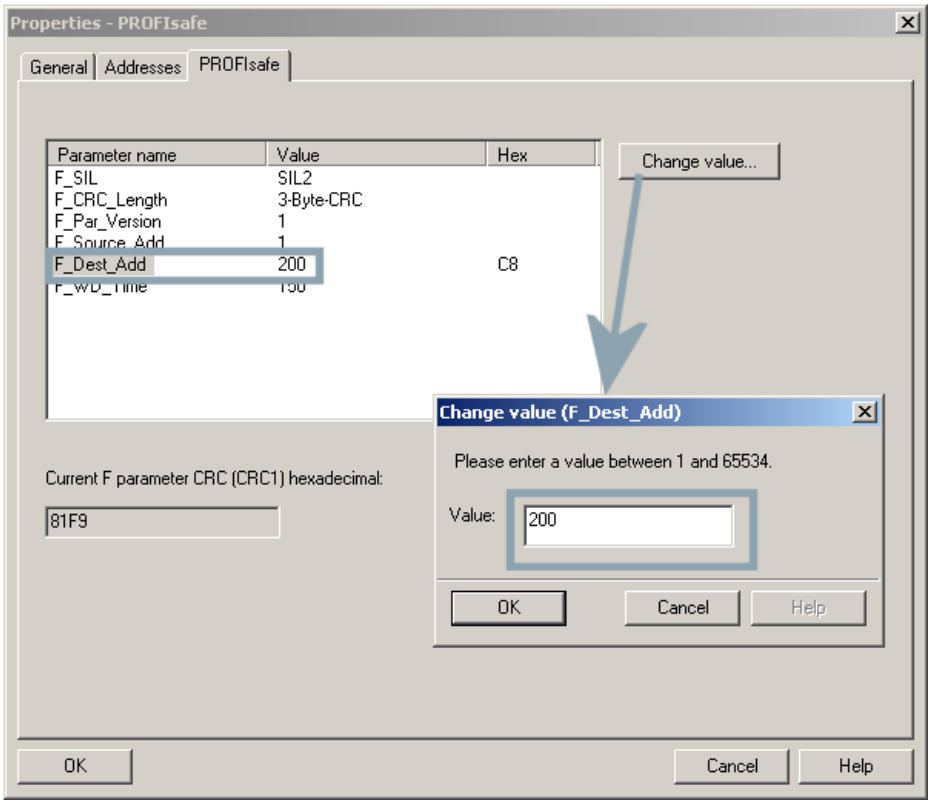

Figure 4-444 Setting the F destination address (F_Dest_Add)

20. The F destination address (F_Dest_Add) must match the PROFIsafe address during Safety configuration of the drive in SIMOTION SCOUT. In the example, this is address 200 dec or C8H. You enter the address in the Configuration window when configuring Safety Integrated. The value is stored in drive parameters p9610/p9810.

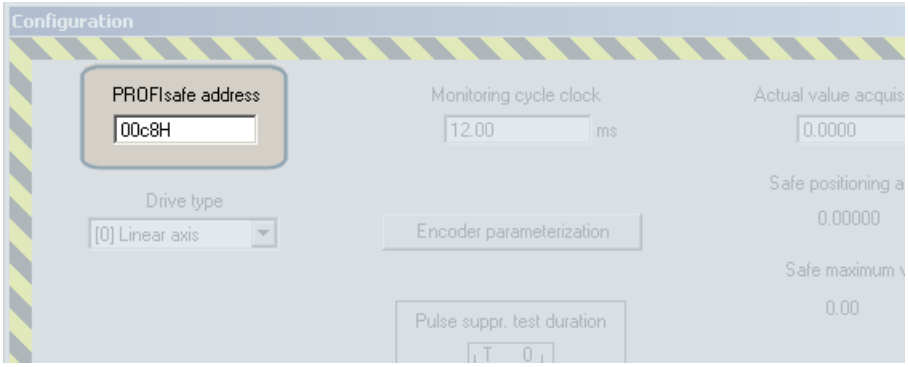

Figure 4-445 Entering F_Dest_Add as PROFIsafe address

21. Now produce the GSD file for the I device F-Proxy. In the menu, select **Options > Create GSD file for iDevice.** In the dialog which opens, click on **Create** and then **Install**. The I device is displayed under **Preconfigured Stations** in the hardware catalog.

22. You can now create a new project with F-CPU or open and use the existing project in the SIMATIC Manager. In our example, open the existing project in the SIMATIC Manager.

23. In the menu, select e.g. **Insert > Station > SIMATIC 300 Station.** Double-click on the station and then the entry **Hardware**. HW Config opens.

24. From the hardware catalog, insert e.g. an S7 300 rack if you want to select an F-CPU from the S7 300 series.

25. Insert the F-CPU, e.g. CPU317-2 PN/DP. This must at least be version V3.2.
26. Use drag&drop to move the I device previously created under **Preconfigured Stations** to the PROFINET IO network. Once saved and compiled, configuration is complete. Please observe the rules regarding device names in the chapter PROFINET IO and I device (Page 2238).

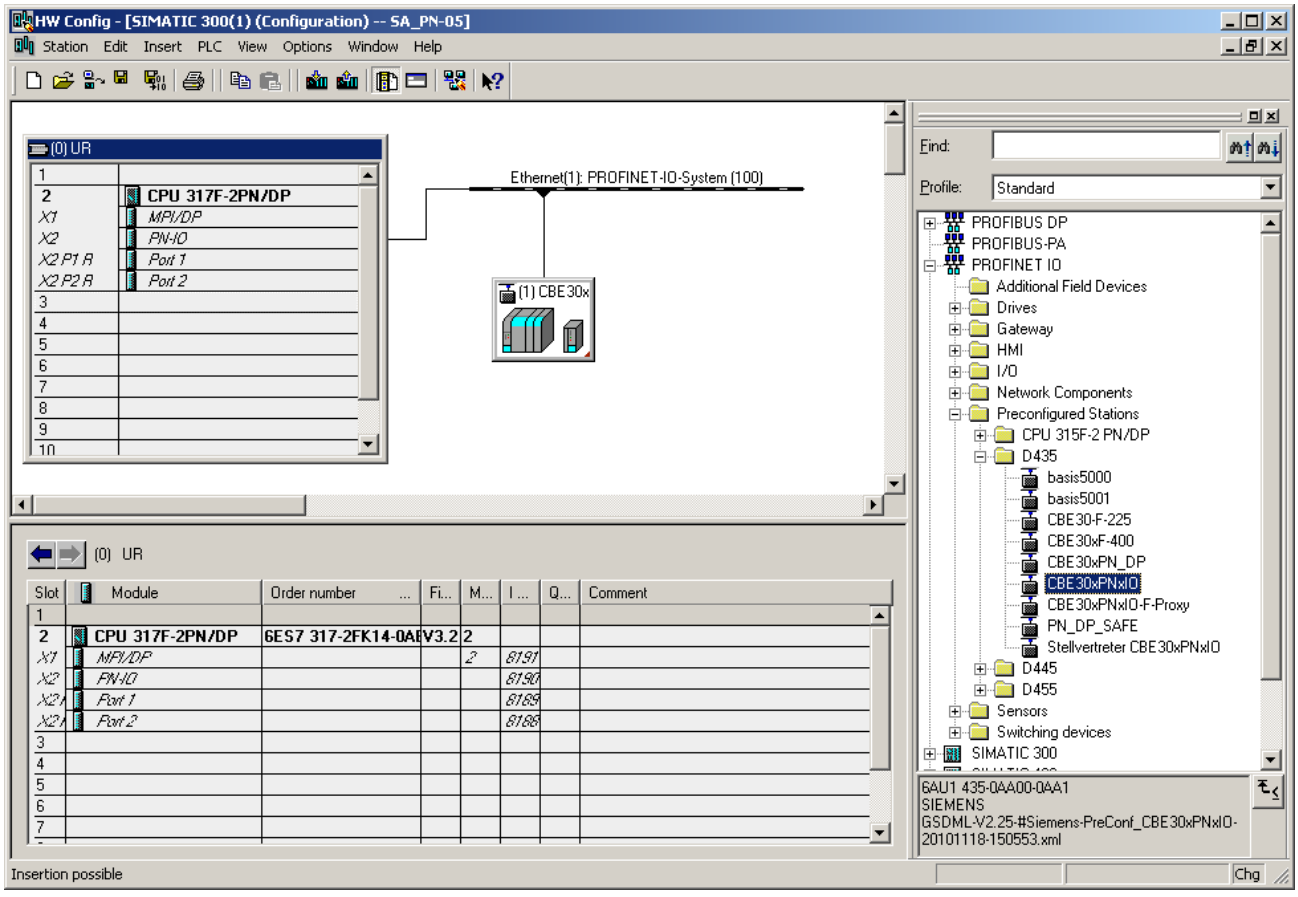

Figure 4-446 Master project with an I device failsafe proxy submodule

Adapting the F destination address (F_Dest_Add) in the existing project

Adapting the F destination address (F_Dest_Add) for the entire project

In an existing project, you can check whether the F destination address (F_Dest_Add) for the iDevice F-Proxy has been set correctly at a later point. The F destination address (F_Dest_Add) must be the same at the following locations:

- PROFIsafe slot of the drive on the SIMOTION CPU (HW Config)
- PROFIsafe slot of the I device for the SIMOTION CPU (HW Config)
- Safety configuration for drive in SIMOTION (SIMOTION SCOUT)

If you want to change the F destination address (F_Dest_Add) at a later point without having to create and install the iDevice again, you must make the change at the three locations referred to above.

In the example below, you set the F destination address (F_Dest_Add) to the value 300 (12CHex) for a SIMOTION CPU with a drive on PROFINET and an F-CPU in the same project.

How to check whether the F destination address (F_Dest_Add) is identical

1. Open the SIMOTION CPU project in HW Config.
2. In the detail view of the drive unit, double-click **PROFIsafe**. In the window that opens, switch to the **PROFIsafe** tab. The value 300 must be present next to **F_Dest_Add**. To change **F_Dest_Add**, click the **Change Value** button and enter 300 in the dialog box that appears.

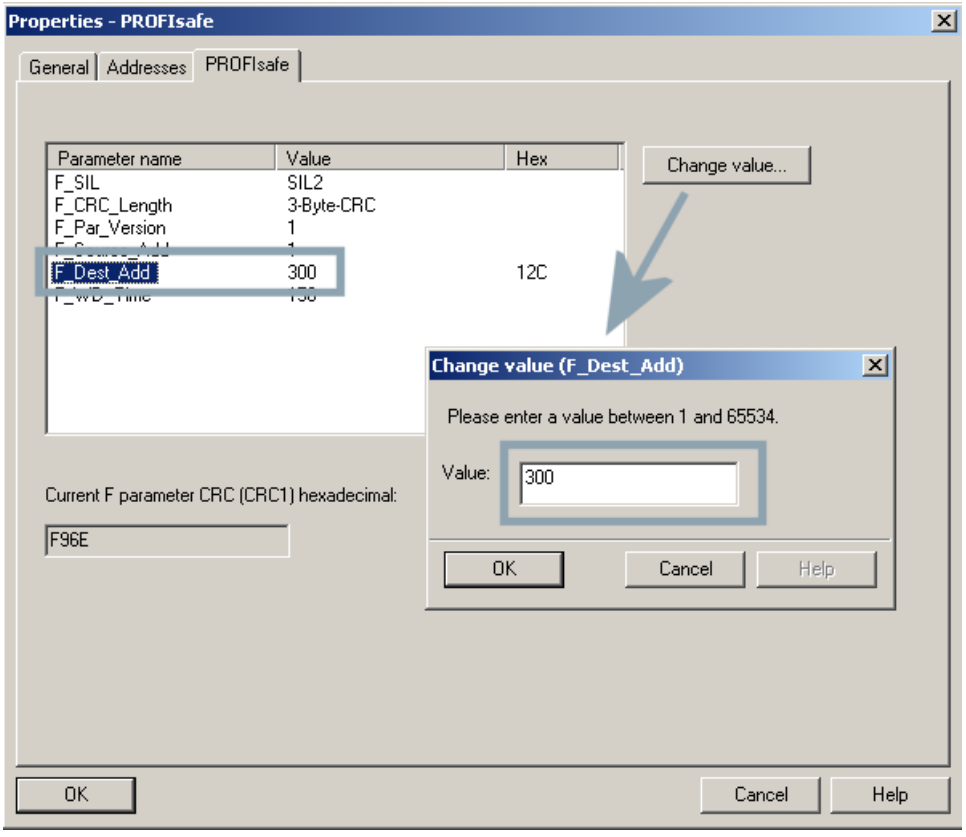

Figure 4-447 F destination address (F_Dest_Add) for PROFIsafe slot on drive unit

3. Confirm by selecting **OK** and save and compile the project.
4. Open the project with the F-CPU in HW Config.

5. In the detail view of the I device, double-click the **PROFIsafe I/O**, e.g. B. 6I/6O F-Periphery. In the window that opens, switch to the **PROFIsafe** tab. The value 300 must be present next to **F_Dest_Add**. To change **F_Dest_Add**, click the **Change Value** button and enter 300 in the dialog box that appears.

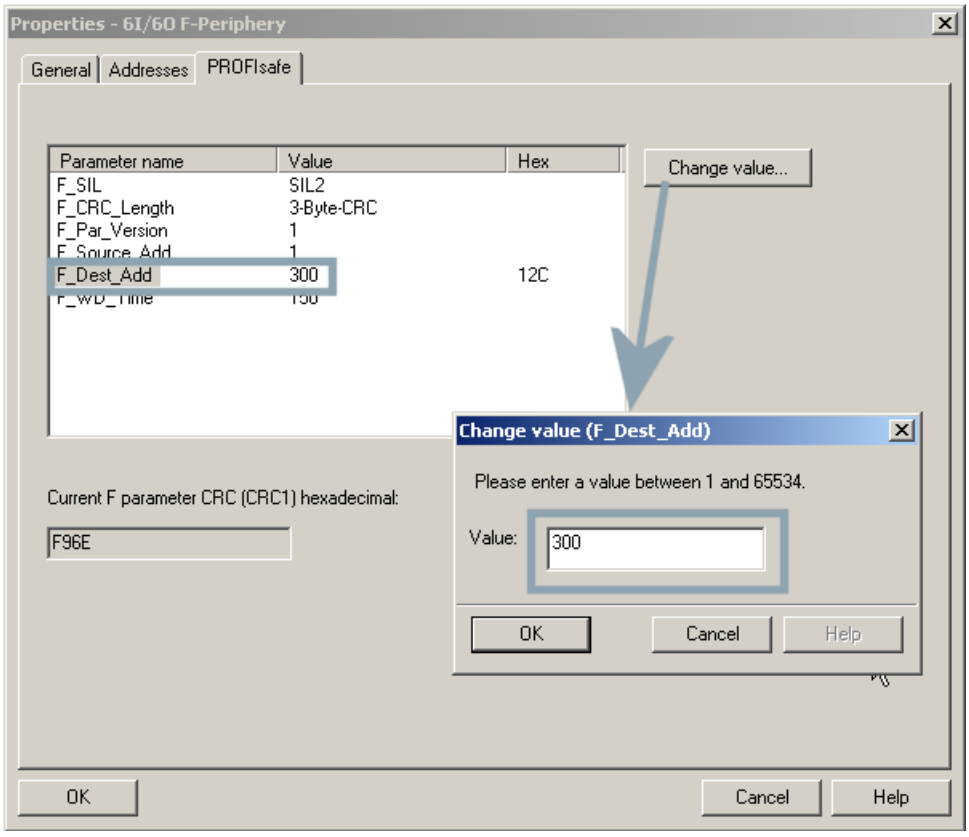

Figure 4-448 F destination address (F_Dest_Add) for iDevice on F-CPU

6. Confirm by selecting **OK** and save and compile the project.
7. Open the SIMOTION project in SIMOTION SCOUT.
8. In the project navigator, navigate to the drive (e.g. D435 > S120xCU320xCBE20 > Drives > Drive_1).
9. Under Functions in the project navigator, double-click **Safety Integrated**.
10. Click the **Configuration** button. The Configuration window appears.

11. Under **PROFIsafe address**, check the value 12CHex (300) and change it if necessary.

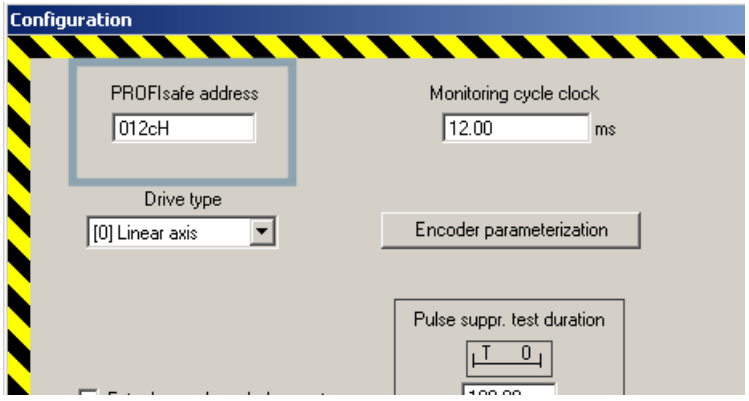

Figure 4-449 F destination address (F_Dest_Add) for configuring Safety Integrated

12. Confirm by selecting **Close** and save and compile the project.

Configuration of D435 with S120 on PROFINET and integrated PROFIBUS

Integrated drive on D435 for PROFIsafe

In the previous example you configured an S120 on D435 with PROFINET and imported it as an I-device. A SINAMICS_Integrated is now added to the project using the internal PROFIBUS DP.

This is how you configure a SINAMICS_Integrated

You have configured a project with D435 and SINAMICS S120 and imported it as an I-device to an F-CPU.

1. In SIMOTION SCOUT, configure the drive unit on SINAMICS_Integrated and insert a PROFIsafe telegram (see points 7-11 in the example Configuration example for SIMOTION D435 and SINAMICS S120 via PROFINET (Page 2350)).
2. In HW Config highlight SINAMICS_Integrated and double-click on the PROFIsafe module in the rack's detail view.
3. In the **Configuration** tab of the dialog which opens, highlight **PROFIsafe telegram** and click on **PROFIsafe...** . In the **PROFIsafe properties** dialog box, you can see and change the F Parameters.
   (If the **PROFIsafe...** button is not shown, you first have to click on the **Activate** button to make changes.)

4. Double-click on the PN IO interface of the SIMOTION CPU. In the **I-Device** tab in the dialog box which opens, select the **I-device mode** check box. Click on **New...** and select the **Fail-safe I/O** entry in the dialog which opens under **Transfer area type**. Click on the **Select I/O** button and select the corresponding PROFIsafe channel in the dialog which opens.

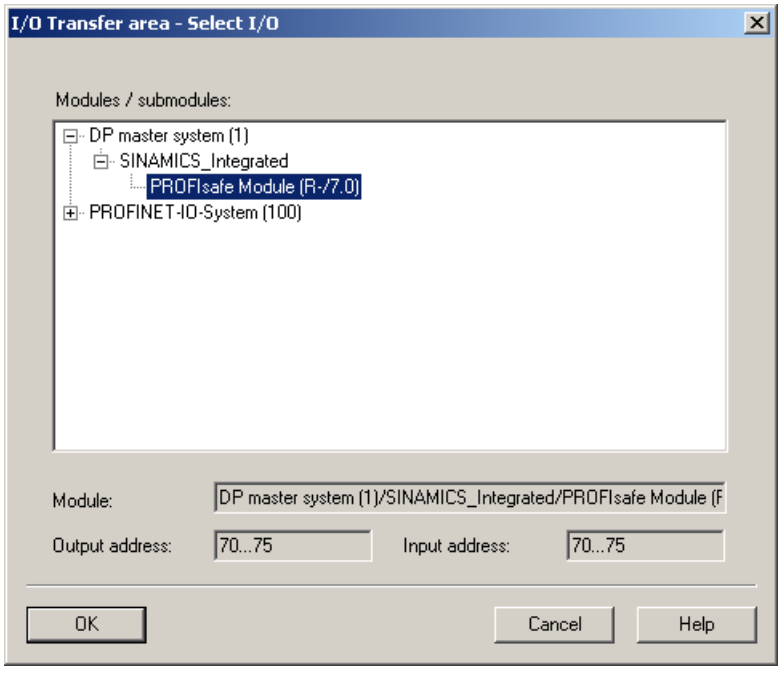

Figure 4-450 Releasing PROFIsafe module for SINAMICS_Integrated for transfer area

5. Click **OK** to confirm the dialog box. In the **Transfer Area Properties** dialog box, the inputs/outputs are assigned and an automatically generated comment is displayed. This comment includes, among other things, the subslot, the SIMOTION device name, the connection, and the device name of the drive. The F_Dest_Add is at the end. You can change the comment if necessary.

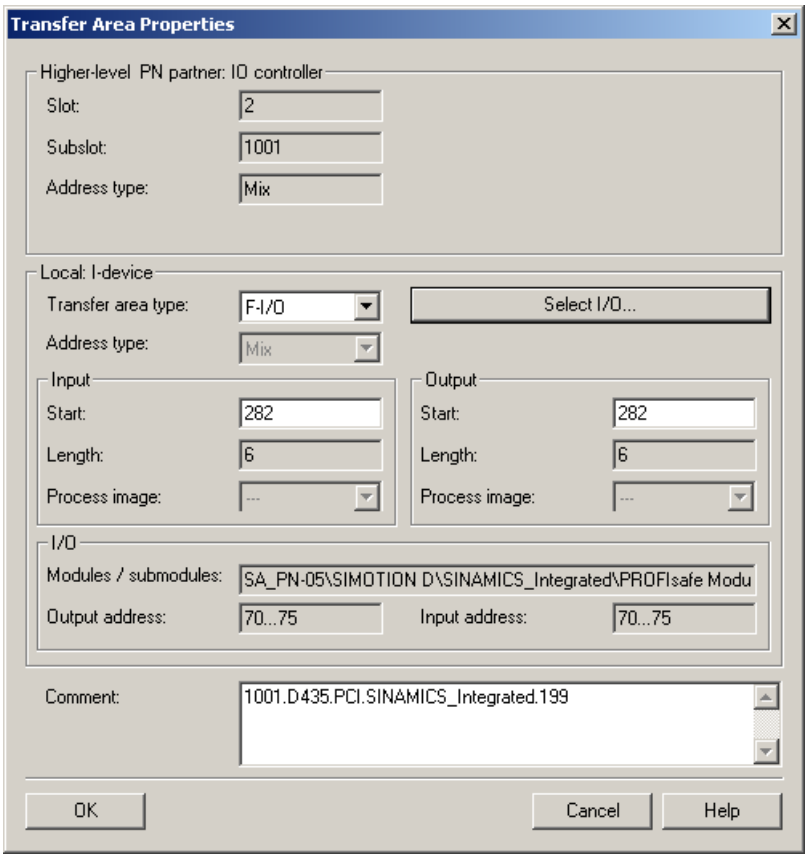

Figure 4-451 Properties of I-device transfer area, comment

6. Click **OK** to confirm this dialog box. The failsafe data for the two drives is displayed in the transfer area.
   This concludes configuration of the lower-level drive. All you need to do now is save and compile the station.

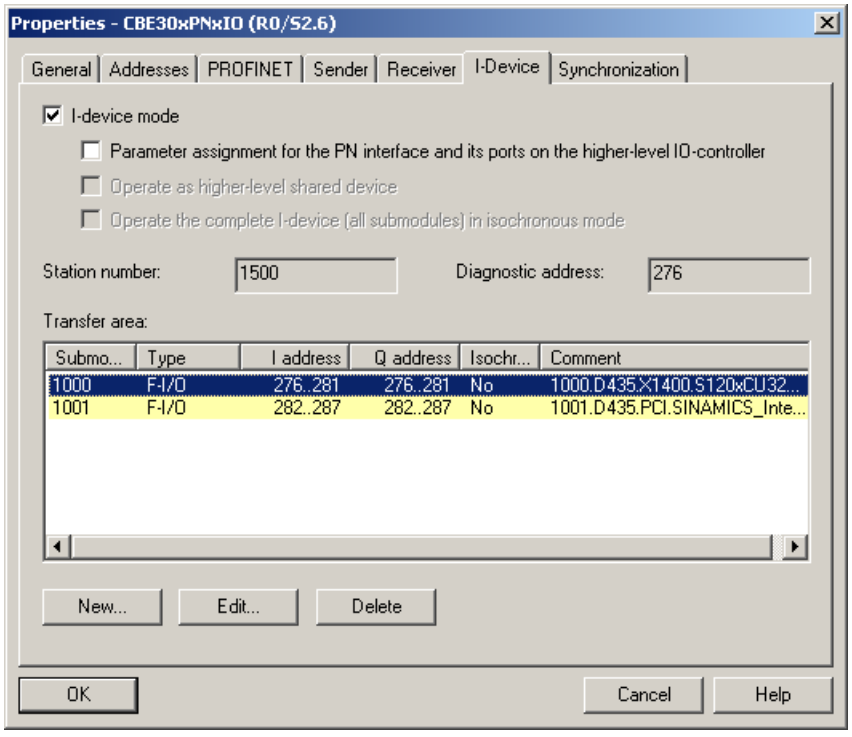

Figure 4-452 I-device transfer area

7. Now produce the GSD file for the I-device F-Proxy. In the menu, select **Options > Create GSD file for I-device**. In the dialog which opens, click on **Create** and then **Install**. The I-device is displayed under Preconfigured stations in the hardware catalog.
8. As in the previous example, create an F-CPU in the project and add the I-device of the SIMOTION module.
   The diagram shows the project with F-CPU and I-device F-Proxy with one drive on PROFINET and one drive on SINAMICS_Integrated on a D435.

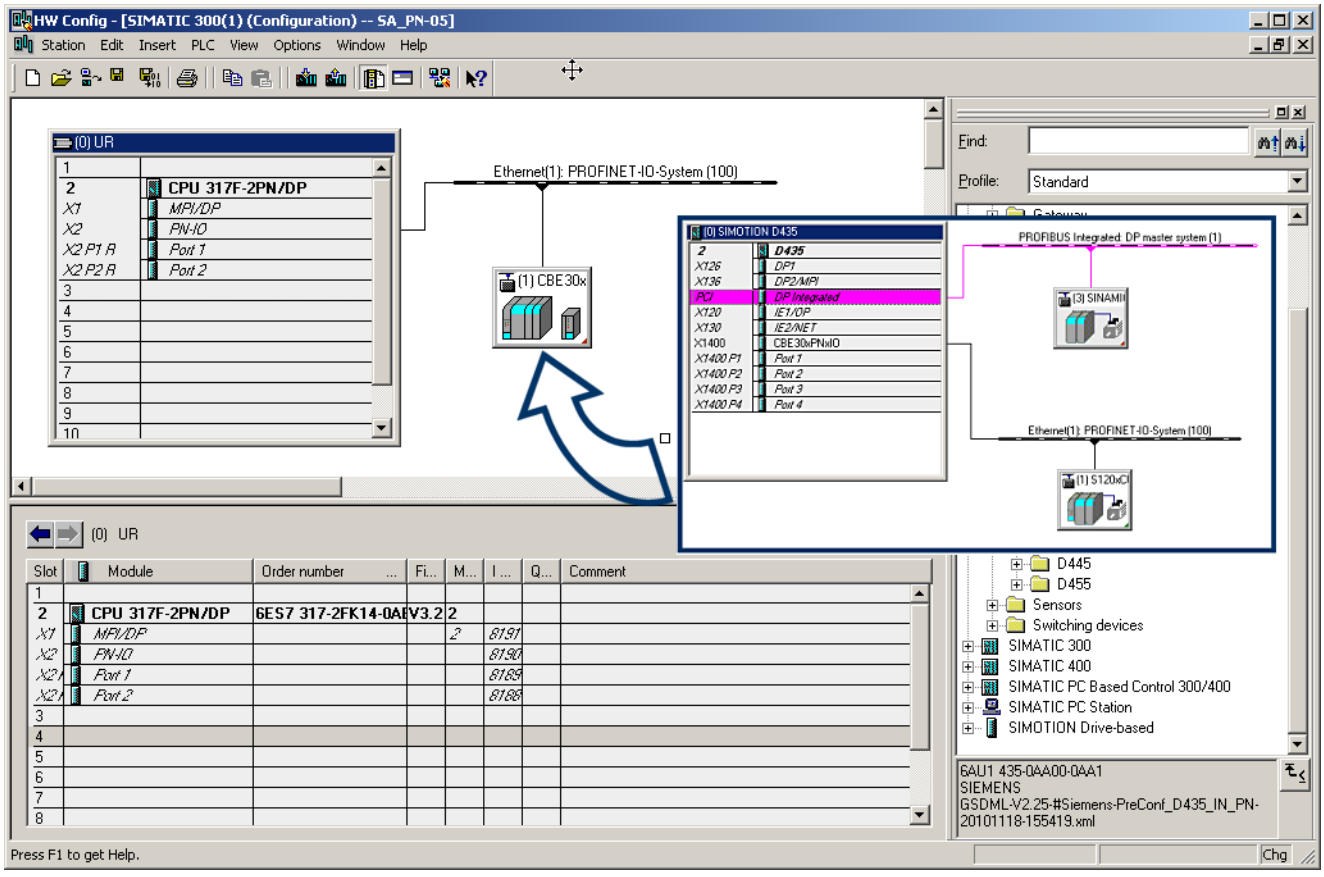

Figure 4-453 F-CPU with I-device F-proxy on PROFINET and integrated PROFIBUS

Upgrading an existing system with PROFIsafe via PROFIBUS to PROFIsafe via PROFINET

PROFIBUS to PROFINET

If PROFIsafe communication on an existing system has been operated via PROFIBUS up until now and you want to switch it to PROFINET, then you will need to upgrade the system.

How to carry out the upgrade

1. Delete the old I slave link.
2. If necessary, switch the DP interface from DP slave to DP master (SIMOTION CPU).
3. The PROFIsafe message frame configuration settings for the drives can remain unchanged.

4. If necessary, create the F parameters **F_Par_Version = 1** and **F_CRC_Length = 3-Byte-CRC** in order to use the PROFIsafe V2 standard. This will mean that a link cannot be established in the I device. V2 is automatically selected when the new PROFIsafe slots are created.

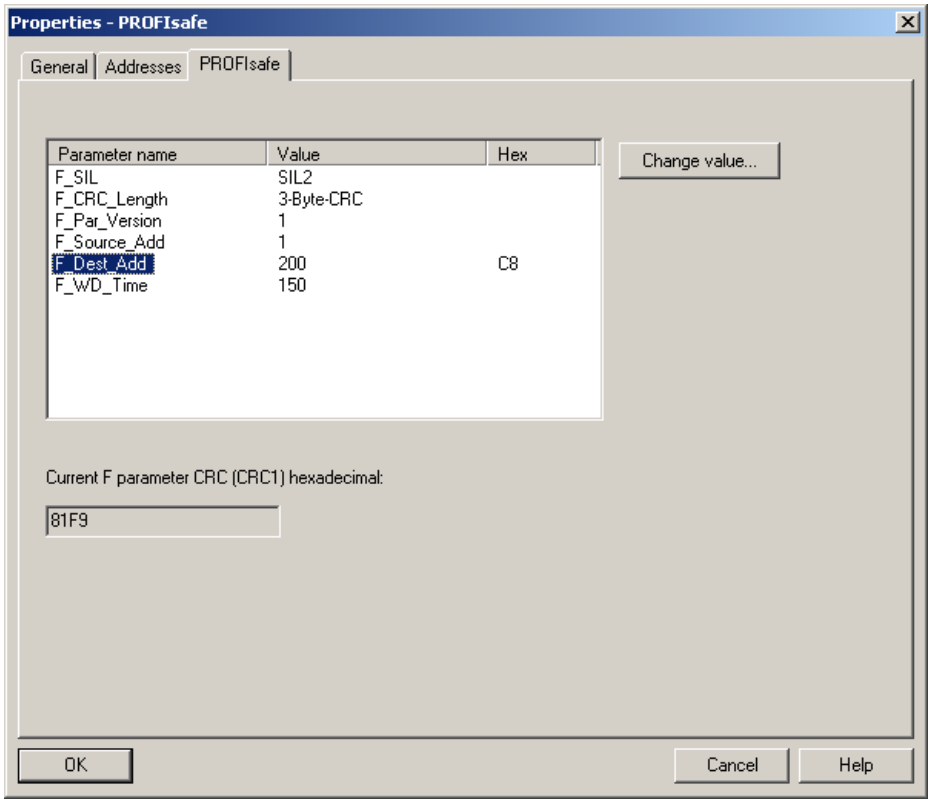

Figure 4-454 Properties of PROFIsafe taking the example of I device failsafe proxy

5. Select I device mode in HW Config on the CBE30.
6. Select **New** , followed by **failsafe periphery** under transfer area type to select the I/O and create a submodule.
7. Then create a new GSD via **Options > Create GSD file for I device...** and install it.
8. Link the GSD file to the S7 F-CPU.

General information on F destination addresses (F_Dest_Add) with iDevice F-Proxy

Communication addresses for F source (F_Source_Add) or F destination address (F_Dest_Add)

Create new F hosts, F modules/submodules in HW Config. HW Config then suggests the F source/ destination address (F_Dest_Add) as a default setting. You can change or overwrite this default setting. The default failsafe addressing is based on the failsafe start address parameter on the F-CPU and also on the SIMOTION CPU if applicable.

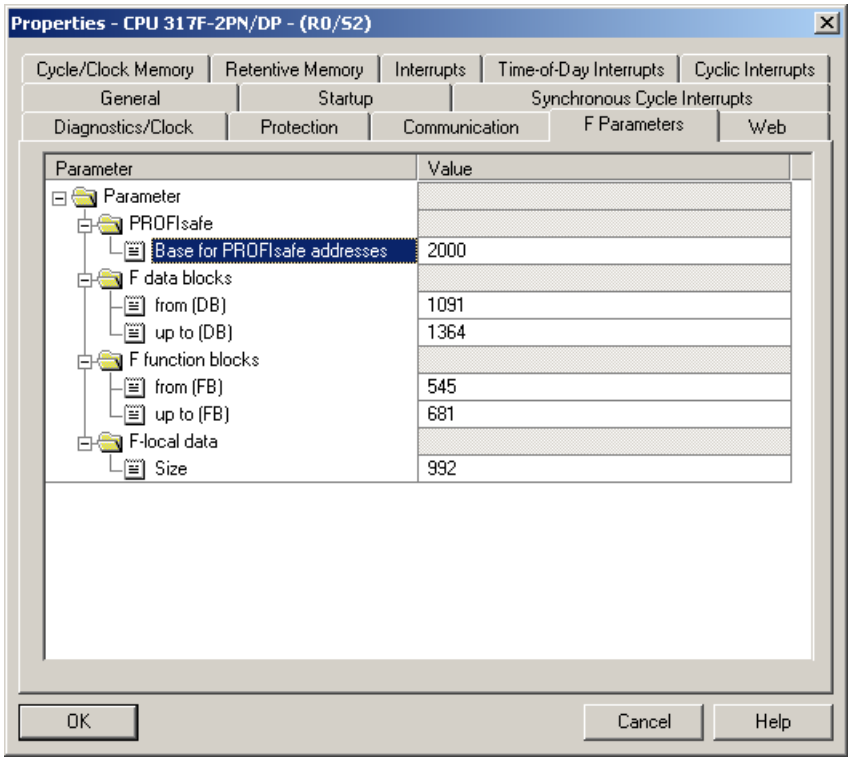

Figure 4-455 PROFIsafe start address

The F source address (F_Source_Add) is assigned in the same way as for Siemens F modules with OM:

- PROFIsafe start address of CPU + number of DP master system for PROFIBUS
- PROFIsafe start address of CPU for PROFINET
- 1, if the CPU does not have a PROFIsafe start address parameter (standard CPU and F-H-CPU)

Guidelines for addressing

- The full range of values between 1...65534 is used for addressing.
- The F destination address (F_Dest_Add) is assigned automatically.
- Automatic issuing takes place when plugging in as with the other failsafe modules in Step7: starting with an start value and working upwards, the system looks for the next free address.
- The start value is the PROFIsafe start address of the CPU/10 (or 1022, if there is no PROFIsafe start address or if it is greater than 10000).

- If the F start address is changed (CPU parameter), then F source and F destination addresses (F_Dest_Add) that have already been issued are not updated (remain in place). The change only affects the default address of newly created submodules.
- Several F-Source addresses may be issued in an F-CPU. The F source address and F destination address (F_Dest_Add) are included in the PROFIsafe CRC total.
- If addresses from an issued range of addresses are no longer used (when failsafe submodules are subsequently deleted), the gaps are filled first when new addresses are issued.

Note

If you want to use Safety to work beyond the project limits/proxies, you must ensure that the F source and F destination addresses are unique within the entire project. Before starting configuration, you should have/produce a failsafe addresses plan where unique ranges of failsafe addresses are assigned to particular sub-projects.

Automatic transfer of the F-destination addresses

Accept F-destination address (V5.2 and higher)

All axes are configured and commissioned during initial commissioning of a machine. Next the PROFIsafe telegrams are added in the telegram configuration of SIMOTION SCOUT or Starter. As soon as the telegram is used for the F-Proxy it can no longer be changed. The logical address is specified during "Save and compile" with symbolic assignment.

After the slot for the PROFIsafe telegram has been accepted in HW Config, the PROFIsafe telegram also receives its F-destination address. Up to V5.2, this address had to be entered manually for all drives with PROFIsafe while commissioning Safety Integrated. To avoid incorrect entries, the "Accept F-destination address" button is available during Safety commissioning as of V5.2 and higher.

F-destination address during Safety Integrated commissioning

You apply the F-destination address for PROFIsafe during drive commissioning.

1. In the SIMOTION SCOUT project navigator, click on "Functions > Safety Integrated" below the drive. The Safety configuration window opens in the work area. PROFIsafe is configured as Safety function.
2. Click the "PROFIsafe configuration" button.
3. You can view the "F_Dest_add" in the "PROFIsafe configuration" window.

4. Click "<" to accept the F-destination address as PROFIsafe address.

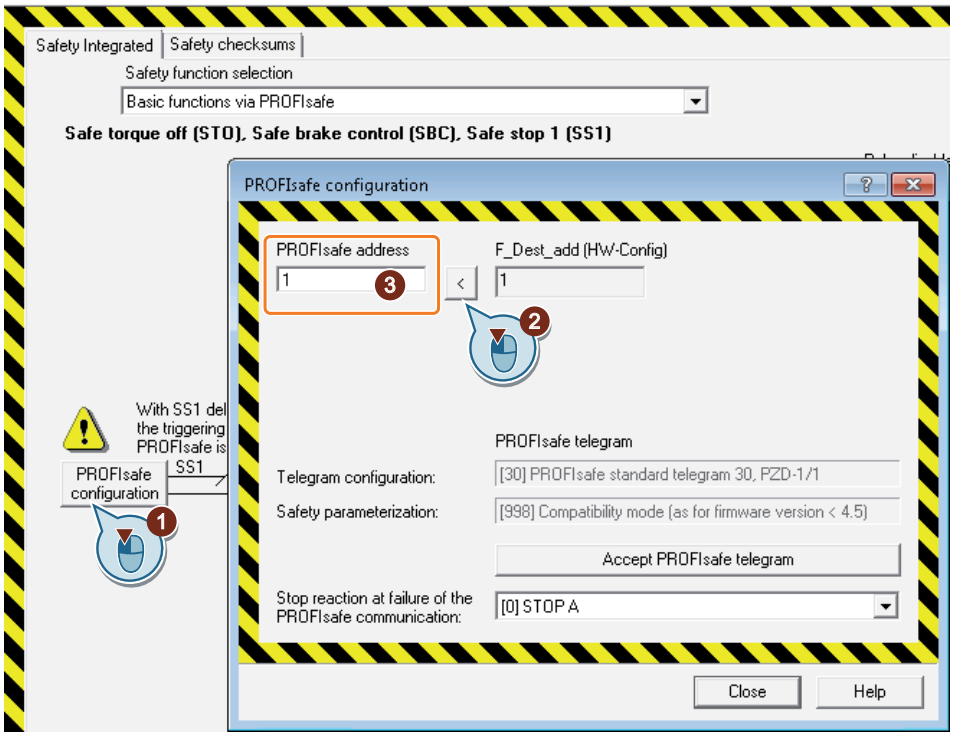

Figure 4-456 Accepting the F-destination address as PROFIsafe address

5. Click "Close" to confirm.

Scripting

The "Accept F-destination address" function can also be programmed via scripting. To do so, program the following scripting commands.

- GetFDestAdressFromHWCN
- SetUpAddresses

Shared device via PROFINET

General information on shared device

Description

With the Shared Device functionality, you can configure access to an IO device with several IO controllers using PROFINET. This enables channels/modules to be flexibly assigned to different IO controllers. This option is available for inputs and outputs. You can use this mechanism to access the fail-safe data of a drive configured below a SIMOTION CPU via the F-CPU, for example.

Note

When configuring PROFIsafe, I-Device F-Proxy functionality should be used rather than Shared Device.

Schematic diagram of Shared Device

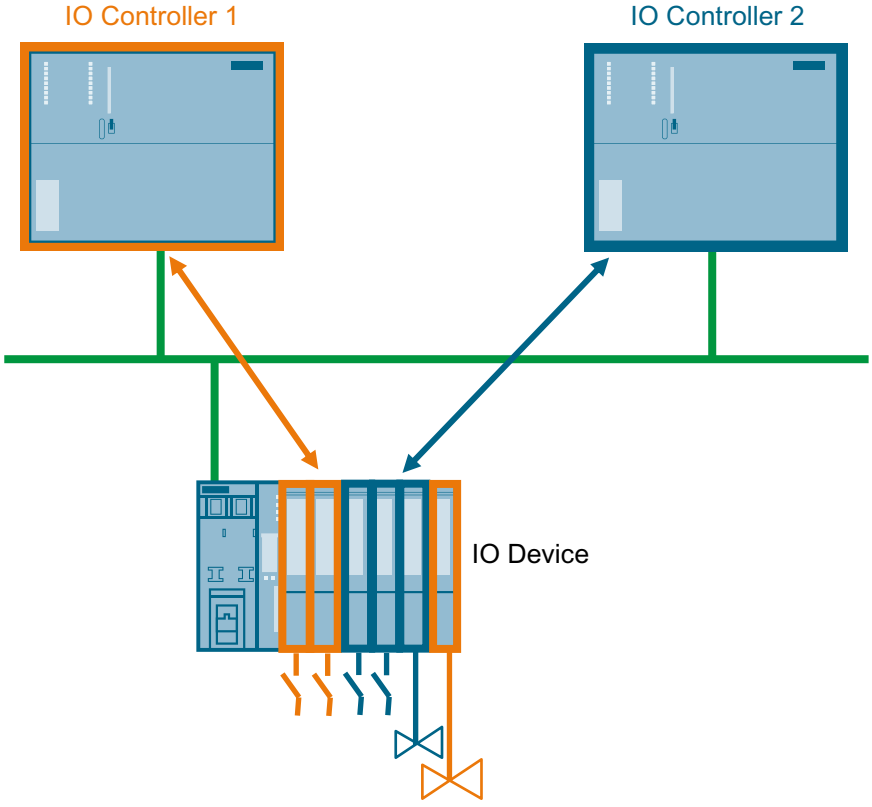

Figure 4-457 Schematic diagram of Shared Device

Software requirements

- SIMATIC Step 7 V5.5 or higher
- SINAMICS firmware and Support Packages V4.3.2 or higher

- SIMOTION SCOUT V4.2 or higher
- S7 F Configuration Pack, V5.5 SP7 or higher (if using Safety/PROFIsafe)
- GSDML file V2.25 or higher

Configuration principles

- I/O addresses can be assigned as usual for the submodules (that are assigned to the controller).
- A shared device must have the same IP parameters and the same device name in each station. There are two types of configuration case:
  - Shared device in the same project: STEP 7 takes important consistency check functions away from the user. STEP 7 checks that the IP parameters have been assigned correctly and monitors the IO controller access to the individual submodules to ensure that it is correct.
  - Shared device in different projects: The stations with the IO controllers that use the shared device are created in different projects. It is important to ensure in each project that the shared device is configured in exactly the same way in each station. Only one IO controller may have full access to a submodule in any case (see below). The IP parameters and device names must be identical. Inconsistencies in the configuration will cause the shared device to fail.

Shared device (Page 2131)

Shared device in a STEP 7 project

Introduction

In the following example, the simplest configuration of a shared device is described: Two IO controllers (SIMOTION D445-2 DP/PN and CPU 317F-2 PN/DP) share the submodules of an IO device (ET200S HF). The two IO controllers are in the same STEP 7 project with the advantage that the consistency check is made automatically.

Procedure

To be able to use the shared device function, you need to take certain configuration steps in SIMOTION SCOUT, SIMATIC Manager, and HW Config.

Preparatory steps for SIMOTION CPU

1. In SIMOTION SCOUT, create a project called **Shared device project**.
2. Insert a SIMOTION D445-2 DP/PN and configure it.
3. Open the SIMOTION CPU in HW Config and configure the PROFINET interface.

4. Configure a PROFINET IO device ET 200S (IM151-3PN HF) with several submodules as shown in the figure below.

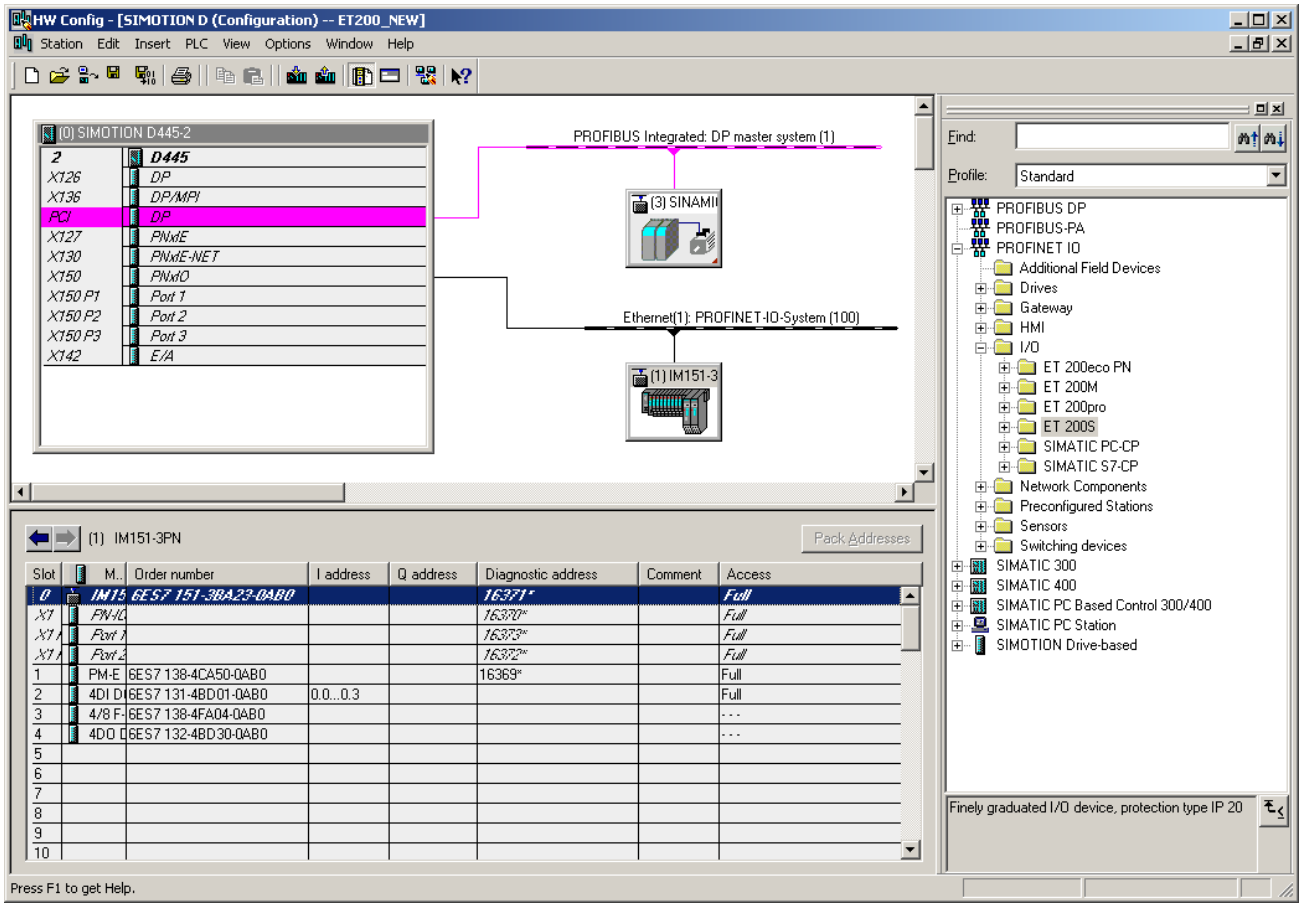

Figure 4-458 SIMOTION D445-2 DP/PN with IO device ET200S

5. **Save and compile** in HW Config.

Preparatory steps for SIMATIC CPU

1. Open the project you created in the SIMATIC Manager.
2. Insert a SIMATIC 300 station and open it in HW Config.
3. Insert a CPU 317F-2 PN/DP, for example, and configure the PROFINET interface.
4. **Save and compile** in HW Config.

Creating the shared device

1. Open one of the SIMOTION CPUs you created in HW Config.
2. **Copy** the IO device ET200S you created using the context menu (right mouse button).
3. **Save** the hardware configuration and close the configured station.
4. Open the station you created previously with the SIMATIC F-CPU in HW Config.

5. In order to add the IO device as a shared device, right click on the PROFINET IO system. Select the context menu command **Paste shared**.

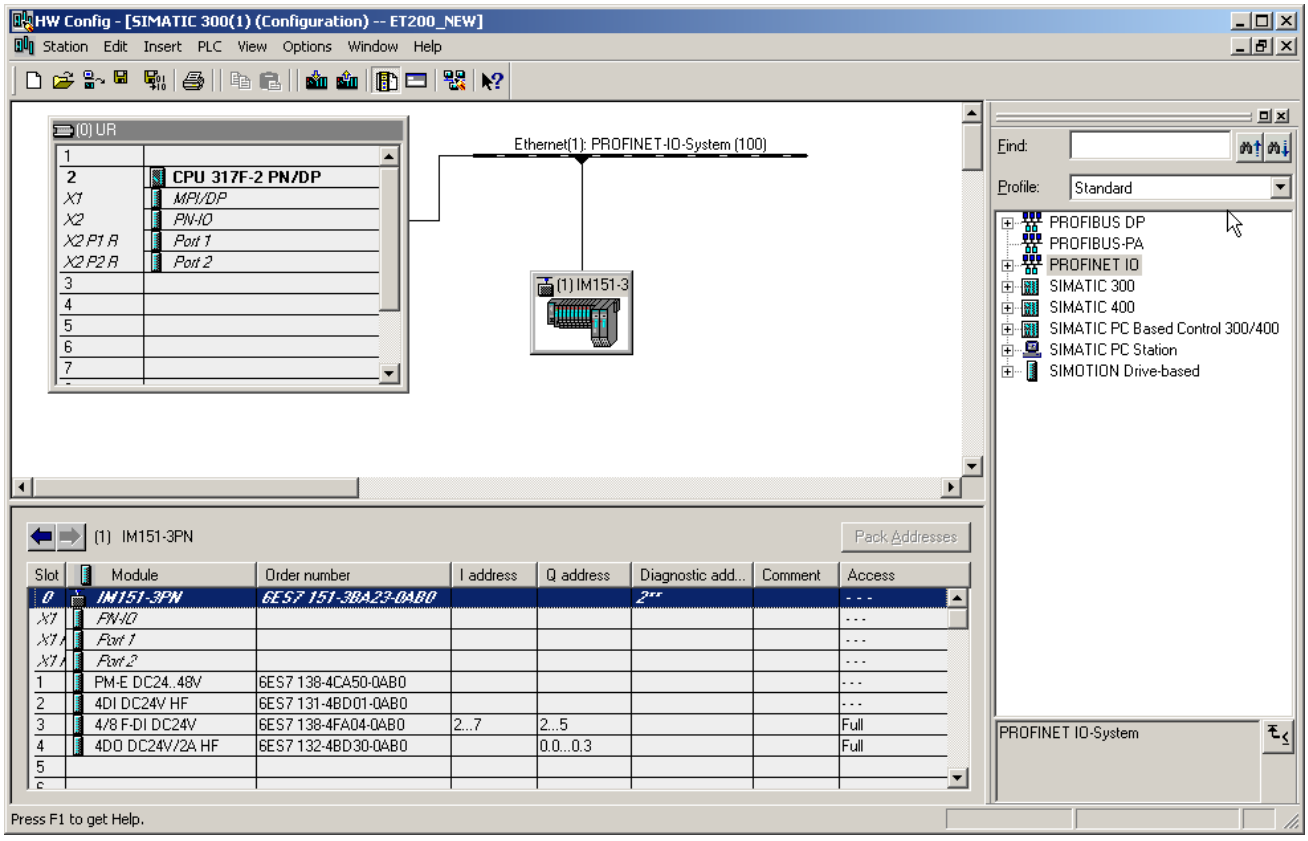

Figure 4-459 SIMATIC CPU 317F-2 PN/DP with shared device ET200S

6. Save the hardware configuration and close the configured station.

You have successfully created the shared device, now set the assignments of the submodules to the configured stations.

Assigning submodules

The submodules must be assigned separately for each station. Remember that changes to a station will also impact the other station(s)! A submodule can only ever be assigned to one station!

1. Open the Properties dialog box of the PROFINET IO device for the SIMOTION CPU.
2. Click the **Access** tab.

3. Configure the access to the individual submodules. To do this, select the type of access from the drop-down list in the **Value** column. You can select from the following:
   – No access to the submodule: "- - -"
   – Full access to the submodule: "full"

   Note that the setting "Full" automatically leads to the setting "- - -" in the other station(s).

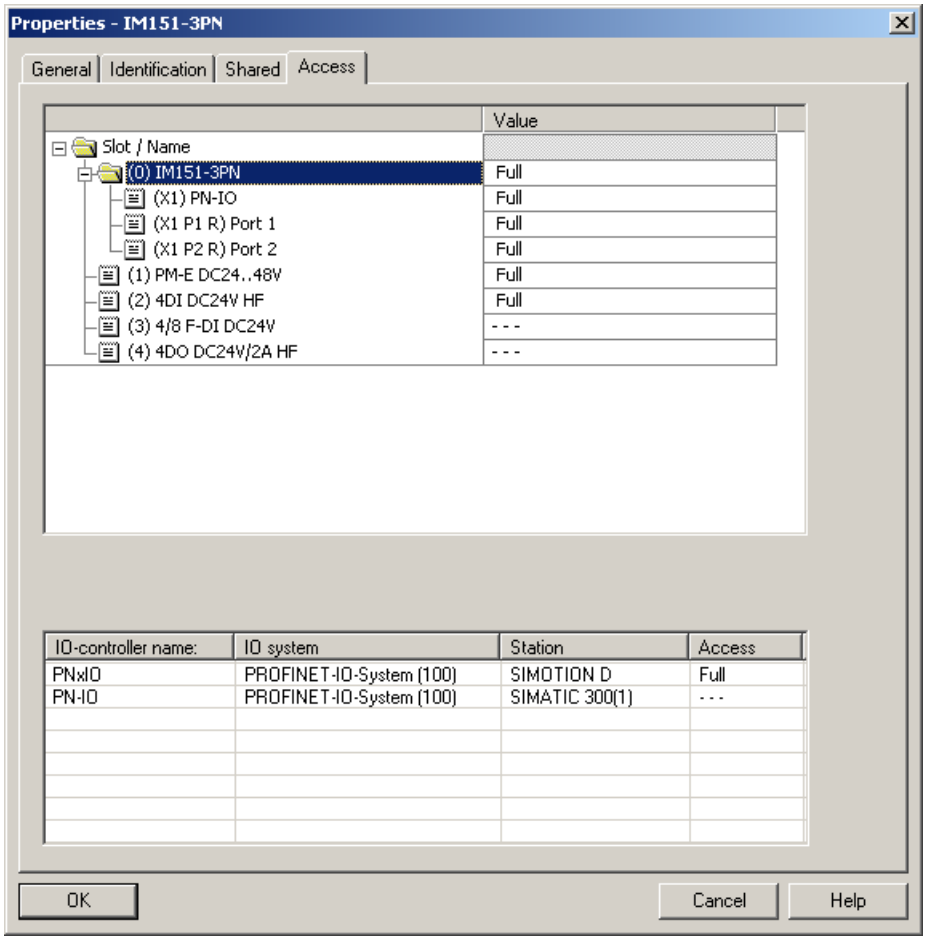

Figure 4-460 SIMOTION D445-2 DP/PN access to ET200S

4. Save and compile the station and close it.

5. Repeat steps 1 to 4 for the shared device on the SIMATIC F-CPU.

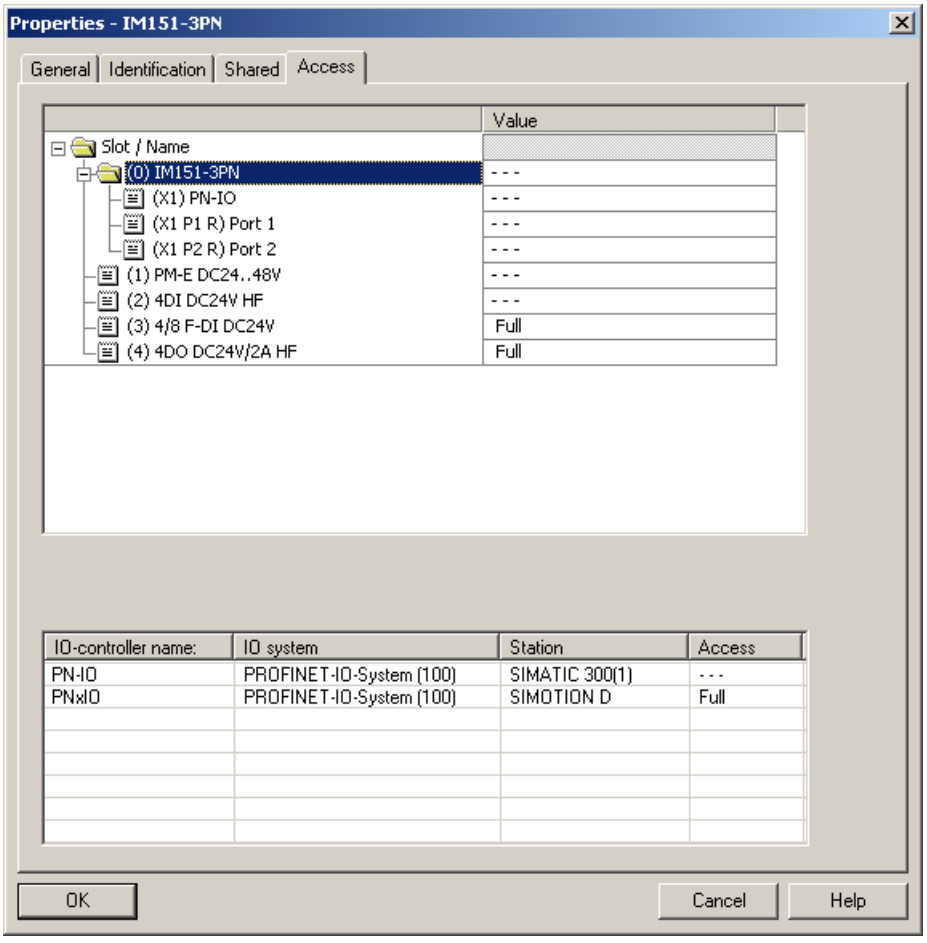

Figure 4-461 SIMATIC CPU 317F-2 PN/DP access to shared device ET200S

6. Then download the configuration to the stations.

Shared device in the user program

The shared device has no special role in the user program. The submodules assigned in the station are addressed as usual through your addresses, the other submodules do not receive addresses.

Shared iDevice and PROFIsafe

Using a shared I-Device

Description

An I-Device can be operated on two higher-level IO controllers as an IO device. This functionality is known as shared I-Device. It provides the following application areas:

- One of the higher-level controllers works as the "Automation CPU" and uses the SIMOTION I-Device as an isochronous I-Device in the IRT operating mode.
- The other higher-level IO controller works as the "Safety CPU" and uses the submodules configured as the F-Proxy in the RT operating mode.

This means that an I-Device can communicate with two higher-level controllers as an IO device. At the same time, higher-level controllers can access certain modules, e.g. an F-CPU can access the F-Proxy submodules, using the shared device.

Schematic diagram

The schematic diagram below shows two IO controllers which share the submodules on the I-Device of a third IO controller.

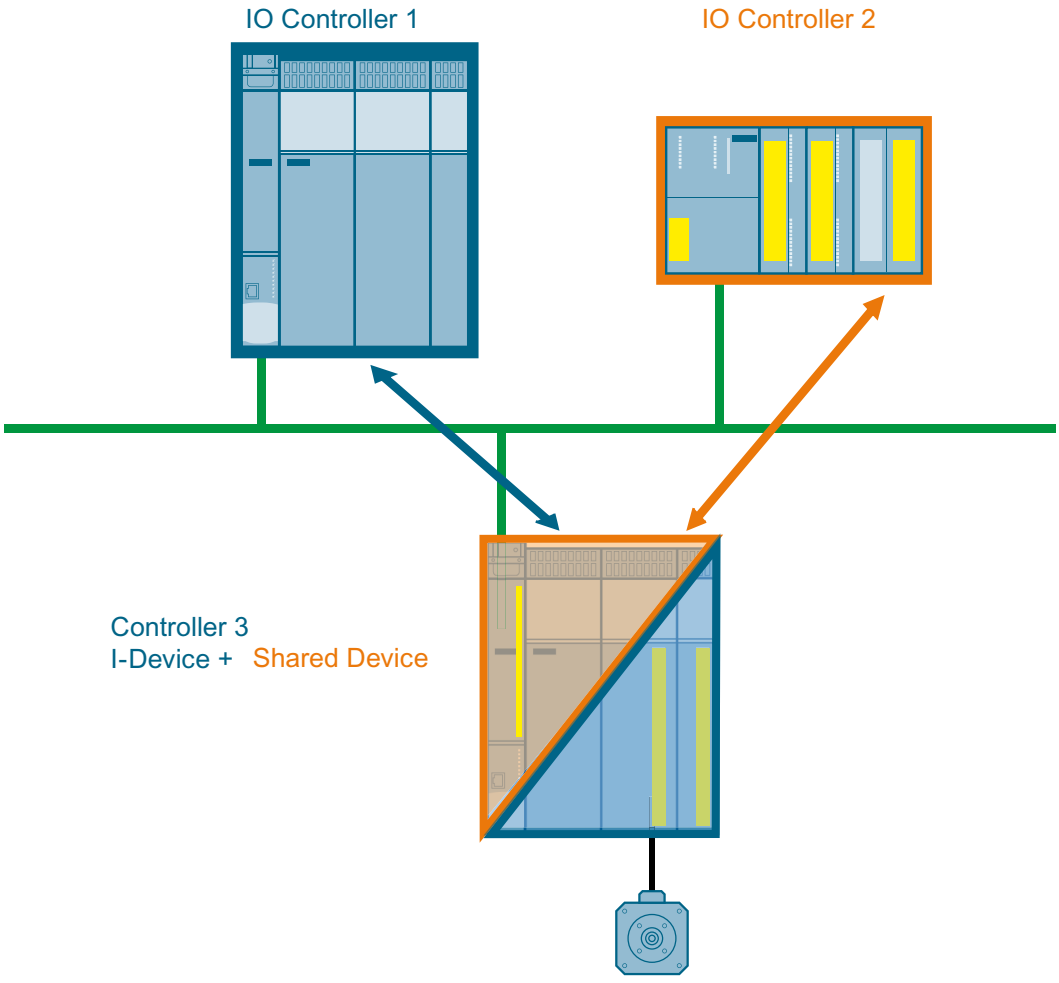

Figure 4-462 I-Device as Shared Device

Note

In this configuration, only the submodules that are used by the "Automation CPU" are configured as isochronous (IRT).

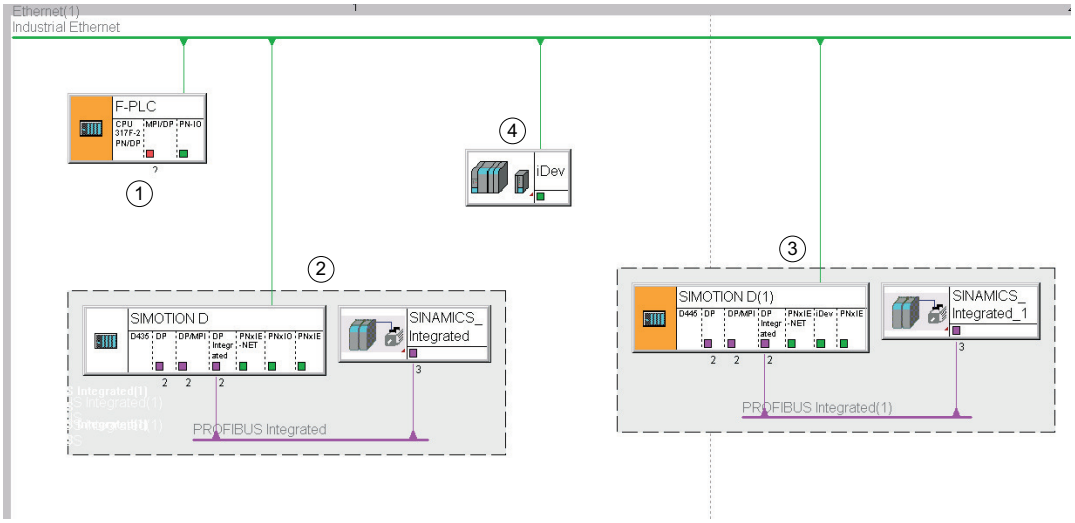
Basic information on this subject can be found in the section Shared I-Device (Page 2255).

Configuration example for shared iDevice and PROFIsafe

Configuration example

In the following example, a SIMOTION D445-2 DP/PN with two Safety drives on SINAMICS_Integrated is operated as a shared iDevice on a SIMOTION D435-2 DP/PN and a SIMATIC CPU317F-2. The SIMOTION D435-2 takes on the motion control tasks, while the SIMATIC CPU317F-2 is responsible for safety monitoring.

The overview diagram below shows the network view. The IO controllers are in the same subnet and are located in a project.



1 SIMATIC CPU 317F-2 as higher-level IO controller in RT mode (F-CPU)

2 SIMOTION D435-2 DP/PN as higher-level IO controller in IRT mode

3 SIMOTION D445-2 DP/PN with two Safety drives on SINAMICS_Integrated (PROFIBUS)

4 iDevice of SIMOTION D445-2 DP/PN which is connected to both higher-level IO controllers (shared iDevice).

Note:
In this example, the SIMOTION D445-2 DP/PN is shown twice in Netpro: Once as an iDevice proxy and once as a complete SIMOTION D device.

Figure 4-463 Configuration example for PROFIsafe via shared iDevice, representation in Netpro

Basic process for the example configuration

The following configuration steps must be observed for the example configuration:

1. Create a new project in SIMOTION SCOUT and configure a SIMOTION D435-2 DP/PN and a SIMOTION D445-2 DP/PN. These must be configured on the same subnet.
2. Configure two drives (power unit, supply, Safety functions, F destination address F_Dest_Add) on the SINAMICS_Integrated of the SIMOTION D445-2 DP/PN. (See also Configuring the iDevice F-Proxy (Page 2350))
3. Create two axes and connect each of them to one of the two drives in the axis configuration.

4. Insert the PROFIsafe telegrams in the telegram configuration for the drive unit and align the telegrams with HW Config.
   The diagram below shows an example project with the PROFIsafe telegram configuration open.

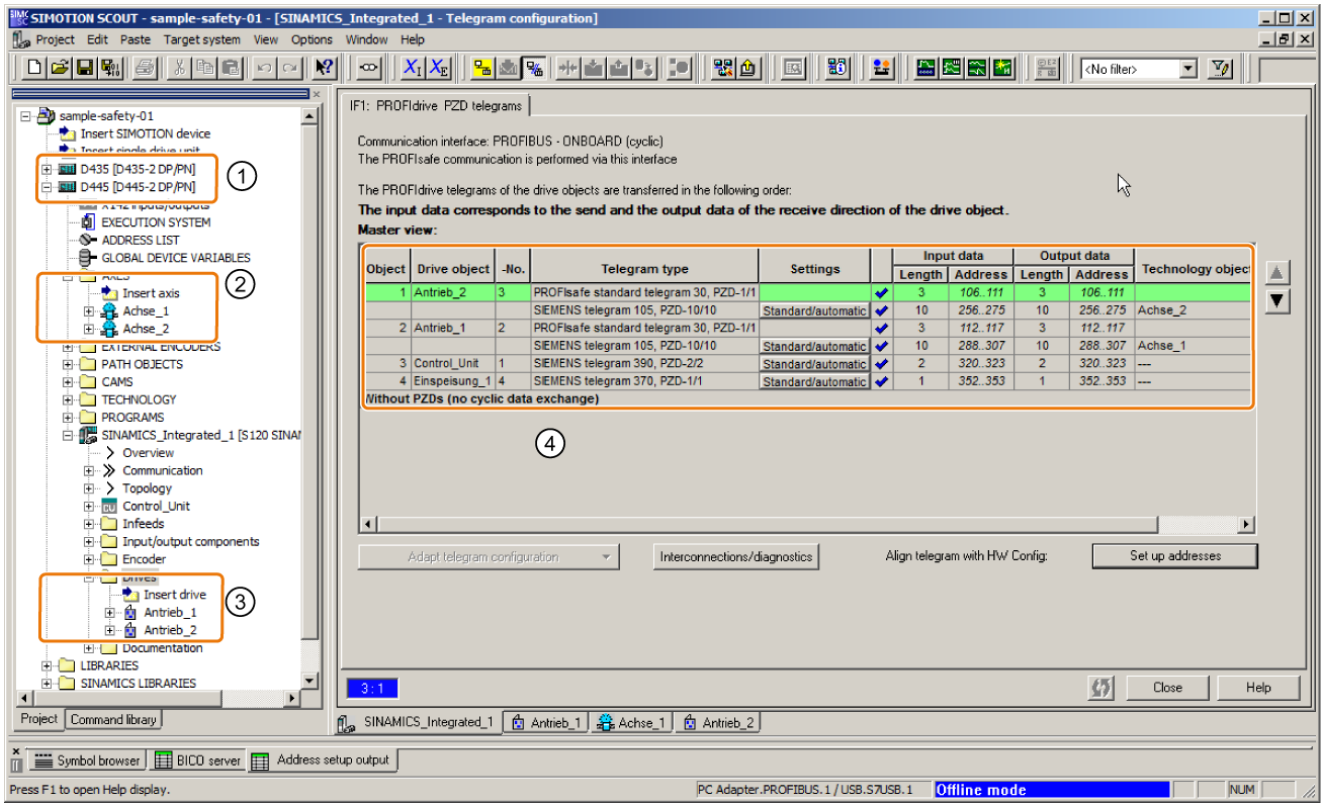


Figure 4-464 Example project for shared iDevice with two SIMOTION D

5. In the project navigator, double-click on a SIMOTION CPU, e.g. D445-2 DP/PN, to open HW Config. Insert a new SIMATIC 300 station with a SIMATIC CPU317F-2 in the project. The F-CPU is located in the same subnet as the SIMOTION CPUs.
6. In HW Config for the SIMOTION D445-2 DP/PN, configure the iDevice (i.e. the iDevice mode and transfer areas) and the isochronous mode. Export and install the iDevice (see also Configuring SIMOTION D for shared iDevice (Page 2378)).
7. When HW Config for the SIMATIC CPU317F-2 is open, add the iDevice to its PROFINET IO system. Copy the iDevice and use "Shared paste" to insert it into the PROFINET IO system of the SIMOTION D435-2 DP/PN. Configure the access to the submodules of the iDevice and the synchronization roles (see also Allocating an iDevice to two IO controllers as a shared device (Page 2380)).
8. **Save and compile** the stations/project.

More details about the configuration process can be found in the following chapters.

Configuring SIMOTION D for shared iDevice

Requirement

A SIMOTION D445-2 DP/PN with two drives on SINAMICS_Integrated and two axes with safety is configured in the example project. The SIMOTION D435-2 DP/PN and the SIMATIC CPU317F-2 are configured in the project as described in the previous step. In the next step, the SIMOTION D445-2 DP/PN will be configured as an I-device.

Configuring and creating a shared I-device

How to configure the SIMOTION D445-2 DP/PN for the creation of the I-device:

1. In the SIMOTION SCOUT project navigator, double-click on the SIMOTION D445-2 DP/PN to open HW Config.
2. Double-click on the **PN interface** (X150) and assign a new **device name** in the Properties dialog box in the **General** tab, e.g. I-Device-Shared.
3. Switch to the **I-Device** tab. Activate the **I-device** option and the additional options **Parameter assignment for the PN interface and its ports on the higher-level IO controller** and **Operate as higher-level shared device.**

4. In this step, you configure the transfer areas (submodules) which are to be shared with the higher-level controllers. Two fail-safe I/Os and two application areas are used in each case.
   - Click **Interconnect fail-safe I/O**. The configured transfer areas are automatically set up for the fail-safe I/O. In the example, two PROFIsafe drives are used. These are **not** operated **isochronously**.
   - Click **New...** and configure the transfer areas for the application area. Two application areas are configured which are operated **isochronously**. The addresses for the transfer areas are suggested by STEP 7. You can also define your own address areas.

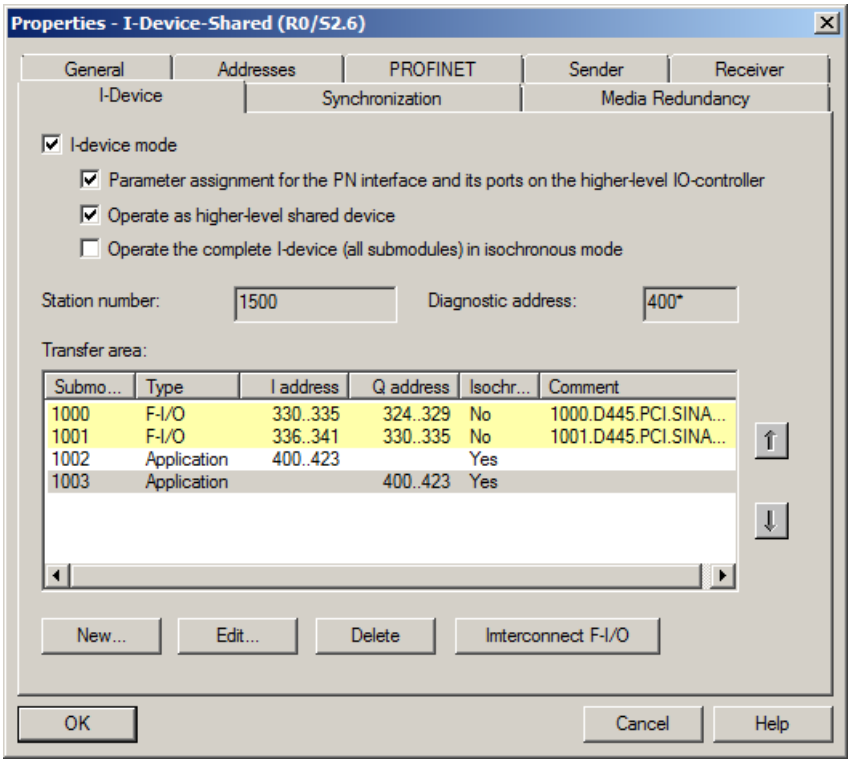

Figure 4-465 Shared I-device transfer areas

5. Activate the option **Use I/O data isochronously to the Servo** for the PN interface in the **Isochronous tasks** tab in the **Properties** of the SIMOTION D445-2 DP/PN and click **OK** to confirm. The I-device is used as a reference clock.
6. In the **PROFINET IO isochronous operation** of the SIMOTION D445-2 DP/PN, select servo as the **Isochronous application**.
7. Select the menu command **Station > Save and Compile**.
8. In the menu, select **Options > Create GSD file for I-device**.
9. Enter a **name** and **comment** for the I-device in the dialog box that appears.
10. Click **Create** and then **Install**. The I-device is displayed under **PROFINET IO > Preconfigured Stations > D445** in the hardware catalog.

In the next step, you will add the I-device to the higher-level IO controllers and configure the access to the transfer areas.

Allocating an iDevice to two IO controllers as a shared device

Requirement

The example project has been completely configured and the GSD file has been created for the iDevice. In the next step, the shared iDevice is configured on the two IO controllers, SIMOTION D435-2 DP/PN and SIMATIC CPU317F-2.

Inserting and configuring a shared iDevice

To configure the shared iDevice, proceed as follows:

1. Open the configured station SIMATIC CPU317F-2 in HW Config.
2. Drag&drop the created iDevice from the hardware catalog (**PROFINET IO > Preconfigured Stations > ...)** to the PN IO system of the SIMATIC CPU. The iDevice is inserted.
3. Double-click on the inserted iDevice. The Properties window is displayed.

Note

The first time you insert a device, you must set up the dialog for the safety password. Enter a password and confirm the dialog. This password will be requested whenever safety-relevant functions are changed.

4. In the **General** tab, enter the **device name** that you assigned earlier on the PN interface of the D445-2 DP/PN before exporting the iDevice (in the example, **iDevice shared**). The device names must be identical in order for communication to be possible.

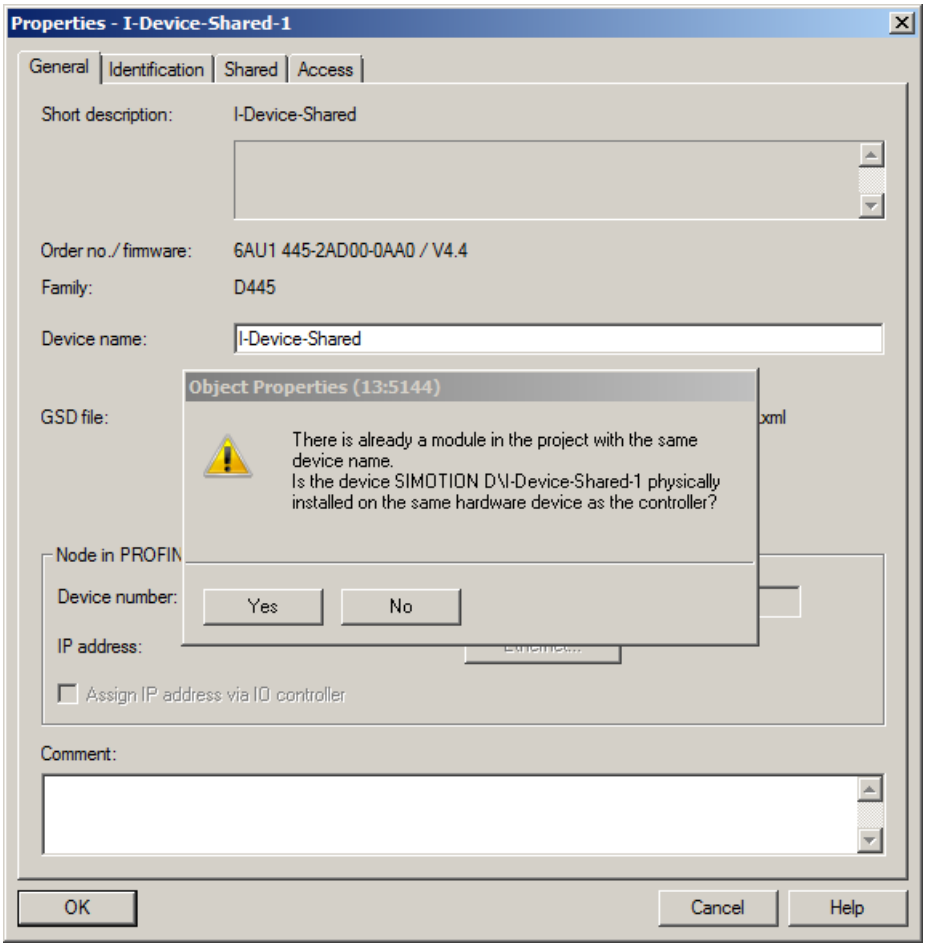

Figure 4-466 Entering a device name for the shared iDevice

Note

A notification informs you that there is already a module in the project with the same device name (IO controller of the iDevice). Click **Yes** to confirm this dialog box. This dialog may appear several times during configuration.

5. In the **Access** tab, enter the access to the submodules of the iDevice. On the F-CPU, the **fail-safe I/O** subslots are configured as **full**. Confirm by clicking **OK** and save and compile the station.

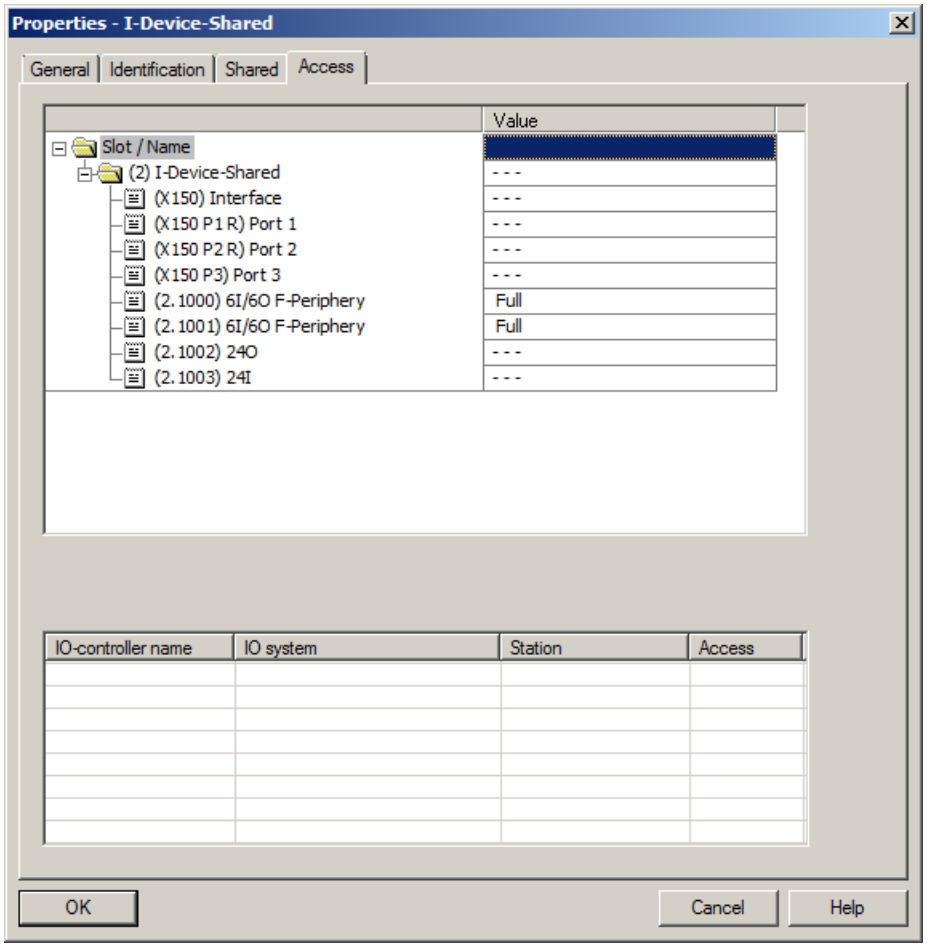

Figure 4-467 Setting access to the submodules for the F-CPU

6. Select the iDevice inserted in HW Config and select **Copy** in the context menu.

7. Switch to HW Config for the SIMOTION D435-2, select the PN IO system, and select **Shared paste** in the context menu. The iDevice is inserted.

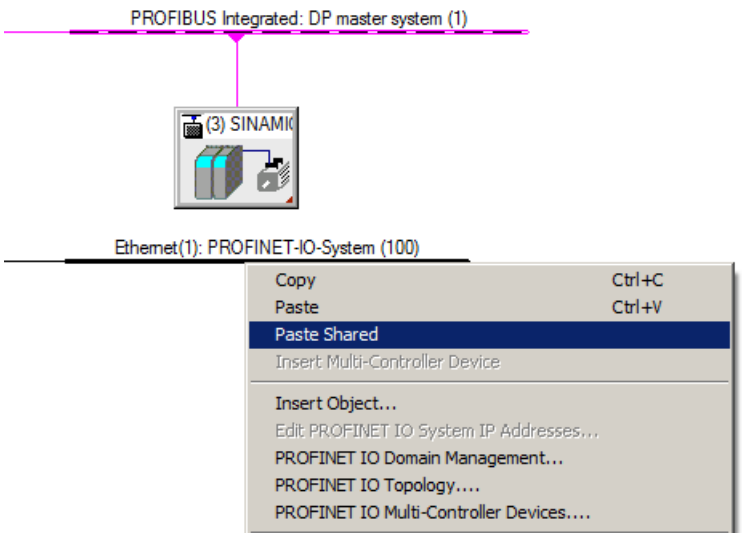

Figure 4-468 Shared paste for iDevice via context menu

8. In the **Access** tab, check the access to the submodules of the iDevice. These are automatically aligned with the HW Config of the F-CPU when the shared iDevice is inserted. The SIMOTION CPU must have full access to all subslots with the exception of the fail-safe I/O. The consistency of the subslots is checked automatically when you select "Save and compile", if the IO controllers are located in the same project.

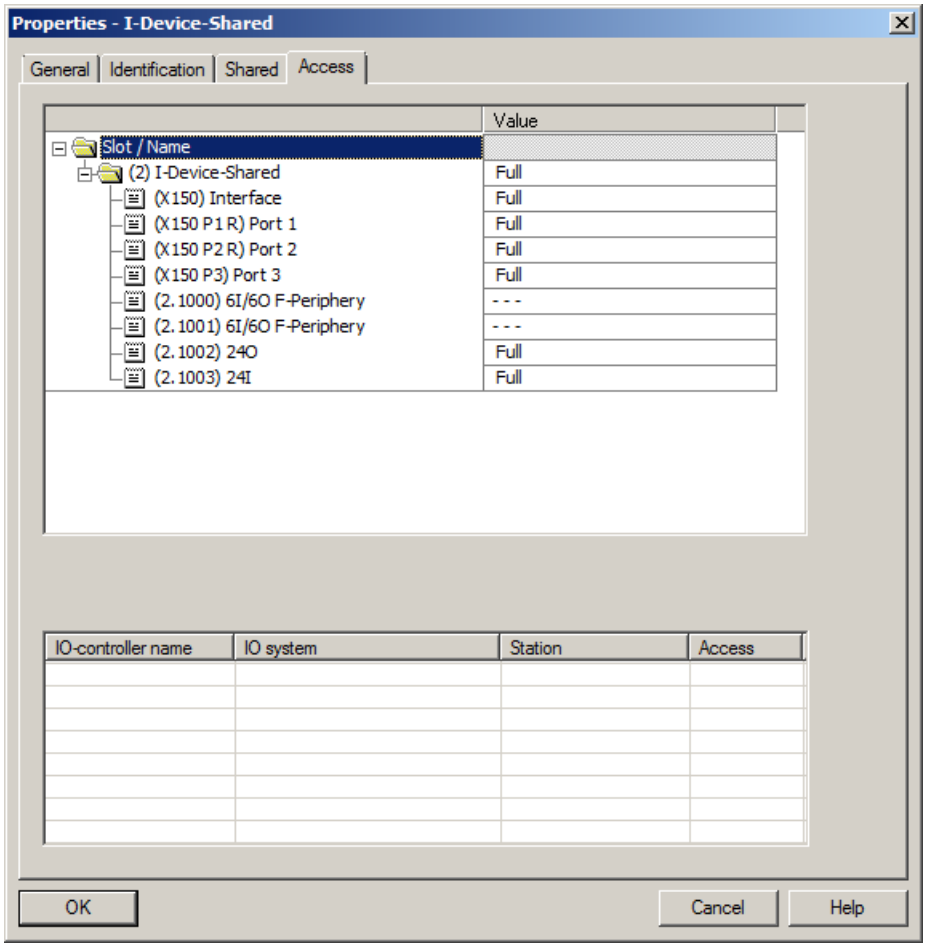

Figure 4-469 Setting access to the submodules for the SIMOTION D

9. On the SIMOTION D435-2, configure the **PN interface** (X150) as the **sync master** and as isochronous to the **servo**. (You should also refer to the chapter Isochronous application (Page 2126)).

10. In the SIMOTION D435-2 station, double-click on **Port 1 (X150 P1)** to interconnect the topology. In the dialog that appears, select a **partner port** of the shared iDevice, e.g. Port 1.

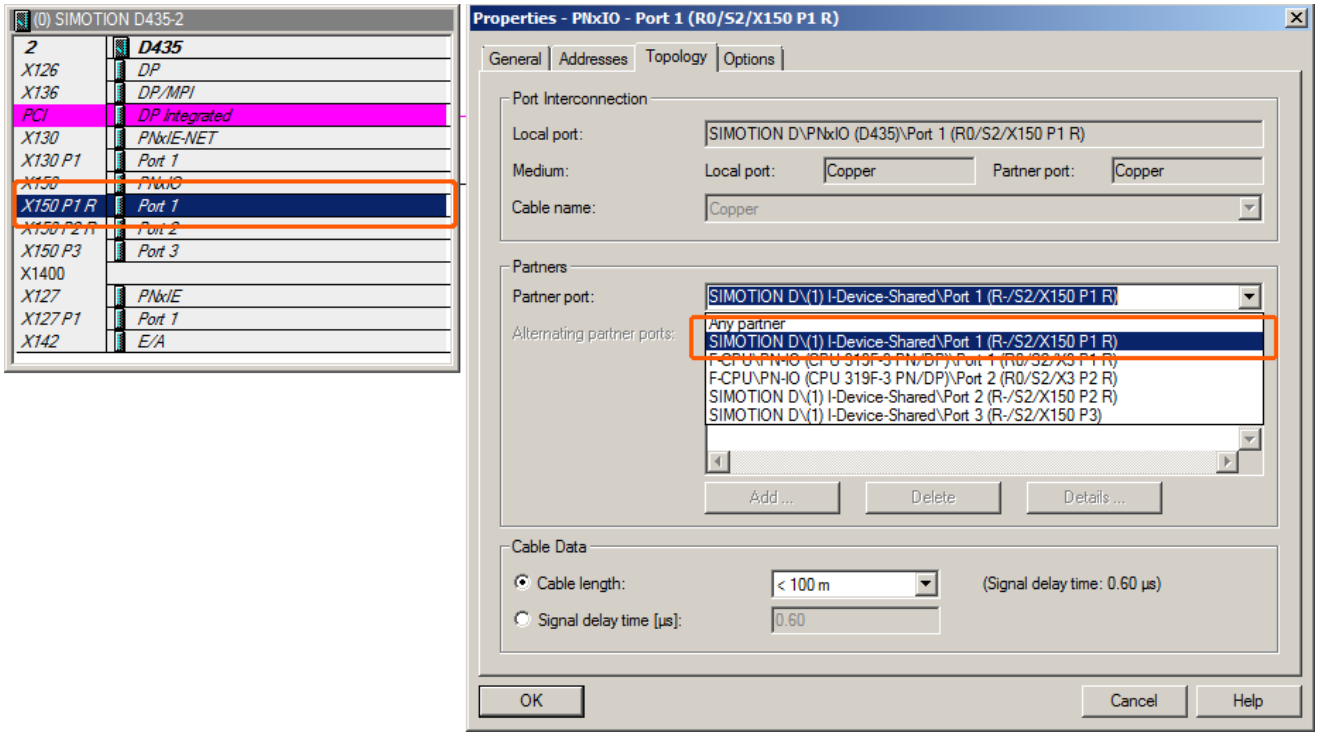

Figure 4-470 Port interconnection on the iDevice

Note

The ports of the SIMOTION D455-2 DP/PN are not displayed in the topology editor, as there is a shared iDevice with the same name in the project. For this reason, the ports must be interconnected using the Properties dialog.

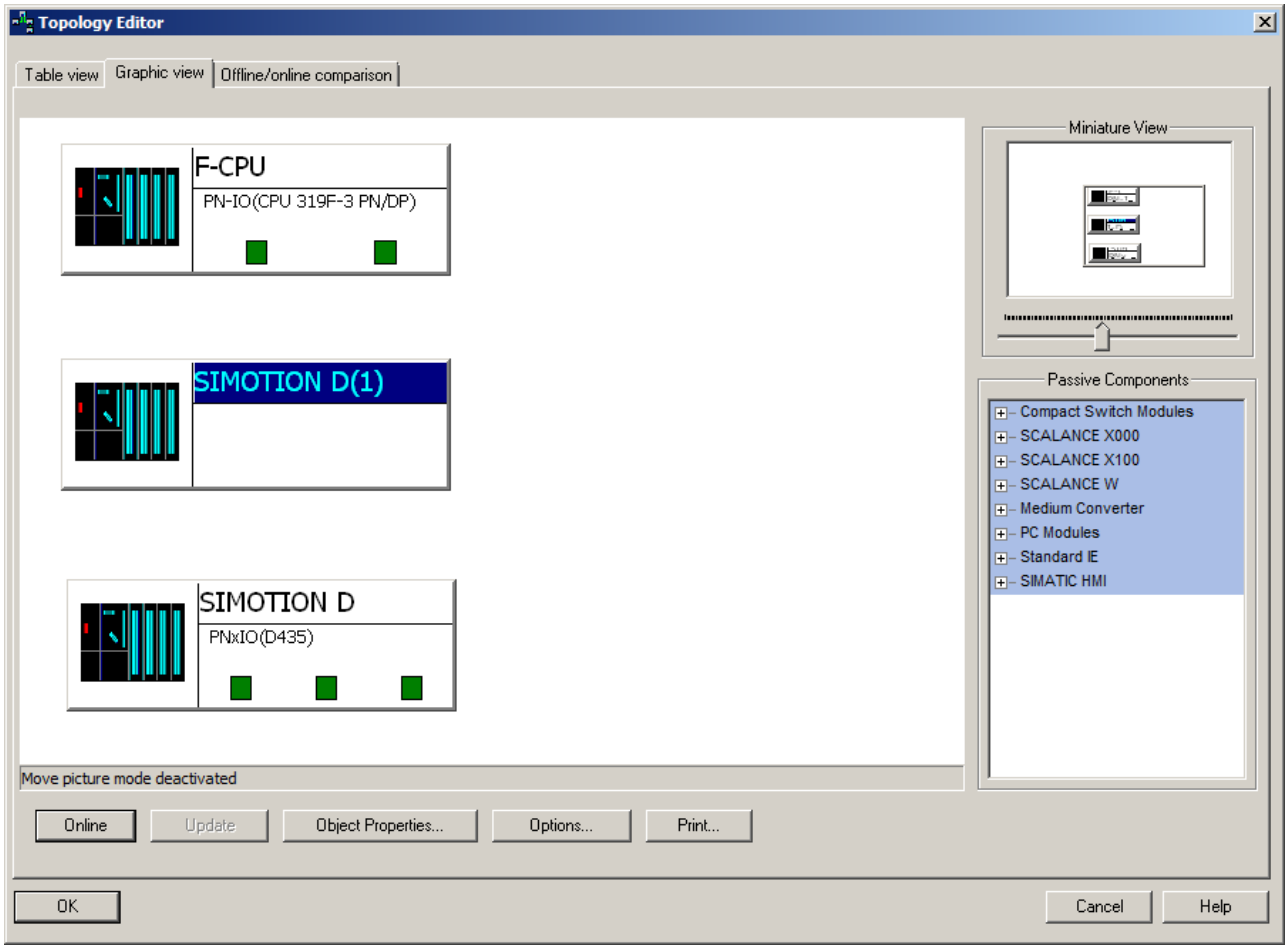

Figure 4-471 Shared iDevice in the topology editor

11. Select the iDevice in the PROFINET IO system of the D435-2 DP/PN and double-click on the PN interface of the iDevice (X150 interface). In the **Properties dialog** that appears, set sync slave and IRT in the **Synchronization** tab. On the **IO Cycle** tab, select **Servo** for the isochronous mode under **Assign IO device isochronously.**

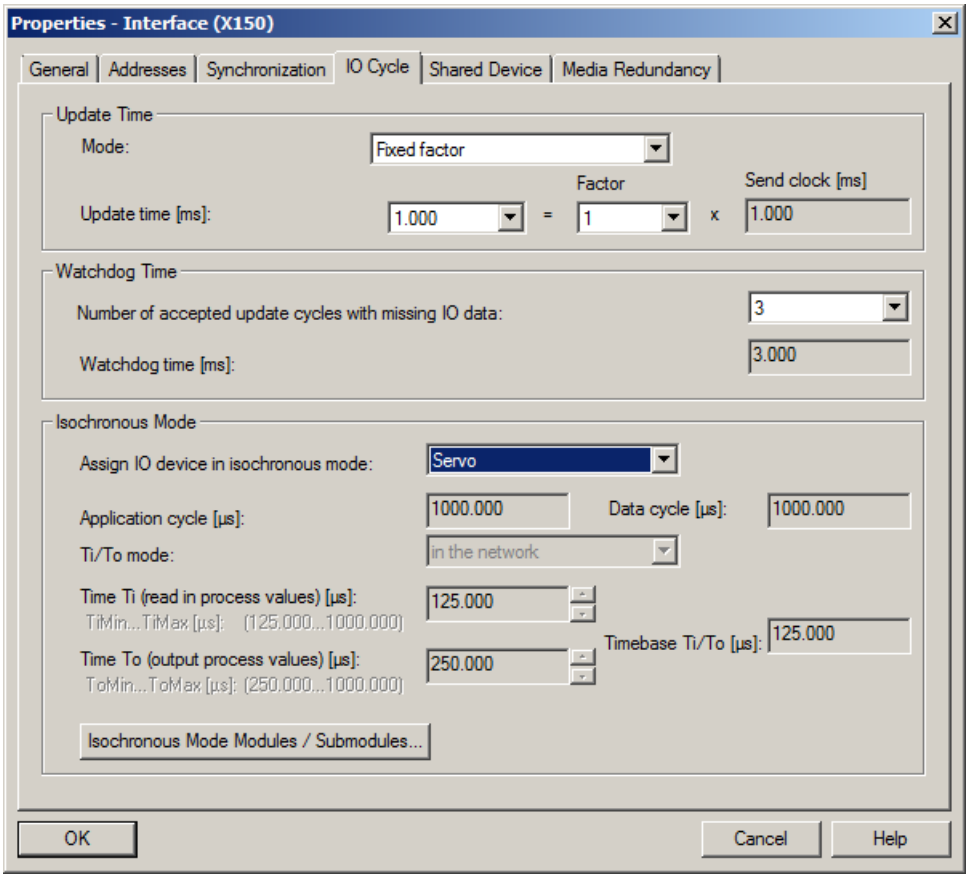

Figure 4-472 Configuring the iDevice as a slave IO device

12. **Save and compile** all stations. Once the stations have been compiled without any errors, configuration is complete.

4.5.9.6 PROFIsafe via PROFIBUS

General information about PROFIsafe on PROFIBUS

Two possibilities for PROFIsafe

There are basically two possible forms of PROFIsafe communication on PROFIBUS:

- **I-slave F-Proxy**
  F-CPU is the DP master in the project and monitors the drives on the lower-level SIMOTION I-slave
- **Failsafe data exchange broadcast**
  SIMOTION is the DP master in the project and the F-CPU monitors the drives as the I-slave.

The procedure for configuring PROFIsafe communication is virtually the same in both cases. The sections below each contain a brief example.

Supported devices and software requirements for PROFIsafe on PROFIBUS

Software packages to be installed on the programming device:

- SIMATIC Manager STEP7 version 5.4 SP2 or higher
- S7 F Configuration Pack Version 5.5 SP3 or higher
- S7 Distributed Safety Programming Version 5.4 SP3 or higher
- SIMOTION SCOUT Version 4.1.1 HF6 or higher
- SINAMICS firmware Version 2.5 or higher

Note

As of SIMOTION firmware 4.1.1 HF10 and SINAMICS firmware 2.5 SP1 HF10, five drives can be configured with a CX32. With earlier firmware versions, a maximum of 4 drives can be configured.

You will find the components suited to PROFIsafe in the *S120 Safety Integrated Function Manual*.

Supported devices

Table 4-244 Device overview

SIMOTION CPU	
Controller Based	C240 C240 PN
PC Based	P350-3 P320-4
Drive-based (blocksize)	D410 DP D410-2 DP D410-2 DP/PN
Drive-based (booksize)	D4x5 D445-1 D4x5-2 DP D4x5-2 DP/PN
SINAMICS drive units	
S120 CX32	CX32 CX32-2
S120	CU320 DP CU320-2 DP CU310 DP CU310-2 DP
S110	CU305 DP

Number of drive axes supported

With PROFIBUS, only 16 drive axes can be used per PROFIBUS interface.

I-slave failsafe proxy

Principles of I-slave failsafe proxy

Short description

Using the I slave F-Proxy you can produce a PROFIsafe configuration with an F host (F-CPU SIMATIC) on PROFIBUS with SIMOTION devices (SIMOTION D, SIMOTION P350, SIMOTION C) for the lower-level drives. Cyclic PROFIsafe data can then be routed to SINAMICS drives on SINAMICS_Integrated / PROFIBUS DP.

A failsafe host communicates with the drives via the I-slave interface and a failsafe proxy of a SIMOTION CPU. The drives may be located on the PROFIBUS DP of the SIMOTION CPU. The SIMOTION CPU's communication segments feature SINAMICS S120/S110 and SINAMICS Integrated/CX32/CX32-2.

Topology for I-slave failsafe proxy for PROFIBUS drive units

Example of topology for I-slave failsafe proxy

The diagram below shows a topology in diagrammatic form in which the Safety drives are connected to the SIMOTION CPU via PROFIBUS DP and this is connected to the F-CPU via PROFIBUS DP.

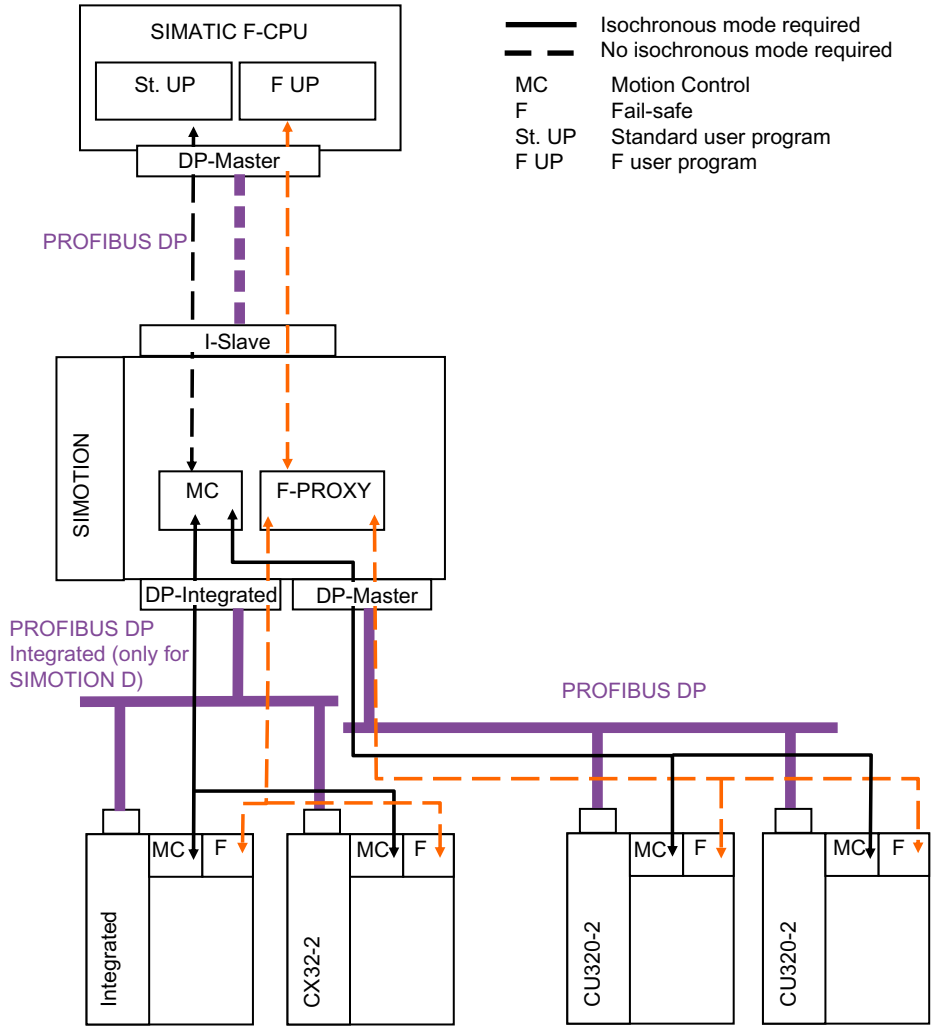

Figure 4-473 Topology for I-slave failsafe proxy for PROFIBUS drive units

PROFIsafe via PROFIBUS when SIMOTION D is used

The next sections deal with the configuration of PROFIsafe communication via PROFIBUS between the integrated drive unit SINAMICS S120 of a SIMOTION D or CX32 and a higher-level SIMATIC F-CPU.

Topology (network view of the project)

The basic topology of the components involved in PROFIsafe communication via PROFIBUS (SIMATIC F-CPU and D4x5 integrated with SINAMICS S120 or CU320) can be found in the previous section.

The drive unit (SINAMICS) and the SIMATIC F-CPU are located on different PROFIBUS subnets. In this case, a PROFIsafe router to SIMOTION D is configured so that the necessary data is copied from one network to the other.

Configuring PROFIsafe communication

The next sections describe the configuration of PROFIsafe communication between a SIMATIC F-CPU and a drive object of an integrated SINAMICS drive unit of a SIMOTION D. The procedure for configuring PROFIsafe communication between a drive unit of a CU320 and a SIMATIC F-CPU is basically the same and is not covered separately.

1. Create an F-CPU (e.g. CPU 317F-2) and a SIMOTION D4x5 controller (with integrated SINAMICS S120) in accordance with the hardware installed.
2. Define a SIMOTION CPU for operation as DP slave and the F-CPU as associated DP master.
3. Configure the SINAMICS drive unit in SIMOTION SCOUT in accordance with your hardware configuration.
4. Then insert a new TO axis and run through the axis wizard. In the wizard, interconnect the axis to the corresponding drive object of the S120 and a corresponding telegram will automatically be created (symbolic assignment).
5. Save and compile the project.

6. Create a PROFIsafe slot in the configuration of the SINAMICS drive unit.
   For this purpose, select in tab **IF1 the following: PROFIdrive PZD message frames** - the drive object which is to communicate with the SIMATIC F-CPU via PROFIsafe. Click on the **Adapt message frame configuration** button and select **Add PROFIsafe**.

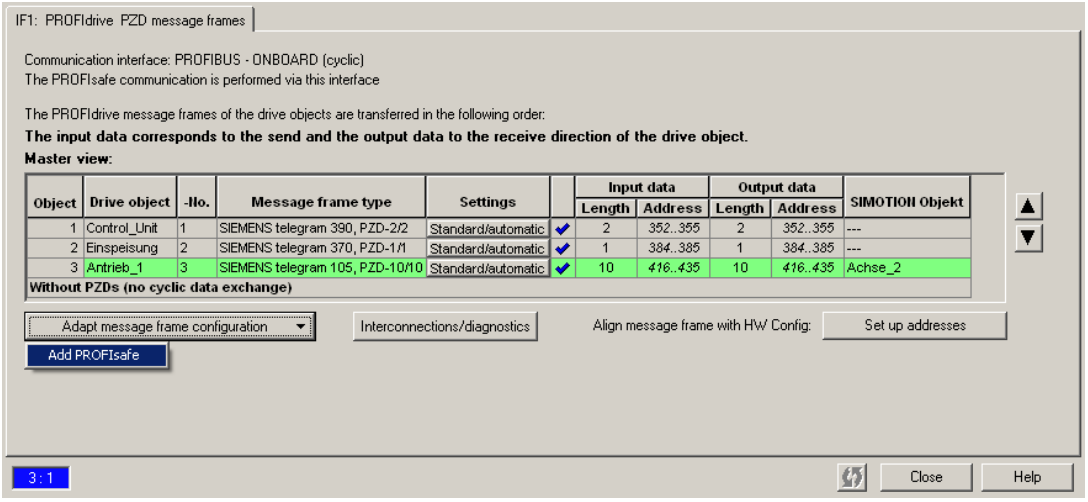

Figure 4-474 Inserting a PROFIsafe slot

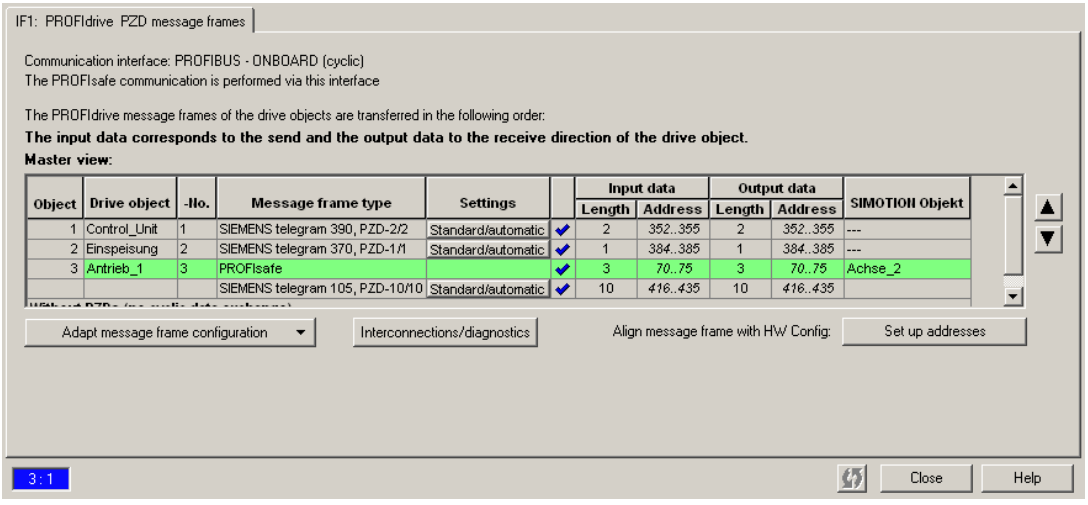

Figure 4-475 PROFIBUS message frame

7. Save and compile the project.
8. Transfer the new PROFIsafe slot to HW Config by clicking on the **Set up address** button.
9. In HW Config for the F-CPU, connect the preconfigured SIMOTION station to the F-CPU (hardware catalog: **PROFIBUS DP > Preconfigured stations** ...).

Note

To configure the SINAMICS Safety Integrated extended functions by means of SIMOTION, the message frames must be extended. To do so, a safety data block is appended to the PROFIdrive actual value message frame. Configuration and parameter assignment of this Safety data block are described in the Function Manual *SIMOTION Motion Control TO Axis electric/hydraulic, external encoder*.

10. You can display the F-communication parameters via the DP slave properties (double-click on SIMOTION I-slave). To do this, go to the **F configuration** tab and click on **New**.
Mode: Displays the communication relationship. F-MS module represents safety-related master-slave communication with SIMOTION.
DP partner (F I/O): SINAMICS drive properties.
Here you can select the relevant PROFIsafe drive via **DP address** or **Address**.
local: Properties of the SIMOTION CPU.
Enter the logical start address for F-communication of the SIMOTION CPU in the "Address" row.
The address space for sending and receiving the safety frames depends on the message frame used and must be located outside the process image of the SIMOTION CPU (>= 64).
Master (safety program): SIMATIC F-CPU properties.
The logical start address for F communication of the SIMATIC F-CPU must be entered here under "Address" (LADDR).
The address space for sending and receiving safety message frames depends on the message frame used and must lie within the process image of the SIMATIC F CPU.
In the SIMATIC F-CPU safety program, this address space can be used to access the PROFIsafe control or status words.
An overview of which message frames are possible for the individual drives can be found in the SIMOTION FAQs.

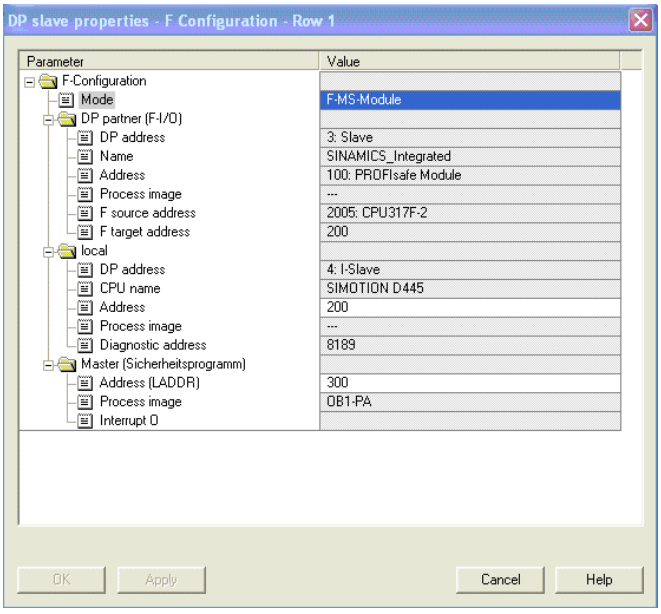

Figure 4-476 Master-slave coupling in PROFIsafe

11. Open the SIMOTION CPU project in HW Config.

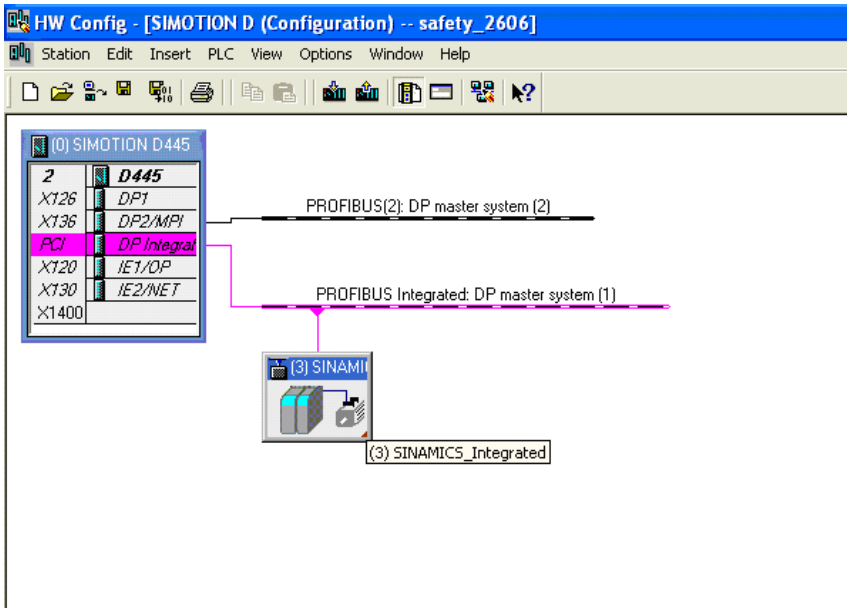

Figure 4-477 SIMOTION D configuration

12. Double-click on the icon of the SINAMICS drive unit and select the **Details** tab in the **Configuration** tab.

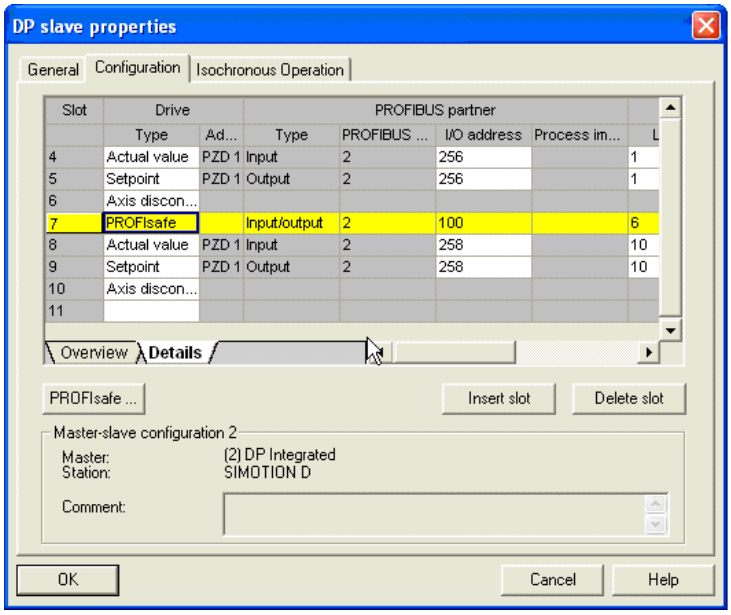

Figure 4-478 PROFIsafe configuration for SINAMICS drive unit

13. Click on the **PROFIsafe...** button and then define the F parameters which are important to F communication. As of STEP7 V5.5, PROFIsafe V2 is used by default.
(If the **PROFIsafe...** button cannot be used, you need to activate it using the **Activate...** button.)
For more information about the fail-safe parameters, see PROFIsafe properties for configuration (Page 2336)

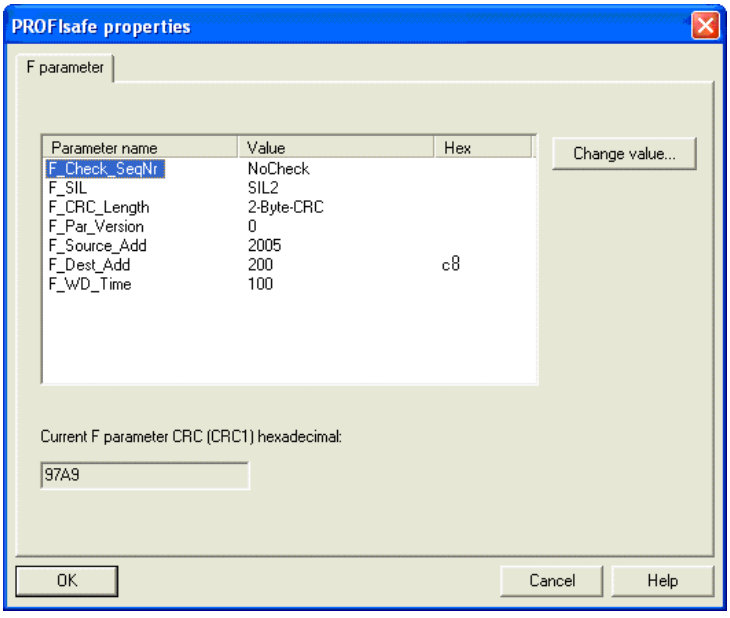

Figure 4-479 PROFIsafe properties (F-parameters)

14. Compile HW Config of the SIMOTION CPU. Compile the F-CPU configuration data in HW Config.

Note

For information about creating a safety program and accessing PROFIsafe useful data (e.g STW and ZSW) within the safety program, refer to the *SIMATIC, S7 Distributed Safety - Configuring and Programming* Programming and Operating Manual.

Safety configuration (online) in the SINAMICS drive

1. Call the configuration for Safety Integrated by selecting "Functions" at the SINAMICS drive entry in the tree structure.
2. Configure Safety Integrated and set to hex representation the F_Dest_Add parameter already defined under the drive's **PROFIsafe address** (p9610/p9810).
3. Finally, perform a POWER ON. The safety configuration is now active in the drive.

Note

For further information on safety configuration, see the SINAMICS S120 Safety Integrated Function Manual.

Failsafe data exchange broadcast

Principles of failsafe data exchange broadcast

Method of operation

SIMOTION CPU is the DP master for failsafe data exchange broadcast. The SIMATIC F-CPU is the DP slave on PROFIBUS DP and controls failsafe communication, e.g. with a CU320 of the SINAMICS S120.

Note

Control for the Safety Integrated functions cannot be routed to the SINAMICS Integrated of the SIMOTION D, Controller Extension CX32/CX32-2, or any other DP network in this constellation.

Topology of failsafe data exchange broadcast via PROFIBUS

Example of topology for failsafe data exchange broadcast for PROFIBUS

The diagram below shows a topology in diagrammatic form in which the Safety drives are connected to the SIMOTION CPU via PROFIBUS DP and the SIMATIC F-CPU is the PROFIBUS I-slave for failsafe communication.

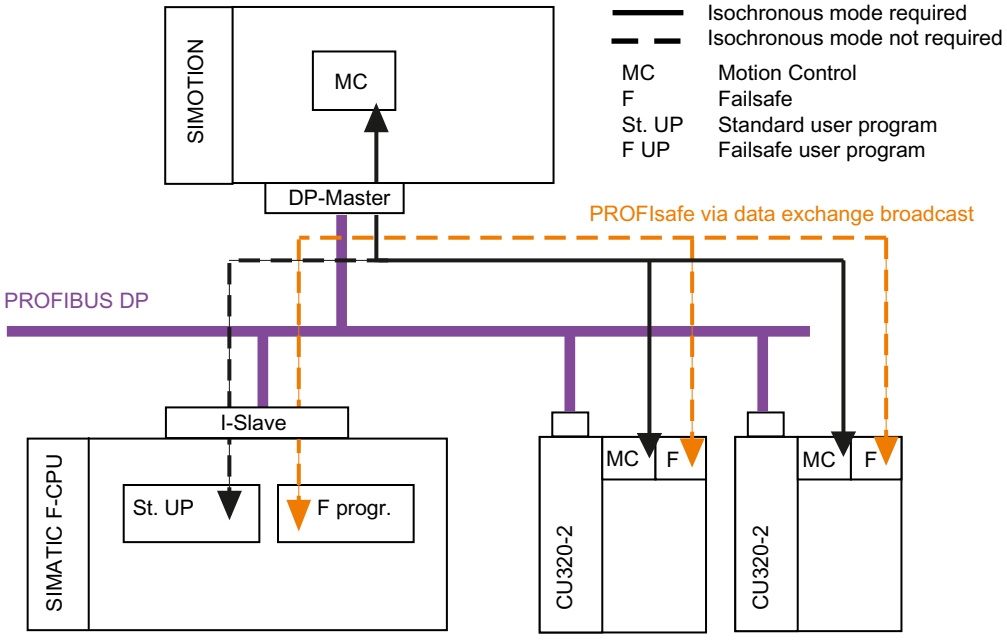

Figure 4-480 Topology of failsafe data exchange broadcast for PROFIBUS drive units

PROFIsafe via PROFIBUS with fail-safe internode data exchange taking the example of SIMOTION D

PROFIsafe communication is to be configured between a SINAMICS S120, SIMOTION D as DP master and SIMATIC F-CPU as I-slave via PROFIBUS.

Topology (network view of the project)

The basic topology of the components involved in PROFIsafe communication via PROFIBUS (SIMATIC F-CPU and D4x5 integrated with SINAMICS S120 or CX32) can be found in the following section:

The drive unit (SINAMICS) and the SIMATIC F-CPU are located in the same PROFIBUS subnet.

Configuring PROFIsafe communication via failsafe data exchange broadcast

1. In HW Config, create an F-CPU (e.g. CPU 317F-2), a SIMOTION D4x5 control and a SINAMICS S120 CU320 in accordance with the hardware installed.
2. Define the desired SIMOTION CPU as the DP master and the connected F-CPU as the associated DP slave.
3. Configure the SINAMICS drive unit in SIMOTION SCOUT in accordance with your hardware configuration.
4. Then insert a new TO axis and run through the axis wizard. In the wizard, interconnect the axis to the corresponding drive object of the S120 and a corresponding message frame will automatically be created (symbolic assignment).
5. Save and compile the project.
6. Create a PROFIsafe slot in the configuration of the SINAMICS drive unit.
   For this purpose, select in tab IF1 the following: PROFIdrive PZD message frames - the drive object which is to communicate with the SIMATIC F-CPU via PROFIsafe. Click on the **Adapt message frame configuration** button and select **Add PROFIsafe**.

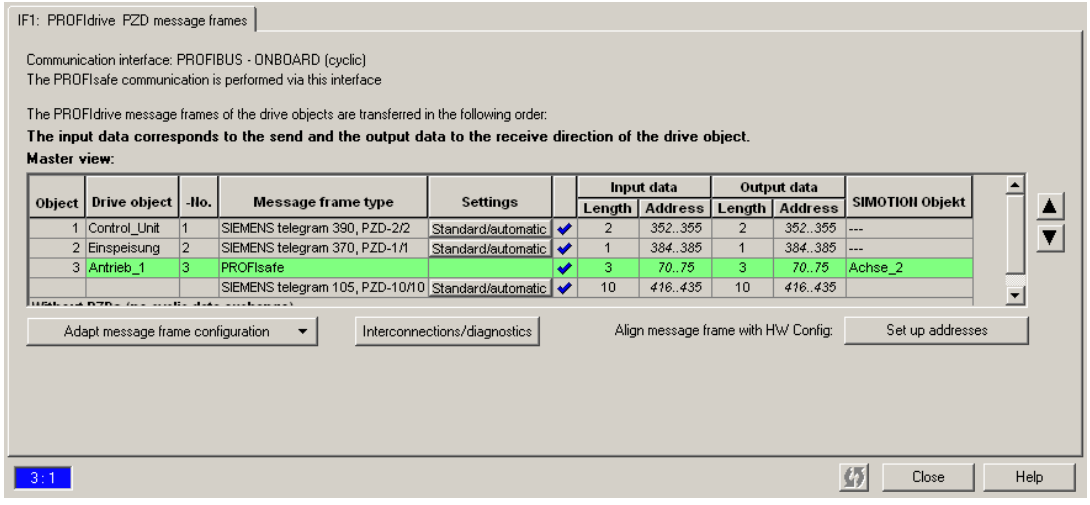

Figure 4-481 PROFIBUS message frame

7. Save and compile the project.
8. Transfer the new PROFIsafe slot to HW Config by clicking on the **Set up address** button.

9. In HW Config for the SIMOTION station, connect the preconfigured F-CPU to the SIMOTION station.(HW catalog: **PROFIBUS DP > Preconfigured stations...).**

10. The F-communication parameters are displayed in the DP slave (F-CPU) properties, tab **F Configuration**.
Mode: Displays the communication relationship. F-DX modules must be selected for data exchange broadcast. This represents a safety-related I-slave-slave relationship.
DP partner (F I/O): SINAMICS drive properties.
Here you can select the relevant PROFIsafe drive via DP address or Address.
local (safety program): SIMATIC F-CPU properties.
The logical start address for F communication of the SIMATIC F-CPU must be entered here under **Address (LADDR)**. The address space for sending and receiving safety message frames depends on the message frame used and must lie within the process image of the SIMATIC F CPU.
In the SIMATIC F-CPU safety program, this address space can be used to access the PROFIsafe control or status words.
Master address: Properties of the SIMOTION CPU.
Enter the logical start address for F communication of the SIMOTION CPU under **Input address** .
The address area for sending and receiving safety messages depends on the message frame used and must be located outside the process image of the process image of the SIMOTION CPU (>=64).
An overview of which message frames are possible for the individual drives can be found in the SIMOTION FAQs.

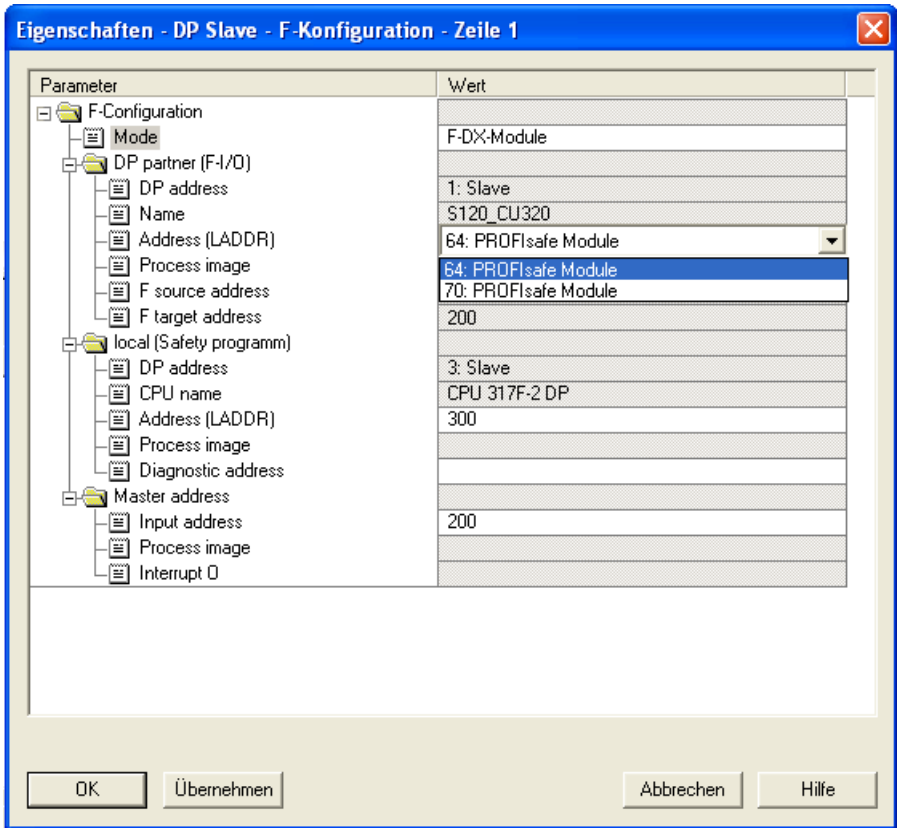

Figure 4-482 Properties of failsafe configuration for data exchange broadcast

11. Open the SIMOTION CPU project in HW Config.

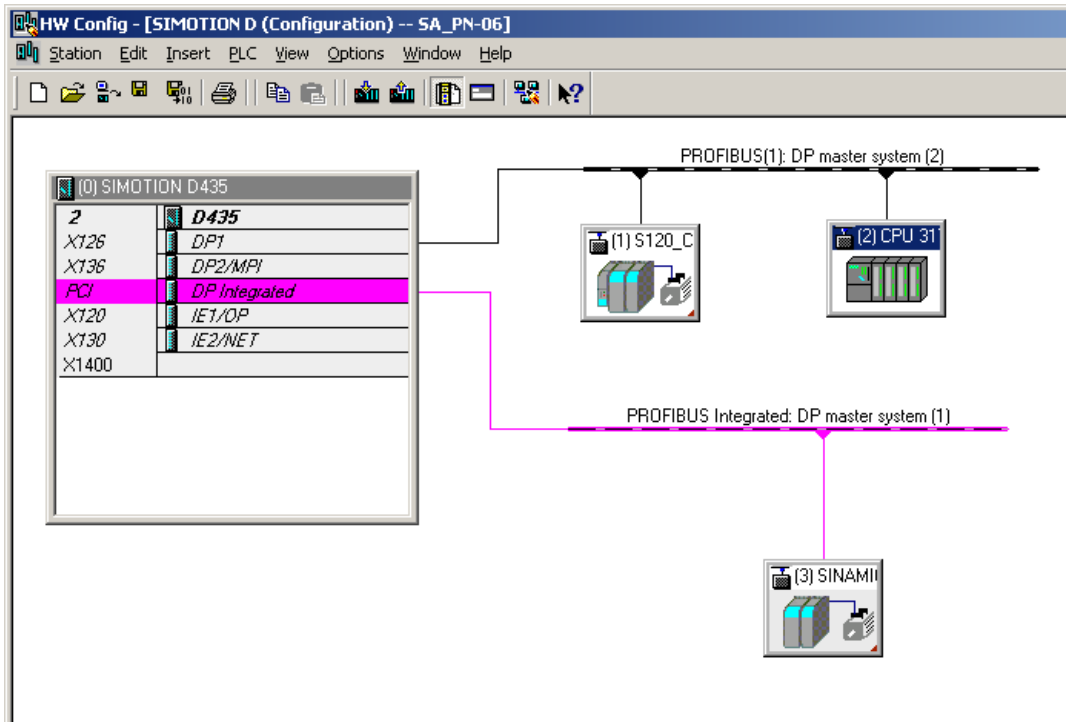

Figure 4-483 HW Config failsafe data exchange broadcast

12. Double-click on the icon of the SINAMICS drive unit and select the **Details** tab in the **Configuration** tab. Click the **PROFIsafe...** button to specify the relevant F Parameters for failsafe communication.
(If the **PROFIsafe...** button cannot be used, you need to activate it using the **Activate...** button.)
For more information about the failsafe parameters, see PROFIsafe properties for configuration (Page 2336)

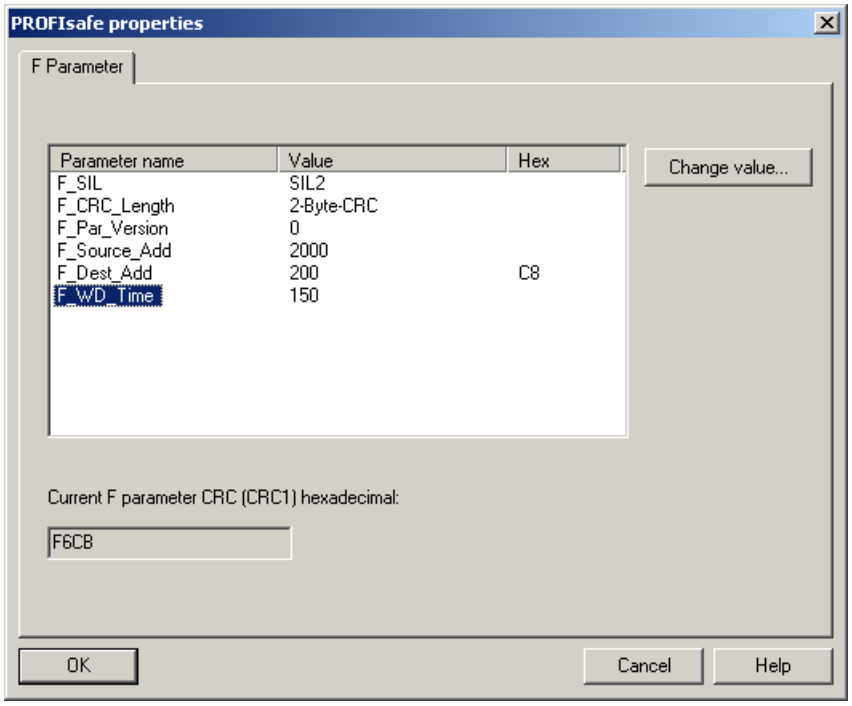

Figure 4-484 PROFIsafe properties failsafe data exchange broadcast mode V1

13. Compile HW Config of the SIMOTION CPU. Compile the F-CPU configuration data in HW Config.

Safety configuration (online) in the SINAMICS drive

1. Call the configuration for Safety Integrated by selecting the **Functions** entry in the structure tree where it says SINAMICS drive.
2. Configure Safety Integrated and set to hex representation the F_Dest_Add parameter already defined under the drive's PROFIsafe address (p9610/p9810).
3. Finally, perform a POWER ON. The safety configuration is now active in the drive.

Note

For further information on Safety configuration, see the *SINAMICS S120 Safety Integrated* Function Manual.

4.5.9.7 PROFIsafe configuration - acceptance test and reports

Acceptance tests and acceptance reports

Once configuring and commissioning has been successfully completed, an acceptance test of the drive safety functions must be carried out. This involves checking correct parameter assignment of the safety functions. The tests carried out are documented in reports.

Note

When carrying out the acceptance test for PROFIsafe communication, please note the information provided in the *SIMATIC, S7 Distributed Safety - Configuring and Programming* Programming and Operating Manual and the *SINAMICS S120 Safety Integrated* Function Manual of the drive used.

4.5.9.8 Additional information on SIMOTION and PROFIsafe

Description

Additional information on the subject of PROFIsafe is available in the following documents:

- For information on how to connect an axis to a SINAMICS drive with Safety Integrated, please refer to the TO Axis / External Encoder Function Manual.
- For information on how to configure a SINAMICS S120 drive or SINAMICS S110 drive with Safety Integrated, please refer to the following:
  - *SINAMICS S120 Function Manual*
  - *SINAMICS S120 Safety Integrated Function Manual*
  - *SINAMICS S110 Function Manual*.

4.5.9.9 Exporting/importing drive objects (DO)

Description

You can replace drive objects (DO) in an existing SIMOTION project. This means that you can replace deleted drive objects with new imported drive objects. You might need to do this, for example, if you want to replace motors with others. Whether replacement is successful or not depends on the configuration (for example, configured PROFIsafe, telegrams).

Requirement

Both the deleted drive object and the new imported drive object must meet the following conditions:

- The drive objects are the same version
- The number of deleted and the number of imported drive objects is identical
- The length of the telegrams is identical. This means, the activated technology data must be identical (TO axis) if they result in a telegram extension.
- F addresses are identical if PROFIsafe (F-Proxy) is used.

This is how you replace drive objects

1. Open the export list of the Control Unit whose drive you want to replace and navigate to parameter P978. This is where the sequence of drive objects is stored.
2. Make a note of the settings of parameter P978 or export the parameter.

   Note

   Alternatively, you can open the telegram configuration and make a mental or written note of the sequence of drive objects.

3. Delete the drive objects via the shortcut menu in the project navigator.
4. Import the new drive objects via the shortcut menu in the project navigator. The new drive objects are inserted automatically and are assigned new address ranges and positions in the telegram. You will have to change these in the next step.

NOTICE
Do not compile or align telegrams After completing this step, **do not** compile (store and compile) the project and **do not** align the telegrams.

5. Open the expert list of the CU and navigate to parameter P978.
6. Enter the sequence of drive objects you previously noted or import the previous values. Alternatively, you can open the telegram configuration and place the imported drive objects in the correct sequence using the arrow buttons on the right.
7. If symbolic assignment is active, go into the address list and open the shortcut menu in the top left field (next to the name) and run the "assignment setup" function.
8. Save and compile the project.

Note about replacing drive objects

If the above requirements for deleting and importing drive objects are not met, the project cannot be made consistent merely by adapting the sequence of drive objects. In this case, you will have to adapt the telegrams and addresses manually. If an F-Proxy is configured, the relevant drive, if it has a red background, must be deleted and created new. It may be necessary to adapt the PROFIsafe configuration on the drive.

4.5.10 PROFIdrive

4.5.10.1 Why profiles?

Profiles used in automation technology define certain characteristics, behaviors, and interfaces for devices, device groups or whole systems which specify their main and unique properties. Only devices with manufacturer-independent profiles can behave in exactly the same way on a fieldbus and thus fully exploit the advantages of a fieldbus for the user.

Profiles are specifications defined by manufacturers and users for certain characteristics, performance features, behaviors, and interfaces of devices and systems. They aim to ensure a certain degree of interoperability of devices and systems on a bus which are part of the same product family due to "profile-compliant" development.

Different types of profiles can be distinguished such as so-called application profiles (general or specific) and system profiles.

- Application profiles mainly refer to devices, in this case drives, and contain an agreed selection of bus communication methods as well as specific device applications.
- System profiles describe system classes and include the master functionality, program interfaces and integration methods.

PROFIdrive

PROFIdrive is a device-specific (Drives) application profile. PROFIdrive essentially describes a "standard interface" for drives to PROFIBUS and PROFINET. It contains a detailed description of how the communication functions "data exchange broadcast", "equidistance" and "isochronous operation" are used in drive applications. In addition, it specifies all device characteristics which influence interfaces connected to a controller over PROFIBUS or PROFINET. This also includes the State machine (sequential control), the encoder interface, the normalization of values, the definition of standard telegrams, the access to drive parameters, the drive diagnostics, etc.

The PROFIdrive profile supports both central as well as distributed motion control concepts.

The basic philosophy: – Keep it simple –

The PROFIdrive profile tries to keep the drive interface as simple as possible and free from technology functions. This philosophy ensures that reference models as well as the functionality and performance of the PROFIBUS/PROFIDRIVE masters have no or very little effect on the drive interface.

4.5.10.2 PROFIdrive overview

The PROFIdrive Profile

The PROFIdrive profile defines the device behavior and the access procedure to drive data for drives on PROFIBUS and on PROFINET, from simple frequency converters up to high performance servo controllers.

PROFIdrive is split into a general part and a bus-specific part. The following properties are defined in the general part.

- Base model
- Parameter model
- Application model

The following assignments are made in the bus-specific part:

- PROFIdrive to PROFIBUS
- PROFIdrive to PROFINET

Details of where to find a precise description of the PROFIdrive profile are given below.

4.5.10.3 PROFIdrive base/parameter model

Description

The PROFIdrive base model describes an automation system in terms of a number of devices and their interrelationships (application interfaces, parameter access).

Table 4-245 The base model distinguishes between the following device classes:

PROFIdrive device class	PROFIBUS DP	PROFINET IO
Controller (higher-level controller or host of the automation system)	DP master Class 1	IO controller
Peripheral device (P device)	DP Slave (I-slaves)	IO device
Supervisor (engineering station)	DP master Class 2	IO supervisor

PROFIdrive device classes

In the picture below, the possible communication relationships of the PROFIdrive device classes are presented.

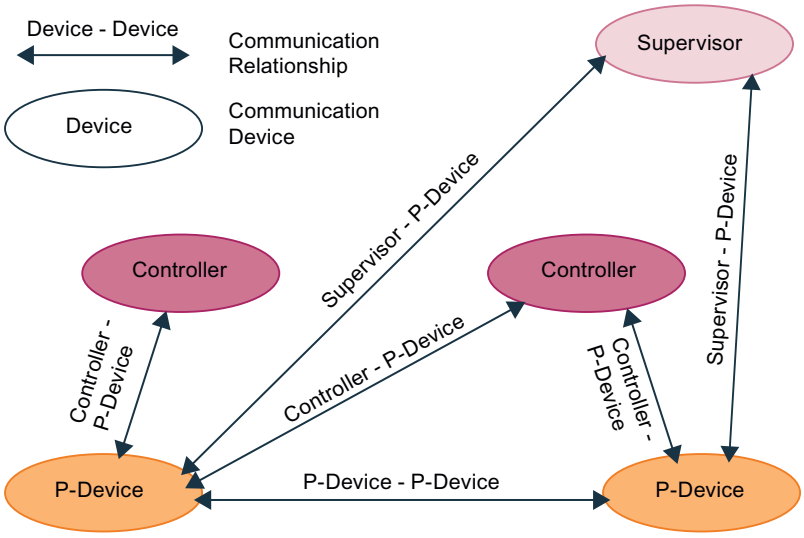

Figure 4-485 Communication between device classes according to PROFIdrive

Example of a PROFIdrive automation concept

The graphic below shows a typical automation concept.

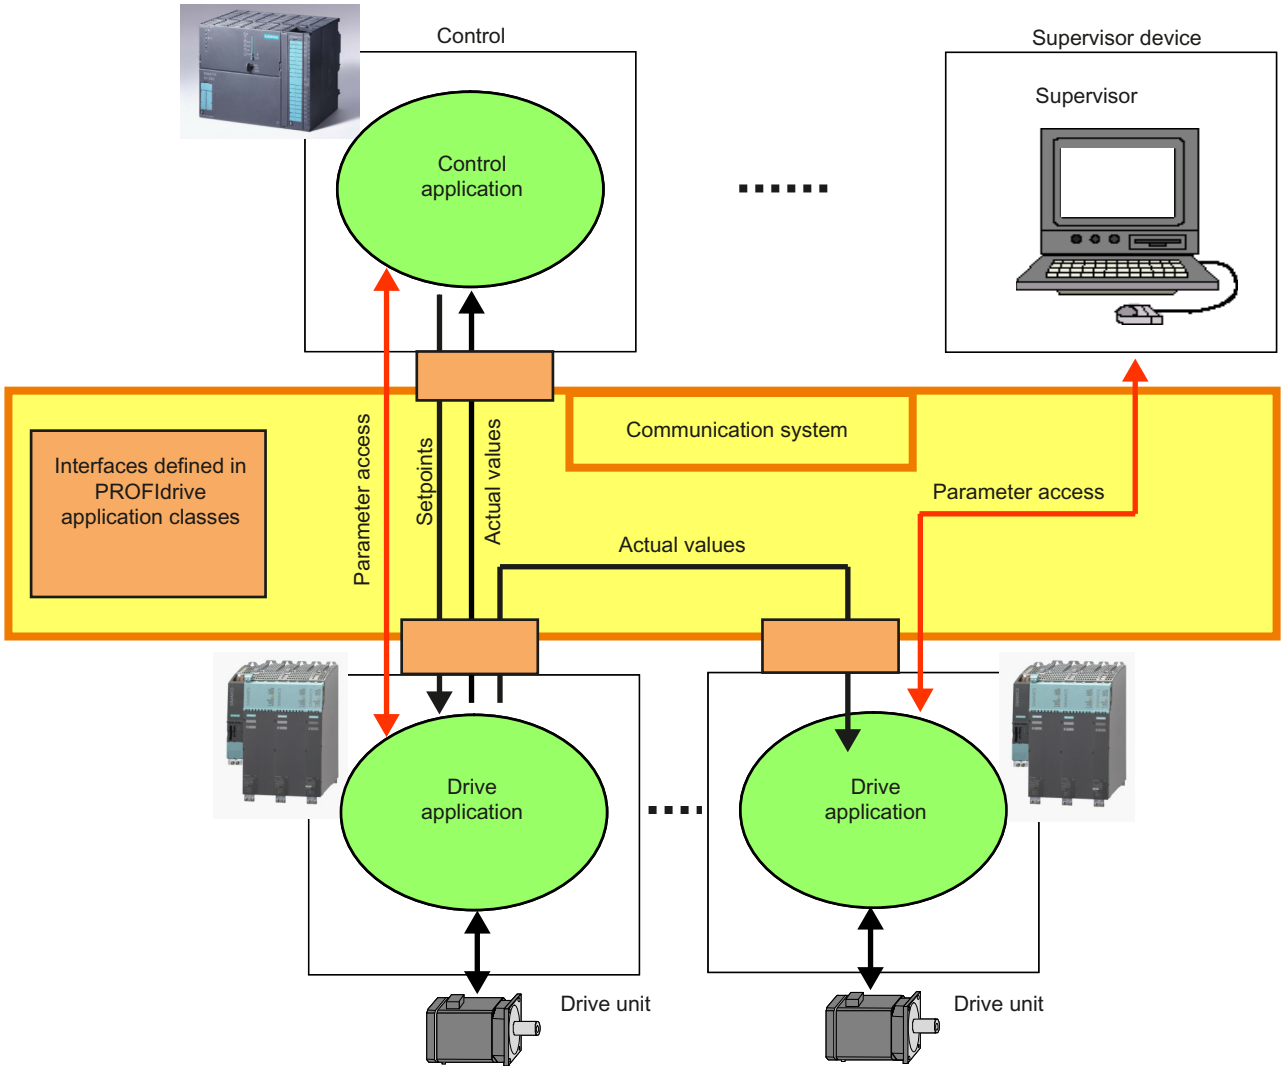

Figure 4-486 Automation concept

Communication services

Two communication services are defined in the PROFIdrive profile; namely, cyclic data exchange and acyclic data exchange.

- Cyclic data exchange via a cyclic data channel
  Motion control systems need cyclically updated data during operation for open- and closed-loop control purposes. This data must be sent to the drive units in the form of setpoints or transmitted from the drive units in the form of actual values, via the communications system. Transmission of this data is usually time-critical.
- Acyclic data exchange via an acyclic data channel
  In addition to cyclic data exchange, there is an acyclic parameter channel for exchanging parameters between the control/supervisor and drive units. Access to this data is not time-critical.

The graphic below shows the data model and data flow in the P device.

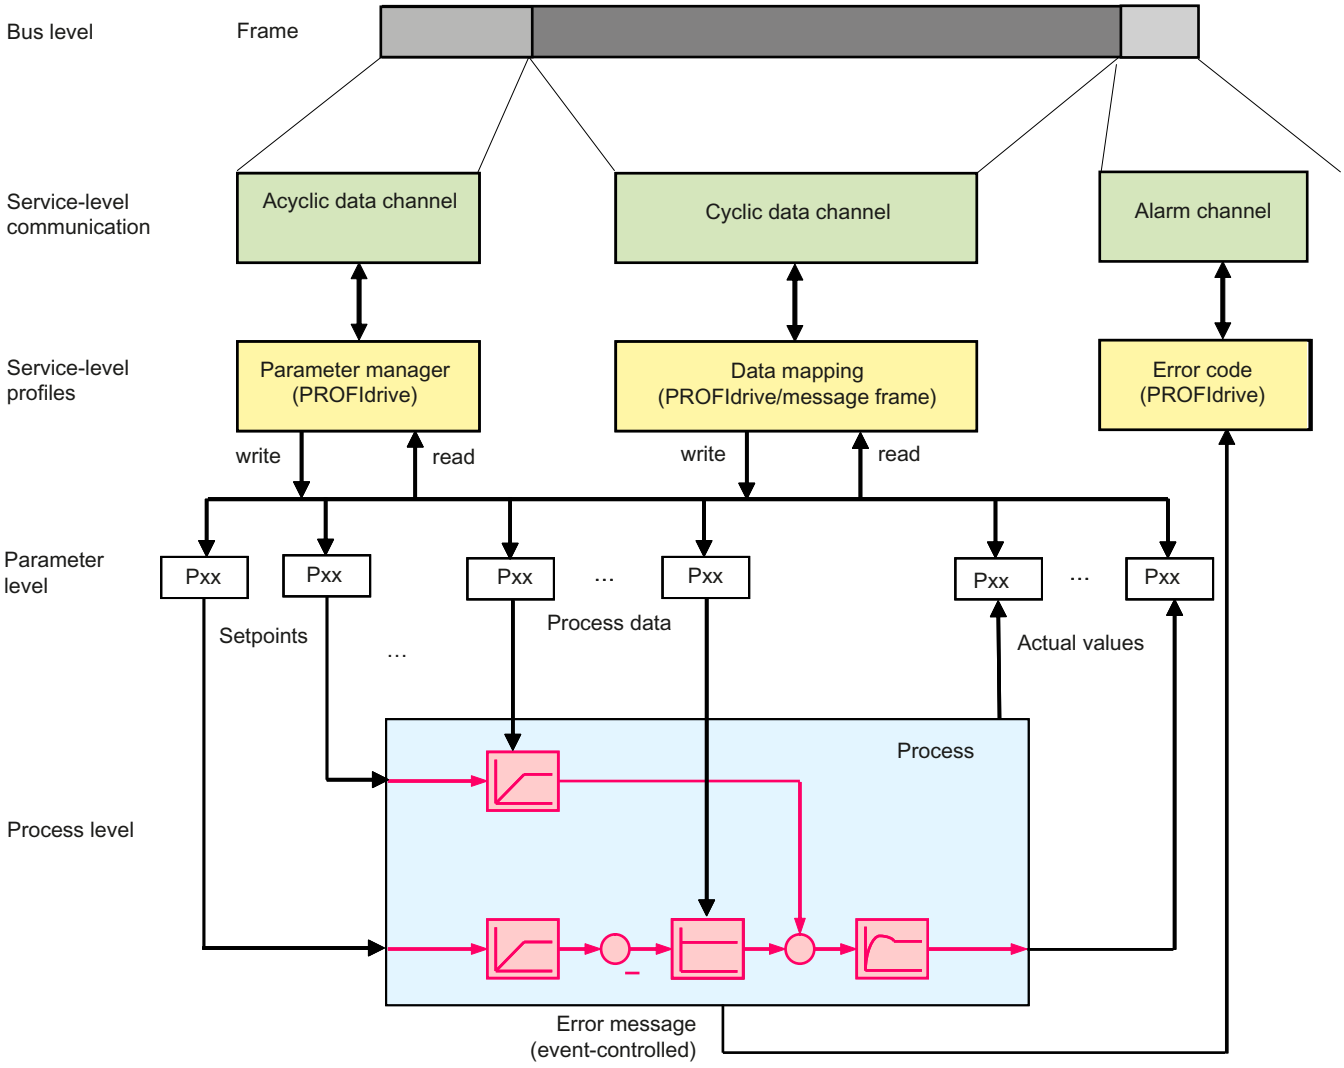

Figure 4-487 Data model and data flow in the P device

Alarms and error messages

Alarms are output on an event-driven basis, and show the occurrence and expiry of error states.

Parameter model

The parameter model in the PROFIdrive profile makes a distinction between profile parameters and manufacturer-specific parameters:

- Profile parameters are defined for objects derived from the device model of the PROFIdrive profile. These may include general functions such as drive identification, fault buffer, or drive control, for example. These parameters are the same for all drives. The profile-specific parameters are in the range 900–999 and 60,000–65,535.
- All other parameters are manufacturer-specific. The parameters are defined by the interface for the application process, rather than by the profile. The manufacturer-specific parameters are in the range 1–699 and 1,000–59,999.

Access to a parameter's elements (values, parameter descriptions, text elements) essentially works on an acyclic basis (with the exception of G120 drives, which can exchange data cyclically with PIV). An independent request/response data structure is defined for this purpose.

PROFIdrive defines a device model based on function modules which cooperate in the device and generate the intelligence of the drive system.

Objects are assigned to these modules that are described in the profile and defined in terms of their function. The overall functionality of a drive is therefore described through the sum of its parameters.

PROFIdrive defines the access mechanism to the parameter (PROFIdrive parameter channel) and approx. 70 profile-specific parameters; e.g. for fault buffer, drive control, and device identification.

All other parameters are manufacturer-specific which gives drive manufacturers great flexibility with respect to implementing control functions. The elements of a parameter are accessed acyclically using what is known as "Base Mode Parameter Access".

PROFIdrive uses DP V0, DP V1, and the DP V2 expansions for PROFIBUS, and the slave data exchange broadcast and isochronous operation functions contained within them as the communication protocol.

PROFIdrive for PROFINET contains the functions PROFINET RT, PROFINET (isochronous mode) and IO controller–IO device communication.

Specifications for PROFIBUS and PROFINET IO (Page 2422)

4.5.10.4 Segmentation in application classes

Integration of drives in automation solutions

The integration of drives into automation solutions depends strongly upon the drive task. To cover the extensive range of drive applications from the most simple frequency converter up to highly dynamic, synchronized multi-axis systems with a single profile, PROFIdrive defines six application categories which can be applied to most drive applications.

Table 4-246 Application classes

Category	Drive
Category 1	Standard drives (such as pumps, fans, agitators, etc.); implemented in SIMOTION and SINAMICS
Category 2	Standard drives with technology functions
Category 3	Positioning drives; implemented in SIMOTION and SINAMICS
Category 4	Motion control drives with central, higher-level motion control intelligence and the "Dynamic Servo Control" position control concept; implemented in SIMOTION and SINAMICS
Category 5	Motion control drives with central, higher-level motion control intelligence and position setpoint interface
Category 6	Motion control drives with distributed, motion control intelligence integrated in the drives

Application classes

Application category 4 is the most important for highly dynamic and highly complex motion control tasks. This application category describes in detail the master/slave relationship between the controller and the drives which are connected to each other over PROFIBUS and PROFINET. The position control loop is closed via the bus. The synchronization of the position control cycles in the control and in the speed controllers in the drive requires a clock synchronization (PROFIBUS DP-V2 or PROFINET with IRT).

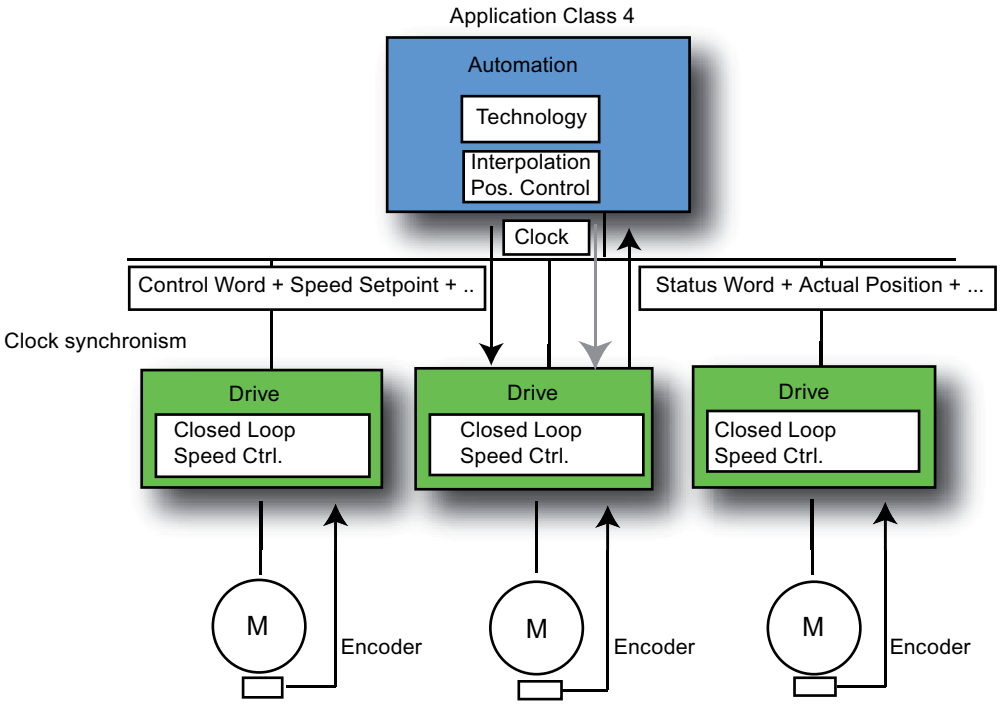

Figure 4-488 Application classes

Using the DSC function (Dynamic Servo Control), the dynamic interference immunity of the position control loop is increased considerably for mechanically rigid systems. This is achieved using an additional minimum dead time position feedback in the drive. As a result, short position control cycle clocks (e.g. for servo 125 µs in the SINAMICS S) are enabled and transmission dead time on the bus then only has an effect on the control behavior of the axis.

4.5.10.5 PROFIdrive-specific data types

Description

A range of data types have been defined for the purpose of using communication that is compliant with PROFIdrive. You will find detailed information on this in the following standards:

- IEC 61800-7-203
- IEC 61800-7-303
- IEC 61158-5

These standards contain detailed descriptions of the data types. The most important data types are listed below. Data types are provided by the _readDriveParameterDescription function, for example.

Note

For the communication with SINAMICS, you will have to use the AnyType_to_BigByteArray() or BigByteArray_to_AnyType() SIMOTION system functions to perform a type conversion for different data types (normalized value N2, N4; normalized value X2, X4; fixed-point value E2, C4 and time constants T2 and T4).

PROFIdrive profile-specific and standard data types

Data types used in the PROFIdrive profile	Definition	Coding (dec.)
Standard data types		
Boolean	Boolean (IEC 61158-5)	1
Integer8	Integer8 (IEC 61158-5)	2
Integer16	Integer16 (IEC 61158-5)	3
Integer32	Integer32 (IEC 61158-5)	4
Unsigned8	Unsigned8 (IEC 61158-5)	5
Unsigned16	Unsigned16 (IEC 61158-5)	6
Unsigned32	Unsigned32 (IEC 61158-5)	7
FloatingPoint32	Float32 (IEC 61158-5)	8
FloatingPoint64	Float64 (IEC 61158-5)	15
VisibleString	VisibleString (IEC 61158-5)	9
OctetString	OctetString (IEC 61158-5)	10
TimeOfDay (with date indication)	TimeOfDay (IEC 61158-5)	11
TimeDifference	TimeDifference (IEC 61158-5)	12
Date	Date (IEC 61158-5)	13
TimeOfDay (without data indication)	TimeOfDay (IEC 61158-5)	52
TimeDifference (with data indication)	TimeDifference (IEC 61158-5)	53
TimeDifference (without data indication)	TimeDifference (IEC 61158-5)	54
Specific data types	**See below for description**	
N2 (normalized value (16-bit))		113
N4 (normalized value (32-bit))		114
V2 bit sequence		115
L2 nibble		116
R2 reciprocal time constant		117
T2 time constant (16-bit)		118
T4 time constant (32-bit)		119
D2 time constant		120
E2 fixed-point value (16-bit)		121
C4 fixed-point value (32-bit)		122

Data types used in the PROFIdrive profile	Definition	Coding (dec.)
X2 normalized value, variable (16-bit)		123
X4 normalized value, variable (32-bit)		124

Normalized value N2, N4

Linear normalized value, 0% corresponds to 0 (0x0), 100% corresponds to 2^{14} (0x4,000) for N2, or 2^{30} (0x40,000,000) for N4. The length is 2 or 4 octets.

Coding

Represented in two's complement; MSB (most significant bit) is the first bit after the sign bit (SN) of the first octet.

- SN = 0; positive numbers with 0
- SN = 1; negative numbers

Range of values N2, N4	Resolution N2, N4	Cod. N2, N4 (dec.)	Octet	Bit							
8	7	6	5	4	3	2	1				
-200% ≤ i ≤ (200-2^{-14})%	2^{-14} = 0,0061%	113	1	SN	2^{0}	2^{-1}	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}
			2	2^{-7}	2^{-8}	2^{-9}	2^{-10}	2^{-11}	2^{-12}	2^{-13}	2^{-14}
-200% ≤ i ≤ (200-2^{30})%	$2^{-30,}$ = 9,3 * 10^{-8}%	114	3	2^{-15}	2^{-16}	2^{-17}	2^{-18}	2^{-19}	2^{-20}	2^{-21}	2^{-22}
			4	2^{-23}	2^{-24}	2^{-25}	2^{-26}	2^{-27}	2^{-28}	2^{-29}	2^{-30}

Normalized value X2, X4 (example X = 12/28)

Linear normalized value, 0% corresponds to 0 (0x0), 100% corresponds to 2^{x}. These structures are identical to N2 and N4, except that normalization is variable. Normalization can be determined from the parameter descriptions. The length is 2 or 4 octets.

Coding

Represented in two's complement; MSB (most significant bit) is the first bit after the sign bit (SN) of the first octet.

- SN = 0; positive numbers with 0
- SN = 1; negative numbers

Range of values X2, X4	Resolution X2, X4	Cod. X2, X4 (dec.)	Octet	Bit							
8	7	6	5	4	3	2	1				
-800% ≤ i ≤ 800-2^{-12})%	2^{-12}	123	1	SN	2^{2}	2^{1}	2^{0}	2^{-1}	2^{-2}	2^{-3}	2^{-4}
			2	2^{-5}	2^{-6}	2^{-7}	2^{-8}	2^{-9}	2^{-10}	2^{-11}	2^{-12}
-800% ≤ i ≤ 800-2^{-28})%	2^{-28}	124	3	2^{-13}	2^{-14}	2^{-15}	2^{-16}	2^{-17}	2^{-18}	2^{-19}	2^{-20}
			4	2^{-21}	2^{-22}	2^{-23}	2^{-24}	2^{-25}	2^{-26}	2^{-27}	2^{-28}

Fixed-point value E2

Linear fixed-point value with seven places after the decimal point. 0 corresponds to 0 (0x0), 128 corresponds to 2^{14} (0x4,000). The length is 2 octets.

Coding

Represented in two's complement; MSB (most significant bit) is the first bit after the sign bit (SN) of the first octet.

- SN = 0; positive numbers with 0
- SN = 1; negative numbers

Range of values E2	Resolution	Cod. (dec.)	Octet	Bit							
8	7	6	5	4	3	2	1				
$-256+2^{-7} \le i \le 256-2^{-7}$	$2^{-7} = 0{,}0078125$	121	1	SN	2^7	2^6	2^5	2^4	2^3	2^2	2^1
			2	2^0	2^{-1}	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	2^{-7}

Fixed-point value C4

Linear fixed-point value with four places after the decimal point. 0 corresponds to 0 (0x0), 0.0001 corresponds to 2^0 (0x0000 0001).

Coding

As with Integer32, the weighting of the bits has been reduced by a factor of 10,000.

Range of values	Resolution	Coding (dec.)	Length
$-214{,}748.3648 \le i \le 214{,}748.3648$	$10^{-4} = 0{,}0001$	122	4 octets

Bit sequence V2

Bit sequence for checking and representing application functions. 16 Boolean variables are combined to form 2 octets.

Range of values	Resolution	Cod. (dec.)	Octet	Bit							
8	7	6	5	4	3	2	1				
		115	1	15	14	13	12	11	10	9	8
			2	7	6	5	4	3	2	1	0

Nibble (half-byte) L2

Four associated bits make up a nibble. Four nibbles are represented by two octets.

Coding

Range of values	Resolution	Cod. (dec.)	Octet	Bit				
8	7	6	5	4	3	2	1	
-	-	116	1	Nibble 3				Nibble 2
			2	Nibble 1				Nibble 0

Overview of time constants T2, T4, D2, and R2

Note

The values for the time parameters of types D2, T2, T4, and R2 always relate to the specified, constant sampling time T_a. The associated sampling time (parameter p0962) is required to interpret the internal value.

Time constants T2 and T4

Time data as a multiple of sampling time T_a. Interpreted value = internal value * T_a

Coding

- T2: As with Unsigned16, with a restricted range of values of $0 \le x \le 32767$.
  When interpreted, internal values that fall outside this range of values are set to 0.
- T4: As with Unsigned32

Range of values	Resolution	Coding (dec.)	Length
$0 \le i \le 32{,}767 * T_a$	T_a	118	2 octets
$0 \le i \le 4{,}294{,}967{,}295 * T_a$	T_a	119	4 octets

Time constant D2

Time data as a fraction of the constant sampling time T_a. Interpreted value = internal value * T_a/16384

Coding

- T2: As with Unsigned16, with a restricted range of values of $0 \le x \le 32767$.
  When interpreted, internal values that fall outside this range of values are set to 0.

Range of values	Resolution	Coding (dec.)	Length
$0 \le i \le (2\text{-}2^{-14}) * T_a$	T_a	120	2 octets

Time constant R2

Time data as a reciprocal multiple of the constant sampling time T_a. Interpreted value = 16384 * T_a/internal value

Coding

- T2: As with Unsigned16, with a restricted range of values of $1 \leq x \leq 16,384$.
  When interpreted, internal values that fall outside this range of values are set to 16,384.

Range of values	Resolution	Coding (dec.)	Length
$1 * Ta \leq i \leq 16,384 * T_a$	T_a	117	2 octets

4.5.10.6 Acyclic communication (Base Mode Parameter Access)

Acyclic communication

Description

PROFIdrive drive devices are supplied with control signals and setpoints by the controller and return status signals and actual values.

These signals are transferred cyclically between the controller and the drive.

In addition, PROFIdrive drive devices recognize parameters in which additional, necessary data are held; such as error codes, warnings, controller parameters, motor data, etc. This data is not usually transmitted cyclically, but "acyclically" only when required. Commands for the drive can also be transferred using parameter accesses.

The reading/writing of parameters from PROFIdrive units is always performed acyclically, using what is known as "Base Mode Parameter Access". "Base Mode Parameter Access" can be used with both PROFIBUS and PROFINET. For differences between PROFIBUS and PROFINET, please refer to Specifications for PROFIBUS and PROFINET IO (Page 2422).

This service is defined and provided by PROFIdrive, and it can be used in parallel to the cyclic communication on the relevant bus. The PROFIdrive profile specifies precisely how this basic mechanism is used for read/write access to parameters of a PROFIdrive-compliant drive.

Note

The DPV1lib significantly simplifies configuration of acyclic communication. You can find it on the SIMOTION DVD U&A under **Applications > Cross-Sector Applications > Drive Communication**.

Reading and writing parameters with Base Mode Parameter Access

Description

Base Mode Parameter Access, whose structure is defined in the PROFIdrive profile, is always used for communicating the writing/reading parameters for PROFIdrive units such as SINAMICS S120. The structure is also contained, for example, in the **Acyclic communication** section of the SINAMICS S120 Function Manual.

Under this arrangement, parameter access always consists of:

- Write request ("Write data set")
- Read request ("Read data set")

This sequence must be observed, irrespective of whether read or write access is involved.

A "Write data record" is used to transfer the parameter job (request); for example, read parameter x. A "Read data record" is used to fetch the response for this parameter job (value of parameter x).

The following figure shows the method of operation of the parameter channel on reading/ writing the data set.

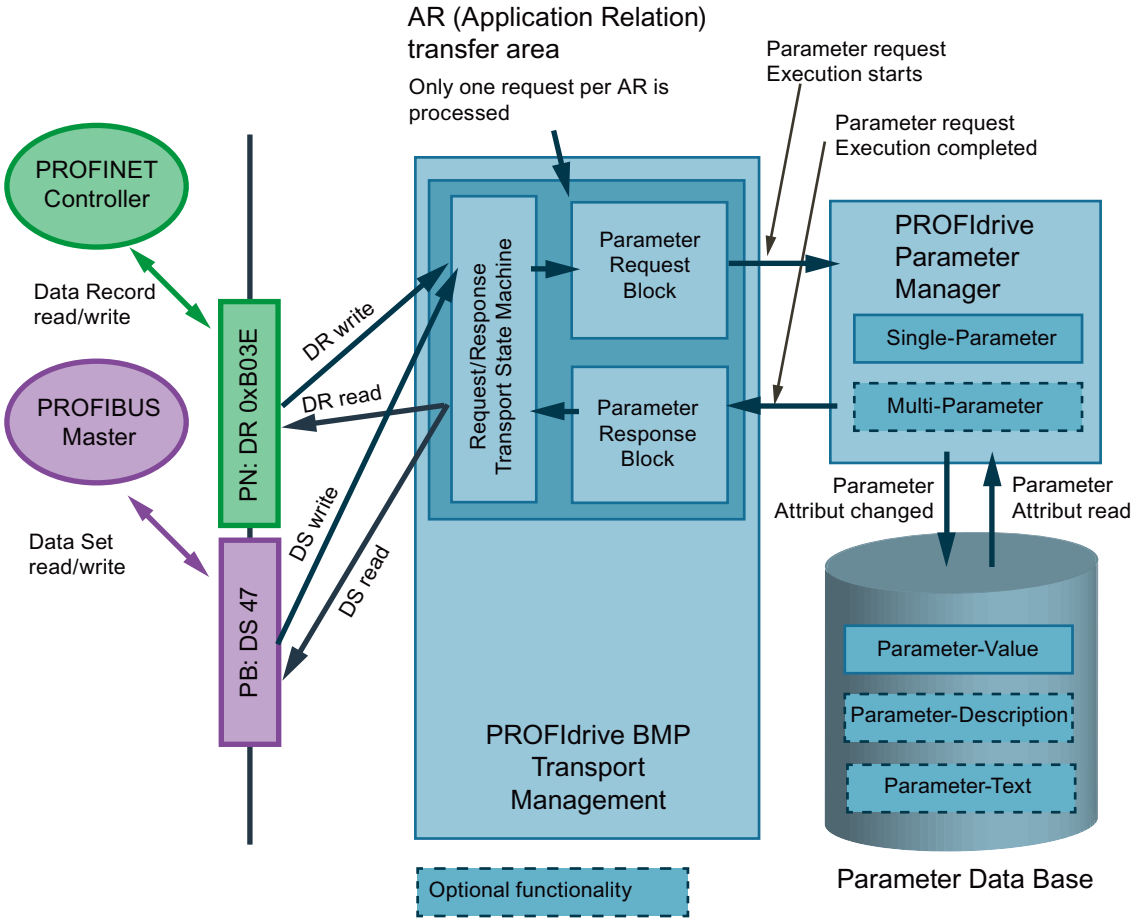

Figure 4-489 Function of the PROFIdrive parameter channel

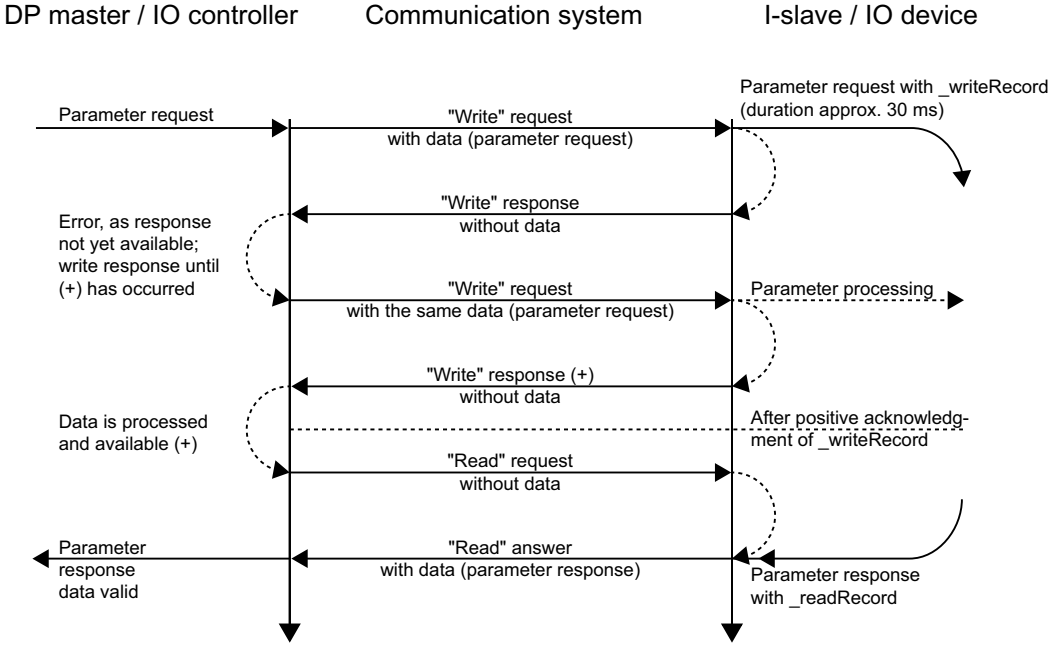

Figure 4-490 Reading and writing acyclically

The figure **Reading and writing acyclically** shows that both "Write data set" and "Read data set" consist of the following elements:

- Request
- Response

Writing parameter records

Initially, data (P request/response data set) is transmitted to the job structure for the purpose of writing (one or more) parameter values. The data is subsequently transmitted with "Write data set" using _writeRecord. Repeated instances of "Write data set" (_writeRecord without data) can be used to monitor the status until a positive acknowledgment is given. With a "Read data set" request (_readRecord), execution is requested in the target device.

Note

An instance of "Write data set" without data enables the status of "Write data set" with data to be determined until the positive acknowledgment is given.

If "Write data set" is successfully completed, this only signifies that the data set has been transmitted via the communication path without any errors; it does not signify that the action has been executed without any errors in the target device. This is checked by the subsequent "Read data set" request.

Reading parameter records

For the purpose of reading parameter values, the data block for determining which parameter(s) is/are to be read is created first. This data record is transferred to the drive as a request using "Write data record" (_writeRecord). A subsequent "Read data set" (_readRecord) as a request then returns the requested values one time.

The processes are also represented above in the form of a diagram.

The PROFIdrive profile specifies how data larger than one byte is to be transferred. The so-called "Big Endian" format, the highest value parts are transferred first, is used:

WORD		High Byte (Byte 1)	Low Byte (Byte 2)
DOUBLE WORD	High Word	High Byte (Byte 1)	Low Byte (Byte 2)
	Low Word	High Byte (Byte 3)	Low Byte (Byte 4)

WORD and DWORD representation in Big Endian format

Since the control has a different internal data representation in certain cases, an explicit conversion must be performed when grouping and evaluating the data in the P request/ response data block (data set 47).

A conversion may be required for SIMOTION, see Program example (Page 2446).

Rule 5 - a maximum of eight concurrent calls is possible in SIMOTION (Page 2434)

Parameter request/response data set (Page 2419)

Parameter request/response data set

Structure of the P request/response data set

This always consists of:

- Header (job identifier (request/change), job reference (job ID), number of parameters in the job, target axis / drive object ID)
- Parameter details (number of elements / indices, attribute, parameter number, subindex)
- Parameter values (only with job identifier "Change")

The data transmitted for a WRITE or READ request has the following structure.

	Job parameters	**Byte n+1**	**Byte**	**Offset**
Header	Request Header	Request Reference	RequestID	0
		Axis	Number of parameters	2
Details	1. parameter	Attribute	Number of elements	4
		Parameter number		6
		Subindex		8
	...			
	nth parameter	Attribute	Number of elements	
		Parameter number		
		Subindex		
Only write values for parameter (change)	1. parameter value(s)	Format	Number of values	
		Values		
	...			
	nth parameter value(s)	Format	Number of values	
		Values		
		...		

Structure after Base Mode Parameter Access - Parameter Request

The following structure is defined for the subsequent Parameter Response. This is received after a request with _readRecord (request).

	Parameter response	**Byte n+1**	**Byte**	**Offset**
	Request Header	Request Reference mirrored	RequestID mirrored or error	0
		Axis no./DO ID mirrored	Number of parameters	2

	Parameter response	Byte n+1	Byte	Offset
Only read values for parameter (request) / Error values for negative response only	1. parameter value(s)	Format	Number of values	4
		Values or error codes		6
		...		
	...			
Only read values for parameter (request) / Error values for negative response only	nth parameter value(s)	Format	Number of values	
		Values or error codes		
		...		

Structure after Base Mode Parameter Access - Parameter Response

The exact coding of the individual parts of the data structure can be obtained from the PROFIdrive profile or the SINAMICS S120 Function Manual. The assignment of "Request" and the related answer "Response" for "Write data record" or "Read data record" using the "Request Reference" job reference is important.

Request Reference

The "Request Reference" is used for the assignment of the write request to the following read request, and the response that follows thereafter, because the control can, in principle, process several actions (as many as 8) in parallel for different target devices using the same fieldbus.

Description of fields in parameter job and response

Field	Data type	Values	Comments
Job reference	Unsigned8	0x01 to 0xFF	
	Unique identification of the job/response pair for the master. The master changes the job reference with each new job. The slave mirrors the job reference in its response.		
Job identifier	Unsigned8	0x01 0x02	Read job Write job
	Specifies the type of job. In the case of a write job, the changes are made in a volatile memory (RAM). A save operation is needed in order to transfer the modified data to the non-volatile memory (p0971, p0977).		

Field	Data type	Values	Comments
Response ID	Unsigned8	0x01 0x02 0x81 0x82	Read job(+) Write job(+) Read job(-) Write job(-)
	Mirrors the job identifier and specifies whether job execution was positive or negative. Negative means: Cannot execute part or all of job. The error values are transferred instead of the values for each subresponse.		
Drive object number	Unsigned8	0x01 to 0xFE	Number
	Setting for the drive object number on a drive unit with more than one drive object. Different drive objects with separate parameter number ranges can be accessed over the same DPV1 connection.		
Number of parameters	Unsigned8	0x01 to 0x27	No. 1 to 39 Limited by DPV1 telegram length
	Defines the number of adjoining areas for the parameter address and/or parameter value for multi-parameter jobs. The number of parameters = 1 for single jobs.		
Attribute	Unsigned8	0x10 0x20 0x30	Value Description Text (not implemented in the case of SINAMICS)
	Type of parameter element accessed		
Number of elements	Unsigned8	0x00 0x01 ... 0xEA	Special function No. 1 to 234 Limited by DPV1 telegram length
	Number of array elements accessed		
Parameter number	Unsigned16	0x0001 to 0xFFFF	No. 1 to 65535
	Addresses the parameter accessed		
Subindex	Unsigned16	0x0000 to 0xFFFE	No. 0 to 65534
	Addresses the first array element of the parameter to be accessed		
Format	Unsigned8	0x02 0x03 0x04 0x05 0x06 0x07 0x08	Data type Integer8 Data type Integer16 Data type Integer32 Data type Unsigned8 Data type Unsigned16 Data type Unsigned32 Data type FloatingPoint
		Other values:	See PROFIdrive PROFILE v3.1
		0x40	Zero (without values as a positive subresponse of a write request)
		0x41 0x42 0x43 0x44	Byte Word Double word Error
	The format and number specify the adjoining space containing values in the telegram. Data types in conformity with PROFIdrive Profile shall be preferred for write access. Bytes, words, and double words are also possible as a substitute.		

Field	Data type	Values	Comments
Number of values	Unsigned8	0x00 to 0xEA	No. 0 to 234 Limited by DPV1 telegram length
	Specifies the number of subsequent values.		
Error values	Unsigned16	0x0000 to 0x00FF	Meaning of error values --> see table 4-29
	The error values in the event of a negative response. If the values make up an odd number of bytes, a zero byte is appended. This ensures the integrity of the word structure of the telegram.		
Values	Unsigned16	0x0000 to 0x00FF	
	The values of the parameter for read or write access. If the values make up an odd number of bytes, a zero byte is appended. This ensures the integrity of the word structure of the telegram.		

For more information on coding PROFIdrive data types, see PROFIdrive-specific data types (Page 2410).

Reading and writing parameters with Base Mode Parameter Access (Page 2416)

Specifications for PROFIBUS and PROFINET IO

Global and local parameters

PROFIdrive makes a distinction between two parameter ranges:

- Global parameters; these are assigned to the drive unit as a whole. If you address different DOs on a drive unit, a global parameter will always show the same value.
- Local parameters; these parameters are specific to an axis or a DO. Axis-specific and DO-specific parameters can have different values for each axis/DO.

In view of this, there are two different types of access under Base Mode Parameter Access:

- Base Mode Parameter Access - local (BMPL)
- Base Mode Parameter Access - global (BMPG)

Note

The PROFIdrive standard states that "pipelining" of jobs on PROFIdrive drives (PROFINET and PROFIBUS) is not supported. For each drive unit/DO, only one "Write/read data set" per AR (Application Relationship = communication relationship = controller) is possible.

If, however, more than one PROFIdrive drive unit is connected to a controller via PROFIBUS or PROFINET, one job can be processed in parallel for each of these drive units. The maximum number then depends on the controller. The data for SIMOTION is specified in Rule 5 - a maximum of eight concurrent calls is possible in SIMOTION (Page 2434).

Specific properties of acyclic communication with PROFIBUS

For communication via PROFIBUS, data set 47 (0x002F) is used to access parameters in PROFIdrive drives. Data set 47 is the parameter access point (PAP). Only the global (BMPG) access option is available on PROFIBUS devices. The desired DOs are addressed by supplying the DO ID in the parameter request job structure.

- Base Mode Parameter Access – global; the drive unit's parameters (all DOs, global and local parameters) can be addressed via all the drive unit's PAPs. The SINAMICS devices have a PAP on each PROFIBUS module. Strictly speaking, the PAP is a data record in the PROFIBUS module.

Specific properties of acyclic communication with PROFINET IO

When using PROFINET nothing changes in the fundamental processes for parameter access; however, there are two PAPs available per DO / module.

Note

The MAP submodule is the DO proxy and hosts the alarm channel along with one or more PAPs (Parameter Access Point). The PAP is a data record in the MAP submodule. MAP is displayed in the GSD file.

In principle, with both BMPL (data set number 0xB02E) and BMPG (data set number 0xB02F) it is possible to access global parameters of a drive via any parameter access point (PAP/MAP) of the drive.

With **BMPL**, when accessing local parameters (DO), addressing automatically takes place at the local parameters of the DO to which the PAP/MAP is assigned. Therefore, there is no need to specify the DO ID in the parameter request structure, or this will be ignored by the drive.

Use case:
Each axis (DO) has its own parameter access point (this is necessarily the case in single-axis drives). The axis is selected using the logical address; the user does not need to worry about managing the DO IDs.
We recommend this type of access for new projects.

With **BMPG**, it is possible to access not only local parameters of a specific DO via the PAP/MAP of the DO, but also local parameters of other DOs. The required DO is addressed via the DO ID in the parameter request structure. This means that in the case of BMPG, a valid DO ID must also be transferred in all cases.

Use case:
If access to the parameters of a multi-axis drive is only to take place via a PAP/MAP (logical address), or if parameters are to be read to DOs that do not have a dedicated MAP/PAP (particularly PROFIBUS devices). In the case of BMPG, the user is responsible for managing the DO IDs for this purpose.
With this type of access, you remain compatible with old or existing user programs which previously ran on PROFIBUS.

Error assessment

Description

Two different types of errors can occur in conjunction with Base Mode Parameter Access services:

- Error in the communication (transfer of data)
  For example, the addressed device may not exist and is not switched on. This type of error is indicated with the return values of the system functions and is defined in the description of the system functions in the SIMOTION reference lists.
- Error during the processing of the jobs themselves
  For example, an attempt is made to write to a read-only parameter.
  Error codes for this second type of error are defined for PROFIdrive-compliant drives in the PROFIdrive standard and listed below.
  The ID 0x81 (hex) or 0x82 (hex) response indicates an error for the parameter access.
  Error codes are returned in the drive unit's response in the P response data block (see table below). The "Format" field in the parameter response can be used to distinguish whether the queried parameter represents an error code or a "true" value. See the Structure after Base Mode Parameter Access - parameter response (Page 2419) table, offset 4, "Format".
  This table also contains the coding for the "Format" field. Code 0x44 (hex) indicates an error code in the "Values" field. Other "Format" values specify the number format (e.g. Bool, Byte, Integer8, etc.) with which the value in the "Values" field was returned.

Note

The error codes up to 0x20 correspond to the PROFIdrive profile. The error codes from 0x65 onwards are manufacturer-specific and may, therefore, vary from drive to drive.

Error codes in Base Mode Parameter Access responses

Error code	Meaning	Comments	Additional info
0x00	Illegal parameter number	Access to a parameter which does not exist	–
0x01	Parameter value cannot be changed.	Modification access to a parameter value which cannot be changed	Subindex
0x02	Lower or upper value limit exceeded	Modification access with value outside value limits	Subindex
0x03	Invalid subindex	Access to a subindex which does not exist	Subindex
0x04	No array	Access with subindex to non-indexed parameter.	–
0x05	Wrong data type	Modification access with a value which does not match the data type of the parameter	–

Error code	Meaning	Comments	Additional info
0x06	Setting not allowed (only reset allowed)	Modification access with a value not equal to 0 in a case where this is not allowed	Subindex
0x07	Description element cannot be changed.	Modification access to a description element which cannot be changed	Subindex
0x09	No description data	Access to a description which does not exist (the parameter value exists)	–
0x0B	No operating priority	Modification access with no operating priority	–
0x0F	No text array exists	Access to a text array which does not exist (the parameter value exists)	–
0x11	Job cannot be executed due to operating mode.	Access is not possible temporarily for unspecified reasons.	–
0x14	Illegal value	Modification access with a value which is within the limits but which is illegal for other permanent reasons (parameter with defined individual values)	Subindex
0x15	Response too long	The length of the present response exceeds the maximum length that can be transferred.	–
0x16	Illegal parameter address	Impermissible or unsupported value for attribute, number of elements, parameter number, subindex, or a combination of these	–
0x17	Illegal format	Write job: illegal or unsupported parameter data format	–
0x18	No. of values inconsistent	Write job: a mismatch exists between the number of values in the parameter data and the number of elements in the parameter address.	–
0x19	Drive object does not exist.	You have attempted to access a drive object that does not exist.	–
0x65	Presently deactivated	You have tried to access a parameter that, although available, is currently inactive (e.g. n control set and access to parameter from V/f control).	–
0x6B	Parameter %s [%s]: no write access with enabled controller	–	–
0x6C	Parameter %s [%s]: unit unknown	–	–
0x6D	Parameter %s [%s]: Write access only in the commissioning state, encoder (p0010 = 4).	–	–
0x6E	Parameter %s [%s]: Write access only in the commissioning state, motor (p0010 = 3)	–	–
0x6F	Parameter %s [%s]: Write access only in the commissioning state, power unit (p0010 = 2)	–	–
0x70	Parameter %s [%s]: Write access only in the quick commissioning mode (p0010 = 1)	–	–
0x71	Parameter %s [%s]: Write access only in the ready state (p0010 = 0)	–	–
0x72	Parameter %s [%s]: Write access only in the commissioning state, parameter reset (p0010 = 30)	–	–

Error code	Meaning	Comments	Additional info
0x73	Parameter %s [%s]: Write access only in the commissioning state, safety (p0010 = 95)	–	–
0x74	Parameter %s [%s]: Write access only in the commissioning state, tech. application/units (p0010 = 5)	–	–
0x75	Parameter %s [%s]: Write access only in the commissioning state (p0010 not equal to 0)	–	–
0x76	Parameter %s [%s]: Write access only in the commissioning state, download (p0010 = 29)	–	–
0x77	Parameter %s [%s] may not be written in download.	–	–
0x78	Parameter %s [%s]: Write access only in the commissioning state, drive configuration (device: p0009 = 3)	–	–
0x79	Parameter %s [%s]: Write access only in the commissioning state, define drive type (device: p0009 = 2)	–	–
0x7A	Parameter %s [%s]: Write access only in the commissioning state, data set basis configuration (device: p0009 = 4)	–	–
0x7B	Parameter %s [%s]: Write access only in the commissioning state, device configuration (device: p0009 = 1)	–	–
0x7C	Parameter %s [%s]: Write access only in the commissioning state, device download (device: p0009 = 29)	–	–
0x7D	Parameter %s [%s]: Write access only in the commissioning state, device parameter reset (device: p0009 = 30)	–	–
0x7E	Parameter %s [%s]: Write access only in the commissioning state, device ready (device: p0009 = 0)	–	–
0x7F	Parameter %s [%s]: Write access only in the commissioning state, device (device: p0009 not equal to 0)	–	–
0x81	Parameter %s [%s] may not be written in download.	–	–
0x82	Transfer of the control authority (master) is inhibited by BI: p0806.	–	–
0x83	Parameter %s [%s]: requested BICO interconnection not possible	BICO output does not supply float values. The BICO input, however, requires a float value.	–
0x84	Parameter %s [%s]: parameter change inhibited (refer to p0300, p0400, p0922)	–	–
0x85	Parameter %s [%s]: access method not defined.	–	–

Error code	Meaning	Comments	Additional info
0xC8	Below the valid values	Modification job for a value that, although within "absolute" limits, is below the currently valid lower limit	–
0xC9	Above the valid values	Modification job for a value that, although within "absolute" limits, is above the currently valid upper limit (e.g. governed by the current inverter rating)	–
0xCC	Write access not permitted	Write access is not permitted because an access key is not available.	–

Additional information for the parameters of a PROFIdrive drive

Description

From a PROFIdrive drive device, not only the values of parameters, but also the descriptions of the parameters, can be read.

The P response/request data block in the "Attribute" field is used to express a preference when sending the "parameter request":

Attribute = 0x10 (hex)	Value
Attribute = 0x20 (hex)	"Parameter Description" parameter description
Attribute 0 0x30 (hex)	Parameter Text

If, rather than the value of a parameter, its "Parameter Description" is requested, the "Value" field in the "Parameter Response" contains the description (data type, possibly the number of indexes of the parameter, ...).

Note

Normally, parameter descriptions are read-only.

System commands in SIMOTION

_writeRecord/_readRecord SIMOTION system commands

Description

A "write data record" can be performed in SIMOTION using the _writeRecord() system command. A "read data record" can be performed in SIMOTION using the _readRecord() system command. This makes it also possible to read, write or fetch the description of parameters in a PROFIdrive drive.

The description of the system functions, their input parameters and return values can be found in the SIMOTION system documentation:

- C2xx reference list
- D4xx/D4xx-2 reference list
- P3xx reference list

The _write/_readRecord system commands can be used universally, not just for PROFIdrive drives, but, for example, also for intelligent sensors on the PROFIBUS or other peripheral modules that support the so-called DP V1 services for PROFIBUS.

Note

For SIMATIC, the corresponding system functions are

SFB52 WR_REC Write data record

SFB53 RD_REC Read data record

The following is required to be able to use the SIMOTION system commands _write/_readRecord:

- PROFIBUS: Access to the logical address of a telegram module or diagnostics address of the device (module 0)
- PROFINET: Data set 0xB02E for BMPG is accessed via the diagnostic address of the MAP submodule of the DOs . The MAP submodule is the DO proxy and hosts the alarm channel along with one or more PAPs (Parameter Access Point). The PAP is a data record in the MAP submodule. In the GSD file, the MAP is stated with submodule ID 0xFFFF and the submodule name "MAP."

Furthermore, the DO ID is only relevant for data set 47 (0x002F) and Global Access (PROFINET 0xB02F). Use data set 47 for compatibility with PROFIBUS user programs.

The diagnostics address of the corresponding PAP is relevant for Local Access (PROFINET IO 0xB02E), the DO ID is not analyzed. Use this type of access for new projects.

As a result, for example in connection with PROFIdrive units, the telegram start address of the PROFIdrive telegram exchanged cyclically with the device is required. Use of the diagnostic address of the MAP submodule is recommended. In SINAMICS drives, the log addresses of the telegram modules can also be used. In this way, an F-controller can also access PROFIsafe submodules.

If a drive has several axes (with a shared PROFIBUS interface connection) on a drive device, to differentiate the axes in the same device, the "Axis-No." or "DO-ID" in data set 47 is also required. SIMODRIVE 611universal and SINAMICS S120 are examples for such multi-axis drives. To determine the "DO-ID" for SINAMICS S120, refer to the **Acyclical Communication** section in the SINAMICS S120 Commissioning Manual.

"Axis-No." or "DO-ID" = 0 can be used to access the so-called "global parameters". Examples of such "global parameters" are:

- P0918: PROFIBUS address
- P0964: Device identification (manufacturer, version, number of axes, etc.)
- P0965: Profile number (the implemented PROFIdrive version)

- P0978: List of the DO Ids (the set "Axis-No." or "DO-ID")
- P61000: Name of the station (PROFINET devices only)

_writeDrive.../_readDrive... SIMOTION system commands

Description

Whereas the _readRecord and _writeRecord system functions can be used universally for all devices on PROFIBUS that support the so-called "read/write data record" DP V1 services, the following commands are specially tailored to PROFIdrive drives using the PROFIdrive profile:

- _read/writeDriveParameter (reads/writes a, possibly indexed, drive parameter)
- _read/writeDriveMultiParameter (reads/writes several, possibly indexed, drive parameters for a drive or drive object)
- _readDriveFaults (reads the current fault buffer entry of a drive or drive object)
- _readDriveParameterDescription (reads the descriptive data of a parameter from the drive or drive object)
- _readDriveParameterDescription (reads the descriptive data of several parameters from the drive or drive object)

The commands create internally the data set 47 required for the individual functions in accordance with PROFIdrive profile using the parameters transferred by the user when the system functions are called, and independently handle the communication to the PROFIdrive drive using "read/write data record".

The commands are described in the SIMOTION system documentation, refer to the reference lists for the associated platform.

See also

Scope for the rules (Page 2437)

Comparison of the system commands

Description

The following table shows the most important differences between the two groups of system commands:

Command group	Advantage	Disadvantages
_readRecord _writeRecord	• Generally usable, not just for DP V1 services for drives • Assumes only the knowledge of some I/O address *on the drive device* and the "DO-ID" or "Axis-No" on the drive device	• The user must create the data record • The user must program two calls for parameter accesses in a PROFIdrive drive • Users may need to perform the required data conversions themselves • "DO-ID" or "Axis-No" must be known
_readDrive... _writeDrive...	• Tailored for the typical communication with PROFIdrive drives • The user does not need to know the structure of data set 47 • Reduced programming effort for the user for communication to drives	• Assumes the presence or knowledge of an I/O address *of the associated drive object* • An I/O address for a drive object exists only for cyclical communication (with PROFIBUS) to the drive object, possibly, for example, not for TB30 and TMxx I/O expansion modules used exclusively in the drive • The user must make any required data conversions

Properties of the system commands

The use of the drive-specific _write/_readDrive... system commands on the one hand makes it easier for you than using general _write/_readRecord commands, since you do not need to know the structure of data set 47 and do not need to program the successive _writeRecord and _readRecord calls in sequencers. Because the general usability of these system functions means the structure of the transferred data records is not known to the system, you may need to perform the required conversion into the representation in accordance with the PROFIdrive profile for sending and receiving yourself, see Program example (Page 2446).

Up to SIMOTION V4.1, the use of the _write/_readDrive... commands is restricted to those cases for which there is cyclic data traffic to the associated drive object, because this is required as an input parameter. From this version up, it is possible to transfer the DO ID or axis no. via the **doId** parameter of the system functions. This means that it is possible to communicate with every DO, even if acyclic data traffic is involved.

In contrast, _write/_readRecord can also be used to access drive objects even when no cyclical data traffic exists (or when the I/O address is not known in the application). This succeeds with _write/_readRecord because the explicit knowledge of the "DO-ID" or "Axis-No." and the

knowledge of some I/O address on the device suffices to construct the data set 47. This can be advantageous, for example, when individual drive objects are used only drive-internal (namely, without cyclical telegram traffic for control) or they are not generally known for "generic programming".

Deleting _readDrive and _writeDrive jobs

Description

You can use the following functions to cancel or delete incorrect read or write jobs, which, for example, were called with the _readDriveParameter:

- _abortReadWriteRecordJobs, for the _readRecord or _writeRecord functions
- _abortAllReadWriteDriveParameterJobs, for the following functions:
  - _readDrive(Multi)ParameterDescription
  - _readDrive(Multi)Parameter
  - _writeDrive(Multi)Parameter
  - _readDriveFaults

You can call the functions without needing to know or read the CommandID.

Rules for using _readRecord and _writeRecord

Rule 1 - the job has its own job reference

Each job has its own job reference

This is required so that different jobs can be assigned. The job reference can be reused when the assignment is clear because of some other characteristic, such as the chronological sequence.

Rule 2 - system functions for asynchronous programming

Description

R2: For asynchronous programming, you must repeatedly call the system function with the same IDs until the function is terminated ("longrunner"). The correct use of the system functions _writeRecord and _readRecord based on communication with SINAMICS S120 is shown in the figure **Correct processing with the _readRecord and _writeRecord system functions**.

The communication for reading and writing parameters for the SINAMICS S120 is always performed using data set 47, whose structure is described in the documentation for the SINAMICS S120, refer to the Acyclical Communication section in the SINAMICS S120 Commissioning Manual.

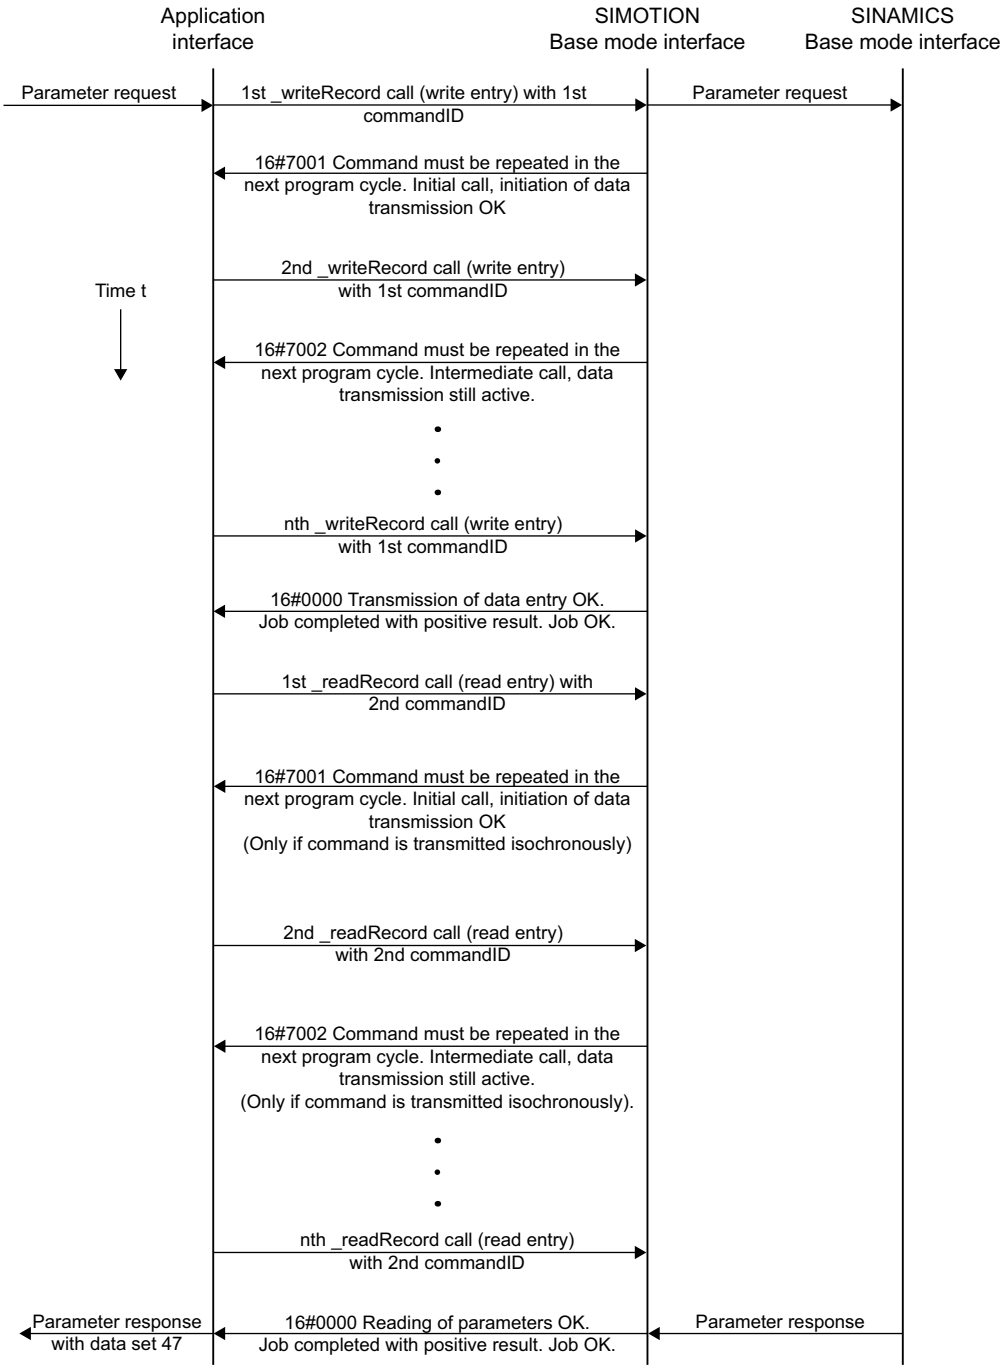

Figure 4-491 Correct processing with the _readRecord and _writeRecord system functions

Rule 3 - read/write data record per PROFIdrive drive unit

Only one read/write data record per PROFIdrive drive device concurrently

The PROFIdrive profile specifies that PROFIdrive drives do not perform any pipelining and consequently only one job will be processed at any one time. Consequently, this is also described for SINAMICS S120 in the Commissioning Manual.

Note

It does not matter which system functions are used for the transmission in the controller. A PROFIdrive drive can process only one job at any one time.

Note

It is certainly possible for other devices on the PROFIBUS that they support several "read/write data record" in parallel.

Note

Because the _write/_readRecord system functions can be used universally, *no* interlock is performed on the controller side to limit only one "read/write data record" per PROFIdrive drive to be initiated at any one time.

Consequence for the application on the controller:

An interlock must be set to prevent the application or different parts of the application from sending overlapping jobs to the same PROFIdrive drive device, also refer to section Interlocking of several calls (Page 2438).

Rule 4 - the last call wins for SIMOTION

In case of doubt, the last call "wins" for SIMOTION

If Rule 3 "Only one read/write data record per PROFIdrive drive device concurrently" is violated by a second _writeRecord command being issued to the same drive in the meantime, the response of the first job can then no longer be read. The attempt to read the drive response to the first job can no longer be processed by the drive and will be acknowledged with an error and terminated. The chronological sequence is shown in the figure **The second _writeRecord call wins in case of doubt**.

To differentiate between the jobs at the controller, a separate commandID was used for each of the calls of the _writeRecord and _readRecord system functions.

To also differentiate between the jobs at the drive, unique job references for the first and second job were assigned in data set 47.

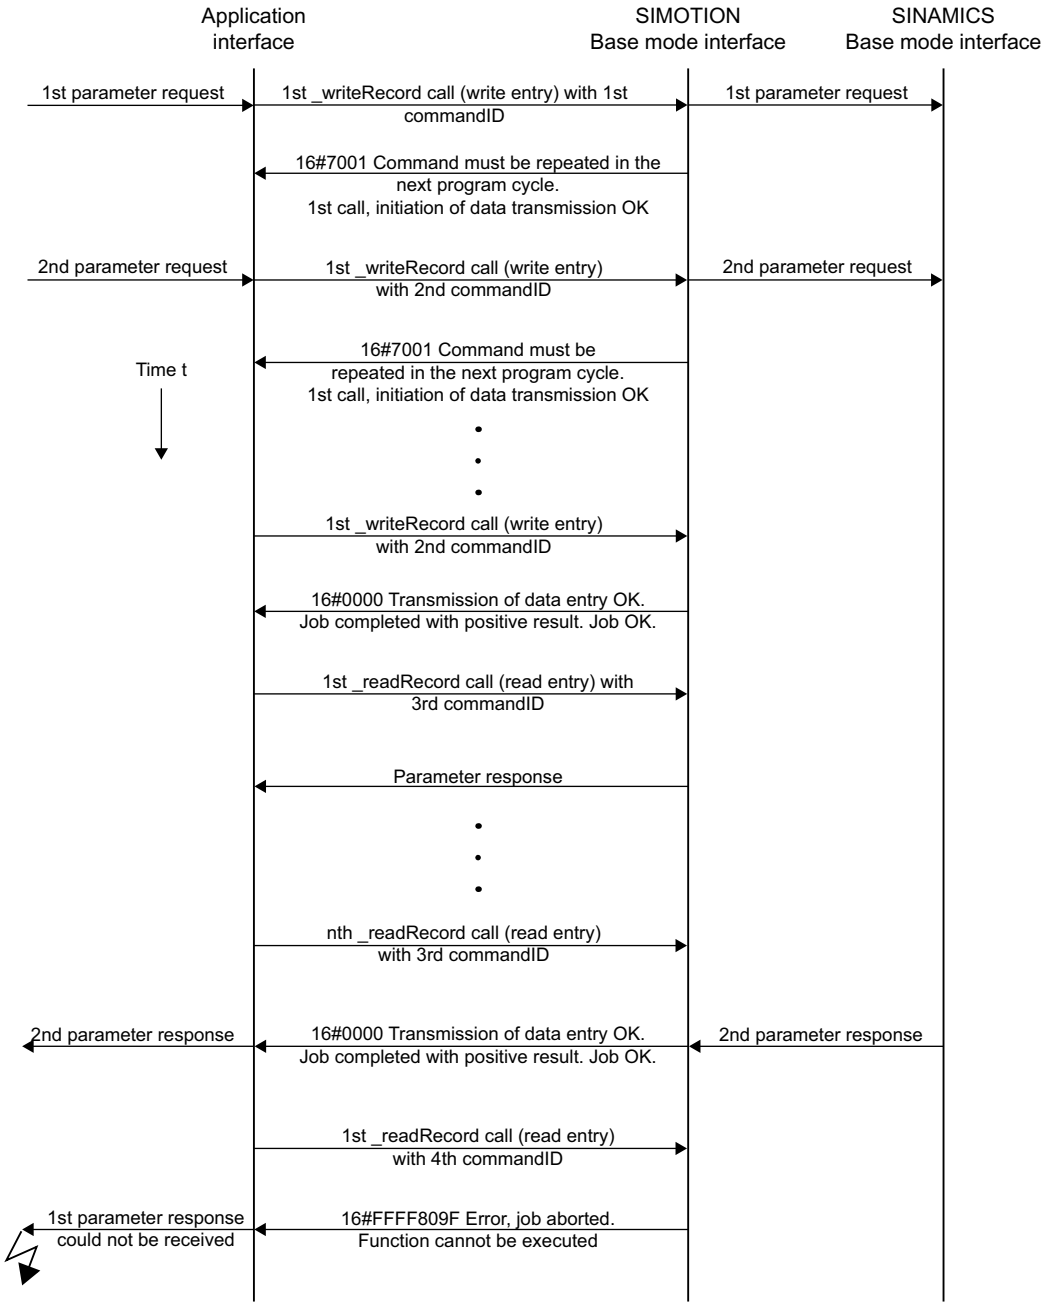

Figure 4-492 The second _writeRecord call wins in case of doubt

Rule 5 - a maximum of eight concurrent calls is possible in SIMOTION

SIMOTION can manage a maximum of eight _write/_readRecord calls concurrently

Although according to rule 3 (see Rule 3 (Page 2433)) only a single job can be processed at any given time for a *single* PROFIdrive drive device, it is still possible for the control program to issue several jobs in parallel.

Although this does not make any sense for a *single* PROFIdrive drive, it can be sensible for communication to *several* drives in parallel (or possibly for other devices that support this).

For SIMOTION, resources are reserved to permit a maximum of eight _write/_readRecord calls to be managed. The _write/_readRecord commandID is used to differentiate between the calls. If an attempt is made to issue a ninth concurrent call, this will be acknowledged by the controller with an error and suppressed.

The chronological sequence is shown in figure **Managing 8 jobs simultaneously**.

Initially seven _writeRecord jobs are initiated but not completed (no further _writeRecord calls to complete the jobs). The eighth _writeRecord job will be initiated and further processed until completion. It is then possible to issue a ninth call (which, however, is not further processed by the user program). The SIMOTION _writeRecord system function then acknowledges the attempt to issue the tenth job with error 16#80C3, because this would have been the ninth "open" job.

Note

The upper limit applies to each SIMOTION controller, not to each bus segment on the controller. This means it does not matter whether the addressed target devices operate on a single PROFIBUS segment or are assigned to several PROFIBUS segments.

Note

Because the _write/_readRecord system functions can be used universally, *no* interlock is performed on the controller side to limit only one "read/write data record" per PROFIdrive drive to be initiated at any one time.

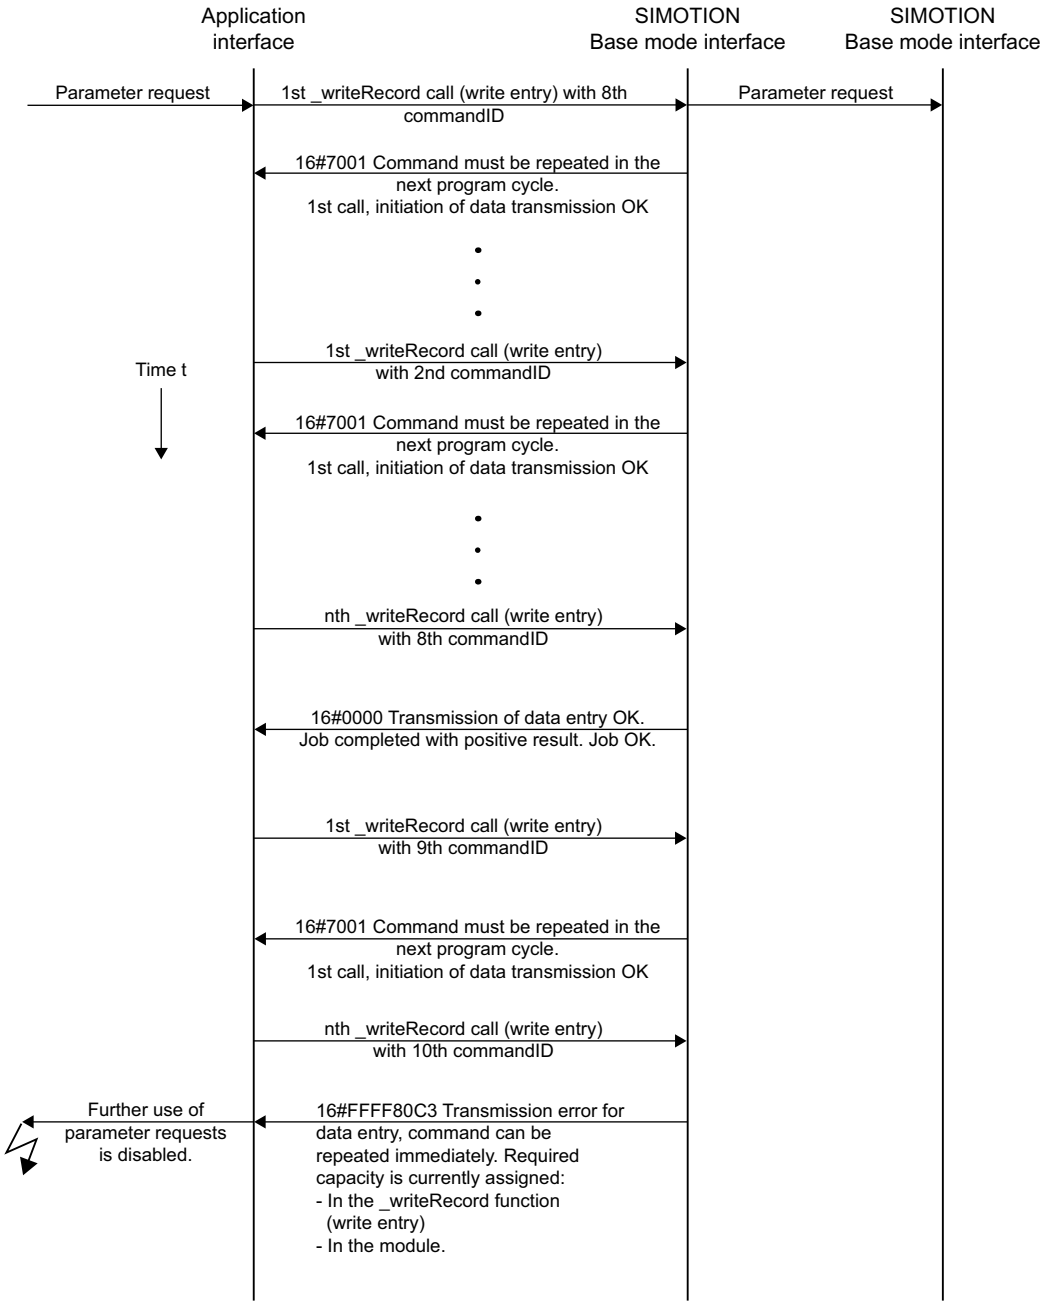

Figure 4-493 Managing 8 jobs simultaneously

Note

If the error 16#80C3 occurs, you must set the CPU to STOP and then back to RUN. This deletes the job buffer. In order to prevent the error, you should end the job with an abort command, if you are unable to end the job.

Rules for SIMOTION _writeDrive.../_readDrive... commands

Scope for the rules

Description

The following examples are shown using the _readDriveParameter system function . The descriptions also apply similarly for the previously mentioned _writeDrive.../_readDrive... system functions.

Rule 6 - repeated call of system function for asynchronous programming

Description

For asynchronous programming, the user must call repeatedly the system function with the same IDs until the function is terminated ("longrunner").

The following figure shows the correct use of the _readDriveParameter system function.

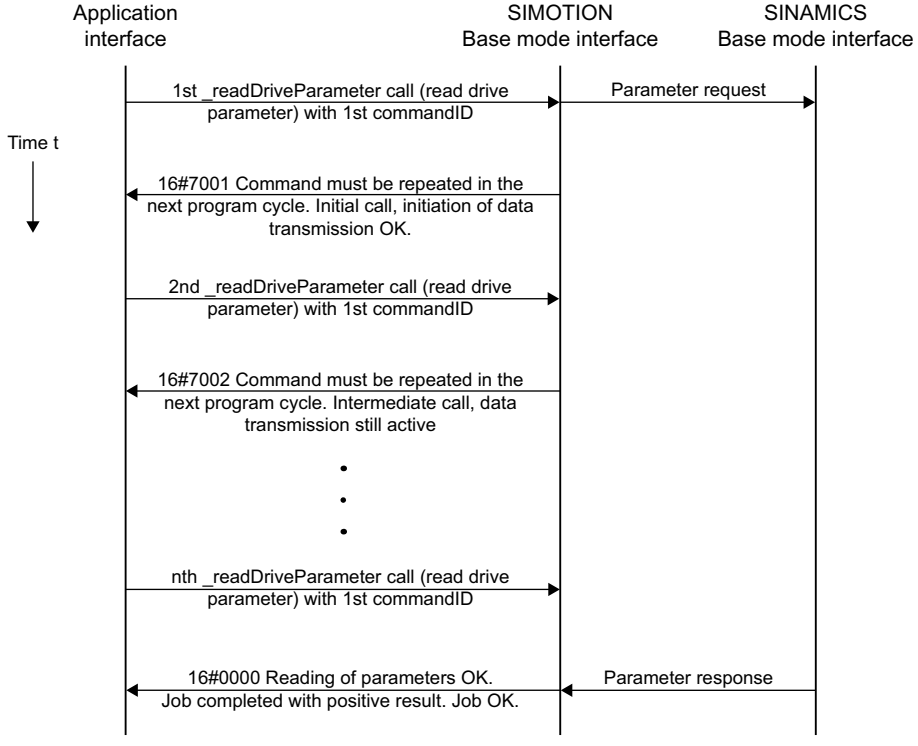

Figure 4-494 Correct processing with the _writeDriveParameter and _readDriveParameter system functions

Rule 7 - multiple concurrent calls per target device

Description

The PROFIdrive standard specifies that PROFIdrive units do not perform any pipelining and consequently only one job will be processed at any one time. Consequently, this is also documented for SINAMICS S120 in the SINAMICS S120 Commissioning Manual.

Because the SIMOTION _write/_readDrive... system commands have been created for the frequent use with PROFIdrive units, this is already handled by the controller.

Note

It does not matter which system functions are used for the transmission in the controller. A PROFIdrive drive can process only one job at any one time.

Consequence for the application on the controller:

An interlock must be set to prevent the application or different parts of the application from sending overlapping jobs to the same PROFIdrive drive device.

The figure below shows the behavior when this is not handled. The attempt to issue a second job (with unique commandID) to the same target device will be acknowledged with an error. A further job to the same target device can then be issued only when the first job has completed or has been canceled, see Section Releasing the Interlocking (Page 2438).

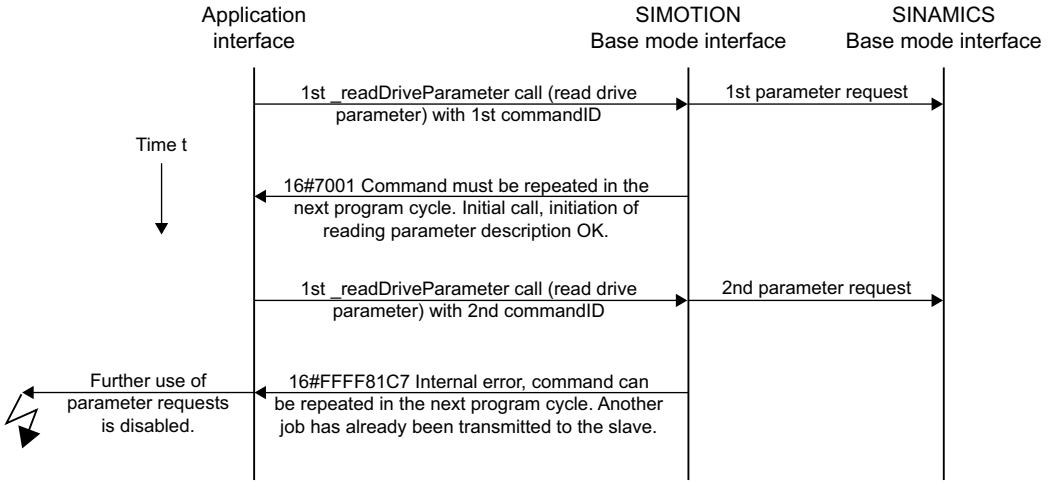

Figure 4-495 Interlocking of several _readDriveParameter jobs on a target device

Rule 8 - release the interlocking after the complete processing of a job

Enable the interlock only after the processing of a job has been completed

The following figure shows that it does not suffice to wait for "something", but rather the _read/_writeDrive... system functions must be called repeatedly until the job has been processed completely. The interlock will not be freed and the internal management resources released beforehand.

The number of calls has been selected so that the SIMOTION DP V1 interface answers each subsequent call for the first job with 16#7002 and thus is not processed completely. Depending on the loading of the bus and the drive, this can also be necessary very frequently (>25 times). This means an estimate cannot be given.

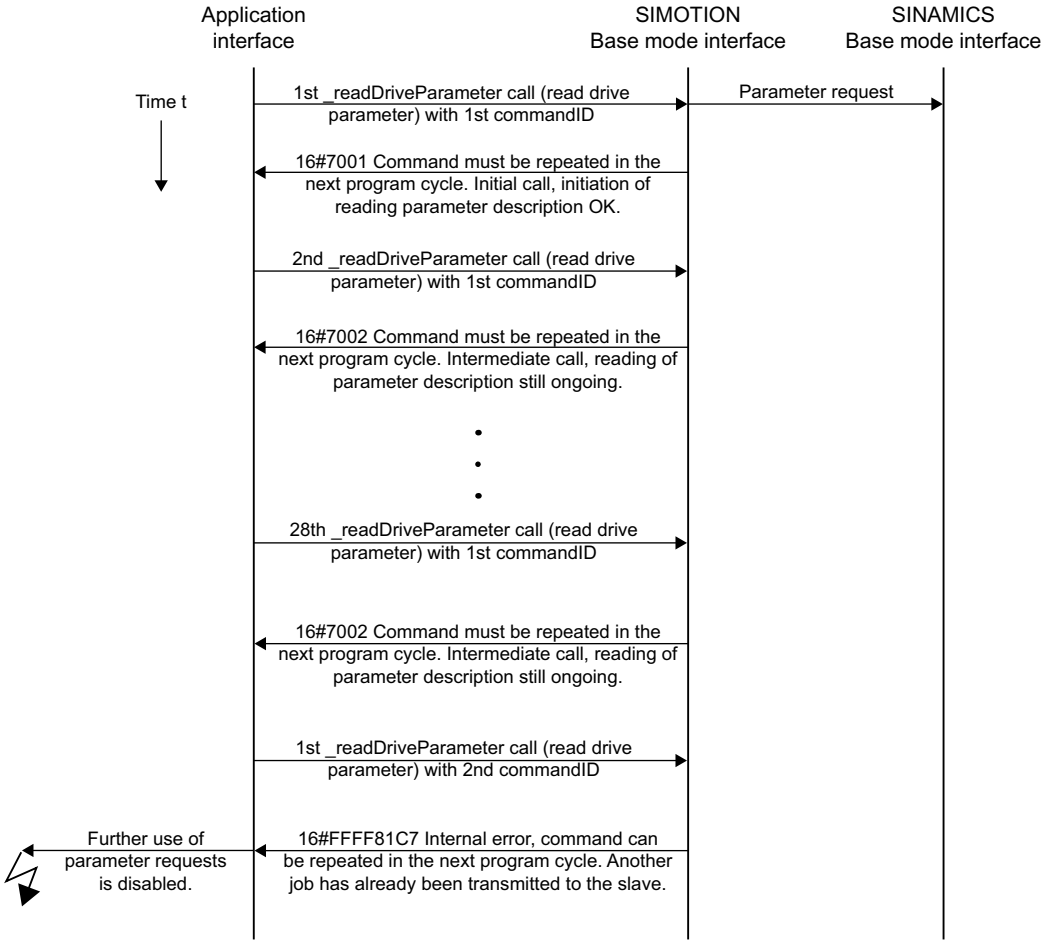

Figure 4-496 Complete processing of a _readDriveParameter required to release the interlock

Rule 9 - canceling jobs for an asynchronous call

CommandID is needed to cancel jobs for an asynchronous call

To re-enable the DP V1 service for the target device,

- either the first job must have completed (repeated calls with the commandID of the first job)
- or cancelled (again a call of the _readDriveParameter function with the same commandID as for the first initiation of the job. In addition, the nextCommand input parameter must have the ABORT_CURRENT_COMMAND value).

Note

From V4.1 and up, it is possible to cancel without knowing the commandID, see Deleting _readDrive and _writeDrive jobs (Page 2431) .

A sample call of the _readDriveParameter function with the first commandID (id1) and ABORTED_CURRENT_COMMAND has the following form:

```
Return_Par_read_delete :=
    readDriveParameter(
    ioId:=INPUT,
    logAddress := 256,
    parameterNumber := number,
    numberOfElements := 0,
    subIndex:= 0,
    nextCommand :=
    ABORT_CURRENT_COMMAND,
    commandId := id1);
```

The figure below shows the chronological sequence.

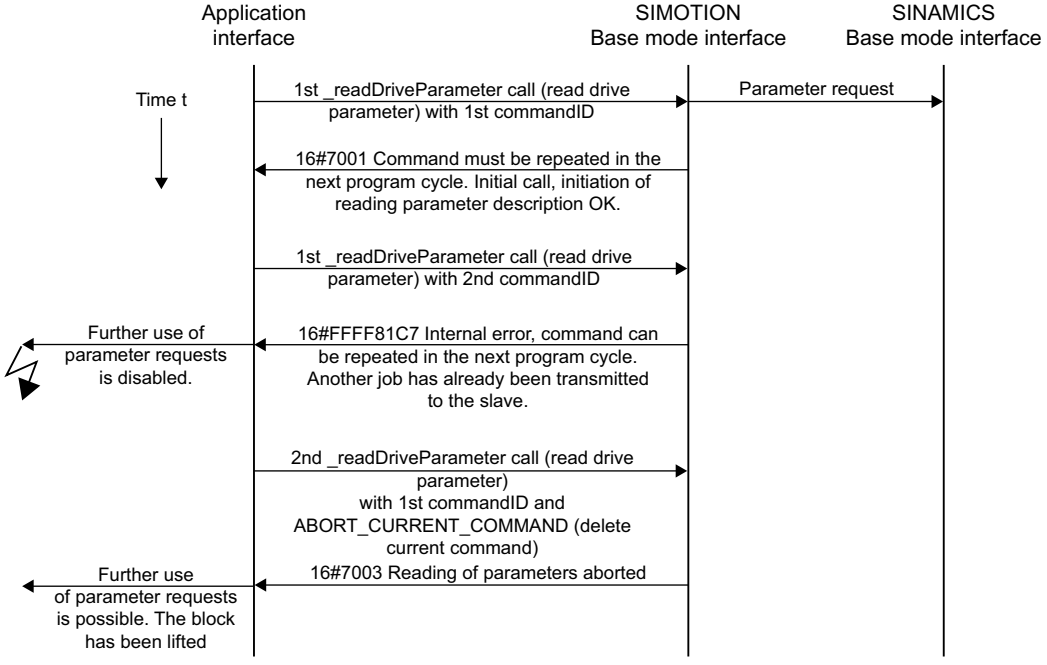

Figure 4-497 Canceling a _readDriveParameter job with known commandID

The process in the following figure shows that it is not possible to cancel a job without knowledge of the original commandID. Not the first job, but rather the cancel attempt will be canceled. The reason is that the commandID is used for managing the various jobs in the system.

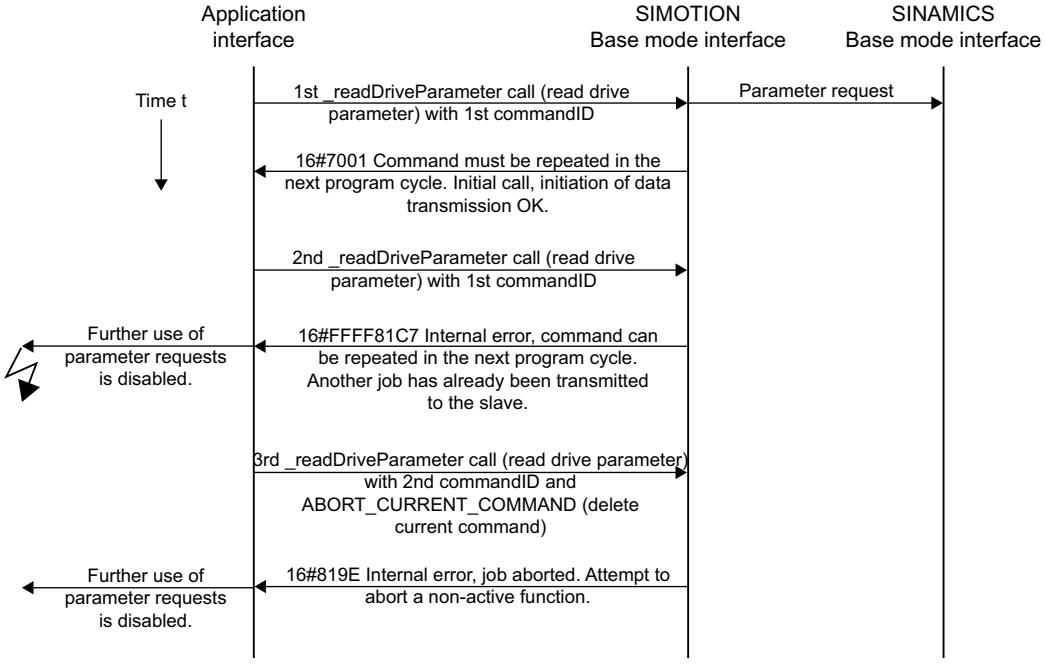

Figure 4-498 No cancelation of a _readDriveParameter job with new CommandID

Note

It is therefore important that the user program retains the commandID of the jobs until the job has completed or has been canceled.

Note

Take particular care, for example, through control by other conditions, that in the user program the processing of the _write/_readDrive... functions is not bypassed before they have completed.

Rule 10 - management of sixteen jobs

SIMOTION manages a maximum of 16 calls in parallel for different devices

The controller has limited resources (memory space) available for storing the management data for _write/_readDrive... system function calls. If too many calls are issued in parallel, an error message will be issued, similar to the limit for _read/_writeRecord in Section Maximum Number of Calls (Page 2434).

For SIMOTION, resources are reserved to permit a maximum of sixteen calls of _writeDrive.../_readDrive... system functions to be managed. The commandID is used to differentiate between

the calls. If an attempt is made to issue a seventeenth concurrent call, this will be acknowledged by the controller with an error and suppressed.

Rule 11 - parallel jobs for different drive devices

Parallel jobs to different drive units are possible

The figure **Parallel processing of _readDriveParameter jobs to different drive devices of a controller** shows that parallel jobs can be processed with different drive devices.. The SIMOTION D445-2 controller uses the SINAMICS Integrated of a D445-2 (for example) as first PROFIdrive drive unit and the CX32-2 expansion module as second PROFIdrive drive unit.

In the example, a total of three read jobs (two jobs to the first drive device (SINAMICS Integrated) and one job to the second drive device (CX32-2)) are issued with the _readDriveParameter system function.

- The first read job for the SINAMICS Integrated is intentionally called just once so that the interlock acts.
- The second read job is then issued to the second PROFIdrive drive device (CX32-2). This job is processed successfully.
- The third read job is addressed again to the first drive device (SINAMICS Integrated) and can no longer be executed successfully because the first job is still running.

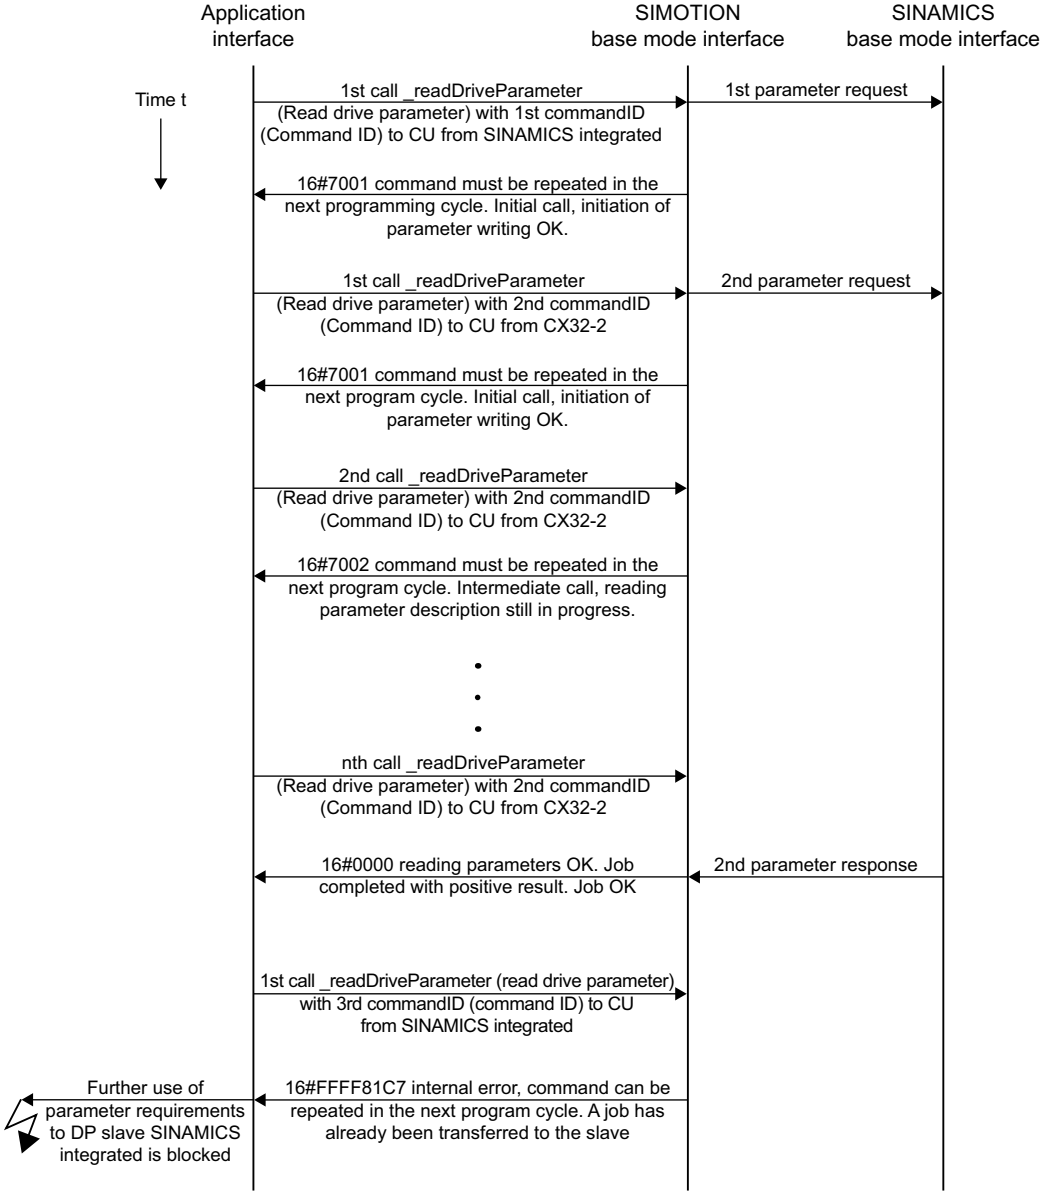

Figure 4-499 Parallel processing of _readDriveParameter jobs to different drive devices of a controller

Special features

Rule 12 - data buffering of up to 64 drive objects

SIMOTION buffers the data of up to 64 drive objects

The first call to the functions _write/_readDrive... after system power-up runs considerably longer than subsequent calls to the same drive object.

- The system must first set up internal management information that can be accessed faster in subsequent calls to the same drive object.

In SIMOTION, the data of up to 64 drive objects can be stored for use with _write/_readDrive... The distinction is made using the I/O address.

Rule 13 - a mix of system functions can be used

A mix of the _writeRecord/_readRecord and _writeDrive.../_readDrive... system functions can be used

A mixed use of the following system commands is generally possible:

- _writeRecord/_readRecord SIMOTION system commands
- _writeDrive.../_readDrive... SIMOTION system commands

Note

However, it is important to appreciate that a missing interlock of the system commands from the two command groups means several jobs could be issued to a PROFIdrive drive (see following section), which a PROFIdrive drive cannot process. Handling the system-internal interlocking for _write/_readDrive....

The figure **Mixed use of _readDrive... and _read/_writeRecord** shows that the _write/_readRecord functions, in particular, can be used for the same target device when, because of a running _readDriveParameter job, further jobs with the same command are suppressed by the system – this situation must be blocked by the user because it cannot be processed by a PROFIdrive.

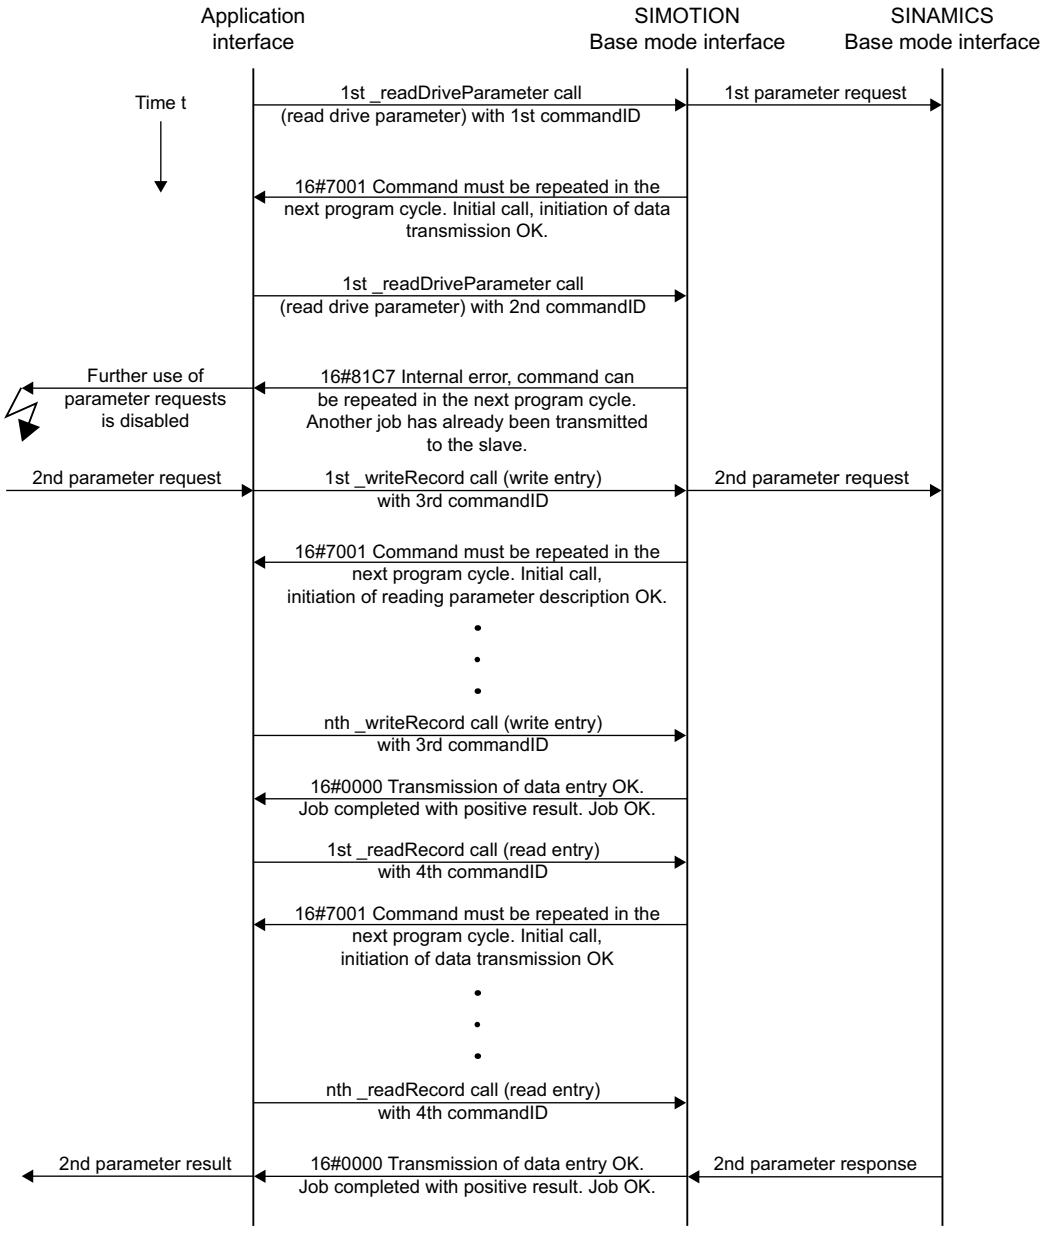

Figure 4-500 Mixed use of _readDrive... and _read/_writeRecord

Rule 14 - interlocking for the mixed use of commands

The user must interlock for the mixed use of the commands from the two command groups

When the following system commands are used together, it is possible that more than one "read/write data record" is issued concurrently to a single device because for SIMOTION interlocking and buffering is performed only within the command groups but not between command groups.

- _writeRecord/_readRecord SIMOTION system commands

and

- _writeDrive.../_readDrive... SIMOTION system commands

If necessary, this must be interlocked by the user to prevent data loss/overlapping because the PROFIdrive profile specifies that a PROFIdrive drive does not perform any pipelining and consequently can process only one job at any given time.

Program examples

Programming example

Description

The following example shows how the _writeRecord and _readRecord system commands can be used to fetch the error code from parameter p0945 of a SINAMICS drive (drive object DO3, I/O address 256).

Example

The sample program can be called, for example, in the BackgroundTask, because so-called "asynchronous programming" is used.

```
//=========================================================================
// demonstrate reading parameter 945 (fault code) via data set 47
// using SIMOTION system functions _write/_readRecord (asynchronous call)
// INPUT address 256 is assumed to address the SINAMICS
// drive is DO3 in SINAMICS S120
//=========================================================================

4.5.11 Appendix

4.5.11.1 Standard PROFIBUS/PROFINET data types (only available in English)

Subset of IEC 61158-5 standard data types for use in PROFIBUS/PROFINET profiles

Coding of most of the data types in these profile guidelines is defined in IEC 61158-6:2003, clause 6.2. However, the usage in practice is different in some cases. Thus it is highly recommended to follow the definitions and hints within this annex. The next edition of IEC 61158 is supposed to comply with the content of this annex.

Boolean

A Boolean is representing a data type that only can have two different values i.e. TRUE and FALSE. Hint: for efficiency reasons this data type is not used in application profiles.

Numeric Identifier	Data type name	Value range	Resolution	Length
1	Boolean	True/false	-	1 Octet

Bits	7	6	5	4	3	2	1	0	
True	x	x	x	x	x	x	x	x	0x01 to 0xFF
False	0	0	0	0	0	0	0	0	0x00

Integer16

An Integer16 is representing a signed number depicted by 16 bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
3	Integer16	$-32768 \leq i \leq 32767$	1	2 Octets

In two's complement; the most significant bit (MSB) is the bit after the sign (SN) in the first Byte.

SN = 0: positive numbers and zero

SN = 1: negative numbers

Bits	7	6	5	4	3	2	1	0
Octets 1	SN	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}
Octets 2	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Integer32

An Integer32 is representing a signed number depicted by 32 bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
4	Integer32	$-2^{31} \leq i \leq 2^{31}-1$	1	4 Octets

In two's complement; the most significant bit (MSB) is the bit after the sign (SN) in the first Byte.

SN = 0: positive numbers and zero

SN = 1: negative numbers

Bits	7	6	5	4	3	2	1	0
Octets 1	SN	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}
Octets 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}
Octets 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}
Octets 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Integer64

An Integer64 is representing a signed number depicted by 64 bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
55	Integer64	$-2^{62} \le i \le 2^{62}-1$	1	8 Octets

In two's complement; the most significant bit (MSB) is the bit after the sign (SN) in the first Byte.

SN = 0: positive numbers and zero

SN = 1: negative numbers

Bits	7	6	5	4	3	2	1	0
Octets 1	SN	2^{62}	2^{61}	2^{60}	2^{59}	2^{58}	2^{57}	2^{56}
Octets 1	2^{55}	2^{54}	2^{53}	2^{52}	2^{51}	2^{50}	2^{49}	2^{48}
Octets 1	2^{47}	2^{46}	2^{45}	2^{44}	2^{43}	2^{52}	2^{41}	2^{40}
Octets 1	2^{39}	2^{38}	2^{37}	2^{36}	2^{35}	2^{34}	2^{33}	2^{32}
Octets 1	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}
Octets 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}
Octets 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}
Octets 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Unsigned8

An Unsigned8 is representing an unsigned number depicted by 8 bits ("enumerated"). Some application profiles (e.g. PROFIsafe) are using this data type for the coding of individual single bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
5	Unsigned8	$0 \le i \le 255$	1	1 Octet

Table 4-247 Enumerated:

Bits	7	6	5	4	3	2	1	0
Octets 1	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Octets 1	7	6	5	4	3	2	1	0

Unsigned16

An Unsigned16 is representing an unsigned number depicted by 16 bits ("enumerated"). Some application profiles (e.g. PROFIsafe) are using this data type for the coding of individual single bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
6	Unsigned16	0 ≤ i ≤ 65535	1	2 Octets

Table 4-249 Enumerated:

Bits	7	6	5	4	3	2	1	0
Octets 1	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}
Octets 2	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Table 4-250 Single bits:

Octets 1	15	14	13	12	11	10	9	8
Octets2	7	6	5	4	3	2	1	0

Unsigned32

An Unsigned32 is representing an unsigned number depicted by 32 bits ("enumerated"). Some application profiles (e.g. PROFIsafe) are using this data type for the coding of individual single bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
7	Unsigned32	0 ≤ i ≤ 4294967295	1	4 Octets

Table 4-251 Enumerated:

Bits	7	6	5	4	3	2	1	0
Octets 1	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}
Octets 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}
Octets 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}
Octets 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Table 4-252 Single bits:

Bits	7	6	5	4	3	2	1	0
Octets 1	31	30	29	28	27	26	25	24
Octets 2	23	22	21	20	19	18	17	16
Octets 3	15	14	13	12	11	10	9	8
Octets 4	7	6	5	4	3	2	1	0

Unsigned64

An Unsigned64 is representing a signed number depicted by 64 bits.

Numeric Identifier	Data type name	Value range	Resolution	Length
56	Unsigned64	$0 \le i \le 2^{64}-1$	1	8 Octets

In two's complement; the most significant bit (MSB) is the bit after the sign (SN) in the first Byte.

SN = 0: positive numbers and zero

SN = 1: negative numbers

Bits	7	6	5	4	3	2	1	0
Octets 1	2^{63}	2^{62}	2^{61}	2^{60}	2^{59}	2^{58}	2^{57}	2^{56}
Octets 2	2^{55}	2^{54}	2^{53}	2^{52}	2^{51}	2^{50}	2^{49}	2^{48}
Octets 3	2^{47}	2^{46}	2^{45}	2^{44}	2^{43}	2^{52}	2^{41}	2^{40}

Visible String

This data type is defined as the ISO 646 string type. Characters are based on 8 Bit ASCII.

Numeric Identifier	Data type name	Value range	Resolution	Length
9	VisibleString	refer to ISO 646	-	variable

Bits	7	6	5	4	3	2	1	0
Octets 1	1. Character							
Octets 2	2. Character							
...	...							
Octets n	n. Character							

OctetString

An OctetString is an ordered sequence of Bytes, numbered from 1 to n.

Numeric Identifier	Data type name	Value range	Resolution	Length
10	OctetString	-	-	variable

Bits	7	6	5	4	3	2	1	0
Octet 1	1. Character							
Octet 2	2. Character							
...	...							
Octet n	n. Character							

BYTE

A Byte is 1 octet.

Numeric Identifier	Data type name	Value range	Resolution	Length
22	Byte	-	-	1 Octet

Bits	7	6	5	4	3	2	1	0
Octet 1	1. Byte							

WORD

A Word is an ordered sequence of 2 octets.

Numeric Identifier	Data type name	Value range	Resolution	Length
23	Word	-	-	2 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	1. Byte							
Octet 2	2. Byte							

DWORD

A DWord is an ordered sequence of 4 octets.

Numeric Identifier	Data type name	Value range	Resolution	Length
24	DWord	-	-	4 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	1. Byte							
Octet 2	2. Byte							
Octet 3	3. Byte							
Octet 4	4. Byte							

LWORD

A LWord is an ordered sequence of 8 octets.

Numeric Identifier	Data type name	Value range	Resolution	Length
25	LWord	-	-	8 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	1. Byte							
Octet 2	2. Byte							
Octet 3	3. Byte							
Octet 4	4. Byte							
Octet 5	5. Byte							
Octet 6	6. Byte							
Octet 7	7. Byte							
Octet 8	8. Byte							

TimeOfDay

This data type is composed of two elements of unsigned values representing the time of day and the date. The first element is an Unsigned32 data type and contains the number of milliseconds since midnight, where midnight = 0.

The second element is of type Unsigned 16 containing the number of completed days since January 1, 1984.

Numeric Identifier	Data type name	Value range	Resolution	Length
12	TimeOfDay	$0 \le i \le (2^{28}-1)$ ms $0 \le i \le (2^{16}-1)$ days	-	6 Octets

The time is interpreted as 32 bit value. The first 4 (MSB) bits have the value zero. The date indication is coded as 16 bit value.

Bits	7	6	5	4	3	2	1	0	
Octets 1	0	0	0	0	2^{27}	2^{26}	2^{25}	2^{24}	Number of millisec-onds since midnight
Octets 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octets 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octets 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	
Octets 5	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	days since January 1st, 1984
Octets 6	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	

TimeDifference

This data type is composed of two elements of unsigned values and expresses the difference in time. The first element is an Unsigned32 data type that contains the fractional portion of one day in milliseconds. The optional second element is an Unsigned16 data type that contains the difference in days.

Numeric Identifier	Data type name	Value range	Resolution	Length
13	TimeDifference	$0 \le i \le (2^{32}-1)$ ms $0 \le i \le (2^{16}-1)$ days	-	4 or 6 Octets

The time is interpreted as 32 bit value. The first 4 (MSB) bits have the value zero. The date indication is coded as 16 bit value.

Bits	7	6	5	4	3	2	1	0	
Octets 1	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Number of millisec-onds (of one day)
Octets 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octets 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octets 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	
Octets 5	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	Number of days (op-tional)
Octets 6	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	

Date

This data type is composed of six elements of unsigned values and expresses calendar date and time. The first element is an Unsigned16 data type and gives the fraction of a minute in milliseconds. The second element is an Unsigned8 data type and gives the fraction of an hour in minutes. The third element is an Unsigned8 data type and gives the fraction of a day in hours with the most significant bit indicating Standard Time or Daylight Saving Time. The fourth element is an Unsigned8 data type. Its upper three (3) bits give the day of the week and its lower five (5) bits give the day of the month. The fifth element is an Unsigned8 data type and gives the month. The last element is Unsigned8 data type and gives the year. The values 0 ... 50 correspond to the years 2000 to 2050; the values 51 ... 99 correspond to the years 1951 to 1999.

Numeric Identifier	Data type name	Value range	Resolution	Length
50	Date	0 ms ≤ i ≤ 99 years	-	7 Octets (Unsigned16 + 5 x Unsigned8)

Bits	7	6	5	4	3	2	1	0	
Octet 1	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	0...59999 millisec-onds
Octet 2	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	
Octet 3	res	res	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	0...59 mi-nutes
Octet 4	SU	res	res	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	0...23 hours
Octet 5	day of week			day of month					1...7 day of week 1...31 day of month
	2^{2}	2^{1}	2^{0}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	

Bits	7	6	5	4	3	2	1	0	
Octet 6	res	res	2^5	2^4	2^3	2^2	2^1	2^0	1...12 month
Octet 7	res	2^6	2^5	2^4	2^3	2^2	2^1	2^0	0...99 years

SU: Standard Time = 0; Daylight Saving Time = 1

day of week: 0 Monday = 1; Tuesday =2.....Sunday = 7

res = reserved

TimeOfDay without date indication

This data type consists of one element of an unsigned value and expresses the time of day without date indication. The element is an Unsigned32 data type and contains the time after midnight in milliseconds.

Numeric Identifier	Data type name	Value range	Resolution	Length
52	TimeOfDay without date indication	$0 \le i \le (2^{28}-1)$	ms	4 Octets (Unsigned32)

The time is interpreted as 32 bit value.

Bits	7	6	5	4	3	2	1	0	
Octet 1	0	0	0	0	2^{27}	2^{26}	2^{25}	2^{24}	Number of milliseconds since midnight
Octet 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8	
Octet 4	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	

TimeDifference with Date indication

This data type is composed of two elements of unsigned values that express the difference in time. The first element is an Unsigned32 data type that provides the fractional portion of one day in milliseconds. The second element is an Unsigned16 data type that provides the difference in number of days.

Numeric Identifier	Data type name	Value range	Resolution	Length
53	TimeDifference with date indication	$0 \le i \le (2^{32}-1)$ ms $0 \le i \le (2^{16}-1)$ days	ms, days	6 Octets (Unsigned32 + Unsigned16)

The time is interpreted as 32 bit value. The date indication is coded as 16 bit value.

Bits	7	6	5	4	3	2	1	0	
Octet 1	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Number of milliseconds (of one day)
Octet 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8	
Octet 4	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	
Octet 5	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8	Number of days
Octet 6	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0	

TimeDifference without Date indication

This data type consists of one element of an unsigned value that expresses the difference in time. he element is an Unsigned32 data type providing the fractional portion of one day in milliseconds.

Numeric Identifier	Data type name	Value range	Resolution	Length
54	TimeDifference without date indication	$0 \le i \le (2^{32}-1)$ ms	ms, days	4 Octets (Unsigned32)

The time is interpreted as 32 bit value.

Bits	7	6	5	4	3	2	1	0	
Octet 1	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Number of milliseconds (of one day)
Octet 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octet 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	

NetworkTime

This data type is based on the RFC 1305 standard and composed of two unsigned values that express the network time related to a particular date. Its semantic has changed in IEC 61158-6:2003.

The first element is an Unsigned32 data type that provides the network time in seconds since 1.1.1900 0.00,00(UTC) or since 7.2.2036 6.28,16(UTC) for time values less than 0x9DFF4400, which represents the 1.1.1984 0:00,00(UTC). The second element is an Unsigned32 data type that provides the fractional portion of seconds in $1/2^{32}$ s. Rollovers after 136 years are not automatically detectable and are to be maintained by the application.

Numeric Identifier	Data type name	Value range	Resolution	Length
58	NetworkTime	Byte 1 to 4: $0 \le i \le (232-1)$ Byte 5 to 8: $0 \le i \le (232-1)$	S $(1/2^{32})$ s	8 Octets (Unsigned32 + Unsigned32)

Bits	7	6	5	4	3	2	1	0	
Octet 1	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Number of seconds since 1.1.1900. Rollover after 136 years. Thus, next would be 7.2.2036.
Octet 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octet 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	
Octet 5	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Fractional portion of seconds: $1/2^{32}$ s
Octet 6	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 7	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octet 8	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	

The Time Stamp mechanism in PROFIBUS DP is using this data type. However, the semantic is slightly different:

- The least significant Bit of the fractional portion (2^0) is device internally used to indicate a synchronized or unsynchronized state of the clock time.

NetworkTimeDifference

This data type is composed of an integer value and of an unsigned value that express the difference in network time. The first element is an Integer32 data type that provides the network time difference in seconds. The second element is an Unsigned32 data type that provides the fractional portion of seconds in $1/2^{32}$ s.

Numeric Identifier	Data type name	Value range	Resolution	Length
59	NetworkTimeDifference	Byte 1 to 4: $-2^{31} \le i \le (2^{31}-1)$ Byte 5 to 8: $0 \le i \le (2^{32}-1)$	S $(1/2^{32})$ s	8 Octets (Integer32 + Unsigned32)

Bits	7	6	5	4	3	2	1	0	
Octet 1	SN	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Signed number of seconds
Octet 2	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 3	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octet 4	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	
Octet 5	2^{31}	2^{30}	2^{29}	2^{28}	2^{27}	2^{26}	2^{25}	2^{24}	Fractional portion of seconds: $1/2^{32}$ s
Octet 6	2^{23}	2^{22}	2^{21}	2^{20}	2^{19}	2^{18}	2^{17}	2^{16}	
Octet 7	2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	
Octet 8	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Existing PROFIBUS/PROFINET profile specific data types

This topic contains the profile specific data types of PROFIBUS/PROFINET.

Float32+Unsigned8 (former "DS33")

This data structure consists of the value and the status of a Float32 parameter. The parameter can be an input or output..

Numeric Identifier	Data type name	Value range	Resolution	Length
101	Float32 +Unsigned8	See Float32 and Unsigned8	-	5 Octets

SN: sign 0 = positive, 1 = negative

Bits	7	6	5	4	3	2	1	0
Octets 1	Exponent (E)							
	SN	2^7	2^6	2^5	2^4	2^3	2^2	2^1
Octets 2	(E)	Fraction (F)						
	2^0	2^{-1}	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	2^{-7}
Octets 3	Fraction (F)							
	2^{-8}	2^{-9}	2^{-10}	2^{-11}	2^{-12}	2^{-13}	2^{-14}	2^{-15}
Octets 4	Fraction (F)							
	2^{-16}	2^{-17}	2^{-18}	2^{-19}	2^{-20}	2^{-21}	2^{-22}	2^{-23}
Octet 5	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0

Unsigned8+Unsigned8 (former "DS34")

This data structure consists of the value and the status of the Unsigned8 parameter. The parameter can be an input or output.

Numeric Identifier	Data type name	Value range	Resolution	Length
102	Unsigned8 + Unsigned8	See Unsigned8	-	2 Octets

In two's complement; the most significant bit (MSB) is the bit after the sign (SN) in the first Byte.

Bits	7	6	5	4	3	2	1	0
Octet 1	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0
Octet 2	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0

OctetString2+Unsigned8 (former "DS35")

This data structure consists of the value and the status of the OctetString parameter. The parameter can be input or output.

Numeric Identifier	Data type name	Value range	Resolution	Length
103	OctetString2 + Unsigned8	see OctetString2 and Unsigned8	-	3 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	1. Byte							
Octet 2	2. Byte							
Octet 3	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0

Unsigned16_S

This data structure consists of the value and the status embedded in an unsigned 16 data type. The parameter using this data type can be input or output.

Numeric Identifier	Data type name	Value range	Resolution	Length
104	Unsigned16_S	0 to 2^{13} + 0 to 3	1	2 Octets

Bits	7	6	5	4	3	2	1	0
Octets 1	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	2^{7}	2^{6}
Octets 2	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	St1	St0

st1 (bit1)	st0 (bit0)	Meaning
0	0	input channel: bad (value is fail-safe value) output channel: reserved
0	1	input channel: simulation output channel: reserved
1	0	input channel: uncertain output channel: reserved
1	1	input channel: good output channel: reserved

Integer16_S

This data structure consists of the value and the status embedded in an integer 16 data type. The parameter using this data type can be input or output.

Numeric Identifier	Data type name	Value range	Resolution	Length
105	Integer16_S	- 2^{12} to 2^{12} –1 + 0 to 3	1	2 Octets

SN: sign 0 = positive, 1 = negative

Bits	7	6	5	4	3	2	1	0
Octets 1	SN	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	2^{7}	2^{6}
Octets 2	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}	St1	St0

st1 (bit1)	st0 (bit0)	Meaning
0	0	input channel: bad (value is fail-safe value) output channel: reserved
0	1	input channel: simulation output channel: reserved
1	0	input channel: uncertain output channel: reserved
1	1	input channel: good output channel: reserved

Unsigned8_S

This data structure consists of the value and the status embedded in an Unsigned8 data type. The parameter using this data type can be an input or output.

Numeric Identifier	Data type name	Value range	Resolution	Length
106	Unsigned8_S	0 to 2^5 + 0 to 3	1	1 Octet

Bits	7	6	5	4	3	2	1	0
Octets 1	2^5	2^4	2^3	2^2	2^1	2^0	St1	St0

st1 (bit1)	st0 (bit0)	Meaning
0	0	input channel: bad (value is fail-safe value) output channel: reserved
0	1	input channel: simulation output channel: reserved
1	0	input channel: uncertain output channel: reserved
1	1	input channel: good output channel: reserved

OctetString_S

This data structure consists of the value and the status embedded in an octet string data type. The parameter using this data type can be an input or output.

In the scope of this profile, this is the preferred data type for digital values. It contains the value of a binary channel as a bit in a value field (ch(x)), and a status information in a status field (st1(x) and st0(x)) coded as shown below. If a channel is unused, its position in the value field and in the status field has to be set to 0.

The value field and the status field are packed into an OctetString with the bit coding as shown below. This data type is defined as OctetString_S.

Numeric Identifier	Data type name	Value range	Resolution	Length
107	OctetString_S	See OctetString and below	-	n Octets

Bits	bit7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
Octet 1	ch(8)	ch(7)	ch(6)	ch(5)	ch(4)	ch(3)	ch(2)	ch(1)
***	***	***	***	***	***	***	***	***
Octet m	ch(n)	ch(n-1)	ch(n-2)	ch(n-3)	ch(n-4)	ch(n-5)	ch(n-6)	ch(n-7)
Octet m+1	st1(4)	st0(4)	st1(3)	st0(3)	st1(2)	st0(2)	st1(1)	st0(1)
***	***	***	***	***	***	***	***	***
Octet 3*m	st1(n)	st0(n)	st1(n-1)	st0(n-1)	st1(n-2)	st0(n-2)	st1(n-3)	st0(n-3)

ch(x) value for channel x; st(x) status information for channel x; 1<x≤n

st1 (bit1)	st0 (bit0)	Meaning
0	0	input channel: bad (value is fail-safe value) output channel: reserved
0	1	input channel: simulation output channel: reserved
1	0	input channel: uncertain output channel: reserved
1	1	input channel: good output channel: reserved

F message trailer with 4 octets

This data structure consists of the status/control byte, consecutive number, and 2 byte CRC parameters in PROFIsafe's V1-mode or status/control byte and 3 byte CRC parameters in PROFIsafe's V2- mode. This data type can be associated with input or output data up to 12 byte. So far the data type "OctetString" with numeric identifier "10" has been used for the coding of the F message trailer. For new product developments the new data type specification shall be considered.

Numeric Identifier	Data type name	Value range	Resolution	Length
110	F message trailer with 4 octets	PROFIsafe: V1-mode and V2-mode	-	4 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	Status/Control octet							
Octet 2	Consecutive number (V1-mode) or High-octet CRC(V2-mode) *)							
Octet 3	CRC *)							
Octet 4	Low-byte CRC (least significant octet) *)							

* Byte ordering according to IEC 61158-5 Type 3

F message trailer with 5 octets

This data structure consists of the status/control byte and 4 byte CRC parameters in PROFIsafe's V2-mode. This data type can be associated with input or output data up to 122 byte.

Numeric Identifier	Data type name	Value range	Resolution	Length
111	F message trailer with 5 octets	PROFIsafe: V2-mode	-	5 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	Status/Control octet							
Octet 2	1. byte CRC (most significant octet) *)							
Octet 3	2. byte CRC *)							

Bits	7	6	5	4	3	2	1	0
Octet 4	3. byte CRC *)							
Octet 5	4. byte CRC (least significant octet) *)							

* Byte ordering according to IEC 61158-5 Type 3

F message trailer with 6 octets

This data structure consists of the status/control byte, consecutive number and 4 byte CRC parameters in PROFIsafe's V1-mode. This data type can be associated with input or output data up to 122 byte. So far the data type "Octet String" with numeric identifier "10" has been used for the coding of the F message trailer. For new product developments the new data type specification shall be considered.

Numeric Identifier	Data type name	Value range	Resolution	Length
111	F message trailer with 6 octets	PROFIsafe: V1-mode	-	6 Octets

Bits	7	6	5	4	3	2	1	0
Octet 1	Status/Control octet							
Octet 2	Consecutive number							
Octet 3	1. byte CRC (most significant octet) *)							
Octet 4	2. byte CRC *)							
Octet 5	3. byte CRC *)							
Octet 6	4. byte CRC (least significant octet) *)							

* Byte ordering according to IEC 61158-5 Type 3

4.6 TO Path Object

Preface

Contents

This document is part of the **System and Function Descriptions documentation package**.

Scope

This manual is valid for SIMOTION SCOUT in conjunction with the SIMOTION Cam, Path or Cam_ext technology package for product version V5.3.

Chapters in this manual

The following is a list of chapters included in this manual along with a description of the information presented in each chapter.

Chapters in this manual

The following describes the purpose and objectives of the manual:

- **Overview of Path Interpolation**
  This chapter contains an overview of the TO functionality and a definition of the terms.
- **Basics of Path Interpolation**
  This chapter explains the basic setting options and functions of the Path Interpolation technology object.
- **Configuring the Path Object**
  This chapter explains the configuration procedure with reference to various tasks.
- **Sample Project for the Path Interpolation**
  This chapter contains a sample project for the path interpolation.
- **Programming/Homing Path Interpolation**
  This chapter explains the commands and functions in greater detail.
- **Appendix A**
  This chapter explains the specific kinematics with TrafoID 1001.
- **Index**
  Keyword index for locating information.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.3:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C

- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

4.6.1 Fundamental safety instructions

4.6.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life caused by machine malfunctions caused by incorrect or changed parameterization

Incorrect or changed parameterization can cause malfunctions on machines that can result in injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

4.6.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that can be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

4.6.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

4.6.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

4.6.2 Overview of Path Interpolation

4.6.2.1 Overview of Functions

As of Version V4.1, SIMOTION provides **path interpolation** functionality. This functionality enables up to three path axes to travel along paths. In addition, a position axis can be traversed synchronously with the path.

Paths can be combined from segments with linear, circular, and polynomial interpolation in 2D and 3D.

The path interpolation technology is provided by the **path object**, which represents an independent functionality.

The TO pathObject is interconnected to **path axes**, and can also be interconnected to a position axis.

The dynamic response parameters are predefined on the path motion.

The path motions of individual path commands can be blended together to form a complete path with no intermediate stop.

The machine kinematics are adapted to the Cartesian axes of the path coordinate system via the kinematic transformation.

As of V4.1.2, the functionality is available for the synchronization of the path motions with an externally specified position value, e.g. with the motion of a conveyor. This supports the system handling for the moved conveyor.

The **path interpolation** technology contains transformations for the following orthogonal kinematics:

- Cartesian linear aches
- SCARA
- 2D roller picker
- 3D roller picker
- 2D delta picker
- 3D delta picker
- 2D articulated arm
- 3D articulated arm
- 2D swivel arm
- 3D cylindrical robot

As of V4.4, it is also possible to create your own transformations with the aid of the 2D or 3D user function.

During a path motion, a position axis can be traversed synchronously with the path. The axis can approach a programmed, axis-specific target position synchronously or it can execute a motion according to the path length, thus enabling implementation of path-length-based output cams and measuring inputs.

Path interpolation functions are required for such applications as feeding or withdrawal of materials to or from a machine.

The application of commands for individual path segments requires a total path plan in the user program or application.

CNC programming according to DIN 66025 is not supported by SIMOTION.

4.6.2.2 Terminology

Axis coordinates

Coordinates of the path axes or the position axis with path-synchronous motion.

Path-axis interface

Interfaces for bidirectional data exchange between the path object and interconnected path axes.

Path axis

Axis that can execute a path motion along with other path axes via a path object.

Path motion

Motion resulting from the interpolation of a path motion command; output on path axes.

Path interpolation

Motion along a path with an assignable dynamic response.

Path interpolation generates the traversing profile for the path, calculates the path interpolation points in the interpolation cycle, and uses the kinematic transformation to derive the axis setpoints for the interpolation cycle points.

Path interpolation grouping

Several path and positioning axes connected by a path object or interpolation.

Path object

The path object provides the functionality for the path interpolation and for other tasks connected with the path interpolation. It also contains the kinematics transformations implemented in the system.

Path control panel

The path control panel enables the control and monitoring of path objects without a user program. It is mainly used to commission kinematic transformations.

Continuous-path control

Motion along a path at a definable velocity.

This can include velocity-based smoothing of the segment transitions by insertion of transition segments.

Basic coordinate system (BCS)

Coordinate system of path interpolation. A clockwise, rectangular coordinate system in accordance with DIN 66217 is used.

Motion sequence

Permits the coupling of the kinematic end point with a coupled OCS and so, for example, the coupling with the actual value of a conveyor. This means, for example, a product can be taken from a running conveyor or placed there.

As of SIMOTION V4.1.2, position details in the motion commands can be related optionally to the basic coordinate system or to an **object coordinate system** (**OCS**).

Motion sequence reference value (trackingInPosition)

The value made available to the **TrackingIn interface** of the path object by another technology object. This can be, for example, the actual value of an external encoder.

Motion sequence value (trackingPosition)

The current position of a **coupled OCS** with reference to the **OCS reference position**

Frame transformation

A frame transformation describes the position of a coordinate system relative to another coordinate system that defines, for example, the **OCS reference position** relative to the basic coordinate system of the path object. The frame transformation consists of **translations** along the X-, Y-, and Z-axes and **rotations** at the individual axes.

For the transformation, the displacements are performed first and then the rotations in the following order:

- **Roll** at the X axis
- **Pitch** at the (already turned) Y axis
- **Yaw** at the (already twice-turned) Z axis

Main plane

X-Y, Y-Z or Z-X plane or a parallel plane. The third coordinate is not evaluated.

Interface for path-synchronous motion

Interface for bidirectional data exchange between the path object and an interconnected position axis for path-synchronous motion.

Cartesian axes

Axes X, Y, and Z of the path object

Kinematics

The term "kinematics" in the context of robots and handling devices in motion control systems refers to the abstraction of a mechanical system onto the variables relevant for motion and motion control, i.e. the motion-capable elements (articulations) and their geometric positions relative to each other (arms).

Kinematic transformation, kinematic adaptation

Conversion of specifications in Cartesian coordinates to specifications for individual path axes, and vice versa.

Circular path

Path in 2D or 3D that describes a circle or an arc path.

Linear path

Path in 2D or 3D that describes a straight path.

Coupled OCS

An **object coordinate system (OCS)** coupled synchronously to the **trackingIn interface**.

Object coordinate system (OCS)

As of SIMOTION V4.1.2, in addition to the **base coordinate system (BCS)**, object coordinate systems (OCS) with the path object are also available. Path motions can be specified either in the BCS or in the OCS. The object coordinate systems are defined in their reference position using frame transformations for the BCS. They can be coupled with a specified motion value in the x direction of the OCS on the **TrackingIn interface**.

OCS reference position

Position of the OCS for the motion sequence value equal to zero. The OCS reference position for the BCS is defined using a **frame transformation**.

Polynomial path

Path in 2D or 3D that describes a polynomial segment.

Synchronous motion, path-synchronous motion

Synchronous coupling of an axis with a path motion; output on a position axis.

TrackingIn interface

The **trackingIn** input interconnection interface of the path object can be interconnected with another TO that provides an output interface with motion information. This can be, for example, the motion setpoint or actual value of an axis or the actual value of an external encoder.

4.6.3 Basics of Path Interpolation

4.6.3.1 Path interpolation

The **path interpolation** technology provides functionality for interpolating linear, circular, and polynomial paths in two dimensions (2D) and three dimensions (3D).

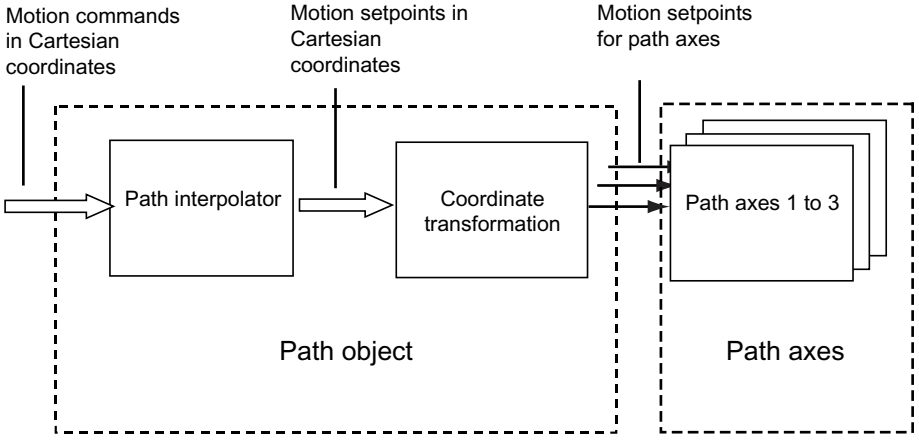

Figure 4-501 Role and basic principle of the path interpolator

Objects involved in path interpolation

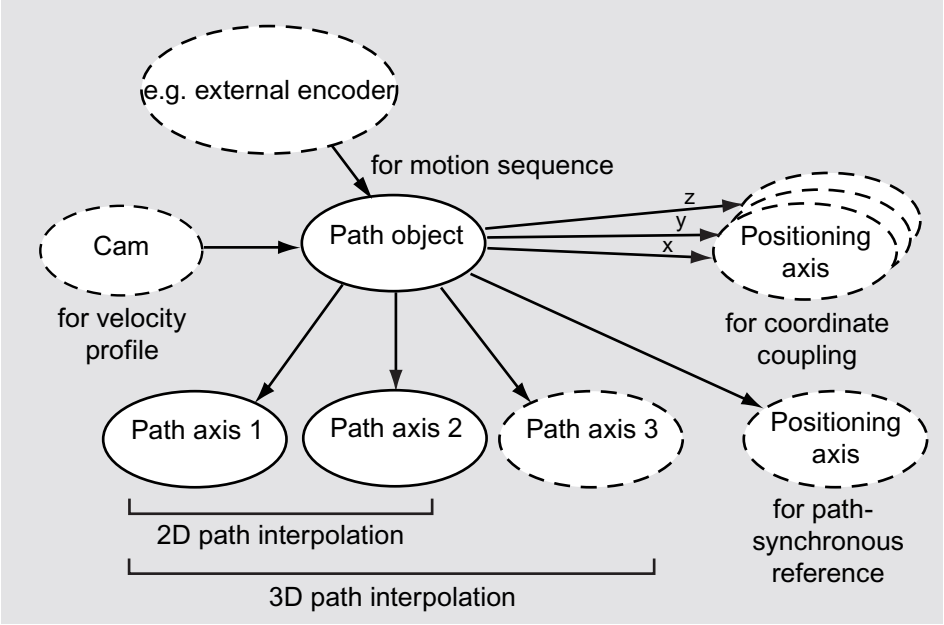

Figure 4-502 Objects involved in path interpolation

The path interpolation technology is made available in the Path Object technology object (TO Path Object).

The TO Path Object is interconnected with 2 or 3 path axes.

In addition, the TO Path Object can be interconnected with a positioning axis for path-synchronous motion and with positioning axes for connection to a coordinate. Likewise, it can be interconnected with a cam.

From V4.5 the TO Path Object can also be interconnected with an orientation axis.

The **TrackingIn** interface can be used to interconnect a technology object that provides motion information with a position (the motion sequence value), such as:

- External encoder
- Positioning axis

Role of the path axis

All single-axis functions can be executed on the path axis without limitations.

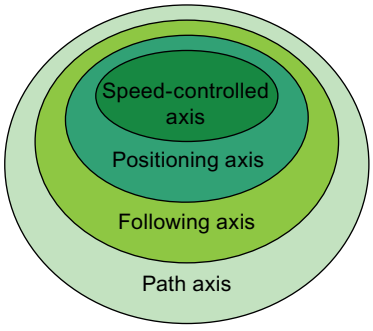

Figure 4-503 Role of the path axis

The path interpolation functionality is independent of the physical axis type. Path interpolation can be applied to electric axes, hydraulic axes, and stepper motor axes (real axes) as well as to virtual axes.

Inclusion of path interpolation in technology packages

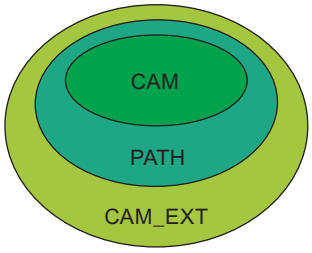

Figure 4-504 Inclusion of path interpolation in technology packages

Path functionality is made available in the **PATH** technology package, which also includes the functionality of the CAM technology package. The extensions include the TO Path Object and the TO Path Axis.

Thus, the **CAM_EXT** technology package also contains these object types.

For additional information, see **Motion Control Basic Functions**, "Available technology objects".

4.6.3.2 Coordinate system

The path interpolation functions require a Cartesian coordinate system. A clockwise, rectangular coordinate system in accordance with DIN 66217 is used.

The user programs in this right-handed system, irrespective of the real kinematics.

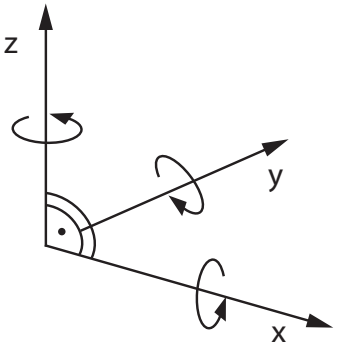

Figure 4-505 Cartesian coordinate system, right-handed system

Main planes

It is easy to program two-dimensional motions (2D) directly in one of the three main planes X-Y, Y-Z, or Z-X. In this case, the third coordinate remains constant and does not have to be programmed.

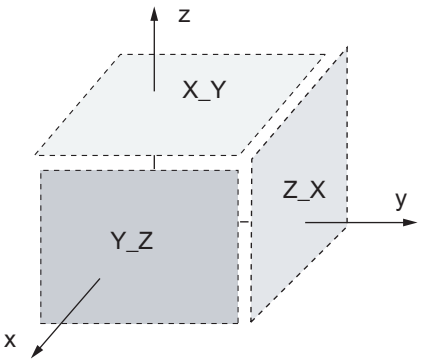

Figure 4-506 Main planes in 3D

4.6.3.3 Modulo properties

Both path axes and positioning axes can be used as modulo axes. However, no modulo range change for the path axis may occur in the path traversal area. The kinematic transformation does not take account of any modulo range change.

Consequently, only one modulo range of the path axis can be used for the traversal area on the path object. The activation of the path interpolation defines the modulo range for the path motion.

This means that the modulo transition of the axis must not be in the traversing range of the path motions. The modulo range and the modulo starting point as well as the position of the modulo range relative to the intended path travel range must be set appropriately, for example, using the settings for reference point and reference point offset during homing.

4.6.3.4 Units

All axis-related values are displayed in the quantity and unit of the assigned (interconnected) axes.

The Cartesian coordinates are indicated in a unit of length. The default setting for Cartesian values is [mm].

The default unit for rotary values, such as rotary angle, is [°] and calculated as degrees.

The transformation calculates directly with the numerical values. There is no unit conversion for transformations provided by the system. Thus, the same units must be used for the same base value, e.g, length specification.

Note

Use the same units for all objects associated with the path object that have the same reference quantities (e.g. linear axes in mm, rotary axes in °). Avoid, for example, the mixing of metric and non-metric units for the involved axes.

4.6.3.5 Path interpolation types

Path interpolation types

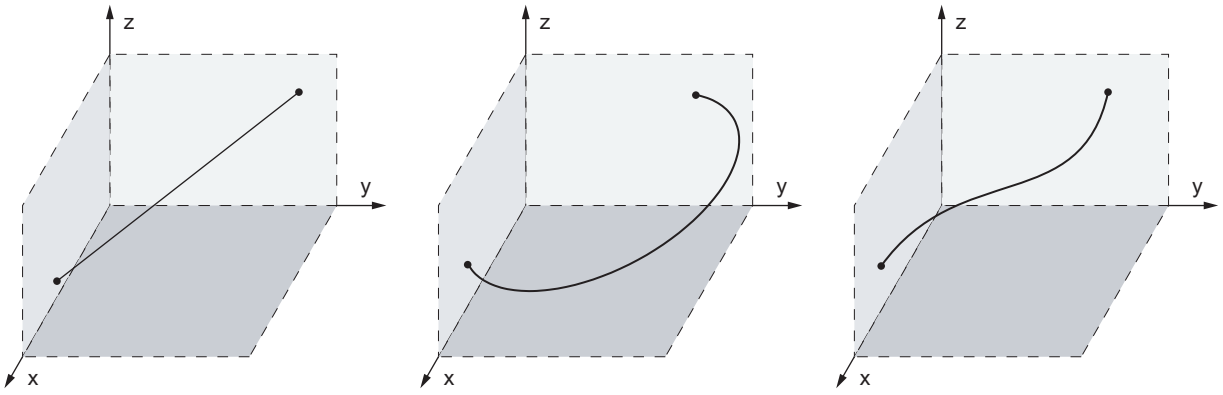

Figure 4-507 Examples of linear path in 3D, circular path in 3D, polynomial path in 3D

The following interpolation modes are available for the path object:

- Linear paths (Page 2480)
  - 2D in a main plane
  - 3D
- Circular paths (Page 2481)
  - 2D in a main plane with radius, end point, and orientation
  - 2D in a main plane with center point and angle
  - 2D with intermediate and end points
  - 3D with intermediate and end points
- Polynomial paths (Page 2485)
  - 2D in a main plane with explicit specification of geometric derivatives in the start point or with a geometrically continuous attachment
  - 3D with explicit specification of geometric derivatives in the start point or with a geometrically continuous attachment
  - 2D with explicit specification of polynomial parameters
  - 3D with explicit specification of polynomial parameters

The main plane (2D) or the 3D mode in which the path motion occurs can be specified with the **pathPlane** parameter of the interpolation command.

The third path coordinate perpendicular to the main plane is not changed in a 2D path.

Structure of commands for path interpolation

The following path interpolation commands are available:

- Linear interpolation: `_movePathLinear()`
- Circular interpolation: `_movePathCircular()`
- Polynomial interpolation: `_movePathPolynomial()`

These commands contain the following parameters:

- Specification of the object instance in `pathObjectType`
- Specification of the path plane in `pathPlane`
  This parameter is used to set the path plane. The main plane (2D) or the 3D mode in which the path motion should occur can be specified.
- Specification of the path mode in `pathMode`
  This parameter is used to set whether the value for the end point is specified as an absolute value or whether it is to be evaluated relative to the start point.
- Specification of the end point in `x, y, z`
- Specification of the blending mode in `blendingMode`
- Specification of the merge behavior in `mergeMode`
- Specification of the command transition in `nextCommand`
- Specification of the command ID in `commandId`

Specifications for the linear path only (_movePathLinear()):

(see Linear paths (Page 2480))

- None

Specifications for the circular path only (_movePathCircular())

(see Circular paths (Page 2481))

- Specification of the circle type in `circularType`
- Specification of the circle direction in `circleDirection`
- Specification of the intermediate point mode in `ijkMode`
- Specification of the intermediate point mode in `i, j, k`
- Specification of the arc angle in `arc`
- Specification of the circle radius in `radius`

Specifications for the polynomial path only (_movePathPolynomial())

(see Polynomial paths (Page 2485))

- Specification of polynomial mode in `polynomialMode`
- Specification of the vector components in `vector1x` to `vector4z`

Specifications for the dynamics

(see Path dynamics (Page 2491))

- Velocity profile in `velocityprofile`
- Velocity in `velocity`
- Acceleration in `positiveAccel`
- Deceleration in `negativeAccel`
- Jerk on start of acceleration in `positiveAccelStartJerk`
- Jerk at acceleration end in `positiveAccelEndJerk`
- Jerk on start of deceleration in `negativeAccelStartJerk`
- Jerk at deceleration end in `negativeAccelEndJerk`
- Selection of specific profile in `specificVelocityProfile`
- Specifies the velocity profile with a cam in `profileReference`
- Start point for specific profile in `profileStartPosition`
- End point for specific profile in `profileEndPosition`
- Adaptation to the axis dynamics in `dynamicAdaption`

Specifications for path-synchronous motion

(see Functionality of path-synchronous motion (Page 2505))

- Mode of path-synchronous motion in `wMode`
- Direction of path-synchronous motion in `wDirection`
- End point of path-synchronous motion in `w`

Details of the object coordinate system

(see Object coordinate system (OCS) on the path object (Page 2545))

- Specification of the coordinate system in `csType`
  This parameter is used to set whether the motion should be performed in the base coordinate system or in an object coordinate system.
- Specification of the object coordinate system in `csNumber`
  This parameter is used to set which object coordinate system should be used for the motion.

Linear paths

In the case of linear path interpolation, an end point is approached on a straight line starting from the current position.

Linear paths are traversed with the **_movePathLinear()** command.

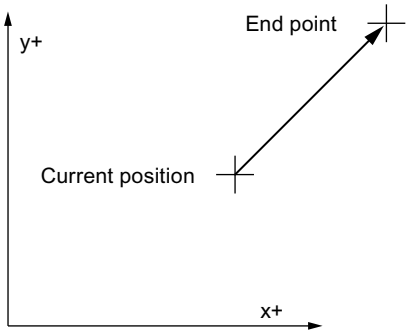

Figure 4-508 Example of a linear path

Example of a linear path in ST

In this example, the current position and the end point lie in the X-Y plane. Each end point is separated by 10 units in the positive direction from the current position along both axes.

```
myRetDINT :=
    _movePathLinear(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        pathMode:=relative,
        x:=10.0,
        y:=10.0
);
```

Circular paths

Circular paths

For a circular path, approach is made from the current position to a specified end point following an arc.

Circular paths are traversed with the **_movePathCircular()** command.

The arc can be specified using several modes. The **circularType** parameter specifies the mode to be used.

- Circular interpolation in a main plane with radius, end point, and orientation (Page 2482)
- Circular interpolation in a main plane with center point and angle (Page 2483)
- Circular interpolation with intermediate and end points (Page 2484)

If a circular path is not traversed because of the geometry, the **50002** error will be issued.

Circular path in a main plane with radius, end point, and orientation

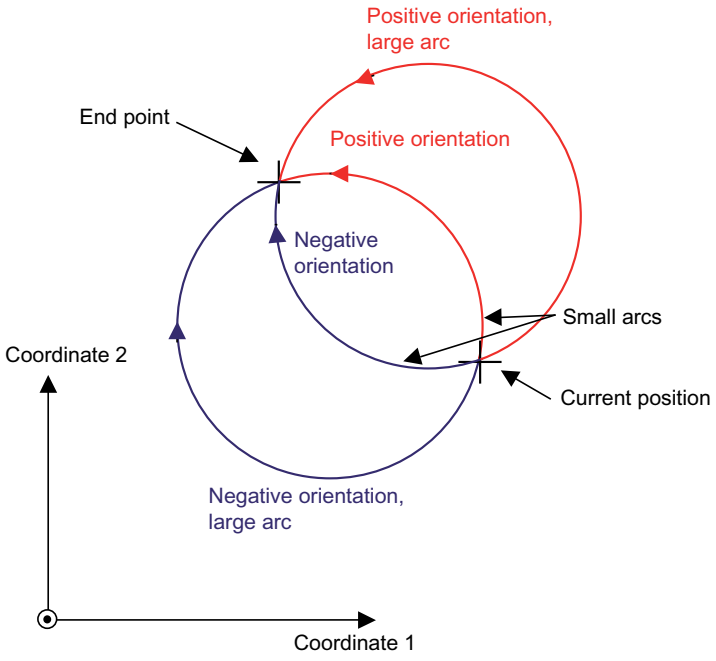

Figure 4-509 Circular path with radius, end point, and orientation

To perform circular interpolation in a main plane with specification of radius, end point, and orientation, you set **circularType:=WITH_RADIUS_AND_ENDPOSITION** in the **_movePathCircular()** command.

The end point is approached on a circular path starting from the current position. The current position and the end point lie in the same main plane. Circle radius, orientation (travel in the positive or negative direction of rotation), and travel on large or small arcs are specified in the command.

The end point position is entered in the x, y, and z parameters.

Example of a circular path with radius, end point, and orientation

In this example, the current position and the end point lie in the X-Y plane. The end point is separated from the current position by -10 units along the x-axis and 10 units along the y-axis. The large circle is traveled in the positive direction.

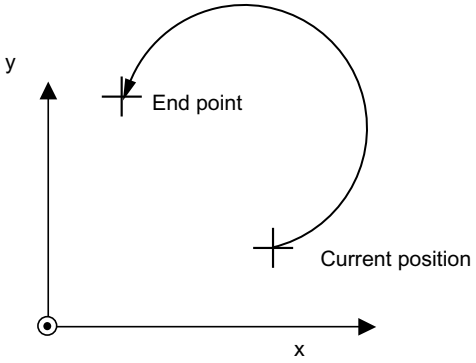

Figure 4-510 Example of circular path with radius, end point, and orientation

```
myRetDINT :=
    _movePathCircular(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        circularType:=WITH_RADIUS_AND_ENDPOSITION,
        circleDirection:=LONG_RUN_POSITIVE,
        pathMode:=RELATIVE,
        x:=-10.0,
        y:=10.0,
        radius:=12.0
);
```

Circle using center and angle

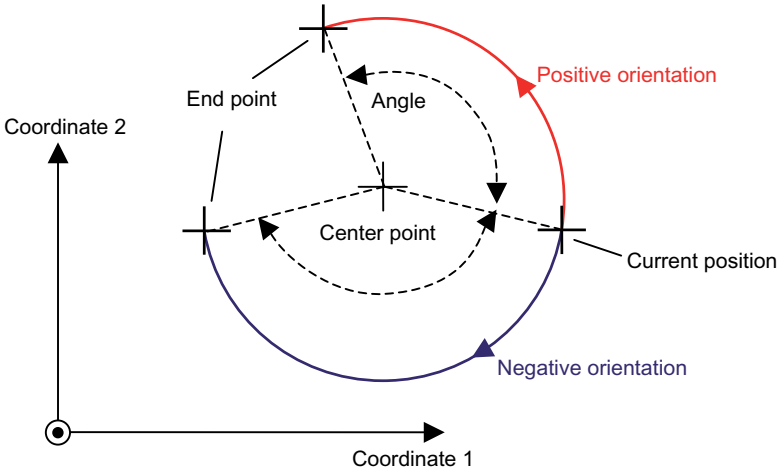

Figure 4-511 Circular path with center point and angle

To perform circular interpolation starting from the current position in a main plane with specification of center point and angle, you set **circularType:= BY_CENTER_AND_ARC** in the **_movePathCircular()** command.

The center point of the circle, the angle to be traveled, and the orientation (travel in the positive or negative direction of rotation) are specified in the command.

The position of the center point of the circle is entered in the **i**, **j**, and **k** parameters.

You use the **ijkMode** parameter to set whether the circle center point coordinates are entered absolutely or relative to the start point or whether the setting in the **pathMode** parameter should be used.

Example of a circular path with center point and angle

In this example, the center point is separated by -10 units from the current position along the X-axis. An angle of 90 degrees in the positive direction is traveled.

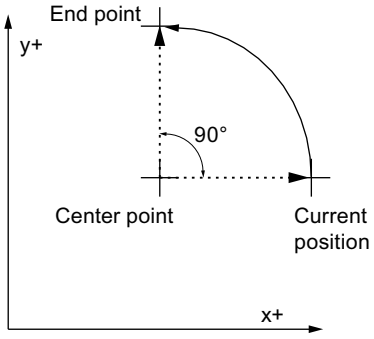

Figure 4-512 Example of a circular path with center point and angle

```
retval := _movePathCircular(
    pathObject := pathIpo,
    pathPlane := X_Y,
    circularType := BY_CENTER_AND_ARC,
    circleDirection := POSITIVE,
    ijkMode := RELATIVE,
    i := -10.0, j := 0.0,
    arc := 90.0
);
```

Circular path using intermediate point and end point

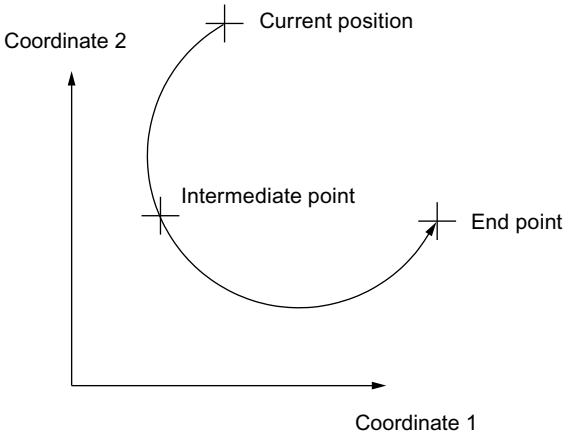

Figure 4-513 Circular path with intermediate and end points

To perform circular interpolation starting from the current position over an intermediate point to the end point, you set **circularType:=OVER_POSITION_TO_ENDPOSITION** in the **_movePathCircular()** command.

The current position, intermediate point, and end point specify the plane for the circular path.

The end point position is entered in the **x**, **y**, and **z** parameters.

The intermediate point is entered in the **i**, **j**, and **k** parameters.

You use the **ijkMode** parameter to set whether the intermediate point coordinates are to be evaluated absolutely or relative to the start point or according to the setting in **pathMode** of the end point.

Example of a circular path with intermediate point and end point

In this example, the end point of the circle is separated by 10 units from the current position in the X-direction. Each intermediate point is separated by 5 units in the X-, Y- and Z-direction from the current position.

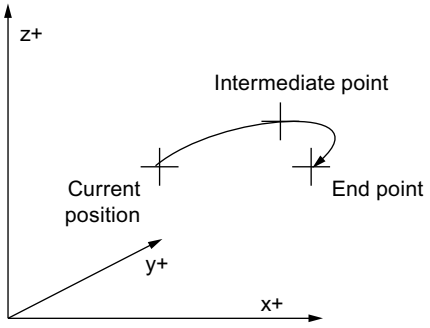

Figure 4-514 Example of a circular path with intermediate and end points

```
retval := _movepathcircular(
    pathObject := pathIpo,
    pathPlane := X_Y_Z,
    circularType := OVER_POSITION_TO_ENDPOSITION,
    pathMode := RELATIVE,
    x:=10.0, y:=0.0, z:=0.0,
    ijkMode := RELATIVE,
    i:=5.0, j:=5.0, k:=5.0
);
```

Polynomial paths

Polynomial paths

A polynomial segment enables you to achieve a constant-velocity and constant-acceleration transition between two geometry elements and to make use of user-programmable curve shapes, e.g. from a higher-level CAD system.

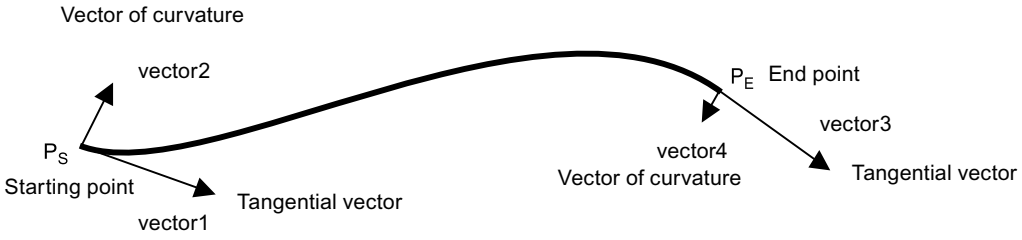
In addition to the implicit start point (P_S) of the polynomial, the end point (P_E) as well as four three-dimensional vectors for defining the polynomial coefficients are specified in the command parameters of the **_movePathPolynomial()** command

The vectors are entered in the command using their components. Thus, for example, **vector1** is entered with command parameters **vector1x**, **vector1y**, and **vector1z**.

The polynomial can be defined in three ways:

- Direct specification of the polynomial coefficients (Page 2487)
- Explicit specification of starting point data (Page 2487)
- Attach continuously (Page 2489)

For the two **explicit specification of the start point data** and **attach continuously** types, the derivatives at the start and end points of the polynomial are required. They can be determined using integrated functions.



First geometric derivative (tangential vector) $\dot{P} = \frac{dP}{ds}$; $|\dot{P}| = 1$

Second geometric derivative (vector of curvature) $\ddot{P} = \frac{d^2P}{ds^2}$

Figure 4-515 Polynomial description by specification of the geometric derivatives

Smooth-path transition between two linear paths

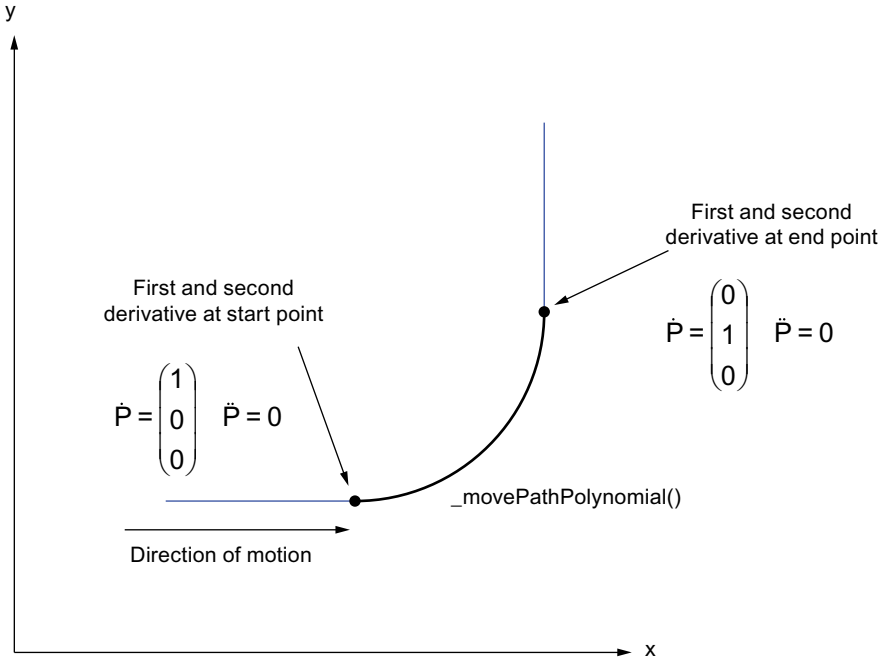


Figure 4-516 Specification of derivatives for polynomial transition between two linear paths

The derivatives at the end point of the previous geometry and at the start point of the following geometry can be calculated with the **_getLinearPathGeometricData()**, **_getCircularPathGeometricData()** and **_getPolynomialPathGeometricData()** commands.

If a polynomial path is not traversed because of the geometry, the **50002** error will be issued.

Effect of the start and end points

When polynomials are used, they must be linked smoothly to the previous and subsequent path segment. Depending on the choice of the start and end points, there are consequently different polynomial curves that can deviate significantly from a circular path.

The following graphic shows the curve of a polynomial path with different start points:

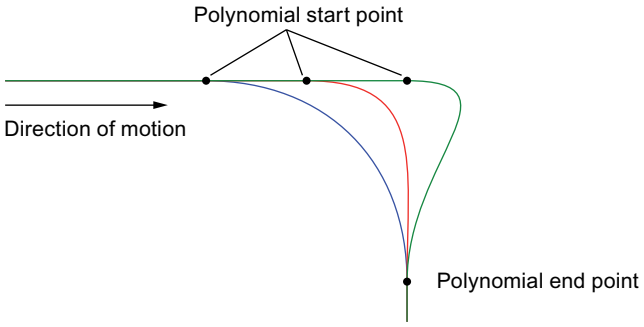

Figure 4-517 Behavior of a polynomial path with different start points

Polynomial path - direct specification of the polynomial coefficients

For the polynomial specification using (**polynomialMode:=SETTING_OF_COEFFICIENTS()**) polynomial coefficients, the polynomial path is determined using a function of the fifth degree:

$P = A_0 + A_1 \bullet p + A_2 \bullet p^2 + A_3 \bullet p^3 + A_4 \bullet p^4 + A_5 \bullet p^5$, $p \in [0,1]$

- **vector1**: A_2
- **vector2**: A_3
- **vector3**: A_4
- **vector4**: A_5
- A_0 and A_1 result from the start point and end point, and the predefined coefficients. For the parameter area indicated above, this means:
  - A_0 = start point
  - A_1 = end point - start point - A_2 - A_3 - A_4 - A_5

Polynomial paths - explicit specification of the starting point data

For the **polynomialMode:=SPECIFIC_START_DATA** setting and the explicit specification of the starting point data, the two geometric derivatives at the start point must also be specified for the derivatives at the end point of the polynomial.

The derivatives must be specified as follows:

- **vector1**: First geometric derivative/tangential vector in start point
- **vector2**: Second geometric derivative/curvature vector in start point
- **vector3**: First geometric derivative/tangential vector in end point
- **vector4**: Second geometric derivative/curvature vector in end point

Example of a polynomial path with explicit specification of the starting point data

This example connects a linear path and a circular path:

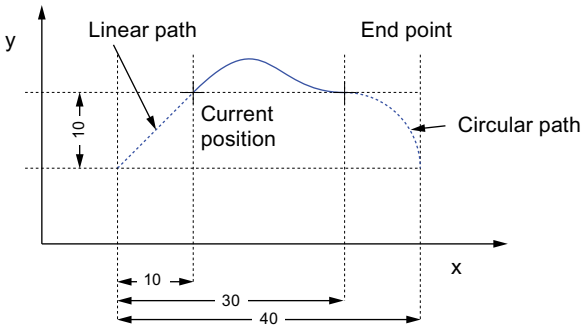

Figure 4-518 Example of a polynomial path with explicit specification of the starting point data

The two derivatives in the starting point of the polynomial must be calculated first. The **_getLinearPathGeometricData()** function used for this purpose calculates the two derivatives for the end point of the straight line (starting point of the polynomial) using the coordinates of the straight line.

The two derivatives of the polynomial end point are then determined. The **_getCircularPathGeometricData()** command used for the calculation uses the starting point of the arc (end point of the polynomial) as basis.

```
// StartPoly must be defined as
// StructRetGetLinearPathGeometricData
// EndPoly must be defined as
// StructRetGetCircularPathGeometricData
StartPoly :=
    _getLinearPathGeometricData(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        pathMode:=ABSOLUTE,
        xStart:=10.0,
        yStart:=10.0,
        xEnd:=20.0,
        yEnd:=20.0,
        pathPointType:=END_POINT
);
EndPoly :=
    _getCircularPathGeometricData(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        circularType:=WITH_RADIUS_AND_ENDPOSITION,
        circleDirection:=NEGATIVE,
        pathMode:=ABSOLUTE,
        xStart:=40.0,
        yStart:=20.0,
        xEnd:=50.0,
        yEnd:=10.0,
        radius:=10.0,
        pathPointType:=START_POINT
);
```

```
myRetDINT :=
    _movePathPolynomial(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        pathMode:=ABSOLUTE,
        polynomialMode:=SPECIFIC_START_DATA,
        x:=40.0,
        y:=20.0,
        vector1x:=StartPoly.firstGeometricDerivative.x,
        vector1y:=StartPoly.firstGeometricDerivative.y,
        vector2x:=StartPoly.secondGeometricDerivative.x,
        vector2y:=StartPoly.secondGeometricDerivative.y
        vector3x:=EndPoly.firstGeometricDerivative.x,
        vector3y:=EndPoly.firstGeometricDerivative.y,
        vector4x:=EndPoly.secondGeometricDerivative.x,
        vector4y:=EndPoly.secondGeometricDerivative.y
);
```

Polynomial paths - attach continuously

Polynomial paths can be attached continuously to a previous path segment using the **polynomialMode:=ATTACHED_STEADILY** setting. Because the geometric derivatives at the start point of the polynomial are taken from the predecessor geometry, only the first and the second derivative at the end point needs to be specified directly.

The two derivatives for the polynomial command are specified as following:

- **vector1**: First geometric derivative/tangential vector in end point
- **vector2**: Second geometric derivative/curvature vector in end point

If the geometric derivative cannot be determined in the start point (if no current motion is available), the command is not executed and error message 50002 "Calculation of the geometry element not possible, reason 3" is output.

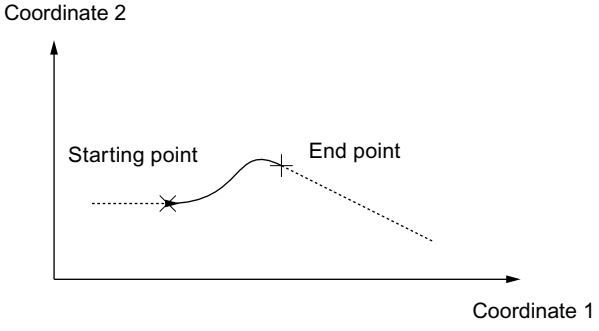

Figure 4-519 Polynomial path - attach continuously

Example of a polynomial path attached continuously

This example connects two straight lines using a polynomial.

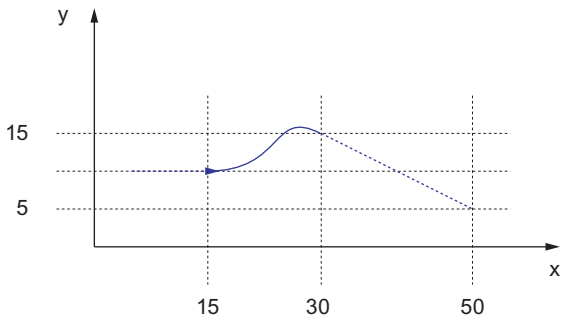

Figure 4-520 Example for the continuous attachment of polynomial paths

The two derivatives at the end point of the polynomial must be calculated first. The **_getLinearPathGeometricData()** function used here returns a structure with the derivatives. The function calculates the derivatives for the start point of the straight lines (end point of the polynomial) using the start and end point coordinates of the straight lines.

```
// EndPoly must be defined as
// StructRetGetLinearPathGeometricData
EndPoly :=
    _getLinearPathGeometricData(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        pathMode:=ABSOLUTE,
        xStart:=30.0,
        yStart:=15.0,
        xEnd:=50.0,
        yEnd:=5.0,
        pathPointType:=START_POINT
);
myRetDINT :=
    _movePathPolynomial(
        pathObject:=pathIPO,
        pathPlane:=X_Y,
        pathMode:=ABSOLUTE,
        polynomialMode:=ATTACHED_STEADILY,
        x:=30.0,
        y:=15.0,
        vector1x:=EndPoly.firstGeometricDerivative.x,
        vector1y:=EndPoly.firstGeometricDerivative.y,
        vector2x:=EndPoly.secondGeometricDerivative.x,
        vector2y:=EndPoly.secondGeometricDerivative.y
);
```

4.6.3.6 Path dynamics

Path dynamics

The path dynamics can be specified through preset dynamic values or a dynamic response profile.

The dynamic limits of the individual axes for motion along the path can also be taken into consideration.

An error message is output if the dynamic values are exceeded.

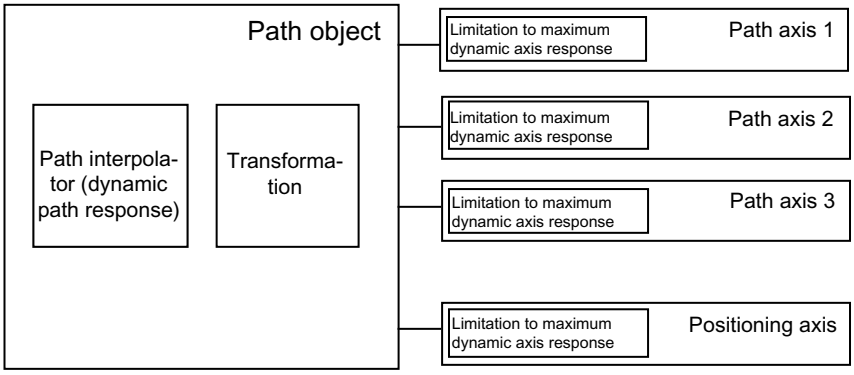

Figure 4-521 Path dynamics during path interpolation and dynamic limiting on the axis

Preset path dynamics

The path dynamics can be specified in three different ways in the respective motion command:

- Preset path dynamics via command parameters
- Preset path dynamics via velocity profile/cam
- Preset path dynamics via DynamicsIn

Preset path dynamics via command parameters

The dynamic values (velocity, acceleration, and, if applicable, jerk) are explicitly specified in the velocity profile type.

The path interpolator calculates the velocity profile for the path motion. Criteria for calculating the velocity profile include:

- The dynamic values for velocity, acceleration, and jerk specified in the path motion command
- The type of velocity profile set in **velocityProfile**:
  - **TRAPEZOIDAL**: Without jerk limitation; the path will be traveled with constant acceleration and deceleration.
  - **SMOOTH**: With jerk limitation; the path will be traveled with smooth acceleration and deceleration curve.

Preset path dynamics via velocity profile/cam

The path object can be interconnected with a cam for specifying a velocity profile.

Velocity as well as the derived values for acceleration and, if applicable, jerk, are taken from the velocity profile.

The base value (domain) is the path length. To rule out rounding errors in the path length calculation and to enable optimized calculation of profiles over more than one motion, parameters can be programmed simultaneously for the start and end points of the cam domain of the respective motion.

At the command end, the dynamics specified in the profile are also applied to the motion.

If additional follow-on motions are programmed, these dynamics are also applied to the transition to the new motion command. Possible settings for the path behavior at the motion end are ignored.

If no additional follow-on motions are programmed or if the motion is to stop at the command end, the dynamics in the profile should be selected such that a stop at the motion end is possible; a velocity of 0 with a braking dynamic that can be achieved with certainty.

In addition, the profile dynamics are limited by the dynamic values for the individual commands, taking into account the preassigned velocity profile type.

Preset path dynamics via DynamicsIn

From V4.3 and higher, the path dynamics can be specified via DynamicsIn. The position specified in the DynamicsIn vector refers to the path/path length. The position must be specified with the velocity and the acceleration at this path point. These values must be provided to the TO cyclically using system variables or TO interconnection.

The dynamic planning and dynamic response adaptation of the TO path is completely deactivated, i.e. there is no limit and no monitoring.

The dynamic limitations of the axes are still effective.

Note

The path movements are not blended with active DynamicsIn

The settings POLYNOMIAL and CIRCULAR have no effect when PathDynamicsIn := TO_Connection.

With deactivated DynamicsIn, the path movements are blended. With active DynamicsIn, programmed geometric blending is ignored and you can calculate the geometric blending segments yourself and specify them for the system. Circular and polynomial commands are available for this.

See also

Blending and substitution with insertion of intermediate segments (Page 2499)

Limiting the path dynamics

Technological limiting

The individual axis setpoints resulting from the path interpolation are limited to the dynamic limits specified for each path axis and positioning axis involved in path-synchronous motion.

The dynamic values of the axis for the path object are only taken into account if this has been programmed accordingly (command parameter **blendingMode := ACTIVE_WITH_DYNAMIC_ADAPTION** and/or **dynamicAdaption <> INACTIVE**).

Path velocity limiting, path acceleration limiting, and path jerk limiting can be specified in the **limitsOfPathDynamics** system variables. Changes in the system variables take effect immediately.

The maximum dynamic values over the path result from the lesser of the dynamic parameters set in the command, the dynamic limits on the path specified via the system variables (**limitsOfPathDynamics**), and, if programmed, the maximum dynamic values of the axes along the path.

Note that the path velocity for active dynamic adaptation, possibly also reduced, if the dynamic limits of the axes would not be violated even without active dynamic adaptation.

Because the reserve used for the active dynamic adaptation, the maximum possible dynamic path response will not always be attained.

The limitation of dynamic values to the individual axes can lead to dynamic and distance deviations on the path. Path dynamics and axis limits should be set so that the axis limits are not exceeded during path motion.

Allowance for dynamic limits of path axes

A reference to the dynamic limits of the axis can be established in the path object using the **dynamicAdaption** command parameter. The following settings are possible:

- No allowance for maximum dynamic values of path axes (**INACTIVE**)
  With this setting, the axial limits are not taken into account within the path interpolation. However, path axis limiting is still active and, if a violation occurs, a setpoint-side path error can result.
  The setting is useful if:
  - There are no transformed dynamic values
  - It can be ensured in advance (e.g. during commissioning) that the axial limit values are not exceeded
  - The axial limits have been taken into account through an application, e.g. through calculation of an optimized velocity profile
  - Superimposed axis motions occur
- Reduction in the maximum path dynamics according to the maximum dynamic values of path axes (**ACTIVE_WITH_CONSTANT_LIMITS**)
  The velocity and acceleration of the path is limited in the path interpolator to the maximum values in the Cartesian coordinates calculated from the maximum value settings of the individual path axes.
  Axis-specific jerk limits in the preliminary path plan are not taken into account. However, the jerk can be limited by specifying the pathMotion monitoring on the path axis accordingly. This can result in a setpoint-side path error.
  If the dynamic limits of an axis are reached, i.e. if the programmed path velocity/acceleration cannot be achieved due to these limits, an alarm will be issued.
  If the dynamic limits of the path axes are changed online, the changes take effect immediately but not for the currently active or decoded motion command.
- Segment-by-segment reduction in the maximum path dynamics according to the maximum dynamic values of path axes in these segments (**ACTIVE_WITH_VARIABLE_LIMITS**).
  This setting is equivalent to **ACTIVE_WITH_CONSTANT_LIMITS**, except that the path is segmented. Overall, the path is travelled faster; the velocity is not constant over the entire path.

From system variable **kinematicsData.transformationsOfDynamics** of the path object, you can read out whether the maximum dynamic values of the axis are transformed values. If not, the path dynamics are always limited with the path object dynamic limits, regardless of the setting in the **dynamicAdaption** command parameter.

Difference between ACTIVE_WITH_CONSTANT_LIMITS and ACTIVE_WITH_VARIABLE_LIMITS

The following trace shows the difference between **ACTIVE_WITH_CONSTANT_LIMITS** and **ACTIVE_WITH_VARIABLE_LIMITS**. Two circular paths are traveled with a 2D portal; the maximum velocities of the path axes follow:

- **Axis_X**: 500 mm/s
- **Axis_Y**: 200 mm/s

A path velocity of 400 mm/s is defined in the path commands.

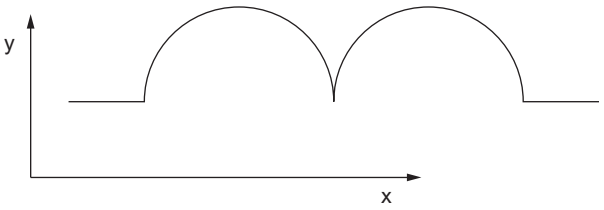

Figure 4-522 Example: Limiting the path dynamics

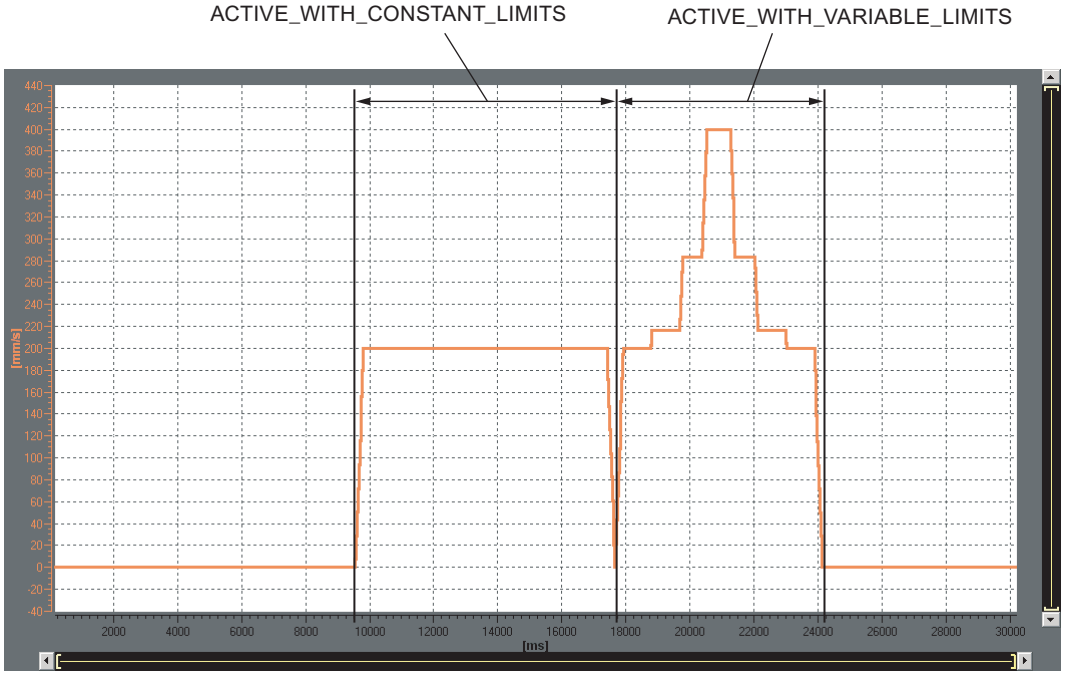

Figure 4-523 Trace: ACTIVE_WITH_CONSTANT_LIMITS, ACTIVE_WITH_VARIABLE_LIMITS

Override

A velocity override (system variable **override.velocity**) and an acceleration override (system variable **override.acceleration**) are available on the path object.

4.6.3.7 Stopping and resuming path motion

The **_stopPath()** command can be used to stop the current path motion. A stopped, but not canceled, path motion can be continued with the **_continuePath()** command.

When the path motion is resumed, the motion properties (velocity profile, acceleration, etc.) of the interrupted path command are applied. With SIMOTION V4.2 and higher, other dynamism parameters can be specified directly at the command _continuePath().

In the case of canceled path motions, if you want the application to start at the abort position, the last calculated setpoint position on the path is indicated in the **abortPosition** system variable.

Dynamic response for _stopPath()

The **_stopPath()** command can be used to define the dynamic response during deceleration. If the braking dynamic in the **_stopPath()** command is smaller than the braking dynamic in the active motion command, faults can occur in some situations.

If the dynamic response defined in the **_stopPath()** command in the previously defined path segments (i.e. in the path segment of the active command or in the path segment of the buffered commandPuffer) can be used to stop the path object, the path object will stop with error.

If the dynamic response defined in the **_stopPath()** command cannot stop the path object by the end of the previously defined path, the following can occur:

- The path interpolation is terminated.
- Each axis is delayed using the maximum dynamic response defined in the axis.
- The **50006** error message is generated.

As an example: The following path consists of three motion commands that blend in each other. This means, if the first command is active, the second command will be placed in the buffer. If the second command is active, the third command will be placed in the buffer. If the third command is active, it will be completed.

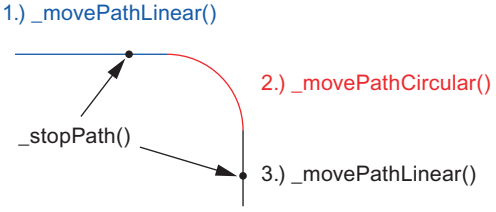

Figure 4-524 Dynamic response for _stopPath()

If **_stopPath()** with reduced dynamic response is called within the first linear path segment, the path object will be delayed using the dynamic response defined in the **_stopPath()** command. Under some circumstances, the path object stops in the circle section, it remains, however, on the path profile.

If **_stopPath()** with reduced dynamic response is called within the second linear path segment, the path object cannot stop before the end of the defined path. The axes are delayed with maximum dynamic response, the path profile may possibly by left, the **50006** error will be issued.

4.6.3.8 Path behavior at motion end

Path behavior at motion end

If the path dynamics are specified via a velocity profile, the behavior at the motion end is determined from the dynamics specified in the profile at the path end point.

If the path dynamics are specified via dynamic response parameters, the transition can be set. In addition to stopping at the end command, two sequential path segments can be dynamically linked together so that they do not have to be decelerated, see also *Axis Manual, Positioning with Blending section*.

No intermediate segments for the fillet are generated by the path interpolation for this blending.

Taking into account the axial limits, there are three transition types that can be set in the **blendingMode** parameter of the next command.

- Stopping at motion end (Page 2497) (**blendingMode:=INACTIVE**)
- Blending with dynamic adaptation (Page 2498) (**blendingMode:=ACTIVE_WITH_DYNAMIC_ADAPTION**)
- Blending without dynamic adaptation (Page 2498) (**blendingMode:=ACTIVE_WITHOUT_DYNAMIC_ADAPTION**)

The **blendingMode** parameter is only evaluated if the command is programmed with **mergeMode:=SEQUENTIAL** or **mergeMode:=NEXT_MOTION**.

The blending mode is specified in the motion command in which blending is to be performed.

Dynamic planning is executed by means of two motion commands. In SIMOTION V4.3 and higher, dynamic planning can be set by means of three motion commands (current, next and second motion command) (default setting when creating a new path object). This allows short intermediate commands to be blended without velocity reduction.

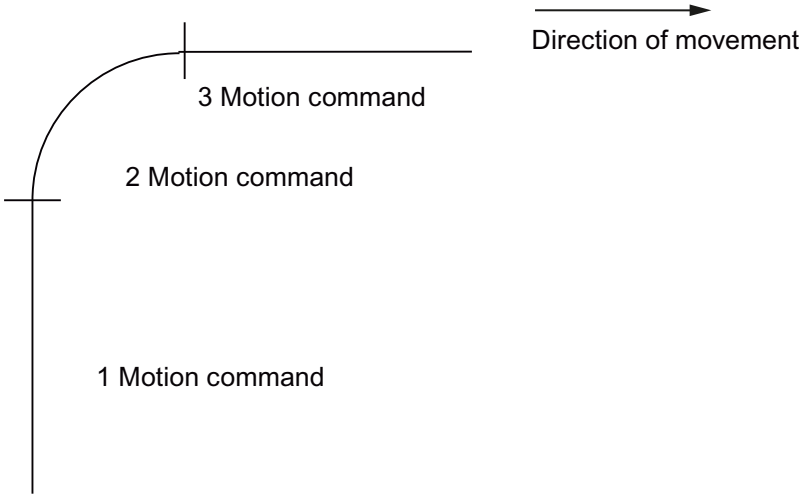

Figure 4-525 Dynamic planning via 3 motion commands

Stopping at motion end

The motion is ended in the target position of the path command. The path velocity and acceleration is zero. Any new path motion becomes active only after **END_OF_INTERPOLATION** (end of setpoint generation).

Blending with dynamic adaptation

During blending, the system supports a constant-velocity transition (with velocity profile type **TRAPEZOIDAL**) or a constant-velocity and constant-acceleration transition (with velocity profile type **SMOOTH**).

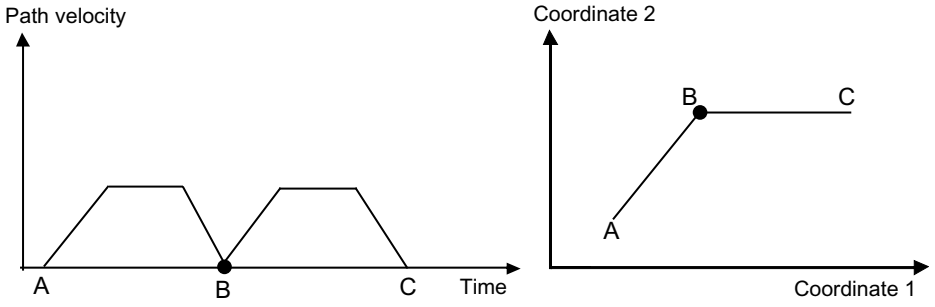

Figure 4-526 Example of blending with dynamic adaptation: Straight line - straight line

With this setting, the dynamic limits of the axis are taken into account directly when calculating the travel profile for path blending.

The axial limits for velocity and acceleration are also taken into account in the blending velocity.

For non-tangential path transitions (corners), the path velocity is reduced such that a velocity jump greater than the maximum acceleration does not occur for any of the participating axes. The result is a velocity-dependent smoothing of the path end point.

Note that with active dynamic adaptation, the dynamic axis response is set to the smaller value from axis acceleration and axis deceleration. Therefore, when an axis has a maximum acceleration of 1000 mm/s^2 and a maximum deceleration of 500 mm/s^2, the value for the deceleration is used for the calculation.

Blending without dynamic adaptation

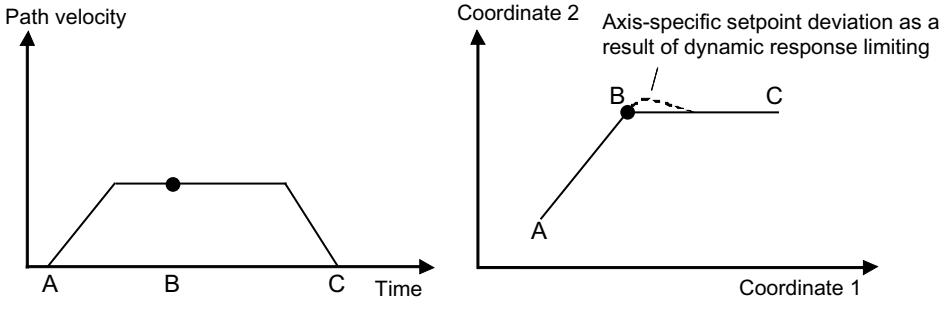

Figure 4-527 Example of blending without dynamic adaptation: Straight line - straight line

With this setting, the dynamic limits of the axis are not taken into account in path blending.

The path velocity is controlled as a scalar variable that is independent of direction and curvature.

A non-tangential attachment of path segments has no effect on the path velocity profile; for this reason, the velocity is not reduced during blending.

Because the setpoints that are generated for the individual axes are limited to the axis-specific dynamic limits for the axes, this can result in an axis setpoint error relative to the setpoint from

the path interpolation. This ultimately leads to an axis-specific deviation from the path in the blending range.

For example, this mode is applicable if the dynamic limits of the axes are to be adhered to on the path (when approaching positions, for example) but an axis-specific axis setpoint error relative to the path is acceptable at the segment transitions in the blending range.

Blending and substitution with insertion of intermediate segments

Blending with insertion of blending segments

When blending with insertion of transition segments, a blending segment is inserted between the two path segments. Either circular or polynomial segments can be inserted. As an alternative, an exact stop or blending can be carried out on the transitions without changing the path geometry.

Transition segments can even be inserted in substitute path motions.

Blending segment:

A polynomial segment can serve as a blending segment. A circular segment is also possible between two linear sets.

The command transition is the start of the blending. The path length of the blending segment and "remaining segment" is fully output on the 2nd motion command.

Blending with insertion of a polynomial segment:

Blend with insertion of a polynomial segment is possible between all path types. The transition between the segments and the polynomial path is consistent in terms of position, velocity and acceleration.

Blending with insertion of a circular segment:

Blending with insertion of a circular segment is only possible between 2 linear sets. The transition between the linear segments and the circuit is consistent in terms of position and velocity.

To determine the circular blending segment, the starting point for the blend segment (SU), the end point of blend segment (EU) and the blend radius, beginning with the common start and end point (SE) of segments 1 and 2, are required (see figure below). The distances between SE and SU, as well as SE and EU, correspond to the programmed blending clearance a. When blending, clearance is not the geometric distance between the points, but rather path lengths of segments 1 and 2 starting from SE (only relevant for non-linear segments). As in the past, the end point SE is programmed as target point of segment 1.

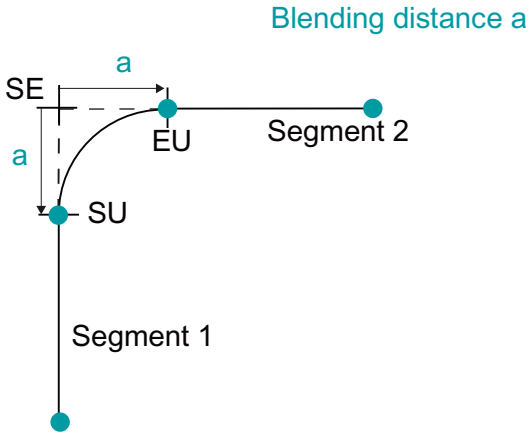

Figure 4-528 Inserting a circular blending segment between 2 linear path segments

The insertion of a circular segment is rejected by others as linear path commands and a technological alarm is issued:

"50013 blending segment not possible, reason 2: Circular blending segment can only be inserted between linear sets".

Substitution with insertion of transition segments

Behavior prior to V4.3

With **mergeMode:=IMMEDIATELY**, there is immediate replacement of the current path motion by the new path motion with the dynamic response parameters of new motion command, regardless of the setting in the **blendingMode** parameter.

Behavior as of V4.3

The system allows the insertion of transition segments even in substitute path motions. In this case, the settings for the replacement **in blendingMode** and **transitionType** are effective. With the setting **blendingMode:=INACTIVE** the substitute behavior as prior to V4.3 is effective. With the setting **blendingMode:=ACTIVE_WITHOUT_DYNAMIC_ADAPTION** or

blendingMode:=ACTIVE_WITH_DYNAMIC_ADAPTION the behavior depends on the setting in parameter **transitiontype**:

- **transitionType:=DIRECT:** (Compatibility mode, default setting)
  Substitute behavior as prior to V4.3, no transition segment, direct transition;
- **transitionType:=STOP:** Delay of the active path motion to standstill, start the new path motion; the dynamic response values of the new path motion are immediately effective, i.e., already also effective for the stop motion;
- **transitionType:=POLYNOMIAL | CIRCULAR**: A transition segment is inserted by the system, starting from the current position on the path; the blending distance to the current path point is applied.

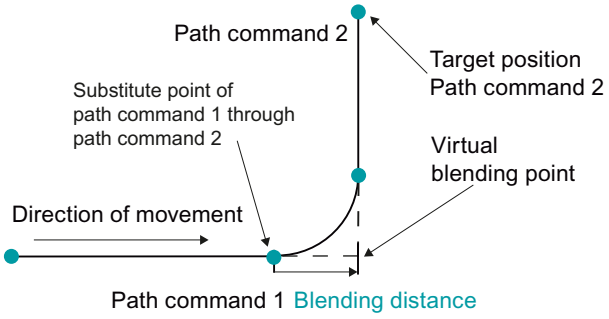

Figure 4-529 Blending when substituting commands

The virtual blending point formed is used as the end point of the current motion and as the starting point of the newly programmed motion. Blending with polynomial segment or circular segment is possible depending on the specifications.

The following applies here:

- Circular segment is possible if a linear set is blended,
- Polynomial segment is always possible

Blending dynamics

The blending velocity in the area of the blending geometry can be traversed with reference to the first or second path command. The selection is determined by setting the higher or the lower velocity of the two commands to run.

Acceleration and jerk for the velocity transition are assumed by the second path command.

Blending with mergeMode = SEQUENTIAL / NEXT_MOTION / IMMEDIATELY, transitionType:= DIRECT / STOP / POLYNOMIAL / CIRCULAR and transitionVelocityMode:= HIGH_VELOCITY / LOW_VELOCITY

HIGH_VELOCITY Running the blending geometry with the higher of the two velocities		LOW_VELOCITY Running the blending geometry with the lower of the two velocities		
Extended behavior in substitute motions

An additional mode is available in substitute path motions. This mode first stops the substituted motion and then starts the new motion in the stop position. The result is a geometrically variable change point for the new substitute command.

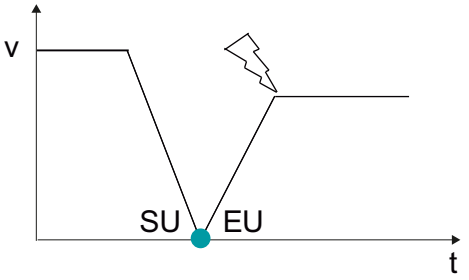

Figure 4-530 Behavior in the case of a stopped substitute motion

Overlap of blending distance

The behavior during detection of an overlap of blending distances can be configured as shown in the following diagram.

When blending several segments, overlapping blending distances may occur where necessary:

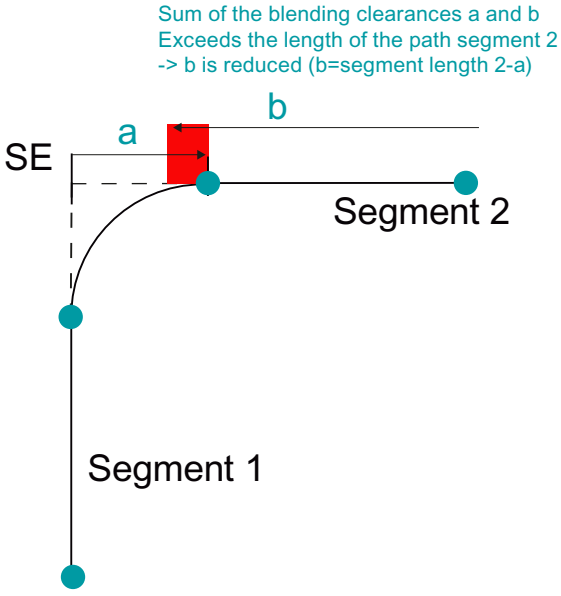

Figure 4-531 Overlapping blending distances

If an overlap of the blending distances is detected, the blending radius is reduced by the system to the maximum value (e.g. for b to MAX(s-a, s/2)), and the warning "50013 blending distance modified" is output in the alarm window. The alarm can be deactivated.

4.6.3.9 Display and monitoring options on the axis

Display and monitoring options for path motion on the axis

An active path motion is indicated on the path axis in system variable **pathMotion.state**.

Display of path-synchronous motion on the positioning axis

An active synchronous axis motion is indicated on the positioning axis in system variable **pathSyncMotion.state**.

Monitoring for setpoint error

The path axis or positioning axis can be monitored for setpoint errors (discrepancy between the setpoint specified by the path object and the setpoint output on the axis).

The difference between the setpoint and the actual value is not monitored.

Limiting and monitoring the setpoint error:

- With setting **enableCommandValue := NO_ACTIVATE**:
  - The dynamic limitation is performed without taking the jerk into account.
  - The resulting setpoint error is not monitored.
- With setting **enableCommandValue := WITHOUT_JERK**:
  - The dynamic limitation is performed without taking the jerk into account.
  - The resulting setpoint error is monitored.
- With setting **enableCommandValue := WITH_JERK**:
  - The dynamic limitation is performed taking the jerk into account.
  - The resulting setpoint error is monitored.

	Path motion on the path axis	Synchronous motion on the positioning axis

4.6.3.10 Allowance for axis-specific traversing range limits

The traversing range limits of the path and positioning axes, i.e. active software limit switches, are taken into account in the participating axes and not in the path object.

If a participating axis detects a possible violation of its axis-specific working area, an alarm is triggered along with an appropriate error response.

4.6.3.11 Behavior of path motion when an error occurs on a participating path axis or positioning axis

If an error occurs on a path axis or the positioning axis for path-synchronous motion causing the axis motion to stop and the command to be canceled, the path interpolation is canceled and the specified error response is performed.

See Local alarm response (Page 2613).

The other axes participating in the path motion travel to velocity 0.0 with the maximum dynamic values.

4.6.3.12 Functionality of path-synchronous motion

Functionality of path-synchronous motion

A path-synchronous motion on a positioning axis can be specified synchronous to the path motion with which it is specified. This causes the path-synchronous motion to start and end at the same time as the path motion. This enables a gripper to rotate in synchronism with the path motion, for example.

The path motion and the path-synchronous motion follow a common traversing profile. This also applies to the blending between two path segments.

The current path length can be output via w or w2. This is set with parameters in the path command.

Specification of path-synchronous motion

There are several options for path-synchronous motion, which are specified in the **wMode** parameter of the respective motion command:

- Movement to a defined end point of the path-synchronous axis w
  The target position of the path-synchronous motion is specified in the path command. This can be a relative (**RELATIVE**) or absolute (**ABSOLUTE**) position.
  As for the positioning command of the axis, the direction of the synchronous motion is specified using a parameter (**wDirection**).
  For further information, refer to the **Motion Control, TO axis, electrical / hydraulic, external encoder** Function Manual, "Positioning".
  The motion dynamics conform to the path, and the axis is "carried along". If the maximum dynamic values of the positioning axis are thereby violated, the dynamic parameters of the path are reduced accordingly.
  If the path length is zero and a path-synchronous motion is programmed, an error will be issued and the path-synchronous motion set to the programmed end position. The resulting setpoint jump is traversed axially with the maximum values.
  In this case, it is important to note that configured monitoring of the setpoint error of the path-synchronous axis also affects the setpoint jump.
- Movement according to the current path length via w or w2
  The current path distance is output. There are two ways of doing this:
  - Reference to the command (**OUTPUT_PATH_LENGTH**)
    The axis position is first set to 0.0 before the path distance is traveled.
    The reset of the axis position to zero is equivalent to a synchronized **_redefinePosition()** command.
  - Accumulated output without reset (**OUTPUT_PATH_LENGTH_ADDITIVE**)
    The path distance accumulated via the command limit is output.

Dynamics of path-synchronous motion

The path object does not keep its own dynamic response parameters for path-synchronous motion.

The following applies when calculating the path velocity profile for simultaneous traversing of a path-synchronous motion:

- Calculation of the path velocity profile without dynamic adaptation:
  - The velocity profile for the path is determined from the dynamic response parameters of the path, see Path dynamics (Page 2491).
  - The setpoints of the path interpolator for the path-synchronous motion are limited to the maximum dynamic values on the positioning axis.
  - The dynamic values (velocity, acceleration, and jerk) are adapted to the ratio of the path axis distance to the path-synchronous motion distance.

$$\frac{\text{Path (path motion)}}{\text{Path (path-synchronous motion)}} = \frac{\text{Velocity (path motion)}}{\text{Velocity (synchronous path motion)}} = \frac{\text{Acceleration (path motion)}}{\text{Acceleration (synchronous path motion)}} = \frac{\text{Jerk (path motion)}}{\text{Jerk (path-synchronous motion)}}$$

Use of this formula assumes that the unit settings for the path object and the participating axes are the same.

- Calculation of the path velocity profile with dynamic adaptation:
  The dynamics of the path-synchronous motion are incorporated into the path plan the same as an additional orthogonal coordinate, and, if necessary, the path velocity profile is adapted in such a way that the dynamic limits of the positioning axis are not violated by the path velocity profile.

Path blending with a path-synchronous motion

- Path blending with dynamic adaptation
  The dynamics of the path-synchronous motion are incorporated into the motion plan the same as an additional orthogonal coordinate, and, if necessary, the velocity profile in the blending range is adapted accordingly.
- Path blending without dynamic adaptation
  If the quotient of the distance length (path motion) / distance length (path-synchronous motion) is not equal over the individual path segments, the path segment transitions will be discontinuous with regard to the velocity setpoints of the path object for the path-synchronous motion.

The setpoints resulting from the path interpolation for the path-synchronous motion are limited on the positioning axis using the axis-specific dynamic limits of that axis.

For example, if the path object is limited over the path using just the dynamic limits available on the path object, this can result in a setpoint error on the positioning axis relative to the calculated setpoint on the path object for the path-synchronous motion. See Display and monitoring options on the axis (Page 2503).

Output of the path distance to the positioning axis

Alternatively, the traveled path distance, i.e. the current path length, can be output to the positioning axis. This distance can be relative to an individual path segment or added up over multiple path segments.

The setting is made in the path command.

For example, this can be used to output path distance-related output cams or measuring inputs.

Output of Cartesian coordinates using the MotionOut Interface

The **motionOut.x/y/z** interfaces can be used to interconnect the Cartesian coordinates directly with other technology objects, e.g. with the MotionIn interfaces of positioning axes.

For example, this functionality can be used in the application to implement output cams and measuring inputs on Cartesian axes.

4.6.3.13 Kinematic adaptation

Kinematic adaptation

The kinematic transformation or the kinematic adaptation is used to convert path axis values to the Cartesian axes, and vice versa.

Kinematic adaptation – fundamentals

Scope of the transformation functionality

During forward calculation of the kinematics (including direct kinematics, forward kinematics or forward transformation) for position and motion conversion, the position of the end point of the kinematics is determined in the basic coordinate system from the position of the articulation angle and its spatial arrangement.

During backward calculation (including backward transformation or inverse kinematics), the position of the individual articulation angle is determined from the position of the end point of the kinematics in the basic coordinate system. For path interpolation, the position of the end point of the kinematics in the basic coordinate system is calculated over time.

The position and the dynamic values are transformed.

If the axis settings are outside the transformation range, the values in the BCS and OCS will be set to zero.

The current modulo range is retained in path axes specified as modulo axes.

See Modulo properties (Page 2477).

Reference points

The following reference points are used in path interpolation:

- Cartesian zero point
- Kinematic zero point
- Kinematic end point
  (because a tool is not taken into account, this is equal to the path point)

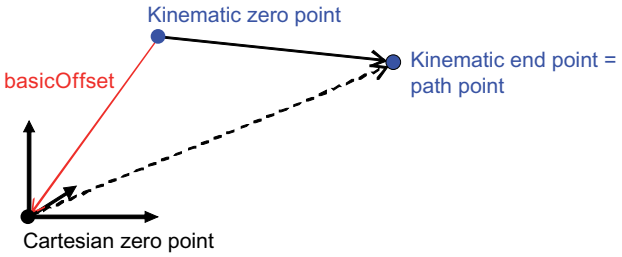

Figure 4-532 Reference points of the coordinate systems in path interpolation

The path object calculates the position on the path. This is also the kinematic end point.

System variables for path interpolation and transformation on the path object

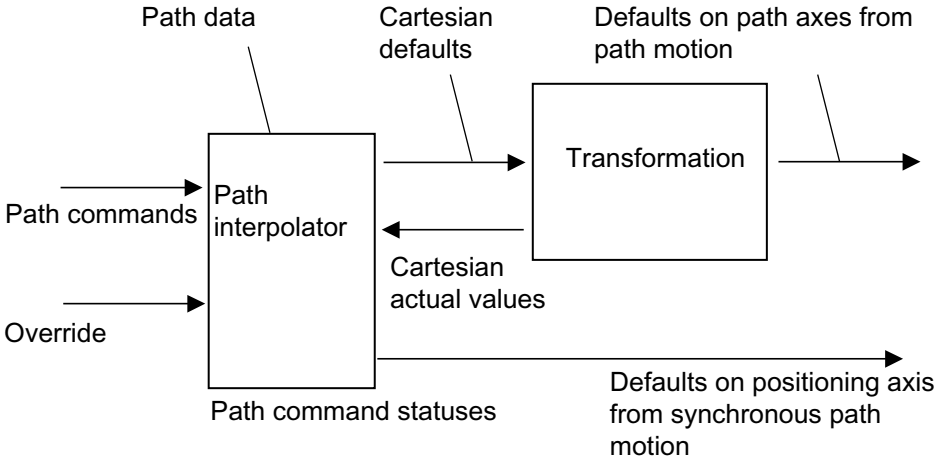

Figure 4-533 Overview of system variables of the path object

The position values and dynamic values can be accessed via a system variable:

Path data

System variables	Description
path.acceleration	Path acceleration
path.command	Status of a motion command
path.dynamicAdaption	Display showing whether adaptation of the path dynamics to the dynamic limit values of the path axes is active.
path.length	Length of the current path
path.motionState	Motion status of path motion

System variables	Description
path.position	Path position (within the path length)
path.velocity	Path velocity
path.csType	Type of coordinate system
path.csNumber	Number of the coordinate system (in OCS)

Cartesian specifications in the basic coordinate system / path-synchronous motion

System variables	Description
bcs.x/y/z/w.position	Set positions
bcs.x/y/z/w.velocity	Set velocities
bcs.x/y/z/w.acceleration	Set accelerations
bcs.linkConstellation	Set link constellation

Cartesian actual values

System variables	Description
bcs.x/y/zActual.position	Actual value of the Cartesian positions of the path axes
bcs.linkConstellationActual	Current articulated joint positioning space

Defaults on path axes from path motion

System variables	Description
mcs.a1/a2/a3.acceleration	Accelerations of the path axes
mcs.a1/a2/a3.position	Positions of path axes in the axis coordinates
mcs.a1/a2/a3.velocity	Velocities of the path axes

Object coordinate system

System variables	Description
ocs[1..3].trackingIn	Interface for motion sequence reference value with which the OCS is to be coupled (e.g. TO external encoder)
ocs[1..3].trackingInPosition	Current value of the motion sequence
ocs[1..3].trackingPosition	Position of the OCS relative to the reference position
ocs[1..3].trackingState	Synchronization status
ocs[1..3].x/y/z.accelaration	Acceleration
ocs[1..3].x/y/z.position	Item
ocs[1..3].x/y/z.velocity	Velocity

Override

System variables	Description
override.acceleration	Acceleration override
override.velocity	Velocity override

Path command statuses

System variables	Description
linearPathCommand.state	Status of linear interpolation
circularPathCommand.state	Status of circular interpolation
polynomialPathCommand.state	Status of polynomial interpolation

Velocity profile

System variables	Description
specificVelocityProfile.state	Information as to whether a velocity profile is in use
specificVelocityProfile.value	Profile value
specificVelocityProfile.activeProfile	Active profile reference
specificVelocityProfile.processingState	Status of the profile processing

Command queue

System variables	Description
motionBuffer.numberOfExistentEntries	Number of commands in the command buffer
motionBuffer.state	Status of the command buffer

Interconnections on the path object

System variables	Description
connection.a1	1. Path axis on the path object
connection.a2	2. Path axis on the path object
connection.a3	3. Path axis on the path object
connection.w	Path-synchronous axis on the path object

Transformation of the dynamic values

The **kinematicsData.transformationOfDynamics** system variable indicates whether a kinematic transformation supports the dynamics transformation functionality.

Differentiation of link constellations

If Cartesian kinematics end points can be reached via various articulation positions, articulation positioning spaces are defined for the corresponding kinematics.

All path motions take place in the same link constellation. For this reason, a change to another link constellation is not possible when a path is being executed. A change to another link constellation is possible through individual axis motions but not via a motion on the path object.

The current transformation-specific link constellation is indicated on the setpoint side in the **bcs.linkConstellation** variable and on the actual value side in the **bcs.linkConstellationActual** variable.

The link constellation is defined specifically for each transformation. See Supported kinematics (Page 2513).

Information commands for the kinematic transformation

In addition to the implicit conversion in the system, the transformation calculations can also be accessed directly via user commands.

- The **_getPathCartesianPosition()** command is used to calculate the Cartesian positions for the axis positions specified in the command.
- The **_getPathAxesPosition()** command is used to calculate the axis positions from the Cartesian positions.
- The **_getPathCartesianData()** command is used to calculate the Cartesian data for the position, velocity, and acceleration from the axis positions, axis velocities, and axis accelerations specified in the command.
- The **_getPathAxesData()** command is used to calculate the axis positions, axis velocities, and axis accelerations from the Cartesian data for the position, velocity, and acceleration specified in the command.

For the calculation of axis positions, the values are specified in the axis coordinate of the path axis, and not relative to the kinematic zero point of the axis.

The modulo range is taken into account.

For the transformation of Cartesian values to path axis values, a link constellation and not a reference position of the axes has to be specified in order to ensure uniqueness.

Axis-specific zero point offset in the transformation

It is possible to set an axis-specific offset of the zero position of the axis in the axis-specific coordinate system as well as the zero definition of the axis in the transformation.

The positive direction of the axis and of the axis in the transformation must be the same. These settings are made for the axis.

The offset of the kinematic zero point relative to the axis zero point is specified in the positive direction of the axis.

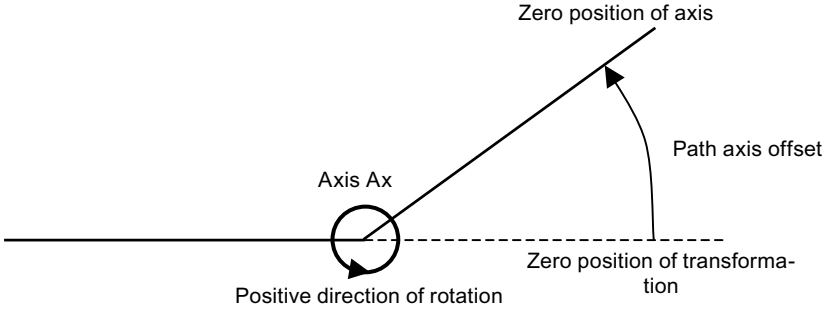

Figure 4-534 Path axis offset

When modulo axes are used for rotary links with a limited domain in kinematics, such as SCARA, the axis-specific zero point offset and the modulo property of the relevant path axis are defined such that the permissible modulo range of the path axis coincides with the domain of the relevant arm within the kinematics. Otherwise, this can cause an additional limitation in the traversing range of the kinematics.

Example: If a link is limited to [-180°; 180°) and a modulo range of 0° to 360° is defined on the path axis, the zero point offset to -180° should be specified.

Offset of the kinematic zero point relative to the Cartesian zero point

An offset of the kinematic zero point of the transformation relative to the Cartesian zero point can be set in the **basicOffset** configuration data.

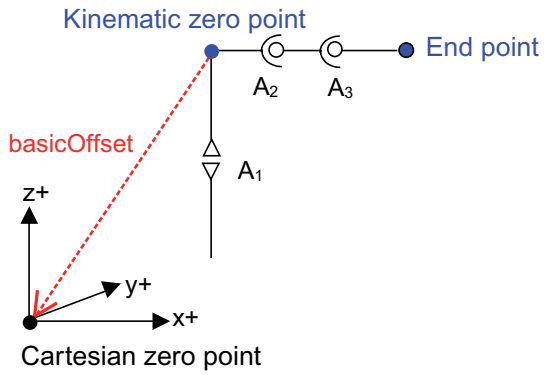

Figure 4-535 Example of kinematic offset

The above example produces negative values for the kinematic offsets.

Offset in example:
x: -100
y: -100
z: -200

With SIMOTION V4.2 and higher, not only can the BCS be offset but also rotated, allowing for any rotation of the coordinate system from the kinematics zero point. This allows flexible assignment of the BCS to the handling equipment's kinematics.

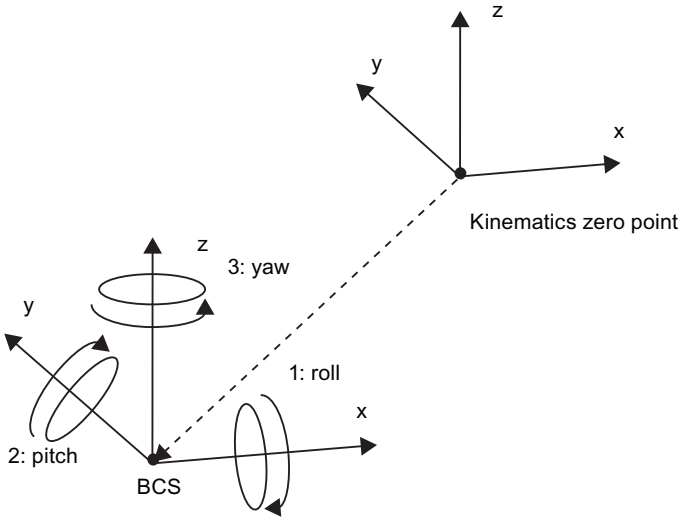

Figure 4-536 Coordinate system offset and rotation

The rotations are undertaken after the offset in the following order:

1. Roll around x axis
2. Pitch around (already rotated) y axis
3. Yaw around (already twice rotated) z axis

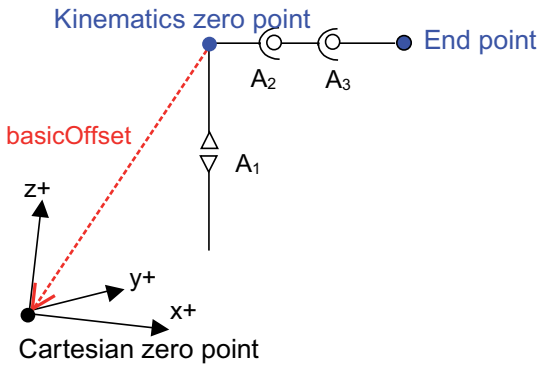

Figure 4-537 Example of kinematics offset with rotation

Offset and rotation (around the y axis) in the example:

x: -100
y: -100
z: -200
roll: 0°
pitch: +15°
jaw: 0°

Supported kinematics

Supported kinematics and their assignment

The following kinematics can be set using the **typeOfKinematics** configuration data:

- Cartesian 2D/3D gantries (Page 2517) (**CARTESIAN**):
- 2D roller picker (Page 2518) (**ROLL_PICKER**)
- 3D roller picker (Page 2520) (**ROLL_PICKER_3D**) available as of V4.4.
- 2D delta picker (Page 2521) (**DELTA_2D_PICKER**)
- 3D delta picker (Page 2523) (**DELTA_3D_PICKER**)
- SCARA kinematics (Page 2526) (**SCARA**)
- 2D articulated arm kinematics (Page 2530) (**ARTICULATED_ARM_2D**) available as of V4.2.
- 3D articulated arm kinematics (Page 2531) (**ARTICULATED_ARM**)
- 2D swivel arm kinematics (Page 2534) (**SWIVEL_ARM**) available as of V4.2.
- 3D cylindrical robot (Page 2536) (**CYLINDRICAL**) available as of V4.4.
- 2D/3D user function (Page 2538) (**USER_FUNCTION**) available as of V4.4.
- Other special kinematics (**SPECIFIC**)

A transformation can be selected for each path object.

Thus, multiple transformations can be configured/active in a SIMOTION system when multiple path objects are used.

Because a path axis can be interconnected with more than one path object, a path axis can theoretically be involved in multiple kinematic assemblies but obviously can only be active in one path group at a time.

Specific kinematics (Page 2544)

Configuration screens

With SIMOTION version 4.2 and higher you can use parameterization screens to configure the kinematics. You can access the screens via the configuration menu.

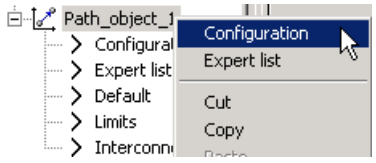

Figure 4-538 Open configuration

Depending on the kinematics, the screen will contain several tabs where you can enter mechanical data and offsets and rotations.

Example: Cartesian kinematics 2D

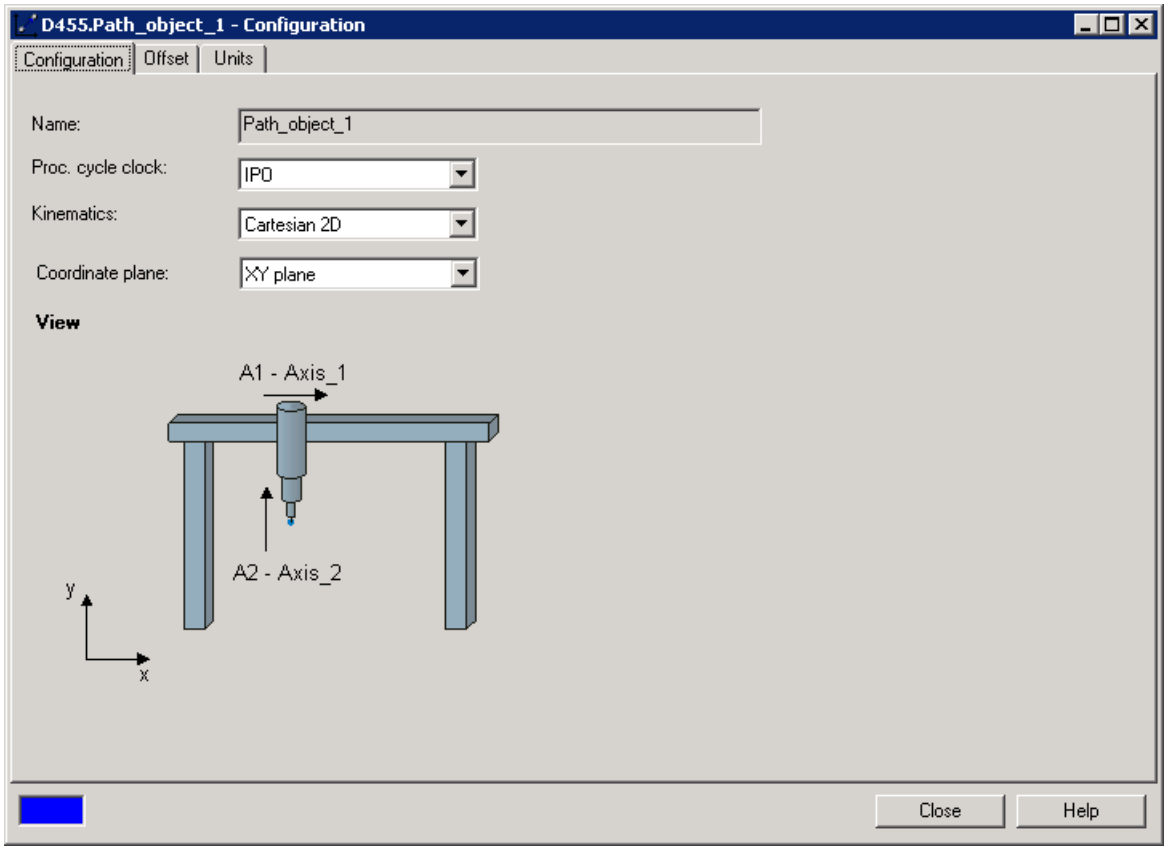

Figure 4-539 Cartesian kinematics 2D - configuration

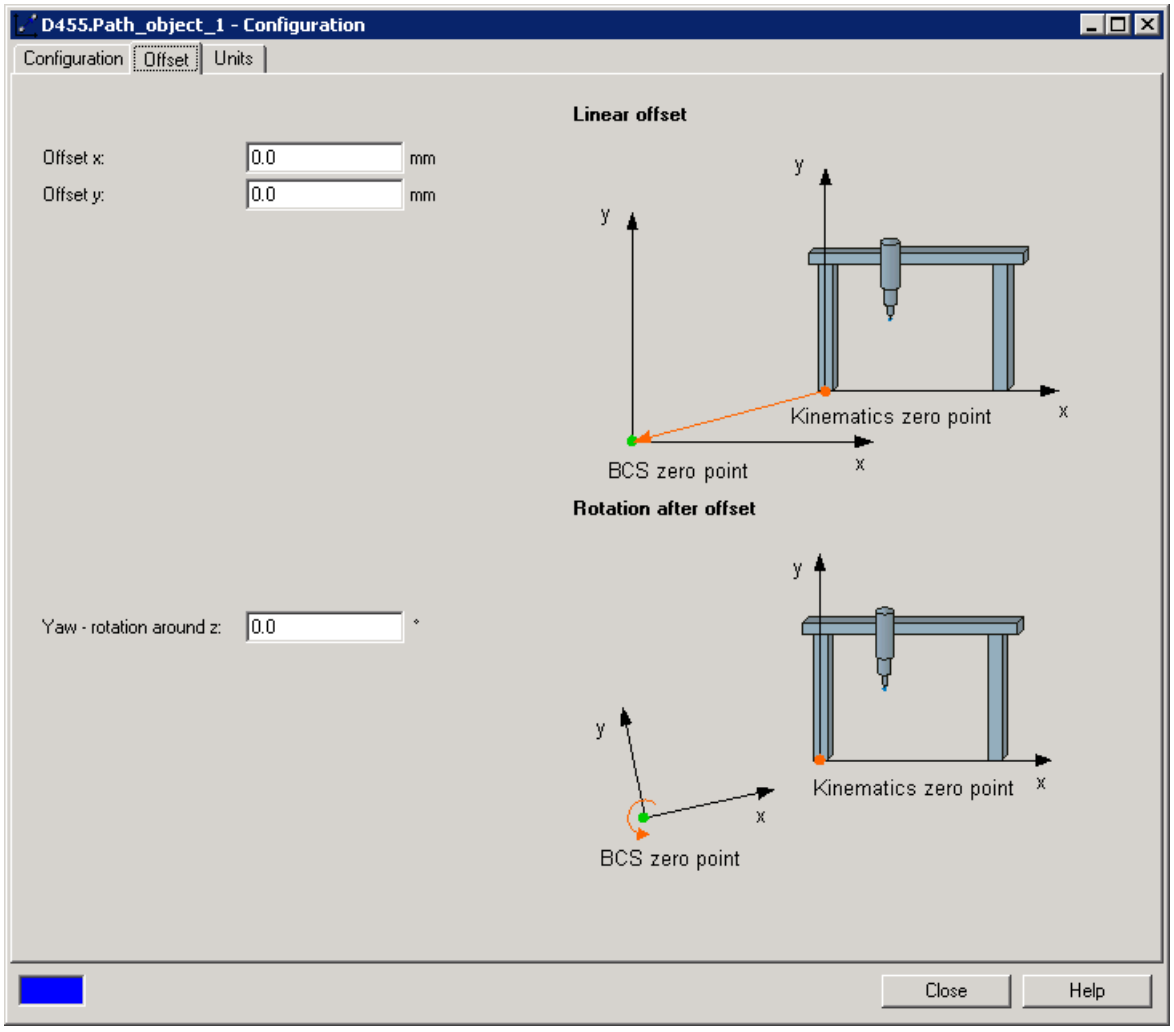

Figure 4-540 Cartesian kinematics 2D - offset

Cartesian 2D/3D gantries

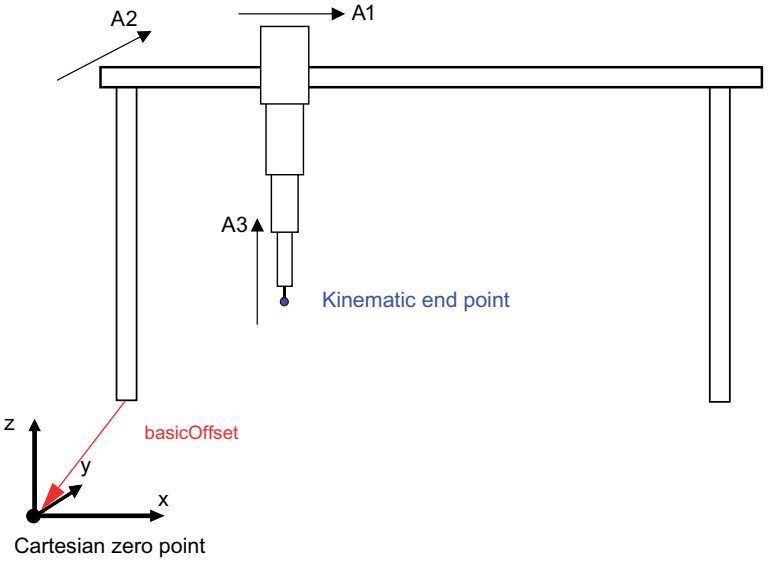

Figure 4-541 Kinematics example: 2D/3D gantry

Table 4-253 Configuration data for the Cartesian kinematics

typeOfKinematics: CARTESIAN	Cartesian gantry kinematic type

2D roller picker

General

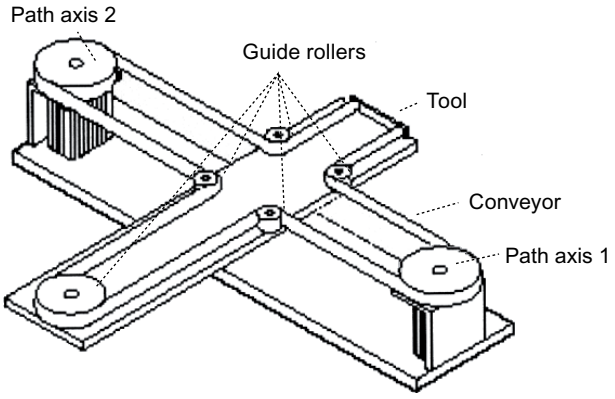

Figure 4-542 2D roller picker: Representation of the axis system

The 2D roller picker has two-dimensional kinematics. You can configure 2D roller pickers in all three main planes. This description is based on a configuration in the x-y plane.

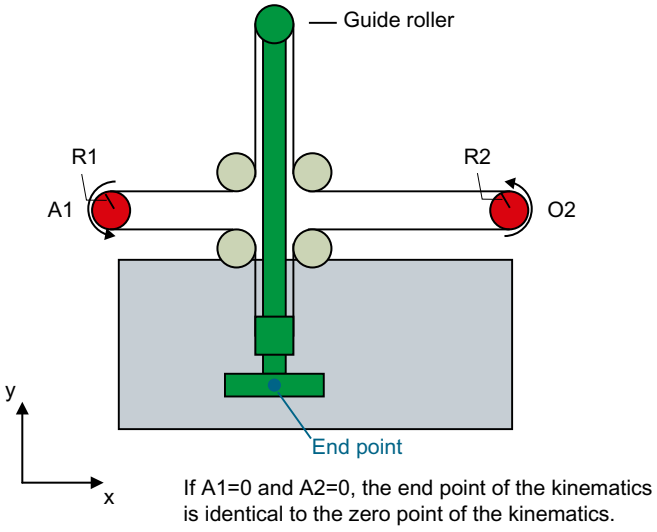

Figure 4-543 Kinematics of the 2D roller picker (guide pulley on the opposite side of the tool)

The guide pulley must be located on the opposite side of the tool.

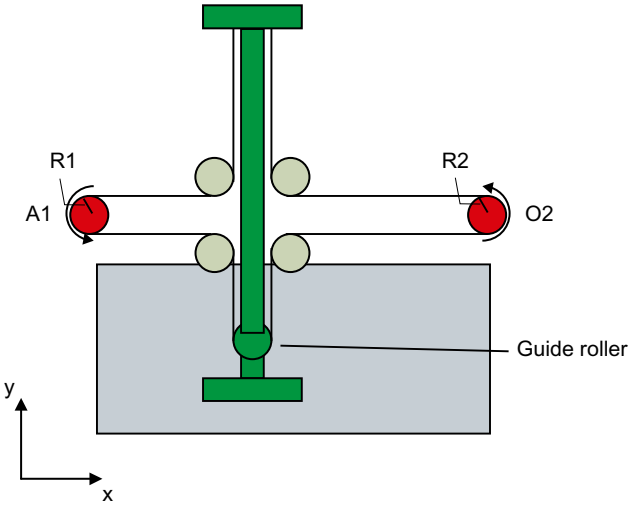

Figure 4-544 Kinematics of the 2D roller picker (guide pulley on the tool; this case is not considered)

The alternative variant with the guide pulley on the tool can be derived by converting the coordinates:

Guide pulley on the tool	Guide pulley on the opposite side of the tool
x	-x
y	-y
R1	R2
R2	R1

Note

The two path axes must be configured so that 360 axis-units (i.e. mm, degree, etc.) produce a disk revolution. The "modulo axis" setting should be prevented. See Units (Page 2477) and Modulo properties (Page 2477).

3D roller picker

General

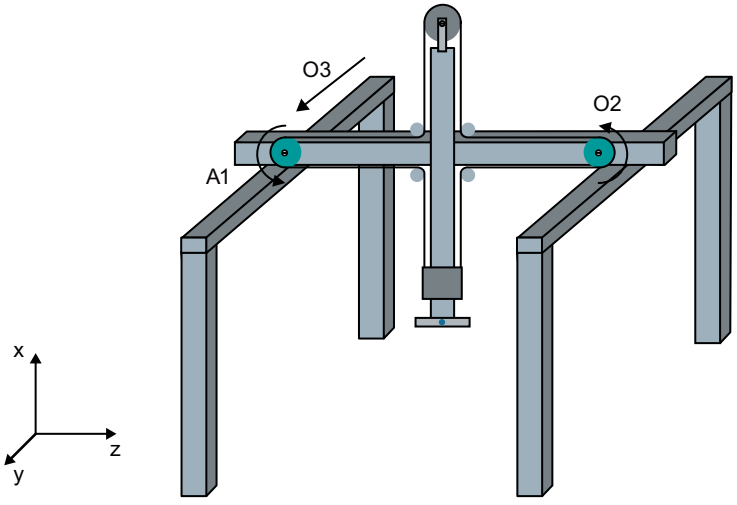

Figure 4-545 Kinematics of the 3D roll picker for a roll picker in the z-x plane

The 3D roller picker is a 2D roller picker that can be moved via an additional linear axis in a further Cartesian coordinate direction. You can set the 3D roller picker in all three main planes as with the 2D roller pickers. The third path axis then extends in the third Cartesian direction. In the example, the roll picker is set in the z-x plane.

A1 and A2 are the two axes of the roll picker in the example figure. The linear axis A3 is indicated by the arrow in the y direction.

Further information can be found in the documentation of the 2D roller picker (Page 2518).

2D delta picker

General

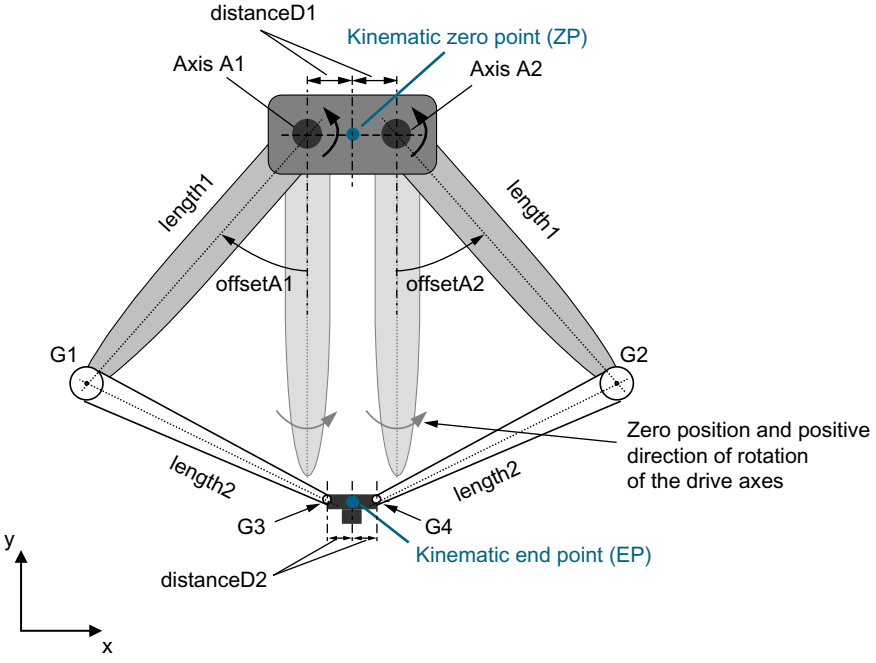

Figure 4-546 Kinematics of the 2D delta picker (x-y plane example)

Definitions

- The complete structure is contained in one of the two-dimensional main planes. The x-y plane is used as an example in the following description.
- A1 and A2 denote the two active drive axes of the kinematic structure. They lie on the straight line y = 0 and are separated from each other by the distance 2x **distanceD1**. Their zero position within the kinematic structure corresponds to the orientation of the upper arm segments (**length1**) in the direction of the negative y axis. Positive displacements occur as shown in the figure.

- It is assumed that the lower connection plate between G3 and G4 is always oriented horizontally.
  This results in $y_{G3} = y_{G4}$ and a horizontal distance of 2x **distanceD2**.
- If $x_{ZP} = y_{ZP} = 0$, the zero position of the kinematics is located midway between the drive axes A1 and A2.
- The target point of the direct transformation, with its coordinates x_{EP} and y_{EP} is defined as being midway between G3 and G4. This results in the position G3 = (x_{EP}-distanceD2; y_{EP}) and G4 = (x_{EP}+distanceD2; y_{EP}).

Table 4-260 Configuration data for the 2D delta picker kinematics

typeOfKinematics: DELTA_2D_PICKER	2D delta picker kinematics type
basicOffset	Offset of the kinematic zero point (ZP) relative to the Cartesian zero point

3D delta picker

General

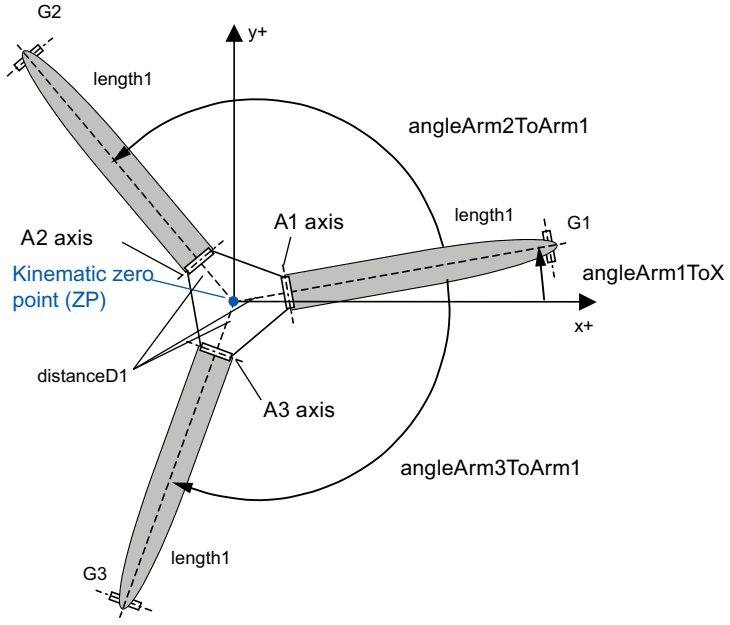

Figure 4-548 Kinematics of the 3D delta picker (top view)

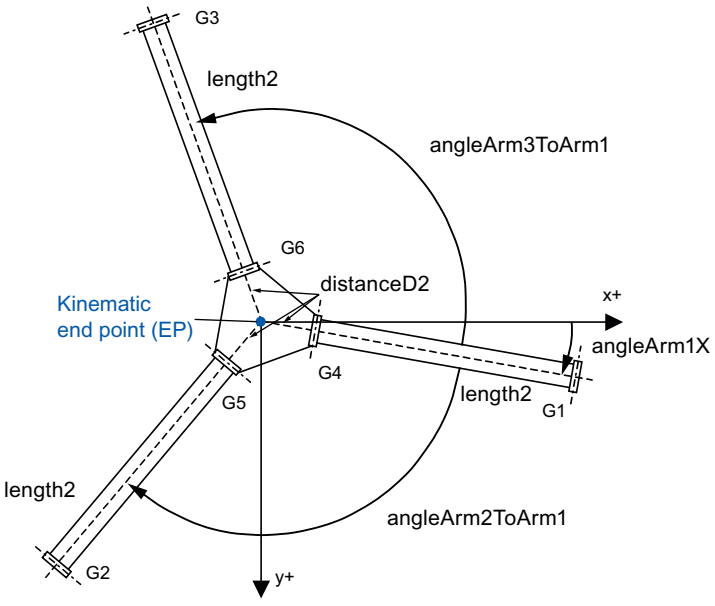

Figure 4-549 Kinematics of the 3D delta picker (bottom view)

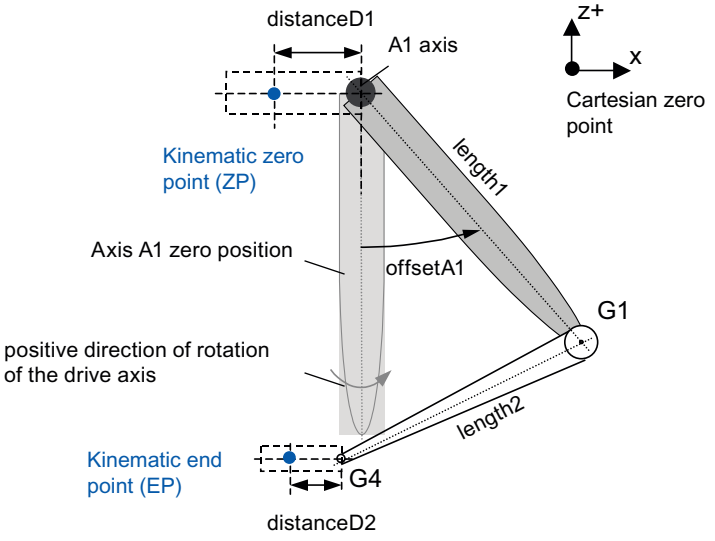

Figure 4-550 Kinematics of the 3D delta picker (single arm in the example, axis A1)

Definitions

- A1, A2 and A3 denote the three active drive axes of the kinematic structure. They are in the x-y plane where z = 0, and each is at distance **distanceD1** from the kinematic zero point (ZP). Their zero position within the kinematic structure corresponds to direct orientation of the upper arm segments (**length1**) in the direction of the negative Z axis. Positive displacements occur counterclockwise, as shown in the previous figure.
- G1 to G6 denote the freely movable joints.
- It is assumed that the connection of the joints at the end point (EP) has a horizontal orientation based on the parallel struts. This results in $y_{G4} = y_{G5} = y_{G6}$. G4 to G6 are all at the horizontal distance **distanceD2** from the end point (EP).

- If $x_{ZP} = y_{ZP} = z_{ZP} = 0$, the zero position of the kinematics is located midway between the drive axes A1 to A3.
- The target point of the transformation, with its coordinates x_{EP}, y_{EP} and z_{EP} is defined as being midway between G4 and G6.

Table 4-262 Configuration data for the 3D delta picker kinematics

angleArm3ToArm1	Angular offset of arm A3-G3-G6 with respect to arm A1-G1-G4 for rotation around the positive z axis.

Table 4-263 Possible articulated joint positioning spaces

The following angles are always in relation to the direct orientation φ_0 of the active axis to the end point.		
LinkConstellation	1	Angle of axis A1 in the range [0°, 180°]. Angle of axis A2 in the range [0°, 180°]. Angle of axis A3 in the range [0°, 180°].
	2	Angle of axis A1 in the range (-180°, 0°). Angle of axis A2 in the range [0°, 180°]. Angle of axis A3 in the range [0°, 180°].

	3	Angle of axis A1 in the range [0°, 180°]. Angle of axis A2 in the range (-180°, 0°). Angle of axis A3 in the range [0°, 180°].
	4	Angle of axis A1 in the range [0°, 180°]. Angle of axis A2 in the range [0°, 180°]. Angle of axis A3 in the range (-180°, 0°).
	5	Angle of axis A1 in the range (-180°, 0°). Angle of axis A2 in the range (-180°, 0°). Angle of axis A3 in the range [0°, 180°].
	6	Angle of axis A1 in the range (-180°, 0°). Angle of axis A2 in the range [0°, 180°]. Angle of axis A3 in the range (-180°, 0°).
	7	Angle of axis A1 in the range [0°, 180°]. Angle of axis A2 in the range (-180°, 0°). Angle of axis A3 in the range (-180°, 0°).
	8	Angle of axis A1 in the range (-180°, 0°). Angle of axis A2 in the range (-180°, 0°). Angle of axis A3 in the range (-180°, 0°).

You will find an illustration of the articulated joint positioning options for a single axis in 2D delta picker (Page 2521).

SCARA kinematics

General

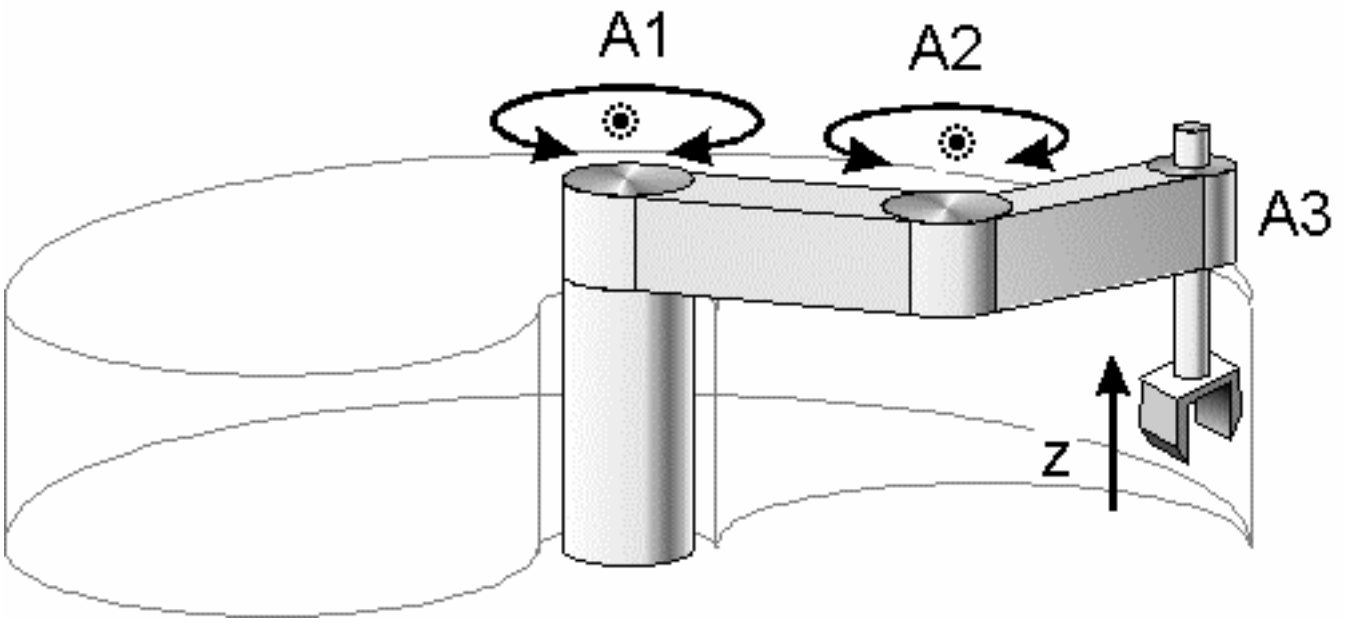

Figure 4-551 SCARA: Representation of the axis system

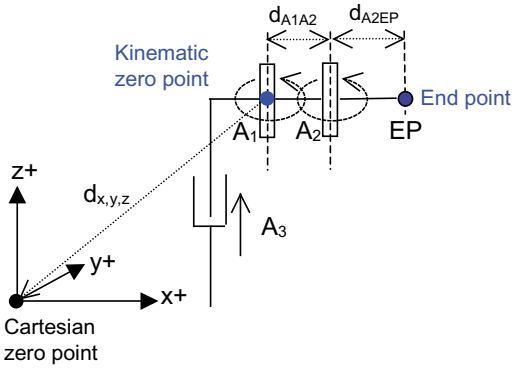

Figure 4-552 SCARA: Kinematics

The kinematic zero point is at point A1.

The zero positions of the A1 axis and A2 axis are as follows:

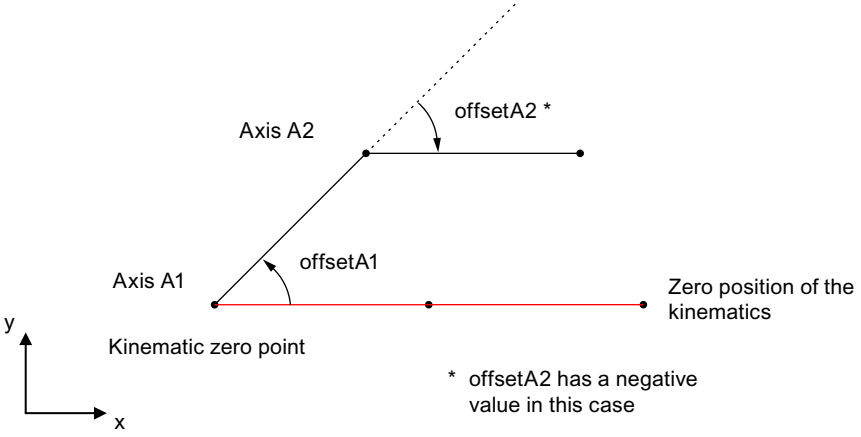

Figure 4-553 SCARA: Zero positions

The definition range of the single A1 and A2 axes is limited to [-180°; 180°).

Link compensations

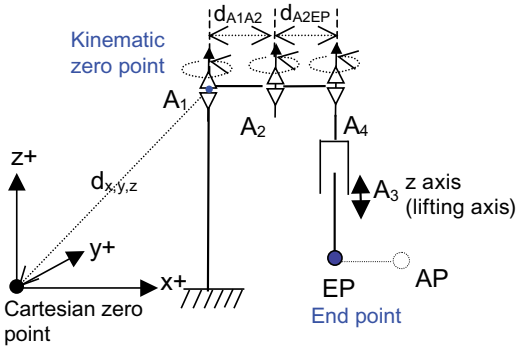

Figure 4-554 SCARA: Kinematics with link compensation

Coupled axes

Mechanical couplings are possible:

- between A1 and A2
- between A1, A2, and $A_{synchronous}$ (A4)
- between $A_{synchronous}$ (A4) and A3

The following axis couplings can be compensated via the system:

- A coupling from axis A1 to axis A2
- A coupling from axis A1 and axis A2 to the path-synchronous controlled axis A4
  That is, the setpoint of axis A4 is changed to the position axis in accordance with the changes of A1 and A2.
  If axis A1 and/or axis A2 is traversed and a path-synchronous motion in w is specified in parallel, the system superimposes/adds a path-synchronous motion specification and compensation onto the position axis.
- A coupling from axis A4 to axis A3 (lifting axis)
  If axis A3 is traversed via the path motion and a compensation from w to axis A3 is required simultaneously, the specifications are superimposed.

The compensation functionality and the specifications to the path-synchronous axis w via the path-synchronous motion are independent of one another and are executed simultaneously by the system.

Effective direction of the coupled axes

For the coupling of axis A1 to axis A2 and of axis A4 to axis A3, the following applies:

For a coupling factor of > 0.0, the transformation is based on the assumption that a positive motion on the first axes results in a negative motion on the second axis.

For the coupling of axis A1 to axis A4 and of axis A2 to axis A4, the following applies:

For a coupling factor of > 0.0, the transformation is based on the assumption that a positive motion on the first axes results in a positive motion on the second axis.

The coupling between axis A4 and axis A3 is implemented as a spindle pitch, i.e. for a coupling factor of +1.0, 360.0 degrees on axis A4 correspond to a path of -1.0 mm on axis A3.

Table 4-264 Configuration data for the SCARA kinematics

typeOfKinematics: SCARA	SCARA kinematics type
basicOffset.x	Offset of the kinematic zero point relative to the Cartesian zero point, the x coordinate
basicOffset.y	Offset of the kinematic zero point relative to the Cartesian zero point, the y coordinate
basicOffset.z	Offset of the kinematic zero point relative to the Cartesian zero point, the z coordinate
basicOffset.roll	Rotation about x (roll)
basicOffset.pitch	Rotation about y (pitch)
basicOffset.yaw	Rotation about z (yaw)
offsetA1	Offset of the axis zero point of axis A1 relative to zero position of axis A1 in the transformation

distanceA1A2	Distance A1 - A2
offsetA2	Offset of the axis zero point of axis A2 relative to zero position of axis A2 in the transformation
distanceA2Endpoint	A2 - end point distance
linkCompensationA2.enableA1A2	Compensate articulated joint dependency of A1 to A2
linkCompensationA2.factorA1A2	Coupling factor for the compensation on axis A2
linkCompensationA4.enableA1A4	Compensate articulated joint dependency of A1 to A4
linkCompensationA4.factorA1A4	Coupling factor for the compensation on axis A4
linkCompensationA4.enableA2A4	Compensate articulated joint dependency of A2 to A4
linkCompensationA4.factorA2A4	Coupling factor for the compensation on axis A4
linkCompensationA3.enableA4A3	Compensate articulated joint dependency of A4 to A3
linkCompensationA3.factorA4A3	Coupling factor for the compensation on axis A3

3D articulated arm kinematics

General

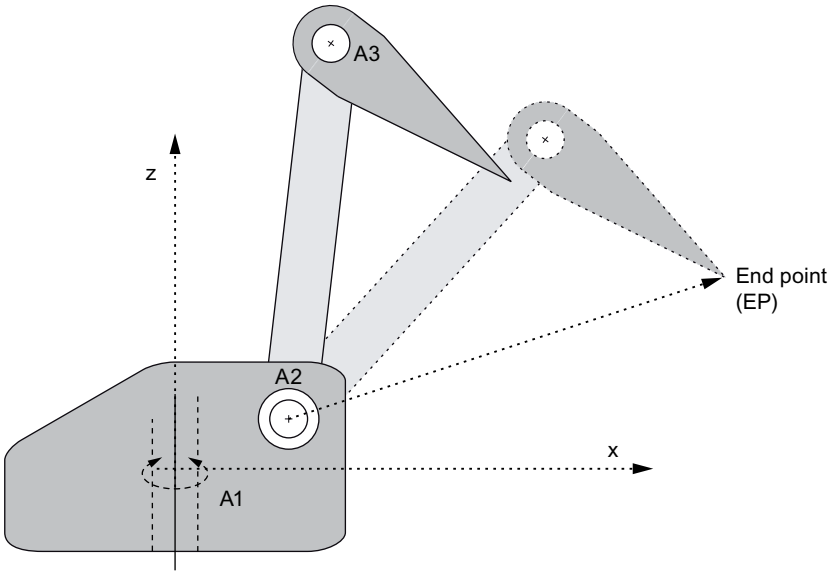

Figure 4-557 3D articulated arm: Display of the axes

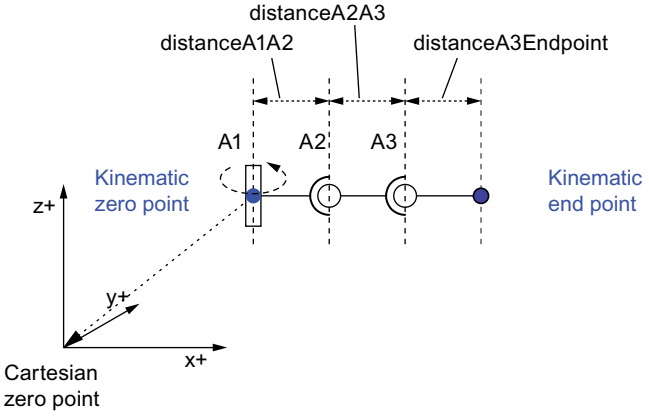

Figure 4-558 3D articulated arm: Kinematics

The kinematic zero point is at point A1.

The point is the zero position of the kinematics if **distanceA1A2**, **distanceA2A3**, and **distanceA3EP** are pointing in the Cartesian x-direction.

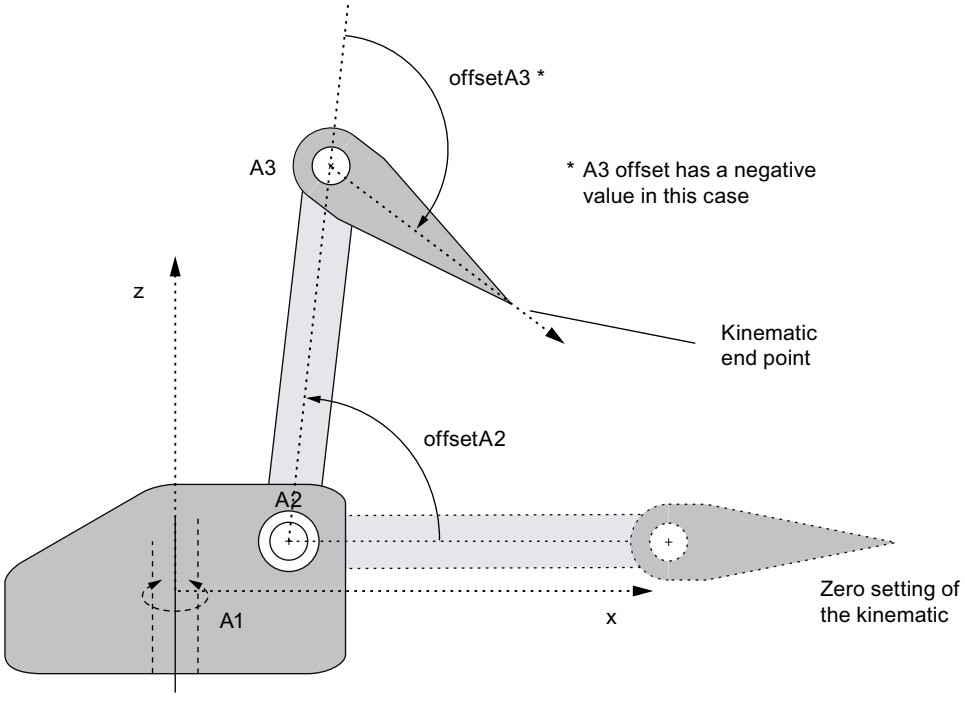

Figure 4-559 3D articulated arm: Zero positions of axes A2 and A3

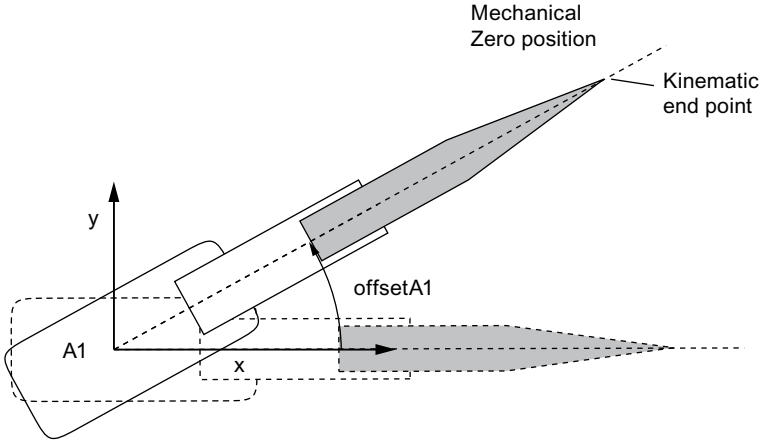

Figure 4-560 3D articulated arm: Zero position of axis A1

The definition range of the single A1 to A3 axes is limited to [-180°; 180°).

Coupled axes

If a positive coupling factor between two axes is specified, the transformation assumes that a positive motion on the first axes leads to a negative motion on the second axis.

Table 4-268 Configuration data for the 3D articulated arm kinematics

	2	Angle of axis A3 in the range [-180°, 0°) relative to the kinematic zero point Angle of axis A1 corresponds to atan(EPy/EPx)
	3	Angle of axis A3 in the range [0°, 180°) relative to the kinematic zero point Angle of axis A1 corresponds to –atan(EPy/EPx)
	4	Angle of axis A3 in the range [-180°, 0°) relative to the kinematic zero point Angle of axis A1 corresponds to –atan(EPy/EPx)

2D swivel arm kinematics

2D swivel arm kinematics

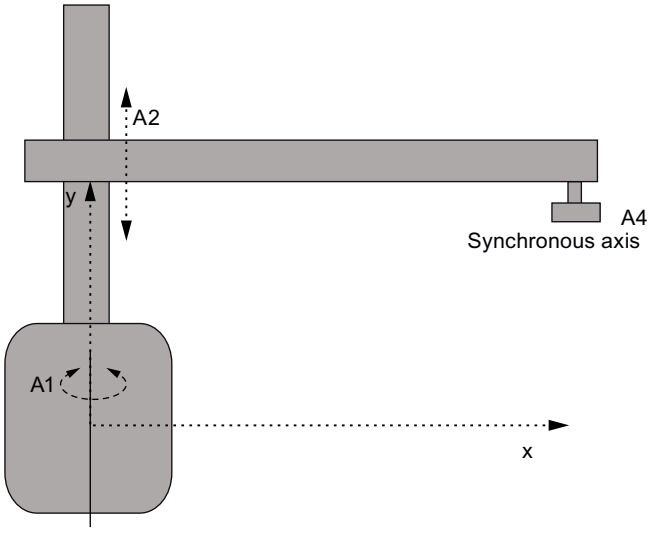

Figure 4-561 Display of the axes

2D swivel arm

In swivel arm kinetics, programming settings are made on the lateral surface that can be accessed by the kinematics.

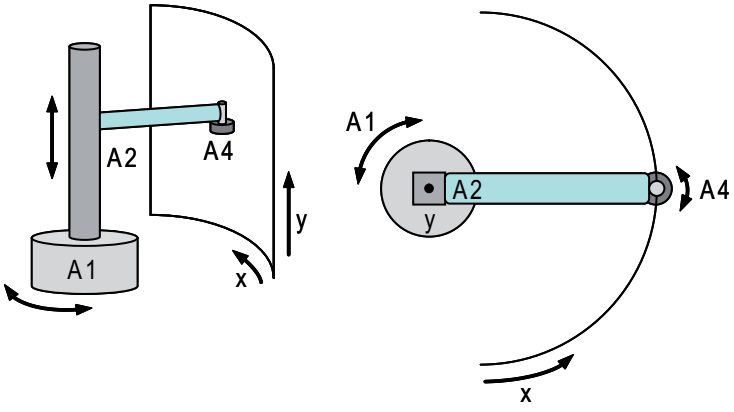

Figure 4-562 Kinematics working area

Unraveling the lateral surface results in a 2D plane, for which coordinate-plane and offset parameters can be assigned in the same way as with Cartesian 2D (Page 2517) kinematics. The offsets are applied to the set coordinate plane and rotation is about the axis that is perpendicular to the plane.

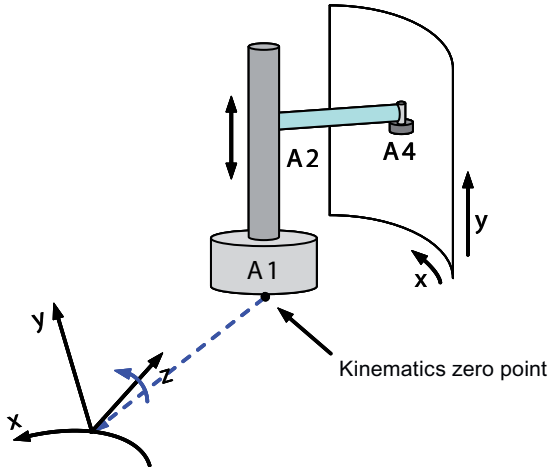

Figure 4-563 Kinematic offset and rotation

Depending on the plane used, the following parameters are effective:

X_Y plane:

Offset in x and y directions and rotation about the z axis

Y_Z plane:

Offset in y and z directions and rotation about the x axis

Z_X plane:

Offset in z and x directions and rotation about the y axis

With this type of kinematics, rotation does not serve any useful purpose.

The link compensations **LinkCompensationA1** and **LinkCompensationA2** and angular offset **offsetA1** at rotary joint A1 work in the same way as with SCARA kinematics (Page 2526).

With this type of kinematics, the conveyor tracking function (see Motion sequence at path object (Page 2545)) does not serve any useful purpose.

3D cylindrical robot

General

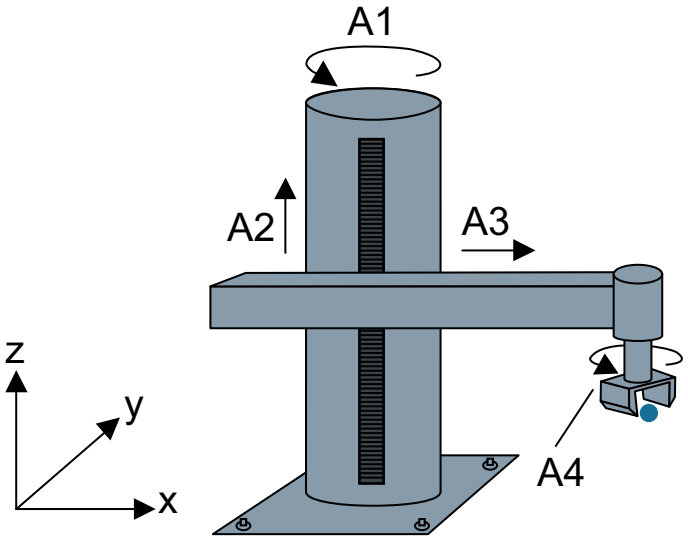

Figure 4-564 3D cylindrical robot: Overview of axes

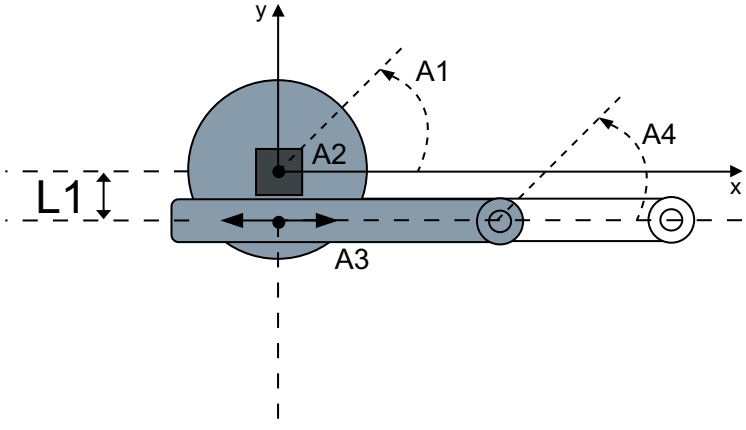

Figure 4-565 3D cylindrical robot: Plan view and display of the axes

In the 3D cylindrical robot, one of the Cartesian axes is replaced by a rotary axis. The working area is cylindrical.

Definitions

- A1, A2, A3 and A4 designate the four active drive axes of the kinematic structure. A1 and A4 are rotary axes and A2 and A3 linear axes.
- L1 designates the distance between axes A2 and A3. In the zero position, this corresponds to the distance between axis A3 to the x axis. This distance therefore also has an effect on the calculation of the end point of the transformation. Positive run in the direction of the y axis. In the above plan view, the value of L1 is therefore negative.
- The definition range of axis A1 is limited to [-180°; 180°).

Coupled axes

Mechanical couplings are possible:

- between A1 and A4
- between A4 and A2

The following axis couplings can be compensated via the system:

- a coupling from axis A1 to axis A4
- a coupling from axis A4 to axis A2

Effective direction of the coupled axes

For the coupling of axis A1 to axis A4, the following applies:

For a coupling factor of > 0.0, the transformation is based on the assumption that a positive motion on the first axes results in a positive motion on the second axis.

For the coupling of axis A4 to axis A2, the following applies:

For a coupling factor of > 0.0, the transformation is based on the assumption that a positive motion on the first axes results in a negative motion on the second axis.

The coupling between axis A4 and axis A2 is implemented as a spindle pitch, i.e. for a coupling factor of +1.0, 360.0 degrees on axis A4 correspond to a path of -1.0 mm on axis A2.

2D/3D user function

General

The kinematics 2D/3D user function allows the use of a transformation function provided by the user. This user function is created in ST notation and executed via a hook interface in the TO execution context. Compiled ST code in the TO execution context can be executed via the hook interface provided on the TO.

The function interface for the 2D/3D user function is permanently defined in ST. The input parameters are written by the TO and the calculated output values by the ST function.

Hook interface

Two different interfaces are defined for the forward and backward transformations. Each of the two transformation directions is therefore implemented by a function.

Table 4-272 FC input parameters for the forward transformation

Name	Type	Description
a1Position	LREAL	Position, axis 1
a1Velocity	LREAL	Velocity, axis 1

Table 4-275 FC output parameters for the backward transformation

Name	Type	Description
functionResult	DINT	Function result 0: OK, velocity and acceleration have not been calculated 1: OK, velocity and acceleration have been calculated Other values: Error
a1Position	LREAL	Position, axis 1
a1Velocity	LREAL	Velocity, axis 1
a1Acceleration	LREAL	Acceleration, axis 1
a2Position	LREAL	Position, axis 2
a2Velocity	LREAL	Velocity, axis 2
a2Acceleration	LREAL	Acceleration, axis 2
a3Position	LREAL	Position, axis 3
a3Velocity	LREAL	Velocity, axis 3

Name	Type	Description
a3Acceleration	LREAL	Acceleration, axis 3
a4Position	LREAL	Position, axis 4
a4Velocity	LREAL	Velocity, axis 4
a4Acceleration	LREAL	Acceleration, axis 4

Note

The functionResult output parameter

The user must set the functionResult output parameter to 1 if the velocities and the accelerations are to be calculated in the FCs in addition to the positions. If the parameter is not set explicitly, then it corresponds to 0. In this case, only the calculated position values of the FC are taken into account.

Note

Units for the interface variables

All variables at the interface are available in the set user units.

Function creation

The transformation functions can be created in the ST programming language. In order to be able to use the functions for the transformation, a pragma with attribute must be set.

```
ToHookApplicable := YES | NO
```

If the pragma is set, only certain operations are permitted.

Permitted operations

- Numeric and logic standard functions
- Access to bits in bit strings
- Standard functions for data type conversion
- Converting between any data types and byte arrays
- Combination of bit-string data types
- Functions for verification of floating-point numbers
- Functions for selection
- Access to global variables
- Consistent access to global variables of derived data types (UDT)
- Determination of the memory size of a variable or of a data type

Operations that are not permitted

- System functions on the TO
- Access functions to the TO (configuration data, system variables)
- Access functions to the I/O data and the I/O container
- System functions on devices

- Standard functions for controlling I/O modules and drive components
- System functions for controlling axes according to PLCopen
- Data backup and initialization from user program
- Communication functions
- System function blocks (for example counters, edge encoders or timers)
- Marshalling
- String machining
- Conversion of technology object data types

Note

In the functions of the user program, you must ensure that floating-point function calls (e.g ACOS) are called with valid values when working with the free transformation interface.

Example

Here is a minimal example of the FCs of the forward and backward transformation.

Forward transformation

```
FUNCTION FC_trans_Direct_Real  :StructPathDirectUserTransformationOut
{ToHookApplicable:= YES}
    VAR_INPUT
        ParIn : StructPathDirectUserTransformationIn;
    END_VAR
    FC_trans_Direct_Real.xPosition      := ParIn.a1Position;
    FC_trans_Direct_Real.yPosition      := ParIn.a2Position;
    FC_trans_Direct_Real.zPosition      := ParIn.a3Position;
    FC_trans_Direct_Real.wPosition      := ParIn.a4Position;
    FC_trans_Direct_Real.functionResult := 0;
END_FUNCTION
```

Backward transformation

```
FUNCTION FC_trans_Inverse_Real  :StructPathInverseUserTransformationOut
{ToHookApplicable:= YES}
    VAR_INPUT
        ParIn : StructPathInverseUserTransformationIn;
    END_VAR
    FC_trans_Inverse_Real.a1Position     := ParIn.xPosition;
    FC_trans_Inverse_Real.a2Position     := ParIn.yPosition;
    FC_trans_Inverse_Real.a3Position     := ParIn.zPosition;
    FC_trans_Inverse_Real.a4Position     := ParIn.wPosition;
    FC_trans_Inverse_Real.functionResult := 0;
END_FUNCTION
```

Execution time

The time for execution of the user transformation function is included in the execution time of the IPO system task. You will find more information on monitoring functions and settings of the IPO system task in the Basic functions Manual in Section AUTOHOTSPOT.

Breakpoints

For the FCs of the user transformation function, breakpoints are ignored.

Definitions

Table 4-276 Configuration data for the user-specific coordinate transformation

typeOfKinematics: USER_FUNCTION	2D/3D user function kinematics type
kinematicsType	Setting of the kinematics for the user function • **_2D**: 2D programming in a plane • **_3D**: 3D programming in space
basicOffset	Offset of the kinematic zero point (ZP) relative to the Cartesian zero point
basicOffset.x	Offset of the kinematic zero point relative to the Cartesian zero point, the x coordinate
basicOffset.y	Offset of the kinematic zero point relative to the Cartesian zero point, the y coordinate
basicOffset.z	Offset of the kinematic zero point relative to the Cartesian zero point, the z coordinate
basicOffset.roll	Rotation about x (roll)
basicOffset.pitch	Rotation about y (pitch)
basicOffset.yaw	Rotation about z (yaw)
config2D	Main plane of the path axes
parameter	Up to 32 user-defined parameters for the transformation
userTrafoID	Identifier of the user-defined coordinate transformation

Use of virtual axes

If you want to set up kinematics that cannot be mapped onto any existing kinematics but not all axes are used as real axes for these kinematics, you must create and interconnect the missing axes as virtual path axes.

As an example: The articulated arm kinematics provides three axes.

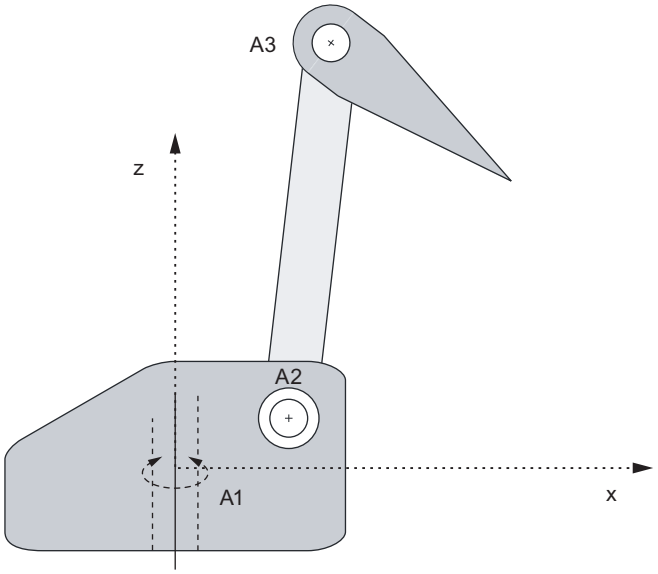

Figure 4-566 Articulated arm kinematics: Axes

- **A1** axis: 1. Path axis
- **A2** axis: 2. Path axis
- **A3** axis: 3. Path axis

If your kinematic system does not provide any axis for the first path axis, you must create a virtual axis for the first path axis and so interconnect the path object. The path object must then only be traversed and displayed in the corresponding main plane.

Specific kinematics

SPECIFIC kinematics type

The SPECIFIC kinematics type can be set using the typeOfKinematics configuration datum.

Example of settings on path object

Kinematics.typeOfKinematics = SPECIFIC (6)

The kinematics and parameters required can then be specified by the TrafoID and a parameter list.

See also

Appendix A (Page 2614)

4.6.3.14 Object coordinate systems and motion sequences on the path object

Object coordinate system (OCS) on the path object

As of SIMOTION V4.1.2, position details in the motion commands can be related optionally to the basic coordinate system (BCS, previously present functionality) or to an object coordinate system (OCS).

The motion sequence is available as from V4.2

An OCS can be permanent (static OCS) or coupled with a motion value supplied to the **trackingIn** interface of the path object.

A technology object that provides motion information with a position (the motion sequence reference value) can use the **TrackingIn** interface to interconnect with the path object. This can be, for example, an external encoder or a positioning axis.

If path motions relate to an OCS, then, for example, products can be taken from a moving belt or placed there.

Note

For an active motion sequence, a blending with dynamic response adaptation (`blendingMode:= ACTIVE_WITH_DYNAMIC_ADAPTION`) is not supported. Motions programmed with blending will then be performed without blending.

Three object coordinate systems are available on the path object and the positions of the working point are displayed in the relevant OCS (see also system variable `ocs`).

Activating OCS

The reference position of the OCS relative to the BCS is set again via the system function `_setPathObjectOcs`. The default values can be set in the SCOUT form **Object coordinate systems**. However, these values are only activated after `_setPathObjectOcs` has been called. The corresponding system variable for the default values is `userDefaultOcs`.

The default values can also be set by calibration (Page 2573). In this case, the new values are first written into `userDefaultOcs`. The reference position of the object coordinate system is itself not overwritten. For this, it is not necessary to call `_setPathObjectOcs`.

If the parameter `ocsSettingType` of the system function `_setPathObjectOcs` is set to the value `DIRECT`, values for offset and rotation can be entered directly.

Coupled OCS

A coupled OCS is an OCS coupled with a motion value of a technology object interconnected to the **trackingIn** interface.

Static OCS

A static OCS is an OCS not coupled with a motion value. The position of a static OCS is always the **OCS reference position**.

A static OCS can be used to perform motions in a coordinate system displaced relative to the BCS and has been rotated.

Motion sequence

The **motion sequence** functionality permits the synchronous coupling of a kinematic end point with a coupled OCS. It contains the functions for the synchronization and coupling with a moving product on a conveyor.

Motion sequence – fundamentals

Defining an OCS reference position

The reference position of the OCS is defined compared to the BCS in the OCS basic frame. The OCS basic frame contains the translation of the Cartesian X-, Y-, and Z-axes and the subsequent rotation at the individual axes.

To define the reference position of the OCS, the translation is performed first:

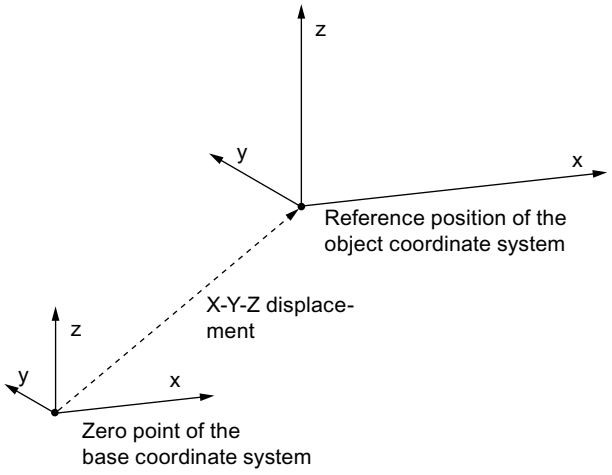

Figure 4-567 Translation of the OCS compared to the BCS

The rotations are then performed in the following sequence:

1. **Roll** at the X axis
2. **Pitch** at the (already turned) Y axis
3. **Yaw** at the (already twice-turned) Z axis

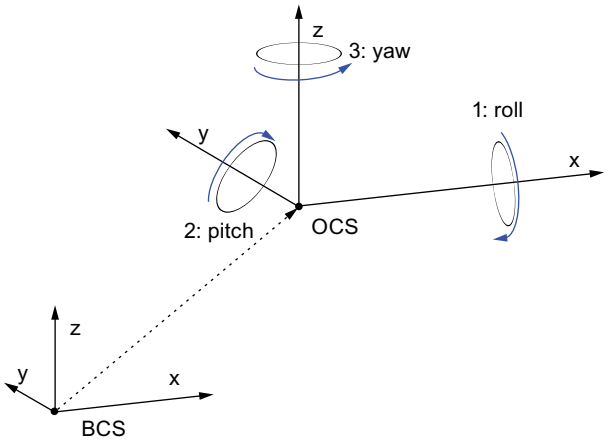

Figure 4-568 Rotations of the OCS

The **_setPathObjectOcs()** command can be used to set the basic frame for each OCS on the path object. Either default values in the system variables can be used or other values specified directly.

Definition of the terminology

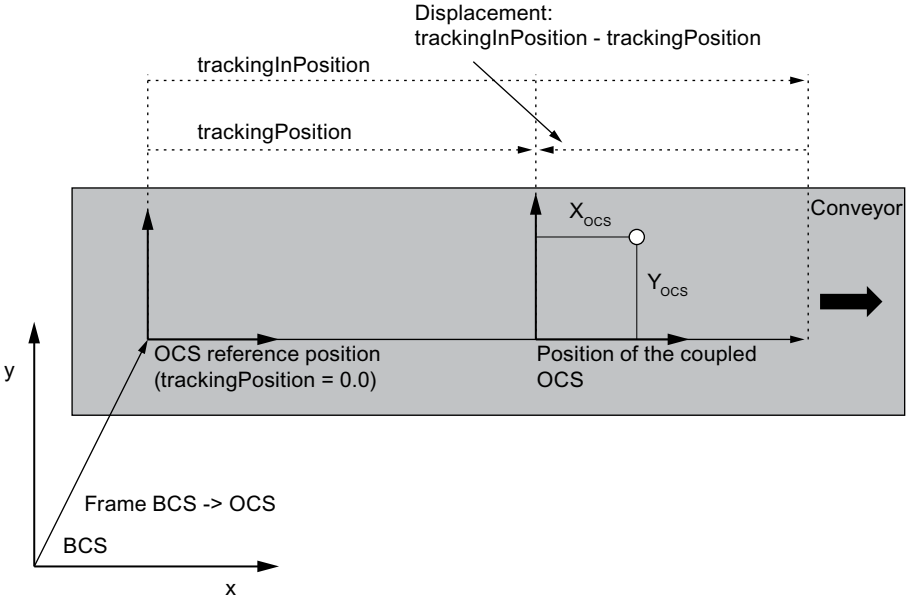

Figure 4-569 Schematic drawing of the motion sequence

OCS	Object coordinate system
BCS	Basic coordinate system
Frame	Translation and rotation of the OCS for the BCS

Reference position	Position of the OCS after translation/rotation in accordance with the basic frame
Motion sequence reference value	For example, actual value of an external encoder
Motion sequence value	Current position of the coupled OCS relative to the OCS reference position
X_{OCS} ,Y_{OCS}	Translation of the kinematic end point to the position of the coupled OCS

Assigning an OCS to a motion sequence reference value

The **trackingIn** input interconnection interface of the path object can be interconnected with another TO that provides an output interface with motion information. This can be, for example, the motion setpoint or actual value of an axis or the actual value of an external encoder.

The motion sequence value and the motion sequence reference value are assigned to the X-direction of the OCS. The OCS is coupled to the motion sequence reference value, the OCS coupling position is translated by the motion sequence value with regard to the OCS reference position in the X-direction of the OCS.

If the OCS is not interconnected or no TO is specified in the **_setPathObjectOcs()** command (**trackingIn:=TO#NIL**), the OCS then acts in its reference position.

If the kinematic end point is synchronized to a coupled OCS or is already synchronous with it (**trackingIn** <> **TO#NIL** and **trackingState** <> **INACTIVE**), the **_setPathObjectOCS()** command is not performed on this OCS and an error message issued. Before executing the command, the synchronized state ('**SYNCHRONIZED**' status) on this OCS must be ended.

See Terminate the coupling of the kinematic end point to a controlled OCS ('desynchronize') (Page 2552) for further information.

Defining the translation of the position of the coupled OCS

Because normally a product-based programming is performed, the position of the OCS on the conveyor must be modified appropriately for the product position, i.e. translated.

The **_redefinePathObjectOCS()** command is used to translate the position of the OCS in the X-direction and so in the direction of the value on the motion sequence input.

If the kinematic end point is synchronized to a coupled OCS or is already synchronous with it (**trackingIn <> TO#NIL** and **trackingState <> INACTIVE**), the **_redefinePathObjectOCS()** command is not performed on this OCS and the 30002 error message issued. Before executing the command, the synchronized state (**SYNCHRONIZED** status) on this OCS must be ended.

The current position values of the coupled OCS and the motion sequence input will be displayed in the following system variables:

- **Motion sequence reference value**
  The **trackingInPosition** system variable contains the position value present at the motion sequence input of the OCS, the motion sequence reference value (the conveyor position).
- **Motion sequence value**
  The **trackingPosition** system variable contains the position of the coupled OCS, the motion sequence value.
  trackingPosition = trackingInPosition + translation

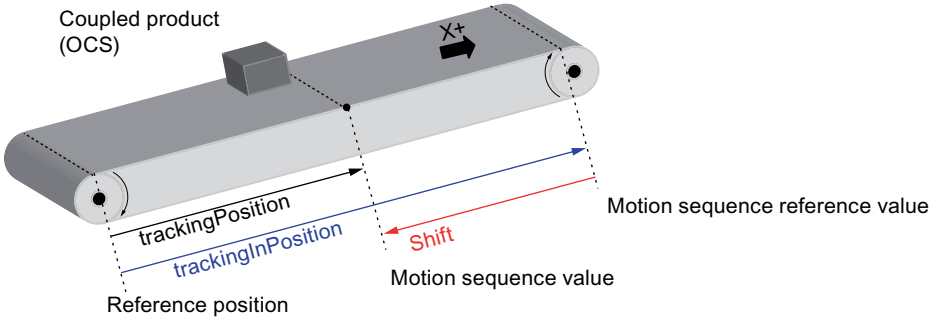

Figure 4-570 Current position of the OCS

Behavior of the OCS for modulo encoders

The motion sequence value indicates the continuing value on the motion sequence input without considering the modulo properties, i.e. the motion sequence value will not be reset when the motion sequence reference value on the modulo range end is reset, refer to the following figure.

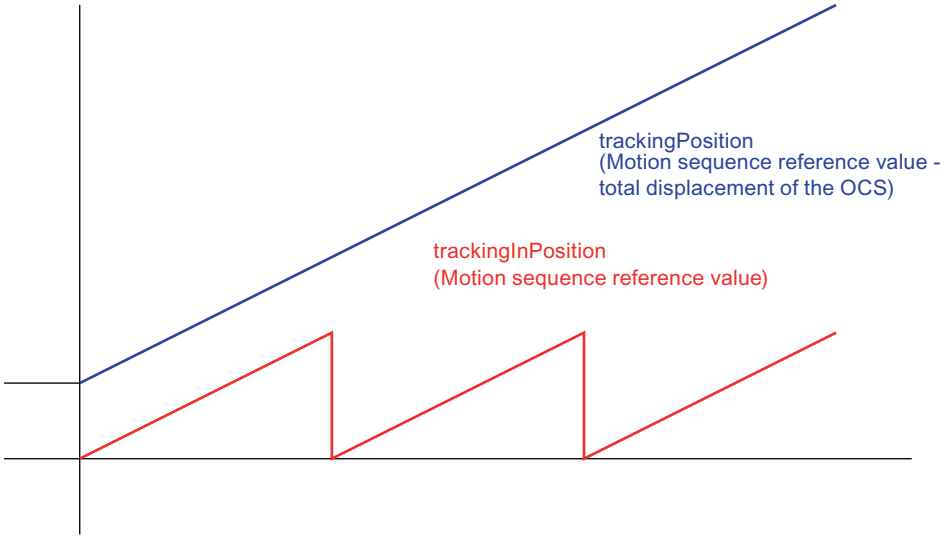

Figure 4-571 Behavior of trackingPosition for modulo-assigned value in trackingInPosition

Resetting trackingPosition

The **_redefinePathObjectOCS()** function can be used to set or translate **trackingPosition** only when the kinematic end point is not synchronous to this OCS or currently being synchronized (indicated using the **trackingState:=INACTIVE** variable).

There are 2 modes for translating the **trackingPosition** with the function **_redefinePathObjectOcs()** - absolute or relative.

For the respective mode the value for **trackingPosition** can be calculated as follows:

- For **mode:= RELATIVE**
  trackingPosition:=trackingPosition + value
- For **mode:= ABSOLUTE**
  trackingPosition:=trackingPosition + value

The use of **mode:=ABSOLUTE** has the advantage that translating always refers to trackingInPosition, which means that previous translations do not have to be buffered in the application. For **mode:= RELATIVE** it is necessary to buffer the translation in the application.

The **_redefinePathObjectOCS()** and **_setPathObjectOCS()** functions are not executed for the associated OCS when it is in the '**SYNCHRONIZED**' status.

See Terminate the coupling of the kinematic end point to a controlled OCS ('desynchronize') (Page 2552) for further information.

Synchronizing motion on the path object to the coupled OCS

A handling application for which, for example, a product is to be fetched from a moving conveyor, is realized with an OCS coupled with the conveyor. The motion commands are configured here so they act directly in the OCS.

This requires the motion calculated for the path object for the kinematic end point to be synchronized to the coupled OCS.

In the simplest case, after the synchronization, the kinematic end point moves with a defined point in the OCS and so with a point located on the conveyor. Furthermore, after the synchronization in the coupled OCS, linear, circular or polynomial paths can also be followed.

The **_enablePathObjectTrackingSuperimposed()** command is used to synchronize the kinematic end point with an OCS coupled with the motion sequence reference value (e.g. position of a conveyor). Some of the arguments specified with the command:

- Synchronization mode (**synchronizingMode**)
  The following synchronization modes are available:
  - Other coupling with the position in the OCS specified in the command
    (setting: **synchronizingMode:=IMMEDIATELY**)
    Synchronization is executed immediately and coupled with the OCS.
  - Synchronization and coupling in the OCS at the position of the OCS specified in the command, i.e. as soon as the **ocsTrackingPosition** (e.g. of a conveyor belt) has reached a specified value (the synchronization position)
    (setting: **synchronizingMode:=ON_POSITION**).
    For this synchronization mode, a preliminary synchronization is made to the specified synchronization position in the OCS.
- The synchronization position (**position**)
  The specification of a motion sequence value, above which travel synchronous with the OCS is to take place. This value is used only for **synchronizingMode:=ON_POSITION**.

The following applies for both synchronization modes:

- The synchronization on the conveyor belt occurs where necessary superjacent to a motion that is still active in the BCS.
- No further motion commands are possible in the BCS during synchronization.
- Motion commands in the OCS are only possible once the status **SYNCHRONIZED** has been reached.

The desired position of the product in the OCS can be approached after the synchronization via a path command in the OCS.

The following applies for the synchronization mode **ON_POSITION**:

The synchronization process will be aborted when the direction of the encoder value reverses during the synchronization.

This can occur when the external encoder of a conveyor belt delivers a fluctuating position value during standstill due to missing filters or an insufficient tolerance window (with Extrapolation) which results in a direction reversal of the acutal position.

Synchronization status

The synchronization status of the kinematic end point to a coupled OCS is indicated in the **ocs[i].trackingState** system variables on the OCS.

The synchronization status is **SYNCHRONIZED** when

- there is **no motion active in the BCS**, the speed of the kinematic end point is equal to the speed of the conveyor belt and the position misalignment of the synchronization motion resulting from the synchronization has been rectified.
- **a motion is active in the BCS**, the speed of the overlying synchronization motion is equal to the speed of the conveyor belt and the position misalignment of the synchronization motion resulting from the synchronization has been rectified.

A static OCS interconnected with **TO#NIL** always has the **SYNCHRONIZED** status. In addition to the static OCS, not more than one coupled OCS can have the **SYNCHRONIZED** status.

Dynamic values for the synchronization action

Dynamic values for the synchronization action can be specified in the **_enablePathObjectTrackingSuperimposed ()** command.

The default dynamic values of the path object can be used or the values specified explicitly.

The overall dynamics during the synchronization process result from the active path motion in the BCS (where necessary) and the overlying synchronization motion. This must be taken into consideration when specifying the dynamics, as otherwise this can cause the programmed or maximum dynamic values on the path object to be exceeded.

Performing path motions in the coupled OCS

Path motions can be related using the **csType** command parameter optionally to the BCS or an OCS.

Prerequisite for path commands in the OCS acting is that the OCS has the **SYNCHRONIZED** status. Otherwise the path motion command for the OCS will not be performed. Path motion commands for the OCS can only be issued after synchronization.

- **csType**
  This parameter specifies whether the coordinates apply to the OCS or the BCS.
- **csNumber**
  This parameter is the index of the OCS (1...3).

Terminate the coupling of the kinematic end point to a controlled OCS ('desynchronize')

The coupling of the kinematic end point to a controlled OCS is terminated by the coming into force of a path motion command related to the BCS or a static OCS.

Any existing path motion commands are discarded; the new path motion command will be executed immediately.

The system variables for **PATH** on the path object indicate the state of the path in the BCS or OCS coordinates system selected.

When revoking a synchronous motion sequence (conveyor synchronization) using **_stopPath** in the BCS, **no path active** and/or zero values are displayed for removal of the motion from the motion sequence.

Stopping in the OCS

The **_stopPath()** command can be stopped relative to the OCS. The **SYNCHRONIZED** status with the coupled OCS is retained. This means the motion can be continued using **_continuePath()** relative to the coupled OCS.

Motion sequence – sample application

Sample application of an OCS

The use of an OCS for the motion sequence is explained using a short example.

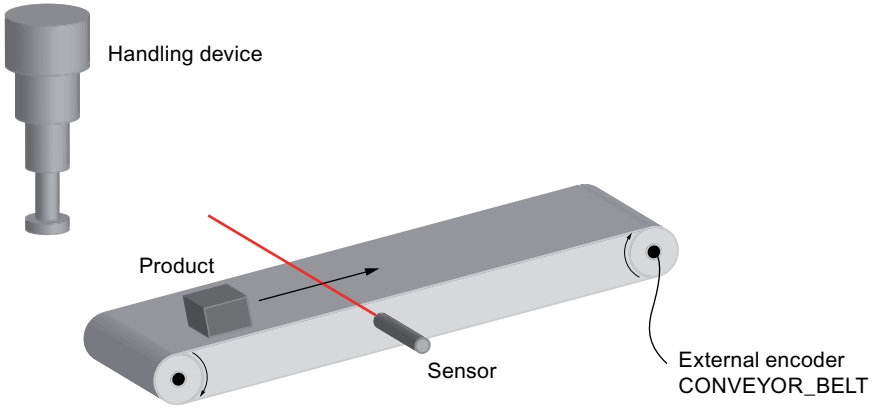

Figure 4-572 Overview of the sample application

In this example, products are placed on a conveyor. A sensor records the exact position of the products. The handling device should fetch products from the conveyor and place them at another location.

Defining the reference position of the OCS

The reference position of the OCS is defined in the system variables.

In this example, the OCS1 is used. The settings for this coordinate system are made in the **userdefaultocs[1]** structure.

userdefaultocs	User defaults of the object coordinate s		
userdefaultocs[1]	User defaults of the object coordinate s		
frame	Transformation frame		
pitch	Rotation at the Y vector after rotation at	-15.0	°
roll	Rotation at the X vector after the offset	0.0	°
x	Offset in X direction	100.0	mm
y	Offset in Y direction	0.0	mm
yaw	Rotation at the Z vector after rotation at	0.0	°
z	Offset in Z direction	15.0	mm
userdefaultocs[2]	User defaults of the object coordinate s		
userdefaultocs[3]	User defaults of the object coordinate s		

Figure 4-573 OCS-relevant system variables

Consequently, the OCS is displaced by 100 mm in the X-direction and 15 mm in the Z-direction:

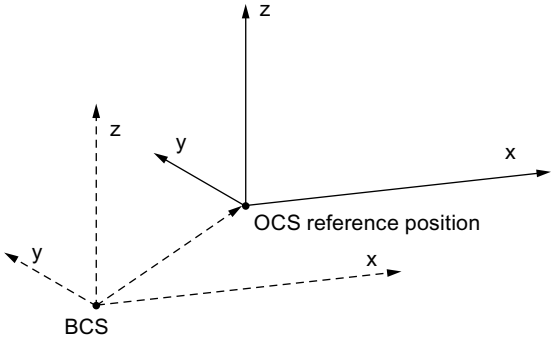

Figure 4-574 Displacement of the OCS

The OCS is rotated by -15° at the Y-axis.

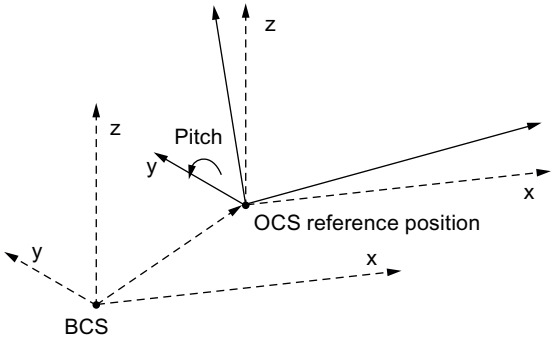

Figure 4-575 Rotation of the OCS

Determining the motion sequence reference value of the OCS

The position and motion data of the conveyor are acquired using the **CONVEYOR_BELT** external encoder. For the OCS, the base frame is set and activated with the **CONVEYOR_BELT** motion sequence reference value. The OCS is then coupled with the conveyor, in particular, at the position supplied by the **CONVEYOR_BELT** external encoder.

```
// Set OCS_1 to CONVEYOR_BELT,
// for the BCS base frame for the OCS,
// use the default settings.
myRetDINT :=
    _setPathObjectOcs(
        pathObject:=Portal_3D,
        ocsNumber:=1,
        trackingIn:=CONVEYOR_BELT,
        ocsSettingType:=USER_DEFAULT
);
```

Defining the position of the OCS relative to the motion sequence reference value

The sensor, for example, a light barrier, is triggered by the passing product. The current value of the **CONVEYOR_BELT** external encoder is stored in the **belt_position** variable.

Because the position of the sensor related to the reference position of the OCS is known, the position of the product with regard to the motion sequence reference value is known.

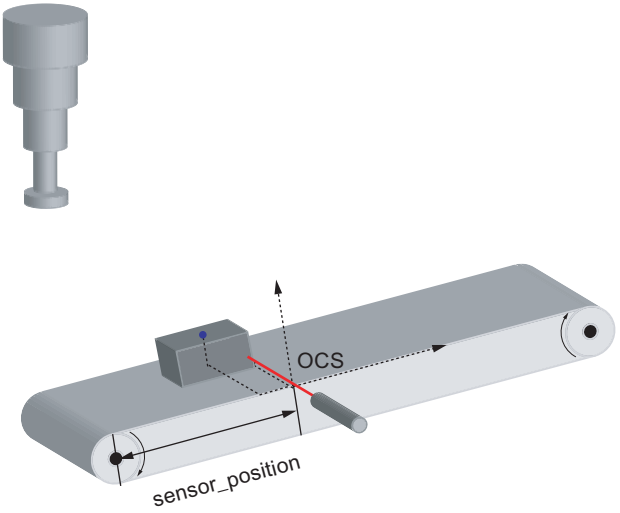

Figure 4-576 Defining the position of the OCS

```
myRetDINT :=
    _redefinePathObjectOcs(
        pathObject:=Portal_3D,
        ocsNumber:=1,
        mode:=RELATIVE,
        value:=belt_position - sensor_position
);
```

Synchronizing motion on the path object to the coupled OCS

The handling device should be coupled synchronous with the product after a **synch_space** travel length after the sensor.

The acting point position of the grabber is specified in the OCS. In the example, this is done using the **offset_x**, **offset_y** and **offset_z** variables. This displacement is then used for positioning after synchronization by means of a command in the OCS so that the gripper can hold the product above its center of gravity.

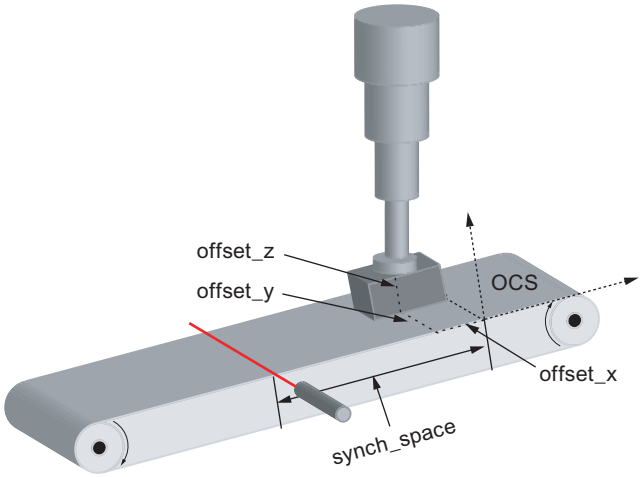

Figure 4-577 Synchronizing the handling device

```
myRetDINT :=
    _enablePathObjectTrackingSuperimposed(
        pathObject:=Portal_3D,
        ocsNumber:=1,
        synchronizingMode:=ON_POSITION,
        position:=sensor_position + synch_space
);
```

When the status "synchronous" has been reached (**ocs[1].trackingState = SYNCHRONIZED**), the command for positioning the gripper at the acting point of the product (**offset_x**, **offset_y**, **offset_z**) can be issued in the OCS.

```
myRetDINT :=
    _movePathLinear(
        pathObject:=Portal_3D,
        pathMode:=ABSOLUTE,
        x:=offset_x,
        y:=offset_y,
        z:=offset_z,
        csType:=OCS,
        csNumber:=1
);
```

Performing path motions in the coupled OCS

The handling device now moves itself 15 mm away from the conveyor and brings the product to the placement position (**dispose_x**, **dispose_y**, **dispose_z**). The first motion occurs in the OCS, the second in the BCS. The synchronization is terminated by calling the second command.

```
myRetDINT :=
    _movePathLinear(
        pathObject:=Portal_3D,
        pathMode:=RELATIVE,
        z:=15.0,
        csType:=OCS,
        csNumber:=1
);

myRetDINT :=
    _movePathLinear(
        pathObject:=Portal_3D,
        pathMode:=ABSOLUTE,
        x:=dispose_x,
        y:=dispose_y,
        z:=dispose_z,
        cstype:=BCS
);
```

4.6.3.15 Interconnection, interconnection rules

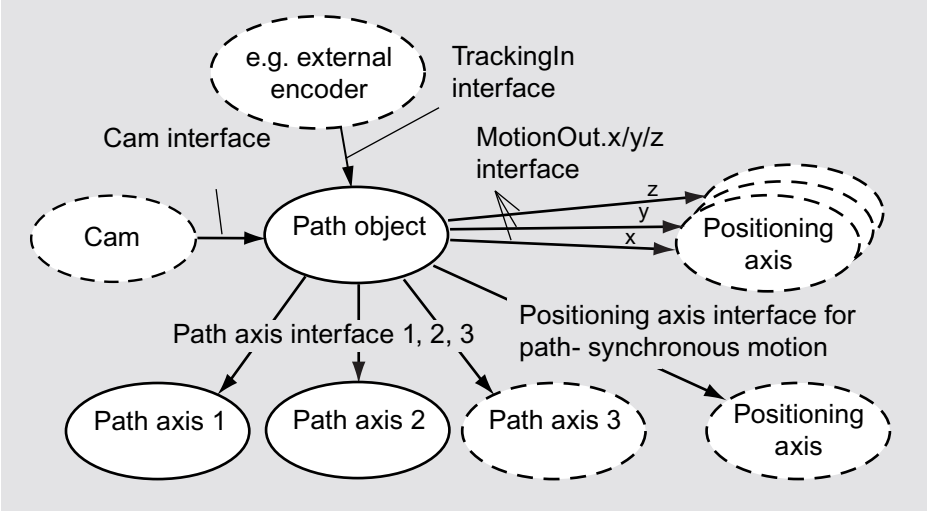

Figure 4-578 Interfaces on the path object

- Path axis interface 1 and path axis interface 2 of a path object must be interconnected with path axes.
- Path axis interface 3 of the path object can optionally be interconnected with a path axis, irrespective of the kinematic settings.
- The positioning axis interface for the path-synchronous motion can optionally be interconnected with a positioning axis.
- The MotionOut.x, MotionOut.y or MotionOut.z interface can optionally be interconnected with a positioning axis.

- The path object can be interconnected with a cam for specifying a velocity profile.
- To specify a motion sequence reference value, the TrackingIn interface can be interconnected with a TO that provides an output interface with position value.

For additional information, see **Motion Control Basic Functions** Function Manual, "Available technology objects".

Notes:

- The path interfaces cannot be distributed, i.e. all objects involved in the path group (path object, path axes, and positioning axes) must be on the same device.
- The objects involved in a path interpolation group (path object, path axes and, if applicable, a positioning axis) must be assigned to the same IPO or IPO_2 execution level. The SERVO setting is not possible.
- The currently effective interconnections are shown in the system variables **specificVelocityProfile**, **motionBuffer**, **connections**.

4.6.3.16 Simulation operation

A path interpolation can be switched to simulation, i.e. values are calculated on the path object but are not output to the slave axes/positioning axis.

It is possible to enable and disable the path simulation at any time, including while the relevant axes are in motion, provided there is no error response.

The **simulation [ACTIVE/INACTIVE]** system variable provides information about the simulation status of the path object.

Commands for the simulation operation

- The **_enablePathObjectSimulation()** command sets the path interpolation to simulation mode.
  Values are calculated but are not output to the path axes/positioning axis. This can be done at any time.
- The **_disablePathObjectSimulation()** command resets the path interpolation from simulation mode.
  Values are output to the path axes/positioning axis again.
  If there is a discrepancy between the axis setpoint calculated from the path interpolation and the current setpoint on the axis, the change in the axis setpoint on the axis is limited due to the maximum dynamic limits of the axis.

Maintaining the setpoint calculation on the path object even when the axis enables are canceled

The configuration data **decodingConfig.disablePathOperation** can be used to specify whether the setpoints on the path object will continue to be calculated even when the axis enables are canceled.

- If **NO** (default), the path interpolation is also canceled in simulation mode if the enables on the path axis/positioning axis have been canceled.
- If **YES**, the path interpolation is not canceled in simulation mode if the enables on the path axis/positioning axis have been canceled while the path object is in simulation mode.
  Any path commands that are undergoing execution are retained.

4.6.4 Configuring the Path Object

4.6.4.1 Selecting the path interpolation technology package

1. Select the device in the project navigator and select **Select technology packages** in the shortcut menu (right-click).
2. Select the **PATH** option and confirm with **OK**.

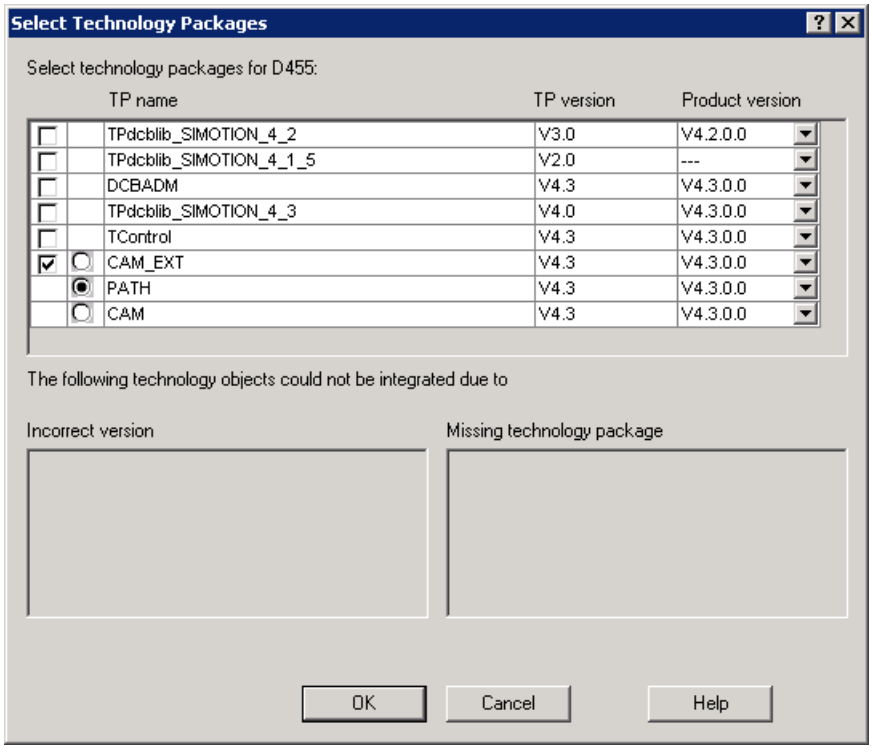

Figure 4-579 Selection of technology packages

4.6.4.2 Creating axes with path interpolation

- When creating an axis in **SCOUT**, enable the **path interpolation** technology.

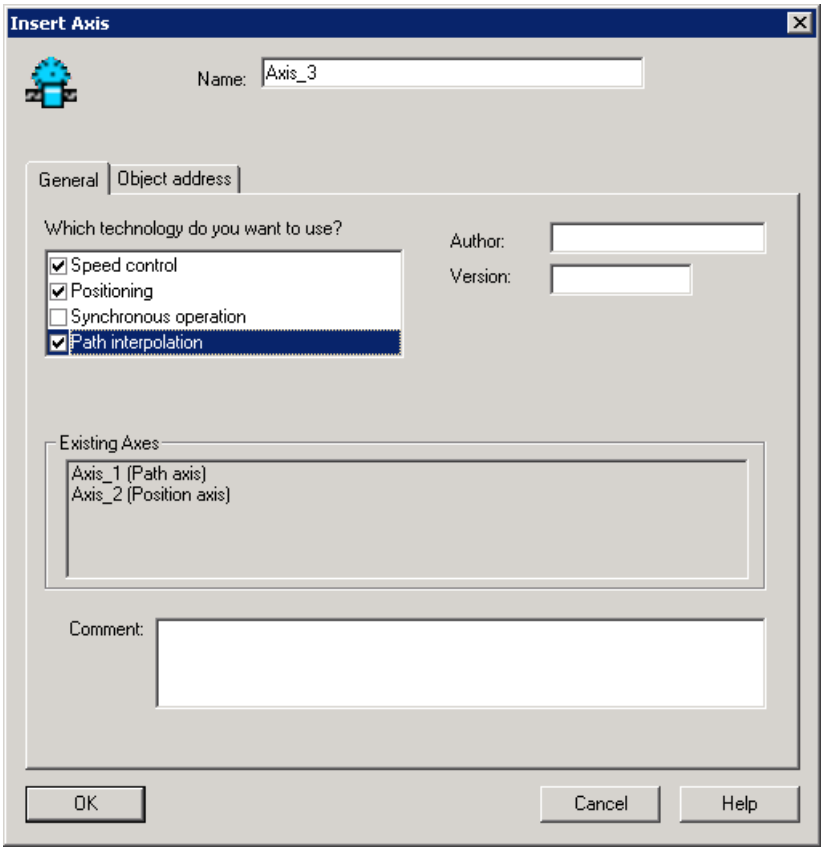

Figure 4-580 Inserting an axis with path interpolation

Notes

When you specify the path interpolation technology for an Axis technology object, a path object is not inserted automatically.

A positioning axis, for example, cannot be changed into a path axis at a later point.

Interconnections are made on the path object.
See Interconnecting a path object (Page 2570).

4.6.4.3 Creating a path object

In SIMOTION SCOUT, path objects are created at the same level as an Axis and a Cam technology object. These path objects can be assigned to all applicable axes of the device.

1. To create a new path object, double-click **Insert path object** under **PATH OBJECTS** in the project navigator.
   You can also copy an existing path object to the clipboard and then insert it under another name.

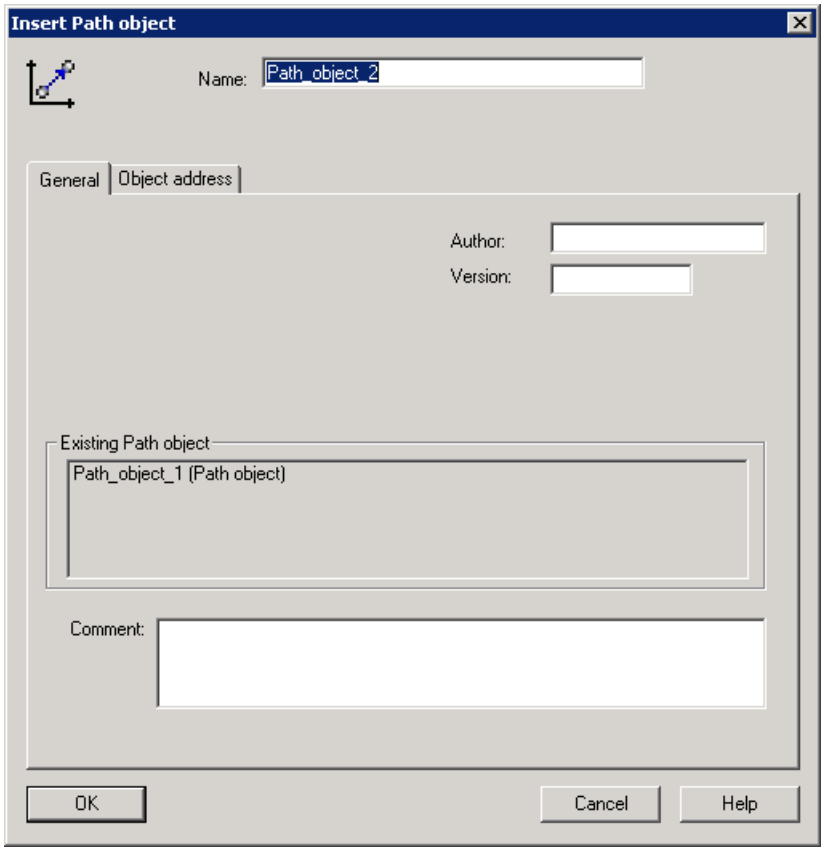

Figure 4-581 Inserting a path object

2. Enter a name and, if necessary, the author, version, and comments, and click **OK** to confirm.

The new path object will be inserted under **TECHNOLOGY**.

4.6.4.4 Representation in the project navigator

The path object appears in the project navigator at the same level as the Axis and Cam technology objects. Links symbolize the connection to path axes or a positioning axis for path-synchronous motion.

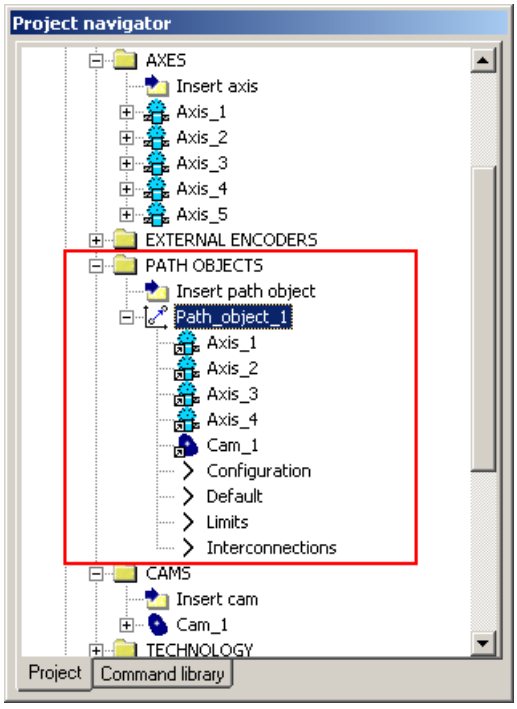

Figure 4-582 Project with path interpolation in the project navigator

4.6.4.5 Assigning path object parameters/default values

- In the project navigator, double-click **Default** under the path object.
  In this window, you define the substitute values (default) for calling the path object (**_movePath...()**, **_stopPath()**, **_setPathObjectOcs()**, etc.).

Default for object coordinate systems

On the **Object coordinate systems**, you can define the default values for the three available OCS.

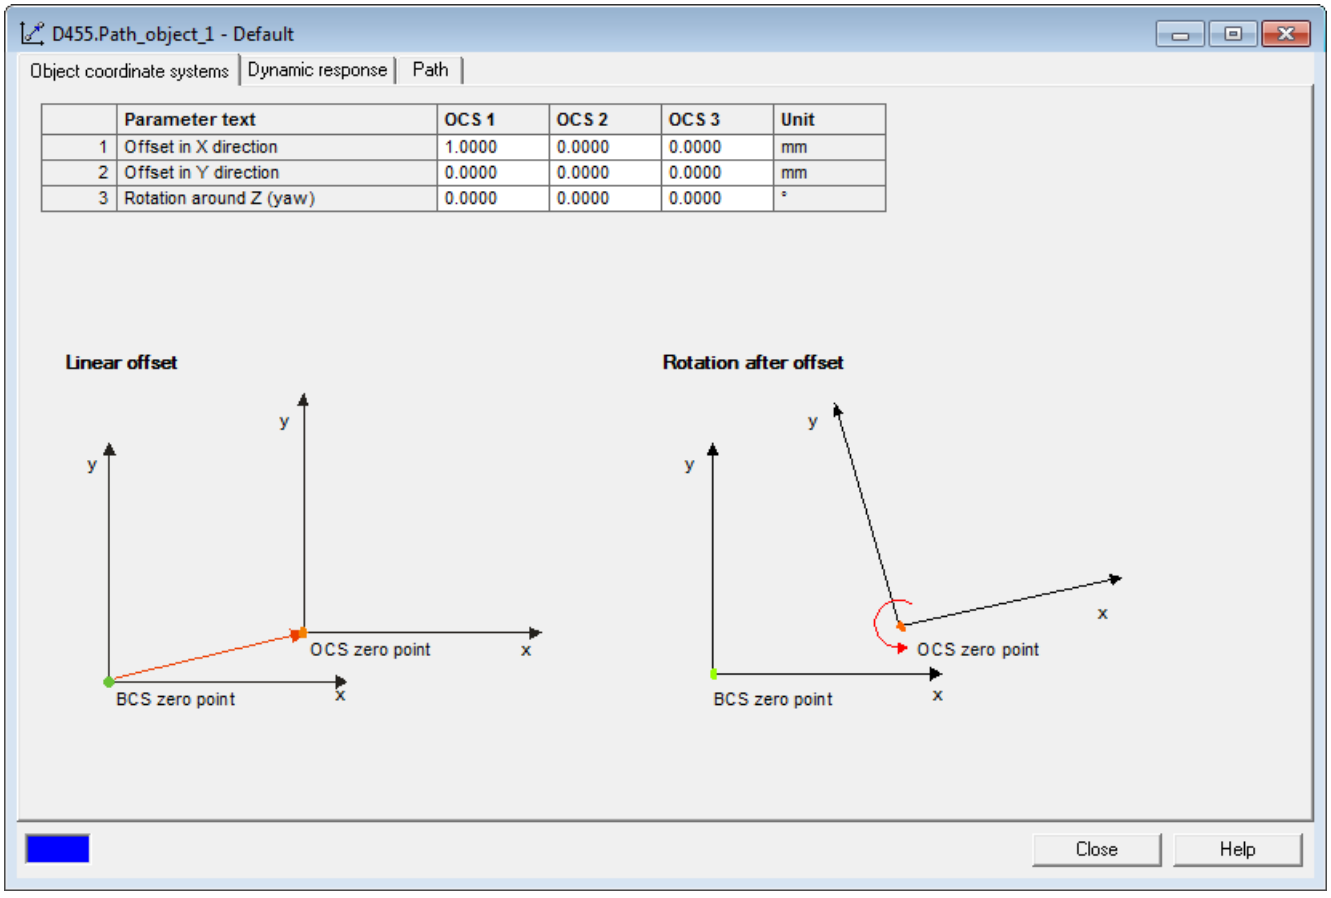

Figure 4-583 Path object: Default - Object coordinate systems tab

In this window, you can define the values for the object coordinate systems that are used by default.

For more information, refer to Object coordinate system (OCS) on the path object (Page 2545).

Dynamic response parameters

You specify the path velocity, the velocity profile, and the acceleration/deceleration and jerk on the **Dynamic response** tab.

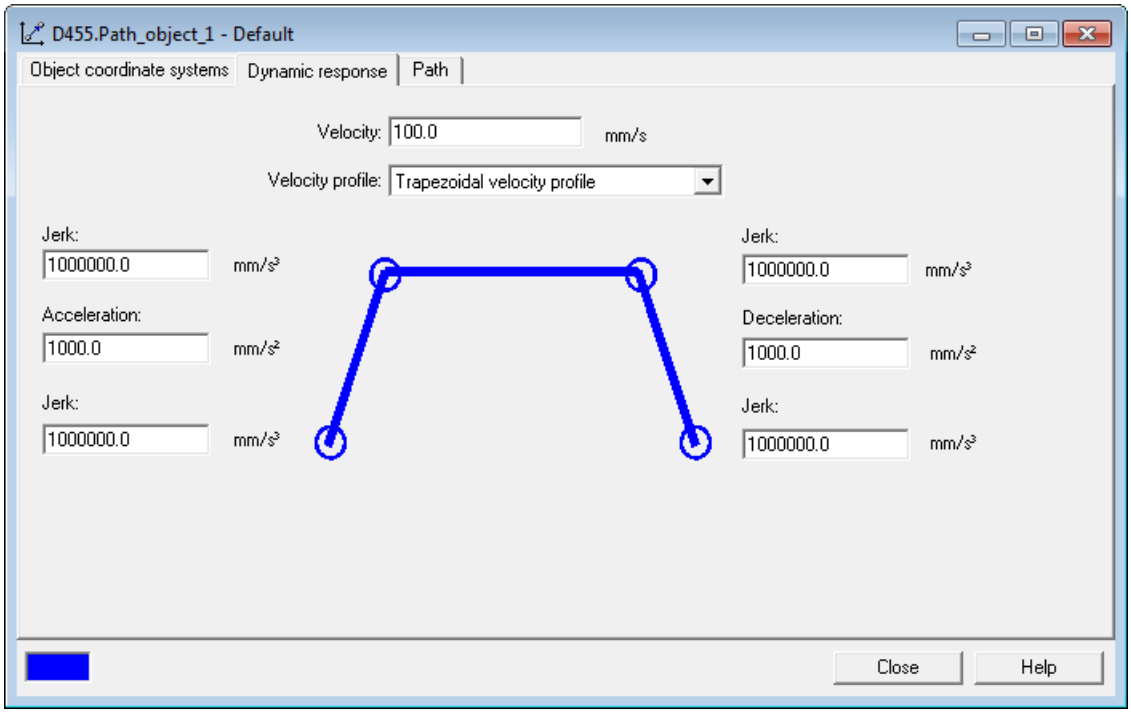

Figure 4-584 Path object: Default settings - Dynamic response tab

You define the substitute values (default settings) for the dynamic response in this window.

You can set the following parameters:

Field/button	Meaning/instruction
Velocity	Enter the substitute value for the path velocity here. (`userDefault.pathdynamics.velocity`)
Velocity profile	Select the velocity profile here. (`userDefault.pathdynamics.profile`)
Acceleration	Enter the substitute value for the path acceleration here. (`userDefault.pathdynamics.positiveAccel`)
Deceleration	Enter the substitute value for the path deceleration here. (`userDefault.pathdynamics.negativeAccel`)
Jerk	Enter the substitute value for the path jerk here. (`userDefault.pathdynamics.positiveAccelStartJerk` / `positiveAccelEndJerk` / `negativeAccelStartJerk` / `negativeAccelEndJerk` / `profile`)

For more information, refer to Path dynamics (Page 2491).

The meaning of the parameters in the dialog box and their permissible value ranges can be found in the SIMOTION reference lists.

Path parameters

You specify the default settings for the path on the **Path** tab.

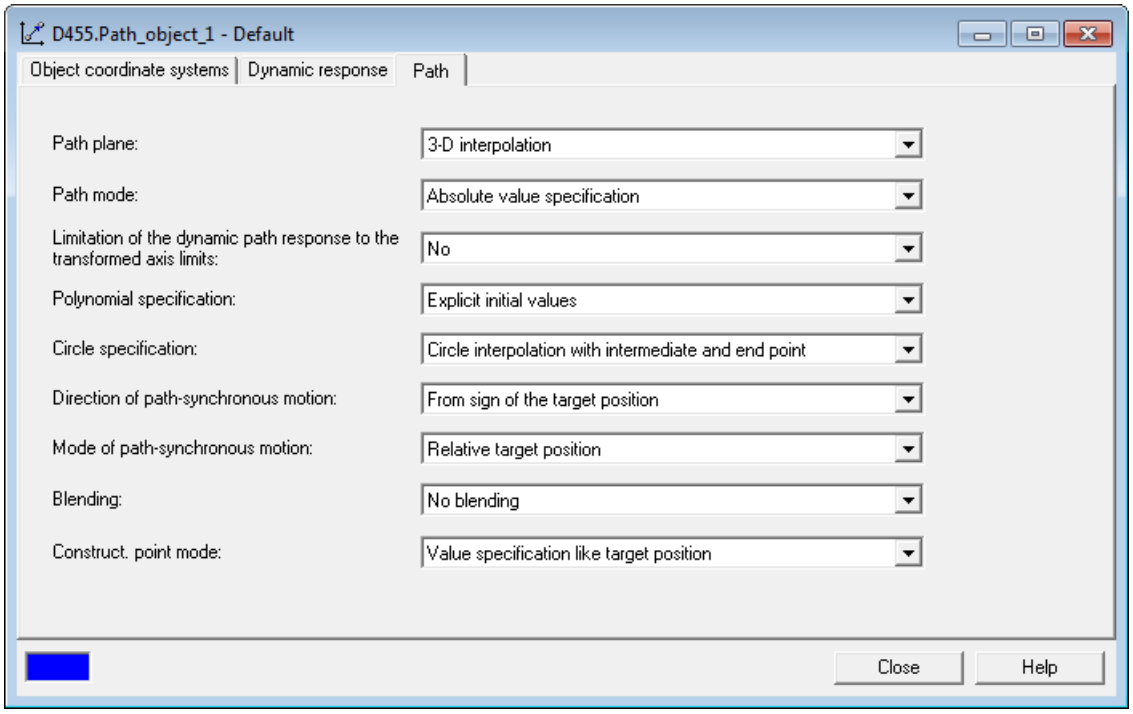

Figure 4-585 Path object: Default settings - Path tab

You define the substitute values (default settings) for the path in this window.

You can set the following parameters:

Field/button	Meaning/instruction
Path plane	Here, you specify the path plane: X_Y_Z / X_Y / Y_Z / Z_X (default: X_Y_Z, for 3D; for 2D kinematics, this is implicitly X_Y) (`userDefault.path.plane`)
Path mode	Specify the path mode: absolute or relative (userDefault.path.mode)
Limit dynamic path response to transformed axis limit values	Here, you specify whether the dynamic path response should be limited to the transformed axis limit values. (`userDefault.path.dynamicAdaption`) See Limiting the path dynamics (Page 2492).
Polynomial default	Here you can define the type of polynomial interpolation. (`userDefault.path.polynomialMode`) See Polynomial paths (Page 2485).
Circle default	Here you can define the type of circular interpolation. (`userDefault.path.circularType`) See Circular paths (Page 2481).
Direction of synchronous path motion	Here, you specify the direction of the positioning axis for path-synchronous motion. (`userDefault.w.direction`) See Functionality of path-synchronous motion (Page 2505).

Field/button	Meaning/instruction
Mode of path-synchronous motion	Here, you specify the synchronous axis mode: • Absolute • Relative • Output path lengths • Additive output of path lengths (`userDefault.w.mode`) See Functionality of path-synchronous motion (Page 2505).
Blending	Here, you specify whether and how blending is performed. (`userDefault.blendingMode`) See Path behavior at motion end (Page 2496).
Construction point mode	Center point or intermediate point: • Absolute • Relative • Same as target position mode (`userDefault.path.ijkMode`) See Circular paths (Page 2481).

Note:

Transformations are set via the Configuration (Page 2565) form or via the expert list.

For more information, refer to Basics of Path Interpolation (Page 2474).

The meaning of the parameters in the dialog box and their permissible value ranges can be found in the SIMOTION reference lists.

4.6.4.6 Configuring a path object

- In the project navigator, double-click **Configuration** under the path object.

Configuration of the path object

On the **Configuration** tab car, you define the type of kinematics, the processing cycles, and, depending on the kinematics, the coordinate plane.

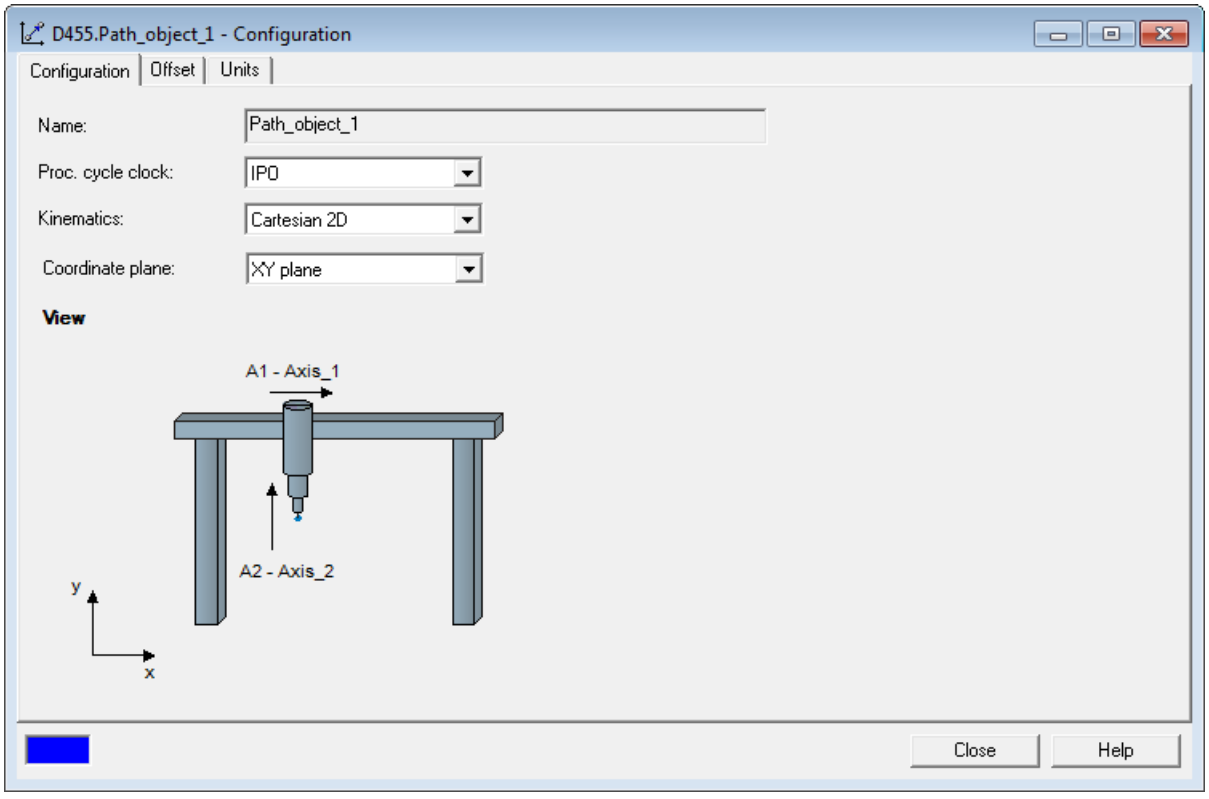

Figure 4-586 Path object: Configuration - Configuration tab

In this window, you can define the following parameters:

Field/button	Meaning/instruction
Processing cycle clock	You define here whether the path object is processed in the IPO or in the IPO_2. All TOs (path object, path axes, positioning axis for path-synchronous motion) involved in a path interpolation grouping must be assigned to the same interpolation cycle! (`Execution.executionlevel`)
Kinematics	This is where you set the desired kinematics. (`Kinematics.typeOfKinematics`)
Coordinate plane	This is where you set the coordinate plane. This setting is not available for all kinematics. (`config2D`)

Offset and rotation on the path object

On the **Offset** tab, you define the translation or rotation of the kinematic zero point relative to the BCS zero point.

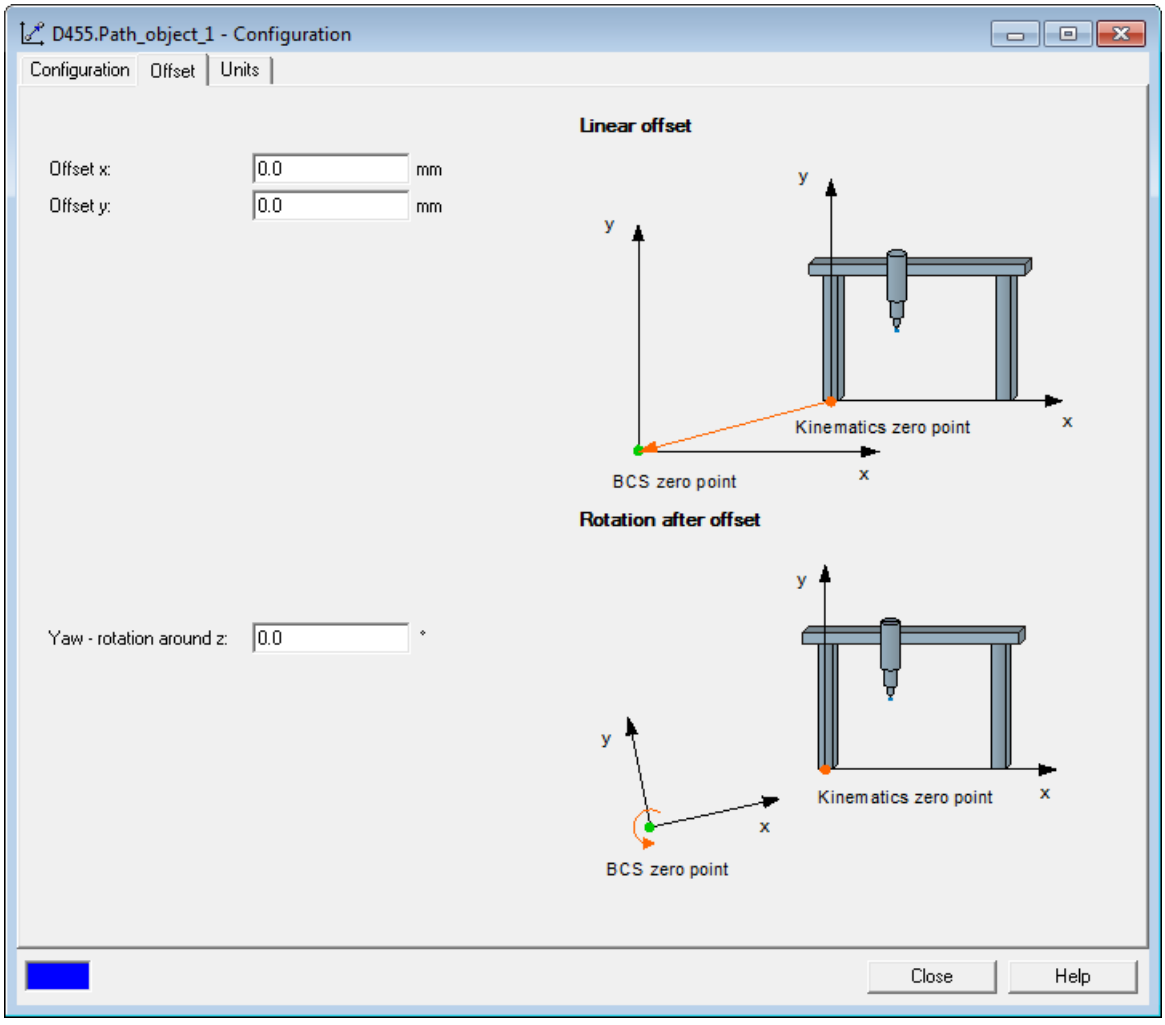

Figure 4-587 Path object: Configuration - Offset tab

In this window, you can define the following parameters:

Field/button	Meaning/instruction
Offset x Offset y Offset z	Here, you set the offset of the kinematic zero point. Depending on the kinematic type and/or set coordinate level, only certain fields exist. In this example, it is 2D kinematics or coordinate level XY. For this reason, the offset can only be set in the x and y direction. (`basicOffset.x`, `basicOffset.y`, `basicOffset.z`)
roll - rotation about x pitch - rotation about y yaw - rotation about z	Here, you set the rotation of the kinematic zero point. Depending on the kinematic type and/or set coordinate level, only certain fields exist. In this example, only rotation about the z axis is possible. (`basicOffset.roll`, `basicOffset.pitch`, `basicOffset.yaw`)

Units used for the path object

On the **Units** tab, you define the units to be used on the path object.

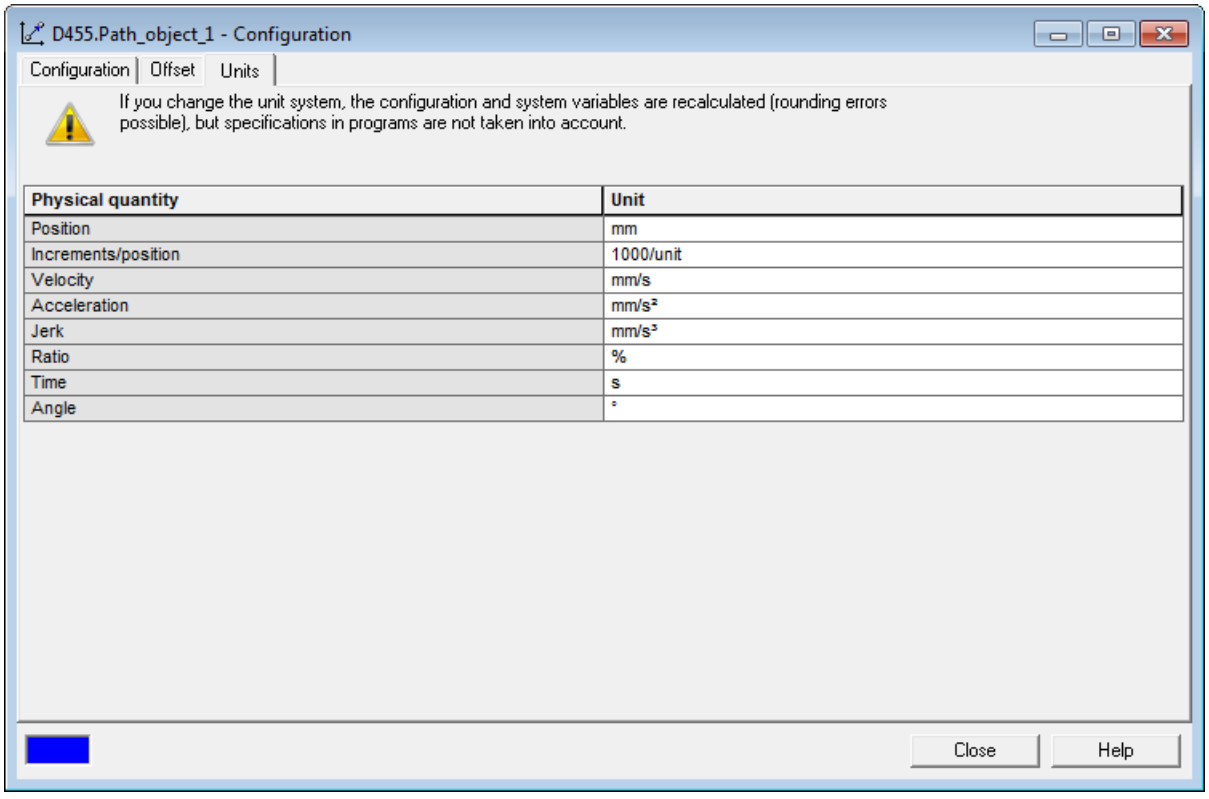

Figure 4-588 Path object: Configuration - Units tab

Further information

For an overview of functions, refer to Overview of Path Interpolation (Page 2470).

For a description of functions, refer to Basics of Path Interpolation (Page 2474).

The meaning of the configuration data and the permissible value ranges can be found in the SIMOTION reference lists.

4.6.4.7 Defining limits

- In the project navigator, double-click **Limits** under the object.

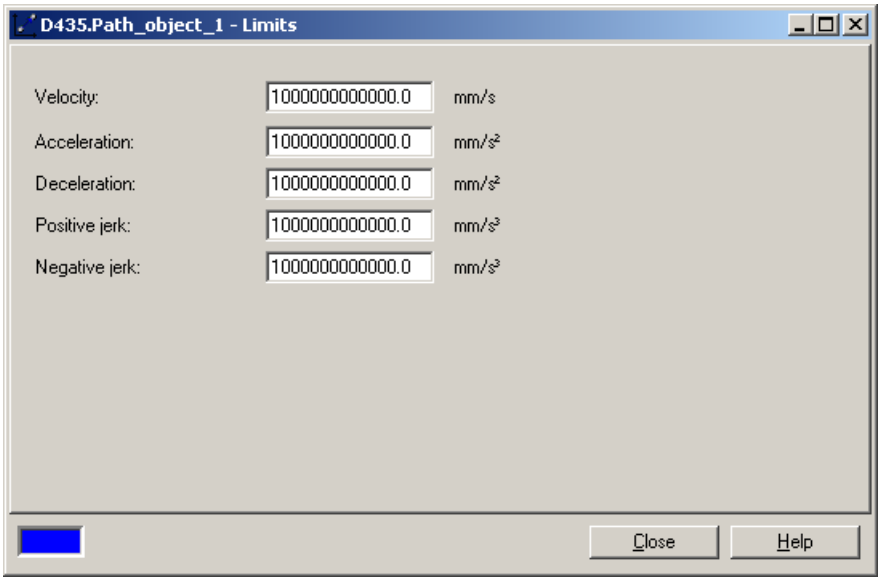

Figure 4-589 Limits on the path object

In this window, you specify the maximum dynamic path limit values:

Field/button	Meaning/instruction
Velocity	Enter the maximum velocity here. (`limitsOfPathDynamics.velocity`)
Acceleration	Enter the maximum acceleration here. (`limitsOfPathDynamics.positiveAccel`)
Deceleration	Enter the maximum deceleration here. (`limitsOfPathDynamics.negativeAccel`)
Positive jerk	Here, you enter the maximum jerk during acceleration build-up / deceleration reduction. (`limitsOfPathDynamics.positiveJerk`)
Negative jerk	Here, you enter the maximum jerk during acceleration reduction / deceleration build-up. (`limitsOfPathDynamics.negativeJerk`)

For more information, refer to Path dynamics (Page 2491).

The meaning of the configuration data and the permissible value ranges can be found in the SIMOTION reference lists.

4.6.4.8 Interconnecting a path object

- In the project navigator, double-click **Interconnections** under the object.

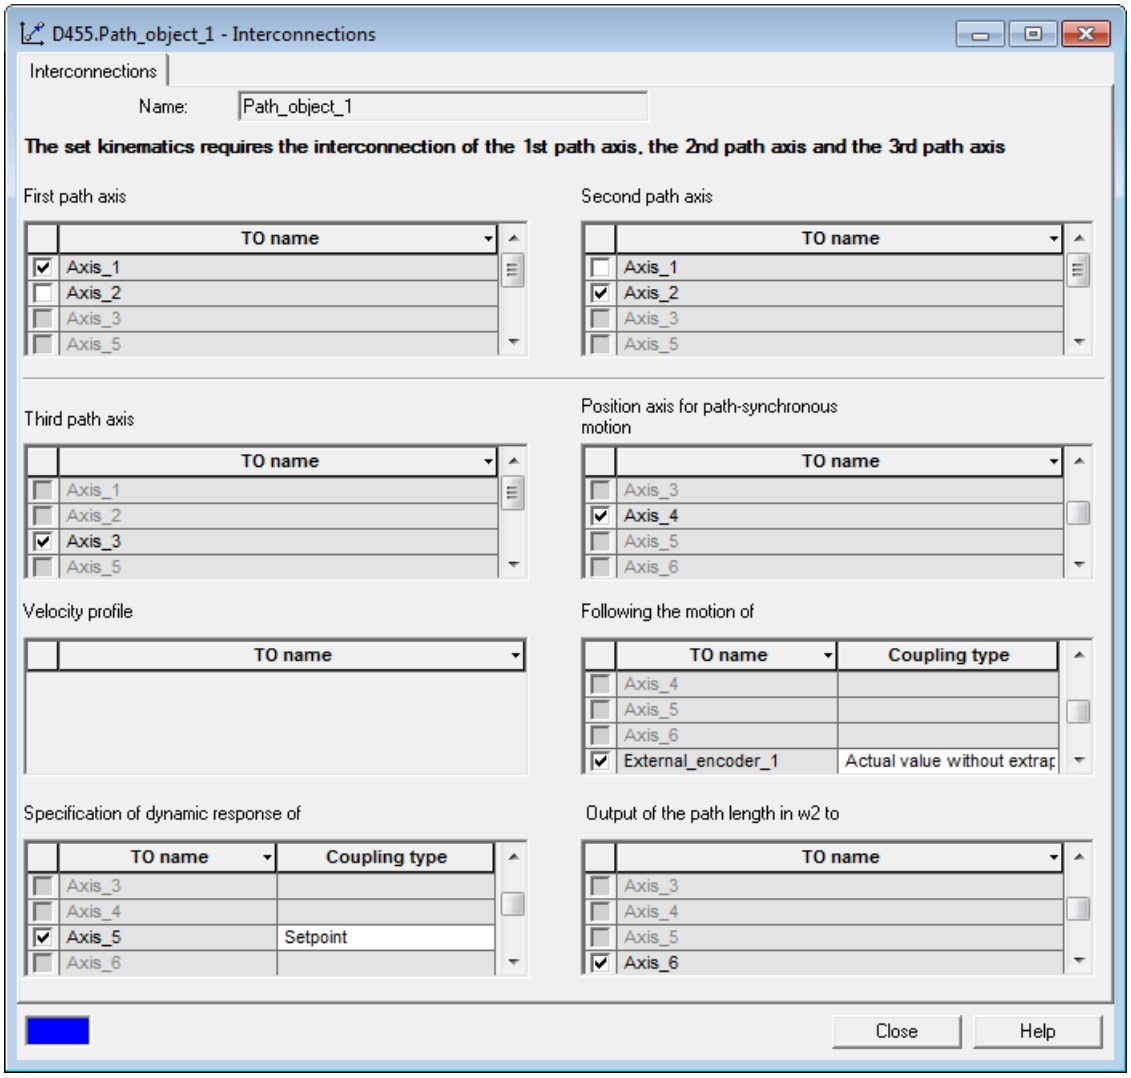

Figure 4-590 Interconnecting a path object

In this window, you interconnect the outputs of the path object with the path axes or with a position axis. (The objects must have already been created.)

Place a check mark beside the required objects.

A path object must be interconnected with at least two path axes.

The following connectors of the path object must be interconnected:

- **Path axis 1**: With a path axis
- **Path axis 2**: With a path axis

The following connectors of the path object can be interconnected:

- **Path axis 3**: With a path axis
- **Axis for path-synchronous motion**: With a position axis, synchronous axis, or path axis

- **Velocity profile**: With a cam
- **Output of the path length in w2** (as of V4.4): with a positioning axis

For more information, refer to Interconnection, interconnection rules (Page 2556).

Following the motion of

As from V4.2, an axis or an external encoder can be interconnected for the motion sequence. For more information, refer to Object coordinate systems and motion sequences on the path object (Page 2545).

Specification of the dynamics

As of V4.3, the path dynamics can be specified via DynamicsIn. For more information, refer to Preset path dynamics (Page 2491).

4.6.4.9 Path control panel

The path control panel is used to commission kinematics. It is therefore possible to control and monitor path objects without a user program. Applications include the following:

- Enabling and disabling all connected axes
- Function test of path objects and the connected axes
- Commissioning and setting up the kinematics
- Cartesian traversing in the BCS or in an OCS
- Traversing in machine axes
- Monitoring axis positions and Cartesian coordinates

control priority

The control priority for the path object and the connected axes can either be with the path control panel or with the user program. If the control priority is with the path control panel, motion commands on the path object and the axes involved are refused.

⚠ **WARNING**
Danger to life from unexpected machine movement Failure to observe the safety instructions can result in personal injury and material damage. • Note the safety instructions in the **Assume Control Priority** SCOUT dialog box.

Requirements

- An online connection to the SIMOTION device must be established.
- The current configurations of the axes and the path object must be on the target device. If necessary, download the project or upload the configuration data for alignment purposes (Target system > Load > Load configuration data to PG).

You can find additional information in the SCOUT online help (index: Path control panel).

4.6.4.10 Configuring kinematic adaptation in the expert list

All configuration data and system variables for the **Path object** technology object can be displayed and changed in the expert list.

Here, you define the kinematic type and adapt it for your requirements (see Kinematic adaptation (Page 2507)).

For additional information, see **Motion Control Basic Functions** Function Manual, "Expert list".

4.6.4.11 Configuring path monitoring

Path monitoring can be configured on the axis.

In the project navigator, double-click **Monitoring** under the axis object.

Set the required parameters on the **Path motion** or **Synchronous path motion** tab.

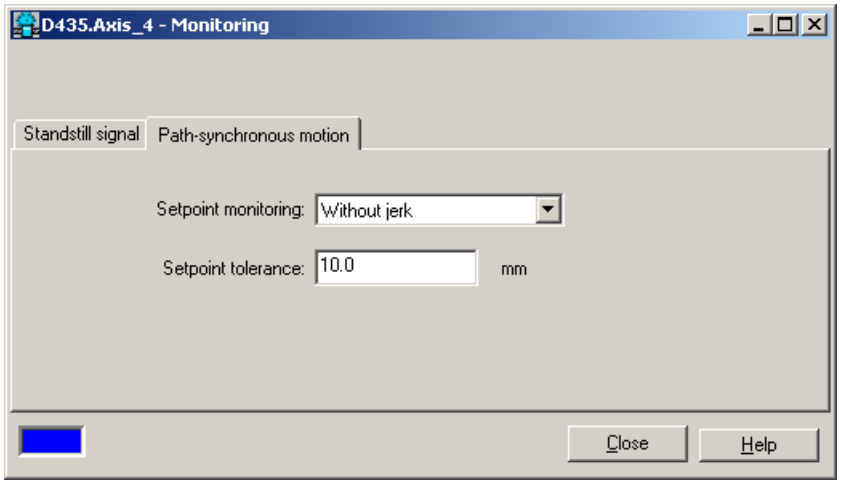

Figure 4-591 Monitoring on the axis with path interpolation

Path motions

Field/button	Meaning/instruction
Setpoint monitoring	Here, you activate the setpoint monitoring for the path axis. (pathAxisPosTolerance.enableCommandValue)
Setpoint tolerance	Here, you specify the permissible deviation of the setpoint on the axis calculated by the path object for the path axis, taking into account the limits of the executable setpoint. (pathAxisPosTolerance.commandValueTolerance) An alarm will be initiated if exceeded.

Path-synchronous axis - monitoring functions - path-synchronous movement

Field/button	Meaning/instruction
Setpoint monitoring	Here, you activate the setpoint monitoring for the positioning axis. (pathSyncAxisPosTolerance.enableCommandValue)
Setpoint tolerance	Here, you specify the permissible deviation of the setpoint on the axis calculated by the path object for the positioning axis, taking into account the limits of the executable set-point. (pathSyncAxisPosTolerance.commandValueTolerance) An alarm will be initiated if exceeded.

For additional information, see Display and monitoring options on the axis (Page 2503).

4.6.4.12 Calibrate path object

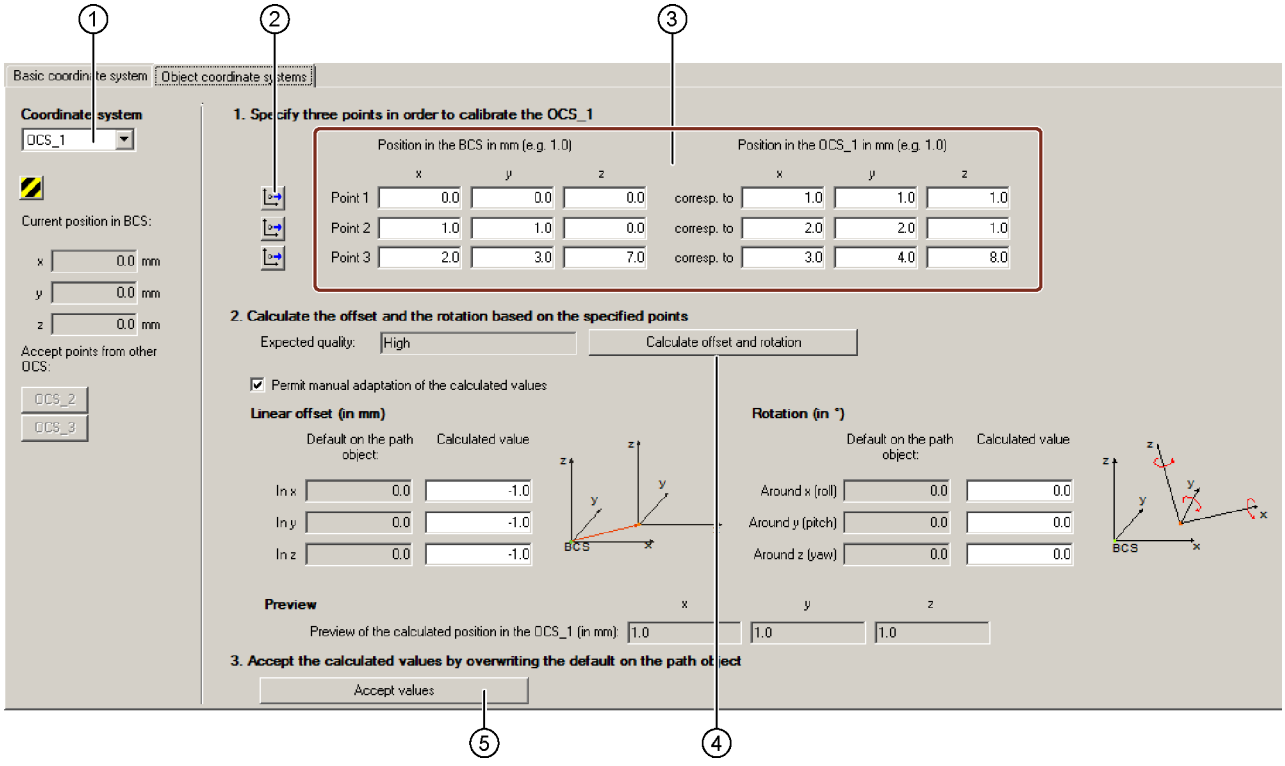

Figure 4-592 Calibration

You calibrate the path object in this window by re-aligning the coordinate systems. The basic coordinate system can be aligned with the kinematic zero point or an object coordinate system with the basic coordinate system.

The following five steps are required for the example:

① Select an OCS

② If required, accept the current position of the kinematics

③ Specify the actual positions and the position setpoints of the kinematics

④ Start the calculation of the offset and the rotation

⑤ If required, accept the calculated values as the new values for the kinematics

Step 1 is omitted when calibrating the basic coordinate system.

Calibrating the basic coordinate system (BCS)

You calibrate the BCS to the kinematic zero point on the **Basic coordinate system** tab. Depending on the dimensions of the selected kinematics, you must specify two or three points in the BCS and two or three corresponding new points from which the offset and the rotation then result. Input fields for at least two coordinates are available for each point. With 3D kinematics, there is also an additional input field for the third coordinate. Individual points in the BCS can also be taken over directly from the current position of the path object using the button to the left of the input fields.

After entering valid coordinates, a button appears to calculate the offset and rotation for the BCS. The calculated values are displayed and can be transferred to the offline data management via a further button for the path object. If the checkbox for manual adaptation is activated, the calculated values can be subsequently edited.

You can open the path control panel via the black and yellow button. This button is only available when the controller is in online mode.

Calibrating the object coordinate system (OCS)

You calibrate the OCS_1, OCS_2 and OCS_3 object coordinate systems on the **Object coordinate systems** tab. The respective OCS is selected in the area on the left. The calibration is similar to that of the BCS to the kinematics zero point. The difference is that the inputs refer to reference positions in the BCS and positions in the respective OCS.

It is also possible to take over the points of a previously calibrated OCS for another OCS. The appropriate buttons are on the left.

4.6.4.13 Path interpolation - context menu

You can select the following functions:

Function	Meaning/Description
Configuration	This function opens the configuration for the path object selected in the project navigator. Define the processing cycle clock in this window.
Expert list	This function opens the expert list for the path object selected in the project navigator. The configuration data and system variables can be displayed and changed in this list.
Default	This function opens the defaults for the path object selected in the project navigator. You define the substitute values for the object coordinate systems, the dynamic response, and the path in this window.
Calibration	With this function, you open a window for calibrating the path object. In this window you can calibrate the values for the BCS or the three OCS.

Function	Meaning/Description
Limits	This function opens the limits for the path object selected in the project navigator. You define the dynamic limits for the path object in this window.
Interconnections	This function opens the interconnections for the path object selected in the project navigator. You can see the inputs of the axes in this window.
Expert	This function opens the submenu for the expert settings.
• Import object	Use **Import object** to open a window for the XML import. You can define the parameters for the XML import in this window.
• Save project and export object	Use **Save project and export object** to open a window for the XML export. You can define the parameters for the XML export in this window.

4.6.5 Sample Project for the Path Interpolation

4.6.5.1 Overview of the example

To illustrate how the path interpolation is configured, the following sections describe a sample project step-by-step.

The following descriptions assume that the project with the SIMOTION device and the drives have already been created in the HW Config.

In this example, the following 2D gantry is created:

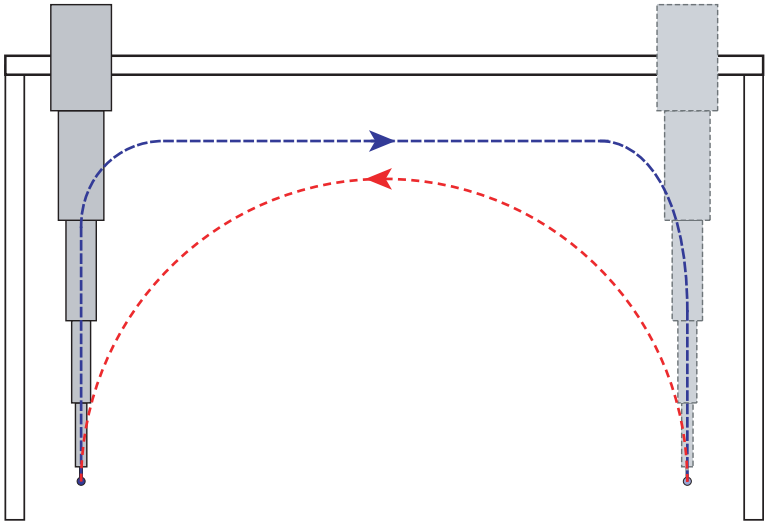

Figure 4-593 Overview

This 2D gantry comprises the following axes:

- Vertical axis: 1400 cm traversing length, axis zero point at the lowest position
- Horizontal axis: 2000 cm traversing length, axis zero point at the left-hand side

This means the zero point of the path object is at the lower left.

How to create and use the 2D gantry:

- Select technology package (Page 2576)
- Create axes. (Page 2577)
- Creating a path object (Page 2579)
- Defining the kinematics (Page 2580)
- Interconnecting a path object (Page 2580)
- Programming a path in MCC (Page 2584)
- Checking a motion with trace (Page 2602)

To show how a path-synchronous axis (Page 2603) operates, a gripper will also be created at the end of the example.

4.6.5.2 Select technology package

The **PATH** and **CAM_EXT** technology packages support path interpolation.

Right-click the device in the project navigator, select **Select technology package** in the context menu and use the **PATH** technology package.

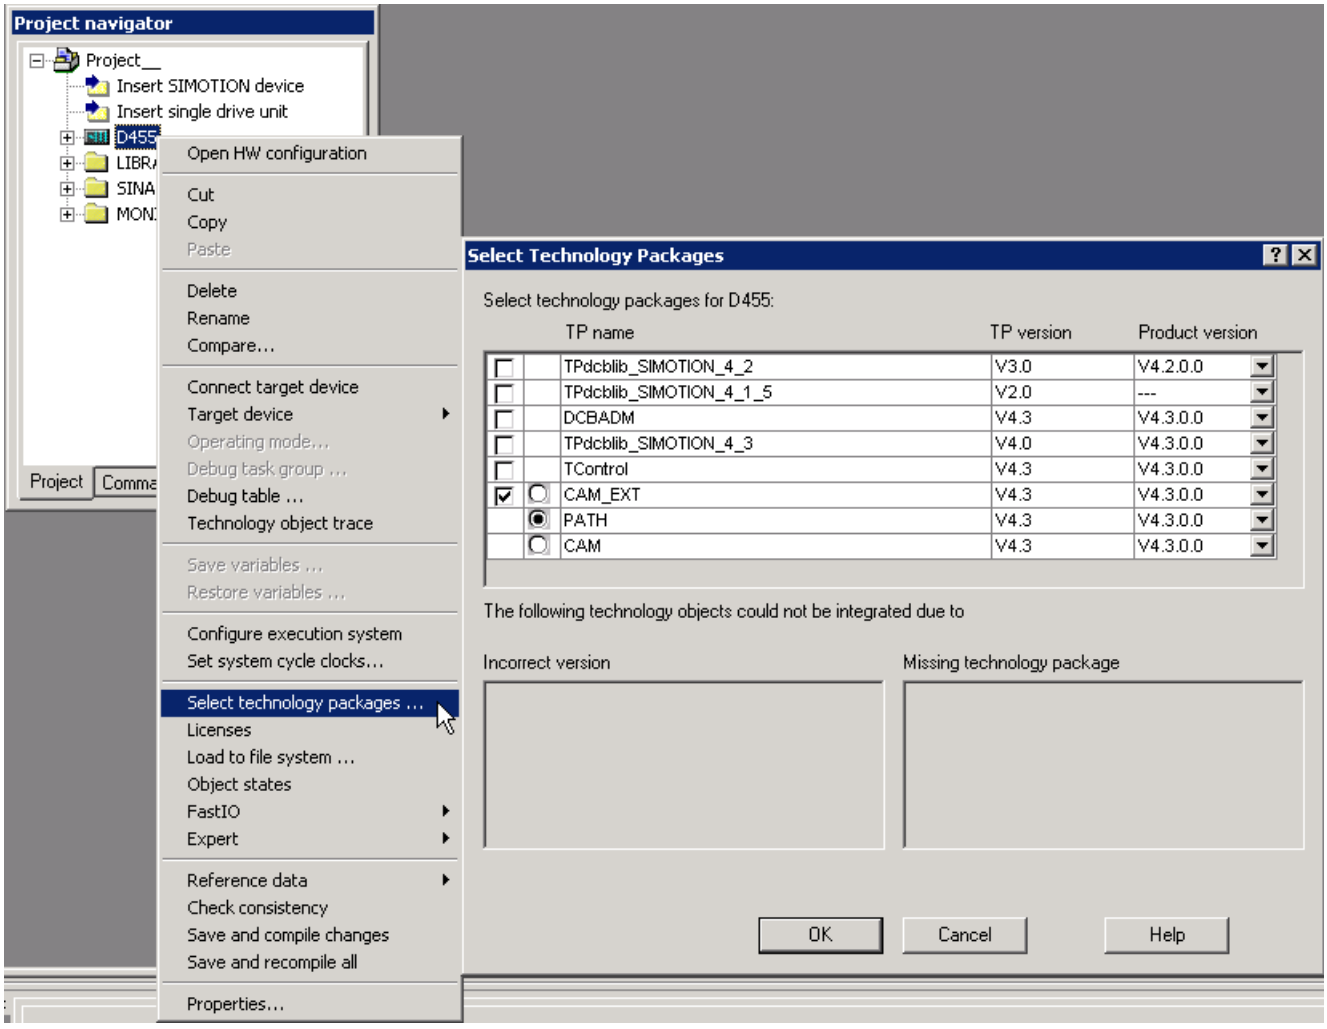

Figure 4-594 Select technology package

4.6.5.3 Create axes.

The example project requires two linear axes: **Axis_X** and **Axis_Z**. These axes are created with the **path interpolation** technology. Both axes are created as linear, virtual, non-modular axes.

Click **AXES -> Insert axis** to add an axis to the device. Name the first axis **Axis_X** and the second axis **Axis_Z**, and set up the two as follows:

1. **Path interpolation** technology selected

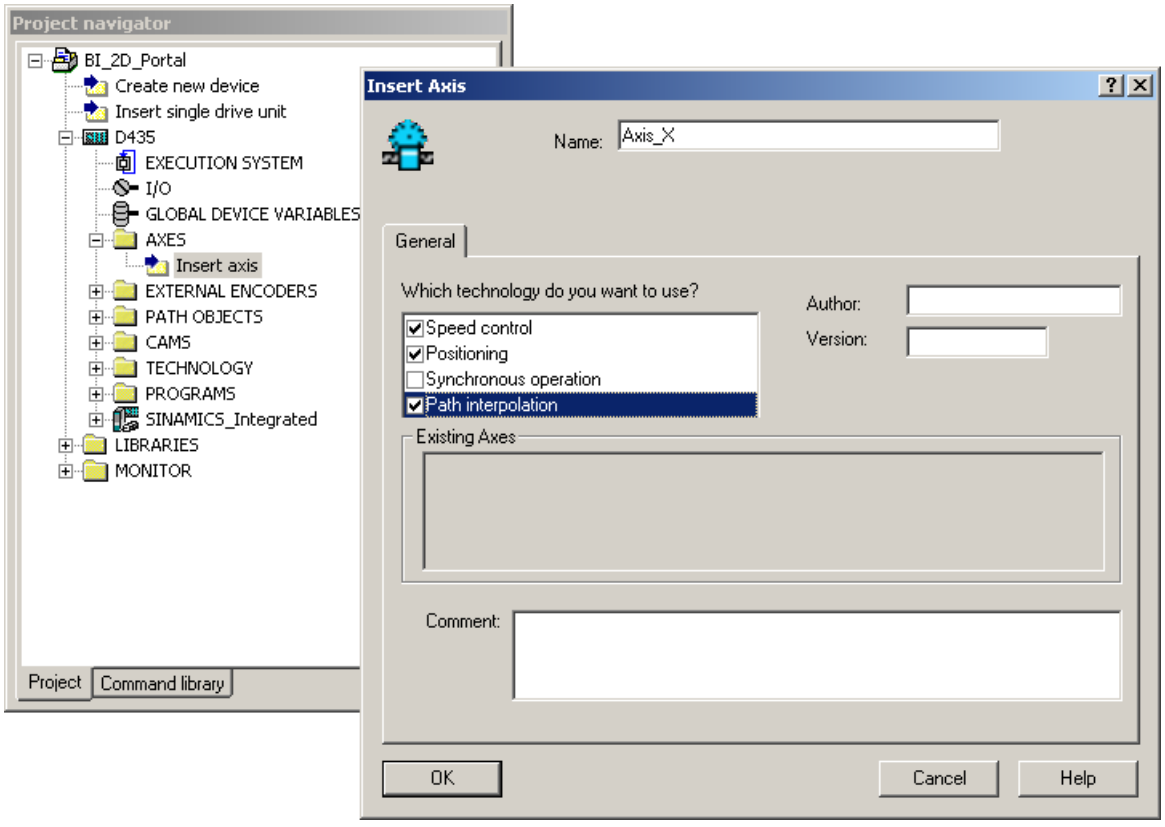

Figure 4-595 Creating an axis

2. Linear, virtual, non-modular axis
   The configuration of the two axes is as follows:

```
Configuration of this axis:
Name:
  - Axis_X
Technology:
  - Path axis
Axis type:
  - Linear axis
  - No modulo selected
Drive:
  - Axis is virtual
```

Figure 4-596 Sample summary of the configuration (Axis_X axis)

The project navigator should now look like this:

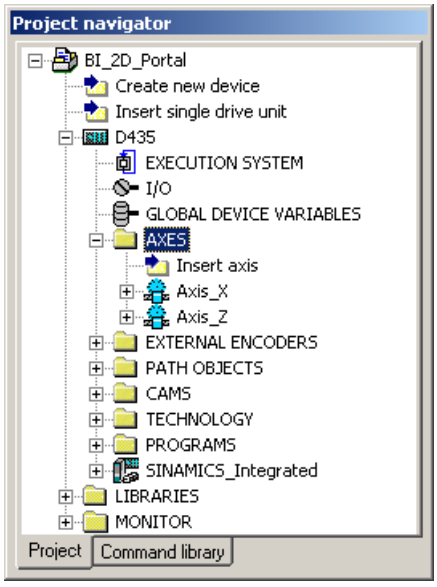

Figure 4-597 Project navigator with created axes

4.6.5.4 Creating a path object

Insert a new path object for the device under **PATH OBJECTS**. Name the path object **Portal_2D**.

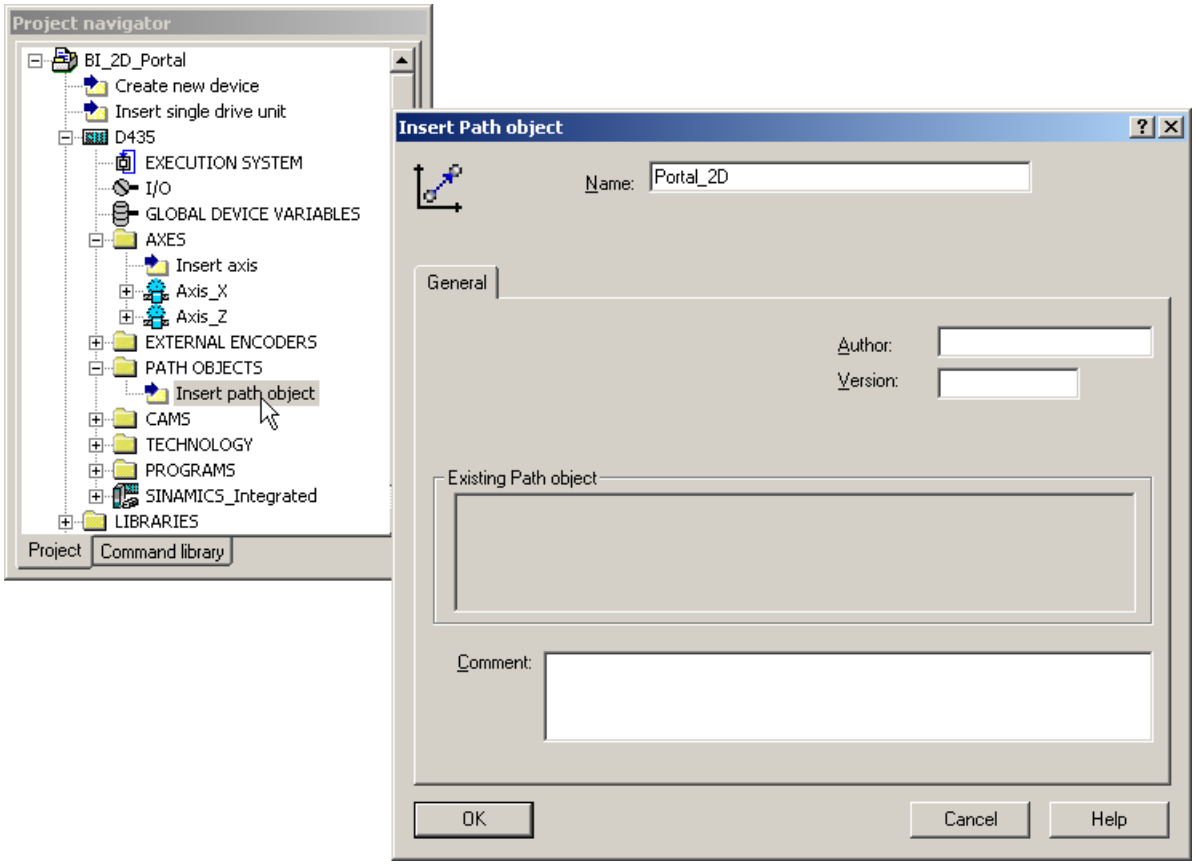

Figure 4-598 Creating a path object

4.6.5.5 Defining the kinematics

For the definition of the kinematics, the kinematics type with its mechanical data and the displacement of the coordinate system at the zero point of the base coordinate system are specified.

Open the Configuration window for the path object. In this form, youc an set the type of kinematics and the coordinate plane as follows:

- Kinematics: **Cartesian 2D**
- Coordinate plane: **ZX plane**

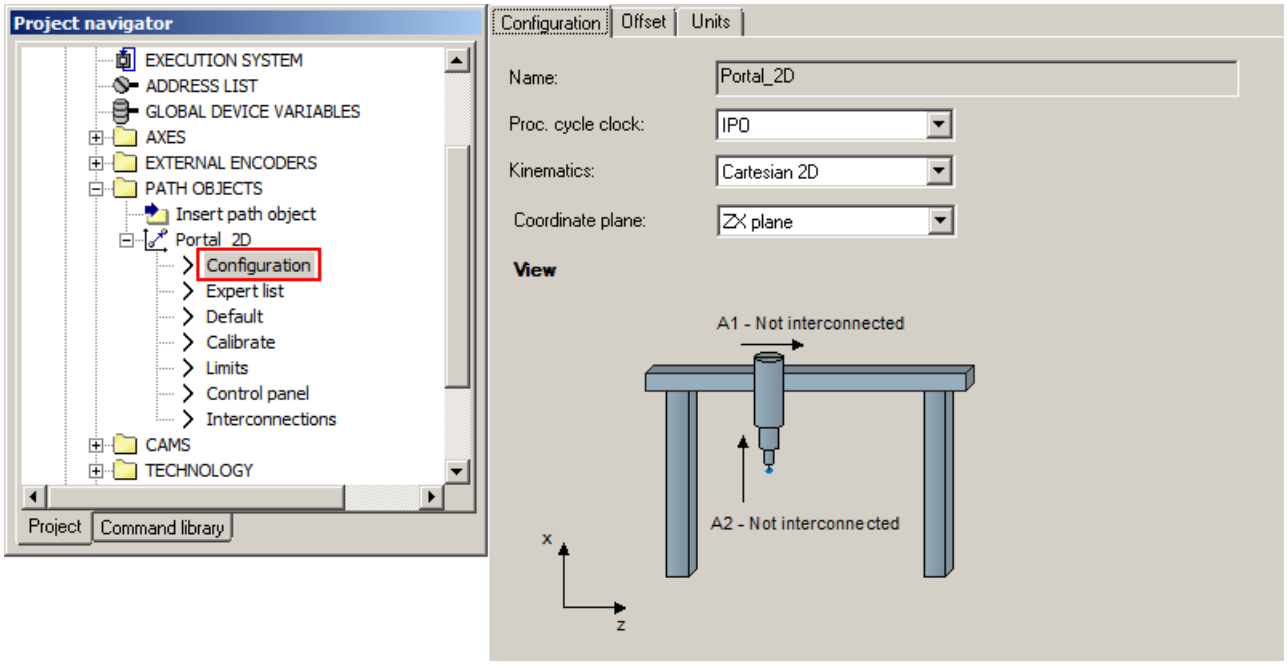

Figure 4-599 Configuration of the kinematics

4.6.5.6 Interconnecting a path object

Open the **Interconnections** window for the path object. In this screen form, assign the axes to the path object.

Because the kinematics operate in the Z-X plane, the Z-axis must be used as first path axis and the X-axis as second path axis.

Parameterize the **interconnections** of the path object as follows:

- 1. Path axis: **Axis_Z**
- 2. Path axis: **Axis_X**

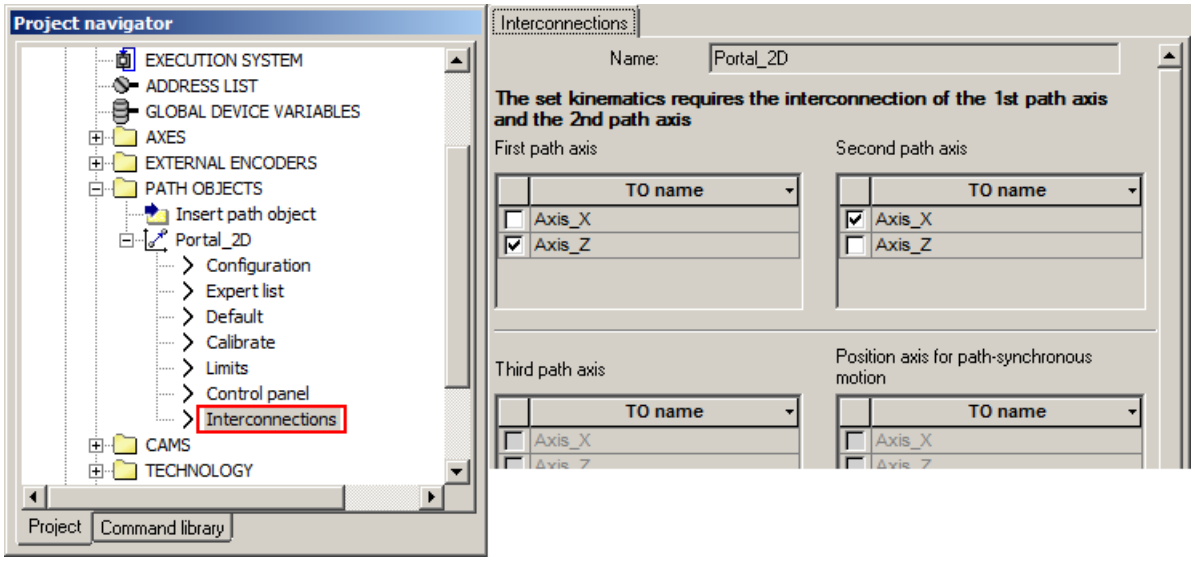

Figure 4-600 Interconnecting a path object

4.6.5.7 Setting the default settings of the path object

The settings described below must be made for the default of the path object.

How to set the defaults for the path object:

1. For the path object, click **Default**.
2. In the **Default** window, on the **Object coordinate systems** tab, you can set the object coordinate system:

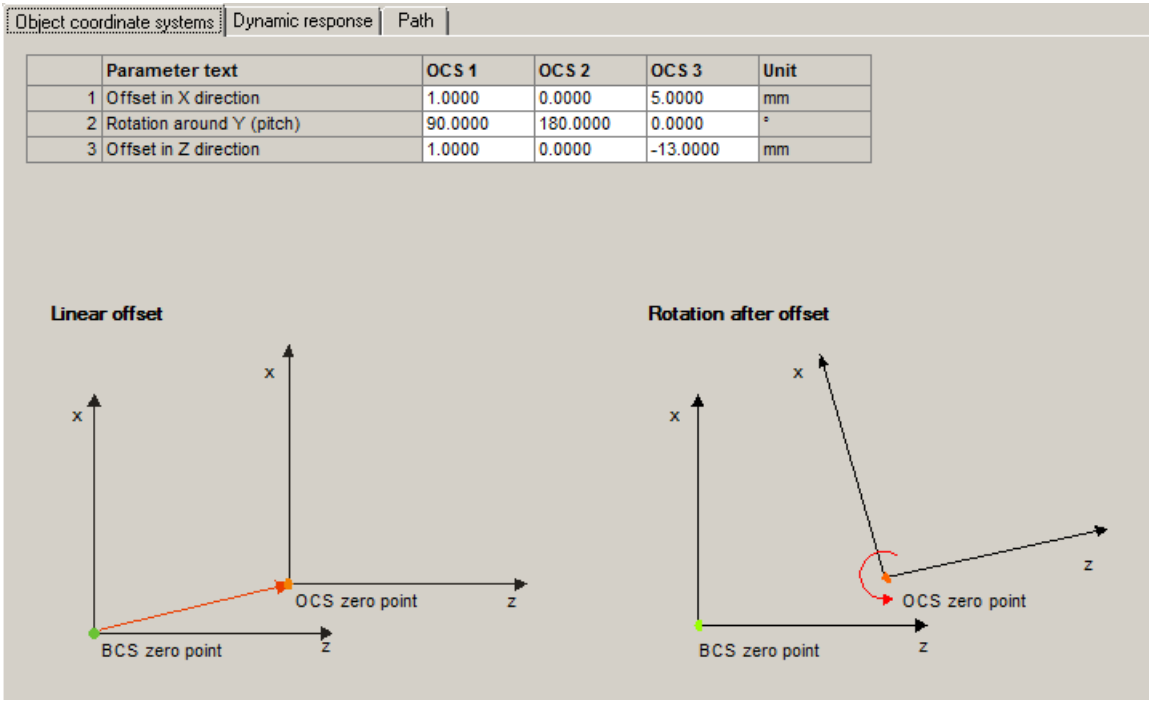

Figure 4-601 Default - Object coordinate systems

If you want to activate an object coordinate system, you must call the command `_setPathObjectOcs` (see Object coordinate system (OCS) on the path object (Page 2545)).

3. On the **Dynamic response** tab, you can set the path object, for example, as follows:

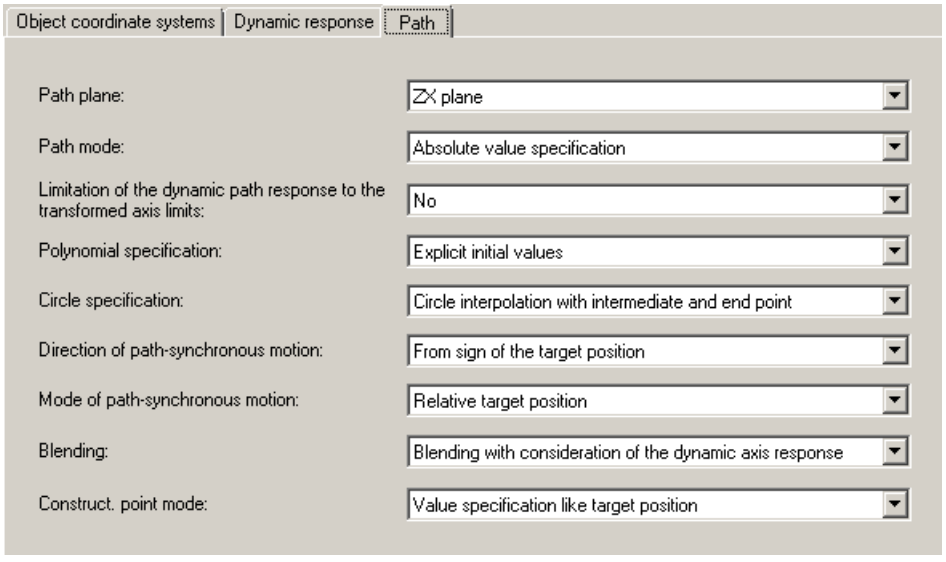

Figure 4-602 Default - dynamic response

4. Make the following settings on the **Path** tab:

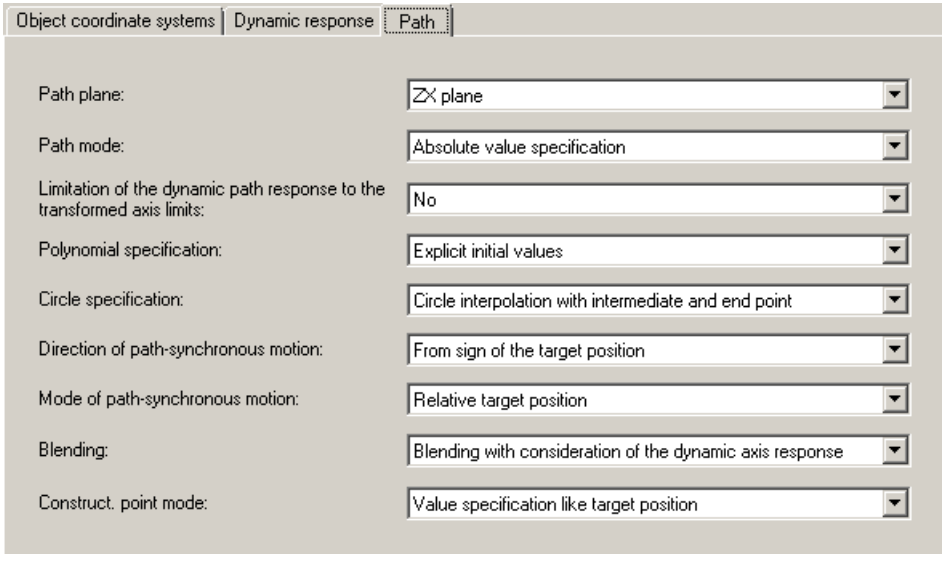

Figure 4-603 Default - path

4.6.5.8 Programming the path interpolation in MCC

Programming the travel commands in MCC

The following path should be created for this example:

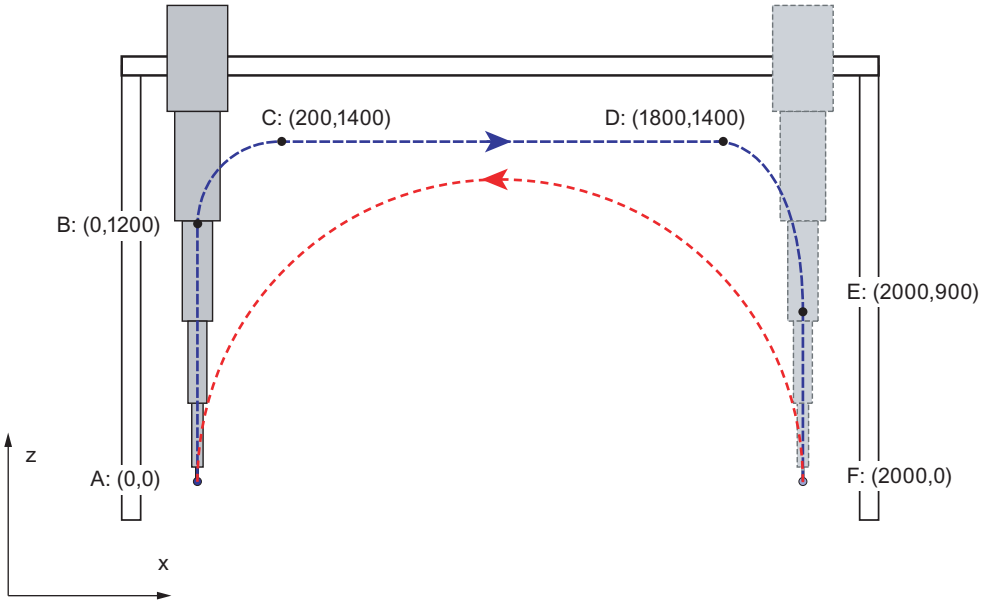

Figure 4-604 Path to be traversed

This path consists of the following path segments:

Segment	Path type	Start point (x,z)	End point (x,z)
A - B	Linear path	(0,0)	(0,1200)
B - C	Polynomial path	(0,1200)	(200,1400)
C - D	Linear path	(200,1400)	(1800,1400)
D - E	Polynomial path	(1800,1400)	(2000,900)
E - F	Linear path	(2000,900)	(2000,0)
F - A	Circular path	(2000,0)	(0,0)

Creating the program

1. In the project navigator, click **Insert MCC source file**. Name the MCC source file **MCC_Example**.

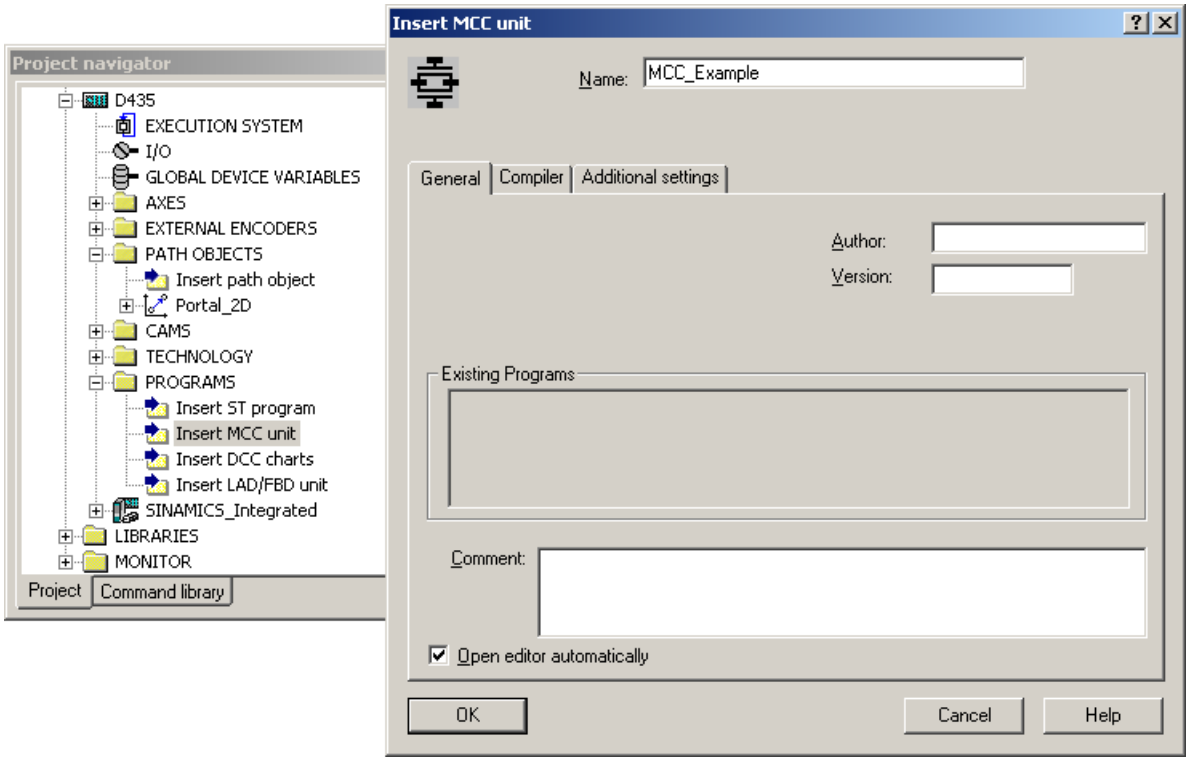

Figure 4-605 Creating an MCC source file

2. Define the following variables in the **Interface** of the MCC source file:
   - **start_move** (BOOL, true): The gantry should perform the motion when **start_move=true** is set and stop when **start_move=false**.

– **forw_back** (BOOL, false): The forw_back variable indicates whether the gantry moves forwards (true, A->F) or backwards (false, F->A).

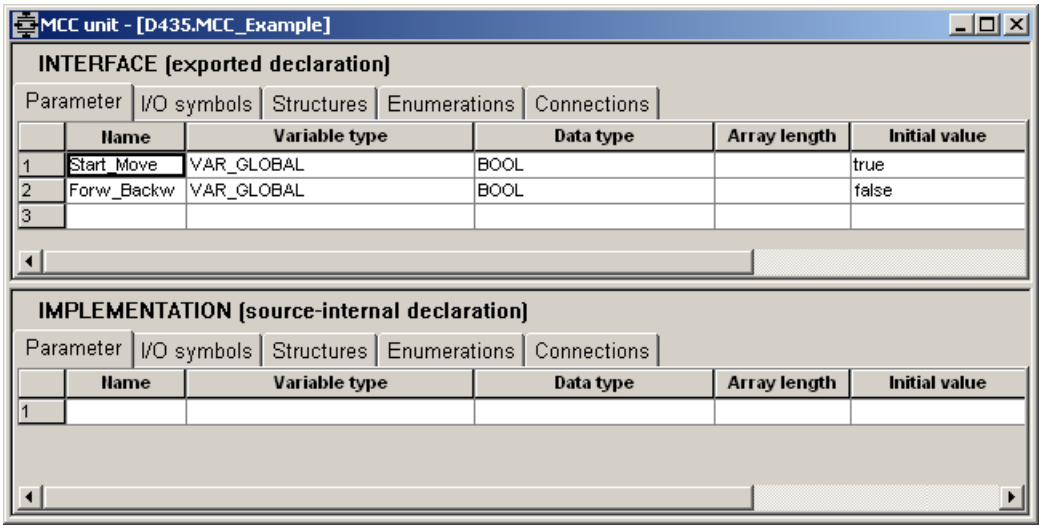

Figure 4-606 Defining variables in the MCC source file

3. In the project navigator, click **Insert MCC chart** for the new MCC source file. Name this chart **TopLoader**.

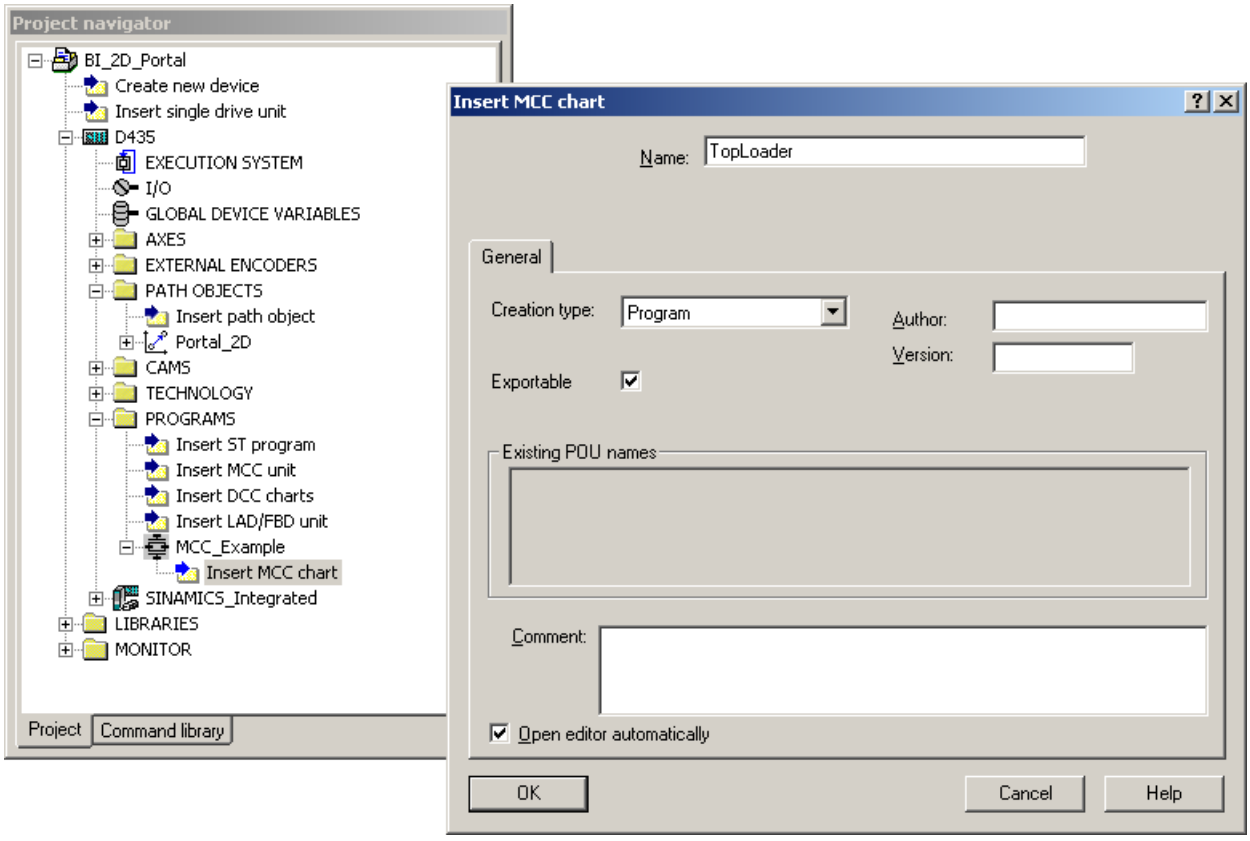

Figure 4-607 Inserting an MCC chart

4. Open the MCC chart and define the following variables.
   - **endPoly**, **startPoly**: structRetGetLinearPathGeometricData
   - **x_start**, **z_start**, **x_end**, **z_end**: LREAL

   These variables are used for calculating the data for the polynomial interpolation.

	Name	Variable type	Data type	Array length	Initial value	Comment
1	endPoly	VAR	structretgetlinearpathgeom			
2	startPoly	VAR	structretgetlinearpathgeom			
3	x_End	VAR	LREAL			
4	z_End	VAR	LREAL			
5	x_Start	VAR	LREAL			
6	z_Start	VAR	LREAL			
7						

Figure 4-608 Creating variables in the MCC source file

Programming the traversing program

Programming the traversing program

The following traversing program should be programmed:

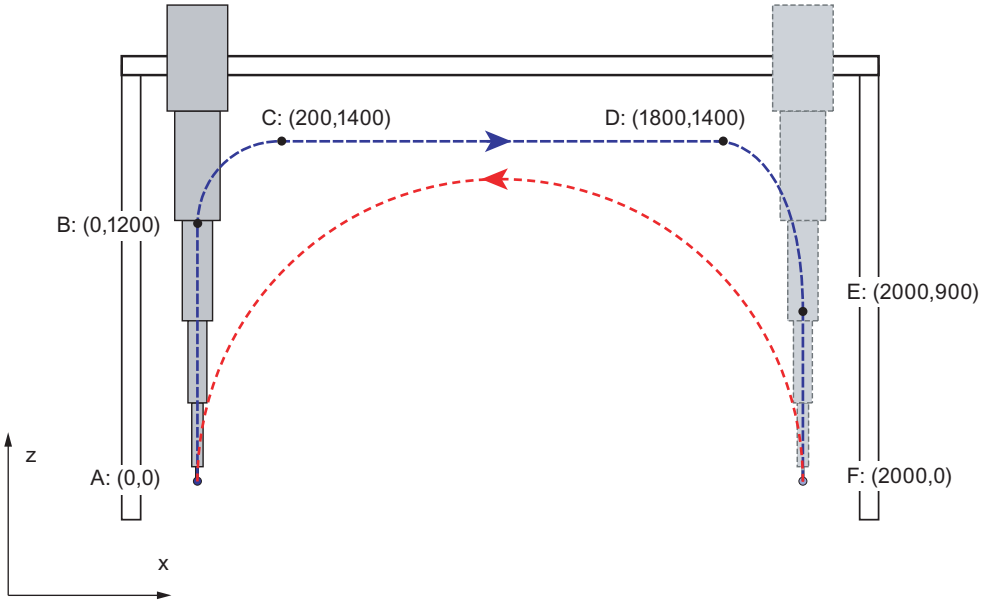

Figure 4-609 Path to be traversed

The traversing program should be performed within a **While** loop. It will be performed while **start_move** is set to **true**.

Creating a WHILE loop

For the example, a While loop is created that is run while **start_move** is set to true.

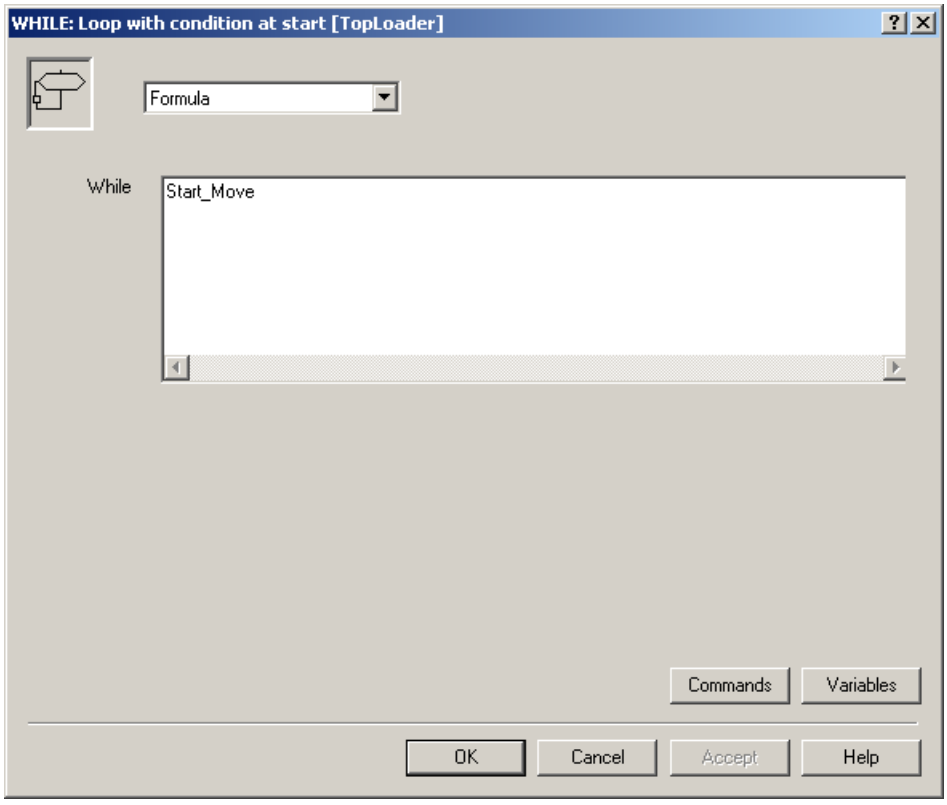

Figure 4-610 WHILE loop

Programming the A - B linear path

Before starting the forwards motion, the **forw_back** direction flag is set to **true**. This is performed using a variable assignment.

To do this, place an ST zoom-in command within the While loop and program it as follows:

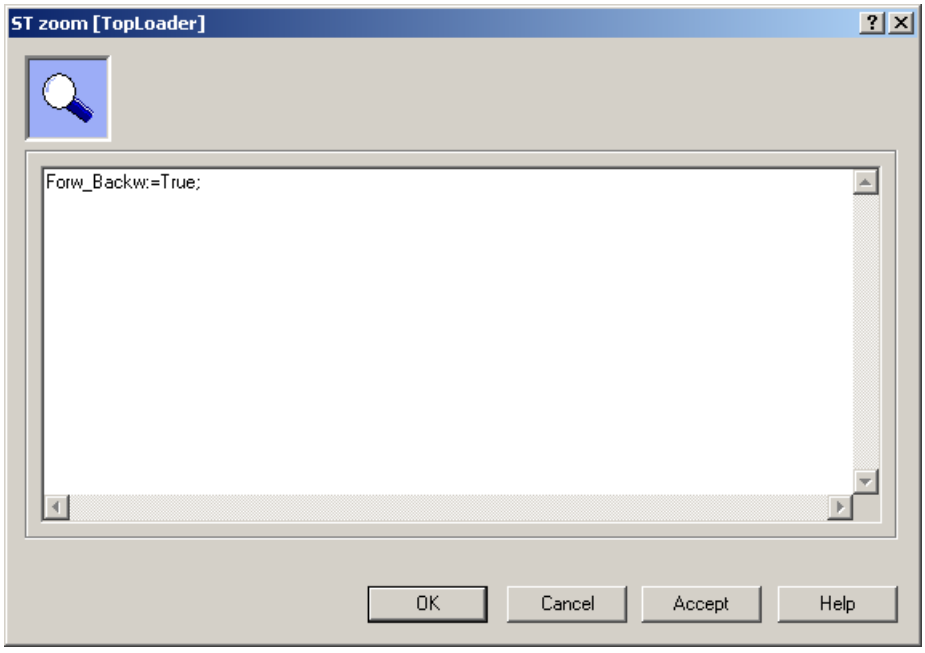

Figure 4-611 Set forw_back to true

Then add a **travel linear path** command to the While loop. Define the **A-B** linear path as follows:

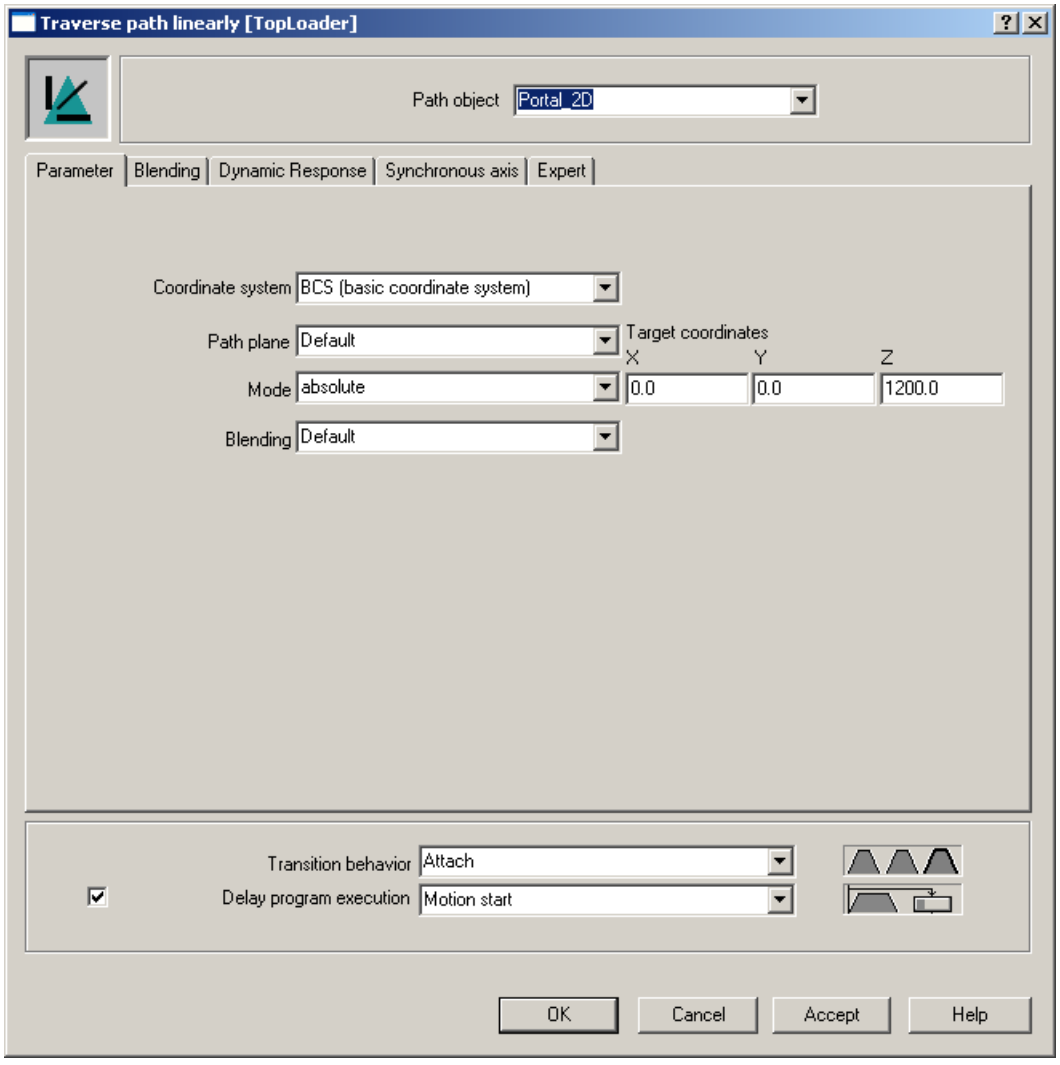

Figure 4-612 Programming the A - B linear path

Programming the B-C polynomial path

To program the **B-C** polynomial path, the geometric derivatives for the start and end points must be calculated in an ST zoom-in.

Add an ST zoom-in command for both the start point and the end point in the While loop, and program it as shown:

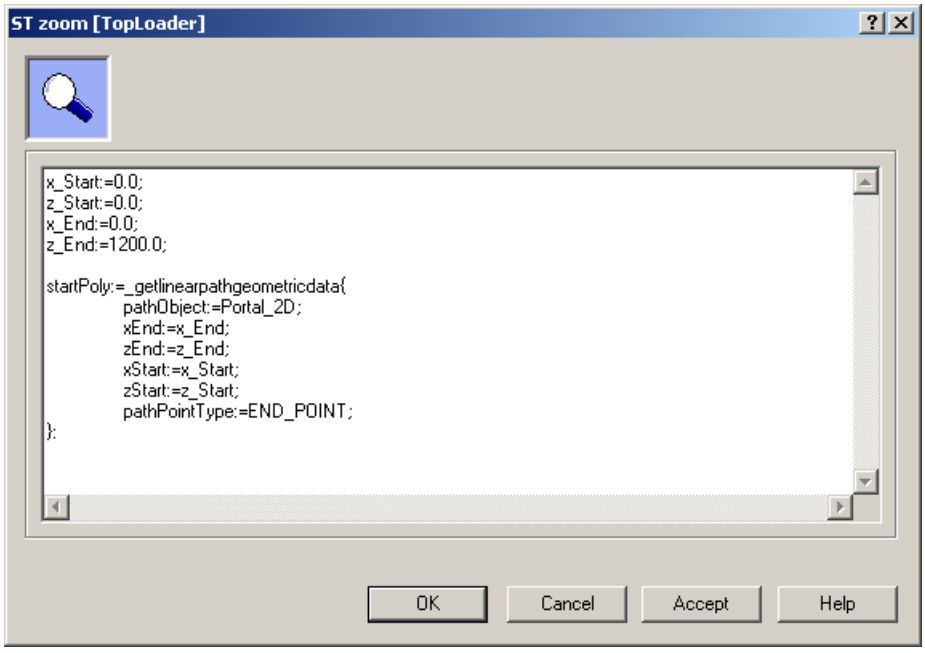

Figure 4-613 Calculating the derivatives at the start point of the first polynomial path

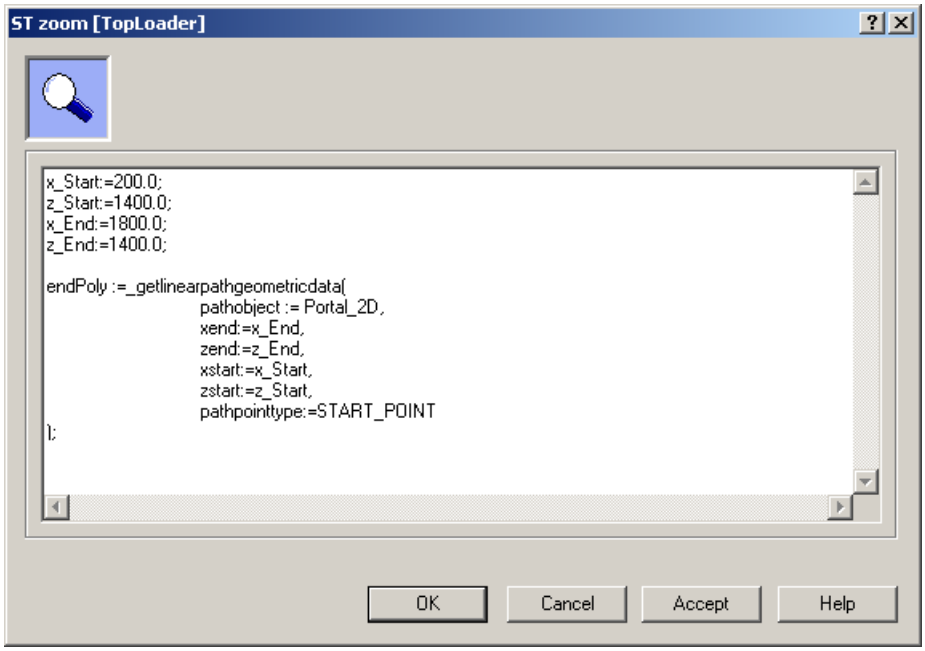

Figure 4-614 Calculating the derivatives at the end point of the first polynomial path

Now add a **travel polynomial path** command to the While loop and define the polynomial path as follows:

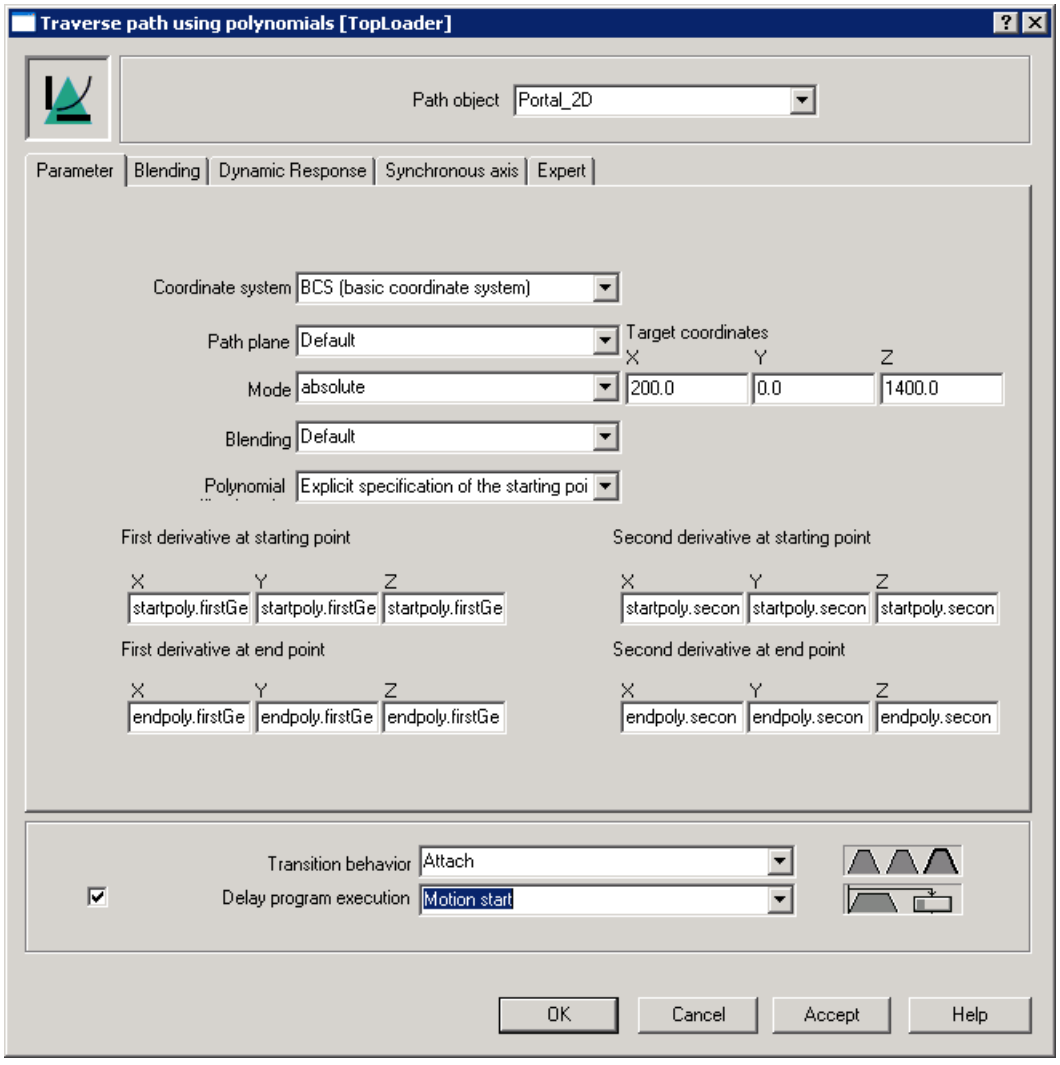

Figure 4-615 Programming the B-C polynomial path

The previously calculated derivatives are specified as follows in the command:

- First derivative at the start point: **startpoly.firstGeometricDerivative.x / .y / .z**
- Second derivative at the starting point: **startpoly.secondGeometricDerivative.x / .y / .z**
- First derivative at the end point: **endpoly.firstGeometricDerivative.x / .y / .z**
- Second derivative at the starting point: **endpoly.secondGeometricDerivative.x / .y / .z**

Note

An alternative polynomial assignment is described for the programming of the D-E polynomial path.

Programming the C-D linear path

For the **C-D** linear path, add the **travel linear path** command to the While loop and make the following settings:

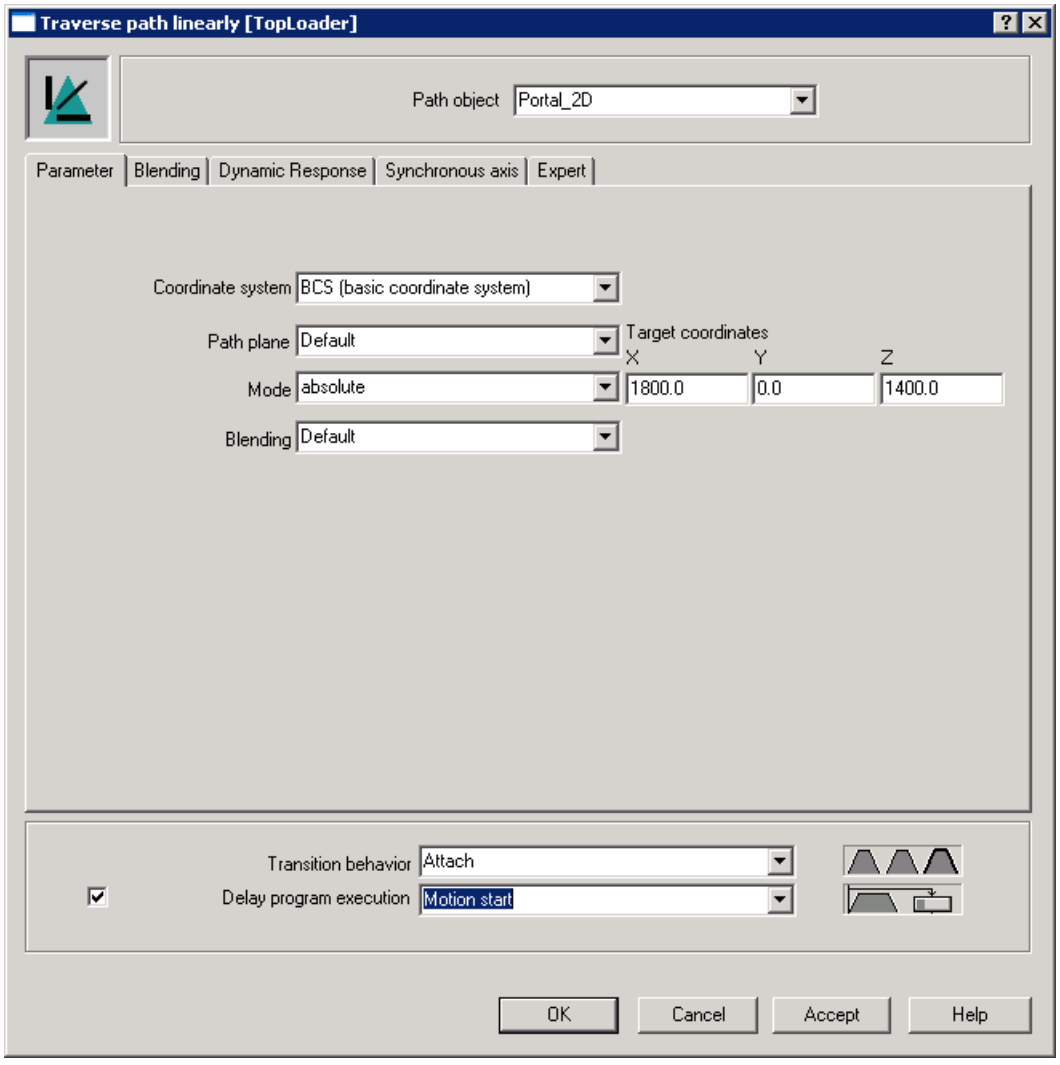

Figure 4-616 Programming the C-D linear path

Programming the D-E polynomial path

The **attach continuously** type of polynomial specification is used for the **D-E** polynomial path. The geometric deviations of the start point are calculated using the previous path segment. Only the deviations for the end point need to be calculated using an ST zoom-in.

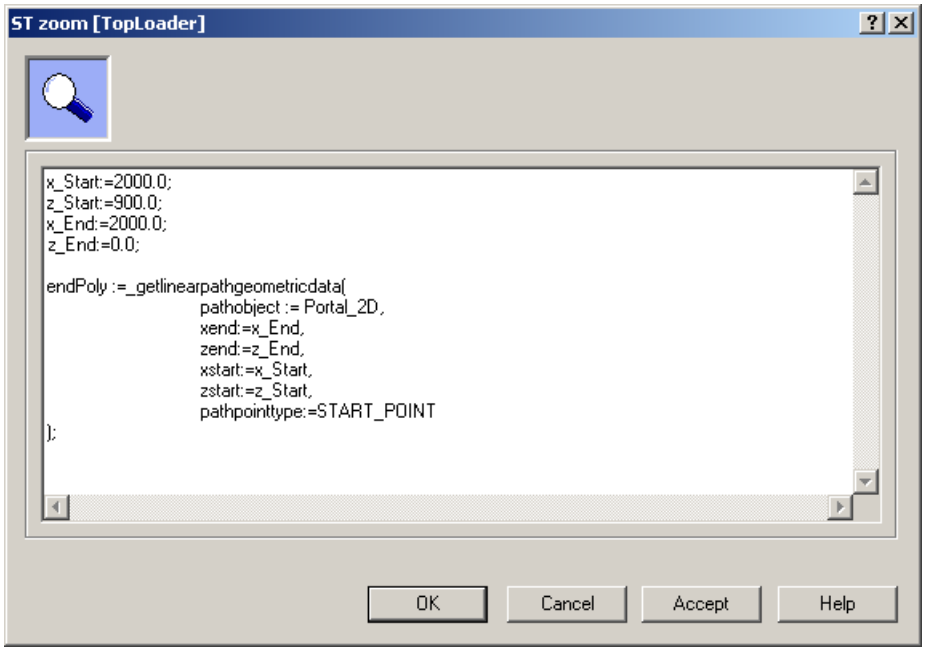

Figure 4-617 Deviations at the end point of the D-E polynomial path

Both the ST zoom-in command and the **travel polynomial path** command must be added successively to the While loop.

Parameterize the polynomial path as shown.

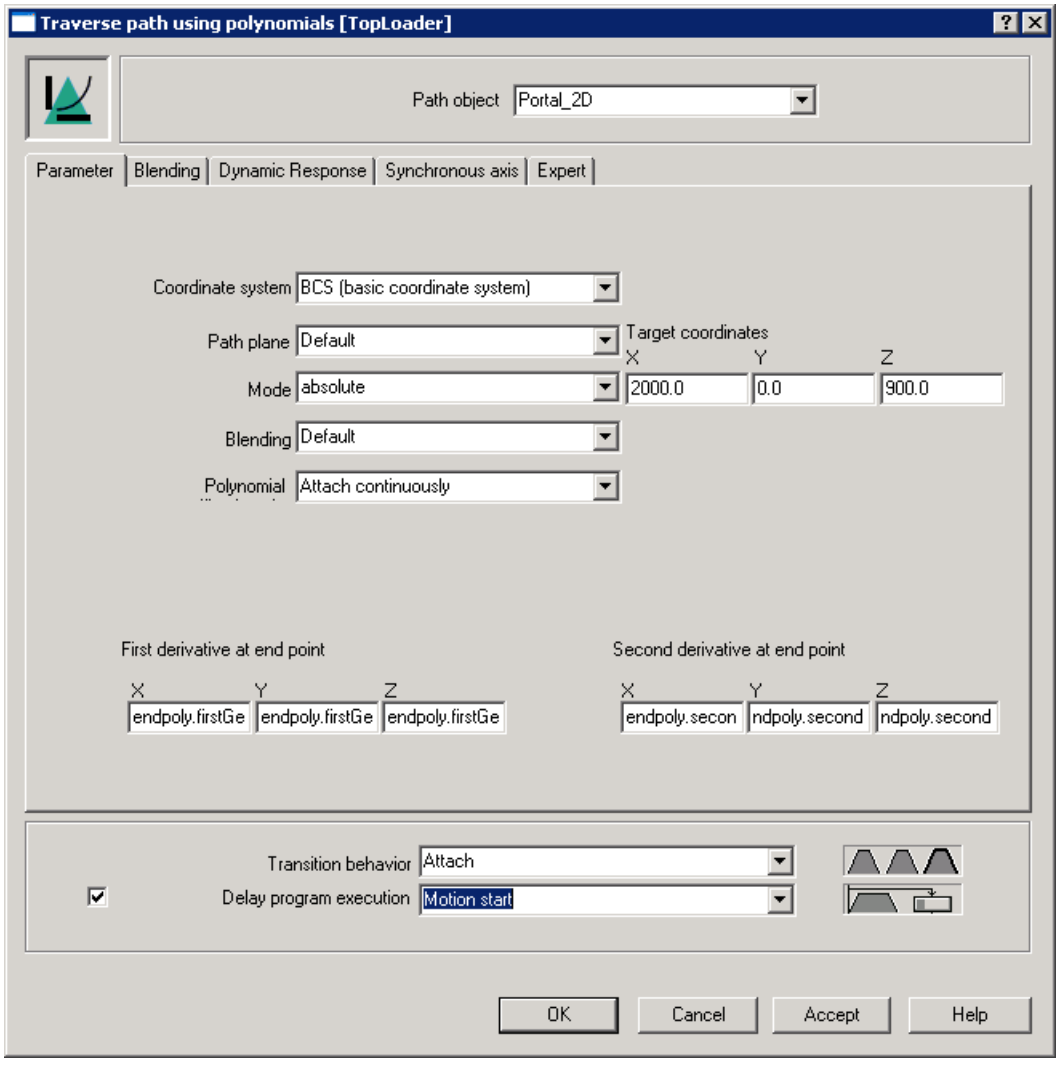

Figure 4-618 Programming the D-E polynomial path

Programming the E-F linear path

For the **E-F** linear path, add the **travel linear path** command and make the following settings:

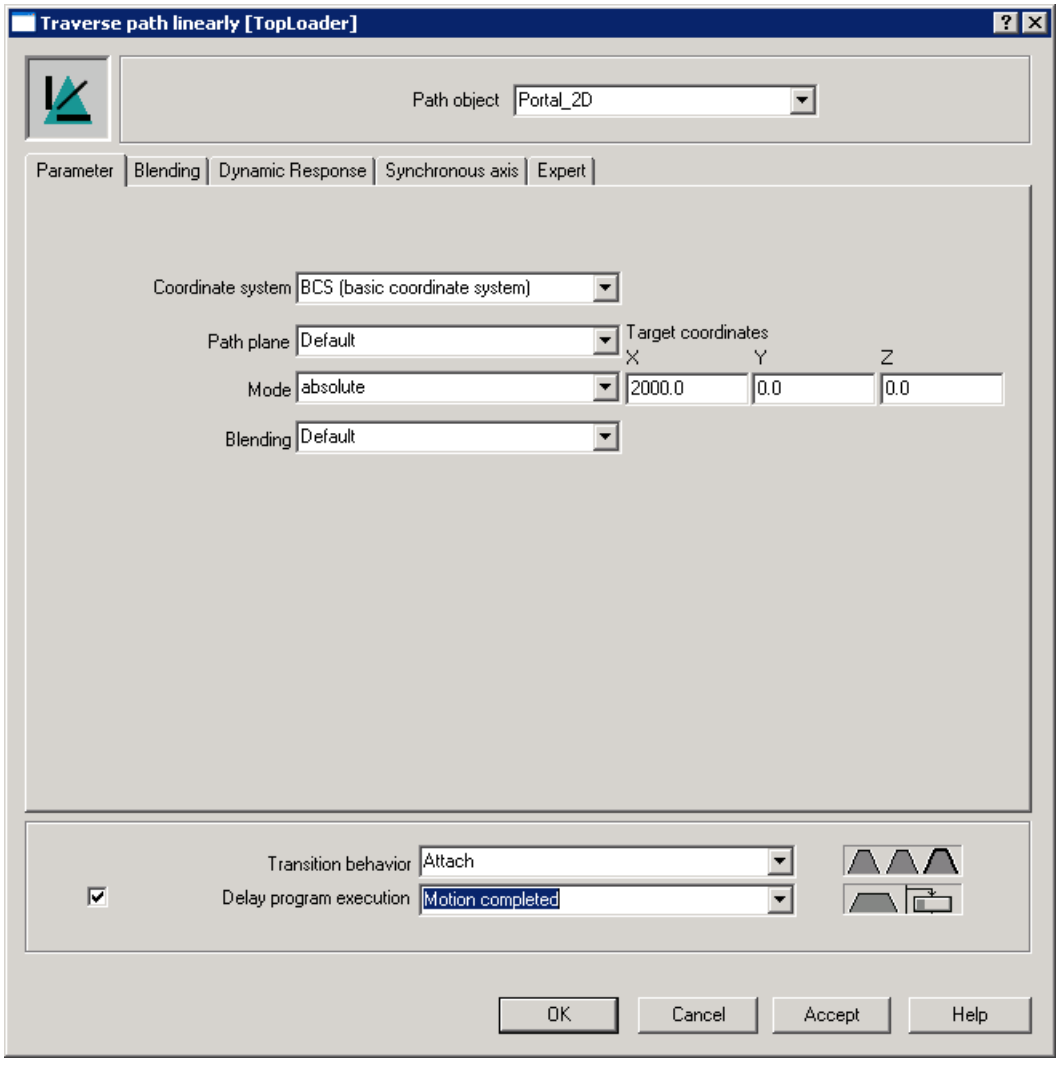

Figure 4-619 Programming the E-F linear path

Programming the F-A return travel

The gantry grabber should return to the initial position taking a circular path. The start point of the circular path is (2000, 0), the end point is (0, 0).

There are several ways of defining the circular path. For this example, the circular path should be defined using an intermediate point and the end point. The point (1000, 1000) is chosen as intermediate point.

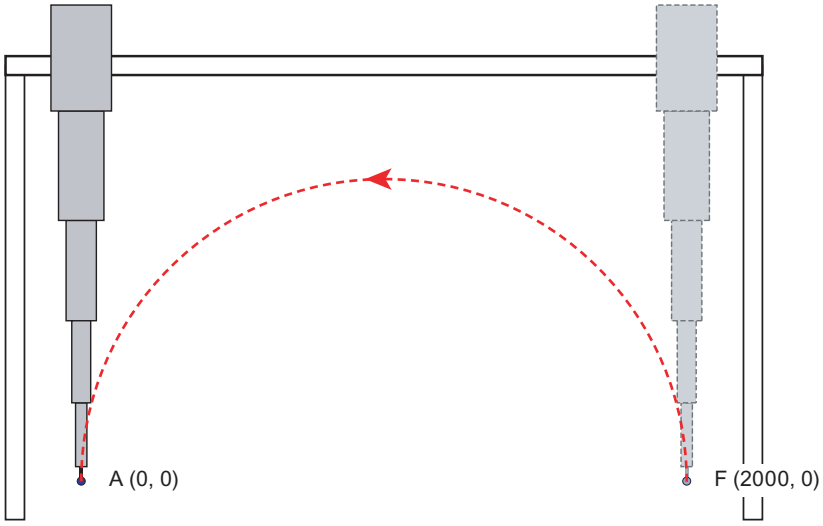

Figure 4-620 Defining the return circular path

To indicate the reverse motion, the **forw_back** variable is set to **false** in an ST zoom-in command.

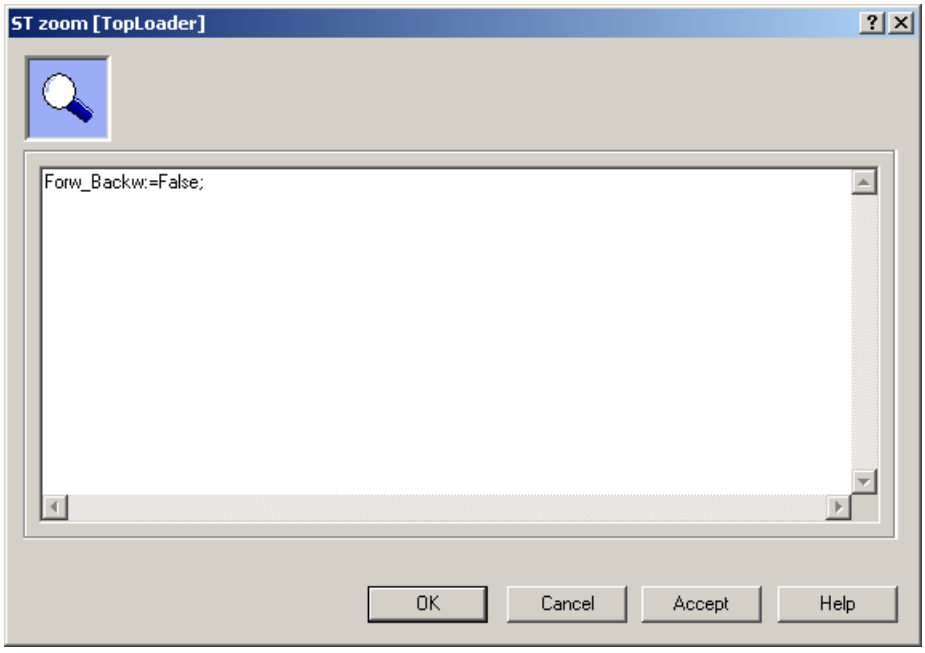

Figure 4-621 Set forw_back to false

The **travel circular path** command is then added and the following settings made:

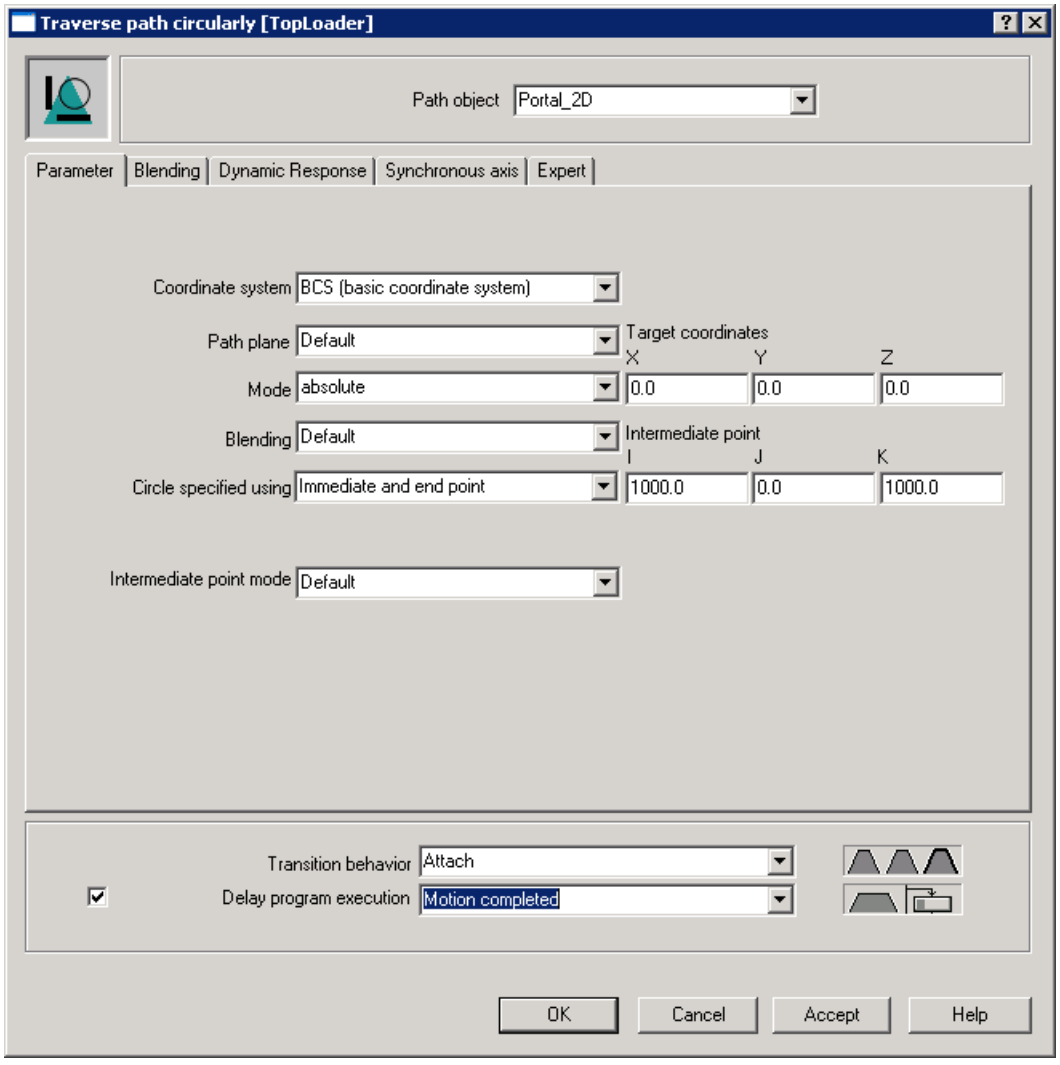

Figure 4-622 Programming the F-A circular path

Activating the axis enables and homing the axes

To move the axes, an enable must be made for each of them. The axes must also be homed. This requires that the the **enable axis** and **home axis** commands are added for each axis before the While loop.

You can use the default values for the **enable axis** commands.

For the **home axis** commands, set the **home coordinates** to **0 mm**. The other values do not need to be changed.

MCC diagram

The MCC chart now has the following form:

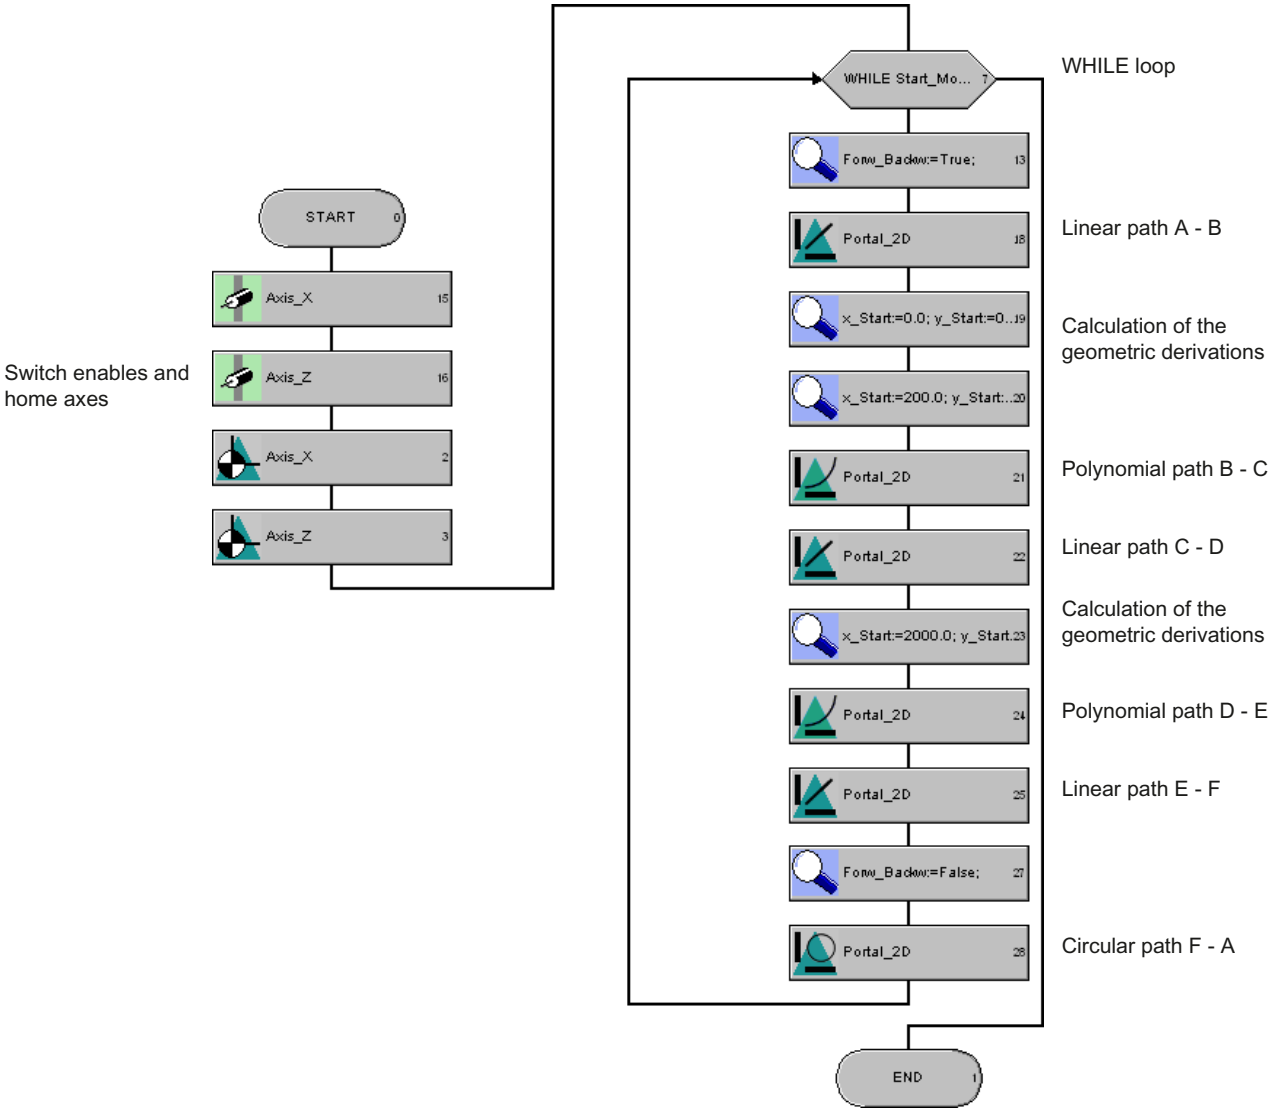

Figure 4-623 MCC chart

Assigning MCC chart in the execution system

The MCC chart must be assigned in the execution system to any MotionTask. The MotionTask must be activated after the StartupTask.

To assign the MCC chart to a MotionTask, proceed as follows:

1. In the project navigator, select any **MotionTask** and move the **MCC_Example.toploader** program to the **used programs**.

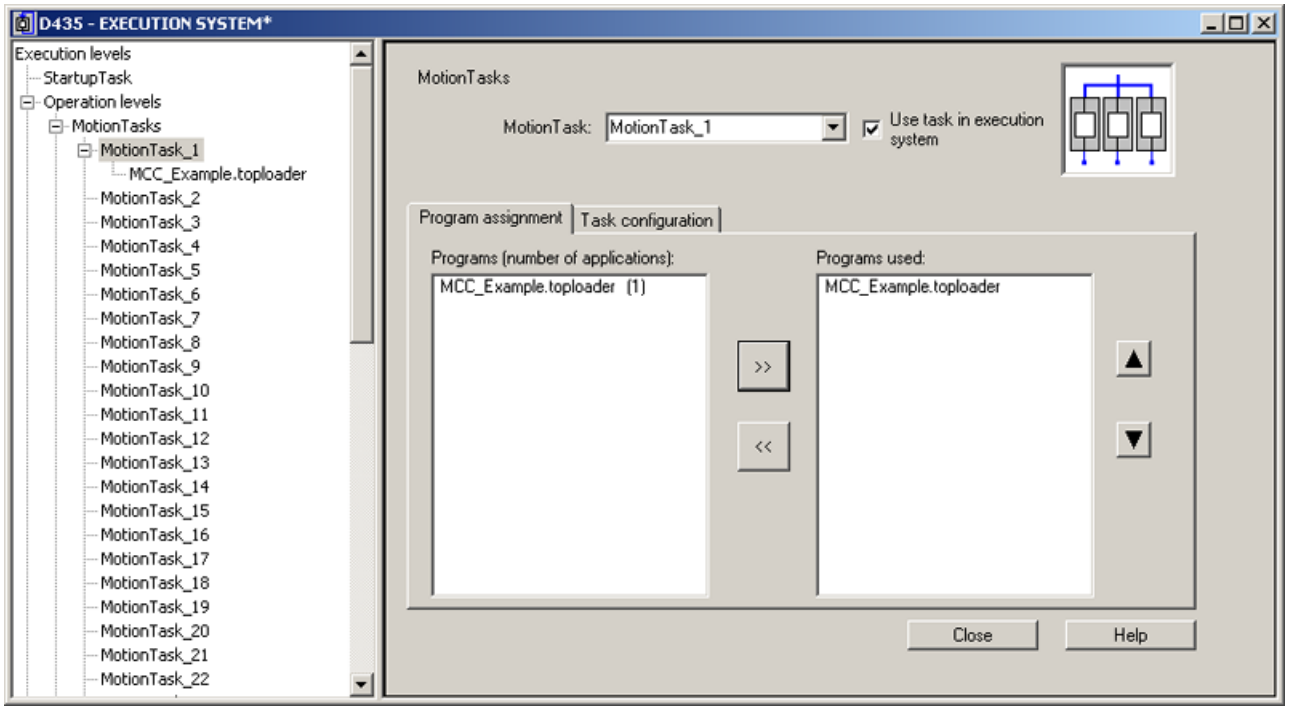

Figure 4-624 Assigning the MotionTask in the execution system

2. In the task configuration of the MotionTask, select **activation after StartupTask**.

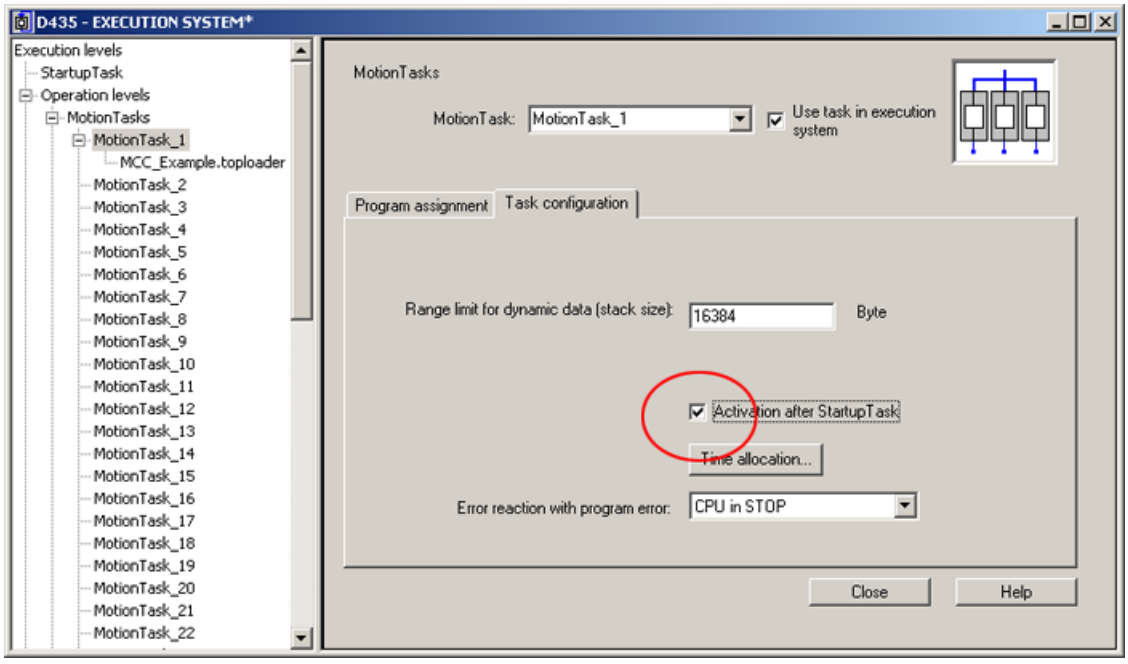

Figure 4-625 Configuring the MotionTask in the execution system

Checking a motion with trace

To see how the motion runs, a trace of the following variables is defined:

- **TO.Axis_X.positioningstate.actualposition**
- **TO.Axis_Z.positioningstate.actualposition**
- **Forw_back**

A log of the motion loop now has the following form:

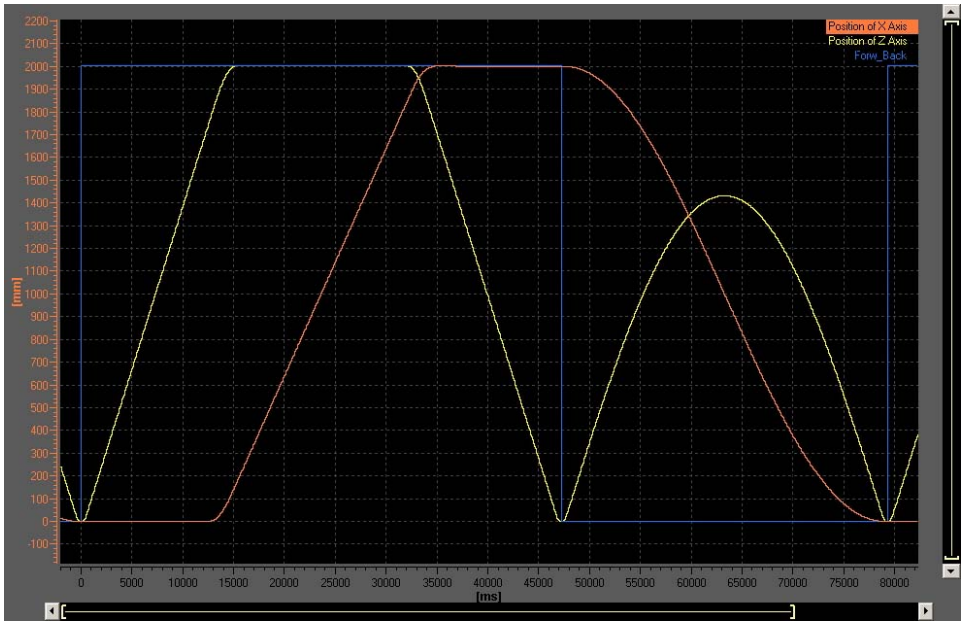

Figure 4-626 Result of the example as trace

4.6.5.9 Creating a path-synchronous axis

To show the functionality of the path-synchronous motion, a path-synchronous axis is added to the project. The path-synchronous axis is used, for example, to additionally rotate products during the motion. The path-synchronous axis is to rotate the gripper by 90° between the **C** and **D** points.

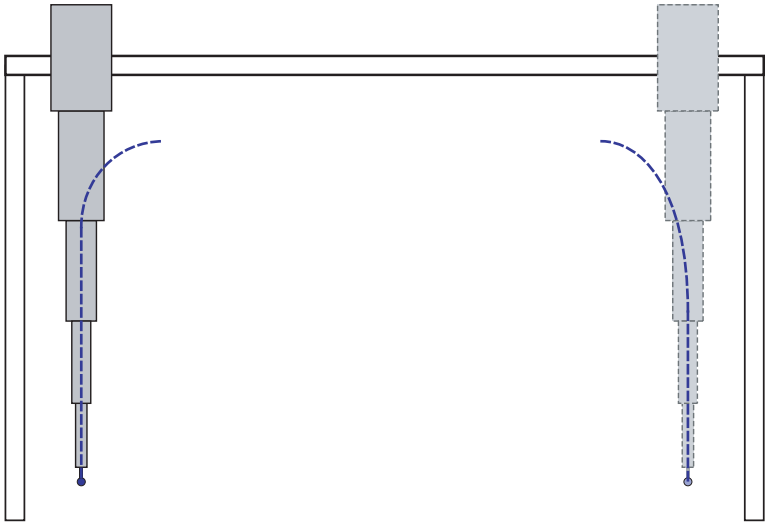

Figure 4-627 Path-synchronous axis

Creating an axis

Add a positioning axis with the name **Axis_Sync** to the project. This axis is created as linear, virtual, non-modular axis. Note that the path axis functionality is not used for this axis.

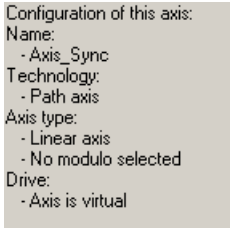

Figure 4-628 Creating the "Axis_Sync" axis

Creating a path object

For **interconnections** of the path object, select the **Axis_Sync** axis as **positioning axis for path-synchronous motions**.

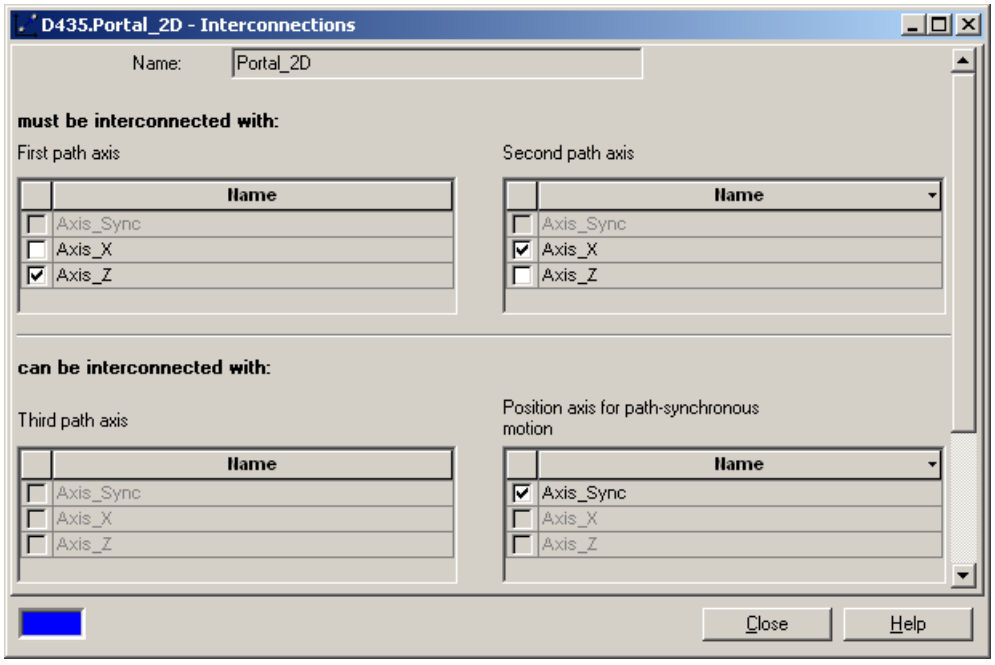

Figure 4-629 Interconnecting the "Axis_Sync" axis

Modifying MCC charts

Perform the following changes in the MCC chart:

- Before the While loop, add the **enable axis** and **home axis** commands for the **Axis_Sync** axis analog to those for the X- and Z-axis.
- The **Axis_Sync** axis should also rotate synchronously in the C-D linear path.
  To rotate the axis as required, open the travel command for the **C-D** linear path and select the **Synchronous axis** tab. Make the following settings there:

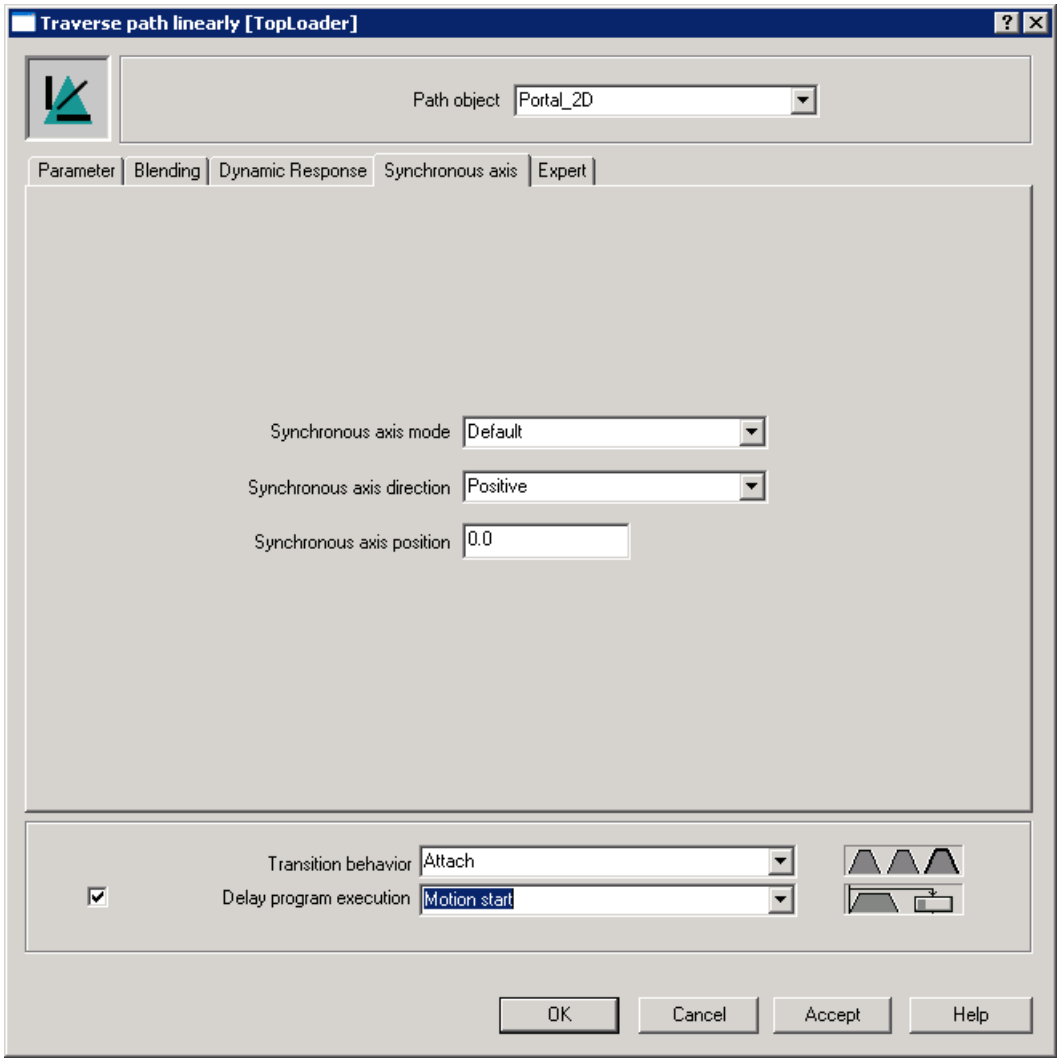

Figure 4-630 Rotating the "Axis_Sync" axis synchronously

- In the **F-A** circular path, the **Axis_Sync** axis should be rotated back to the zero position.

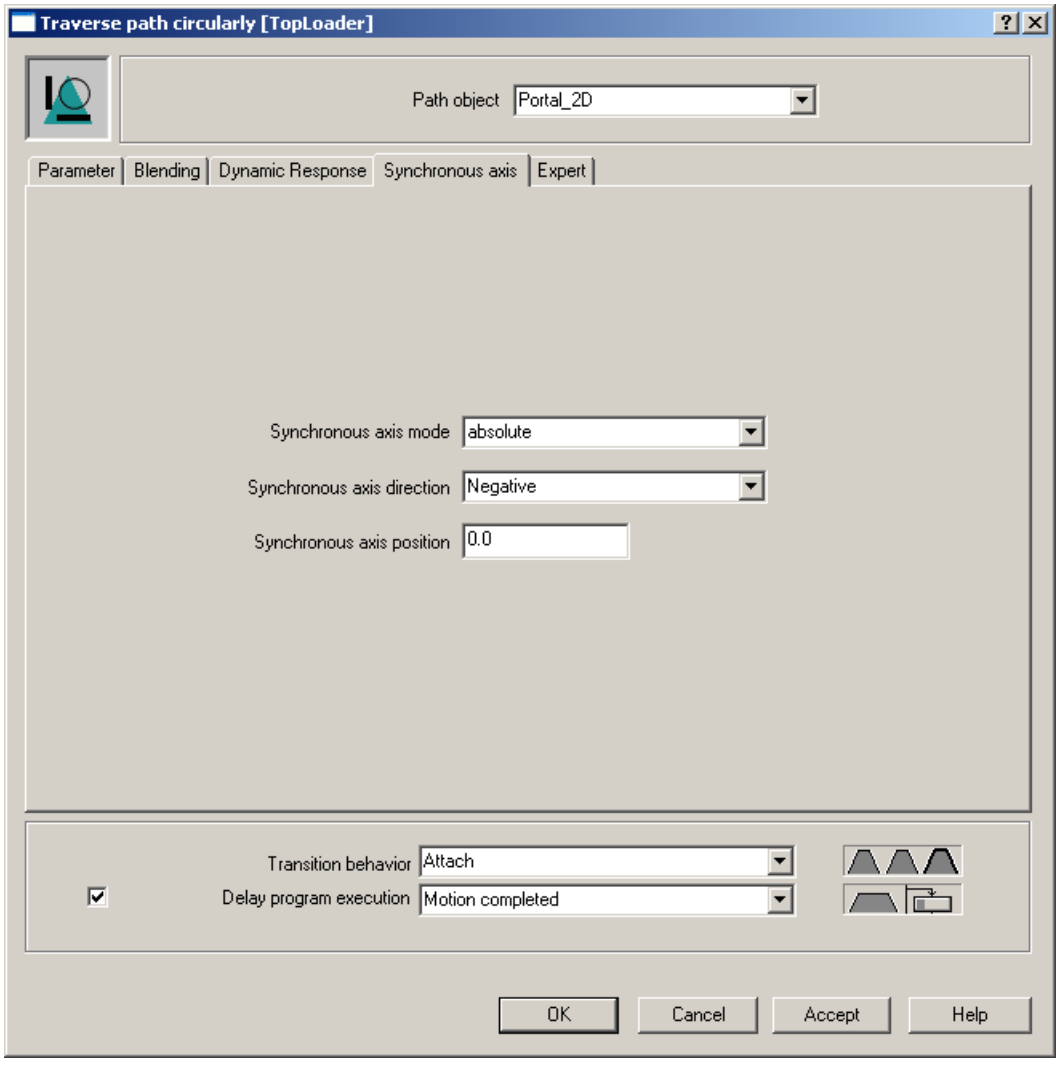

Figure 4-631 Moving the synchronous path back to the zero position

4.6.6 Programming/homing path interpolation

4.6.6.1 Programming

Programming: Overview

The following section provides information about the commands and the alarm responses of the path object technology package. Further information is contained in the reference lists of the technology packages.

The description of the functions for the "Toploading" standard library based on the TO path object is contained on the "Application Toploading" function description.

Overview of commands

Information and conversion

Calculating the path length:

The following commands calculate the path length without starting or executing the path motion.

The start and end points must be specified in the command.

- **_getLinearPathData()**
- **_getCircularPathData()**
- **_getPolynomialPathData()**

Geometric path analysis:

The commands listed below are used to calculate Cartesian path data, such as path direction and path curvature, at the start point, endpoint, and a specifiable point on the path without starting or executing the path motion.

The point on the path is specified by means of the default setting of the path length distance to the start point.

The start point is specified in the command, as is the position with reference to the path length where the information data is determined.

- **_getLinearPathGeometricData()**
- **_getCircularPathGeometricData()**
- **_getPolynomialPathGeometricData()**

With SIMOTION V4.2 and higher, the calculated geometry is stored in a geometry cache and a cacheID is provided as the return value. If the path segment is queried several times and only the queried point changes, this cacheID can be used to access the data already calculated. This can greatly improve the performance of the information functions.

Conversion commands

- **_getPathCartesianPosition()**
  Calculates the Cartesian positions from the axis positions.
- **_getPathAxesPosition()**
  Calculates the axis positions from the Cartesian positions.
- **_getPathCartesianData()**
  Calculates the Cartesian data for position, velocity, and acceleration from the axis positions, axis velocities, and axis accelerations.
- **_getPathAxesData()**
  Calculates the axis positions, axis velocity, and axis accelerations from the Cartesian data for position, velocity, and acceleration.

Command tracking

The current processing and motion status of motion commands can be tracked using the following commands. Permanent storage of the states associated with a **CommandId** makes it possible to evaluate them beyond the lifetime of the motion command.

- **_getStateOfPathObjectCommand()**
- **_getMotionStateOfPathObjectCommand()**
- **_bufferPathObjectCommandId()**
- **_removeBufferedPathObjectCommandId()**

Motion

- **_movePathLinear()**
  Interpolation of linear paths (Page 2480)
  - 2D in a main plane
  - 3D
- **_movePathCircular()**
  Interpolation of circular paths (Page 2481)
  - 2D in a main plane with radius, end point, and orientation
  - 2D in a main plane with center point and angle
  - 2D with intermediate and end points
  - 3D with intermediate and end points
- **_movePathPolynomial()**
  Interpolation of polynomial paths (Page 2485)
  - 2D in a main plane
  - 3D
- **_stopPath()**
  Stops the current motion without terminating.
- **_continuePath()**
  Continues a stopped motion.
  With V4.2 and higher, the motion properties can be stated to continue the movement.

Object and Alarm Handling

- **_cancelPathObjectCommand()**
  Cancels a command that is waiting or active in the Ipo. The command to be canceled is specified by the indication of its CommandId in the **commandToBeCancelled** parameter.
- **_enablePathObjectSimulation()**
  Places a path object in simulation mode, path values are calculated, but are not output on the axes.
- **_disablePathObjectSimulation()**
  Ends simulation mode.

- **_resetPathObject()**
  This command resets the path interpolator to its initial state. Active commands are stopped, commands are aborted, and errors are reset. If required, system variables can be reset to their default values or configuration data can be read in again.
- **_resetPathObjectError()**
  This command resets all errors or a specific error on the path object.
- **_getPathObjectErrorNumberState()**
  Reads out the status of a specific error.
- **_getPathObjectErrorState()**
  This command provides information on whether alarms are pending on the path object and if so, how many. It also outputs information about these errors.
- **_resetPathObjectConfigDataBuffer()**
  Resets the configuration data buffer.
- **_getStateOfPathObjectMotionBuffer()**
  Returns the status of the command queue of the path object.
- **_resetPathObjectMotionBuffer()**
  Clears all pending commands from the command queue.
  The **030002 Command aborted** alarm is issued for each of the deleted commands.

Object coordinates

- **_enablePathObjectTrackingSuperimposed()**
  Starts the synchronization action of a path object on an OCS.
- **_getPathObjectBCSFromOCSData()**
  Calculates a position (x, y, z) in the base coordinate system of the path object using the position in the object coordinate system.
- **_getPathObjectOCSFromBCSData()**
  Calculates a position (x, y, z) in the object coordinate system using the position in the base coordinate system of the path object.
- **_redefinePathObjectOCS()**
  Displaces the object coordinate system along the X-axis (travel direction).
- **_setPathObjectOCS()**
  Defines the translational and rotatory displacement of the object coordinate system compared with the base coordinate system of the path object.

Command execution

Command buffer

The path object has three command buffers for every command.

- One buffer for motion commands has an immediate (**IMMEDIATELY**) and sequential (**SEQUENTIAL**) effect
- A separate buffer for stopping path motion (**_stopPath()**) and continuing path motion (**_continuePath()**)
- A buffer for other (i.e. superimposed) instructions

Command	Function	Position*)
_movePathLinear()	Starts linear path motion	4
_movePathCircular()	Starts circular path motion	4
_movePathPolynomial()	Starts polynomial path motion	4
_stopPath()	Stops motion	1 for stop without command abort 4 for stop with command abort
_continuePath()	Resume motion	1
_getLinearPathData()	Linear path length	5
_getCircularPathData()	Circular path length	5
_getPolynomialPathData()	Polynomial path length	5
_getPathCartesianPosition()	Axis to path	5
_getPathAxesPosition()	Path to axis	5
_getPathCartesianData()	Axis to path with dynamic response data	5
_getPathAxesData()	Path to axis with dynamic response data	5
_getLinearPathGeometricData()	Geometric linear path data	5
_getCircularPathGeometricData()	Geometric circular path data	5
_getPolynomialPathGeometricData()	Geometric polynomial path data	5
_enablePathObjectSimulation()	Places path object in simulation mode	3
_disablePathObjectSimulation()	Resets the path object out of simulation	3
_resetPathObject()	Resets the path object	5
_resetPathObjectError()	Reset error	5
_getStateOfPathObjectCommand()	Read out command status	5
_getMotionStateOfPathObjectCommand()	Read out motion phase of a command	5
_bufferPathObjectCommandId()	Permanently stores the command ID	5
_removeBufferedPathObjectCommandId()	Terminates permanent storage	5
_getPathObjectErrorNumberState()	Reads out the status of a path object error	5
_getPathObjectErrorState()	Reads out the status and number of the pending path object error	5
_resetPathObjectConfigDataBuffer()	Deletes that configuration data collected in the buffer since the last activation	5
_getStateOfPathObjectMotionBuffer()	Returns the status of the command queue of the path object.	5

Command	Function	Position*)
_resetPathObjectMotionBuffer()	Clears all pending commands from the command queue.	5
_enablePathObjectTrackingSuperimposed()	Starts the synchronization action of the path object on an OCS.	3
_getPathObjectBCSFromOCSData()	Calculates a position in the BCS using a position in the OCS.	5
_getPathObjectOCSFromBCSData()	Calculates a position in the OCS using a position in the BCS.	5
_redefinePathObjectOCS()	Displaces the OCS along the X-axis.	3
_setPathObjectOCS()	Defines the displacement of the OCS compared with the BCS.	3
_cancelPathObjectCommand()	Cancels a command that is waiting or active in the Ipo.	1

***) Legend:**

1 Buffer for Stop-Continue commands
2 Not used
3 Buffers for superimposed commands
4 Sequential command buffer
5 Not assigned to the command buffers (commands can be executed in parallel)

Override behavior

The response to command insertion is defined in the **mergeMode** command parameter.

- Override current interpolator command
  (**mergeMode:=IMMEDIATELY**)
- Overwrite commands in the buffer
  (**mergeMode:=NEXT_MOTION**)
  This command is executed as soon as the current interpolator command has been executed.
- Append to commands already in the buffer
  (**mergeMode:=SEQUENTIAL**)
  If the buffer is full, the command can wait until an entry becomes available or the command execution can continue without a wait time.

Commands are decoded in the task context, i.e. in the execution level of the user task that issued the command (before it is entered in the command buffer).

mergeMode has the same settings and action as in the Axis technology object.

Interactions between the path object and the axis

Override behavior

The response to other active motions on the axis is defined with the **mergeMode** parameter of the path object motion command.

With the **substitute** setting, all active assigned axis motions are canceled (as a function of the **transferSuperimposedPosition** setting in the configuration data).

- When a path motion is substituted by an additional path command, an immediate transition takes place to the path that yields the new end point at the point of the substitution.
- When a path is substituted by a motion command, such as **_move...()**, the other axes involved in the path motion and, if applicable, the positioning axis for path-synchronous motion stop with the maximum dynamic values.
  The action of the other override responses is the same as for synchronous operation.
  The following applies when motion commands occur simultaneously on the respective object within one interpolation cycle, i.e. one on the synchronous object, one on the path object, and one on the axis:
  - When **mergeMode=SEQUENTIAL/NEXT_MOTION**, the synchronous/path command is executed.
  - When **mergeMode=IMMEDIATELY**, the command on the axis is executed.
- The **_stop()** command from an axis involved in the path motion or participating via the path-synchronous motion does not stop the path motion on the path object, i.e. it has no effect (this is the same behavior as for the synchronous motion on the Synchronous technology object).
  _stop() only stops motions that were initiated on the axis.
  The **_stopEmergency()** command is also effective on motions initiated on the Synchronous operation and Path object technology objects.
- Superimpositions can only take place on the axis (axis motion or synchronous operation), not on the path object.
- If a positioning axis for path-synchronous motion of the path group is overridden by means of an axis command on this axis, this has the same effect on the path as when a path axis is overridden.
- Path axes and positioning axes for path-synchronous motion have the same response.

With the other settings, the path motion is started after the end of all previous axis motions or an active path motion.

Sequence of effectiveness

Technology objects are processed in the sequence: Path object - Synchronous object - Axis object. In the case of simultaneous motion commands on several technology objects that are interconnected with an axis and have the same override response, the motion commands take effect according to the processing order and the setting in the **mergeMode** parameter:

- When **mergeMode:=IMMEDIATELY**, the motion command on the axis takes effect (last processed command).
- When **mergeMode:=SEQUENTIAL/NEXT_MOTION**, the motion command on the path object takes effect (first effective command).

Interaction with the axis

If the motion of an axis is stopped as a result of its local alarm response or if the interconnection of the path object to the axis becomes invalid, the path motion is canceled, the other axes are also traversed with the maximum dynamic values to velocity 0.0, and a technological alarm is issued.

If the remaining distance is smaller than the deceleration distance, the new target position is overshot, and the axis travels back to the target position (with a reversing motion). The other axes travel with their maximum dynamic values to velocity 0.0. However, these axes do not travel back to the cancellation point. Depending on the general conditions (number of participating axes, dynamic values), the path is no longer maintained.

See **Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder** Function Manual, "Motion transitions"

Interactions with other path motions

If a path axis is interconnected with several path objects, and if a path motion on a path axis substitutes another path motion on another path object, the other path axes are traversed with the maximum dynamic values to velocity 0.0, and a technological alarm is issued.

4.6.6.2 Local alarm response

Local alarm responses are specified by means of the system.

The following responses are possible:

- **NONE**: No response
- **DECODE_STOP**: Command decoding is canceled, but the current motion and command in the buffer remain active.
- **END_OF_MOTION_STOP**: Abort at end of error-causing command; motion on the path stops.
- **MOTION_STOP**: Controlled motion stop with programmed dynamic path values on the path. Motion can be continued by acknowledging the error.
- **MOTION_EMERGENCY_STOP**: Controlled motion stop with maximum dynamic path values/ limit values for the axis. Motion can be continued by acknowledging the error.
- **MOTION_EMERGENCY_ABORT**: Controlled motion stop with maximum dynamic path values on the path. Active commands in the path interpolator are canceled; read-in of new commands is prevented and is only possible following error acknowledgement. Active commands (IPO) are fed back to the user program with an error code.
- **DISABLE_MOTION**: Motion stop on path axes and positioning axis for path-synchronous motion. The path motion component is realized by means of a stop with the maximum dynamic values of the axis followed by cancellation of the path motion component. Thus, the path group is ungrouped. Active commands in the path interpolator are canceled; read-in of new commands is prevented and is only possible following error acknowledgement.

4.6.7 Appendix A

4.6.7.1 Specific kinematics with TrafoID 1001

Type of kinematics

The kinematics can be used with the TrafoID 1001. However, it can only be selected via the expert list by entering the corresponding ID there.

Kinematics 1001 are 2D kinematics (X-Y)

The following types of axes can be used:

- Axis A1 (X axis): Rotary or linear axis without modulo function
- Axis A2 (Y axis): Rotary axis without modulo function

Display of kinematics

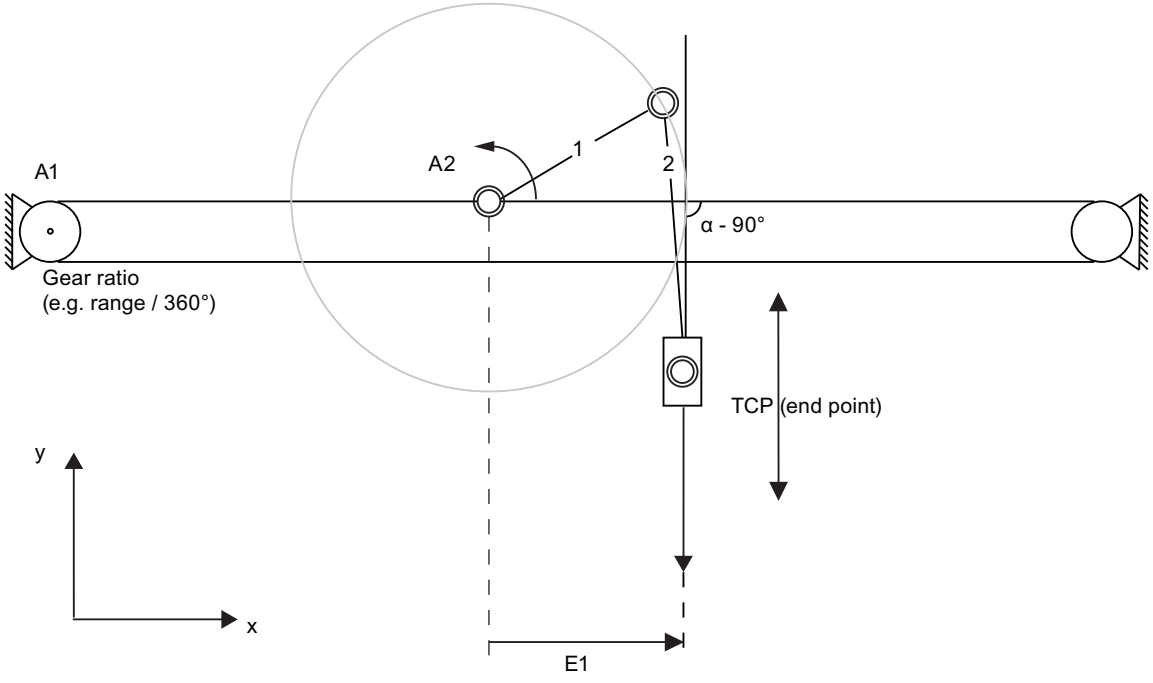

Figure 4-632 Kinematics display

Settings on path object

Kinematics.typeOfKinematics = SPECIFIC (6)

Kinematics.specTrafoId = 1001

Table 4-277 Kinematics parameter

Parameter	Use	Unit	Type	Min.	Max
Kinematics.parameter[1]	basicOffsetX	e.g. mm	LREAL	-1E+012	1E+012
Kinematics.parameter[2]	basicOffsetY	e.g. mm	LREAL	-1E+012	1E+012
Kinematics.parameter[3]	Reserved				
Kinematics.parameter[4]	ratioA1	e.g. mm/°	LREAL	-1E+012	1E+012
Kinematics.parameter[5]	length1	e.g. mm	LREAL	0	1E+012
Kinematics.parameter[6]	length2	e.g. mm	LREAL	0	1E+012
Kinematics.parameter[7]	distanceE1	e.g. mm	LREAL	-1E+012	1E+012
Kinematics.parameter[8]	verticalPosition2 lower / upper	0: lower, ≠0: upper	LREAL	-1E+012	1E+012
Kinematics.parameter[9]	offsetA2	e.g.	LREAL	-1E+012	1E+012

Kinematics reference

The position of the TCP/ end point depends on the orientation (see **Traversing range** section) of rod 2. If the **lower** orientation is selected (as in the kinematics reference diagram), the position of the TCP/ EP can be determined as follows if the kinematics are in a neutral position:

$$X_{(EP\_bottom)} = 0.0 - basicOffsetX$$

$$Y_{(EP\_bottom)} = -\sqrt{(length2)^2 - (length1 - distanceE1)^2} - basicOffsetY$$

If the **upper** orientation is selected:

$$X_{(EP\_top)} = 0.0 - basicOffsetX$$

$$Y_{(EP\_top)} = \sqrt{(length2)^2 - (length1 - distanceE1)^2} - basicOffsetY$$

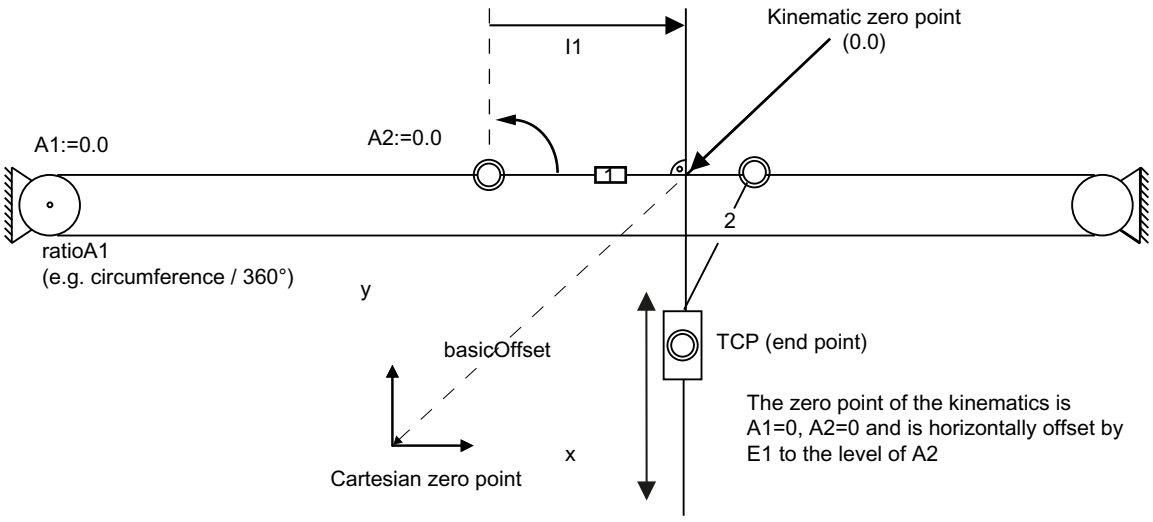

Figure 4-633 Kinematics reference

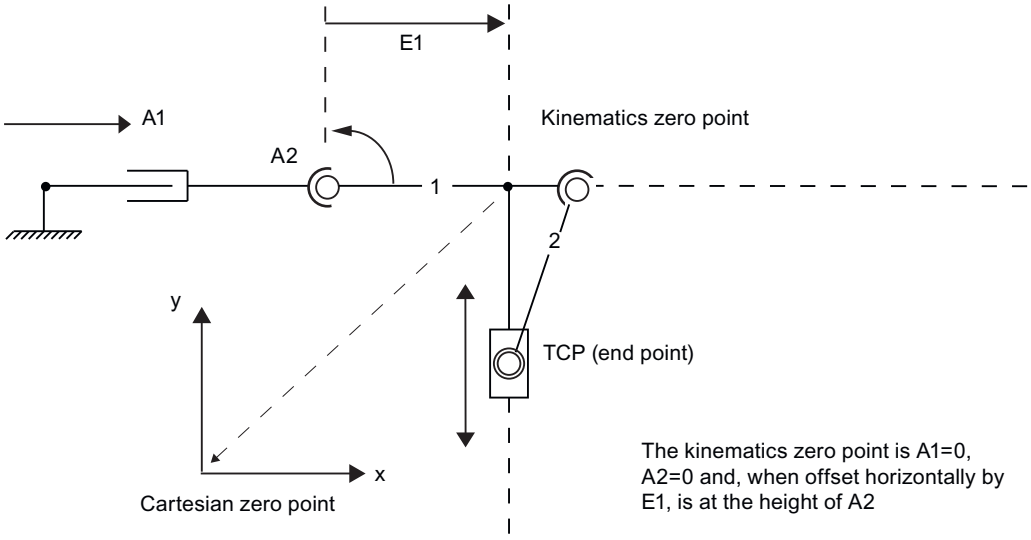

Figure 4-634 Schematic display - kinematics 1001

Transformation in X direction

Transformation in X direction can be used for linear and rotary axes (belt drive, spindle etc.).

BCS.x.position=(axis position A1 * parameter[4]) - parameter[1]

BCS.x.position=(axis position A1 * ratioA1) - basicOffsetX

Transformation in Y direction

Within the traversing range, transformation (MCS -> BCS) of the path object provides valid Cartesian values. If the axis is outside this range, 0.0 is output.

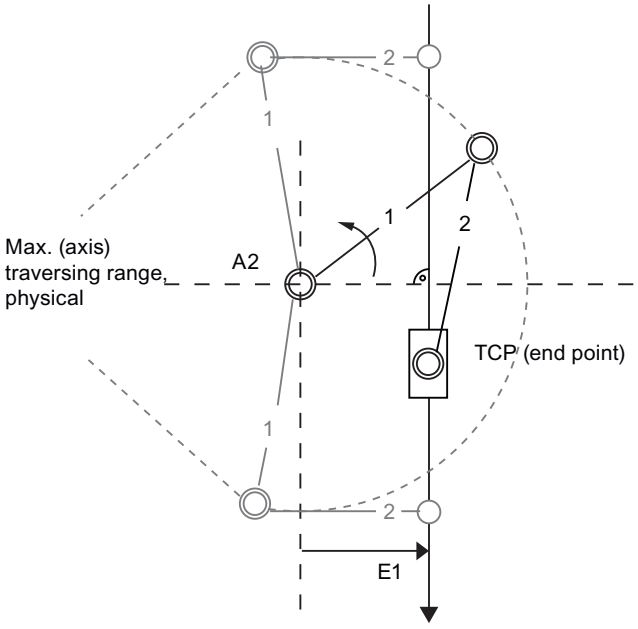

Figure 4-635 physical traversing range

Traversing range

The traversing range is determined by the orientation (position) of the sliding range. This can be determined using Kinematics.parameter[8].

Upper orientation

Kinematics.parameter[8] ≠ 0.0 (e.g. 1.0)

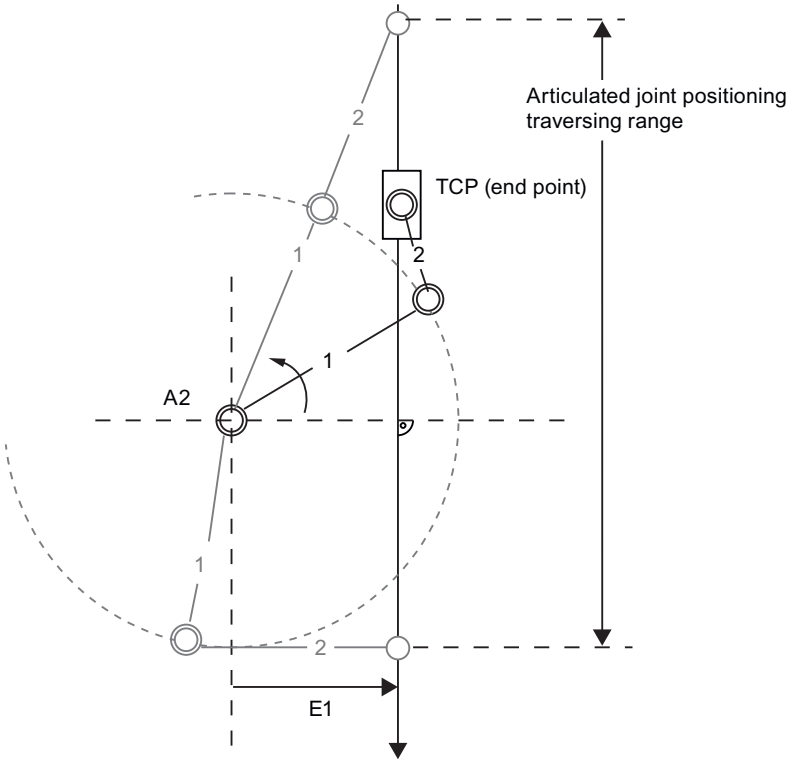

Figure 4-636 Traversing range with orientation selected as upper

Lower orientation

Kinematics.parameter[8] = 0.0

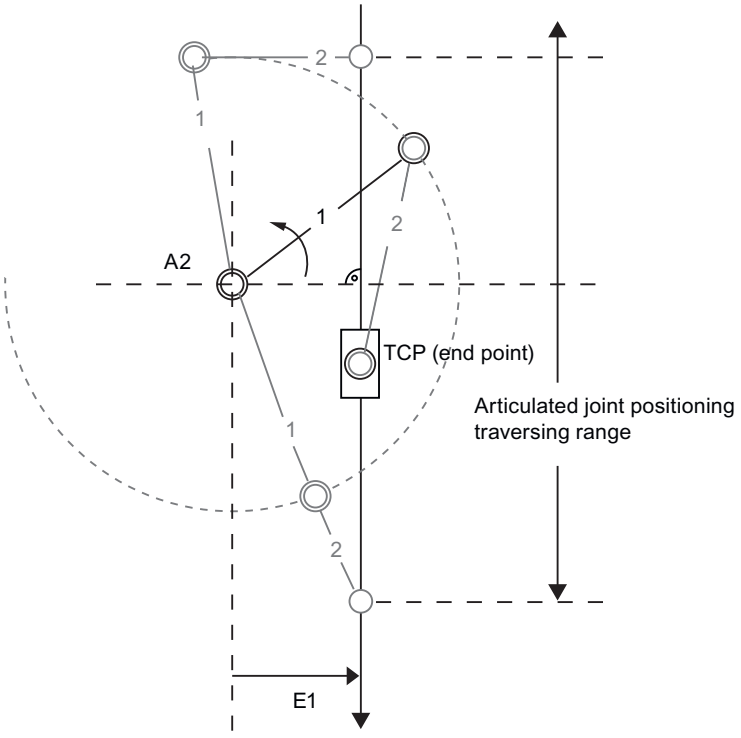

Figure 4-637 Traversing range with orientation selected as lower

4.7 Technology Objects Synchronous Operation, Cam

Preface

Preface

This **document** is part of the **System and Function Descriptions documentation package**.

Scope

This manual is valid for the following versions:

- SIMOTION SCOUT V4.5
- SIMOTION Kernel V4.5, V4.4, V4.3, V4.2, V4.1, V4.0, V3.2, V3.1 or V3.0
- SIMOTION technology packages Cam, Cam_ext/Path (as of Kernel V3.2) and TControl in the version for the respective kernel (including technology packages Gear, Position and Basic MC up to Kernel V3.0)

Chapters in this manual

The following is a list of chapters included in this manual along with a description of the information presented in each chapter.

- Synchronous Operation (Page 2624) (Part I)
  Function of the synchronous operation, i.e. the grouping of a master object and a following axis
- Distributed Synchronous Operation (Page 2758) (Part II)
  Function of the distributed synchronous operation, i.e. synchronous operation across different controllers
- Synchronous Operation IPO - IPO_2 (Page 2824) (Part III)
  Function of synchronous operation with master object and following axis in different interpolator cycle clocks (IPO or IPO_2)
- Cam (Page 2830) (Part IV)
  Function of the Cam technology object
- Index
  Index for locating information.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P

- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

4.7.1 Fundamental safety instructions

4.7.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

4.7.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

4.7.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

4.7.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

4.7.2 Part I - Synchronous Operation

4.7.2.1 Overview of synchronous operation

This part describes the function of the **synchronous operation** technology. It introduces you to the setting and configuration functions, as well as providing information about the supplementary conditions and the operating characteristics of synchronous objects.

What is synchronous operation used for?

Synchronous operation functions are taking on an increasingly significant role in automation engineering. The progress in open-loop and closed-loop control engineering and the availability of increasingly more powerful systems mean that solely mechanical solutions are more and more frequently being replaced with "electronic" variants.

The synchronous operation functions of the SIMOTION technology provide the option of replacing rigid mechanical connections with "control engineering", thus producing more flexible, maintenance-friendly solutions.

What is synchronous operation in SIMOTION?

The synchronous operation functionality of axes is provided by the synchronous object. A leading object (master) generates a master value, which is processed by the synchronous object according to specific criteria (gear ratio, scaling, offset, cam) and assigned to the following axis (slave) as a reference variable.

Mechanical model

The mechanical model for a synchronous operation relationship is, for example, a gear with a drive wheel and an output wheel. The model for camming could be a cam gear with a mechanical cam and sampling mechanism. A coupling used for enabling and disabling the following motion on-the-fly is also used as a model.

Synchronous operation functions

The following synchronous operation functions can be implemented:

- With gearing (Page 2631), a linear transmission function between a master value and a following axis can be achieved using control engineering, thus producing the same result as could be achieved mechanically using a gear. A gear ratio can be specified for use in linear mapping of the master axis position onto the following axis position.

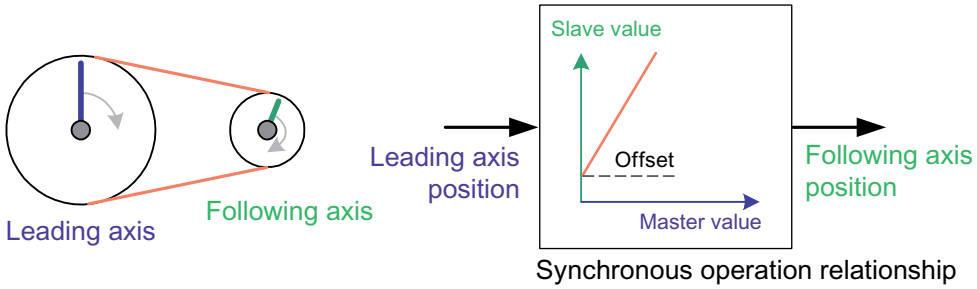

Figure 4-638 Gearing synchronous operation function (mechanical example)

- With velocity gearing (Page 2637), a constant velocity coupling is implemented (as of V3.1).
- With camming (Page 2638), a non-linear transmission function between a master value and following axis can be achieved. The slave value is generated from the master value using the transmission function defined in the cam. The cam is defined using interpolation points or mathematical functions and is interpolated between the specifications.

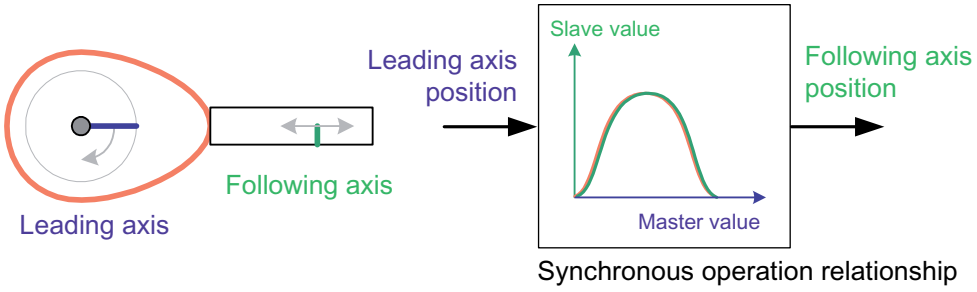

Figure 4-639 Camming synchronous operation function (mechanical example)

A synchronous operation sequence

Synchronous operation of a following axis to a master value using the SIMOTION synchronous operation functions is divided into three phases:

- Synchronization
- Synchronized traversing
- Desynchronization

Within these phases, there are several options for influencing the synchronous operation functions.

Synchronization/Desynchronization

The synchronous operation to the master value during synchronization or desynchronization can be defined differently depending on the application.

It is determined on the basis of:

- The synchronization criterion/synchronization position
- Synchronization direction
- The position of the synchronization range relative to the synchronization position
- Synchronization profile

See the section titled Synchronization (Page 2652).

Objects

A *synchronous operation relationship* exists between the following objects:

- At least one *master object* (master)
  The master object is a technology object that provides motion information with a position (the motion slave value). This can be, for example, a positioning axis or an external encoder.
- At least one *synchronized axis*, comprising:
  - A *following axis* (slave)
  - One or two *synchronous objects*
  - Possibly one or more *cams*

A synchronous object is automatically created as a separate object in SIMOTION SCOUT when an axis with synchronous operation technology is created.

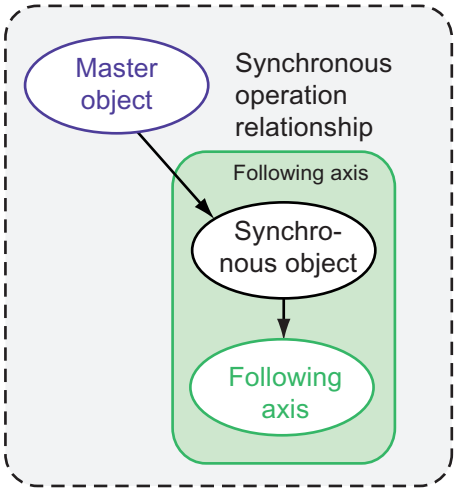

Figure 4-640 Objects in gearing

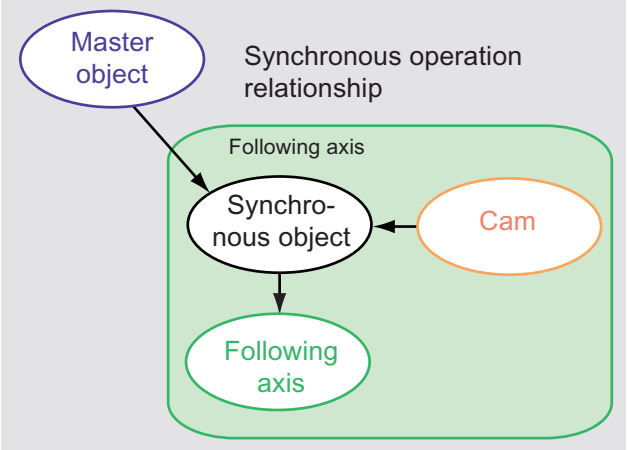

Figure 4-641 Objects in camming

Master values

The master value can be specified by the following technology objects:

- Axis
- External encoder

With restrictions (not for distributed synchronous operation or synchronous operation IPO-IPO_2), the following technology objects can also specify the master value:

- Fixed gear
- Addition object
- Formula object

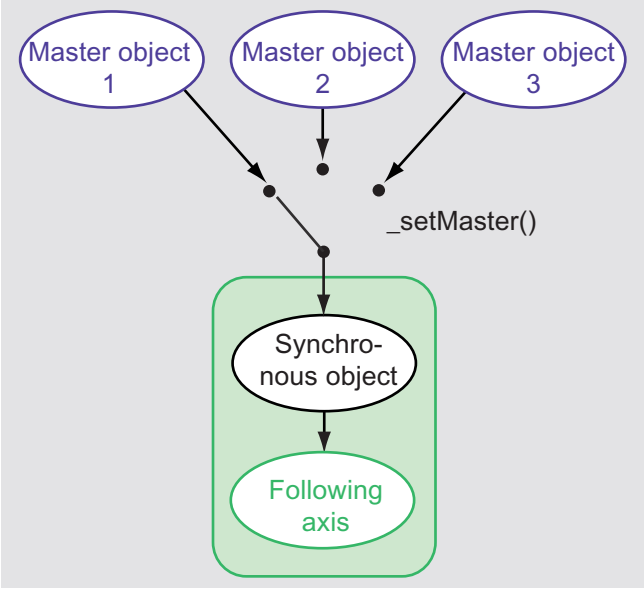

Figure 4-642 Example: Synchronous object with several master values

A following axis can be interconnected with more than one master value by means of the synchronous object. However, only one of these master values can be activated at any given

time. The process of switching over to a different master value is described in the section titled Switching over the master value source (Page 2680).

When axes serve as the master value source, the setpoint coupling or the actual value coupling with extrapolation can be selected. When external encoders serve as the master value source, actual value coupling/actual value coupling with extrapolation (V3.0 and higher) can be selected. See the section titled Setpoint/actual value coupling (Page 2647).

Note

A drive axis cannot be used as the master value source for a gearing.

Processing cycle clock of the synchronous object

The processing cycle clock of the synchronous object and the processing cycle clock of the synchronized axis must be identical.

Note

If you change the processing cycle clock of the synchronized axis using the configuration screen form, the processing cycle clock of the synchronous object is changed automatically. If you change the processing cycle clock of the synchronized axis or of the synchronous object using the expert list, the processing cycle clock of the synchronous object or synchronized axis is *not* changed.

Recursive synchronous operation interconnection

A recursive synchronous operation interconnection is present when, in a single synchronous operation relationship, a synchronized axis is interconnected directly or indirectly again as a master value via other technology objects. A synchronized axis cannot act as a following axis to a master value and as a master value for the same axis simultaneously. Recursive synchronous operation interconnections can result if, for example, a synchronous operation relationship is to be switched over in the event of an error. Also refer to the section titled Error handling in the user program (Page 2756).

Units

The master and slave values are coupled without physical conversion *in the relevant parameterized units*. If, for example, the master axis is a linear axis and the following axis is a rotary axis, a length unit corresponds to an angular unit (for a 1:1 conversion ratio).

Modulo behavior

Different modulo ranges on the master value object and the following axis are taken into account on the synchronous object.

Camming with several cams

Several cams can be used in one camming operation. You can switch over to another cam dynamically using the **_enableCamming()** command in the user program.

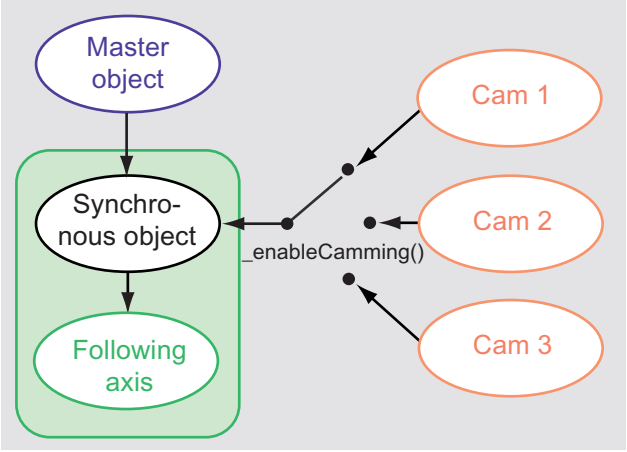

Figure 4-643 Example: Camming with several cams

Rules for interconnection

To recap, the following rules apply to synchronous operation:

- The synchronous object and following axis must be on the same runtime system (SIMOTION device).
- The master object and the following axis can be in different SIMOTION devices.
  In this case, we talk about distributed synchronous operation (Page 2758).
- The master object and synchronized axis may operate in different IPO cycles
  (see Overview of synchronous operation IPO - IPO_2 (Page 2824)).
- The synchronous object and the following axis are permanently assigned to each other during configuration.
- Up to two synchronous objects can be interconnected to one following axis.
- The master value object can be interconnected to several followings.
- The synchronous object can be interconnected to several master values and cams.
- A cam can be interconnected with several synchronous objects.

Superimposed synchronous operation

In superimposed synchronous operation, two synchronous objects can be connected to one following axis. The two synchronous operations superimpose one another (V3.0 and higher).

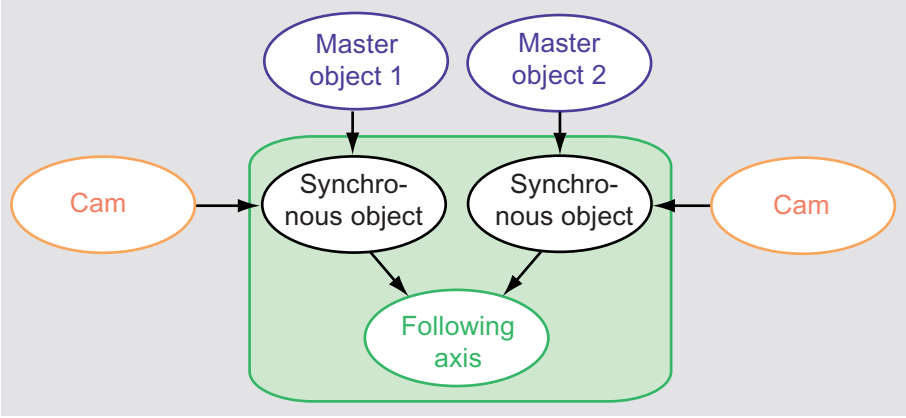

Figure 4-644 Example of superimposed synchronous operation

For additional information, see the section titled Superimposed synchronous operation (Page 2683).

Synchronous Operation Configuration (Page 2721)

Synchronous Operation Programming/References (Page 2744)

4.7.2.2 Fundamentals of Synchronous Operation

Gearing

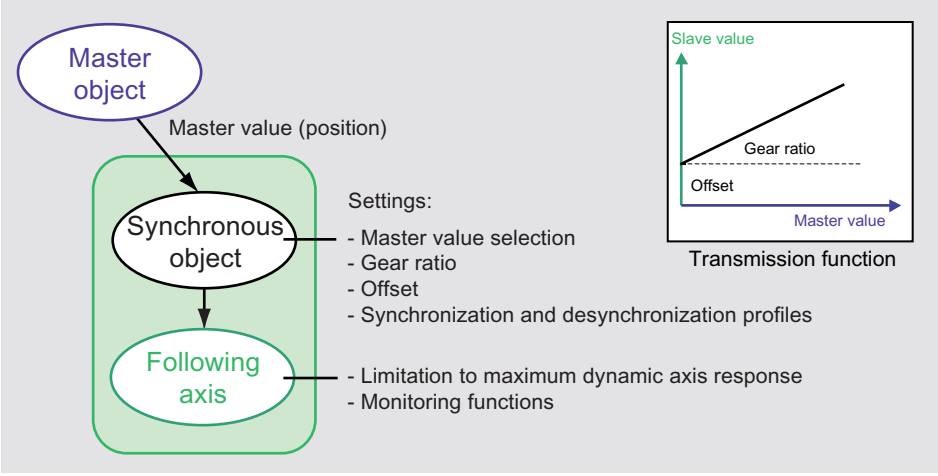

Figure 4-645 Gearing

Gearing is characterized by a linear transmission function between the master value source and the following axis/axes.

Slave value = Gear ratio x Master value + Offset

This gear ratio can be specified as the ratio of two decimal numbers (numerator/denominator) or as a rational number. A zero point offset can be included in the calculation. Absolute or relative gearing can be set using the gearingType parameter of the **_enableGearing()** command.

Absolute gearing

With absolute gearing (**gearingType=ABSOLUTE**), the synchronous operation occurs absolutely relative to the zero point of the master value and slave value, taking into account the gear ratio.

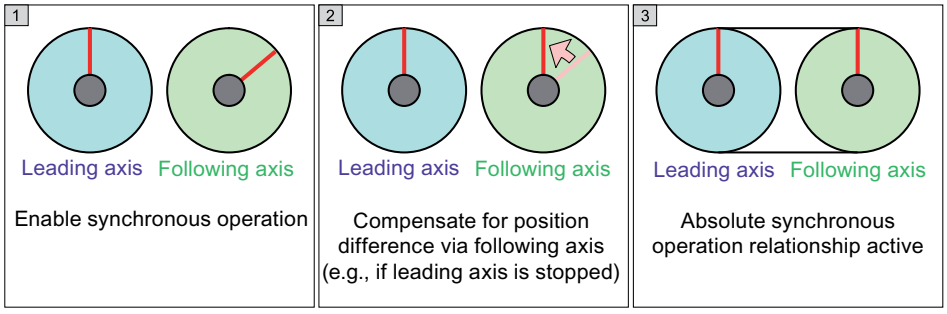

Figure 4-646 Sequence of the absolute gearing synchronization (simplified example)

A specified offset of the slave value is included. This offset is equal to zero, except when the synchronization criterion **ON_MASTER_AND_SLAVE_POSITION** or **IMMEDIATELY_AND_SLAVE_POSITION** is set in the **syncPositionSlave** parameter, in which case an offset is specified.

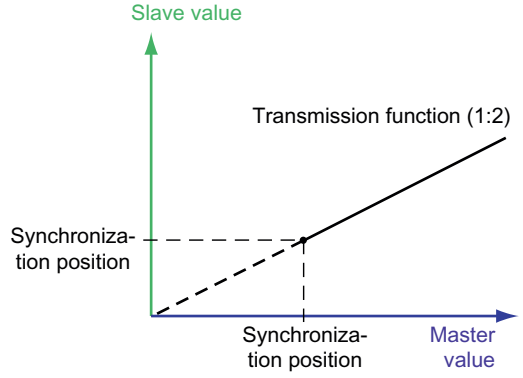

Figure 4-647 Absolute gearing without specification of the slave value position

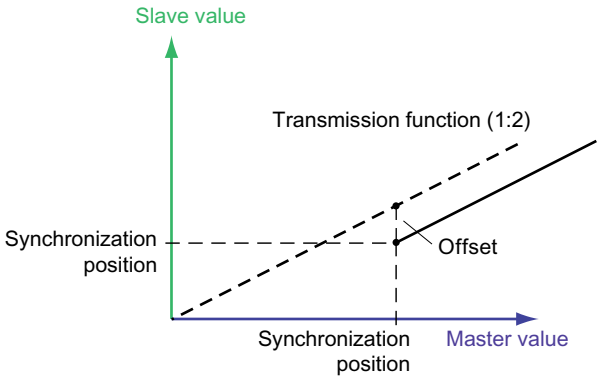

Figure 4-648 Absolute gearing with specification of the slave value position

Position differences on the slave value side are compensated for during synchronization. Modulo settings are taken into account.

Relative gearing

With relative gearing (**gearingType:=RELATIVE**), the synchronous operation occurs relative to the synchronization position on the master value and slave value sides.

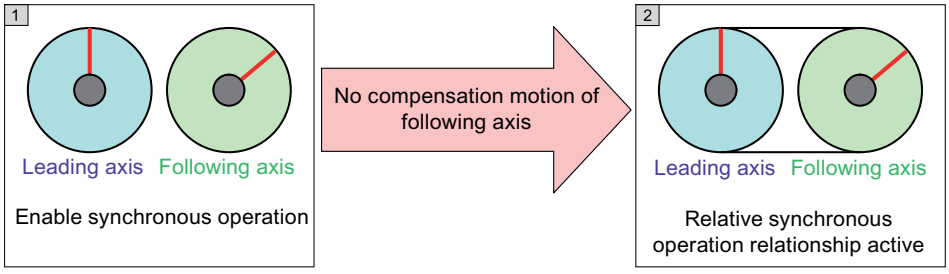

Figure 4-649 Sequence of the relative gearing synchronization (simplified example)

The offset is determined implicitly in the transmission function:

- If programmed without a specified offset: The offset is derived from the current position of the following axis at the start of synchronization and from an offset derived implicitly during synchronization if the axis is driven to a velocity (and acceleration) derived from the gear ratio.
- If programmed with a specified offset: Using the synchronization criterion setting **ON_MASTER_AND_SLAVE_POSITION** or **IMMEDIATELY_AND_SLAVE_POSITION**, the offset is determined from the current following axis position at the start of synchronization and the offset programmed in **syncPositionSlave**.

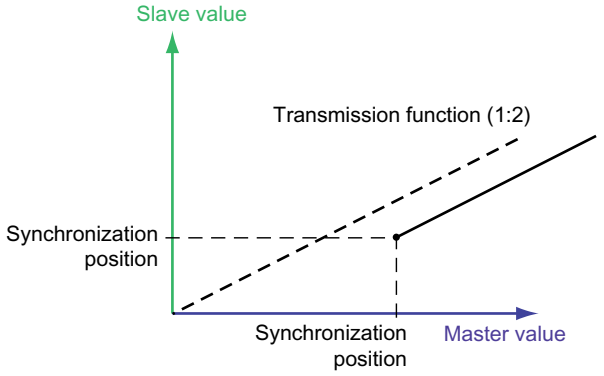

Figure 4-650 Relative gearing without offset

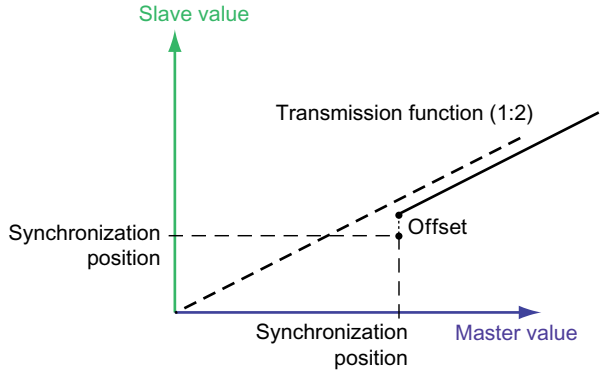

Figure 4-651 Relative gearing with offset

From the point at which the status becomes "synchronous", relative gearing is also in positional synchronism. In other words, the offset remains constant in the transmission function from this point onwards.

Gear ratio

The gear ratio is used to define the transmission function of the gearing between the master value and slave value. The gear ratio corresponds to the slope of the transmission function. It can entered as either a fraction or a floating-point number using the **gearingMode** parameter of the **_enableGearing()** command.

- As a fraction (**gearingMode:=GEARING_WITH_FRACTION**)
  The gear ratio is specified as a fraction (slave value difference/master value difference) using the following function parameters:
  - **gearingRatioType**: Type of gear ratio specification (directly or via replacement values)
  - **gearingNumerator**: Value for direct specification of the gear ratio numerator
  - **gearingDenominator**: Value for direct specification of the gear ratio denominator
- As a floating-point number (**gearingMode=GEARING_WITH_RATIO**)
  The gear ratio is specified as a floating-point number using the following function parameters:
  - **gearingRatioType**: Type of gear ratio specification (directly or via replacement values)
  - **gearingRatio**: Value for direct specification of the gear ratio as a floating-point number
    Disadvantage: Gear ratios such as 1/3 ≈ 0.333 are subject to rounding errors.

The long-term effect is to be taken into account with modulo axes. If master and slave axes are configured as modulo axes, to ensure the long-term stability of the gear, the gear ratio is preferably to be entered as a nominator/denominator ratio. If this is not possible, a LREAL value with corresponding decimal places should be used.

Direction of gearing

The gear ratio can be set in the same direction or in the opposite direction (corresponding to a negative gear ratio) using the **direction** parameter of the **_enableGearing** command.

- For **POSITIVE**, traversal is made in the same direction as the master values, this means that the axes run in the same direction.
- For **NEGATIVE**, traversal is made in the opposite to master values, this means that the axes run in the opposite direction.
- With **CURRENT**, the direction of the current slave values is retained; along with the direction of the master value; this results in coupling in the same or opposite direction, which is then maintained for the entire command execution time (that is, if the master value direction changes, then the slave direction changes as well).
- **REVERSE** means movement in the inverse direction of the slave values.

If the slave values are at a standstill at the point at which the command is activated, the following conversion is performed: **CURRENT** becomes **POSITIVE** and **REVERSE** becomes **NEGATIVE**.

Change in the offset

The **activationMode** parameter of the **_setGearingOffset()** command specifies when the offset takes effect (as of V3.1).

The changeover applies as follows:

- *For the next synchronous operation and all subsequent synchronous operations* if **DEFAULT_VALUE** is set
- *For the current synchronous operation only* if **ACTUAL_VALUE** is set
- *For the current synchronous operation and all subsequent synchronous operations* if **ACTUAL_AND_DEFAULT_VALUE** is set

Note the following:

- If the synchronization operation of the **_enableGearing()** command is not yet active, the current offset is carried out without compensation, that is, it is figured in directly.
- If the **_setGearingOffset()** command is programmed to current values during synchronization, the offset does not take effect until after synchronization. A compensating movement takes place.

Apply offset as superimposition

The **dynamicReference** parameter of the **_setGearingOffset** command can be used to specify whether the dynamic parameters refer to the total motion or the motion difference (V3.2 and higher).

- **TOTAL_MOVE**: Dynamic response parameters refer to the total motion. (Default setting)
  The transition is determined entirely on the basis of the offset values and the dynamic response parameters.
- **OFFSET_MOVE**: Dynamic response parameters refer to the motion difference.
  The transition is determined on the basis of the current synchronous operation definition as superimposed motion with the specified dynamic values.

Note

With a constant master value velocity, the dynamic transitions have a similar form and differ as a result of the dynamic response parameters that act differently.

See also

Example of applying offset as superimposition (Page 2712)

Velocity gearing

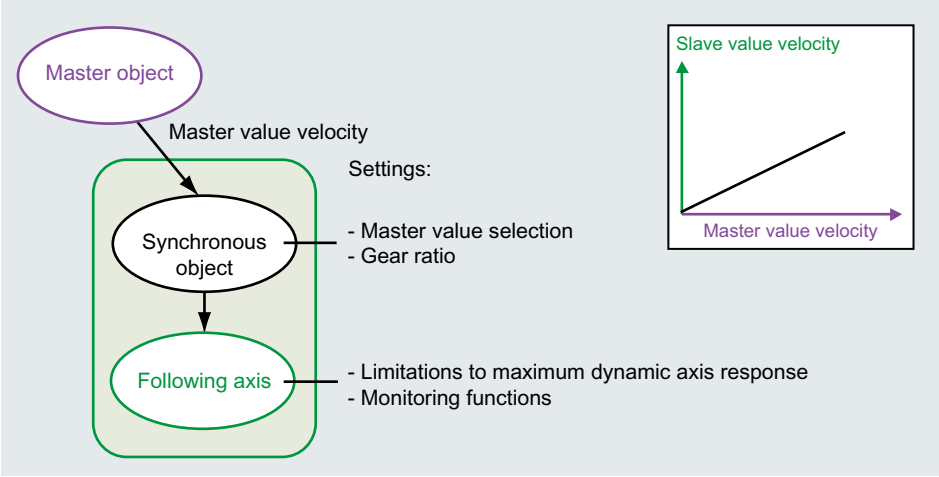

Figure 4-652 Velocity gearing

In contrast to gearing or camming, which relate to the position of an axis, **synchronous velocity operation** (V3.1 and higher) relates to the *velocity of an axis*. A velocity setpoint is calculated for the following axis. After activation, the axis travels immediately at the specified acceleration to the synchronous operation velocity. A linear transmission function is implemented.

The gear ratio can be specified as a positive floating-point number.

The gear ratio can be set in the same direction or in the opposite direction (corresponding to a negative gear ratio) using the **direction** parameter of the **_enableVelocityGearing()** command.

- **POSITIVE** means that the axes are running in the same direction.
- **NEGATIVE** means that the axes are running in opposite directions.

See also

Substitution of velocity gearing with absolute synchronous operation (Page 2717)

Camming

Description

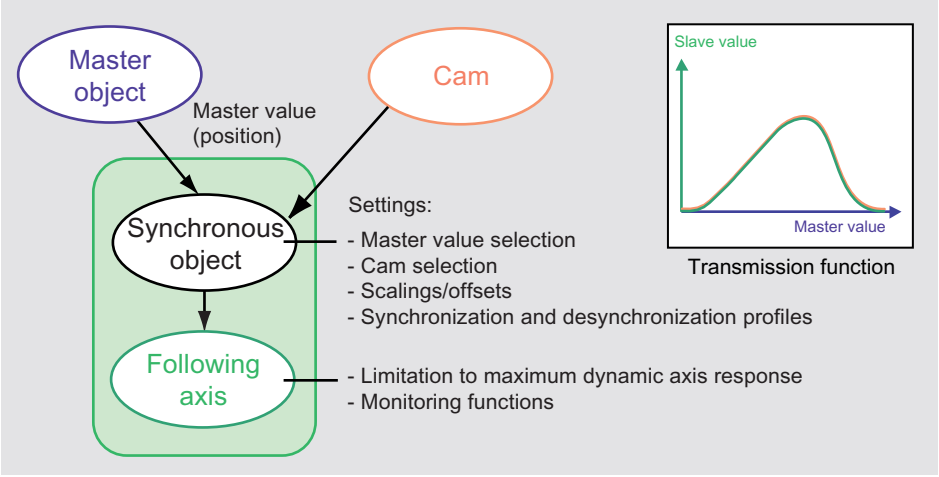

Figure 4-653 Camming

With **camming**, a non-linear transmission function between the master value position and following axis position is implemented using a **cam** .

See Cam, Definition (Page 2831)

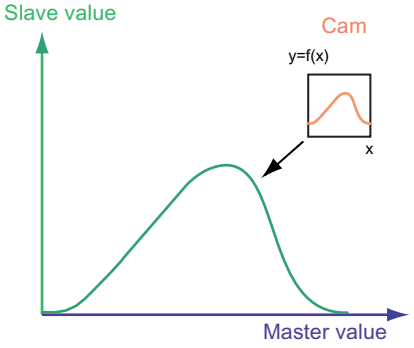

Figure 4-654 Example of transmission function for camming

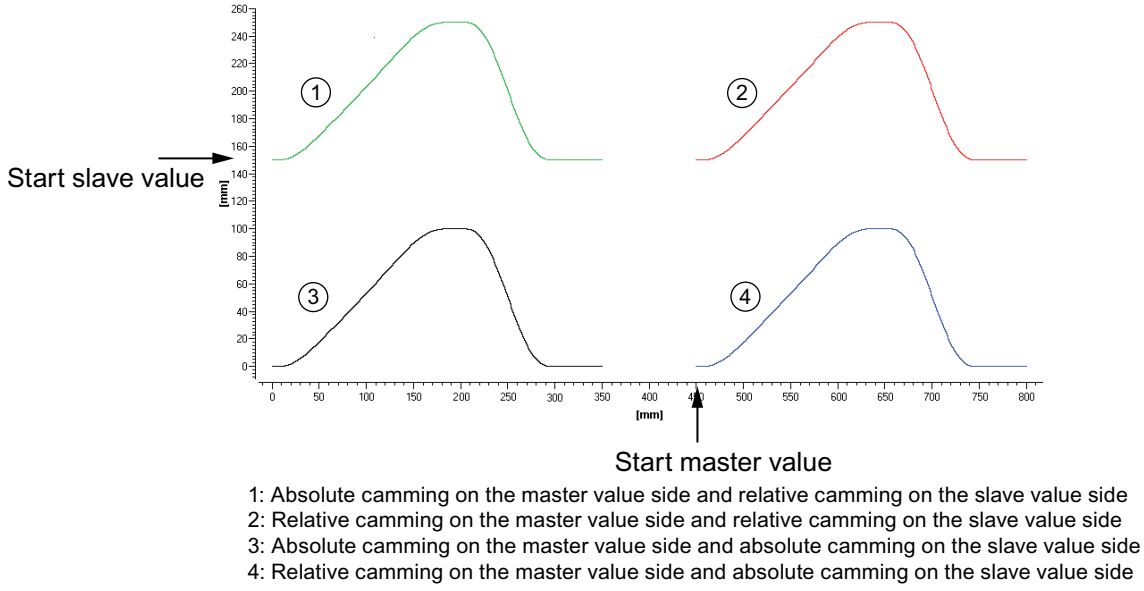
The cam can be applied as an absolute cam or as a relative cam in both the definition range (master values) and the value range (slave values). The setting is made for the master values in the masterMode parameter and for the slave values in the slaveMode parameter of the _enableCamming() command.

The figure below compares the relationship between the master value and slave value with the following supplementary conditions:

- Same cam: here, with definition range {0.0, 300.0} and value range {0.0, 100.0}
- Same initial value of following axis: here, 150 mm
- Same initial value of master value: here, 450 mm (master value is modulo value 0 to 1000 mm)



1: Absolute camming on the master value side and relative camming on the slave value side
2: Relative camming on the master value side and relative camming on the slave value side
3: Absolute camming on the master value side and absolute camming on the slave value side
4: Relative camming on the master value side and absolute camming on the slave value side

Figure 4-655 Possible combinations of absolute/relative camming on the master/slave value side

Absolute camming on the slave value side

Absolute camming on the slave value side is set in **slave Mode:=ABSOLUTE**. With absolute camming on the slave value side, the slave values are taken directly from the value range of the cam. The offset on the slave value side is equal to zero, except when the synchronization criterion **ON_MASTER_AND_SLAVE_POSITION** or **IMMEDIATELY_AND_SLAVE_POSITION** is set in the syncPositionSlave parameter, in which case an offset is specified. (Case 3 and 4 in Figure **Possible combinations of absolute/relative camming on the master/slave value side**).

Relative camming on the slave value side

Relative camming on the slave value side is set in **slaveMode:=RELATIVE**. With relative camming in slave mode, the initial value of the cam is offset to the slave value position at the start of synchronization (case 1 and 2 in Figure **Possible combinations of absolute/relative camming on the master/slave value side**).

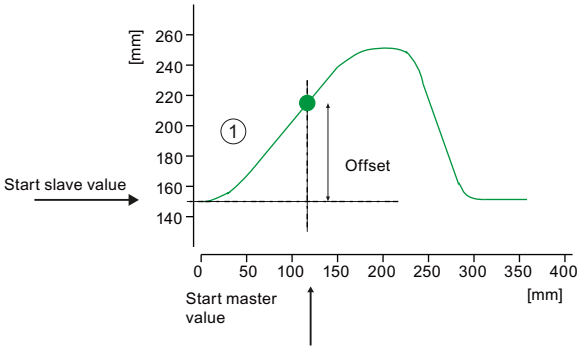
The offset on the slave value side is determined as follows:

- If programming is performed without a specified offset, the offset is determined from the offset of the cam initial value to the slave value position at the start of synchronization
- If programming is performed with a specified offset in the synchronization criterion setting **ON_MASTER_AND_SLAVE_POSITION** or **IMMEDIATELY_AND_SLAVE_POSITION**, the offset is determined from the offset of the cam initial value to the slave value position at the start of synchronization plus the offset programmed in the **syncPositionSlave** parameter.

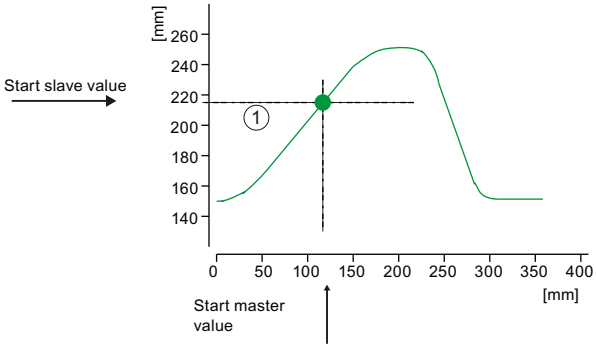
From the point at which the status becomes "synchronous", the offset on the slave value side remains constant in the transmission function.

In V4.2 and higher, there is new configuration data element **syncingMotion.camReferenceBySlaveModeRelative** with the following settings:

- Effectiveness in the case of relative camming on the slave value side and
  - on the absolute master value side with and without master value offset or
  - relative master value side with master value offset
- **BEGIN_OF_CAM** is based on the current following axis position to the initial cam value. During the synchronization, the following axis also covers the path differential between the start of the cam and the cam start value if this is not offset by a following value offset.



- **POSITION_AT_START_OF_CAMMING** is based on the current following axis position to the starting point of the synchronization within the cam. The difference between the slave-side starting point and the initial cam value does not have to be specified in the slave-value offset.



- In projects upgraded from < V4.2 to >= V4.2, the configuration data is set to **COMPATIBILITY_MODE**. This corresponds to **SYNCPOSITION_AT_START_OF_CAMMING** for synchronization at a standstill and **BEGIN_OF_CAM** with moving following axis or moving master value.
- When creating a new project as of V4.2, **syncingMotion.camReferenceBySlaveModeRelative:=BEGIN_OF_CAM** is set.

Absolute camming on the master value side

Absolute camming on the master value side is set in **masterMode:=ABSOLUTE**.
With **ABSOLUTE,** the master values are used as absolute values in the definition range of the cam.

Relative camming on the master value side

Relative camming on the master value side is set in **masterMode:=RELATIVE**. With relative camming on the master value side, the synchronization position on the master value side is assigned to the position within the cam definition range specified in the **camStartPositionMaster** parameter. The offset on the master value side is determined from the difference between the synchronization position on the master value side and the value specified in the **camStartPositionMaster** parameter.

If the position specified in **camStartPositionMaster** is not within the definition range of the cam, alarm "40017 Cam starting point is outside the definition range" is generated. From the point at which the status becomes "synchronous", the offset on the master value side remains constant in the transmission function.

Loading a new camming

A new cam is loaded by a recalling an **_enableCamming** command. Using the **synchronizingMode** parameter, the synchronization criterion is specified (e.g. at the end of the current camming with **AT_THE_END_OF_CAM_CYCLE**).

If the transition from the old cam to the new cam is already smooth, the synchronization parameters should be selected in such a way that either the synchronization length is very small for master value reference or the dynamics are very high for the forward time reference or, alternatively, use the synchronization profile with backward time reference.

Non-cyclic/cyclic cam application

The **cammingMode** parameter of the **_enableCamming()** command can be used to set the cam for either a non-cyclic application or a cyclic application.

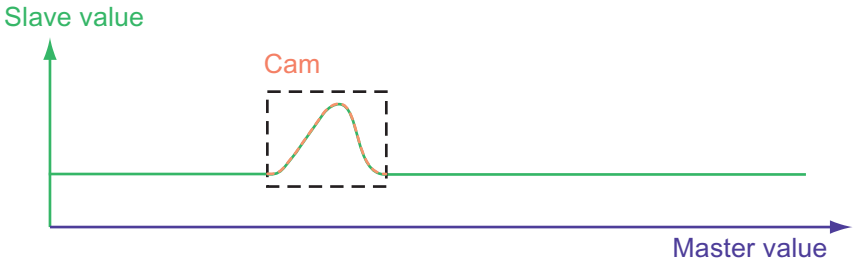


Figure 4-656 Non-cyclic cam application

- Non-cyclic (**NOCYCLIC**) means that the cam is applied exactly once in the defined master value range. When the end point or starting point of the cam is reached, the cam terminates itself.
  If the master value range is run through again either in the same direction or, after reversing, in the opposite direction, the cam is not applied again.

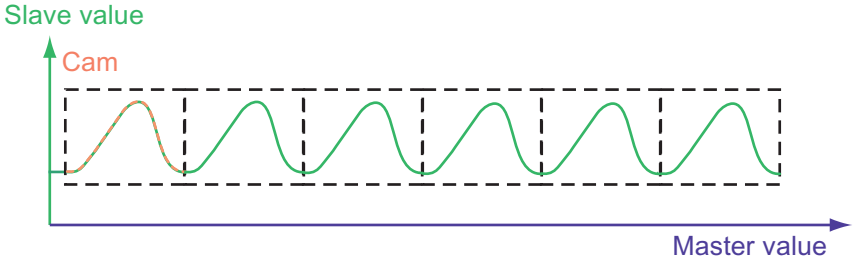

Figure 4-657 Cyclic cam application

- With the cyclic (**CYCLIC**) application of a cam, the definition range of the cam is mapped cyclically onto the master values.
  If the master values reverse, the cam is also continued cyclically beyond the original starting point.

Cyclic application of a cam with absolute synchronous operation on the slave value side

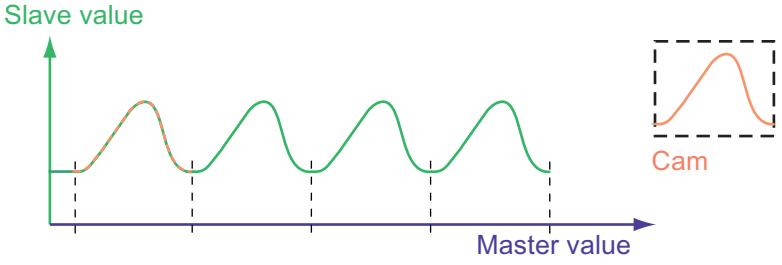

Figure 4-658 Cyclic absolute cam application with equal initial and end values on the slave value side

- If the function values of the cam are equal at the start and end of the definition range of the cam, the motion can be continued smoothly.
  This produces a periodic motion.

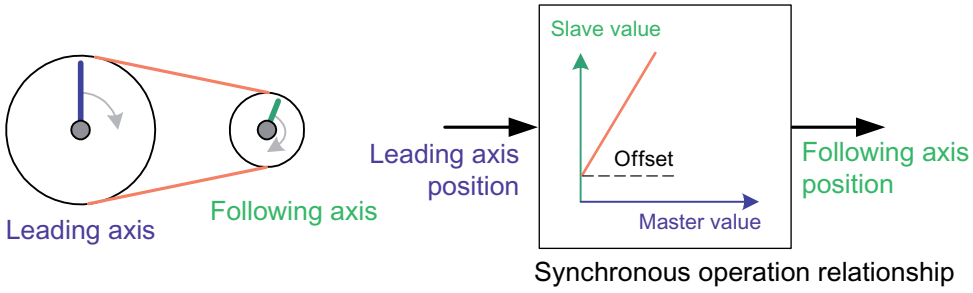

Figure 4-659 Cyclic absolute cam application with unequal start and end values on the slave value side

- If the function values of the cam are not equal at the start and end of its definition range, this results in a discontinuity in the position.
  This is limited on the following axis to the maximum dynamic values.

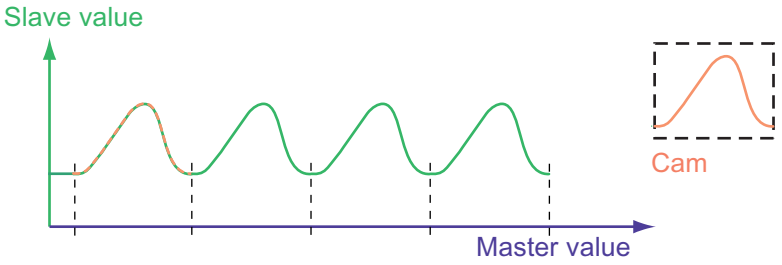

Figure 4-660 Example of cyclic cam application with identical start and end values

- If the function value of the cam is *not* identical, or equal in terms of a modulo relationship, at the start and end of its definition range, the new starting point of the cam is the end point of the executed cam.

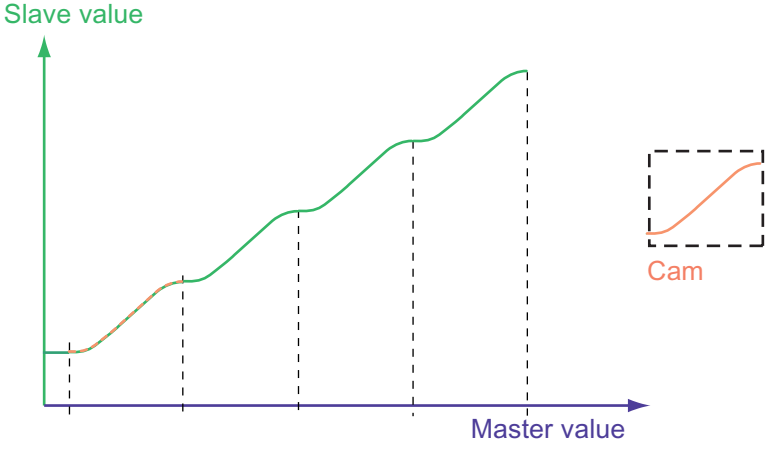

Figure 4-661 Example of cyclic cam application with different start and end values - relative

Cam direction

The **direction** parameter of the **_enableCamming** command can be used to set the cam in a positive or negative direction.

- **POSITIVE** means in the same direction. Increasing master values correspond to increasing values in the definition range of the cam, and vice versa.

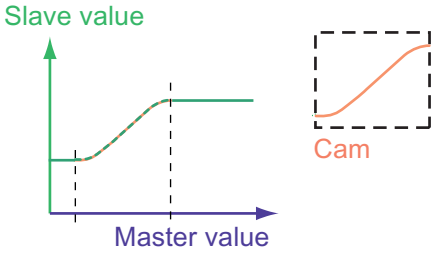

Figure 4-662 Positive cam application (POSITIVE)

- **NEGATIVE** means in the opposite direction. Decreasing master values correspond to increasing values in the cam definition range, and vice versa.
  The cam is mirrored at the center of its definition range.

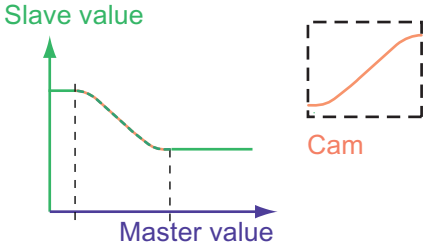

Figure 4-663 Negative cam application (NEGATIVE)

Example application:
The aim is to use the same cam for deceleration as for acceleration, but in the opposite direction.

Correction of camming motions

Synchronous motions can be corrected by changing the scaling and offset of the master value and the slave value.

Other options include:

- Offset and scaling on the cam itself
- Superimposed motions on the following axis
- On-the-fly setting of the reference point on the leading value source and the following axis

Scaling and offset

The *scaling* and *offset* can be specified on the *synchronous object* for camming on both the master value side and slave value side.

The slave value is determined from the master value using the following equation:

$$\text{Slave value} = F_{CAM}\left(\frac{\text{Master value} - \text{Offset}_{\text{master value}}}{\text{Scaling}_{\text{master value}}}\right) \bullet \text{Scaling}_{\text{slave value}} + \text{Offset}_{\text{slave value}}$$

Figure 4-664 Equation for scale and offset on the camming

See also Example of offset and scaling on the synchronous object (Page 2709)

Scaling/offset on the cam

In addition to the option of the scaling/offset on the synchronous object, a scaling/offset is also possible on the cam. This enables a cam to be custom-adjusted in its definition range and value range.

See Scaling and offset (Page 2833)

Changing the scaling and offset

The **_setCammingScale()** and **_setCammingOffset()** commands can be used to switch the scaling and offset within active, cyclic camming. The **activationMode** parameter determines when these take effect:

- For the next camming operation and all subsequent operations if **DEFAULT_VALUE** is set.
- For the current camming operation, only if **ACTUAL_VALUE** is set.
- For the current camming operation and all subsequent operations if **ACTUAL_AND_DEFAULT_VALUE** is set

Note the following:

- If synchronization of the **_enableCamming()** command is not yet active, the current scaling/offset is carried out without compensation; that is, it is included directly.
- If the **_setCammingScale()**/**_setCammingOffset()** command is programmed with new values during synchronization (using the **ACTUAL_VALUE** setting), the scaling/offset only becomes active after synchronization. A compensating movement takes place.

Effectiveness of scaling and offset

The **scaleSpecification**/**offsetSpecification** parameter of the **_setCammingScale()** or **_setCammingOffset()** command is used to program the effectiveness of a new scaling or offset procedure.

- With immediate effect (**IMMEDIATELY**)
- At the start of a new cycle for a cyclic cam application (**NEXT_CAM_CYCLE**)

Comment: If a **_setCammingScale()**/**_setCammingOffset()** command is canceled during the compensating movement due to another **_setCammingScale()**/**_setCammingOffset()** command with **NEXT_CAM_CYCLE**, compensation is canceled and a jump in the setpoints can occur. The new command is enabled at the beginning of the new cam cycle.

Examples

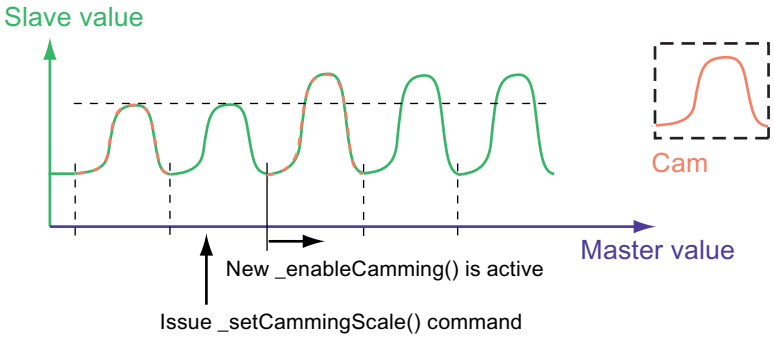

Figure 4-665 Example of switchover from scaling during cyclic synchronous operation; setting: activationMode:=DEFAULT_VALUE; effective: scaleSpecification:=NEXT_CAM_CYCLE

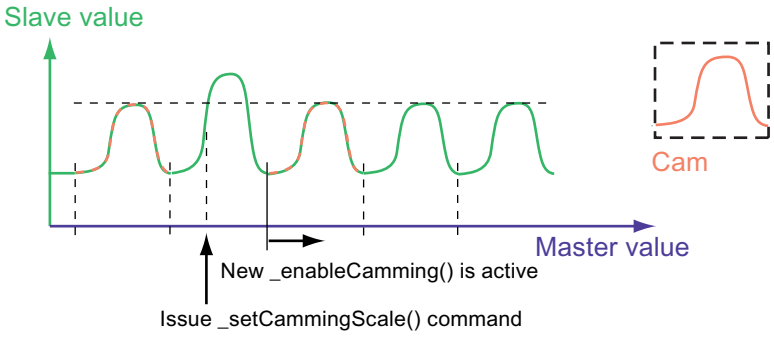

Figure 4-666 Example of switchover from scaling during cyclic synchronous operation; setting: activationMode:=ACTUAL_VALUE; effective: scaleSpecification:=IMMEDIATELY

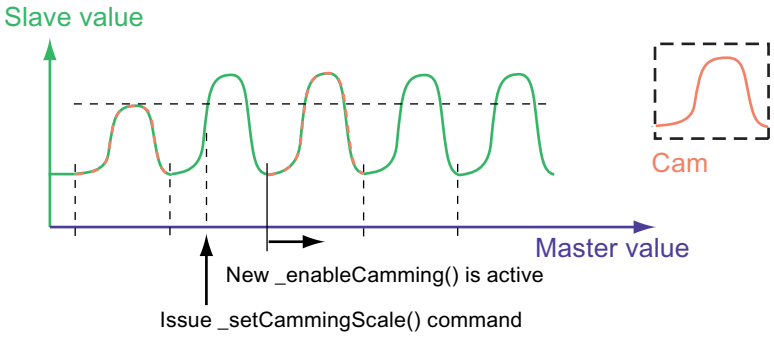

Figure 4-667 Example of switchover of scaling and offset during cyclic synchronous operation, ACTUAL_AND_DEFAULT_VALUE setting with effectiveness IMMEDIATELY

Applying scaling/offset as superimposition

The **dynamicReference** parameter of the **_setCammingScale()** or **_setCammingOffset()** command can be used to specify whether the dynamic parameters refer to the total motion or the motion difference (V3.2 and higher).

See **Apply offset as superimposition** at Gearing (Page 2631).

See also

Display of the synchronous position (Page 2673)

Setpoint/actual value coupling

Overview

When an axis is used as a master value object, the following can be configured for the synchronous operation:

- **Setpoint coupling**: The setpoint of the axis is used as the master value for the following axis. This is advantageous if the control specifies the setpoints for both the master axis and following axis, and the axes are to behave synchronously in relation to one another. In general, setpoint coupling is recommended for purposes of signal quality.
- **Actual value coupling with extrapolation** (V3.0 and higher): The actual value of an axis is used as the master value for the following axis.
  The actual value can be extrapolated in order to compensate for delays caused by actual value acquisition, actual/master value processing in the control, and the dynamic follow-up response of the following axis. Since the actual values are equal to the setpoints for the virtual axis, an extrapolated setpoint can be set.

When an external encoder is used as a master value object, the following can be configured for the synchronous operation:

- **Actual value coupling**: The actual value of an external encoder is used as the master value for the following axis.
- **Actual value coupling with extrapolation** (V3.0 and higher): The actual value can be extrapolated in order to compensate for delay times caused by actual value acquisition, actual/master value processing in the control, and the dynamic follow-up response of the following axis.

A tolerance window with respect to the actual value behavior can be specified for the actual value coupling.

Note

If the actual values/setpoints are required to be equal during a synchronous operation, the same Ti (actual value acquisition)/To (setpoint acceptance) times must be adopted for all drive units used (e.g. SINAMICS_Integrated, CU320).

See also

Actual value coupling with tolerance window (Page 2651)

Actual value coupling with extrapolation

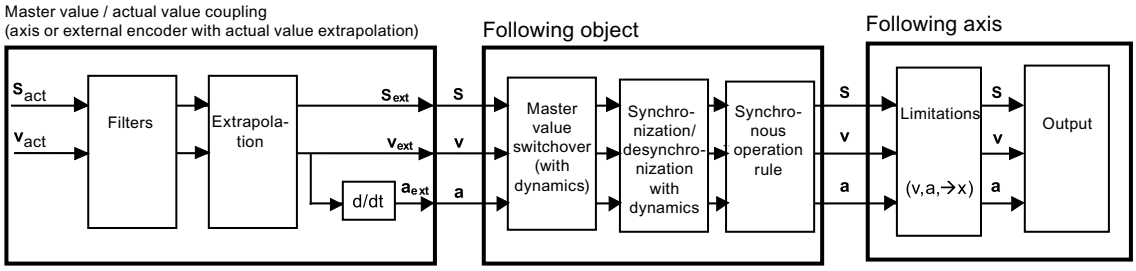

Figure 4-668 Principle of actual value coupling (overview)

For a synchronized group with actual value coupling (e.g. master value is the actual encoder value of an axis or an external encoder), the associated principle means delay times result because of bus communication, system cycle clocks and clock-pulse scaling, fine interpolation, position setpoint filters, and controller settings. These times can be compensated for using an extrapolation.

Extrapolation means you know the history and are looking into the future (extrapolation time).

The extrapolation time should be as short as possible for dynamic master value changes. An IPO : Servo pulse duty factor of 1:1 is good.

If an actual encoder value is assumed as the master value, it is useful to extrapolate the measured actual value for the synchronous operation in order to compensate for dead times that result within the system when acquiring actual values, e.g. due to bus communication and system processing times.

The extrapolation is set on the leading axis or on the external encoder.

Noisy sensor signals result in large velocity jumps which affect the extrapolation. These can be reduced or compensated by using suitable filter settings.

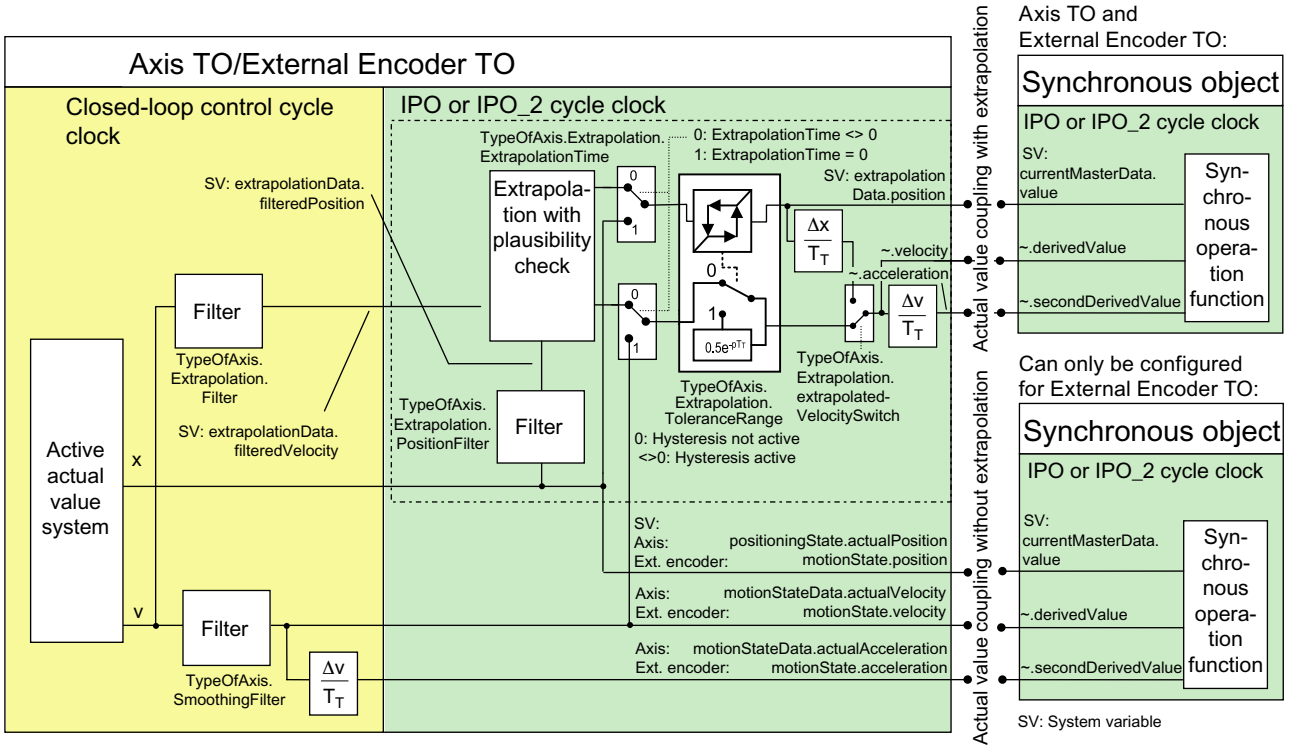

Figure 4-669 Actual value coupling with extrapolation for the Axis TO or External Encoder TO

You can find an overview of the actual value coupling with and without extrapolation in the axis configuration in the SCOUT signal flow dialog (project navigator, select Axis TO > **Signal flow > Extrapolation**).

Filtering of actual position

The actual position value for the synchronous operation can be filtered separately for the extrapolation using a PT2 filter (as of V4.1). The filter for the actual position value of the axis is set using the **typeOfAxis.extrapolation.positionFilter.T1** and **typeOfAxis.extrapolation.positionFilter.T2** configuration data. The filter acts on the actual position for the extrapolation. The velocity for the extrapolation is taken over from the actual values of the axis or External Encoder before application of the smoothing filter (**typeOfAxis.smoothingFilter**).

Filtering of actual velocity

The position is extrapolated based on the filtered or averaged velocity value.

We recommend setting the velocity filter (Extrapolation.Filter) first and then also using the position filter if the result is not satisfactory.

The position filter times are an additional factor to be taken into account in the extrapolation time.

The velocity filter (Extrapolation.Filter) does not affect the extrapolation time, but does have influence during dynamic changes to master values (due to delayed values). See also the *TO axis, Electric/hydraulic, External encoder* Manual.

- **TypeofAxis.Extrapolation.filter.timeConstant:** Time used for averaging or time constant for filtering

Extrapolation of actual velocity and actual position

These delay times can be compensated using an extrapolation.

- **TypeofAxis.Extrapolation.extrapolationTime:** Time definition for extrapolation

Extrapolation is not performed if 0.0 is specified. The extrapolated values (position and velocity) can be monitored (**extrapolationData** system variable). The extrapolation compensates for the local delays that result from use of the actual value instead of the setpoint.

Note

Extreme care must be taken when changing the extrapolation time to the runtime; otherwise knocking could result in the machine.

Note

SIMOTION contains utilities & applications which are included in the scope of delivery of SIMOTION SCOUT, a tool to assist in calculating the extrapolation times.

Switch for the velocity master value during master value extrapolation

The **TypeofAxis.Extrapolation.extrapolatedVelocitySwitch** configuration data element is used to select whether the velocity master value is generated from the extrapolated or filtered position master value using differentiation or if the extrapolated velocity master value is used.

Display

The extrapolated and filtered values are indicated in the following system variables:

- **sensorData[n].position**
- **sensorData[n].velocity**
- **sensorData[n].acceleration**

The system variables for **sensorData** are calculated in the position control cycle clock.

The actual axis value that is active for closed-loop control, the IPO cycle, and master value coupling

is displayed in the following variables:

- **positioningState.actualPosition**
- **motionStateData.actualVelocity**
- **motionStateData.actualAcceleration**

The system variables for **positioningState** and **motionState** are calculated in the IPO cycle.

These actual values are the reference for the output cam calculation in the IPO cycle, for the

actual value connection with the external encoder without extrapolation, for the actual value reference in the IPO cycle,

e.g. for profiles relating to actual position.

Reduction in reaction times/dead times

The **Execution.executionLevel:=SERVO** setting on the master value object, e.g. External Encoder technology object, can be configured in the Synchronous Object technology object and Following Axis technology object to enable execution of the IPO system component of the master value, synchronous operation, and axis in the Servo following actual value acquisition.

For further information, refer to the **Motion Control Technology Objects Axis Electric/ Hydraulic, External Encoder** Function Manual, "Motion execution/interpolator".

Transferring the actual velocity from the drive (V4.2 and higher)

With the
setting
typeOfAxis.numberOfEncoders.encoder_n.encoderValueType:=POSITION_AND_PROFIDRIVE_NIST_B, you have the option of converting the speed of rotation transferred in **PROFIdrive NIST_B** to a velocity and applying this value as the actual velocity of the encoder/sensor. In this case, the actual position of the sensor does not need to be differentiated to derive the actual velocity.

With the setting **typeofAxis.numberOfEncoders.encoder_n.encoderValueType:= POSITION_AND_DIRECT_NIST**, a speed of rotation transferred in the I/O area and normalized as NIST_B is taken as the actual value and converted to an actual velocity. In this case, 4000H corresponds to 100%. The address is set in **typeofAxis.numberOfEncoders.encoder_n.sensorNist.logAddress**, and the reference value is set in **typeofAxis.numberOfEncoders.encoder_n.sensorNist.referenceValue**. With encoders with nact evaluation, the speed determined by the encoder and the resulting velocity can be accepted by the encoder. In this case, the actual position of the sensor does not need to be differentiated to derive the actual velocity. Two methods of transmission are available:

- Transmission in the PROFIdrive message frame
- Transmission in the I/O area

See also *section Actual value acquisition / Actual value system in the Manual TO Axis electric/ hydraulic, External Encoder*.

Actual value coupling with tolerance window

If the master value is superimposed with high-frequency noise signals that cannot be followed by the synchronous operation, this can cause the dynamic response boundaries to be exceeded or the master value to briefly change directions during synchronization.

In the **typeOfAxis.extrapolation.toleranceRange** configuration data element *on the master axis* or external encoder, a tolerance window can be set around the actual position (V3.1 and higher), to prevent, for example, the dynamic limits from being exceeded on the following axis in the case of a master value with high-frequency disturbances, or direction changes during synchronization.

Synchronization

In order for the following axis to follow the master value according to the transmission function, the following axis must first be synchronized to the master value.

The type of synchronization is determined from several assignable parameters/settings:

- The **synchronization criterion/synchronization position**, which corresponds to the setting specified in the **synchronizingMode** parameter; the synchronization position on the master value side and/or the synchronization position on the slave value side are directly specified here or are derived from the synchronization criterion and, if necessary, the transmission function
- The **synchronization direction**, the motion direction of the slave values during synchronization; can be set in the **synchronizingDirection** parameter
- **Position of synchronization range relative to synchronization position:** Leading, trailing, or symmetrical synchronization; can be set in the **syncPositionReference** parameter
- the **reference of the synchronization profile**; can be set in the **syncProfileReference**
  - **Synchronization over a specifiable master value distance**
    The synchronization length over the master value is specified in the synchronization command.
  - **Synchronization profile via specifiable dynamic response parameters (time reference)**
    The dynamic response parameters are specified in the synchronization command.

Properties of different synchronization options

Synchronization criterion

Synchronization criterion/synchronization position

The **synchronization criterion** can be set for synchronization using the synchronizingMode parameter of the **_enableGearing()**/**_enableCamming()** or **_disableGearing()**/ **_disableCamming()** command as outlined below. Synchronization can be performed over several modulo ranges of the master value or slave value.

Synchronization on current master value position without specification of an offset on the slave value side

The current master value position is the synchronization criterion and the synchronization position on the master value side. The synchronization criterion is set with **synchronizingMode:=IMMEDIATELY**. The **syncPositionMaster** parameter is not active. An offset on the slave value side is not specified, and the **syncPositionSlave** parameter is not active. With relative camming on the master value side, the **camStartPosition** parameter is active. Synchronization starts immediately. Synchronization occurs subsequently.
The **syncPositionReference** parameter is not active.

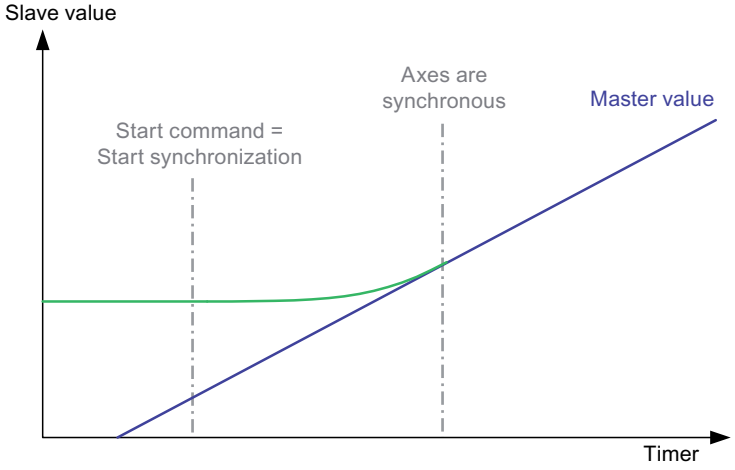

Figure 4-671 Example of synchronization - immediately active, trailing synchronization, absolute without offset, ratio 1:1

Synchronization on current master value position with specification of an offset on the slave value side

The current master value position is the synchronization criterion, and an offset on the slave value side is specified. The synchronization criterion is set with **synchronizingMode:=IMMEDIATELY_AND_SLAVE_POSITION**. The synchronization position on the master value side is the current master value position. The **syncPositionMaster** parameter is not active. The offset on the slave value side is specified in the **syncPositionSlave** parameter. With relative camming on the master value side, the **camStartPosition** parameter is active. Synchronization starts immediately. Synchronization occurs subsequently.
The **syncPositionReference** parameter is not active.

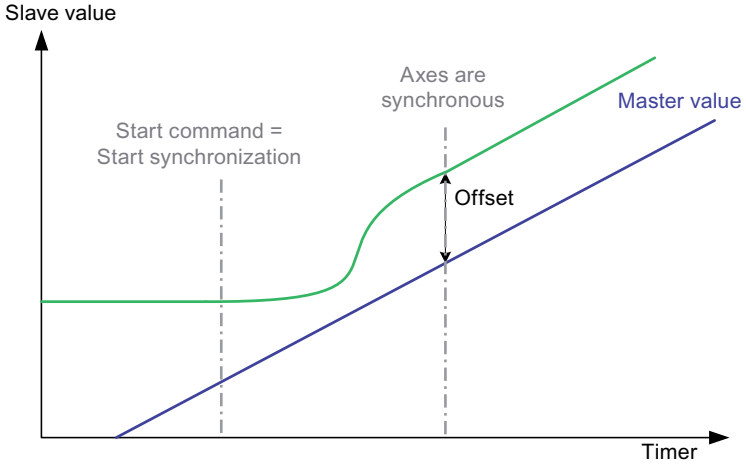

Figure 4-672 Example of synchronization - immediately active, trailing synchronization, absolute and offset on following axis position, ratio 1:1

Synchronization on specified master value position without specification of an offset on the slave value side

The specified master value position is the synchronization criterion. The synchronization criterion is set with **synchronizingMode:=ON_MASTER_POSITION**. The synchronization position on the master value side is set in the **syncPositionMaster** parameter. An offset on the slave value side is not specified, and the **syncPositionSlave** parameter is not active. With relative camming on the master value side, the **camStartPosition** parameter is active.
The **syncPositionReference** parameter specifies whether to activate leading, symmetrical (only for synchronization via a specifiable master value distance), or trailing synchronization.

Regarding the start of synchronization, see Position of synchronization range relative to synchronization position (Page 2660).

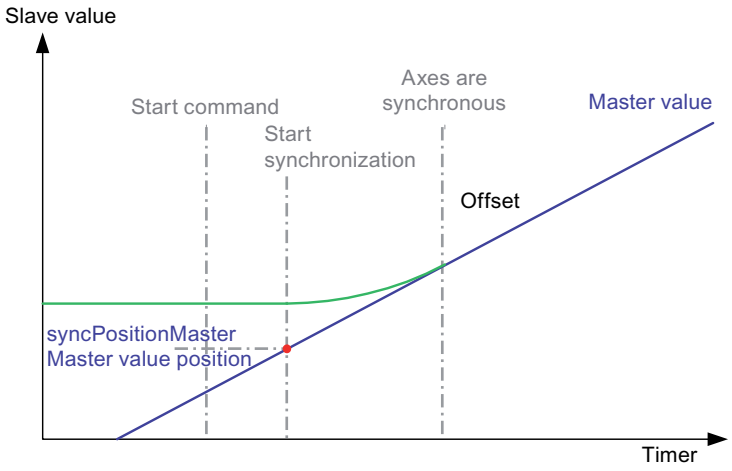

Figure 4-673 Example of synchronization - specification of master value synchronization position, trailing synchronization, absolute, ratio 1:1

Synchronization on specified master value position with specification of an offset on the slave value side

The specified master value position is the synchronization criterion. The synchronization criterion is set with **synchronizingMode:=ON_MASTER_AND_SLAVE_POSITION**. The synchronization position on the master value side is set in the **syncPositionMaster** parameter. With relative camming on the master value side, the **camStartPosition** parameter is active. The offset on the slave value side is specified in the **syncPositionSlave** parameter.
The **syncPositionReference** parameter specifies whether to activate leading, symmetrical (only for synchronization via a specifiable master value distance), or trailing synchronization.

Regarding the start of synchronization, see Position of synchronization range relative to synchronization position (Page 2660).

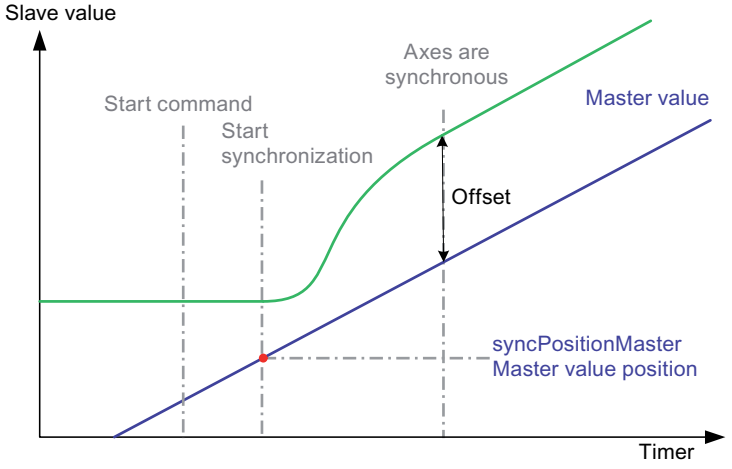

Figure 4-674 Example of synchronization - specification of master value synchronization position and following axis offset, trailing synchronization, absolute, ratio 1:1

Synchronization on the specified following axis position

The specified following axis position is the synchronization criterion. The synchronization criterion is set with **synchronizingMode:=ON_SLAVE_POSITION**. The synchronization position on the slave value side is specified in the **syncPositionSlave** parameter. An offset on the slave value side cannot be specified. The synchronization position on the master value side is determined from the application of the inverse transmission function to the synchronization position on the slave value side. With relative camming on the master value side, the **camStartPosition** parameter is active. The **syncPositionMaster** parameter is not active. Synchronization starts if the synchronization position specified in the **syncPositionSlave** parameter is reached on the following axis as a result of a motion initiated elsewhere.

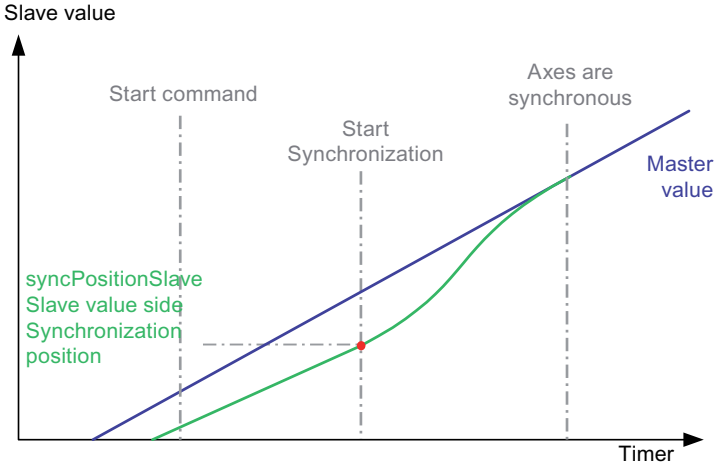

Figure 4-675 Example of synchronization - specification of following axis synchronization position, trailing synchronization, absolute, ratio 1:1

Synchronization at the end of the current camming cycle

The master value position at the end of the current camming cycle is the synchronization criterion. This setting can only be assigned in conjunction with relative camming on the master value side and already active camming. The synchronization criterion is set with **synchronizingMode:=AT_THE_END_OF_CAM_CYCLE**. The synchronization position on the master value side is the master value position at the end of the current camming cycle. The **syncPositionMaster** parameter is not active. With relative camming on the master value side, the **camStartPosition** parameter is active. An offset on the slave value side cannot be specified, and the **syncPositionSlave** parameter is not active. The **syncPositionReference** parameter specifies whether to activate leading, symmetrical (only for synchronization via a specifiable master value distance), or trailing synchronization.

Synchronization direction

The **synchronizingDirection** parameter of the synchronous operation commands can be used to specify the direction of the motion for synchronization. If a specific synchronization direction is specified, the synchronization motion is in this direction only.

The synchronization direction of the following axis in the synchronization phase can be specified with the **synchronizingDirection** parameter in the **_enableGearing(), _disableGearing(), _enableCamming()**, and **_disableCamming()** commands (V3.1 and

higher). This function is relevant, for example, for axes, for which synchronization is possible in both directions.

For information on axes with backstop, refer to the **Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder** Function Manual, "Manipulated variable limitation (backstop)"

Synchronization with direction of specification can be set as follows:

- **Maintain present system behavior (SYSTEM_DEFINED):**
  This corresponds to the **shortest path** setting, however the direction of motion is maintained for the axis motion.
- **Maintain direction of the following axis (SAME_DIRECTION):**
  The current direction of following axis motion is maintained during the synchronization phase.
  - The direction of following axis motion is maintained during synchronization when the master value is at a standstill.
  - The synchronization occurs in the positive direction during synchronization at both the master value standstill and the following axis standstill.
- **POSITIVE_DIRECTION** setting: A **positive** synchronization direction is defined.
- **NEGATIVE_DIRECTION** setting: A **negative** synchronization direction is defined.
- **SHORTEST_WAY** setting: Synchronize to the **shortest way**, regardless of which direction of motion ensues in the synchronization phase.
  With this setting, however, a direction reversal could occur during synchronization.

Position of synchronization range relative to synchronization position

The position of the synchronization range relative to the synchronization position can be set with the **syncPositionReference** parameter of the **_enableGearing()** or **_enableCamming()** command:

- Synchronize before the specified synchronization position: **Leading synchronization (syncPositionReference:=BE_SYNCHRONOUS_AT_POSITION)**
  - The end point of the synchronization is specified via the synchronization criterion.
  - The starting point of synchronization is determined for synchronization via a specifiable master value distance, on the basis of the specified synchronization length, and is calculated with reference to the dynamic response parameters of the system in accordance with the specified dynamic values and the master value behavior.
- Synchronize starting from the specified synchronization position: **Trailing synchronization (syncPositionReference:=SYNCHRONIZE_WHEN_POSITION_REACHED)**
  - The starting point of synchronization is specified directly or implicitly (by means of the following axis position).
  - The end point of the synchronization is calculated for synchronization via a specifiable master value distance from the specified synchronization length and is calculated with reference to the dynamic response parameters of the system according to the dynamic response parameters and the master value behavior.
- Symmetrically relative to the specified synchronization position **(syncPositionReference:=SYNCHRONIZE_SYMMETRIC)**
  - With synchronization via a specifiable master value distance, the starting point and end point of synchronization are determined on the basis of the master value positions, in accordance with the specified synchronization length.
  - Synchronization with the SYNCHRONIZE_SYMMETRIC specification is not possible with a synchronization profile using specifiable dynamic response parameters (RELATE_SYNC_PROFILE_TO_TIME). This command is rejected with TO alarm "30001: illegal parameter".

Synchronization starts under the following conditions:

- With trailing synchronization: When the synchronization position on the master value side or slave value side is reached.
- With symmetrical synchronization: When the master value has reached the synchronization position, reduced by half the synchronization length in the master value direction of motion Master value>= synchronization position (synchronization length in direction of motion of master value/2).
- With leading synchronization: When the synchronization position on the master value side is reached, reduced by the synchronization length in the direction of motion.

Note the following:

- With trailing synchronization and absolute synchronous operation, the following axis distance to be traveled according to the transmission function based on the progress of the master value must be applied too. For this reason, leading synchronization should be used whenever possible.
- With synchronization criterion **synchronizingMode:=IMMEDIATELY** or **IMMEDIATELY_AND_SLAVE_POSITION**, trailing synchronization is implicitly present.

Synchronization via a specifiable master value distance

With synchronization via a specifiable master value distance, a synchronization profile is calculated from a specifiable path length of the master value and is applied relative to the master value.

The setting is made with the **syncProfileReference:= RELATE_SYNC_PROFILE_TO_LEADING_VALUE parameter.**

The path length of the master value is specified in the parameter **syncLength.** As a result, synchronism is always achieved in the setpoint specification. The dynamic response during synchronization is dependent on the calculated profile via the master value and on the change in the master value. The dynamic response values specified in the command are not active.

Synchronization length

The synchronization operation takes place as long as the master value is within this defined length. No dynamic response values are taken into account. The profile is calculated as a function of the master value velocity. (See **Synchronization profile type**)

The **synchronization range** is specified using the synchronization length of the master value defined in the **syncLength** parameter of the **_enableGearing()** or **_enableCamming()** commands.

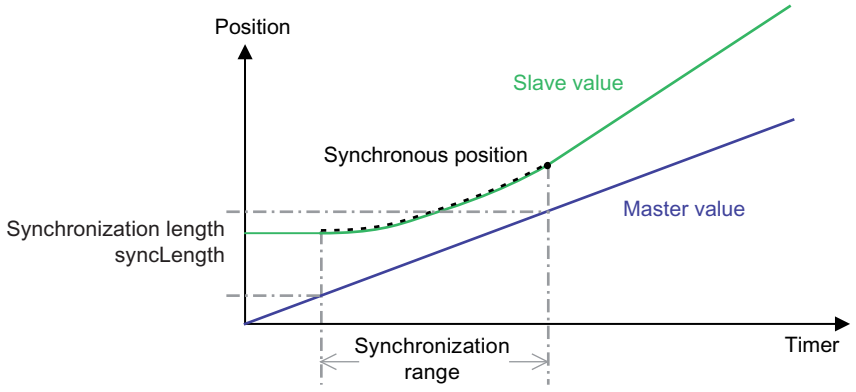

Figure 4-676 Synchronization length for synchronization via a specifiable master value distance

The "synchronous" status is set immediately if the master value source and following axis are at a standstill and the synchronization criterion has already been fulfilled. In this case, the message "50006 Activation/deactivation of synchronous operation executed directly" is output.

Synchronization profile type

The synchronization profile type for synchronization with master value reference is set using the **syncingMotion.velocityMode** configuration data element:

- In the **CONTINUOUS** setting (default), the synchronization profile is calculated with a constant position and constant velocity, but not with constant acceleration.
  The slave value is synchronized using a polynomial profile and the master value. Therefore, the resulting velocity and acceleration of the following axis for synchronization are dependent on the synchronization length and the dynamic response of the master value during synchronization.
- In the **NON_CONTINUOUS** setting, the synchronization profile is calculated using the specified master value length with a constant position only in the slave value behavior. The slave value is synchronized using a linear profile and the master value.

Synchronization profile

Synchronization profile based on specifiable dynamic response parameters (time reference)

When this synchronization profile is used, a synchronization profile is calculated according to the specified dynamic response parameters and the master value dynamic response that exists at the start of the profile. The profile is applied *according to the master value* for leading synchronization and *according to time* for trailing synchronization.

The setting is made with the **syncProfileReference:= RELATE_SYNC_PROFILE_TO_TIME parameter.**

The dynamic response for the synchronization is specified in the dynamic response parameters for the synchronous operation commands. A velocity profile with constant velocity (**TRAPEZOIDAL**) or constant acceleration (**SMOOTH**) can be specified using the **velocityProfile** parameter. For synchronization with a synchronization profile based on dynamic response parameters and with constant acceleration, any reversing that occurs during synchronization is at zero acceleration at the reversing point.

The synchronization profile based on dynamic response parameters can be applied:

- For leading synchronization
- For trailing synchronization

Symmetrical synchronization is not possible.

See also Position of synchronization range relative to synchronization position (Page 2660), as well as section Adapt the synchronization velocity to the master value velocity (Page 2718).

Application

A synchronization profile based on dynamic response parameters is especially suited for:

- Time-optimized synchronization, according to dynamic response specifications

Adaptation to the dynamic response of the master value (leading and trailing synchronization)

If the current dynamic response variables of the master value are larger than the dynamic response parameters of the synchronization command, the parameters can be automatically adapted to the dynamic response parameters (as of V3.1).

Parameters for adapting the synchronization dynamic response to the target dynamic response can be assigned on the synchronous object under **Settings (syncingMotion.synchronizing-Adaption)**.

If dynamic response adaptation is disabled, the synchronization dynamic response is no longer adapted to the required target dynamic response. This can result in the situation where, during trailing synchronization, the synchronized axis can no longer synchronize with the leading axis. During leading synchronization, the synchronization motion may not be started under certain circumstances.

Overdrive factor

The permissible magnification of the specified dynamic response values for making up a constant path difference is specified using the magnification factor **(syncingMotion.overdriveFactor)** under **Settings**. The magnification factor relates to the dynamic response of the master value. At 100% magnification, the dynamic response of the synchronization is adapted to the current dynamic response of the master value, taking into account the transmission. When **overDriveFactor** > 100% is set and has taken effect, the "synchronous" status can also be established if the master value is in the acceleration or deceleration phase during synchronization.

If an overshoot occurs, alarm 40012 "Dynamic limitations (type: ...) are violated" is output at the synchronous object.

Application

If a low synchronization velocity is selected on the command, the adaptation is set, and a corresponding overshoot factor is selected, the synchronization velocity of the following axis is adapted to the master value velocity.

Direction-dependent dynamic response

Direction-dependent or direction-independent effectiveness of the programmed dynamic response values can be set with **syncingMotion.directionDynamic**.

See **Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder** Function Manual, "Dynamic limits"

Leading synchronization with synchronization profile based on dynamic response parameters

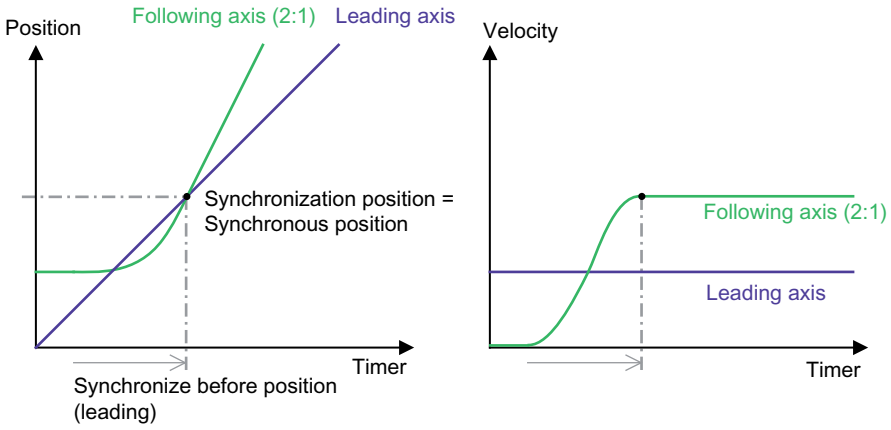

Figure 4-677 Example of leading synchronization (gearing with 2:1 gear ratio, synchronize following axis from standstill)

Only with a synchronization profile based on specifiable dynamic response parameters is a synchronization profile calculated for leading synchronization, taking into account the current master value velocity, the current position, and the dynamic response of the following axis, as well as the dynamic values for synchronization specified in the command. The synchronization profile is then traversed relative to the master value. In addition, if the master value dynamic response changes, the synchronization profile is not recalculated. For this reason, a change in the master value velocity can be seen superimposed in the synchronization operation.

In addition, with the **Extended Look ahead** setting, the acceleration of the master value in the synchronization profile is not taken into account.

Start of synchronization

The synchronization operation starts:

- At the time calculated by the system from which the specified dynamic response parameters can be optimally synchronized with respect to time at a constant master value velocity
- Immediately, if it is not possible to calculate an optimum synchronization time and the synchronization position can be reached (with static master value, for example)

Application

Leading synchronization is appropriate in the following cases:

- If there is to be synchronism at the specified synchronous position and the synchronous position can be easily specified from the application, taking into account the required synchronization operation.
- If dynamic response changes for the master value can be expected during synchronization and are taken into account in the synchronization profile but are not to be reinforced through extrapolation.

Comments

- The programmed velocity profile (SMOOTH, TRAPEZOID) is applied.
- The **syncingMotion.smoothAbsoluteSynchronization** configuration data element is not relevant for leading synchronization.
- Synchronization with extended look-ahead is not active with leading synchronization.
- With leading synchronization, the current master value velocity, and the resulting synchronization profile, if there is insufficient time for synchronization before the master value reaches the synchronization position, synchronization does not occur. The status can be read out via system variables.
  Exception: Modulo master value; in this case, the next possible synchronization position is awaited.

Trailing synchronization with synchronization profile based on dynamic response parameters

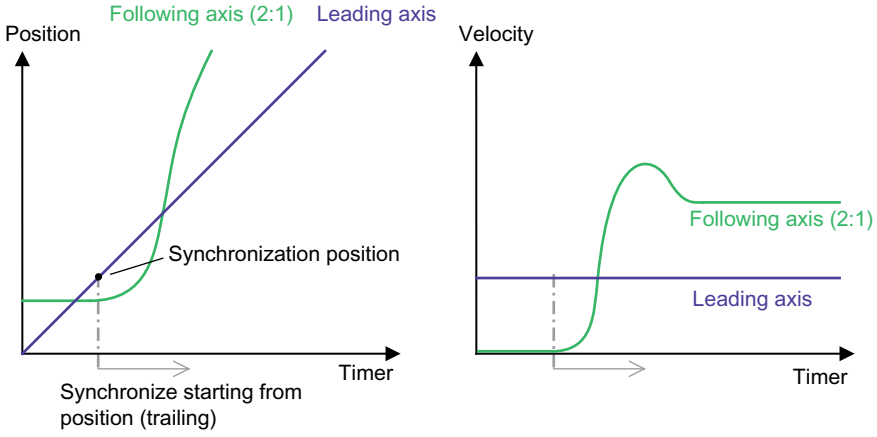

Figure 4-678 Example of trailing synchronization (gearing with 2:1 gear ratio, synchronize following axis from standstill)

With trailing synchronization, the synchronization operation starts when the synchronization criterion is reached. Taking into account the current master value velocity and the specified dynamic response values, the system calculates and executes a time-related synchronization profile such that synchronization is achieved as fast as possible. When calculating the synchronization profile, the current master value acceleration is only taken into account in cases where extended look-ahead is specified.

Changes of the master value for the synchronization are directly taken into account.

Application

Trailing synchronization is appropriate in the following cases:

- When the current master value position must be used directly as the synchronization position.
- When no dynamic response changes of the master value during synchronization are expected.
- When other reasons dictate that synchronization can take place only after the synchronization position.
  Depending on the position of the slave value at the synchronous position, large dynamic movements of the slave value may occur since, in order to comply with the dynamic limits and taking into account the master value dynamic response, the following must occur:
  - Synchronism must be achieved
  - If there are dynamic response changes to the master value, the (anticipated) position changes to the master value must be made up for.

Comments

Trailing synchronization is not suitable for non-constant velocity and acceleration of the master value (i.e. if the acceleration/deceleration changes continually).

Smooth synchronization

Absolute trailing synchronization with consideration of jerk

The **syncingMotion.smoothAbsoluteSynchronization** configuration data element can be used to specify whether a smooth velocity profile is supported during the succeeding synchronization (as of V3.2).

Synchronization is not calculated subject to changes in the master value velocity.

- Provision for jerk during absolute synchronization can be made by setting **syncingMotion.smoothAbsoluteSynchronization:= YES**.
- A setting of **NO** means that jerk will not be taken into account during absolute synchronization, even with velocity profile **SMOOTH**.

Trailing synchronization with extended look ahead

The synchronization with extended look-ahead allows a constant acceleration/deceleration of the master value to be used during the synchronization.

- With synchronization with **standard look ahead**, the position and the velocity are included in the synchronization calculation.
- For synchronization with **extended look-ahead**, the current values of the master axis for position, velocity and acceleration/deceleration are used to calculate the synchronization distance of the following axis (as of V3.2).
  Any changes to the acceleration of the master axis during the synchronization action are ignored and can cause a longer synchronization distance than for synchronization with standard look-ahead.
- During the braking phase of the master synchronization, it can occur that the synchronization process is terminated only after the braking phase of the master. In this case, synchronization without **extended look-ahead**, i.e. in **Standard** mode, can be executed. It can nevertheless occur that the following axis becomes synchronous only after the braking phase.

The function can be activated via the **synchronizingWithLookAhead** parameter of the **_enableGearing()** command.

Extended look-ahead can be preset on the synchronous object via system variable **.gearingSettings.synchronizingWithLookAhead** (as of V4.0).

Position of synchronization range relative to synchronization position (Page 2660)

Settings for evaluation of the master value behavior during synchronization

Toleration of a master value reversal during synchronization:

During synchronization, when the direction of the master value is reversed, the synchronization process is canceled with error message 50007 output at the synchronous object.

If the direction reversal is based on tolerable and predominantly non-influenceable master value fluctuations during downtime, as they occur in the case of an actual value coupling (so-called actual value "noise") or primary extrapolation of the master value, cancelation of synchronization can be prevented by specifying a tolerance band for the master value reversal (master value hysteresis) (as of V4.0).

The maximum master value fluctuation to be tolerated by the system is to be parameterized in the configuration data **syncingMotion.masterReversionTolerance** in the master value positioning unit. An effective hysteresis at a value greater than 0 freezes the master value in the reversal point during direction reversal and thus simulates a still-standing master value for synchronization.

The master value tolerance continuously acts on the active or soon-to-be active master value (see master value switching), beginning with activation of the master value and the hysteresis.

Note

When a master value tolerance > 0 is specified, the system is permitted to immediately offset the following axis change corresponding to one of these master value variables, with maximum dynamics on the following axis, e.g. during use in connection with time-related synchronization. During this process, the current effective coupling factor must also be taken into account.

The variable of the master value tolerance should therefore be selected at as low a level as possible and should be immediately oriented toward the measured fluctuations of the actual value or the extrapolation error.

The effective hysteresis, and thus also an existing reversal point, can be reset by setting the master value tolerance to the value 0. The change, in the same way as setting the tolerance to a value greater than 0, immediately becomes active.

Effective direction of the hysteresis

The effective direction of the hysteresis is automatically determined by the system and is maintained by the permanent functionality that is also outside of synchronization.

As of V4.4, you can specify the effective direction of the master value via the configuration data item **syncingMotion.toleranceDirection**.

- **BOTH_DIRECTIONS** (default)
- **POSITIVE**. The effective direction of the tolerance band is positive. The tolerance band is effective in the positive direction for a master motion, i.e. the hysteresis function takes effect when the master moves from a positive to a negative direction, but not vice versa.
- **NEGATIVE**. The effective direction of the tolerance band is negative. The tolerance band is effective in the negative direction for a master motion, i.e. the hysteresis function takes effect when the master moves from a negative to a positive direction, but not vice versa.

No synchronized status while master value in the hysteresis

As of V4.4 there is a configuration data item **syncingMotion.enableSyncWithinTolerance** with which the reaching of the **synchronized** status is retained within the hysteresis of the master value, or the new response that the **synchronized** status is only reached by the master value when it has left the hysteresis range.

You can set that synchronous operation does not go into **synchronized** status and therefore refers to the current position of the master value using the synchronous operation rule as long as the master value is in the hysteresis as a result of a change of direction. In this way, the difference that results from the synchronous operation rule and the position of the master value at the start of the hysteresis and the current position, is no longer traversed with the maximum dynamic response of the following axis.

If a master value reversal tolerance greater than zero is set for the synchronization, with

- synchronization with master value reference: relative synchronization at rest
- synchronization trailing with time reference: synchronization ends within the tolerance

an unexpected traversing motion can occur when the synchronized status is reached, because the difference resulting from the synchronous operation slave value at the start of the hysteresis and from the synchronous operation slave value for the current master value position is traversed immediately with the maximum dynamic response of the following axis when the **synchronized** status is reached.

Example of switchover in the hysteresis:

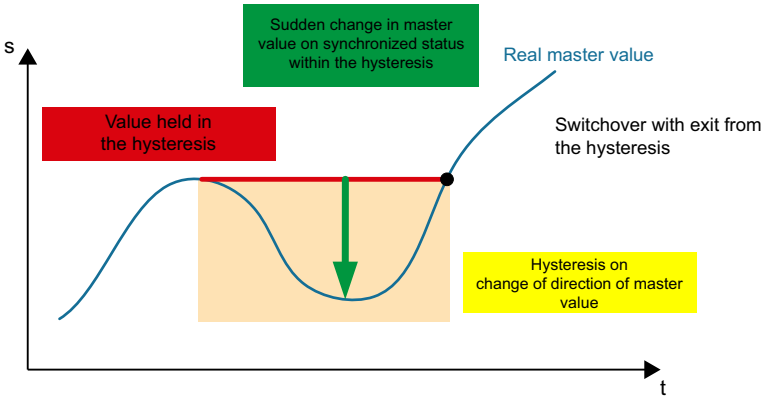

Figure 4-679 Switchover in the hysteresis

To prevent that, as of V4.4 there is a configuration data item **syncingMotion.enableSyncWithinTolerance**.

- **Synchronized status also in hysteresis**
  With the setting **syncingMotion.enableSyncWithinTolerance = YES** (system default setting, compatibility setting), the **synchronized** status can also be reached by the master value within the hysteresis.
- **No synchronized status in hysteresis**
  With the setting **syncingMotion.enableSyncWithinTolerance = NO** (system setting when creating a new synchronous axis), the **synchronized** status is not set for the master value in the hysteresis range.

Toleration of master value velocity changes during synchronization:

The tolerance of the velocity changes of the master value can be set in the configuration data **syncingMotion.maximumOfMasterChange** (default setting: 20%).
If, during synchronization with a synchronization profile based on the master value distance, there is a change to the master value velocity in excess of what has been parameterized in the configuration data element, an error message is output and the synchronization profile is recalculated.
If, during synchronization with a synchronization profile based on dynamic response parameters and with leading synchronization, there is a change to the master value velocity in excess of what has been set in the configuration data element, an error message is generated but the profile is not recalculated.
During synchronization with a synchronization profile based on dynamic response parameters and with trailing synchronization, the configuration data element is not active. A change to the master value velocity produces an immediate response.

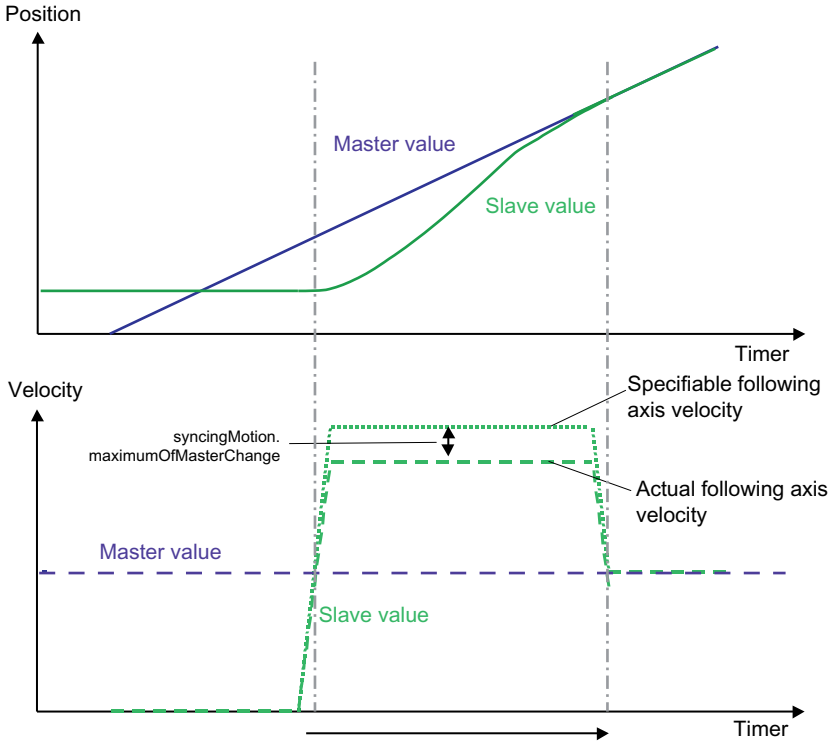

Figure 4-680 Example of syncingMotion.maximumOfMasterChange for leading synchronization with synchronization profile based on specifiable dynamic response parameters

The values of customizable dynamic parameters for synchronization profiles are initially reduced by the values defined in the **syncingMotion.maximumOfMasterChange** configuration data element. The following axis is then accelerated at reduced acceleration to the reduced velocity, in order to maintain reserves and to terminate synchronization safely at the specified synchronization position.

If the master value velocity changes, then the same changes are made to the dynamic response values of the synchronization procedure. Error message "50009 Changing the dynamic response of the master leads to a dynamic violation when synchronizing/desynchronizing" is issued if the parameterized tolerance is exceeded.

If the direction of the master value reverses during synchronization, the synchronization procedure is aborted with the "50007 Error occurred while activating/deactivating the synchronous operation" error. This does not apply for immediate synchronization or synchronization starting at a defined reference point when **syncProfileReference:=RELATE_SYNC_PROFILE_TO_TIME** with **synchronizingMode:=IMMEDIATELY** or **syncProfileReference:=RELATE_SYNC_PROFILE_TO_TIME** with **synchronizingMode:=SYNCHRONIZE_WHEN_POSITION_REACHED**.

With trailing synchronization, the **syncingMotion.maximumOfMasterChange** configuration data element is not active, i.e. responses are issued continuously.

Monitoring the synchronization

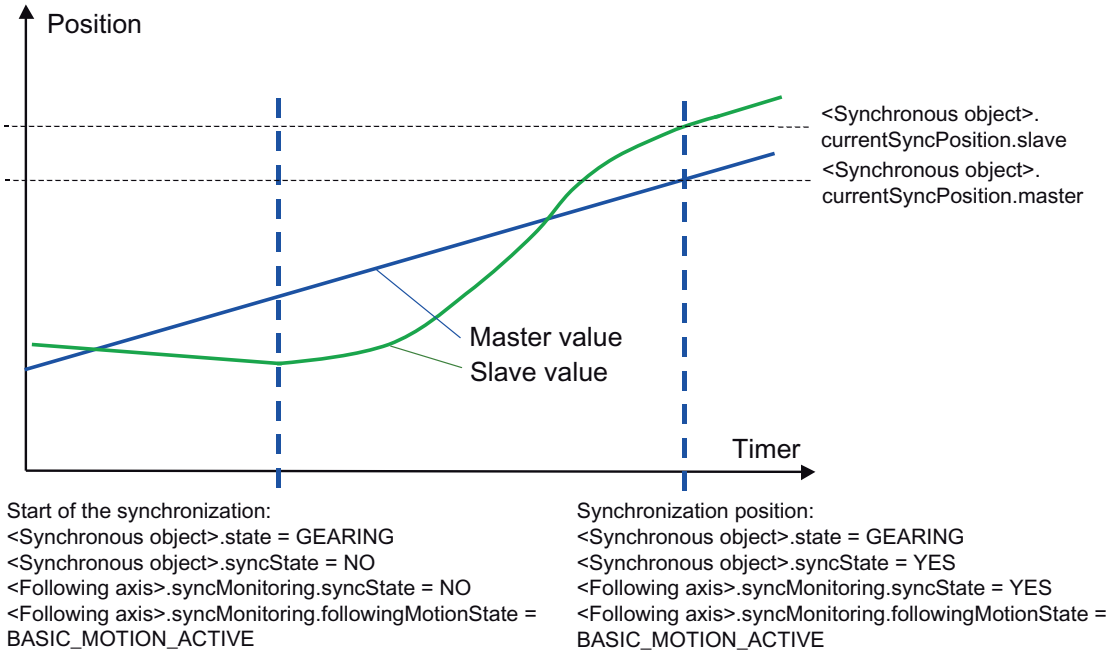

Figure 4-681 System variables for the synchronization

Synchronization state on synchronous object

- The **state** system variable on the synchronous object indicates whether a synchronous operation is active:
  - With state:=**CAMMING** a camming is active.
  - With state:=**GEARING** a gearing is active.
  - With state:=**VELOCITY_GEARING** a velocity gearing is active.
  - With state:=**INACTIVE**, no function is active on the synchronous object.
    When synchronization starts, the system variable is set to the appropriate value and reset again once synchronization is complete.
- The **syncState** system variable on the synchronous object indicates whether the slave value calculated on the synchronous object is synchronous with the master value.
  - If both the master value and slave value are synchronous, this variable will be set to the **YES** state.
    The master value pending on the synchronous object (**currentMasterData.value**) and the slave value output to the following axis (**currentSlaveData.value**) will then be synchronous.
  - The start of desynchronization or any other loss of synchronism causes the variable to be reset to the **NO** value.
    Any restrictions imposed on the slave value transferred by the following axis as a result of the limitation to the maximum dynamic values and the associated non-synchronization of the master and following axis are *not* reflected in the state of the **syncState** variable.
    For the dynamic response limits on the following axis, see Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder Function Manual, "Dynamic limits."
- The master value information on the synchronous operation object does not match the input values from the master value object 1:1, but is instead influenced by:
  - Extrapolation/interpolation for distributed synchronous operation
  - Extrapolation/interpolation through task-wide synchronous operation
  - Extrapolation/interpolation through setpoint output delays
  - Plausibility check at standstill of the master value

  Example:
  If the actual velocity adopts the value zero (because two position values are the same in succession), the filtered value is no longer taken for the actual velocity, but is instead set directly to zero. In the active synchronous operation object therefore 0 is taken for a cycle in currentMasterData.derivedValue. If the (position) setpoint change = 0, the dynamics for preventing reverse procedures are already adjusted to the position change with the setpoint calculation.
- The associated synchronization position of the master and the slave value, i.e. the position from where the master and the slave axis run synchronously are contained in the **currentSyncPosition** system variables on the synchronous object.
  See Display of the synchronization position (Page 2673).

- The state of the synchronization can be queried using the **synchronizingState** system variable on the synchronous object (as of V3.2).
  - **WAITING_FOR_SYNC_POSITION**: Waiting for master value synchronization position
  - **WAITING_FOR_CHANGE_OF_MASTER_DIRECTION**: Waiting for master value direction reversal
  - **SYNCHRONIZING_NOT_POSSIBLE**: Synchronization is not possible
  - **SYNCHRONIZING**: Synchronization in progress
  - **INACTIVE**: Synchronization phase is not active
  - **WAITING_FOR_MERGE**: Synchronization command issued, but not yet active
- The execution state of the active command for activation/deactivation is described in the **enableCommand** and **disableCommand** system variables.
  - **INACTIVE** means that no command is configured.
  - **WAITING_FOR_START** means that the command is executed during slave value generation, and that it is waiting for the start criterion for synchronization to be reached.
  - **ACTIVE** means that synchronization is active and that the operation is synchronous.
  - If there are two commands during slave value generation, both system variables can assume a value not equal to **INACTIVE**. If both are enable commands, the state of the current command is displayed (the state of the next command is always **WAITING_FOR_START**).
- The relevant active command parameter and the parameter for synchronization are grouped together and can be read out in the **effectiveData** system variable structure.

Synchronization state on following axis

- The **syncMonitoring.syncState** variable on the following axis indicates the synchronous operation state on the setpoint side.
  During synchronization and desynchronization, syncState:=NO.
- The **syncMonitoring.followingMotionState** variable on the following axis indicates the state of the synchronous motions:
  - **INACTIVE**: Synchronous motion is not active
  - **BASIC_MOTION_ACTIVE**: Synchronous operation is active as main motion
  - **SUPERIMPOSED_MOTION_ACTIVE**: Synchronous operation is active as superimposed motion
  - **BASIC_AND_SUPERIMPOSED_MOTION_ACTIVE**: Synchronous operation is active as main and superimposed motion

Display of the synchronous position

The **currentSyncPosition** system variables on the synchronous object indicate the last calculated synchronous position of a synchronous operation.

- **currentSyncPosition.master**: Synchronous position of the master value
- **currentSyncPosition.slave**: Synchronous position of the following axis

These values are valid only when "syncState = YES."

Start position of the cam on the axis

The master value and slave value at the cam start of the current camming operation are shown in system variables (V4.0 and higher). The values can also be shown when the starting point of the synchronous operation lies within the cam.

- **currentSyncPosition.camMasterMatchPosition**:
  Master value at the cam start
- **currentSyncPosition.camSlaveMatchPosition**:
  Slave value at the cam start
- **currentSyncPosition.distanceCamMasterMatchPostion**:
  Current relative position in the cam (distance to the cam start)
  Application: Calculation of the corresponding axis positions, also for camming, e.g. a desynchronization position. The axis position must be specified absolute in relation to the axis, even for relative synchronous operation.
  These system variables, can be used, for example, to determine the exact position of the cam for the axis, even for relative camming, and to specify the desynchronization position relative to the axis.

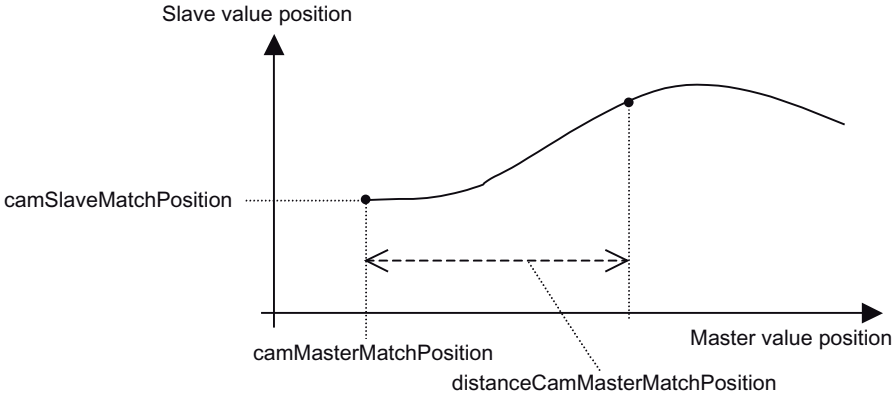

Figure 4-682 Display of the master value and slave value positions in the currentSyncPosition system variable

Position reproduction for modulo axes with gearing

The **currentSyncPosition.slavePositionAtMasterModuloStart** system variable can be used to read out the slave value position at the modulo starting point of the master value (V4.0 and higher).

- **currentSyncPosition.slavePositionAtMasterModuloStart**:
  Slave value position at the modulo starting point of the master value **currentSyncPosition.slave** will be indicated if no modulo is active at the master value.

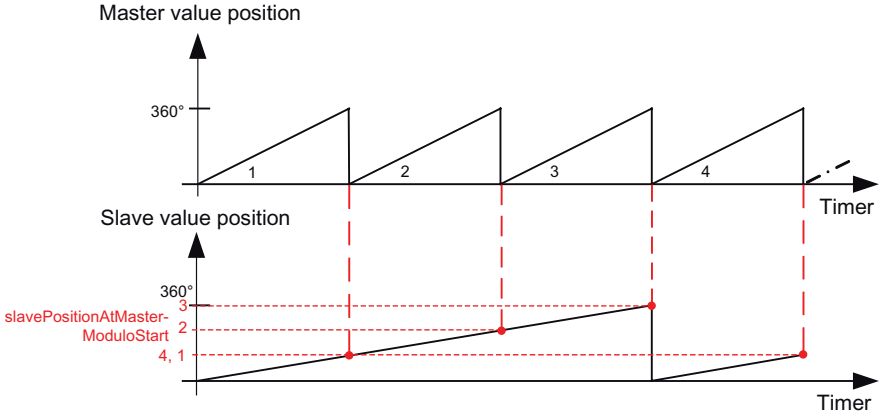

Figure 4-683 Position difference caused by a different modulo starting point

Application

For known gear ratio and known modulo lengths, the assignment of master value and slave value can be closed, even when the slave value modulo length does not correspond to the master value modulo length.

"Synchronous" status during synchronization

- With synchronization via a specifiable master value distance, the "synchronous" status is achieved at the end of the synchronization distance.
- The "synchronous" state of synchronization with a synchronization profile based on customizable dynamic response parameters and leading synchronization is achieved when the synchronization position is reached. (In this case, this is the same as the synchronous position.)
  At the synchronous point, synchronism is present in the position, velocity, and acceleration (only with **SMOOTH** velocity profile).
- With synchronization using a synchronization profile based on specifiable dynamic response parameters and with trailing synchronization, the "synchronous" status is achieved when synchronism exists in the position, velocity, and acceleration (only with profile **SMOOTH** and **syncingMotion.smoothAbsoluteSynchronization:=YES**) in accordance with the transmission function.

With relative gearing without offset, the position is not evaluated during synchronization.

Desynchronization

Desynchronization - Overview

Desynchronization refers to the termination of the synchronous operation.

The desynchronization is defined by several parameters/settings:

- **Desynchronization criterion/desynchronization position**
- **Position of synchronization range relative to desynchronization position**
- the **desynchronization profile**
  - **Desynchronization over a specifiable master value distance**
    The desynchronization length is specified in the desynchronization command.
  - **Desynchronization profile via specifiable dynamic response parameters**
    The dynamic response parameters are specified in the desynchronization command.

Desynchronization criterion/desynchronization position

The desynchronization criterion/desynchronization position is specified in **syncOffMode**.

- Desynchronization at the current master value position; immediate desynchronization
  Desynchronization at the current master value position is set in **syncOffMode:=IMMEDIATELY**. Only trailing desynchronization can occur. The setting in the **syncOffPositionReference** parameter is not active. The **syncOffPositionMaster** parameter is not active. The **syncOffPositionSlave** parameter is not active.
- Desynchronization at a specified master value position
  Desynchronization at a specifiable master value position is set in **syncOffMode:=ON_MASTER_POSITION**. The **syncOffPositionReference** parameter can be used to set leading, symmetrical (only with desynchronization via master value distance), and trailing desynchronization. The desynchronization position on the master value side is set in the **syncOffPositionMaster** parameter. The **syncOffPositionSlave** parameter is not active.
- Desynchronization at a specified slave value position
  Desynchronization at a specifiable slave value position is set in **syncOffMode:=ON_SLAVE_POSITION**. The **syncOffPositionReference** parameter can be used to set leading, symmetrical (only with desynchronization via master value distance), and trailing desynchronization. The desynchronization position on the slave value side is specified in the **syncOffPositionSlave** parameter. The **syncOffPositionMaster** parameter is not active.
- Desynchronization at the end of cam cycle
  Desynchronization at the end of the cam cycle is set in **syncOffMode:=AT_THE_END_OF_CAM_CYCLE**. The **syncOffPositionMaster** parameter is not active. The **syncOffPositionSlave** parameter is not active.

Desynchronization over a specifiable master value distance

Desynchronization via a specifiable master value distance is set in the **syncProfileReference:=RELATE_SYNC_PROFILE_TO_LEADING_VALUE** parameter. The slave values travel to zero velocity while the master value travels through the desynchronization length. The desynchronization length is specified in the **syncOffLength** parameter.

See also Synchronization over a specifiable master value distance (Page 2661).

Desynchronization profile via specifiable dynamic response parameters

Desynchronization based on specifiable dynamic response parameters is set in the **syncProfileReference:=RELATE_SYNC_PROFILE_TO_TIME** parameter. The slave values travel to zero velocity with the dynamic response values specified in the desynchronization command according to the specified desynchronization criterion.

See also Synchronization profile based on specifiable dynamic response parameters (time reference) (Page 2664).

Position of synchronization range relative to desynchronization position

The position of the synchronization range relative to the desynchronization position can be specified more precisely with the **syncPositionReference** parameter of the **_disableGearing()** or **_disableCamming()** command:

- Desynchronization before the specified desynchronization position
  Desynchronization before the specified desynchronization position is set using the **syncOffPositionReference:=AXIS_STOPPED_AT_POSITION** parameter. The slave value travels to zero velocity to the specified desynchronization position.
- Desynchronization starting from the specified desynchronization position
  Desynchronization starting from the specified desynchronization position is set using the **syncOffPositionReference:=BEGIN_TO_STOP_WHEN_POSITION_REACHED** parameter. The slave value travels to zero velocity starting from the specified desynchronization position.
- Symmetrical desynchronization relative to the specified desynchronization position
  Symmetrical desynchronization relative to the specified desynchronization position is set with the **syncOffPositionreference:= STOP_SYMMETRIC_WITH_POSITION** parameter. The slave value travels at zero velocity symmetrically to the specified desynchronization position. The setting is not possible for the desynchronization profile based on dynamic response parameters.

Replacement of an active synchronous operation

If a synchronous operation is active, it can be replaced by another synchronous operation only when the synchronization criterion of the following synchronous operation can be maintained.

Example:

- For an active camming, the following axis travels only in the negative direction.
- A **_enableCamming()** command with **synchronizingDirection:=POSITIVE_DIRECTION** is issued at the end of the cam cycle (or the criterion, for example, the specified master distance ensures this).

In this case, the first active camming is not ended: the system waits until the following axis travels in the positive direction, which never occurs because of synchronous operation is active. To prevent the described behavior, change the synchronization criterion appropriately or end the active synchronous operation first (using a **_disable** command) and then activate the new synchronous operation.

Replacement of a synchronous operation with small synchronization length

If a synchronous operation group is ended using a **_disable** command with a very short desynchronization length, high dynamic response values result that must be replaced using discontinuous acceleration. If the **_disable** command is replaced before its ending by a new motion command with continuous velocity profile, the still-present high acceleration values are replaced prior to processing the added command. This results in a longer traversal distance of the axis that can also cause the reversing of the axis.

In cases in which an immediate replacement of the synchronous operation is necessary, for the described reason, no **_disable** command should be used, but rather an immediate switch made to the replacing motion command. In this case, the jerk for the following command may need to be increased.

If no **_disable** command is necessary, the subsequent move/pos command for a continuous velocity command should have high dynamic response values or traverse on a "trapezoidal profile."

Substituting motions

A motion that is in an acceleration or deceleration phase is replaced by a motion with jerk limitation (**smooth**). Correspondingly long times can result from the reduced jerk until the current acceleration is reduced.

For an actual value coupling, the result is essentially a noisy signal, depending on the encoder quality. In the case of substitution with jerk limiting (**smooth**), the slave movement is continued relative to this noise-prone signal (acceleration). The system interprets the signal as if the default value is in an acceleration or braking phase and reduces it via the jerk limitation.

With the optional **abortAcceleration** parameter, the functions **_stop** and **_stopEmergency** can be set so that any acceleration is reduced immediately and not via the jerk limitation.

Dynamic response effect on slave values

The dynamic response of the slave values is determined from:

- The dynamic response of the master value
- The dynamic response of any master value switchover occurring during the motion
- The dynamic response of the synchronization
- The dynamic response resulting from the transmission function
- If necessary, the dynamic response resulting from the application of offsets and scaling changes
- The limitation of the slave value dynamic response to the maximum values of the following axis

The dynamic response specifications on the synchronous object refer to the slave values calculated on the synchronous object during synchronization. The dynamic limits of the following axis are not taken into account by the synchronous object.

To avoid excessive dynamic response specifications on the slave values,

- The slave values calculated from the the master value based on the transmission function should not exceed the dynamic limits
- The dynamic response specifications for synchronization and master value switchover should not exceed the dynamic limits

The resulting dynamic values are limited to the maximum values on the following axis based on the axis configuration.

The individual dynamic response parameters that are active during synchronous operation are illustrated in the figure below.

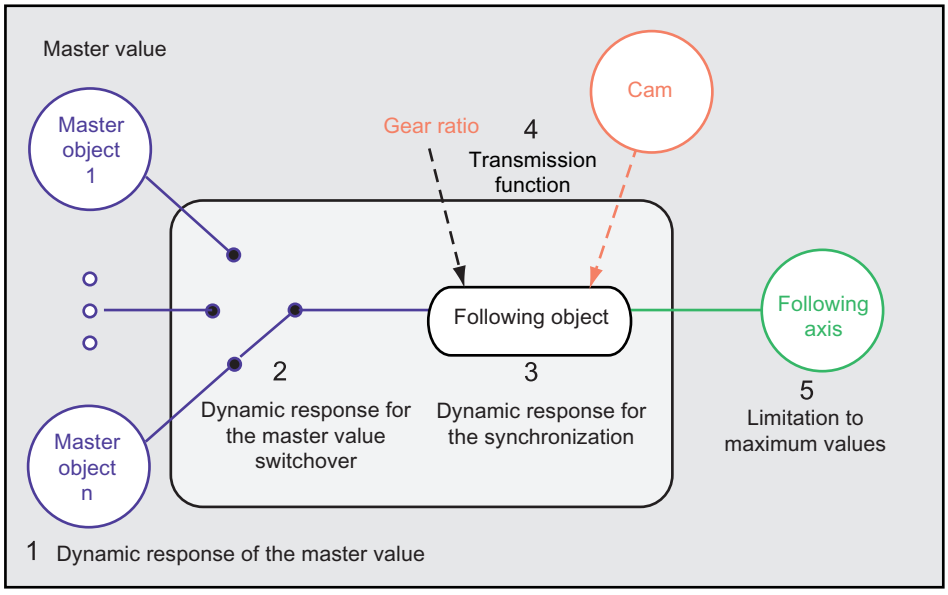

Figure 4-684 Dynamic response during synchronous operation

Legend:

1. The dynamic response of the master value is determined by the motion.
2. The dynamic response of the master value switchover can be specified using the **_setMaster()** command.
3. Synchronization/desynchronization and compensation:
   - *Without* dynamic specification during synchronization via a specifiable master value distance **(RELATE_SYNC_PROFILE_TO_LEADING_VALUE)**
   - Synchronization profile based on specifiable dynamic response parameters (time reference) **(RELATE_SYNC_PROFILE_TO_TIME)**
     The dynamic values set on the synchronous object are only valid for camming or gearing *during synchronization/desynchronization* and when applying corrections, but not in "synchronous" status. See Synchronization (Page 2652), Desynchronization (Page 2676).

4. The dynamic response specification for the following axis is determined by the synchronous object and the gear ratio. The synchronous object is *not* subject to any dynamic limitation in the 'synchronous' status.
5. The slave setpoints on the following axis are limited to the maximum axial dynamic response.
   Configuration data: **TypeOfAxis.MaxAcceleration/MaxVelocity/MaxJerk**
   System variables: **plusLimitsOfDynamics/minusLimitsOfDynamics**. The lowest limit is taken into account in each case.
   See the **Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder** Function Manual, "Dynamic limits."
   The maximum axial jerk is only used to monitor and, when appropriate, limit the synchronous operation setpoints if synchronous operation monitoring has been activated with provision made for jerk. The setting for synchronous operation monitoring has no effect on the synchronous operation setpoints generated. This even applies for the synchronization procedure, for example.
   The alarm "40202 Dynamic response of the synchronous operation setpoint cannot be achieved" is output if the slave setpoints calculated by the synchronous operation are higher than the active axial limits for velocity and acceleration. If the slave values are limited as a result of this or due to dynamic discontinuity of slave values for synchronous operation (caused by master value jumps, for example), a setpoint error is generated in the slave values.
   See Synchronous operation monitoring (Page 2687).
   The maximum jerk on the axis can be exceeded during synchronization and desynchronization if the jerk setting in the synchronization parameters on the synchronous object is greater than the maximum jerk on the axis. To prevent this, an alarm response can be configured, for example.
6. If desynchronization occurs within one system clock cycle and the target dynamics are therefore zero in respect of velocity and acceleration when the next clock cycle starts, no alarm will be output.

Switching of the master value source

Switching over the master value source – Overview

If more than one master value is assigned to a synchronized axis, the master value source can be selected and switched over on the synchronous object using the **_setMaster** command.

If a synchronous object is assigned to multiple master values, a random master value source is selected internally following system startup. The correct master value source must be specified in the user program. The master value source can be switched "on-the-fly". When it is enabled, the master values are referenced to the units system of the current master value source. A relative or absolute coupling influences the transition process.

The master value transition can be set with and without dynamic response using the **transientBehavior** parameter of the **_setMaster** command (V3.2 and higher):

- **DIRECT**: Without dynamic response (default)
- **WITH_DYNAMICS**: With dynamic response
- **WITH_NEXT_SYNCHRONIZING**: With next synchronization (as of V4.1)

See also

Master value switchover without dynamic response (Page 2681)

Master value switchover with dynamic response (Page 2681)

Master value switchover with next synchronization (V4.1 and higher) (Page 2682)

Master value switchover without dynamic response

The transition behavior when the master value source is changed is different for absolute synchronous operation and relative synchronous operation.

- With relative synchronous operation, an additional slave value difference occurs only if the dynamic master values are different with regard to velocity and acceleration.
- With absolute synchronous operation, a non-continuous master value transition can occur. Discontinuities in the slave values are limited to the maximum dynamic axis parameters on the following axis. A compensation movement is generated in certain circumstances.

Different modulo settings of the master value sources are taken into account.

Master value switchover with dynamic response

The dynamic response parameters: The velocity profile, velocity, acceleration, and, if necessary, jerk can be specified directly in the **_setMaster()** command. These parameters refer to the dynamic response of the transition of the master value source. The **setMasterCommand** system variable indicates the status of the **_setMaster()** motion on the synchronous object.

Note

If the **_setMaster** command switches over the master value, the output of the synchronous object remains asynchronous to the new master value during the transition. The system variables for the synchronization remain unaffected. The transition behavior of the master value does not have any effect on the active gearing/camming.

Please note that a master value switchover does not constitute a new synchronization procedure, i.e. the syncState system variable (on the synchronous object) indicates YES.

To ensure setpoint synchronism, the **setMasterCommand** and **syncState** system variables must be monitored.

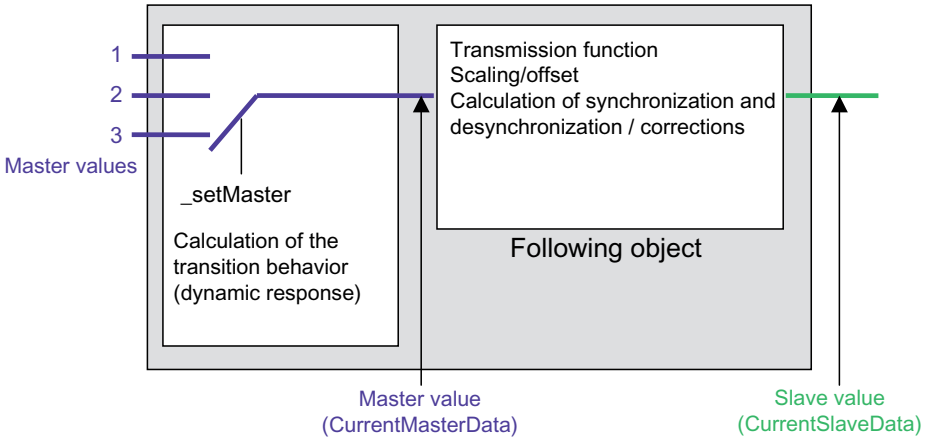

Figure 4-685 Transition behavior and master value for the master value switching with dynamic response

The transition behavior for the new master value is calculated separately from the synchronization and desynchronization, and until the end of the compensation is used as master value for the setpoint monitoring and the evaluation of the **syncState, synchronizingState** synchronization status.

The comparison of this value with the output value of the synchronous object sets the **syncState** and **synchronizingState** variables: **syncState=YES** and **synchronizingState=INACTIVE**. Despite the switching, the **differenceCommandValue** setpoint difference is zero.

Master value switchover with next synchronization (V4.1 and higher)

The master value switchover is active together with the next **_enableCamming()/ _enableGearing()** synchronization command, whereby all specifications refer to the new master value. The dynamic response values in the **setMaster()** command are not active because the dynamic response values of the synchronization command are active during synchronization.

System variable **stateSetMasterCommand** indicates the current status. Parameter **transientBehaviour** sets the master value switchover:

- Master value switchover: is not active: system variable **stateSetMasterCommand = INACTIVE ,** parameter **transientBehaviour = INACTIVE**
- Master value switchover is active, switchover occurs directly: system variable **stateSetMasterCommand = TRANSIENT_BAHAVIOR_DIRECT,** parameter **transientBehaviour = DIRECT**
- Master value switchover is active, switchover occurs with dynamic response values: system variable **stateSetMasterCommand = TRANSIENT_BAHAVIOR_WITH_DYNAMICS ,** parameter **transientBehaviour = WITH_DYNAMICS**
- Master value switchover is active; switchover occurs with next synchronization: system variable **stateSetMasterCommand = TRANSIENT_BAHAVIOR_WITH_NEXT_SYNC,** parameter **transientBehaviour = WITH_NEXT_SYNCRONIZING)**

Superimposed synchronous operation

Description

Two synchronous operations can be *superimposed* by creating another synchronous object on an axis (as of V3.0).

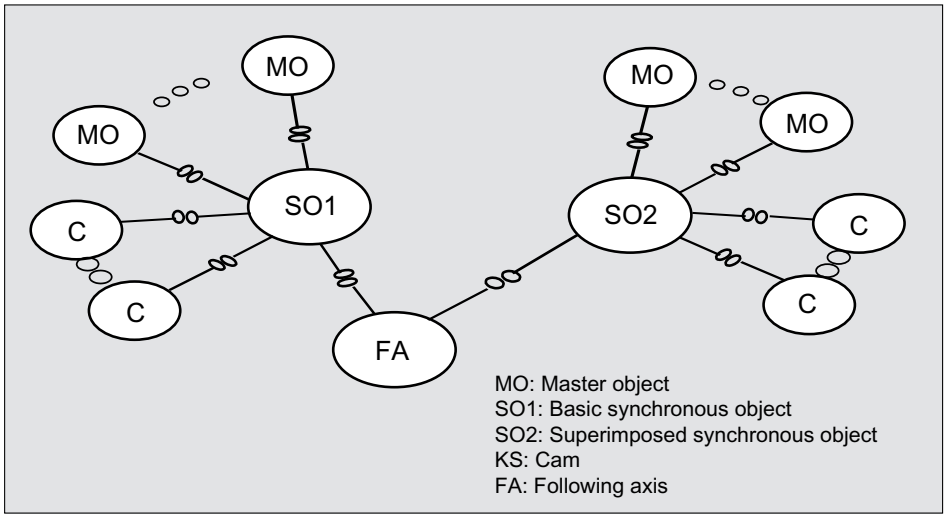

Figure 4-686 Schematic of a superimposed synchronous operation

To differentiate from the simple synchronous operation, the first synchronous operation is called a *basic synchronous operation* and the second is called a *superimposing synchronous operation*. The synchronous objects are called accordingly *basic synchronous object* and *superimposing synchronous object*.

The synchronous operation can be set on the synchronous object to act as the basic motion, main motion (has the same effect as non-superimposed synchronous operation), or superimposed (or secondary) motion (**syncingMotion**.**motionImpact:=STANDARD**/ **SUPERIMPOSED_MOTION** configuration data element).

A maximum of one basic synchronous object can be interconnected to an axis, plus one superimposed synchronous object on the same axis.

Creating an axis with superimposed synchronous operation

In the project navigator under <**Axis_n**>, it is possible to insert a maximum of one further synchronous object <**Axis_n_SYNCHRONOUS_OPERATION_1**>, which is then superimposed, i.e. configuration data **motionImpact** is initialized to **SUPERIMPOSED_MOTION**.

1. Select the axis in the project navigator.
2. Select **Expert > Superimposed synchronous object** from the shortcut menu.

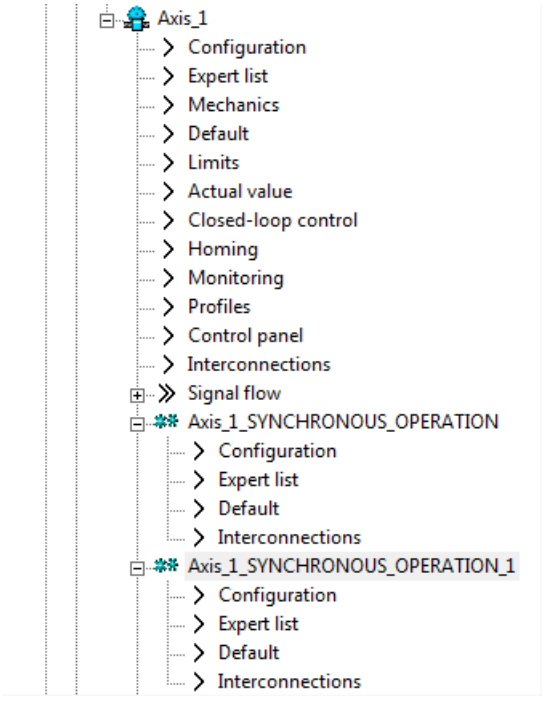

Figure 4-687 Representation of superimposed synchronous operation in the project navigator

The configuration and settings for superimposed synchronous operation are made in the same way as for the basic synchronous object.

Programming

All functions of the basic synchronous object (e.g. _enableGearing, _disableGearing, etc.) can be applied on the superimposed synchronous object. Cross-references between synchronous objects are not possible.

Absolute or relative superimposed synchronous operation

With superimposed synchronous operation, the properties for absolute or relative are the same as for basic synchronous operation, with the exception that the coordinates refer to the superimposed coordinate system on the following axis.

Coordinates

For the basic synchronous object, the synchronization parameters specified for the slave value position refer to:

- The total coordinate system with **mergeMode:=IMMEDIATELY** and **TypeOfAxis.decodingConfig.transferSuperimposedPosition <> TRANSFER_RESET**
- The basic coordinate system in all other cases

The superimposed synchronous object refers to the superimposed coordinates where slave value position specifications have been given.

$$\begin{pmatrix} s \\ v \\ a \end{pmatrix}_{\substack{\text{Cumulative} \\ \text{coordinates}}} = \begin{pmatrix} s \\ v \\ a \end{pmatrix}_{\substack{\text{Basic} \\ \text{coordinates}}} + \begin{pmatrix} s \\ v \\ a \end{pmatrix}_{\substack{\text{Superimposed} \\ \text{coordinates}}}$$

Figure 4-688 Coordinates for superimposed synchronous operation

Just as with a superimposed motion, each synchronous object has its own coordinate system. The "outputs" of the synchronous objects are added in the Slave Axis technology object. If, for example, the basic synchronous operation and superimposed synchronous operation have the same master value, and motion takes place in absolute gearing with a ratio of 1:1, the position value of the following axis will be twice that of the master axis after both synchronous objects have been synchronized.

Behavior of superimposed synchronous operation in relation to basic motion

Superimposed synchronous operation behaves like a superimposed positioning motion with regard to the basic motion on the axis (motion or synchronous operation). **TypeOfAxis.decodingConfig.transferSuperimposedPosition** configuration data on the synchronous axis set when superimposed motions will be applied to the basic motion, and when they will be substituted. This setting determines, for example, when **mergeMode=IMMEDIATELY** that the superimposed motion is to be substituted on the basic motion. These configuration data settings also apply to superimposed synchronous operations (see also here (Page 2749)).

There can be only *one* superimposed motion on the axis at one time, for example, a **superimposed positioning motion** *or* **superimposed synchronous operation**. A **superimposed synchronous operation** can be active without a basic motion being active at the same time.

See also superimposed motion for axis, **Motion Control Technology Objects Axis Electric/ Hydraulic, External Encoder** Function Manual.

Monitoring

The output values of a synchronous object (and thus also the motion component of the superimposed synchronous operation for the axis) can be read out in the **currentSlaveData** system variable on the synchronous object.

Table 4-278 Coordinates on the following axis for the superimposed synchronous operation

	System variable	Description
All coordinates:		
positioningState.	**commandPosition**	Target position (total)
motionStateData.	**commandVelocity**	Target velocity (total)
	commandAcceleration	Target acceleration (total)
Basic coordinates:		
basicMotion.	**position**	Position in the basic coordinate system
	velocity	Velocity in the basic coordinate system
	acceleration	Acceleration in the basic coordinate system
Superimposed coordinates:		
superimposedMotion.	**position**	Position in the superimposed coordinate system
	velocity	Velocity in the superimposed coordinate system
	acceleration	Acceleration in the superimposed coordinate system

The **syncMonitoring** system variable on the following axis also displays the state of the synchronous operation motion (as of V3.0):

- **followingMotionState =**
  - **INACTIVE**: Synchronous motion is not active
  - **BASIC_MOTION_ACTIVE**: Standard synchronous operation is active
  - **SUPERIMPOSED_MOTION_ACTIVE**: Superimposed synchronous operation is active
  - **BASIC_AND_SUPERIMPOSED_MOTION_ACTIVE**: Standard synchronous operation and superimposed synchronous operation are active

Compensations during distributed synchronous operation

Compensation during distributed synchronous operation is also useful/effective during superimposed synchronous operation.

See Compensations for distributed synchronous operation (Page 2767).

Synchronous operation monitoring / state

- The following table describes the conditions that apply when the state is synchronous (**syncMonitoring.syncstate = YES**):

Basic synchronous operation	Superimposed synchronous operation
Not sychronous (**synchState = No**)	Synchronous (**synchState = Yes**)
Basic synchronous operation synchronous (**synchState = Yes**)	Not synchronous (**synchState = No**)

- The Not synchronous state (**syncMonitoring.syncstate = No**)only applies during the synchronization/desynchronization process (**synchronizingState <> Inactive**)

Example:
A synchronous operation is started. After synchronization, the synchronous operation is assigned the 'synchronized' state. Now another synchronous operation is started. The 'synchronized' state disappears for the duration of the synchronization and is not reset until the synchronization of the second synchronous operation is complete.

The variables and monitoring on the axis refer to the total synchronous operation. Error messages (synchronous operation errors on the synchronized axis) are issued on all interconnected synchronous objects.

Synchronous operation monitoring

The slave values calculated by the synchronous object (**currentSlaveData**) and any additional setpoints on the axis are limited on the following axis to the maximum dynamic response values. The deviation in the slave values resulting from this limitation is monitored. The current maximum limits for velocity and acceleration (and jerk) on the axis influence this monitoring process.

See the **Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder** Function Manual, "Dynamic limits".

The **syncMonitoring** system variables on the following axis indicate setpoint and actual value differences:

- **Setpoint monitoring**
  differenceCommandValue shows the difference between the setpoint generated at the synchronous object and the executable setpoint at the axis, with dynamic limits taken into account. **limitCommandValue** shows that the difference between the calculated slave value and executable setpoint is above the permissible tolerance.
- **Actual value monitoring**
  differenceActualValue contains the sum from **differenceCommandValue** (the difference between the setpoint generated at the synchronous object and the executable setpoint at the axis, with dynamic limits taken into account) and the position lag at the following axis. **limitCommandValue** shows that the difference between the calculated slave value and the actual value lies above the permissible tolerance.

Setpoint monitoring

On the axis, the slave values calculated by the synchronous operation are limited to the maximum dynamic response values of the axes. This can cause the setpoints on the axis to change.

Consequently, the setpoint error is the difference between the calculated setpoint of the synchronous object (**currentSlaveData**) and the associated setpoint at the following axis that results from observing the acting dynamic maximum limits of the following axis (**basicMotion.position**).

The setpoint error of one of the motions possibly superimposed to the synchronous operation is the difference between the calculated setpoint of the synchronous object (**currentSlaveData**)

and the superimposed setpoint at the following axis that results from observing the acting dynamic maximum limits of the following axis (**superimposedMotion.position**).

The setpoint error from the main and superimposed motion is displayed in **syncMonitoring.differenceCommandValue** on the following axis.

The **syncMonitoring.syncState** synchronization state on the following axis is set according to the **syncState** on the synchronous object. Exception: Superimposed synchronous operation Superimposed synchronous operation (Page 2683).

The following comparison must be performed to determine whether the following axis is synchronized on the setpoint value side:

(<following axis>.**syncMonitoring.syncState:=YES) AND**

(<following axis>.**syncMonitoring.differenceCommandValue = 0)**

Actual value monitoring

The **syncMonitoring.differenceActualValue** system variable allows the position lag present at the following axis, including any acting dynamic response limitation of the following axis (setpoint error in **syncMonitoring.differenceCommandValue**), to be queried. The position lag for DSC operation applies to the position lag present at the position controller in the drive.

For versions earlier than V4.2, the difference is formed between the setpoint calculated on the synchronous object and the actual value present in the interpolator.

Velocity gearing monitoring

The **syncMonitoring** system variable on the following axis also displays the status of the velocity gearing (as of V3.1):

- **differenceCommandVelocity**: velocity difference on the setpoint side between the velocity setpoint calculated on the synchronous object (**currentSlaveData**) and the executable velocity on the following axis (only applies to synchronous velocity operation).
- **differenceActualVelocity**: velocity difference on the actual value side between the velocity setpoint calculated on the synchronous object (**currentSlaveData**) and the executable velocity on the following axis (only applies to velocity gearing).

Configuration

The synchronous operation monitoring is set on the following axis under **Monitoring - Synchronous operation monitoring** (**GearingPosTolerance** configuration data element).

Limiting and monitoring the setpoint error:

- With setting **enableCommandValue := NO_ACTIVATE**:
  - the tolerance monitoring of the setpoints is not activated.
- With setting **enableCommandValue := WITHOUT_JERK**:
  - the tolerance monitoring of the setpoints is activated without inclusion of the jerk. Alarm 40201 is output if the setpoint tolerance is exceeded.
- With setting **enableCommandValue := WITH_JERK**:
  - the tolerance monitoring of the setpoints is activated with inclusion of the jerk. Alarm 40201 is output if the setpoint tolerance is exceeded. The jerk on the axis is also monitored.

  Note

  For distributed synchronous operation with extrapolation on the following axis, the setpoint monitoring with jerk setting is not appropriate.

The actual value deviation monitoring is set via **GearingPosTolerance.enableActualValue**. The synchronous operation monitoring setting only becomes active after synchronization is complete **(syncState = YES).**

For the dynamic response limits on the following axis, see the Motion Control Technology Objects Axis Electric/Hydraulic, External Encoder Function Manual, "Dynamic limits".

Error handling

When the synchronous operation tolerance is exceeded, the following axis issues the technological alarm "40201 Synchronous operation tolerance exceeded on the following axis". An alarm message can also be sent to the master value source; this setting is made in the **TypeOfAxis.GearingPosTolerance.enableErrorReporting** configuration data element. Here, a distinction can be made between deviation tolerance violations of the calculated slave value setpoint and of the calculated slave value actual axis value. The leading axis then issues the error "40110 Error triggered on slave during synchronous operation (error number: ...)".

As of V4.2, an error message is also output on the master object when the following axis disconnects the synchronous coupling for any reason in the event of an error.

Note

If the **ALL_ERRORS_WITH_ABORT_SYNCHRONIZATION** parameter is set, error message 40110 is triggered on the relevant master object (e.g. also with following error on following axis).

If the synchronous motion is interrupted by a substitutional motion, no error message is generated.

Only following axis errors are reported to the master object. Errors occurring on the synchronous object on command output and/or synchronization are not taken into account.

The troubleshooting can be set using the following configuration data element:

- <Following axis>.TypeOfAxis.GearingPosTolerance.enableErrorReporting
  - **NO_REPORTING**- (default) no message, present
  - **COMMAND_VALUE_TOLERANCE**- setpoint monitoring, present
  - **ACTUAL_VALUE_TOLERANCE**- actual value monitoring, present
  - **ALL_ERRORS_WITH_ABORT_SYNCHRONIZATION**- all errors that occurred

Simulation mode

Synchronous operation can be switched to *simulation*, in which the values at the synchronous object are calculated but not output to the following axis. The synchronous operation simulation can be activated and deactivated at any time provided there are no faults present.
The **simulation** [ACTIVE/INACTIVE] system variable provides information about the simulation status of the axis.

Application: Retaining a synchronous operation connection with _disableAxis() (Page 2716).

Commands for the simulation operation

- The **_enableFollowingObjectSimulation()** command sets a synchronous operation into simulation mode. The synchronous values are calculated, but are not output to the following axis. This can be done at any time. However, the axis states are taken into account in generating the slave values.
- The **_disableFollowingObjectSimulation()** command resets the synchronous operation relationship out of simulation mode. The synchronization values are output to the following axis again.
  If there is a difference between the setpoint calculated in synchronous operation and the setpoint present at the axis, or superimposed motion has occurred, only dynamic limitation to the maximum values of the following axis is performed.

Configuration data for the simulation operation

The **disableSynchronousOperation** configuration data can be used to set whether master values are to be forwarded to the slave axis.

- If **NO** (default), the synchronous operation is also canceled in simulation mode, provided that the enables on the following axis have been canceled.
- If **YES**, the synchronous operation is not canceled in simulation mode if the enables on the following axis have been canceled while synchronous operation is in simulation mode. Any synchronous operation commands that are undergoing execution are retained.

Configuring units

You can define the basic units for each technology object. The same physical variables can have different units in different technology objects. These are converted:

How to configure the units:

1. In the project navigator, open the context menu under the TO.
2. In the context menu, select Expert > Configure units. The Configure Units window appears in the working area.
3. Select the unit for the physical variables. These units are used for the technology object, for example, s for units of time.

or

1. In the project navigator, open the Configuration under the TO.
2. Select the "Units" tab.

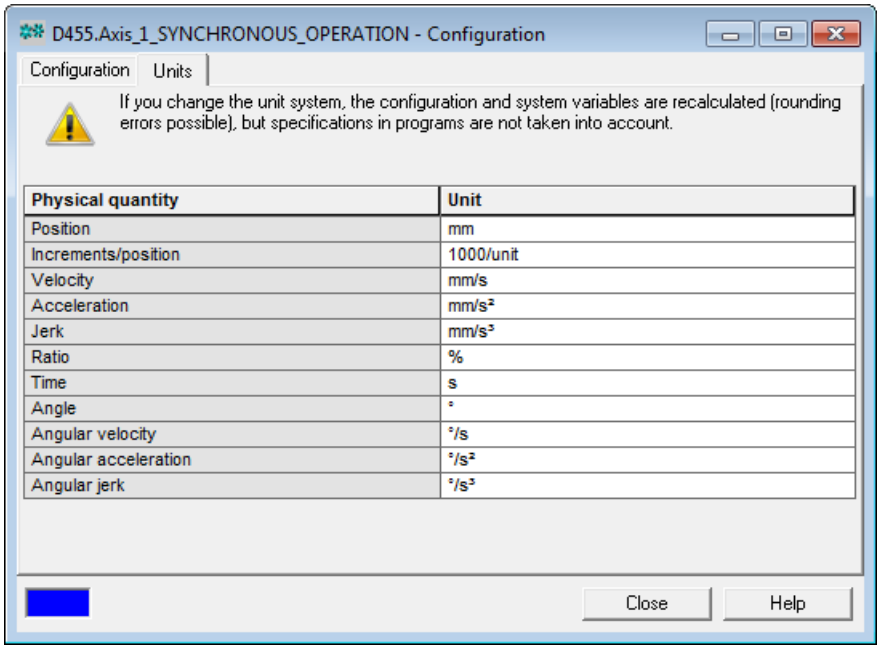

Figure 4-690 Synchronous operation units

You can set the following parameters:

Field/Button	Meaning/Instruction
Table with units	
Physical variable column	Shows the physical variable. The physical variables which are used by the TO are available for the configuration.
Unit column	Displays and configures the unit. Clicking on the cell opens up a combo box for selecting the unit.
Toolbar	
	• Displays whether offline data or online data is shown • Blue field = offline display • Yellow field = online display
Close	Button for closing the dialog.
Help	Button for opening the online help for the dialog.

Examples of synchronization operations as a function of the output position on the slave value side

Synchronization via a specifiable master value distance

Together with the master value behavior, the starting position of the following axis relative to the synchronous position on the following axis side largely determines the characteristic of the synchronization profile.

Influence of starting position of the following axis

Example:

- Absolute 1:1 gear without offset
- Constant master value velocity
- Slave value at start of synchronization at standstill
- Synchronization over a master value distance
- Velocity profile type **CONTINUOUS** for synchronization

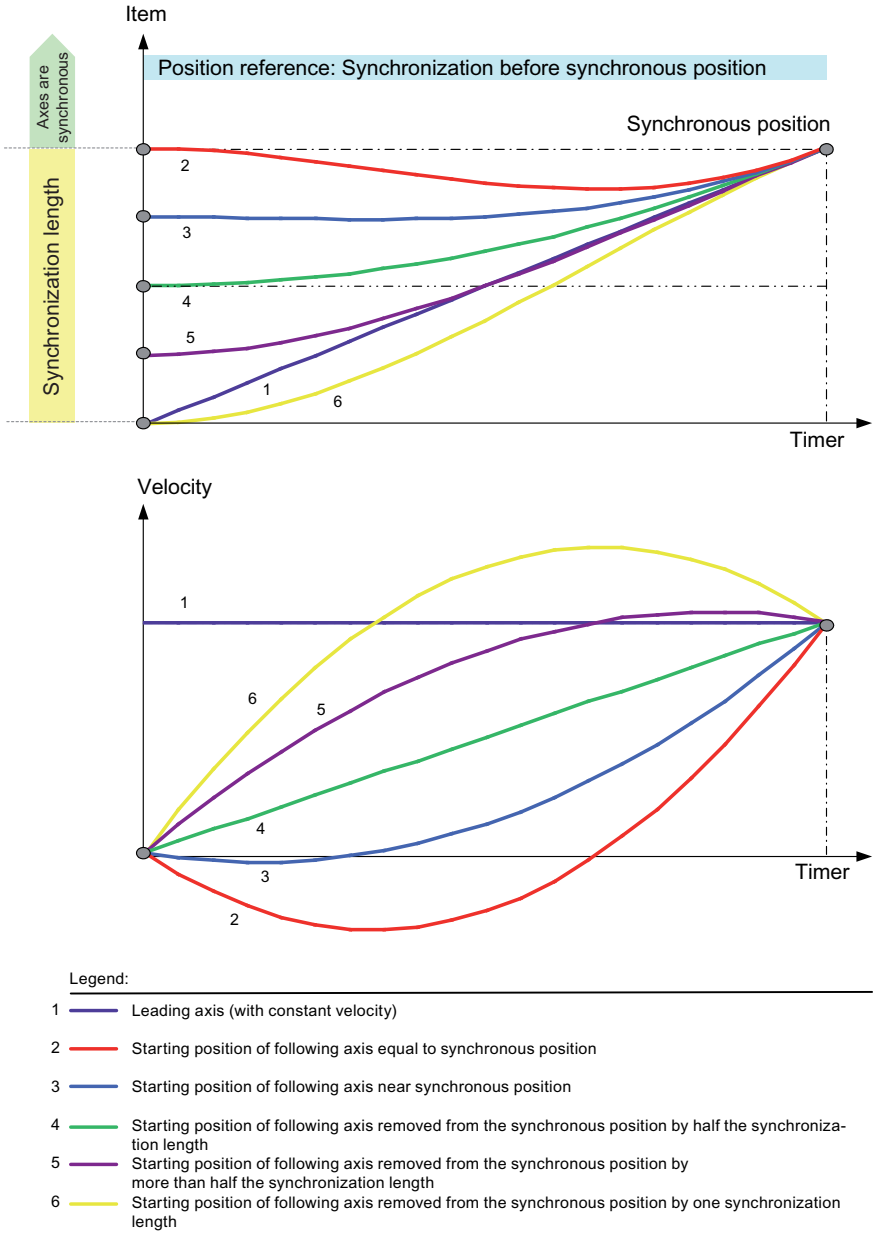

Figure 4-691 Synchronization via a specifiable master value distance

While the position characteristics of the individual synchronization operations do not differ very much, the velocity characteristics differ significantly:

- To accelerate to the synchronous velocity at the synchronous position, motion in the opposite direction following by reversal is required (2).
- It is possible to accelerate directly to the synchronous velocity and synchronous position; the position difference to be applied is minor (3).
- The acceleration to the synchronous velocity in the synchronous position is even (4).
- Direct acceleration to the synchronous velocity in the synchronous position is possible. While the position difference to be applied is greater, a velocity greater than the synchronous velocity and, thus, a velocity reversal is not required for synchronization (5).
- To apply the position difference, a velocity greater than the synchronous velocity and, thus, a velocity reversal is required for synchronization (6).

Recommendation for master value-related synchronization

Recommendation for synchronization via master value distance with 1:1 gear and synchronization from standstill:

- Starting position of the following axis removed from the synchronous position by half the synchronization length.
- Synchronization range symmetrical relative to the synchronous position.

Synchronization profile based on specifiable dynamic response parameters

Together with the master value behavior, the starting position of the following axis relative to the synchronous position on the following axis side largely determines the characteristic of the synchronization profile.

Influence of starting position of the following axis with leading synchronization

Example:

- Absolute 1:1 gear without offset
- Constant master value velocity
- Following axis at start of synchronization at standstill

- Synchronization profile based on dynamic response parameters
- Velocity profile type TRAPEZOID for synchronization

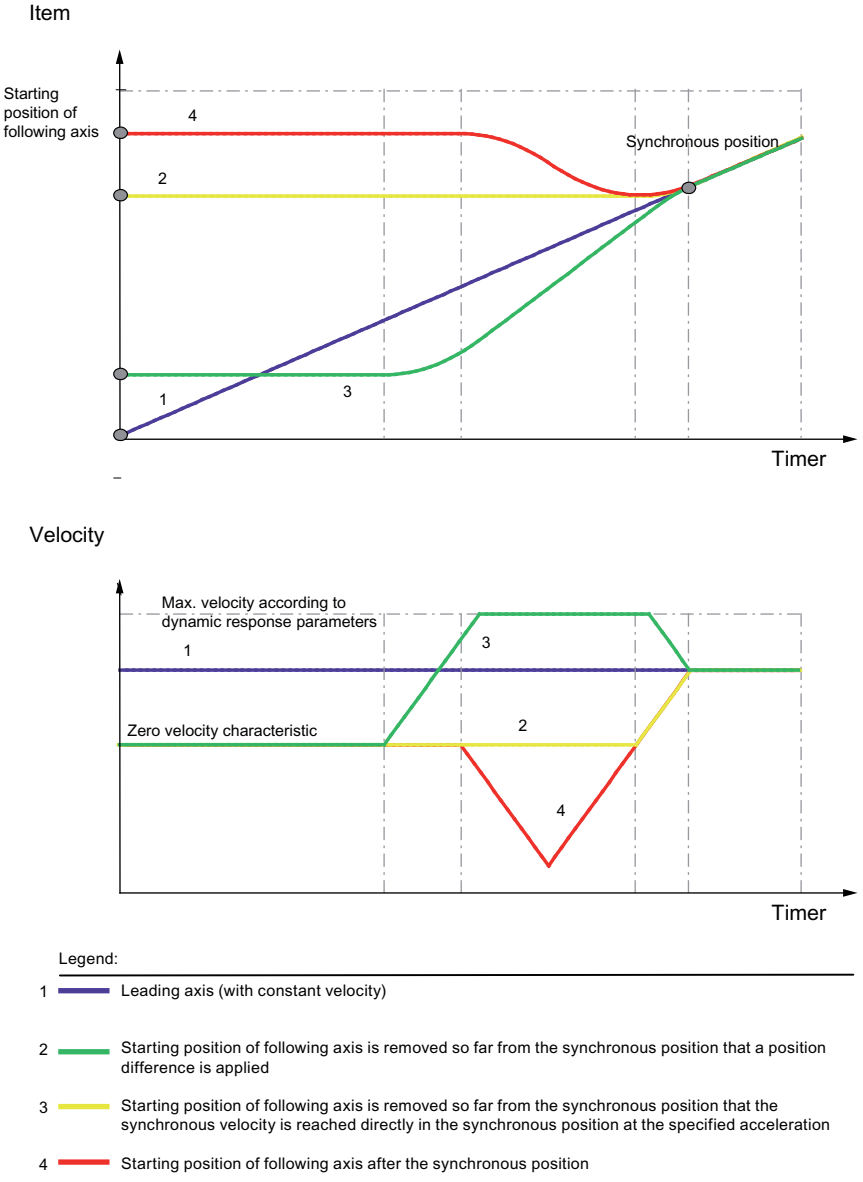

Figure 4-692 Synchronization profile based on specifiable dynamic response parameters and leading synchronization

In the case of leading synchronization based on dynamic response parameters, synchronization starts differently depending on the starting position of the following axis:

- If necessary, the following axis can be accelerated directly to the synchronous velocity and synchronous position (2).
- If the starting position of the following axis is below this point, a position difference must also be applied with the specified dynamic values (3).
- If the starting position is above this point, reversing (i.e. traveling in the opposite direction) is required in order to traverse to the synchronous point at the required synchronous velocity (4).

Influence of starting position of the following axis with trailing synchronization

Together with the master value behavior, the starting position of the following axis relative to the synchronous position on the following axis side largely determines the characteristic of the trailing synchronization profile.

Example:

- Absolute 1:1 gear without offset
- Constant master value velocity
- Following axis at start of synchronization at standstill
- Synchronization profile based on dynamic response parameters
- Velocity profile type **TRAPEZOID** for synchronization

With this type of dynamic response-related synchronization, a master value position is defined from which the synchronization procedure between the master value and following axis is initiated. Here, the desynchronization operation itself is performed based on the dynamic response value settings.

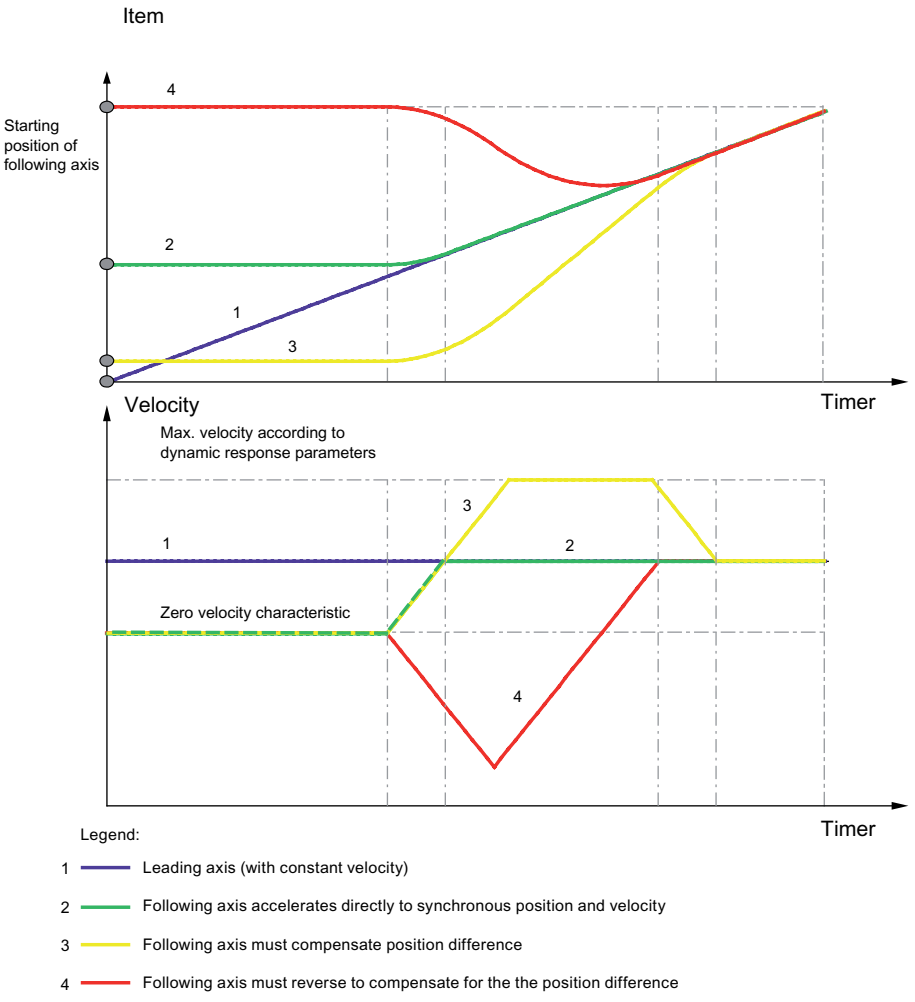

Figure 4-693 Synchronization profile based on specifiable dynamic response parameters and trailing synchronization

With trailing synchronization via dynamic response parameters, "synchronous" status is achieved at different times, depending on the starting position of the following axis.

Depending on the starting position of the following axis:

- If necessary, the following axis can be accelerated directly to the synchronous velocity and synchronous position (2).
- If the starting position of the following axis is below this point, a position difference must also be applied with the specified dynamic values (3).
- If the starting position of the following axis is above this point, reversing (i.e. traveling in the opposite direction) is required in order to traverse to the synchronous point at the required synchronous velocity (4).

Examples

Examples of typical synchronization operations

Several examples for synchronization operations of the gearing and their parameterization in MCC and ST commands are listed here.

Note

The function parameters that are not important to function calls are omitted from the examples. The required parameters are entered directly.

Relative synchronization with master value reference

The master axis moves at a velocity of 100 mm/s. The following axis is stationary at position 0 mm. The synchronization is started immediately; after 20 mm, this should result in relative synchronism between the master axis and following axis.
