LAD stands for ladder logic. LAD is a graphical programming language. The statement syntax corresponds to a circuit diagram. LAD enables simple tracking of the signal flow between conductor bars via inputs, outputs and operations.
LAD statements consist of elements and boxes which are graphically connected to networks (which are displayed in conformity with the IEC 61131-3 standard). LAD operations follow the rules of Boolean logic.

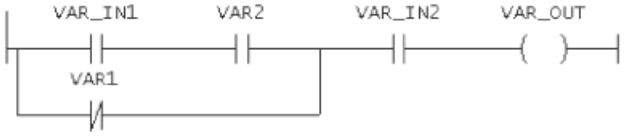

Figure 7-440 Representation of a network in LAD

The LAD program can also be displayed as an FBD program.

The LAD programming language

The LAD programming language features all the elements required for the creation of a complete user program. LAD features an extensive command set. This includes the various basic operations with a comprehensive range of operands and how to address them. The design of the functions and function blocks enables you to structure the LAD program clearly.

The program package

The LAD programming package is an integral part of the basic SIMOTION software, so that after your SIMOTION software has been installed, all editor, compiler and test functions for LAD are available for use.

7.3.2.3 What is FBD?

FBD stands for function block diagram. FBD is a graphics-based programming language that uses the same type of boxes used in boolean algebra to represent logic (networks are displayed in conformity with the IEC 61131-3 standard). In addition, complex functions (e.g. mathematical functions) can be represented directly in conjunction with the logic boxes.

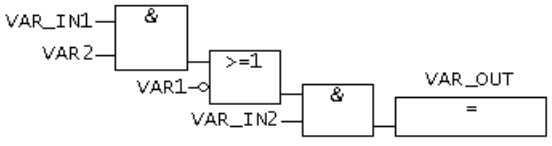

Figure 7-441 Representation of a network in FBD

The FBD program can usually also be displayed as an LAD program.

The FBD programming language

The FBD programming language features all the elements required for the creation of a complete user program. FBD features an extensive command set. This includes the various basic operations with a comprehensive range of operands and how to address them. The design of the functions and function blocks enables you to structure the FBD program clearly.

The program package

The FBD programming package is an integral part of the basic SIMOTION software, so that after your SIMOTION software has been installed, all editor, compiler and test functions for FBD are available for use.

7.3.2.4 Unit, program organization unit (POU) and program source

The term "unit" represents a program source.

The terms "program organization unit (POU)" and "LAD/FBD program" are generic terms and may refer to a program, a function (FC), or a function block (FB).

The term "program source file" is a generic term and may refer to a LAD/FBD unit, an MCC unit or an ST source file.

7.3.3 LAD/FBD editor

7.3.3.1 The LAD/FBD editor in the workbench

The workbench represents the framework for SIMOTION SCOUT. Using the workbench tools, you can carry out all the steps required to configure, optimize, and program a machine in order to complete a required task.

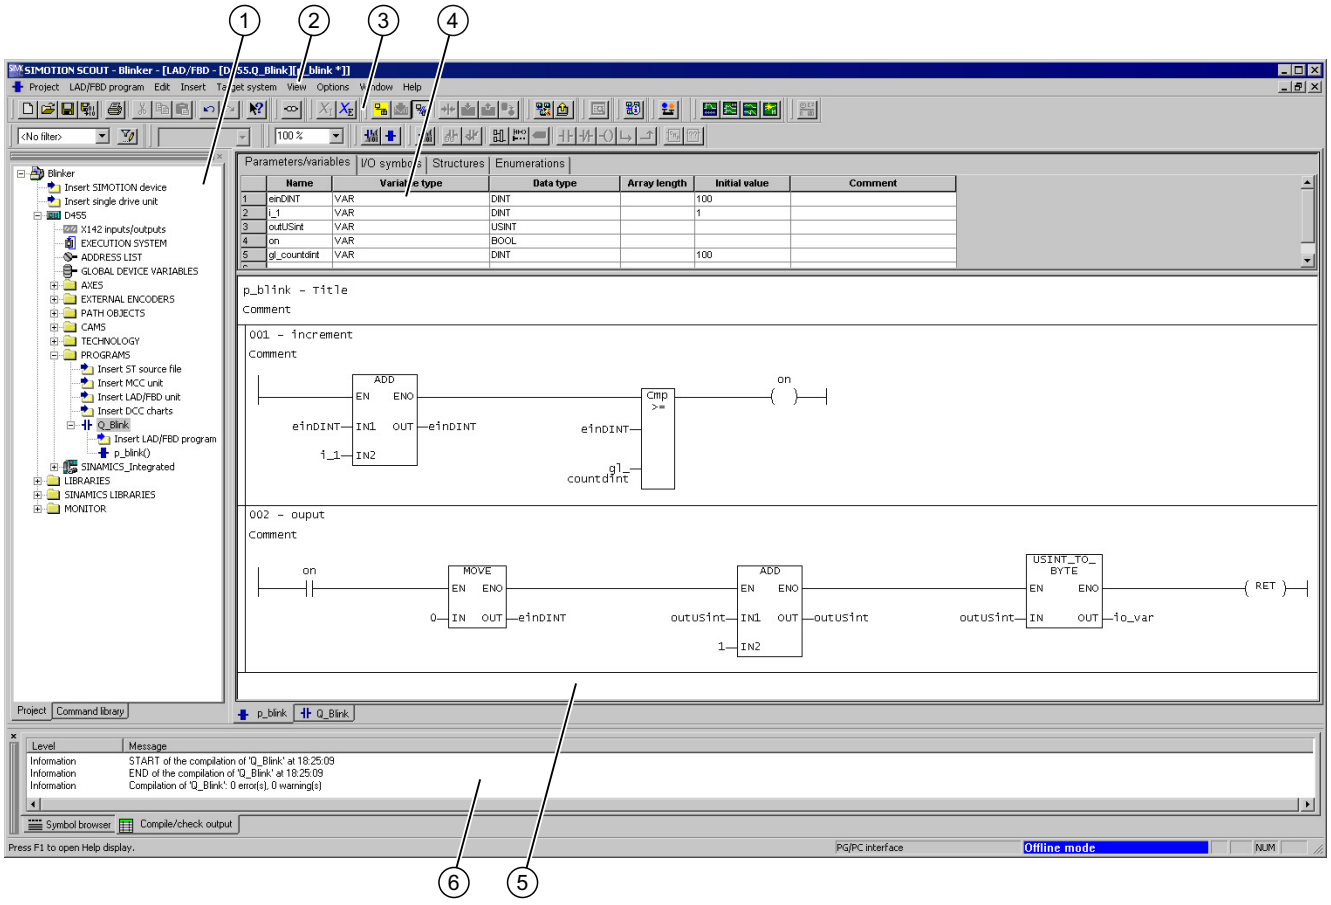

Figure 7-442 Elements of the workbench in a LAD/FBD program

The workbench contains the following elements:

- ① Project navigator
  The project navigator shows the entire project and its elements as a tree structure.
- ② Menu bar
  The menu bar contains menu commands which you can use to control the workbench, call up tools, etc.
- ③ Toolbars
  Many of the available menu commands can be executed by clicking the appropriate icon in one of the toolbars.
- ④ Declaration tables
  Declaration tables are used for LAD/FBD units and programs. You define variables and constants in the declaration tables.

- ③ Working area
  You carry out job-specific operations in this area. The working area contains an LAD/FBD program, a declaration table, and an editor for graphical displays.
- ⑥ Detail view
  More detailed information about the elements selected in the project navigator are displayed, e.g. the windows **Symbol browsers**, **Compile/check output**.

7.3.3.2 Maximizing working area and detail view

The windows working area and detail view can be set to maximum zoom.

The selection is made under the following menu items:

- **View > Maximize working area** (e.g., when creating programs)
  or
- **View > Maximized detail view** (e.g., monitoring global variables)

7.3.3.3 Enlarging or reducing the content of the working area

There are several options available to change the size of the LAD/FBD editor's display, i.e. the size of the elements in this area.

- **Zoom** list on the **Zoom factor** toolbar:
  Select a factor from the **Zoom** list, or enter an integer value of your own choice.
  - or -
  View > Zoom in menu command or **View > Zoom out.**
  - or -
  Key combination **Ctrl+Num+** (enlarge) or **Ctrl+Num-** (reduce).
  - or -
  Press the **Ctrl** key while turning the mouse wheel.

This change always applies to the active LAD/FBD editor. The setting is only saved when saving if changes have been made in the respective editor window.

7.3.3.4 Bringing the LAD/FBD editor to the foreground

If several LAD/FBD editors are open in the working area, these are usually overlaid. This means that only the top LAD/FBD editor is visible. There are several ways to bring the concealed editors to the foreground.

To bring the editor to the foreground, proceed as follows:

- Select the appropriate tab below the working window
  - or -
  Select the appropriate program name in the Window menu.
  - or -
  Press the **Ctrl+Tab** key combination as often as required.

7.3.3.5 Hiding and displaying the declaration table

If you need more space, you can hide the **Interface (exported declaration)** declaration area and/or the declaration area for a LAD/FBD program completely

To hide and display the declaration table, proceed as follows:

1. Double-click the separation line to hide the declaration table.
2. In order to display the declaration line again, double-click the separation line again.

7.3.3.6 Enlarging/reducing the declaration table

To change the size of the declaration table, proceed as follows:

1. Move the mouse cursor onto the separation line until the mouse pointer changes to a double line.
2. Hold down the left mouse button and drag the separation line upwards in order to reduce the size of the declaration area.
   - or -
   In order to enlarge the declaration area, move the separation line downwards.

7.3.3.7 Operation

Operating the LAD/FBD editor

The LAD/FBD editor provides the programmer with a variety of different operator input options. Alternatives for executing individual operator inputs include the following:

- The menu bar
- Context menus
- Toolbars
- Key combinations
- Texts and variables can be moved to the input field with drag-and-drop:
  - From the project navigator
  - From the declaration tables
  - From the detail view (Symbol browser tab, address list, watch table)
  - From the command library

Menu bar

You can start all of the programming functions from the menu bar.

The LAD/FBD program item only appears if a LAD/FBD editor is active in the working area.

Context menu

To use the context menu for an object, proceed as follows:

1. Select the appropriate object with the left mouse button (left click).
2. Briefly click the right mouse button.
3. Left-click the appropriate menu item.

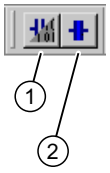
Toolbars

The dynamic toolbars contain icons for important, frequently used functions, e.g. for inserting or saving elements.

The "dynamic toolbar" changes depending on which workspace is active/selected, e.g. MCC chart, ST program or LAD/FBD program.

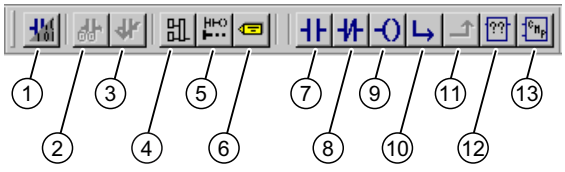
The toolbars can be positioned as required within the Workbench. Once moved, they can be shown or hidden using **View > Toolbars**.

The LAD/FBD editor toolbar contains the full range of LAD/FBD commands. The command list is displayed whenever the workspace for a program is active or open.



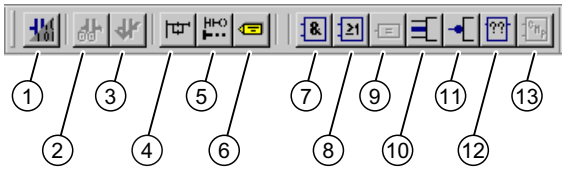
1) Accept and compile
2) Insert LAD/FBD program

Figure 7-443 Picture of the toolbar for a LAD/FBD unit



1) Accept and compile
2) Program status
3) Symbol check and type update
4) Switch to FBD
5) Insert network
6) Jump label ON/OFF
7) Insert NO contact
8) Insert NC contact
9) Insert coil
10) Open branch
11) Close branch
12) Insert comparator
13) Insert an empty box

Figure 7-444 View of the LAD editor toolbar



1) Accept and compile
2) Program status
3) Symbol check and type update
4) Switch to LAD
5) Insert network
6) Jump label ON/OFF
7) Insert AND box
8) Insert OR box
9) Insert assignment
10) Binary input
11) Negate binary input
12) Insert comparator
13) Insert an empty box

Figure 7-445 View of the FBD editor toolbar

Key combinations

Use the key combinations for fast operation in the LAD/FBD editor.

Within an LAD/FBD network, you can switch between LAD/FBD elements, select the required input/output of an LAD/FBD element and switch to the adjacent LAD/FBD network using the **left/right arrow buttons** and the **up/down arrow buttons**. Using the **Return** key, you can open the input field of a selected input/output and make an entry as well as close the field again using the **Return** key.

The shortcuts (Page 5408)available in the LAD/FBD editor are listed in the Appendix.

Drag&Drop of variables

Variables are dragged from the detail view (**Symbol browser**, **Watch table** or **Address list** tab) and dropped in the input field.

To paste in variables using drag&drop, proceed as follows:

1. Left-click the line number of the variable you wish to move.
   The line with the variables is highlighted.
2. Keeping the left mouse button pressed, drag the line number into the input field of the parameter screen form.
3. Release the left mouse button. The variable is pasted in at the selected position.

Drag&drop from the declaration tables

Variable names can be dragged from a declaration table and dropped into an LAD/FBD network.

To paste in variable names using drag&drop, proceed as follows:

1. Left-click the line number with the name of the variable you wish to move.
   The line is shown on a black background.
2. Continue to press the left mouse button as you drag the variable name to any input field.
3. Release the left mouse button.
   The variable name is pasted in at the selected position.

Drag&drop within the declaration table

You can change the order of the variable declaration in the declaration table.

To change the order using drag&drop, proceed as follows:

1. Left-click the line number of the variable you wish to move.
   The line is shown on a black background.
2. Press the **Shift** key and continue to press the left mouse button as you drag the line to the desired position in the declaration table.
   A red line indicates the point of insertion.
3. Release the left mouse button.
   The line moves to the corresponding position.

Note

To move several adjacent lines together, hold the **Shift** key down as you select the lines you wish to move.

Using Drag&Drop for LAD/FBD elements

LAD/FBD elements can be pasted into the LAD/FBD network from the project navigator (**Command library** tab) using drag-and-drop.

To paste in LAD/FBD elements using drag&drop, proceed as follows:

1. Left-click the required LAD/FBD element.
2. Hold the left mouse button down and drag the LAD/FBD element into the ladder diagram line of the LAD/FBD network.
3. Release the left mouse button.
   The LAD/FBD element is pasted in at the selected position.

Command call drag&drop

The commands in the command library can be inserted into LAD/FBD programs.

To insert command calls using drag&drop, proceed as follows:

1. Left-click the required command call.
2. Continue to hold the left mouse button down as you drag the command call to the LAD/FBD program.
3. Release the left mouse button.
   The command call is inserted at the selected position.

Drag&Drop of command names

Command names can be moved using drag-and-drop from the project navigator (tab **Command library**) into the input field of an empty box that has already been generated.

To paste in **command names** using drag&drop, proceed as follows:

1. Left-click the required command name.
2. Holding the left mouse button down, drag the command name into the input field of an empty box.
3. Release the left mouse button.
   The command name is pasted in at the selected position.

Using drag&drop for elements in a network

To insert elements in a network using drag&drop, proceed as follows:

1. Left-click the required LAD element.
2. To move an element, proceed as follows:
   Holding the left mouse button down, drag the element to the required position in the ladder diagram line.
3. To copy an element, proceed as follows:
   Keeping the **CTRL** key depressed, drag the element with the left mouse button to the required position in the ladder diagram line.
4. Release the left mouse button.
   The LAD element is inserted at the selected position.

Using drag&drop for functions and function blocks from other sources

Successfully compiled functions and function blocks from other source files can be pasted into a ladder diagram line from the project navigator. The connection to the "original source" is automatically entered in the **Connections** tab of the current source file.

To paste in functions and function blocks using drag&drop, proceed as follows:

1. Left-click the required FC/FB.
2. Holding the left mouse button down, drag the FC/FB into the input field of an empty box.
3. Release the left mouse button.
   An FC/FB call box is pasted in.

Automatic completion (Autocomplete)

In the LAD/FBD editor, you can automatically complete identifiers. A drop-down list box with identifiers that begin with the previously entered characters will be displayed. This operates on a context-sensitive basis, whereby the expected type for the identifier being sought and its visibility in the current program context determine which entries are displayed as options in the drop-down list box.

Depending on the context, the entries displayed in the drop-down list box are filtered and sorted:

- The filtering process may determine, for example, that only structure components are displayed for a structure.
- Entries are sorted according to their relevance to the context, with the more relevant identifiers appearing higher in the list (e.g. local variables are listed before global variables).

With LAD/FBD source files and LAD/FBD programs, the identifiers can be completed automatically in the following input fields/editable drop-down list boxes:

- Declaration table of the LAD/FBD unit
  - "Type" column
  - "Variable type" column
  - "Data type" column
- Declaration table of the LAD/FBD program
  - "Variable type" column
  - "Data type" column
- Input fields for the inputs of an LAD/FBD element (variables and other symbols for the expected type)
- Input fields for the outputs of an LAD/FBD element (variables for the expected type)
- Input field for the instance variable of a function block (variables for the expected FB type (box type))
- Input field for the NC contact, NO contact, and coil LAD elements (BOOL type variables)

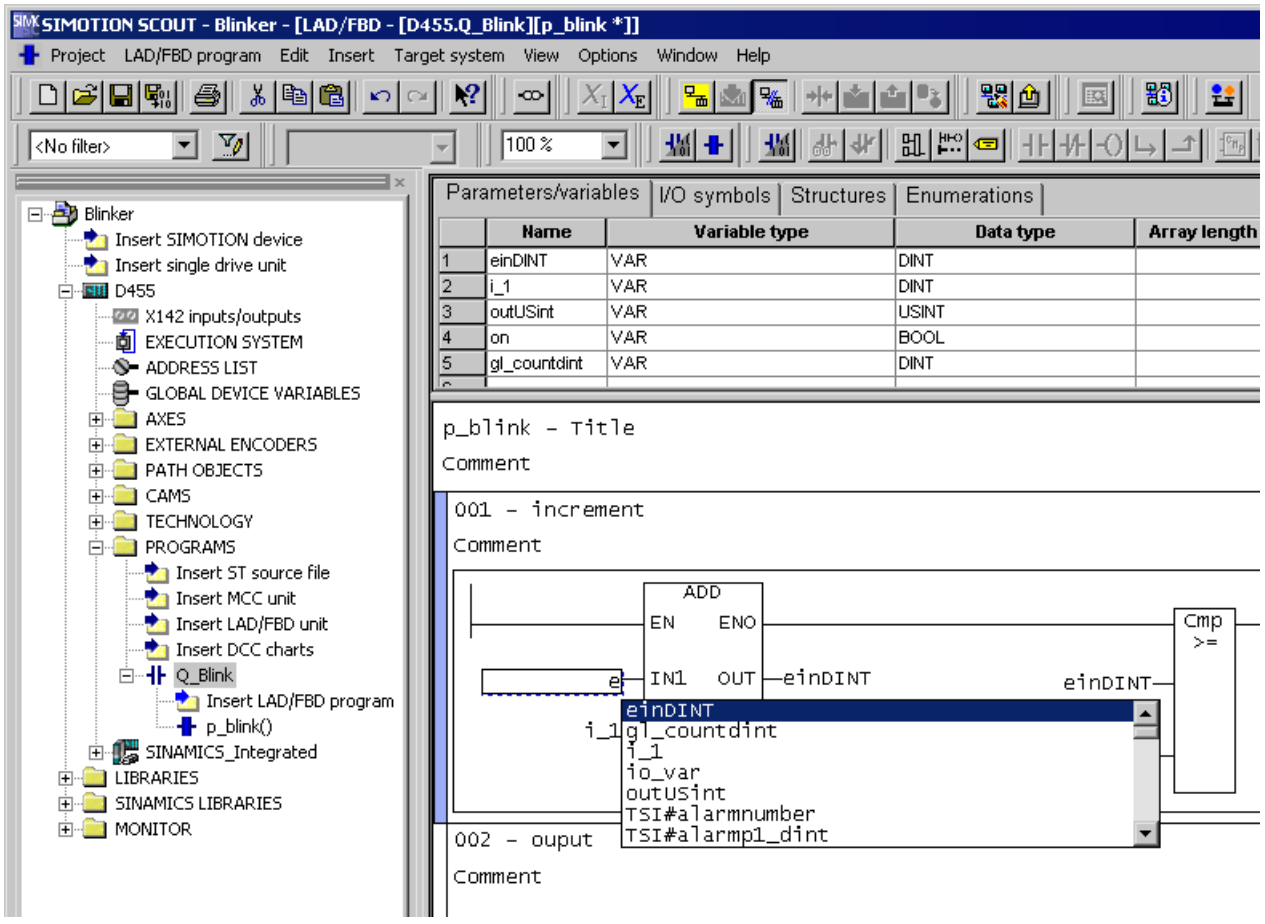


Figure 7-446 Automatic completion of an identifier at the input for an LAD/FBD element

Procedure

To complete an identifier automatically (Autocomplete), proceed as follows:

1. Write the first characters of the identifier (e.g. the first letters of a word) in the input field/ editable drop-down list box.
2. Press the **Ctrl+space** key combination.
   A drop-down list box opens containing the filtered/sorted identifiers for the current context. The identifiers listed start with the characters input so far or the characters up to where the cursor is positioned within an existing identifier.

   Note

   When the drop-down list box has been expanded and is editable (by clicking the symbol), automatic completion is already activated.

3. Expand or refine the options displayed:
   - Enter additional characters.
   - Delete characters.
   - Move the cursor with the left/right arrow keys.
4. Select the required identifier with the up/down arrow keys.
5. Press the **Return** key.
   The identifier is accepted by the input field/editable drop-down list box and the current word is overwritten.

   Note

   If only a single identifier is offered for selection, the selection window will not be opened and the identifier completed immediately.

Functional description

The following identifiers that begin with the specified characters will be offered:

- ST expressions
- ST program sections
- Identifiers from the command library
- Library, unit, POU, or system function names
- For technology objects including their system variables and configuration data

- Identifiers for the relevant LAD/FBD unit or LAD/FBD program:
  - Program organization units (POU) and FB instances
  - Data types
  - Variables and constants
  - Structure elements
- Identifiers from imported program sources

Note

Identifiers from the relevant LAD/FBD unit or LAD/FBD program or from imported program sources will only be displayed correctly if the corresponding program source has been compiled.

The display operates on a context-sensitive basis, i.e. only those types of identifiers that are appropriate at the associated location of the LAD/FBD unit or LAD/FBD program are offered:

- Within a declaration table, data types and variable types only
- Within a program organization unit (POU), no data types
- For a structure (e.g. var_struct.xx), only structure components

7.3.3.8 Settings

Settings in the LAD/FBD editor

You can define the layout for creating a program in the LAD/FBD programming language:

1. To change the settings, select the **Options > Settings** menu command.
   The **Settings** dialog box opens.
2. Select the tab **LAD/FBD editor**.

3. Make the required settings here.

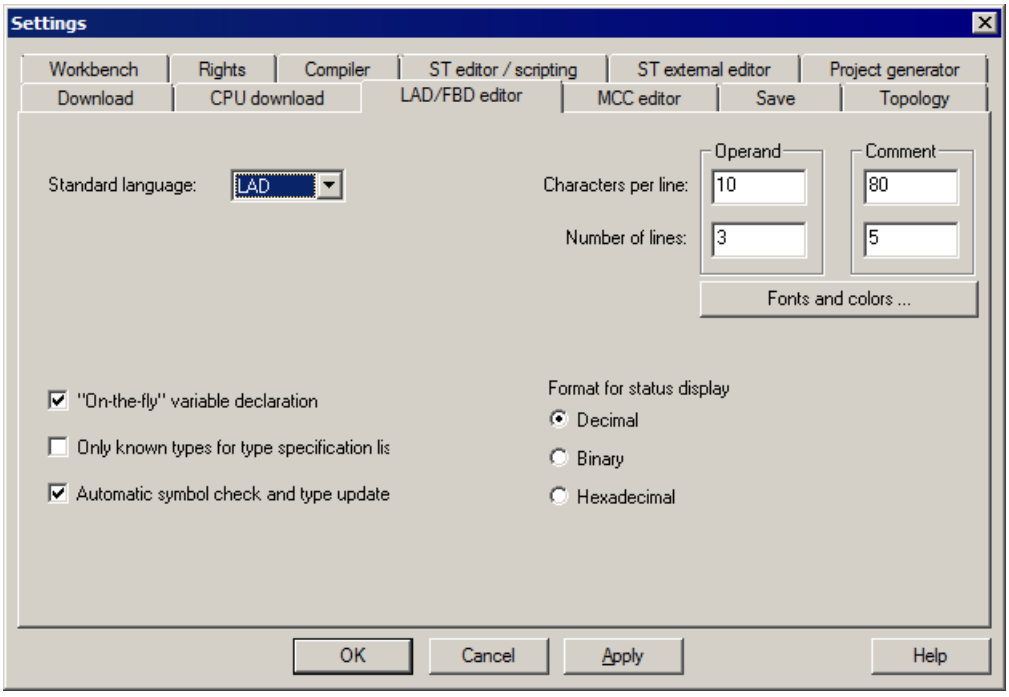

Figure 7-447 LAD/FBD editor settings

4. Click **OK** or **Accept** to confirm.

The table below contains a description of the individual parameters.

Table 7-523 LAD/FBD editor parameter settings

Parameter	Description
Default language	Defines the default graphical programming language for creating a new LAD/FBD program in the LAD/FBD editor.
"On-the-fly" variable declaration	If activated, a dialog box appears when an unknown symbol is entered in the LAD or FBD diagram. You can carry out the variable declaration in this dialog box. See: Defining variables in the Variable declaration dialog box ("on-the-fly" variable declaration) (Page 5175)
Only known types if type lists exist	If activated, only those function blocks which also have an entry in the Connections tab appear in the list of data types. See: Setting the data type list of the declaration table

Parameter	Description
Automatic symbol check and type update	If active, an automatic symbol check and type update take place once changes affecting the LAD/FBD program open in the LAD/FBD editor have been made in the project. The automatic symbol check and type update are activated by default in the LAD/FBD editor. See: Activating automatic symbol check and type update Example of a type update (Page 5096) Example of a symbol check (Page 5098) Deactivating automatic symbol check and type update Performing symbol check and type update at a specified time
Operand	You can change the options for displaying the operand by entering the number of **Characters per line** and **Number of lines** for the Operand field. Changes to settings are only applied to LAD/FDB editors that are opened afterwards.
Comment	You can change the options for displaying the comment by entering the number of **Characters per line** and **Number of lines** for the Comment field. Changes to settings are only applied to LAD/FDB editors that are opened afterwards.
Fonts and colors	You can change the fonts and colors of the LAD/FBD editor. See: Changing fonts Changing colors Changes to settings are only applied to LAD/FDB editors that are opened afterwards.
Format for status display	Format in which the values of variables with bit data type are displayed in program status and variable status. See: Starting and stopping the program execution monitoring (Page 5349) Variable status (Page 5345)

Activating automatic symbol check and type update

To enable automatic symbol check and type update, follow these steps:

1. Select the **Options > Settings** menu item.
2. Select the tab **LAD/FBD editor**.
3. Activate the checkbox **Automatic symbol check and type update**.
4. Confirm with **OK**.

Note

The automatic symbol check and type update is activated by default in the LAD/FBD editor.

If the symbol check is activated, the automatic symbol check and type update is performed for an LAD/FBD program if the following requirements are met:

- changes are made in the project (see list below) which impact upon the LAD/FBD program
- the focus is on the LAD/FBD program, i.e. it is opened in the KOP/FUP editor, or the LAD/FBD editor from the LAD/FBD program which is already open appears in the foreground (Page 5084)

In the event of subsequent changes within a project, automatic symbol check and type update is performed for an LAD/FBD program if the change affects the LAD/FBD program:

- A program source is changed, e.g. deleted or renamed.
  The changes are only identified for associated program sources and their LAD/FBD programs when the changed program source is compiled. In other words, to enable the automatic symbol check and type update to take place, the changed program source must be compiled before the focus changes to an LAD/FBD program from an associated program source.
- The declaration tables in the LAD/FBD source file and/or from LAD/FBD programs within the LAD/FBD source file are changed.
  The symbol check/type update takes place for an LAD/FBD program belonging to the LAD/FBD source file if the changes affect that LAD/FBD program.
  The following cases are possible:
  - A declaration table is changed within an LAD/FBD program.
    The automatic symbol check and type update only takes place after changing from the declaration table to the network.
  - The change within a declaration table takes place within an LAD/FBD program and affects another LAD/FBD program within the same program source.
    The automatic symbol check and type update takes place when the focus is on that other LAD/FBD program.
  - Changes within a declaration table take place within a program source and affect an LAD/FBD program in another program source.
    The automatic symbol check and type update for the LAD/FBD program from another program source can only take place once the changed program source has been compiled.
- A technology object (such as an axis) used by the LAD/FBD program is changed.
  The automatic symbol check and type update takes place when the focus is on the LAD/FBD program.

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC), or a function block (FB).

If you click the mouse on the relevant place in the network (box parameter, input field, symbol highlighted in red) following a symbol check/type update, the tool tip indicates the following:

- the expected data type among the box parameters
- The data type of the variable with labeled input fields
- the cause of trouble in symbols which are highlighted in red whereby the symbol errors may have the following reasons:
  - The specified symbol does not exist
  - The specified symbol is not visible in the current context (incorrect or missing entry of the connections in the declaration table)
  - The specified variable does not have the appropriate type

Note

The symbol check is automatically updated as soon as the declaration table has been edited and left.
All errors, including errors in the declaration table, are displayed in the detail view.

Example of a type update

Introduction

During the type update all the data types used are updated:

- the list of permitted data types in an input field
- an LAD/FBD program's box type, i.e. in terms of the creation type (program, FB or FC) selected for the LAD/FBD program
- a box's interface in terms of the list of permitted data types per box parameter
- other data types (structures, enumerations, etc.)

For example, a structure AAA {a : BOOL} is used in an LAD/FBD program. If this structure is changed, e.g. AAA {a : BOOL, b : LREAL}, this change is applied by the LAD/FBD program during the type update.

Initial situation

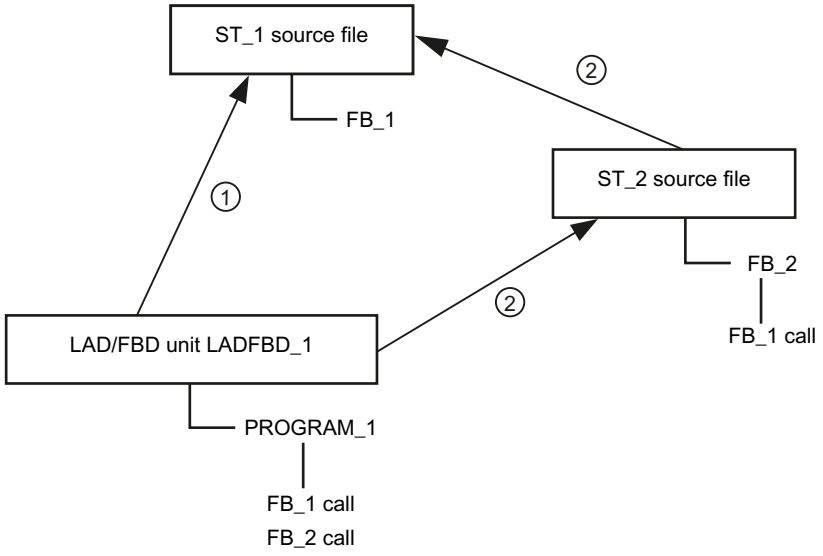
The following are present:

- an ST source ST_1 with a function block FB_1
- an ST source ST_2 with a function block FB_2
- an LAD/FBD unit LADFBD_1 with an LAD/FBD program PROGRAM_1
- FB_1 is called within ST_2, i.e. a connection (Page 5222) to ST_1 has to be declared in the ST_2 declaration table

- FB_1 is called within PROGRAM_1, i.e. a connection (Page 5222) to ST_1 has to be declared in the LADFBD_1 declaration table
- FB_2 is called within PROGRAM_1, i.e. a connection (Page 5222) to ST_2 has to be declared in the LADFBD_1 declaration table

How the type update works

This is a special scenario where a program source (in this case LADFBD_1) imports another program source (in this case ST_1) both explicitly and by means of inheritance. Inheritance takes place via another imported program source (in this case ST_2) which, in turn, imports other sources (in this case ST_1).



① LADFBD_1 explicitly imports ST_1

② LADFBD_1 imports ST_1 by means of inheritance (ST_1 → ST_2 → LADFBD_1)

Figure 7-448 Special scenario of explicit import and inheritance

Changes are now made at the interface of the FB_1, for example one or more input/output parameters are added (see also interface adjustment in FB/FC (Page 5252)) and ST_1 is recompiled.

When PROGRAM_1 is opened in the LAD/FBD editor, the FB_1 call is automatically updated, i.e. a type update occurs via which the changed interface is updated.

Despite the fact that the type update runs error-free, the compiler issues an error message during the compilation of LADFBD_1 because the import of ST_1 by inheritance via the imported ST_2 presupposes that ST_2 is also recompiled.

In order to recompile ST_2 without errors, the changed interface of the FB_1 call must be updated manually within ST_2.

Note

If program sources are imported which import other program sources themselves (inheritance), an error message may be output by the compiler during the compilation of the program source which is being imported, even if the type update runs error-free.

Example of a symbol check

Introduction

During the symbol check, the symbols used in the network are checked in context.

For example, the network includes a box with a BOOL-type input. An LREAL-type variable is now assigned to this input. The symbol check determines that this variable cannot be used in this context and, therefore, flags up this variable in red.

Initial situation

The following are present:

- an ST source ST_1 with the unit variable VAR_1
- an LAD/FBD unit LADFBD_1 with an LAD/FBD program PROGRAM_1
- the unit variable VAR_1 is used within PROGRAM_1, i.e. a connection (Page 5223) to ST_1 has to be declared in the LADFBD_1 declaration table

How the symbol check works

The unit variable VAR_1 is now changed, e.g. the name is changed.

If ST_1 is recompiled after this change, the unit variable VAR_1 is invalid in LADFBD_1.

When PROGRAM_1 is opened in the LAD/FBD editor, an automatic symbol check is performed, i.e. the changed variable is highlighted in red lettering.

The changed variable must be updated manually in PROGRAM_1.

Deactivating automatic symbol check and type update

The automatic update of the symbol check and type database should only be deactivated if computation speed is unduly reduced, e.g. if a large project is being processed on a slow computer and the hourglass is displayed after any change in the declaration table or in referenced external units.

To deactivate automatic symbol check and type update, proceed as follows:

1. Select the **Options > Settings** menu item.
2. Select the **LAD/FBD editor** tab.

3. Deactivate the **Automatic symbol check and type update** checkbox.
4. Confirm with **OK**.

Note

If the automatic symbol check is deactivated, the display may sometimes be inaccurate, e.g. after an external call has been inserted, the call box interface may be incorrectly displayed (i.e. not updated), or not displayed at all. This is because the current information only becomes available to the LAD/FBD editor after the "Symbol check and type update at a specified time" (Page 5099) has been called.

Perform symbol check and type update at a specified time

To perform a symbol check at a specified time, proceed as follows:

- Select the **LAD/FBD program > Symbol check and type update** menu item (shortcut Ctrl+T).
  - or -
  Click the **Symbol check and type update** icon.

Note

The symbol check at a specified time can only be performed when the "Automatic symbol check and type update" (Page 5094) is deactivated.

Setting the data type list of the declaration table

In the declaration area, all function blocks of the project not used in the program are stated in the list of data types by default.

To improve clarity, it is possible to set that only those function blocks are displayed for which an entry in the **Connections** tab exists.

To set the data type display, proceed as follows:

1. Select the **Options > Settings** menu item.
2. Select the tab **LAD/FBD editor**.
3. Click the **Only known types if type lists exist** check box.
4. Confirm with **OK**.

Changing fonts

Use the following procedure to change the font of the LAD/FBD editor:

1. Select the **Options > Settings** menu item.
2. Select the tab **LAD/FBD editor**.
3. Click the **Fonts and colors button**.
   The **Fonts and colors** dialog box with the **Fonts** tab appears.

4. Select the font, font size, type, or display you require.

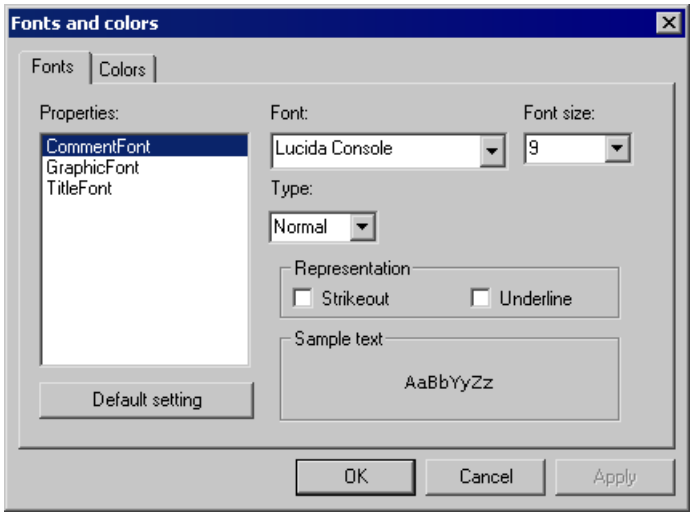


Figure 7-449 Fonts and colors dialog box

5. Confirm with **OK**.

Changes to settings are only applied to LAD/FDB editors that are opened afterwards.

Changing colors

Use the following procedure to change the colors of the LAD/FBD editor:

1. Select the **Options > Settings** menu item.
2. Select the tab **LAD/FBD editor**.
3. Click the **Fonts and colors button**.
   The **Fonts and colors** dialog box appears.
4. Click the **Colors** tab.

5. Choose a color.

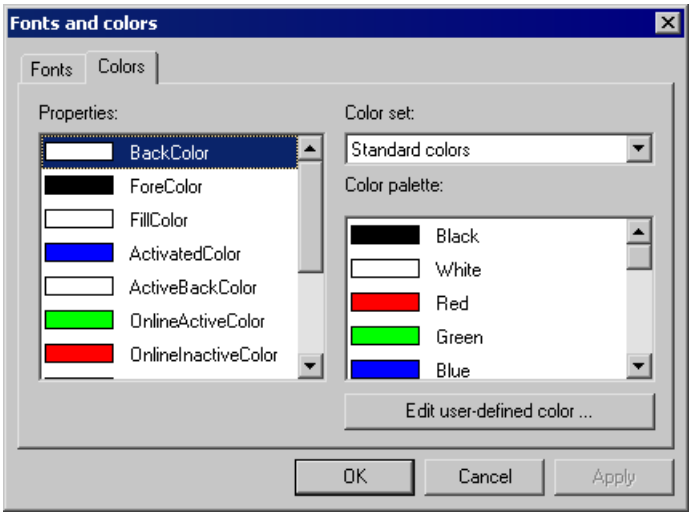

Figure 7-450 Fonts and colors dialog box

6. Confirm with **OK**.

Changes to settings are only applied to LAD/FDB editors that are opened afterwards.

Calling online help in the LAD/FBD editor

The online help can provide assistance for many of the operating steps. Call up the online help using either the:

- **Help** menu
  - Help topics
  - Context-sensitive help
  - Getting Started
- General help with the F1 key
- **Help** button, which appears in an open dialog box
- Context-sensitive help with the Shift+F1 key combination or the arrow with question mark icon (also for LAD/FBD elements in a network).

7.3.4 LAD/FBD programming

7.3.4.1 Programming software

This chapter describes the various operator control options in the LAD/FBD editor and the basic procedure for LAD/FBD programming.

7.3.4.2 Managing LAD/FBD source file

LAD/FBD units are assigned to the SIMOTION device on which the LAD/FBD programs contained in the unit will subsequently be run (e.g. SIMOTION D455-2). They are stored in the project navigator under the SIMOTION device in the PROGRAMS folder.

The individual program organization units (POU, LAD/FBD programs) are stored under a LAD/FBD unit.

Note

ST source files, MCC units and DCC charts are also stored in the **PROGRAMS** folder under the SIMOTION device.

For a description of the SIMOTION ST (Structured Text) programming language, refer to the SIMOTION ST Programming and Operating Manual.

For a description of the SIMOTION MCC (Motion Control Chart) programming language, refer to the SIMOTION MCC Programming and Operating Manual.

Inserting a new LAD/FBD source file

LAD/FBD units are assigned to the SIMOTION device on which the LAD/FBD programs contained in the unit will subsequently be run (e.g. SIMOTION D455-2).

There are several ways of inserting a new LAD/FBD unit.

- In the project navigator: in the **PROGRAMS** folder using the **Insert LAD/FBD unit** element
- Select the **PROGRAMS** folder in the project navigator and choose the command **Insert > Program > LAD/FBD unit** in the menu.
- Select the **PROGRAMS** folder in the project navigator and choose the command **Insert new object > LAD/FBD unit** in the context menu.

Procedure

To insert a new LAD/FBD unit using the context menu:

1. Open the appropriate SIMOTION device in the project navigator.
2. Select the **PROGRAMS** folder.
3. Select the **Insert new object > Insert LAD/FBD unit** context menu.

4. Enter the name of the LAD/FBD unit.
   The names of program sources must comply with the rules for identifiers (Page 5155): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters.
   The permissible length of the name depends on the SIMOTION Kernel version:
   - SIMOTION Kernel as of version V4.1: a maximum of 128 characters.
   - SIMOTION Kernel up to version V4.0: a maximum of 8 characters.

   Names must be unique within the SIMOTION device. Protected or reserved identifiers (Page 5410) are not permitted.
   Existing program sources (e.g. LAD/FBD units, ST source files) are displayed.
5. You can also enter an author, version, and a comment.
6. Activate the **Open editor automatically** checkbox.
7. If necessary, select the **Compiler** tab and make any local compiler settings; see Local compiler settings (Page 5112).
8. Confirm with **OK**.

Note

When you click **OK**, the LAD/FBD unit is transferred to the project only. The data, together with the project, is only saved to the data carrier if you select, for example, **Project > Save**, **Project > Save and compile changes**, or **Project > Save and recompile all**.

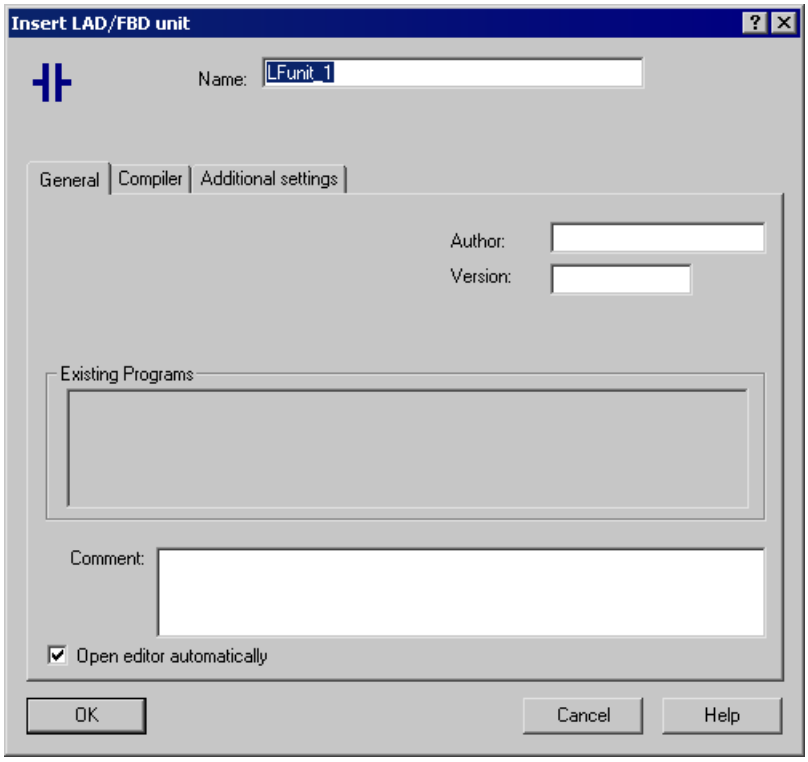

Figure 7-451 Insert LAD/FBD Unit dialog box

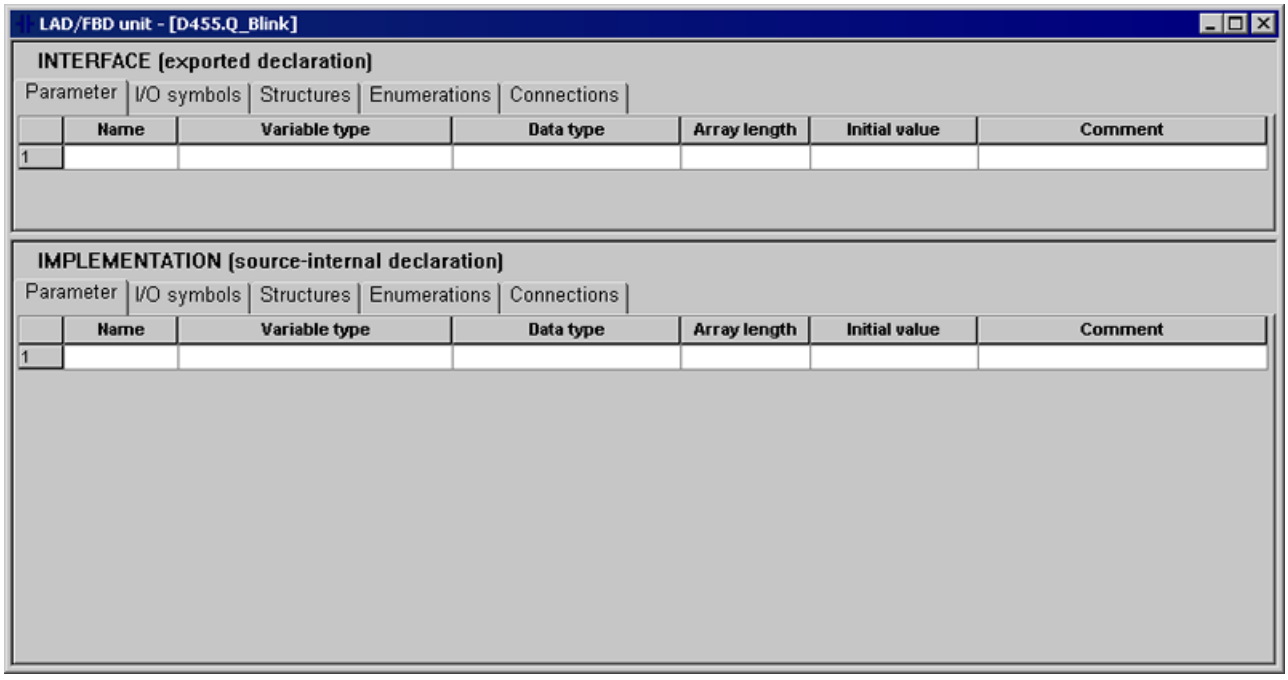

Figure 7-452 New LAD/FBD unit (declaration table for the interface and implementation sections)

Opening an existing LAD/FBD source file

Procedure

To open an existing LAD/FBD unit, proceed as follows:

1. Open the subtree of the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder.
3. Select the required LAD/FBD unit.
4. Select the **Open** context menu.
5. Only for LAD/FBD units with know-how protection (Page 5106):
   If the LAD/FBD unit (or a program of this unit) is not already open and the login assigned to the LAD/FBD unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (until the unit and all its programs are closed).
   - If required, activate the "Use login as a standard login" checkbox.
     You will be logged in with this login and can now open additional units to which the same login is assigned without having to re-enter the password.

The LAD/FBD unit (declaration table) opens in the workspace. Multiple units can be opened.

Note

You can also double-click the required LAD/FBD unit to open it.

Saving and compiling a LAD/FBD source file

Requirements:

Ensure that the LAD/FBD unit or one of the associated LAD/FBD programs is the active window in the workbench.

To save a LAD/FBD unit and all its associated LAD/FBD programs in the project and start the compiler:

- Select the **Save and compile** icon in the LAD/FBD editor toolbar.
  - or -
  Select the **LAD/FBD unit > Save and compile** menu item.
  - or -
  Select the LAD/FBD unit or a LAD/FBD program in the project navigator and select **Save and compile** in the context menu.
  - or -
  Shortcut **Ctrl+B**.

Note

Save and compile only applies the changes to LAD/FBD units and associated LAD/FBD programs in the project. The data is only saved to the data carrier, together with the project, if you select **Project > Save** or **Project > Save and compile changes**.

A LAD/FBD unit can also be saved outside the project (exported).

Error messages and warnings relating to compilation are displayed in the **Compile/check output** tab in the detail view.

Closing a LAD/FBD source file

To close a LAD/FBD unit opened in the working window, proceed as follows:

1. Click the **x** button (cross) in the title bar of the dialog box of the LAD/FBD unit.
   - or -
   Select the **LAD/FBD unit > Close** menu item.
   - or -
   Select **Windows > Close all windows** menu item.
   - or -
   Shortcut **Ctrl+F4**.
   If the changes have not yet been saved in the project, you can save or cancel them, or abort the close operation.

Cut/copy/delete operations in a LAD/FBD source file

A LAD/FBD source file can be cut or copied together with all its associated LAD/FBD programs and pasted into the same or another SIMOTION device.

It is not possible to paste in a LAD/FBD source file that has been deleted.

To **cut**, **copy** or **delete**, proceed as follows:

1. In the project navigator, select the required LAD/FBD source file.
2. In the context menu, select the appropriate item (**Cut**, **Copy**, or **Delete**).
3. Change the name, if necessary (refer to "See also").

See also

Renaming a LAD/FBD source file (Page 5110)

Inserting a cut or copied LAD/FBD source file

To paste in a cut or copied LAD/FBD source file:

1. Under the SIMOTION device, select the **PROGRAMS** folder.
2. In the context menu, select **Paste**.
   The LAD/FBD source file is pasted in under a new name.
3. If required, amend the name.

Know-how protection for LAD/FBD source files

You can protect LAD/FBD units against being accessed by unauthorized third parties. Protected LAD/FBD units and all associated LAD/FBD programs can only be opened or exported in EXP format when the password is entered.

The SIMOTION online help provides additional information on know-how protection.

Note

If you export in XML format, the LAD/FBD units are exported in an encrypted format. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

7.3.4.3 Exporting and importing LAD/FBD source files

The export and import functions offer you the option of saving a LAD/FBD source file outside the project on your hard disk so that you can copy it from there into another project.

Exporting a LAD/FBD source file in XML format

You can use an XML export to save an LAD/FBD unit in a directory outside the project, independently of any particular version or platform.

To export a LAD/FBD unit in XML format:

1. In the project navigator, select the required LAD/FBD unit.
2. Select the **Expert > Save project and export object** context menu or the **Project > Save and export** menu.
3. Select the directory for the XML export and confirm with **OK**.

Note

Structures (e.g. several POUs in one unit, advance binary switching) can be used with SIMOTION Kernel as of version V4.1. These structures may not be supported by previous versions.

Note

LAD/FBD units with know-how protection can also be exported in XML format. The LAD/FBD units are exported in encrypted format. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

Importing LAD/FBD source files as XML data

To import a LAD/FBD source file in XML format:

1. In the project navigator, select the **PROGRAMS** entry or a LAD/FBD source file.
2. In the context menu, select **Import object** or **Expert > Import object**.
3. Select the XML data to be imported and click **OK** to confirm.
   The LAD/FBD source file is inserted.

Exporting a POU in XML format

Note

Structures (e.g. several POUs in one unit, advance binary switching) can be used with SIMOTION Kernel as of version V4.1. These structures may not be supported by previous versions.

You can use an XML export to save individual program organization units in a directory outside the project, independently of any particular version or platform.

To export a POU in XML format, proceed as follows:

1. In the project navigator in the LAD/FBD unit, select the POU you want to export.
2. In the context menu, select **Export as XML**.

3. Only for POUs in LAD/FBD units with know-how protection and which are not already open:
   If the associated LAD/FBD unit (or a POU of this unit) is not already open and the login assigned to the LAD/FBD unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this chart is temporarily canceled (for this export).
   - If required, activate the **Use login as a standard login** checkbox.
     You will be logged in with this login and can now export or open additional units to which the same login is assigned without having to re-enter the password.
4. Select the directory for the XML export and confirm with **OK**.
5. Enter the path and file name for the XML export and click **Save** to confirm.

The POU is saved as XML format; the file name is given the default extension *.xml

Note

A POU with know-how protection is exported without protection.

Importing a POU from XML format

To import a POU in XML format, proceed as follows:

1. In the project navigator, select the **PROGRAMS** entry or a LAD/FBD unit.
2. In the context menu, select **Import object**.
3. Select the XML data to be imported and click **OK** to confirm.
   The POU is inserted.

Exporting a LAD/FBD source file in EXP format

With the export in the EXP format, you can save an LAD/FBD unit in a format that can also be interpreted by third-party controllers.

To export an LAD/FBD unit in EXP format, proceed as follows:

1. Select the LAD/FBD unit in the project navigator.
2. Select the context menu **Expert > Export as .EXP**.
3. Only for LAD/FBD units with know-how protection (Page 5106) and which are not already open:
   If the LAD/FBD unit (or a program of this unit) is not already open and the login assigned to the LAD/FBD unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (for this export).
   - If required, activate the **Use login as a standard login** checkbox.
     You will be logged in with this login and can now export or open additional units to which the same login is assigned without having to re-enter the password.
4. Enter the path and file name for the EXP export and click **Save** to confirm.

The LAD/FBD unit is saved in EXP format and given the file extension *.exp by default.

Note

The export of an LAD/FBD unit in EXP format and subsequent import of the EXP data can change the structure of the networks in the LAD/FBD programs. The compilation result remains unchanged.

An LAD/FBD unit with know-how protection is exported without protection.

Importing EXP data into a LAD/FBD source file

With the import of EXP data, you can create an LAD/FBD unit from third-party programs that are available EXP format.

To import EXP data into a LAD/FBD unit:

1. Select the LAD/FBD unit in the project navigator.
2. Select the context menu **Expert > Import from .EXP**.
3. Select the EXP file to be imported.
4. Select the program sources to which Connections (Page 5222) care to be created.
5. Confirm with **OK**.

The EXP file is imported into the LAD/FBD unit and the corresponding LAD/FBD programs created. The connections to the selected program sources are also created.

Note

Note the following when importing EXP data:

- It is possible to import from XOR to FBD.
- Preconnection with simple data types (signal connection) is not generally supported.
- The original structure is retained when you import data from EXP files. If the structure cannot be compiled due to type conflicts, the relevant parameters are highlighted in red.
  A type conflict can be resolved by manual revision.

7.3.4.4 LAD/FBD source files - defining properties

Defining the properties of a LAD/FBD source file

Procedure

1. Under the SIMOTION device, open the **PROGRAMS** folder.
2. Select the required LAD/FBD unit.

3. Select the **Edit > Object Properties** menu command.
4. If necessary, select further tabs to make local settings (only valid for this LAD/FBD unit):
   - **General** tab: General details for the LAD/FBD unit, e.g. timestamp of the last change and the storage location of the project (see figure).
   - **Compiler** tab: Local settings of the compiler (Page 5112) for code generation and message display.
   - **Additional settings** tab: Display of the compiler options in accordance with the current compiler settings (see the SIMOTION ST Programming and Operating Manual).
   - **Compilation** tab: Display of the compiler options during the last compilation of the LAD/FBD unit (see the SIMOTION ST Programming and Operating Manual).
   - **Object address** tab: Set the internal object address of the LAD/FBD unit. The object addresses of the other program sources are displayed.

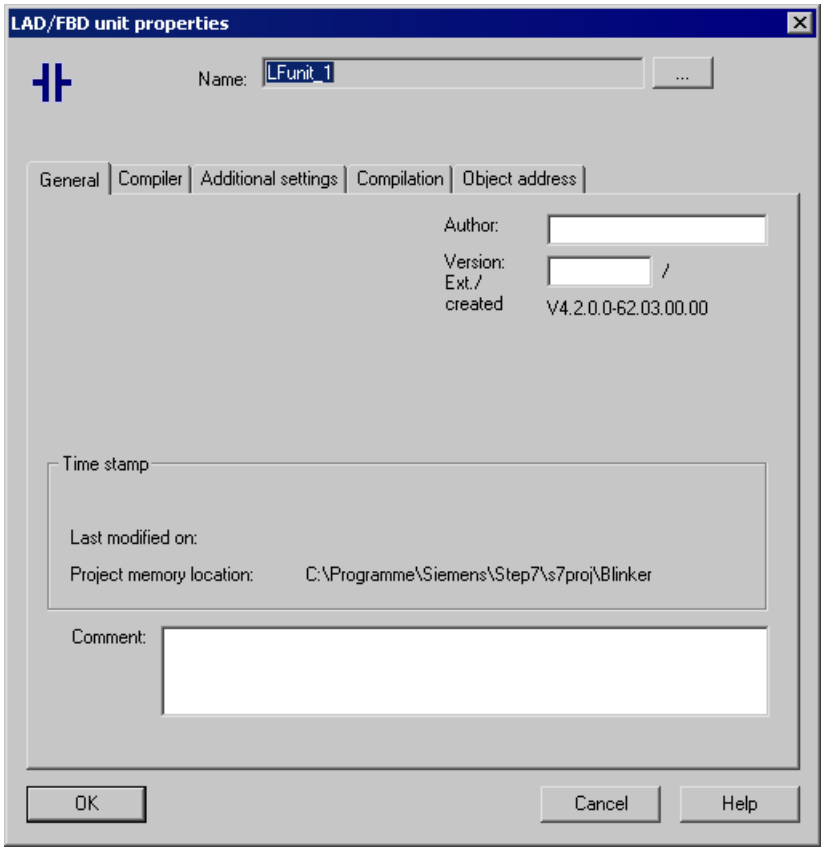

Figure 7-453 Properties of a LAD/FBD source file

Renaming a LAD/FBD source file

To rename a LAD/FBD source file:

1. Open the Properties window of the LAD/FBD source file.
2. Click ... .

3. Confirm the message with **OK** and enter the new name in the **New name** input field of the **Change Name** dialog box.
4. Acknowledge the entries with **Apply**.

Making settings for the compiler

You can define the compiler settings as follows:

- globally for the SIMOTION project, always applicable to all programming languages, see Global compiler settings (Page 5111)
- locally for an individual LAD/FBD source within the SIMOTION project, see Local compiler settings (Page 5112)

Global compiler settings

The global settings are always valid for all programming languages within the SIMOTION project. If there are global settings which only apply to specific programming languages, this is specified on the **Compiler** tab.

Procedure

1. Select the menu **Options > Settings**.
2. Select the **Compiler** tab.
3. Make the settings in accordance with the parameter description in the SIMOTION ST Programming and Operating Manual.
4. Confirm with **OK**.

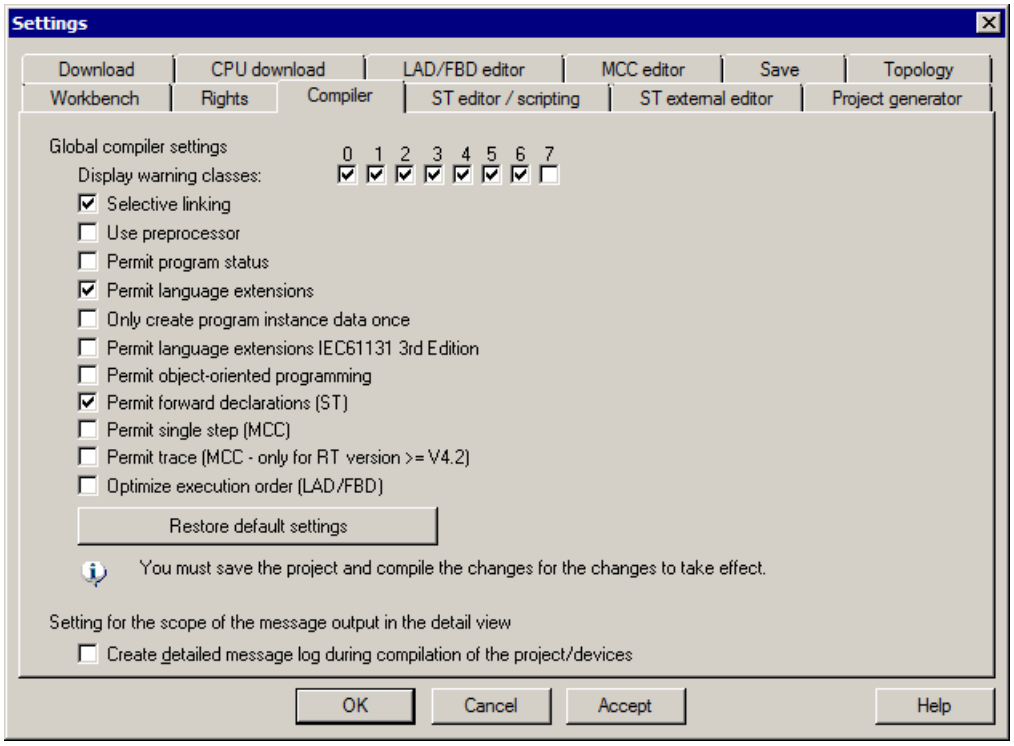

Figure 7-454 Global compiler settings

Parameter

For a description of the parameters of the global compiler settings, refer to SIMOTION ST Programming and Operating Manual.

Local compiler settings

Local settings are configured individually for each LAD/FBD unit; local settings overwrite global settings.

Procedure

To select the compiler options, proceed as follows:

1. Open the Properties window for the LAD/FBD unit (see Defining the properties of an LAD/FBD unit (Page 5109)).
2. Select the **Compiler** tab.
3. Define the settings according to the following table.
4. Click **OK** to confirm.

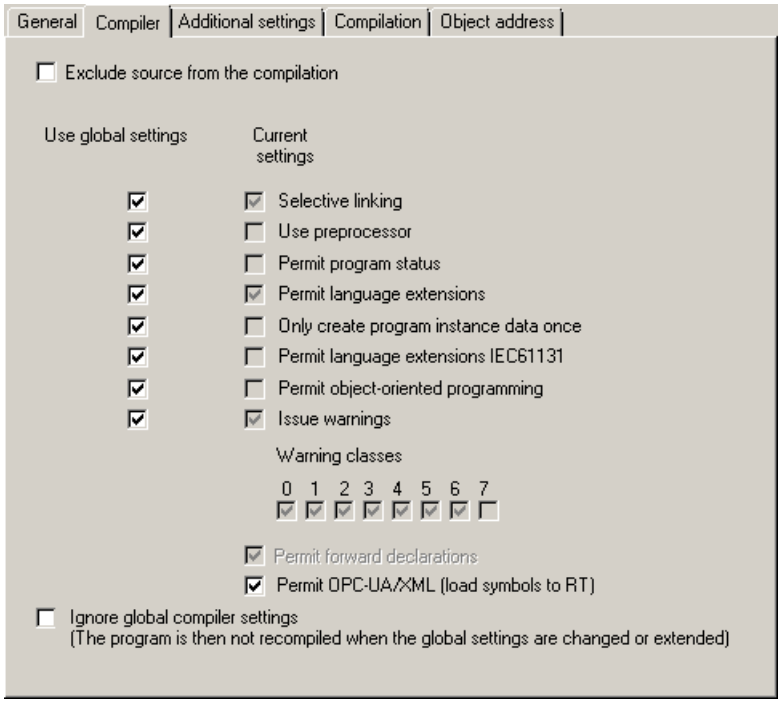

Figure 7-455 Local compiler settings for LAD/FBD units in the Properties window

The current compiler options (the combination of global and local compiler settings which currently applies) for the program source are displayed on the **Additional settings** tab. The compiler options used the last time the program source was compiled can be seen on the **Compilation** tab.

The SIMOTION ST Programming and Operating Manual contains further information on what the compiler options mean.

Table 7-524 Local compiler settings

Parameter	Description
Exclude the source from the compilation	**Active**: This source is not compiled upon compilation of the project, the device or the library (e.g. Menu **Project > Save and recompile all**). The source is marked accordingly in the project navigator. Corresponding information is provided upon compilation. **Inactive** (standard): The source is compiled upon compilation of the project, the device or the library.
Use global settings	This checkbox is available for every parameter which also has a global setting. This is where you define whether the global settings are adopted or whether the local settings will apply. See the description under Effectiveness of global or local settings in the SIMOTION ST Programming and Operating Manual. Use the second checkbox or the other checkboxes for the relevant parameters (described below) to define the local settings.
Selective linking[1]	**Active**: Unused code is removed from the executable program. **Inactive**: Unused code is retained in the executable program. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).

Parameter	Description
Use preprocessor[1]	**Active**: Preprocessor is used, see SIMOTION ST Programming and Operating Manual. **Inactive**: Preprocessor is not used. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).
Enable program status[1]	**Active**: Additional program code is generated to enable monitoring of program variables (including local variables). **Inactive**: Program status not possible. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Program status (Page 5348).
Permit language extensions[1]	**Active**: Language elements are permitted that do not comply with IEC 61131-3. • Direct bit access to variables of a bit data type, see the SIMOTION ST Programming and Operating Manual. • Accessing the input parameter of a function block when outside the function block, see the SIMOTION ST Programming and Operating Manual. • Calling a program while in a different program, see the SIMOTION ST Programming and Operating Manual. **Inactive**: Only language elements are permitted that comply with IEC 61131-3. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).
Only create program instance data once[1]	**Active**: The local variables of a program are only stored once in the user memory of the unit. This setting is required when calling a program while in a different program, see the SIMOTION ST Programming and Operating Manual. **Inactive**: The local variables of a program are stored according to the task assignment in the user memory of the associated task. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Memory areas for the variable types in the SIMOTION ST Programming and Operating Manual. For further information, refer to the SIMOTION Basic Functions Function Manual.

Parameter	Description
Permit language extensions, IEC61131 3rd edition[1]	**Active**: Additional language elements can be used in accordance with IEC 61131-3 3rd edition. The corresponding keywords are locked as reserved or protected identifiers. • Nested block comments (ST) • CONTINUE statement (ST) • Standard-compliant system functions LOWER_BOUND and UPPER_BOUND for determining the limits of a dynamic ARRAY • Additional system functions: – FROM_BIG_ENDIAN – FROM_LITTLE_ENDIAN – IS_VALID – TO_BIG_ENDIAN – TO_LITTLE_ENDIAN **Inactive**: The additional language elements cannot be used. The corresponding keywords are not locked. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). **Note** When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.
Permit object-oriented programming[1]	**Active**: The keywords for object-oriented programming according to IEC 61131-3 3rd edition are locked as reserved or protected identifiers. General references (Page 5194) can also be formed. **Inactive** (standard): The keywords for object-oriented programming are not locked. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). **Note** Independently of the setting the program organization units created in ST sources using object-oriented programming (e.g. classes, methods) can be used in this source. No program organization units can be created in LAB/FBD using object-oriented programming. When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

Parameter	Description
Issue warnings Warning classes[1]	In addition to error messages, the compiler can issue warnings and information. You can set the scope of the warning messages to be issued. "Issue warnings" checkbox: **Active**: The compiler issues the warnings and information according to the warning class selection that follows. **Inactive**: The compiler suppresses all warnings and information concerning this source file. The checkboxes for the warning classes are hidden. **Gray background** (display only): Operating on a global setting basis, the compiler always issues warnings and information in accordance with the global warning class selection shown below (if "Use global settings" = active). "Warning classes" checkboxes (only if "Issue warnings" = active): **Active**: The compiler issues warnings and information for the selected class. **Inactive**: The compiler suppresses warnings and information for the associated class. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See also Meaning of the warning classes in the SIMOTION ST Programming and Operating Manual.
Permit forward declarations	Forward declarations enable you to use program organization units (POUs) before they are completely defined. See the SIMOTION ST Programming and Operating Manual. This setting is always **active**. Forward declarations are always permitted for the LAD/FBD programming language.
Permit OPC-UA / -XML (load symbols to RT)	**Active:** Symbol information for the unit variables of the LAD/FBD unit is available in the SIMOTION device. This is required for: • The *_exportUnitDataSet* and *_importUnitDataSet* functions; see the SIMOTION Basic Functions Function Manual • The watch function of IT DIAG **Inactive:** Symbol information is not created.
Exclude the source from the compilation	**Active**: This source is not compiled upon compilation of the project, the device or the library (e.g. Menu **Project > Save and recompile all**). The source is marked accordingly in the project navigator. Corresponding information is provided upon compilation. **Inactive** (standard): The source is compiled upon compilation of the project, the device or the library.
Ignore global compiler settings (The program is not compiled again if the global settings are changed or extended.)	**Active:** The global settings of the compiler are ineffective for all parameters. The "Use global settings" checkboxes cannot be selected and are grayed out. When changing the global compiler settings, the LAD/FBD unit is not recompiled. **Inactive:** The checkboxes "Use Global Settings" can be selected for all parameters and are presented against a white background. These checkboxes specify whether the global properties are taken over for the corresponding parameters. See the description under Effectiveness of global or local settings in the SIMOTION ST Programming and Operating Manual.

[1] Global setting is also possible (**Options > Settings > Compiler** menu), see Global compiler settings (Page 5111). See also the description on Effectiveness of global or local compiler settings in the SIMOTION ST Programming and Operating Manual.

7.3.4.5 Managing LAD/FBD programs

LAD/FBD programs are the individual program organization units (program, function, function block) in a LAD/FBD source file. They are stored under the LAD/FBD source file in the project navigator.

Inserting a new LAD/FBD program

You can insert a new LAD/FBD program as program organization unit (POU) for an existing LAD/FBD source as follows (see Inserting a new LAD/FBD source (Page 5102)):

- In the project navigator: Below an LAD/FBD unit using the element **Insert LAD/FBD program**
- Select the required LAD/FBD unit in the project navigator followed by **Insert > Program > LAD/FBD program**
- Open the required LAD/FBD unit and select the **Insert LAD/FBD program** icon in the **LAD/FBD unit** toolbar

Procedure

To insert a new LAD/FBD program, proceed as follows:

1. Open the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder and a LAD/FBD unit.
3. Double-click the entry **Insert LAD/FBD program**.
4. Enter the name of the program in the **Insert LAD/FBD Program** dialog box.
   Names for LAD/FBD programs must comply with the Rules for identifiers (Page 5155): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters. Protected or reserved identifiers (Page 5410) are not allowed. The permissible length of the name is 25 characters.
   The names must be unique within the LAD/FBD source. The names of all exportable program organization units (POUs) must also be unique within the SIMOTION device. The names of all LAD/FBD programs of the program source as well as the names of all exportable POUs of the device are displayed.
5. Optionally enter the identifier of an object-oriented namespace.
   Identifiers for namespaces must comply with the Rules for identifiers (Page 5155) (see above).
   When an identifier is entered, the MCC chart is assigned to the specified namespace.
   The compiler option (Page 5111) "Permit object-oriented programming" must be activated.
   For further information on object-oriented namespaces, see the appropriate section in the SIMOTION ST Programming and Operating Manual.
6. Select Program, Function, or Function block as the **Creation type**. See also Changing the LAD/FBD program creation type (Page 5124).
7. For the Function creation type only:
   Select Return value data type as the Return type
   (<--> for no return value).

8. Activate the **Exportable** checkbox if you want the LAD/FBD program to also be available in other program sources (LAD/FBD units, MCC units, or ST source files) or in the execution system.
9. You can also enter an author, version, and a comment.
10. Activate the **Open editor automatically** checkbox.
11. Click **OK** to confirm.

Note

When you click **OK**, the LAD/FBD program is transferred to the project only. The data is only saved to the data carrier, together with the project, if you select, for example, **Project > Save**, **Project > Save and compile changes**, or **Project > Save and recompile all**.

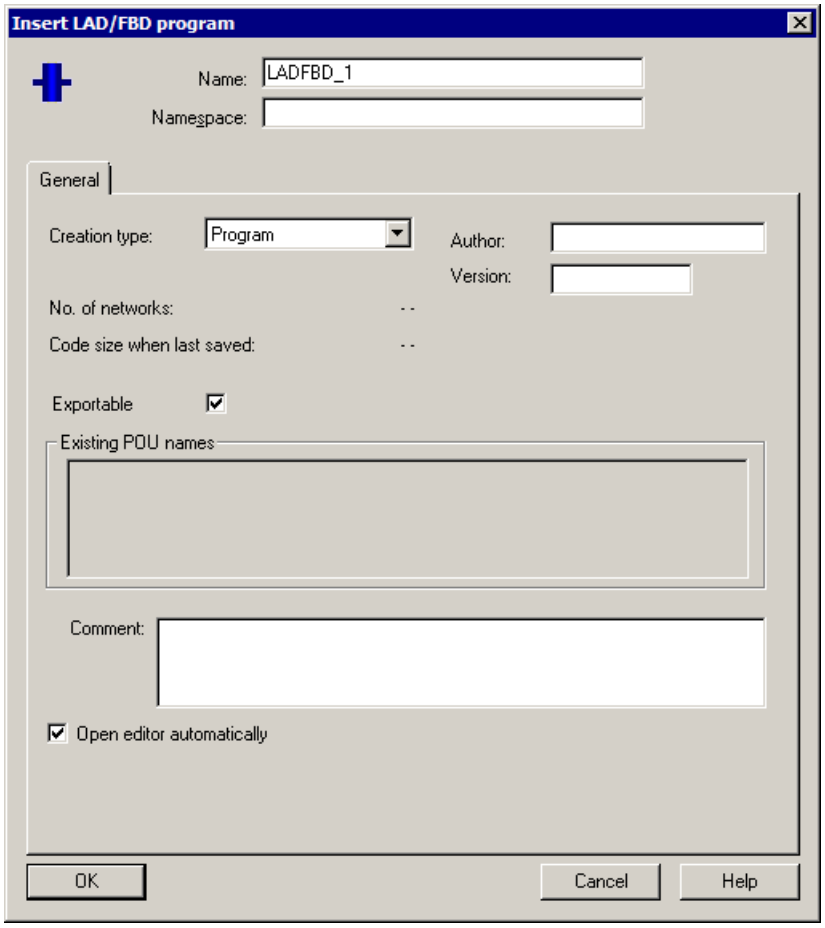

Figure 7-456 Insert LAD/FBD Program dialog box

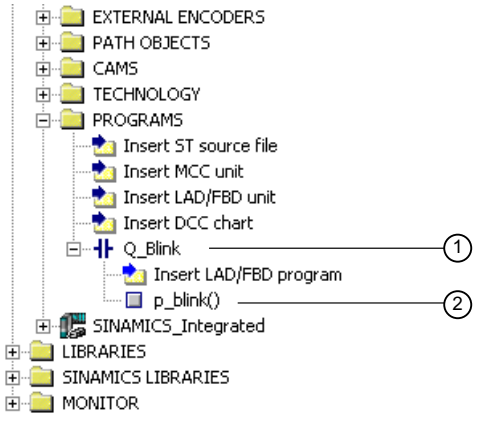
Note

Existing POE names are only displayed if the check box "Show existing POE names (insert dialog POE for LAD/FBD and MCC)" is set in the Settings > Workbench. If there are a large number of POEs in the project, it is recommended to deselect this option, as the computer memory for the process may not be sufficient to refresh the display.



① Name of the LAD/FBD unit

② Name of the LAD/FBD program

Figure 7-457 Displaying the unit and program name in the project navigator

Opening an existing LAD/FBD program

All LAD/FBD programs belonging to an LAD/FBD unit are located in the project navigator underneath the LAD/FBD unit.

Procedure

To open an available program, proceed as follows:

1. Open the subtree of the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder.
3. Open the LAD/FBD unit containing the required LAD/FBD program.
4. Select the required LAD/FBD program.

5. Select the **Open** context menu.
6. Only for programs below LAD/FBD units with know-how protection (Page 5106):
   If the LAD/FBD unit (or a program of this unit) is not already open and the login assigned to the LAD/FBD unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (until the unit and all its programs are closed).
   - If required, activate the "Use login as a standard login" checkbox.
     You will be logged in with this login and can now open additional units to which the same login is assigned without having to re-enter the password.

The LAD/FBD program opens in the working area. Several LAD/FBD programs can be opened at the same time.

Note

You can also double-click the required LAD/FBD program to open it.

Defining the order of the LAD/FBD programs in the LAD/FBD source file

As of Version V4.2 of SIMOTION SCOUT, the user no longer needs to respect the POU order in the LAD/FBD unit, as this no longer has any role to play in terms of compilability. The user may wish to change the POU order so that the POUs are arranged in a more logical way from his or her own perspective.

Exception

When a project is saved in a format older than Version V4.2 of SIMOTION SCOUT, the order of the LAD/FBD programs in the LAD/FBD source file is of relevance as far as compilation is concerned. A subroutine (function, function block, or program ("program in program")) must be defined before it is used. This is the case when the LAD/FBD program of the subroutine appears in the project navigator above the LAD/FBD program in which it is used. If necessary, reorder the charts (see Subroutine call of function (FC) (Page 5235)).

Prior to saving a project in a project format earlier than version 4.2, you can test the project for downward compatibility (i.e. the correct POU order, etc.) via Project > Old project format > Test the project for downward compatibility.

Procedure

To change the order:

1. Select a LAD/FBD program in the project navigator.
2. In the context menu, select **Up / Down**

Copying the LAD/FBD program

To copy a LAD/FBD program:

1. In your LAD/FBD unit, select the POU you want to copy.
2. In the context menu, select **Copy**.
3. Select the LAD/FBD unit which is to be inserted in the POU.
4. In the context menu, select **Insert.**
   The LAD/FBD program is inserted.

Saving and compiling a LAD/FBD program

An asterisk is appended in the title bar of the project to the name of a program which has been modified but not yet saved.

Note

The entire unit and its POUs are saved and compiled

To save the LAD/FBD program and start the compilation:

1. Click the **Save and compile** icon in the LAD/FBD editor toolbar.
   - or -
   Select the **LAD/FBD program > Save and compile** menu item.
   - or -
   Select the LAD/FBD program in the project navigator and select **Save and compile** in the context menu.
   - or -
   Shortcut **Ctrl+B**.
   - or -
   If you want to save and compile all the available LAD/FBD programs, select the **Project > Save and compile changes** menu command.
   If any errors occur during compilation, the error locations are displayed in the **Detail view**.
2. To fix an error, double-click an error message in the detail view in the **Compile / check output** tab.
   The faulty element is selected and positioned in the window.

Note

Backward compatibility

This SCOUT program version supports structures (e.g. several POUs in one unit, advance binary switching) which may not be able to be processed by previous versions.

Closing a LAD/FBD program

To close a LAD/FBD program opened in the working window, proceed as follows:

1. Click the **x** button (cross) in the title bar of the dialog box of the LAD/FBD **program**.
   - or -
   Select the **LAD/FBD program > Close** menu item.
   - or -
   Select the **Windows > Close all** menu item.
   - or -
   Shortcut **Ctrl+F4**.
   If the changes have not yet been saved, you can save or cancel them, or abort the close operation.

Deleting the LAD/FBD program

To delete a LAD/FBD program:

1. In the project navigator, select the required LAD/FBD program.
2. In the context menu, select **Delete**.

Note

It is not possible to insert a LAD/FBD program that has been deleted.

7.3.4.6 LAD/FBD programs - defining properties

The properties of a LAD/FBD program are specified when it is inserted.

However, these properties can be viewed and modified by doing the following:

1. Open the **PROGRAMS** folder under the SIMOTION device in the project navigator.
2. Open the required LAD/FBD unit.
3. Select the required LAD/FBD program.
4. From the context menu, select **Properties**.
   The **LAD/FBD program properties** dialog box opens.

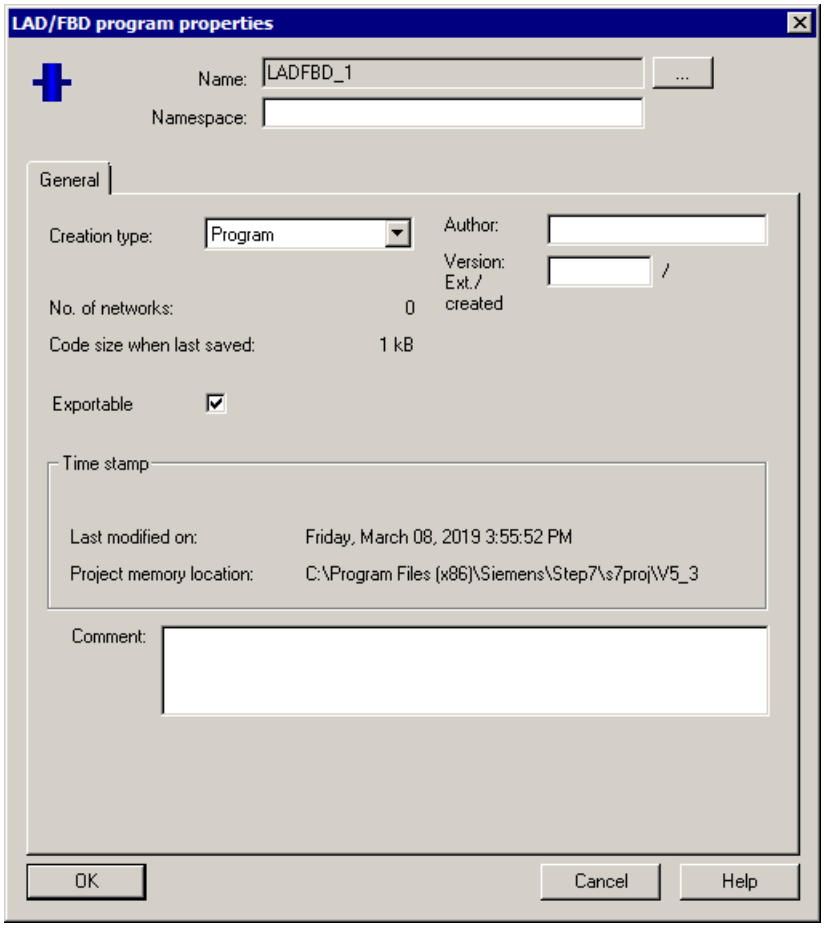


Figure 7-458 Properties of an LAD/FBD program

Renaming a LAD/FBD program

To rename a LAD/FBD program:

1. Open the property view for the LAD/FBD program.
2. Click ... .
3. Confirm the message with **OK** and enter the new name in the **New name** input field of the **Change Name** dialog box.
4. Acknowledge the entries with **Apply**.

Assigning an LAD/FBD program to an object-oriented namespace

Proceed as follows to assign an LAD/FBD program to an object-oriented namespace:

1. Open the Properties window of the LAD/FBD program.
2. Enter the identifier of an object-oriented namespace in the **Namespace** field. Identifiers for namespaces must comply with the Rules for identifiers (Page 5155).
3. Confirm with **OK**.

When an identifier is entered, the LAD/FBD program is assigned to the specified namespace. The compiler option (Page 5111) "Permit object-oriented programming" must be activated.

For further information on object-oriented namespaces, see the appropriate section in the SIMOTION ST Programming and Operating Manual.

Changing the LAD/FBD program creation type

To change the LAD/FBD program creation type:

1. Select the new creation type:
   Program
   Programs can be compared with function blocks. Local variables can be stored here either statically or temporarily. In contrast to FBs or FCs, programs can be assigned to a task or an execution level in SIMOTION SCOUT.
   Programs cannot be called up with parameters. Therefore, unlike FBs and FCs, programs do not have any formal parameters.
   Function block (FB)
   A function block (FB) is a program with static data, i.e. all local variables retain their values after the function block has been executed. Only variables explicitly declared as temporary variables lose their value between two calls.
   Before an FB is used, an instance must be defined: Define a variable (VAR or VAR_GLOBAL) and enter the name of the FB as data type. The FB static data is saved in this instance. You can define multiple instances of an FB, with each instance being independent of the others.
   The static data of an FB instance are retained until the next time the instance is called; the static data are reinitialized when the variable type of the FB instance is reinitialized.
   Data transfer to the FB takes place via input or input/output parameters, and the data return from the FB takes place via input/output parameters or output parameters.
   Function (FC)
   A function (FC) is a function block without static data, that is, all local variables lose their value when the function has been executed. They are reinitialized the next time the function is started.
   Data transfer to the function takes place by means of input parameters; output of a function value (return value) is possible.

7.3.4.7 Printing source files and programs

You can print general information about the LAD/FBD source files and programs. Various print options can be set for the printout.

To print LAD/FBD units and programs, proceed as follows:

1. Select a LAD/FBD source file or program in the project navigator.
2. From the context menu, select **Print** or **Print preview**.
   The **Print** dialog box will appear, enabling you to set various print options.

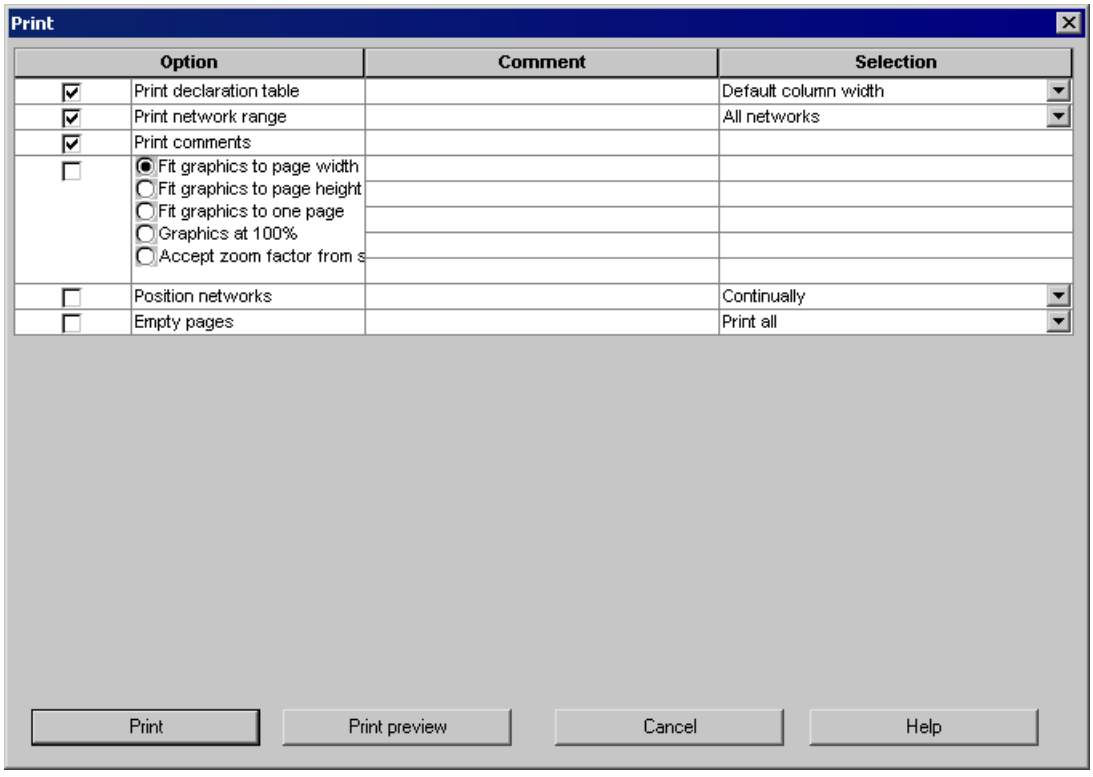

Figure 7-459 Dialog box for setting print options

3. Click the **Print** button.
   The source file or LAD/FBD program is printed with the selected options. General information, the declaration table and diagram all appear in the printout.

Printing a declaration table

To print a declaration table, proceed as follows:

1. Activate the **Print declaration table** check box.
2. Select **Column widths by screen**.
   The contents of the declaration table are printed with the set column widths.
   - or -
   Select **Default column widths**.

Printing a network area

To print a network area, proceed as follows:

1. Activate the **Print network area** check box.
2. Select **All networks**.
   - or -
   Select **Selected networks only**.
   Prints only the networks selected in the editor (blue selection mark on the left side).

Printing comments

You can only select this option if you have already selected the **Print network area** option.

To print comments, proceed as follows:

1. Activate the **Print comments** check box.
2. To obtain a shorter, more concise print image, unselect the **Print comments** option.

Defining print variants

To define the print variant, proceed as follows:

1. Activate the check box.
2. Select **Scale graphics to page width**.
   The print image is scaled so that the widest LAD/FBD network fits on one page width. The print image is one page in width and one or more pages in length, depending on the size of the program.
   - or -
   Select **Scale graphics to page height**.
   The print image is scaled so that the entire graphic fits on one page height. The print image is one page in length and takes up one or more page widths, depending on the width of the networks.
   - or -
   Select **Scale graphics to one page**.
   The print image is reduced so that all networks fit on one page.
   - or -
   Select **Graphic at 100%**.
   The image is printed in its original size. The print image can consist of more than one page vertically or horizontally.
   - or -
   Select **Save screen zoom factor**.
   The image is printed according to the zoom factor set in the editor. The print image can consist of more than one page vertically or horizontally.

Note

If the print image consists of more than one page, an index page is printed to give an overview.

Placing networks

With **Placing networks** you define how the networks are distributed over the pages for printing.

To place networks, proceed as follows:

1. Activate the **Place networks** check box.
2. Select **Continuous**.
   The networks are printed one after another. Page breaks are not taken into account in this case.
   - or -
   Select **All on new page**.
   All networks are printed beginning on a new page. If a network is longer than one page, it is printed on the next page.
   - or -
   Select **Optimized**.
   This minimizes the horizontal break between networks to save more space. E.g.: If a network does not fit on the current page and is not longer than one page, this network will be printed on the next page. If the network is longer, then a page break must be inserted.

Blank pages

You can select how blank pages are printed out. The layout is displayed on the index page. Pages marked with an X are omitted.

To set the printing of blank pages, proceed as follows:

1. Activate the **Blank pages** checkbox.
2. Select **Print all**.
   All blank pages are printed.
   - or -
   Select **Omit at end**.
   Blank pages at the end are not printed. Blank pages in the middle are retained.
   - or -
   Select **Omit all**.
   Blank pages in the middle and at the end are omitted.

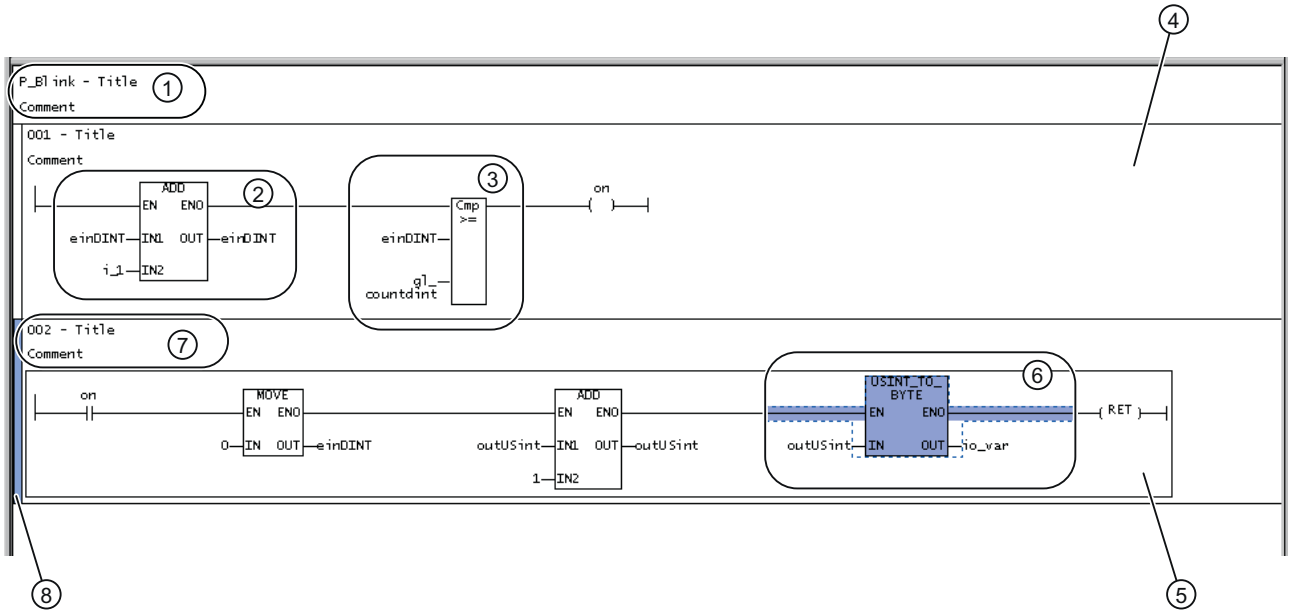
7.3.4.8 LAD/FBD networks and elements

The LAD/FBD program is organized in networks which are displayed in the editor area. A network contains a logic circuit representing the ladder diagram line.

The rules for the structure of a network according to IEC standard 61131-3 apply to the display of a network. Several LAD/FBD elements and boxes can be inserted, copied or deleted in a network.

Note

Use the key combinations (Page 5087)for fast operation in the LAD/FBD editor.



①	Name of program and comment field	⑤	Network 2
②	Call box	⑥	Selected LAD element
③	LAD element	⑦	Name of network and comment field
④	Network 1	⑧	Selected network

Figure 7-460 Display of the networks in the LAD/FBD editor

See also

Numbering the networks (Page 5129)

Inserting networks

To paste in a network:

1. Select an existing network or click in the working window of the open LAD/FBD program.
2. From the context menu, select **Insert network**.
   - or -
   Select **LAD/FBD program > Insert network**.
   - or -
   Click the **Insert network** icon.
   The new network is pasted in directly after the network which is currently selected. If no network is selected, the new network is pasted in at the front.

See also

LAD/FBD networks and elements (Page 5127)

Selecting networks

The relevant networks have to be selected before they can be copied.

To select networks:

1. Select the desired network.
   The network is selected (see figure).
   - or -
   If you want to select several adjacent networks, click the first required network and then, keeping the **Shift** key depressed, click the last one required.
   - or -
   If you want to select several networks which are not adjacent to one another, hold the **Ctrl** key down and click each network you need.

Selected networks are indicated by a light blue edge on their left-hand side. You can choose the selection color in the **LAD/FBD editor** tab of the **Settings** dialog box.

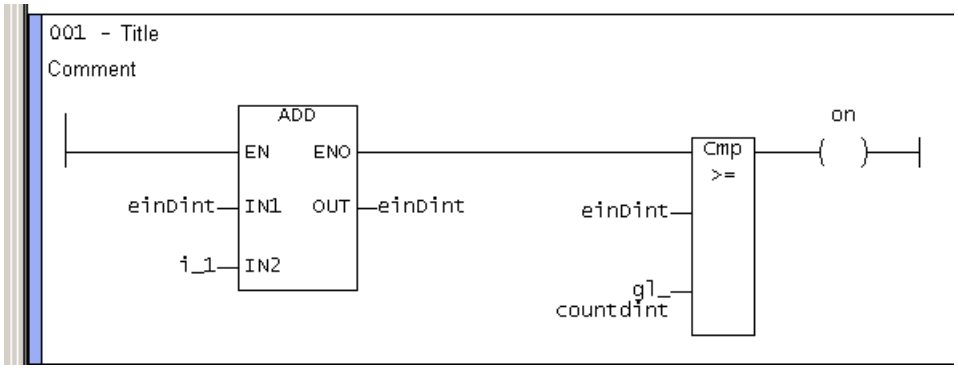


Figure 7-461 Selected network

See also

Settings in the LAD/FBD editor (Page 5092)

Numbering the networks

When a network is pasted in, it is automatically given the next consecutive number. This number is unique and is used to identify the network.

Note

You cannot change the numbering. When a network is deleted, the numbering is automatically adjusted.

See also

LAD/FBD networks and elements (Page 5127)

Enter title/comment

Titles and comments

By default, the LAD/FBD program and/or the network contain a title and a comment field. The title and comment texts are language-dependent.

Language-dependent texts

You can use the **Project > Language-dependent texts** menu item to import and export ASCII files containing translations of LAD/FBD network comments and symbol browser comments (I/O variables, global device variables).

The exported files (**Export** button) can be re-imported into the project using the import function (**Import** button) once they have been translated.

After a language change, the user-defined comments in the project are available in the respective compiled languages.

Assigning a title

The title/name is used for the documentation of the LAD/FBD program or network. It is initialized with the name "Title".

To enter a title, proceed as follows:

1. Click in the title line.
2. Enter a different title/name in the window which appears.
   There is no maximum text length. The length of text visible on the screen depends on the font, font size and screen resolution.

Entering/modifying comments

You can enter a comment in every program or network.

To enter a comment, proceed as follows:

1. Click in the comment line.
2. Enter the text of the comment in the window which appears.
3. To change an existing comment, double-click the existing comment.
4. Overwrite the now selected text.

Showing/hiding a comment line

In every program/network, you can hide a comment that has been entered:

To hide and show comments, proceed as follows:

1. Click in the working window of the open LAD/FBD program.
2. From the context menu, select **Display > Comments on/off**.
   - or -
   Select the **LAD/FBD program > Display > Comments on/off** menu item.
   - or -
   Shortcut **Ctrl+Shift+K**.

This change always applies to the active LAD/FBD editor. The setting is only saved when saving if changes have been made in the respective editor window.

Showing/hiding a jump label

You can paste a jump label in every network.

To paste in or hide jump labels, proceed as follows:

1. Select the network in which the jump label is to be pasted.
2. From the network context menu, select **Jump label ON/OFF**.
3. Enter the text of the jump label in the window that appears.
   Only alphanumeric characters and underscores are allowed during input. The text length of a label must not exceed 480 characters.

   Note

   The jump label is deleted if it contains an error and cannot be corrected.

4. If you want to hide a jump label, select the required jump label and select **Jump label ON/OFF** in the context menu.

See also

Overview of jump operations (Page 5310)

Copying/cutting/pasting networks

If a network is copied or cut, and then pasted in again, all LAD/FBD elements in the network are taken with it.

To copy a network, proceed as follows:

1. Select the required network.
2. In the context menu, select **Copy**or **Cut**.
   - or -
   Select the **Edit > Copy** or **Edit > Cut** menu item.
   The copied network can be pasted again at any place or even in other LAD/FBD programs. A new/copied or cut network is always pasted in after the selected network. If no network is selected, the new network is placed as the first network.

Undo/redo actions

Note

The following actions cannot be undone:

- Save
- Save and compile

To undo or redo actions, proceed as follows:

1. Select the **Edit > Undo** menu command or the **Undo** symbol.
   The actions are undone in reverse order.
2. If you want to redo one or more undone actions, select the **Edit > Redo** menu item or the **Redo** icon.

Deleting networks

To delete a network:

1. Click in a network in the open LAD/FBD program.
2. From the context menu, select **Delete network**.

7.3.4.9 Displaying LAD/FBD elements

LAD diagram

LAD diagram

The LAD diagram complies with Standard IEC 61131-3 and is organized around the binary ladder diagram line. The ladder diagram line begins with a vertical line (conductor bar) and ends with a coil, call-up (box) or with a jump to another network. In between, there are special LAD elements (NO contacts, NC contacts, connectors), general logical elements (SR, RS flipflop), system components call-ups (e.g arithmetic operations), and user functions or function blocks.

Rules for entering LAD statements

- Start of a LAD network
  The left conductor bar is the network's starting point. Crossed lines are not permitted in a LAD diagram. The following elements are not permitted at the beginning of a network: (P), (N), (#).
- LAD network termination
  Every LAD network must terminate with a coil or a box. Multiple outputs are possible.
  The following LAD elements may not be used to terminate a network:
  - (P),
  - (N),
  - POS,
  - NEG,
  - Comparator.
- Placement of empty boxes
  Empty boxes can be placed anywhere in a network except on the right-hand edge or in a parallel branch. Preconnection at binary inputs is supported.
- Placement of coils
  Coils are automatically placed on the right-hand edge of the network, where they are used to terminate a branch.

- Parallel branches
  Parallel branches are
  - opened downward and closed upward.
  - opened behind the selected LAD element.
  - closed behind the selected LAD element.

  Another branch can be inserted between two parallel branches.
  To delete a parallel branch, you must delete all LAD elements of this branch.
  When the last LAD element is removed from the branch, the rest of the branch is also removed.
  The following elements are not permitted in the parallel branch:
  - (P),
  - (N),
  - (#),
  - Empty box.

  The following elements are permitted in the parallel branch:
  - Contacts,
  - Comparators,
  - Edge detection (POS, NEG).

  Parallel branches which branch directly off the power rail are an exception to these placement rules: All elements can be placed in these branches.
- Constants and enums
  Binary operations can also be assigned constants (e.g. TRUE or FALSE).
  FB/FC parameters can be connected with constants that reflect the parameter data type.
  If a parameter is connected with an enum value that is not unique project-wide, preface the enum value with the enum type separated by #.

Meaning of EN/ENO

Enable input (EN) and enable output (ENO) of the LAD box

The LAD box enable input (EN) and enable output (ENO) parameters function according to the following principles:

- If EN is not enabled (i.e., the signal is set to "0"), then the box will not execute its function, and ENO is not enabled (i.e., the signal is also "0").
- If EN is enabled (i.e., the signal is set to "1"), then the appropriate box executes its function, and then ENO is also enabled (i.e., the signal is also "1").

FBD diagram

FBD diagram

An FBD diagram complies with IEC standard 61131-3.
The main binary signal line begins with a logic box (top left) and ends with an assignment, call (box), or with a jump to another network. In between, there are logic elements (AND, OR box), general logic elements (SR, RS flip-flop), system component call-ups (e.g. arithmetic operations), and user function or function block call-ups.

Rules for entering FBD statements

- Placement of boxes
  Empty boxes (flipflops, counters, timers, arithmetic operations, device-specific commands, TO-specific commands, etc.) can be attached to boxes with binary connections (&, =1, XOR). Preconnections on binary inputs (e.g. S input on flipflop) are allowed.
  Separate connections with separate outputs cannot be programmed in a network. Junctions are not supported.

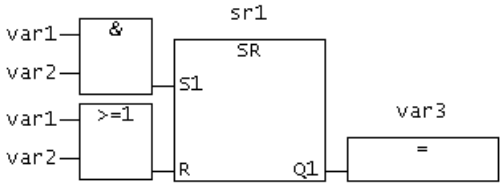

Figure 7-462 FBD with binary preconnection

- &, >=1, XOR boxes
  Binary inputs can be inserted, deleted, or negated in these boxes.
- Enable input/enable output
  Connection of the enable input EN and/or the enable output ENO of boxes is possible.
- Constants and enums
  Binary operations can also be assigned constants (e.g. TRUE or FALSE).
  FB/FC parameters can be connected with constants that reflect the parameter data type.
  If a parameter is connected with an enum value that is not unique project-wide, preface the enum value with the enum type separated by #.

Converting between LAD and FBD representation

Converting from LAD to FBD representation

To switch from **LAD to FBD representation**, proceed as follows:

1. Open an existing LAD project.
2. Select the **LAD/FBD program > Switch to FBD** menu item.
   - or -
   Click the button for "Switch to FBD" (Ctrl+3 shortcut) in the LAD editor toolbar.
   The project is now displayed in the **FBD** programming language.

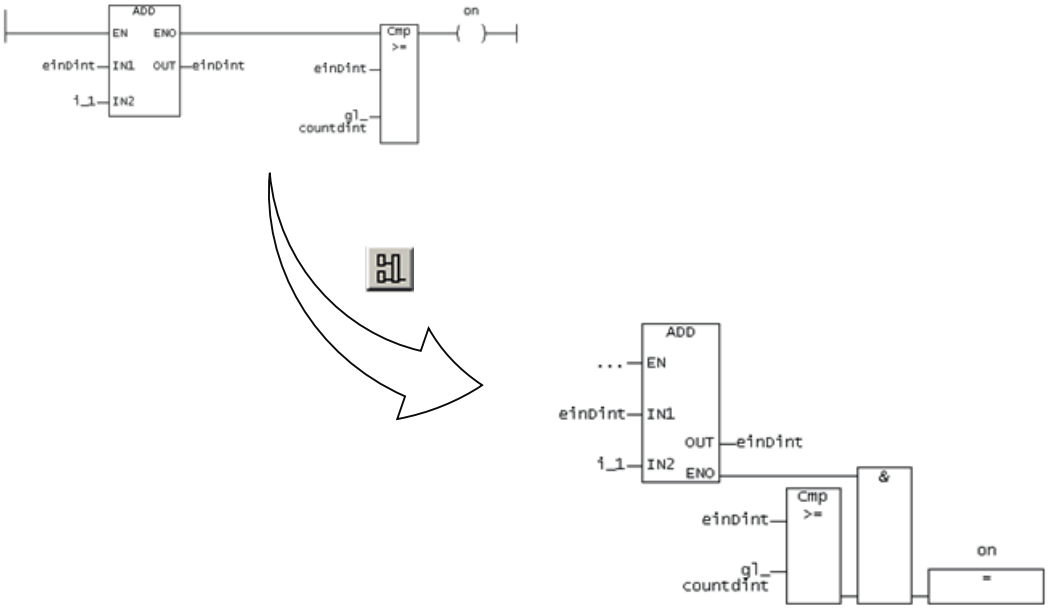

Figure 7-463 Switching from LAD to FBD

Note

A conversion sequence of **LAD - FBD - LAD** always produces the original network.

Anything generated in LAD can always be displayed in FBD.

Converting from FBD to LAD representation

To switch from **FBD to LAD representation**, proceed as follows:

1. Open an existing FBD project.
2. Select the **LAD/FBD program > Switch to LAD** menu command.
   - or -
   Click the button for "Switch to LAD" (Ctrl+1 shortcut) in the FBD editor toolbar.
   The project is now displayed in the **LAD** programming language.

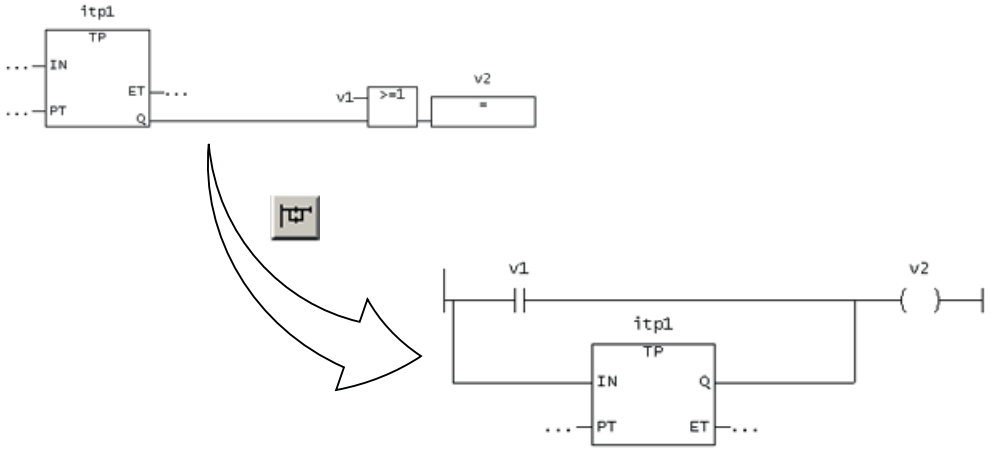

Figure 7-464 Switching from FBD to LAD, example with OR box

Note

A conversion sequence of **FBD- LAD- FBD** only produces the original LAD network if the FBD structure can be converted to LAD.

Something generated in FBD cannot always be displayed in LAD.

Example of a non-convertible FBD structure

Figure 7-465 FBD structure with binary XOR box

7.3.4.10 Editing LAD/FBD elements

Inserting LAD/FBD elements

LAD/FBD elements are usually inserted to the right of the selected position in the network.

FBD elements are usually inserted at a boolean input of a block or at an assignment (left).

Special case:

If the right-hand edge of a network or a coil (LAD) or an assignment (FBD) is selected, the next element is added in the network on the left-hand side of it.

To insert an LAD/FBD elements:

1. Select the position in a network behind which you want to insert an LAD/FBD element.
2. Insert an LAD/FBD element:
   - Via the icons on the toolbar
   - Using the menu item, e.g. **LAD/FBD program > Insert element > Empty box**
   - With a drag and drop operation from the **Command library** tab
   - By double-clicking the element in the **Command library** tab
   - By selecting the element in the **Command library** tab and confirming with the **Enter key**

   The selected LAD/FBD element is inserted and the placeholders and ... are inserted for variables and parameters.

Note

A red **???** symbol indicates mandatory parameters that must be connected.

A black ... character string indicates optional parameters that can be connected.

Move the cursor over the parameter name to display the expected data type.

Syntax check in LAD

An automatic syntax check during input prevents the incorrect placement of elements.

- NOT in parallel branch
- FB/FC call in parallel branch
- Connector in parallel branch
- Check 0 -> 1 edge and 1 -> 0 edge in parallel branch
- XOR in parallel branch

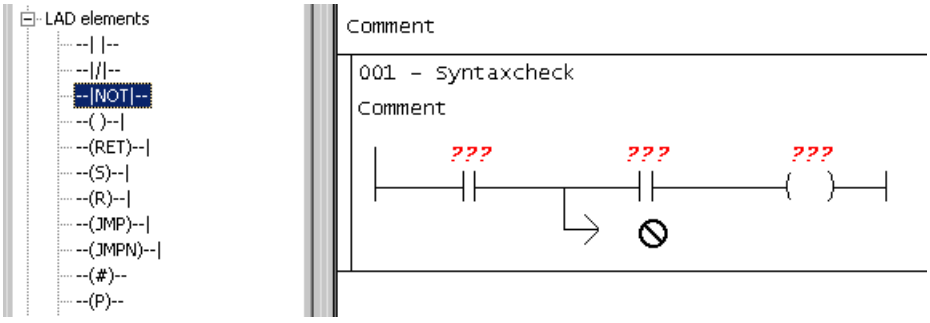

Figure 7-466 Syntax check

Selecting LAD/FBD elements

LAD/FBD networks must be selected before they can be deleted, for example.

To select an individual LAD/FBD element:

- Click the required LAD/FBD element.
  The LAD/FBD element is selected (see figure below).

To select several consecutive LAD/FBD elements, proceed as follows:

1. Click the first LAD/FBD element to select it.
2. Then, keeping the **Shift** key pressed, click the last LAD/FBD element to be selected.
   The consecutive LAD/FBD elements are selected.

To select several specific LAD/FBD elements, proceed as follows:

1. Click the first LAD/FBD element to select it.
2. Keeping the **Ctrl** key pressed, click all the other LAD/FBD elements to be selected.
   The specific LAD/FBD elements are selected.

Selected LAD/FBD elements have a light blue background. You can choose the selection color in the **LAD/FBD editor** tab of the **Settings** dialog box.

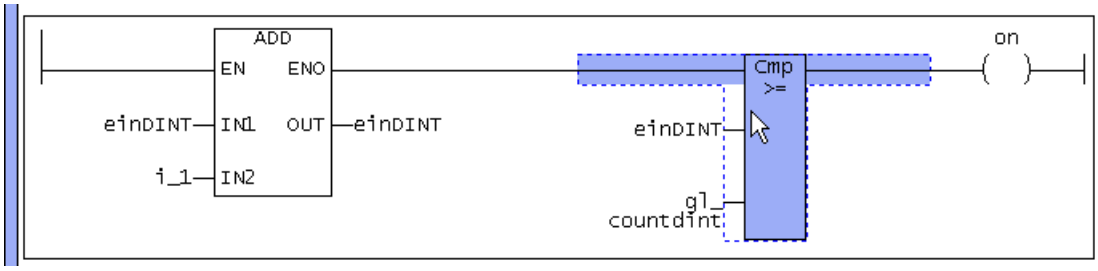

Figure 7-467 Selected LAD/FBD elements

Copy/cut/delete operations in LAD/FBD elements

To **copy/cut/delete**, proceed as follows:

1. Select a LAD/FBD element.
2. In the context menu or in the **Edit** menu, select e.g. **Copy**.
   The copied/cut LAD/FBD element can be inserted into other LAD/FBD programs.
   If you delete an FB/FC box with binary preconnections, this results in several open branches (in LAD) or sub-networks (in FBD) which can be further connected.

LAD/FBD elements - defining parameters (labeling)

To label the elements, proceed as follows:

1. Click the parameter.
2. Label the parameter:
   - Select the corresponding parameter from the pull-down menu (for box-type only).
     - or -
   - Enter the appropriate variable.
     - or -
   - Drag the corresponding variable from the declaration table using a drag-and-drop operation.
3. Confirm the entry with the **Return** key.

See also

Setting call parameters (Page 5147)

Defining variables in the Variable declaration dialog box ("on-the-fly" variable declaration) (Page 5175)

Labeling LAD/FBD elements with the symbol input help dialog

To label the element with the **Symbol input help**, proceed as follows:

1. Select the parameter you want to label.
2. Right-click to open the context menu.
3. Click the **Symbol input help menu.**
   - or -
   Call the symbol input help with the key shortcut **Ctrl+Alt+H.**
   The **Symbol input help** dialog box opens. The tree structure shows all variables which exist in the project and which can be used.
4. Select the desired variable and click **OK** to confirm.
   The label is entered in the selected parameter. If the variable is defined in another program source or in a library, a Connection (Page 5222) is created automatically.

Setting the LAD/FBD element display

In order to ensure a manageable view of relatively large call boxes, you can set the display mode of **LAD/FBD elements**.

To set the **LAD/FBD element** display, proceed as follows:

1. Click in the editor area of the LAD/FBD program.
2. Select the required display mode:
   - In the context menu, select **View > No box parameters** or the **LAD/FBD program > View > No box parameters** menu item.
     - or -
   - In the context menu, select **View > Only assigned box parameters** or the **LAD/FBD program > View > Only assigned box parameters** menu item.
     - or -
   - In the context menu, select **View > Mandatory and assigned box parameters** or the **LAD/FBD program > View > Mandatory and assigned box parameters** menu item.
     - or -
   - In the context menu, select **View > All box parameters** or the **LAD/FBD program > View > All box parameters** menu item.
     This box parameter setting is also saved when storing.

Note

If a call box has non-represented parameters, this is indicated by **...** at the bottom of the box.

Select box type with empty box

Requirement

You have inserted an empty box into the network, e.g. via the **LAD/FBD program > Insert element > Empty box** menu.

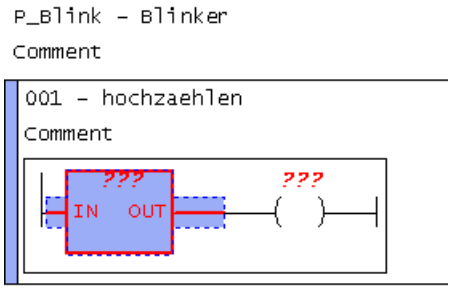

Figure 7-468 Empty box

Specify empty box

There are two alternatives for specifying the box type:

- Via an editable combo box (Page 5142)
- Via the call assistance (Page 5143)

Specify the box type via the editable combo box

Requirement

Empty box is inserted.

Procedure

How to open the editable combo box at the empty box (alternatives):

- Select Empty box and press **Enter**.
- Click on the **???** field.

The editable combo box opens.

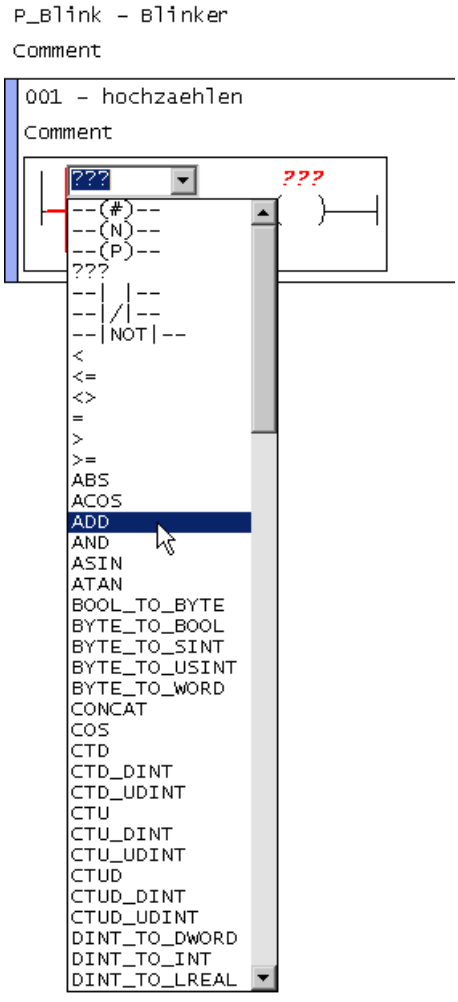

Figure 7-469 Drop-down menu for the combo box

The following are available for selection in the drop-down menu:

- The standard functions and function blocks, see Functions (Page 5269)
- The functions and function blocks of the own LAD/FBD source
- The functions and function blocks exported into connected program sources or libraries
- The public methods of exported classes (as of Kernel V4.5) and function blocks defined in connected ST source files or libraries.

Select the required box type. Alternatively, you may enter the box type into the combo box.

The empty box is replaced by the appropriate box for selection.

Specify box type via call assistance

Requirement

The empty box is inserted.

Procedure

How to open the call assistance:

- Double-click the **???** field.

The "Call Assistance" window opens.

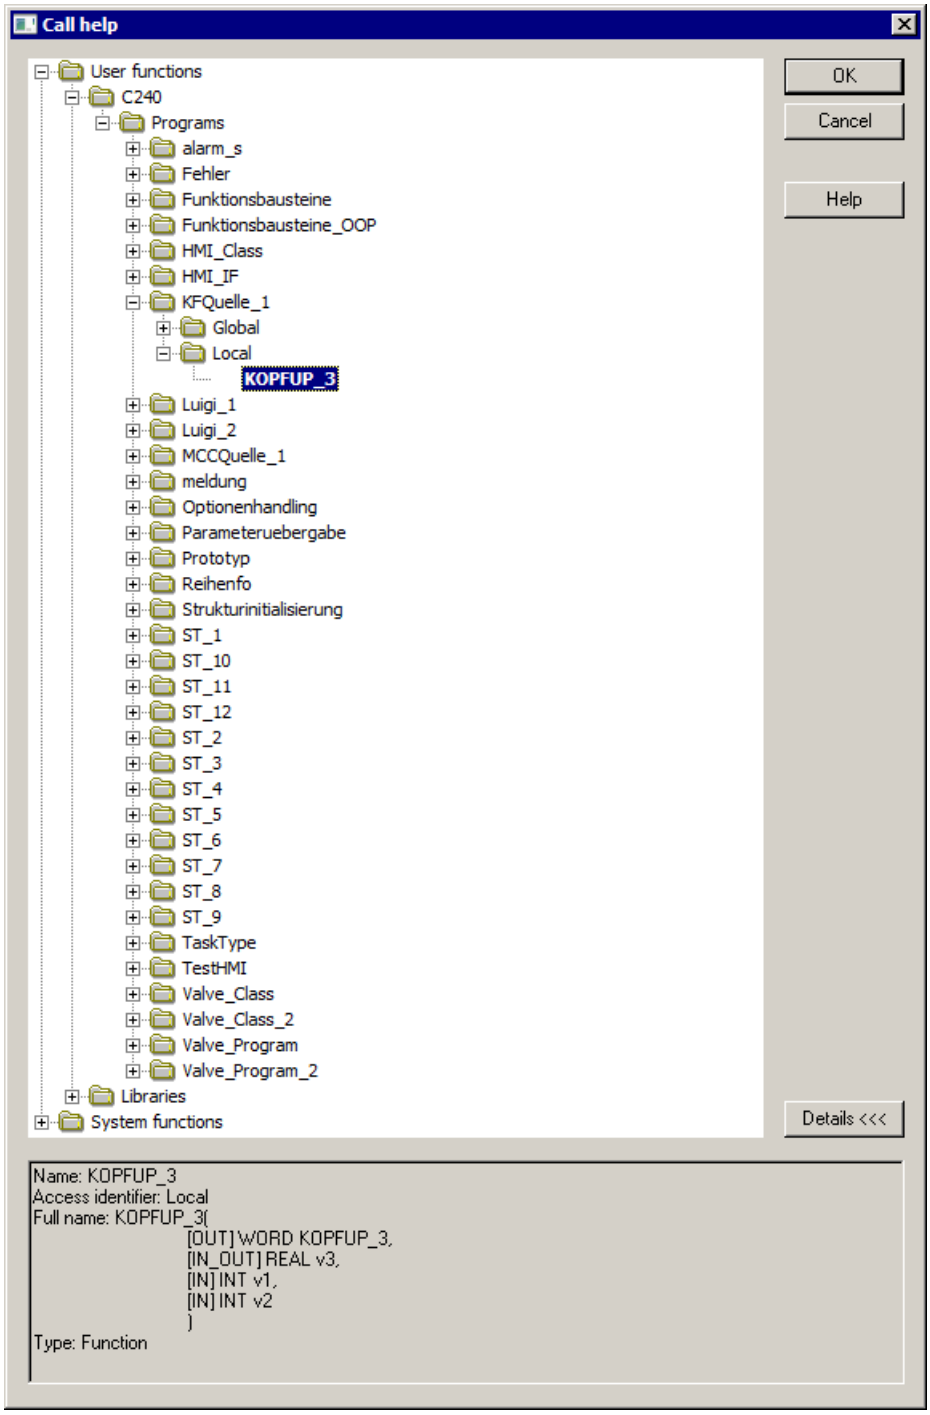

Figure 7-470 Call assistance

The following are displayed as roots in a tree topology:

- User functions
  All program sources for the SIMOTION device and for the libraries for the project are displayed beneath this. You can select the following program organization units (POUs):
  - All functions and function blocks of the own LAD/FBD unit
  - The functions and function blocks exported into program sources or libraries
  - The public methods of exported classes (as of Kernel V4.5) and function blocks defined in ST source files or libraries.

  Functions, function blocks or methods that are assigned to an object-oriented namespace are displayed below the program source or library as subelement of the namespace.
- System functions
  The standard functions and function blocks, see Functions (Page 5269)

Information about the selected POU can be found in the window footnote. This information can be hidden with the **Details <<<** button.

To select the desired POU (alternatives):

- Select the desired POU and click **OK**.
- Double-click the desired POU.

The "Call Assistance" window closes and the empty box is replaced by the appropriate box for selection.

Note

The LAD/FBD editor saves information on the origin of the subprogram when it is selected. This has no effect on the code generation.

This way you can subsequently move the source of a subprogram from the device to a connected library without changing the parameters of the box. The LAD/FBD unit is still compiled correctly.

A check as to whether an identifier of a subprogram is hidden by an identifier with the same name in the LAD/FBD unit, is not performed. You can avoid name conflicts by using namespaces.

Setting the call parameter for an individual parameter

To set an individual call parameter, proceed as follows:

1. Double-click the parameter input/output you want to set.
   The **Enter call parameter for individual parameter** dialog box appears.

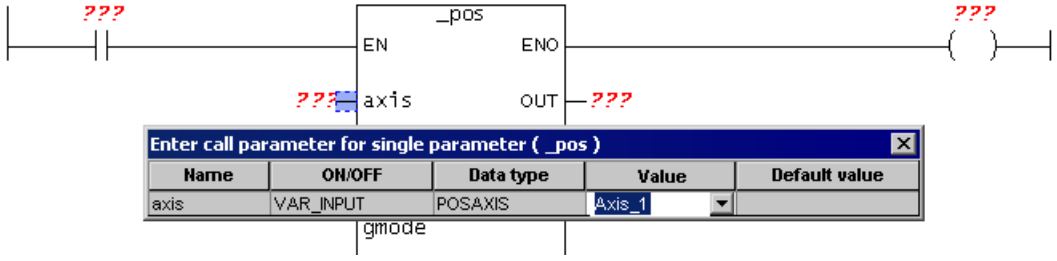

Figure 7-471 Dialog box for setting an individual call parameter

2. Assign a variable or value to the parameter from the **Values** list.
3. Confirm your selection twice with the Enter key to close the dialog box again.

Setting call parameters

To set the call parameters, proceed as follows:

1. Label the type parameters of the box.
2. Double-click the box.
   - or -
   In the shortcut menu, select **Call parameters ...**.
   The **Enter call parameters** dialog box appears.
   Only variables which have already been declared and symbols/variables offered by the system are displayed.

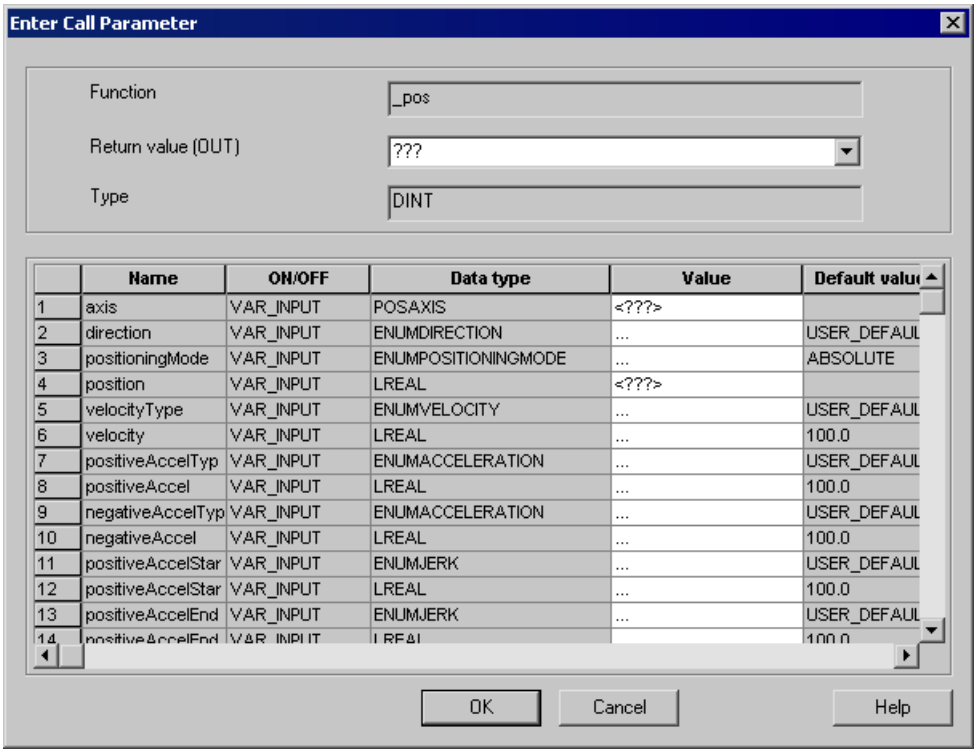

Figure 7-472 Dialog box for setting call parameters

3. Enter:
   - **Instance**
     Here, you enter the instance of the function block or the class.
   - **Return value**
     Here you assign the function or method return value to a variable of the calling program.
   - **Value**
     Here, you can assign current variables or values to the parameters.

   See also Overview of subprogram call parameters (Page 5230).
4. Confirm with **OK**.

Note

The **Value** list includes all visible symbols in the current target (variables, Enum values, etc.) whose type matches the data type of the parameter. Implicit data type conversion is taken into consideration here. You can select a symbol from the list or enter one yourself.

The value of string constants must be entered in inverted commas
(e.g. 'st_until')

7.3.4.11 Command library

LAD/FBD functions in the command library

The command library appears automatically as a tab in the project navigator. The command library stays open after the programming window is closed.

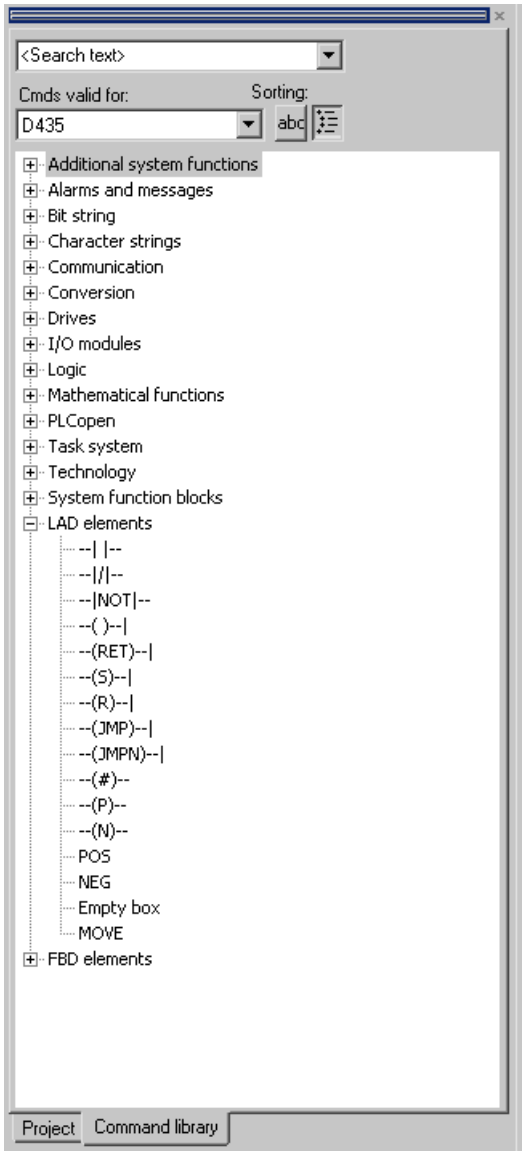

Figure 7-473 Command library tab of the project navigator

Inserting elements/functions from the command library

To paste elements/functions into a programming window:

1. Left-click the desired function in the command library, drag the function onto the editor window while keeping the left mouse button depressed and then release the left mouse button.
   - or -
   Double-click the desired function.
   - or -
   Select the desired function and press the Enter key.

LAD/FBD elements are usually pasted in to the right of the selected position in the network. FBD elements are usually pasted in at a boolean input of a block or at an assignment (left).

Description of PLCopen blocks

PLCopen blocks are preferably used for the programming of motion control tasks in the LAD/FBD programming language. The PLCopen blocks are intended for use in cyclic programs/tasks.

The following standard function blocks are available in the command library in SIMOTION. They are certified in accordance with "PLCopen Compliance Procedure for Motion Control Library V1.1".

The details and the use of the PLCopen blocks are described in the PLCopen Blocks Function Manual.

An example for the use of the PLCopen blocks is contained in Section "Positioning axis program (Page 5390)".

Table 7-525 Single-axis function blocks for the axis

Function block	Description
_MC_Power()	Enabling/disabling axis
_MC_Stop()	Stopping the axis
_MC_Home()	Homing axis/clearing absolute value encoder offset
_MC_MoveAbsolute()	Absolutely positioning axis
_MC_MoveRelative()	Relatively positioning axis
_MC_MoveVelocity()	Traversing axis at defined velocity
_MC_MoveAdditive()	Positioning relative to current target position (traversing axis using an additional, defined path, relative to current position setpoint)
_MC_MoveSuperimposed()	Superimposed positioning (traversing axis relative to current motion)
_MC_PositionProfile()	Traveling through position/time profile (traversing axis along a predefined, fixed position/time profile)
_MC_VelocityProfile()	Traveling through velocity/time profile (traversing axis along a predefined, fixed velocity/time profile)
Basic functions	
_MC_Reset()	Resetting errors/alarms on the axis or triggering a restart
_MC_ReadActualPosition()	Reading the actual position of axis
_MC_ReadStatus()	Reading the status of an axis
_MC_ReadAxisError()	Reading the error of an axis

Function block	Description
_MC_ReadParameter()	Reading axis parameter and outputting in data type LREAL
_MC_ReadBoolParameter()	Reading axis parameter and outputting in data type BOOL
_MC_WriteParameter()	Writing axis parameter of data type LREAL
_MC_WriteBoolParameter()	Writing axis parameter of data type BOOL
In addition to the standard function blocks, the following function block is available for an axis:	
_MC_Jog()	Continuous or incremental jogging

Table 7-526 Multi-axis function blocks for the axis

Function	Description
_MC_GearIn()	Starting gearing (synchronizing master and slave axis while taking into account a positional relationship described by a fixed gear ratio)
_MC_GearOut()	Terminating gearing (desynchronizing master and slave axis)
_MC_CamIn()	Starting camming (synchronizing master and slave axis while taking into account a positional relationship described by a cam)
_MC_CamOut()	Terminating camming (desynchronizing master and slave axis)
_MC_Phasing()	Changing phase shift between the leading axis and following axis

Table 7-527 Function blocks for the external encoder

Function	Description
_MC_Power()	Enabling external encoder
_MC_Reset()	Resetting external encoder
_MC_Home()	Homing external encoder
_MC_ReadActualPosition()	Reading actual position of external encoder
_MC_ReadStatus()	Reading external encoder status
_MC_ReadAxisError()	Reading external encoder error
_MC_ReadParameter()	Reading external encoder parameter and outputting in data type LREAL
_MC_ReadBoolParameter()	Reading external encoder parameter and outputting in data type BOOL

Special features of the command library

Special features

The following ST commands have no corresponding function that can be used with LAD/FBD:

- BOOL := _checkequaltask([IN]TASK, [IN]TASK)
  Two **StructTaskID** or two **StructAlarmID** can be compared to one comparator.
- StructAlarmID := _getalarmid([IN]ALARM)
  These alarm commands can be found in the **_alarm** name space (_alarm.myalarm).
- StructTaskID := _gettaskid([IN]TASK id:=TaskIdThis)
  The task commands can be found in the **_task** name space (_task.backgroundtask).

Examples for parameters of type _alarmid and _starttaskid

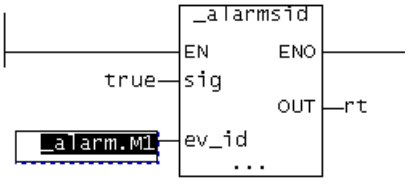

Figure 7-474 Examples for StructAlarmID

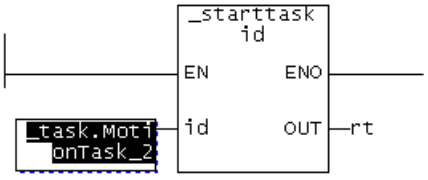

Figure 7-475 Example for StructTaskID

7.3.4.12 General information about variables and data types

Overview of variable types

The following table shows all the variable types available for programming with ST.

- System variables of the SIMOTION device and the technology objects
- Global user variables (I/O variables, device-global variables, unit variables)
- Local user variables (variables within a program, a function, or a function block)

System variables

Variable type	Meaning
System variables of the SIMOTION device	Each SIMOTION device and technology object has specific system variables. These can be accessed as follows: • Within the SIMOTION device from all programs • From HMI devices You can monitor system variables in the symbol browser.
System variables of technology objects	

Global user variables

Variable type	Meaning
I/O variables	You can assign symbolic variable names to the I/O addresses of the SIMOTION device or the peripherals. This allows you to have the following direct accesses to the I/O: • Within the SIMOTION device from all programs • From HMI devices You create these variables in the symbol browser after you have selected the I/O element in the project navigator. You can monitor I/O variables in the symbol browser.
Global device variables	User-defined variables which can be accessed by all SIMOTION device programs and HMI devices. You create these variables in the symbol browser after you have selected the GLOBAL DEVICE VARIABLES element in the project navigator. Global device variables can be defined as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor global device variables in the symbol browser.
Unit variables	User-defined variables that all programs (programs, function blocks, and functions) can access within a unit (source file). You declare these variables in the declaration table of the source file: • In the interface section: These variables are exported and can be used in other units (e.g. ST source files, MCC source files, LAD/FBD source files) after a connection has been defined (Page 5223). They are also available on HMI devices as standard. • In the implementation section: You can only access these variables within the source file. You can declare unit variables as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor unit variables in the symbol browser.

Local user variables

Variable type	Meaning
	User-defined variables that can only be accessed within the program/chart (program, function, function block) in which they were defined.
Variable of a program (program variable)	Variable is declared in a program. The variable can only be accessed within this program. A differentiation is made between static and temporary variables: • Static variables are initialized according to the memory area in which they are stored. Specify this memory area by means of a compiler option. By default, the static variables are initialized depending on the task to which the program is assigned (see *SIMOTION Basic Functions* Function Manual). You can monitor static variables in the symbol browser. • Temporary variables are initialized every time the program in a task is called. Temporary variables cannot be monitored in the symbol browser.
Variable of a function (FC variable)	Variable is declared in a function (FC). The variable can only be accessed within this function. FC variables are temporary; they are initialized each time the FC is called. They cannot be monitored in the symbol browser.
Variable of a function block (FB variable)	Variable is declared in a function (FB). The variable can only be accessed within this function block. A differentiation is made between static and temporary variables: • Static variables retain their value when the FB terminates. They are initialized only when the instance of the FB is initialized; this depends on the variable type with which the instance of the FB was declared. You can monitor static variables in the symbol browser. • Temporary variables lose their value when the FB terminates. The next time the FB is called, they are reinitialized. Temporary variables cannot be monitored in the symbol browser.

Scope of the declarations

Scope of variable and data type declarations according to location of declaration

Location of declaration	What can be declared here	Scope
Symbol browser	• Global device variables • I/O variables	The declared variables are valid in all units (e.g., ST source files, MCC source files, LAD/FBD source files) of the SIMOTION device. All programs, function blocks, and functions in all units of the device can access the variables.
Interface section of the unit[1]	• Unit variables • Data types • Symbolic accesses to the fixed process image of the BackgroundTask	The declared variables, data types, etc., are valid in the entire unit (e.g., ST source file, MCC source file, LAD/FBD source file); all programs, function blocks, and functions within the unit can access them. In addition, they are also available in other units after connection (see Define connections (Page 5223)).
Implementation section of the unit[1]	• Unit variables • Data types • Symbolic accesses to the fixed process image of the BackgroundTask	The declared variables, data types, etc., are valid in the entire unit (e.g., ST source file, MCC source file, LAD/FBD source file); all programs, function blocks, and functions within the source file can access them.

Location of declaration	What can be declared here	Scope
POU (program/ function block/ function)[2]	• Local variables • Data types • Symbolic accesses to the fixed process image of the BackgroundTask	The declared variables, data types, etc., can only be accessed within the POU in which they were declared.

[1] MCC and LAD/FBD programming languages: in the declaration table of the respective source file.

[2] MCC and LAD/FBD programming languages: in the declaration table of the respective chart/program.

Rules for identifiers

Names for variables, data types, charts/programs must comply with the following rules for identifiers:

1. They are made up of letters (A to Z, a to z), numbers (0 to 9), and underscores (_).
2. The first character must be a letter or underscore.
3. This can be followed by as many letters, digits or underscores as needed in any order.
4. Exception: You must not use more than one underscore in succession.
5. Both upper- and lower-case letters are allowed. No distinction is made between upper- and lower-case notation (thus, for example, Anna and AnNa are regarded as identical).

Note

Reserved identifiers

Reserved identifiers may only be used as predefined. You may not declare a variable or data type with the name of a reserved identifier.

There is no distinction between upper- and lower-case notation.

You can find a list of all the identifiers whose meanings are predefined in SIMOTION in the SIMOTION Basic Functions Function Manual.

Note

Identifiers for SIMOTION devices

Identifiers for SIMOTION devices do not have to comply with rules specified above. When used in SIMOTION SCOUT they must be enclosed in double inverted commas (", ASCII code $22). See the SIMOTION ST Programming and Operating Manual.

Frequently used arrays in declarations

Reference (as of kernel V4.5)

References can be formed as of version V4.5 SIMOTION Kernel. The compiler option (Page 5111) "Object-oriented programming" must also be activated.

By activating the **Reference** checkbox, you specify that the declared variable (or the component of a structure) contains the reference to the specified data type. This means that the variable can contain address information for a variable of the specified data type.

The following are permitted as data types to which references can be formed:

- Elementary data types (e.g. INT, DINT, REAL, WORD, TIME, STRING)
- User-defined data types (UDT)
- System data types
- Function blocks, provided they contain at least one static variable
- Classes (from ST sources)

No references can be formed to the following data types because references exist already:

- Technology object data types
- Object-oriented interfaces (from ST sources)
- General references
- I/O references (from ST sources)

Array length and array element

A field is a chain of variables of the same type that can be addressed with the same name and different indices.

You can define the variable as a field [0...N-1] by entering a field length N.

You have the following options for entering the field length:

- You can enter a constant positive integer value.
- You can enter a value range with ".." separating the min. and max. values.
- You can enter a constant expression of data type DINT (or of a data type that is implicitly convertible to DINT).

If the field is empty, a single variable is set up rather than a field.

Example definition of a field in the declaration table

	Name	Variable type	Data type	Array length	Initial value	Comment
1	const_1	VAR_GLOBAL CONSTANT	INT		11	constant
2	const_2	VAR_GLOBAL CONSTANT	INT		5	constant
3	array_4	VAR_GLOBAL	INT	11	11(5)	specification of the array length by value
4	array_5	VAR_GLOBAL	INT	const_1	11(5)	specification of the array length by constant expression
5	array_6	VAR_GLOBAL	INT	-5 .. 5	11(5)	specification of the array length by range of values
6	array_7	VAR_GLOBAL	INT	const_2 .. 3 * const_2	11(5)	specification of the array length by range of values as constant expression
7						

Figure 7-476 Defining the length of a field

Example of use of field elements in a variable assignment

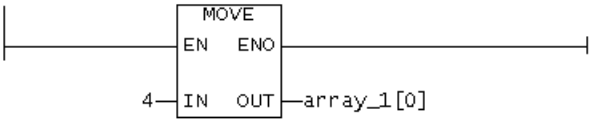

Figure 7-477 Use of field elements in a variable assignment

Initial value

You can specify an initialization value in this column. The field cannot be edited, but is provided as button.

1. Click the button. A window opens:

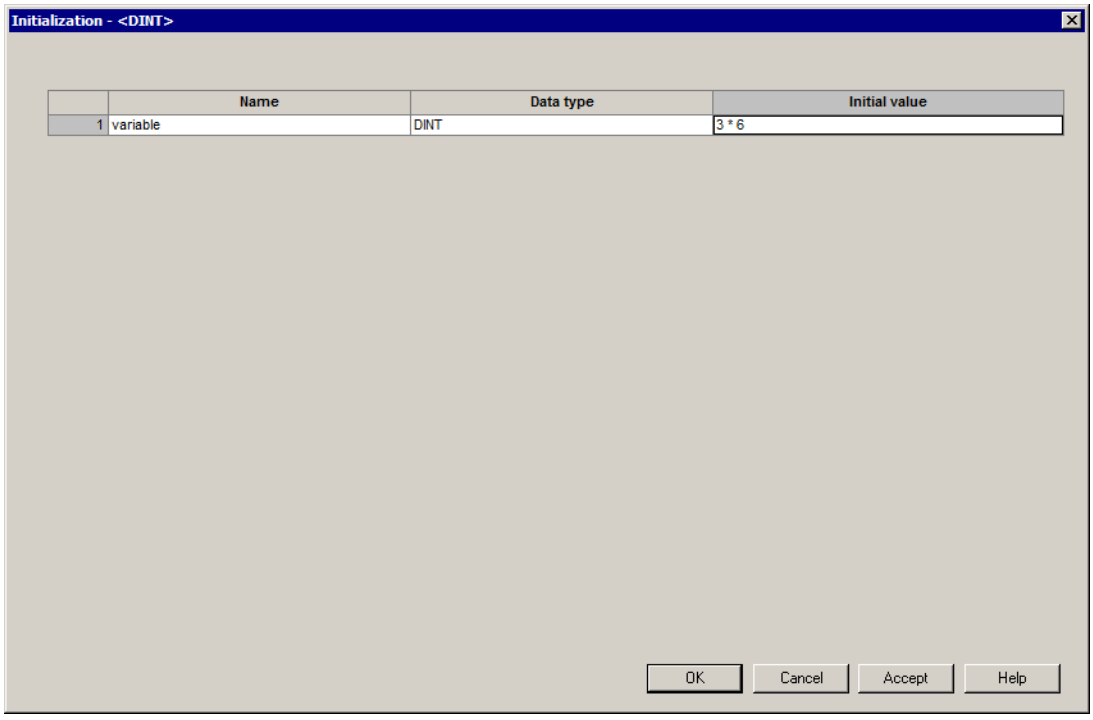

Figure 7-478 Definition an initialization value

2. Enter the initialization value in the **Initial value** column.
   You can specify this initialization value as a constant or as an expression. The following are permissible:
   - Constants
   - Arithmetic operations
   - Bit slice and data conversion functions
3. Confirm with **OK**.

Variables of a technology object data type cannot be assigned an initialization value. They are always initialized by the compiler with TO#NIL.

Initialization of arrays

Per default, the compiler assigns all array elements the initialization value of the data type. The initialization values can be changed by specifying an array initialization list according to the following example.

Table 7-528 Preassignment of array elements

10(1)	10 array elements [0..9] are pre-assigned the same value "1".
1,2,3,4,5	5 array elements [0..4] are pre-assigned different values "1", "2", "3", "4" and "5".
5(3),10(99),3(7),2(1)	The following array elements are pre-assigned the following values: • Five array elements [0..4] with the same value "3". • 10 array elements [5..14] with the same value "99". • 3 array elements [15..17] with the same value "7". • 2 array elements [18..19] with the same value "1".

Definition of these initialization values in the declaration table:

	Name	Variable type	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	array_1	VAR_GLOBAL	INT		10	10(1)	all array elements equal
2	array_1_	VAR_GLOBAL	INT		5	1, 2, 3, 4, 5	all array elements diverse
3	array_1_	VAR_GLOBAL	INT		20	5(3), 10(99), 3(7), 2(1)	several array elements respectively equal
4							

Figure 7-479 Definition of the initialization values of an array

Initialization of structures

Per default, the compiler assigns all components of a structure the initialization value of their data type. By specifying an initial value for a component, its initialization can be changed.

When using the structure in another declaration (e.g. variable or structure definition), the initialization values of individual components can be changed by assigning a structure initialization list, enclosed in round brackets ( ), in accordance with the following example.

	Structure name	Element name	Data type	Array length	Initial value	Comment
1	type_struct_1	s11	INT		1	
2		s12	DINT	3	3(2)	
3		s13	UDINT		3	
4	type_struct_2	s21	LREAL		3.0	
5		s22	DWORD		16#0000_FFFF	
6	type_struct_3	s31	type_struct_1		(s11 := 10, s12 := [3(20)])	
7		s32	type_struct_2		(s22 := 16#0000_00FF)	
8		s33	REAL		10.0 / 3.0	
9						

Figure 7-480 Definition of the initialization values of a structure

Instance-specific initialization of classes and function blocks

For the instance formation of classes and function blocks created during the object-oriented programming, variables declared as VAR OVERRIDE or VAR PUBLIC can be initialized instance-specific. The initialization values specified for the definition of the associated program organization unit (POU) are overwritten.

Proceed as follows to initialize the instance variables instance-specific:

1. Click the button in the **Initial value** column. A window opens.

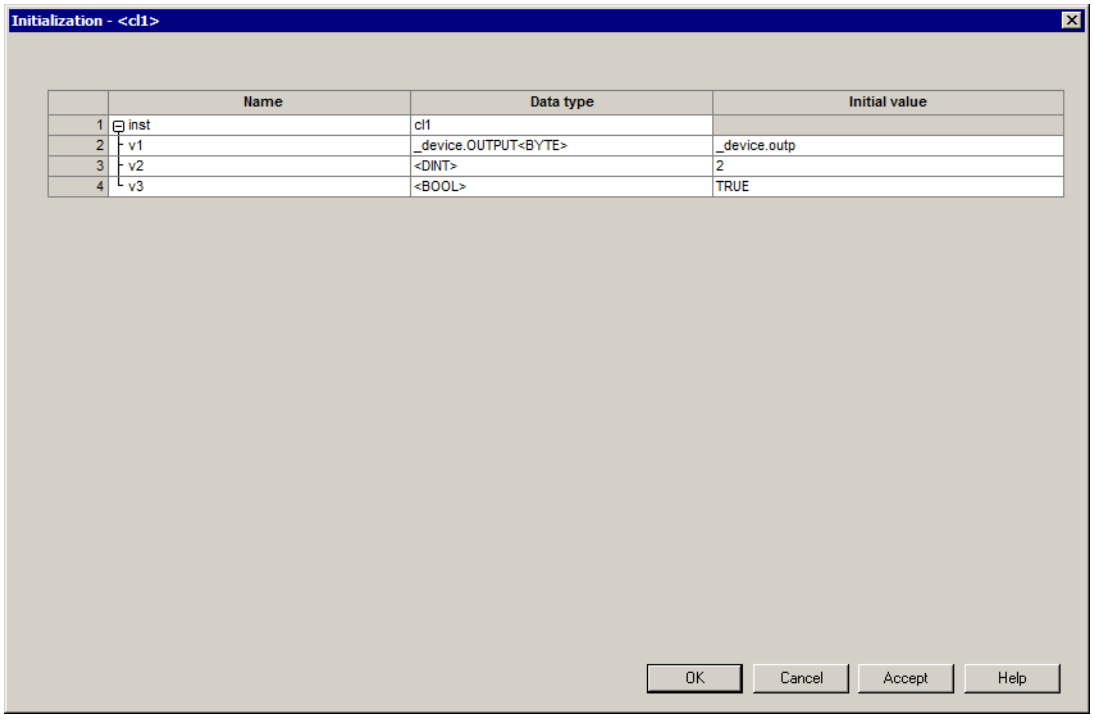

Figure 7-481 Definition of the initialization values of a class or function block

   Variables that must be initialized are already displayed in this window with their name and data type; the associated line is color-highlighted.

2. You can add additional lines for variables whose initialization is optional:
   - Click the number in line 1 and select **Add new line** in the context menu.
   - Enter the name of the variable. The data type is then initialized automatically.
3. Enter the initialization values of the associated variables.
4. Click **OK** to confirm.

Comments

A comment can be entered in this column. It may contain any characters or special characters.

Sorting in the declaration tables

You can specify a sorting order for a column in the declaration tables. The lines of the declaration table are arranged so that the entries (character strings) of the relevant column are sorted according to the sorting criterion. The characters are sorted according to their ANSI code; the sorting is not case-sensitive.

The following sorting criteria are available:

- **Sort in ascending order**
  Alphabetic sorting is ascending order (0 ... 9, a ...z).
- **Sort in descending order**
  Alphabetic sorting is descending order (z ... a, 9 ... 0).
- **Original order**
  No sorting. The lines of the declaration table are arranged in the order of declaration.

As long as the sorting order is not accepted (see below), the following applies:

- The sorting only affects the display. The data storage remains unchanged.
- The declaration table is saved in the original order.
- The compiler processes the declaration table in the original order.

Special features when sorting structures and enumerations

When sorting structures (Page 5166) and enumerations (Page 5167), the following applies:

- When sorting according to the **Structure name** or **Enumeration name** column:
  - The structures or enumerations are sorted according to their names.
  - The elements of these structures and enumerations remain in their original order.
- When sorting according to the other columns:
  - The structures and enumerations remain in their original order.
  - The elements within the structures and enumerations are sorted.

Special feature of pragma lines

For the declaration tables of a unit (interface section and implementation section), the following applies:

If in the declaration of unit variables (Page 5172) (Parameters tab), pragma lines (Page 5178) are available, the lines are sorted between the individual pragma lines.

Note

In the sorted view of a declaration table, the following is not possible:

- Insertion of new elements (e.g. variables, structures, enumerations as well as elements of structures and enumerations).
- Insertion of new or copied lines.
- Insertion of pragma lines.

Procedure

To sort the entries of the declaration table:

- Double-click the appropriate column header.
  The sorting changes between the sorting criteria.
  A double-click in another column header results sorting in ascending order according to this column.
- Or alternatively:
  - Move the cursor to the appropriate column header.
  - Select the sorting criterion in the context menu

  The sorting is performed according to the selected sorting criterion.
  The original order can only be selected in the context menu of a sorted column.

Accepting the sorting order

Proceed as follows:

1. Move the cursor to an arbitrary column header.
2. Select **Accept sorting order** in the context menu.

The sorting order is taken over as original order.

Note

Observe the following when accepting the sorting order in a declaration table:

- No "Undo" possible.
- The data storage and the declaration order are changed.
- The corresponding unit is changed and must be compiled again.
- The compiler processes the declaration table in the changed order.
- The relevant variable blocks are initialized during the download of the unit.
- HMI-relevant data is no longer consistent.

7.3.4.13 Data Types

A data type is used to determine how the value of a variable or constant in a program source is to be used.

The following data types are available to the user:

- Elementary data types (Page 5162)
- User-defined data types (UDT) (Page 5165)
  - Enumerations
  - Structures (Struct)
- Technology object data types (Page 5168)
- System data types (Page 5169)

Elementary data types

Elementary data types define the structure of data that cannot be broken down into smaller units. An elementary data type describes a memory area with a fixed length and stands for bit data, integers, floating-point numbers, duration, time, date and character strings.

All the elementary data types are listed in the table below:

Table 7-529 Bit widths and value ranges of the elementary data types

Type		Reserv. word	Bit width	Range of values
Bit data type Data of this type uses either 1 bit, 8 bits, 16 bits, or 32 bits. The initialization value of a variable of this data type is 0.				
	Bit	BOOL	1	0, 1 or FALSE, TRUE
	Byte	BYTE	8	16#0 to 16#FF
	Word	WORD	16	16#0 to 16#FFFF
	Double word	DWORD	32	16#0 to 16#FFFF_FFFF
Numeric types These data types are available for processing numeric values. The initialization value of a variable of this data type is 0 (all integers) or 0.0 (all floating-point numbers).				
	Short integer	SINT	8	-128 to 127 (-2**7 to 2**7-1)
	Unsigned short integer	USINT	8	0 to 255 (0 to 2**8-1)
	Integer	INT	16	-32_768 to 32_767 (-2**15 to 2**15-1)
	Unsigned integer	UINT	16	0 to 65_535 (0 to 2**16-1)
	Double integer	DINT	32	-2_147_483_648 to 2_147_483_647 (-2**31 to 2**31-1)
	Unsigned double integer	UDINT	32	0 to 4_294_967_295 (0 to 2**32-1)
	Floating-point number (per IEEE -754)	REAL	32	-3.402_823_466E+38 to -1.175_494_351E-38, 0.0, +1.175_494_351E-38 to +3.402_823_466E+38 Accuracy: 23-bit mantissa (corresponds to 6 decimal places), 8-bit exponent, 1-bit sign.
	Long floating-point number (in accordance with IEEE-754)	LREAL	64	-1.797_693_134_862_315_7E+308 to -2.225_073_858_507_201_4E-308, 0.0, +2.225_073_858_507_201_4E-308 to +1.797_693_134_862_315_7E+308 Accuracy: 52-bit mantissa (corresponds to 15 decimal places), 11-bit exponent, 1-bit sign.
Time types These data types are used to represent various date and time values.				

Type		Reserv. word	Bit width	Range of values
	Duration in increments of 1 ms	TIME	32	T#0d_0h_0m_0s_0ms to T#49d_17h_2m_47s_295ms Maximum of 2 digits for the values day, hour, minute, second and a maximum of 3 digits for milliseconds Initialization with T#0d_0h_0m_0s_0ms
	Date in increments of 1 day	DATE	32	D#1992-01-01 to D#2200-12-31 Leap years are taken into account, year has four digits, month and day are two digits each Initialization with D#0001-01-01
	Time of day in increments of 1 ms	TIME_OF_DAY (TOD)	32	TOD#0:0:0.0 to TOD#23:59:59.999 Maximum of two digits for the values hour, minute, second and maximum of three digits for milliseconds Initialization with TOD#0:0:0.0
	Date and time	DATE_AND_TIME (DT)	64	DT#1992-01-01-0:0:0.0 to DT#2200-12-31-23:59:59.999 DATE_AND_TIME consists of the data types DATE and TIME Initialization with DT#0001-01-01-0:0:0.0
String type Data of this type represents character strings, in which each character is encoded with the specified number of bytes. The length of the string can be defined at the declaration. Indicate the length in "[" and "]", e.g. STRING[100]. The default setting consists of 80 characters. The number of assigned (initialized) characters can be less than the declared length.				
	String with 1 byte/character	STRING	8	You may use all the characters in the extended ASCII character set (ASCII code $00 to $FF). Default ' ' (empty string)

Note

During variable export to other systems, the value ranges of the corresponding data types in the target system must be taken into account.

Value range limits of elementary data types (Page 5163)

General data types (Page 5164)

Elementary system data types (Page 5165)

Value range limits of elementary data types

The value range limits of certain elementary data types are available as constants.

Table 7-530 Symbolic constants for the value range limits of elementary data types

Symbolic constant	Data type	Value	Hex notation
SINT#MIN	SINT	-128	16#80
SINT#MAX	SINT	127	16#7F
INT#MIN	INT	-32768	16#8000

Symbolic constant	Data type	Value	Hex notation
INT#MAX	INT	32767	16#7FFF
DINT#MIN	DINT	-2147483648	16#8000_0000
DINT#MAX	DINT	2147483647	16#7FFF_FFFF
USINT#MIN	USINT	0	16#00
USINT#MAX	USINT	255	16#FF
UINT#MIN	UINT	0	16#0000
UINT#MAX	UINT	65535	16#FFFF
UDINT#MIN	UDINT	0	16#0000_0000
UDINT#MAX	UDINT	4294967295	16#FFFF_FFFF
T#MIN TIME#MIN	TIME	T#0ms	16#0000_0000[1]
T#MAX TIME#MAX	TIME	T#49d_17h_2m_47s_295ms	16#FFFF_FFFF[1]
TOD#MIN TIME_OF_DAY#MIN	TOD	TOD#00:00:00.000	16#0000_0000[1]
TOD#MAX TIME_OF_DAY#MAX	TOD	TOD#23:59:59.999	16#0526_5BFF[1]
[1] Internal display only			

General data types

General data types are often used for the input and output parameters of system functions and system function blocks. The subroutine can be called with variables of each data type that is contained in the general data type.

The following table lists the available general data types:

Table 7-531 General data types

General data type	Data types contained
ANY_BIT	BOOL, BYTE, WORD, DWORD
ANY_INT	SINT, INT, DINT, USINT, UINT, UDINT
ANY_REAL	REAL, LREAL
ANY_NUM	ANY_INT, ANY_REAL
ANY_DATE	DATE, TIME_OF_DAY (TOD), DATE_AND_TIME (DT)
ANY_ELEMENTARY	ANY_BIT, ANY_NUM, ANY_DATE, TIME, STRING
ANY	ANY_ELEMENTARY, user-defined data types (UDT), system data types, data types of the technology objects

Note

You **cannot** use general data types as type identifiers in variable or type declarations.

The general data type is retained when a user-defined data type (UDT) is derived directly from an elementary data type (only possible with the SIMOTION ST programming language).

Elementary system data types

In the SIMOTION system, the data types specified in the table are treated in a similar way to the elementary data types. They are used with many system functions.

Table 7-532 Elementary system data types and their use

Identifier	Bit width	Use
StructAlarmId	32	Data type of the alarmId for the project-wide unique identification of the messages. The alarmId is used for the message generation. Please refer to the *SIMOTION Basic Functions* Function Manual. Initialization with STRUCTALARMID#NIL
StructTaskId	32	Data type of the taskId for the project-wide unique identification of the tasks in the execution system. Please refer to the *SIMOTION Basic Functions* Function Manual. Initialization with STRUCTTASKID#NIL

Table 7-533 Symbolic constants for invalid values of elementary system data types

Symbolic constant	Data type	Meaning
STRUCTALARMID#NIL	StructAlarmId	Invalid AlarmId
STRUCTTASKID#NIL	StructTaskId	Invalid TaskId

User-defined data types

Defining user-defined data types (UDT)

You can create user-defined data types in units and programs/charts:

- Structures (Page 5166)
- Enumerations (Page 5167)

The scope of the data type declaration (Page 5166) depends on the location of the declaration.

Scope of the data type declaration

You create derived data types in the declaration tables of the source file or the program/chart. The scope of the data type declaration depends on the location of the declaration.

- In the declaration table of the unit, **Interface (exported declaration)** section:
  The data type is valid for the entire source file; all programs/charts (programs, function blocks, and functions) within the source file can access the data type.
  These variables are also available, if appropriately connected (see Define connections (Page 5223)), in other source files (or other units).
- In the declaration table of the unit, **Implementation (unit-internal declaration)** section:
  The data type is valid in the source file; all programs/charts (programs, function blocks, and functions) within the source file can access the data type.
- In the declaration table of the program/chart:
  The data type can only be accessed within the program/chart in which it is declared.

Defining structures

You define structures in the declaration tables of the unit or the program/chart. The scope (Page 5166) of the structures depends on the location of the declaration.

To define structures, proceed as follows:

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Structures** tab.
3. Enter the name of the structure.
4. In the same line, enter:
   - The name of the first component in the **Element name** field.
   - Data type of the component.
     You can select already defined data types.
     See also:
     Elementary data types (Page 5162).
     User-defined data types (Page 5165).
     Technology object data types (Page 5168).
     System data types (Page 5169).
   - Activating the optional **Reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 5155).
   - Optional array length (to define the array size).
     See also: Array length and array element (Page 5156).
   - Optional initial value (initialization value).
     See also: Initial value (Page 5157).
   - Optional comment.
     See also: Comment (Page 5159).

5. Enter additional elements of the structure in the following lines; leave the **Structure name** field empty.
6. Begin the definition of the new structure by entering a new name in the **Structure name** field.

Example

This example shows the definition of a structure with three components:

	Structure name	Element name	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	t_struct	comp_1	INT	☐			
2		comp_2	REAL	☐	5	3(2), 2(3)	
3		compp_3	STRING	☐		'Example'	
4				☐			

Figure 7-482 Definition of a structure

Defining enumerations

You define **enumerations** in the declaration tables of the unit or the program/chart. The scope (Page 5166) of the enumerations depends on the location of the declaration.

To define enumerations, proceed as follows:

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Enumerations** tab.
3. Enter the name of the enumeration.
4. In the same line, enter:
   - The name of the first element
   - Optionally, the initialization value of the enumeration data type
5. Enter additional elements of the enumeration in the following lines; leave the **Enumeration name** field empty.
6. You begin the definition of the new enumeration by entering a new name in the **Enumeration name** field.

Example

This example shows the definition of an enumeration data type with the name **Color** and the enumeration elements **Red**, **Blue**, and **Green**, as well as the initialization value (initial value) **Green**.

If no initialization value is entered during the enumeration definition (data type declaration), the first value of the enumeration is assigned to the data type. In this example, this means **Red** would be used for the initialization because it is defined as the first enumeration element.

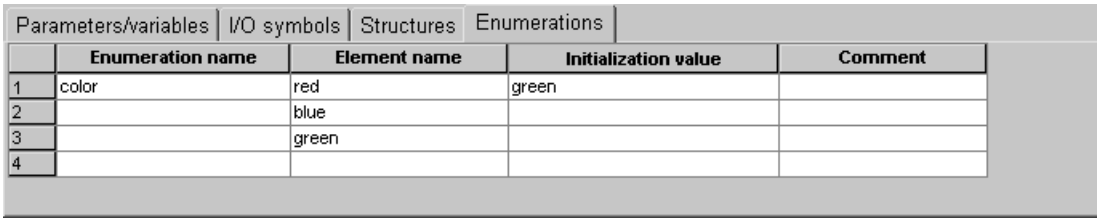

Figure 7-483 Definition of an enumeration data type

Technology object data types

Description of the technology object data types

You can declare variables with the data type of a technology object (TO). The following table shows the data types for the available technology objects in the individual technology packages.

For example, you can declare a variable with the data type *posaxis* and assign it an appropriate instance of a position axis. Such a variable is often referred to as a reference.

Table 7-534 Data types of technology objects (TO data type)

Technology object	Data type	Contained in the technology package
Drive axis	DriveAxis	CAM, PATH[1], CAM_EXT
External encoder	ExternalEncoderType	CAM, PATH[1], CAM_EXT
Measuring input	MeasuringInputType	CAM, PATH[1], CAM_EXT
Output cam	OutputCamType	CAM, PATH[1], CAM_EXT
Cam track	_CamTrackType	CAM, PATH[1], CAM_EXT
Position axis	PosAxis	CAM, PATH[1], CAM_EXT
Following axis	FollowingAxis	CAM, PATH[1], CAM_EXT
Following object	FollowingObjectType	CAM, PATH[1], CAM_EXT
Cam	CamType	CAM, PATH[1], CAM_EXT
Path axis[1]	_PathAxis	PATH[1], CAM_EXT
Path object[1]	_PathObjectType	PATH[1], CAM_EXT
Fixed gear	_FixedGearType	CAM_EXT
Addition object	_AdditionObjectType	CAM_EXT
Formula object	_FormulaObjectType	CAM_EXT
Sensor	_SensorType	CAM_EXT
Controller object	_ControllerObjectType	CAM_EXT
Temperature channel	TemperatureControllerType	TControl
General data type, to which every TO can be assigned	ANYOBJECT	

[1] Available as of version V4.1.

You can access the elements of technology objects (configuration data and system variables) via structures (see SIMOTION Basic Functions Function Manual).

Table 7-535 Symbolic constants for invalid values of technology object data types

Symbolic constant	Data type	Meaning
TO#NIL	ANYOBJECT	Invalid technology object

See also

Inheritance of the properties for axes (Page 5169)

Inheritance of the properties for axes

Inheritance for axes means that all of the data types, system variables and functions of the TO driveAxis are fully included in the TO positionAxis. Similarly, the position axis is fully included in the TO synchronizedAxis, the following axis in the TO pathAxis. This has, for example, the following effects:

- If a function or a function block expects an input parameter of the driveAxis data type, you can also use a position axis or a synchronized axis or a path axis when calling.
- If a function or a function block expects an input parameter of the posAxis data type, you can also use a synchronized axis or a path axis when calling.

System data types

There are a number of system data types available that you can use without a previous declaration. And, each imported technology packages provides a library of system data types.

Additional system data types (primarily enumeration and STRUCT data types) can be found

- In parameters for the general standard functions (see SIMOTION Basic Functions Function Manual)
- In parameters for the general standard function blocks (see SIMOTION Basic Functions Function Manual)
- In system variables of the SIMOTION devices (see relevant parameter manuals)
- In parameters for the system functions of the SIMOTION devices (see relevant parameter manuals)
- In system variables and configuration data of the technology objects (see relevant parameter manuals)
- In parameters for the system functions of the technology objects (see relevant parameter manuals)

7.3.4.14 Variables

Variables are an important component of programming and provide structure to programs. They are placeholders which can be assigned values that can be accessed several times in the program.

Variables have:

- A specific initialization behavior and scope of validity
- A data type and operations which are defined for that data type

User and system variables are differentiated. User variables can be defined by the user. System variables are provided by the system.

Keywords for variable types

The various keywords for variable types are shown in the following table.

Description of keywords for variable types

Keyword	Description	Use
Global user variables (declared in the interface or implementation section of the unit[1])		
VAR_GLOBAL	Unit variable; can be accessed by all POUs within the source file. If the variable was declared in the interface section, it can be used in another source file once a connection has been defined in its declaration table (see Define connections (Page 5223)).	FB, FC, program
VAR_GLOBAL RETAIN	Retentive unit variable; retained during power outage.	FB, FC, program
VAR_GLOBAL CONSTANT	Unit constant; cannot be changed from the program.	FB, FC, program
Local user variables (declared within a POU[2])		
VAR	Local variable (static for FB and program, temporary for FC)	FB, FC, program
VAR_TEMP	Temporary local variable	FB, FC, program
VAR_INPUT	Input parameters: Local variable; value is supplied from external source and can only be read in the FB or FC.	FB, FC
VAR_OUTPUT	Output parameters: Local variable; value is sent to an external destination by the FB. It can be read as an instance variable after being called by the FB (FB instance name.variable name).	FB, FC
VAR_IN_OUT	In/out parameter; the FB or FC accesses this variable directly (by means of a reference) and can change it directly.	FB, FC
VAR OVERRIDE	Static variable whose initialization value can be overwritten for an instance formation. The compiler option (Page 5111) "Permit object-oriented programming" must be activated.	FB
VAR CONSTANT	Local constant; cannot be changed from the program.	FB, FC, program

[1] MCC and LAD/FBD programming languages: in the declaration table of the associated source file.

[2] MCC and LAD/FBD programming languages: in the declaration table of the associated chart/program.

Defining variables

Variables are defined in the symbol browser or in the declaration table of the source file or chart/program. The following table provides an overview of where the relevant variable is defined.

Definition of variables

Variable type	Defined in...
Global device user variables	Symbol browser
unit variable	Declaration table of the source file as VAR_GLOBAL, VAR_GLOBAL RETAIN or VAR_GLOBAL CONSTANT
Local variable	Declaration table of the program/chart as: • VAR, VAR_TEMP, or VAR CONSTANT • Additionally for function blocks as VAR_INPUT, VAR_OUTPUT, VAR_IN_OUT • Additionally for functions as VAR_INPUT, VAR_IN_OUT
I/O variable	Symbol browser
Symbolic access to the fixed process image of the BackgroundTask	• Declaration table of the source file • Declaration table of the program/chart (programs and FB only)

Use of global device variables

Global device variables are user-defined variables that you can access from all program sources (e.g. ST source files, MCC source files) of a SIMOTION device.

Global device variables are created in the symbol browser tab of the detail view; to do this, you must be working in offline mode.

Here is a brief overview of the procedure:

1. In the project navigator of SIMOTION SCOUT, select the **GLOBAL DEVICE VARIABLES** element in the SIMOTION device subtree.
2. In the detail view, select the **Symbol browser** tab and scroll down to the end of the variable table (empty row).
3. In the last (empty) row of the table, enter or select the following:
   - **Name** of variable
   - **Data type** of variable (only elementary data types are permitted)
4. Optionally, you can make the following entries:
   - Activation of **Retain** checkbox (This declares the variable as retentive, so that its value will be retained after a power failure.)
   - **Field length** (array size)
   - **Initial value** (if array, for each element)
   - **Display format** (if array, for each element)

You can now access this variable using the symbol browser or any program of the SIMOTION device.

In ST source files, you can use a global device variable, just like any other variable.

Note

If you have declared unit variables or local variables of the same name (e.g. *var-name*), specify the global device variable with *_device.var-name*.

An alternative to global device variables is the declaration of unit variables in a separate unit, which is imported into other units. This has the following advantages:

1. Variable structures can be used.
2. The initialization of the variables during the STOP-RUN transition is possible (via Program in StartupTask).
3. For newly created global unit variables, a download in RUN is also possible.

Please refer to the SIMOTION Basic Functions Function Manual.

Declaring a unit variable in the source file

The unit variable is declared in the unit. The scope of validity of the variable is dependent on the section of the declaration table in which the variable is declared:

- In the interface section of the declaration table (INTERFACE):
  The unit variable is valid for the entire unit; all programs/charts (programs, function blocks, and functions) within the unit can access the unit variable. It is exported and can be used in other source files or units (e.g. ST source files, MCC units, LAD/FBD units) after a connection has been defined (Page 5223). It is also available on HMI devices as standard. The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.
- In the implementation section of the declaration table (IMPLEMENTATION):
  The unit variable is valid in the unit only; all programs/charts (programs, function blocks, and functions) within the unit can access the unit variable.

If you insert pragma lines (Page 5178) into the declaration table, you can split the unit variables into data blocks with a separate version code (Page 5189). You can also use the pragma lines to define a separate initialization behavior (Page 5184) for each of these data blocks and change the defaults for HMI export (Page 5190).

Proceed as follows; the unit (declaration table) is open, see Open existing program source (Page 5104):

1. In the declaration table, select the section for the desired scope.
2. Then select the **Parameters** tab.
3. Enter:
   - Name of the variable.
   - Variable type.
     See also: Keywords for variable types (Page 5170).
   - Data type of the variables.
     You can select already defined data types.
     See also: Data types (Page 5161).
   - Activating the optional **Reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 5155).
   - Optional array length (to define the array size).
     See also: Array length and array element (Page 5156).
   - Optional initial value (initialization value).
     See also: Initial value (Page 5157).
   - Optional comment.
     See also: Comment (Page 5159).

The variable is then declared and can be used immediately within the unit.

Note

Outside the unit (e.g. in the symbol browser), the variable is only available after the unit has been compiled.

INTERFACE (exported declaration)

Parameter | I/O symbols | Structures | Enumerations | Connections

	Name	Variable type	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	var_in1	VAR_GLOBAL	REAL	☐			
2				☐			

IMPLEMENTATION (source-internal declaration)

Parameter | I/O symbols | Structures | Enumerations | Connections

	Name	Variable type	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	var_in2	VAR_GLOBAL	BOOL	☐			
2	var_out	VAR_GLOBAL	INT	☐	10		
3				☐			

Figure 7-484 Example: Declaring a unit variable in the unit

Note

The declaration table of the unit is read each time parameters are assigned for a command. Inconsistent data within the declaration table may, therefore, cause unexpected error messages during parameter assignment.

Declaring local variables

A local variable can only be accessed within the program/chart (program, function, function block) in which it is declared.

We distinguish between the following:

- Static variables:
  Static variables retain their value over all passes of the unit section (block memory).
- Temporary variables:
  Temporary variables are initialized each time the unit section is called again.

See also: Initialization of local variables (Page 5185).

If you insert a pragma line (Page 5178) at the start of the declaration table, you can influence the initialization of static variables of programs (Page 5186).

Proceed as follows; the program/chart with the declaration table is open (see Open existing program source (Page 5104)):

1. In the declaration table, select the **Parameters/Variables** tab.
2. Enter:
   - Name of the variable.
   - Variable type for variables.
     See also: Keywords for variable types (Page 5170).
   - Data type of the variables.
     You can select already defined data types.
     See also: Data types (Page 5161).
   - Activating the optional **Reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 5155).
   - Optional array length (to define the array size).
     See also: Array length and array element (Page 5156).
   - Optional initial value (initialization value).
     See also: Initial value (Page 5157).
   - Optional comment.
     See also: Comment (Page 5159).

The variable is now declared and can be used immediately.

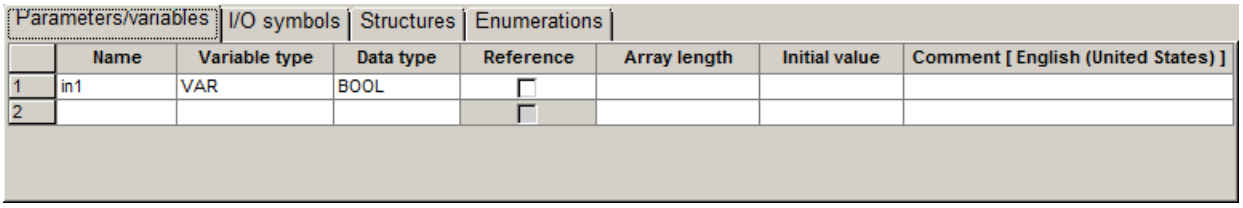

Figure 7-485 Example: Declaring a local variable in the chart/program

Note

The declaration table of the program/chart is read each time parameters are assigned for a command. Inconsistent data within the declaration table may, therefore, cause unexpected error messages during parameter assignment.

Defining variables in the Variable declaration dialog box ("on-the-fly" variable declaration)

As soon as you enter an unknown variable in the parameter screen form for an MCC command or an LAD/FBD graphic, the **Variable declaration** dialog box appears.

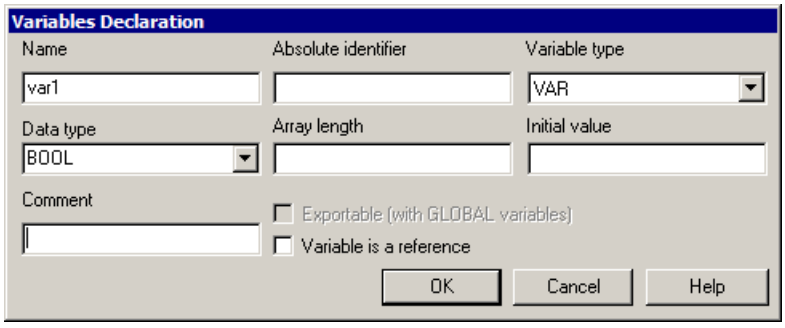

Figure 7-486 Variable declaration dialog box

Note

In order for the **Variable declaration** dialog box to appear, the **on-the-fly variable declaration** checkbox must be activated in the **Settings** dialog box.

Procedure

To define variables "on-the-fly" in the **Variable declaration** dialog box, proceed as follows:

1. Enter only the name of the variables in an input field of the parameter screen for an MCC command or LAD/FBD graphic and press the **Return** key.
   If the entered identifier is not a valid variable name, the dialog box **Variable declaration** appears.
2. Enter:
   - Another variable name, if required.
   - The **Data type** of the variables
     Available for selection are all elementary data types (Page 5162) and, where appropriate, the data type suitable for the input field.
     Select the data type or enter the identifier of a data type.
   - The **variable type**.
     Available for selection are all permitted keywords for variable types (Page 5170).
     Select the variable type.
     If you select a global variable type (e.g. VAR_GLOBAL), the checkbox **Exportable** becomes active.
   - The **Absolute identifier** for access to the fixed process image of the background task (Page 5211).
     You can only enter the identifier for the absolute access to the fixed process image of the background task if you have selected a data type that is included in the general data types (Page 5164) ANY_BIT or ANY_INT.
     Enter the absolute identifier according to the Syntax (Page 5218).
     The variable is displayed in the register **I/O symbols** of the declaration table.
   - Optional **array length**.
     Here, you specify the size of the array.
     Not available if an absolute identifier is entered.
     See also: Array length and array element (Page 5156).
   - Optional **initial value** (initialization value).
     Not available if an absolute identifier is entered.
     See also: Initial value (Page 5157).
   - Optional **comment**.
     See also:Comment (Page 5159).
   - Optionally, activate the **Variable is a reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 5155).

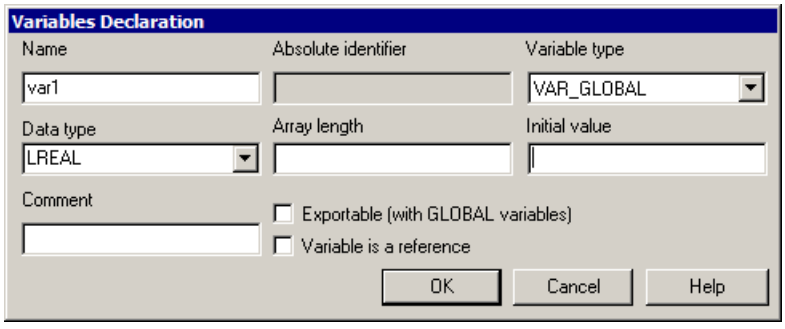

Figure 7-487 Example: Variable declaration

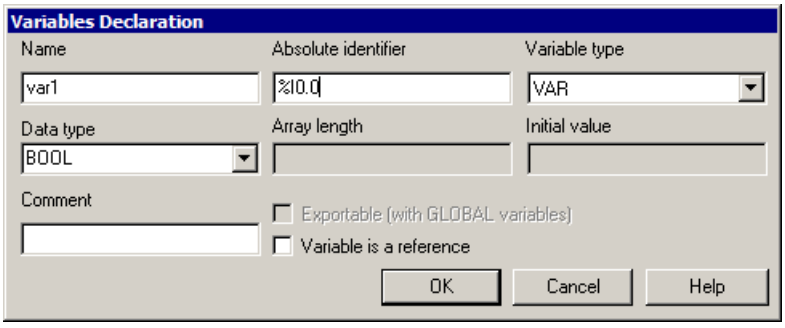

Figure 7-488 Example: Variable declaration (absolute name)

3. Confirm with **OK**.

Result

The variable is defined and entered in the declaration table of the source or the MCC chart or the LAD/FBD program, depending on the selected variable type and the **Exportable checkbox:**

- With local variables (e.g. VAR), the **Exportable** checkbox has a gray background and the new variable is entered in the declaration table of the MCC chart or the LAD/FBD program.
- With global variables (e.g. VAR_GLOBAL), the **Exportable** checkbox is shown activated:
  - If the **Exportable** checkbox is activated, the new variable is entered in the implementation section of the unit's declaration table.
  - If the **Exportable** checkbox is not activated, the new variable is entered in the interface section of the unit's declaration table.

Note

If you leave the **Variable declaration** dialog box by clicking **Cancel**, your input remains as it is, and the variable is not created.

Pasting pragma lines during variable definition

Pragma lines in declaration tables have the following function:

- In declaration tables of units (declaration of unit variables):
  Pragma lines in the interface section or implementation section of the declaration table split the variables of the respective section into different subsections:
  - The 1st subsection begins at the start of the relevant table and finishes at the 1st Pragma line.
  - All the other subsections start at one pragma line and finish at the next (or at the end of the table if starting at the last pragma line).

  Within these subsections of the table, each of the variables declared with VAR_GLOBAL or VAR_GLOBAL RETAIN forms a data block with a separate version code (Page 5189). If the version code is changed, only the data block concerned will be initialized during a download. Configure the pragma line in order to change the initialization behavior or the HMI export of the next data block (see following Section *Pragmas in the declaration tables of the unit variables*).
- In the declaration table of a program/chart (declaration of local variables):
  Line 1 may only contain one pragma line for changing the initialization behavior of programs' static variables (see the section titled *Pragmas in the declaration tables for local variables* later in this document).

Note

The SIMOTION Kernel version partially determines the effectiveness of pragma lines. This is specified for individual parameters.

Inserting a pragma line

To insert a pragma line into the declaration table, proceed as follows:

1. Select the **Parameters** tab (for unit variables) or **Parameters/variables** tab (for local variables).
2. In the declaration table, set the cursor to the number of the line at which a new data block is to be started.
   Only line 1 can be used in the declaration table for local variables.
3. Select the **Insert pragma line** context menu.
   A new line containing the **Pragmas** button only is inserted above the line.
4. Left-click the **Pragmas** button.
   A window containing configuration options for the relevant declaration table opens.
5. Enter the settings.
6. Confirm with **OK**.

Pragmas in the declaration tables for unit variables

A pragma line has been inserted into the declaration table for unit variables. If you click the "Pragmas" button in the table, the following window appears:

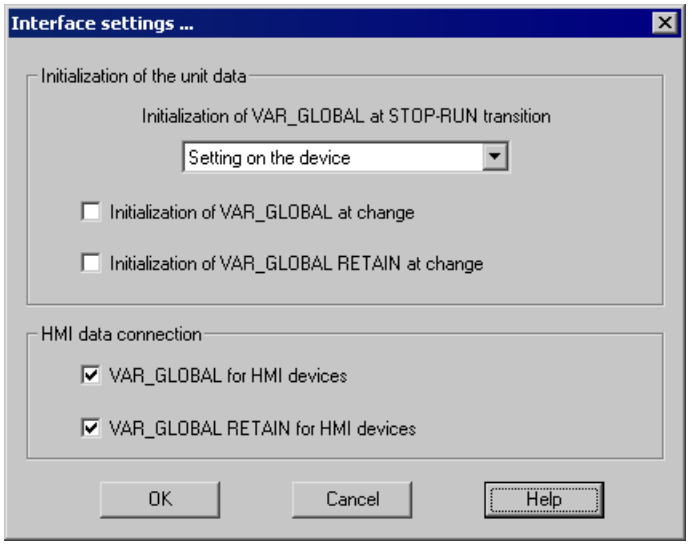

Figure 7-489 Pragma settings in the declaration table for unit variables (e.g. interface section)

This window is for making the settings below. These influence the data block following the pragma line:

Table 7-536 Parameters for pragma settings in the declaration table for unit variables

Parameter		Description
Initialization of unit data		
	Initialization of VAR_GLOBAL during STOP-RUN transition	Only as of version V4.1 of the SIMOTION Kernel. This setting determines whether the next data block of the non-retentive unit variables is initialized during the transition from STOP to RUN operating state. **Setting on the device** (standard): • As of version V4.2 of the SIMOTION Kernel: The setting made on the SIMOTION device applies. • Up to version V4.1 of the SIMOTION Kernel: Variables are **not** initialized. **Always**: Variables are initialized. **Never**: Variables are **not** initialized.
	Initialization of VAR_GLOBAL during a change	This setting determines whether a download for the next data block of the non-retentive unit variables can be performed in RUN if the version code has changed. **Active**: A download in RUN is possible. **Inactive** (standard): A download in RUN is **not** possible.
	Initialization of VAR_GLOBAL RETAIN during a change	This setting determines whether a download for the next data block of the retentive unit variables can be performed in RUN if the version code has changed. **Active**: A download in RUN is possible. **Inactive** (standard): A download in RUN is **not** possible.
HMI data connection		

Parameter		Description
		Use the settings below to change which unit variables are available on which HMI devices by default. Detailed description of the HMI export, in particular the effect of the settings depending on SIMOTION Kernel version: see Variables and HMI devices (Page 5190).
	VAR_GLOBAL for HMI devices	**Active** (standard in the interface section): The next data block of the non-retentive unit variables is available on HMI devices. **Inactive** (standard in the implementation section): The next data block of the non-retentive unit variables is **not** available on HMI devices.
	VAR_GLOBAL RETAIN for HMI devices	**Active** (standard in the interface section): The next data block of the retentive unit variables is available on HMI devices. **Inactive** (standard in the implementation section): The next data block of the retentive unit variables is **not** available on HMI devices.

Pragmas in the declaration tables for local variables

A pragma line has been inserted into line 1 of the declaration table for local variables. If you click the "Pragmas" button in the table, the following window appears:

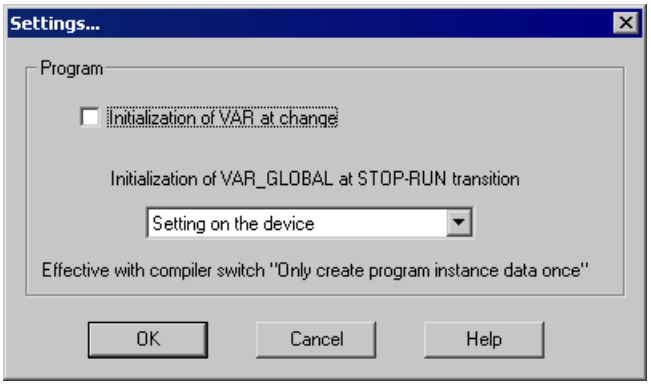

Figure 7-490 Pragma settings in the declaration table for local variables

You can make the following settings in this window:

Note

These settings only take effect in the following scenarios:

1. The "Only create program instance data once" compiler option is active on the higher-level unit.
2. The creation type of the program/chart is "Program".

Table 7-537 Parameters for pragma settings in the declaration table for local variables

Parameter	Description
Initialization of VAR during a change	This setting determines whether a download for the next static variables can be performed in RUN if the version code has changed. **Active**: A download in RUN is possible. **Inactive** (standard): A download in RUN is **not** possible.
Initialization of VAR during STOP-RUN transition	Only as of version V4.1 of the SIMOTION Kernel. This setting determines whether the next static variables are initialized during the transition from STOP to RUN operating state. **Setting on the device** (standard): • As of version V4.2 of the SIMOTION Kernel: The setting made on the SIMOTION device applies. • Up to version V4.1 of the SIMOTION Kernel: Variables are **not** initialized. **Always**: Variables are initialized. **Never**: Variables are **not** initialized.

Time of the variable initialization

The timing of the variable initialization is determined by:

- Memory area to which the variable is assigned
- Operator actions (e.g. source file download to the target system)
- Execution behavior of the task (sequential, cyclic) to which the program was assigned.

All variable types and the timing of their variable initialization are shown in the following tables. You will find basic information about tasks in the *SIMOTION Basic Functions* Function Manual.

The behavior for variable initialization during download can be set: To do this, as a default setting select the **Options > Settings** menu and the **Download** tab or define the setting during the current download.

Note

You can upload values of unit variables or global device variables from the SIMOTION device into SIMOTION SCOUT and save them in XML format.

1. Save the required data segments of the unit variables or global device variables as a data set with the function *_saveUnitDataSet*.
2. Use the **Save variables** function in SIMOTION SCOUT.

You can use the **Restore variables** function to download these data sets and variables back to the SIMOTION device.

For more information, refer to the SIMOTION SCOUT Configuration Manual.

This makes it possible, for example, to obtain this data, even if it is initialized by a project download or if it becomes unusable (e.g. due to a version change of SIMOTION SCOUT).

Initialization of retentive global variables

Retentive variables retain their last value after a loss of power. All other data is reinitialized when the device is switched on again.

Retentive global variables are initialized:

- When the backup or buffer for retentive data fails.
- When a memory reset (MRES) is performed.
- With the restart function (Del. SRAM) in SIMOTION P320 or P350.
- By applying the *_resetUnitData* function, possible selectively for different data segments of the retentive data.
- When a download is performed according to the following description.
- With a firmware update (upgrade) or activation of a kernel in accordance with the following description.

Behavior during download

Table 7-538 Initializing retentive global variables during download

Variable type	Time of the variable initialization
Retentive global device variables	The behavior during the download depends on the *Initialization of retentive program data and retentive global device variables* setting[1]: • **Yes**[2]: All retentive global device variables are initialized. • **No**[3]: The retentive global device variables are only initialized if their version code is changed. See: Version code of global variables and their initialization during download (Page 5189).
Retentive unit variables	The behavior during the download depends on the *Initialization of retentive program data and retentive global device variables* setting[1]: • **Yes**[2]: All retentive unit variables (all units) are initialized. • **No**[3]: A data block (= declaration block)[4] of the retentive unit variables in the interface or implementation section is only initialized[5] if its version code is changed. See: Version code of global variables and their initialization during download (Page 5189).

[1] Default setting in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding check box is active.

[3] The corresponding check box is inactive.

[4] With the **SIMOTION ST** programming language:
A data block of the retentive unit variables corresponds to a VAR_GLOBAL RETAIN/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** and **SIMOTION LAD/FBD** programming languages:
A data block of the retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL RETAIN in the interface section or implementation section of the declaration table: Pragma lines (Page 5178) within a section of the declaration table separate the variables into different data blocks.

[5] Initialization of a changed data block also occurs during a download in RUN mode, provided the following condition is fulfilled:
With the **SIMOTION ST** programming language
The following attribute has been specified within a pragma: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line (Page 5178) is inserted in the declaration table with the following check box enabled in this line: *Initialization of VAR_GLOBAL RETAIN during a change*. All the variables declared with VAR_GLOBAL RETAIN up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see the SIMOTION Basic Functions Function Manual.

Behavior during upgrade or configuration change

When the SIMOTION device is upgraded to a new version of the SIMOTION Kernel or if the configuration is changed, the retentive variables are initialized as described below:

Table 7-539 Initialization of retentive global variables during upgrade or configuration change

Variable type	Time of the variable initialization
Retentive global device variables	This data is always initialized.
Retentive unit variables	This data can be retained. See section "Retaining retentive data" in the "Basic Functions for Modular Machines" Function Manual.

Initialization of non-retentive global variables

Non-retentive global variables lose their value during power outages. They are initialized:

- During the initialization of retentive global variables (Page 5182), e.g. during a firmware update or overall reset (MRES).
- During switch-on.
- By applying the *_resetUnitData* function, possible selectively for different data segments of the non-retentive data.
- During a download as described in the following table.
- During the transition from STOP to RUN mode as described at the end of the section.

Behavior during download

Table 7-540 Initializing non-retentive global variables during download

Variable type	Time of the variable initialization
Non-retentive global device variables	The behavior during the download depends on the *Initialization of non-retentive program data and non-retentive global device variables* setting[1]: • **Yes**[2]: All non-retentive global device variables are initialized. • **No**[3]: The non-retentive global device variables are only initialized if their version code is changed. See: Version code of global variables and their initialization during download (Page 5189).
Non-retentive unit variables	The behavior during the download depends on the *Initialization of non-retentive program data and non-retentive global device variables* setting[1]: • **Yes**[2]: All non-retentive unit variables (all units) are initialized. • **No**[3]: A data block (= declaration block)[4] of the non-retentive unit variables in the interface or implementation section is only initialized[5] if its version code is changed. See: Version code of global variables and their initialization during download (Page 5189).

[1] Default in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding check box is active.

[3] The corresponding check box is inactive.

[4] With the **SIMOTION ST** programming language:
A data block of the non-retentive unit variables corresponds to a VAR_GLOBAL/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A data block of the non-retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL in the interface section or implementation section of the declaration table: Pragma lines (Page 5178) within a section of the declaration table separate the variables into different data blocks.

[5] Initialization of a changed data block also occurs during a download in RUN, provided the following condition is fulfilled:
With the **SIMOTION ST**
programming language: The following attribute has been specified within a pragma in the relevant declaration block: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line (Page 5178) has been pasted into the declaration table and the following check box is activated: *Initialization of VAR_GLOBAL during a change*. All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see SIMOTION Basic Functions Function Manual.

Behavior during STOP-RUN transition

The values of non-retentive global variables are retained by default during the transition from STOP to RUN mode.

You can, however, make a setting whereby the non-retentive global variables are initialized during the STOP-RUN transition:

- **As of Version V4.2 of the SIMOTION Kernel**, by activating the **Initialization of non-retentive global variables and program data during STOP-RUN transition** checkbox on the SIMOTION device.
  With non-retentive unit variables, this setting can be overwritten by a pragma or pragma line (Page 5178) in the relevant data blocks of the program sources.
- **As of Version V4.1 of the SIMOTION Kernel**, by a pragma or pragma line in the relevant data blocks of the program sources (only with non-retentive unit variables):
  - With the **SIMOTION ST** programming language:
    Specify the following attribute within a pragma in the relevant VAR_GLOBAL/END_VAR declaration block: { BlockInit_OnDeviceRun := ALWAYS; }
  - With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
    Paste a pragma line (Page 5178) with the following setting into the declaration table: "*Initialization during STOP-RUN transition* = **Always**". All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block which is initialized during the STOP-RUN transition.

Note

With SIMOTION devices up to SIMOTION Kernel Version V4.0, non-retentive global variables are never initialized during the STOP-RUN transition.

Initialization of local variables

Local variables are initialized:

- For the initialization of retentive unit variables (Page 5182).
- For the initialization of non-retentive unit variables (Page 5184).
- Also, according to the following description:

Table 7-541 Initialization of local variables

Variable type	Time of the variable initialization
Local program variables	Local variables of programs are initialized differently: • Static variables (VAR) are initialized according to the memory area in which they are stored. See: Initialization of static program variables (Page 5186). • Temporary variables (VAR_TEMP) are initialized every time the program of the task is called.
Local variables of function blocks (FB)	Local variables of function blocks are initialized differently: • Static variables (VAR, VAR_IN, VAR_OUT) are only initialized when the FB instance is initialized. See: Initialization of instances of function blocks (FBs) (Page 5187). • Temporary variables (VAR_TEMP) are initialized every time the FB instance is called.
Local variables of functions (FC)	Local variables of functions are temporary and are initialized every time the function is called.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 5259) function.

Initialization of static program variables

The following versions affect the following static variables:

- Local variables of a unit program declared with VAR
- Function block instances declared with VAR within a unit program, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT).

The initialization behavior is determined by the memory area in which the static variables are stored. This is determined by the "Only create program instance data once" (Page 5111) compiler option.

- For the deactivated "Only create program instance data once" compiler option (default):
  The static variables are stored in the user memory of each task which is assigned to the program.
  The initialization of the variables thus depends on the execution behavior of the task to which the program is assigned (see SIMOTION Basic Functions Function Manual):
  - Sequential tasks (MotionTasks, UserInterruptTasks, SystemInterruptTasks, StartupTask, ShutdownTask): The static variables are initialized every time the task is started.
  - Cyclic tasks (BackgroundTask, SynchronousTasks, TimerInterruptTasks): The static variables are only initialized only during the transition from STOP to RUN operating state.
- For the activated "Only create program instance data once" compiler option:
  This setting is necessary, for example, if a program is to be called within a program.
  The static variables of all programs from the program source (unit) involved are only stored once in the user memory of the unit.
  They are thus initialized together with the non-retentive unit variables, see Initialization of non-retentive global variables (Page 5184).
  They are not initialized by default during the transition from STOP to RUN operating state.
  You can, however, make a setting whereby they are initialized during the STOP-RUN transition:
  - **As of version V4.2 of the SIMOTION Kernel**, by activating the **Initialization of non-retentive global variables and program data during STOP-RUN transition** checkbox on the SIMOTION device.
    This setting can be overwritten by a pragma or pragma line (Page 5178) in the data block of the relevant program organization unit (POU).
  - **As of version V4.1 of the SIMOTION Kernel**, by a pragma or pragma line in the data block of the relevant program organization unit (POU):
    With the **SIMOTION ST** programming language:
    Specify the following attribute within a pragma in the VAR/END_VAR declaration block:
    { BlockInit_OnDeviceRun := ALWAYS; }
    With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
    The declaration table starts with a pragma line (Page 5178) containing the following setting: "*Initialization during STOP-RUN transition* = **Always**". All the variables declared with VAR in the table are initialized during the STOP-RUN transition.

Initialization of instances of function blocks (FBs) or classes

The initialization of a function block instance (Page 5240) or a class instance (as of version V4.5 of the SIMOTION Kernel) is determined by the location of its declaration:

- Global declaration (within VAR_GLOBAL/END_VAR in the interface of implementation section):
  Initialization as for a non-retentive unit variable, see Initialization of non-retentive global variables (Page 5184).
- Local declaration in a program (within VAR / END_VAR):
  Initialization as for static variables of programs, see Initialization of static variables of programs (Page 5186).

- Local declaration in a function block (within VAR / END_VAR):
  Initialization as for an instance of this function block.
- Declaration as in/out parameter in a function block or a function (within VAR_IN_OUT / END_VAR):
  For the initialization of the POU, only the reference (pointer) will be initialized with the instance of the function block remaining unchanged.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 5259) function.

Initialization of system variables of technology objects

The system variables of a technology object are usually not retentive. Depending on the technology object, a few system variables are stored in the retentive memory area (e.g. absolute encoder calibration).

The initialization behavior (except in the case of download) is the same as for retentive and non-retentive global variables. See Initialization of retentive global variables (Page 5182) and Initialization of non-retentive global variables (Page 5184).

The behavior during the download is shown below for:

- Non-retentive system variables
- Retentive system variables

Table 7-542 Initializing technology object system variables during download

Variable type	Time of the variable initialization
Non-retentive system variables	Behavior during download, depending on the *Initialization of all non-retentive data for technology objects* setting[1]: • **Yes**[2]: All technology objects are initialized. – All technology objects are restructured and all non-retentive system variables are initialized. – All technological alarms are cleared. • **No**[3]: Only technology objects changed in SIMOTION SCOUT are initialized. – The technology objects in question are restructured and all non-retentive system variables are initialized. – All alarms that are pending on the relevant technology objects are cleared. – If an alarm that can only be acknowledged with *Power On* is pending on a technology object that will not be initialized, the download is aborted.
Retentive system variables	Only if a technology object was changed in SIMOTION SCOUT, will its retentive system variables be initialized. The retentive system variables of all other technology objects are retained (e.g. absolute encoder calibration).

[1] Default in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding checkbox is active.

[3] The corresponding checkbox is inactive.

Version ID of global variables and their initialization during download

Table 7-543 Version code of global variables and their initialization during download

Data segment		Description of version code
Global device variables		
	Retentive global device variables Non-retentive global device variables	• Separate version code for each data segment of the global device variables. • The version code of the data segment changes for: – Add or remove a variable within the data segment – Change of the identifier or the data type of a variable within the data segment • This version code does not change on: – Changes in the other data segment – Changes to initialization values[1] • During downloading[2], the rule is: This data segment is only initialized when the version code of a data segment is changed.
Unit variables of a unit		
	Retentive unit variables in the interface section Retentive unit variables in the implementation section Non-retentive unit variables in the interface section Non-retentive unit variables in the implementation section	• Several data blocks (= declaration blocks)[3] are possible in each data segment. • **Separate version code** for each data block. • The version code of the data block changes for: – Add or remove a variable in the associated declaration block – Change of variable sequence in the relevant declaration block – Change of the identifier or the data type of a variable in the associated declaration block – Change of a data type definition (from a separate or imported[4] unit) used in the associated declaration block – Add or remove declaration blocks within the same data segment **before** the associated declaration block • This version code does not change on: – Add or remove declaration blocks in other data segments – Add or remove declaration blocks within the same data segment **after** the associated declaration block – Changes in other data blocks – Changes to initialization values[1] – Changes to data type definitions that are not used in the associated data block – Changes to functions • During downloading[2], the rule is: This data block is only initialized when the version code of a data block is changed[5]. • Functions for data backup and initialization take into account the version code of the data blocks.
Retentive variables of function blocks and classes (The instances are declared as non-retentive unit variables)		

Data segment		Description of version code
	Non-retentive unit variables in the interface section	Only as of version V4.5 of the SIMOTION Kernel. • The retentive variables of all instances within a declaration block (VAR_GLOBAL / END_VAR) are summarized as a separate retentive data block • to which a separate version code is assigned. • The version code of this retentive data block changes: – The data structure of the retentive local variables for the instances within the declaration block changes. – The sequence of the declaration blocks (VAR_GLOBAL / END_VAR) within the program source changes. • During downloading[2], the rule is: This data block is only initialized when the version code of a data block is changed[5]. • Functions for data backup and initialization take into account the version code of the data blocks.
	Non-retentive unit variables in the implementation section	

[1] Changed initialization values are not effective until the data block or data segment in question is initialized.

[2] If *Initialization of retentive program data and retentive global device variables* = No and *Initialization of non-retentive program data and non-retentive global device variables* = No.
In the case of other settings: See the sections "Initialization of retentive global variables (Page 5182)" and "Initialization of non-retentive global variables (Page 5184)".

[3] With the **SIMOTION ST** programming language:
A data block corresponds to a VAR_GLOBAL/END_VAR or VAR_GLOBAL RETAIN/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A data block of the non-retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL or VAR_GLOBAL RETAIN in the interface section or implementation section of the declaration table: Pragma lines (Page 5178) within a section of the declaration table separate the variables into different data blocks.

[4] The use of units depends on the programming language, refer to the relevant section (Page 5223).

[5] Initialization of a changed data block also occurs during a download in RUN mode, provided that the following condition is fulfilled:
With the **SIMOTION ST** programming language
The following attribute has been specified within a pragma: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line (Page 5178) is inserted in the declaration table with the following check box enabled in this line: *Initialization of VAR_GLOBAL during a change*. All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see SIMOTION Basic Functions Function Manual.

Variables and HMI devices

Exported variables

The following variables are exported to HMI devices where they are available:

- System variables of the SIMOTION device
- System variables of technology objects
- I/O variables
- Global device variables

- Retentive and non-retentive unit variables of the interface section (default setting).
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes.
  - In the SIMOTION MCC and SIMOTION LAD/FBD programming languages:
    For the variable declarations following a pragma line (Page 5178), if you deactivate the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* parameters in this pragma line.

  The unit variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.
- Non-retentive static variables (VAR) of programs provided that the compiler option "Only create program instance data once" is activated
- Non-retentive static variables (VAR) of function blocks
  This is the default setting when the compiler option "Permit object-oriented programming" is enabled. Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.
  The pragma is not evaluated if the compiler option "Permit object-oriented programming" is **not** activated. The export behavior cannot be changed.
- Non-retentive public variables (VAR PUBLIC) of classes (default setting, as of version V4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.

Note

The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.

The effect of the `{ HMI_Export := FALSE; }` / `{ HMI_Export := TRUE; }` pragma (or the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* settings in a pragma line) depends on the SIMOTION Kernel version:

- As of Version V4.1 of the SIMOTION Kernel:
  The pragma affects the export of the corresponding declaration block to HMI devices **and** the structure of the HMI address space:
  - Only those variables in declaration blocks exported to HMI devices occupy the HMI address space.
  - Within the HMI address space, the variables are arranged according to order of their declaration.
- Up to Version V4.0 of the SIMOTION Kernel:
  The pragma affects **only** the export of the corresponding declaration block to HMI devices. The HMI address space is also occupied by unit variables of the interface section whose declaration blocks are not assigned to HMI devices.
  Within the HMI address space, the variables are sorted in the following order:
  - Retentive unit variables of the interface section (exported and not exported).
  - Retentive unit variables of the implementation section (only exported).
  - Non-retentive unit variables of the interface section (exported and not exported).
  - Non-retentive unit variables of the implementation section (only exported).

  Within these segments, the variables are arranged according to order of their declaration.

Non-exported variables

The following variables are **not** exported to HMI devices and are **not** available there:

- Retentive and non-retentive unit variables of the implementation section (default setting)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`
    See also Controlling compiler with attributes.
  - In the SIMOTION MCC and SIMOTION LAD/FBD programming languages:
    For the variable declarations following a pragma line (Page 5178), if you activate the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* parameters in this pragma line.

  The unit variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
- Local variables (VAR, VAR_TEMP) of functions or methods
- Temporary variables (VAR_TEMP) of programs, function blocks or classes
- Retentive local variables (VAR RETAIN) of programs (as of version 4.5 of the SIMOTION Kernel)

- Retentive local variables (VAR RETAIN) of function blocks (as of version 4.5 of the SIMOTION Kernel)
  This is the default setting when the compiler option "Permit object-oriented programming" is enabled. Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
  The pragma is not evaluated if the compiler option "Permit object-oriented programming" is **not** activated. The export behavior cannot be changed.
- Retentive local variables (VAR RETAIN) of classes (default setting, as of version 4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
- Non-retentive static variables (VAR) of programs provided that the compiler option "Only create program instance data once" is **not** activated
- Non-retentive protected or private variables (VAR, VAR PROTECTED, VAR PRIVATE) of classes (default setting, as of version V4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.

Example for the SIMOTION ST programming language

Table 7-544 Example for the control of the HMI export with the corresponding pragma

```
INTERFACE
    VAR_GLOBAL
        // HMI export
        x1 : DINT;
    END_VAR
    VAR_GLOBAL
        { HMI_Export := FALSE; }
        // No HMI export
        x2 : DINT;
    END_VAR
    // ...
END_INTERFACE

IMPLEMENTATION
    VAR_GLOBAL
        // No HMI export
        y1 : DINT;
    END_VAR
    VAR_GLOBAL
        { HMI_Export := TRUE; }
        // HMI export
        y2 : DINT;
    END_VAR
    // ...
END_IMPLEMENTATION
```

7.3.4.15 General references (as of kernel V4.5)

Defining general references

General references contain the address assignment to a variable or an instance of a function block or class:

General references require a SIMOTION Kernel as of version V4.5. The compiler option (Page 5111) "Permit object-oriented programming" also must be activated.

References can be defined as variables or elements of structures.

To do this, activate the **Reference** checkbox in the **Parameters/variables** or **Structures** tab in the declaration table of the program source or program organization unit. The declaration is also possible as array element. See also the description for the "Reference (Page 5155)" checkbox.

This creates the "Reference to data type" (REF_TO *data_type*) that can contain the address to an existing data type (reference data type).

The following are permitted as data types to which references can be formed:

- Elementary data types (e.g. INT, DINT, REAL, WORD, TIME, STRING)
- User-defined data types (UDT)
- System data types

- Function blocks, provided they contain at least one static variable
- Classes (from ST sources)

No references can be formed to the following data types because references exist already:

- Technology object data types
- Object-oriented interfaces (from ST sources)
- General references
- I/O references (from ST sources)

Variables of general references can be declared in the interface and implementation sections as well as in all program organization units and classes. The data type to be referenced must be declared beforehand and lie within the scope of the POU. The declaration as element of a structure or an ARRAY is also possible.

All variable types for the relevant program organization unit are permitted with the exception of:

- VAR_IN_OUT.
  Arrays, structures, function blocks or classes that contain general references may nonetheless be transferred as VAR_IN_OUT.
- VAR RETAIN or VAR_GLOBAL RETAIN is not permitted.
  However, structures that contain at least one element other than reference types (general references, data types of the technology objects, object-oriented interfaces), can be stored retentive.
- VAR CONSTANT or VAR_GLOBAL CONSTANT is not meaningful.
  General references must be initialized with "NULL".

Forming general references

A reference to a variable is formed with the REF standard function (in := *var_name*). This function is described in detail in the "SIMOTION Basic Functions" Function Manual.

The REF function can be used on the following variables:

- Retentive and non-retentive unit variables or instances of classes or function blocks or their elements declared as such.
- In methods within classes or function blocks:
  - Static variables (VAR) of the higher-level class or function block (including instance variables for classes or function blocks).
  - The THIS keyword. Enables access to the instance variable of the higher-level class or function block.
- In function blocks:
  - Static variables (VAR) of the function block (including instance variables of classes or function blocks).
  - The THIS keyword. Permits access to the instance variable of the function block.

The variable must be able to be read and written.

Not permitted are:

- Variables of technology object data types
- Variables of object-oriented interfaces
- Variables of general references
- Retentive local variables within classes or function blocks
- I/O variables
- Global device variables
- Constants

The return value has the data type "Reference to the data type of the input parameter *in*". The return value can be assigned with the assignment operator ":=" to a variable that has REF_TO *type* data type. A data type conversion is not possible.

Note

Note for instances of function blocks that are passed as in/out parameter (VAR_IN_OUT):

- The REF function cannot be used for static variables (VAR) of function blocks imported from technology packages or device-independent libraries.

The restriction does not apply to class instances.

Operations with general references

Assignment operator ":="

For the assignment of a reference variable, the address of the variable rather than the variable value is passed. Consequently, the reference data types must be identical on both sides of the operator. No implicit data type conversion is possible.

The only exception is for references to classes. A reference to a derived class of a reference to the base class can be assigned here.

For the assignment, no check is made for the validity of the reference; the assignment is always possible.

An explicit assignment with NULL is also possible.

The validity of references should be checked by comparing with NULL before use.

Dereferencing with operator "^"

The reference content can be accessed with the postfix operator "^", e.g. *ref_var*^.

If the reference does not contain a valid value at runtime, the processing task is aborted and the ExecutionFaultTask called.

Before access, a check for validity by comparison with NULL is recommended.

Multilevel dereferencing is possible, e.g. reference to a structure that contains further references. Dereferenced variables can be used anywhere in expressions.

If a method is called via a reference to a class or function block, the class or function block must be dereferenced.

Dereferenced values cannot be used as actual parameters for the _releaseSemaphore() and _testandSetSemaphore() system functions.

Dynamic type conversion with the operator "?="

The operator "?=" can be used for dynamic type conversion only with references to classes and with interface variables (variables for object-oriented interfaces). It supports the following variants:

- Assignment between references to classes.
- Assignment of a reference to a class for an interface variable.
  Whereby, the reference to a class must be specified with the dereferencing operator "^".
- Assignment of an interface variable for a reference to a class.
- Assignment between interface variables

A dynamic type conversion is performed if the following two conditions are satisfied:

1. The variable to the right of the operator contains the reference to the instance of a class.
2. For the variable to the left of the operator, the following applies:
   - The variable is an interface variable:
     The object-oriented interface that this variable has as data type must implement the class on the right-hand side.
   - The variable is a reference to a class:
     This class corresponds to the class on the right-hand side or is a base class for this class.

In this case, the reference on the right-hand side is converted and transferred to the left-hand side.

If the type conversion fails, the variable on the left-hand side contains the "NULL" value.

Comparison operators

Only the comparison operators "=" and "<>" can be used to check for equality or inequality.

The operators ">", "<", ">=", "<=" as well as the MIN and MAX standard functions are not permitted.

7.3.4.16 Access to inputs and outputs (process image, I/O variables)

Overview of access to inputs and outputs

SIMOTION provides several possibilities to access the device inputs and outputs of the SIMOTION device as well as the central and distributed I/O:

- Via direct access with I/O variables
  Direct access is used to access the corresponding I/O address directly.
  Define an I/O variable (name and I/O address) without assigning a task to it. The entire address space of the SIMOTION device can be used.
  It is preferable to use direct access with sequential programming (in MotionTasks); access to current input and output values at a particular point in time is especially important in this case.
  Further information: Direct access and process image of the cyclic tasks (Page 5202).
- Via the process image of cyclic tasks using I/O variables
  The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming).
  Define an I/O variable (name and I/O address) and assign a task to it. The entire address range of the SIMOTION device can be used.
  Direct access to this I/O variable is still possible: Specify direct access with *_direct.var-name*.
  Further information: Direct access and process image of the cyclic tasks (Page 5202).
- Using the fixed process image of the BackgroundTask
  The process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device, on which a subset of the I/O address space of the SIMOTION device is mirrored. The mirror image is refreshed with the BackgroundTask and is consistent throughout the entire cycle. This process image is used preferentially when programming the BackgroundTask (cyclic programming).
  The address range 0 .. 63 can be used. Exception: I/O addresses that are accessed using the process image of the cyclic task can only be used with the setting “Common process image” (Page 5213) (as of Kernel V4.2).
  Further information: Access to the fixed process image of the BackgroundTask (Page 5211).

A comparison of the most important properties is contained in "Important properties of direct access and process image" (Page 5199).

You can use I/O variables like any other variable, see "Access I/O variables" (Page 5221).

Note

An access via the process image is more efficient than direct access.

Important features of direct access and process image access

Table 7-545 Important properties of direct access and process image access

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
Permissible address range	Entire address range of the SIMOTION device **Exception**: I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously (example: PIW63 or PQD62 are not permitted).		Addresses 0 .. 63. **Exception**: Up to version V4.1 of the SIMOTION Kernel or the "Separate process image" setting, addresses used for the process image of the cyclic tasks are not permitted.
Address configuration	Necessary. The addresses used must be present in the I/O and appropriately configured. The "Rules for I/O addresses for direct access and the process image of the cyclic tasks" (Page 5205) must be observed.		Not necessary. Addresses that are not present in the I/O or have not been configured can also be used.
Assigned task	None.	Cyclic task for selection: • SynchronousTasks, • TimerInterruptTasks, • BackgroundTask.	BackgroundTask.
Memory area for process images	-	Depends on the SIMOTON Kernel version: • Up to version V4.1: Separate memory areas in all cases • As of version V4.2: Option to select a common memory area	

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
Update	• Onboard I/O of SIMOTION devices C230-2, C240, and C240 PN: Update occurs in a cycle clock of 125 µs. • With I/O devices – via PROFIBUS DP or PROFINET on an isochronous SIMOTION device[1] – via DRIVE-CLiQ – Onboard I/O of SIMOTION D devices: The update is performed in the position control cycle clock[2]. • With I/O devices – via PROFIBUS DP or PROFINET on a **non**-isochronous SIMOTION device[1] – via P-Bus: The update is performed in the interpolation cycle[2 3]. Inputs are read at the start of the cycle clock. Outputs are written at the end of the cycle clock.	Update occurs with the assigned task: • Inputs are read before the assigned task is started and transferred to the process input image. • Process output image is written to the outputs after the assigned task has been completed.	An update is made with the *BackgroundTask*: • Inputs are read before the *BackgroundTask* is started and is transferred to the process input image. • Process output image is written to the outputs when the *BackgroundTask* is complete.
Consistency	–	During the entire cycle of the assigned task. **Exception**: Direct access to output occurs.	During the entire cycle of the *BackgroundTask*. **Exception**: Direct access to output occurs.
	Consistency is only ensured for elementary data types. When using arrays, the user is responsible for ensuring data consistency.		
Use	Preferred in MotionTasks	Preferred in the assigned task	Preferred in the BackgroundTask
Declaration as variable	Necessary, for the entire device as an I/O variable in the symbol browser. Each byte of the address range may only be assigned to a single I/O variable. Syntax of I/O address: e.g. PIW1022, PQ63.3.		Possible, but not necessary: • For the entire device as I/O variable in the symbol browser • As unit variable • As local static variable in a program
Download of new or changed I/O variables	Only possible in STOP mode.		-
Use the absolute address	Not supported.		Possible, with the following syntax: E.g. %IW62, %Q63.3.

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
Byte order when forming the process image	-	As supplied by the I/O	Depends on the SIMOTION Kernel version and the memory area setting for the process images: • Up to version V4.1 or the "Separate process image" setting: Always Big Endian • As of version V4.2 and the "Common process image" setting: As supplied by the I/O
Byte order during access	Depends on I/O		Always Big Endian
Writeability of inputs	No	Depends on the SIMOTION Kernel version: • Up to version V4.1: No • As of version V4.2: Yes	Yes
Write protection for outputs	Possible; **Read only** status can be selected.	Not supported.	Not supported.
Declaration of arrays	Possible.		Not supported.
Further information	Direct access and process image of the cyclic tasks (Page 5202).		Access to the fixed process image of the BackgroundTask (Page 5211).
Responses in the event of an error	Error during access from user program, alternative reactions available: • CPU Stop[4] • Substitute value • Last value See SIMOTION Basic Functions Description of Functions.	Error during generation of process image, alternative reactions available: • CPU stop[5] • Substitute value • Last value See SIMOTION Basic Functions Description of Functions.	Error during generation of process image, reaction: CPU stop[5] **Exception**: If a direct access has been created at the same address, the behavior set there applies.
Access			
• In the RUN operating state	Without any restrictions.	Without any restrictions.	Without any restrictions.
• During the StartupTask	Possible with restrictions: • Inputs can be read. • Outputs are not written until StartupTask is complete.	Possible with restrictions: • Inputs are read at the start of the StartupTask. • Outputs are not written until StartupTask is complete.	Possible with restrictions: • Inputs are read at the start of the StartupTask. • Outputs are not written until StartupTask is complete.

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
• During the ShutdownTask	Without any restrictions.	Possible with restrictions: • Inputs retain status of last update • Outputs are no longer written.	Possible with restrictions: • Inputs retain status of last update • Outputs are no longer written.

[1] A SIMOTION device is considered isochronous if at least one PROFIBUS DP or PROFINET interface is operated isochronously (constant bus cycle time). For SIMOTION D there is an exception with the DP Integrated interface to which the SINAMICS Integrated is connected.

[2]The following SIMOTION devices are updated in the Servo_fast cycle or IPO_fast cycle, if the cycles are configured: D445-2 DP/PN, D455-2 DP/PN (as of version V4.2) and D435-2 DP/PN (as of version V4.3).

3 IPO or IPO_2 adjustable, see “Setting system cycle clocks" section in the Basic Functions Function Manual.

[4] Call the ExecutionFaultTask.

[5] Call the PeripheralFaultTask.

Direct access and process image of cyclic tasks

Property

Direct access to inputs and outputs and access to the process image of the cyclic task always take place via I/O variables. The entire address range of the SIMOTION device (Page 5204) can be used.

A comparison of the most important properties, including in comparison to the fixed process image of the BackgroundTask (Page 5211) is contained in "Important properties of direct access and process image" (Page 5199).

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 5205).

It is particularly important that every address used in an I/O variable is available in the I/O and configured; each byte in the address range may be assigned to no more than one I/O variable (does not apply to access with data type BOOL).

A detailed status of I/O variables (Page 5209) can be read as of version V4.2 of the SIMOTION Kernel, for example, in order to check the availability of the I/O variables.

Direct access

Direct access is used to access the corresponding I/O address directly. Direct access is used primarily for sequential programming (in MotionTasks). The access to the current value of the inputs and outputs at a specific time is particularly important.

For direct access, you define an I/O variable (Page 5206) without assigning it a task.

Process image of the cyclic task

The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming). The consistency during the complete cycle of the task is particularly important.

For the process image of the cyclical task you define an I/O variable (Page 5206) and assign it a task.

Direct access to this I/O variable is still possible: Specify direct access with *_direct.var-name*.

Note

An access via the process image is more efficient than direct access.

Additional properties as of version V4.2 of the SIMOTION Kernel

As of version V4.2 of the SIMOTION Kernel, direct access to inputs/outputs and the process image of the cyclic tasks offers additional properties:

- As far as the process image of the cyclic tasks is concerned, a common memory area with the fixed process image of the BackgroundTask can be set (standard with newly created devices)
- As far as the process image of the cyclic tasks is concerned, I/O variables for inputs can be written to (i.e. they can be assigned values).
- A detailed status of I/O variables (Page 5209) can be read, for example, in order to check the availability of the I/O variables.

Memory area with the fixed process image of the BackgroundTask

- **As of version V4.2 of the SIMOTION Kernel**, selecting a "Common process image" setting on the device ensures the memory area for the fixed process image of the BackgroundTask is a subset of the memory area for the process image of the cyclic tasks.
- **Up to version V4.1 of the SIMOTION Kernel** or the "Separate process image" setting on the device (as of version V4.2 of the SIMOTION Kernel), the fixed process image of the BackgroundTask and the process image of the cyclic tasks occupy different memory areas.

Note

If (and only if) you are also using the fixed process image of the BackgroundTask, it is important to consider the effects of the "Common process image" or "Separate process image" settings on the fixed process image of the BackgroundTask (Page 5211).

Table 7-546 Effect of "Common process image" or "Separate process image" settings on the process image of the cyclic tasks

	Common process image	Separate process image
Availability	Only available as of version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard for newly created devices	Up to version V4.1 of the SIMOTION Kernel applies: • System characteristic, not configurable. The following applies as of version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard with device upgrades
Download of new or changed I/O variables	Only possible in STOP mode.	Only possible in STOP mode.
Byte order when forming the process image and during access	Depends on connected I/O	
Effects on the fixed process image of the BackgroundTask	See the relevant table in "Access to the fixed process image of the BackgroundTask" (Page 5212).	
Further information	Common process image (Page 5213)	Separate process image (Page 5215)

Address range of the SIMOTION devices

The address range of the SIMOTION devices is specified in the following table according to the version of the SIMOTION Kernel concerned. The complete address range can be used for direct access and process image of the cyclical tasks.

Table 7-547 Address range of the SIMOTION devices according to the version of the SIMOTION Kernel

SIMOTION device	Address range for SIMOTION Kernel version					
	V3.2	V4.0	V4.1	4.2	V4.3	As of V4.4
C230-2	0 .. 2047 [3]	0 .. 2047 [3]	0 .. 2047 [3]	–	–	–
C240	–	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]
C240 PN [1]	–	–	0 .. 4095 [4]	0 .. 4095 [4]	0 .. 4095 [4]	0 .. 4095 [4]
D410 DP	–	–	0 .. 8191 [3]	0 .. 8191 [3]	0 .. 8191 [3]	–
D410 PN	–	–	0 .. 8191 [4]	0 .. 8191 [4]	0 .. 8191 [4]	–
D410-2	–	–	–	–	0 .. 8191 [3 4]	0 .. 8191 [3 4]
D425	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D425-2	–	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D435	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D435-2	–	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D445	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–	–
D445-1 [1]	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D445-2	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D455-2	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]
P320 [2]	–	–	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	–

SIMOTION device	Address range for SIMOTION Kernel version					
	V3.2	V4.0	V4.1	4.2	V4.3	As of V4.4
P320-4	–	–	–	–	–	0 .. 4095 [3]
P350	0 .. 2047 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	–

[1] Available as of V4.1 SP2 HF4

[2] Available as of V4.1 SP5

[3] For distributed I/O (over PROFIBUS DP), the transmission volume is restricted to 1024 bytes per PROFIBUS DP line.

[4] For distributed I/O (over PROFINET), the transmission volume is restricted to 4,096 bytes per PROFINET segment.

Rules for I/O addresses for direct access and the process image of the cyclical tasks

Note

You must observe the following rules for the I/O variable addresses for direct access and the process image of the cyclic task (Page 5202). Compliance with the rules is checked during the consistency check of the SIMOTION project (e.g. during the download).

1. Addresses used for I/O variables must be present in the I/O and configured appropriately in the HW Config.
2. I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously.
   The following I/O addresses are not permitted:
   - Inputs: PIW63, PID61, PID62, PID63
   - Outputs: PQW63, PQD61, PQD62, PQD63
3. All addresses of an I/O variable comprising more than one byte (e.g. WORD, ARRAY data type) must be within a continuous address range configured in HW Config, e.g. within the address range (slot or subslot) of *one* I/O module.
4. An I/O address (input or output) can only be used by a single I/O variable of data type BYTE, WORD or DWORD or an array of these data types. Access to individual bits with I/O variables of data type BOOL is possible.
5. If several processes (e.g. I/O variable, technology object, PROFIdrive telegram) access an I/O address, the following applies:
   - Only a single process can have write access to an I/O address of an output (BYTE, WORD or DWORD data type).
     Read access to an output with an I/O variable that is used by another process for write access, is possible.
   - All processes must use the same data type (BYTE, WORD, DWORD or ARRAY of these data types) to access this I/O address. Access to individual bits is possible irrespective of this. Please be aware of the following, for example, if you wish to use an I/O variable to read the PROFIdrive telegram transferred to or from the drive: The length of the I/O variable must match the length of the telegram.
   - Write access to different bits of an address is possible from several processes; however, write access with the data types BYTE, WORD or DWORD is then not possible.

Note

These rules do not apply to accesses to the fixed process image of the BackgroundTask (Page 5211). These accesses are not taken into account during the consistency check of the project (e.g. during download).

Creating I/O variables for direct access or process image of cyclic tasks

Create I/O variables for direct access or a process image of the cyclic tasks in the address list of the detail view.

This is only possible in offline mode.

Here is a brief overview of the procedure:

1. Select the "Address list" tab in the detail view and choose the SIMOTION device
   or
   In the project navigator of SIMOTION SCOUT, double-click the "ADDRESS LIST" element in the SIMOTION device subtree.
2. Select the line before which you want to insert the I/O variable and, from the context menu, select **Insert new line**
   or
   Scroll to the end of the table of variables (empty line).
3. In the empty row of the table, enter or select the following:
   - Names of the **I/O variables**
   - **I/O address**
     Select the "IN" or "OUT" entries if you wish to assign symbols to the I/O variable (input or output). As of Version V4.2 of the SIMOTION Kernel the symbolic assignment must be activated, menu **Project > Use symbolic assignment**.
     Or enter a fixed address according to "Syntax for entering I/O addresses" (Page 5208).
   - Optional for outputs:
     Activate the **Read only** checkbox if you only want to have read access to the output. You can then read an output that is already being written by another process (e.g. output of an output cam, PROFIdrive telegram).
     A read-only output variable cannot be assigned to the process image of a cyclic task.
   - **Data type** of the variables in accordance with "Possible data types of the I/O variables" (Page 5209).

4. Optionally, you can also enter or select the following (not for data type BOOL):
   - **Array length** (array size).
   - **Process image** or direct access:
     Can only be assigned if the **Read only** checkbox is deactivated.
     For process image, select the cyclic task to which you want to assign the I/O variable. To select a task, it must have been activated in the execution system.
     For direct access, select the blank entry.
   - **Strategy** for behavior in the event of an error, see SIMOTION Basic Functions Function Manual.
   - **Display format** (if array, for each element), when you monitor the variable in the address list
   - **Substitute value** (if array, for each element).
5. Only if you have selected "IN" or "OUT" as the I/O address (symbolic assignment).
   - In the **Assignment** column, click the **[...]** button.
     A window opens displaying the possible assignment targets of the SIMOTION device and, if necessary, of SINAMICS Integrated. Only those assignment targets are displayed that match the data direction (input/output) and data type.
   - Select the assignment target.
     The **Assignment status** column indicates whether the assignment was successful or not.

   For details regarding symbolic assignment, refer to the SIMOTION Basic Functions Function Manual.

You can now access this variable using the address list or any program of the SIMOTION device.

Details on how to manage the address list can be found in the online help.

Note

Note the following for the process image for cyclic tasks:

- A variable can only be assigned to one task.
- Each byte of an input or output can only be assigned to one I/O variable.

In the case of data type BOOL, please note:

- The process image for cyclic tasks and a strategy for errors cannot be defined. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access or CPU stop).
- The individual bits of an I/O variable can also be accessed using the bit access functions.

Take care when making changes within the I/O variables (e.g. inserting and deleting I/O variables, changing names and addresses):

- In some cases the internal addressing of other I/O variables may change, making all I/O variables inconsistent.
- If this happens, all program sources that contain accesses to I/O variables must be recompiled.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and then use them in your program sources (e.g. ST sources, MCC sources, LAD/FBD sources).

Outputs can be read and written to, but inputs can only be read.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables" (Page 5221).

Syntax for entering I/O addresses

Syntax

For the input of the I/O address for the definition of an I/O variable for direct access or process image of cyclical tasks (Page 5202), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

Table 7-548 Syntax for the input of the I/O addresses for direct access or process image of the cyclic tasks

Data type	Syntax for		Permissible address range					
	Input	Output	Direct access		Process image		e.g. direct access D435 V4.1	
BOOL	PIn.x	PQn.x	n: x:	0 .. *MaxAddr* 0 .. 7		-[1]	n: x:	0 .. 16383 0 .. 7
BYTE	PIBn	PQBn	n:	0 .. *MaxAddr*	n:	0 .. *MaxAddr*	n:	0 .. 16383
WORD	PIWn	PQWn	n:	0 .. 62 64 .. *MaxAddr* - 1	n:	0 .. 62 64 .. *MaxAddr* - 1	n:	0 .. 62 64 .. 16382
DWORD	PIDn	PQDn	n:	0 .. 60 64 .. *MaxAddr* - 3	n:	0 .. 60 64 .. *MaxAddr* - 3	n:	0 .. 60 64 .. 16380
n = logical address x = bit number								
MaxAddr =	Maximum I/O address of the SIMOTION device depending on the SIMOTION Kernel version, see Address range of the SIMOTION devices (Page 5204).							
[1] For data type BOOL, it is not possible to define the process image for cyclic tasks. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access).								

Examples

Input at logic address 1022, WORD data type: **PIW1022**.

Output at logical address 63, bit 3, BOOL data type: **PQ63.3**.

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 5205).

Possible data types of I/O variables

The following data types can be assigned to the I/O variables for direct access and process image of the cyclical tasks (Page 5202). The width of the data type must correspond to the data type width of the I/O address.

If you assign a numeric data type to the I/O variables, you can access these variables as integer.

Table 7-549 Possible data types of the I/O variables for direct access and the process image of the cyclical tasks

Data type of I/O address	Possible data types for I/O variables
BOOL (PIn.x, PQn.x)	BOOL
BYTE (PIBn, PQBn)	BYTE, SINT, USINT
WORD (PIWn, PQWn)	WORD, INT, UINT
DWORD (PIDn, PQDn)	DWORD, DINT, UDINT

For details of the data type of the I/O address, see also "Syntax for entering I/O addresses" (Page 5208).

Detailed status of the I/O variables (as of Kernel V4.2)

As of version V4.2 of the SIMOTION Kernel, the status of an I/O variable can be queried using *_quality.var-name*, for example, in order to check the availability of the I/O variables. It is supplied as an OR logic operation of the following status values in the DWORD data type and can be assigned to an appropriate variable, for example. The value 16#0000_0000 indicates the connected I/O are operating without error.

The same value is supplied for every I/O variable within an address range (slot or subslot) configured in HW Config.

Table 7-550 Meanings of status values of I/O variables

Value (DWORD)	Bit x = 1	Meaning
16#0000_0000	-	No error occurred.
16#0000_0001	0	**Maintenance required** The connected module signals that it requires maintenance. The component needs to be checked within a foreseeable period (e.g. the printer cartridge must be changed within a period of several days).
16#0000_0002	1	**Maintenance demanded** The connected module demands maintenance. The component needs to be checked soon (e.g. the printer cartridge must be changed immediately).
16#0000_0004	2	**Warning pending** (drive warning, TM17 warning, etc.) The connected module has signaled a warning. This has been entered in the diagnostics buffer. The precise cause can be determined from the documentation for the relevant module.
16#0000_0008	3	**Fault pending** (diagnostic interrupt, drive fault, TM17 fault, etc.) The connected module has signaled an error. This has been entered in the diagnostics buffer. The precise cause can be determined from the documentation for the relevant module.

Value (DWORD)	Bit x = 1	Meaning
16#0000_0010	4	**This parameter assignment does not match the parameter assignment being compared.** A difference was detected when this parameter assignment was compared with the parameter assignment of the connected module. As such, the required functionality cannot be guaranteed. Remedy: Save the project and compile changes, reload both application and counterpart.
16#0000_0020	5	**Application and counterpart are not isochronous** (error involving the dynamic life-sign). Certain telegrams (axis, synchronous operation, output cam, measuring input telegrams) are synchronized by exchanging cyclic life-signs. Errors are detected when the cyclic life-sign is checked. This invalidates the data in the telegram. Remedy: Await synchronization, check the parameter assignment (e.g. does the master application cycle set on the device in HW Config match the position control cycle clock), save the project and compile changes, reload both application and counterpart.
16#0000_0040	6	**I/O cannot be used synchronously in all cycles.** A fast application cycle (Servo_fast) and a slow application cycle (Servo) are running asynchronously in relation to one another. The I/O can only be used synchronously in the cycles associated with the bus cycle. Access from other cycles is asynchronous and inconsistent. Remedy: Call the _synchronizeDpInterfaces() function.
16#0000_0080	7	**I/O cannot be used synchronously** The SIMOTION control is the sync slave on a bus. The bus connection is running synchronously in relation to the sync master, but is not yet running synchronously in relation to the application cycles of the SIMOTION control. Access to the I/O is asynchronous and inconsistent. Remedy: Call the _synchronizeDpInterfaces() function.
16#0000_0100	8	**Bus connection (sync slave) is not isochronous in relation to the sync master.** The SIMOTION control is the sync slave on a bus and has not yet synchronized its bus connection with the sync master. The isochronous I/O on this bus cannot be used yet. Remedy: Switch on/connect the sync master.
16#0000_0200	9	**DP station is deactivated.** The partner module has been deactivated. Remedy: Activate the partner module (_activateDpSlave() function).
16#0000_0400	10	**The partner of the inputs (e.g. I-device, I-slave) is in STOP.** The connected module is in STOP mode and not sending any new data as a result. Remedy: Switch the connected module to RUN.
16#0000_0800	11	**PROFINET: Failure detected by submodule** (e.g. channel error) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0000_1000	12	**PROFINET: Failure detected by module** (e.g. submodule failed, removed, etc.) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0000_2000	13	**PROFINET: Failure detected by device** (e.g. device in STOP, module removed, etc.) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config

Value (DWORD)	Bit x = 1	Meaning
16#0000_4000	14	**PROFINET: Failure detected by controller** (e.g. not connected, etc.) There is no connection to a partner on PROFINET. Possible cause: Partner is switched off, cable pulled out, incorrect parameter assignment for connection Troubleshooting: Best to use the PROFINET topology editor in HW Config.
16#0000_8000	15	**Slot/subslot is not connected** (disconnection alarm). The connection to the connected device is OK. The error must be searched for in the connected device (e.g. module/submodule removed). Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0001_0000	16	**Device is not connected** (station failure). There is no connection to a partner. Possible cause: Partner is switched off, cable pulled out.
16#0002_0000	17	**Substitute value behavior during access** There is no connection to the counterpart (sum signal from bits 9 to 16), i.e. there is no valid input data or the output data is not reaching the terminal. The substitute value behavior set (substitute value, last value) takes effect during direct access to this address or during process image updates.
16#4000_0000	30	**Diagnostics address only** No cyclic I/O data is configured for this address. It is possible, however, to query submodule diagnostic information.
16#8000_0000	31	**Address gap** There is no hardware configured for this logical address.

Access to fixed process image of the BackgroundTask

The fixed process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device on which a subset of the I/O address space of the SIMOTION device is mirrored. Preferably, it should be used for programming the BackgroundTask (cyclic programming) as it is consistent throughout the entire cycle.

The size of the fixed process image of the BackgroundTask for all SIMOTION devices is 64 bytes (address range 0 .. 63).

Note

The fixed process image of the BackgroundTask can be used to access addresses that are not available in the I/O or not configured in HW Config. These are treated like normal memory addresses.

Memory area

- **As of Version V4.2 of the SIMOTION Kernel**, selecting a "Common process image" setting on the device ensures the memory area for the fixed process image of the BackgroundTask is a subset of the memory area for the process image of the cyclic tasks.
  I/O addresses can be read and written to using both the fixed process image of the BackgroundTask and the process image of the cyclic tasks.
- **With Version V4.1 and lower of the SIMOTION Kernel** or the "Separate process image" setting on the device (as of Version V4.2 of the SIMOTION Kernel), the fixed process image of the BackgroundTask and the process image of the cyclic tasks occupy different memory areas. I/O addresses accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask. They are treated like normal memory addresses.

Table 7-551 Effect of "Common process image" or "Separate process image" settings on the fixed process image of the BackgroundTask

	Common process image	Separate process image
Availability	Only available as of Version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard for newly created devices	Version V4.1 and lower of the SIMOTION Kernel applies: • System characteristic, not configurable The following applies as of Version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard with device upgrades
Memory area	Subset of the memory area for the process image of the cyclic tasks	Separate memory area for the process image of the cyclic tasks
Using I/O addresses accessed using the process image of the cyclic tasks	Possible. Updates use the configured cyclic tasks.	Not supported. The addresses are treated like normal memory addresses.
Byte order when forming the process image	As supplied by the I/O	Always Big Endian
Byte order when accessing the process image	Always Big Endian	Always Big Endian
Access to I/O operating in the Little Endian byte order	Same result as during direct access or for the process image of cyclic tasks (apart from WORD or DWORD data types).	Results differ depending on the I/O variables created for direct access.
Effects on the process image of the cyclic tasks	See the relevant table in "Direct access and process image of the cyclic tasks (Page 5204)".	
Further information	Common process image (Page 5213)	Separate process image (Page 5215)

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

A comparison of the most important properties in comparison to the direct access and process image of the cyclic tasks (Page 5202) is contained in "Important properties of direct access and process image" (Page 5199).

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 5205) do **not** apply. Access to the fixed process image of the BackgroundTask is not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

You can access the fixed process image of the BackgroundTask by means of:

- Using an absolute PI access (Page 5217): The absolute PI access identifier contains the address of the input/output and the data type.
- Using a symbolic PI access (Page 5219): You declare a variable that references the relevant absolute PI access:
  - A unit variable
  - A static local variable in a program.
- Using an I/O variable (Page 5221): In the symbol browser, you define a valid I/O variable for the entire device that references the corresponding absolute PI access.

Common process image (as of Kernel V4.2)

As of Version V4.2 of the SIMOTION Kernel, the "Common process image" setting can be selected on the SIMOTION device. This means addresses 0 .. 63 of the process image of the cyclic tasks and the fixed process image of the BackgroundTask occupy the same memory area.

This is the default for SIMOTION devices newly created in the project as of Version V4.2.

Property of the common process image

1. The memory area for the fixed process image of the BackgroundTask (Page 5211) is a subset of the memory area for the process image of the cyclic tasks (Page 5202).
2. This means I/O addresses already accessed using the process image of the cyclic tasks may also continue to be used for the fixed process image of the BackgroundTask. Updates, however, use the configured cyclic tasks.
3. The following applies when forming the fixed process image of the BackgroundTask:
   The byte order is the same as supplied by the I/O:
   - Big Endian, e.g. for I/O via PROFIBUS DP, PROFINET, P-Bus, DRIVE-CLiQ
   - Little Endian, e.g. for onboard I/O of C240, C240 PN SIMOTION devices

   Any I/O variable created for the relevant addresses for the purpose of direct access or the process image of the cyclic tasks has no effect on the byte order.

4. Access to the fixed process image of the BackgroundTask always takes place using the Big Endian byte order.
5. These last two properties (nos. 3 and 4) affect access to inputs and outputs operating with the Little Endian byte order (e.g. onboard I/O of C240, C240 PN SIMOTION devices).
   If the fixed process image of the BackgroundTask is used for access, this leads to the following behavior, regardless of whether I/O variables have been created for the relevant addresses for the purpose of direct access or the process image of the cyclic tasks:
   - Access to individual bytes always supplies the same result via an I/O variable or the fixed process image of the BackgroundTask.
   - With the fixed process image of the BackgroundTask, bytes only change places if data type WORD is used for access.

   Please also refer to the example below.

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

Example for common process image: Access to I/O operating with the Little Endian byte order

The digital inputs of the C240 SIMOTION device operate with the Little Endian byte order and occupy addresses 66 (bits 0 ..7) and 67 (bits 0.. 3) by default. The start address is changed to 60 in HW Config to ensure it is in the range occupied by the fixed process image of the BackgroundTask. Addresses 60 and 61 are now accessed using various I/O variables and the process image of the BackgroundTask.

The following three scenarios are considered, which differ in terms of whether and which I/O variables are created for direct access or the process image of the cyclic tasks:

1. Scenario A:
   No I/O variables are created for addresses 60 and 61.
2. Scenario B:
   Two I/O variables with data type BYTE are created for addresses 60 and 61: io_byte_60 (PIB60) and io_byte_61 (PIB61).
3. Scenario C:
   For adresss 60, **one I/O-Variable** with data type WORD is created; this also covers address 61: io_word_60 (PIW60).

Two additional I/O variables are also created in each of the three scenarios, making it possible to access bit 3: io_bit_60_3 (PI60.3) and io_bit_61_3 (PI61.3).

The table below lists which values are generated with the following access types:

- Direct access or access to the process image of the cyclic tasks:
  - Access to individual bytes or the word using the relevant I/O variables
  - Access to each individual byte using the _getInOutByte function (direct access only)
  - Access to the respective bit 3 using the relevant I/O variables
- Access to the fixed process image of the BackgroundTask:
  - Access to individual bytes using an absolute name
  - Access to the word using an absolute name
  - Access to the respective bit 3 using an absolute name

Table 7-552 "Common process image" setting (as of Kernel V4.2): Different types of access to the process images of an input operating with the Little Endian byte order

	Access using	**Scenario A** [1]	**Scenario B** [1]	**Scenario C** [1]
Direct access or access to the process image of the cyclic tasks	io_byte_60 (PIB60)	-	16#08	-
	io_byte_61 (PIB61)	-	16#00	-
	io_word_60 (PIW60)	-	-	16#0008
	_getInOutByte (IN, 60)	16#08	16#08	16#08
	_getInOutByte (IN, 61)	16#00	16#00	16#00
	io_bit_60_3 (PI60.3)	TRUE	TRUE	TRUE
	io_bit_61_3 (PI61.3)	FALSE	FALSE	FALSE
Access to the fixed process image of the BackgroundTask	%IB60	16#08	16#08	16#08
	%IB61	16#00	16#00	16#00
	%IW60	**16#0800** [2]	**16#0800** [2]	**16#0800** [2]
	%I60.3	TRUE	TRUE	TRUE
	%I61.3	FALSE	FALSE	FALSE

[1] Scenarios A, B, or C determine whether and which I/O variables are created for direct access or the process image of the cyclic tasks; see the explanation provided in the body of the document.

[2] The two bytes in the word change places, as a value saved in the Little Endian byte order is being read using Big Endian.

Separate process image (up to Kernel V4.1)

With Version V4.1 and below of the SIMOTION Kernel, the process image of the cyclic task and the fixed process image of the BackgroundTask are stored in different memory areas (separate process image).

As of Version V4.2 of the SIMOTION Kernel, the "Separate process image" setting can be selected on the SIMOTION device. This setting ensures there is compatibility with earlier Kernel versions.

It is the default for SIMOTION devices upgraded to Version V4.2 or higher.

Property of the separate process image

1. The fixed process image of the BackgroundTask (Page 5211) and the process image of the cyclic tasks (Page 5202) are stored in different memory areas.
2. This means I/O addresses that are already accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask. They are treated like normal memory addresses.
3. I/O variables for direct access influence the fixed process image of the BackgroundTask:
   – The fixed process image of the BackgroundTask is always formed for the relevant addresses in the Big Endian byte order.
4. Access to the fixed process image of the BackgroundTask always takes place using the Big Endian byte order.
5. These last two properties (nos. 3 and 4) affect access to inputs and outputs operating with the Little Endian byte order (e.g. onboard I/O of C230-2, C240, C240 PN SIMOTION devices). If an I/O variable is created for the relevant addresses for the purpose of direct access using data type WORD and access takes place using the fixed process image of the BackgroundTask, this leads to the following behavior:
   – Access with the data type WORD supplies the same result via the I/O variable and the fixed process image of the BackgroundTask.
   – Access to individual bytes using the _getInOutByte function (see SIMOTION Basic Functions Function Manual) supplies these in the Little Endian order.
   – Access to the individual bytes or bits with the fixed process image of the BackgroundTask supplies these in the Big Endian order.

   Please also refer to the example below.

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

Example for separate process image: Access to I/O operating with the Little Endian byte order

The digital inputs of the C240 SIMOTION device operate with the Little Endian byte order and occupy addresses 66 (bits 0 ..7) and 67 (bits 0.. 3) by default. The start address is changed to 60 in HW Config to ensure it is in the range occupied by the fixed process image of the BackgroundTask. Addresses 60 and 61 are now accessed using various I/O variables and the process image of the BackgroundTask.

The following three scenarios are considered, which differ in terms of whether and which I/O variables are created for direct access:

1. Scenario A:
   No I/O variables are created for addresses 60 and 61.
2. Scenario B:
   Two I/O variables with data type BYTE are created for addresses 60 and 61: io_byte_60 (PIB60) and io_byte_61 (PIB61).
3. Scenario C:
   For adresss 60, **one I/O-Variable** with data type WORD is created; this also covers address 61: io_word_60 (PIW60).

Two additional I/O variables are also created in each of the three scenarios, making it possible to access bit 3: io_bit_60_3 (PI60.3) and io_bit_61_3 (PI61.3).

The table below lists which values are generated with the following access types:

- Direct access:
  - Access to individual bytes or the word using the relevant I/O variables
  - Access to each individual byte using the _getInOutByte function
  - Access to the respective bit 3 using the relevant I/O variables
- Access to the fixed process image of the BackgroundTask:
  - Access to individual bytes using an absolute name
  - Access to the word using an absolute name
  - Access to the respective bit 3 using an absolute name

Table 7-553 "Separate process image" setting or Kernel up to Version V4.1: Different types of access to the process images of an input operating with the Little Endian byte order

	Access using	**Scenario A** [1]	**Scenario B** [1]	**Scenario C** [1]
Direct access	io_byte_60 (PIB60)	-	16#08	-
	io_byte_61 (PIB61)	-	16#00	-
	io_word_60 (PIW60)	-	-	16#0008
	_getInOutByte (IN, 60)	16#08	16#08	16#08
	_getInOutByte (IN, 61)	16#00	16#00	16#00
	io_bit_60_3 (PI60.3)	TRUE	TRUE	TRUE
	io_bit_61_3 (PI61.3)	FALSE	FALSE	FALSE
Access to the fixed process image of the BackgroundTask	%IB60	16#08	16#08	**16#00** [3]
	%IB61	16#00	16#00	**16#08** [3]
	%IW60	**16#0800** [2]	**16#0800** [2]	16#0008
	%I60.3	TRUE	TRUE	**FALSE** [3]
	%I61.3	FALSE	FALSE	**TRUE** [3]

[1] Scenarios A, B, or C determine whether and which I/O variables are created for direct access; see the explanation provided in the body of the document.

[2] The two bytes in the word change places, as a value saved in the Little Endian order is being read using Big Endian.

[3] The two adjacent bytes change places, as the relevant word is saved in the Big Endian order.

Absolute access to the fixed process image of the BackgroundTask (absolute PI access)

You make absolute access to the fixed process image of the BackgroundTask (Page 5211) by directly using the identifier for the address (with implicit data type). The syntax of the identifier (Page 5218) is described in the following section.

You can use the identifier for the absolute PI access in the same manner as a normal variable.

Note

Outputs can be read and written to, but inputs can only be read.

Syntax for the identifier for an absolute process image access

For the absolute access to the fixed process image of the BackgroundTask (Page 5217), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

You also use these identifiers:

- For the declaration of a symbolic access to the fixed process image of the BackgroundTask (Page 5219).
- For the creation of an I/O variables for accessing the fixed process image of the BackgroundTask (Page 5221).

Table 7-554 Syntax for the identifier for an absolute process image access

Data type	Syntax for		Permissible address range	
	Input	Output		
BOOL	%In.x or %IXn.x [1]	%Qn.x or %QXn.x[1]	n: x:	0 .. 63 [2] 0 .. 7
BYTE	%IBn	%QBn	n:	0 .. 63 [2]
WORD	%IWn	%QWn	n:	0 .. 63 [2]
DWORD	%IDn	%QDn	n:	0 .. 63 [2]
n = logical address x = bit number				
[1] The syntax %IXn.x or %QXn.x is not permitted when defining I/O variables.				
[2] For a separate process image (Page 5215), the following applies: No addresses that are used in the process image of the cyclic tasks. See note below.				

Examples

Input at logic address 62, WORD data type: **%IW62**.

Output at logical address 63, bit 3, BOOL data type: **%Q63.3**.

Note

Up to Version V4.1 of the SIMOTION Kernel or the "Separate process image" (Page 5215) setting on the device (as of Version V4.2 of the SIMOTION Kernel), the following applies:

- Addresses accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask.

This restriction no longer applies as of Version V4.2 of the SIMOTION Kernel or with the "Common process image" (Page 5213) setting on the device.

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 5205) do **not** apply. Access to the fixed process image of the BackgroundTask is not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

Defining symbolic access to the fixed process image of the BackgroundTask

You create symbolic access to the fixed process image of the BackgroundTask in the declaration tables of the source file, MCC chart, or LAD/FBD program (only in the case of programs). The scope of the symbolic process image access is dependent on the location of the declaration:

- In the interface section of the declaration table of the source file (INTERFACE):
  Symbolic process image access behaves like a unit variable; it is valid for the entire source file; all MCC charts or LAD/FBD programs (programs, function blocks, and functions) within the source file can access the process image.
  In addition, these variables are available on HMI devices and, once connected, in other source files (or other units), as well.
  The total size of all unit variables in the interface section is limited to 64 Kbytes.
- In the implementation section of the declaration table of the source file (IMPLEMENTATION):
  Symbolic process image access behaves like a unit variable; it is only valid in the source file; all MCC charts or LAD/FBD programs (programs, function blocks, and functions) within the source file can access it.
- In the declaration table for the MCC chart or LAD/FBD program (only in the case of programs):
  Symbolic process image access behaves like a local variable; it can only be accessed within the MCC chart or LAD/FBD program in which it is declared.
  No symbolic process image access can be declared in functions or function blocks.

Proceed as follows; the source file or the MCC chart or LAD/FBD program (in the case of programs only) with the declaration table is opened:

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the I/O Symbols tab.
3. Enter:
   - Name of symbol (variable name)
   - For Absolute ID, the identifier of the absolute process image access (Page 5218).
   - Data type of symbol (Page 5220) (this must agree with the length of the process image access).

Possible data types for symbolic PI access

In the following cases, a data type that differs from that of the absolute PI access can be assigned to the fixed process image of the BackgroundTask (Page 5211). The data type width must correspond to the data type width of the absolute PI access.

- For the declaration of a symbolic PI access (Page 5219).
- For the creation of an I/O variable (Page 5221).

If you assign a numeric data type to the symbolic PI access or to the I/O variables, you can access these variables as integer.

Table 7-555 Possible data types for symbolic PI access

Data type of the absolute PI access	Possible data types of the symbolic PI access
BOOL (%In.x, %IXn.x, %Qn.x. %QXn.x)	BOOL
BYTE (%IBn, %QBn)	BYTE, SINT, USINT
WORD (%IWn, %QWn)	WORD, INT, UINT
DWORD (%IDn, %PQDn)	DWORD, DINT, UDINT

For the data type of the absolute PI access, see also "Syntax for the identifier for an absolute PI access (Page 5218)".

Example: Defining symbolic access to the fixed process image of the BackgroundTask

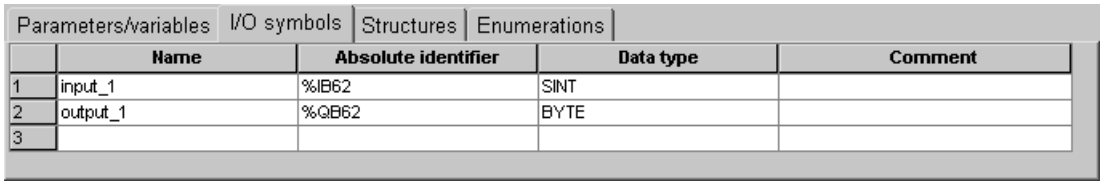

Figure 7-491 Example: Defining symbolic access to the fixed process image of the BackgroundTask

Creating an I/O variable for access to the fixed process image of the BackgroundTask

You create I/O variables for access to the fixed process image for the background task in the symbol browser in the detail view; you must be in offline mode to do this.

Here is a brief overview of the procedure:

1. Select the "Address list" tab in the detail view and choose the SIMOTION device
   or
   In the project navigator of SIMOTION SCOUT, double-click the "ADDRESS LIST" element in the SIMOTION device subtree.
2. Select the line before which you want to insert the I/O variable and, from the context menu, select Insert new line
   or
   Scroll to the end of the table of variables (empty line).
3. In the detail view, select the Symbol browser tab and scroll down to the end of the variable table (empty row).
4. In the empty row of the table, enter or select the following:
   - **Name** of variable.
   - Under **I/O address**, the absolute PI access according to the "Syntax for the identifier for an absolute PI access" (Page 5218)
     (exception: The syntax %IXn.x or %QXn.x is not permitted for data type BOOL).
   - **Data type** of the I/O variables according to the "Possible data types of the symbolic PI access" (Page 5220).
5. Select optionally the display format used to monitor the variable in the symbol browser.

You can now access this variable using the address list or any program of the SIMOTION device.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and use them in your program sources.

Note that you can read and write outputs but you can only read inputs.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables" (Page 5221).

Accessing I/O variables

You have created an I/O variable for:

- Direct access or process image of the cyclic tasks (Page 5202).
- Access to the fixed process image of the BackgroundTask (Page 5211).

You can use this I/O variable just like any other variable.

Note

Consistency is only ensured for elementary data types.

When using arrays, the user is responsible for ensuring data consistency.

Note

If you have declared unit variables or local variables of the same name (e.g. *var-name*), specify the I/O variable using *_device.var-name* (predefined name space, see the "Predefined name spaces" table in "Name spaces").

It is possible to directly access an I/O variable that you created as a process image of a cyclic task. Specify direct access with *_direct.var-name* or *_device._direct.var-name*.

If you want to deviate from the default behavior when errors occur during variable access, you can use the _getSafeValue and _setSafeValue functions (see *SIMOTION Basic Functions* Function Manual).

For Errors associated with access to I/O variables, see *SIMOTION Basic Functions* Function Manual.

7.3.4.17 Connections to other program source files or libraries

In the declaration table of a unit, you can define connections to:

- LAD/FBD units under the same SIMOTION device
- MCC units under the same SIMOTION device
- ST source files under the same SIMOTION device
- Libraries

This will then allow you to access the following in this unit:

- For connected program sources (Page 5223), the following items which are defined there
  - Functions
  - Function blocks
  - Classes and methods contained therein (only for ST source files)
  - Programs (optional)
  - Unit variables
  - User-defined data types (structures, enumerations)
  - Symbolic accesses to the fixed process image of the BackgroundTask
- For connected libraries (Page 5224), the following items which are defined there
  - Functions
  - Function blocks
  - Classes and methods contained therein (only for ST libraries)
  - Programs (optional)
  - User-defined data types (structures, enumerations)

Program sources and libraries must be compiled beforehand.

For information about the library concept, see also the SIMOTION ST Programming Manual.

Note

Libraries can be created in all programming languages (MCC, ST, or LAD/FBD).

Defining connections

Procedure for defining connections to other program sources (units)

Connections to other units (program sources) are defined in the declaration table of the source file. The mode of action of a connection is dependent on the section of the declaration table in which it is defined.

- In the interface section of the declaration table:
  The imported functions, variables, etc., will continue to be exported to other units and to HMI devices. This can lead to name conflicts.
  This setting is necessary, for example, if unit variables are declared in the interface section of the source file with a data type that is defined in the imported program source.
- In the implementation section of the declaration table:
  The imported functions, variables, etc. will no longer be exported.
  This setting is usually sufficient.

Proceed as follows; the source file (declaration table) is open (see Open existing program sources (Page 5104)):

1. In the declaration table, select the section for the desired mode of action.
2. Select the **Connections** tab.
3. For the connection type, select: **Program/Unit**
4. In the same line, select the name of the unit to be connected:
   Units (program sources) must be compiled beforehand.

Procedure for defining connections to libraries

Connections to libraries are defined in the declaration table of the source file.

Proceed as follows; the unit (declaration table) is open, see Open existing program sources (Page 5104):

1. In the interface section of the declaration table, select the **Connections** tab.
2. For the connection type, select: **Library**.
3. In the same line, select the name of the library to be connected.
   Libraries must be compiled beforehand.
4. Optionally, you can define a name space for libraries, see Using name space (Page 5224):
   To do this, enter a name under **Name space**.

Note

When programming the "Subprogram call" command (see Inserting and parameterizing subroutine calls (Page 5228)) with a library function or a library function block, the connection to the library is automatically entered into the declaration table of the program source.

Using the name space

You can optionally assign a namespace to every connected library. You define the designation of the namespace when connecting the library (see How to define connections to libraries (Page 5224)).

It is important to specify the namespace if the current LAD/FBD program / MCC chart or program source contains variables, data types, functions, or function blocks with the same name as the connected library. The namespace will then allow you specific access to the variables, data types, functions, or function blocks in the library. This can also resolve naming conflicts between connected libraries.

If you wish to use variables, data types, functions, or function blocks from the connected library in a command in the LAD/FBD program or MCC chart, insert the designation of the namespace in front of the variable name, etc., from the library and separate them with a period (for example, namespace.var_name, namespace.fc_name).

Predefined namespaces

Namespaces are predefined for device-specific and project-specific variables, direct accesses to I/O variables, and variables of TaskId and AlarmId in the following table: If necessary, write their designation before the variable name, separated by a period, e.g. *_device.var_name* or *_task.task_name*.

Table 7-556 Predefined namespaces

Namespace	Description
_alarm	For AlarmId: The _alarm.name variable contains the AlarmId of the message with the name identifier – see SIMOTION Basic Functions Function Manual.
_device	For device-specific variables (global device user variables, I/O variables, system variables, and system variables of the SIMOTION device)
_direct	For direct access to I/O variables – see Direct access and process image of the cyclic tasks (Page 5202). Local namespace for _device. Nesting as in _device._direct.*name* is permitted.
_project	For names of SIMOTION devices in the project; only used with technology objects on other devices. With unique project-wide names of technology objects, used also for these names and their system variables
_quality	As of Version V4.2 of the SIMOTION Kernel: For the detailed status of I/O variables (Page 5209). A value with data type DWORD is supplied. Local namespace for _device. Nesting as in _device._quality.*name* is permitted.
_task	For TaskID: The _task.name variable contains the TaskId of the task with the *name* identifier – see SIMOTION Basic Functions Function Manual.
_to	For technology objects configured on the SIMOTION device and their system variables and configuration data Not for system functions and data types of the technology objects. In this case, use the user-defined namespace for the imported technology package, if necessary.

Object-oriented namespaces

You can assign functions, function blocks or programs to an object-oriented namespace. Enter the identifier of the object-oriented namespace when creating (Page 5117) or in the Properties window (Page 5122) of the respective program organization unit (POU). The compiler option (Page 5111) "Permit object-oriented programming" must be activated.

A POU within the namespace can only be accessed from a POU outside the namespace when the identifier of the namespace is added as prefix to the identifier of the POU, separated by a dot.

In the project navigator, the POU is shown as subelement of the namespace below the program source.

7.3.4.18 Subroutine

Universal, reusable sections of a program can be created in the form of subroutines.

When a subroutine is called, the program branches from the current task into the subroutine. The commands in the subroutine are executed. The program then jumps back to the previously active task.

Subroutines can be called repeatedly, as required, by one or more LAD/FBD programs of the SIMOTION device.

Subroutine as a function (FC), function block (FB), or program

The creation type of a subroutine can be a function (FC), a function block (FB) or, as an option, a program ("program in program").

- Function
  A function (FC) is a subroutine without static data, that is, all local variables lose their value when the function has been executed. They are re-initialized when the function is next started.
  Data are transferred to the function using input or in/out parameters; the output of a function value (return value) is also possible.
- Function block
  A function block (FB) is a subroutine with static data, that is, local variables retain their value after the function block has been executed. Only variables that have been explicitly declared as temporary lose their value.
  An instance has to be defined before using an FB: Define a variable (VAR or VAR_GLOBAL) and enter the name of the FB as data type. The FB static data is saved in this instance. You can define several FB instances; each instance is independent from the others.
  The static data of an FB instance remain stored until the instance is next called; they are reinitialized when the variable type of the FB instance is initialized again (see Initialization of instances of function blocks (FB) (Page 5187)).
  Data are transferred to the FB using input parameters or in/out parameters; the data are returned from the FB using in/out or output parameters.
- Program ("program in program")
  You also have the option of calling a program within a different program or a function block. This requires the following compiler options to be activated (see Global compiler settings (Page 5111) and Local compiler settings (Page 5112)):
  - "Permit language extensions" for the program source of the calling program or function block and
  - "Only create program instance data once" for the program source of the called program. The static data of the called program is stored in the user memory of the program source (unit) of said called program.

  Most of the programming work involved in assigning the programs to the tasks can be performed by calling up programs within another program. In the execution system, only one associated calling program needs to be assigned to the tasks concerned.
  A program is called without parameters or return values.
  Further information on calling a program within a program can be found in the ST Programming and Operating Manual.

Note

The activated "Only create program instance data once" compiler option causes:

- The static variables of the programs (program instance data) to be stored in the user memory of the program source (unit) (see the SIMOTION ST Programming and Operating Manual). This also causes the initialization behavior to change (see the SIMOTION ST Programming and Operating Manual).
- All called programs with the same name to use the same program instance data.

Exchange of information between the subroutine and calling program

Function (FC) and function block (FB) as a subroutine

Information is exchanged between the subroutine and the calling program using transfer parameters or global variables (e.g. unit variables).

Transfer parameters can be input, input/output or output parameters. They are defined in the declaration table for the subroutine:

- Input parameters: As variable type VAR_INPUT
- In/out parameter: As variable type VAR_IN_OUT
- Output parameter (for FB only): As variable type VAR_OUTPUT

For functions, a function value can be returned; you specify the data type of the return value when you paste in (create) the function (see Paste in function (FC) or function block (FB) (Page 5228)).

You assign current values to the input and/or in/out parameters when you call the subroutine (FC or FB instance). You may only assign user-defined variables to the in/out parameters of an FB because the called FB accesses the assigned variables directly and can therefore change them.

The output parameters of an FB can be read-accessed as often as required in the calling program.

A function does not formally contain any output parameters, since the result of the function can in this case be assigned to the return value of the function.

See also the examples of functions (Page 5233) and function blocks (Page 5238).

Program as subroutine ("program in program")

A program is called without parameters or return values. This means that information can only be exchanged between the calling program and the called program (subroutine) using global variables (e.g. unit variables).

See also

Inserting a subroutine call into the LAD/FBD program and assigning parameters (Page 5228)

Inserting a function (FC) or function block (FB)

The creation dialog is similar to that of an LAD/FBD program:

1. LAD/FBD unit must already exist (see Managing LAD/FBD programs (Page 5117)).
2. In the project navigator, open the relevant LAD/FBD unit.
3. Double-click the entry **Insert LAD/FBD program**.
   The input screen form opens.
   - Enter the name of the LAD/FBD program (see Rules for identifiers (Page 5155)).
   - For the creation type, select **Function** or **Function block**.
   - With creation type Function only:
     Select the data type of the return value as the return type (<--> for no return value).
   - Check the **Exportable** option if the function or function block is to be used in other program source files (LAD/FBD, MCC or ST source files).
     When the checkbox is cleared, the LAD/FBD program can only be used in the associated LAD/FBD unit.
   - You can also enter an author, version, and a comment.
   - Confirm with **OK**.
4. Program the instructions in the function or function block.
   Assign an expression to the return value of a function (= function name) or to the output parameters of a function block.
5. Accept and compile the LAD/FBD unit. The subroutine you have created will then be displayed in the list.

Inserting a subroutine call into the LAD/FBD program and assigning parameters

In order to execute a call of a subprogram (function, function block, or program), the relevant subprogram must have been inserted in the network of an LAD/FBD program from the project navigator using drag-and-drop. When the subprogram inserted in the network is reached during a program run, the subprogram is called and the program branches from the current task into the subprogram.

You can use drag-and-drop to insert the following FCs, FBs, methods and programs in an LAD/FBD program and call them as a subprogram:

- Functions, function blocks, or programs of the same LAD/FBD unit or a different program source (e.g. MCC unit, ST source file).
- Methods within classes or function blocks of an ST source file.
- Library functions, library function blocks or library methods from a program library.

The subprogram call is parameterized, i.e. specifications are made as to which variables are to be transferred when the subprogram is called and returned once it has been executed, in the **Enter Call Parameter** parameter screen form.

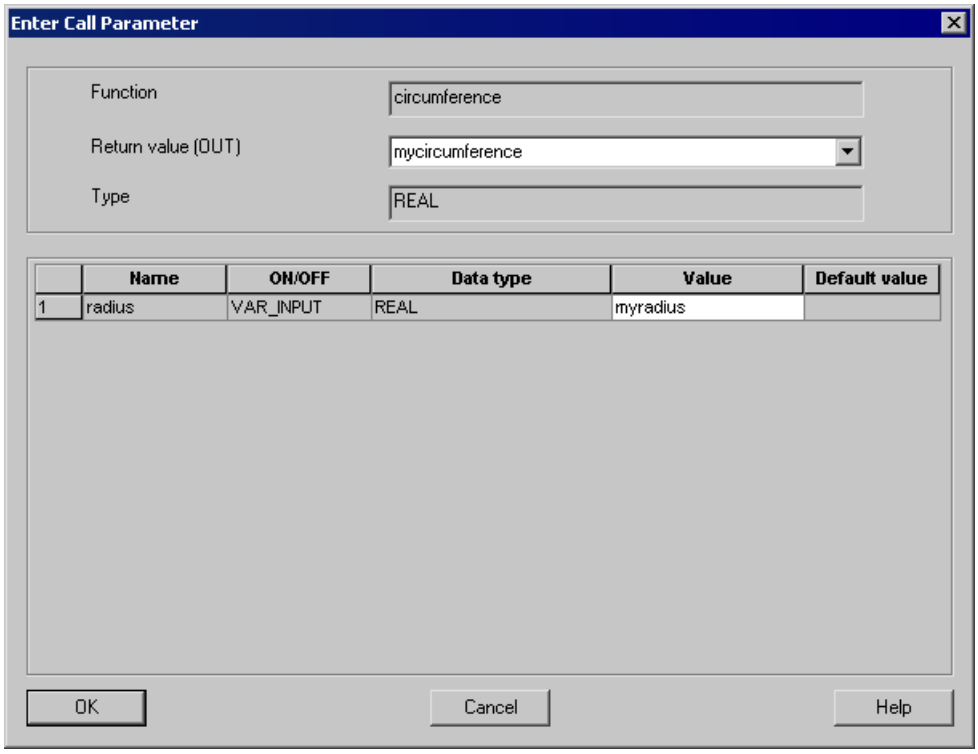

Figure 7-492 Parameterization of a function's subprogram call

Note

The LAD/FBD editor saves information on the origin of the subprogram when it is inserted in the network. This has no effect on the code generation.

This way you can subsequently move the source of a subprogram from the device to a connected library without changing the parameters. The LAD/FBD unit is still compiled correctly.

A check as to whether an identifier of a subprogram is hidden by an identifier with the same name in the LAD/FBD unit, is not performed. You can avoid name conflicts by using namespaces.

Note

Saving a project in a format older than Version V4.2 of SIMOTION SCOUT

Pay attention to the order of the LAD/FBD programs in an LAD/FBD unit. A subprogram (function, function block or program ("program in program")) must be defined before it is used. This is the case when the subprogram appears above the LAD/FBD program in which it is used in the project navigator. If necessary, reorder the LAD/FBD programs.

See also: Subprogram call of the function (FC) (Page 5235)

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC) or a function block (FB).

Overview of parameters for

You can set the following parameters when parameterizing the subroutine call:

Overview of Subroutine call parameters

Field/Button	Explanation/instructions
Subroutine type/ Subroutine	The type and name of the subroutine are displayed here: **Function** A function is a sub-program that has no memory beyond the call. In other words, the data is lost once the function has run and the output parameters and return value have been transferred. A function can also have a return value (function value) in addition to input, in/out and output parameters. **Function block** A function block is a sub-program which has a memory beyond the call. In other words, the values of the function block are retained after it has run. Variables of the data type for this function block must be declared. These variables are identified as instances of the function block; they include the memory of the function block beyond the calls. A function block only has input, in/out and output parameters but does not have a return value. The output parameters of the function block can be accessed even at a later time (after the function block has run) at the function block instance. **Program ("program in program")** You also have the option of calling a program within a different program or a function block. This requires the following compiler options to be activated, see Global compiler settings (Page 5111) and Local compiler settings (Page 5112): • "Permit language extensions" for the program source of the calling program or function block and • "Only create program instance data once" for the program source of the called program. The static data of the called program is stored in the user memory of the program source (unit) of said called program. The same program instance data is used every time the program is called. A program is called without parameters or return values.
Subprogram type/ subprogram (continued)	**Method** Methods are structuring tools for object-oriented programming. They largely correspond with functions, but are encapsulated in higher-level structuring tools (classes, function blocks). You can only generate methods and classes in the Structured Text (ST) programming language. Nevertheless classes and public methods (access identifier PUBLIC) can be used in LAB/FBD. A SIMOTION Kernel as of version V4.5 is mandatory for classes and their methods. Activating the following compiler options is recommended, see Global settings of the compiler (Page 5111) and Local settings of the compiler (Page 5112): • "Permit object-oriented programming" for the LAD/FBD source file of the LAD/FBD program being called. Variables of the data type for the higher-level structuring tools (class, function block) must be declared. These variables are identified as instances, and include the memory of the higher-level structuring tool beyond the calls. The methods themselves have no memory beyond the call. In other words, the data is lost once the method has run and the output parameters and return value have been transferred. A method can also have a return value (function value) in addition to input, in/out and output parameters.

Field/Button	Explanation/instructions
Instance	For subprogram type "function block" or “method": • In the case of a “function block” subprogram type: Here, enter the name of the function block instance. The instance contains the memory of the function block in the form of instance data. You define the instance as a variable whose data type is the name of the function block in one of the following ways: – In the declaration table of the LAD/FBD source as VAR_GLOBAL or – In the declaration table of the LAD/FBD program as VAR. • The following applies to “method” subprogram types: Enter the name of the class or function block instance to which the method belongs here. The instance contains the memory of the class or the function block in the form of instance data. You define the instance as a variable whose data type is the name of the class or of a class derived from this or the name of the function block in one of the following ways: – In the declaration table of the LAD/FBD source as VAR_GLOBAL or – In the declaration table of the LAD/FBD program as VAR.
Return value	For subprogram type "Function" or “Method": Here, you enter the variable in which the return value is to be stored. The type of variable must match the return value type.
Type	For subprogram type "Function" or “Method": The data type of the return value is displayed.
List of transfer parameters	
Name	The name of the transfer parameter is displayed here.
On / Off	The variable type of the transfer parameter is displayed here. **VAR_INPUT** Input parameters (for functions, function blocks and methods) **VAR_IN_OUT** In/out parameters (for functions, function blocks and methods) **VAR_OUTPUT** Output parameters (for functions, function blocks and methods)

Field/Button	Explanation/instructions
Data type	The data type of the transfer parameter is displayed here.
Value	Mandatory parameters are marked with "<???>" and optional parameters with "...". • The following applies to functions (FC) and methods: – Input parameters without a declared initial value and in/out parameters are mandatory parameters. – Input parameters with a declared initial value and output parameters are optional parameters. A subroutine call will only be functional if all the mandatory parameters are set. • The following applies to function blocks (FB): All parameters are optional. • The following applies to programs ("program in program"): No parameters present. Here, you can assign current variables or values to the transfer parameters: • Input parameter (variable type VAR_IN): Here, you enter a variable name or an expression. The assignment of system variables or I/O variables is permissible; type transformations are possible. • In/out parameter (variable type VAR_IN): Enter a variable name; the variable must be directly writable and readable. System variables of SIMOTION devices and technology objects are not permitted nor are I/O variables. The data type of the in/out parameter must correspond to that of the assigned variables; application of type transformation functions is not possible. • Output parameter (variable type VAR_OUTPUT): The assignment of an output parameter to a variable is optional. – The following applies to function blocks: You can also access an output parameter after executing the function block. – The following applies to functions and methods: The values for the output parameters are lost after executing the function or method unless they have been assigned in the parameter screen. When assigned in this parameter screen form: Enter a variable name. The data type of the output parameter must correspond to that of the assigned variables; the application of type transformation functions is not possible.

Example: Function (FC)

You want to create a subroutine with a circumference calculation for a circle. The calculation is performed in a function (FC). This is named **Circumference**.

The circle circumference calculation can thus be called as a subroutine by any task.

Formula for circumference calculation: Circumference = PI * 2 * radius

You define the Radius and PI variables in the declaration table of the function.

Creating and programming the function (FC)

1. In the project navigator, open the LAD/FBD unit in which you want to create the function.
2. Double-click the entry **Insert LAD/FBD program**.
   - Enter the name **Circumference**.
   - For creation type, select **Function**.
   - For return type (data type of return value), select **REAL**.
   - Click **OK** to confirm.
3. In the declaration table, define the **radius** input parameters, the **diameter** parameter, and the **PI** constant.

Parameters/variables | I/O symbols | Structures | Enumerations

	Name	Variable type	Data type	Array length	Initial value	Comment
1	radius	VAR_INPUT	REAL			
2	PI	VAR CONSTANT	REAL		3.14159	
3	diameter	VAR	REAL			
4						

Figure 7-493 Declaring variables (e.g. input parameters) in the LAD/FBD program

4. Click the **Insert Network** button on the LAD editor toolbar.
   A network is inserted into the **Circumference** function.
5. Drag the LAD/FBD element **MUL** from the command library and drop it into the network of the **circumference** function twice.
6. Program the circumference calculation for the return value by assigning the variables accordingly to the input/output parameters of the two **MUL** LAD/FBD elements.

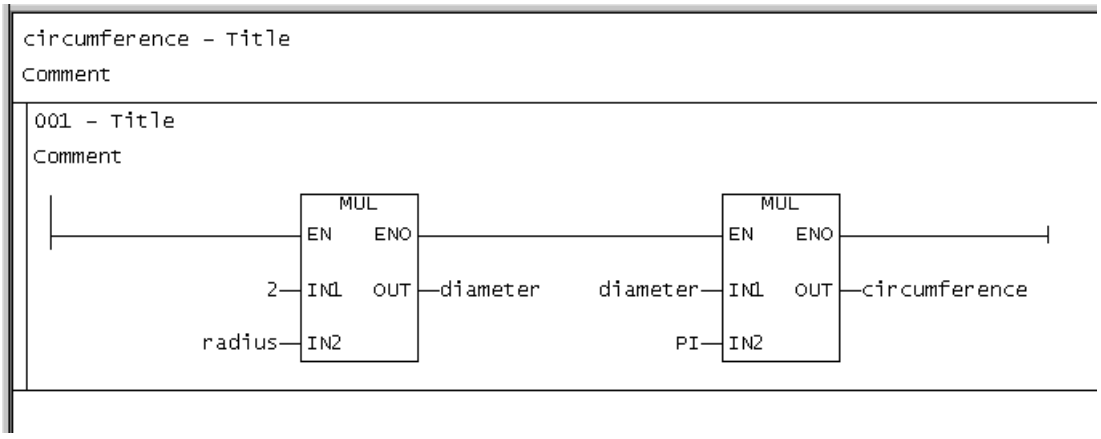

Figure 7-494 Programming the **Circumference** subroutine (e.g. assignment to a return value)

7. Accept and compile the LAD/FBD unit.

You have now finished programming the **Circumference** function.

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC), or a function block (FB).

Subroutine call of function (FC)

The function (FC) is called from a program in the example.

1. Create an LAD/FBD program as a program in the same LAD/FBD unit (see Inserting a new LAD/FBD program (Page 5117)):
   - Enter the name **Program_circumference**.
   - For creation type, select **Program**.
   - Click **OK** to confirm.
2. Declare the following in the LAD/FBD unit or the LAD/FBD program:
   - The **mycircum** variable.
     The return value of the "Circumference" function is assigned to this variable.
   - The **myradius** variable.
     This variable contains the radius and is assigned to the input parameter **Radius** of the **Circumference** function.

   Note that the validity range of the variables is dependent on the declaration location (see Define variables (Page 5171)).

	Name	Variable type	Data type	Array length	Initial value	Comment
1	mycircum	VAR	REAL			
2	myradius	VAR	REAL			
3						

① You can continue to use the myumfang (mycircum) variable in the program.

Figure 7-495 Declaring a variable in the LAD/FBD program

3. Click the **Insert Network** button on the LAD editor toolbar.
   A network is inserted into the **Program_circumference** program.
4. Drag the **Circumference** function from the project navigator and drop it into the network of the **Program_circumference** program.
5. Select the inserted function, **Circumference**, followed by the **Parameterize call** command from the context menu.

6. Assign parameters to the subroutine call in the **Enter Call Parameter** parameter screen form.

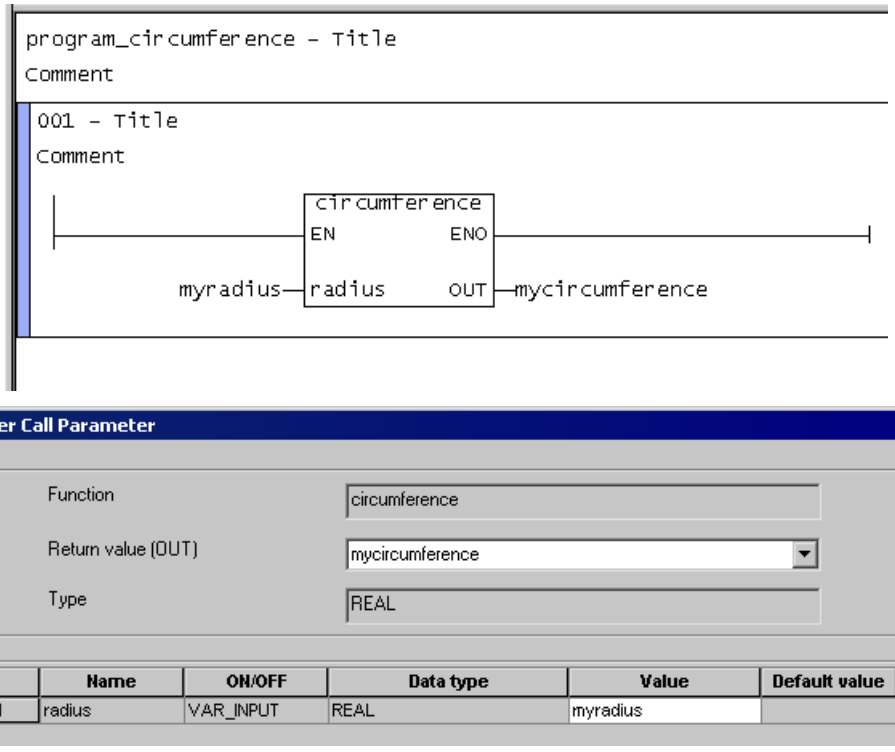

Figure 7-496 Opened parameter screen form for assigning parameters to the subroutine call

Note

Mandatory parameters are marked with "<???>" and optional parameters with "...". A subroutine call will only be functional if all the mandatory parameters are set.

7. Accept and compile the LAD/FBD unit.

You have now finished programming the subroutine call.

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC), or a function block (FB).

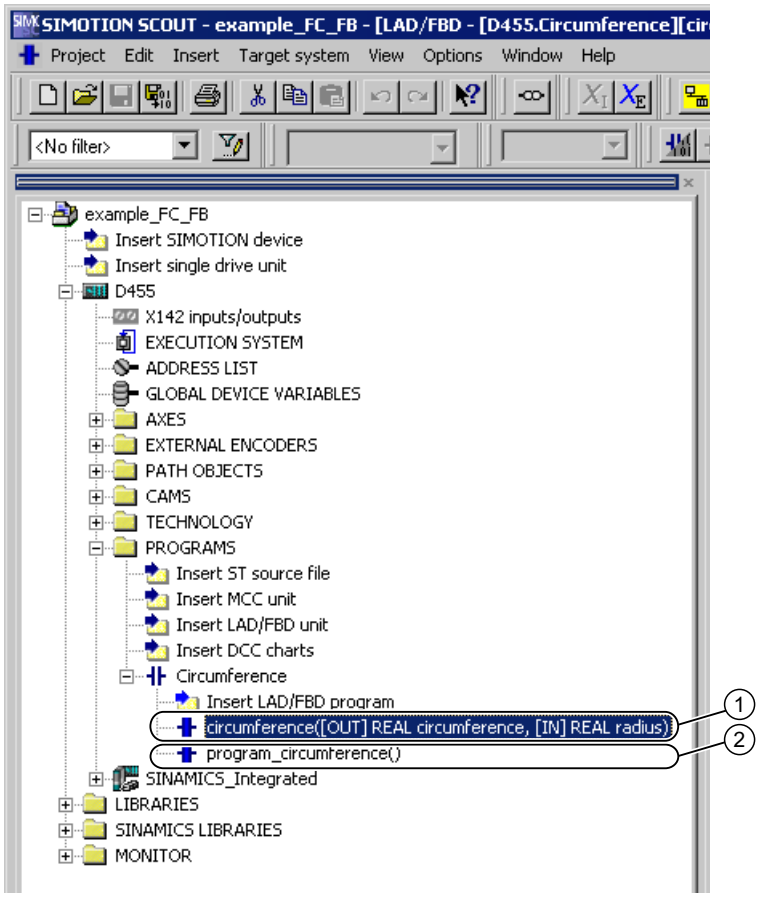
Note

Saving a project in a format older than Version V4.2 of SIMOTION SCOUT

Pay attention to the order of the LAD/FBD programs in the LAD/FBD unit (see figure below). A subroutine (function, function block, or program ("program in program")) must be defined before it is used. This is the case when the MCC chart of the subroutine appears in the project navigator above the chart in which it is used.

As far as the example described here is concerned, the LAD/FBD program with the function (FC) must appear in the project navigator above the LAD/FBD program containing the program with the subroutine call.

In other words, the **circumference** function must be positioned above the **program_circumference** program in the project navigator. If necessary, reorder the LAD/FBD programs by selecting the relevant LAD/FBD program in the project navigator, then selecting the **Down** or **Up** command in the context menu.



① **Circumference** function

② **Program_circumference** program, which contains the subroutine call of the **Circumference** function

Order of LAD/FBD programs

Opening the function (FC) directly from the subroutine call

You can open subprograms directly from their respective subprogram call by using the context menu:

- This works regardless of the programming language (ST, MCC, LAD/FBD) used to create the subprogram.
- The subprogram opens in a separate editor or an editor already opened for the subprogram is moved to the foreground.

A subprogram may be a:

- User-defined function (FC)
- User-defined function block (FB)
- User-defined program called as a subprogram ("program in program")
- Library function
- Library function block
- Library program called as a subprogram ("program in program")

Procedure

To open the FC directly from the subprogram call, proceed as follows:

1. In the LAD/FBD network, select the subprogram call used to call the FC.
2. Select the **Open called block** command in the context menu (Ctrl+Alt+O shortcut).

The FC opens in a separate editor or an editor already opened for the FC is moved to the foreground.

Note

If the called FC has not yet been created, the **Open called block** command appears inactive (grayed out) in the context menu.

Note

If the called FC is in a program source with know-how protection, the same steps that apply when opening the protected program source directly also apply here (see Know-how protection for LAD/FBD units (Page 5106)).

Example: Function block (FB)

You want to calculate a following error. The calculation is performed in a function block (FB) named **FollError**. The following error calculation can thus be called as a subroutine by any task.

Formula for following error calculation: Difference = Specified position – Actual position

Define the required input and output parameters Set position, Actual position, and Difference (with the other variables, if necessary) in the LAD/FBD program (function block) or LAD/FBD unit.

Creating and programming the function block (FB)

1. In the project navigator, open the LAD/FBD unit in which you want to create the function block.
2. Double-click the entry **Insert LAD/FBD program**.
   - Enter the name **FollError**.
   - For creation type, select **Function block**.
   - Confirm with **OK**.
3. In the declaration table, define the variables (e.g. input and output parameters).

	Name	Variable type	Data type	Array length	Initial value	Comment
1	Setpoint_position	VAR_INPUT	LREAL			
2	Actual_position	VAR_INPUT	LREAL			
3	Difference	VAR_OUTPUT	LREAL			
4						

Figure 7-497 Declaring variables (e.g. input and output parameters) in the LAD/FBD program

4. Click the **Insert network** button on the LAD editor toolbar.
   A network is inserted into the **FollError** function block.
5. Drag the LAD/FBD element **SUB** from the command library and drop it into the network of the **FollError** function block.
6. Program the following error calculation by assigning the variables accordingly to the input/output parameters of the **SUB** LAD/FBD element.

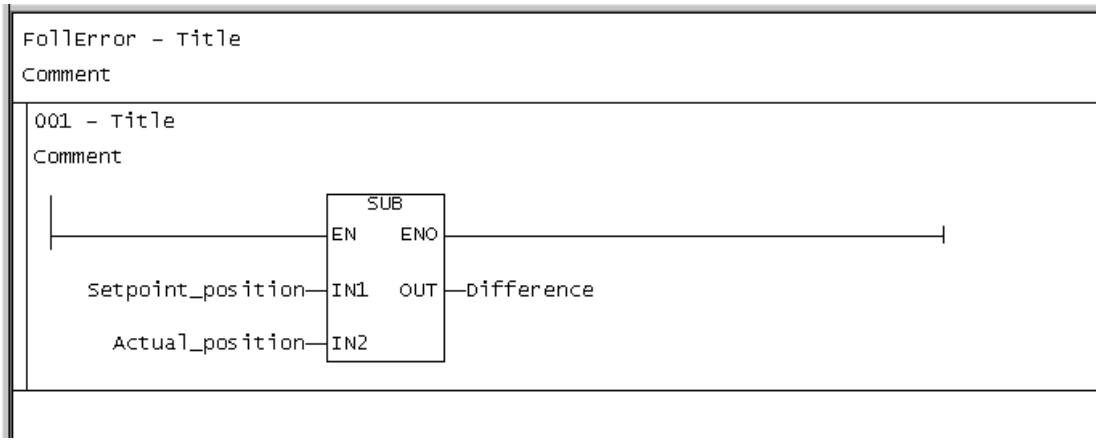


Figure 7-498 Programming the following error calculation

7. Accept and compile the LAD/FBD unit.

You have now finished programming the **FollError** function block.

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC), or a function block (FB).

Subroutine call of function block (FB)

In this example, the function block (FB) is called from a program.

1. Create an LAD/FBD program as a program (see Inserting a new LAD/FBD program (Page 5117)).
2. Create a function block instance.
   – In the LAD/FBD unit or LAD/FBD program, declare the instances of the function block along with the variables.

   Note that the validity range of the instance and variables is dependent on the declaration location (see Define variables (Page 5171)).
3. Call the function block:
   – Program the subroutine call.
4. After executing an instance of the function block, you can access the output parameters at any location in the calling program.
   – Program the **MOVE** command.
5. Accept and compile the program.

You have now finished programming the subroutine call.

Creating a function block instance

Before you can use a function block, you must define an instance. Each instance of an FB is independent of the others; once an instance has ended, its static variables remain stored.

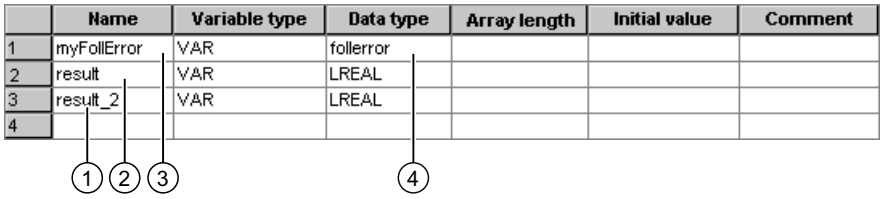
Instances of an FB are defined in the declaration tables of the LAD/FBD source or of the LAD/FBD program. The scope of the instance declaration is dependent on the location of the declaration:

- In the interface section of the declaration table of the LAD/FBD source:
  The instance behaves like a unit variable; it is valid for the entire LAD/FBD source; all LAD/FBD programs (programs, function blocks, and functions) within the LAD/FBD source can access the instance.
  The instance is also available:
  – On HMI devices
  – In other LAD/FBD source files (or other units) once connected, see “How to define connections to other units (program sources)” (Page 5223).

  The total size of all unit variables in the interface section is limited to 64 Kbytes.
- In the implementation section of the declaration table of the LAD/FBD source:
  The instance behaves like a unit variable which is only valid in the LAD/FBD source; all LAD/FBD programs (programs, function blocks, and functions) within the LAD/FBD source can access the instance.
- In the declaration table of the LAD/FBD program (for programs and function blocks only):
  The instance behaves like a local variable; it can only be accessed within the LAD/FBD program in which it is declared.

Proceed as follows (the LAD/FBD source or the LAD/FBD program with the declaration table is open, see "Opening an existing LAD/FBD source" (Page 5104) or "Opening an existing LAD/FBD program" (Page 5119):

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Parameters** tab.
3. Enter or select the following:
   - **Name** of instance (variable name – see Rules for identifiers (Page 5155))
   - **Variable type** VAR or VAR_GLOBAL, depending on the declaration location (in LAD/FBD program or LAD/FBD source respectively)
   - Designation of the function block as **data type**.
4. Declare the other variables.



① The output parameter Difference is assigned to the variable Result_2 during subsequent program runtime. You can use the Result_2 variable for other purposes in the program.

② The output parameter Difference is assigned to the variable Result in the subroutine call. You can use the Result variable for other purposes in the program.

③ Creating an instance

④ Select the required FB as the data type.

The created function blocks are offered as data types in the drop-down list box depending on the LAD/FBD editor settings (Page 5099):

- Only function blocks with the same program source or from connected program sources or libraries
- All function blocks defined in the project

Figure 7-499 Defining an instance of the function block and variables in the LAD/FBD program or the LAD/FBD unit

Programming the subroutine call of the function block

1. Drag the **FollError** function block from the project navigator and drop it into the network of the **program_FollError** LAD/FBD program.
2. Select the inserted function block, **FollError**, followed by the **Display > All Box Parameters** command from the context menu.
   All the input/output parameters of the inserted function block **FollError** are shown.

Note

Mandatory parameters are marked with "???" in the LAD/FBD network and optional parameters with "...". Function blocks (FBs) only have optional parameters.

3. Select the inserted function block, **FollError**, followed by the **Parameterize call** command from the context menu.

4. Assign parameters to the subroutine call in the **Enter Call Parameter** parameter screen form:
   – Enter the instance **myfollerror**, defined in the declaration table, in the **Instance** field.

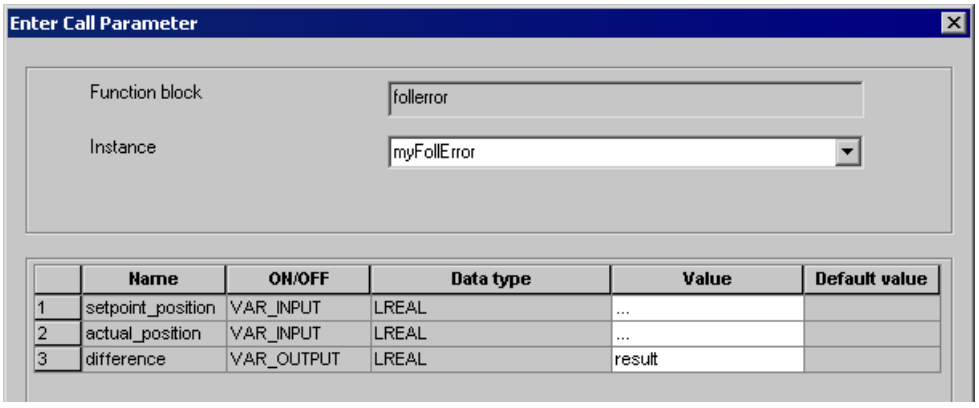


Figure 7-500 Opened parameter screen form for assigning parameters to the subroutine call

Note

Mandatory parameters are marked with "<???>" and optional parameters with "...". Function blocks (FBs) only have optional parameters.

Assign the current values to the transfer parameters:

– Input parameters: Variable or expression
– In/out parameter: Directly readable/writable variable
– Output parameter (optional): Variable
  In the example, for the **Difference** output parameter select the **Result** variable in the **Value** column.

You can use drag-and-drop to assign unit variables and system variables from the detail view to the input, output, or in/out parameters of the instance of the **FollError** function block inserted into the LAD/FBD network.

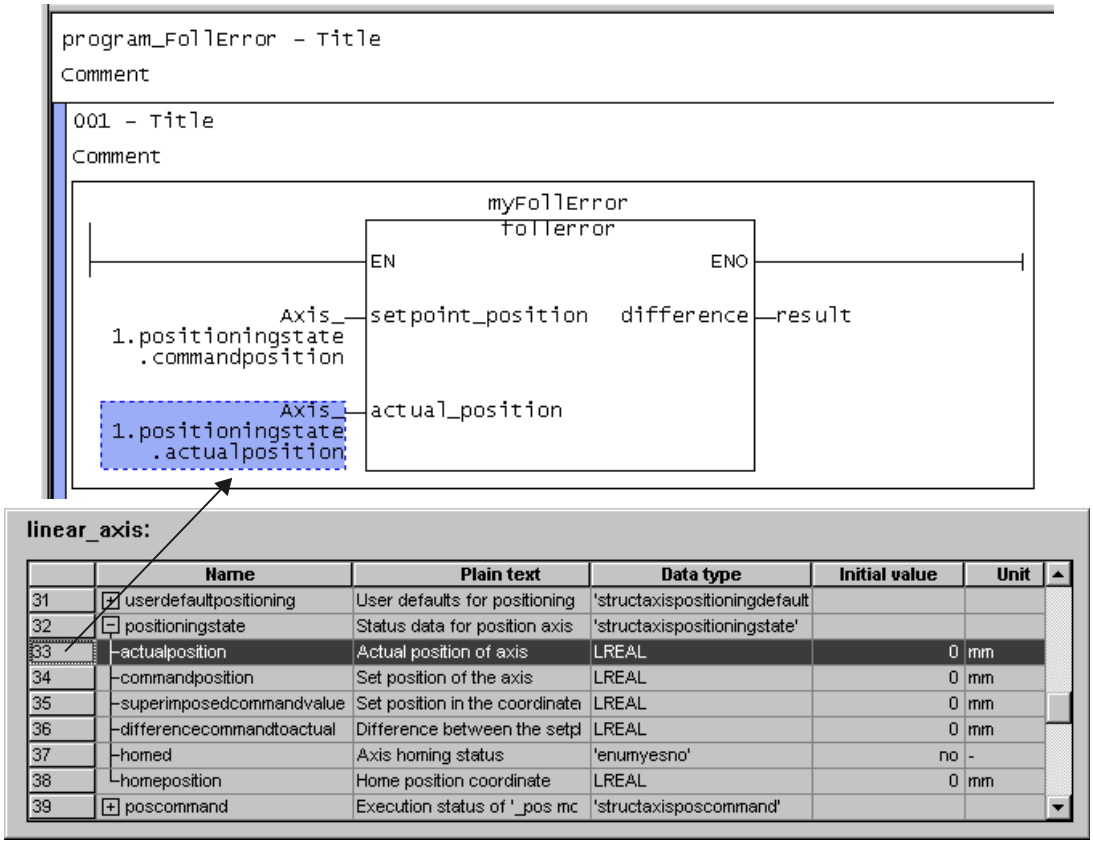

Figure 7-501 Assigning system variables from the detail view to the transfer parameters using drag-and-drop

5. Confirm with **OK**.

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC), or a function block (FB).

Note

Saving a project in a format older than Version V4.2 of SIMOTION SCOUT

Pay attention to the order of the LAD/FBD programs in the LAD/FBD unit. A subroutine (function, function block, or program ("program in program")) must be defined before it is used. This is the case when the LAD/FBD program of the subroutine appears in the project navigator above the LAD/FBD program in which it is used.

As far as the example described here is concerned, the LAD/FBD program with the function block (FB) must appear in the project navigator above the LAD/FBD program containing the program with the subroutine call.

In other words, the **distance** function block must be positioned above the **program_distance** program in the project navigator. If necessary, reorder the LAD/FBD programs by selecting the relevant LAD/FBD program in the project navigator, then selecting the **Down** or **Up** command in the context menu.

See also: Subroutine call of the function (FC) (Page 5235).

Opening the function block (FB) directly from the subroutine call

You can open subprograms directly from their respective subprogram call by using the context menu:

- This works regardless of the programming language (ST, MCC, LAD/FBD) used to create the subprogram.
- The subprogram opens in a separate editor or an editor already opened for the subprogram is moved to the foreground.

A subprogram may be a:

- User-defined function (FC)
- User-defined function block (FB)
- User-defined program called as a subprogram ("program in program")
- Library function
- Library function block
- Library program called as a subprogram ("program in program")
- Class method
- Interface method

Procedure

To open the FB directly from the subprogram call, proceed as follows:

1. In the LAD/FBD network, select the subprogram call used to call the FB.
2. Select the **Open called block** command in the context menu (Ctrl+Alt+O shortcut).

The FB opens in a separate editor or an editor already opened for the FB is moved to the foreground.

Note

If the called FB has not yet been created, the **Open called block** command appears inactive (grayed out) in the context menu.

Note

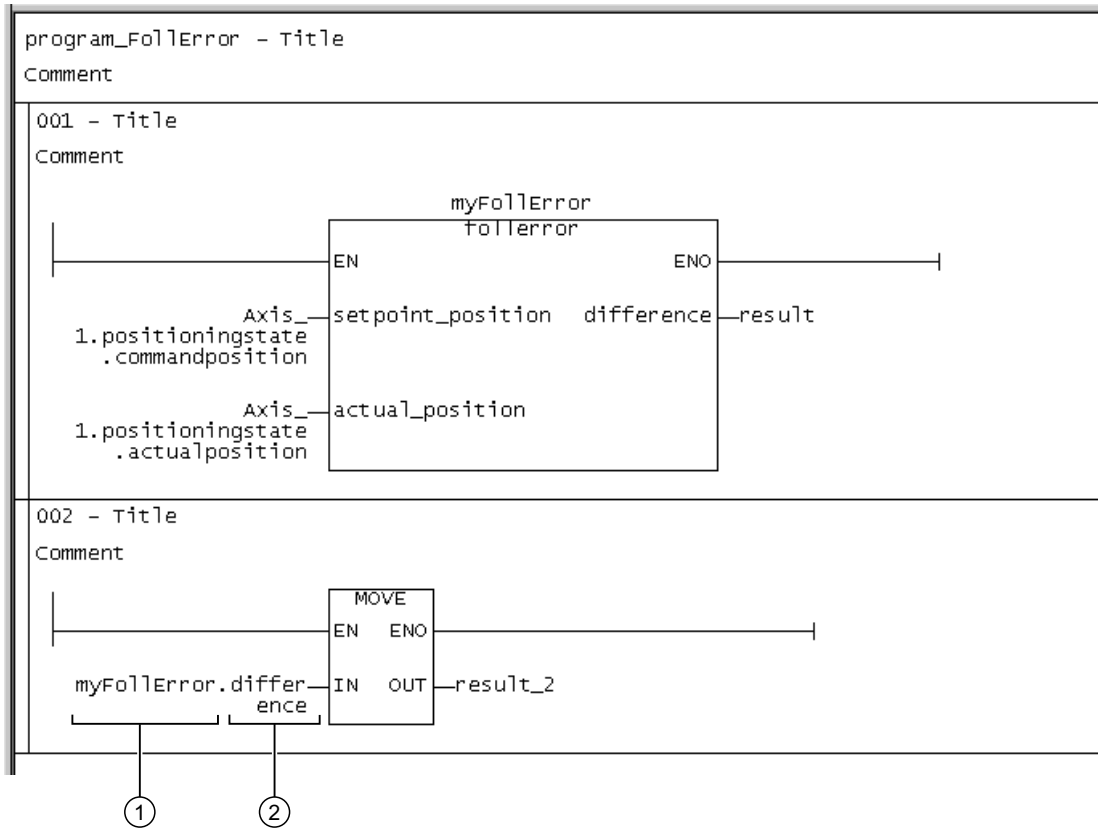
If the called FB is in a program source with know-how protection, the same steps that apply when opening the protected program source directly also apply here (see Know-how protection for LAD/FBD units (Page 5106)).

Accessing the output parameters of the function block retrospectively

After an instance of the function block has been executed, the static variables of the function block (including the output parameters) are retained. You can access the output parameters at any point in the calling program.

If you have defined the FB instance as VAR_GLOBAL, you can also access the output parameter in other LAD/FBD programs.

1. Insert the **MOVE** command into the LAD/FBD program.
2. Program the command (see figure).



① Name of the FB instance ② Output parameter

Figure 7-502 Programming a variable assignment

Example: Method

Example: Methods

In LAD/FDB programs you can call up public methods which have been defined in ST source files within classes and function blocks.

You can use methods in function blocks irrespective of the SIMOTION Kernel version.

Methods in classes can only be used in SIMOTION Kernel as of version V4.5.

No classes or methods can be defined in the LAD/FBD programming language itself. The same applies to methods within function blocks.

Requirements

In an ST source file the COUNTER class is defined with both public methods UP and DOWN: Both methods increment or decrement an internal counter variable until either the maximum value or minimum value is reached.

- The UP method has the following interface:
  - Input parameter INC with data type INT and initial value 1.
    You enter the increment here (standard = 1).
  - Output parameter QU with data type BOOL and initial value FALSE.
    The maximum value is reached when QU = TRUE.
  - Return value with data type INT.
    The return value shows the latest status for the internal counter variables.
- The DOWN method has the following interface:
  - Input parameter DECC with data type INT and initial value 1.
    You enter the increment here (standard = 1).
  - Output parameter QU with data type BOOL and initial value TRUE.
    The minimum value is reached when QU = FALSE.
  - Return value with data type INT.
    The return value shows the latest status for the internal counter variables.

The maximum value and minimum value for the counting range are stipulated in the private variables MAX_Val and MIN_Val for the class. They are pre-assigned with 100 or 0 respectively as standard. However, the initial values can be overwritten with the declaration of an instance for this class.

Subprogram call of the method

The method is called from a program in the example.

1. Generate an LAD/FBD program as a program (see Inserting a new LAD/FBD program (Page 5117)).
2. Create an instance for the higher-level class.
   - In the LAD/FBD source or LAD/FBD program, declare the instances of the class along with the variables.

   Note that the validity range of the instance and variables is dependent on the declaration location (see Define variables (Page 5171)).
3. Call the method:
   - Program the **Subroutine call** command.
4. Accept and compile the program.

You have now finished programming the subroutine call.

Creating an instance for the class or the function block

Before you can use a method, you must define an instance for the higher-level class or the higher-level function block. Each instance of a class or FB is independent of the others; once an instance has ended, its static variables remain stored.

Instances of a class or of an FB are defined in the declaration tables of the LAD/FBD source or of the LAD/FBD program. The scope of the instance declaration is dependent on the location of the declaration:

- In the interface section of the declaration table of the LAD/FBD source:
  The instance behaves like a unit variable; it is valid for the entire LAD/FBD source; all LAD/FBD programs (programs, function blocks, and functions) within the LAD/FBD source can access the instance.
  The instance is also available:
  - On HMI devices.
  - In other LAD/FBD source files (or other units) once connected, see "How to define connections to other units (program sources)" (Page 5223).

  The total size of all unit variables in the interface section is limited to 64 Kbytes.
- In the implementation section of the declaration table of the LAD/FBD source:
  The instance behaves like a unit variable which is only valid in the LAD/FBD source; all LAD/FBD programs (programs, function blocks, and functions) within the LAD/FBD source can access the instance.
- In the declaration table of the LAD/FBD program (for programs and function blocks only):
  The instance behaves like a local variable; it can only be accessed within the MCC chart in which it is declared.

Proceed as follows (the LAD/FBD source or the LAD/FBD program with the declaration table is open, see "Opening an existing LAD/FBD source" (Page 5104) or "Opening an existing LAD/FBD program" (Page 5119)):

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Parameters** tab.
3. Enter or select the following:
   - **Name** of instance (variable name – see Rules for identifiers (Page 5155))
   - **Variable type** VAR or VAR_GLOBAL, depending on the declaration location (in LAD/FBD program or LAD/FBD source respectively)
   - Designation of the function block as **data type**.
4. Declare the other variables.

Programming the subprogram call of the method

1. From the project navigator drag the **UP** method from the **COUNTER** class to the network for the LAD/FBD program **KOP/FUP_1**.
2. Select the **counter.up** method inserted and select the **Display > All box parameters** command from the shortcut menu.
   All input/output parameters for the **UP** method inserted are displayed.

   Note

   Mandatory parameters are marked with "???" in the LAD/FBD network and optional parameters with "...".

3. Select the inserted **counter.up** method followed by the **Assign parameters to a call** command from the shortcut menu.
4. Assign parameters to the subroutine call in the **Enter Call Parameter** parameter screen form:
   - Enter the instance **C1** defined in the declaration table in the **Instance** field.
   - Select the **CountOut** variable in the return value field defined in the declaration table.

   Note

   Mandatory parameters are marked with "<???>" and optional parameters with "...".

5. Assign the current values to the transfer parameters:
   - Input parameters: Variable or expression
   - In/out parameter: Directly readable/writable variable
   - Output parameter (optional): Variable
     In the example for the output parameters **QU** in the **Value** column select the variable **UpValReached**.

   You can use drag-and-drop to assign unit variables and system variables from the detail view to the input, output, or in/out parameters of the instance of the **counter.up** method inserted into the LAD/FBD network.
6. Confirm with **OK**.

Note

The term "LAD/FBD program" is a generic term and may refer to a program, a function (FC), or a function block (FB).

Note

Saving a project in a format older than Version V4.5 of SIMOTION SCOUT

Projects which include classes and methods cannot be saved in a format older than Version V4.5 of SIMOTION SCOUT.

Opening the method directly from the subprogram call

You can open subprograms directly from their respective subprogram call by using the context menu:

- This works regardless of the programming language (ST, MCC, LAD/FBD) used to create the subprogram.
- The subprogram opens in a separate editor or an editor already opened for the subprogram is moved to the foreground.

A subprogram may be a:

- User-defined function (FC)
- User-defined function block (FB)
- User-defined program called as a subprogram ("program in program")
- Library function
- Library function block
- Library program called as a subprogram ("program in program")

Procedure

To open the method directly from the subprogram call, proceed as follows:

1. In the LAD/FBD network, select the subprogram call used to call the method.
2. Select the **Open called block** command in the context menu (Ctrl+Alt+O shortcut).

The method opens in the ST editor or the ST editor opened for the method is placed in the foreground.

Note

If the called method is in a program source with know-how protection, the same steps that apply when opening the protected program source directly also apply here, see Know-how protection for LAD/FBD sources (Page 5106).

Limitations with advance signal switching

An output from an LAD/FBD element can only be connected in advance of an LAP/FBD element input if both the input and output are of data type BOOL. As a result, only Boolean advance signal switching is possible in a network.

An output parameter from an FB or a return value from an FC cannot be switched to an input parameter of a different FB/FC, i.e. Boolean advance signal switching is not possible here either.

Non-Boolean advance signal switching and output/input parameter switching with the FB/FC can be implemented with the aid of an additional network and a temporary variable. If the output from an LAD/FBD element cannot be assigned directly to the input of the other LAD/FBD element, then the former LAD/FBD element is added to this additional network. The same temporary variable is assigned to both output and input, and so the output and input are switched via the temporary variable.

Alternatively, this can also be implemented with just one network and a temporary variable, with the result that both LAD/FBD elements are in the same network.

Example of output/input parameter switching with FB/FC

In the ST programming language, with TO commands from the commands library the "commandid" input parameter can be assigned directly with the *_getcommandid* function.

This output/input parameter switch with FB/FC can be implemented in the LAD/FBD programming language with an additional network for the *_getcommandid* function and a temporary variable.

The *_getcommandid* function is added to the upper network, and the temporary variable "var_commandid" is assigned to its output "OUT". The TO command *_pos* is added to the lower network, and the temporary variable "var_commandid" is likewise assigned to its input "commandid". The switching of the output "OUT" of *_getcommandid* and of the input "commandid" of *_pos* is thus effected using the temporary variable.

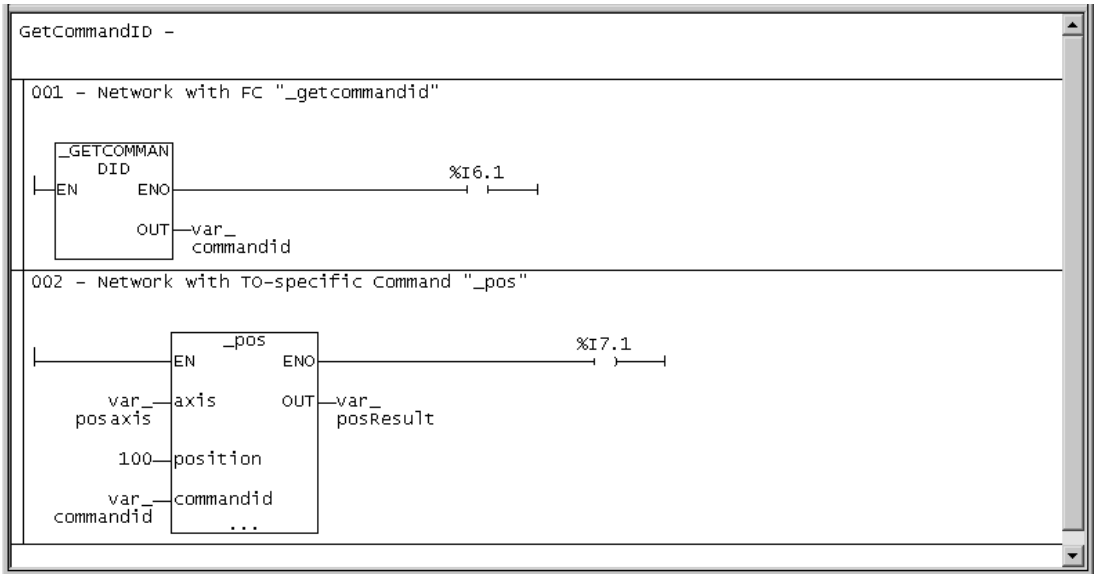


Figure 7-503 Output/input parameter switching with FB/FC

Interface adjustment with FB/FC

If the properties of an FB/FC that has been added to the network are modified, then in the following cases there will be an interface adjustment:

1. One or more new input/output parameters are added
2. One or more unused input/output parameters are deleted
3. One or more used input/output parameters are deleted

In cases 1 and 2 the network is updated immediately when it is opened in the LAD/FBD editor, or immediately after it is opened.

In case 3 the FB/FC call is shown in red in the network, and a manual update must be carried out. An existing Boolean advance switching of a deleted input parameter is not deleted; instead it is

merely separated off and, for instance, shown in the LAD display as an as an open ladder diagram in the network.

Manual update of a specific FB/FC call

To manually update a particular FB/FC call, follow these steps:

1. Click on the desired FB/FC call.
2. Select the **Update call** command in the context menu.
   The FB/FC call is shown with the input/output parameters which are currently present, i.e. without the deleted input/output parameters.

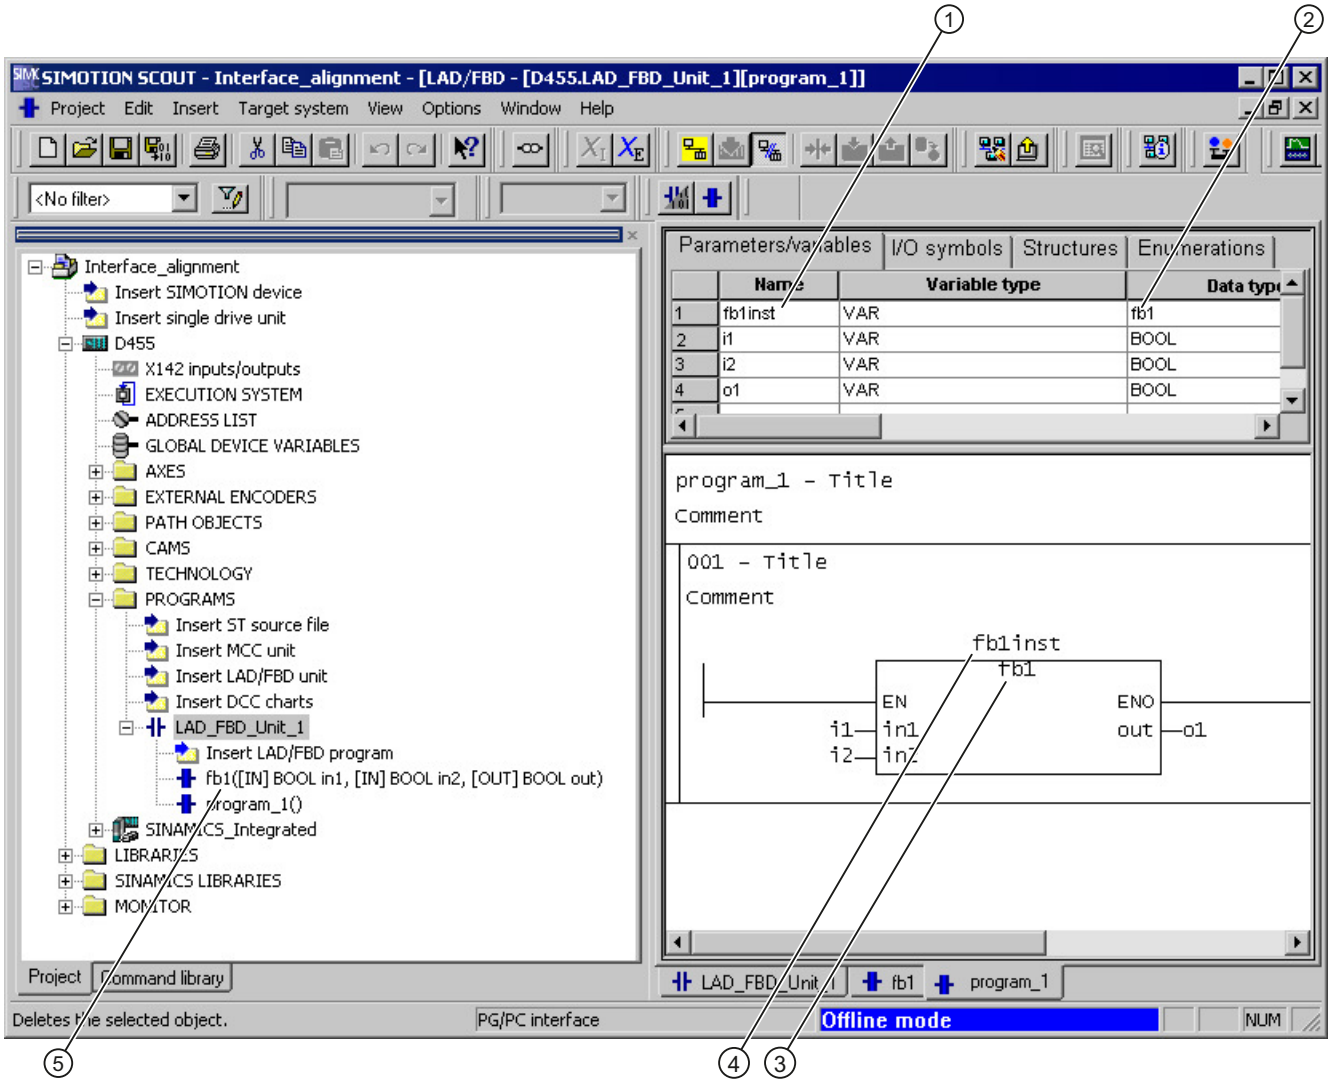
Manually updating all FB/FC calls

To manually update all the FB/FC calls for the program organization unit (POU) currently displayed in the working area, follow these steps:

1. Click on an empty position in the network.
2. Select the **Update all calls for all networks** command in the context menu.
   The FB/FC calls are shown with the input/output parameters which are currently present, i.e. without the deleted input/output parameters.

For the following cases there is no interface adjustment available, and so updating must be performed by entering data manually or with Find/Replace (Page 5263):

- Changing the name of the instance variable (only for FBs)
- Changing the name, the data type of the box type of the FB/FC call



① Instance variable (instance name)
Only used with FBs.
In the declaration table an FB instance is declared by specifying the instance variable with the name of the FB as the data type. This instance variable (instance name) is used for calling up the FB.

② Data type
The relevant FB is assigned to the instance variable as its data type.
In order for an FB call to work correctly, the data type and box type must be identical, otherwise the FB call will be displayed in red in the network.

③ Box type, consisting of:

- The type name, e.g. MOVE, ADD etc. or the names of user programs/FBs/FCs
- The type, i.e. the selected creation type (program, FB or FC) of the LAD/FBD program

④ Instance variable (instance name)
Only for FBs.

⑤ Name of the FB/FC (type of a (user-defined) FB/FC)
FB: The name of the FB is used as the data type in the FB instance declaration in the declaration table.
FC: The name of the FC is used as the box type.

Figure 7-504 Overview of FB/FC terms used

Display in the Detail view

Only in case 3 are the deleted input/output parameters and the deleted variables assigned to them displayed in the Detail view in the **Compile/check output** window immediately after a manual update. Deleted input parameters with Boolean advance switching are not displayed because the advance switching is merely separated off and therefore continues to exist in the network.

7.3.4.19 Reference data

The reference data provide you with an overview of:

- on utilized identifiers with information about their declaration and use (Cross-reference list (Page 5255)).
- on function calls and their nesting (Program structure (Page 5259))
- on the memory requirement for various data areas of the program sources (Code attributes (Page 5260))

Cross reference list

The cross-reference list shows all identifiers in program sources (e.g. ST source files, MCC units):

- Declared as variables, data types, or program organization units (program, function, function block)
- Used as previously defined types in declarations
- Used as variables in the statement section of a program organization unit.

Generating and updating a cross-reference list

Initially, the cross-reference list is generated automatically when opening. Open a cross-reference list, e.g. after selecting an ST source file or library via the **Edit > Display reference data > Cross-references** menu. After changes, the update is partly performed automatically and can always be triggered manually in the detail view via the button. When updating via the button, a check is performed as to whether a compilation is required. If a compilation is required, this is indicated by a yellow triangle next to the button.

Update of the cross-reference list when selecting a program

The list is updated automatically when opening the selected program. The local defined identifiers are therefore up-to-date.

External identifiers in the program are not updated when opening.

The opened cross-reference list is also updated automatically when compiling the program.

Update of the cross-reference list when selecting a tree (CPU, project, library, program folder)

The cross-reference list is generated automatically when opening the first time. There is no automatic update when opened again.

Note

An error-free compilation is required for a correct, consistent display of the reference data. If required, compile the project, the CPU, the program or the library first.

Content of the cross-reference list

The cross-reference list contains all the identifiers assigned to the element selected in the project navigator. The applications for the identifiers are also listed in a table:

Details of how to work with the cross-reference list are provided in the section titled "Working with the cross-reference list (Page 5258)".

Table 7-557 Meanings of columns and selected entries in the cross-reference list

Column	Entry in column	Meaning
Name		Identifier name
Type		Identifier type
	Name	• Data type of a variable (e.g. REAL, INT) • POU type (e.g. PROGRAM, FUNCTION)
	DERIVED	Derived data type
	DERIVED ANY_OBJECT	TO data type
	ARRAY ...	ARRAY data type
	ENUM ...	Enumerator data type
	STRUCT ...	STRUCT data type
Declaration		Location of declaration
	Name (UNIT)	Declaration in the program source *name*
	Name (LIB)	Declaration in the library *name*
	Name (TO)	System variable of the technology object *name*
	Name (TP)	Declaration in the default library specified: • Technology package *name* • std_fct = IEC library • device = device-specific library
	Name (DV)	Declaration on the SIMOTION device *name* (e.g. I/O variable or global device variable)
	_project	Declaration in the project (e.g. technology object)
	_device	Internal variable on the SIMOTION device (e.g. TaskStartInfo)
	_task	Task in the execution system
Use		Use of identifier
	CALL	Call as subprogram (static binding)
	CALL VTAB	Call of a method of the dynamic binding

Column	Entry in column	Meaning
	ENUM *name*	As element when declaring the enumerator data type *name*
	I/O	Declaration as I/O variable
	R	Read access
	R (TYPE)	As data type in a declaration
	R/W	Read and write access
	STRUCT *name*	As component when declaring the structure *name*
	TYPE	Declaration as data type or POU
	Variable type (e.g. VAR, VAR_GLOBAL)	Declaration as variable of the variable type specified
	W	Write access
Path specification		Path specification for the SIMOTION device or program source
	Name	SIMOTION device *name*
	Name1/*Name2*	• Program source *name2* on SIMOTION device *name1* • Program source *name2* in library *name1*
	Name/taskbind.hid	Execution system of the SIMOTION device *name*
Range		Range within the SIMOTION device or program source
	INTERFACE	Interface section of the program source
	POE type name (i.e. CLASS *name*, FUNCTION *name*, FUNCTION_BLOCK *name* INTERFACE *name* PROGRAM *name*)	Program Organization Unit (POU) *Name* within the program source. • In an MCC chart: Additional serial numbers for the command (block numbers) • In a LAD/FBD program: Additional serial numbers of the network
	I/O address	I/O variable
	METHOD *Name_1*::*Name_2*	Method *Name_2* within the class or the function block *Name_1*
	TASK *name*	Assignment for the task *name*
	UNIT	Implementation section of the program source, additional specification as POU to be made public in the interface section of the program source
	UNIT - IMPLEMENTATION	Implementation section of the program source
	_device	Global device variable
Language		Programming language of the program source
Line/Block		• In an ST source: Line number within the program source • In an MCC or LAD/FBD source: Relative line number within the command (block) or network. **Note** The absolute line number within the program source, which you need, for example, for the trace function "Trigger to code point", is obtained as follows: – Press the **Determine program line** button. – In the dialog box, press the button **Copy program line to the clipboard**.

Note

Single-step tracking and trace diagnostic functions in MCC programming

Additional variables and functions are created or used for these diagnostics functions:

- The variables TSI#dwuser_1 and TSI#dwuser_2 of the TaskStartInfo are used for the single-step tracking diagnostic function.
- Various internal functions and variables, whose identifier begins with an underscore, are automatically created by the compiler for the trace diagnostic function. The TSI#currentTaskId variable of the TaskStartInfo is also used.

With activated diagnostic function, these variables and functions are used for the control of the diagnostics function. These variables and functions must not be used in the user program.

Working with a cross-reference list

In the cross-reference list you are able to:

- Sort the column contents alphabetically:
  - To do this, click the header of the appropriate column.
- Search for an identifier or entry:
  - Click the "Search" button and enter the search term.
- Filter (Page 5258) the identifiers and entries displayed.
- Copy contents to the clipboard in order to paste them into a spreadsheet program, for example.
  - Select the appropriate lines and columns.
  - Press the CTRL+C shortcut.
- Print the content (**Project > Print**).
- Open the referenced program source and position the cursor on the relevant line of the ST source file (or MCC command or LAD/FBD element):
  - Double-click on the corresponding line in the cross-reference list.
    or
  - Place the cursor in the corresponding line of the cross-reference list and click the "Go to application" button.

Further details about working with cross-reference lists can be found in the online help.

Filtering the cross-reference list

You can filter the entries in the cross-reference list so that only relevant entries are displayed:

1. Click the "Filter settings" button.
   The "Filter Setting for Cross References" window will appear.
2. Activate the "Filter active" checkbox.

3. If you also want to display system variables and system functions:
   – Deactivate the "Display user-defined variables only" checkbox.
4. Set the desired filter criterion for the relevant columns:
   – Select the relevant entry from the drop-down list box or enter the criterion.
   – If you want to search for a character string within an entry: Deactivate the "Whole words only" checkbox.
5. Confirm with **OK**.

The contents of the cross-reference list will reflect the filter settings selected.

Note

A filter is automatically activated after the cross-reference list has been created.

Program structure

The program structure contains all the function calls and their nesting within a selected element.

You can display the program structure selectively for:

- An individual program source (e.g. ST source file, MCC unit, LAD/FBD source file)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Proceed as follows:

1. In the project navigator, select the element for which you want to display the program structure.
2. Select the **Edit > Display reference data > Program structure** menu command.
   The cross-reference tab is replaced by the program structure tab in the detail view.

Note

The display data is updated every time the program structure is opened.

You can update the detail view of an opened program structure with the F5 key.

Content of the program structure

A tree structure appears, showing:

- as base respectively
  – the program organization units (programs, functions, function blocks) declared in the program source, or
  – the execution system tasks used
- below these, the subroutines referenced in this program organization unit or task.

For structure of the entries, see table:

Table 7-558 Elements of the display for the program structure

Element	Description
Base (declared POU or task used))	List separated by a comma • Identifier of the program organization unit (POU) or task The specification *Name_1::Name_2* means: Method *Name_2* within the class or the function block *Name_1*. • Identifier of the program source in which the POU or task was declared, with add-on [UNIT] • Minimum and maximum stack requirement (memory requirement of the POU or task on the local data stack), in bytes [Min, Max] • Minimum and maximum overall stack requirement (memory requirement of the POU or task on the local data stack including all called POUs), in bytes [Min, Max]
Referenced POU	List separated by a comma: • Identifier of called POU The specification *Name_1::Name_2* means: Method *Name_2* within the class or the function block *Name_1*. • Optionally: Identifier of the program source / technology package in which the POU was declared: Add-on (UNIT): User-defined program source Add-on (LIB): Library Add-on (TP): System function from technology package • with function blocks or methods only: Identifier of the instance of the function block or the higher-level class • with function blocks or methods only: Identifier of program source in which the instance of the function block or of the higher-level class was declared: Add-on (UNIT): User-defined program source Add-on (LIB): Library • Number of the line in the (compiled) source in which the POE is called; several line numbers are separated by "/".

Code attributes

You can find information on or the memory requirement of various data areas of the program sources under code attribute.

You can display the code attributes selectively for:

- An individual program source (e.g. ST source file, MCC unit, LAD/FBD source file)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Proceed as follows:

1. In the project navigator, select the element for which you want to display the code attributes.
2. Select the **Edit > Display reference data > Code attributes** menu command.
   The **Cross-references** tab is now replaced by the **Code attributes** tab in the detail view.

Note

The display data is updated every time the code attributes are opened.

You can update the detail view of the opened code attributes with the F5 key.

Code attribute contents

The following are displayed in a table for all selected program sources:

- Identifier of program source,
- Memory requirement, in bytes, for the following data areas of the program source:
  - **Dynamic data**: All unit variables (retentive and non-retentive, in the interface and implementation sections),
  - **Retain data**: Retentive unit variables in the interface and implementation section,
  - **Interface data**: Unit variables (retentive and non-retentive) in the interface section,
- the **Code size** during the last compilation in bytes,
- the **Number of referenced sources**:
  The maximum number of connected sources is displayed (including system libraries), regardless of whether they are downloaded to the target system at a later date.

Reference to variables

If you have selected the identifier of a variable in the open Editor window for each programming language, you can use the other places of use over the context menu to list or to skip these variables.

You select the identifier of a variable:

- In SIMOTION ST: In the Editor window of an ST source.
- In SIMOTION MCC: In the input field on the parameter screen of an open MCC command within an MCC chart
- In SIMOTION LAD/FBD: In the Editor window of a LAD/FBD program

An identifier is recognized as a variable under the following conditions:

1. The identifier is declared as a variable. The scope of the variable includes the respective window (ST source, MCC chart, LAD/FBD program).
2. The program source is compiled.
3. The variable is selected as follows (in an open parameter screen within an MCC chart):
   – The identifier is fully marked
   or
   – The cursor is within the identifier.

Note

In arrays and structures, only the variable can be selected, not a single element.

Using the **Go to** context menu, you have the following options:

- To jump to the next local place of use:
  Select the context menu **Go to > Local use >>**.
  The next place of use of the variables within the same Editor window (ST source, MCC chart, LAD/FBD program) is selected. In an MCC chart, the corresponding MCC command opens.
- Jump to the previous local place of use:
  Select the context menu **Go to > Local use <<**.
  The previous place of use of the variables within the same Editor window (ST source, MCC chart, LAD/FBD program) is selected. In an MCC chart, the corresponding MCC command opens.
- Jump to the declaration position:
  Select the context menu **Go to > Declaration position**.
  The declaration position of the variables is selected. The corresponding program source is opened, if necessary.
- List all places of use
  Select the context menu **Go to > Places of use ...**.
  In the detailed view, all places of use of the variables within their scope (including the declaration position) are listed The structure of this list is similar to the List of cross references (Page 5256).
  This is how you jump to a preferred place of use:
  – Double-click on the corresponding line.
  or
  – Place the cursor in the corresponding line and click the "Go to application" button.

7.3.4.20 Find and replace

The following options are available when searching for a given piece of text or for variables only:

- Find or find and replace in the entire project (project-wide search).
  This is described in detail in the Online help.

  Note

  Following a find and replace operation in the whole project, it may be necessary to compile the project, so as to update all symbol information.

- Find or find and replace in a certain program source or their subprograms (local search).
  The following is described in this manual:
  - Finding in an LAD/FBD unit or an LAD/FBD program (Page 5263)
  - Finding and replacing in an LAD/FBD unit or an LAD/FBD program (Page 5264)

  See the respective manuals for a description of the local search in the other programming languages.

Find in LAD/FBD unit or LAD/FBD program

Range of the local search

With local searching, only the contents of the window (LAD/FBD unit or LAD/FBD program) in which the local search was triggered are searched.

- The following are searched in an LAD/FBD unit:
  - All tabs of the declaration table (INTERFACE and IMPLEMENTATION)

  The assigned LAD/FBD programs are **not** searched.
- The following are searched in an LAD/FBD program:
  - All tabs of the declaration table
  - Program title and comment
  - All networks (title, comment, LAD/FBD elements with parameter labelling)

The dialog box open during the local search is assigned to the respective window and is hidden when changing to another window and displayed again when returning.

Procedure

If you want to conduct local searching for arbitrary text in an LAD/FBD unit or LAD/FBD program, proceed as follows:

1. Open the desired LAD/FBD unit (Page 5104) or the LAD/FBD program (Page 5119).
2. In the menu, select **Edit > Find** (shortcut Ctrl+F).
   The **Find** dialog box opens.
   A character string selected in the LAD/FBD editor is automatically taken as a search term.

3. Enter the required search term in the **Find** input field.
   Wildcards such as "*" or "?" are not permitted.
4. If required, select a search option as well as the search direction (**Up**/**Down**).
   - If you activate the **Whole words only** checkbox, only a whole word is searched for.
   - If you activate the **Match case** checkbox, the search takes upper- and lower-case into account.
   - If you activate the **Variables only** checkbox, the search is performed only in fields that contain identifiers of variables.
5. Click the **Find next** button (shortcut F3).
   The search is started in the selected direction. The first matching text pattern is highlighted.
6. Click the **Find next** button again to display the next matching text pattern.

Note

You can also continue searching with F3 even when the dialog box is closed.

Displaying search results

- The relevant tab is automatically activated in a declaration table and the found search term is highlighted.
- The found search term is highlighted in the LAD/FBD program.

The respective editor window can also be edited when the dialog box is open.

Find and replace in LAD/FBD unit or LAD/FBD program

The process of finding and replacing on a local basis works like local finding (Page 5263), but also makes it possible to specify an expression to replace a search term once found.

Procedure

If you want to conduct local searching for arbitrary text in an LAD/FBD unit or LAD/FBD program, proceed as follows:

1. Open the desired LAD/FBD unit (Page 5104) or the LAD/FBD program (Page 5119).
2. In the menu, select **Edit > Replace** (shortcut Ctrl+H).
   The **Replace** dialog box opens.
   A character string selected in the LAD/FBD editor is automatically taken as a search term.
3. Enter the required search term in the **Find** input field.
   Wildcards such as "*" or "?" are not permitted.

4. If required, select a search option.
   - If you activate the **Whole words only** checkbox, the search looks for a whole word.
   - If you activate the **Match case** checkbox, the search takes upper- and lower-case into account.
   - If you activate the **Variables only** checkbox, the search is performed only in fields that contain identifiers of variables.
5. Enter the expression that should replace the search term in the **Replace with** input field.
6. Click the **Find next** button (shortcut F3).
   The search begins in the **Down** direction and the first matching text pattern is highlighted. The **Replace** button also becomes active if a replacement is permitted at this position, see Rules for replacing.
   - If you want to replace the search term found, click the **Replace** button.
     The search term found, now selected and displayed, is replaced and the next length of text to match the criteria is displayed.
   - If you do not want to replace the search term found, click the **Find next** button.
     The next length of text to match the criteria is displayed.

Rules for replacing

When replacing, a check is made as to whether the resulting term after replacement is permitted in principle at this position, for example:

- For identifiers of variables and data types, a check is made as to whether the Rules for identifiers (Page 5155) have been observed.
- For selection fields (combo boxes), a check is made whether the resulting term is available as a selection option. Some examples are shown below:
  - In the declaration table of an LAD/FBD unit, VAR_GLOBAL cannot be replaced by VAR or VAR_TEMP.
  - The LAD/FBD element ADD can be replaced by other mathematical functions, but not, for example, by MAX or a comparison operator.
  - A comparison operator can only be replaced by another comparison operator, but not, for example, by a mathematical or logical function.
- Generally, the following cannot be replaced:
  - Wildcards, such as "..." or "???"
  - The elements listed in the command library under "LAD elements" and "FBD elements".

Note

If an item cannot be replaced at a particular position, the **Replace** button appears inactive (grayed out).

Further checks are not made, for example

- Whether variables or data types have already been defined.
- Whether there are further dependencies between fields and will be violated by the replacement.

In declaration tables, some columns are generally blocked for replacing, for example:

- The **Absolute identifier** column in the **I/O symbols** tab
- The **Type** column in the **Connections** tab

7.3.4.21 Execution order

Non-optimized execution order

Requirements

The non-optimized execution order is active for LAD networks by default. In the "Global settings of the compiler" (Page 5111), the **Optimize execution order (LAD/FBD)** checkbox is inactive.

Calculation of the non-optimized execution order

The LAD network is calculated in the following order:

1. At the end of the last parallel branching (at ① in the example), the lower parallel branches are calculated first in the order 2 - 3 - 4 ... before the top parallel branch is calculated.
2. The elements are calculated from left to right within a parallel branch.
3. Within the lower parallel branches, further parallel branches (at ② in the example) are calculated in the normal order from top to bottom.
4. In the top parallel branch, further parallel branches (at ③ in the example) are calculated in the order described in 1.

This produces the specified order (1 ... 7) in the following example.

Example of a non-optimized execution order

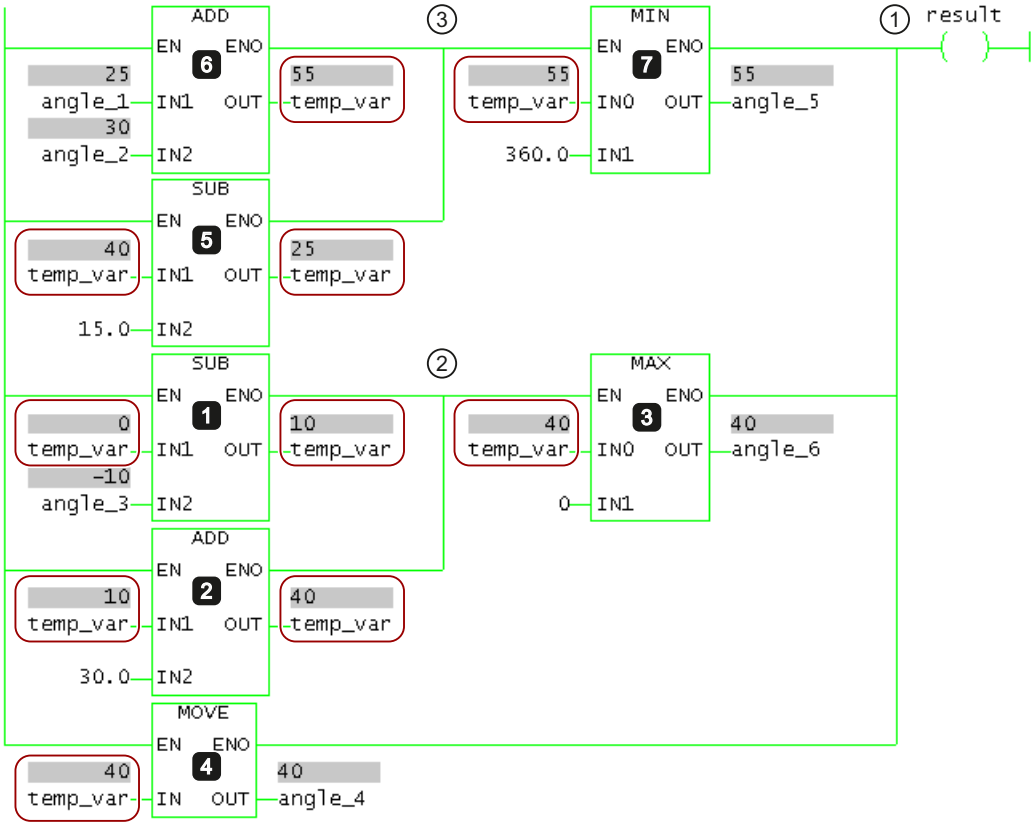


Figure 7-505 Example of a non-optimized execution order

Optimized execution order

Requirements

The setting for the optimized execution order is made globally for the entire project in the "Global compiler settings" (Page 5112). The **Optimize execution order (LAD/FBD)** checkbox is active.

Note

Note when saving the project in the old project format: In project formats up to version V4.2, the optimized execution order is not taken into account.

Calculation for the optimized execution order

The LAD network is calculated in the following order:

1. At the end of parallel branching (at ① in the example), the parallel branches are calculated from top to bottom.
2. The elements are calculated from left to right within a parallel branch.
3. Within the parallel branches, further parallel branches (at ② or ③ in the example) are calculated from top to bottom.

This produces the specified order (1 ... 7) in the following example.

Example of an optimized execution order

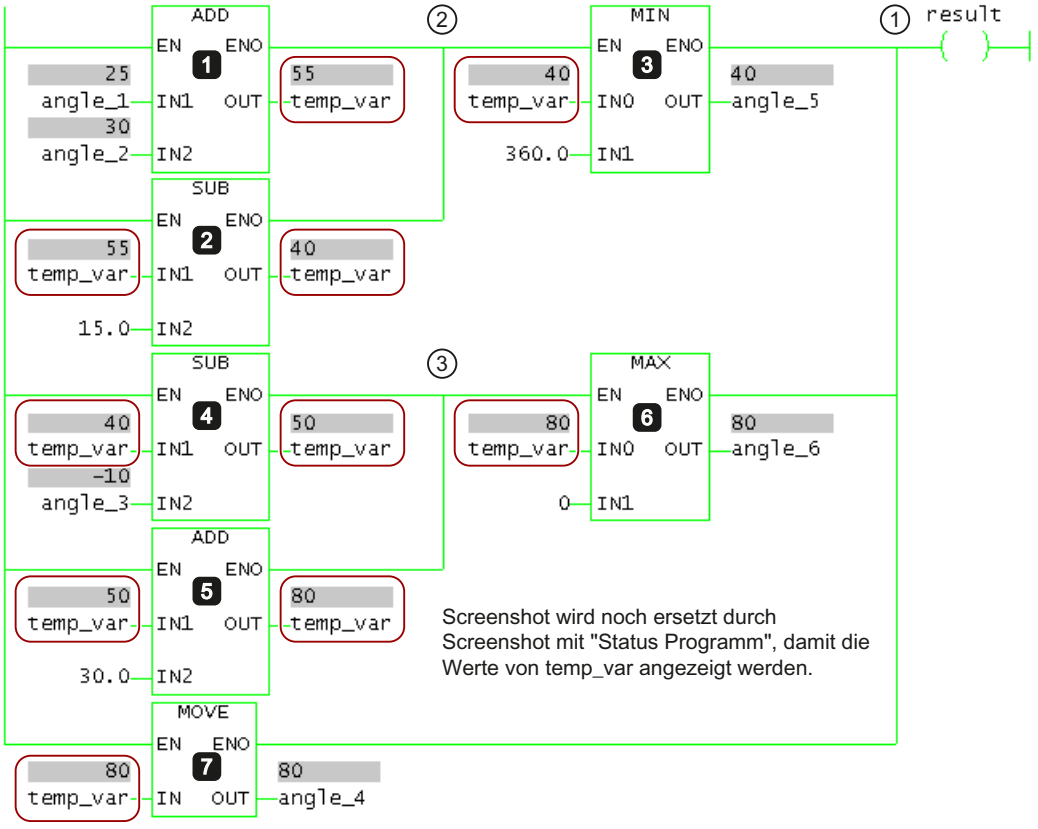

Figure 7-506 Example of an optimized execution order

7.3.5 Functions

This chapter provides a detailed description of the commands with the parameters. The commands described are applicable to both the LAD editor and the FBD editor. Examples are provided to illustrate individual commands in the LAD and FBD editors. Where there are differences such as bit logic, you should refer to the relevant LAD bit logic instructions (Page 5269) editor.

Note

Functions not described in this section can be found in the following sections of the "SIMOTION Basic Functions" Function Manual.

- AUTOHOTSPOT
- AUTOHOTSPOT
- AUTOHOTSPOT

7.3.5.1 LAD bit logic instructions

Bit logic operations work with the numbers **1** and **0**. These numbers form the basis of the binary system and are called binary digits or bits. In connection with AND, OR, XOR and outputs, a **1** stands for logic YES and a **0** for logic NO.

The bit logic operations interpret the signal states **1** and **0** and link them according to boolean logic.

The following bit logic operations are available:

- ---| |--- NO contact
- ---| / |--- NC contact
- XOR Linking EXCLUSIVE OR
- ---( ) Relay coil, output
- ---(#)--- Connector
- ---|NOT|--- Invert signal state

The following operations react to a signal state of **1**:

- ---(S) Set output
- ---(R) Reset output
- SR Prioritize set flip-flop
- RS Prioritize reset flipflop

Some operations react to a rising or falling edge change, so that you can perform one of the following operations:

- --(N)-- Scan edge 1 -> 0
- --(P)-- Scan edge 0 -> 1

- NEG edge detection (falling)
- POS edge detection (rising)

---| |--- NO contact

Symbol

<Operand>

---| |---

Parameter	Data type	Description
<Operand>	BOOL	Scanned bit

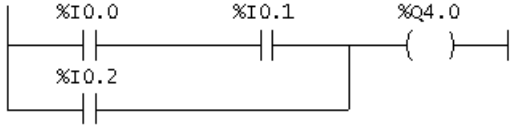
Description

---| |--- (NO contact) is closed if the value of the scanned bit, saved at the specified **<Operand>**, is equal to **1**.

Otherwise, if the signal state at the specified **<address>** is "0", the contact is open.

With series connections, the **---| |---** contact is linked by AND. With parallel connections, the contact is linked by OR.

Example



Output %Q 4.0 is **1**, if (%I 0.0 = **1** AND %I 0.1 = **1**) OR %I 0.2 = **1**.

---| / |--- NC contact

Symbol

<Operand>

—| / |—

Parameter	Data type	Description
<Operand>	BOOL	Scanned bit

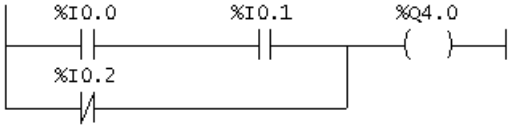
Description

---| / |--- (NC contact) is closed if the value of the scanned bit, saved at the specified **<Operand>**, is equal to **0**.

Otherwise, if the signal state at the specified **<address>** is "1", the contact is open.

With series connections, the **---| / |---** contact is linked bit for bit by AND. With parallel connections, the contact is linked by OR.

Example

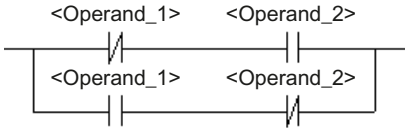


Output %Q 4.0 is **1**, if (%I 0.0 = **1** AND %I 0.1 = **1**) OR %I 0.2 = **0**.

XOR Linking EXCLUSIVE OR

Symbol

For the function **XOR**, a network of NC contacts and NO contacts must be created:

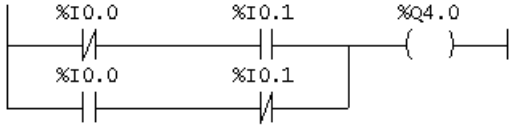


Parameter	Data type	Description
<Operand_1>	BOOL	Scanned bit
<Operand_2>	BOOL	Scanned bit

Description

The value of an **XOR** (Link EXCLUSIVE OR) link is **1** if the signal states of both specified bits are different.

Example



Output %Q 4.0 is **1** if (%I 0.0 = 0 AND %I 0.1 = 1) OR (%I 0.0 = 1 AND %I 0.1 = 0).

---|NOT|--- Invert signal state

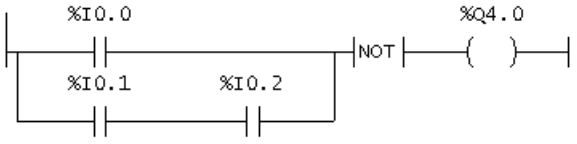
Symbol

---|NOT|---

Description

---|NOT|--- (Invert signal state) inverts the signal bit.

Example



Output %Q 4.0 is **0**, if %I 0.0 = **1** OR (%I 0.1 = **1** AND %I 0.2 = **1)**.

---( ) Relay coil, output

Symbol

<Operand>

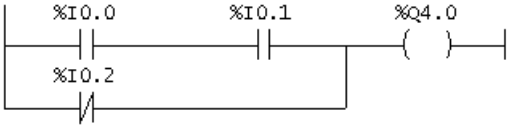
---( )

Parameter	Data type	Description
<Operand>	BOOL	Assigned bit

Description

--- ( ) (Relay coil, output) works like a coil in a circuit diagram. If current flows to the coil, the bit at the **<Operand>**is set to **1**. If no current flows to the coil, the bit at the **<Operand>** is set to **0**. An output coil can only be positioned at the right-hand end of a ladder diagram line in a ladder logic. A negated output can be created with the operation ---|NOT|---.

Example



Output %Q 4.0 is **1**, if (%I 0.0 = **1** AND %I 0.1 = **1**) OR %I 0.2 = **0**.

---(#)--- Connector (LAD)

Symbol

<Operand>

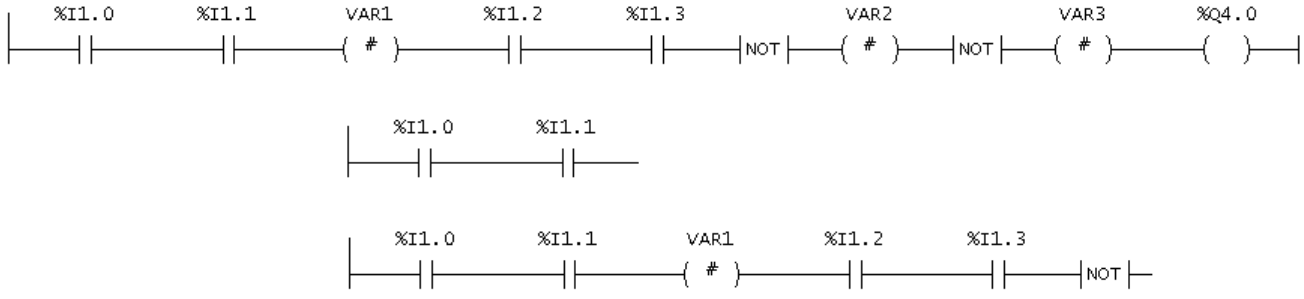
---(#)---

Parameters	Data type	Description
<Operand>	BOOL	Assigned bit

Description

---(#)--- (Connector) is an interposed element with assignment function which saves the current signal state of the signal flow at a specified **<Operand>**. This assignment element saves the bit logic of the last opened branch in front of the assignment element. If connected in series with other elements, the **---(#)---**operation is pasted in as a contact. The **---(#)---** element can never be connected to the conductor bar, nor positioned directly behind a branch, nor used as the end of a branch. A negated element **---(#)---** can be created with the element ---|NOT|--- (Invert signal state).

Example



---(R) Reset output (LAD)

Symbol

<Operand>

---(R)

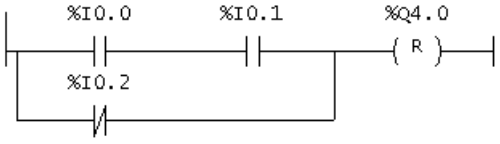
Parameter	Data type	Description
<Operand>	BOOL	Assigned bit

Description

---(R) (Reset output) is executed only if the signal state of the previous operations is **1** (signal flow at the coil). If the signal state is **1**, the specified **<Operand>** of the element is set to **0**.

A signal state of **0** (no signal flow at the coil) has no effect, so that the signal state of the operand of the specified element is not changed.

Example



Output %Q 4.0 is set to **0**, if (%I 0.0 = **1** AND %I 0.1 = **1**) OR %I 0.2 = **0**.

If the signal state is **0**, the signal state of %Q 4.0 remains the same.

---(S) Set output (LAD)

Symbol

<Operand>

---(S)

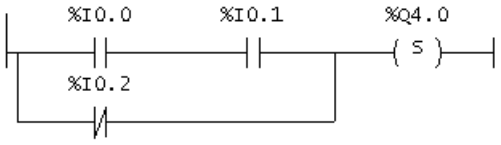
Parameter	Data type	Description
<Operand>	BOOL	Set bit

Description

---(S) (Set output) is executed only if the signal state of the previous operations is **1** (signal flow at the coil). If the signal state is **1**, the specified **<Operand>** of the element is set to **1**.

A signal state = 0 has no effect, so that the current signal state of the specified element's operand is not changed.

Example

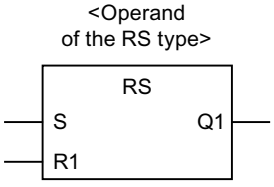


Output %Q 4.0 is set to **1**, if %I 0.0 = **1** AND %I 0.1 = **1**) OR %I 0.2 = **0**.

If the signal state is **0**, the signal state of %Q 4.0 remains the same.

RS Prioritize reset flipflop

Symbol



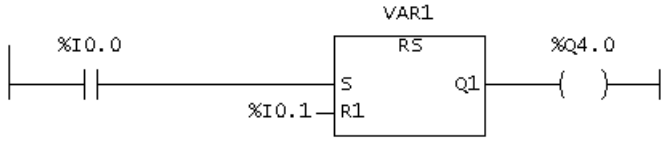
Parameters	Data type	Description
<Operand>	RS	Instance variable of FB type RS
S	BOOL	Set
R1	BOOL	Reset
Q1	BOOL	Signal state of <address>

Description

RS (Prioritize reset flip-flop) is reset if the state at input R1 is **1**. For the state at output Q1, this means:

- Q1 = **0**, if input R1 has state **1** irrespective of the state at the S input.
- Q1 = **1**, if input S has state **1** and input R1 has state **0**.
- Q1 unchanged, if both R1 and S inputs have state **0**.

Example



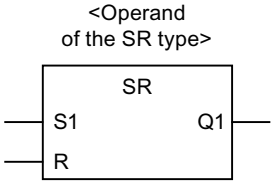
VAR1 is declared as a variable of data type RS and is used as instance of the function block. The I/O addresses %I 0.0 and %I 0.0 (process image of the inputs) are connected to the inputs S and R1 of the function block. Output Q1 of the function block is connected to I/O address %Q 4.0 (process image of the outputs).

The following applies for the signal state at output address %Q 4.0 depending of the signal state at input addresses %I 0.0 and %I0.1:

- %I 0.0 = **1** and %I 0.1 = **1** ⇒ %Q 4.0 = **0**.
- %I 0.0 = **1** and %I 0.1 = **0** ⇒ %Q 4.0 = **1**.
- %I 0.0 = **0** and %I 0.1 = **1** ⇒ %Q 4.0 = **0**.
- %I 0.0 = **0** and %I 0.1 = **0** ⇒ %Q 4.0 remains the same.

SR Prioritize set flipflop

Symbol



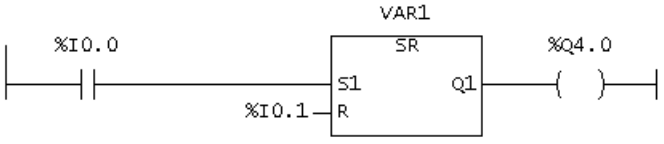
Parameters	Data type	Description
<Operand>	SR	Instance variable from FB type SR
S1	BOOL	Set
R	BOOL	Reset
Q1	BOOL	Signal state of <address>

Description

SR (Prioritize set flip-flop) is set if input S1 has state **1**. For the state at output Q1, this means:

- Q1 = **1**, if input S1 has state **1** irrespective of the state at the R input.
- Q1 = **0**, if input R has state **1** and input S1 has state **0**.
- Q1 unchanged, if both R and S1 inputs have state **0**.

Example



VAR1 is declared as a variable of data type SR and is used as instance of the function block. The I/O addresses %I 0.0 and %I 0.0 (process image of the inputs) are connected to the inputs S1 and R of the function block. Output Q1 of the function block is connected to I/O address %Q 4.0 (process image of the outputs).

The following applies for the signal state at output address %Q 4.0 depending of the signal state at input addresses %I 0.0 and %I0.1:

- %I 0.0 = **1** and %I 0.1 = **1** ⇒ %Q 4.0 = **1**.
- %I 0.0 = **1** and %I 0.1 = **0** ⇒ %Q 4.0 = **1**.
- %I 0.0 = **0** and %I 0.1 = **1** ⇒ %Q 4.0 = **0**.
- %I 0.0 = **0** and %I 0.1 = **0** ⇒ %Q 4.0 remains the same.

--(N)-- Scan edge 1 -> 0 (LAD)

Symbol

<Operand>

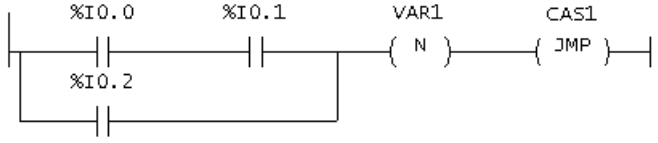
---(N)---

Parameters	Data type	Description
<Operand>	BOOL	N connector bit, saves the previous signal state

Description

---(N)--- (Scan edge 1 -> 0) recognizes a signal state change in the operand from **1** to **0** and displays this after the operation with signal state = 1. The current signal state is compared to the signal state of the operand, the N connector. If the signal state of the operand is **1** and the signal state before the operation is **0**, then the signal after the operation is **1** (pulse), in all other cases **0**. The signal before the operation is saved in the operand.

Example



The N-connector saves the signal state of the result of the entire bit logic.

If the signal state changes from **1** to **0** the jump to the CAS1 jump label is performed.

--(P)-- Scan edge 0 -> 1 (LAD)

Symbol

<Operand>

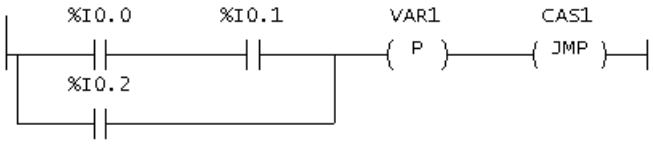
---(P)---

Parameters	Data type	Description
<Operand>	BOOL	P connector bit, saves the previous signal state

Description

---(P)--- (Scan edge 0 -> 1) recognizes a signal state change in the operand from **0** to **1** and displays this after the operation with signal state = 1. The current signal state is compared to the signal state of the operand, the P connector. If the signal state of the operand is **0** and the signal state before the operation is **1**, then the signal after the operation is **1** (pulse), in all other cases **0**. The signal before the operation is saved in the operand.

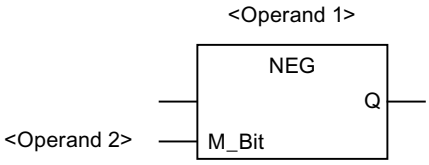
Example



The P-connector saves the signal state of the result of the entire bit logic. If the signal state changes from **0** to **1** the jump to the CAS1 jump label is performed.

NEG edge detection (falling)

Symbol

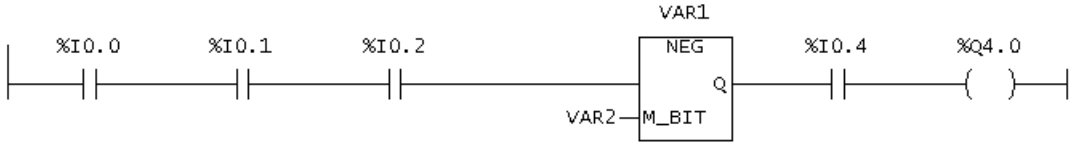


Parameters	Data type	Description
<Operand1>	BOOL	Scanned signal
<Operand2>	BOOL	Connector bit, saves the previous signal state from <Operand1>
Q	BOOL	Signal change detection

Description

NEG (edge detection) compares the signal state of **<Operand1>** with the signal state of the previous scan, which is saved in **<Operand2>**. If the current state of the signal is **0** and the previous state was **1** (detection of a falling edge), output Q is **1** after this function, in all other cases **0**.

Example

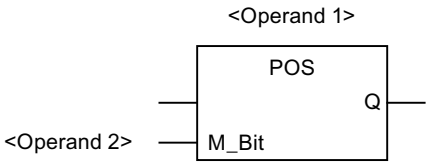


Output %Q 4.0 is **1** if:

(The state at %I 0.0 AND at %I 0.1 AND at %I 0.2 = **1**) AND VAR1 has a falling edge AND the state at %I 0.4 = **1**.

POS edge detection (rising)

Symbol

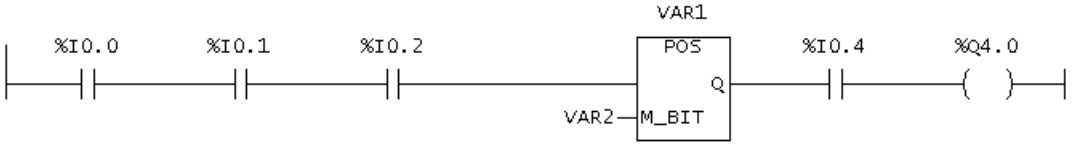


Parameters	Data type	Description
<Operand1>	BOOL	Scanned signal
<Operand2>	BOOL	Connector bit, saves the previous signal state from <Operand1>
Q	BOOL	Signal change detection

Description

POS (edge detection) compares the signal state of **<Operand1>** with the signal state of the previous scan, which is saved in **<Operand2>**. If the current state of the signal is **1** and the previous state was **0** (detection of a rising edge), output Q is **1** after this operation, in all other cases **0**.

Example



Output %Q 4.0 is **1** if:

(The state at %I 0.0 AND at %I 0.1 AND at %I 0.2 = **1**) AND VAR1 has a rising edge AND the state at %I 0.4 = **1**.

Open branch

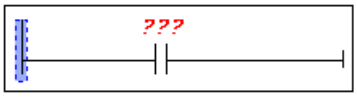
Parallel branches are opened downward.

Parallel branches are always opened behind the selected LAD element.

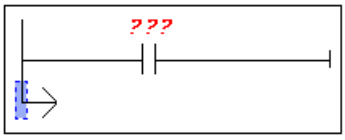
Procedure

To open a parallel branch downward, follow these steps:

1. Use the cursor to select the position where the branch is to be opened.



2. Click the button (shortcut Shift+F8) on the LAD editor toolbar.
   The branch is opened behind the selected element.



Close branch

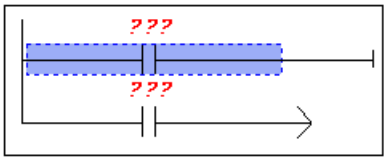
Parallel branches are closed upward.

Parallel branches are always closed behind the selected LAD element.

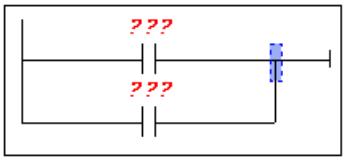
Procedure

To close a parallel branch upward, follow these steps:

1. Use the cursor to select the position where the branch is to be closed.

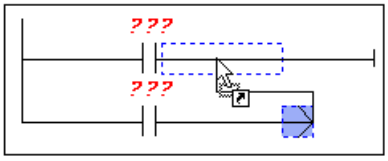


2. Click the button (shortcut Shift+F9) on the LAD editor toolbar.
   The branch is closed behind the selected element.

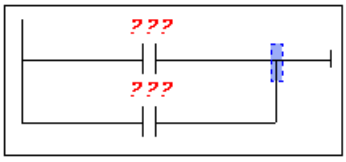


Or:

1. Using the cursor, select the parallel branch to be closed.
2. Holding down the left mouse button, move the selected branch to the position at which it is to be closed.



3. Release the left mouse button.
   The branch is closed at the selected position.



7.3.5.2 FBD bit logic instructions

FBD bit logic instructions

Bit logic operations work with the numbers **1** and **0**. These numbers form the basis of the binary system and are called binary digits or bits. In connection with AND, OR, XOR and outputs, a **1** stands for logic YES and a **0** for logic NO.

The bit logic operations interpret the signal states **1** and **0** and link them according to boolean logic.

The following bit logic operations are available in the FBD editor:

- & AND box
- >=1 OR box
- XOR Exclusive OR box
- [=] Assignment
- [#] Connector

The following operations react to a signal state of 1:

- [R] Reset assignment
- [S] Set assignment
- RS Prioritize reset flipflop
- SR Prioritize set flip-flop

Some operations react to a rising or falling edge change, so that you can perform one of the following operations:

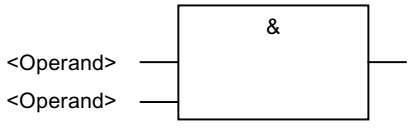
- [N] Scan edge 1 -> 0
- [P] Scan edge 0 -> 1
- NEG edge detection (falling)
- POS edge detection (rising)

The other operations directly affect the signal states:

- --| Inserting a binary input
- --o| Negating a binary input

& AND box

Symbol

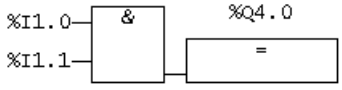


Parameters	Data type	Description
<Operand>	BOOL	Scanned bit

Description

With the **AND** operation, you can scan the signal states of two or more specified operands at the inputs of an AND box. If the signal status of all operands is **1**, the condition is fulfilled and the result of the operation is **1**. If the signal status of one operand is **0**, the condition is not fulfilled and the operation returns a result of **0**.

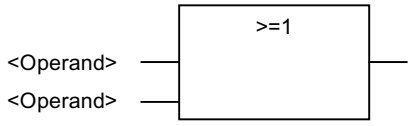
Example



Output %Q 4.0 is set when the signal state at input %I 1.0 AND %I 1.1 is **1**.

>=1 OR box

Symbol

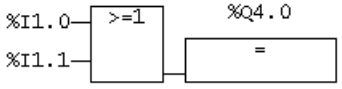


Parameters	Data type	Description
<Operand>	BOOL	Scanned bit

Description

With the **OR** operation, you can scan the signal states of two or more specified operands at the inputs of an OR box. If the signal status of one of the operands is **1**, the condition is fulfilled and the result of the operation is **1**. If the signal status of all operands is **0**, the condition is not fulfilled and the operation returns a result of **0**.

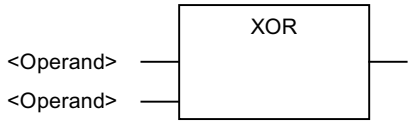
Example



Output %Q 4.0 is set when the signal state at input %I 1.0 OR %I 1.1 is **1**.

XOR EXCLUSIVE OR box

Symbol

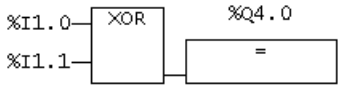


Parameters	Data type	Description
<Operand>	BOOL	Scanned bit

Description

In an **EXCLUSIVE OR** box, the signal state is **1** if the signal state of one of the two specified operands is **1**.

Example



At output %Q 4.0, the signal state is **1** if the signal state is **1** either EXCLUSIVELY at input %I 0.0 OR at input %I 0.1.

--| Inserting a binary input

Symbol

<Operand>

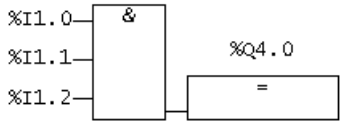
---|

Parameters	Data type	Description
<Operand>	BOOL	Scanned bit

Description

The **Insert binary input** operation inserts a binary input in an AND, OR, or XOR box behind the selection mark.

Example



Output % Q 4.0 is **1** when the state %I 1.0 AND %I 1.1 AND %I 1.2 = 1.

--o| Negating a binary input

Symbol

<Operand>

–o|

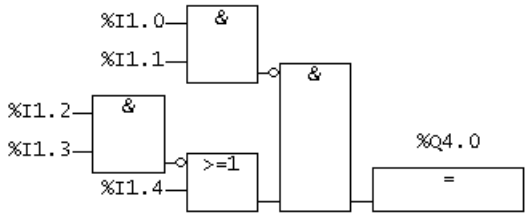
Parameters	Data type	Description
<Operand>	BOOL	Scanned bit

Description

The **Negate binary input** operation negates the signal state.

All binary inputs of any elements can be negated.

Example

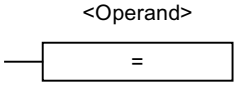


Output %Q 4.0 is **1** if:

- The signal state at %I 1.0 AND %I 1.1 is NOT 1
- AND the signal state at %I 1.2 AND %I 1.3 is NOT 1
- OR the signal state at %I 1.4 = 1.

[=] Assignment

Symbol



Parameters	Data type	Description
<Operand>	BOOL	Assigned bit

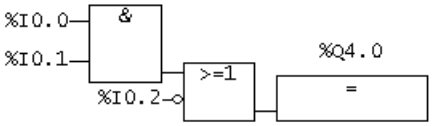
Description

The **Assignment** operation supplies the value. The box at the end of the logic operation carries a signal of 1 or 0 according to the following criteria:

- The output carries a signal of 1 when the conditions of the logic operation are fulfilled before the output box.
- The output carries a signal of 0 when the conditions of the logic operation are not fulfilled before the output box.

The FBD logic operation assigns the signal state to the output that is addressed by the operation. If the conditions of the FBD logic operation are fulfilled, the signal state at the output box is **1**. Otherwise, the signal state is **0**.

Example

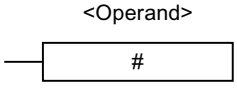


Output %Q 4.0 is **1** if:

- At inputs %I 0.0 AND %I 0.1, the signal state is 1,
- OR %I 0.2 = 0.

[#] Connector (FBD)

Symbol

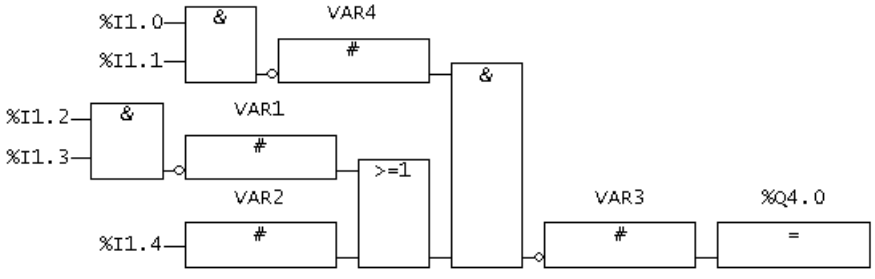


Parameters	Data type	Description
<Operand1>	BOOL	Assigned bit

Description

The **Connector** operation is an intermediate assignment element that stores the signal state. Specifically, this assignment element saves the bit logic of the last opened branch in front of the assignment element.

Example



Connectors store the following logic operation results:

VAR4 saves the negated signal state of

%I1.0

%I1.1

VAR1 saves the negated signal state of

%I1.2

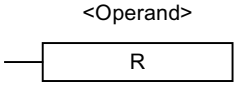
%I1.3

VAR2 saves the negated signal state of %I 1.4.

VAR3 saves the negated signal state of the entire bit logic operation.

[R] Reset assignment (FBD)

Symbol

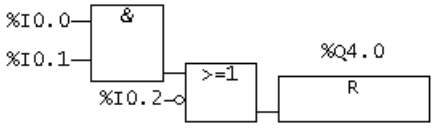


Parameters	Data type	Description
<Operand>	BOOL	Assigned bit

Description

The **Reset assignment** operation then is only performed when the signal state = 1. If the signal state = 1, the specified operand is reset to **0** by the operation. If the signal state = 0, the operation does not affect the specified operand. The operand remains unchanged.

Example



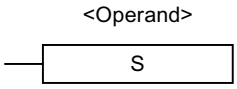
The signal state at output %Q 4.0 is only reset to **0** if:

- The signal state is 1 at inputs %I 0.0 AND %I 0.1
- OR the signal state at input %I 0.2 = 0

If the signal state of the branch = 0, the signal state at output %Q 4.0 is not changed.

[S] Set assignment (FBD)

Symbol

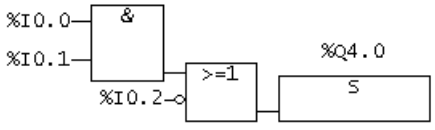


Parameters	Data type	Description
<Operand>	BOOL	Set bit

Description

The **Set assignment** operation is only performed when the signal state = 1. If the signal state = 1, the specified operand is reset to **1** by the operation. If the signal state = 0, the operation does not affect the specified operand. The operand remains unchanged.

Example



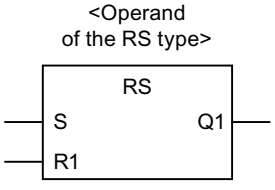
The signal state at output %Q 4.0 is only reset to **1** if:

- The signal state is 1 at inputs %I 0.0 AND %I 0.1
- OR the signal state at input %I 0.2 = 0

If the signal state of the branch = 0, the signal state of %Q 4.0 is not changed.

RS Prioritize reset flipflop

Symbol



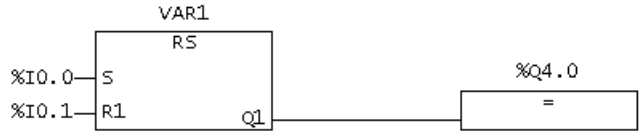
Parameters	Data type	Description
<Operand>	RS	Instance variable of FB type RS
S	BOOL	Enable set
R1	BOOL	Enable reset
Q1	BOOL	Signal state of <address>

Description

The **Prioritize reset flipflop** operation only performs operations such as Set assignment (S) or Reset assignment (R1) if the signal state = 1. A signal state of 0 has no effect on these operations; the operand specified in the operation is not changed.

Prioritize reset flipflop is reset when the signal state at input R1 = 1 and the signal state at input S = 0. The flipflop is set when input R1 = 0 and input S = 1. If the signal state at both inputs is **1**, the flipflop is reset.

Example

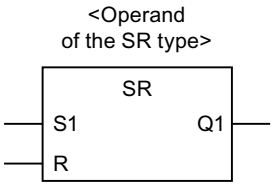


If the state at input %I 0.0 = **1** and at input %I 0.1 = **0**, the variable VAR1 is set and output %Q 4.0 is **1**. Otherwise, if the signal state at input %I 0.0 = **0** and the signal state at input %I 0.1 = **1**, the variable VAR1 is reset and %Q 4.0 is **0**.

If both signal states are **0**, nothing is changed. If both signal states are **1**, the reset operation has priority. VAR1 is reset and %Q 4.0 is **0**.

SR Prioritize set flipflop

Symbol



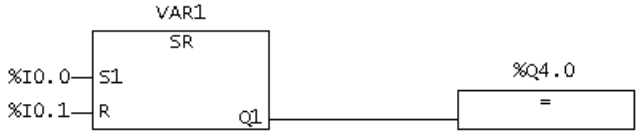
Parameters	Data type	Description
<Operand>	SR	Instance variable from FB type SR
S1	BOOL	Enable set
R	BOOL	Enable reset
Q1	BOOL	Signal state of <address>

Description

The **Prioritize set flipflop** operation only performs operations such as Set (S1) or Reset (R) if the signal state = 1. A signal state of **0** has no effect on these operations; the operand specified in the operation is not changed.

Prioritize set flipflop is set when the signal state at input S1 = 1 and the signal state at input R = 0. The flipflop is reset when input S1 = 0 and input R = 1. If the signal state at both inputs is **1**, the flipflop is set.

Example

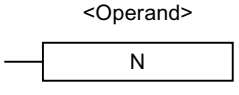


If the state at input %I 0.0 = **1** and at input %I 0.1 = **0**, the variable VAR1 is set and output %Q 4.0 is **1**. Otherwise, if the signal state at input %I 0.0 = 0 and the signal state at input %I 0.1 = 1, the variable VAR1 is reset and %Q 4.0 is **0**.

If both signal states are **0**, nothing is changed. If both signal states are **1**, the set operation has priority. VAR1 is set and %Q 4.0 is **1**.

[N] Scan edge 1 -> 0 (FBD)

Symbol

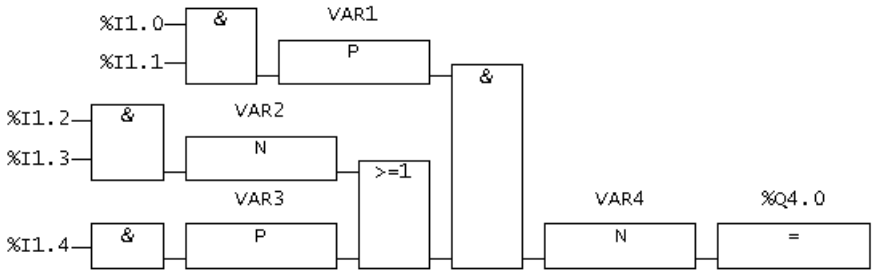


Parameters	Data type	Description
<Operand>	BOOL	N connector bit, saves the previous signal state

Description

The **Scan edge 1 -> 0** recognizes a signal state change in the specified operands from **1** to **0** (falling edge) and displays this after the operation with signal state = 1. The current signal state is compared to the signal state of the operand, the edge variable. If the signal state of the operand is **1** and the signal state before the operation is **0**, then the signal after the operation is **1** (pulse), in all other cases **0**. The signal state before the operation is saved in the operand.

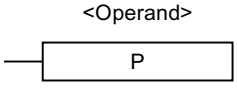
Example



The VAR4 variable saves the signal state.

[P] Scan edge 0 -> 1 (FBD)

Symbol

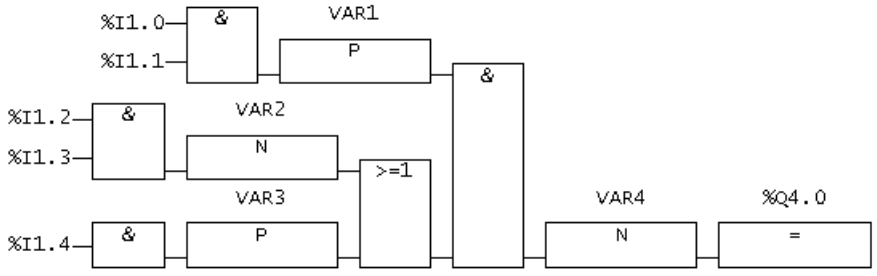


Parameters	Data type	Description
<Operand>	BOOL	P connector bit, saves the previous signal state

Description

The **Scan edge 0 -> 1** recognizes a signal state change in the specified operands from **0** to**1** (rising edge) and displays this after the operation with signal state = 1. The current signal state is compared to the signal state of the operand, the edge variable. If the signal state of the operand is **0** and the signal state before the operation is **1**, then the signal state after the operation is 1, in all other cases **0**. The signal state before the operation is saved in the operand.

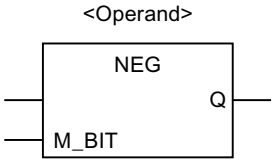
Example



The VAR1 variable saves the signal state.

NEG edge detection (falling)

Symbol

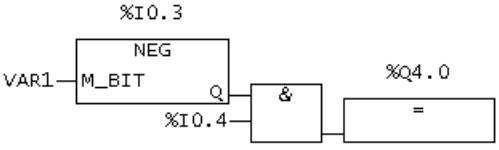


Parameters	Data type	Description
<Operand1>	BOOL	Scanned signal
M_BIT	BOOL	The M-BIT operand indicates the variable in which the previous signal state of NEG is saved.
Q	BOOL	Signal change detection

Description

The **Edge detection** (falling) operation compares the signal state of <Operand1> with the signal state of the previous scan, which is saved in M_BIT. If a change has occurred from **1** to **0**, then output Q = **1**, in all other cases **0**.

Example

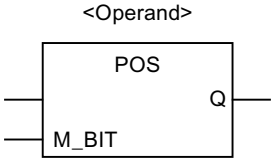


Output %Q 4.0 is **1** if:

- Input %I 0.3 has a falling edge
- AND the signal state at input %I 0.4 = 1.

POS edge detection (rising)

Symbol

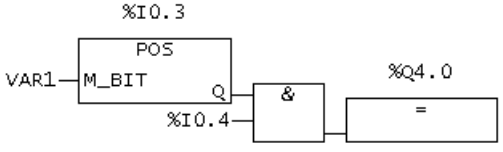


Parameters	Data type	Description
<Operand1>	BOOL	Scanned signal
M_BIT	BOOL	The M-BIT operand indicates the variable in which the previous signal state of POS is saved.
Q	BOOL	Signal change detection

Description

The **Edge detection** (rising) operation compares the signal state of <Operand1> with the signal state of the previous scan, which is saved in M_BIT. If a change has occurred from **0** to **1**, then output Q = **1**, in all other cases **0**.

Example



Output %Q 4.0 is **1** if:

- Input %I 0.3 has a rising edge
- AND the signal state at input %I 0.4 = 1.

7.3.5.3 Relational operators

Overview of comparison operations

Description

The inputs IN1 and IN2 are compared using the following comparison methods:

= IN1 is equal to IN2
<> IN1 is not equal to IN2
> IN1 is greater than IN2
< IN1 is less than IN2
>= IN1 is greater than or equal to IN2
<= IN1 is less than or equal to IN2

The following comparison operation is available:

- CMP comparator

CMP Compare numbers

Icons

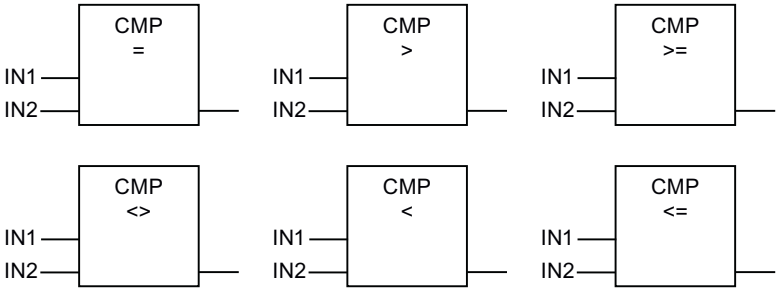


Table 7-559 Parameters for CMP <, CMP > CMP >=, CMP <=

Parameter	Data type	Description
Box output	BOOL	Result of the comparison, processing is only continued if the signal state at the box input = 1.
IN1	ANY_NUM[1] ANY_BIT DATE TIME_OF_DAY (TOD) DATE_AND_TIME (DT) TIME STRING[2]	First comparison value

Parameter	Data type	Description
IN2	ANY_NUM[1] ANY_BIT DATE TIME_OF_DAY (TOD) DATE_AND_TIME (DT) TIME STRING[2]	Second comparison value
The first and second comparison values must be of the same data type, e.g. ANY_NUM and ANY_NUM, DATE and DATE, STRING and STRING. [1] It must be possible to convert both comparison values into the most powerful data type by means of implicit conversion. [2] Variables of the STRING data type can be compared irrespective of the declared length of the string.		

Table 7-560 Parameter for CMP =, CMP <>

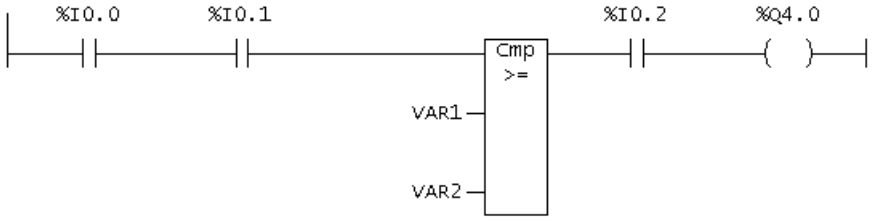
Parameter	Data type	Description
Box output	BOOL	Result of the comparison, processing is only continued if the signal state at the box input = 1.
IN1	ANY_NUM[1] ANY_BIT DATE TIME_OF_DAY (TOD) DATE_AND_TIME (DT) TIME STRING[2] Enumeration[3] Array[3] Structure[3] STRUCTTASKID STRUCTALARMID ANYOBJECT	First comparison value
IN2	ANY_NUM[1] ANY_BIT DATE TIME_OF_DAY (TOD) DATE_AND_TIME (DT) TIME STRING[2] Enumeration[3] Array[3] Structure[3] STRUCTTASKID STRUCTALARMID ANYOBJECT	Second comparison value
The first and second comparison values must be of the same data type, e.g. ANY_NUM and ANY_NUM, DATE and DATE, STRING and STRING. [1] It must be possible to convert both comparison values into the most powerful data type by means of implicit conversion. [2] Variables of the STRING data type can be compared irrespective of the declared length of the string. [3] The data type specifications (see the SIMOTION ST Programming and Operating Manual) must be identical for both comparison values.		

Description

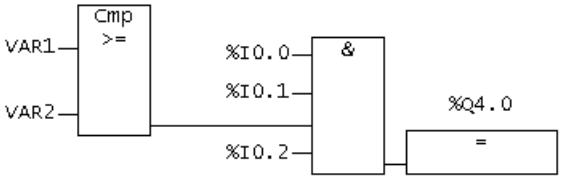
CMP (Compare numbers) can be used like a normal contact. The box can be used at the positions where a normal contact can also be positioned. IN1 and IN2 are compared with the comparison method selected by you.

If the comparison is true, then the value of the operation is **1**. The value of the whole ladder diagram line is linked by AND if the comparison element is connected in series or by OR if the box is connected in parallel.

Example



Representation in the LAD editor



Representation in the FBD editor

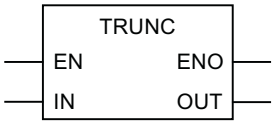
%Q 4.0 is set when:

- VAR1 >= VAR2
- AND the signal state at input %I 0.0 is (1).
  AND the signal state at input %I 0.1 is (1).
  AND the signal state at input %I 0.2 is (1).

7.3.5.4 Conversion instructions

TRUNC Generate integer

Symbol

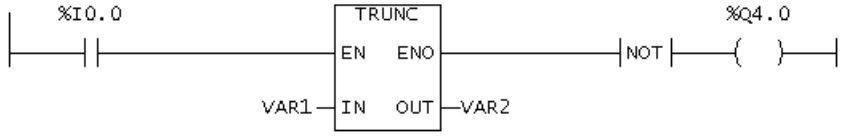


Parameters	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN	ANY_REAL	Number which is to be converted
OUT	ANY_INT	Integral part of the value from IN

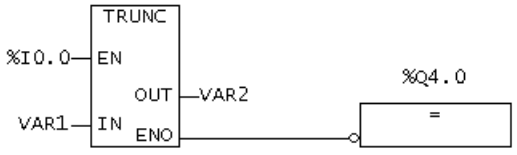
Description

TRUNC (generate integer) reads the contents of the IN parameter as a floating-point number and converts this value to an integer (32-bit). The result is the integral part of the floating-point number which is output by the OUT parameter.

Example



Representation in the LAD editor



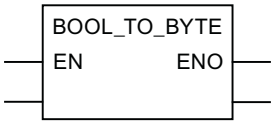
Representation in the FBD editor

If %I 0.0 = 1, the contents of VAR1 are read as a floating-point number and converted to an integer (32-bit). The result is the integral part of the floating-point number which is saved in VAR2.
Output %Q 4.0 is **1** if an overflow occurs or the statement is not processed (%I 0.0 = 0).

Generating numeric data types and bit data types

Symbol

e.g. BOOL_TO_TYPE



Description

You can carry out the explicit data type conversion with the standard functions listed in the tables below.

- Input parameters
  Each function for the conversion of a data type has exactly one input parameter.
- Function value
  The function value is always the return value of the function. The table shows the rules with which a data type can be converted.
- Naming
  Because the data types of the input parameter and the function value come from the respective function name, they are not listed specially in the table "Functions for conversion of numerical data types and bit data types": E.g. with function BOOL_TO_BYTE, the data type of the input parameter is BOOL, the data type of the function value BYTE.

Table 7-561 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
BOOL_TO_BYTE	Accept as least significant bit and fill the rest with 0.	yes
BYTE_TO_BOOL	Accept the least significant bit.	no
BYTE_TO_SINT	Accept bit string as SINT value.	no
BYTE_TO_USINT	Accept bit string as USINT value.	no
BYTE_TO_WORD	Accept least significant bit and fill the rest with 0.	yes

Table 7-562 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
DINT_TO_DWORD	Accept value as bit string.	no
DINT_TO_INT	Cut off two most significant bytes.	no
DINT_TO_LREAL	Accept value.	yes
DINT_TO_REAL	Accept value (accuracy may be lost).	no
DINT_TO_UDINT	Accept value as bit string.	no
DINT_TO_UINT	Cut off two most significant bytes.	no
DINT_TO_WORD	Cut off two most significant bytes.	no

Table 7-563 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
DWORD_TO_DINT	Accept bit string as DINT value.	no
DWORD_TO_INT	Accept the two least significant bytes as INT value.	no
DWORD_TO_REAL	Accept bit string as REAL value (validity check of the REAL number is **not** carried out!).	no
DWORD_TO_UDINT	Accept bit string as UDINT value.	no

Function name	Conversion rule	Implicit okay
DWORD_TO_UINT	Accept the two least significant bytes as UINT value.	no
DWORD_TO_WORD	Accept the two least significant bytes of the bit string.	no

Table 7-564 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
INT_TO_DINT	Accept value.	yes
INT_TO_LREAL	Accept value.	no
INT_TO_REAL	Accept value.	yes
INT_TO_SINT	Cut off the most significant byte.	no
INT_TO_UDINT	Accept value as bit string; the two most significant bytes are filled with the most significant bit of the input parameter.	no
INT_TO_UINT	Accept value as bit string.	no
INT_TO_WORD	Accept value as bit string.	no

Table 7-565 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
LREAL_TO_DINT	Round off to integer part.	no
LREAL_TO_INT	Round off to integer part.	no
LREAL_TO_REAL	Accept value (accuracy may be lost).	no
LREAL_TO_UDINT	Round off to integer part.	no
LREAL_TO_UINT	Round off to integer part.	no

Table 7-566 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
REAL_TO_DINT	Round off to integer part.	no
REAL_TO_DWORD	Accept bit string.	no
REAL_TO_INT	Round off to integer part.	no
REAL_TO_LREAL	Accept value.	yes
REAL_TO_UDINT	Round off to integer part.	no
REAL_TO_UINT	Round off to integer part.	no

Table 7-567 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
SINT_TO_BYTE	Accept bit string.	no
SINT_TO_INT	Accept value.	yes
SINT_TO_USINT	Accept bit string.	no

Table 7-568 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
UDINT_TO_DINT	Accept bit string.	no
UDINT_TO_INT	Cut off numerical sequence (2 most significant bytes).	no
UDINT_TO_DWORD	Accept bit string.	no
UDINT_TO_LREAL	Accept value.	yes
UDINT_TO_REAL	Accept value (accuracy may be lost).	no
UDINT_TO_UINT	Cut off numerical sequence (2 most significant bytes).	no
UDINT_TO_WORD	Cut off numerical sequence (2 most significant bytes).	no

Table 7-569 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
UINT_TO_DINT	Accept value.	yes
UINT_TO_DWORD	Accept bit string, fill rest with zeros.	no
UINT_TO_INT	Accept bit string.	no
UINT_TO_LREAL	Accept value (accuracy may be lost).	no
UINT_TO_REAL	Accept value.	yes
UINT_TO_UDINT	Accept value.	yes
UINT_TO_USINT	Cut off numerical sequence (most significant byte).	no
UINT_TO_WORD	Accept bit string.	no

Table 7-570 Functions for conversion of numerical data types and bit data types

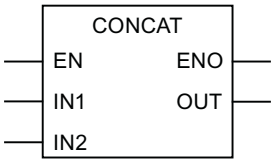
Function name	Conversion rule	Implicit okay
USINT_TO_BYTE	Accept bit string.	no
USINT_TO_INT	Accept value.	yes
USINT_TO_DINT	Accept value.	no
USINT_TO_SINT	Accept bit string.	no
USINT_TO_UINT	Accept value.	yes

Table 7-571 Functions for conversion of numerical data types and bit data types

Function name	Conversion rule	Implicit okay
WORD_TO_BYTE	Cut off most significant byte.	no
WORD_TO_DINT	Accept bit string, fill rest with zeros.	no
WORD_TO_DWORD	Accept the two least significant bytes and fill the rest with 0.	yes
WORD_TO_INT	Accept bit string and interpret this as an integer.	no
WORD_TO_UDINT	Accept bit string, fill rest with zeros.	no
WORD_TO_UINT	Accept bit string.	no

Generating date and time

Symbol



Description

The table below shows the standard functions for date and time data types:

Table 7-572 Standard functions for date and time

Function name	Data type of input parameter	Data type of function value	Description
CONCAT	1: DATE 2: TIME_OF_DAY	DATE_AND_TIME	Compress DATE and TIME_OF_DAY to DATE_AND_TIME.
DT_TO_TOD	DATE_AND_TIME	TIME_OF_DAY	Accept time of day.
DT_TO_DATE	DATE_AND_TIME	DATE	Accept date.

Note

Data type TIME can be converted to numerical data types as follows:

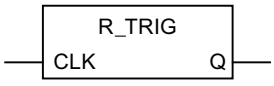
- To data type UDINT:
  Divide it by a standardization factor of data type TIME.
  Multiply the reconversion by the same standardization factor.

7.3.5.5 Edge detection

System function block R_TRIG can be used to detect a rising edge; F_TRIG can detect a falling edge. You can use this function, for example, to set up a sequence of your own function blocks.

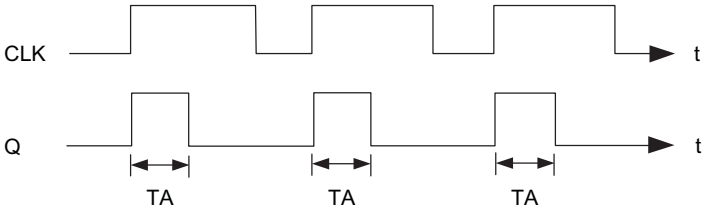
Detection of rising edge R_TRIG

Symbol



Description

If a rising edge (R_TRIG, Rising Trigger), i.e. a status change from 0 to 1, is present at the input, 1 is applied at the output for the duration of one cycle.



TA Cycle time

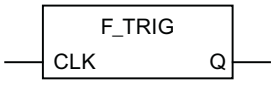
Figure 7-507 Mode of operation of R_TRIG (rising edge) function block

Table 7-573 Call parameters for R_TRIG

Identifier	Parameter	Data type	Description
CLK	Input	BOOL	Input for edge detection
Q	Output	BOOL	Status of edge

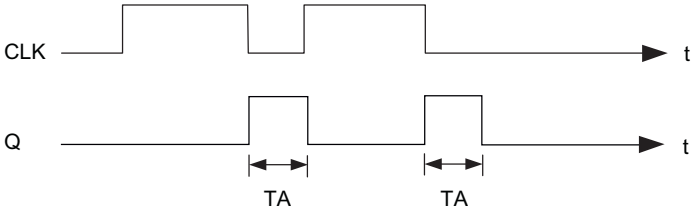
Detection of falling edge F_TRIG

Symbol



Description

When a falling edge (F_TRIG, falling trigger), i.e. a status change from 1 to 0, occurs at the input, the output is set to 1 for the duration of one cycle time.



TA Cycle time

Figure 7-508 Mode of operation of F_TRIG (falling edge) function block

Table 7-574 Call parameters for F_TRIG

Identifier	Parameter	Data type	Description
CLK	Input	BOOL	Input for edge detection
Q	Output	BOOL	Status of edge

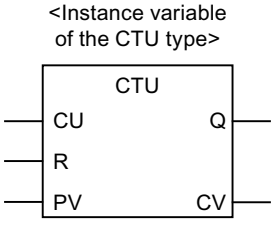
7.3.5.6 Counter operations

Overview of counter operations

Every call-up of the function block and the function should be recorded in a counter.

CTU up counter

Symbol



Description

The CTU counter allows you to perform upward counting operations:

- If the input is R = TRUE when the FB is called up, then the CV output is reset to 0.
- If the CU input changes from FALSE to TRUE (0 to 1) when the FB is called (positive edge), then the CV output is incremented by 1.
- Output Q specifies whether CV is greater than or equal to comparison value PV.

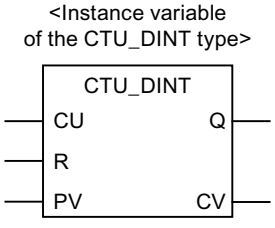
The CV and PV parameters are both INT data types, which means that the maximum counter reading possible is 32767 (= 16#7FFF).

Table 7-575 Parameters for CTU

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (positive edge)
R	Input	BOOL	Reset the counter to 0
PV	Input	INT	Comparison value
Q	Output	BOOL	Status of counter (CV >= PV)
CV	Output	INT	Counter value

CTU_DINT up counter

Symbol



Description

The method of operation is the same as for the CTU incrementer except for the following:

The CV and PV parameters are both DINT data types, which means that the maximum counter reading possible is 2147483647 (= 16#7FFF_FFFF).

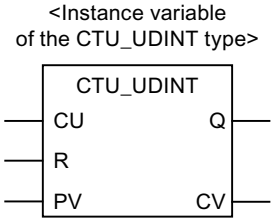
Table 7-576 Parameters for CTU_DINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (positive edge)
R	Input	BOOL	Reset the counter to 0

Identifier	Parameter	Data type	Description
PV	Input	DINT	Comparison value
Q	Output	BOOL	Status of counter (CV >= PV)
CV	Output	DINT	Counter value

CTU_UDINT up counter

Symbol



Description

The method of operation is the same as for the CTU incrementer except for the following:

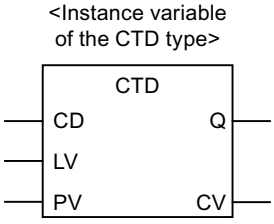
The CV and PV parameters are both UDINT data types, which means that the maximum counter reading possible is 4294967295 (=16# FFFF_FFFF).

Table 7-577 Parameters for CTU_UDINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (positive edge)
R	Input	BOOL	Reset the counter to 0
PV	Input	UDINT	Comparison value
Q	Output	BOOL	Status of counter (CV >= PV)
CV	Output	UDINT	Counter value

CTD down counter

Symbol



Description

The CTD counter allows you to perform downward counting operations.

- If the LD input = TRUE when the FB is called, then the CV output is reset to start value PV.
- If the CD input changes from FALSE to TRUE (0 to 1) when the FB is called (positive edge), then the CV output is decremented by 1.
- Output Q specifies whether CV is less than or equal to 0.

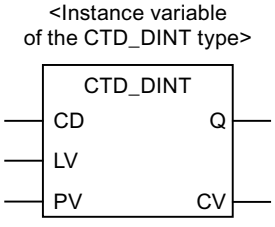
The CV and PV parameters are both INT data types, which means that the minimum counter reading possible is -32,768 (= 16#8000).

Table 7-578 Parameters for CTD

Identifier	Parameter	Data type	Description
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (positive edge)
LD	Input	BOOL	Reset the counter to start value
PV	Input	INT	Start value of counter
Q	Output	BOOL	Status of counter (CV <= 0)
CV	Output	INT	Counter value

CTD_DINT down counter

Symbol



Description

The method of operation is the same as for the CTD up counter except for the following:

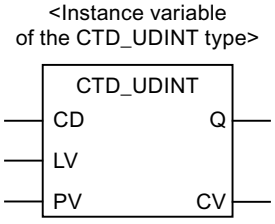
The CV and PV parameters are both DINT data types, which means that the minimum counter reading possible is -2147483648 (= 16#8000_0000).

Table 7-579 Parameters for CTD_DINT

Identifier	Parameter	Data type	Description
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (positive edge)
LD	Input	BOOL	Reset the counter to start value
PV	Input	DINT	Start value of counter
Q	Output	BOOL	Status of counter (CV <= 0)
CV	Output	DINT	Counter value

CTD_UDINT down counter

Symbol



Description

The method of operation is the same as for the CTD up counter except for the following:

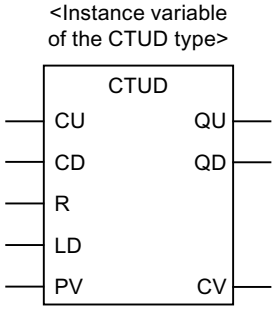
The CV and PV parameters are both UDINT data types, which means that the minimum counter value possible is 0.

Table 7-580 Parameters for CTD_DINT

Identifier	Parameter	Data type	Description
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (positive edge)
LD	Input	BOOL	Reset the counter to start value
PV	Input	UDINT	Start value of counter
Q	Output	BOOL	Status of counter (CV <= 0)
CV	Output	UDINT	Counter value

CTUD up/down counter

Symbol



Description

The CTUD counter allows you to perform both upward and downward counting operations.

- Reset the CV count variable:
  - If the input is R = TRUE when the FB is called up, then the CV output is reset to 0.
  - If the LD input = TRUE when the FB is called, then the CV output is reset to start value PV.
- Count:
  - If the CU input changes from FALSE to TRUE (0 to 1) when the FB is called (positive edge), then the CV output is incremented by 1.
  - If the CD input changes from FALSE to TRUE (0 to 1) when the FB is called up (positive edge), then the CV output is decremented by 1.
- Counter status QU or QD:
  - Output Q specifies whether CV is greater than or equal to comparison value PV.
  - Output QD specifies whether CV is less than or equal to 0.

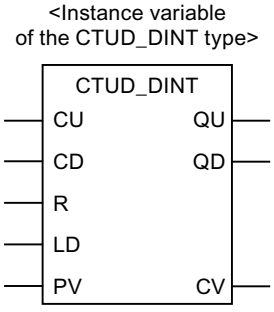
Table 7-581 Parameters for CTUD

Identifier	Parameters	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (positive edge)
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (positive edge)
R	Input	BOOL	Reset the counter to 0 (up counter)
LD	Input	BOOL	Reset the counter to PV start value (down counter)
PV	Input	INT	Comparison value (for up counter) Start value (for down counter)
QU	Output	BOOL	Status as up counter (CV >= PV)

Identifier	Parameters	Data type	Description
QD	Output	BOOL	Status as down counter (CV <= 0)
CV	Output	INT	Counter value

CTUD_DINT up/down counter

Symbol



Description

The method of operation is the same as for the CTUD up counter except for the following:

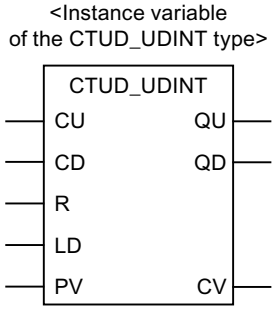
The CV and PV parameters are both DINT data types.

Table 7-582 Parameters for CTD_DINT

Identifier	Parameters	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (positive edge)
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (positive edge)
R	Input	BOOL	Reset the counter to 0 (up counter)
LD	Input	BOOL	Reset the counter to PV start value (down counter)
PV	Input	DINT	Comparison value (for incrementer) Start value (for decrementer)
QU	Output	BOOL	Status as up counter (CV >= PV)
QD	Output	BOOL	Status as down counter (CV <= 0)
CV	Output	DINT	Counter value

CTUD_UDINT up/down counter

Symbol



Description

The method of operation is the same as for the CTUD up counter except for the following:

The CV and PV parameters are both UDINT data types.

Table 7-583 Parameters for CTD_DINT

Identifier	Parameter	Data type	Description
CU	Input	BOOL	Count up if value changes from FALSE to TRUE (positive edge)
CD	Input	BOOL	Count down if value changes from FALSE to TRUE (positive edge)
R	Input	BOOL	Reset the counter to 0 (up counter)
LD	Input	BOOL	Reset the counter to PV start value (down counter)
PV	Input	UDINT	Comparison value (for incrementer) Start value (for decrementer)
QU	Output	BOOL	Status as up counter (CV >= PV)
QD	Output	BOOL	Status as down counter (CV <= 0)
CV	Output	UDINT	Counter value

7.3.5.7 Jump instructions

Overview of jump operations

Description

Jump operations can be used in all logic blocks, e.g. programs, function blocks (FBs), and functions (FCs).

Jump label as operand

The operand of a jump operation is a jump label. The jump label specifies the point to where the program is to jump.

Enter the jump label via the JMP coil. The jump label consists of up to 480 characters. The first character must be a letter, the other characters can be either letters or numbers (e.g. SEG3).

Jump label as target

The target jump label can be at the start of a network.

See also

Showing/hiding a jump label (Page 5131)

---(JMP) Jump in block if 1 (conditional)

Symbol

<jump label>

---(JMP)

Description

---(JMP) (Jump in block if 1) functions as a conditional jump if the pending signal of the previous logic operation is **1**.

There must also be a target (LABEL) for every ---(JMP).

The operations between the jump operation and the jump label are not executed!

Note

An unconditional jump is created by hanging the --(JMP) element directly on the power rail.

---(JMPN) Jump in block if 0 (conditional)

Symbol

<jump label>

---(JMPN)

Description

---(JMPN) (Jump in block if 0) functions as a conditional jump if the pending signal of the previous logic operation is **0**.

There must also be a target (LABEL) for every ---(JMPN).

The operations between the jump operation and the jump label are not executed!

LABEL Jump label

Symbol

Description

LABEL marks the target of a jump operation. It can have a maximum of 80 characters. The first character must be a letter, the other characters can be letters or numbers, e.g. CAS1.

There must be a target (LABEL) for every ---(JMP) or ---(JMPN).

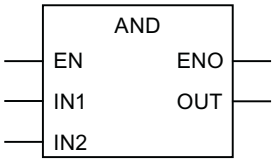
Note

Only alphanumeric characters are allowed during input. The jump label is deleted if it contains an error and cannot be corrected.

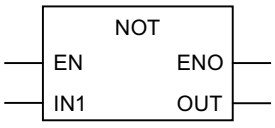
7.3.5.8 Non-binary logic

Symbol

e.g. AND



e.g. NOT



Description

Logic operations (AND, OR, XOR, NOT) are also provided as boxes with EN/ENO for non-binary values in the LAD/FBD editor.

The logical operations are listed in the table below.

There is only one operand for **NOT**.

Note

In the Command library tab of the project navigator, the elements **AND**, **XOR**, and **OR, NOT** are represented in the **Logic** entry.

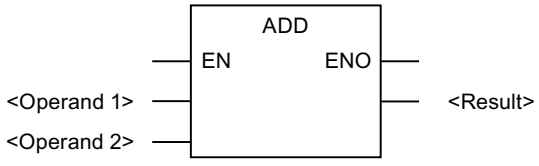
Table 7-584 Non-binary logic

Operator Parameters	AND	XOR	OR	NOT
IN1	ANY_BIT	ANY_BIT	ANY_BIT	ANY_BIT
IN2	ANY_BIT	ANY_BIT	ANY_BIT	
EN	BOOL	BOOL	BOOL	BOOL
ENO	BOOL	BOOL	BOOL	BOOL
OUT	ANY_BIT	ANY_BIT	ANY_BIT	ANY_BIT

7.3.5.9 Arithmetic operators

Symbol

e.g. addition



Description

An arithmetic expression is composed of arithmetic operators. These expressions allow numerical data types to be processed.

The divide operators DIV and MOD require that the second operand is not equal to zero.

Note

In the Command library tab of the project navigator, the elements **ADD**, **SUB**, **MUL**, and **DIV** are represented as **+**, **-**, *****, and **/**.

The execution of a network, for example, is simply aborted in the event of an overflow, and the relevant/assigned event-triggered task (ExecutionFaultTask) is started.

The table below contains a list of the arithmetic operators:

Table 7-585 Arithmetic operators

Instruction	Operator	1. Operand (IN1)	2. Operand (IN2)	Result (OUT)
Addition	ADD	ANY_NUM	ANY_NUM	ANY_NUM[1]
		BYTE	BYTE	BYTE
		WORD	WORD	WORD
		DWORD	DWORD	DWORD
		TIME	TIME	TIME[2]
		TOD	TIME	TOD[2]
		DT	TIME	DT[3]
Multiplication	MUL	ANY_NUM	ANY_NUM	ANY_NUM[1]
		BYTE	BYTE	BYTE
		WORD	WORD	WORD
		DWORD	DWORD	DWORD
		TIME	ANY_INT	TIME
Subtraction	SUB	ANY_NUM	ANY_NUM	ANY_NUM[1]
		BYTE	BYTE	BYTE
		WORD	WORD	WORD
		DWORD	DWORD	DWORD
		TIME	TIME	TIME
		TOD	TIME[4]	TOD
		TOD	TOD	TIME[5]
		DT	TIME	DT
		DT	DT	TIME[5]
Division	DIV	ANY_NUM	ANY_NUM[6]	ANY_NUM[1]
		BYTE	BYTE[6]	BYTE
		WORD	WORD[6]	WORD
		DWORD	DWORD[6]	DWORD
		TIME	ANY_INT[6]	TIME
		TIME	TIME[6]	UDINT
Modulo division.	MOD	ANY_INT	ANY_INT[6]	ANY_INT[1]
		BYTE	BYTE[6]	BYTE
		WORD	WORD[6]	WORD
		DWORD	DWORD[6]	DWORD

[1] The data types of the operands and of the result must be identical.

[2] Addition, possibly with overflow.

[3] Addition with date correction.

[4] Restriction of TIME to TOD before calculation.

[5] These operations are based on the modulo of the maximum value of the TIME data type.

[6] The second operand must not be equal to zero.

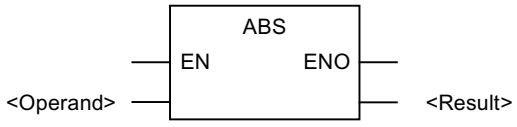
7.3.5.10 Numeric standard functions

Every numeric standard function has an input parameter. The result is always the function value.

General numeric standard functions

Symbol

e.g. absolute value



Description

General numeric standard functions are used for:

- Calculation of the absolute value of a variable
- Calculation of the square root of a variable

The table below shows the general numeric standard functions:

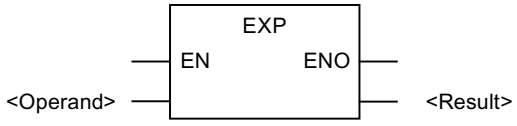
Table 7-586 General numeric standard functions

Function name	Input parameter data type (IN)	Function value data type (OUT)	Description
ABS	ANY_NUM	ANY_NUM[1]	Absolute value
SQRT	ANY_REAL	ANY_REAL[1]	Square root
[1] Identical to the data type of the input parameter IN			

Logarithmic standard functions

Symbol

e.g. exponential value



Description

Logarithmic standard functions are functions for calculating an exponential value or a logarithm of a value.

The table below shows the logarithmic standard functions:

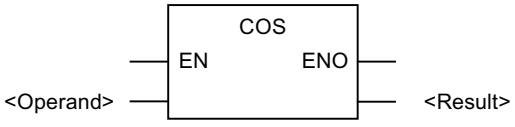
Table 7-587 Logarithmic standard functions

Function name	Input parameter data type (IN)	Data type of function value (OUT)	Description
EXP	ANY_REAL	ANY_REAL[1]	e^x (natural exponential function)
EXPD	ANY_REAL	ANY_REAL[1]	10^x (decimal exponential function)
EXPT	ANY_REAL (IN1) ANY_NUM (IN2)	ANY_REAL[2]	Exponentiation
LN	ANY_REAL	ANY_REAL[1]	Natural logarithm
LOG	ANY_REAL	ANY_REAL[1]	Common logarithm
[1] Identical to the data type of the input parameter IN [2] Identical to the data type of the input parameter IN1			

Trigonometric standard functions

Symbol

e.g. COS



Description

The trigonometric standard functions listed in the table expect and calculate variables of angles in radian measure.

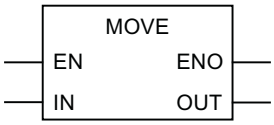
Table 7-588 Trigonometric standard functions

Function name	Input parameter data type	Data type of function value	Description
ACOS	ANY_REAL	ANY_REAL	Arc cosine (main value)
ASIN	ANY_REAL	ANY_REAL	Arc sine (main value)
ATAN	ANY_REAL	ANY_REAL	Arc tangent (main value)
COS	ANY_REAL	ANY_REAL	Cosine (radian measure input)
SIN	ANY_REAL	ANY_REAL	Sine (radian measure input)
TAN	ANY_REAL	ANY_REAL	Tangent (radian measure input)

7.3.5.11 Move

MOVE Transfer value

Symbol



Parameters	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN	ANY	Source value
OUT	ANY	Destination address

Description

MOVE (Assign a value) is activated by the enable input EN. The value specified by the IN input is copied to the value specified in the OUT output. ENO has the same signal state as EN.

7.3.5.12 Shifting operations

Overview of shifting operations

Description

The contents of input IN can be moved bit-by-bit to the left or right using shifting operations. A shift of n bits to the left multiplies the contents of input IN by 2 to the power of n; a shift of n bits to the right divides the contents of input IN by 2 to the power of n. If, for example, you move the binary equivalent of the decimal value 3 by 3 bits to the left, this gives the binary equivalent of the decimal value 24. Shift the binary equivalent of the decimal value 16 by 2 bits to the right, this gives the binary equivalent of the decimal value 4.

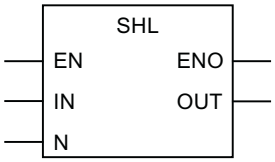
The number that you specify at input N indicates the number of bits by which to shift. The places which become free as a result of the shifting operation are filled up with zeroes.

The following shifting operations are available:

- shift bit to the left
- shift bit to the right

SHL Shift bit to the left

Symbol



Parameters	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN	ANY_BIT	Value to be shifted
N	USINT	Number of bit positions to be shifted
OUT	ANY_BIT	Result of shifting operation

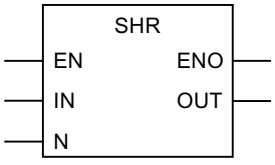
Description

SHL (e.g. shift left by 32 bits) is activated if the enable input (EN) has the signal state **1**. The operation SHL shifts the bits 0 to 31 of the input IN bit-by-bit to the left. Input N specifies the number of bit positions to be shifted. If N is greater than 32, the command writes a **0** in the OUT output. The same number (N) of zeros is shifted from the right in order to occupy the positions which have become free. The result of the shifting operation can be queried at output OUT.

ENO has the same signal state as EN.

SHR Shift bit to the right

Symbol



Parameters	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN	ANY_BIT	Value to be shifted
N	USINT	Number of bit positions to be shifted
OUT	ANY_BIT	Result of shifting operation

Description

SHR (e.g. shift right by 32 bits) is activated if the enable input (EN) has the signal state **1**. The operation SHR shifts the bits 0 to 31 of the input IN bit-by-bit to the right. Input N specifies the number of bit positions to be shifted. If N is greater than 32, the command writes a **0** in the OUT output. The same number (N) of zeros is shifted from the left in order to occupy the positions which have become free. The result of the shifting operation can be queried at output OUT.

ENO has the same signal state as EN.

7.3.5.13 Rotating operations

Overview of rotating operations

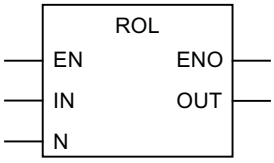
Description

The entire contents of input IN can be rotated bit-by-bit to the left or right using rotating operations. The positions which become free are filled up with the signal states of the bits which have been moved out of the IN input.

At the input N you can specify the number of bits for the rotation.

ROL Rotate bit to the left

Symbol



Parameters	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN	ANY_BIT	Value to be rotated
N	USINT	Number of bit positions to be rotated
OUT	ANY_BIT	Result of rotation operation

Description

ROL (e.g. rotate left by 32 bits) is activated if the enable input (EN) has the signal state **1**. The operation ROL rotates the entire contents of the IN input bit-by-bit to the left. Input N specifies the number of bit positions by which to rotate. If N is greater than 32, the double word IN is rotated by ((N-1) modulo 32)+1 positions. The bit positions coming from the right are occupied with the signal state of the bits which have been rotated to the left (left rotation). The result of the rotation operation can be queried at output OUT.

ENO has the same signal state as EN.

Example

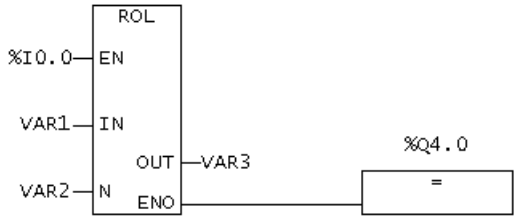


Figure 7-509 Representation in the FBD editor

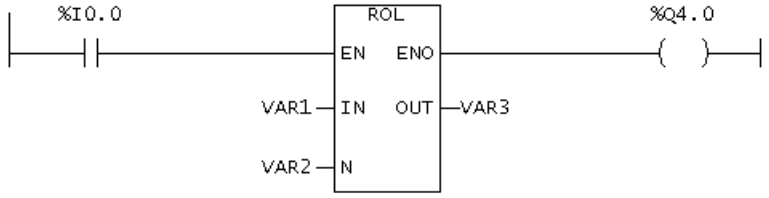

Figure 7-510 Representation in the LAD editor

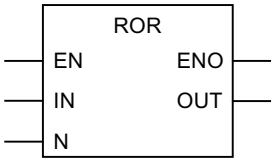
The ROL box is executed if %I 0.0 = 1. VAR1 is loaded and rotated to the left by the number of bits specified in VAR2. The result is written to VAR3. %Q 4.0 is set.

ROR Rotate bit to the right

Symbol



Parameter	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN	ANY_BIT	Value to rotate
N	USINT	Number of bit positions to rotate
OUT	ANY_BIT	Result of rotation operation

Description

ROR (e.g. rotate right by 32 bits) is activated if the enable input (EN) has the signal state **1**. The operation ROR rotates the entire contents of the IN input bit-by-bit to the right. Input N specifies the number of bit positions by which to rotate. If N is greater than 32, the double word IN is rotated by ((N-1) modulo 32)+1 positions. The bit positions coming from the left are occupied by the signal state of the bits which have been rotated to the right (right rotation). The result of the rotation operation can be queried at output OUT.

ENO has the same signal state as EN.

Example

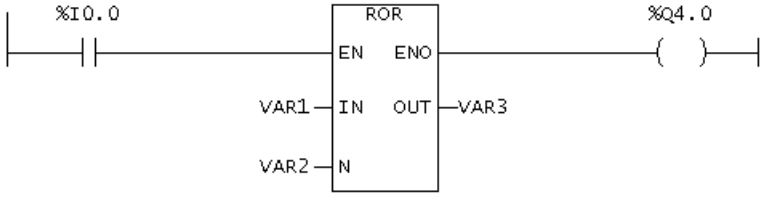


Figure 7-511 Representation in the LAD editor

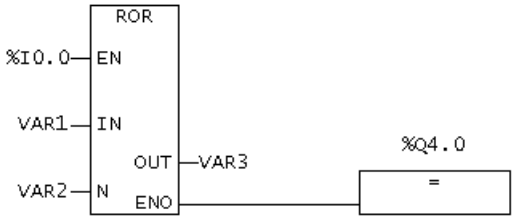

Figure 7-512 Representation in the FBD editor

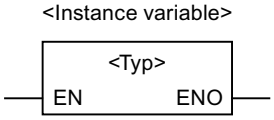
The ROR box is executed if %I 0.0 = 1. VAR1 is loaded and rotated to the right by the number of bits specified in VAR2. The result is written to VAR3. %Q 4.0 is set.

7.3.5.14 Program control instructions

Calling up an empty box

Symbol



Parameters	Data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output

Parameters	Data type	Description
<Type>	FB / FC	FC/FB type
<Instance variable>	FB	FB instance variable

Description

The symbol for an empty box depends on the function block/function (according to how many parameters there are). EN, ENO and the name of the FB/FC must be available.

You do not have to specify EN/ENO in the variable declaration. The input and output are automatically allocated by the system.

The EN input can be used to inhibit a block call and redirect the block of the EN input to the ENO output.

It is not possible to control the ENO output in the block itself.

Note

You can use an empty box to insert a call (Page 5137). As soon as you enter the type, the box transforms and displays the parameters of the specified FB/FC call.

See also

Inserting LAD/FBD elements (Page 5137)

RET Jump back

Symbol

---(RET)

Description

RET (jump back) is used for the conditional exit from blocks. A preceding logic operation is necessary for this output.

Example

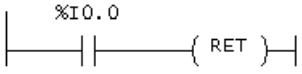


Figure 7-513 Representation in the LAD editor

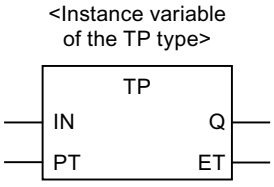
Figure 7-514 Representation in the FBD editor

The operation is executed if %I 0.0 = 1.

7.3.5.15 Timer instructions

TP pulse

Symbol



Description

With a signal state change from 0 to 1 at the IN input, time ET is started. Output Q remains at 1 until elapsed time ET is equal to programmed time value PT. As long as time ET is running, the IN input has no effect.

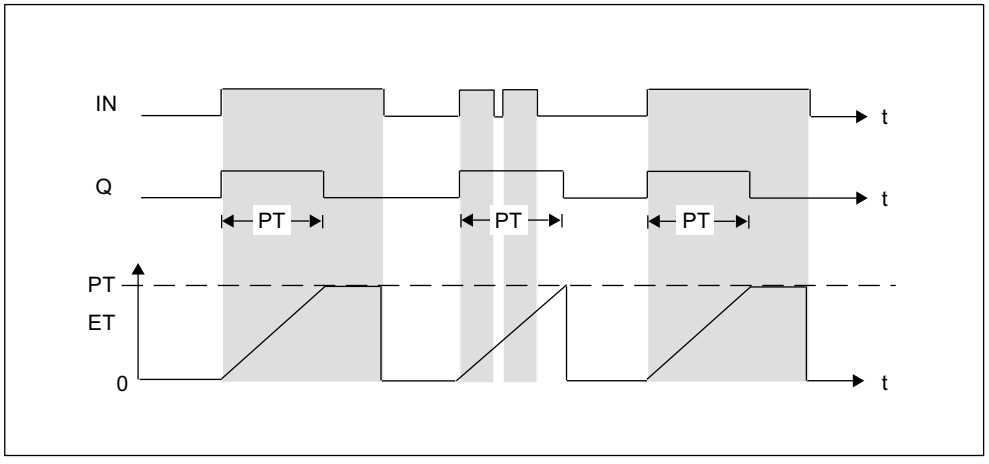


Figure 7-515 Mode of operation of TP pulse timer

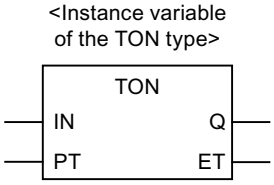
Table 7-589 Call parameters for TP

Identifier	Parameters	Data type	Description
IN	Input	Input	Start input
PT	Input	TIME	Duration of pulse
Q	Output	BOOL	Status of time
ET	Output	TIME	Elapsed time

TON ON delay

Symbol



Description

With the signal state change from 0 to 1 at the IN input, time ET is started. The output signal Q only changes from 0 to 1 if the time ET = PT has elapsed and the input signal IN still has the value 1, i.e. the output Q is switched on with a delay. Input signals of shorter durations than programmed time PT do not appear at the output.

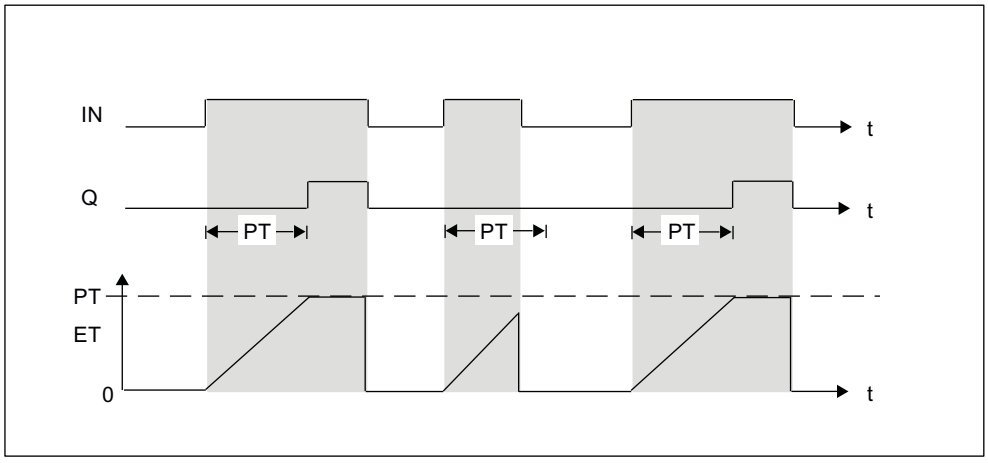


Figure 7-516 Mode of operation of TON on delay timer

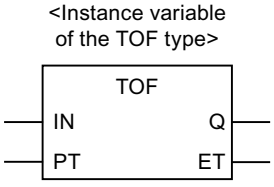
Table 7-590 Call parameters for TON

Identifier	Parameters	Data type	Description
IN	Input	BOOL	Start input
PT	Input	TIME	Duration for which the rising edge at input IN is delayed.
Q	Output	BOOL	Status of time
ET	Output	TIME	Elapsed time

TOF OFF delay

Symbol



Description

With a signal state change from 0 to 1 at start input IN, state 1 appears at output Q. If the state at the start input IN changes from 1 to 0, then time ET is started. If a change occurs at input IN from 0 to 1 before time ET has elapsed, then the timer operation is reset. A start is initiated again when the state at input IN changes from 1 to 0. Only after the duration ET = PT has elapsed does output Q adopt a signal state of 0. This means that the output is switched off with a delay.

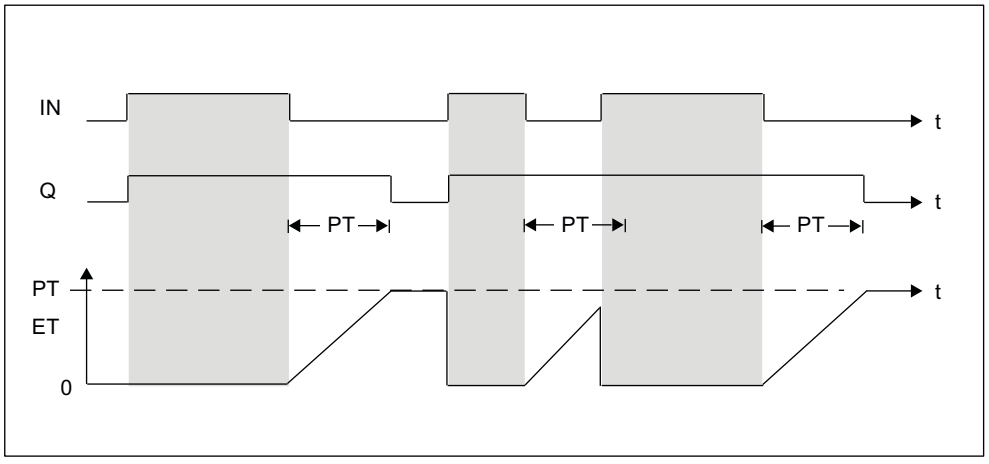


Figure 7-517 Mode of operation of TOF off delay timer

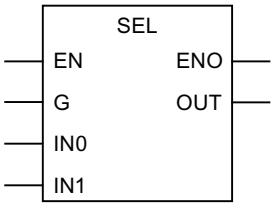
Table 7-591 Call parameters for TOF

Identifier	Parameters	Data type	Description
IN	Input	BOOL	Start input
PT	Input	TIME	Duration for which the falling edge at input IN is delayed.
Q	Output	BOOL	Status of time
ET	Output	TIME	Elapsed time

7.3.5.16 Selection functions

SEL Binary selection

Symbol



Parameters	Input parameter data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
G	BOOL	Input parameter
IN0	ANY	Input parameter
IN1	ANY	Input parameter

Description

The function value is one of the input parameters IN0 or IN1, depending on the value of the input parameter G.

The input parameters IN0 and IN1 must be the same data type or must be capable of implicit conversion into the same data type.

The return value is data type ANY.

Selected input parameter

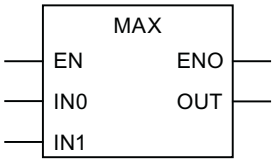
IN0 if G = 0 (FALSE)

IN1 if G = 1 (TRUE)

The data type corresponds to the common data type of the input parameters IN0 and IN1.

MAX Maximum function

Symbol



Parameter	Input parameter data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN0	ANY_ELEMENTARY	Input parameter
IN1	ANY_ELEMENTARY	Input parameter

Description

The function value is the maximum value of both input parameters IN0 and IN1.

The input parameters IN0 and IN1 must be the same data type or must be capable of implicit conversion into the most powerful data type.

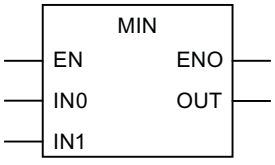
The return value is of data type ANY_ELEMENTARY.

Maximum of the input parameters.

The data type corresponds to the most powerful data type of the input parameters IN0 and IN1.

MIN Minimum function

Symbol



Parameter	Input parameter data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
IN0	ANY_ELEMENTARY	Input parameter
IN1	ANY_ELEMENTARY	Input parameter

Description

The function value is the minimum value of both input parameters IN0 and IN1.

All IN0 and IN1 input parameters must be the same data type or capable of implicit conversion into the most powerful data type.

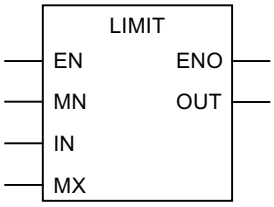
The return value is of data type ANY_ELEMENTARY.

Minimum of the input parameters.

The data type corresponds to the most powerful data type of the input parameters IN0 and IN1.

LIMIT Limiting function

Symbol



Parameters	Input parameter data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
MN	ANY_ELEMENTARY	Input parameter Lower limiting value
IN	ANY_ELEMENTARY	Input parameter Value to be limited
MX	ANY_ELEMENTARY	Input parameter Upper limiting value

Description

The input parameter IN is limited to values lying between the lower limit value MN and the upper limit value MX.

All input parameters must be the same data type or capable of conversion into the most powerful data type by implicit conversion.

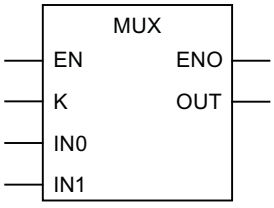
The return value is of data type ANY_ELEMENTARY.

MIN (MAX (IN, MN), MX)

The data type corresponds to the most powerful data type of the input parameters.

MUX Multiplex function

Symbol



Parameters	Input parameter data type	Description
EN	BOOL	Enable input
ENO	BOOL	Enable output
C	ANY_INT	Input parameter
IN0	ANY	Input parameter
IN1	ANY	Input parameter

Description

The function value is one of the two input parameters IN0 or IN1, depending on the value of the input parameter K.

The input parameters IN0 and IN1 must be the same data type or must be capable of implicit conversion into the same data type.

The return value is data type ANY.

The data type corresponds to the common data type of the input parameters IN0 and IN1.

7.3.6 Commissioning (software)

7.3.6.1 Commissioning

This chapter describes how to assign created programs to the task system of a control unit and how to download them to the target system.

7.3.6.2 Assigning programs to a task

Programs must be assigned to a task before they can be downloaded to the target system (the SIMOTION device).

Various tasks are made available by SIMOTION, each with different priorities or system responses (e.g. during initialization).

Further information can be found in the SIMOTION SCOUT Basic Functions Function Manual, and in SIMOTION online help.

Assigning programs to a task:

1. In the project navigator, double-click under the corresponding SIMOTION device the **EXECUTION SYSTEM** element.
   The configuration window for the execution system opens.
2. Select the required task (e.g. MotionTask_1) from the left pane.
3. Select the **Program assignment** tab.
4. Select the program to be assigned from the **Programs** list.

5. Click the button **>>**.
6. Select the **Task configuration** tab to specify additional settings for the task if required.

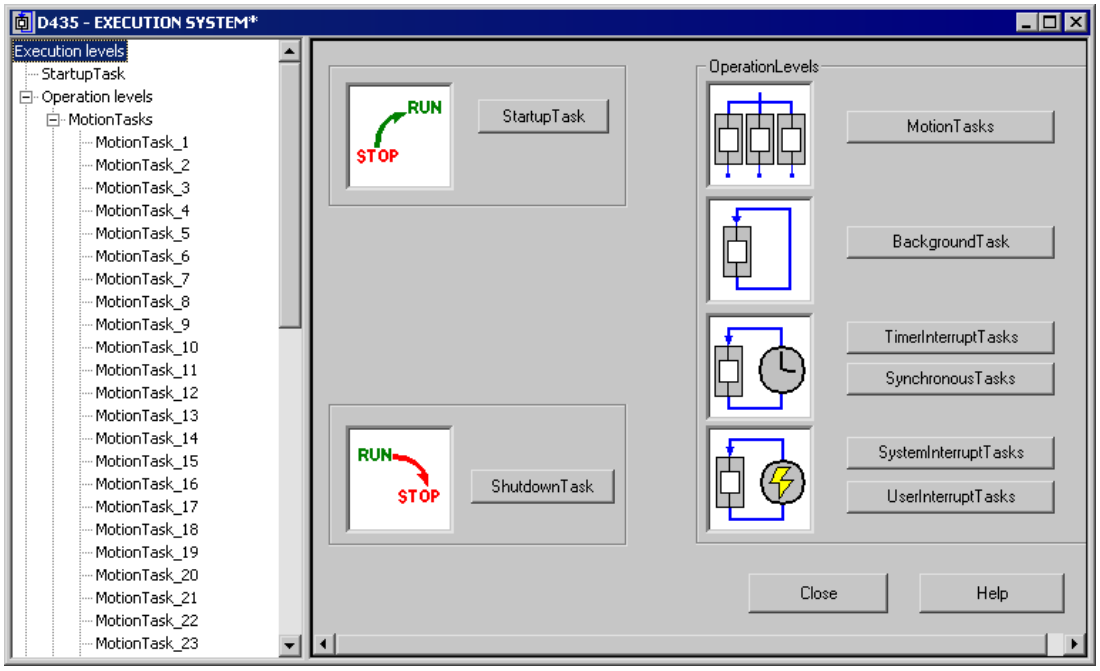


Figure 7-518 Configure execution system

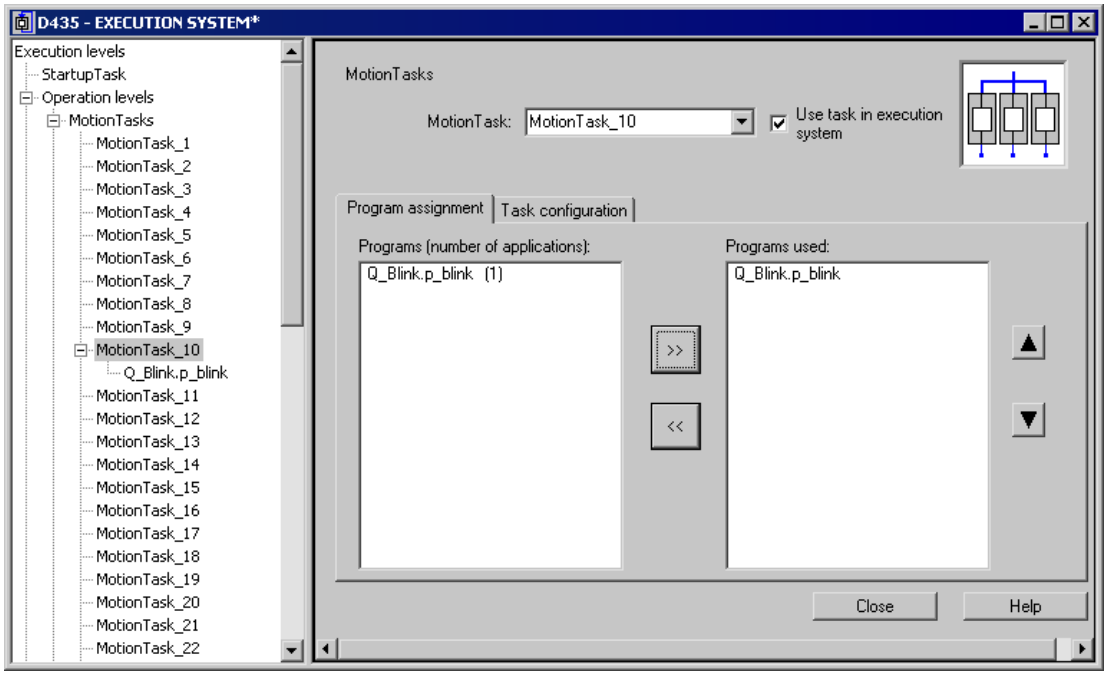

Figure 7-519 Assigning a program to a motion task

7.3.6.3 Execution levels and tasks in SIMOTION

Here the execution levels and the tasks assigned are shown in tabular format for an initial overview.

Further information on execution levels and tasks can be found in the SIMOTION Basic Functions Function Manual.

Table 7-592 Description of the execution levels and of the tasks

Execution level	Description
Time-controlled	Cyclic tasks: They are restarted automatically once the assigned programs have been executed.
• SynchronousTasks	Tasks are started periodically, synchronous with specified system cycle clock. • ServoTask_Fast: Synchronous with Servo_fast cycle clock. The Servo_fast cycle clock is a second servo cycle clock and only available: – For D445-2 DP/PN and D455-2 DP/PN as of version V4.2 – For D435-2 DP/PN as of version V4.3. • ServoSynchronousTask: Synchronous with the position control cycle clock • IpoTask_Fast: Synchronous with IPO_fast cycle clock. The IPO_fast cycle clock is the IPO cycle clock for the second servo cycle clock and only available: – For D445-2 DP/PN and D455-2 DP/PN as of version V4.2 – For D435-2 DP/PN as of version V4.3. • IPOsynchronousTask: Synchronous with interpolator cycle clock IPO • IPOsynchronousTask_2: Synchronous with interpolator cycle clock IPO_2 • PWMsynchronousTask: Synchronous with PWM cycle clock (for TControl technology package) • InputSynchronousTask_1: Synchronous with Input1 cycle clock (for TControl technology package) • InputSynchronousTask_2: Synchronous with Input2 cycle clock (for TControl technology package) • PostControlTask_1: Synchronous with Control1 cycle clock (for TControl technology package) • PostControlTask_2: Synchronous with Control2 cycle clock (for TControl technology package)
• TimerInterruptTasks	Tasks are started periodically in a fixed time frame. This time frame must be a multiple of interpolator cycle clock IPO.
Interrupts	Sequential tasks: They are executed once after the start and then terminated.
• SystemInterruptTasks	Started when a system event occurs: • ExecutionFaultTask: Error processing a program • PeripheralFaultTask: Error on I/O • TechnologicalFaultTask: Error on the technology object • TimeFaultBackgroundTask: BackgroundTask timeout • TimeFaultTask: TimerInterruptTask timeout
• UserInterruptTasks	They are started when a user-defined event occurs.

Execution level	Description
Round robin	MotionTasks and BackgroundTasks share the free time remaining after execution of the higher-priority system and user tasks. The proportion of the two levels can be assigned.
• MotionTasks	Sequential tasks: They are executed once after the start and then terminated. Start takes place: • Explicitly via a task control command in a program assigned to another task. • Automatically when RUN operating state is attained if the corresponding attribute was set during task configuration. The priority of a MotionTask can be increased temporarily: • In the MCC programming language with the "Wait for..." commands, see Wait for axis, Wait for signal, Wait for condition. • In the ST programming language with the WAITFORCONDITION statement.
• BackgroundTask	Cyclic task: It is restarted automatically once the assigned programs have been executed. The task cycle time depends on the runtime.
StartupTask	Task is executed once when there is a transition from STOP or STOP U operating state to RUN operating state. SystemInterruptTasks are started by their triggering system event.
ShutdownTask	Task is executed once when there is a transition from RUN operating state to STOP or STOP U operating state. STOP or STOP U operating state is reached by: • Activating the operating state switch • Calling the relevant system function, for example, MCC Change operating state command • Occurrence of a fault with the appropriate error response SystemInterruptTasks and PeripheralFaultTasks are started by their triggering system event.
For information on the behavior of sequential and cyclic tasks: • During initialization of local program variables: See Initialization of local variables (Page 5185). • In the event of execution errors in the program: See SIMOTION Basic Functions Function Manual. For information about options for accessing the process image and I/O variables: see Important properties for direct access and process image (Page 5199).	

7.3.6.4 Task start sequence

When the StartupTask is completed, RUN mode is reached.

The following tasks are then started:

- SynchronousTasks
- TimerInterruptTasks
- BackgroundTask
- MotionTasks with startup attribute.

Note

The sequence in which these tasks are first started after RUN mode has been reached does not conform to the task priorities.

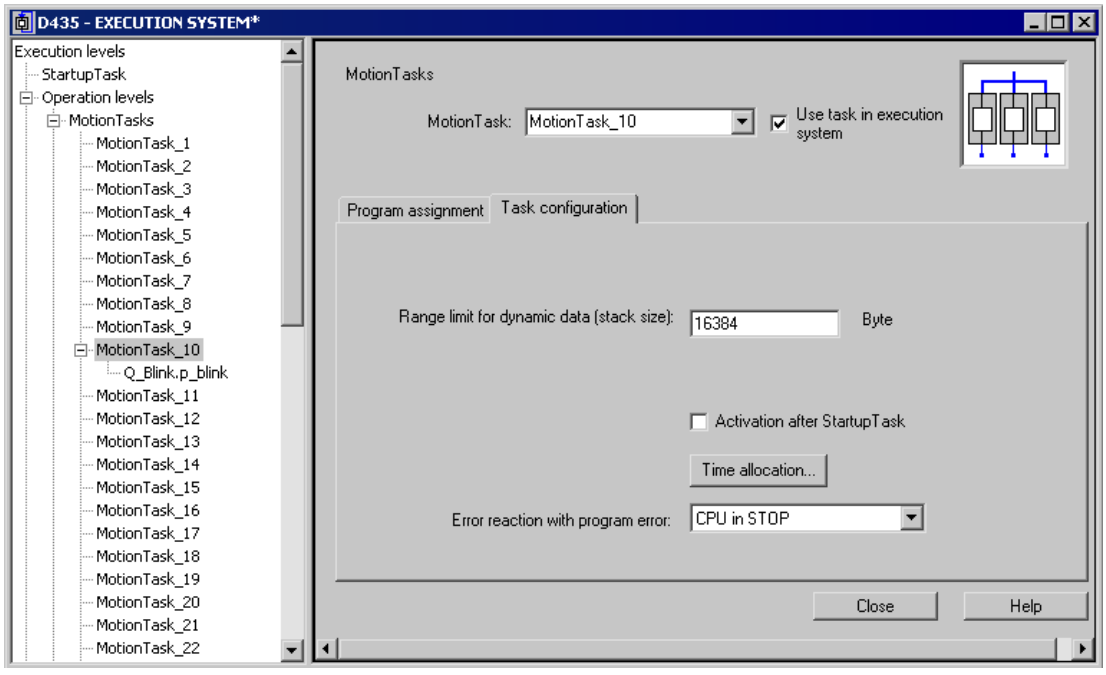

Figure 7-520 Task configuration of a motion task

7.3.6.5 Downloading programs to the target system

The program has to be downloaded into the target system, together with the technology objects etc., before being executed.

To download the program to the target system, proceed as follows:

1. Select **Project > Save and recompile all**.
   The project is locally saved on the hard disk and compiled, with due regard for all dependencies.
2. Select the **Project > Check consistency** menu command to check the project for consistency. This is not necessary if the **Check consistency before loading** option is activated under **Options > Settings** on the **Download** tab (this option is activated by default). This means the consistency check is performed automatically during the download to the target system.

3. Select the **Project > Connect to selected target devices** menu command or click  .
   Online mode is activated.
4. Select the **Target system > Load > Download project to target system** menu command or click  .
   The project data (including the sample program) and the data of the hardware configuration are downloaded to the RAM of the target system.

For more information about downloading a program to the target system, see the SIMOTION Basic Functions Function Manual.

7.3.7 Debugging Software / Error Handling

7.3.7.1 Operating modes for program testing

Modes of the SIMOTION devices

Various SIMOTION device operating modes are available for program testing.

Table 7-593 Operating modes of a SIMOTION device

Operating mode	Meaning
Process mode	Program execution on the SIMOTION device is optimized for maximum system performance. The following diagnostic functions are available, although they may have only restricted functionality because of the optimization for maximum system performance: • Monitor variables in the symbol browser or a watch table • Program status (only restricted): – Restricted monitoring of variables (e.g. variables in loops, return values for system functions). – Maximum of 1 program source (e.g. ST source file, MCC unit, LAD/FBD unit)[1] can be monitored. • Trace tool (only restricted) with measuring functions for drives and function generator, see online help: – Maximum of **1** trace on each SIMOTION device.
Test mode	The diagnostic functions of the process mode are available to the full extent: • Monitor variables in the symbol browser or a watch table • Program status: – Monitoring of all variables possible. – As of version V4.0 of the SIMOTION Kernel: Several program sources (e.g. ST source files, MCC units, LAD/FBD units)[1] can be monitored per task. – For version V3.2 of the SIMOTION Kernel: Maximum of 1 program source (e.g. ST source file, MCC unit, LAD/FBD unit)[1] can be monitored per task. • Trace tool with measuring functions for drives and function generator, see online help: – Maximum of **4** traces on each SIMOTION device. In addition, the following diagnostics function is available: • Trace for monitoring the program execution in program branches which are executed cyclically (only for the MCC programming language and for SIMOTION Kernel V4.2 and higher). **Note** Runtime and memory utilization increase as the use of diagnostic functions increases.

Operating mode	Meaning
Debug mode	In addition to the diagnostic functions of the test mode, you can use the following functions: • Breakpoints Within a program source, you can set breakpoints (Page 5353). When an activated breakpoint is reached, selected tasks will be stopped. • Controlling MotionTasks On the "Task Manager" tab of the device diagnostics, you can use task control commands for MotionTasks; see the SIMOTION Basic Functions Function Manual. No more than 1 SIMOTION device of the project can be switched to debug mode. SIMOTION SCOUT is in online mode, i.e. connected to the target system. Observe the following section: Important information about the life-sign monitoring (Page 5337).

[1] Each with 1 MCC chart or 1 LAD/FBD program in a program source.

Selecting the operating mode

How to select the operating mode of a SIMOTION device:

1. Make sure a connection to the target system has been established (online mode).
2. Highlight the SIMOTION device in the project navigator.
3. Select the "Operating mode" context menu.
4. Select the required operating mode (see the table above).
   If you have selected "Debug mode":
   – Accept the safety information.
   – Parameterize the sign-of-life monitoring.

   Observe the following section: Important information about the life-sign monitoring (Page 5337).
5. Confirm with **OK**.
   The SIMOTION device switches to the selected operating mode (apart from with debug mode; see the explanation below).

Special features with debug mode

Debug mode can only be selected for one SIMOTION device.

If you have selected debug mode, only SIMOTION SCOUT switches to it; the SIMOTION device is in test mode.

- The project navigator indicates that debug mode is activated for SIMOTION SCOUT by means of a symbol next to the SIMOTION device.
- The breakpoints toolbar (Page 5359) is displayed.

Debug mode is not enabled for the SIMOTION device until at least one set breakpoint is activated. If all breakpoints are deactivated, debug mode is canceled for the SIMOTION device.

The status bar indicates that debug mode is activated for the SIMOTION device.

Important information about the life-sign monitoring.

⚠ WARNING

Dangerous plant states possible

If problems occur in the communication link between the PC and the SIMOTION device, this may result in dangerous plant states (e.g. the axis may start moving in an uncontrollable manner).

Therefore, use the debug mode or a control panel only with the life-sign monitoring function activated with a suitably short monitoring time!

You must observe the appropriate safety regulations.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

In the following cases, the SIMOTION device and SIMOTION SCOUT regularly exchange life-signs to ensure a correctly functioning connection:

- In debug mode with activated breakpoints.
- When controlling an axis or a drive via the control panel (control priority at the PC):

If the exchange of the life-signs is interrupted longer than the set monitoring time, the following reactions are triggered:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to the STOP operating state.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis is brought to a standstill.
  - The enables are reset.

Accept safety notes

After selecting the debug mode or a control panel, you must accept the safety notes. You can set the parameters for the life-sign monitoring.

Proceed as follows:

1. Click the **Settings** button.
   The "Debug Settings" window opens.
2. Read there, as described in the following section, the safety notes and parameterize the life-sign monitoring.

Parameterizing the life-sign monitoring

In the "Life-Sign Monitoring Parameters" window, proceed as described below:

1. Read the warning!
2. Click the **Safety notes** button to open the window with the detailed safety notes.
3. Do not make any changes to the defaults for life-sign monitoring.
   Changes should only be made in special circumstances and in observance of all danger warnings.
4. Click **Accept** to confirm you have read the safety notes and have correctly parameterized the life-sign monitoring.

Note

The life-sign monitoring also responds in the following cases:

- Pressing the spacebar.
- Switching to a different Windows application.
- Too high a communication load between the SIMOTION device and SIMOTION SCOUT (e.g. by uploading task trace data).

The following reactions are triggered:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to the STOP operating state.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis or the drive is brought to a standstill.
  - The enables are reset.

⚠ WARNING

Dangerous plant states possible

This function is not guaranteed in all operating states.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Life-sign monitoring parameters

Table 7-594 Life-sign monitoring parameter description

Field	Description
Life-sign monitoring	The SIMOTION device and SIMOTION SCOUT regularly exchange life-signs to ensure a correctly functioning connection. If the exchange of the life-signs is interrupted longer than the set monitoring time, the following reactions are triggered: • In debug mode for activated breakpoints: – The SIMOTION device switches to the STOP operating state. – The outputs are deactivated (ODIS). • For controlling an axis or a drive using the control panel (control priority for the PC): – The axis is brought to a standstill. – The enables are reset. The following parameterizations are possible: • Checkbox **active**: If the checkbox is activated, life-sign monitoring is active. The deactivation of the life-sign monitoring is not always possible. • Monitoring time: Enter the timeout. **Prudence** Do not make any changes to the defaults for life-sign monitoring, if possible. Changes should only be made in special circumstances and in observance of all danger warnings.
Safety information	**Please observe the warning!** Click the button to obtain further safety information. See: Important information about the life-sign monitoring (Page 5337)

7.3.7.2 Editing program sources in online mode

Online editing in process or test mode

If SIMOTION SCOUT is connected to a target system which is in the "process mode" or "test mode" operating mode, program sources (e.g. ST source files, MCC units with MCC charts) can generally be edited, compiled, and loaded to the target system in STOP operating mode. For information on downloading in RUN operating mode, see the corresponding section in the "SIMOTION Basic Functions" Function Manual.

However, you can only activate the "program status", "monitor program execution" (only for MCC), and trace (only for MCC) test functions for a program source or a program organization unit (POU) if the following conditions are met:

1. This program source or any POU of this source (e.g. MCC chart) does not contain any changes which have not been saved.
2. The program source (unit) in SCOUT is consistent with the target system.

Note

If the "program status" test function is activated, editing of the corresponding program source or one of its POUs is disabled.

If an MCC unit or MCC chart is changed and the "monitor program execution" or trace test functions are active for that unit or chart, the test functions are canceled.

Online editing in debug mode

If SIMOTION SCOUT is in debug mode, editing is possible as long as the SIMOTION device is not in debug mode, i.e. no breakpoints are activated.

You can only activate breakpoints and, as a result, switch the SIMOTION device to debug mode if the corresponding program source and all its POUs are saved, compiled so they are up to date, and consistent with the target system.

If you attempt to edit a program source or POU when the SIMOTION device is in debug mode, you are requested to deactivate all breakpoints and, as a result, to switch the SIMOTION device out of debug mode.

Note

If breakpoints have been activated and the SIMOTION device is in debug mode:

Entering a space switches the SIMOTION device to STOP operating mode and deactivates all outputs (ODIS).

7.3.7.3 Symbol Browser

Characteristics

In the symbol browser, you can view and, if necessary, change the name, data type, and variable values. You can see the following variables in particular:

- Unit variables and static variables of a program or function block
- System variables of a SIMOTION device or a technology object
- I/O variables or global device variables.

For these variables, you can:

- View a snapshot of the variable values
- Monitor variable values as they change
- Change (modify) variable values

However, the symbol browser can only display/modify the variable values if the project has been loaded in the target system and a connection to the target system has been established.

Using the symbol browser

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system (see Download programs to the target system (Page 5333)).
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

The procedure depends on the memory area in which the variables to be monitored are stored.

Procedure

Proceed as follows:

1. Select the appropriate element in the project navigator in accordance with the following table.
2. In the detail view, click the **Symbol browser** tab.
   The corresponding variables are displayed in the symbol browser.
3. Select how each variable in the "Display format" column should be displayed.

Table 7-595 Elements in the project navigator and variables to be monitored in the symbol browser

Variables to be monitored in the symbol browser	Element to be selected in the project navigator
Variables in the unit's user memory or in the retentive memory, see SIMOTION ST Programming and Operating Manual: • Retentive and non-retentive unit variables of the interface section of a program source (unit) • Retentive and non-retentive unit variables of the implementation section of a program source (unit) • Static variables of the function blocks whose instances are declared as unit variables. • In addition, if the program source (unit) has been compiled with the "Only create program instance data once" compiler option (Page 5111): – Static variables of the programs. – Static variables of the function blocks whose instances are declared as static variables of programs.	Program source (unit)
Variables in the user memory of the task, see SIMOTION ST Programming and Operating Manual: If the program source (unit) was compiled without the "Only create program instance data once" (default) compiler option (Page 5111), the user memory of the task to which the program was assigned contains the following variables: • Static variables of the programs. • Static variables of the function blocks whose instances are declared as static variables of programs.	EXECUTION SYSTEM
System variables of a SIMOTION device	SIMOTION device
System variables of a technology object	Instance of the technology object
Global device variables	GLOBAL DEVICE VARIABLES
I/O variables (in the Address list tab of the detail view). The Address list tab of the detail view can be opened by double-clicking the ADDRESS LIST element in the project navigator.	ADDRESS LIST

Note

You can monitor temporary variables (together with unit variables and static variables) with **Program status** (see Properties of the program status (Page 5348)).

Note

Trace diagnostic function for MCC programming

Various internal variables, whose identifier begins with an underscore, are automatically created by the compiler for the trace diagnostic function. These variables are displayed in the symbol browser.

With activated diagnostic function, these variables are used for the control of the diagnostics function. These variables must not be used in the user program.

Status and controlling variables

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

⚠ WARNING

Dangerous plant states possible

You assign the entered values to the variables during control. This can result in dangerous plant states, e.g. unexpected axis motion.

Note

Note when you change the values of several variables:

The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the symbol browser. There is therefore no guarantee of consistency.

Working with the symbol browser

The functions of the symbol browser and how you work with them are described in detail in the online help.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the symbol browser (independently of the SIMOTION device):

Table 7-596 Display invalid floating-point numbers

Display	Meaning
1.#QNAN -1.#QNAN	Invalid bit pattern in accordance with IEEE 754 (NaN Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).
1.#INF -1.#INF	Bit pattern for + infinity in accordance with IEEE 754 Bit pattern for – infinity in accordance with IEEE 754
-1.#IND	Bit pattern for indeterminate

7.3.7.4 Watch tables

Monitoring variables in watch table

Watch table options

With the symbol browser, you see only the variables of an object within the project. With program status, you see only the variables for a freely selectable monitoring area in the program

With watch tables, by contrast, you can monitor selected variables from different sources as a group (e.g. program sources, technology objects, SINAMICS drives - even on different devices).

You can see the data type of the variables in offline mode. You can view and also modify the value of the variables in online mode.

Creating a watch table

Procedure for creating a watch table and assigning variables:

1. In the project navigator, open the **Monitor** folder.
2. Double-click the **Insert watch table** entry to create a watch table and enter a name for it. A watch table with this name appears in the **Monitor** folder.
3. In the project navigator, click the object from which you want to move variables to the watch table.
4. In the symbol browser, select the corresponding variable line by clicking its number in the left column.
5. From the context menu, select **Add to watch table** and the appropriate watch table, e.g. **Watch table_1**.
6. If you click the watch table, you will see in the detail view of the **Watch table** tab that the selected variable is now in the watch table.
7. Repeat steps 3 to 6 to monitor the variables of various objects.

If you are connected to the target system, you can monitor the variable contents.

Status and controlling variables

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

⚠ WARNING

Dangerous plant states possible

You assign the entered values to the variables during control. This can result in dangerous plant states, e.g. unexpected axis motion.

Note

Note when you change the values of several variables:

The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the watch table. There is therefore no guarantee of consistency.

Working with the watch table

The functions of the watch table and how you work with them are described in detail in the Online help.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the watch table (independently of the SIMOTION device):

Table 7-597 Display invalid floating-point numbers

Display	Meaning
1.#QNAN -1.#QNAN	Invalid bit pattern in accordance with IEEE 754 (NaN Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).
1.#INF -1.#INF	Bit pattern for + infinity in accordance with IEEE 754 Bit pattern for – infinity in accordance with IEEE 754
-1.#IND	Bit pattern for indeterminate

7.3.7.5 Variable status

"Variable status" enables you to monitor the current value for an individual variable, selected using the cursor, in an open program source or program organization unit (e.g. ST source file, MCC chart, LAD program).

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system. For information on loading a project, see "Downloading programs to the target system (Page 5333)".
- The program source containing the program organization unit (POE) whose variables you want to monitor must be consistent with the target system.

- The associated source (e.g. ST source file, MCC chart, LAD program) must be open.
- With the MCC programming language only: The parameter screen form for the command in which the variable you want to monitor is being used must be open.
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

Procedure

To monitor an individual variable using variable status:

1. Position the cursor above the identifier for a variable.
   - With the ST programming language: in the open ST source file
   - With the ST programming language: within an input field in the open parameter screen form
   - With the LAD/FBD programming language: within a network of the LAD/FBD program
2. Briefly position the cursor above the identifier.

The tool tip shows the current value of the variable. If you keep the cursor above the identifier for a longer period, the value is updated on an ongoing basis.

Note

With "variable status", the current value for the variable is displayed, wherever the selected variable is being used.

The "variable status" function enables you to monitor all those variables you are also able to monitor in the symbol browser (Page 5341) or the address list. These are:

- System variables of SIMOTION devices
- System variables of technology objects
- Global device variables
- Retentive and non-retentive unit variables of the interface section of a program source (unit)
- Retentive and non-retentive unit variables of the implementation section of a program source (unit)
- Static variables of the programs
- Static variables of the function blocks whose instances are declared as unit variables
- Static variables of the function blocks whose instances are declared as static variables of programs
- I/O variables

7.3.7.6 Trace

Trace options

Trace allows you to record and save signal characteristics of inputs/outputs or the variable values. This allows you to document the optimization, for example, of axes.

You can set the recording time, display up to four channels with eight values each in the test or debug mode, select trigger conditions, parameterize timing adjustments, select between different curve displays and scalings, etc.

The SIMOTION online help provides additional information on the trace tool.

7.3.7.7 Program run

Program run: Display code location and call path

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path.

Follow these steps:

1. Click the **Show program run** button on the Program run toolbar.
   The "Program run call stack (Page 5347)" window opens.
2. Select the desired MotionTask.
3. Click the **Update** button.

The window shows:

- The position in the code being executed (e.g. line of the ST source file) stating the program source and the POU.
- Recursively positions in the code of other POUs that call the code position being executed.

The following names are displayed for the SIMOTION RT program sources:

Table 7-598 SIMOTION RT program sources

Name	Meaning
taskbind.hid	Execution system
stdfunc.pck	IEC library
device.pck	Device-specific library
tp-name.pck	Library of the *tp-name* technology package, e.g. cam.pck for the library of the CAM technology package

Program run parameters

You can display the following for all configured tasks:

- the current code position in the program code (e.g. line of an ST source file)
- the call path of this code position

Table 7-599 Program run parameter description

Array	Description
Selected CPU	The selected SIMOTION device is displayed.
Refresh	Clicking the button reads the current code positions from the SIMOTION device and shows them in the open window.
Calling task	Select the task for which you want to determine the code position being executed. All configured tasks of the execution system.
Current code position	The position being executed in the program code (e.g. line of an ST source file) is displayed (with the name of the program source, line number, name of the POU).
is called by	The code positions that call the code position being executed within the selected task are shown recursively (with the name of the program source, line number, name of the POU, and name of the function block instance, if applicable).

For names of the SIMOTION RT program sources, refer to the table in Program run (Page 5347).

Program run toolbar

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path with this toolbar.

Table 7-600 Program run toolbar

Symbol	Meaning
	Display program run Click this symbol to open the Program run call stack window. In this window, you can display the currently active code position with its call path. See: Program run: Display code position and call path (Page 5347)

7.3.7.8 Program status (monitoring program execution)

Monitoring the program execution

Monitoring the program execution does not affect the actual execution of the program, but does increase the communication load. This has an impact on the execution of MotionTasks and the BackgroundTask.

Program status can be switched on and off during all operating modes of a SIMOTION device (Page 5335).

Note

In the process mode, the program status can be called only once for a LAD/FBD program, FB or FC. If you do not observe the restriction, error message 25023 "No resources in the runtime" will appear.

In the test mode, the program status can be called simultaneously for several LAD/FBD programs, FB or FC. The maximum possible number depends on the utilization of the SIMOTION device.

The values of the following variables are displayed:

- Simple data type variables (INT, REAL, etc.)
- Individual elements of a structure, provided an assignment is made
- Individual elements of an array, provided an assignment is made
- Enumeration data type variables

Note

The values of constants are not displayed.

Due to the restricted buffer capacity and the requirement for minimum runtime tampering, the following variables cannot be displayed:

- Complete arrays
- Complete structures

Individual array elements or individual structure elements are displayed, however, provided an assignment is made in the ST source file.

Starting and stopping program status (monitoring program execution)

You can call up information on network status in two different ways using program status:

- You can select specific networks to display their status. Multiple selection (Shift key) and the selection of all networks (Ctrl+A) is possible. The boxes will be displayed in the same color as the corresponding output.
  The left-hand border of a selected network is highlighted in blue.
- If you do not select a network, the status is displayed for those networks that are visible on the screen. If you scroll down, the status of those visible networks is now displayed.

Preparing program status

Before you can work with program status, additional code must be generated during compilation:

1. Select the **Project > Connect to selected target devices** menu command or click the button.
   Online mode is activated.
2. Select the SIMOTION device, followed by **Operating mode** in the context menu.
3. Select **Test mode**.
   Program status is available in this operating mode without restrictions, see Operating modes for SIMOTION devices (Page 5335).
4. Open the Properties window for the LAD/FBD unit, see Defining the properties of an LAD/FBD unit (Page 5109).
5. Activate the **Permit program status** compiler option on the **Compiler** tab as the local compiler setting (Page 5112) for this LAD/FBD unit.

   Note

   Alternatively, select **Options > Settings > Compiler**, then activate the **Permit program status** compiler option as the global compiler setting (Page 5111) for all program sources (ST, MCC and LAD/FBD units).

6. Select the **LAD/FBD unit > Accept and compile** menu command.
   The LAD/FBD unit is compiled.

   Note

   If the **Permit program status** global compiler option is changed, you need to select **Project > Save and compile changes** to compile all the program sources affected by the change.

7. Select the **Target system > Load > Project to target system** menu command or click the button.
   The programs are downloaded to the target system. Make sure that the target system is in STOP mode.

Starting the Status program

Requirement

- The corresponding LAD/FBD program is opened.
- The LAD/FBD program does not contain any unsaved changes.
- The LAD/FBD unit in SCOUT must be consistent with the target system.

Procedure

To start program status, proceed as follows:

1. Select the **LAD/FBD program > Program status on/off** menu command or click the button  for **Program status** (Ctrl+F7 shortcut) to start this test mode.
2. If the LAD/FBD program is assigned to more than one task, the **Call path/task selection Program status** dialog box opens:
   – In this dialog box, select the task in which you want to monitor the program.

   The 

symbol on the tab for the open LAD/FBD program indicates that program status has started, as does the symbol for the respective combination of the currently activated test functions (program status, breakpoints).

Note

Start program status for multiple windows for each SIMOTION device

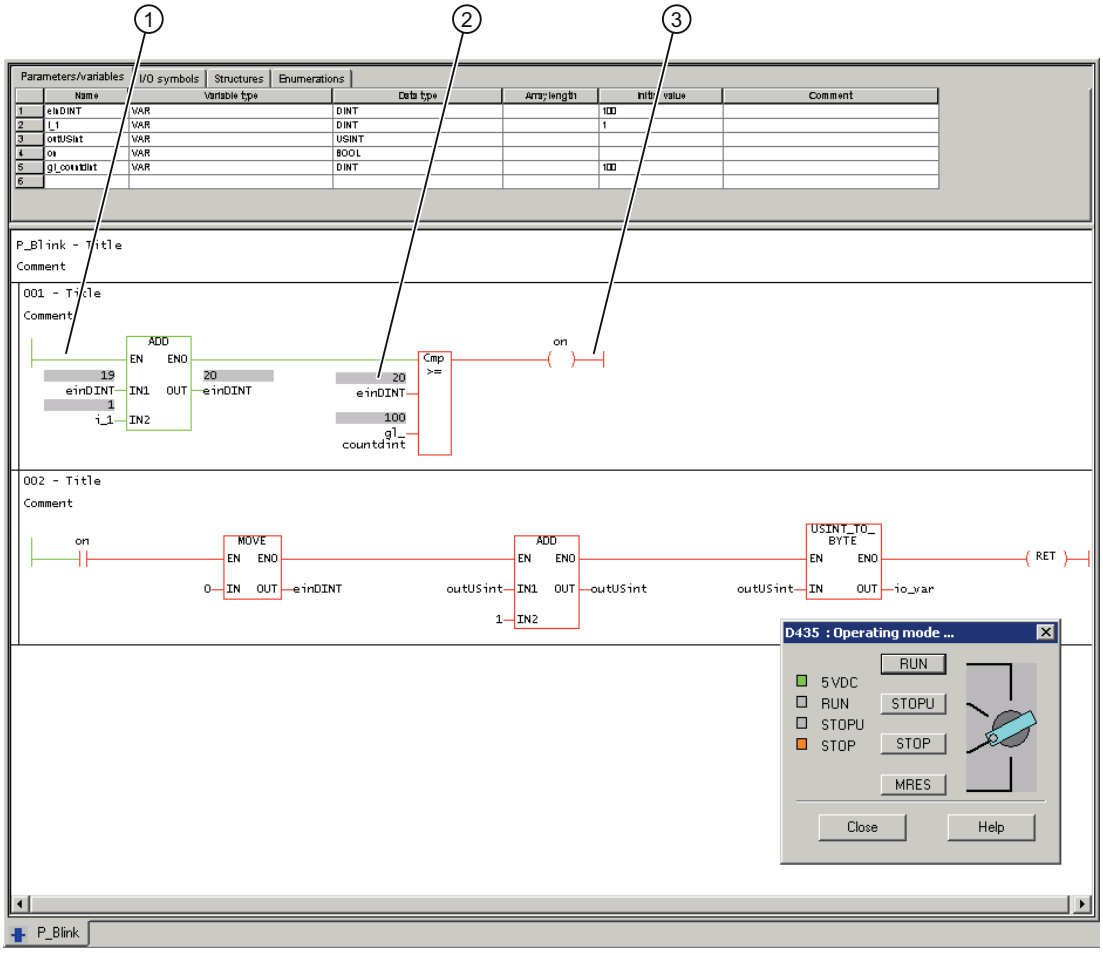
A window can be an open ST source file, an open LAD/FBD program or an open MCC chart. An active window is located in the foreground and the current status values are displayed (MCC: open MCC command).

In **Process mode**, program status can only be started for one window.

In **Test mode**, program status can be started simultaneously for several windows per task. The maximum possible number depends on the utilization of the SIMOTION device.

If program status is started for an additional window (**Process mode**) or starting it causes the maximum possible number to be exceeded (**Test mode**), program status is automatically deactivated for the currently active window (**Process mode**) or the oldest active window (**Test mode**), i.e. momentarily paused, but not stopped. If a window with deactivated program status is brought to the foreground (MCC: open MCC command), program status is automatically reactivated and the current status values are displayed again.

If the program execution monitoring is activated, the ladder diagram lines/signal paths of the selected networks or the networks displayed on the screen are colored according to the current values:



① Green: Lines: Value = TRUE (Data type BOOL)

Boxes: Result = TRUE or box is activated (enable input EN = TRUE).

Non-binary connections are shown in green.

Binary connections are displayed according to their values (green or red).

② Gray: Only when boxes are active: Non-binary values are shown on gray background.

③ Red: Lines: Value = FALSE (Data type BOOL)

Boxes: Result = TRUE or box is activated (enable input EN = TRUE).

Non-binary connections are shown in red.

When the boxes are inactive, binary connections are shown in cyan.

Figure 7-521 Online display in the LAD/FBD editor

Note

When a constant is used in a network, the current value of the constant is also displayed during program execution.

A constant which is not included is colored turquoise.

Stopping program status

To stop program status, proceed as follows:

1. Select the **LAD/FBD program > Program status on/off** menu command or click the button for **Program status** (Ctrl+F7 shortcut).
   Program status is stopped.

Disabling program status

Disabling program status frees up CPU resources.

To disable program status, proceed as follows:

1. First, stop the program status function, see Stopping program status.
2. Open the Properties window for the LAD/FBD unit, see Defining the properties of an LAD/FBD unit (Page 5109).
3. Deactivate the **Permit program status** compiler option on the **Compiler** tab as the local compiler setting (Page 5112) for this LAD/FBD unit and confirm by clicking **OK**.

   Note

   If the **Permit program status** compiler option is activated as the global setting for the compiler (Page 5111), you can deactivate this for either one LAD/FBD unit by deactivating the relevant **Use global settings** checkbox, see Local compiler settings (Page 5112) or for all the program sources by selecting **Options > Settings > Compiler**.

4. Select the SIMOTION device, followed by **Operating mode** in the context menu.
5. Select **Process mode**.
   Program execution is optimized for this operating mode to ensure maximum performance, see Operating modes for SIMOTION devices (Page 5335).
6. Recompile the program and download it to the target system.

Note

If the **Permit program status** global compiler option is changed, you need to select **Project > Save and compile changes** to compile all the program sources affected by the change.

7.3.7.9 Breakpoints

General procedure for setting breakpoints

You can set breakpoints within a POU of a program source (e.g. ST source, MCC chart, LAD/FBD source). On reaching an activated breakpoint, the task in which the POU with the breakpoint is called is stopped. If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser.

Requirement:

- The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.

Procedure

Follow these steps:

1. Select "Debug mode" for the associated SIMOTION device; see Setting debug mode (Page 5354).
2. Specify the tasks to be stopped, see Specifying the debug task group (Page 5355).
3. Set breakpoints, see Setting breakpoints (Page 5357).
4. Define the call path, see Defining a call path for a single breakpoint (Page 5360).
5. Activate the breakpoints, see Activating breakpoints (Page 5364).

Setting the debug mode

⚠ WARNING

Dangerous plant states possible

If problems occur in the communication link between the PC and the SIMOTION device, this may result in dangerous plant states (e.g. the axis may start moving in an uncontrollable manner).

Therefore, use the debug mode only with activated life-sign monitoring (Page 5337) with a suitably short monitoring time!

You must observe the appropriate safety regulations.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect!

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Requirement

1. A connection to the target system must have been established (online mode)
2. Debug mode must not be selected for any SIMOTION device.

Procedure

To set the debug mode, proceed as follows:

1. Highlight the SIMOTION device in the project navigator.
2. Select **Operating mode** from the context menu.
3. Select **Debug** mode (Page 5335).

4. Accept the safety information
5. Parameterize the sign-of-life monitoring.
   See also section: Important information about the life-sign monitoring (Page 5337).
6. Confirm with **OK**.

SIMOTION SCOUT switches to debug mode for this device; the SIMOTION device itself remains in "test mode", as long as at least one breakpoint is activated:

The project navigator indicates that debug mode is activated for SIMOTION SCOUT by means of a symbol next to the SIMOTION device.

The breakpoints toolbar (Page 5359) is displayed.

As long as no breakpoints are activated, you can edit program sources in debug mode (Page 5339).

Debug mode is not enabled for the SIMOTION device until at least one set breakpoint is activated. If all breakpoints are deactivated, debug mode is canceled for the SIMOTION device. The status bar indicates that debug mode is activated for the SIMOTION device.

Note

Pressing the spacebar or switching to a different Windows application causes the following to happen if the SIMOTION device is in debug mode (breakpoints activated):

- The SIMOTION device switches to the STOP operating state.
- The outputs are deactivated (ODIS).

⚠ WARNING

Dangerous plant states possible

This function is not guaranteed in all operating states.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Define the debug task group

On reaching an activated breakpoint, all tasks that are assigned to the debug task group are stopped.

Requirement

1. A connection to the target system must have been established (online mode).
2. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 5354).

Procedure

How to assign a task to the debug task group:

1. Highlight the relevant SIMOTION device in the project navigator.
2. Select **Debug task group** from the context menu.
   The Debug Task group window opens.
3. Select the tasks to be stopped on reaching the breakpoint:
   - If you only want to stop individual tasks (in RUN operating state): Activate the **Debug task group** selection option.
     Assign all tasks to be stopped on reaching a breakpoint to the **Tasks to be stopped** list.
   - If you only want to stop individual tasks (in HOLD operating state): Activate the **All tasks** selection option.
     In this case, also select whether the outputs and technology objects are to be released again after resumption of program execution.

Note

Note the different behavior when an activated breakpoint is reached, see the following table.

Table 7-601 Behavior at the breakpoint depending on the tasks to be stopped in the debug task group.

Property		Tasks to be stopped	
		Single selected tasks (debug task group)	**All tasks**
Behavior on reaching the breakpoint			
	Operating state	RUN	STOP
	Stopped tasks	Only tasks in the debug task group	All tasks
	Outputs	Active	Deactivated (ODIS activated)
	Technology	Closed-loop control active	No closed-loop control (ODIS activated)
	Runtime measurement of the tasks	Active for all tasks	Deactivated for all tasks
	Time monitoring of the tasks	Deactivated for tasks in the debug task group	Deactivated for all tasks
	Real-time clock	Continues to run	Continues to run
Behavior on resumption of program execution			
	Operating state	RUN	RUN
	Started tasks	All tasks in the debug task group	All tasks

Property		Tasks to be stopped	
		Single selected tasks (debug task group)	All tasks
	Outputs	Active	The behavior of the outputs and the technology objects depends on the **'Continue' activates the outputs (ODIS deactivated)** checkbox. • Active: ODIS will be deactivated. All outputs and technology objects are released. • Inactive: ODIS remains activated. All outputs and technology objects are only enabled for one STOP-RUN transition.
	Technology	Closed-loop control active	

Note

You can only make changes to the debug task group if no breakpoints are active.

The settings of the debug task group are retained after exiting "Debug mode".

Proceed as follows:

1. Set breakpoints (see Setting breakpoints (Page 5357)).
2. Define the call path (see Defining a call path for a single breakpoint (Page 5360)).
3. Activate the breakpoints (see Activating breakpoints (Page 5364)).

Setting breakpoints

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 5354).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 5355).

Procedure

How to set a breakpoint:

1. Select the code location where no breakpoint has been set:
   - SIMOTION ST: Place the cursor on a line in the ST source file that contains a statement.
   - SIMOTION MCC: Select an MCC command in the MCC chart (except module or comment block).
   - SIMOTION LAD/FBD: Set the cursor in a network of the LAD/FBD program.
2. Perform the following (alternatives):
   - Select the **Debug > Set/remove breakpoint** menu command (shortcut F9).
   - Click the  button in the Breakpoints toolbar.

To remove a breakpoint, proceed as follows:

1. Select the code position with the breakpoint.
2. Perform the following (alternatives):
   - Select the **Debug > Set/remove breakpoint** menu command (shortcut F9).
   - Click the  button in the Breakpoints toolbar.

To remove all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Remove all breakpoints** menu command (shortcut CTRL+F5).
  - Click the  button in the Breakpoints toolbar.

Note

You cannot set breakpoints:

- For SIMOTION ST: In lines that contain only comment.
- For SIMOTION MCC: On the module or comment block commands.
- For SIMOTION LAD/FBD: Within a network.
- At code locations in which other debug points (e.g. trigger points) have been set.

You can list the debug points in all program sources of the SIMOTION device in the debug table:

- Click the  button for "debug table" in the Breakpoints toolbar.

In the debug table, you can also remove all breakpoints (in all program sources) of the SIMOTION device:

- Click the button for "Clear all breakpoints".

The breakpoints set also remain saved after leaving debug mode; they are displayed in debug mode only.

You can use the program status (Page 5349) diagnosis functions and breakpoints together in a program source or POU. However, the following restrictions apply depending on the program languages:

- SIMOTION ST: For version V3.2 of the SIMOTION Kernel, the (marked) ST source file lines to be tested with program status must not contain a breakpoint.
- SIMOTION MCC and LAD/FBD: The commands of the MCC chart (or networks of the LAD/FBD program) to be tested with program status must not contain a breakpoint.

Proceed as follows

1. Define the call path, see Defining a call path for a single breakpoint (Page 5360).
2. Activate the breakpoints, see Activating breakpoints (Page 5364).

Breakpoints toolbar

This toolbar contains important operator actions for setting and activating breakpoints:

Table 7-602 Breakpoints toolbar

Symbol	Meaning
	Set/remove breakpoint Click this icon to set at breakpoint for the selected code position or to remove an existing breakpoint. See: Setting breakpoints (Page 5357).
	Activate/deactivate breakpoint Click this icon to activate or deactivate the breakpoint at the selected code position. See: Activating breakpoints (Page 5364).
	Edit the call path Click this icon to define the call path for the breakpoints: • If a code position **with** breakpoint is selected: The call path for this breakpoint. • If a code position **without** breakpoint is selected: The call path for all breakpoints of the POU. See: Defining the call path for a single breakpoint (Page 5360), Defining the call path for all breakpoints (Page 5362).
	Activate all breakpoints of the active POU Click this symbol to activate all breakpoints in the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Activating breakpoints (Page 5364).
	Deactivate all breakpoints of the active POU Click this symbol to deactivate all breakpoints in the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Activating breakpoints (Page 5364).
	Remove all breakpoints of the active POU Click this symbol to remove all breakpoints from the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Setting breakpoints (Page 5357).

Symbol	Meaning
	Debug table Click this icon to display the debug table. See: Debug table parameters.
	Display call stack Click this icon after reaching an activated breakpoint to: • View the call path at the current breakpoint. • View the code positions at which the other tasks of the debug task group have been stopped together with their call path. See: Displaying the call stack (Page 5366).
	Resume Click this icon to continue the program execution after reaching an activated breakpoint. See: Resuming program execution (Page 5367), Displaying the call stack (Page 5366).
	Next step (SIMOTION Kernel as of version V4.4) Only available for the MCC and LAD/FBD programming languages: Click this icon to resume the program execution until the next MCC command or LAD/FBD network is reached. See: Resume program execution in single steps (Page 5367).
	Step through the subprogram (SIMOTION Kernel as of version V4.4) Only available for the MCC programming language. Click this icon to jump to the called subprogram and stop at the first command. The subprogram must be created in the MCC or LAD/FBD programming language. See: Resume program execution in single steps (Page 5367).

Defining the call path for a single breakpoint

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 5354).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 5355).
5. Breakpoint is set, see Setting breakpoints (Page 5357).

Procedure

To define the call path for a single breakpoint, proceed as follows:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the  button for "edit call path" in the Breakpoints toolbar.
   In the Call path / task selection breakpoint window, the marked code position is displayed (with the name of the program source, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when the selected breakpoint is reached.
   The following are available:
   - **All calling locations starting at this call level**
     The user program will always be started when the activated breakpoint in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when the breakpoint in the selected task is reached. The task must be in the debug task group.
     The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).
   The following are available:
   - **All calling locations starting at this call level**
     No call path is specified. The user program is always stopped at the activated breakpoint if the POU in the selected tasks is called.
   - Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
     The call path is specified. The user program will be stopped at the activated breakpoint only when the POU is called from the selected code position.
     If the POU of the selected calling code position is also called from other code positions, further lines are displayed successively in which you proceed similarly.
5. If the breakpoint is only to be activated after the code position has been reached several times, select the number of times.

Note

You can also define the call path to the individual breakpoints in the debug table:

1. Click the button for "debug table" in the Breakpoints toolbar.
   The "Debug table" window opens.
2. Click the appropriate button in the "Call path" column.
3. Proceed in the same way as described above:
   – Specify the task.
   – Define the call path (only for functions and function blocks).
   – Specify the number of passes after which the breakpoint is to be activated.

Proceed as follows:

- Activate the breakpoints, see Activating breakpoints (Page 5364).

Note

You can use the "Display call stack (Page 5366)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

See also

Defining the call path for all breakpoints (Page 5362)

Defining the call path for all breakpoints

With this procedure, you can:

- Select a default setting for all future breakpoints in a POU (e.g. MCC chart, LAD/FBD program or POU in an ST source file).
- Accept and compare the call path for all previously set breakpoints in this POU.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 5354).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 5355).

Procedure

To define the call path for all future breakpoints of a POU, proceed as follows:

1. Select the code location where **no** breakpoint has been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the  button for "edit call path" in the Breakpoints toolbar.
   In the "Call path / task selection all breakpoints for each POU" window, the marked code position is displayed (with the name of the program source, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when a breakpoint in this POU is reached.
   The following are available:
   - **All calling locations starting at this call level**
     The user program will always be started when an activated breakpoint of the POU in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when a breakpoint in the selected task is reached.
     The task must be in the debug task group.
     The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).
   The following are available:
   - **All calling locations starting at this call level**
     No call path is specified. The user program is always stopped at an activated breakpoint when the POU in the selected tasks is called.
   - Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
     The call path is specified. The user program will be stopped at an activated breakpoint only when the POU is called from the selected code position.
     If the selected calling code position is in turn called by other code positions, further lines are displayed successively in which you proceed similarly.
5. If a breakpoint is only to be activated after the code position has been reached several times, select the number of times.
6. If you want to accept and compare this call path for all previously set breakpoints in this POU:
   - Click **Accept**.

Proceed as follows:

- Activate the breakpoints, see Activating breakpoints (Page 5364).

Note

You can use the "Display call stack (Page 5366)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

See also

Defining the call path for a single breakpoint (Page 5360)

Activating breakpoints

Breakpoints must be activated if they are to have an effect on program execution.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 5354).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 5355).
5. Breakpoints are set, see Setting breakpoints (Page 5357).
6. Call paths are defined, see Defining a call path for a single breakpoint (Page 5360).

Activating breakpoints

How to activate a single breakpoint:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source file.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Perform the following (alternatives):
   - Select the **Debug > Activate/deactivate breakpoint** menu command (shortcut F12).
   - Click the  button in the Breakpoints toolbar.

To activate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Activate all breakpoints** menu command.
  - Click the  button in the Breakpoints toolbar.

Once the first breakpoint has been activated, the SIMOTION device switches to debug mode. It remains in this mode until the last breakpoint is deactivated.

In the Task status function bar, (Page 5368) the tasks with activated breakpoints are highlighted in gray ( ).

Note

Breakpoints of all program sources of the SIMOTION device can also be activated and deactivated in the debug table:

1. Click the  button for "debug table" in the Breakpoints toolbar.
   The "Debug Table" window opens.
2. Perform the action below, depending on which breakpoints you want to activate or deactivate:
   - Single breakpoints: Check or clear the corresponding checkboxes.
   - All breakpoints (in all program sources): Click the corresponding button.

The following applies up to version V4.3 of the SIMOTION Kernel:

- In the case of activated breakpoints, the "Single step" test function of the SIMOTION MCC programming language cannot be used.

The following applies as of version V4.4 of the SIMOTION Kernel:

- The "Single step" test function of the SIMOTION MCC programming language is not available in the Debug mode.

Breakpoints cannot be activate if the control priority is at the axis control panel. Conversely, you cannot fetch the control priority for the axis control panel when a breakpoint activated.

Behavior at the activated breakpoint

On reaching an activated breakpoint (possibly using the selected call path (Page 5360)), all tasks assigned to the debug task group will be stopped. The behavior depends on the tasks in the debug task group and is described in "Defining a debug task group (Page 5355)". The breakpoint is highlighted.

In the Task status function bar, (Page 5368) the task in which the breakpoint was reached is highlighted in red ( ).

The following applies to the programming languages MCC or LAD/FBD: If the debug task group is stopped by a breakpoint, then the user has the option to change to another task, belonging to the debug task group, in the combo box. Always the breakpoint of the currently selected task is visualized.

If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser (Page 5341).

You can use the "Display call stack (Page 5366)" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Resuming program execution

You can resume the execution of the stopped tasks, see "Resuming program execution" (Page 5367).

As of version V4.4 of the SIMOTION Kernel, you can resume the task in single steps that has been stopped at the activated breakpoint in the MCC and LAD/FBD programming languages, see Resuming program execution in single steps (Page 5367).

Deactivate breakpoints

To deactivate a single breakpoint, proceed as follows:

1. Select the code position with the activated breakpoint.
2. Perform the following (alternatives):
   - Select the **Debug > Activate/deactivate breakpoint** menu command (shortcut F12).
   - Click the  button in the Breakpoints toolbar.

To deactivate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Deactivate all breakpoints** menu command.
  - Click the  button in the Breakpoints toolbar.

Once the last breakpoint has been deactivated, the SIMOTION device switches to "test mode"; SIMOTION SCOUT continues to run in debug mode.

Display call stack

You can use the "Display call stack" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Requirement

The user program is stopped at an activated breakpoint, i.e. the tasks of the debug task group (Page 5355) have been stopped.

Procedure

To call the "Display call stack" function, proceed as follows:

- Click the  button for "display call stack" in the Breakpoints toolbar.
  The "Breakpoint call stack" dialog opens. The current call path (including the calling task and the number of the set passes) is displayed.
  The call path cannot be changed.

To use the "Display call stack" function, proceed as follows:

1. Keep the "Breakpoint call stack" dialog open.
2. To display the code position at which the other task was stopped, proceed as follows:
   – Select the appropriate task. All tasks of the debug task group can be selected.

   The code position, including the call path, is displayed. If the code position is contained in a user program, the program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) will be opened and the code position marked.
3. How to resume program execution:
   – Click the button for "resume" (Ctrl+F8 shortcut) on the Breakpoint toolbar.

   When the next activated breakpoint is reached, the tasks of the debug task group will be stopped again. The current call path, including the calling task, is displayed.
4. Click **OK** to close the "Breakpoint call stack" dialog box.

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 5347)".

Resuming program execution

How to resume program execution:

- Perform the following (alternatives):
  – Select the **Debug > Continue** menu command (shortcut CTRL+F8).
  – Click the button on the Breakpoint toolbar (Page 5359) to "Continue".

The stopped task is continued until the next active breakpoint is reached.

Resuming program execution in single steps (as of Kernel V4.4)

This function is available as of SIMOTION Kernel version V4.4.

In the MCC and LAD/FBD programming languages you can resume the task in single steps that was stopped at an activated breakpoint (Page 5353).

The current MCC command or the current LAD/FBD network and all stopped tasks of the debug task group are executed.

All tasks that are assigned to the debug task group are stopped at the following MCC command or LAD/FBD network or the next activated breakpoint within the debug task group.

Next step

To execute the current MCC command or the current LAD/FBD network at which the program has been stopped, proceed as follows:

- Perform the following (alternatives):
  – Select the **Debug > Next step** menu command (shortcut CTRL+F10).
  – Click the button for "Next step" in the Breakpoints toolbar (Page 5359).

The current MCC command or the current LAD/FBD network is executed. The program is stopped at the following MCC command or the current LAD/FBD network.

A subprogram call is executed without interruption as long as no breakpoint is activated within the subprogram. If a

Stepping through the subprogram (MCC only)

If the program execution has been stopped at the "Subprogram call" command in the MCC programming language, you can jump to the subprogram and run through it in single steps. The subprogram must have been created in the MCC or LAD/FBD programming language.

- Perform the following (alternatives):
  - Select the **Debug > Step through subprogram** menu command (shortcut CTRL+SHIFT +F10).
  - Click the  button on the Breakpoint toolbar (Page 5359) to "Step through subprogram".

The appropriate MCC chart or LAD/FBD program is opened and the program execution stopped at the first MCC command or LAD/FBD network.

Note

Stepping is not possible in MCC charts and LAD/FBD programs whose sources are in libraries.

Stepping is not possible in ST source files.

You can only open MCC charts and LAD/FBD programs with know-how protection if you have the required authorization (e.g. password).

7.3.7.10 Task status function bar

In a combo box, the Task status function bar displays all tasks of the active SIMOTION device, to which a program is assigned.

They are displayed under the following conditions:

1. SIMOTION SCOUT is in online mode.
2. The affected SIMOTION device is active, e.g.
   - In the project navigator, the SIMOTION device or an element in its subtree is selected (such as program source, technology object).
   - In the working area, an open window is active that belongs to an element in the subtree of the SIMOTION device.
3. The SIMOTION device is consistent.

A background color highlights the occurrence of specific events in the affected task, see the following table. The task in question is displayed in the combo box of the function bar according to the event priority.

Table 7-603 Meaning of background colors in the Task status function bar

Background color	Meaning	Priority
Cyan	The affected task waits for a command at the "Single step" test function (only for SIMOTION MCC programming language).	Highest  Lowest
Red	The affected task is located at a breakpoint (Page 5364).	
Blue	In the affected task, the "Single step" test function is activated (only for SIMOTION MCC programming language)	
Gray	In the affected task, at least 1 breakpoint (Page 5364) is activated.	
Yellow	In the affected task, the "Monitoring" test function is activated (only for SIMOTION MCC programming language).	
White	In the affected task, none of the above-mentioned test functions are activated.	

Note

A selection of a task in the combo box is only possible:

- For the following test functions of the SIMOTION MCC programming language:
  - Monitoring
  - Single step
  - Trace
- at activated breakpoints (Page 5364) in the MCC or LAD/FBD programming languages.

7.3.7.11 Project comparison

SIMOTION SCOUT has a **project comparison** function (start this via the **Start object comparison** button) for comparing objects within the same project and/or objects from different projects (online or offline).

Project comparison allows you to establish any differences and, if necessary, run a data transfer to rectify them.

Objects are devices and their sub-objects, programs, technology objects (TOs) or drive objects (DOs), and libraries. Comparing projects is useful if you need to carry out service work on the system.

Further information on project and detail comparisons can be found in the SIMOTION Project Comparison Function Manual.

7.3.8 Application Examples

7.3.8.1 Examples

You will be given an introduction to the LAD and FBD programming languages using two simple examples.

7.3.8.2 Creating sample programs

Requirements for program creation

The project is the highest level in the data management hierarchy. SIMOTION SCOUT saves all data which belongs, for example, to a production machine, in the project directory.

This means that the project therefore brackets together all SIMOTION devices, drives, etc., belonging to one machine.

Within the project, the hardware used must be made known to the system, including:

- SIMOTION device
- Centralized I/O (with I/O addresses)
- Distributed I/O (with I/O addresses)

A SIMOTION device must be configured before you can insert and edit LAD/FBD sources.

Sample programs

We will create two short programs (position blinker program, axis program) that demonstrate all the work steps from the creation through to the start and testing of a program.

7.3.8.3 Blinker program

Prerequisites

A project must have been created and the hardware used in the project must be known to the system.

Task specification

Output of a cyclically changing bit pattern after exceeding a limit value.

This task is divided into the following parts:

- Insert LAD/FBD source file
- Insert LAD/FBD program
  Network one
  A program variable is incremented and compared to a reference value
  Network two
  When the reference value is exceeded, the program variable is reset and a bit pattern is output
- Compiling
- Insert program in a task
- Download program onto target device

You can observe the result of your program at the outputs of your target system.

This example deals only with the LAD programming aspect.

Insert LAD/FBD source file

To insert a new LAD/FBD unit using the context menu:

1. Select the **PROGRAMS** folder of the relevant SIMOTION device in the project navigator.
2. Double-click the entry **Insert LAD/FBD unit**.

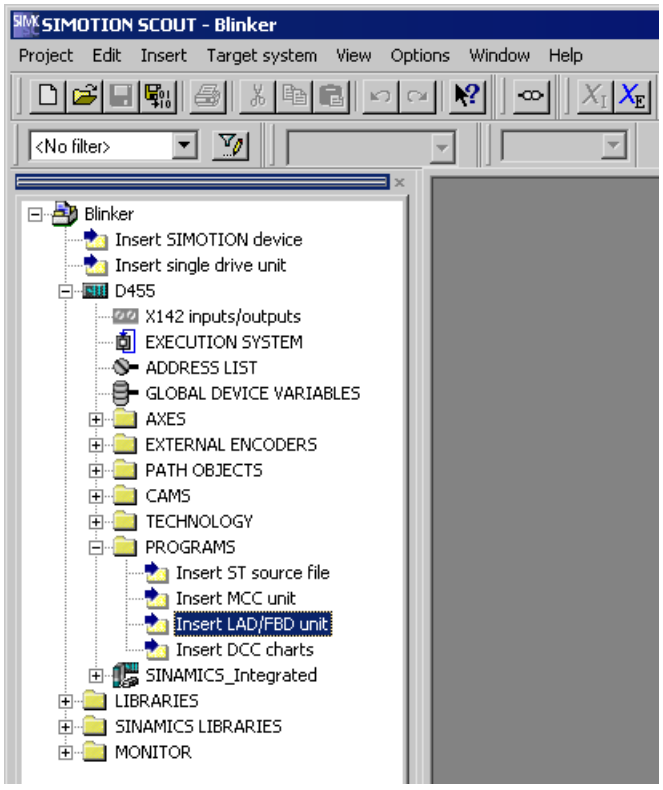


Figure 7-522 Project folder

The **Insert LAD/FBD Unit** dialog box appears.

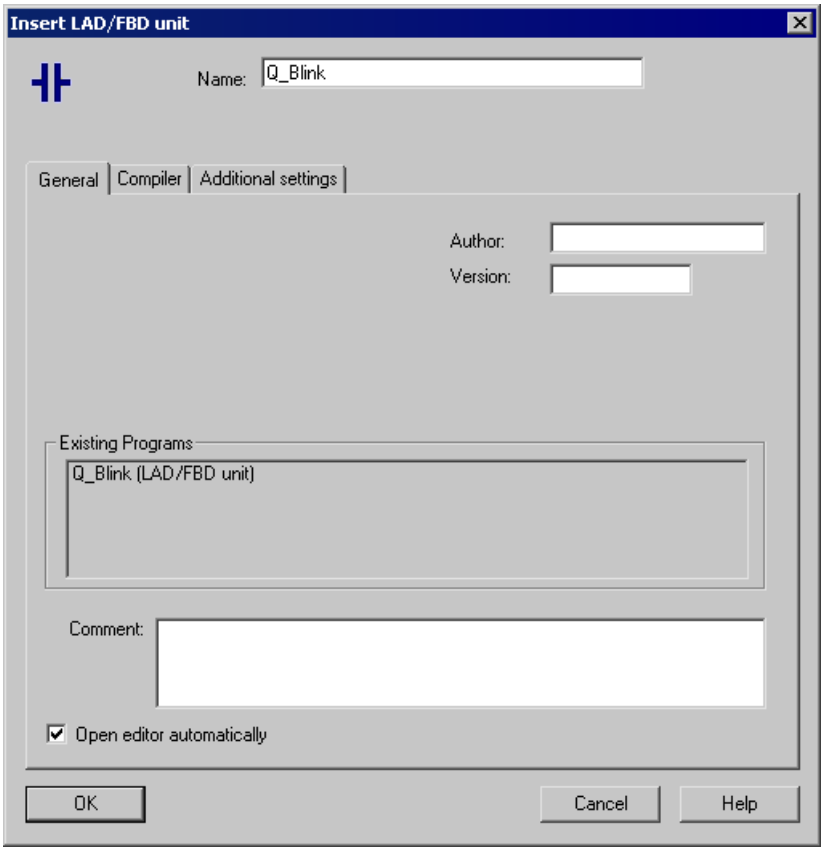

Figure 7-523 Insert LAD/FBD Unit dialog box

3. Enter the name of the LAD/FBD unit.
   The names of program sources must comply with the rules for identifiers (Page 5155): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters.
   The permissible length of the name depends on the SIMOTION Kernel version:
   - SIMOTION Kernel as of version V4.1: Maximum 128 characters.
   - SIMOTION Kernel up to version V4.0: Maximum 8 characters.

   Names must be unique within the SIMOTION device. Protected or reserved identifiers (Page 5410) are not permitted.
   Existing program sources (e.g. LAD/FBD units, ST source files) are displayed.
4. Activate the **Permit program status** compiler option to be able to use the online status display later:
   - Deactivate the associated checkbox in the "Global settings" column.
   - Activate the associated checkbox in the "Current settings" column.
5. In the **Compiler** tab, activate the **Permit program status** checkbox
6. You can also enter an author, version, and a comment.

7. Activate the **Open editor automatically** checkbox.
8. Confirm with **OK**.
   The declaration tables for exported and source-internal variables appear in the working area.
   No variables are defined here in the sample program.

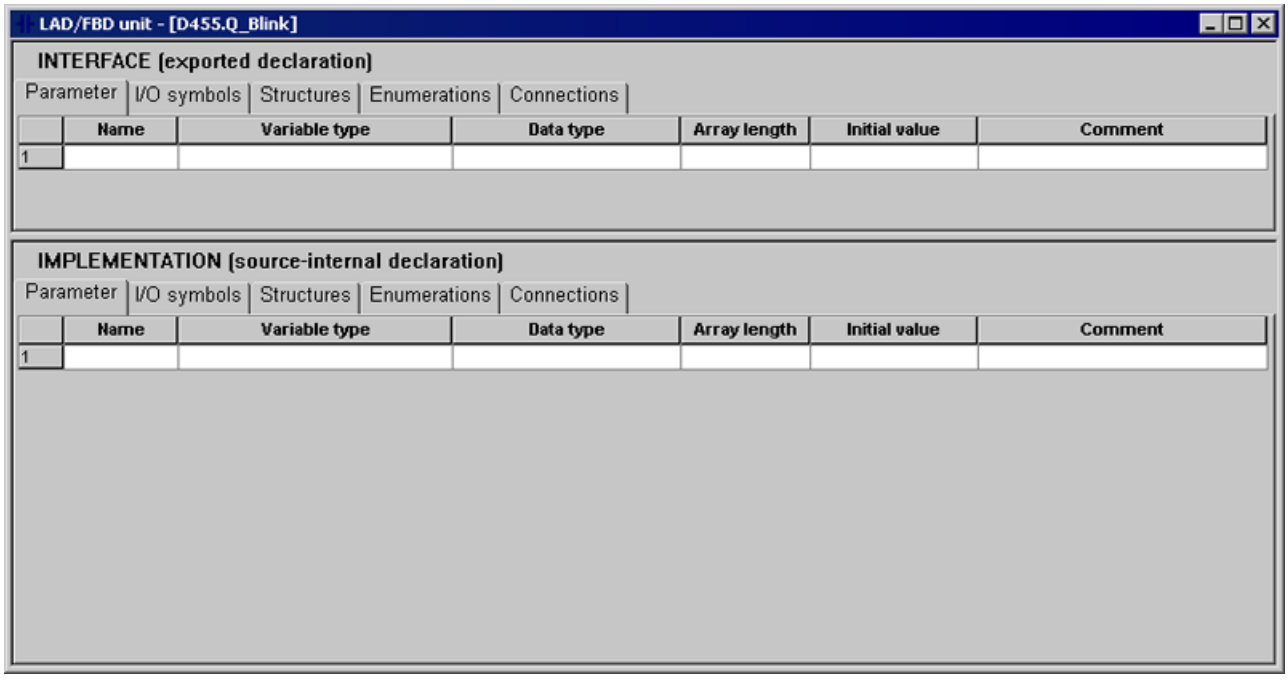

Figure 7-524 Declaration tables for exported and source-internal declarations

Insert LAD/FBD program

To insert an LAD/FBD program, proceed as follows:

1. In the **PROGRAMS** folder in the project navigator, open the LAD/FBD unit you just inserted.
2. Double-click the entry **Insert LAD/FBD program** in the LAD/FBD unit.

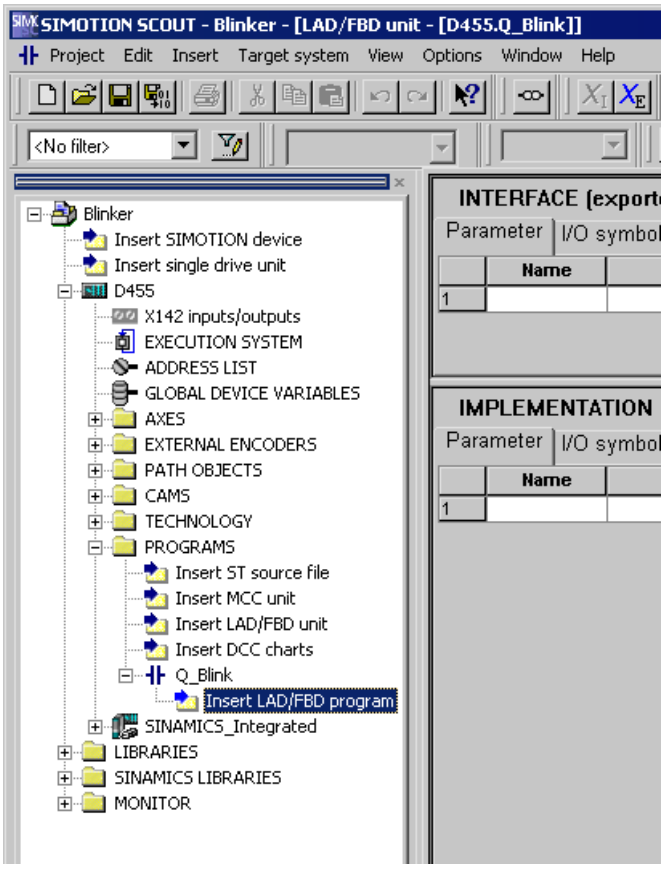

Figure 7-525 Opening a project folder

The **Insert LAD/FBD Program** dialog box appears.

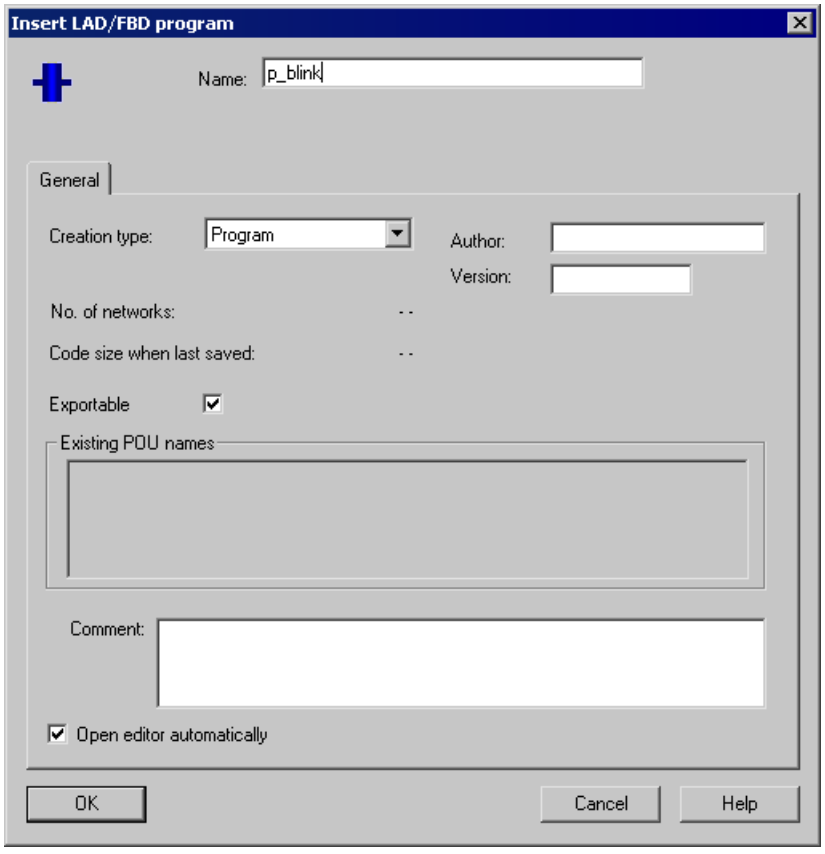

Figure 7-526 Insert LAD/FBD Program dialog box

3. Enter the name of the program in the **Insert LAD/FBD Program** dialog box.
   Names for LAD/FBD programs must comply with the Rules for identifiers (Page 5155): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters. Protected or reserved identifiers (Page 5410) are not permitted.
   The permissible length of the name is 25 characters.
   The names must be unique within the LAD/FBD unit. The names of all exportable program organization units (POUs) must also be unique within the SIMOTION device. The names of all LAD/FBD programs of the program source as well as the names of all exportable POUs of the device are displayed.
4. For **Creation type**, select program.
5. Activate the **Exportable** checkbox that must be available for the LAD/FBD program in the execution system.
6. Activate the **Open editor automatically** checkbox.
7. Confirm with **OK**.

A blank LAD/FBD program is opened.

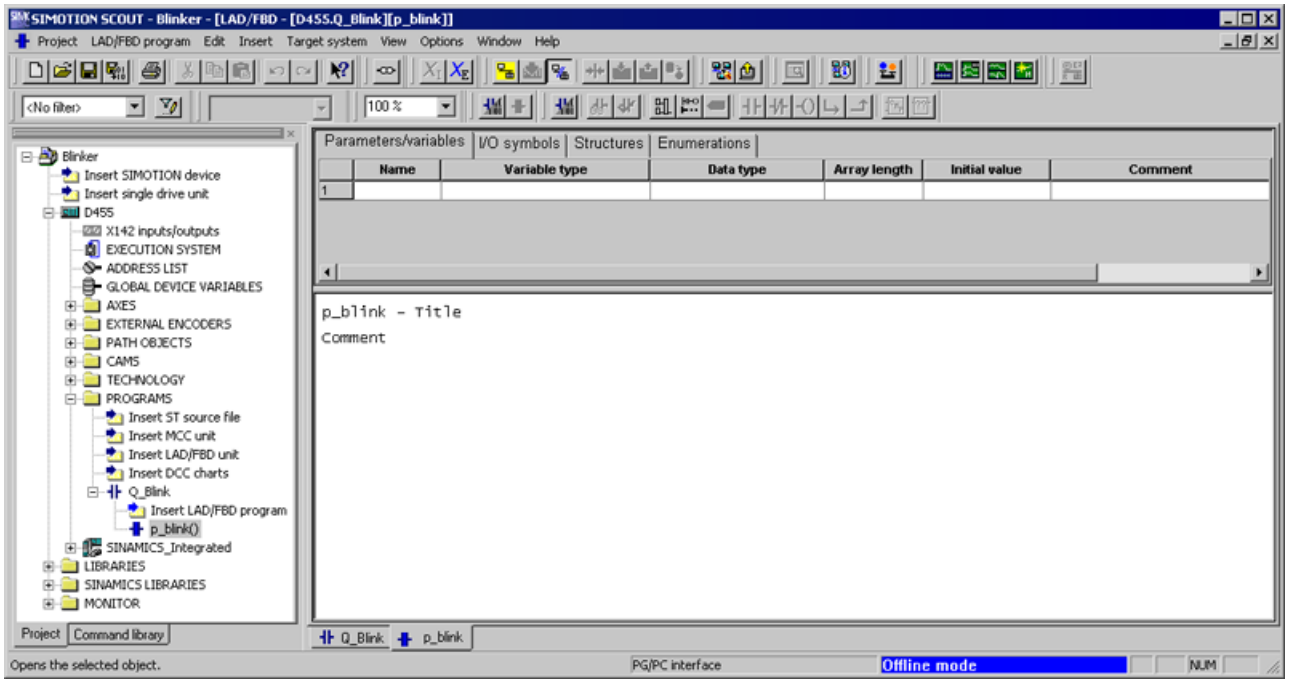

Figure 7-527 Open LAD/FBD program

Entering variables in the declaration table

To enter variables, proceed as follows:

1. Select the **Parameters/variables** tab.
2. Enter name, variable type, data type and/or start value in the declaration table (as shown in the figure below).

Parameters/variables | I/O symbols | Structures | Enumerations

	Name	Variable type	Data type	Array length	Initial value	Comment
1	einDINT	VAR	DINT		100	
2	i_1	VAR	DINT		1	
3	outUSint	VAR	USINT			
4	on	VAR	BOOL			
5	gl_countdint	VAR	DINT		100	
6						

Figure 7-528 Variables in the declaration table

3. Select the **I/O Symbols** tab.
4. Enter the name and absolute identifier (in accordance with the figure below).
   The **data type** is entered automatically.

Parameters/variables | I/O symbols | Structures | Enumerations

	Name	Absolute identifier	Data type	Comment
1	io_var	%QB4	BYTE	
2				

Figure 7-529 I/O symbols in the declaration table

Entering a program title

To enter a program title, proceed as follows:

1. Click in the title line.
2. Enter the program name in the window.

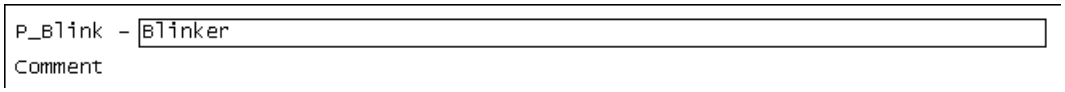

Figure 7-530 Program title

Inserting network

To paste in a network:

1. Select **LAD/FBD program > Insert network**.

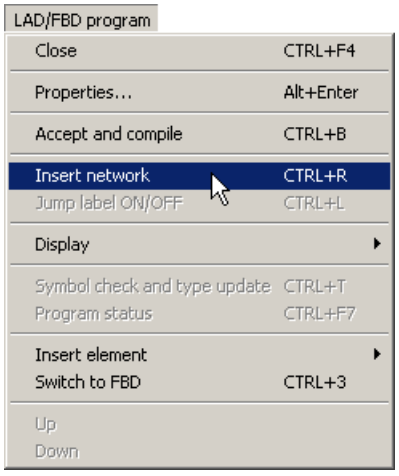

Figure 7-531 Menu selection

2. Click in the title line.
3. Enter the network name in the window.

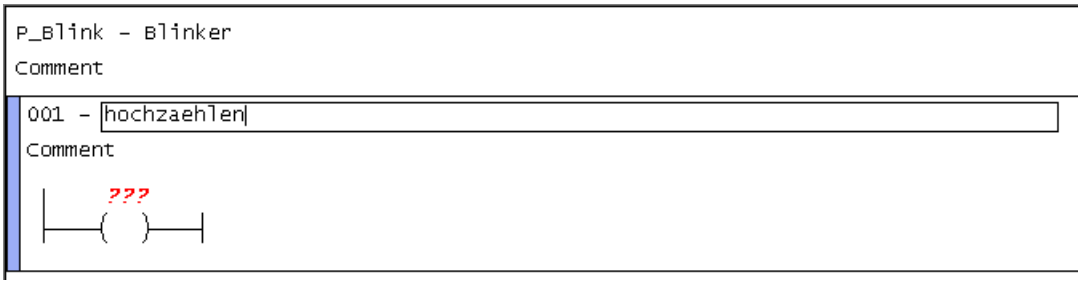

Figure 7-532 Network with entered name

4. Click the power rail to the left of the coil.

Inserting an empty box

To insert an empty box, proceed as follows:

1. From the menu, select the **LAD/FBD program > Insert element > Empty box** menu item.

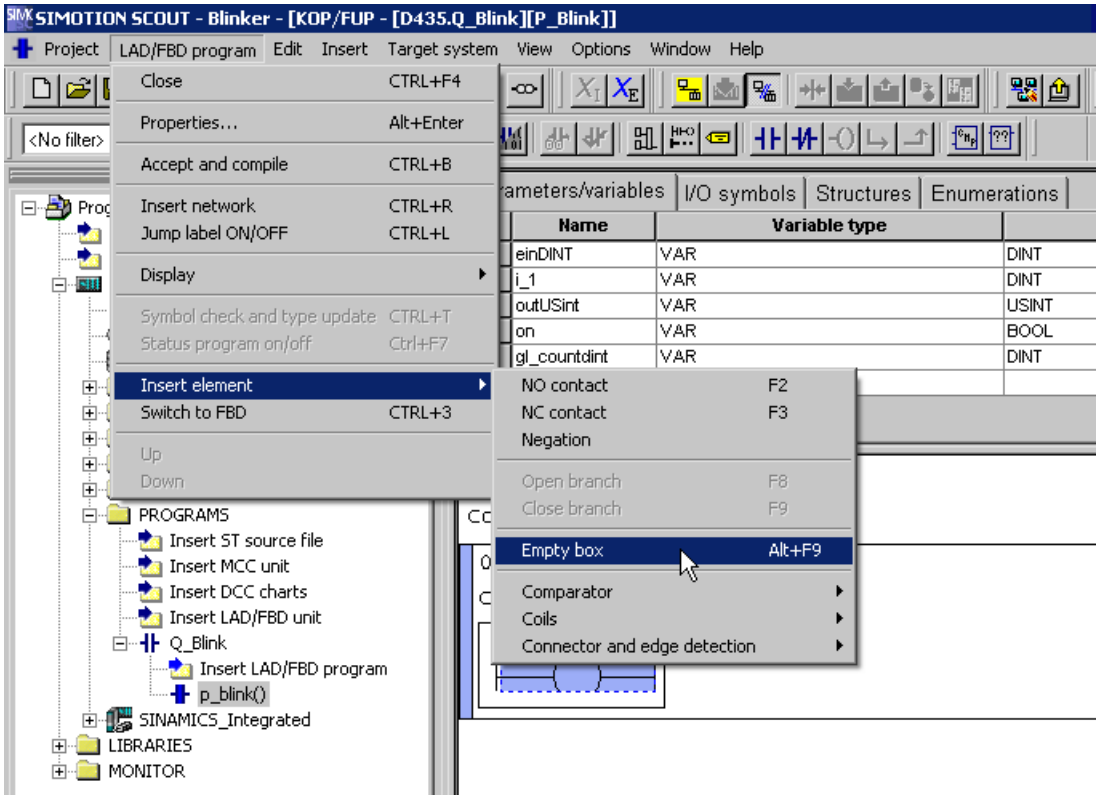

Figure 7-533 Insert an empty box

An empty box is inserted.

Mandatory parameters in a network are identified by **???**, optional parameters by **...** .

Selecting box type

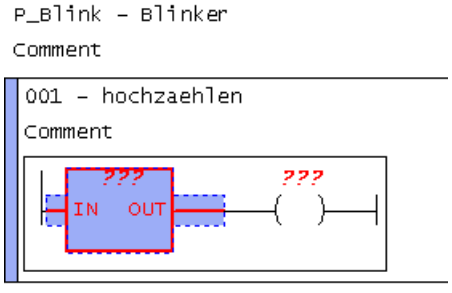

Figure 7-534 Empty box

To select a box type, proceed as follows:

1. Press the **Enter key** in the selected empty box.
   A drop-down menu appears.
2. Select the **ADD** box type from the drop-down menu and confirm your selection by pressing the **Enter key**.

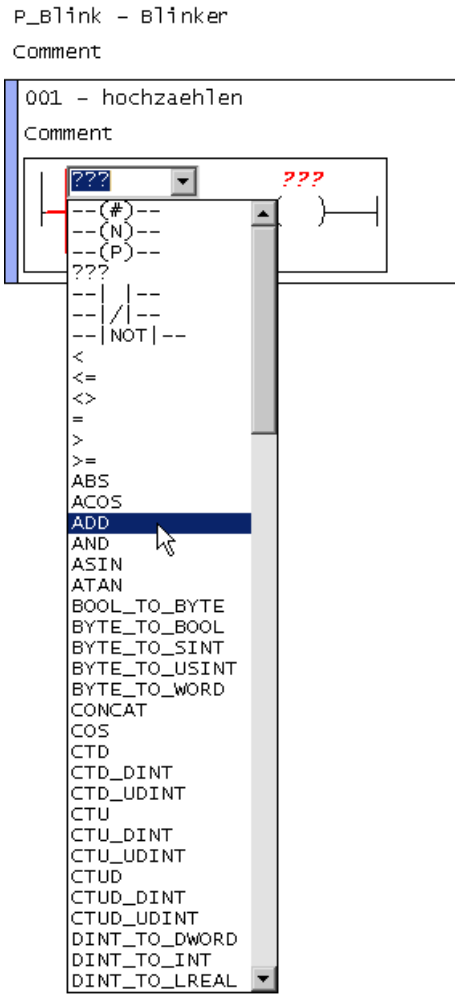

Figure 7-535 Selection of box type

Parameterizing the ADD call-up

To parameterize the ADD call-up, proceed as follows:

1. Click in the other mandatory input fields **???**.

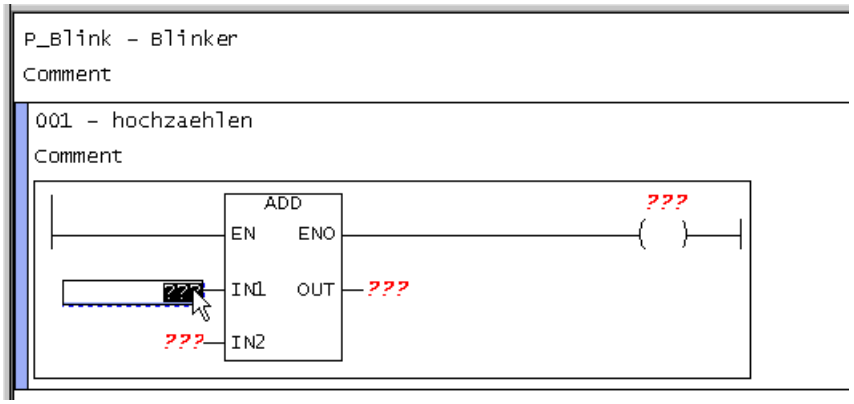

Figure 7-536 ADD box

2. Enter the appropriate values.

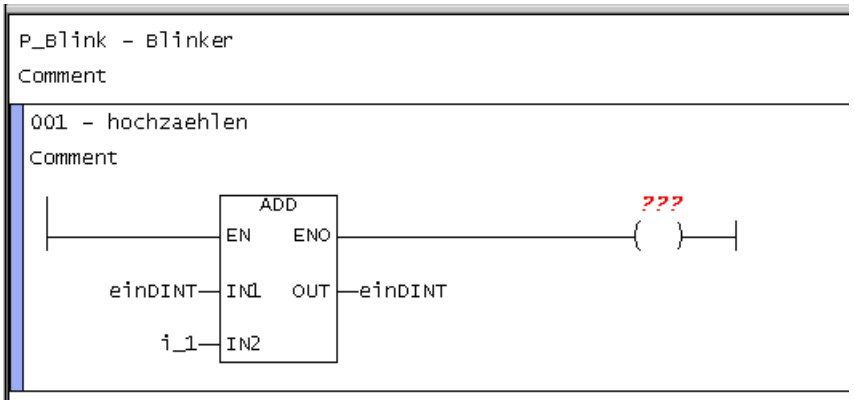

Figure 7-537 Parameterized ADD box

Inserting comparator

To insert a comparator, proceed as follows:

1. Select the ADD box.

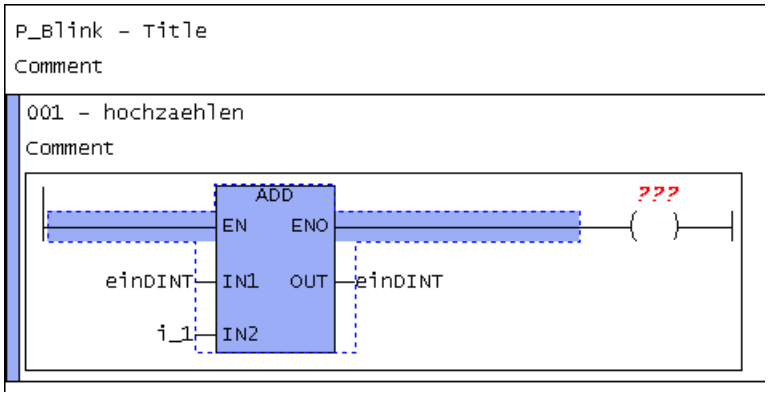

Figure 7-538 Selected ADD box

2. Select **LAD/FBD program > Insert element >Comparator > > =.**

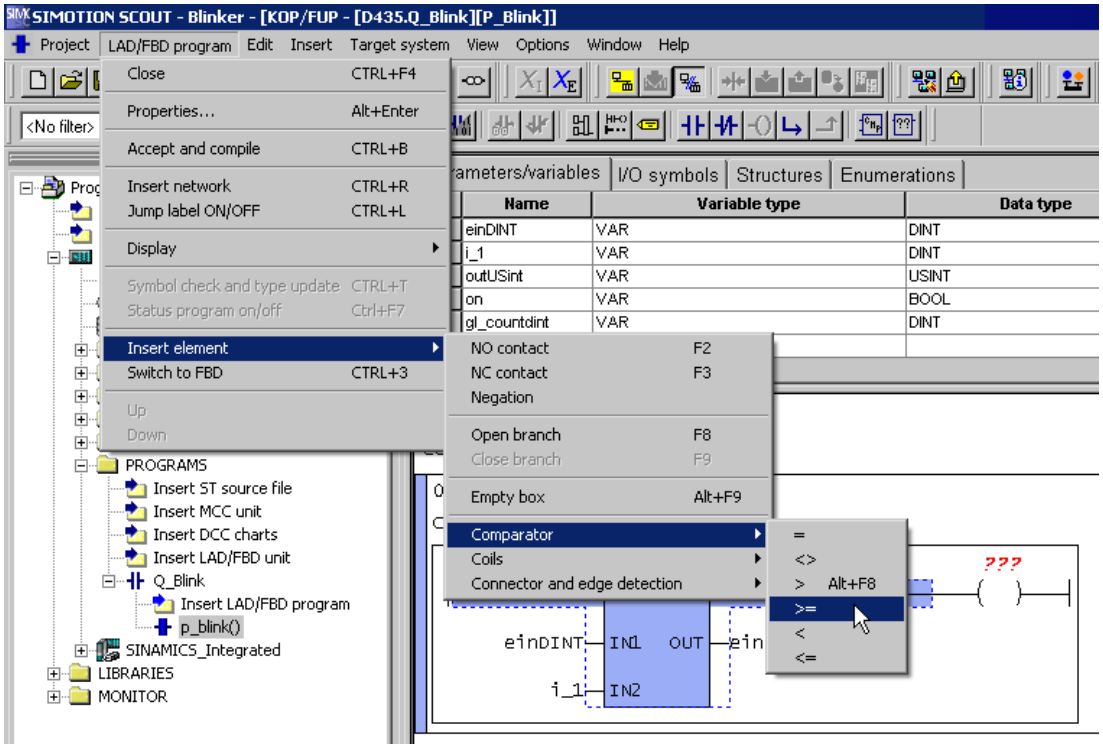

Figure 7-539 Select comparator

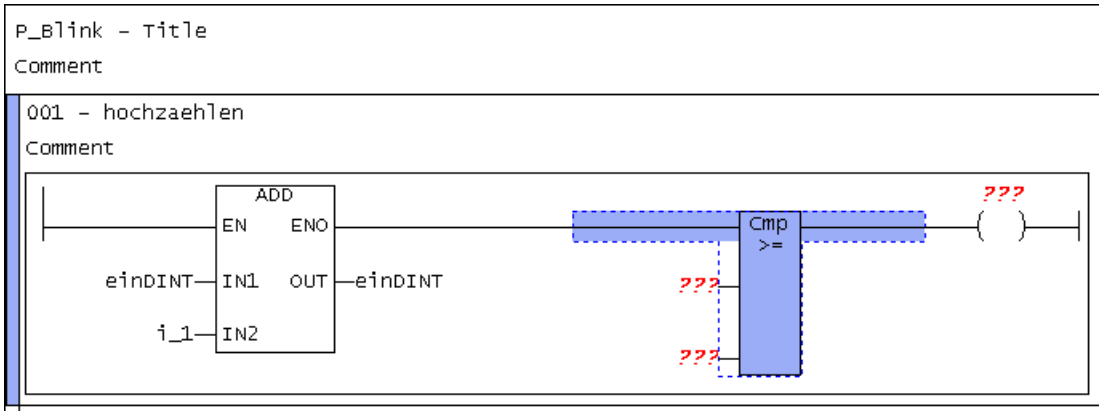

Figure 7-540 Inserted comparator

Labeling the comparator

To label the comparator, proceed as follows:

1. Click each comparator input field individually.
2. Enter the appropriate values for the comparator.

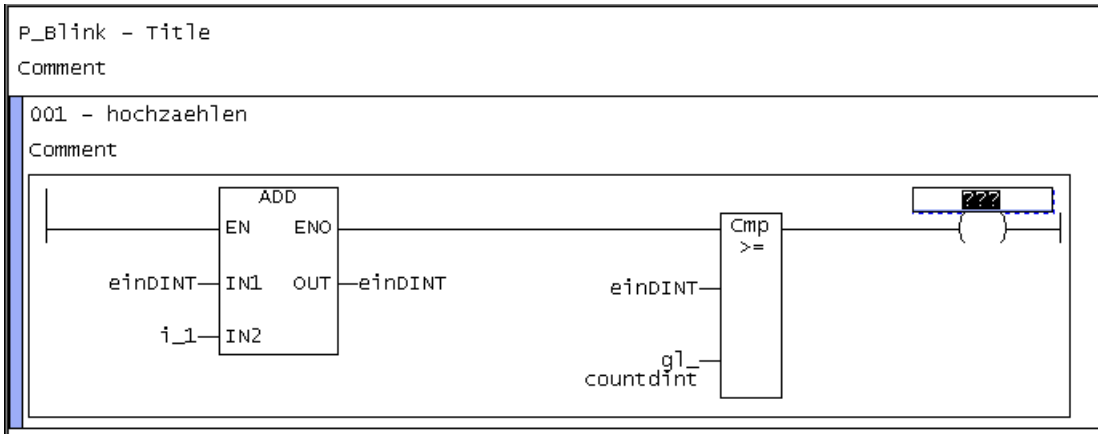

Figure 7-541 Labeled comparator

Initializing a coil

To initialize a coil, proceed as follows:

1. Click in the input field **???** of the coil.
2. Enter the appropriate variable.

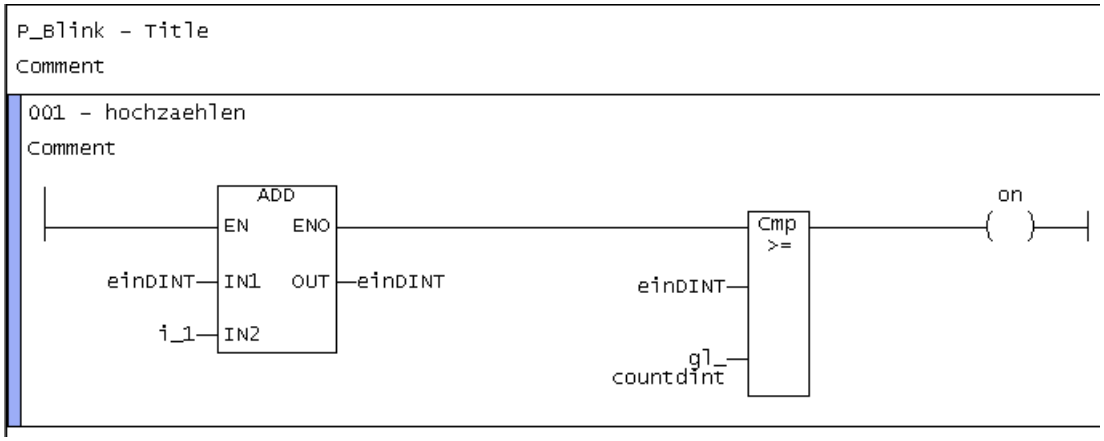

Figure 7-542 Initialized coil

Inserting next network

To paste in another network, proceed as follows:

1. To paste in the second network, repeat the steps used to paste in the first network.

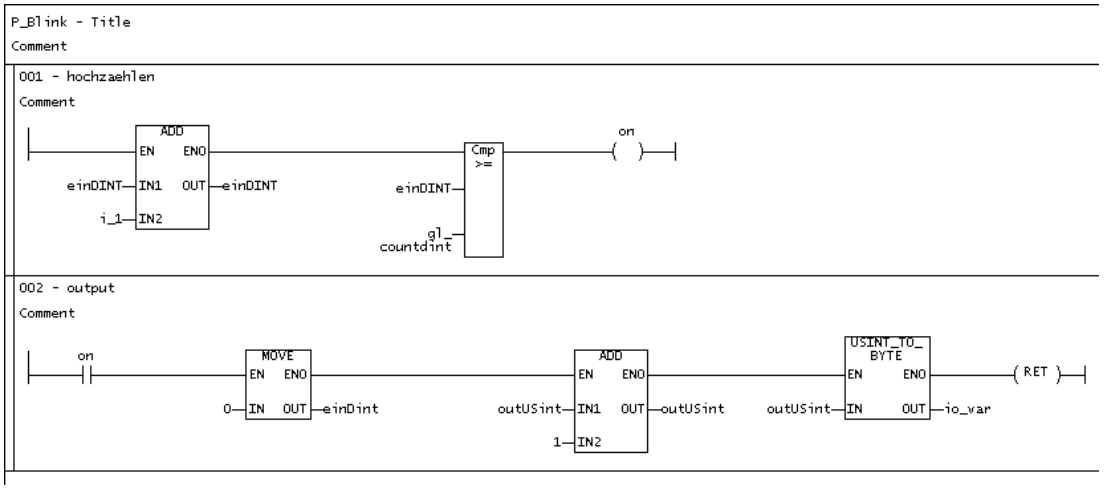

Figure 7-543 Project with two networks

Details view

To show the detail view, proceed as follows:

1. Select the **View > Detail view** menu command.
   Information, e.g. compiler messages, will be displayed during the compilation of a program.

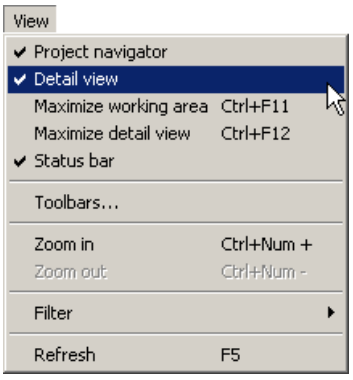

Figure 7-544 Detail view menu selection

Compiling

To compile the created program, proceed as follows:

1. Select the program in the project navigator.
2. Open the **LAD/FBD program** menu and select **Accept and compile**.
   The source file and its POUs are saved and compiled.
   During the compilation process, messages on the successful compilation status are displayed in the detail view. Should any error occur during compilation, they will be displayed in plain text there.

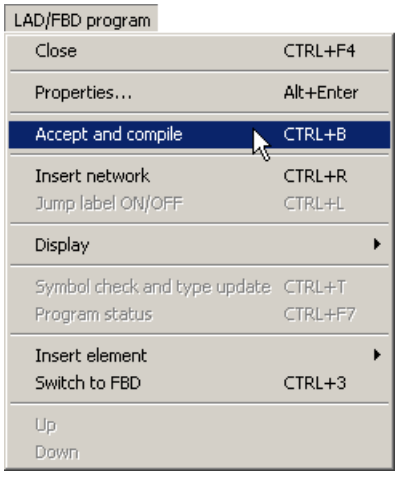

Figure 7-545 Save and compile menu selection

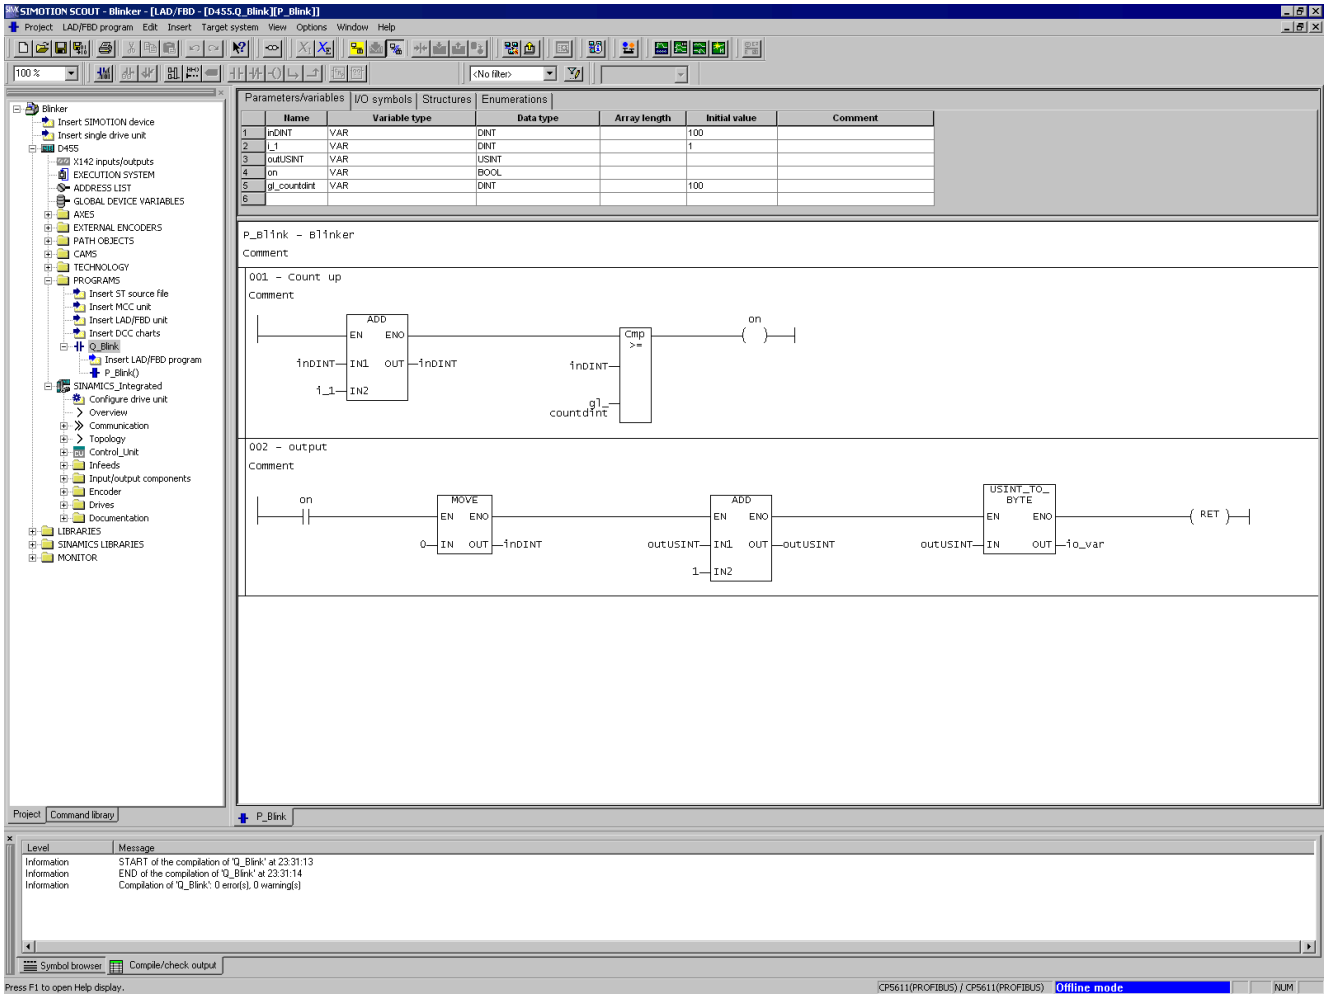

Figure 7-546 Compiled project with compiler information in the detail view

Assigning a sample program to an execution level

To assign a program to an execution level, proceed as follows:

1. Double-click the **EXECUTION SYSTEM** folder in the project navigator.
2. Click **BackgroundTask**.
3. Click the **Program assignment** tab.
4. Select the program **Q_blink.p_blink**.

5. Click the button **>>**.

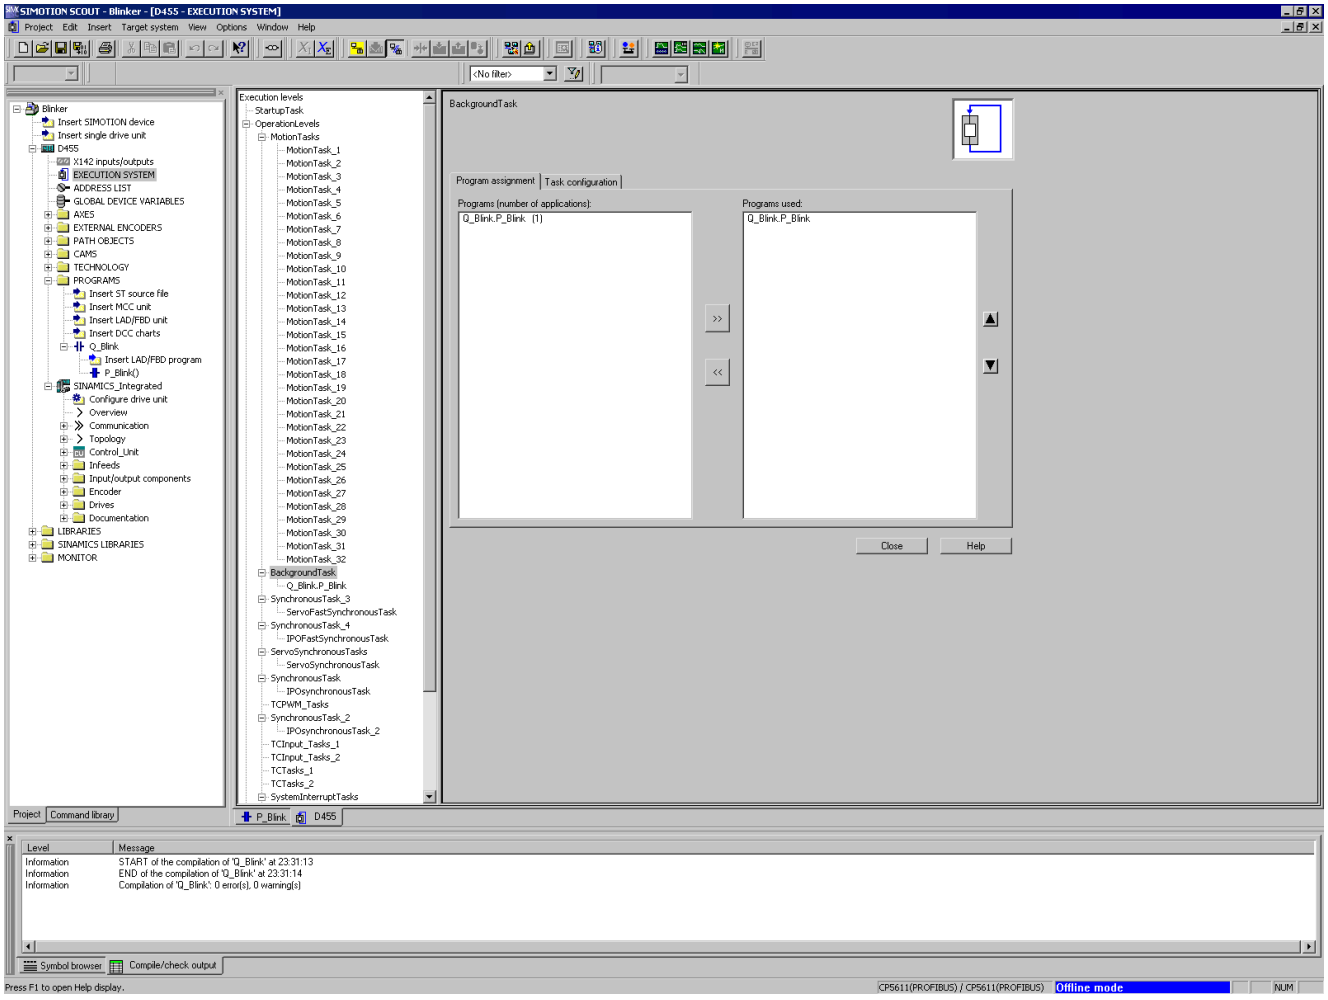

Figure 7-547 Assigning a program to the BackgroundTask

6. Click **Close** and acknowledge the message saying the execution system has changed by clicking **Yes**.
   The changes are accepted into the project.

Starting sample program

To start a program, proceed as follows:

1. Make sure the LAD/FBD unit creates the additional debug code for **program status** during compilation:
   Open the Properties window for the LAD/FBD unit (see Defining the properties of an LAD/FBD unit (Page 5109)).
2. Activate the **Permit program status** compiler option on the **Compiler** tab as the local compiler setting (see Local compiler settings (Page 5112)) for this LAD/FBD unit.
   See also the description relating to Effectiveness of local or global compiler settings (see the SIMOTION ST Programming and Operating Manual).

3. Select **Project > Save and recompile all**.
   The project is locally saved on the hard disk and compiled.
4. Select the **Project > Connect to selected target devices** menu command or click .
   Online mode is activated.
5. Select the **Target system > Load > Download project to target system** menu command or click .
   The project data (including the sample program) and the data of the hardware configuration are downloaded to the RAM of the target system.
6. Select both networks and click the button for **program status** (Ctrl+F7 shortcut) in the LAD editor function bar (Page 5086).
   Monitoring the program execution (Page 5348) is switched on.
7. Mark the SIMOTION device in the project navigator and select **Target device > Operating mode** in the context menu.
   The **Operating mode** window with the software switch for modes opens.
8. Click the **RUN** button in the software switch.
   The SIMOTION device is in **RUN** mode. The sample program is run and the current paths/signal paths are color-coded in accordance with the current signal values (Page 5348).

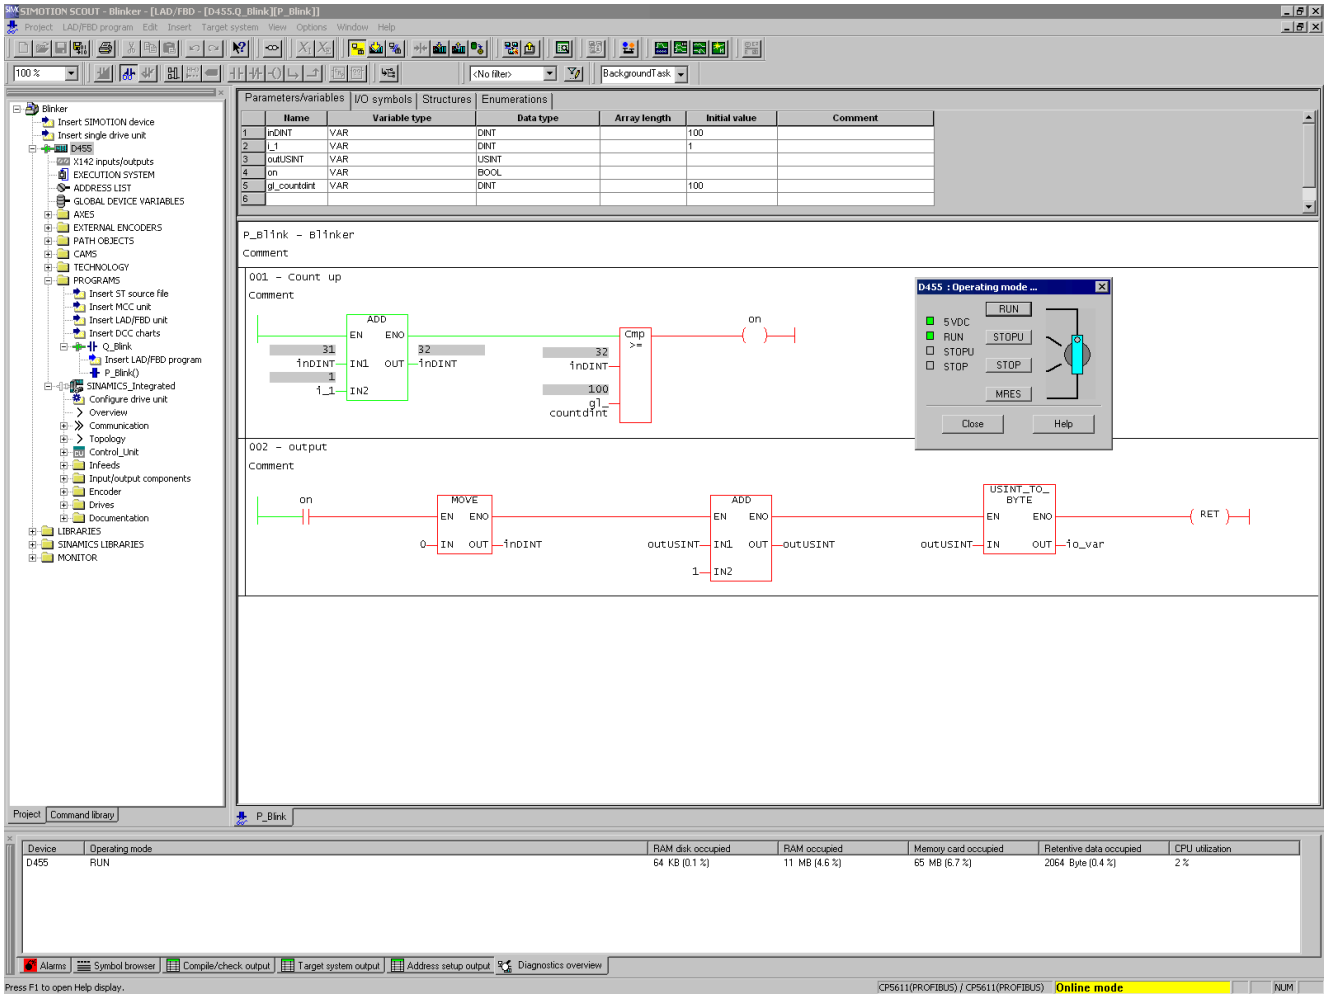

Figure 7-548 Sample program is started

7.3.8.4 Position axis program

Requirements

A project must be created. In the project, a CPU and a virtual position axis must be created (name of the axis: posAxis).

Task specification

An axis is to be traversed at a velocity of 10 mm/s from the current position 100 mm in the negative direction.

This task is divided into the following parts:

- Insert LAD/FBD unit
- Insert LAD/FBD program
  - Insert network
  - Set axis enable signals
  - Traverse axis to position
  - Remove axis enable
- Compile program
- Insert program in a task
- Download program onto target device

PLCopen blocks are used for the programming. The PLCopen blocks are designed for use in cyclic programs/tasks and enable motion control programming in a PLC environment. They are used primarily in the LAD/FBD programming language.

PLCopen blocks are available as standard functions (directly from the command library).

You can find further information about PLCopen blocks in the SIMOTION PLCopen Blocks Function Manual.

There is a TO-specific command available for the aforementioned subtasks **Set axis enable** and **Traverse axis to position/Remove axis enable**. Each command is represented by a box in LAD/FBD. The parameters for individual commands (position = 100, speed = 10 etc.) are entered

via the **Variable declaration** dialog box.

- or -

via the **Enter call parameters** dialog box

- or -

by entering the values in the input fields on each connector.

The task is implemented using LAD programming.

Insert LAD/FBD source file

To insert an LAD/FBD unit (for details of how to insert the unit and program, see also the blinker program (Page 5370) example), proceed as follows:

1. Open the **PROGRAMS** folder of the relevant SIMOTION device in the project navigator.
2. Double-click the entry **Insert LAD/FBD unit**.
   The **Insert LAD/FBD Unit** dialog box appears.
3. Enter the name of the LAD/FBD unit.
   The names of program sources must comply with the rules for identifiers (Page 5155): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters.
   The permissible length of the name depends on the SIMOTION Kernel version:
   - SIMOTION Kernel as of version V4.1: Maximum 128 characters.
   - SIMOTION Kernel up to version V4.0: Maximum 8 characters.

   Names must be unique within the SIMOTION device. Protected or reserved identifiers (Page 5410) are not permitted.
   Existing program sources (e.g. ST source files, MCC units) are displayed.
4. In the **Compiler** tab, activate the **Permit program status** checkbox, to use the online status display later.
5. You can also enter an author, version, and a comment.
6. Activate the **Open editor automatically** checkbox.
7. Confirm with **OK**.
   The declaration tables for global and unit-local variables appear in the working area.

Insert LAD/FBD program

To insert an LAD/FBD program, proceed as follows:

1. In the **PROGRAMS** folder within the project navigator, open the LAD/FBD unit you just pasted in.
2. Double-click the entry **Insert LAD/FBD program** in the LAD/FBD unit.
   The **Insert LAD/FBD Program** dialog box appears.
3. Enter the name of the program in the **Insert LAD/FBD Program** dialog box.
   Names for LAD/FBD programs must comply with the Rules for identifiers (Page 5155): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters. Protected or reserved identifiers (Page 5410) are not permitted.
   The permissible length of the name is 25 characters.
   The names must be unique within the LAD/FBD unit. The names of all exportable program organization units (POUs) must also be unique within the SIMOTION device. The names of all LAD/FBD programs of the program source as well as the names of all exportable POUs of the device are displayed.
4. For **Creation type**, select program.
5. Activate the **Open editor automatically** checkbox.

6. Confirm with **OK**.
   A blank LAD/FBD program is opened.
7. Click the working area and select **LAD/FBD program > Insert network** from the menu to paste in a new network.

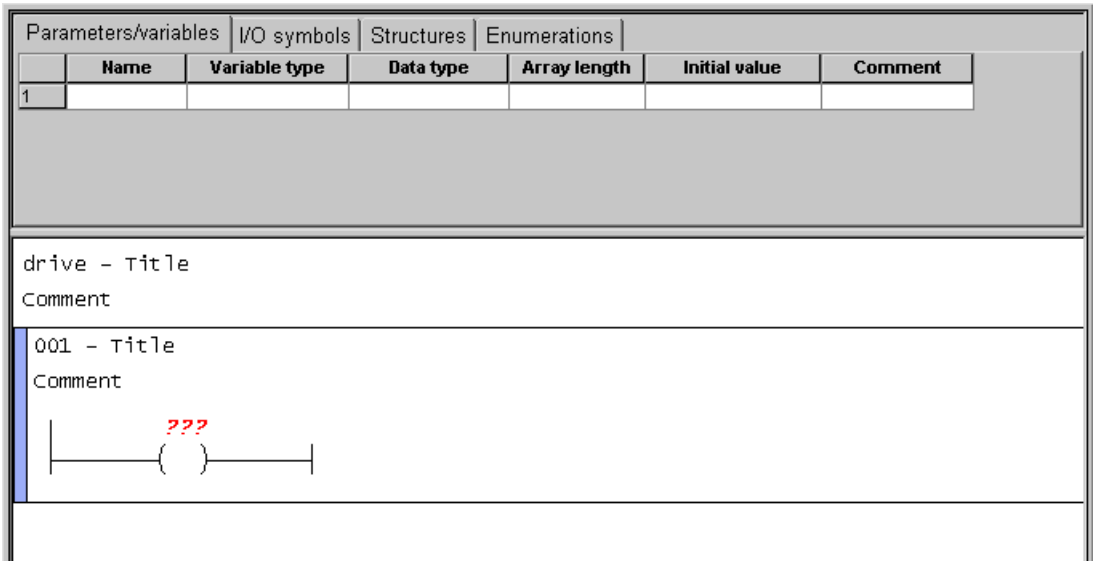

Figure 7-549 Pasted network

Note

Mandatory parameters in a network are identified by **???**, optional parameters by **...** .

8. Select the pasted box and select **Delete** in the context menu.
   The box is removed from the network.

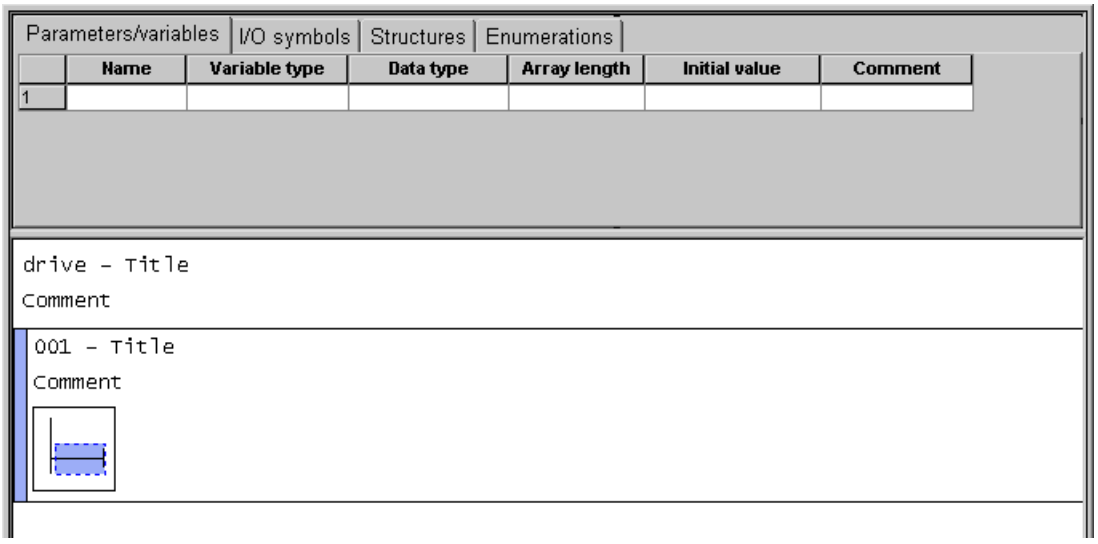

Figure 7-550 Pasted network without a box

Inserting a TO-specific command

To insert a **TO-specific command**, proceed as follows:

1. To enhance the display in the working area, open the shortcut menu of the network and select **Display > Mandatory and assigned box parameters**.
2. Select the **Command library** tab in the project navigator.
   The command groups appear.
3. Click the relevant plus sign to open the **PLCopen > SingleAxis** command group.

4. Drag and drop the **_MC_Power** command into the network (see Network with RET assignment).
   This command serves to enable the command.

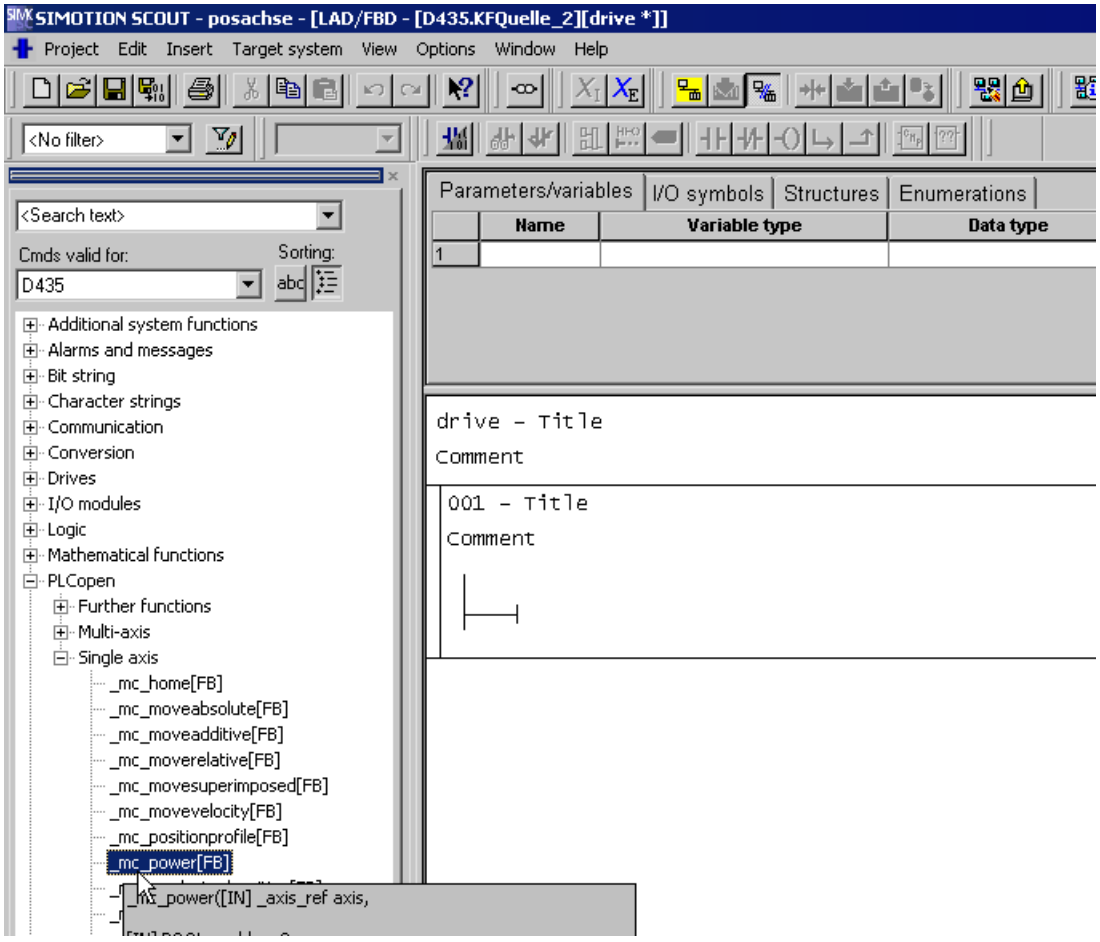

Figure 7-551 TO-specific command (_MC_Power) from the command library

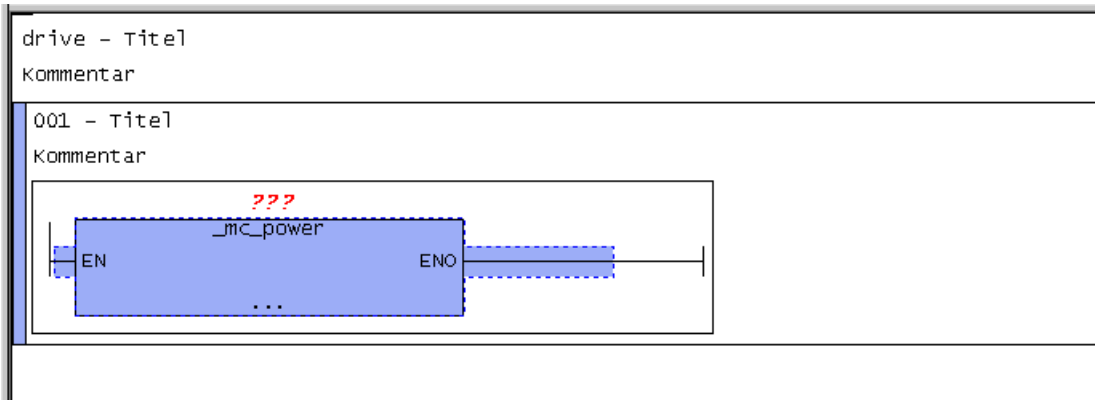

Figure 7-552 Network with inserted _MC_Power Box

5. Mark the network and select **LAD/FBD program > Insert network** from the menu to insert a second network.

6. Mark the inserted box from the second network and select **Delete** in the context menu.
   The box is removed from the network.
7. Drag and drop the **_MC_MoveRelative** command from the command library to the marked position in the second network.
   The axis is positioned at the specified speed with this command.

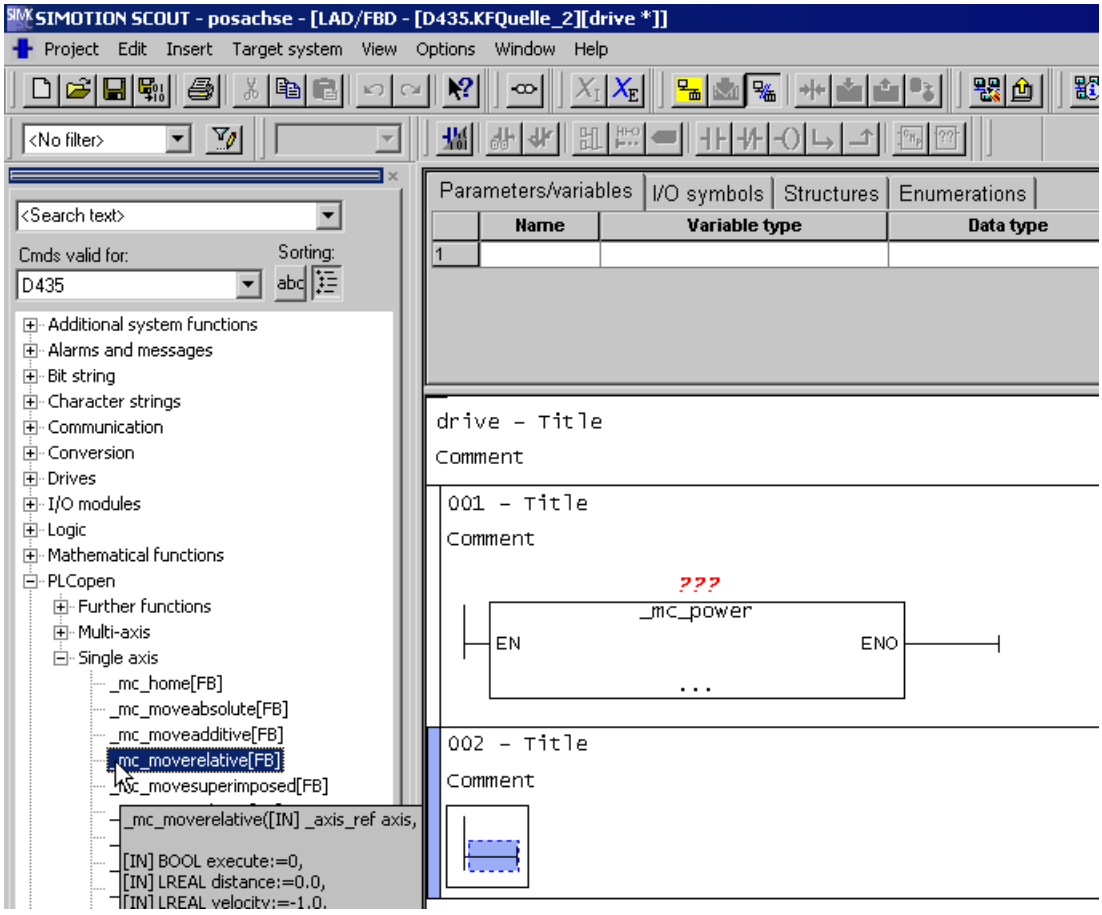

Figure 7-553 TO-specific command (_MC_MoveRelative) from the command library

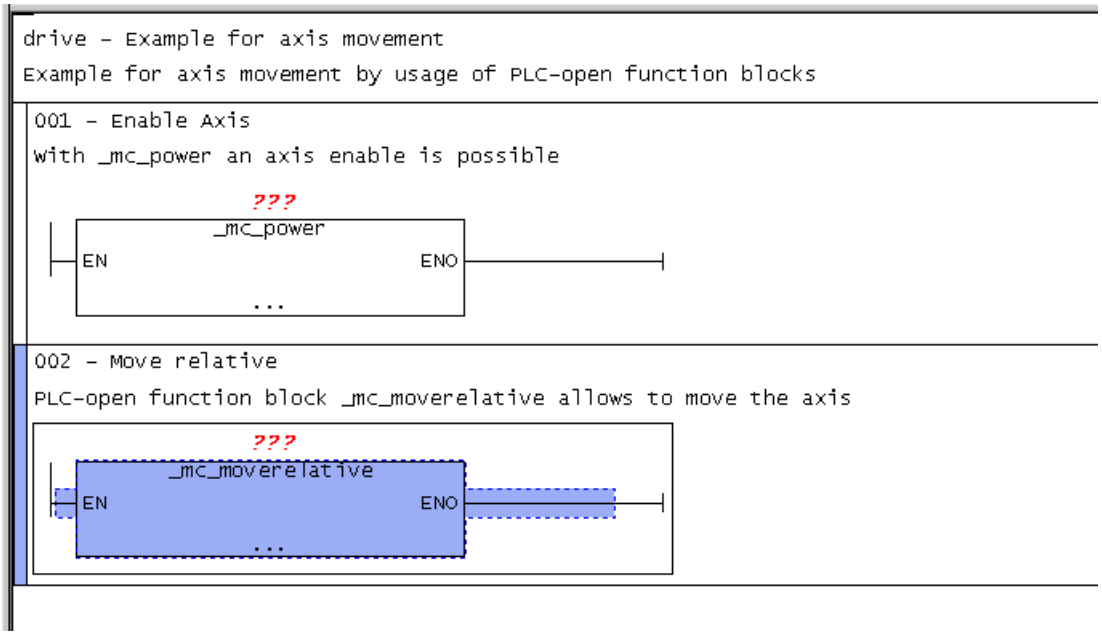

Figure 7-554 Network with inserted _MC_MoveRelative box

Connecting the enable inputs

The **enable** input for the **_MC_Power** command and the **execute** enable input for the **_MC_MoveRelative** command still have to be connected to NO contacts.

How to insert the NO contacts:

1. Click in the working area and select **Display > All box parameters** in the context menu. All the inputs and outputs of the boxes are shown.
2. Select the **Command library** tab in the project navigator. The command groups appear.
3. Click the plus symbol to open the command group **LAD elements**.

4. Drag and drop the **NO contact** LAD element to the **enable** input of the **_MC_Power** function block.

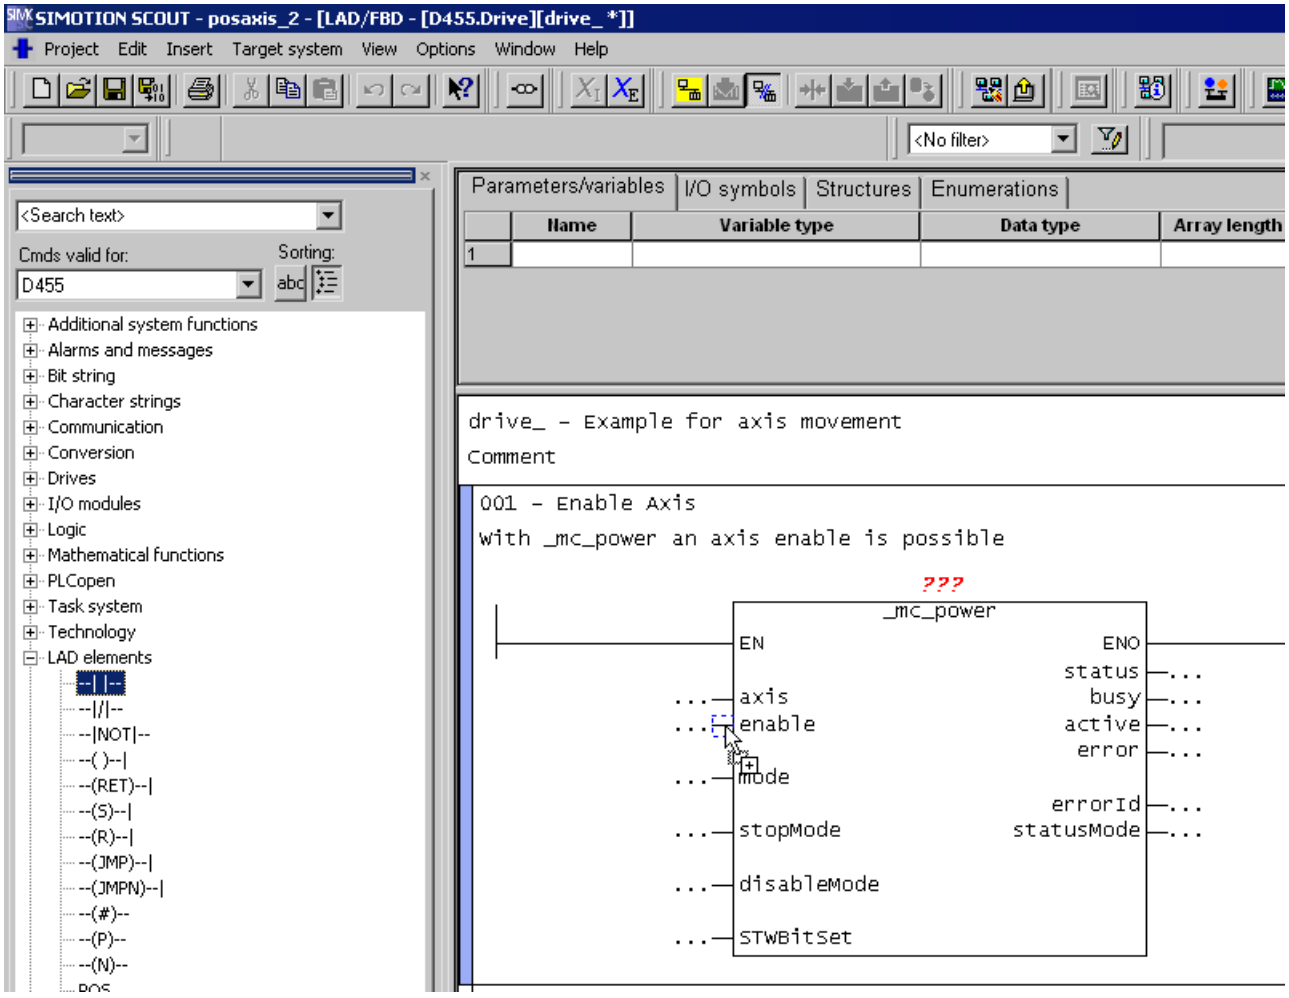

Figure 7-555 Drag&drop the NO contact LAD element to the connector of the enable input

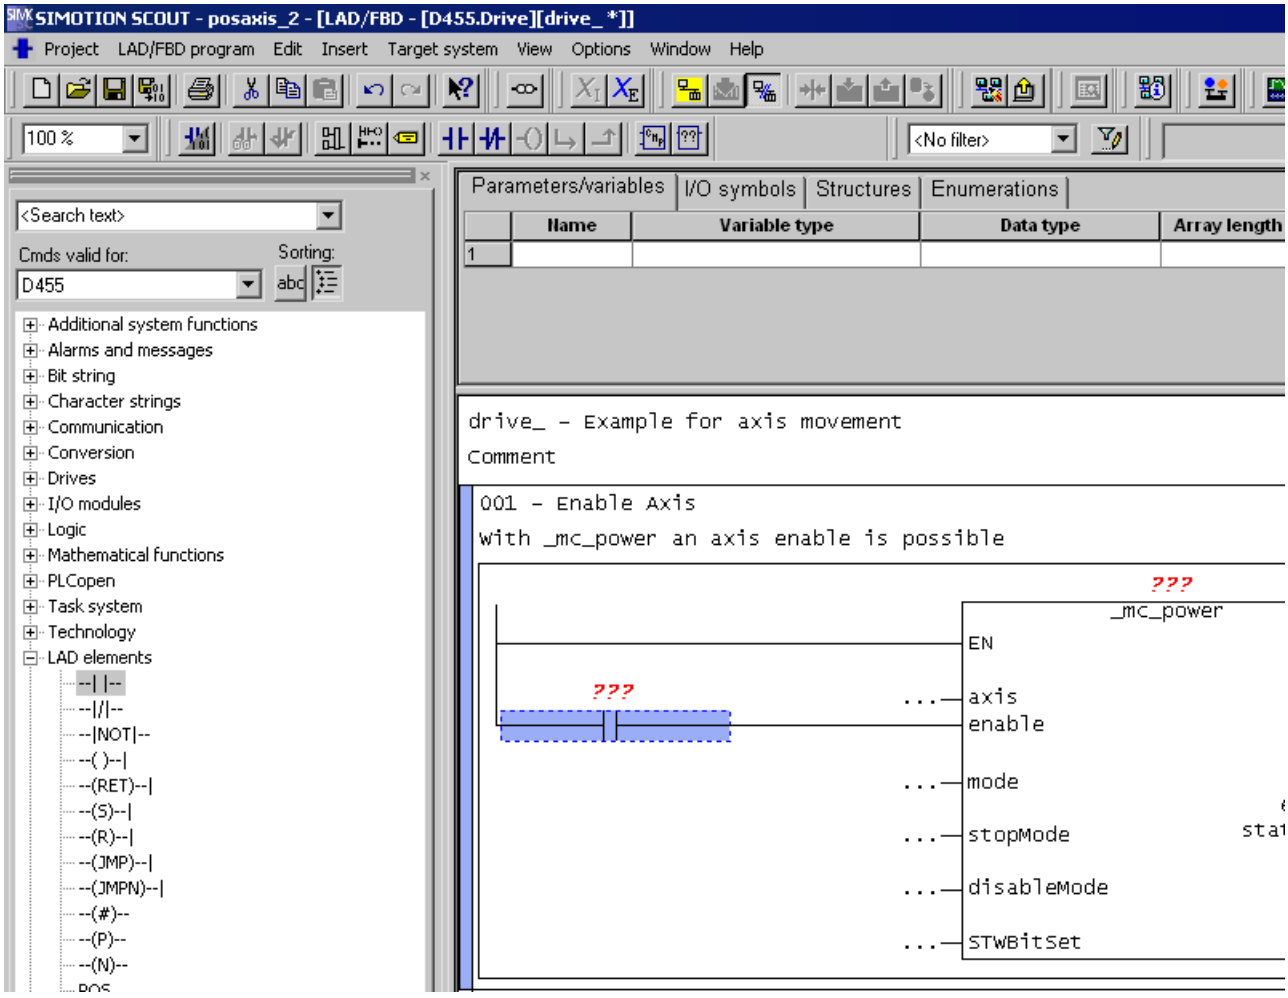

Figure 7-556 Network with a NO contact LAD element inserted

5. Drag and drop two **NO contact** LAD elements to the **execute** enable input of the **_MC_MoveRelative** function block.

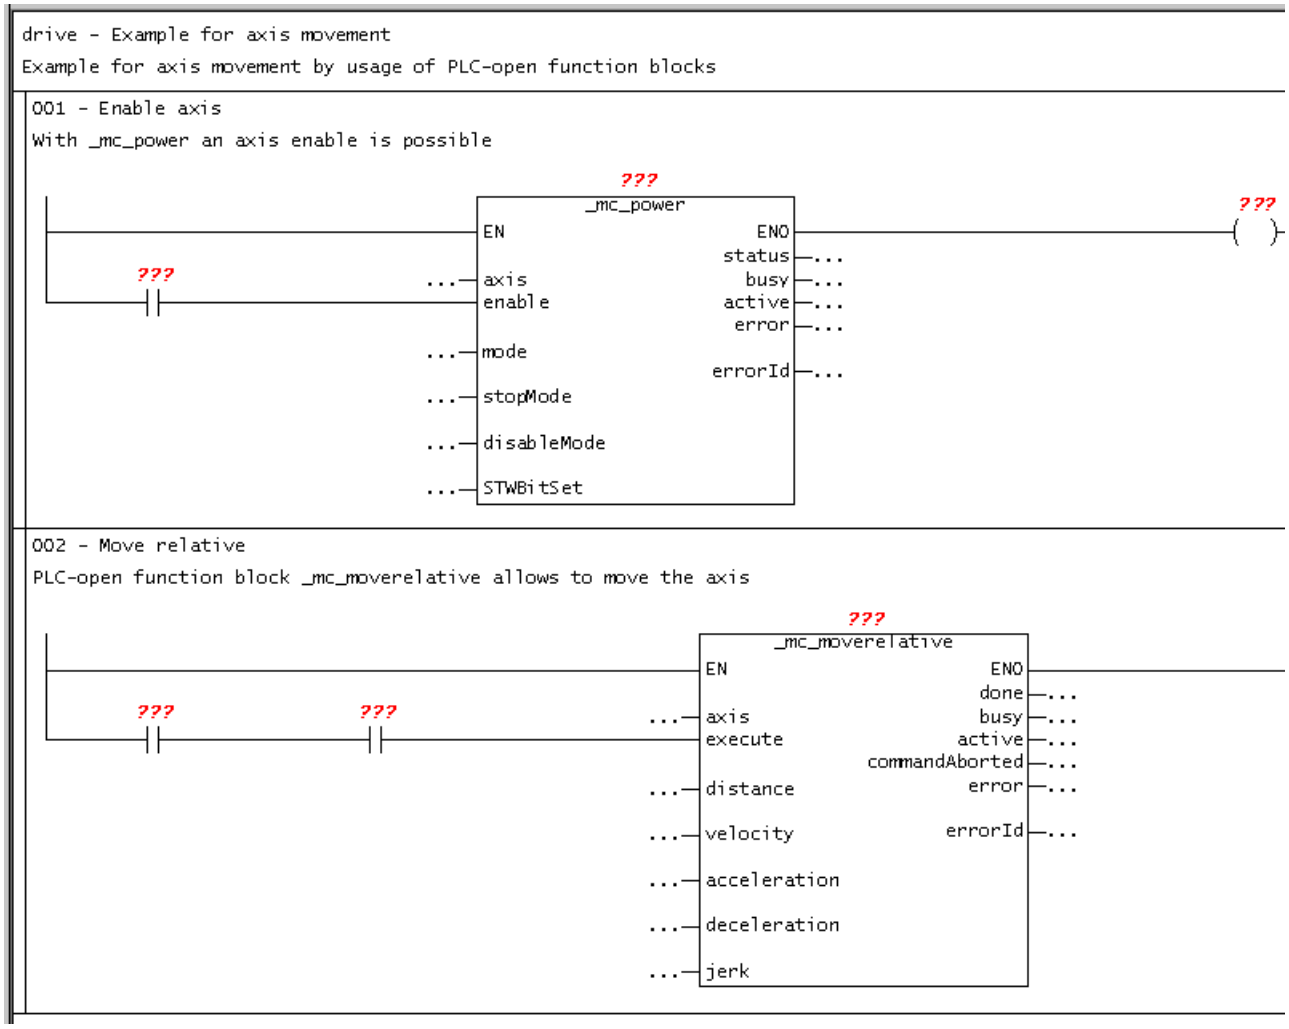

Figure 7-557 Networks with NO contacts inserted

Entering variables in the declaration table

To enter variables, proceed as follows:

1. Select the **Parameters/variables** tab.
2. Enter name, variable type, data type and/or start value in the declaration table (as shown in the figure below).
   In order to use PLCopen blocks, you must create one instance for each the used blocks **(_MC_Power** and **_MC_MoveRelative**). The data type of the instance corresponds to the block name. The variables **i_mc_power** and **i_mc_moverelative** are instance variables for the two function blocks **_MC_Power** and **_MC_MoveRelative**.
   You can find further information about the declaration and use of instance variables in Example: Function block (FB) (Page 5238).

Parameters/variables | I/O symbols | Structures | Enumerations

	Name	Variable type	Data type	Array length	Initial value	Comment
1	enable	VAR	BOOL			
2	move	VAR	BOOL			
3	i_mc_power	VAR	_MC_POWER			
4	i_mc_moverelative	VAR	_MC_MOVERELATIVE			
5	o_enabled	VAR	BOOL			
6						

Figure 7-558 Variables in the declaration table

Parameterization of the NO contacts

How to parameterize each of the NO contacts:

1. Click in the input field **???** for the NO contact.
2. Enter the appropriate variable.
3. Press **Enter**.

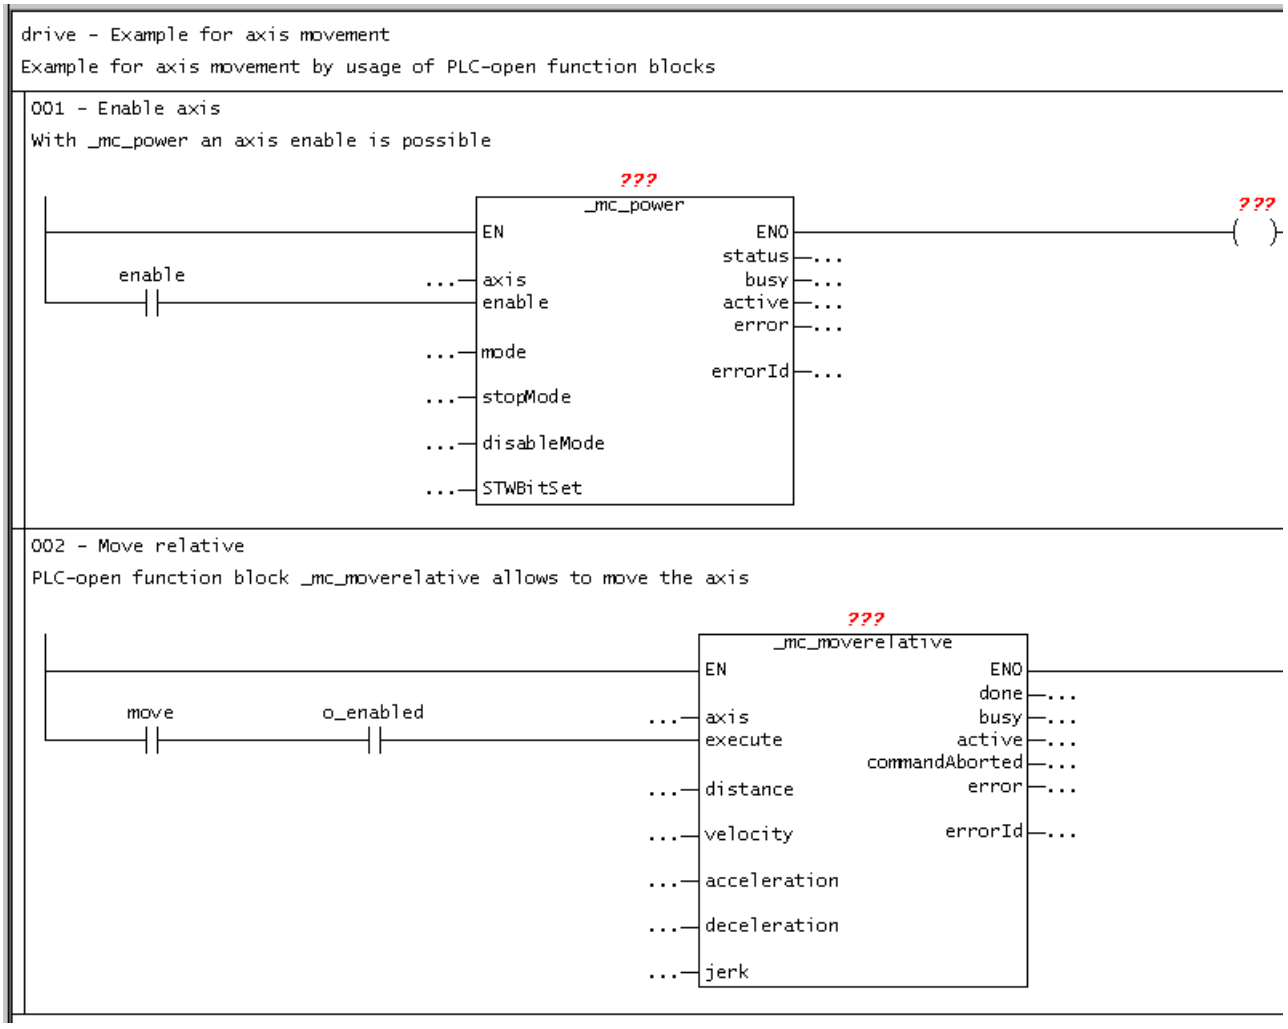

Figure 7-559 Parameterization of the NO contacts

Setting call parameters for the _MC_Power command

Note

The **Enter Call Parameters** dialog box displayed below is available for each SIMOTION command.

To set the call parameters, proceed as follows:

1. Double-click the box.
2. Select the instance, the homing axis, the axis enables to be set, stop mode and enable mode for the axis.
   If you print the project, your parameters appear in the printout according to your settings, e.g. **only allocated box parameters**.
3. Confirm with **OK**.

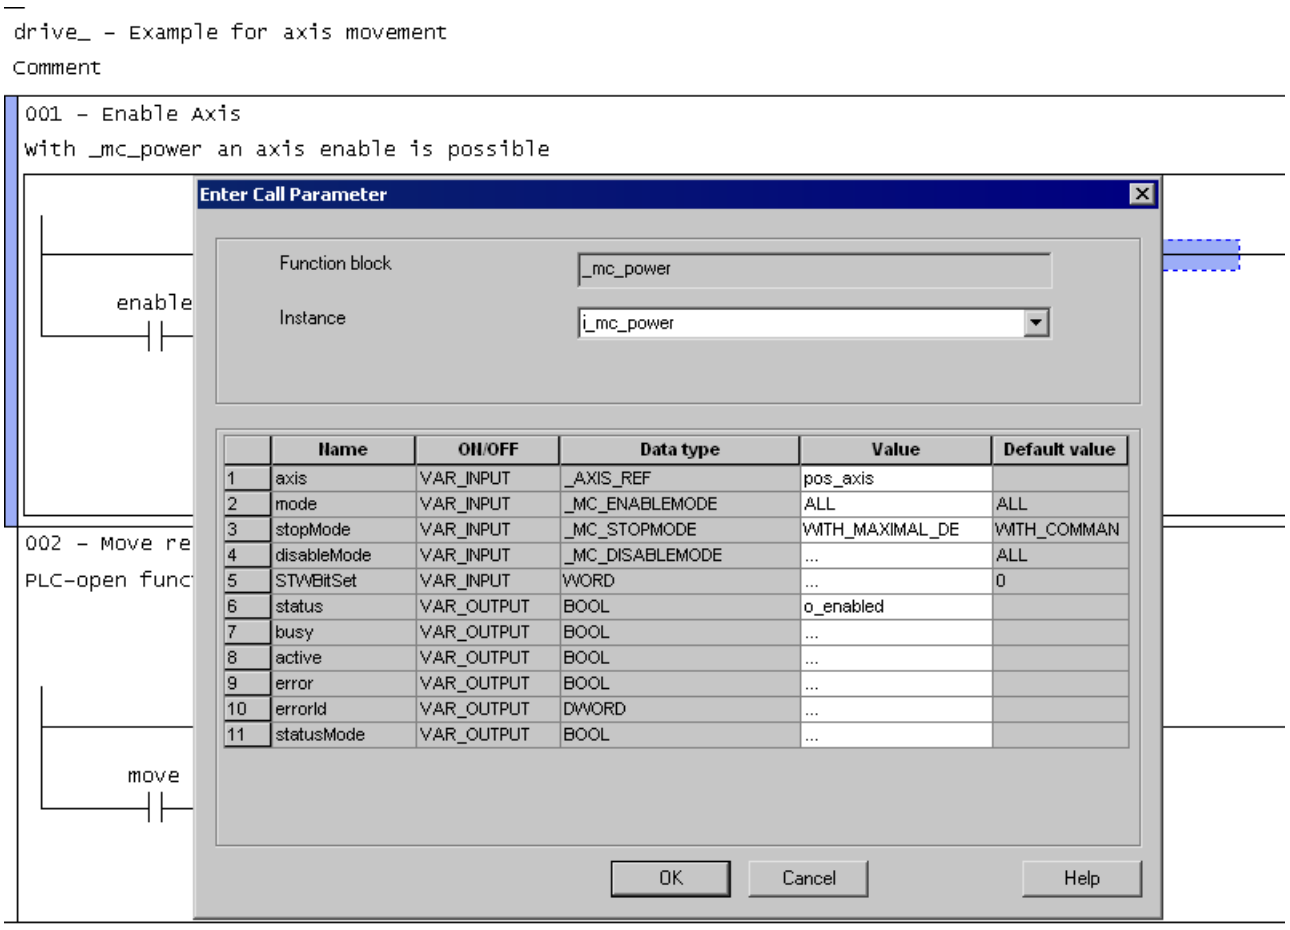

Figure 7-560 Set call parameters for the PLCopen block _MC_Power

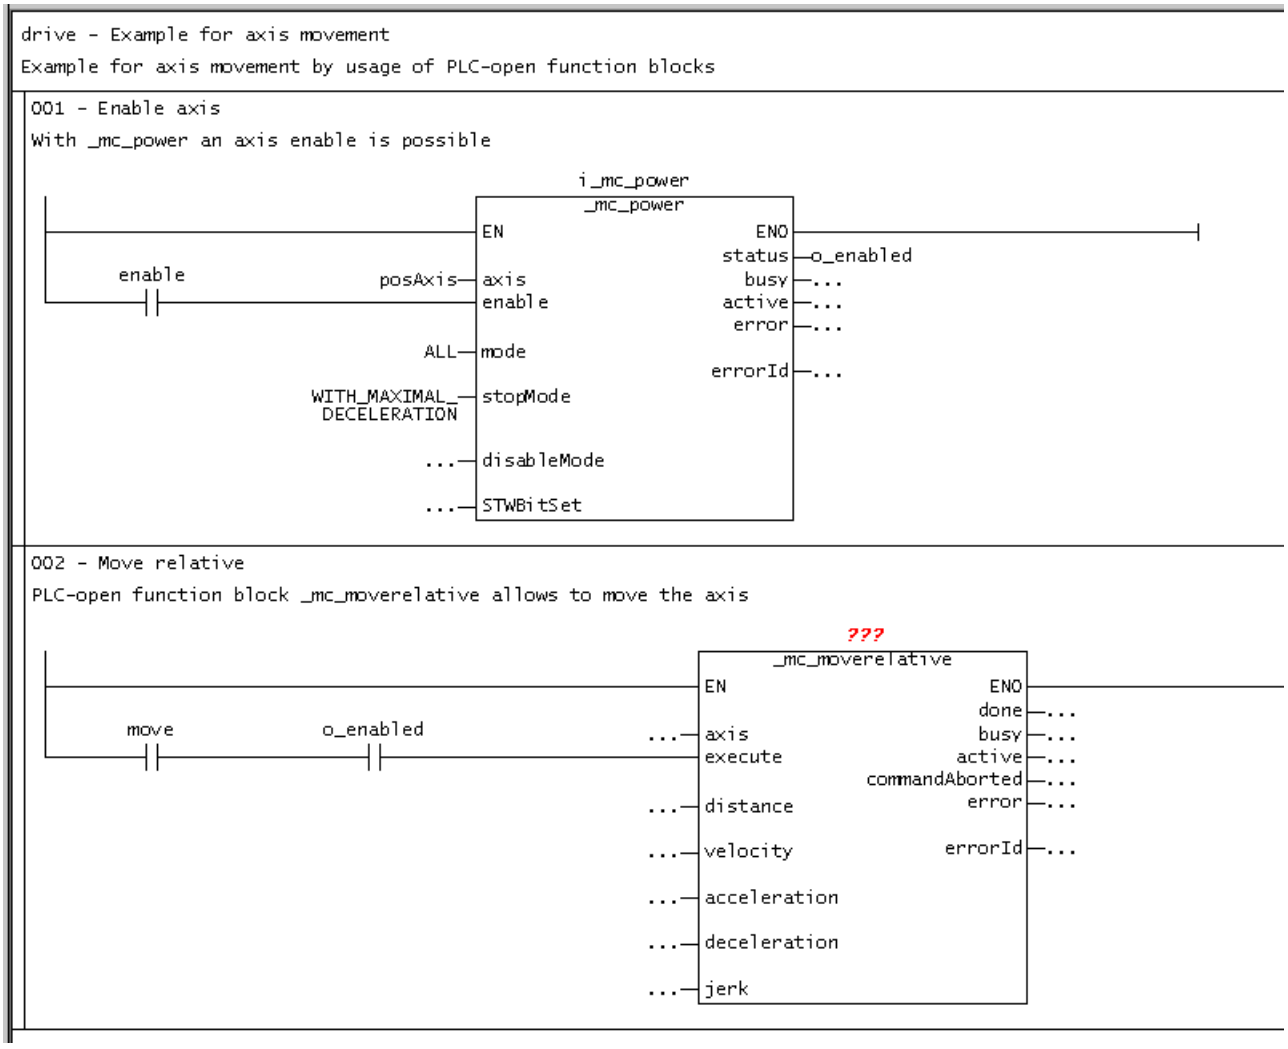

Figure 7-561 Labelled _MC_Power box

Setting call parameters for the _MC_MoveRelative command

To set the call parameters, proceed as follows:

1. Double-click the _mc_moverelative box.
2. Select the instance and the homing axis. Enter values for the difference in distance traveled and for the maximum speed of the axis.
   If you print the project, your parameters appear in the printout according to your settings, e.g. **only allocated box parameters**.
3. Confirm with **OK**.

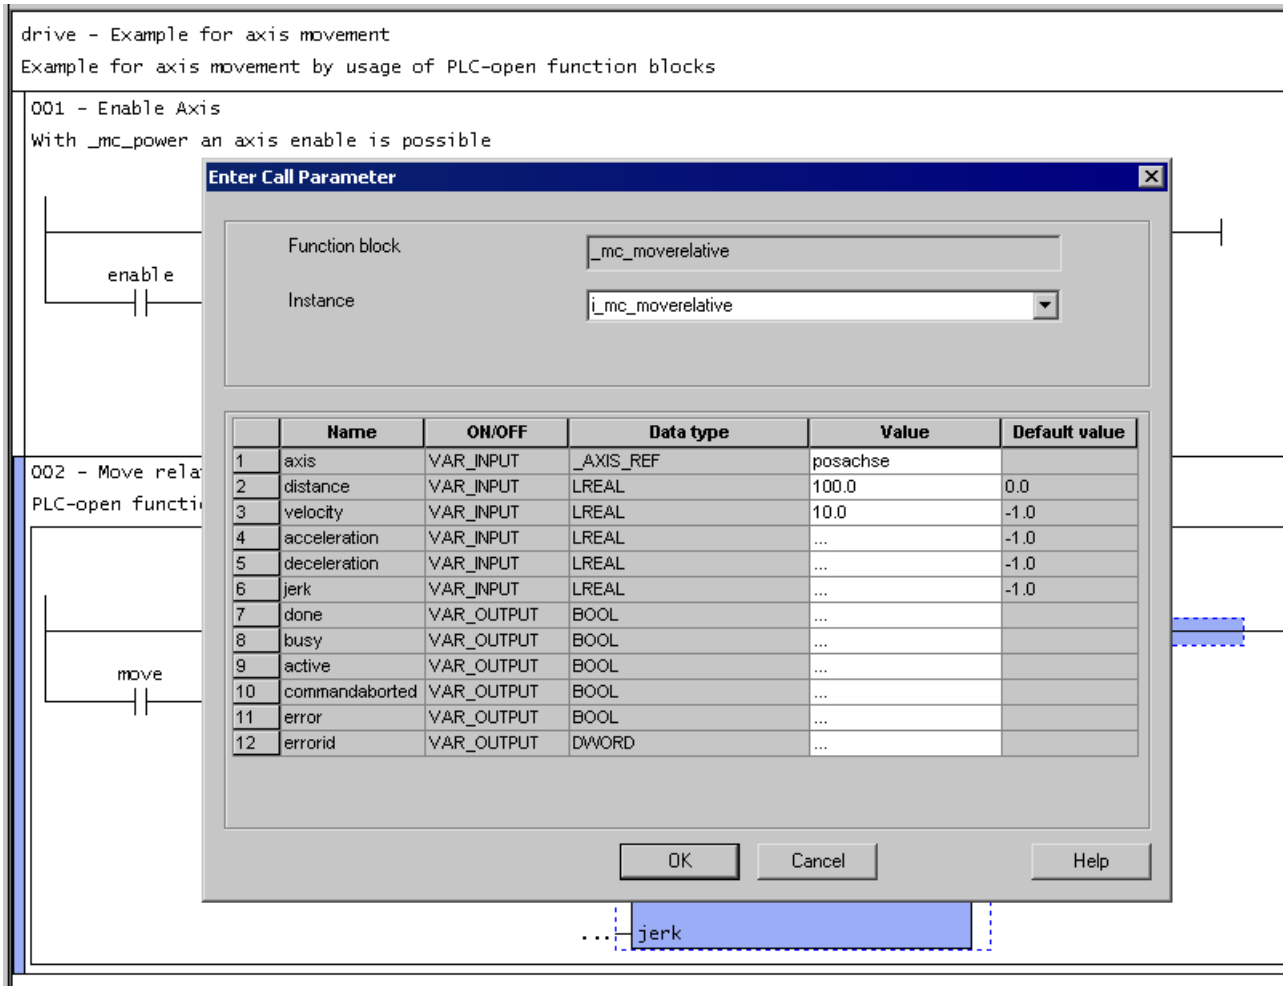

Figure 7-562 Set call parameters for the PLCopen block _MC_MoveRelative

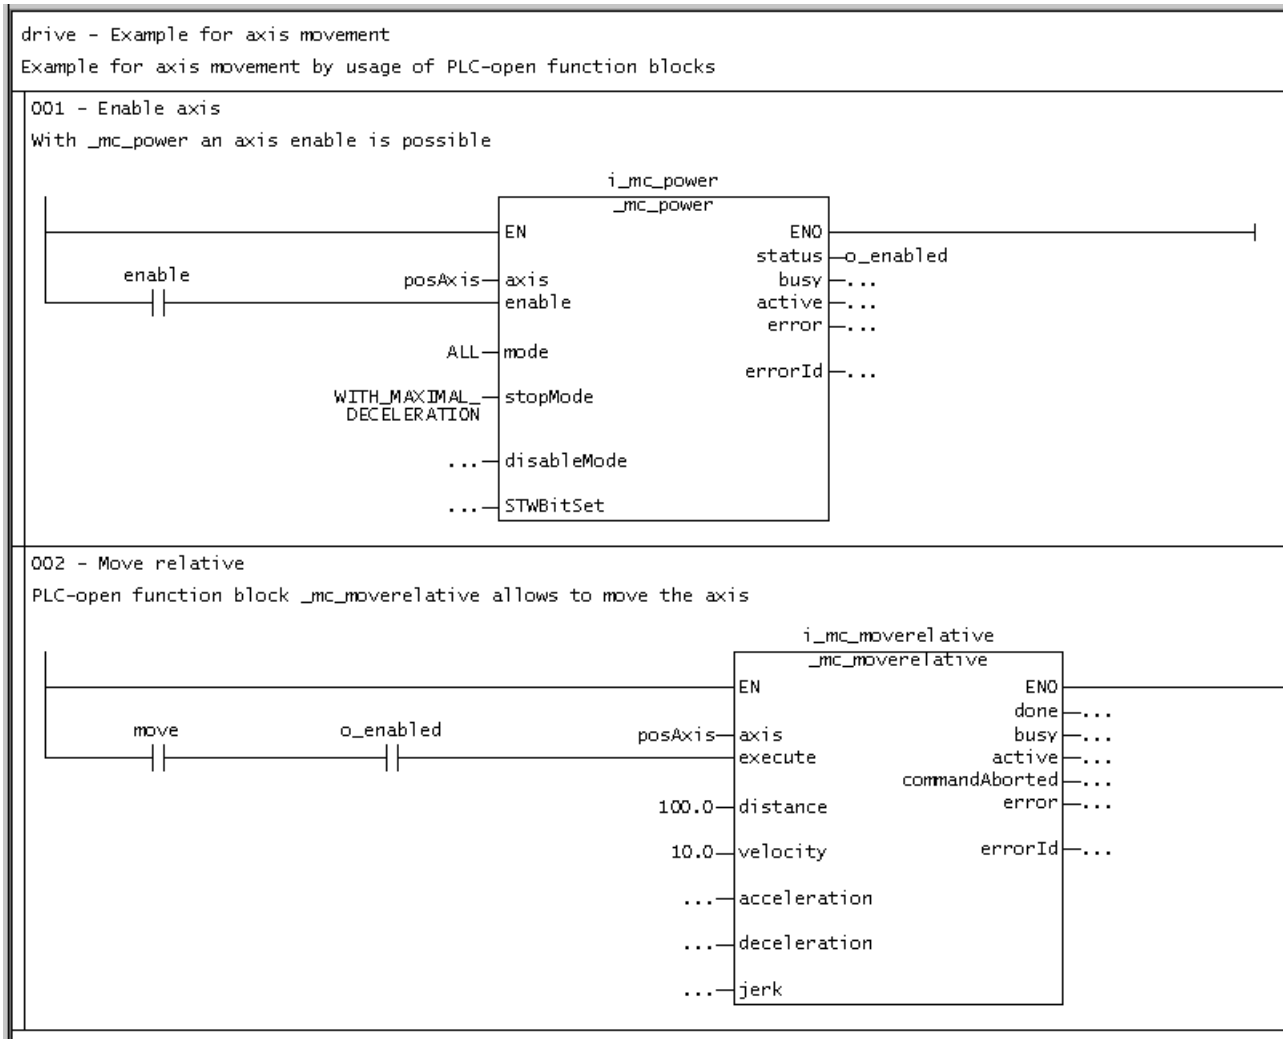

Figure 7-563 Network with entered variables

Details view

To show the detail view, proceed as follows:

1. Select the **View > Detail view** menu item.
   Information, e.g. compiler messages, will be displayed during the compilation of a program.

Compiling

To compile the program, proceed as follows:

1. Select the program in project navigation.
2. Open the **LAD/FBD program** menu and select **Accept and compile**.

During the compilation process, messages on the successful compilation status are displayed in the detail view. Should any error occur during compilation, they will be displayed in plain text there.

Assigning a sample program to an execution level

Before you can run the sample program, you must assign it to an execution level or a task. When you have done this, you can establish the connection to the target system, download the program to the target system, and then start it.

To assign the program to an execution level (see also the blinker program (Page 5387) example), proceed as follows:

1. Double-click the **EXECUTION SYSTEM** folder in the project navigator.
2. Mark the **BackgroundTask**.
3. Click the **Program assignment** tab.
4. Select the program.
5. Click the button **>>**.
6. Click **Close**.

See also

Assigning a sample program to an execution level (Page 5387)

Starting sample program

To start a program, proceed as follows:

1. Make sure the LAD/FBD unit creates the additional debug code for **program status** during compilation:
   Open the Properties window for the LAD/FBD unit (see Defining the properties of an LAD/FBD unit (Page 5109)).
2. Activate the **Permit program status** compiler option on the **Compiler** tab as the local compiler setting (see Local compiler settings (Page 5112)) for this LAD/FBD unit.
   See also the description relating to Effectiveness of local or global compiler settings (see the SIMOTION ST Programming and Operating Manual).
3. Select **Project > Save and recompile all**.
   The project is locally saved on the hard disk and compiled.
4. Select the **Project > Connect to selected target devices** menu command or click  .
   Online mode is activated.
5. Select the **Target system > Load > Download project to target system** menu command or click  .
   The project data (including the sample program) and the data of the hardware configuration are downloaded to the RAM of the target system.
6. Select both networks and click the  button for **program status** (CTRL+F7 shortcut) in the LAD editor function bar (Page 5086).
   Monitoring the program execution (Page 5349) is switched on.

7. Mark the SIMOTION device in the project navigator and select **Target device > Operating mode** in the context menu.
   The **Operating mode** window with the software switch for modes opens.
8. Click the **RUN** button in the software switch.
   The SIMOTION device is in **RUN** mode. The sample program is run and the current paths/ signal paths are color-coded in accordance with the current signal values (Page 5349).

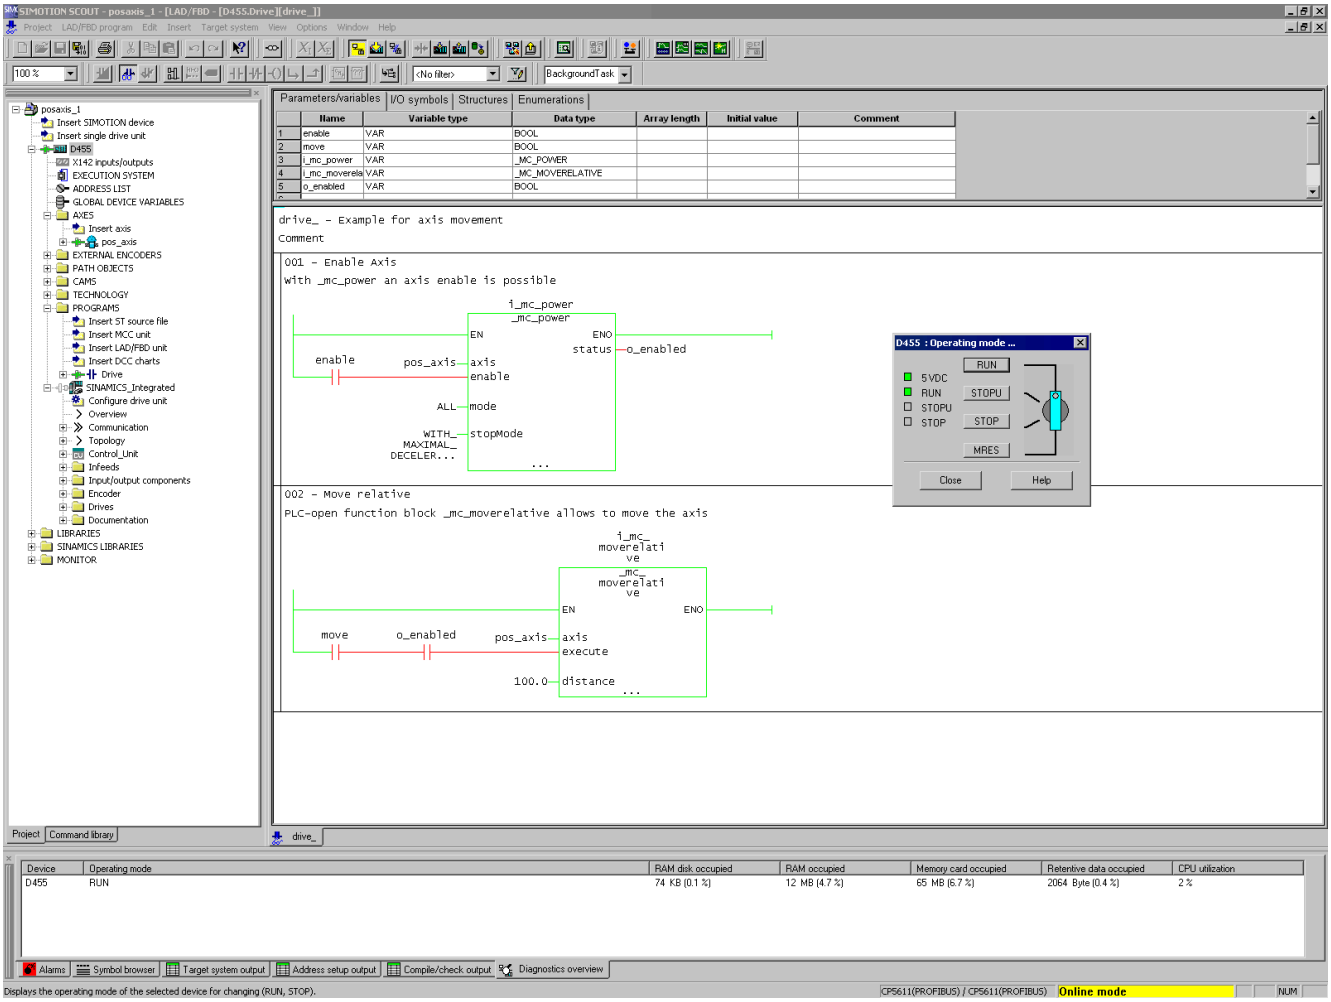

Figure 7-564 Sample program is started

7.3.9 Appendix

7.3.9.1 Key combinations

The following key combinations are available:

With LAD/FBD editor open	
Left/right arrow buttons Up/down arrow buttons	With a selected operator: Navigation between the individual operators
Ctrl+down arrow button	Selects previous network
Ctrl+up arrow button	Selects next network
Ctrl+F7	Switches the program status (Page 5348) function on and off
Ctrl+space	Automatic completion (Autocomplete) (Page 5089)
Pg Up	Selects the network at the start of the visible editor area
Pg Dn	Selects the network at the end of the visible editor area
Del	Deletes an operator
Tab / Shift+Tab	Jumps forward to next button / input field / jumps back to previous button / input field
Return	Opens the input field of the current operand or confirms the entry made in the input field
Esc	Aborts the entry while input field is open
Shift+F6	Switches between declaration table and editor area
Ctrl+Alt+H	Opens the symbol input help dialog window

Window menu	
Ctrl+Shift+F5	Rearranges all windows opened in this application in horizontal tiled format
Ctrl+Shift+F3	Rearranges all windows opened in this application in vertical tiled format
Ctrl+Tab	Switches between windows of the working area

View menu	
Ctrl+F11	Maximizes the working area
Ctrl+F12	Maximizes the detail view
Ctrl+Num+	Enlarges the contents of the working area
Ctrl+Num-	Reduces the contents of the working area
F5	Updates the view

LAD/FBD unit menu	
Ctrl+F4	Closes the LAD/FBD unit
Alt+Enter	Displays the properties of the active/selected object for editing
Ctrl+B	Accepts and compiles the active/selected object
Ctrl+R	Inserts a new network

LAD/FBD program menu	
Ctrl+F4	Closes the LAD/FBD program
Alt+Enter	Displays the properties of the active/selected object for editing
Ctrl+B	Accepts and compiles the active/selected object
Ctrl+R	Inserts a new network
Ctrl+L	Jump label ON/OFF
Ctrl+Shift+K	Shows/hides the comment line
Ctrl+Shift+B	Display options for boxes
Ctrl+T	Symbol check and type update
Ctrl+F7	Program status On/Off
Alt+Shift+F8	Inserts a comparator
Alt+Shift+F9	Inserts an empty box
Ctrl+1	Switches to LAD
Ctrl+3	Switches to FBD

Edit menu	
Ctrl+Z	Undoes the last action (except: Save)
Ctrl+Y	Redoes the last action which was undone
Ctrl+X	Cuts a command
Ctrl+C	Copies a command
Ctrl+V	Inserts a command
Del	Deletes selected commands in the LAD editor
F2	Renames the active/selected object
Alt+Enter	Displays the properties of the active/selected object for editing
Ctrl+Alt+O	Opens the selected object
Ctrl+A	Selects all objects in the current window
Ctrl+F	Local search
Ctrl+Shift+F	Find in the project
F3	Find next (for local search)
Ctrl+H	Local find and replace
Ctrl+Shift+G	Find and replace in a project
Ctrl+J	Next position (for search in the project)

Debug menu	
F12	Activates or deactivates a set breakpoint
Ctrl+F8	Continues the program execution at the activated breakpoint
Ctrl+F10	Next step

LAD elements	
Shift+F2	Inserts an NO contact
Shift+F3	Inserts an NC contact

LAD elements	
Shift+F7	Inserts a coil
Shift+F8	Opens a branch
Shift+F9	Closes a branch

FBD elements	
Shift+F2	Inserts an AND box
Shift+F3	Inserts an OR box
Shift+F4	Inserts an XOR box
Shift+F7	Assignment or jump
Shift+F8	Inserts a binary input
Shift+F9	Negates a binary input

7.3.9.2 Protected and reserved identifiers

Reserved identifiers may only be used as predefined. You may not declare a variable or data type with the name of a reserved identifier.

There is no distinction between upper and lower case notation.

The ST programming language includes protected and reserved identifiers (see the SIMOTION ST Programming and Operating Manual). The same list also applies to the LAD/FBD programming languages. The LAD/FBD programming language also includes the protected and reserved identifiers listed in the table.

You can find a list of all the identifiers whose meanings are predefined in SIMOTION in the SIMOTION Basic Functions Function Manual.

Table 7-604 Protected identifiers applicable only to the LAD/FBD programming language

A	
ANDN	
C	
CAL CALC	CALCN
J	
JMP JMPC	JMPCN
L	
LD	LDN
O	
ORN	
R	
RET RETC	RETCN
S	
ST	STN

X	
XORN	

7.4 SINAMICS/SIMOTION DCC Editor Description

Preface

Compliance with the General Data Protection Regulation

Siemens respects the principles of data privacy, in particular the data minimization rules (privacy by design).

For the product SINAMICS DCC this means:

The product stores personal data only in the project. The user is therefore responsible for ensuring compliance with the statutory data protection provisions. This applies in particular to the transfer of projects. If the user links this data with other data (e.g. shift plans) or if he/she stores person-related data on the same data medium (e.g. hard disk), thus personalizing this data, he/she has to ensure compliance with the applicable data protection stipulations.

The following data must be taken into account.

- Windows login
  In the standard configuration, the product saves the login details of the Windows user together with technical function data (e.g. time stamp) in the project. The specified data is saved in order to trace changes in large configurations.
  With SINAMICS DCC, a personal reference can be established via the project and all elements contained in it (e.g. charts).
  The specified data can be viewed in the properties of the project and the elements in SINAMICS DCC (property "Author") and subsequently changed, with the exception of the last modification of the project.

For the above-mentioned point, the details of the functions mentioned in the respective chapter in the information system of SINAMICS DCC must be observed.

By generating the login or username, personal data can be pseudonymized for the functions. Deleting the project will cause all personal data saved within it to be deleted too.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.3.1:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions

- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

SINAMICS documentation

The SINAMICS documentation is organized on 2 levels:

- General documentation/catalogs
- Manufacturer/service documentation

An overview of the current documentation in the respective available languages can be found on the Internet:

http://www.siemens.com/motioncontrol

Select the menu items "Support" --> "Technical Documentation" --> "Overview of Publications".

Information on the range of training courses and FAQs (Frequently Asked Questions) is available on the Internet:

http://www.siemens.com/motioncontrol

Select the menu item "Support".

Further documentation for the DCC editor

- SINAMICS/SIMOTION Function Manual, *Description of the standard DCC blocks*

Hotline and Internet addresses

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

http://www.siemens.com/motioncontrol/docu

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

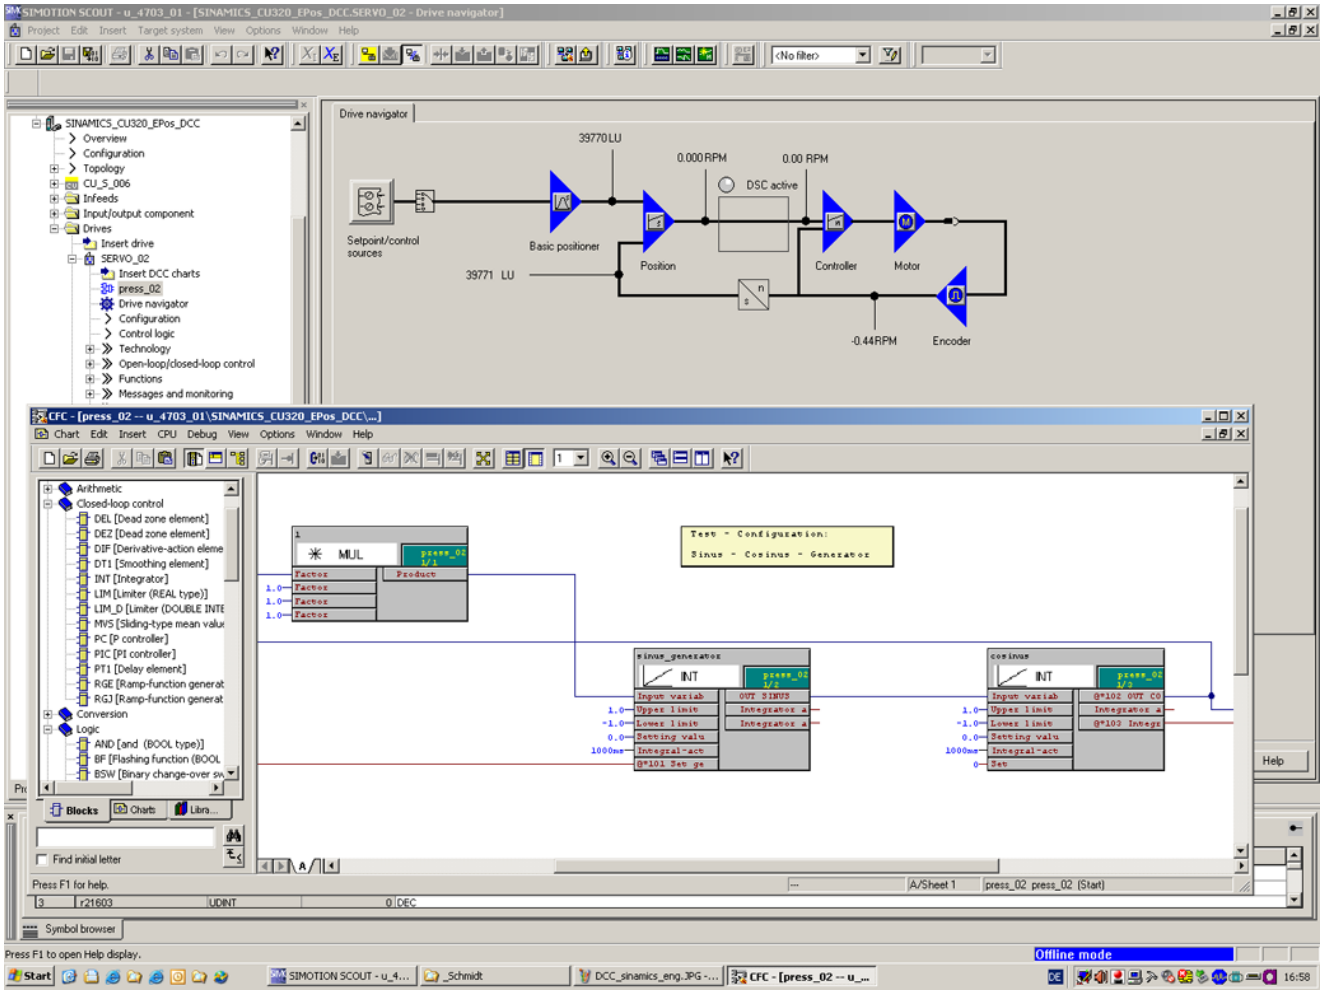
Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

7.4.1 Introduction

Drive Control Chart (DCC) for SINAMICS and SIMOTION means graphic configuration and expansion of the device functionality by means of freely available control, arithmetic and logic blocks

Drive Control Chart (DCC) expands the facility for the simplest possible configuring of technological functions both for the SIMOTION motion control system and the SINAMICS drive system. This opens up a new dimension for users for adapting the specified systems to the specific functions of their machines. DCC has no restriction with regard to the number of usable functions; this is only limited by the performance capability of the target platform.



DCC comprises the DCC editor and the DCB library (block library with standard DCC blocks).

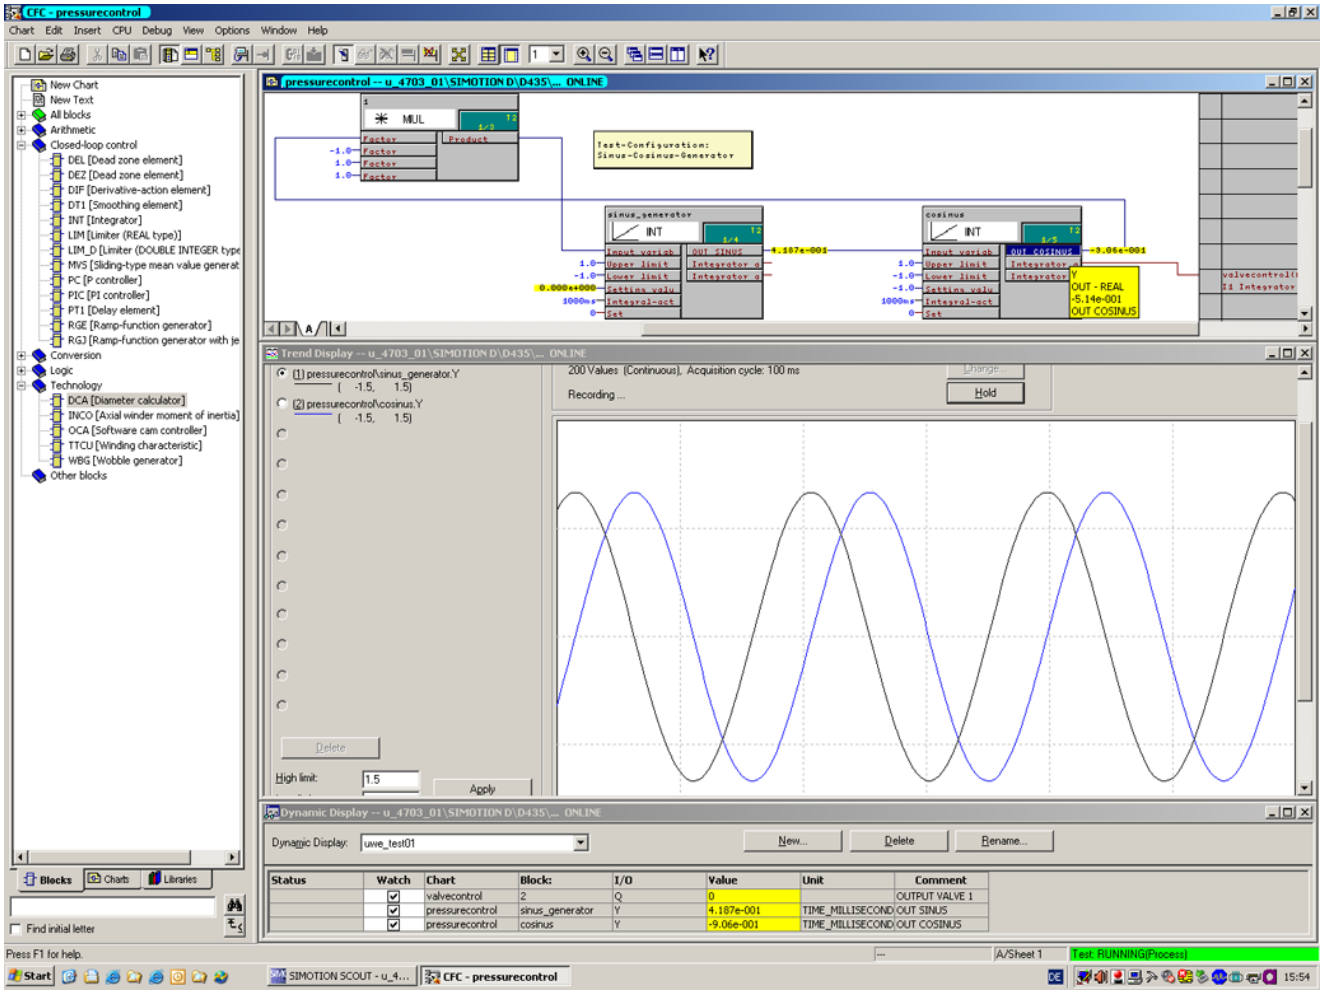
The user-friendly **DCC editor** enables easy graphic configuration and a clear representation of control loop structures as well as a high degree of reusability of existing charts.
The open-loop and closed-loop control functionality is defined by using multi-instance-capable blocks (**Drive Control Blocks, DCBs**) from a pre-defined library (**DCB library**) that are selected and graphically linked by dragging and dropping. Test and diagnostic functions allow verification of program behavior or the identification of causes in the event of errors.

The block library contains a large selection of control, arithmetic and logic blocks as well as extensive open-loop and closed-loop control functions.

All commonly used logic functions are available for selection (AND, XOR, On/Off delay, RS flip-flop, counters, etc.) for the logic operation, evaluation and acquisition of binary signals. Diverse arithmetic functions such as absolute-value generation, dividers and minimum/maximum analysis are available for monitoring and evaluating numeric variables. In addition to the drive control, axial winder functions, PI controllers, ramp-function generators or sweep generators can be configured simply and without problem.

Almost unlimited programming of control structures is possible in conjunction with the SIMOTION motion control system. These can then be combined with other program sections to form an overall program.

Drive Control Chart for SINAMICS drives also provides a convenient basis for resolving drive-level open-loop and closed-loop control tasks directly in the converter. This results in further adaptability of SINAMICS for the tasks set. On-site processing in the drive supports modular machine concepts and results in increased overall machine performance.



- With SINAMICS, DCC can be activated simultaneously on several drive objects (DOs) on a drive unit. With SIMOTION, several DCC charts can be created in a program container.
- Block library with management, arithmetic, control, logic and complex blocks.
- Graphic component connection editor with various editing, macro, help, search, comparison and print functions.
- Simple configuration of axial winder functions, PI controller, ramp-function generator or sweep generator.
- Execution environment for SIMOTION with sampling times that can be selected and mixed, and consistent data transfer between sampling times.
- Execution environment for SINAMICS with the option of embedding technology in SINAMICS using BICO technology so that applications can be set via configured parameters. Up to ten different sampling times can be configured.

- Diagnostics environment with signal display, diagnostic and trace functions.
- Scalability with different performance features and quantity structures in DCC SIMOTION and DCC SINAMICS.

Note

The DCC editor is a programming system based on CFC (Continuous Function Chart). The following sections describe the principles of DCC operation that have not already been covered in the manual titled "CFC Manual for S7".

Note

Further references for the DCC editor:

SINAMICS/SIMOTION Function Manual, *Description of the standard DCC blocks*

Differences between DCC SIMOTION and DCC SINAMICS

DCC SIMOTION and DCC SINAMICS differ to some extent in their mode of operation. The basic differences are listed below:

Table 7-605 Differences between DCC SIMOTION and DCC SINAMICS

	SIMOTION	SINAMICS
System integration	Via interconnection to variables of the basic system	Via adjustable parameter or interconnection via BICO parameter to the basic system
Execution system	Any number of execution groups that can be assigned five time slices (depending on the system cycle clocks)	Maximum of ten execution groups that can be assigned ten different sampling times
Consistency in the data transfer	Consistent data transfer also across the time slices	Consistency in the data transfer must be established by the user, when required, by means of standard blocks (SAH_X)
Scope of standard blocks	See SINAMICS/SIMOTION Function Manual, *Description of the standard DCC blocks*	See SINAMICS/SIMOTION Function Manual, *Description of the standard DCC blocks*

Availability of DCC features

Table 7-606 Availability of DCC features

Feature	Available as of version
Monitoring and tracing of published parameters	SINAMICS 2.5 / SIMOTION 4.1
Online changes in test mode and tracing of unpublished block connections	SINAMICS 2.6 / SIMOTION 4.1
Read back of BICO interconnections from the target device	SINAMICS 2.5 / DCC 2.0.3 / STARTER/SCOUT 4.1.3
Creation of installable libraries	SINAMICS 2.5 / DCC 2.0.3 / STARTER/SCOUT 4.1.3
DCC libraries	SINAMICS 4.4 / DCC 2.1 / STARTER/SCOUT 4.2
Installation of block libraries in the case of an opened SCOUT	SCOUT V4.1.2
Installation of block libraries in the case of an opened STARTER	STARTER V4.2

Feature	Available as of version
Online insertion and deletion of block instances	SINAMICS 2.6 / SIMOTION 4.1.2
Online changes, insertion and deletion of interconnections	SINAMICS 2.6 / SIMOTION 4.1.2
Display of reference data for DCC charts	SCOUT 4.1 / STARTER 4.1.3
Search and replace for DCC sheet bar interconnections	SCOUT/STARTER 4.1.2
Compiling without DCC license	SCOUT/STARTER 4.1.3
Creating C-block libraries automated from DCC libraries	DCC SIMOTION 2.0.3
Fixed execution group "BEFORE actual position value"	SINAMICS 4.3
Chart-by-chart XML export/import	SCOUT/STARTER 4.2 / DCC 2.1
User-defined structures, DCC SIMOTION	SCOUT 4.2 / DCC 2.1
Read back DCC chart sources from the target device	SINAMICS 4.4 (only in conjunction with TPdcblibV3.0_SINAMICS_4_4 or higher) / SCOUT / STARTER 4.2 / DCC 2.1
Automatic library exchange when upgrading the device version	SCOUT/STARTER 4.2
Exchanging target device families for DCC libraries	SCOUT 4.3 / DCC 2.2

7.4.2 Safety instructions and industrial security

7.4.2.1 Fundamental safety instructions

General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

If the safety instructions and residual risks in the associated hardware documentation are not observed, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

Warranty and liability for application examples

Application examples are not binding and do not claim to be complete regarding configuration, equipment or any eventuality which may arise. Application examples do not represent specific customer solutions, but are only intended to provide support for typical tasks.

As the user you yourself are responsible for ensuring that the products described are operated correctly. Application examples do not relieve you of your responsibility for safe handling when using, installing, operating and maintaining the equipment.

Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the Internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit:

Industrial security (http://www.siemens.com/industrialsecurity)

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed at:

Industrial security (http://www.siemens.com/industrialsecurity)

Further information is provided on the Internet:

Industrial Security Configuration Manual (https://support.industry.siemens.com/cs/ww/en/view/108862708)

⚠ WARNING

Unsafe operating states resulting from software manipulation

Software manipulations (e.g. viruses, trojans, malware or worms) can cause unsafe operating states in your system that may lead to death, serious injury, and property damage.

- Keep the software up to date.
- Incorporate the automation and drive components into a holistic, state-of-the-art industrial security concept for the installation or machine.
- Make sure that you include all installed products into the holistic industrial security concept.
- Protect files stored on exchangeable storage media from malicious software by with suitable protection measures, e.g. virus scanners.
- Protect the drive against unauthorized changes by activating the "know-how protection" drive function.

7.4.2.2 Use write and know-how protection

Prevent unauthorized changes by means of know-how protection

⚠ WARNING

Danger to life through manipulation of DCC charts and DCC libraries

The use of unprotected DCCs and DCC libraries entails a higher risk of manipulation of DCCs, DCC libraries and backup files.

- Protect important DCC charts and DCC libraries by using **know-how protection programs** or via the **know-how protection for drive units** in the SCOUT/STARTER. You can prevent manipulation by assigning a strong password.
- For **know-how protection programs** and **the know-how protection of drive units**, use passwords which include at least eight characters, upper and lower cases, numbers and special characters.
- Make sure that only authorized personnel can access the passwords.
- Protect the backup files on your file system using a write protection.

7.4.2.3 Industrial Security Configuration Manual

Manual on industrial security

Further information can be found in the configuration manual "Industrial Security" for SINAMICS, SINUMERIK and SIMOTION at Security Manual (https://support.industry.siemens.com/cs/document/108862708/sinumerik-simotion-sinamics-industrial-security?dti=0&lc=en-DE).

Note in particular the explanations on the cell protection concept in Section "General security measures - Network segmentation".

7.4.3 DCC editor functionality

7.4.3.1 Overview

The product offers a modular, scalable technology option, which has chiefly been developed for drive-related, continuous open-loop and closed-loop control engineering tasks.

The DCC technology option for SIMOTION controllers and SINAMICS drives can be configured graphically using the Drive Control Chart editor (referred to below as DCC editor), which is based on CFC. The following figure illustrates the data flow of the configuration data when configuring with the DCC technology option:

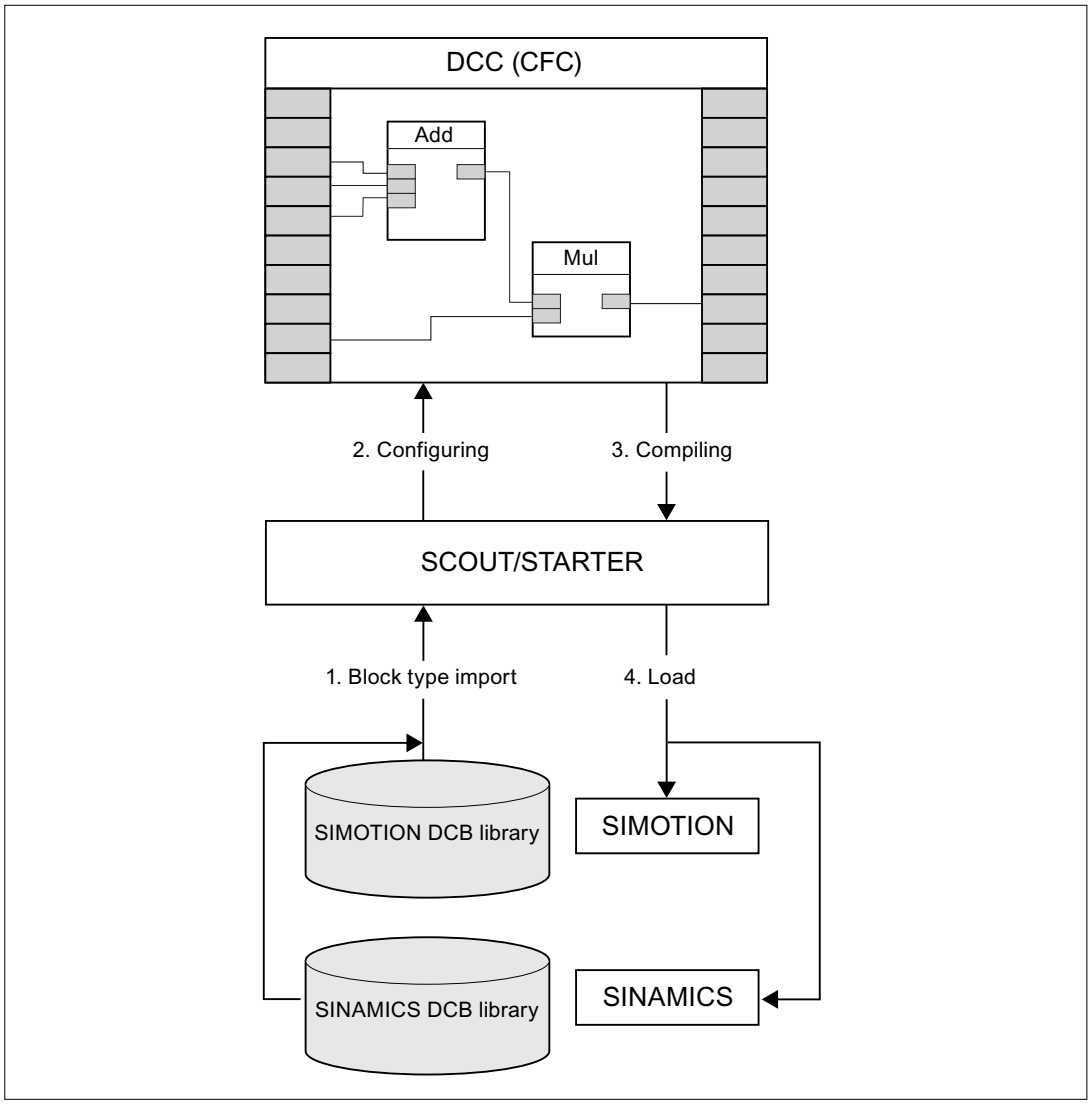


Figure 7-565 Flow of configuration data

1. When a new chart is created, the block types are taken from the device-specific block library and inserted in the DCC editor's block manager.
2. The DCC editor is used to create charts, in which you can insert, parameterize and interconnect blocks.
3. When you compile the charts, an intermediate code is created.
4. This is downloaded to the device or drive unit using STARTER/SCOUT.

7.4.3.2 Requirement

This description refers to the following software versions of the devices and engineering systems:

- DCC V3.3.0.1
- SIMOTION P, C, D as of Version 5.3.1
- SINAMICS Integrated for SIMOTION D as of Version 5.1
- SINAMICS S120, S150, G130, G150 as of Version 5.2
- SINAMICS SM150, GM150, GL150 and SL150 as of Version 4.8.2
- SINAMICS DCM as of Version 1.5
  Except for the utilization display, the SINAMICS DC MASTER as of Version 1.4 supports the same function scope as SINAMICS S120 as of Version 4.7. Detailed information about the SINAMICS DC MASTER Version 1.4 can be found in the SINAMICS DC MASTER 6RA80 DC Converters Operating Instructions, 01/2014 Edition
- SINAMICS DCP as of Version 1.2
- SIMOTION SCOUT/STARTER as of Version 5.3
- Required CFC versions for DCC V3.3.0.1:
  - STARTER: CFC V8.0, CFC V8.0.4, CFC V8.1, CFC 8.2 or CFC V9.0
  - SIMOTION SCOUT: CFC V9.0
- Engineering license required for DCC V3.3.0.1:
  - DCC SINAMICS: CFC for SINAMICS V7.1, V8.0, V8.1, V8.2 or V9.0
  - DCC SIMOTION: CFC for SIMOTION V7.1, V8.0, V8.2 or V9.0

Note

If errors occur when charts are being compiled in SIMOTION SCOUT/STARTER, it is possible to generate a comprehensive error report by compiling them again in the DCC editor. To do this, activate **Display all messages with 'Save and compile changes'** on the **Compiler** tab under the **Settings** menu command in SIMOTION SCOUT. A corresponding error report is automatically created in STARTER.

Note

The DCC editor is installed automatically with the SIMOTION SCOUT/STARTER engineering system.

- DCC setup 2.0.2 - 2.0.5 can be installed with all SIMOTION SCOUT/STARTER V4.1 service packs and hotfixes.
- DCC setup 2.0.2 - 2.0.5 can be installed in SIMOTION SCOUT/STARTER 4.2.
- DCC setup 2.1 can be installed as of SIMOTION SCOUT/STARTER 4.2.
- DCC setup 2.2 can be installed as of SIMOTION SCOUT/STARTER 4.3.
- DCC setup 2.3 can be installed as of SIMOTION SCOUT/STARTER 4.4.
- DCC setup 2.4 can be installed as of STARTER 4.5.
- The DCC setup 3.1 can be installed as of STARTER 5.1.
- DCC setup 3.3.0.1 can be installed as of STARTER 5.3.

An appropriate program license is required for the DCC editor. This is on the USB stick supplied with the DCC SIMOTION or DCC SINAMICS product.

The installation requirements are also stated in the Readme file for the software version.

Note

It is possible to print DCCs in the DCC editor, but not in SIMOTION SCOUT/STARTER.

Note

Only context-sensitive help is available for the DCC blocks, i.e. the descriptions cannot be accessed from the main help page.

Note

If the DCC charts are opened with a different CFC version than the one with which they were created, this may lead to inconsistencies within the project. The DCC chart must be recompiled and reloaded. DCC charts that have been edited with a newer CFC version can no longer be opened with an earlier CFC version. Backward conversion is not possible.

If you open a project whose charts have been created with an older CFC version, you can select whether the data format of the charts should be updated. If you reject this, you can in fact view the CFC charts, but cannot edit them any further. It is recommended to adapt the data format of the CFC charts to the currently installed CFC version.

7.4.3.3 New device versions

SIMOTION

The DCC functionality and performance of the new SIMOTION target devices is compatible with the previous versions, i.e. DCC V3.3.0.1 within the framework of SIMOTION SCOUT 5.3 supports the following target device versions:

- SIMOTION V4.1 devices
- SIMOTION V4.2 devices
- SIMOTION V4.3 devices
- SIMOTION V4.4 devices
- SIMOTION V4.5 devices
- SIMOTION V5.3.1 devices

The DCC functionality and performance of the new SOC2-based SIMOTION target devices (e.g. D410-2 DP) is compatible with the corresponding IDC-based previous devices and versions (e.g. D410 DP).

Note

Device versions

The device versions and software versions supported may be listed in the corresponding Readme files.

Note

A compatibility list is provided on the SIMOTION SCOUT DVD and at the following link on the Internet:
SIMOTION compatibility list (https://support.industry.siemens.com/cs/ww/en/view/18857317)

SINAMICS

DCC SINAMICS supports in STARTER/SCOUT V5.3 all previously released device versions with DCC.

In addition, DCC is offered for:

- SINAMICS 4.8.2, 5.1, 5.1.1 and 5.2
- DCM 1.5

The following device types/device versions are supported with SINAMICS 5.2:

- S120 CU320-2/CU310-2
- S150 CU320-2
- G130 CU320-2
- G150 CU320-2

SINAMICS 4.8.2 supports the following device types/versions:

- GL150 CU320-2
- GM150 CU320-2
- SL150 CU320-2
- SM120 CU320-2

Note

With the installation of an SSP, the latest standard *dcblib* library available for the device is installed and can be used on the device.

7.4.3.4 Establish the project requirements

Create a project

You must create a new project in the SIMOTION SCOUT/STARTER engineering system before using the DCC editor.

Procedure

Proceed as follows to create a project:

1. Start the SIMOTION SCOUT/STARTER engineering system.
2. Execute the **Project > New** function from the menu bar.

3. In the **New Project** window, enter the name of the project in the **Name** field.

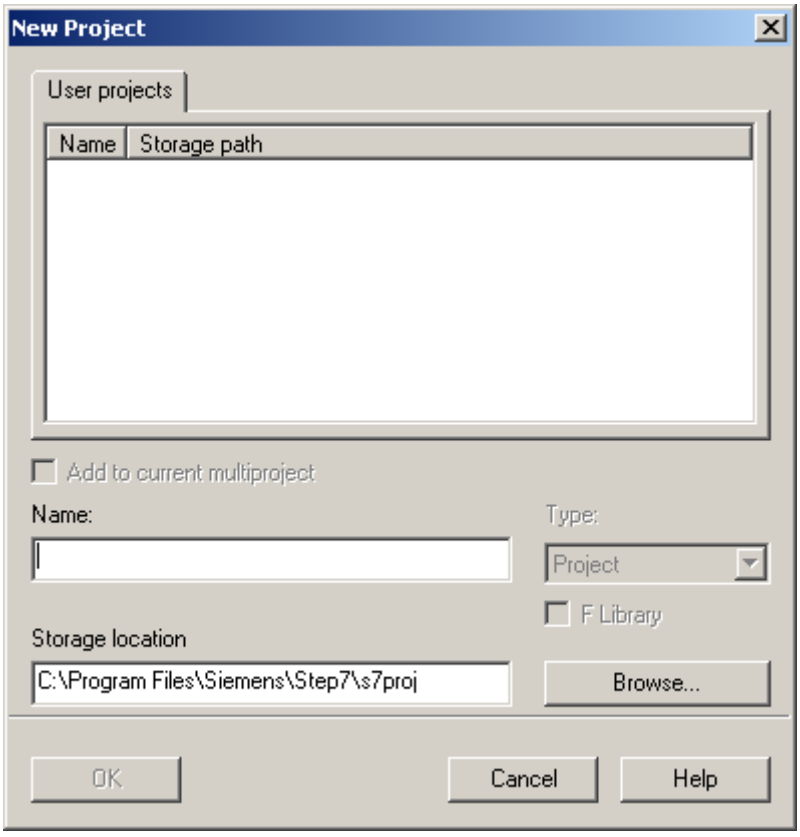

Figure 7-566 Window - New Project

4. Click **OK** to close the window.

The new project is created and then automatically opened.

Note

Convention for assigning names for projects

The project name may contain a maximum of 24 characters. The folder name is generated using the first eight characters of the project name. It is therefore important to ensure that the first eight characters of the project name are unambiguous.

Inserting a device into a project

SIMOTION

Proceed as follows to insert a device into a project:

1. Open an existing SIMOTION SCOUT project if a project is not already open.
2. Execute the **Create new device** command.

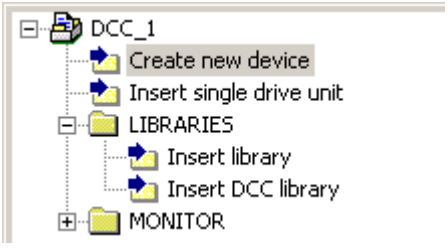

Figure 7-567 SIMOTION: Create new device

3. In the **Create new device** window, select the required device and close the window with **OK**.

Note

For further information on the **Open HW Config** switch, please refer to the documentation for SIMOTION SCOUT.

All requirements for creating a DCC in the project have now been met.

SINAMICS

1. Open an existing project or create a new project in which you want to insert a SINAMICS drive unit (e.g. SINAMICS S120 CU 320). Note that the SINAMICS S110 (CU 305 module) does not support DCC.

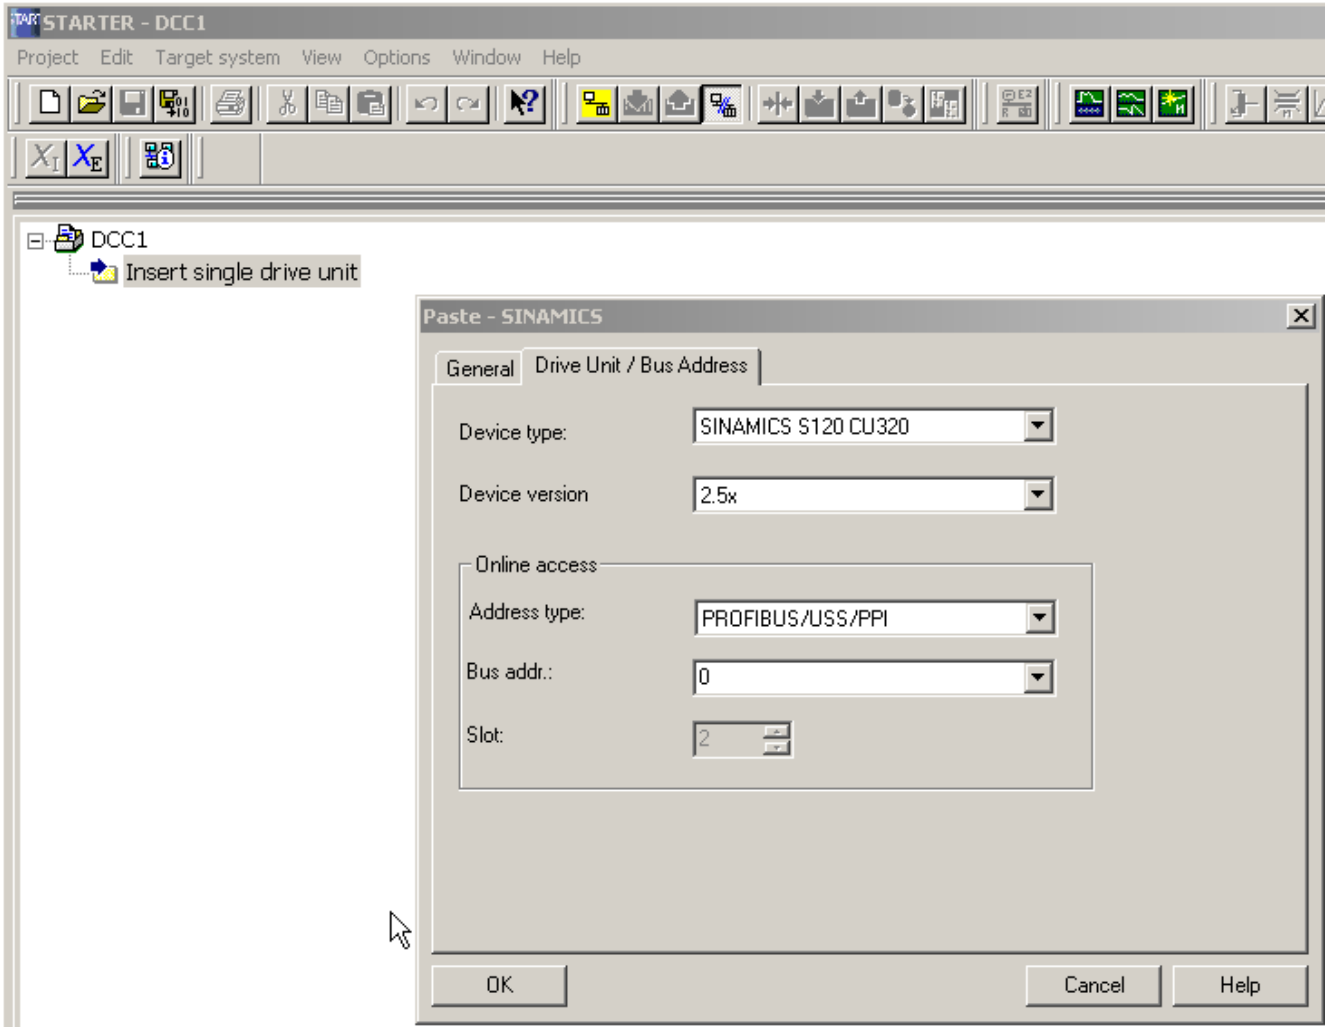

Figure 7-568 Inserting a device into a project

Inserting the DCC chart in a project

You can now insert a DCC chart into the existing project.

Procedure

1. Select a device from the project.
2. **SIMOTION:**
   Execute the **Insert DCC chart** function from the **PROGRAM** subitem of the device.
   SINAMICS, STARTER:
   Execute the **Insert DCC chart** function on the desired drive object. There may only be one DCC chart on a drive object.

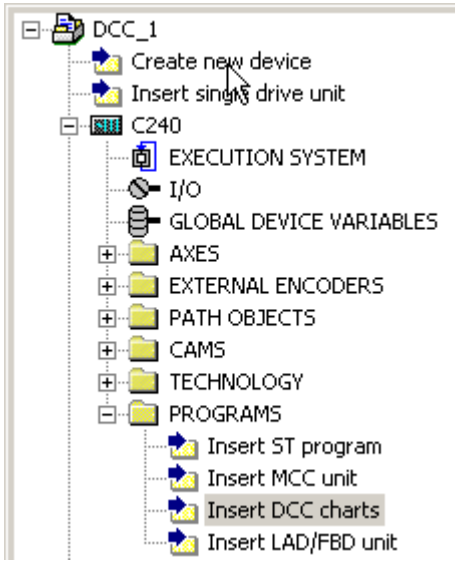

Figure 7-569 SIMOTION SCOUT: Inserting a DCC chart

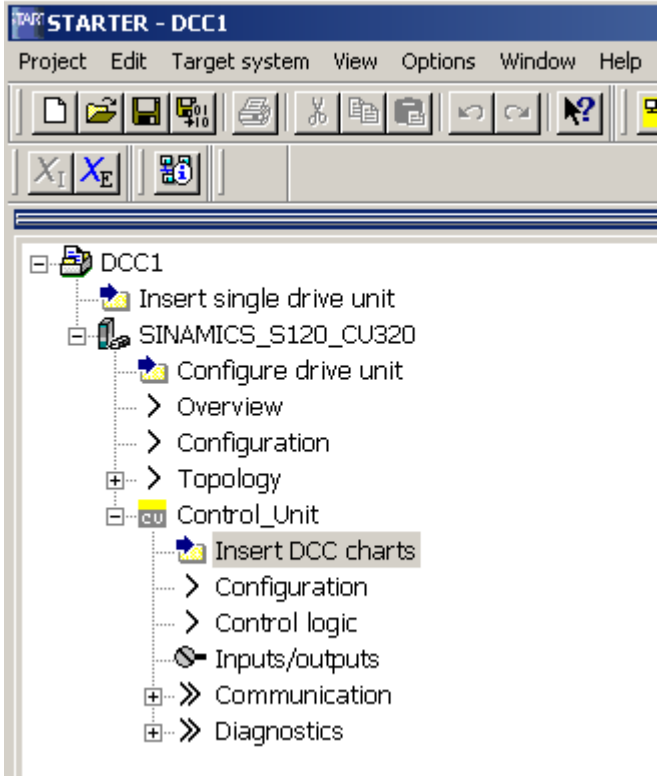

Figure 7-570 Inserting a DCC chart in the CU drive object of a SINAMICS CU3x0.x drive unit with STARTER

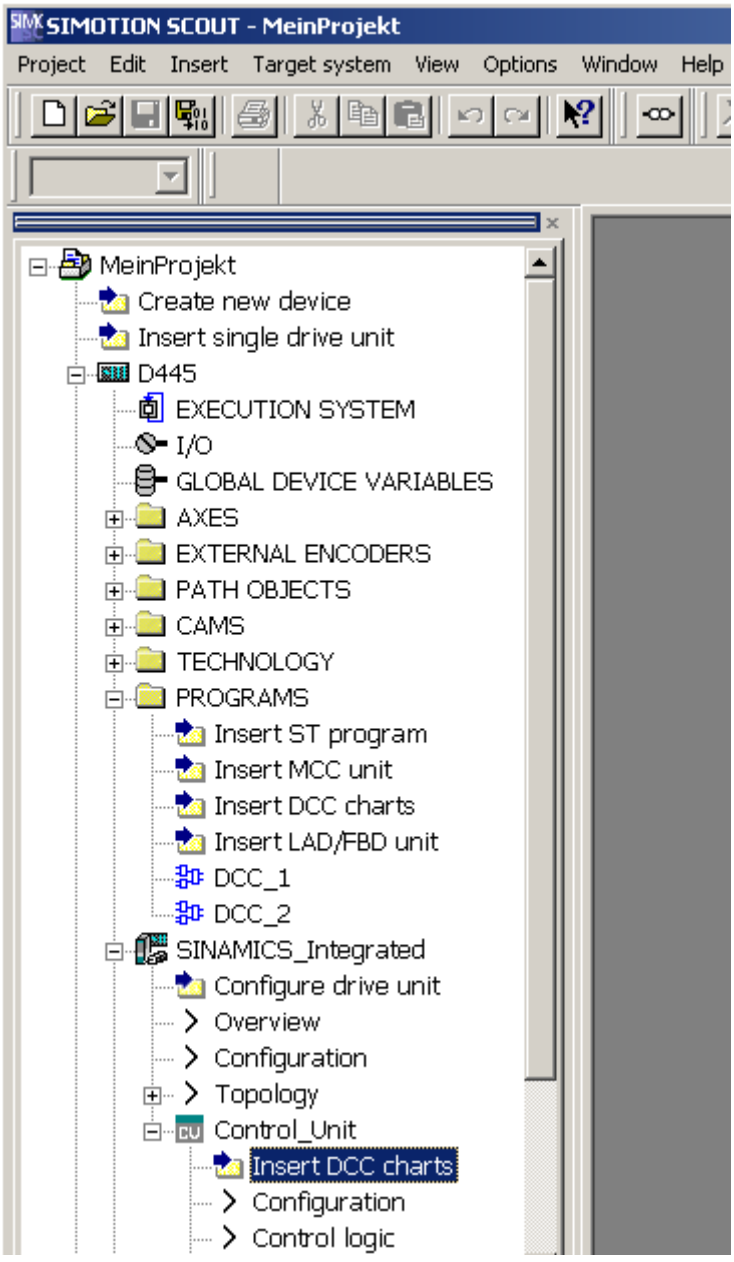

Figure 7-571 SIMOTION D4xx: Inserting a DCC SINAMICS chart on the drive object of the CU with SCOUT

3. The **Insert DCC Chart** window appears.

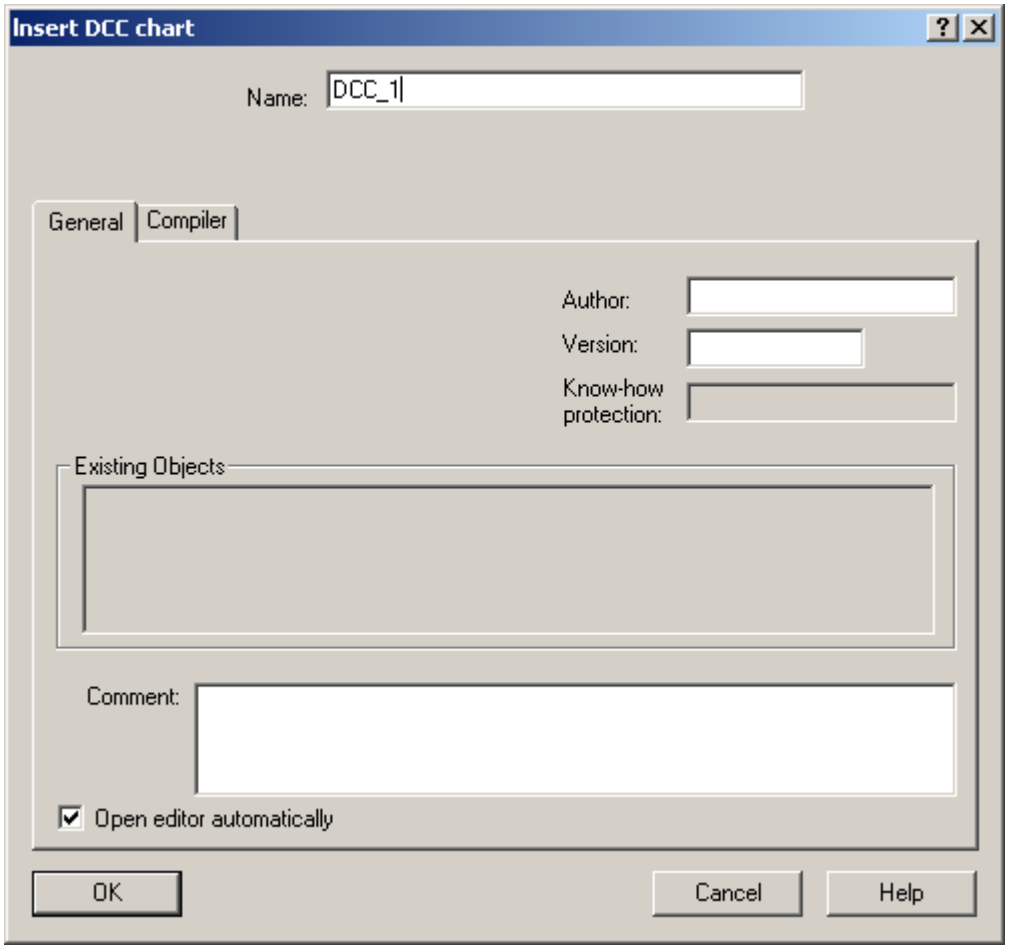

Figure 7-572 Window - Insert DCC Chart

4. Assign a name to the DCC chart.

The DCC chart has now been created.

If you have selected the **Open editor automatically** option in the **Insert DCC Chart** window then the DCC editor opens automatically. When opening the DCC chart for the first time, the **Import DCB Library** window is automatically displayed.

Note

Convention for assigning names to charts

The chart name may contain a maximum of 22 characters.

Explanation of the various types of chart

There are three different types of chart:

- Basic chart
- Chart partition
- Subchart

Charts that are visible within SIMOTION SCOUT/STARTER or the SIMATIC Manager are designated as basic charts. Every basic chart has up to 26 chart partitions and each of these partitions comprises six sheets. Embedded charts - the subcharts - can be used within each sheet. Each of these subcharts may also have its own chart partitions and subcharts. A maximum number of eight nesting levels with subcharts is possible.

Subcharts are not visible as charts in SIMOTION SCOUT/STARTER or in the SIMATIC Manager.

The following graphic clarifies the connection between the three types of chart.

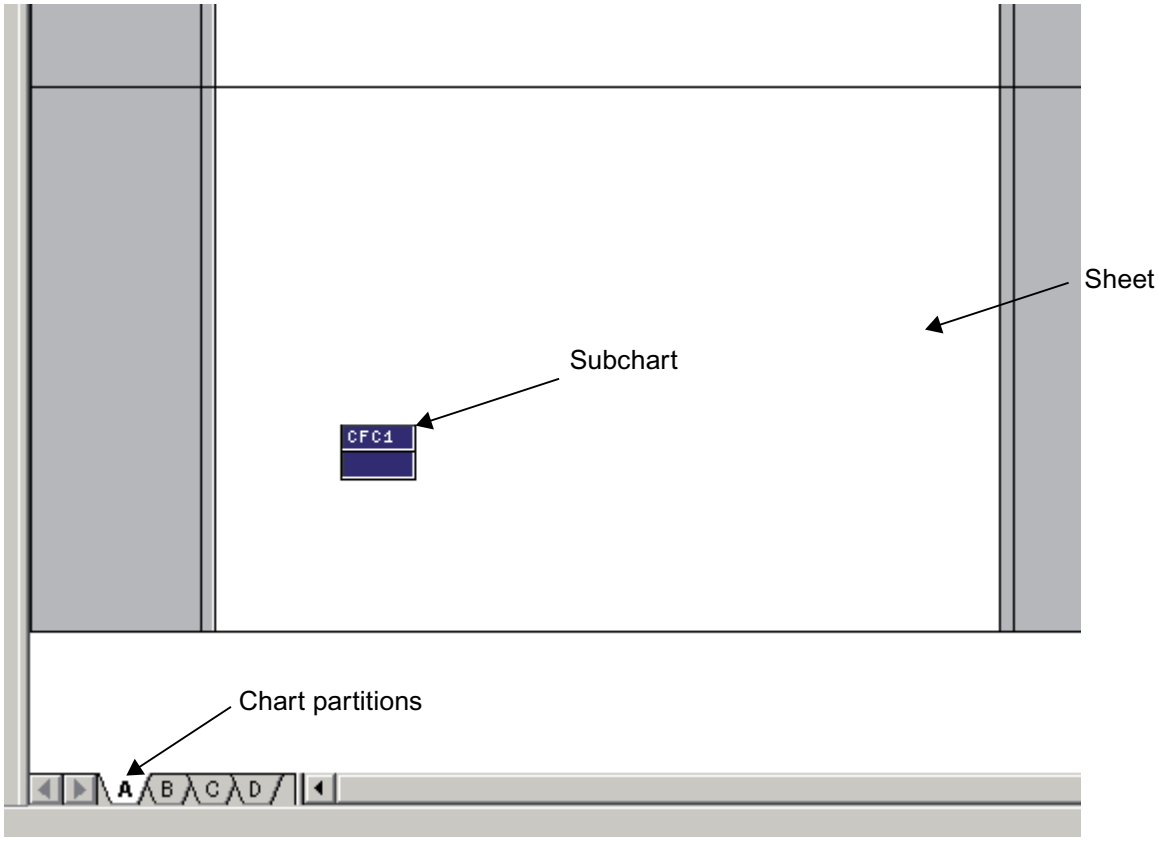

Figure 7-573 Connection between the types of chart in the DCC editor

Select the DCC chart in the project navigator and open the **DCC Chart Properties** dialog via the **Properties...** context menu to access certain properties of the DCC chart. On the **General** tab under **Time stamp** under **Last changed on (STEP7):** you can see the date on which the DCC chart was changed the last time by STEP 7 (CFC editor) or changes accepted in **DCC chart properties**. Under **Last changed on:** you can see the date on which the DCC chart was last

compiled or changes accepted in **DCC chart properties**. Under **Project storage location:** you can see the path under which the project was stored.

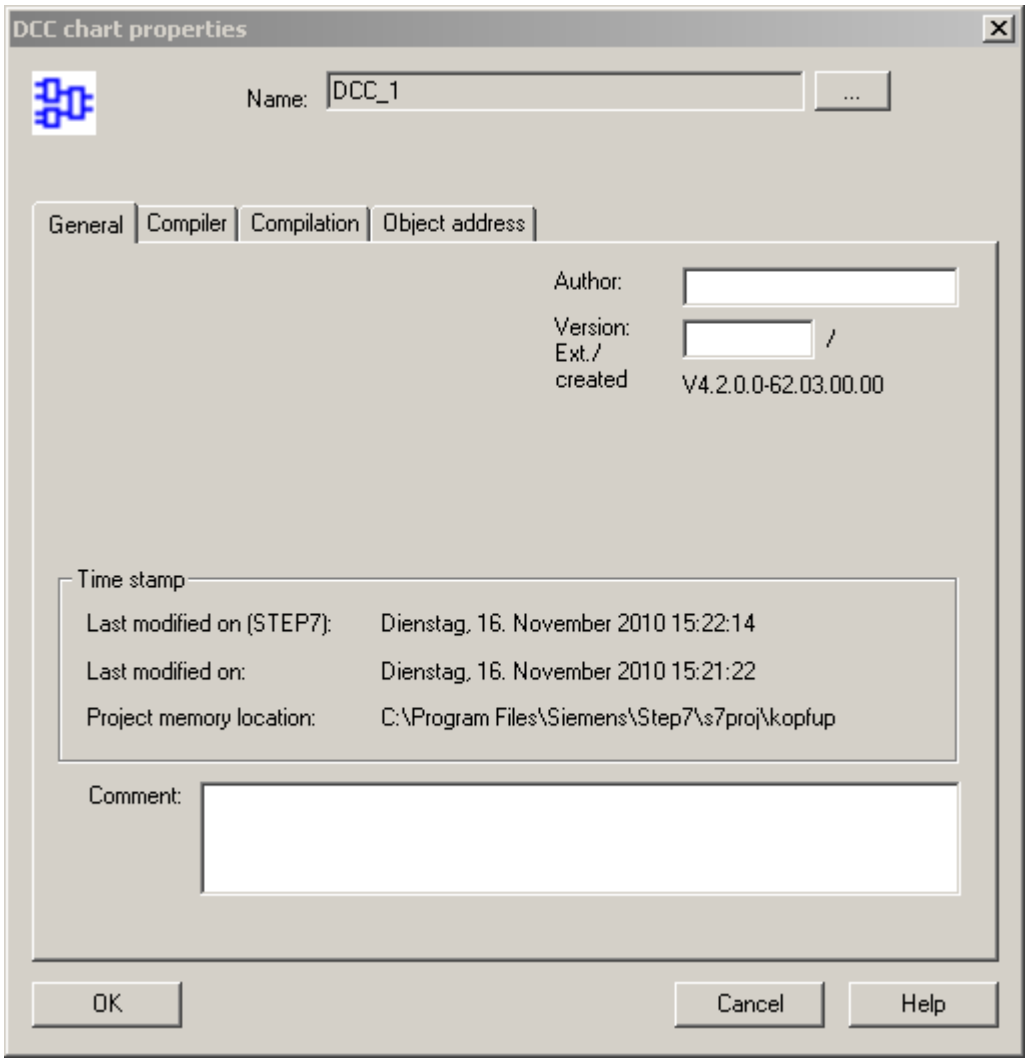

Figure 7-574 DCC chart properties

Inserting a new subchart

A chart (subchart) can be inserted in another chart (chart-in-chart-technique). Hierarchical structures can be formed here. Each chart that is inserted can be opened and modified. A chart can be encapsulated for further use, i.e. chart I/Os added. Which block connections are provided at the chart connections can also be specified individually.

Requirement

You have created a DCC chart in the SIMOTION SCOUT/STARTER engineering system which is opened in the DCC editor.

Procedure

1. Use the **View > Overview** menu command or the  button on the toolbar to switch from the page view to the chart overview. The six pages of the selected DCC chart are shown.
2. Use the **Insert new chart** context-menu command to insert a new subchart, then open the subchart by selecting **Open** from its context menu.

Note

DCC charts should always be created in STARTER/SCOUT.

If a DCC chart that is assigned to a SINAMICS drive object is open and additional DCC charts are created directly in the CFC editor, this can result in compilation errors.

Inserting new chart partitions

Requirement

You have already created a DCC in the SIMOTION SCOUT/STARTER engineering system which is opened in the DCC editor.

Procedure

1. Insert a new chart partition in the desired position using the menu items **Insert > Chart partition > In front of current chart partition** or **At the end**.
2. Alternatively, you can right-click an already existing chart partition on the tab and select **Insert chart partition in front of current chart partition** or **Insert chart partition at the end**.

View and representation

Going into the page view or overview representation

To change to the page view from the overview representation, right-click an empty space in the chart and select **Display this page** in the context menu that appears. The names of the block connections are displayed in this enlarged view.

To change to the overview representation from the page view, right-click an empty space in the chart and select **Overview** in the context menu that appears.

You can also switch to the page view and back to the overview again by double-clicking an empty area on a page.

It is also possible to switch between the page view and overview representation using the **View** menu.

You can switch to a page view with the block catalog displayed on the left using the **View -> Catalog** menu.

7.4.3.5 Handling blocks

Introduction

In this section, you will learn which block types are available and how you can insert blocks in a DCC and delete them. You will also learn how to edit block connections.

Note

The online help provides detailed information (incl. timing diagram and plant view) for the individual blocks. To start the help, select the required block in the chart or in the block catalog and press the F1 key.

User responsibility

The user is responsible for verifying and validating the DCC functions which have been programmed with DCC. The user is responsible for the proper operation of all DCC functions which have been created with DCC.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect programming of the DCC functions

Incorrect programming of DCC functions can cause machines to malfunction, which can lead to injuries or death.

- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).
- Verify and validate the DCC functions you have programmed.

Inserting blocks in the DCC editor

Block types in the DCC editor

The block type inventory featured in the block catalog depends on both the device type and the version of the library. You will find the directories for the block families, as well as the directories **All blocks** (containing all blocks) and **Other blocks** (blocks that are not assigned to a family), in the block catalog. The names of the block families in the DCC editor are always in English.

Inserting a block

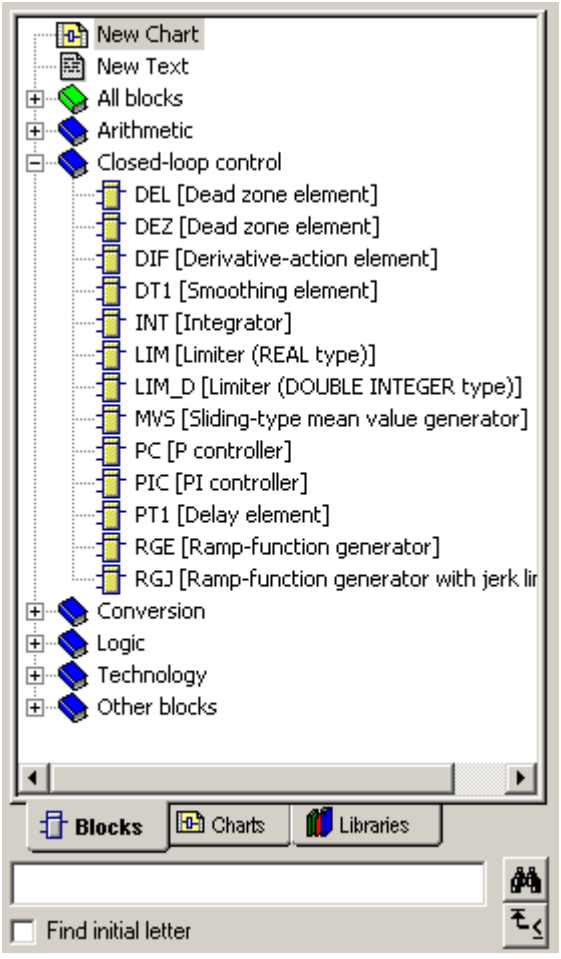

Figure 7-575 Inserting blocks

- Open a block family in the **Closed-loop control** family with the closed-loop control blocks.
- Select the required block and insert it in the chart using drag-and-drop. Only the outline of the block in dashed lines is displayed during the copying procedure. Release the mouse button at the required point.
- To search for a block, enter its name in the input field of the block catalog and click the **binoculars** button. The search process begins.

Note

If blocks are superimposed on the chart with other elements, such as other blocks or the sheet bar, the superimposed block will be displayed in gray and its connections will not be visible. You must reposition the blocks to ensure that all block information can be viewed.

Inserting text

You can add comments to your DCC that you enter in text fields. You can place these at any free position in the chart.

Procedure

Select the **New text** command via the directories of the block types and insert it in the chart using drag-and-drop. Release the mouse button at the required point.

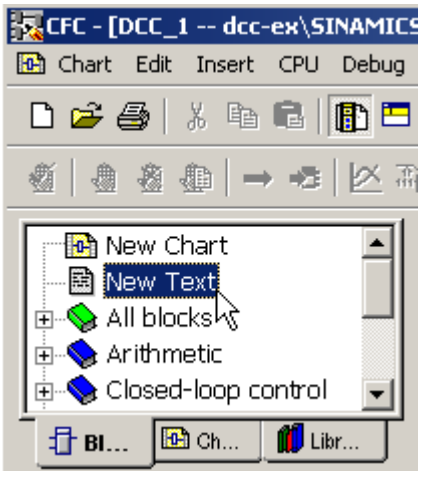

Figure 7-576 Inserting a text field

Alternatively, you can right-click at the desired position in the chart and select the **Insert new text** command in the context menu. Note that this option is only available offline.

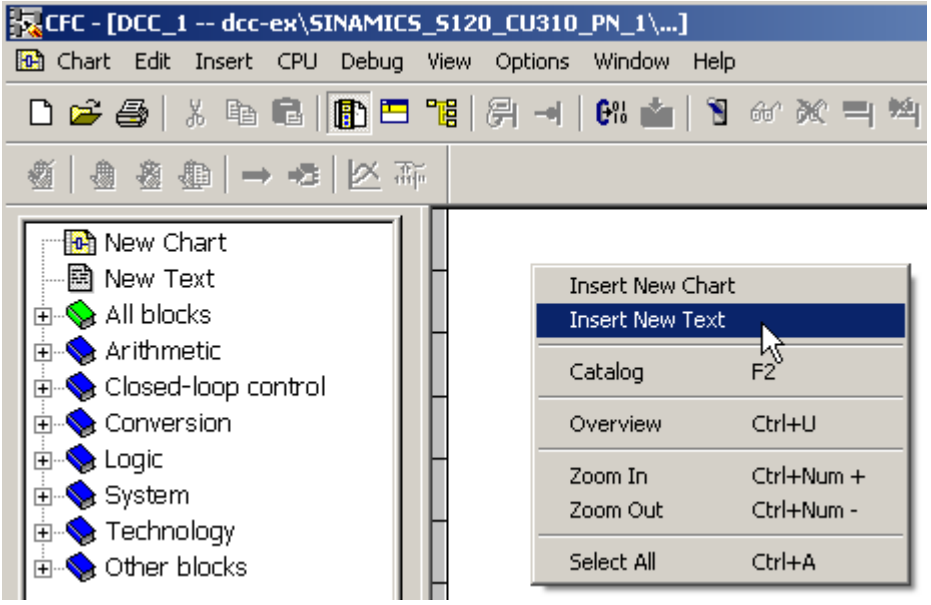

Figure 7-577 Inserting new text

You can adapt the size of the text field to your requirements by selecting the black points at the corners and the sides and dragging them to the desired size.

You can change your comments by clicking the text field and then entering or editing your text.

Specifying execution properties

You can display or change the execution properties of all the used blocks of the program. You can display the properties in the toolbar via **Edit > Execution sequence** or via the button.

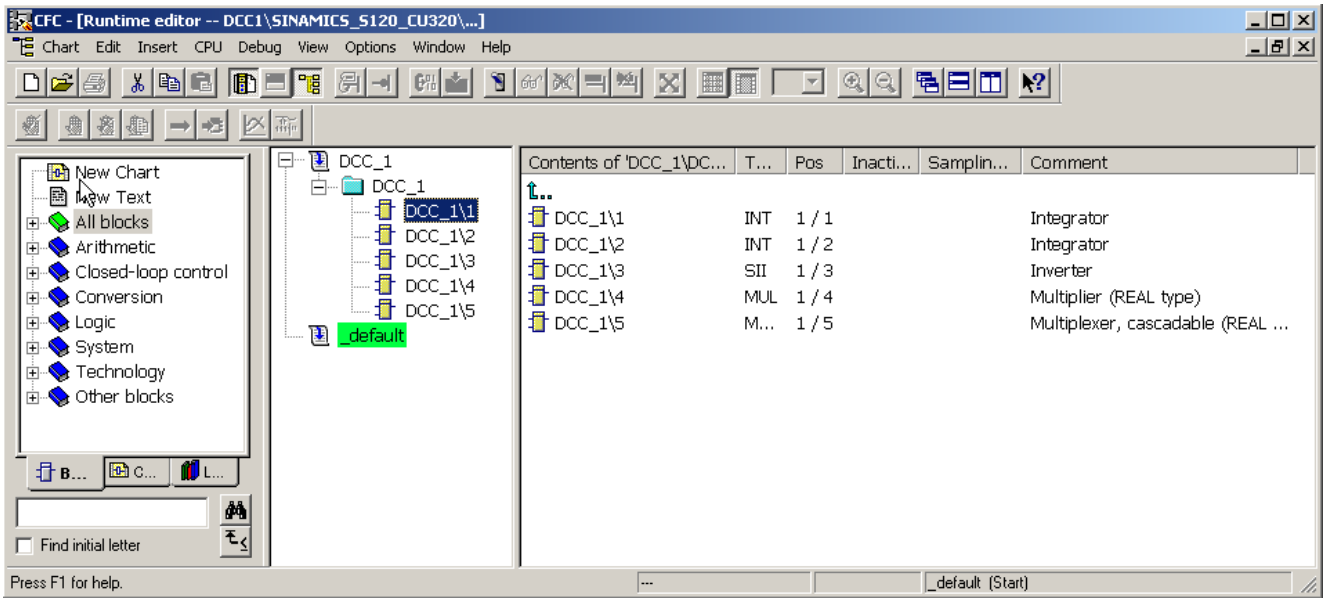

Figure 7-578 Execution editor of the dccReg1 chart with the execution groups Tsg_dccReg1 and Tsg2

In this window, you can also change the insert point in the execution sequence by dragging the block to the desired position. The assignment of a block to an execution group can be changed in the same way.

New inserted blocks are always placed in the execution system behind the block that is defined as predecessor. By default, this is always the block that has been inserted last. If a block is to be inserted in the execution sequence behind an already existing block, select the block with the desired offset in the overview, right-click and select the **Predecessor for insert point** function in the menu. The block now defined as predecessor block is displayed in light green in the DCC editor.

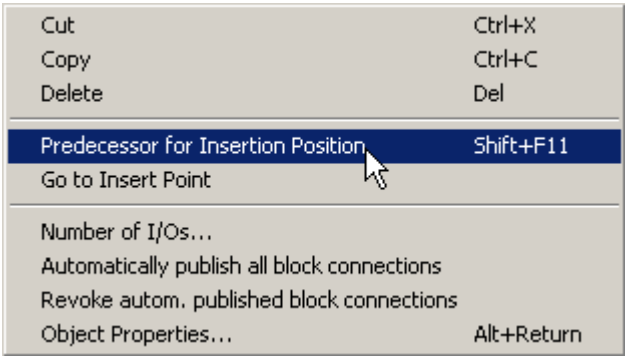

Figure 7-579 Block context menu: Defining predecessor for insert point

The active execution position is displayed in the status bar. This is at the bottom right in the execution editor.

Editing block connections

General

There are two types of block connection (inputs and outputs), each of which has a distinct function and is edited in a particular way.

The following sections contain further information about handling the block connections in the DCC.

Block connection properties

You can double-click each of the individual connections to parameterize it. Alternatively, the **Properties - Connection** window can also be displayed as follows:

1. Select the desired connection.
2. Select **Object properties** in the context menu.
3. The **Properties - Connection** window appears.

However, it is easier to parameterize the inputs as follows:

- Double-click a block header. The **Properties - Block** window appears. You can also open the **Properties - Block** window via the **Object properties** context menu command of the block or via the **Edit > Object properties** menu command.
- Click the **Connections** tab. The parameters in fields with a gray background cannot be changed.
- Enter the required values in the table and click **OK** to close the dialog box.

Input values

At the block inputs, a value can be entered in the **Value** field of the properties dialog box. If the input is not interconnected, it always has the specified value. With interconnected blocks, the output value of the upstream block always applies in the initialization phase and in the first cycle.

Output values

At the block outputs, a value can be entered in the **Value** field of the properties dialog box. In the first cycle however, the specified value is overwritten by the calculated value.

Note

Special feature with hidden block connections

In the DCC editor, you can hide block connections to improve the clarity of the configured charts. However, the hidden block connections remain active in the DCC, so their values are still evaluated. With generic blocks, you can also reduce the number of block connections in the DCC editor. The hidden connections are assigned default values. However, the hidden block connections remain active in the target system, so their values are still evaluated.

It should also be noted that the inputs of these blocks must be interconnected consecutively, starting from the first connection.

Number of block inputs

The number of inputs could be increased for the AND, ADD, MAS, MIS, MUL, NAND, NOR, OR and XOR blocks from the standard library. However, the DCC editor can only evaluate four input signals per block, and therefore this is not permitted. If the demand is greater, the block must be called several times. The note above also applies to data-type-specific variants of the blocks listed above.

Pseudo comments

Comments at block connections that start with @ are pseudo comments; they influence the function of the block connection and serve as interfaces to the basic system.

For further information about the pseudo comments, see:

- Creating customer-specific parameters ("declare") (Page 5543)

Block connection units

The block connection units that can be set in the Properties dialog box serve only as comments in the DCC editor - the values are not used for automatic conversions.

Configuring the block display

You can change the display of the blocks. You can change the block width via **Options > Settings > Block / sheet bar width.....**.

You can change the names of the block inputs/outputs via **Options > Settings > Display** in the submenu **Connections**.

The block type can be displayed in the form of both text and graphics. This can be configured via **Options > Settings > Display** in the submenu **Block headers**.

If you want to display more than the first eight characters of the comment, then select **Options** > **Settings** > **Block / sheet bar width**. Then in the **Blocks / Sheet Bars** window, set the block width to **Wide**. The first twelve characters of the comment are now displayed at the connection.

See also

@ variables (SIMOTION) (Page 5590)

Interconnecting blocks

Blocks can be interconnected with one another. The outputs of a block then form the inputs for further blocks.

Requirement

The inputs and outputs of the blocks must possess compatible data types so that they can be interconnected. An overview of which data types can be interconnected is shown below:

Table 7-607 Conversions

Input	Output	Description
WORD	INT	Interconnection of a word variable to an integer variable
INT	WORD	Interconnection of an integer variable to a word variable
DWORD	DINT	Interconnection of a double word variable to a double integer variable
DINT	DWORD	Interconnection of a double integer variable to a double word variable
BYTE	SINT	Interconnection of a byte variable to a short integer variable
SINT	BYTE	Interconnection of a short integer variable to a byte variable
USINT	BYTE	Interconnection of an unsigned short integer variable to a byte variable
BYTE	USINT	Interconnection of a byte variable to an unsigned short integer variable
USINT	SINT	Interconnection of an unsigned short integer variable to a short integer variable
SINT	USINT	Interconnection of a short integer variable to an unsigned short integer variable
UINT	WORD	Interconnection of an unsigned integer variable to a word variable
WORD	UINT	Interconnection of a word variable to an unsigned integer variable
UINT	INT	Interconnection of an unsigned integer variable to an integer variable
INT	UINT	Interconnection of an integer variable to an unsigned integer variable
UDINT	DWORD	Interconnection of an unsigned double integer variable to a double word variable
DWORD	UDINT	Interconnection of a double word variable to an unsigned double integer variable
UDINT	DINT	Interconnection of an unsigned double integer variable to a double integer variable
DINT	UDINT	Interconnection of a double integer variable to an unsigned double integer variable
SDTIME	REAL	Interconnection of an SDTime variable to a real variable

Procedure

Connect the output of the first block (source) with the input of the second block (sink). You can create this connection either by using drag-and-drop or by latching them together (clicking the relevant input connection and output connection once).

The connection line is automatically drawn from the output of the first block to the input of the second block.

Data type abbreviation in the DCC for connection and transformer blocks

Table 7-608 Table of data types

Abbreviation	Keyword	Name	Bits
BO/B	BOOL	Logical number	8
BY	BYTE	Sequence of 8 bits	8
DI/D	DINT	Double integer	32
DW	DWORD	Sequence of 32 bits	32
I	INT	Integer	16
PC	LREAL	Double floating-point number Accuracy according to IEEE754	64
R	REAL	Floating-point number	32
SI	SINT	Signed short integer	8
TS	SDTIME	The SDTIME data type is derived from the REAL data type; 1.0 corresponds to 1.0 ms Negative values are not defined.	32
UD	UDINT	Unsigned double integer	32
UI	UINT	Unsigned integer	16
US	USINT	Unsigned short integer	8
W	WORD	Sequence of 16 bits	16

Interconnection to chart connections

A chart can be encapsulated for further use, i.e. chart connections added. Which block connections are provided at the chart connections can also be specified individually.

Procedure

1. Model your DCC in the DCC editor.
2. Select the Chart Connections window via **View** -> **Chart connections** or with the button. The chart connections (IN, OUT, IN_OUT) are shown in this window.

   Note

   Please note that chart connections of type IN_OUT are not permitted in DCC!

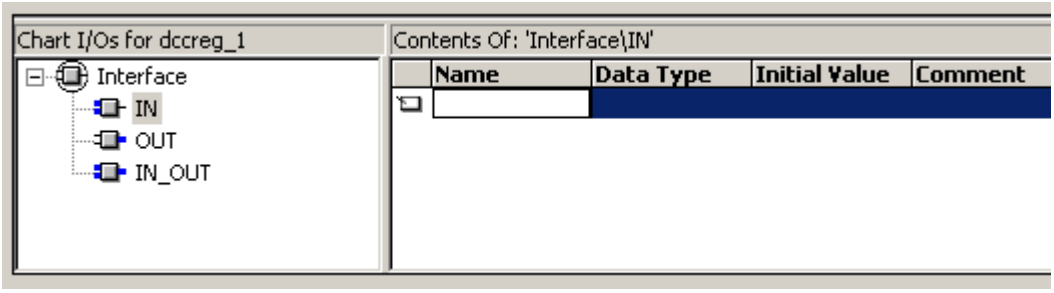

Figure 7-580 Screenshot showing chart connections area of the window

3. Define the required chart connections.
4. Interconnect the block connection to the chart connection. There are three ways of doing this:

   – Option 1:
   Drag the block connection using drag-and-drop to IN (for inputs) or to OUT (for outputs) and keep the Ctrl key pressed. A chart connection is now created automatically.

   – Option 2:
   Select the interface type (IN or OUT) from the left pane and then drag the desired block connection into the last (empty) line in the right pane using drag-and-drop.

   – Option 3:
   Right-click the block connection to be interconnected and select **Interconnection to the chart interface** in the context menu. Then select the appropriate chart connection in the **Insert/Change Interconnection to the Chart Interface** window. Click OK to close the window.

   Note

   The interconnection to the chart connection by the context menu is available only when at least one chart connection exists already. Up to CFC 7.0, the first interconnection to the chart I/O can only be established using drag-and-drop.

The block connection is interconnected to the chart connection. The assignment is displayed in the variables sheet bar of the DCC editor. The block interface is defined as part of assigning block connections to the interface.

Note

DCC SINAMICS: The use of chart I/Os is permitted for subcharts and DCC libraries.

Interconnection to global operands in DCC SIMOTION

Global operands are connection partners located outside of the DCCs.

Interconnections to global operands are entered in the sheet bar.

Where DCC is concerned, the interconnection of global operands serves as an interface to the basic system. You use this function to connect to ST/IO/system variables (in the case of DCC SIMOTION) or BICO parameters (in the case of DCC SINAMICS) in the drive.

Procedure

You can make an interconnection to a global operand as follows:

1. Open the DCC.
2. Right-click the block connection to be interconnected and select **Interconnection to operand** in the context menu.
3. Now select the global operand to be interconnected in the **DCC Signal Selection** window.
4. Click **OK** to close the window.

The block connection is interconnected to the selected global operand.

Deleting blocks

If you want to delete a block from the chart, select it and click **Edit > Delete**. You can also delete blocks using the context menu.

When blocks are deleted, the connections to the block connections are also removed. Output interconnections must first be deleted manually.

If you delete a block in online mode on which the outputs are interconnected with inputs of other blocks, the current signal values will become valid at the inputs of these blocks. These are taken over in the DCC and also saved to the card in the target system at the next RAM to ROM. In offline mode, the default values take effect again at the inputs after deletion of the upstream block.

Note

The STM block cannot be deleted or inserted online.

If you delete a block on which the inputs or outputs are interconnected to chart connections, the connections are deleted, but not the chart connections. If these are not required, you must delete them separately in the Chart connections field.

Rearranging parameter numbers

Call the **Rearrange Parameter Numbers** dialog box via the **Chart -> Rearrange parameter numbers** menu to move parameter numbers.

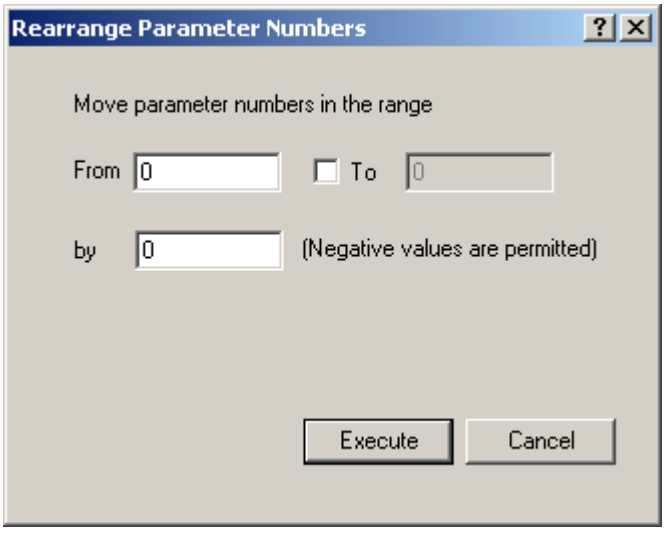

Figure 7-581 Rearranging parameter numbers

Enter the new values and accept these with the **Execute** button.

The following warning is output for an invalid entry.

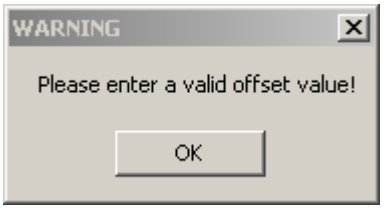

Figure 7-582 Warning message for an invalid entry

Correct your entries.

If your entries were valid, you will find detailed information about moving the parameter numbers in the following **Logs** dialog box on the **Rearrange parameter numbers** tab. In the case of errors, mark the entry and navigate to the problem position with the **Go to** button.

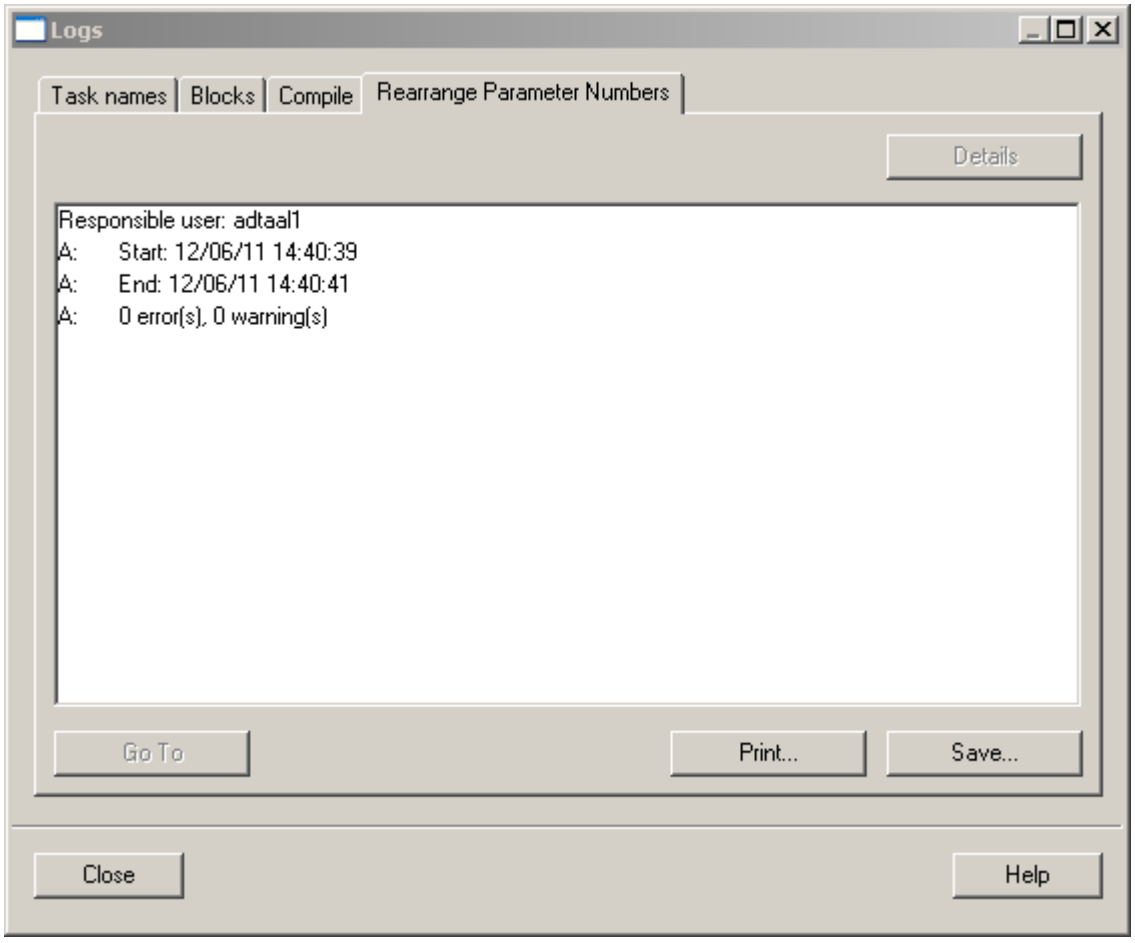

Figure 7-583 **Logs dialog box, Rearrange parameter numbers tab**

Publishing all connections

In the DCC editor, you can publish the connections of all blocks or the connections of one block.

For further information on the publishing of connections, refer to Creating customer-specific parameters ("declare") (Page 5543).

Publishing all connections of all blocks

Publish the connections of all blocks via the menu **Chart -> Publish all connections**.

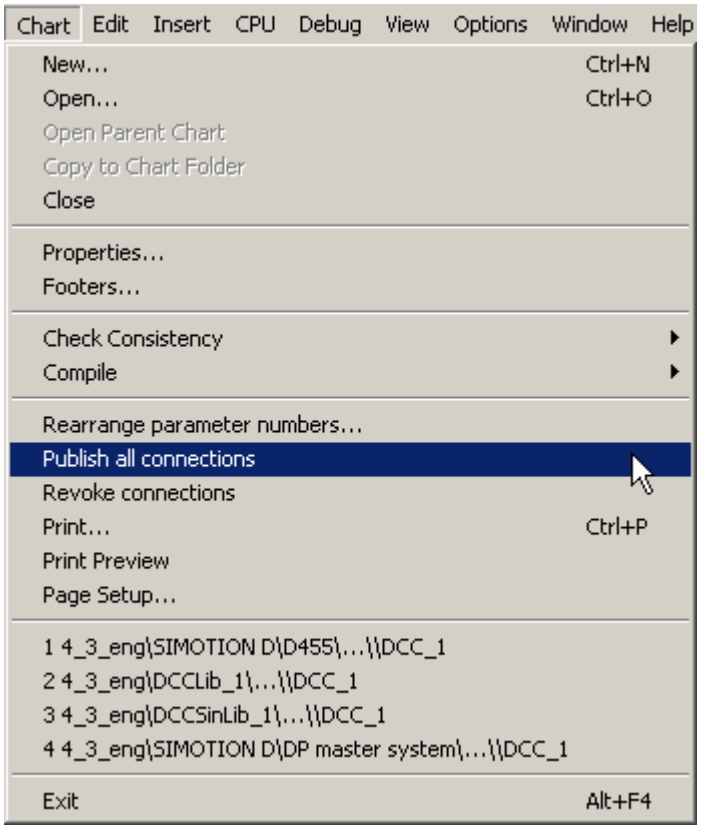

Figure 7-584 Menu **Chart -> Publish all connections**

Publishing all connections of one block

Select a block and publish its connections via the menu **Edit -> Publish all connections**.

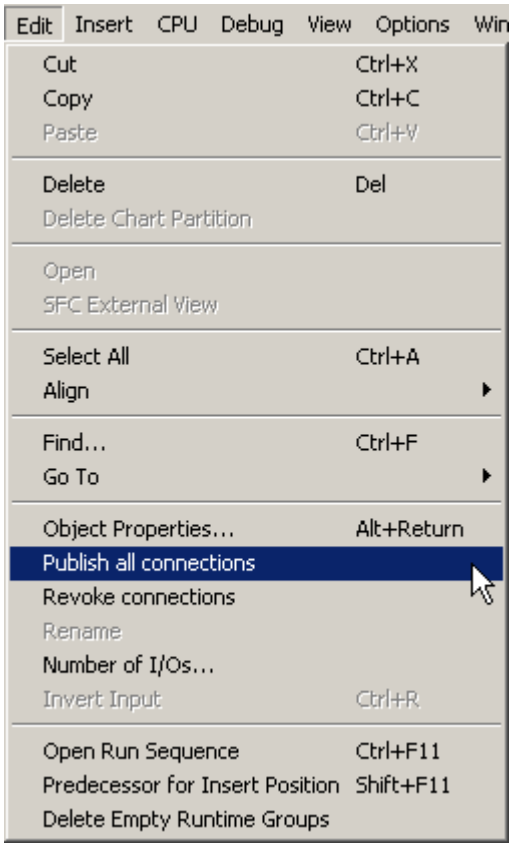

Figure 7-585 Menu **Edit -> Publish all connections**

You can also perform this via the block context menu.

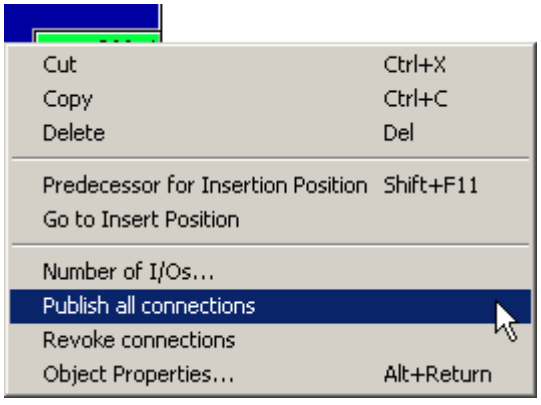

Figure 7-586 Context menu **Publish all connections**

Revoking connections

In the DCC editor, you can revoke the publication of the connections of all blocks and the publication of the connections of one block.

Chart -> Revoke connections

You can revoke the publication of the connections of all blocks via the menu **Chart -> Revoke connections**.

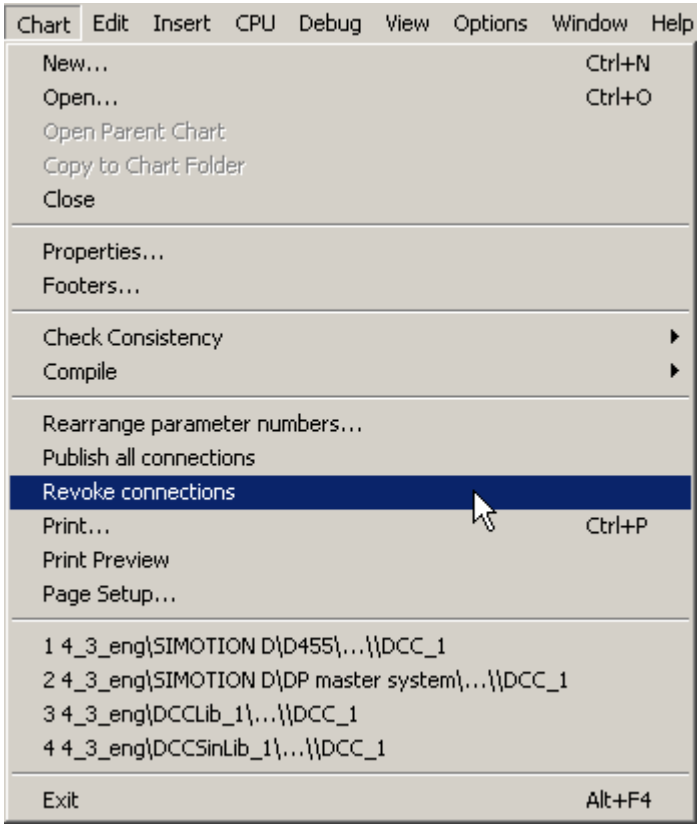

Figure 7-587 Menu **Chart -> Revoke connections**

Edit -> Revoke connections

You can revoke the publication of the connections of one block via the menu **Edit -> Revoke connections**.

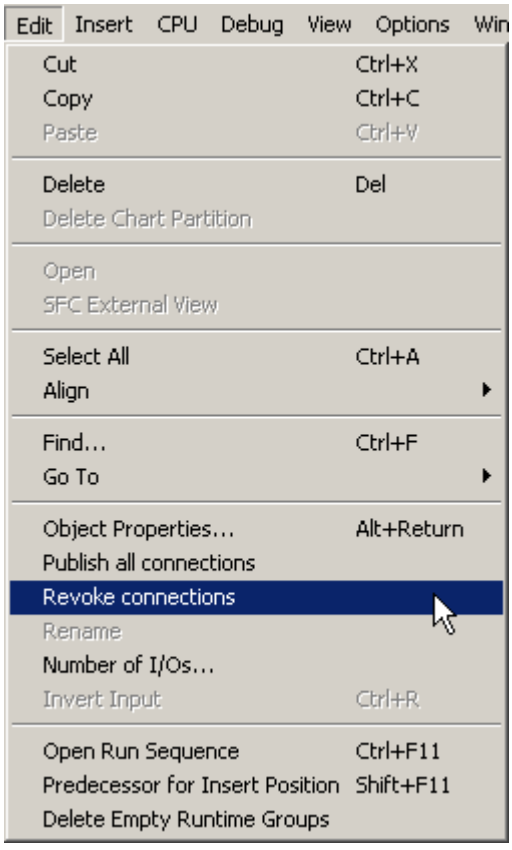

Figure 7-588 Menu **Edit -> Revoke connections**

This function is also available via the block context menu.

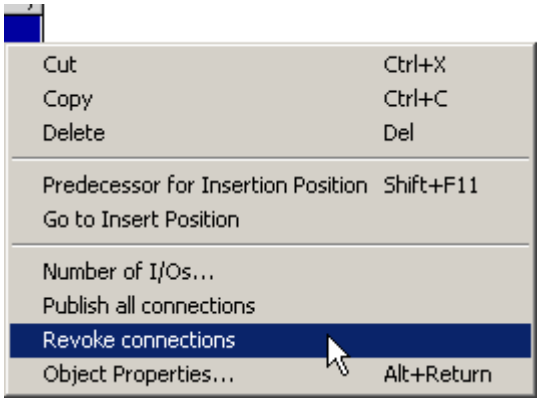

Figure 7-589 Block context menu **Revoke connections**

7.4.3.6 Compiling

Consistency check without code generation

General

Some of the conditions that have to be met if a valid configuration is to be created from DCCs can only be checked once charts have been created.

This procedure is carried out automatically at certain points, e.g. when a project or charts are compiled.

Performing a consistency check

The contents of DCCs can be checked at any time.

To check consistency, click **Chart > Check consistency > Charts as program...**

The **Logs** dialog box is displayed automatically after the consistency check. Here, errors are indicated by an "E" and warnings by a "W".

Error log

You can also display the result of the consistency check via **Options > Logs** in the **Consistency check** tab.

Note

If charts are deleted from previously compiled and downloaded projects, this can lead to inconsistencies during the next compilation/download, as the overall chart execution system has to be adjusted.

Note

Cross-chart consistency checks are performed only after the compilation of the charts.
The consistency check from the DCC chart always applies to the last compilation result.

Compiling the DCC in the DCC editor

Compiling

Please note that before the first compilation of a chart in a project, the project must first be saved in STARTER/SIMOTION SCOUT (via the menu command **Project** -> **Save** or with the button).

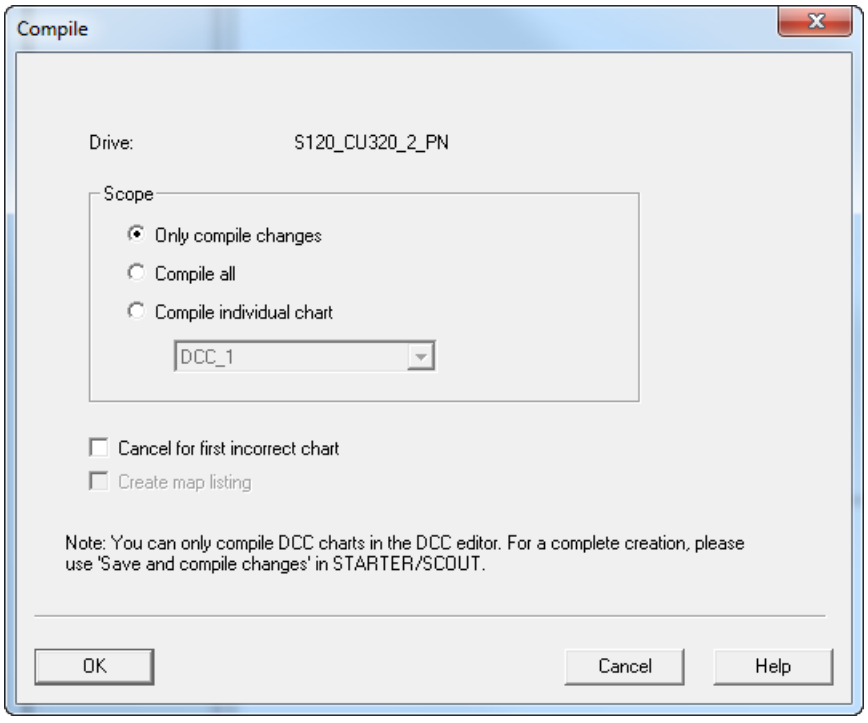

Figure 7-590 Compiling a DCC chart

You can begin compiling with **Chart > Compile > Charts as program ...** or with the button.

Compilation options

You can select the scope of the compilation:

- Scope: **Only compile changes**
  Only those parts of the configuration that have been changed since the last compilation are recompiled. When recompiling, this option reduces compilation time.

  Note

  All the configuration charts will be checked for consistency, even if you select the **Only compile changes** option.

- Scope: **Compile all**
  The entire contents of the configuration are compiled, regardless of whether the configuration has been changed since the last compilation.
- Scope: **Compile individual chart**
  The selected chart is compiled, regardless of whether the configuration has been changed since the last compilation.

Additionally, you can select whether a map listing is to be generated and whether it should be canceled in the event of an error occurring in a chart. A map listing is a list of the global objects, the cross reference and the blocks used in the chart.

The map listing is saved in subfolder U7\debug in the project path.

Note

You can only compile DCC charts in the DCC editor. To carry out the creation process in full, please use **Save and compile all** in STARTER/SCOUT.

As of STARTER/SCOUT V 4.2, this function is available under **Save and recompile all**.

As of STARTER/SCOUT V 4.3, this function is available under **Save and recompile all including DCC libraries**.

As of STARTER/SCOUT V 4.4, this function is available under **Save and recompile all.**

Reorganizing OCM variable interfaces

This option is only available for SIMOTION DCC charts. During the reorganization, the OCM variables are removed from the memory image that was already deleted previously. For further information, refer to HMI variables (Page 5589).

Error log

On completion of the compilation procedure, a detailed compilation log appears. Here, errors are indicated by an "E" and warnings by a "W".

- To navigate to the block that caused the error, select the error line in the log and click **Go to**, or double-click the error line.
- The log can be displayed again at a later point via the menu **Options > Logs** and, if necessary, can also be printed out.

7.4.3.7 Editing configurations further

Editing programs further: overview

This section describes more options for editing an existing program.

The following subjects are covered:

- Changing the block library
- Copy and paste charts or block groups between drive devices

Saving and restoring retain variables - SIMOTION only

DCB block instances may contain retain variables.

Select **Save Variables...** from the context menu of the DCC chart to save the contents of these variables to a file. The values can then be restored from this file. DCC retain data is retained when the platform is changed or the version is upgraded.

Changing the block library

If you want to transfer an existing configuration to a new SCOUT/STARTER version, you can change the library version at a later point. The blocks will be adapted accordingly.

Procedure

1. Open a chart from the relevant configuration and select **Options > Block types** in the menu.
2. The **Import** window is displayed. Click **OK** to close the window. In the window **Import DCB Libraries**, the block libraries installed on your programming device are listed under **Libraries installed in SCOUT/STARTER**. Under **Libraries imported in the chart**, all libraries which have already been imported into this configuration are listed.
3. Check which previously imported libraries have a new version installed, by inspecting the version of the library under **Libraries installed in SCOUT/STARTER** and **Libraries imported in the chart**.
4. Select the library to be updated under **Libraries installed in SCOUT/STARTER** and click **>>**.
5. Click **Accept**.
6. The progress of the update is displayed in a window.

Response

The changes made compared with the old version are transferred to your existing configuration.

Copying of charts or chart sections

In the STARTER and SIMOTION SCOUT engineering systems, charts can be copied within a drive object (SINAMICS) or device (SIMOTION), and between various SIMOTION devices or SINAMICS devices. It is also possible to select block groups within a DCC chart and insert them in other charts of the same device family using copy and paste.

Note

The copying of charts or block groups between SINAMICS devices and SIMOTION devices and vice versa is not supported.

You require a DCC license to copy a DCC chart as a block type into the SINAMICS library.

Note

Cross-chart interconnections

If you want to copy charts that contain cross-chart interconnections, this can lead to errors. Use the XML import/export instead.

Copying a chart (SIMOTION)

To copy a SIMOTION DCC chart, proceed as follows:

1. Select the source device from the project view.
2. Open the PROGRAMS subitem of the device.
3. Select an existing DCC chart and select the **Copy** command in the context menu of the chart.
4. Select the target device from the project view.
5. Open the PROGRAMS subitem of the device.
6. Select the **Paste** command in the context menu of the PROGRAMS subitem of the device.

The chart has been copied from the source device to the target device.

Copying a chart (SINAMICS)

To copy a SINAMICS DCC chart, proceed as follows:

1. Select the source drive unit in the project overview.
2. Open, for example, the Control_Unit subitem of the device.
3. Select an existing DCC chart and select the **Copy** command in the context menu of the chart.
4. Select the target drive unit in the project overview.
5. Open, for example, the Control_Unit subitem of the device.
6. Select the **Paste** command in the context menu of the Control_Unit subitem of the drive unit.

The chart has been copied from the source drive unit to the target drive unit.

Note

After copying, you must check whether the interconnections of block connections in the chart copy have to be adapted to another drive object as a result of the copying. During copying, the published block connections are automatically adapted to the basic system.

Cross-chart interconnections are lost.

DCC SIMOTION: When copying DCC charts, cross-chart interconnections are converted into textual interconnections. They are closed again via **Tools menu -> Close textual interconnections** .

Note

DCC SINAMICS and DCC SIMOTION

Only one SINAMICS DCC chart per drive object may be created.

Note

DCC SINAMICS and DCC SIMOTION

When copying a device, the associated charts are also copied.

An XML export or XML import of individual charts is possible. After the XML import, you must check whether the interconnections of block connections in the XML import have to be adapted to another drive object due to the XML import.

During a project export, the associated DCC charts are exported along with all interconnections.

Note

When copying DCC charts between different devices, the libraries used in the DCC charts are exchanged with the libraries present on the device. In the case of SINAMICS devices, this assumes that a version of the standard library is available for each device. As of SINAMICS 4.4, multiple versions of the standard library are available on a device for compatibility reasons. If the automatic selection option is used, the version with the highest firmware version is used. If multiple library versions are installed for a firmware version, the library with the next-highest version is selected.

For SIMOTION, *dcblibV2_0_simotion4_1_x* is also available on SIMOTION V4.2 devices.

V4.1 libraries are only available on device types that were also available in V4.1. V4.1 libraries cannot be executed on a D455-2 or D455-2. New block types can be found in *dcblibV3_0_simotion4_2*.

Copying of DCC charts to other projects

You can also copy DCC charts from one project to another. As only one project can be opened, you must start STARTER or SCOUT twice for this purpose and start another project.

Note

Please note that you can only copy and paste DCC charts via the engineering system; you cannot cut them.

If you want to copy a SINAMICS DCC chart to another project, then the chart must not use SINAMICS libraries that are only available in the source project. This applies to the libraries in the **SINAMICS LIBRARIES** subitem. In this case, an error message is displayed when the copy action is attempted, and the DCC chart is not copied.

You can use the functionality of the XML export and the XML import in order to always copy DCC charts correctly between projects.

Aborting copying processes with DCC charts

Errors may occur in the following cases when copying DCC charts:

- DCC charts were created using an older version of the DCC editor (CFC version)
- Copying without a DCC license

Copying block groups in the DCC editor

In the DCC editor, you can copy parts from one chart and insert them in another chart. To do this, you must open the source chart and the target chart in the DCC editor.

1. Use the lasso function to select the subsection of the source chart to be copied and select the **Edit > Copy** command in the menu bar.
2. Change to the target chart.
3. Select the **Edit > Paste** command in the menu bar.

The block group has been inserted in the target chart.

Block numbering

When copying blocks or block groups in the DCC editor, the name of the new block is formed as follows: if numeric characters are present at the end of the name, these are all deleted up to the first non-numeric character and replaced by the next free numeric character. It is therefore recommendable to allocate names consisting of letters (and numeric characters) such as block, block1, block2, etc.

Location of the insertion in the execution sequence

Blocks are always inserted into the execution sequence behind the selected block and the most recently added block is always selected automatically.
If a block is to be inserted behind an existing block in the execution sequence, select the block in the overview or in the chart, followed by the function **Predecessor for insert point** in the context menu.
You can change the execution sequence at any time via the **Edit > Execution sequence** command in the menu bar or the  button.

See also Specifying execution properties (Page 5437).

Deleting charts

Deleting a chart in SIMOTION SCOUT

To delete a chart in SIMOTION SCOUT, proceed as follows:

1. Open the SIMOTION SCOUT engineering system.
2. Select the required device in the project overview.
3. Open the PROGRAMS subitem of the device.
4. Select an existing DCC chart and select the **Delete** command in the context menu of the chart.

The chart has been deleted from the device.

Deleting a chart in STARTER

To delete a chart in STARTER, proceed as follows:

1. Open the STARTER engineering system.
2. Select the required drive unit in the project overview.
3. Open, for example, the Control_Unit subitem of the device.
4. Select an existing DCC chart and select the **Delete** command in the context menu of the chart.

The chart has been deleted from the drive unit.

Deleting higher-level elements

DCC charts are also deleted when a higher-level element (e.g. a DO) is deleted.

Search in the project from STARTER/SCOUT

You can use the sheet bar to search for variables and SINAMICS parameters in DCC charts in the open project. The contents of alias definitions can also be found using the search function.

Open the dialog via the menu **Edit > Search in project** or using the shortcut **Ctrl + Shift + F**.

The results are displayed in the search results tab of the detail view.

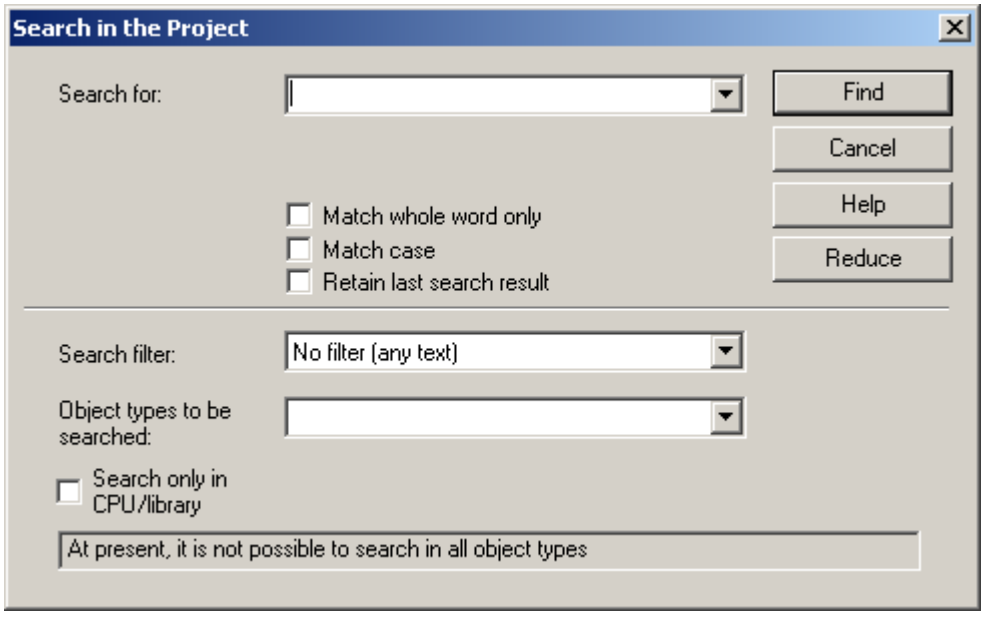

Figure 7-591 Searching in the project

Note

Symbols that are defined from the DCC, so-called @ parameters, DCC parameters (SINAMICS), links to BICO parameters are not considered when searching/replacing.

General conditions

- As of DCC 2.0.2, the symbols (variable in sheet bar) used in the DCC chart and the contents of alias definitions can also be searched for and replaced.
- The CFC editor must be closed during the search/replace operation.
- If the CFC chart sources have been deleted or the charts have know-how protection, searching/replacing of the sheet bar elements is not possible.
- It is not possible to undo these changes.

Replacing in the project

The **Replace in project** function is based on the **Search in project** function.

You can use the **Replace in project** function to quickly adjust the interconnections to the system after copying and inserting DCCs.

Open the dialog via the menu **Edit > Replace in project** or using the shortcut **Ctrl + Shift + G**.

When you carry out a replacement, both the results found and the replacement term are displayed in the **Search result** tab of the **detail view**. The text can be edited again here.

Use the **Replace** button to replace all search results selected using the check box.

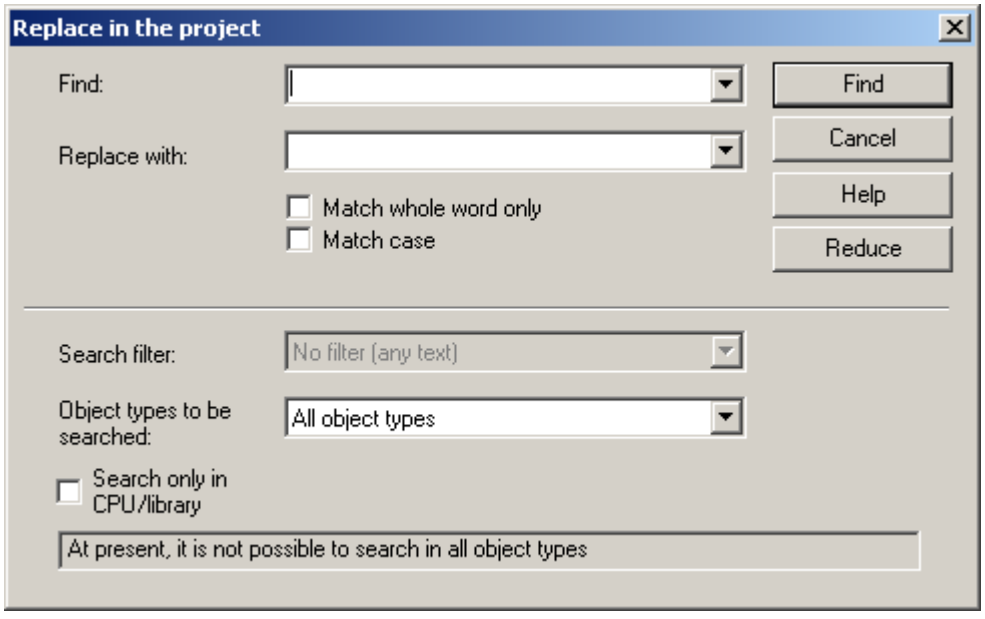

Figure 7-592 Replacing in the project

Note

Symbols that are defined from the DCC, so-called @ parameters, DCC parameters (SINAMICS), links to BICO parameters are not considered when searching/replacing.

Boundary conditions

- As of DCC 2.0.2, the symbols (variable in sheet bar) used in the DCC chart and the contents of alias definitions can also be searched for and replaced.
- The CFC editor must be closed during the search/replace operation.
- If the CFC chart sources have been deleted or the charts have know-how protection, searching/replacing of the sheet bar elements is not possible.
- It is not possible to undo these changes.

7.4.3.8 Test mode

Test modes

There are two types of test mode:

- **Process mode**
  Select this test mode if you want to monitor the behavior of individual instances, e.g. for the error analysis. When test mode is activated, all blocks are set to the status **Monitoring off**. In this test mode, you must select the relevant block connections and explicitly log them on for monitoring.
- **Laboratory mode**
  Laboratory mode is used for convenient, efficient testing and commissioning. When test mode is activated, all blocks are set to the status **Monitoring on**.

You can select the desired test mode in edit mode using the menu commands in the **Test** menu. Once a test mode has been selected it is not possible to switch between them.

Test settings

You can specify the **Monitoring cycle** via the menu **Test > Test settings**. This displays the **Test Settings** window.

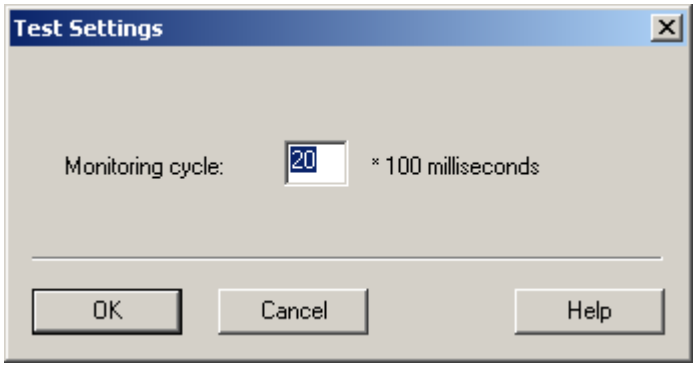

Figure 7-593 Test settings

In this window, you can set the **monitoring cycle** for the objects that have been logged on for testing, i.e. the cycle time for updating these objects. The monitoring cycles can be set in 1 to

100 steps each of 100 milliseconds (SIMOTION). Only whole seconds can be set as monitoring time for SINAMICS.

Note

If you have logged on many objects for the test, it is better to use a slower updating cycle.

Monitoring in laboratory mode

When test mode is activated, the **Monitoring on** function, or  , will also be activated for DCC charts in **Laboratory mode**.

This means that, in test mode, you can also display the development of the values for those block connections that are logged on for display, i.e. the values will be read out and displayed cyclically. You can change the options relating to this dynamic value display and the connection parameters in test mode.

Saving settings

The logging on of blocks for monitoring is rejected when the online test is exited. The settings of the block interfaces with regard to the test are saved in the project.

Display of values during the test

Current values of block interfaces are displayed when they are logged on for the test and their block is logged on for monitoring.

Monitoring in process mode

In **process mode**, the **Monitoring off** function, or  , is activated. This means that you must first select the blocks that you want to monitor (by highlighting them in the chart) before dynamic display can take place. You then need to execute the menu command **Monitoring on**.

Conversely, you can exclude individual blocks from being monitored if there are too many (highlight the block and execute the menu command **Monitoring off**).

Note

If the monitoring function has been deactivated and you highlight a connection in order to log it on for testing via  , monitoring is activated for this connection and for all previously logged-on connections of this block.

By activating test mode, connections are also established with the CPU for all connections listed within a value display window. Activate **monitoring** by selecting the individual connections in the **Monitoring** column.

Logging on/logging off connections for testing

In **edit mode** or **test mode** (process or laboratory mode), you can log on individual block or chart connections for testing:

- Highlight the connection and select **Test > Log on connections** or click the button in the toolbar.

When this is performed in **test mode**, monitoring is also activated, i.e. the connection is displayed with a yellow background and with its current value. If monitoring has been deactivated for this block, it will also be activated for all connections that were logged on for testing prior to this.

In **edit mode** or **test mode** (process or laboratory mode), you can log off individual block or chart connections for testing:

- Select **Test > Log off connections** or click the button in the toolbar.

Note

Alternatively, it is also possible to log on/log off all connections of a block for testing in edit mode by highlighting a block, selecting **Object properties** via the context menu, and selecting or deselecting the individual connections in the **For testing** column of the **Connections** tab.

Activating/deactivating connection monitoring

You can activate/deactivate monitoring (displaying the current values at the connection) of the block connections logged on for testing:

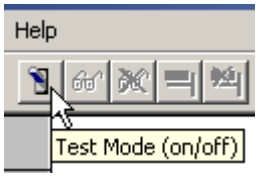
- Automatically, by activating test mode in laboratory mode.
- Via **Test > Monitoring on** or via the button in the toolbar. In both **laboratory mode** and **process mode**, this function concerns only the blocks previously selected in the chart.
- You can deactivate monitoring (meaning that values at the connections will no longer be updated) via **Test > Monitoring off** or by using the button. In both **laboratory mode** and **process mode**, this function concerns only the blocks previously selected in the chart.

All input and output values that have been activated for monitoring purposes are updated in accordance with the set monitoring cycle.

Activating test mode

To activate test mode, proceed as follows:

- Click the **Test mode** button in the toolbar



or click **Test > Test mode**.

Test mode is activated. The menu item is identified by a check mark. Depending on the selected test operating mode, the text **Test: RUN(laboratory mode)** or **Test: RUN(process mode)** is displayed in the status bar with a green background. Any menu functions that are not permitted in test mode are displayed as deactivated (grayed out).

Note

If the DCCs are different in the editor and in the target device, then they can behave differently, see Consistency of charts in test mode (Page 5470).

Requirements for starting test mode

The use of test mode requires an online connection to the device.

As long as the DCCs are identical online and offline, test mode is activated immediately. If the DCCs do not have the same version in the RT system and in the engineering system, values can still be monitored in test mode, but in order to make further changes the consistency must first be restored by uploading the changes from the target system (in this case the changes are not visible in the editor) or by downloading the current version from the engineering system.

Note

Once the project has been uploaded from the target device, it needs to be saved before DCC test mode can be started.

If you have made changes to connections or block types in the DCC, you will be informed that you can still monitor and trace values when test mode starts.

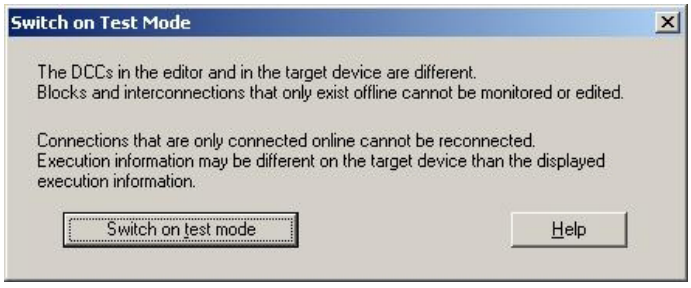


Figure 7-594 Test mode - changes to connections or block types

Online changes can only be performed after the DCC has been recompiled and downloaded to the target system. You are informed about this fact when starting test mode and can return to editing mode or activate test mode for monitoring purposes - as shown in the following dialog box.

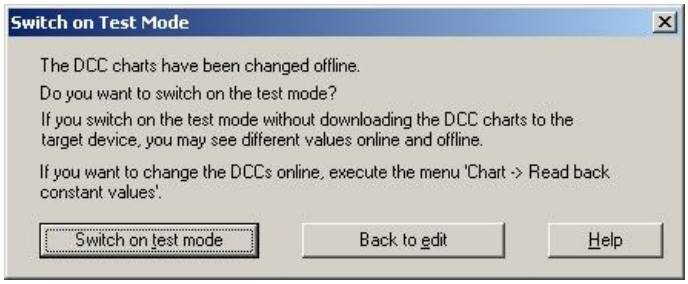

Figure 7-595 Test mode - loading changes to the target device

Monitoring test mode

In test mode, the values of the connections that have been logged on for monitoring are displayed with a yellow background.

Logging on connections for testing

You must explicitly log on to test the connections to be tested. For SIMOTION, the log on to the test can be performed either using the **Log on connection** button in the menu bar or using the context menu of the block connection. Select the **Log on connection** item in the context menu of the connection. For SINAMICS, go to the **Object properties** of the block connection (right-click) and activate the **For test** property. You can also log on the connections directly for the test by clicking with pressed Ctrl key.

Changing input values

You can also change all values of non-interconnected inputs in test mode. To show how changing a value affects execution, assign a new value to an input as follows:

- Double-click the input to be monitored.
- The **Properties - Connection** window appears. Enter the new value for the block input and confirm with **OK**.
- In the chart, you can now see how the value changes on the associated output.

Note

The changed value is only visible when the connection has been logged on for testing.

Logging off connections from testing

You can log off connections logged on for testing. The log off from the test can be performed either using the **Log off connection** button in the menu bar or using the context menu of the block connection. Select the **Log off connection** item in the context menu of the connection. You can also log off the connections directly from the test by clicking with pressed Ctrl key.

Enabling the value and trend display during a test

In test mode, you can use the value and trend display to analyze the input and output values of blocks.

Note

The dynamic display is limited to 256 values.

It includes the structure of a block connection with more than 256 single elements. As such, you can only insert individual elements selectively into the dynamic display and not the block connector in its entirety.

Drag individual elements to the dynamic display by means of drag-and-drop to display currently relevant values.

Please note that monitoring values in the dynamic display influences the performance of the target device

Enabling the value and trend display

You can open the value and trend display using the **View > Value display** and **View > Trend display** commands in the menu bar of the DCC editor. Each of these is an autonomous program window. The windows can be arranged using the minimize and maximize functions.

The block interfaces can now be added to the value or trend display using the **Insert in value display** and **Insert in trend display** commands in the context menu. Current values are displayed when the test mode is switched on.

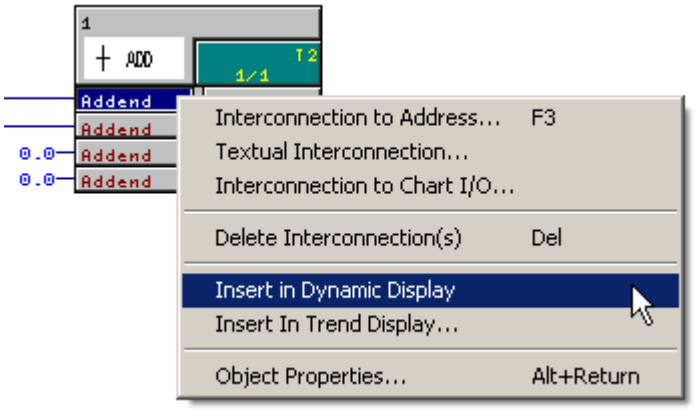

Figure 7-596 Inserting a block pin into the value or trend display

Settings in the Trend Display window

The **Trend Display** window displays the block connections added to the trend display in the form of curves. Each inserted block connection is called a **channel**, whereby a **lower limit** and an **upper limit** can be specified for each channel.

The number of sample values to be displayed on the time axis is specified in the **Display** area of the **Trend Display** window.

The desired trace parameters can be set in the **Trace Parameters** window, which can be accessed via the **Change** button.

Editing DCCs in test mode

To a large extent, you can continue to edit your configurations during test mode. An overview of the changes that can be made during test mode is shown below:

Table 7-609 Further editing of configurations during test mode

Handling blocks (Page 5434)	
Inserting blocks	Call the block catalog using the **View** > **Catalog** command. Open the block family and use drag-and-drop to move the selected block to the working area.
Deleting blocks	Select the block and use the **Edit** > **Delete** command to remove it. In DCC SINAMICS, blocks for which at least one connection has been published as a parameter cannot be deleted. The SAV, SAV_BY, SAV_D, SAV_I and STM blocks cannot be deleted or inserted online.
Moving blocks	Select a block and drag it to the desired position in the chart.
Renaming blocks	Select the block, right-click and select the **Rename** command. • The new block names apply only to the accesses to the input/outputs of the block using Java or Trace; the old names remain valid here. • For those blocks that use retain data, the retain data block on the device is also assigned the new name.
Interconnecting blocks (Page 5440)	
Creating interconnections	In the DCC, select the block connections between which you want to establish a connection. Note that in DCC SINAMICS, block inputs published as BICO parameters can only be connected to block outputs published as BICO parameters or BICO sources of the basic system. BICO inputs and BICO outputs of the basic system can still only be connected to block outputs and inputs published as BICO parameters in the DCC.
Deleting interconnections	In the DCC, select the block connection that you want to disconnect. Then select **Edit** > **Delete** to delete it.
Moving interconnections	In the DCC chart, select the block connection that you want to move. Then move it using drag-and-drop. When moving BICO interconnections, the signal can acquire the value 0 for a few cycles. The no longer interconnected input on the original connection is permanently assigned the value 0.
Changing the signal value of an input	Double-click the block input for which the value is to be changed. The "Properties - Connection" dialog box appears in which you can change the value.
Deleting global interconnections to the sheet bar	In the DCC, select the block connection that you want to disconnect. Then select **Edit** > **Delete** to delete it.
Comments (text)	

Inserting comments (text) in the chart	Select the **New text** command via the directories of the block types and insert it in the chart using drag-and-drop. Release the mouse button at the required point.
Changing comments (text) in the chart	You can move the text field in the DCC by selecting it and then dragging it to the desired position. You can change your comments by double-clicking the text field and then entering or editing your text.

Deactivating test mode

Deactivate test mode to return to edit mode.

- Click the **Test mode** button in the toolbar.

  or click **Test > Test mode**.

Edit mode is reactivated.

Changing online during test mode

Preliminary remark

As a general rule, test mode is used for making online changes to values, interconnections, and block instances without stopping the system.

It is not necessary to recompile after changes have been made online.

The changes are made in the target device and offline data storage area at the same time.

However, they must be saved with **Copy RAM to ROM** before Power Off , otherwise they are lost. This is especially important with regard to SAV blocks.

Note

Please note that online changes can only be made in test mode.

In test mode, the "Server busy" message may be intermittently displayed if you attempt to change values online.

You may need to acknowledge this message several times before the value that is being changed online is accepted.

Repair the project using an XML export/import.

Note

In SIMOTION SCOUT, deactivate the option **Options → Settings → Save → Automatic back-up copy of the project data** when working with large projects to prevent a drop in performance.

Otherwise, the entire project would be saved in test mode each time a change was made.

Changing values at block inputs online

Requirement

Only signal values at block inputs that are not interconnected can be changed online.

Procedure

The **Properties** - **Connection** window is opened by double-clicking the desired block connection. A new numerical value can now be entered for the block input in the **Value** line. The new value takes effect and is displayed in the chart when **Accept** is clicked. The window is closed by clicking **OK**.

Note

DCC-SINAMICS 2.5: Only signal values of block inputs can be changed online that have not been published as BICO parameters.

As of SINAMICS 2.6., all non-interconnected block inputs can be changed in test mode. They do not have to be published.

Note

DCC SIMOTION: The signal value at the block input can be changed online, but with active execution group is overwritten in the next cycle. Whether the signal value at the block input can be changed online does not depend on whether it has been declared as an HMI variable or not.

Deleting an interconnection online

Procedure

In the DCC, select the block connection that you want to disconnect. Then remove this with **Edit > Delete** or with the Del key.

Result

The connecting line between the connections disappears and the last value that was transferred on the connection appears as input value at the connection.

Note

DCC SIMOTION: Interconnections to chart connections cannot be deleted online!

Establishing an interconnection online

Procedure

In the DCC chart, select the block connection from which you want to establish an interconnection and drag an interconnection to the block connection to which the interconnection is to be established.

Result

The connecting line between the selected connections is established and the current value that has just been transferred appears at the output.

Note

Up to and including DCC-SINAMICS 2.5, a block input published as a BICO parameter may only be interconnected with outputs published as BICO parameters or with BICO outputs of the basic system.

Block connections cannot be published in test mode, i.e. new @ parameters inserted.

Note

DCC SIMOTION: Connections to published block inputs in the DCC or global operands cannot be recreated online.

Moving interconnections online

Procedure

Select the required interconnection and move it with drag&drop.

Note

When moving BICO interconnections, the signal can acquire the value 0 for a few cycles.

The no longer interconnected input on the original connection is permanently assigned the value 0.

Inserting a block online

Procedure

Call the block catalog using the **View > Catalog** command. Open the block family and use drag-and-drop to move the selected block to the working area.

The block instance is calculated with the next cycle.

The inserted block instance is assigned a standard name that can subsequently be changed online: Select the block, right-click and select **Rename**. Recompilation and loading is only required if the trend display, trace or monitoring of block connections has been activated.

Note

Whether a block can be added or deleted online is described under "Configuration data" in the online help for blocks.

Note

Renaming blocks

When blocks are renamed in online mode, a new block is created that replaces the existing block. This is then recalculated. The initialization values are newly set for the block.

Online renaming allows meaningful names to be assigned also for the online inserting of module instances.

Deleting a block online

Procedure

First delete all output interconnections by selecting the connection and then selecting **Edit > Delete** in the editor menu or with the Del key. Then select the block and remove it with the Del key or the **Edit > Delete** command.

Note

In SINAMICS, blocks for which at least one connection has been published as a parameter cannot be deleted.

Note

DCC SIMOTION: Blocks with interconnections to chart connections cannot be deleted online.

Note

The STM block cannot be deleted or inserted online.

Inserting comments in the chart

Procedure

Select the **New text** command via the directories of the block types and insert it in the chart using drag-and-drop. Release the mouse button at the required point.

Changing comments in the chart

Procedure

You can change your comments by clicking the text field and then entering or editing your text.

You can adapt the size of the text field to your requirements by selecting the black points at the corners and the sides and dragging them to the desired size.

Moving blocks in the chart

Procedure

Select the block and drag it to a suitable free position in the chart.

Consistency of the charts in test mode

As long as the DCC charts are identical in the DCC editor and in the target system, DCC charts can be monitored and changed in test mode.

If the DCC charts are different in the engineering system and in the target system, changes can still be made online as long as the DCC charts are not compiled.

If the charts are different in the editor and the target device and the charts have not yet been compiled, the following dialog box appears:

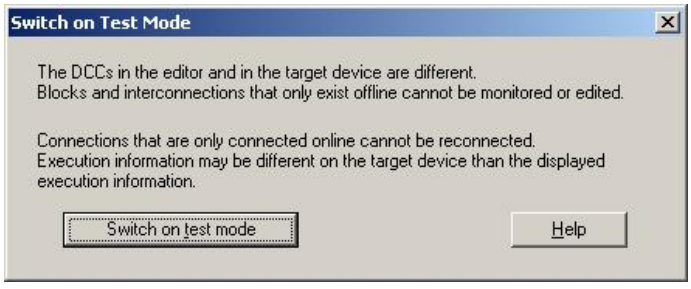

Figure 7-597 Activating test mode with inconsistencies

Click "Switch on test mode" to confirm the dialog.

If only the constant values of the chart are different in the CFC editor and in the target system, the user can recompile the DCC chart and transfer the changes from the target system to the CFC editor with **Options > Read back constant values**. Monitoring, tracing and further online changes can then be performed in test mode.

If the DCC charts differ online and offline and the DCC charts have already been compiled, a prompt appears that the DCC charts are different online and offline.

- If only the constant values of the charts are different, you can restore the consistency using the menu command **Options > Read back constant values**.

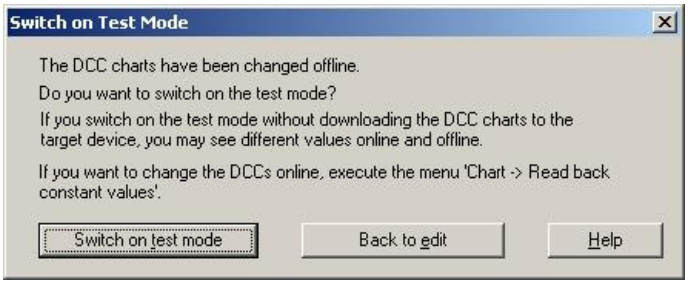

Figure 7-598 Activate test mode - Read back constant values

- If the DCC charts differ online and offline and have already been compiled, a prompt appears that the DCC charts are different online and offline. Download the changes to the target system so that monitoring and changes can be performed in test mode.
  The download is performed when the target device is in the STOP state. With SINAMICS, the download only functions in the "Power-on inhibit" and "Ready for power on" operating modes.

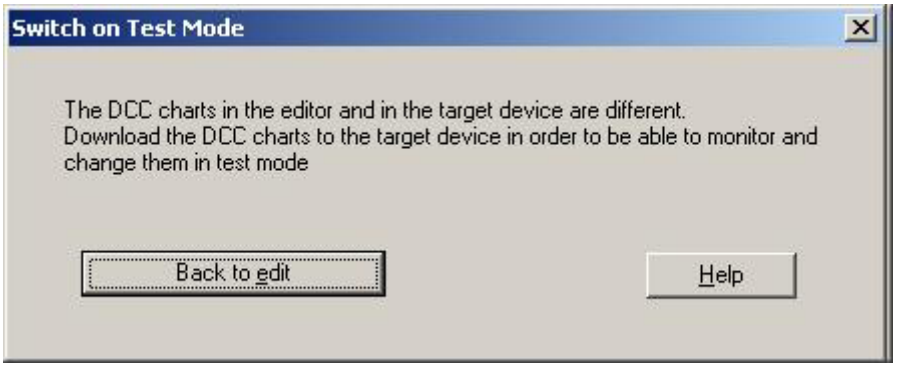

Figure 7-599 Activating test mode

7.4.3.9 Reference data

Chart reference data

As well as displaying the following information graphically in the DCC, you can use the "Chart reference data" (**Options > Chart reference data**) function to display it in the form of a list and print it out:

- Cross references of accesses to different objects
- Execution sequence
  Graphic representation of the entire run sequence of a CPU.

You can use this to check your configuration structure.

You can display and print out the following lists of chart reference data:

- Operand cross references
  This list displays all global operands used on the CPU along with the elements that access them.
- Execution group cross references
  This list displays the existing accesses of any DCCs for all execution groups.
- Block type cross references
  This list displays the block types used and the positions (on the DCC) where they are used.

Note

You can also generate the reference data of a DCC or a DCC library via the context menu with the **Reference data > Generate** command and then display it via **Reference data > Display**.

You can then always display the reference data again, but you only have to generate it once when first called or after changes to the @ variables.

List of block types

The list of block types shows where they are used. Unused block types can be deleted.

You can display the list by opening the **Chart Ref: Display Chart Reference Data** window via the **Options > Chart reference data** menu item. Now select the **View > Block types** menu item or use the  button in this window.

Column heading	Meaning
Block type	Block name (e.g. ADD)
Chart	Name of the DCC in which the block is used
Block	Name of the block instance (e.g. Integrator1)
Block comment	Block comment

Note

Double-clicking one of the displayed block types opens the associated chart and the selected block type is highlighted.

Cross References List Execution Groups (only for DCC-SIMOTION)

The list shows the existing accesses from arbitrary DCCs to the enable attribute of the execution group for all execution groups of the active CPU (the enable attribute can be used to switch individual execution groups on and off, see Enable attribute, execution groups (Page 5608)).

You can display the list by opening the **Chart Ref: Display Chart Reference Data** window via the **Options > Chart reference data** menu item. Now select the **View > Chart element cross references > Execution group** menu item or use the  button in this window.

Column heading	Meaning
Execution group	Group name
(R/W)	Read (R) or write (W) access

Column heading	Meaning
Chart	DCC name
Chart element	Name of the interconnected block and connection
Element comment	Block comment
Type	Block type (e.g. ADD)

Note

The names selected in the execution system (i.e. the names of the execution groups and execution levels) for each device must be unique.

List of operand cross references

This is a list of the global operands used on the CPU or the drive unit, along with the block connections that they are connected to.

You can display this list when you display the **Plan Ref: Chart Reference Data** window from the **Options > Open chart reference data** menu item. Now select the **View > Chart element cross references > Operand** menu item or use the  button in this window.

Table 7-610 Global operands

Column heading	Meaning
Symbol	Name of the global operand
Address	Blank
Data type	Keyword of the data type used
(R/W)	Read (R) or write (W) access
Chart	DCC name
Chart element	Name of the interconnected block and connection
Element comment	Block comment
Type	Block type (e.g. ADD)

7.4.3.10 Library handling

Library compatibility

Compatibility

Please refer to the following table for information on which kernel version supports which DCB libraries.

Kernel version	DCB lib version
SIMOTION 4.1.5	4.1.2, 4.1.4, 4.1.5
SIMOTION 4.2	4.1.5, 4.2

Kernel version	DCB lib version
SIMOTION 4.3	4.1.5, 4.2, 4.3
SINAMICS V2.5.SP1	SINAMICS V2.5
SINAMICS V2.6.x	SINAMICS V2.6
SINAMICS V4.3	SINAMICS V4.3
SINAMICS V4.4	SINAMICS V4.3, SINAMICS V4.4
SINAMICS V4.5	SINAMICS V4.3, SINAMICS V4.4, SINAMICS V4.5
SINAMICS V4.6	SINAMICS V4.3, SINAMICS V4.4, SINAMICS V4.5, SINAMICS V4.6
SINAMICS V4.7	SINAMICS V4.3, SINAMICS V4.4, SINAMICS V4.5, SINAMICS V4.6, SINAMICS V4.7
SINAMICS V4.8	SINAMICS V4.3, SINAMICS V4.4, SINAMICS V4.5, SINAMICS V4.6, SINAMICS V4.7, SINAMICS V4.8

SINAMICS libraries

The following standard libraries are executable with SINAMICS V4.8:

- SINAMICS V4.8 (dcblibV3_0_sinamics4_8)
- SINAMICS V4.7 (dcblibV3_0_sinamics4_7)
- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

The following standard libraries are executable with SINAMICS V4.7:

- SINAMICS V4.7 (dcblibV3_0_sinamics4_7)
- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

The following standard libraries are executable with SINAMICS V4.6:

- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

The following standard libraries are executable with SINAMICS V4.5:

- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V4.4, the following standard libraries are executable:

- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V4.3.x, the following standard libraries are executable:

- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V2.6.x, the following standard libraries are executable:

- SINAMICS V2.6 (dcblibV2_0_sinamics2_6)

With SINAMICS V2.5.SP1, the following standard libraries are executable:

- SINAMICS V2.5 (dcblibV2_0_sinamics2_5_1)

Handling DCC libraries and block types

The creation of SINAMICS DCC libraries is possible from DCC 2.1.

You can exchange block types within the DCC chart using the **Options -> Block types** menu command. If there are no DCC chart sources, the versions of the basic DCB libraries on the chart can be exchanged by selecting **Block types** from the context menu. This enables you to use the same DCC library on different device versions. The relevant DCC license is required for this.

Changes to execution groups are made automatically when saving under a different target device.

If a chart containing multiple execution groups is copied from the device to the library, error messages will appear during compilation. The user needs to correct the execution groups in this case.

It is possible that libraries and block types with the same names are present in the separate directories for the SIMOTION and SINAMICS libraries. Block type names must be unique within a library.

Note

Use the STM block in DCC library blocks that are only instantiated once per DO.

Importing block libraries

When first creating a chart in SCOUT/STARTER, you may be prompted to import a block library for the selected device platform.

The import process involves the DCB library that is already installed in SCOUT/STARTER being mapped to the Step7 data storage area for the device or DCC library, thus making it available for the charts in the DCC/CFC editor. DCC libraries located in the same project can also be imported for SIMOTION and SINAMICS devices.

You need to install libraries in SINAMICS/SIMOTION and then import them for the chart containers (**Programs** folder) before you can use the block types contained in DCC charts.

Only libraries that are appropriate for the device may be used. Only one version of a library should be imported. For a SIMOTION device 4.1, only libraries as of Version 4.1 + ServicePackX (e.g. 4.1.0, 4.1.5) should be imported.

Note

You can no longer use a SINAMICS 2.6 library as of SINAMICS Version 4.x.

If the DCC library required in the chart is not available for selection, this means that a basic library used within the library is not valid for the current device. You can change the basic library in the DCC editor under **Options > Block types**. If a chart source is not available, you can call up the **Block types** menu command from the context menu in the DCC library.

Name ambiguity in blocks from different libraries

If two blocks from different libraries (in the case of SIMOTION) have the same name, then the block from the library whose name comes first in the alphabet will apply.

If a DCC chart has not been inserted for a chart container (Device/Library), it is not possible to import a library.

Note

For SINAMICS, the libraries must always be imported under the device and not under the drive object.

Deleting the last chart of a device clears the selection of the DCB libraries.

When importing a DCC library, it must be compiled.

How to import block libraries:

- Open a chart from the relevant configuration and click **Options > Block types**.
  The **Import** window appears. Click **OK** to close the window. In the **Import DCB Libraries** window, the block libraries installed on your programming device are listed under **Libraries available for the device**. Under **Libraries imported in the chart**, all libraries which have already been imported into this configuration are listed.
- Select the library to be imported under **Libraries available for the device** and click **>>**. The import process is triggered when you click **Accept**.

Checks are performed when a block library is imported.

The names of the block libraries are defined on the basis of a naming convention. The individual parts of the name are explained in the following table. The part in question is shown in bold each time.

Table 7-611 Naming convention for block libraries

Part of the block library name	Meaning
TPdcblib_SIMOTION_4_1_2.2.0 [7.0]	Library identifier
TPdcblib_**SIMOTION**_4_1_2.2.0 [7.0]	Target platform

Part of the block library name	Meaning
TPdcblib_SIMOTION_**4_1_2**.2.0 [7.0]	Target system version
TPdcblib_SIMOTION_4_1_2.**2.0** [7.0]	Library version
TPdcblib_SIMOTION_4_1_2.2.0 **[7.0]**	Build version

Updating the block library

When a DCC chart is open, you can update the block libraries via the menu **Options > Block types**.

For DCC libraries without DCC chart sources, the versions of the basic DCB libraries can be exchanged by selecting **Block libraries** from the context menu.

Note

The library concerned must be selected for this purpose.

How to update block libraries:

- Open a chart from the relevant configuration and click **Options > Block types**.
- The **Import** window is displayed. Click **OK** to close the window. In the window **Import DCB Libraries**, the block libraries installed on your programming device are listed under **Libraries installed in SCOUT/STARTER**. Under **Libraries imported in the chart**, all libraries which have already been imported into this configuration are listed.

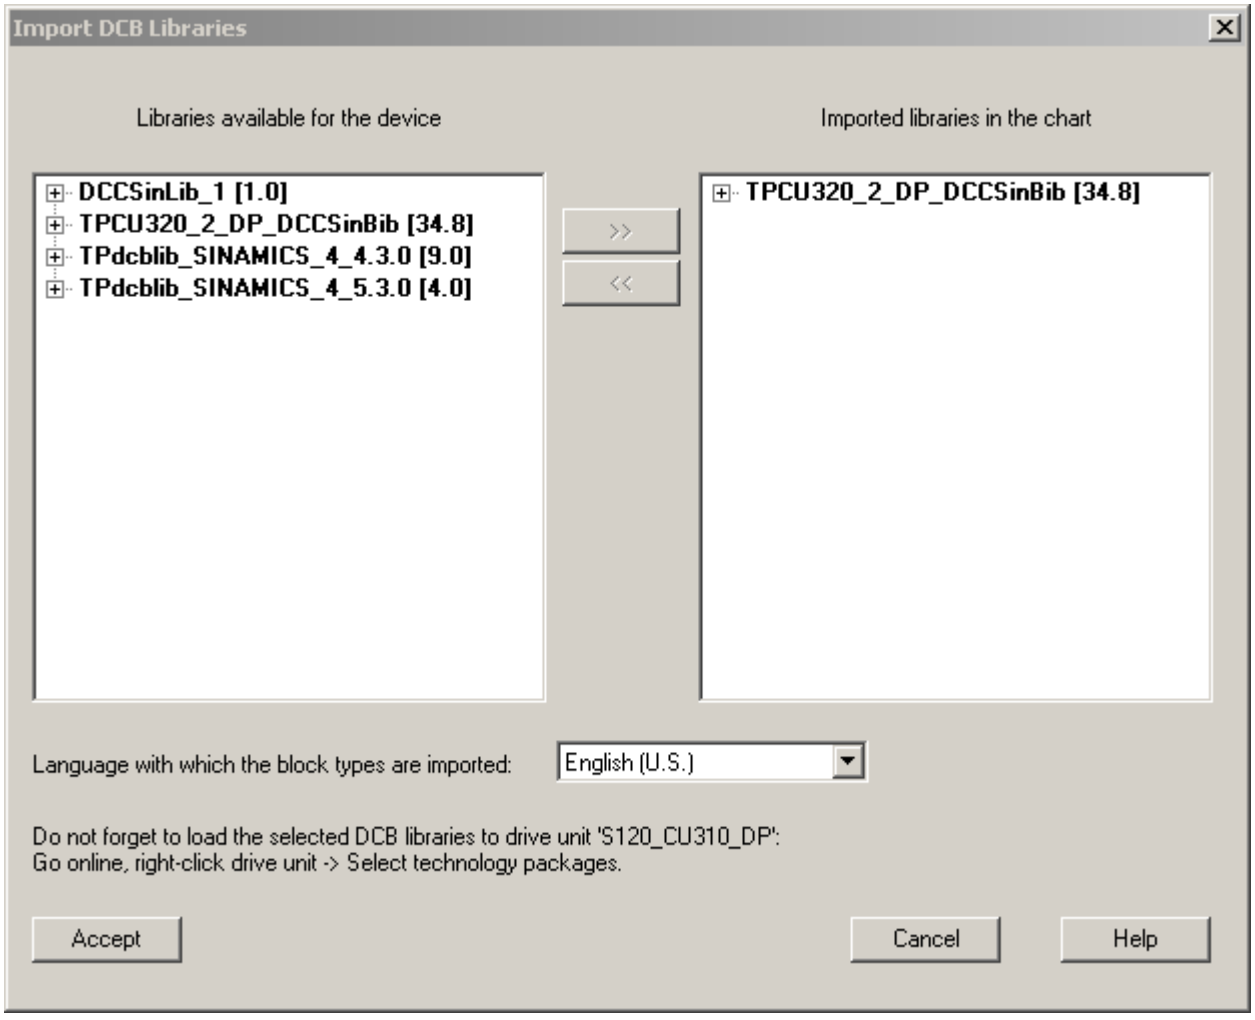

Figure 7-600 Updating the block library

Updating libraries after a device upgrade

As of STARTER 4.2, the system automatically swaps in the correct library version after a device version has been upgraded.

Detailed information about upgrading a device version can be found in the section titled Software upgrade and module exchange (Page 5512).

Note

The standard library is automatically installed during setup, but if you do uninstall it accidentally, you can reinstall it by means of the DCC setup process.

The libraries for SINAMICS can also be installed via the SSPs (SINAMICS Support Packages).

If you wish to reinstall the DCB library from the SSP DVD, switch to directory CD_1\SSP\Disk1 and unzip file dcblib.zip into any directory. Install the library dclbib_Vx.y_sinamics_w.z contained in unzipped files.

As of DCC V2.1 (STARTER 4.2), the libraries for SINAMICS are also available via the menu command **Options -> Install libraries**. See also Installing and uninstalling DCB libraries (SINAMICS).

The libraries for SIMOTION are also available via the menu command **Extras -> Install libraries**. See also Installing and uninstalling DCB libraries (SIMOTION) (Page 5496). Here you will also find information on where installable DCBLIB standard libraries are located and how to reinstall these.

- Check which previously imported libraries have a new version installed, by inspecting the version of the library under **Libraries installed in SCOUT/STARTER** and **Libraries imported in the chart**.
- Select the library to be updated under **Libraries installed in SCOUT/STARTER** and click **>>**.
- Click **Accept**.
- The progress of the update is displayed in a window.

Note

In SINAMICS, you can check a selected device in the engineering system using the **Select technology packages** function in the context menu as to whether all required block libraries and technology packages have been activated.

Note

In SIMOTION, the library is automatically loaded to the device during the project download. In SINAMICS, this action must be performed explicitly by the user before the project download. (Page 5567)

The library to be imported is checked to see whether it contains a block type that has already been imported with another library.

Error log

If errors are detected when a library is being imported, an error log with details of the causes of the errors is displayed.

Exchanging the basic library version for installed libraries

The basic libraries are selected from the DCC charts used in the dialog **Options → Block types** of the DCC editor.

If there are no DCC sources available at the DCC charts, you can open a dialog via the context menu **Block types** of the DCC chart, where you can exchange the block libraries used.

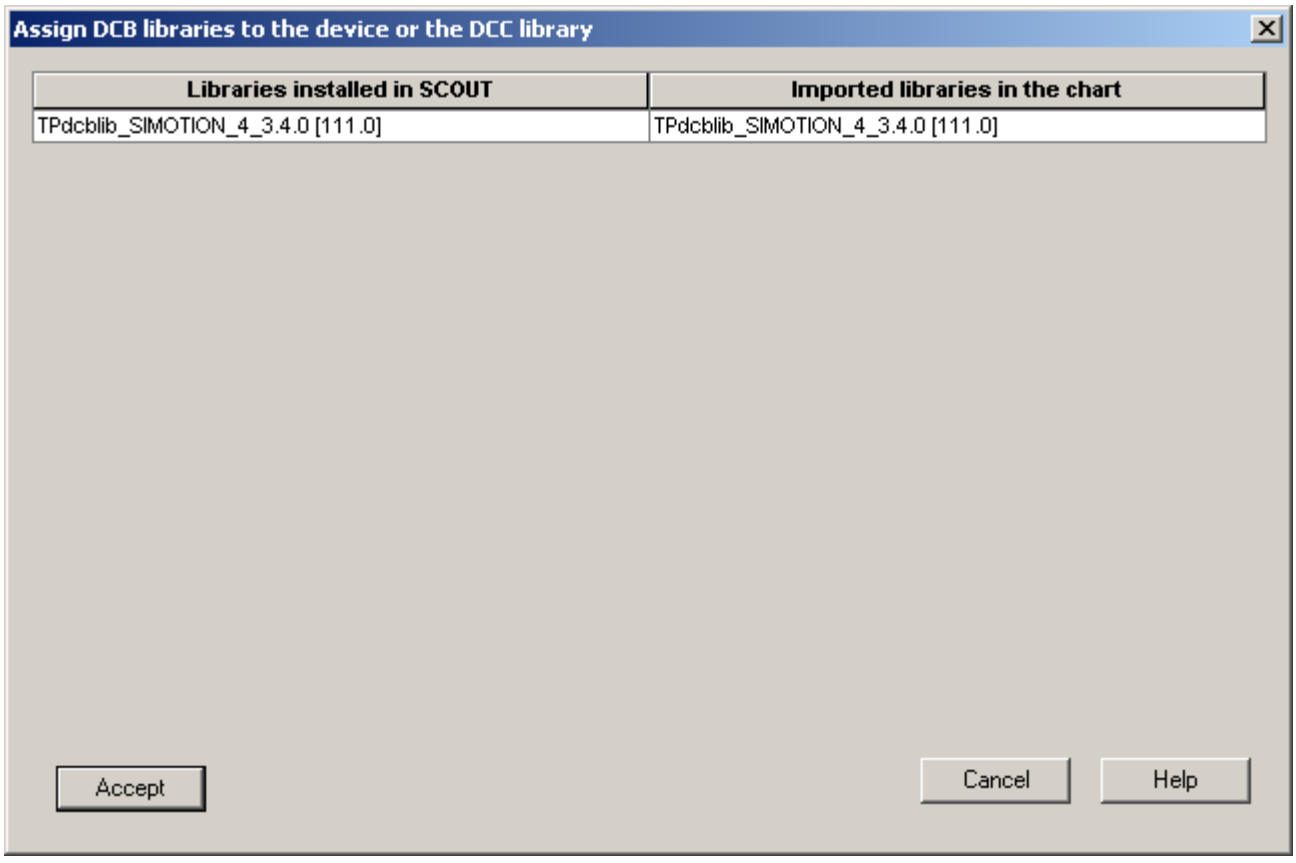

Figure 7-601 Block types

Mark the library in the left-hand column and press **Accept.**

Up to DCC V2.0.1, the version of the basic library used is permanently defined in a DCC library.

Exactly the same basic library version that was used to create the DCC library must be installed.

If the library sources have been deleted, it is not possible to select a new version of the basic library in the typical library.

With DCC 2.0.2, you can combine an installable library that has been supplied with different versions of a DCB library that is being used, provided the interface for the blocks called does not change.

Changing the block library language

You can customize the language of the block type comments via the menu **Options > Block types**.

How to change the language of the block types in a block library:

Checks are performed when a block library is updated.

- Open a chart from the relevant configuration and click **Options > Block types**.
- The **Import** window appears. Click **OK** to close the window.

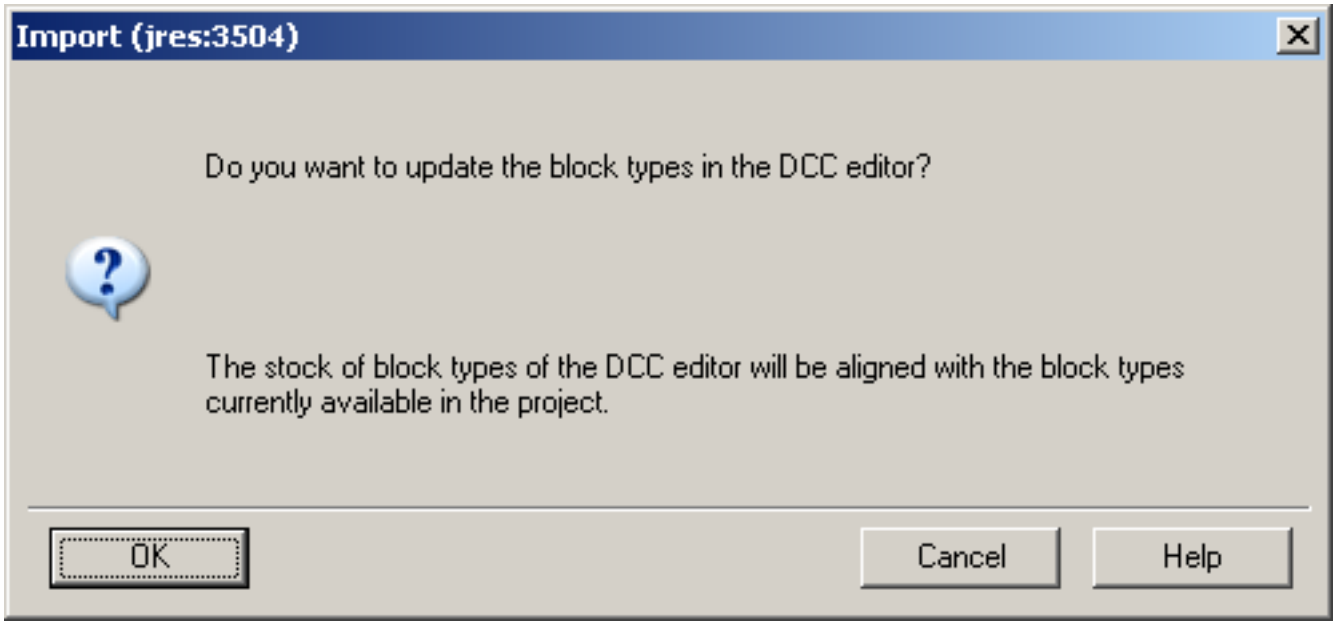

Figure 7-602 Import window

- The **Import DCB Libraries** window appears. The block libraries installed on your programming device are listed under **Libraries installed in SCOUT/STARTER**. Under **Libraries imported in the chart** all libraries which have already been imported into this configuration are listed.
- Select the desired language in the selection list of available languages. The selected language affects all imported libraries.

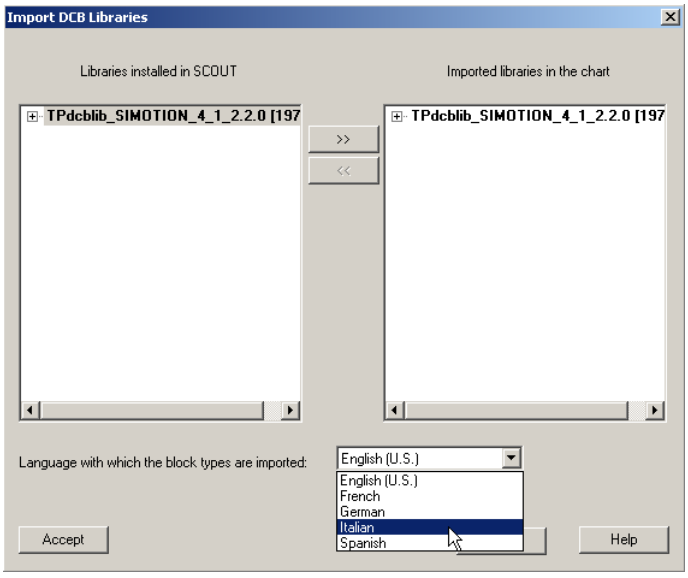

Figure 7-603 Changing the block library language

- Click **Accept**.
- The progress of the update is displayed in a window.

Note

Comments regarding the block types remain in the language in which they were created. The comments regarding block pins are translated if they have not already been altered manually.

Removing block libraries from the configuration

You can delete block libraries whose block types are no longer required in the configuration concerned via the menu **Options > Block types**.

How to delete block libraries:

- Ensure that the block types from the block library to be deleted are no longer to be used at all in the charts of the configuration.
- Open a chart from the relevant configuration and click **Options > Block types**.
- The **Import** window appears. Click **OK** to close the window.
- The **Import DCB libraries** window appears. The block libraries installed on your programming device are listed under **Libraries installed in SCOUT/STARTER**.
  Under **Libraries imported in the chart**, all libraries which have already been imported into this configuration are listed.
- Select the library to be deleted under **Libraries imported in the chart** and click **<<**. The deletion process is triggered when you click **Accept**.

Checks are performed when a block library is deleted. All unused block types of the library will be removed from the selection list of the block types in the DCC editor; used block types remain in the list. The chart cannot be compiled without an imported library if instances of the library are still present in the chart.

7.4.3.11 Creating block libraries

Fundamentals

The DCC editor offers a function for saving a chart as a **block library (DCB library = typical)**. This kind of chart relates to a connection created by the user, which features an interface so that it can be reused and is saved in a library. The charts as block library (DCB library) function therefore include the option of know-how protection, since the configured DCCs are only available as a transparent block within a block library. The DCC configuration that has been created is hidden. The DCC chart created for a block can be permanently deleted via the function **Delete source of the block types...** in the context menu of the library. This command is only available if all blocks in the library have been compiled without errors. If it is executed, all the corresponding chart sources are deleted leaving only what has been compiled in the project. You cannot undo the action. By right-clicking on the DCC chart and selecting the **Block types** command, however, you can open a dialog in which the block libraries used can be exchanged.

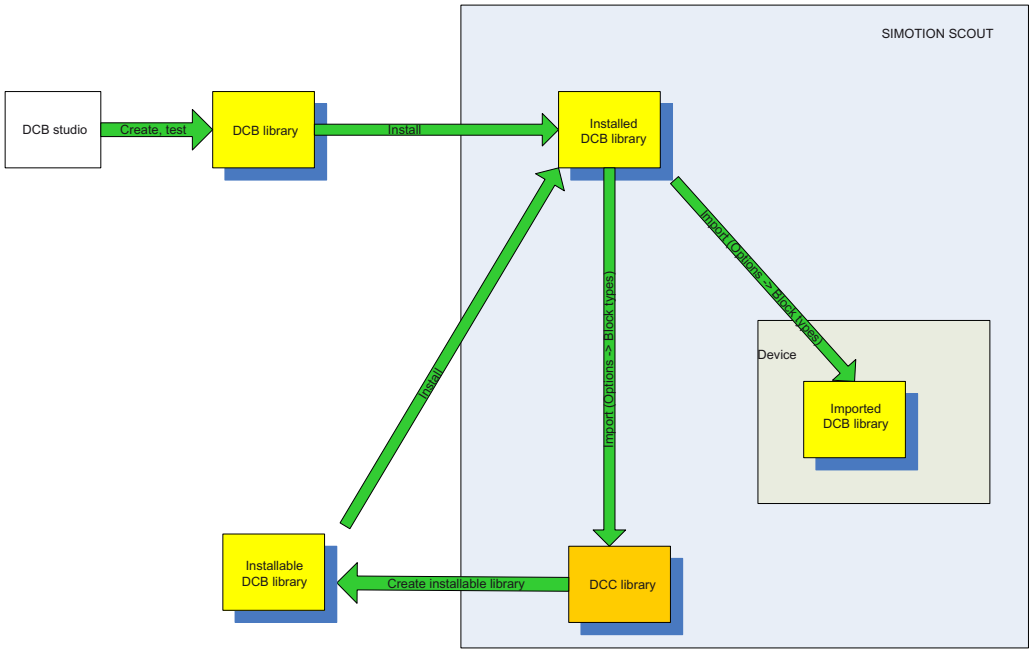

Figure 7-604 Installation of DCB libraries

Requirements

You have already created a new DCC library in the SIMOTION SCOUT engineering system. SIMOTION DCC libraries are located in the folder **Libraries** of the project navigator, DCC libraries in the **SINAMICS Libraries** folder of the project navigator.

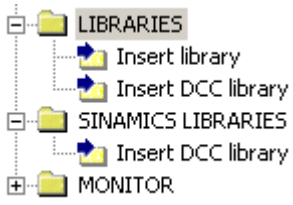

Figure 7-605 Inserting a DCC library

There is already a DCC available for saving in the DCB library.

The chart connections are displayed.

Note

You can display the chart connections via the button in the toolbar.

You can use a library either in DCC charts for SINAMICS or for SIMOTION.

Create DCC libraries for SIMOTION in SCOUT in the **Libraries** container.

As of DCC 2.1 / SCOUT / STARTER V4.2, DCC libraries can also be created for SINAMICS.

For this purpose, the project navigator contains a new program container for SINAMICS libraries under **Libraries -> SINAMICS LIBRARIES**.

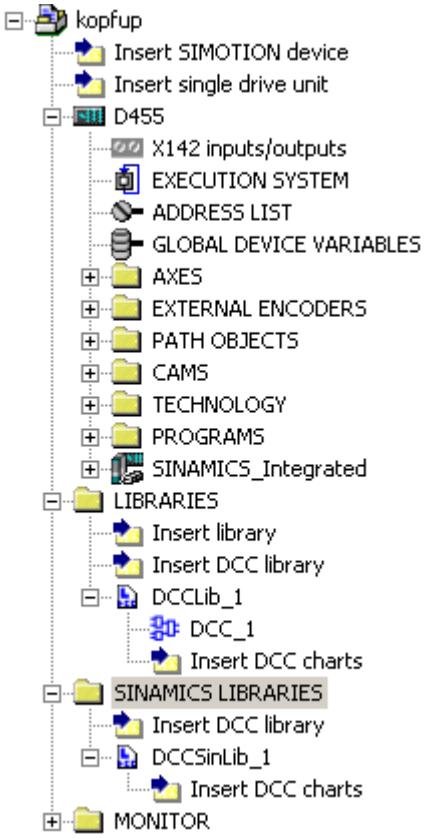

Figure 7-606 Library container for DCC libraries for SINAMICS devices in SIMOTION SCOUT

The DCC libraries for SINAMICS and SIMOTION are distinguished from one another on the basis of the different library containers in the project navigator.

Insert a DCC library for SIMOTION by selecting **Libraries -> Insert DCC library** from the context menu in the project navigator.

Insert a DCC library for SINAMICS by selecting **SINAMICS libraries -> Insert DCC library** from the context menu in the project navigator.

With DCC 2.0, you can insert SIMOTION DCC charts into the library container using copy and paste.

The chart connections of the inserted DCC chart must be connected to the chart connections of the SINAMICS DCC library without BICO interconnections and @ parameters before the compilation.

The DCC libraries, but not the DCB block libraries, are found in the library containers.

By selecting **Generate DCB library...** from the context menu for the selected DCC library, you can create installable DCB libraries from DCC libraries (typical libraries).

It is possible that libraries and block types with the same names are present in the separate directories for the SIMOTION and SINAMICS libraries.

Note

Know-how protection

Protect the DCC blocks, sources and libraries by means of the know-how protection function provided by STARTER/SCOUT.

Note

You need a DCC SIMOTION license to create and edit SIMOTION DCC libraries.

You need a DCC SINAMICS license to create and edit SINAMICS DCC libraries.

Rules for creating DCC libraries

- It is only possible to compile charts in DCC libraries.
- The chart may be hierarchical (chart-in-chart).
- Interconnections between charts in the library are not permitted.
- No HMI variables, BICO interconnections, @ variables or @ parameters must be configured at the chart connections of the basic chart and the blocks it contains.
- All blocks may only by integrated into the same execution level / execution group. Here, the chart blocks must directly follow one another.
- Inside the chart folder that needs to be compiled, all of the blocks from a basic chart must be placed in the execution group with the same name as the chart.
- Global operands are not permitted, but must be modeled as an input or output as chart connection.
- For the DCC library and its connections, please select only names starting with lower-case letters.

Procedure

Model your DCC in the DCC editor.

Insert an **ADD**er and a PI controller (**PIC**), for example, in the chart and interconnect them. See Interconnection to chart connections (Page 5441)

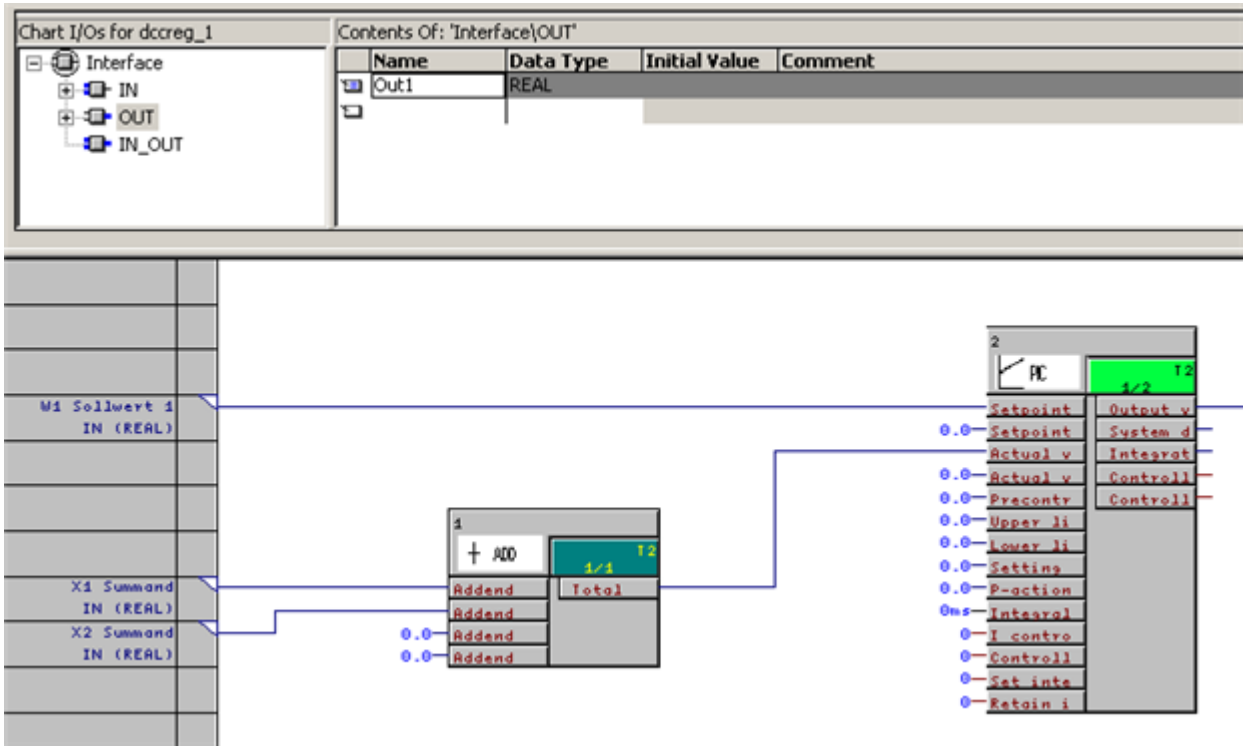

Figure 7-607 Example: Creating a chart as a program

Following successful configuration, the DCC can be compiled as a program. To do this, select **Chart > Compile > Chart as program** in the menu.

The newly created DCB library is available in the menu under **Options > Block types** in the DCC editor. The DCB library is not shown in SIMOTION SCOUT/STARTER; only native libraries are listed there.

See also

Creating an installable DCB library from DCC libraries (Page 5491)

Inserting and programming block types in DCC libraries

Within a library, a DCC chart can be created for each DCC block in the library. A new block type is created using the **Insert DCC chart** context menu.

SIMOTION and SINAMICS libraries are both subject to the same rules for assigning DCC chart names:

- Max. 22 characters, beginning with a letter
- If an underscore is used, only numbers may be used after it.

The following rules apply to the blocks:

- There is no restriction on the number of blocks for a DCC library.
- The name of the block type is formed on the basis of the chart name
- The block inputs and outputs are created in the DCC editor using **View -> Chart I/Os** and interconnected with the inputs and outputs of the block instances
- Within a library, all the blocks must be within the same execution group. This group bears the name of the chart
- The execution group in which the blocks run in the target device depends on the execution group of the block instance that calls the library block.

Special features of the 1:N interconnection of chart connection inputs

If you have defined an interconnection of a chart connection input with blocks for a chart, there are two different scenarios. First, there is the scenario of a 1:1 interconnection, which can be carried out without problems. However, the following must be noted for a multiple interconnection (1:N) of a chart connection input to several blocks.

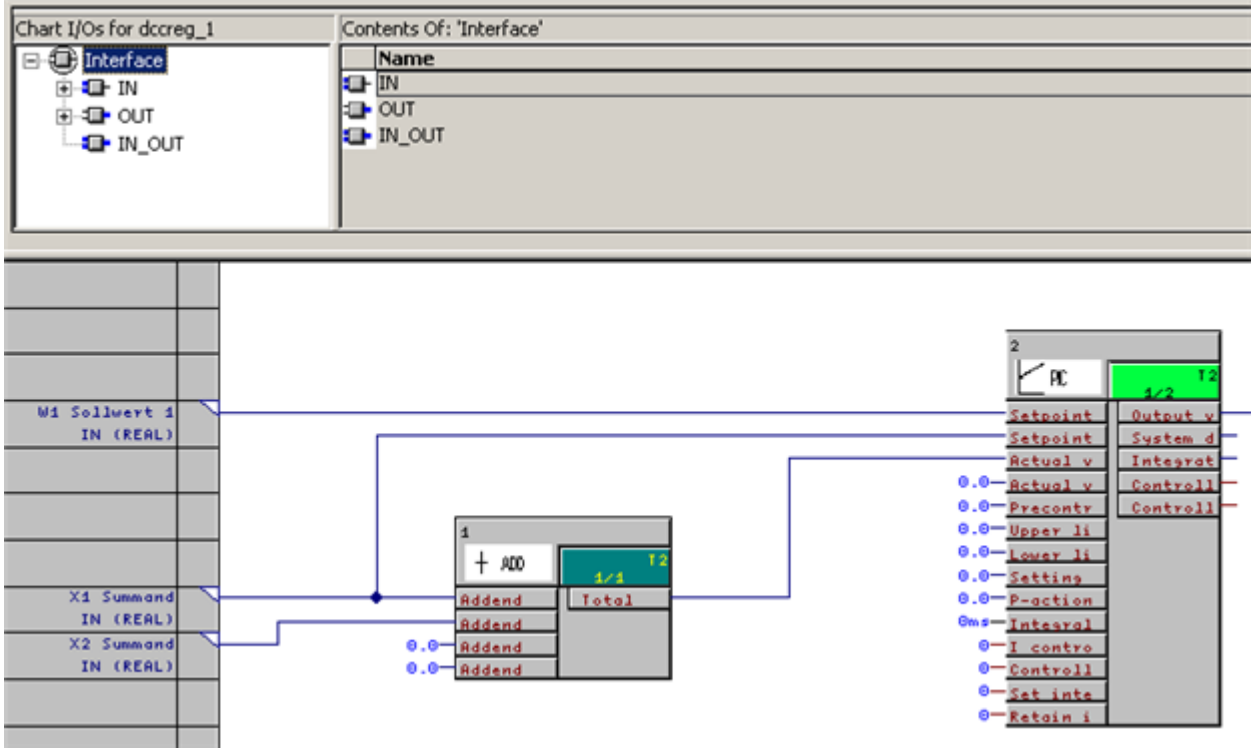

Figure 7-608 Connection example for a 1:N interconnection without NOP block

If there is a 1:N interconnection at an input within a hierarchical chart or block type, an **NOP_x** block must be used in the chart for consistency reasons - refer to the following example:

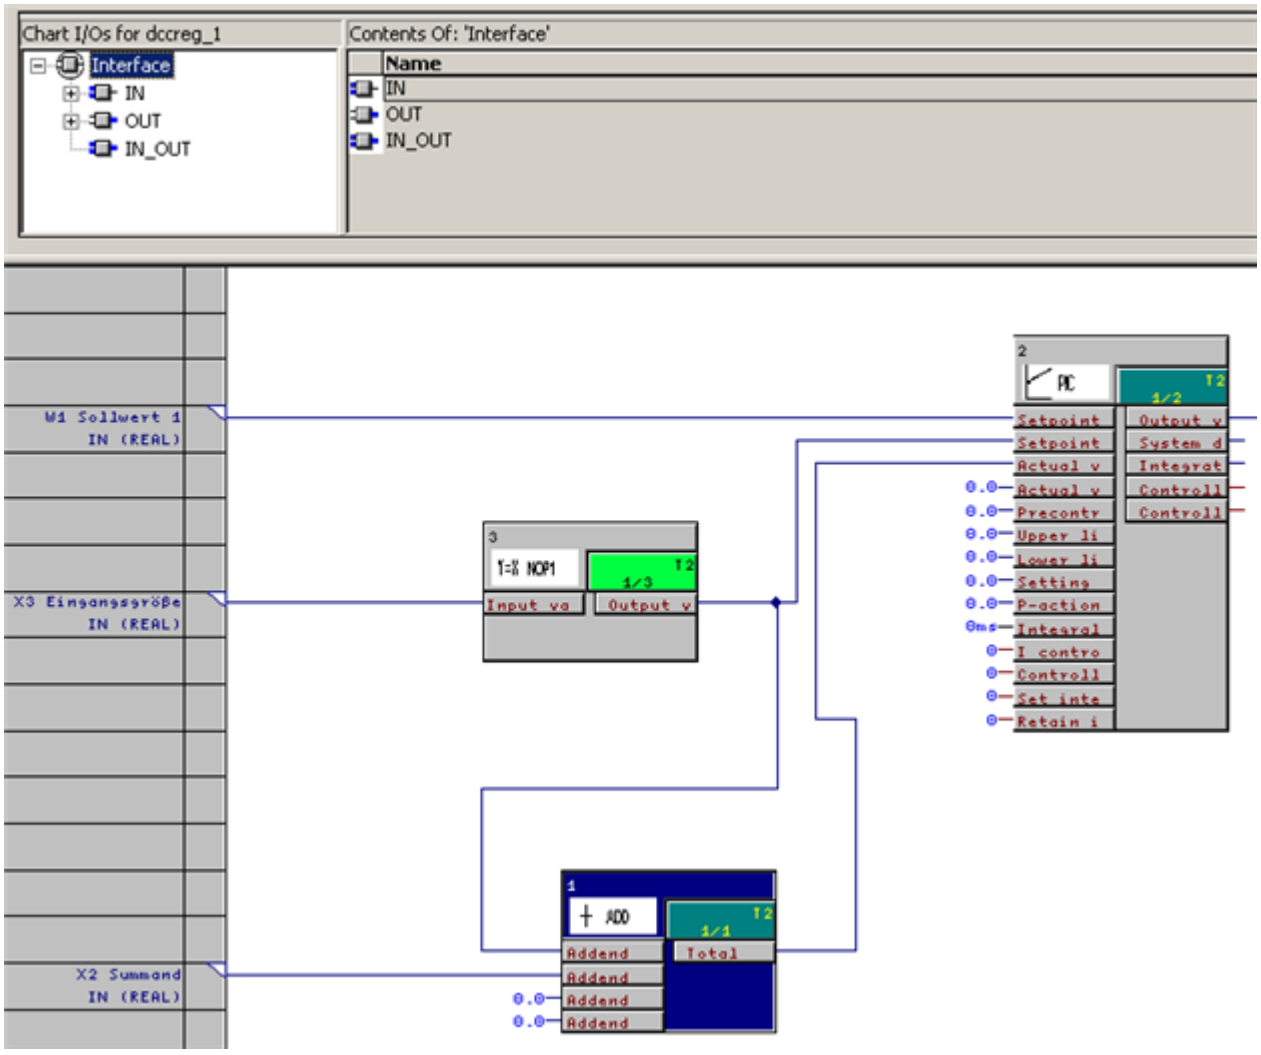

Figure 7-609 Connection example for a 1:N interconnection with NOP block

Creating comments and icons for DCC libraries you have created yourself, and assigning a block family to them

In the engineering system, you can save additional information on individual blocks of a DCB library that you have created yourself.

Procedure

Select the block library you want to edit in the engineering system.

In the context menu of the DCC library, select the **Block type properties** command.

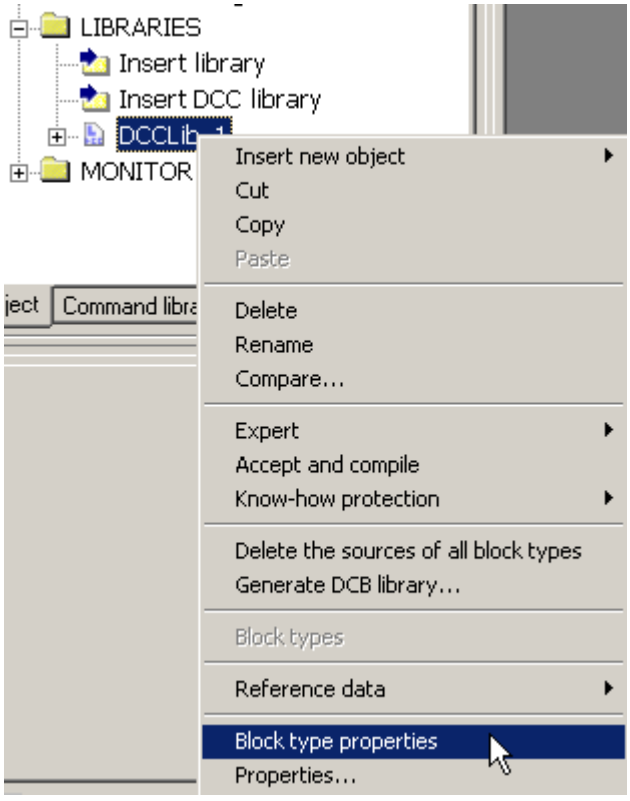

Figure 7-610 The **Block Type Properties** dialog opens.

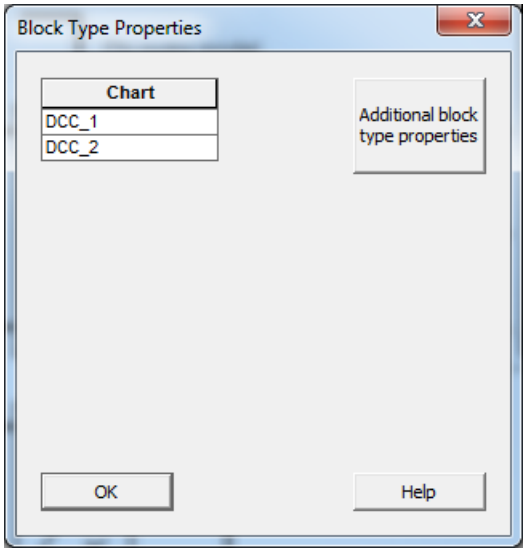

Figure 7-611 Block Type Properties

In the list under **Chart**, select the DCC chart you wish to edit and click the **Additional block type properties** button to open the **Block Type Properties** dialog.

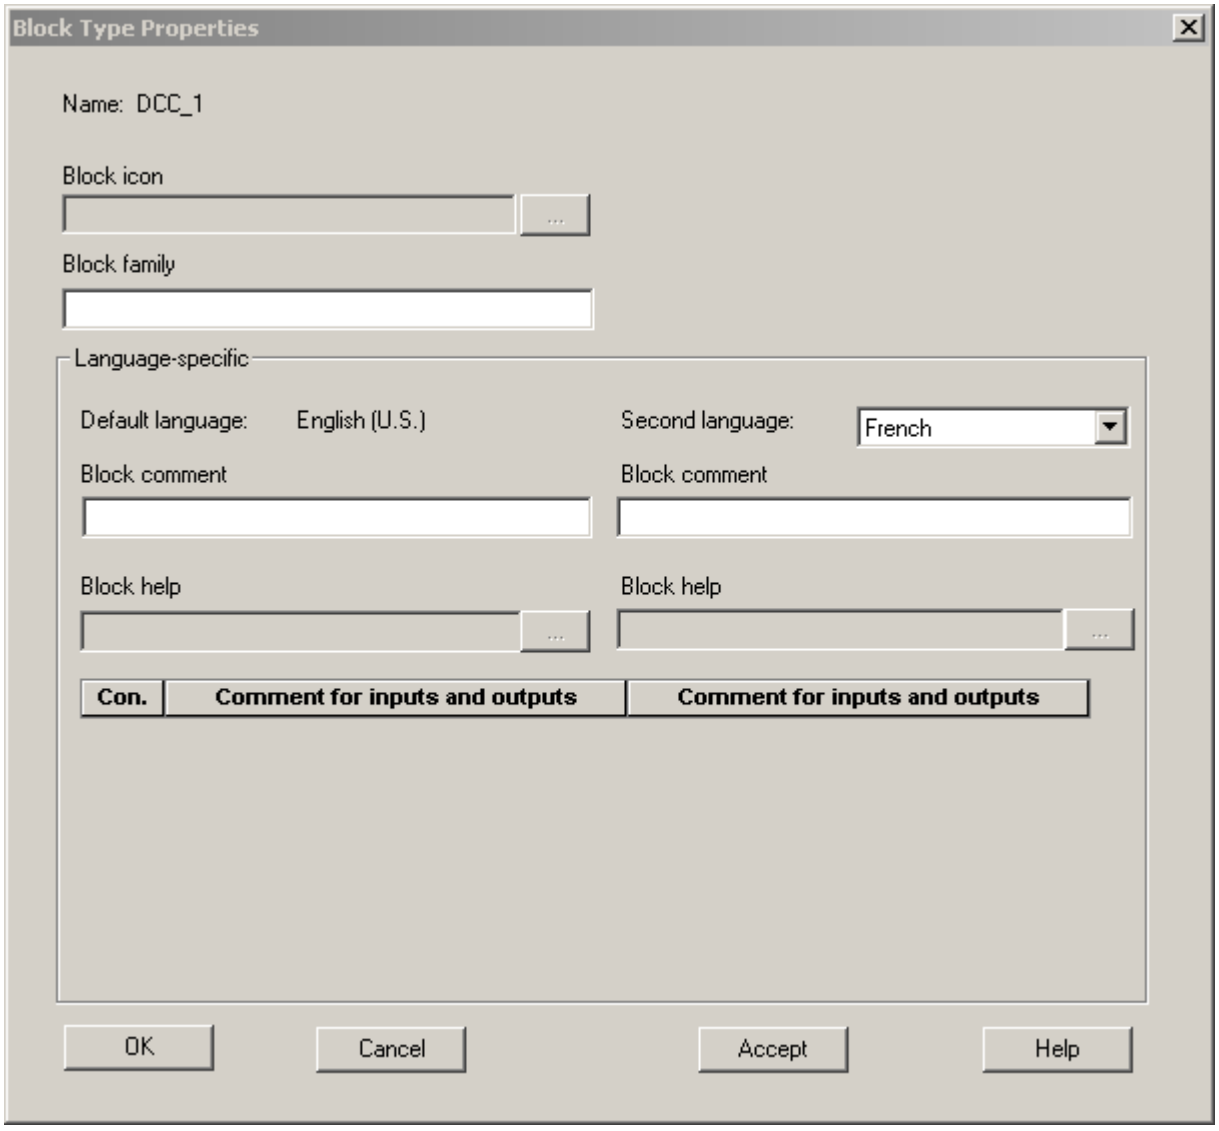

Figure 7-612 Block Type Properties

Block icon

Click the **...** button and load a BMP file you wish to use as a block icon for the DCC chart.

Block family

Enter the family to which you want to assign the DCB library. You can either choose an existing block family (e.g. Logic, System, Conversion, Arithmetic, etc.) or enter a new one, which will then be created automatically. The default language for block families is English.

Block comment

Here you have the option of entering a comment for your DCB library; this will appear in the block header. On the left-hand side, enter the comment in English (the default language). On the right-hand side, you have the option of entering the comment in additional languages. To do this, select the required language from the combo box above and to the right of the field, enter the comment, and click Accept. Repeat this process for all other languages in which you wish to create the comment.

Accept what you have entered using the **Accept** button and click **OK** to close the dialog.

Creating an installable DCB library from DCC libraries

Up to SIMOTION V4.1.1, a DCC library had to be transported as project. As of SIMOTION V4.1.2 / STARTER 4.2, it is possible to create an installable DCB library from a DCC library.

To do this, select the entry **Create DCB library...** in the context menu of the library; the **Create DCB Library** dialog appears.

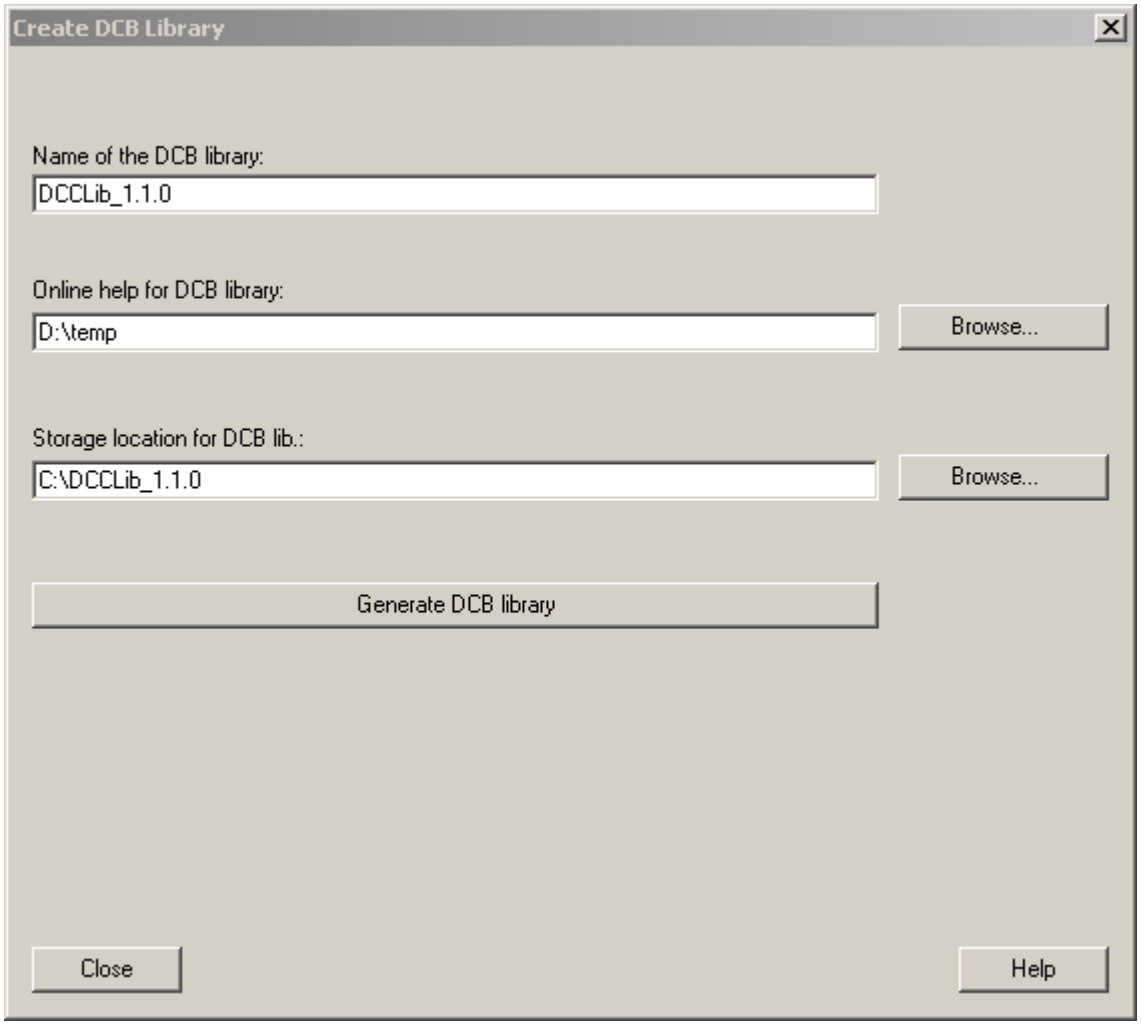

Figure 7-613 Create DCB library

In the dialog box, specify the online help directory for the library.

The name of the DCB library results from the name of the selected DCC library. You can freely select the storage location of the DCB library and then start the creation via the **Create DCB library** button. Information on the creation of the DCB library can be found in the detail view.

You have the option of deleting DCC chart sources for improved know-how protection.

Select the context menu Delete source of all block types in a compiled DCC library to delete the sources of the DCC charts. The charts can then no longer be edited.

By selecting the context menu **Block type -> Properties** at the library, you can allocate comments to block types and block connections in multiple languages.

An installable library may be installed on a different SCOUT/STARTER, regardless of the STEP7 project being used. This library does not contain the CFC chart sources.

Once you have installed the library using **Options -> Install libraries**, it is available for importing into DCC charts on the devices (Options -> Block types).

Note

If you create an installable library from a DCC library, you must replace the DCC library with the installable library in the DCC chart via the menu **Options -> Block types** of the CFC editor.

Note

The sources of the DCCs are no longer contained in the created DCB library. The contained functions can no longer be changed or monitored (know-how protection).

Information on how to create an online help for the DCB library created can be found in the section titled Creating the online help for block libraries (Page 5492).

Note

It is possible to create C block libraries from exported DCC libraries automatically. This results in improvements to the memory utilization in the execution performance of the DCC charts as well as increased know-how protection.

See also

Exchanging the basic library version for installed libraries (Page 5479)

Creating the online help for block libraries

Note

From SCOUT/STARTER 4.4 the block help editor is no longer part of the setup. A help can now be created as part of SIMOTION CLIB Studio or SINAMICS DCB Studio.

You can create a separate online help for the created libraries with the aid of a supplied editor, the **DCB help editor**. You edit your help files in the same view in which they are later displayed.

The DCB help editor can be found at ...*Siemens\Step7\S7BIN\helpeditor\DCB-Help-Editor.exe*.

Storage structure for online help

Save your online help files under the name **<block>_doc.xml**, whereby <block> is the name of the written block library. Create a folder structure comprising a **help** folder, containing the **help_a**, **help_b**, **help_c**, **help_d** and **help_e** folders. This results in the following assignment:

Table 7-612 Storage structure of the online help files

Folder	Subfolder	Language of the help file <block>_doc.xml
help	help_a	German
	help_b	English
	help_c	French
	help_d	Spanish
	help_e	Italian

A **<block>_doc.xml** file can be stored for each block in the help_x folder. For example, save your German language **<block>_doc.xml** file under **help > help_a**.

Procedure

1. Open the DCB help editor with a double-click on *helpeditor DCB-Help-Editor.exe*.
2. The STARTFILE_DOC.XML file, which is filled with elements and dummies, opens automatically.

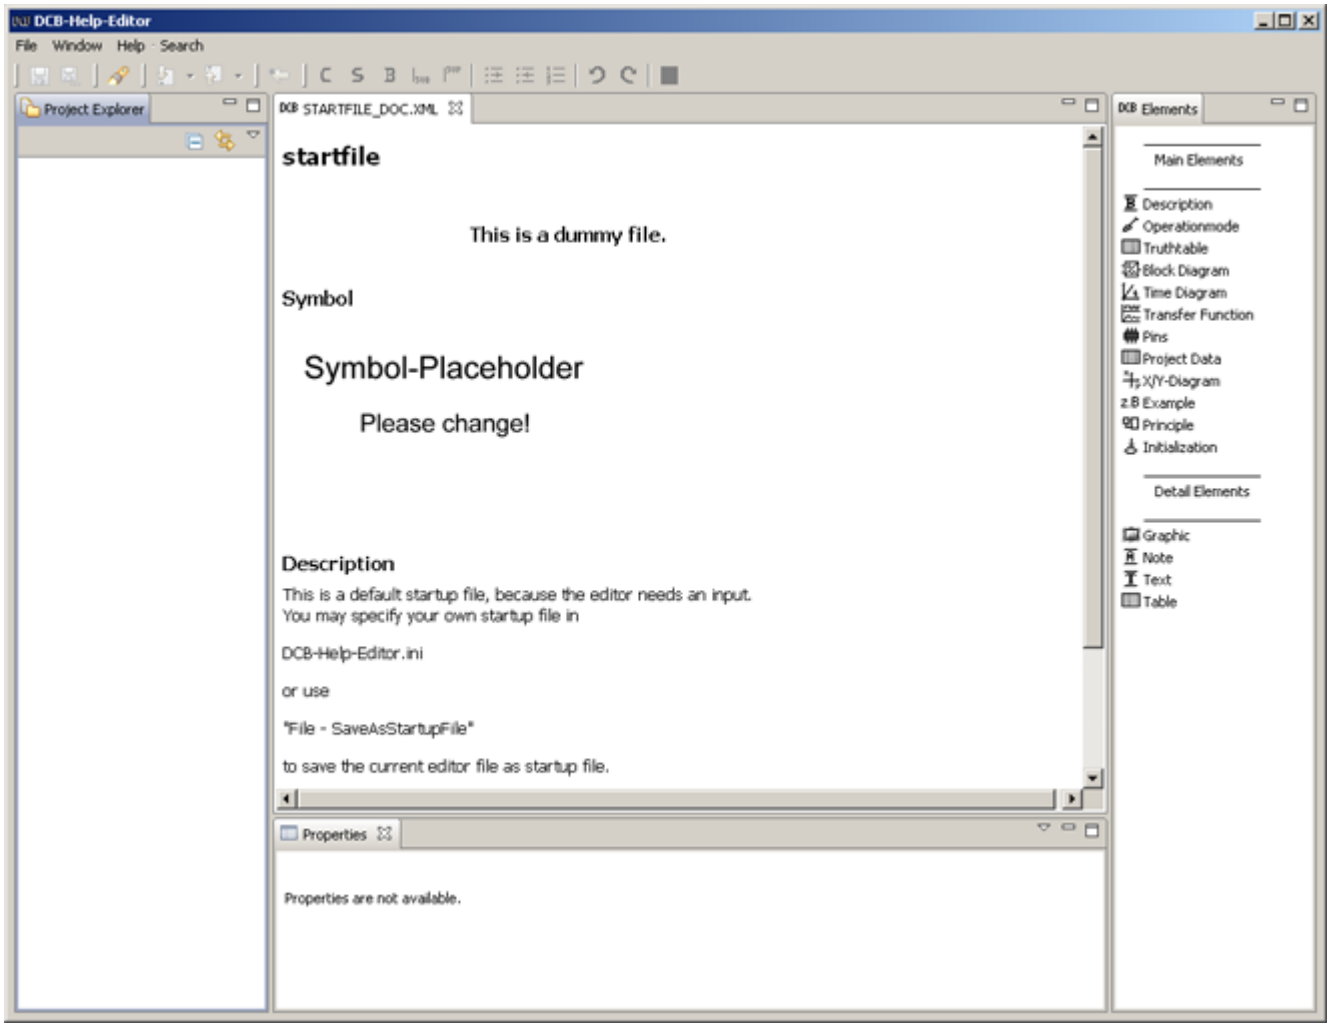

Figure 7-614 DCB help editor with STARTFILE

3. Replace these dummies with your own descriptions by selecting the dummies and entering or copying your text in the file.

4. The **Elements** pane on the right-hand side contains additional elements for the description (e.g. *Truth table*, *Block diagram*, *Example*, etc.), which you can drag to the desired position on your file using drag-and-drop and edit there.

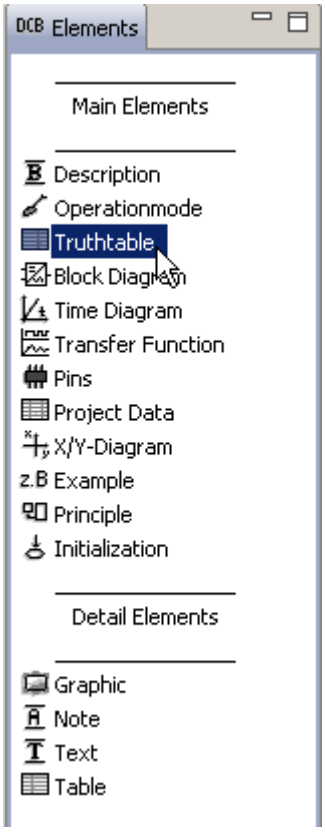

Figure 7-615 Elements for the description

5. Insert your own graphics by dragging the *Graphic* element to a suitable position in the file using drag-and-drop. In the following dialog box, enter the path under which the graphic is stored (use the **Browse** button).

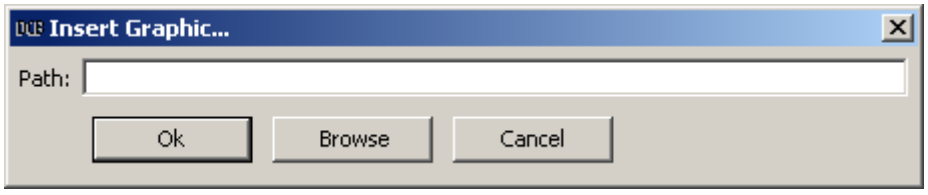

Figure 7-616 Inserting a graphic

6. Save the edited file with the button or via the **File > Save as...** menu in the storage structure described above.

Creating further online help files

You can open existing files via the **File > Open** menu.

You can create a new block description via **File > New**.

Note

Detailed operating instructions for the **DCB help editor** can be found in the menu under **Help > Help contents**.

Installation and uninstallation of DCB libraries

As of DCC Version 2.0.2, you have the option of installing or uninstalling DCB libraries from SIMOTION SCOUT using a dialog. As of DCC Version 2.1, you can install SINAMICS DCB libraries and SINAMICS DCC libraries in STARTER/SCOUT during operation and then use them in DCC charts without having to exit and restart STARTER/SCOUT.

You start the dialog box via the menu command **Options -> Installation of libraries and technology packages ...**

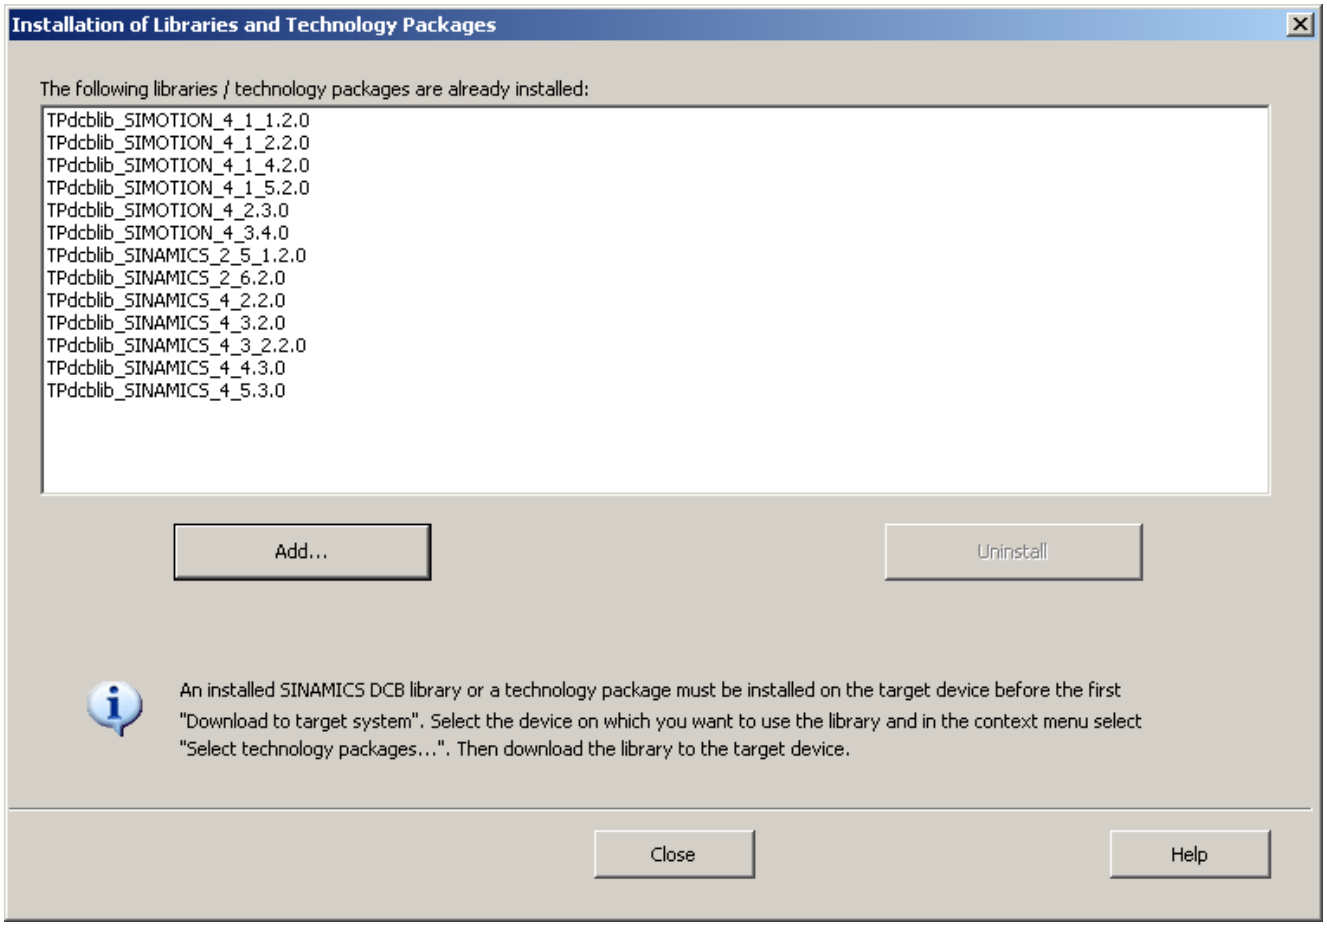

Figure 7-617 Installing and uninstalling DCB libraries - SIMOTION SCOUT

Uninstallation of DCB libraries

Under **Following libraries / technology packages are already installed:** you will see a list of the libraries that have already been installed.

- Select the library to be deleted and select **Uninstall**. The selected library will be uninstalled. A multiple selection is possible. Information on the uninstallation can be found in the detail view.

Installation of DCB libraries

Click the **Add...** button and navigate in the following Open File dialog box to the library to be installed. Select the library and install the selected library by double-clicking or by clicking the **Open** button. A multiple selection is possible. Information on the installation can be found in the detail view.

Exit the **Installation of Libraries and Technology Packages ...** dialog box via the **Close** button.

Note

The libraries are installed independently of the projects in SIMOTION SCOUT/STARTER. The libraries are not transported when projects are archived or exported. If the project is to be loaded on a different SCOUT/STARTER, the libraries used there must be reinstalled. This is also the case after SCOUT/STARTER has been reinstalled.

The DCC standard libraries DCBLIB (supplied from the factory) are preinstalled. If you explicitly require this as an installable library, you can find this library, e.g. "dcblibV2_0_simotion4_1_5.zip" (version-dependent name) after the installation of SCOUT in the"C:\Program Files\Siemens\Step7\U7umc\data\dcc\SIMOTION" directory or, if available, on the DCC DVD under "VOL1\CD_1\DCC\DCC_DCBLIB_SIMOTION\Disk1". You can also, for example, store the standard DCC libraries using the card reader in the USER directory on the CompactFlash card for later service assignments (the version of the standard DCC library may not be available in the engineering tool). This means that if service is required, you can use the CompactFlash card reader and the functions described here to reinstall the relevant libraries.

Note

For SINAMICS libraries as compared with SIMOTION libraries, there is the restriction that DCBLIB standard libraries can only be installed and uninstalled while no project is open.

The libraries are installed independently of the projects in STARTER. The libraries are not transported when projects are archived or exported. If the project is to be loaded on a different STARTER, the DCC libraries used there must be reinstalled. This is also the case after STARTER has been reinstalled.

The DCC standard libraries DCBLIB (supplied from the factory) are preinstalled. If you explicitly require this as an installable library, you can find this library, e.g. "dcblibV2_0_sinamics2_6.zip" (version-dependent name) after the installation of STARTER in the directory "C:\Program Files \Siemens\Step7\U7umc\data\dcc\SINAMICS" or, if available, on the DCC DVD under "VOL1\CD_1\DCC\DCC_DCBLIB_SINAMICS\Disk1". You can also, for example, store the standard DCC libraries using the CompactFlash card reader in the USER directory on the CompactFlash card for later service assignments (the version of the standard DCC library may not be available in the engineering tool). This means that if service is required, you can use the CompactFlash card reader and the functions described here to reinstall the relevant libraries.

See also

Updating the block library (Page 5477)

Exchanging the target device family for DCC libraries

As of SIMOTION SCOUT V4.3 you can exchange DCC libraries between the SINAMICS and SIMOTION target devices. In this way you can use a DCC library available for DCC SIMOTION on a SINAMICS target device or a DCC library available for DCC SINAMICS on a SIMOTION target device.

Note

This function is not available for STARTER.

Proceed as follows to insert DCC libraries in a different target device family:

In the project navigator, select the DCC library to be copied at the appropriate library container and select **Save as DCC SINAMICS library** or **Save as DCC SIMOTION library** in the context menu.

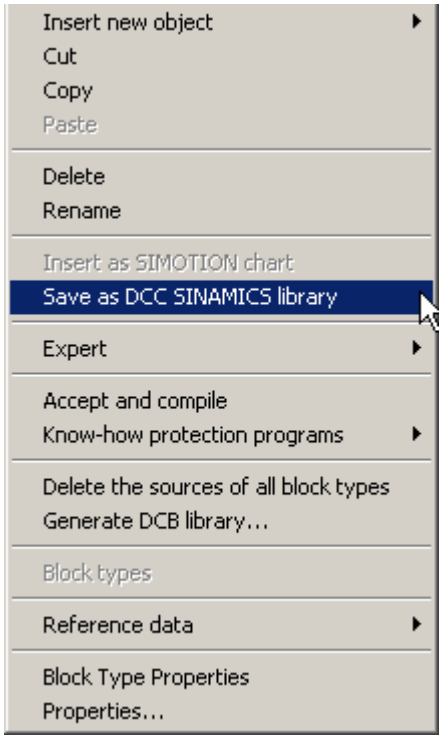

Figure 7-618 Save as DCC SINAMICS library

Proceed as follows to insert DCC library blocks in a DCC library of a different target device family:

In the project navigator, select the DCC chart to be copied on the DCC library at the library container and select **Copy** in the context menu. Switch to the library container for DCC library of the other target device family and insert the DCC chart via the context menu command **Insert as SINAMICS chart** or **Insert as SIMOTION chart**.

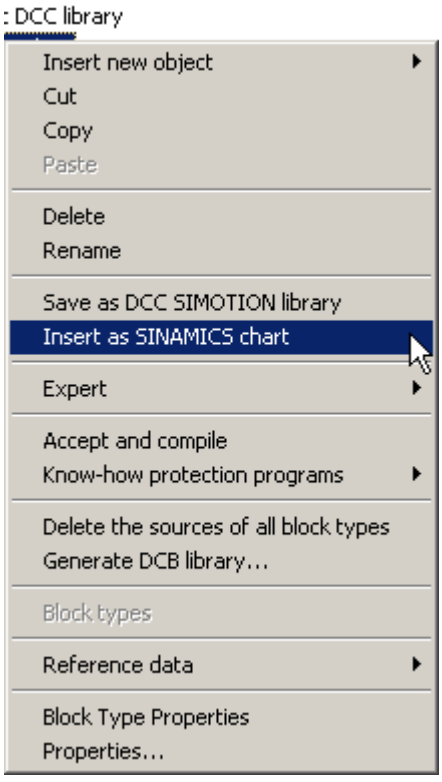

Figure 7-619 Insert as SINAMICS chart

When you insert the chart, the original library/chart name is taken over and an underscore and a number appended to the name. If there is already an underscore and a number appended to the name, the number is incremented.

The execution groups are changed automatically when saving under a different target device family.

Note

If chart sources of the DCC libraries are not available, no DCC editor is installed or there is no license for the DCC editor, you cannot insert DCC libraries into a different target device family. The **Save as** context menu command is then not available.

If block types from the library are not available on the target device, an error is output during compilation of the library. In this case, you must either delete or modify the block instances.

7.4.3.12 Know-how Protection

Know-how protection for libraries and programs

The SIMOTION SCOUT/STARTER engineering system provides know-how protection functions for your data. This enables you to prevent unauthorized access to your programs/parameters in the drive unit. There are two different types of know-how protection:

- Know-how protection for programs (ST source files, MCC charts, LAD/FBD programs and DCC charts) and libraries
- Know-how protection for drive units (as of SINAMICS V4.5)

Know-how protection for programs

The know-how protection installed in SIMOTION SCOUT protects the programs (ST source files, MCC charts, LAD/FBD programs and DCC charts) and libraries in your project.

In the project navigator, the protected programs contained in the project are displayed grayed-out. You can only open these programs for editing after you have entered the password. The know-how protection is retained after copy/paste and also after export/import.

Know-how protection for programs - setting-up/deleting a standard login

If you have not yet set up a standard login for the know-how protection, open the **Edit Standard Login** dialog box via the menu **Project -> Know-how protection for programs -> Edit standard login...** and enter a standard login there. Assign a password, confirm this and close the dialog box with the **OK** button.

⚠ WARNING

Danger to life through manipulation of DCC charts and DCC libraries

The use of unprotected DCC charts and libraries entails a higher risk of manipulation of DCC charts, DCC libraries and backup files.

- Protect important DCC charts and DCC libaries by using **know-how protection programs** or via the **know-how protection for drive units** in the SCOUT/STARTER. You can prevent manipulation by assigning a strong password.
- For **know-how protection programs**, use passwords which include at least eight characters, upper and lower cases, numbers and special characters.
- Make sure that only authorized personnel can access the passwords.

You can delete the standard login in this dialog box. A password is not required for this.

Configuring know-how protection for programs

Call the **Configure Know-how Protection for Programs...** dialog box via the menu **Project -> Know-how protection for programs** and select the desired coding type for programs and libraries.

Note

The dialog box is only available in SIMOTION SCOUT.

Standard (libraries and programs)

This level corresponds to the old security standard. Access to the programs is protected by a login and password. Programs and libraries can be recompiled at any time without knowing the password. This level is completely downward compatible, i.e. you can edit the project in an older version of SIMOTION SCOUT by saving the project in the old project format or by exporting and importing the project again.

Note

Only the standard coding can be used for DCC sources and libraries.

Medium (libraries and programs)

The coding of the password has been improved. Programs and libraries can be recompiled at any time without knowing the password. However, because of the changed coding, downward compatibility is no longer possible without knowing the password. If, for example, the program is exported and imported into an older SIMOTION SCOUT version or uploaded to a SIMOTION SCOUT project of an older version, the source text can no longer be displayed there.

High (for ST source files only)

In this level, (re)compilation is only possible after input of the password. However, libraries protected with this level can of course also be used after an export without knowledge of the password, because in this case the compilation result is also exported. Exports and imports are only possible in the same or higher SIMOTION SCOUT versions.

Note

The various levels of the know-how protection only apply to the new programs to be protected. You may have to delete, reconfigure and activate the know-how protection for already protected programs.

Activating know-how protection for programs

1. Open the project and select the PROGRAMS folder or the individual program in the project navigator.
2. Select the entry **Know-how protection for programs > Set** in the context menu.

Deleting know-how protection for programs

1. Select the PROGRAMS folder or the individual program in the project navigator.
2. Select the entry **Know-how protection for programs > Delete** in the context menu.
3. Enter the password in the following **Know-how Manager** dialog box and close the dialog with the **OK** button.

See also

Know-how protection for drive unit (Page 5502)

Know-how protection for drive unit

As of SINAMICS V4.5, know-how protection is available for drive units in STARTER / SIMOTION SCOUT. You can only activate/deactivate the know-how protection in online mode. When the know-how protection is set, p parameters can be neither read nor written. If certain parameters are to be excluded from the know-how protection, enter them in the expert list under parameter p7764 before you set the know-how protection.

Know-how protection for drive units - default setting

The know-how protection may already have been activated for drive units as soon as you have inserted a drive unit. In this case, consult the documentation for the drive unit.

If you want to change the pre-assigned password for the know-how protection, you must first deactivate the know-how protection via the context menu **Deactivate know-how protection**.

To do this, select the option **Definitive (password will be deleted)** in the **Deactivate know-how protection for drive unit** dialog box.

Enter the default password and close the dialog box with the **OK** button.

Activating know-how protection for a drive unit

When you activate know-how protection for the drive unit, a dialog for entering a password always appears. You can activate the SINAMICS know-how protection for drive units either with or without copy protection**.**

The **Know-how protection without copy protection** option is active by default.

You can select the following copy protection options for devices as of firmware V4.7:

- Basic copy protection (linked to the memory card)
- Extended copy protection (linked to the memory card and the Control Unit)

Only the **With copy protection** option is available for devices up to firmware V4.6; this corresponds to the extended copy protection.

If no know-how protection for the drive unit has been activated, but a password has already been defined (temporarily deactivated know-how protection for the drive unit), you can reactivate know-how protection for the drive unit with the previous password. You can, however, also change the password.

Define password

To define the password, you need to enter and confirm the new password. If you make a mistake, a message appears to inform you that the passwords entered do not match. If this happens, you need to reenter the passwords. Passwords are subject to the following rules:

- Min. length: 1 character, max. length: 30 characters.
- All read and write characters are permitted, see Opening a project under every set Windows language setting (language-neutral).
- It is the personal responsibility of the user to ensure adequate password security.

⚠ WARNING

Danger to life through manipulation of DCC charts and DCC libraries

The use of unprotected DCC charts and libraries entails a higher risk of manipulation of DCC charts, DCC libraries and backup files.

- Protect important DCC charts and DCC libaries by using **know-how protection programs** or via the **know-how protection for drive units** in the SCOUT/STARTER. You can prevent manipulation by assigning a strong password.
- For **the know-how protection of drive units**, use passwords which include at least eight characters, upper and lower cases, numbers and special characters.
- Make sure that only authorized personnel can access the passwords.

Opening a project with any language setting under Windows (language-neutral)

If you want to edit your projects in different Windows systems with different language settings, you should only use characters from the ASCII character set to ensure problem-free working with know-how protection. As a general rule, a project must first be enabled for this purpose in the SIMATIC Manager, but independently of the know-how protection. To do this, open the project in the SIMATIC Manager. Then go to the Edit menu and select the following option under Object properties: Can be opened with any Windows language setting (language-neutral).

Note

If you want to process your projects on Windows systems with different language settings, then you must define this in the project settings. Navigate via the menu **Project -> Properties** to the **Properties - Project** dialog box and activate the **Can be opened under every Windows language setting (language-neutral)** checkbox. Only use ASCII characters for the password of the know-how protection for drive units.

Diagnostics functions

If, despite active know-how protection, you still require the trace, measuring function or the function generator, select the **Permit diagnostic functions** option. You may have to activate the required parameters first in the exception list.

Note

Diagnostic functions possible as of V4.7

Diagnostic functions that work despite active know-how protection are available as of V4.7.

Deactivating know-how protection for a drive unit

To deactivate the feature, you must enter the correct password. The know-how protection for the drive unit can be:

- **temporarily** deactivated: The know-how protection is active again after switching off and switching on.
- **permanently** deactivated: The know-how protection remains deactivated even after switching off and switching on again.

If you select "Permanently", you can also carry out a data backup on the Control Unit with **Copy RAM to ROM**. The checkbox with the same name is active in this case and is automatically activated. If you deactivate this checkbox, you must perform a manual **RAM to ROM** data backup later if the know-how protection remains deactivated after switching off and on.

Absolute know-how protection for the drive unit

Absolute know-how protection that cannot be deactivated is created by deleting parameter p7766 from the exception list and then activating the know-how protection. Create a backup copy of your project before you activate absolute know-how protection.

Combining know-how protection for drive unit with write protection for drive units

You can combine the **Know-how protection for drive unit** with **Write protection for drive units**. Note that you must first set the **Know-how protection for drive unit** and then the **Write protection for drive units**.

If you have combined the **Know-how protection for drive unit** with the **Write protection for drive units**, the parameters of the exception list can only be read. The **Write protection for drive unit** does not apply for parameters with the WRITE_NO_LOCK attribute. These parameters can be written at any time. With combined write and know-how protection, the drive unit behaves similar to absolute know-how protection for drive unit, since a password can no longer be entered due to the write protection.

Functions available for activated know-how protection for drive units

When know-how protection for the drive unit is activated, the following functions remain available:

- Go online
- Restore factory settings
- Get information about the firmware version
- Read out errors (drive status, warnings, faults), alarms, the diagnostics buffer, and the alarm history
- Acknowledge errors/alarms
- Control panel functions
- Display created acceptance documentation
- Upload (restricted scope)

When know-how protection for the drive unit is activated, the following functions are not available:

- Download
- Export/import
- Trace
- Function generator
- Measuring functions
- Automatic controller setting
- Stationary/rotating measurement
- Delete alarm history
- Create acceptance documentation

The following functions are optional:

- Trace
- Function generator
- Measuring functions

These functions can only be executed if the diagnostic functions are permitted when the know-how protection is activated.

Behavior for devices with know-how protection for the drive unit

- Know-how protection always applies to the device, not to individual DOs.
- The content of the project navigator remains unchanged.
- All r parameters can still be read.
- p parameters can be neither read nor written with the following exceptions:
  - Parameters with the KHP_ACTIVE_READ or WRITE_NO_LOCK attribute
  - Parameters from the exception list

- Instead of a complete expert list, only a reduced expert list is displayed. This contains all the r parameters as well as the p parameters that have been enabled by attributes or the exception list. The behavior also applies to functions of the expert list, user-defined lists of values, and watch tables.
- An expert list comparison can be performed, the values of the know-how-protected parameters are displayed as **know-how protected**.
- No wizards are available.
- It is not permissible to delete this device in its entirety or to delete individual components from it.
- It is not permissible to rename the device.
- It is not possible to call dialogs containing functions that are not supported by know-how protection for the drive unit. An error message is displayed.
- Where windows contain functions that are not supported by the know-how protection for the drive unit, they do not show any active contents (with the exception of the expert list and version overview); instead, they indicate that know-how protection for the drive unit is activated.
- Scripts which need read or write access to protected parameters/functions, cannot grant appropriate access and are rejected.

Know-how protection for libraries and programs (Page 5500)

Write protection for drive unit (Page 5510)

Setting know-how protection for a DCC chart

Setting the know-how protection function for a DCC chart

A DCC chart can be protected as follows:

1. Select the chart in the SIMOTION SCOUT/STARTER.
2. In the context menu of the DCC chart, execute the **Know-how protection -> Set** function in offline mode.

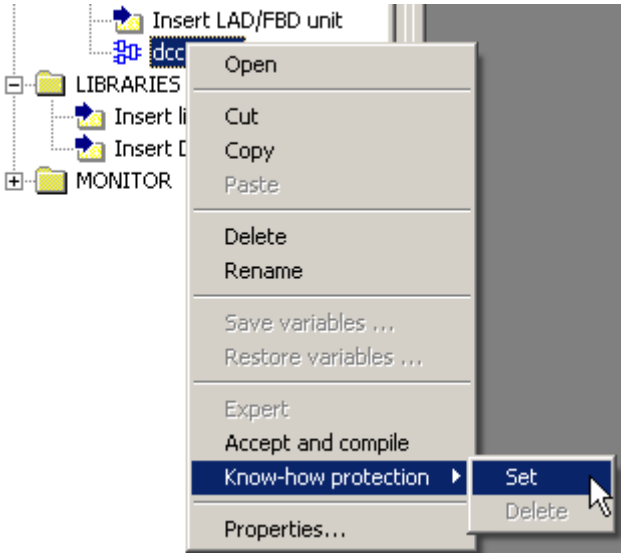

Figure 7-620 Setting know-how protection for a DCC chart

3. When using the know-how protection function for the first time, you will be prompted to enter the required access data (login and password) for protection of the chart in the **Know-How Manager** window. Close the **Know-How Manager** window via the **OK** button.

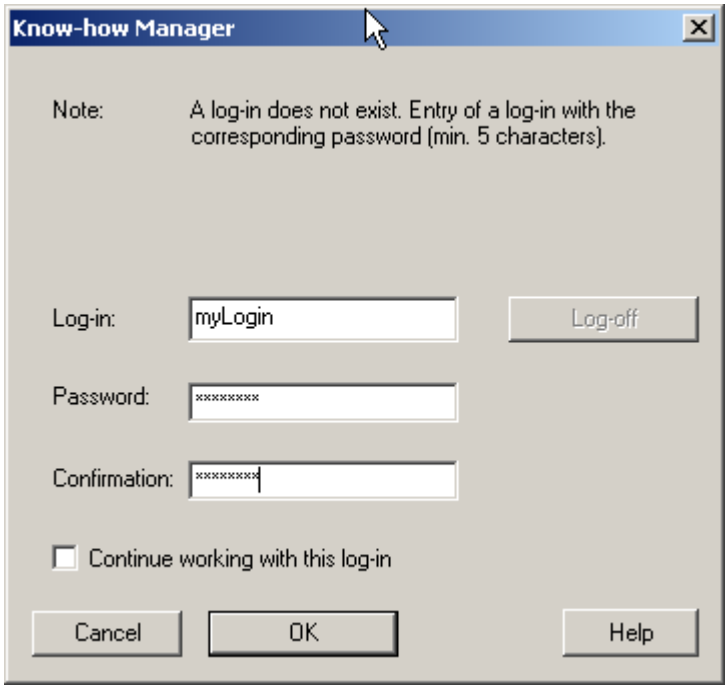

Figure 7-621 Know-how manager

The DCC chart is now shown grayed out.

You can also define a general login with password in the **Project -> Know-how protection** menu item, which then is used automatically for setting the know-how protection on the selected chart. Although you are then automatically logged in with this login, you can at anytime log off from the **Project -> Know-how protection** menu item.

Activating the know-how protection function

To activate the know-how protection, you must log off the logged-in user in the **Know-How Manager** window (access to the **Know-How-Manager** is via **Project -> Know-how protection** in the menu). The protected DCCs of the opened project are then locked and cannot be opened. Only by entering the password can you remove the lock and open the DCC charts.

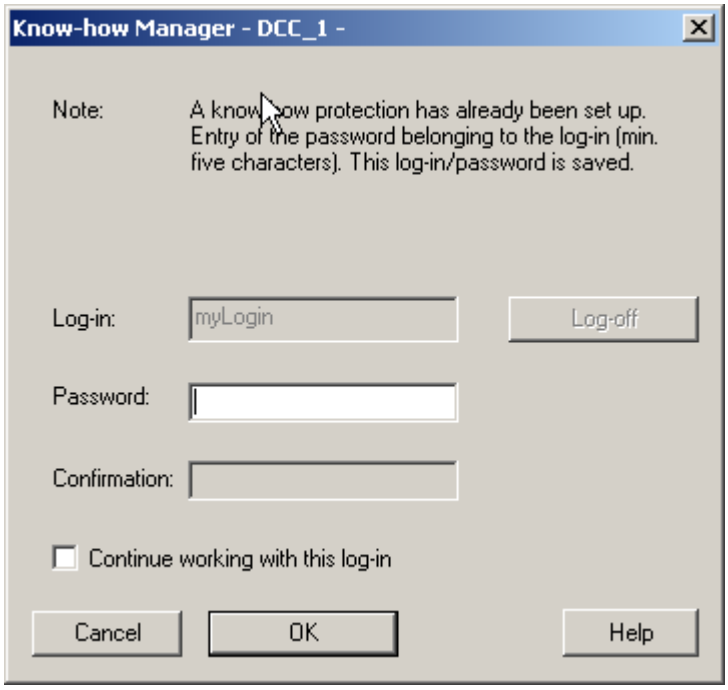

Figure 7-622 Know-how manager

Note

When DCC charts are protected, the execution sequence cannot be protected in the execution system. Although the chart can be moved, it cannot be edited. Note that if the execution sequence of a protected DCC chart is changed, the functionality can no longer be guaranteed or may fail.

Deleting the know-how protection function

To delete the know-how protection, you must first be logged in (if you are not already logged in, you are automatically prompted to do this during the procedure described below).

You can delete the know-how protection of a chart as follows:

1. Select the chart in the SIMOTION SCOUT/STARTER.
2. In the context menu of the DCC chart, execute **Know-how protection -> Delete**.
3. Close the **Know-How Manager** window via the **OK** button after entering the password.

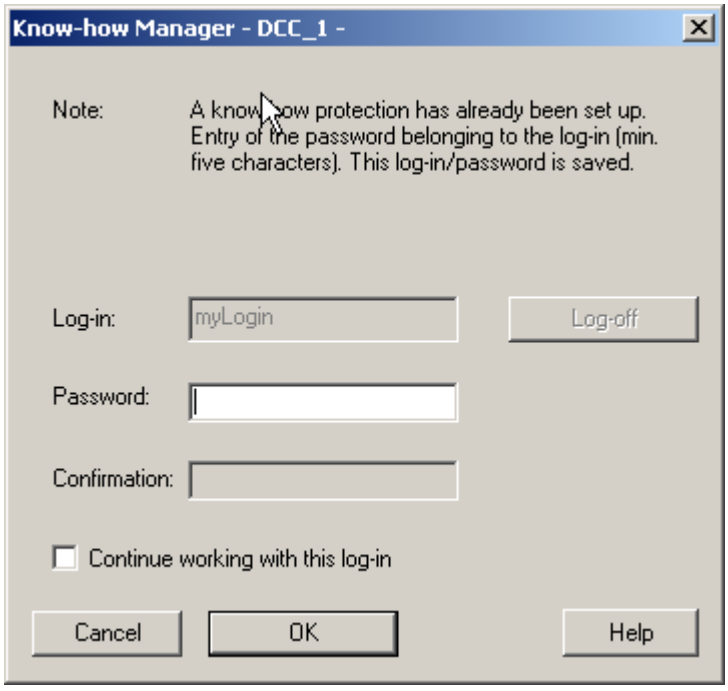

Figure 7-623 Know-how manager

Note

The know-how protection is not automatically reactivated in SIMOTION SCOUT/STARTER when you close the DCC chart.

Canceling the know-how protection

If you want to open a know-how-protected DCC chart, you can do this by double-clicking as usual. If you are already logged in, the know-how protection is automatically canceled, if you are not logged in, you are automatically prompted to do so when opening.

7.4.3.13 Write protection for drive unit

As of SINAMICS V4.5, write protection for drive units is available. You can only activate/deactivate this write protection in online mode.

Activate/deactivate the write protection via the context menu **Write protection for drive unit** of the drive unit or via parameter *p7761* of the expert list. A password is not required to activate/

deactivate the write protection. You can query the status of the write protection via parameter*r7760.0* in the expert list (value = 0 means that the write protection is not set).

When write protection is activated, the following functions can be used in offline mode:

- Inserting, editing, deleting DCC libraries
- Inserting, editing, deleting DCC charts
- Inserting, editing, deleting DCC blocks

Note

When write protection is activated for a SINAMICS target device, however, a download to the target device is not possible. This prevents any changes made offline in DCC charts taking effect in the target device.

The following functions cannot be used when write protection is activated:

- Editing a DCC chart in test mode
- Inserting or deleting blocks online
- Inserting, moving or deleting connections
- Compiling a DCC chart
- Saving and recompiling all
- Downloading the project

With active write protection, compilation of the DCC chart on the DO is rejected both from the workbench as well as from the DCC editor with the following error message:
"Write protection is currently active on the drive unit. The DCC chart cannot be compiled."

Write access to DCC parameters is rejected with the following error message:
"Value was rejected.
Parameter xxx could not be set to this value. The old value will take effect again."

Note

If you want to activate the write protection permanently, execute the **Copy RAM to ROM** function.

See also

Know-how protection for drive unit (Page 5502)

Know-how protection for libraries and programs (Page 5500)

7.4.3.14 Startup behavior

With regard to the startup behavior, note that the respective initialization value is active at the block connections during startup and then the calculated value in each following cycle.

For more detailed information on the start-up behavior, please see Chapter Characteristics of block connections (Page 5438).

7.4.3.15 Software upgrade and module exchange

SCOUT or STARTER projects that contain DCC charts and are compiled with V4.1.1 or V4.1.2 can be opened and loaded with SCOUT/STARTER V4.1.3, even without a DCC license.
This applies regardless of whether or not the DCC chart sources (i.e. original project) are available.

Note

This specification applies as long as the device version does not change. Following a replacement with a new device version, the DCB library versions present on the new device must be imported and the DCC chart recompiled. The corresponding DCC license (CFC for SIMOTION/ SINAMICS) is required for this.

Until DCC 2.1, the library version had to be updated manually after the upgrade of a device version.

As of DCC 2.1 / SCOUT/STARTER V4.2, the library version is upgraded automatically.

Saving and restoring retain variables - SIMOTION only

DCB block instances may contain retain variables.

Select **Save variables...** from the context menu of the DCC chart to save the contents of these variables to a file. The values can then be restored from this file. DCC retain data is retained when the platform is changed or the version is upgraded.

7.4.3.16 Version information

Proceed as follows to display the version information:

1. Left-click the *Help -> Info...* menu item in STARTER/SCOUT
2. Click the *System information...* button in the following *Information* dialog

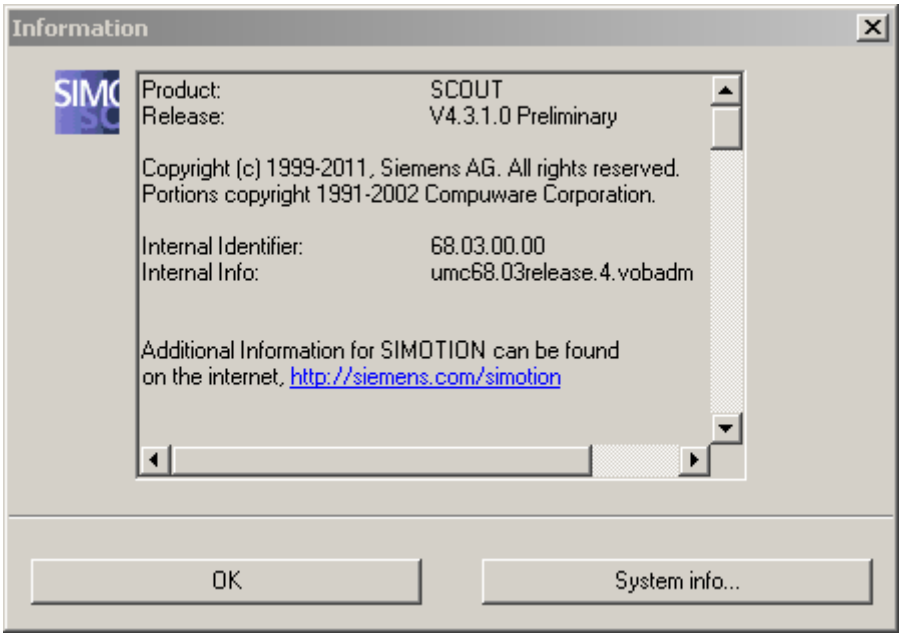

Figure 7-624 Version information - Information

3. The *System Information* dialog with the system information appears.

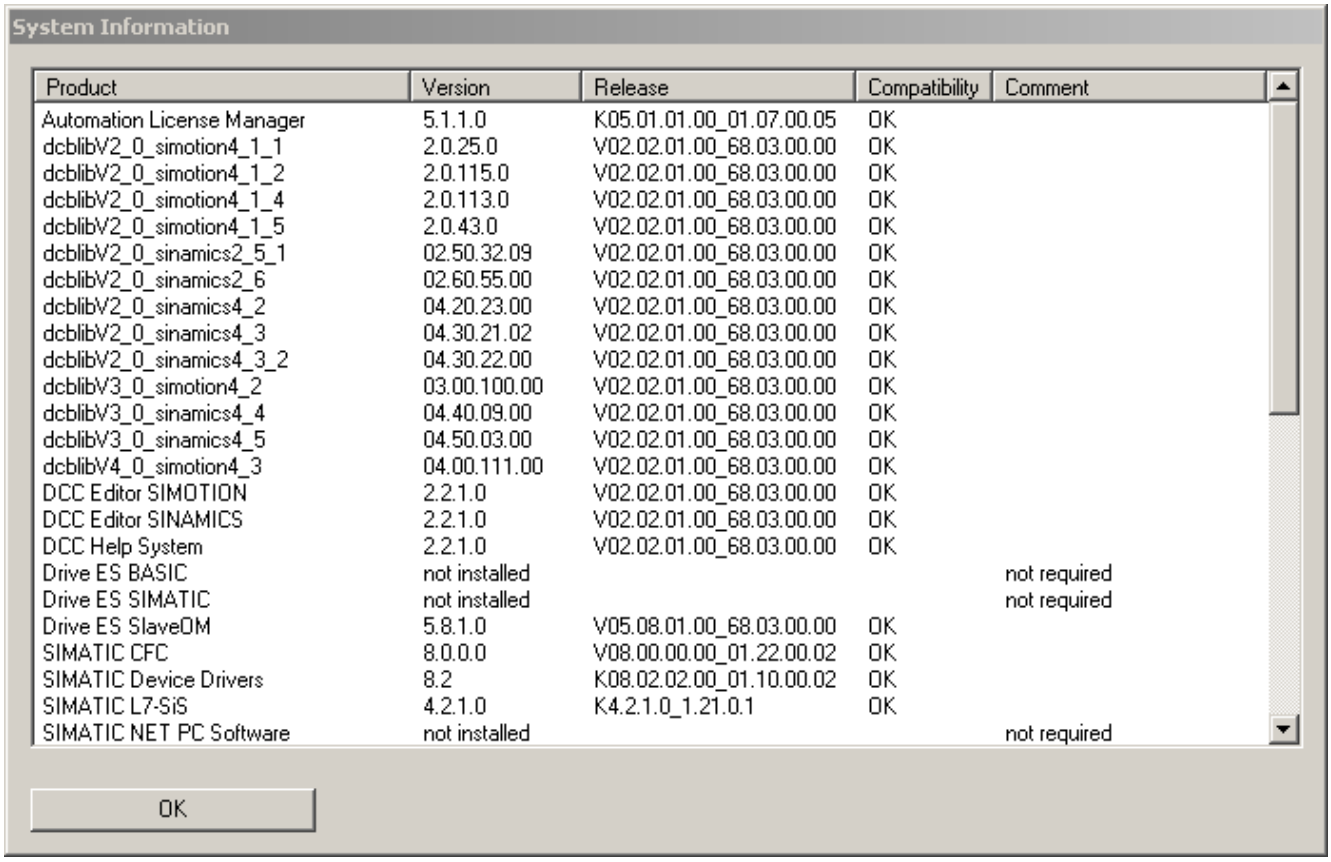

Figure 7-625 Version information - System information

7.4.3.17 XML export/import of DCC charts

During the project export, the CFC charts with the STEP7 data storage are exported in binary format.

From DCC Version 2.1, DCC charts can be individually exported in XML format and imported again during XML import.

This means that you can transfer a DCC chart to another project (from a project with SINAMICS 2.6 devices to a project with SINAMICS 4.x devices, for example).

The following restrictions apply to the XML export/import of DCC charts:

- DCC charts that have been exported from SIMOTION devices cannot be imported into SINAMICS devices, and vice versa
- DCC blocks that have been exported from SIMOTION DCC libraries cannot be imported into SINAMICS DCC libraries, and vice versa.

The table below outlines the compatibility of XML exports/imports in relation to the relevant SCOUT/STARTER version.

Compatibility	
Project	Projects exported with SCOUT/STARTER V4.1 can be imported with V4.2 without any loss of information. After opening the project, the user is asked to convert the CFC charts to CFC 7.1.
	Projects exported with SCOUT/STARTER V4.2 can be imported with V4.1 without any loss of information. However, it is not possible to edit DCC charts with CFC 7.0. In the case of projects that were created with V4.2 and imported using an older version of SCOUT/STARTER, a warning appears when the import process is carried out.
Device	Devices exported with SCOUT/STARTER V4.1 can be imported with V4.2 without any loss of information. If block types that were not available in V4.1 are used in a V4.2 project, the devices can be imported without any loss of information. Errors are reported when compilation is carried out, however.
	Devices exported with SCOUT/STARTER V4.2 can be imported with V4.1. The DCC chart sources are lost when they are imported with V4.1. No errors or warnings are output.
Drive object (DO)	Drive objects exported with SCOUT/STARTER V4.1 can be imported with V4.2. These do not contain any DCC charts.
	Drive objects exported with V4.2 can be imported with V4.1. The DCC chart sources are not imported.
	If a DCC chart is exported on a DO type A and imported on a DO type B, the adaptation process for the sheet bar interconnection is the same as copying/pasting DCC charts. When pasting on the new DO, the old execution group is also transferred. During compilation, the execution group that applies to the new DO is entered automatically.
CFC version	DCC charts that were created with an older CFC version can be imported with a newer CFC version. Downward compatibility is also supported.
	The export/import of projects and chart containers only supports upward compatibility. A chart created using CFC 7.1 can no longer be opened with CFC 7.0.

The following requirement applies to the XML export/import of DCC charts:

- The CFC editor must be installed

XML export/import of DCC charts is possible at the following levels:

- Project
- Device
- DO (drive object, CUxx, TBxx, TMxx)
- DCC chart
- DCC library

The assigned DCC charts are included in the XML export/import of the selected object.

Note

If a CFC editor is not installed, only the DCC charts (i.e. without chart sources) are exported/ imported. No error message is output.

No DCC license is required for exporting/importing DCC charts.

XML export at project level

In SCOUT/STARTER, select **Project -> Save and export...** from the menu or **Expert -> Save and export project** from the context menu, and in the **Export Project** dialog that appears, use the **Browse...** button to specify the target directory for the export or enter this directly in the text field.

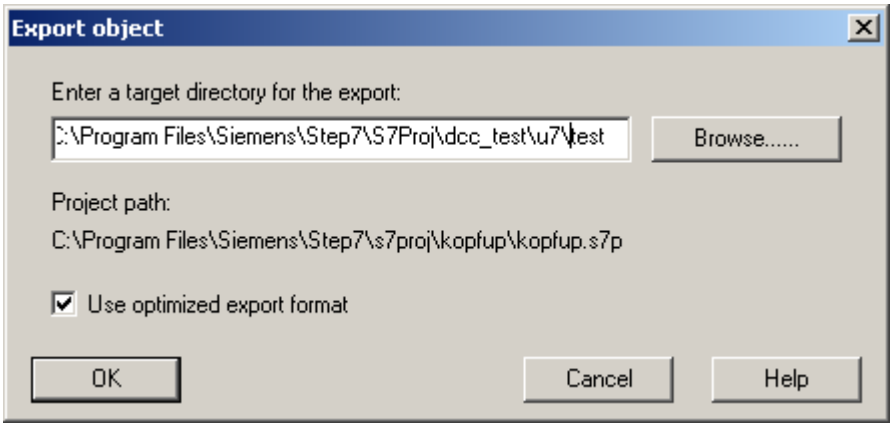

Figure 7-626 Project XML export

Click **OK** to start the export. You can track the progress of the export on the **XML export/import status display** tab.

If the target directory already exists, you will see the following dialog:

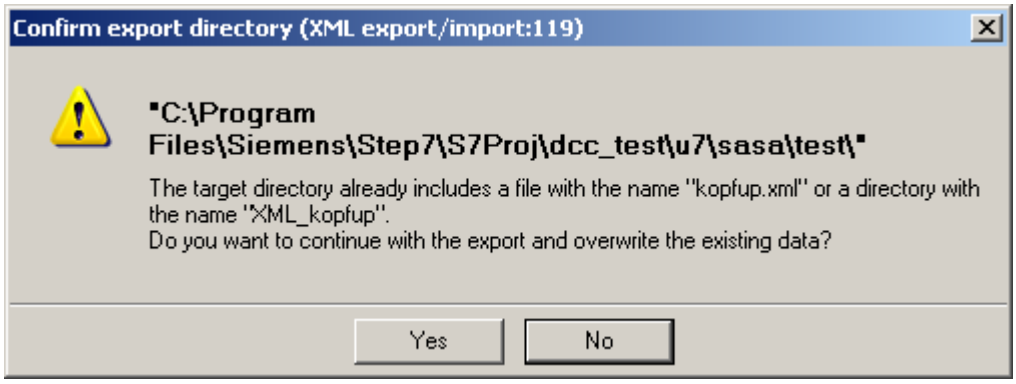

Figure 7-627 XML export - Error message

Choose **Yes** to overwrite the data in the target directory or **No** to cancel the export.

XML export at DCC chart level

Select the DCC chart you wish to export in the project navigator, then select **Expert -> Save project and export object** from the context menu in SCOUT/STARTER. In the following **Export object** dialog, use the **Browse...** button to specify the target directory for the export or enter this directly in the text field.

Click **OK** to start the export. You can track the progress of the export on the **XML export/import status display** tab.

Note

DCC charts that were exported from SCOUT/STARTER cannot be imported into the SIMATIC Manager.

XML import

DCC charts and DCC libraries can be individually exported from SCOUT/STARTER and reimported into a SCOUT/STARTER project. They have the same layout after the import as they did before the export. No information is lost from the DCC chart, i.e. the subcharts, library information, sheet bar interconnections, execution groups, alias definitions, p21000 settings, and know-how protection are all retained during an XML export/import. Know-how protection can be revoked after the import, making it possible to edit the charts again.

You also have the option of importing a previously exported DCC chart into an existing chart.

When importing DCC charts, a distinction is made between importing a DCC chart and importing into an existing DCC chart:

- Container in project navigator -> Expert -> Import object
- DCC chart -> Export/import object

For an XML import, proceed as follows:

In the project navigator, select the object into which you wish to import, and then select **Expert -> Import object** from the context menu in SCOUT/STARTER.

In the dialog that appears next (**Import object**), use the **Browse...** button to specify the source directory for the import or enter this directly in the text field.

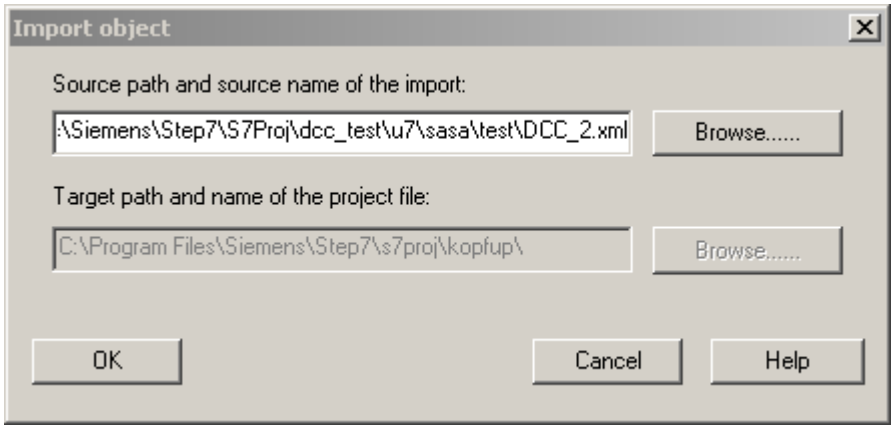

Figure 7-628 XML import

Click **OK** to close the dialog.

In the **Import object** dialog shown below, use the **OK** button to start the import or the **Cancel** button to cancel the import.

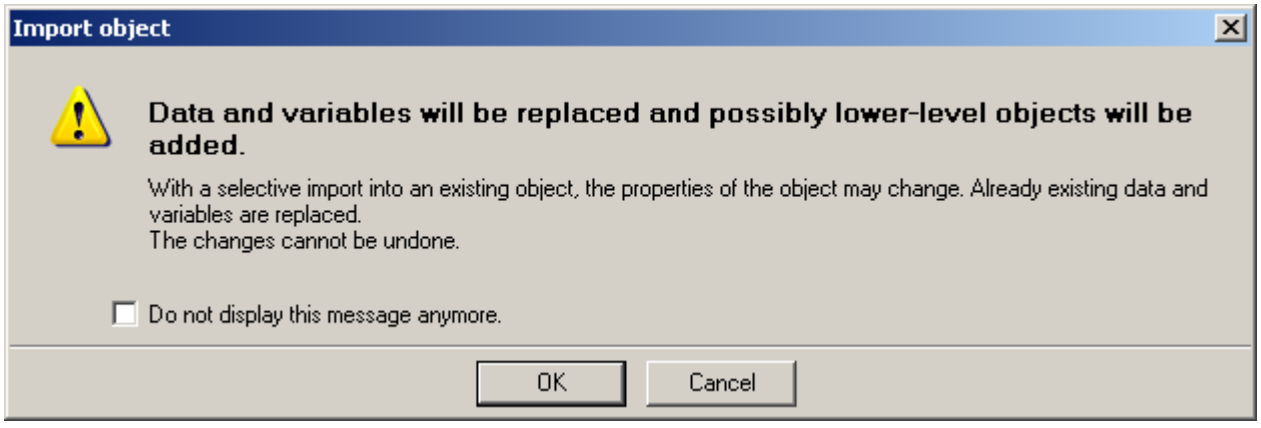

Figure 7-629 XML import warning

You can track the progress of the import on the **XML export/import status display** tab.

Note

It is possible to export/import DCC charts even if the chart in the current project has not been compiled or cannot be compiled without errors.

If the DCC chart has not been compiled so that it is up to date before the export/import, then the imported DCC chart will be empty or will not be up to date.

Even in this case, DCC charts can still be imported without any information being lost, provided that the libraries used in the chart are not yet installed or were imported on the program container. Reinstall the SIMOTION libraries by selecting **Options -> Install libraries...**, or by selecting **Select technology packages...** from the context menu in the case of SINAMICS.

The XML export/import can be carried out for DCC charts with existing DCC chart sources or for DCC charts without DCC chart sources. Please observe the following:

- During the import of DCC charts with DCC chart sources, the set values of the expert list are overwritten with the set values and BICO parameters from the DCC project.
- During the import of DCC charts without DCC chart sources, the adjustable parameters and BICO parameters (@ parameters) are not overwritten.

If the DCC chart sources are not available in a project because the DCC charts were obtained as a result of an upload from the target device or copying without a DCC license, or the DCC chart sources were explicitly deleted, the DCC chart is exported and imported without chart sources. The DCC chart that is created in this way can be loaded and compiled. You can select **Block types** from the context menu to exchange the version of the subordinate basic DCB libraries.

See also

Exchanging the basic library version for installed libraries (Page 5479)

7.4.3.18 XML export/import of DCC libraries

DCC libraries can be exported/imported in their entirety. Alternatively, it is possible to perform an XML export of individual DCC blocks from the DCC library and an XML import into a DCC library.

Data that is specific to the library (description of block connections, comments, block family, etc.) is exported/imported along with it.

Before the library sources are deleted, a check is performed to determine whether the libraries have been compiled so that they are up to date. As of SCOUT/STARTER 4.2, DCC chart sources are always exported/imported too if they are available on the library sources.

7.4.3.19 Reading back DCC chart sources from the target device

In DCC 2.0, DCC charts can be read back from the target device and loaded to another target device of the same type. To enable the DCC charts to be edited further, the DCC chart sources must be present in the original project.

As of DCC 2.1, DCC charts for which no up-to-date DCC chart sources or no DCC chart sources at all are present can be uploaded from the target device and read back to the DCC editor.

Chart sources for DCC libraries (typicals) are downloaded/uploaded via the library context menu. They are uploaded as part of the project uploading process.

Procedure

Under **Options -> Settings** in SCOUT, select the **Download** tab and activate the **Include DCC chart data** checkbox below the **Store additional data on the target device** checkbox to load the DCC chart sources to the target device.

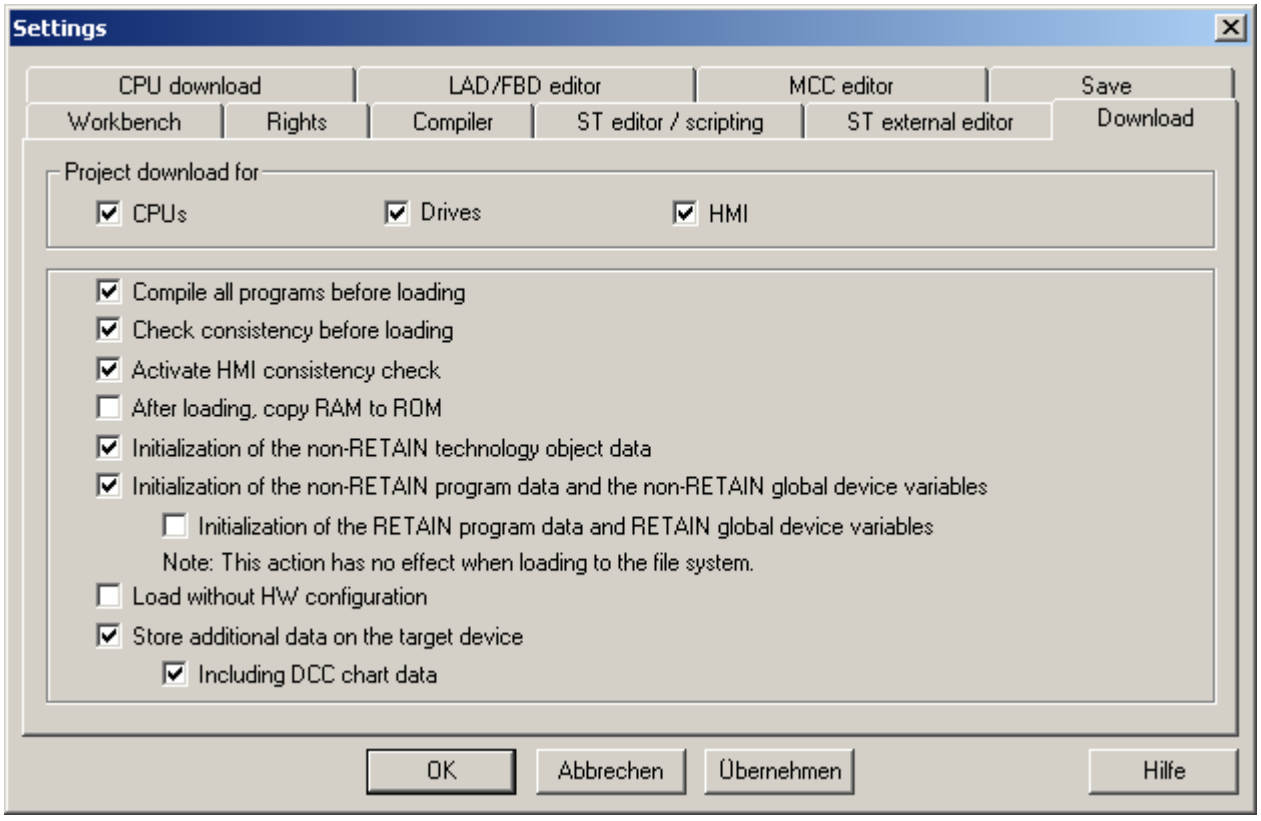

Figure 7-630 Storing additional data and sources on the target device - SCOUT

In STARTER, under **Options -> Settings,** select the **Download** tab and activate the **Store additional data on the target device** checkbox to download the DCC chart sources to the target device.

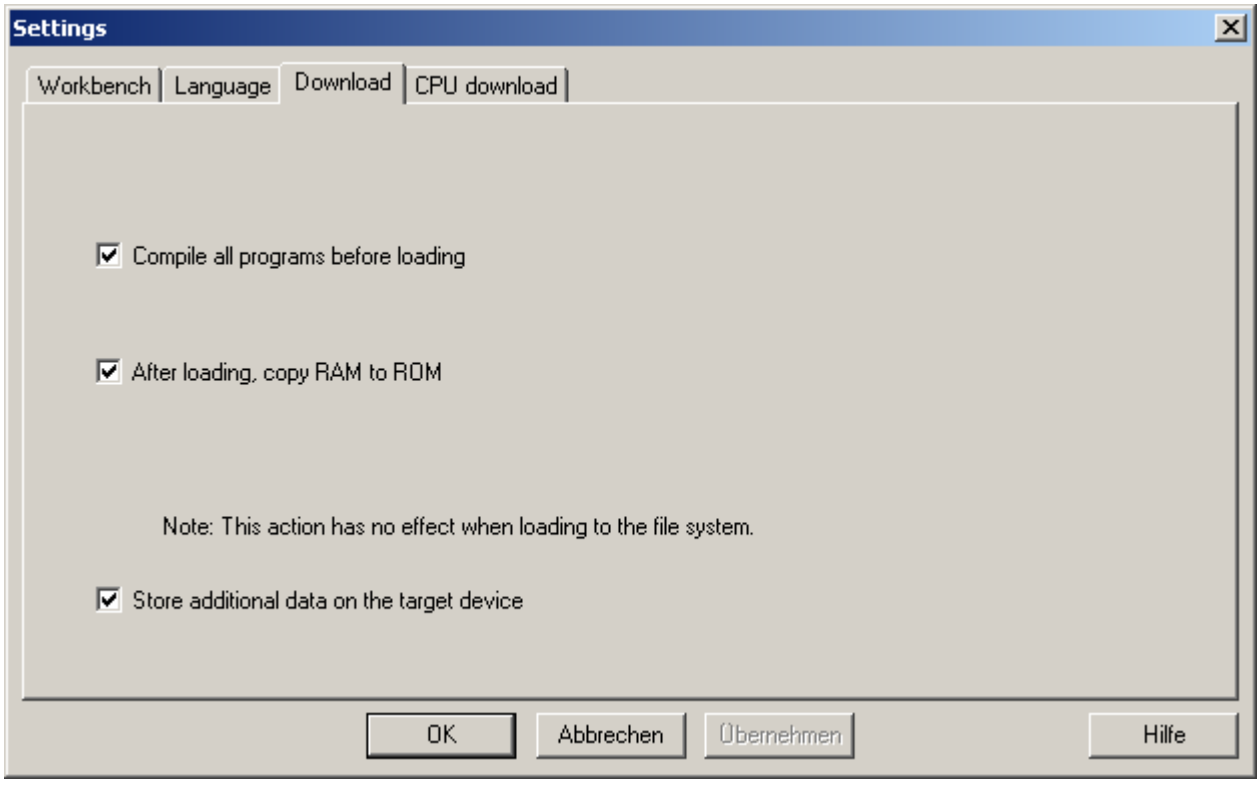

Figure 7-631 Storing additional data and sources on the target device - STARTER

During the CPU download, you can also select whether the DCC chart sources are to be downloaded to the target device for the CPU.

The default setting for the CPU-specific option is taken from **Options -> Settings -> Download**. The option selected for the CPU is then saved as the default setting for the next download.

Once you change the option under **Options -> Settings -> Download,** this is regarded as the default setting for all CPUs.

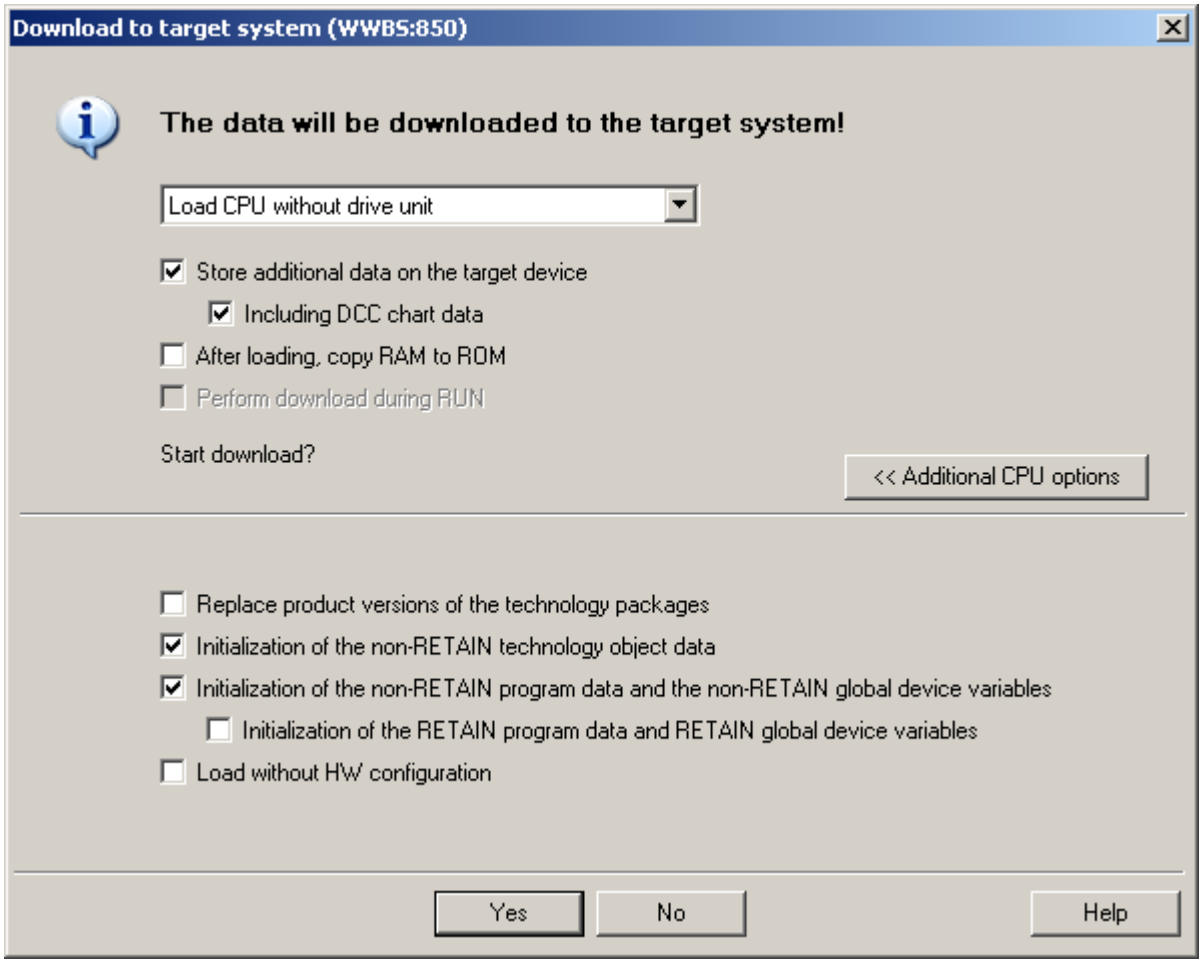

Figure 7-632 Downloading to the target device - SCOUT

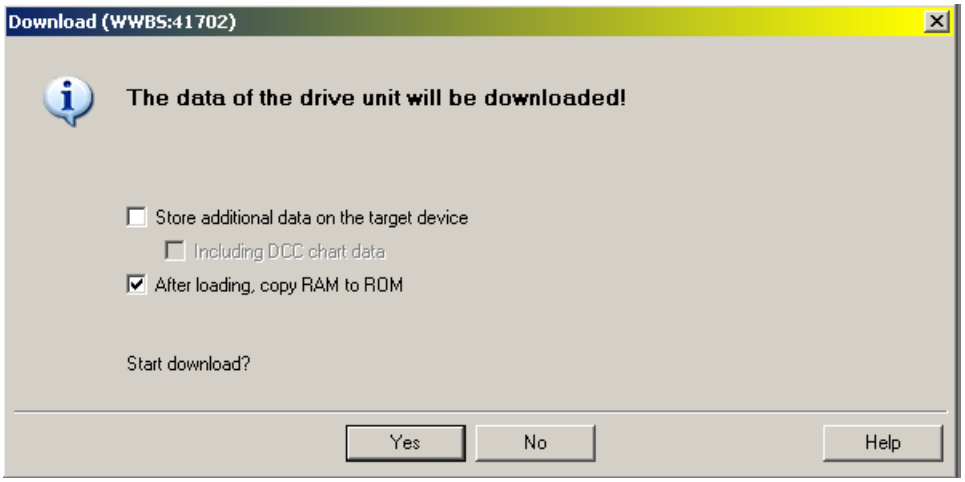

Figure 7-633 Downloading to the target device - STARTER

If you deactivate the **Store additional data on the target device** option, the chart sources in the target device are deleted during the next download.

If you activate the **Store additional data on the target device** option, the chart sources of the DCC libraries are downloaded to the target device, which are used in the DCC charts of the CU or CPU.

If DCC charts are available on the target device, the project is saved following upload.

When downloading to the PG, you must explicitly select whether the library sources from the target device will be loaded into the offline project. In this way, you can keep different library versions in different devices.

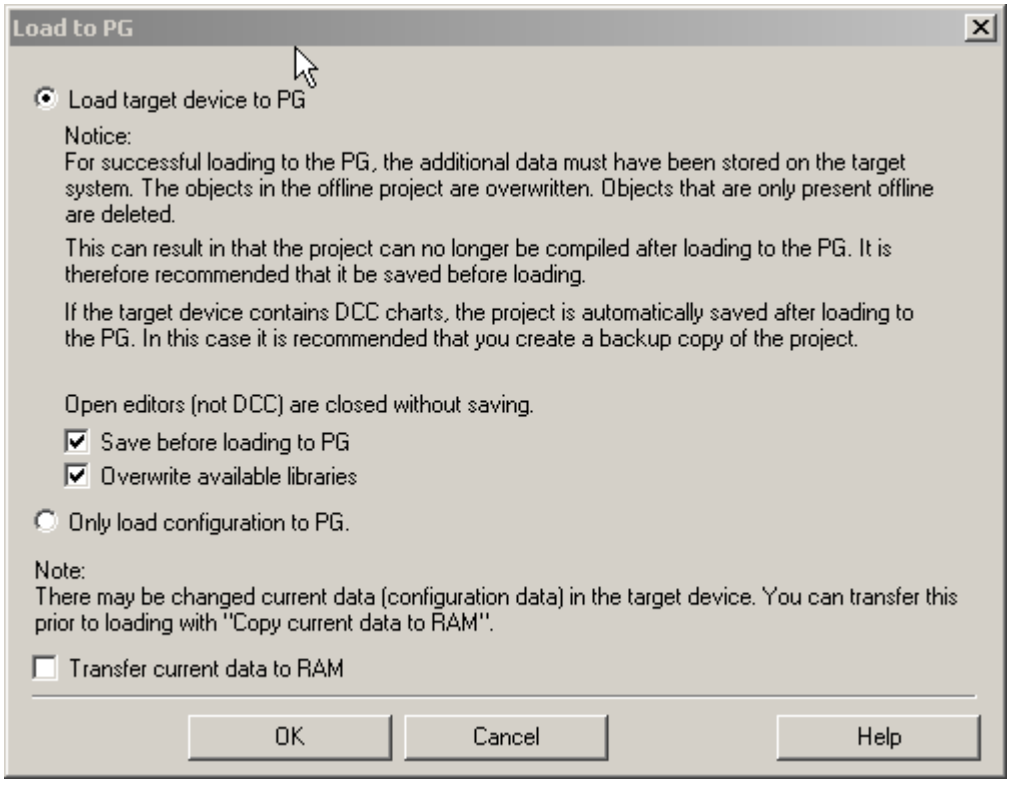

Figure 7-634 Downloading target device to PG - SCOUT

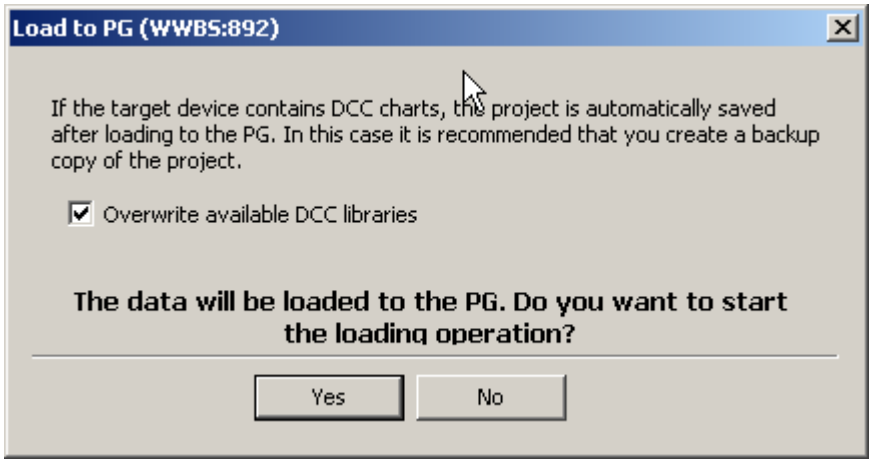

Figure 7-635 Downloading target device to PG - STARTER

Note

In the project comparison, DCC charts are displayed differently following read-back (incl. DCC chart sources), as the DCC chart sources are recreated and therefore have a different time stamp.

Conditions

- If the DCC chart is not open, the chart source will be updated automatically when the project is read back.
- If DCC charts are open in the editor during the project upload, the chart sources will not be updated automatically in the editor. In editor mode, the chart that has been read back can be updated from the CFC using function key **F5**.
- The chart must not be in test mode while it is being read back.
- If the chart sources are not present in SCOUT/STARTER, the DCC chart sources will be created automatically after the project has been uploaded.
- During the project upload, DCC charts with the same name that are already present in the engineering system will be overwritten.
- If the chart names are the same, DCC sources with know-how protection overwrite existing chart sources during the upload to the engineering system.
- DCC libraries are restored when the DCC chart sources are read back.
- The layout of the charts after the read-back process is the same as when they were edited: The positions of the block instances are restored and comments are available in the same position as they were before.
- The libraries used in the charts must be installed in SIMOTION SCOUT/STARTER so that the upload of DCC charts is performed without errors.

The process of reading back DCC charts is independent of the SIMOTION firmware version.

For SINAMICS, it is possible as of SINAMICS V4.4.

The additional data for the read-back process must have been loaded to the target device. Additional data for DCC charts can be created and loaded as of DCC 2.1.

When charts with know-how protection are read back, the know-how protection for the DCC charts is restored in the engineering system.

Changes that have been made online in DCC test mode are taken into account when DCC chart sources are read back.

The following restriction applies if you do not have a DCC license / the CFC has not been installed:

- DCC charts can be uploaded and loaded back onto the target device, but they can no longer be edited - even if the CFC is installed or a DCC license is made available after this.

Note

Up to STARTER/SCOUT V4.1.5, the process of reading back BICOs/parameters for DCC SINAMICS had to be explicitly initiated from the editor after the project had been read back from the target device.

With STARTER/SCOUT V4.2, however, the BICOs/parameters are automatically read back when the project is read back into the DCC chart.

7.4.4 DCC for SINAMICS

7.4.4.1 Overview

Introduction

This product brief is intended for first-time users who are not yet familiar with the DCC program package. Using a short example, you will find out how to create a new DCC, interconnect DCBs (drive control blocks; function blocks), compile the chart, download it to the target device and test it.

Note

In most cases, there are a number of options for working with the DCC editor (e.g. using the keyboard). In this example, one option is used. Apart from a few exceptions, no alternative methods of operation are explored here.

Note

The documentation on SINAMICS refers to versions STARTER 4.4, DCC 2.3 and SINAMICS Firmware 4.7.

Software requirements

The software requirements for DCC are the same as those for SINAMICS STARTER.

You will additionally need:

- **DCC SINAMICS** software option package

Note

The DCC SINAMICS option package contains on a USB stick the Step7 CFC license required for the DCC editor. The installation is made using the Step7 Automation License Manager (refer to the help of the Step7 Automation License Manager). The Step7 Automation License Manager program is installed automatically together with STARTER.

When the product is supplied, the DCC technology option is not yet available on the drive unit. The DCC technology option must be loaded onto the drive unit's CF card in a separate operation using SIMOTION SCOUT or STARTER. Afterwards, the SINAMICS CU3x0, SINAMICS DC MASTER or the SIMOTION D4xx must be switched off and then on again. Only then can the DCCs be downloaded and run on the drive objects.

From SINAMICS 4.3, the dcblib for S120 is already present on the card. For single drive units, POWER ON after the download of the dcblib is no longer necessary.

There is only ever one DCC on a drive object. DCC can be activated simultaneously on several drive objects on a drive unit. DCC is not available on SINAMICS S110 drive units (CU305 module).

SINAMICS system integration

Applications and features

Application

A logic operation, which connects several states (e.g. access control, plant status) to a control signal (e.g. ON command), is required for controlling the drive system in a wide variety of applications.

As well as logic operations, a number of arithmetical operations / storing elements are increasingly becoming a requirement in drive systems.

Note

This additional functionality increases the computing time load. This means that the maximum possible configuration for a Control Unit is restricted.

Drive Control Chart (DCC) functionality is available for every drive object of the drive unit listed in the following table.

Table 7-613 Drive object types for DCC SINAMICS

Drive object type	Object number (r0107)	Meaning
CU_S	1	Control Unit SINAMICS S (SINAMICS S120/ S150)
CU_G	2	Control Unit SINAMICS G (SINAMICS G130/ G150)
CU_I	3	Control Unit SINAMICS Integrated
CU_CX32	4	Controller Extension for boosting the computing performance
CU_GM	5	Control Unit SINAMICS GM
CU_DC	6	SINAMICS DC MASTER Control Unit
CU_GL	7	Control Unit SINAMICS GL
CU_SL	101	Control Unit SINAMICS SL
A_INF	10	Active Infeed control
SERVO	11	Servo control
VECTOR	12	Vector control
VECTORMV	13	Vector control for SINAMICS GM
VECTORGL	14	Vector control for SINAMICS GL
VECTORSL	16	Vector control for SINAMICS SL
DC_CTRL	17	Closed-loop control for DC drives
S_INF	20	Smart Infeed control
B_INF	30	Basic Infeed control
A_INFMV	40	Active Infeed control for SINAMICS SM150
B_INFMV	41	Basic Infeed control for SINAMICS GM150
TB30	100	Terminal Board 30
TM31	200	Terminal Module 31
TM41	201	Terminal Module 41
TM15DI/DO	204	Terminal Module 15 (for SINAMICS)
TM120	207	Temperature evaluation with safe electrical isolation
DO encoder	300	Drive object encoder
HLA	70	Hydraulic Linear Axis
RIC	21	Renewable Infeed Control

Execution groups in the DCC editor

Description

Exactly one DCC chart can be created per drive object (DO = drive object). This DCC chart can contain up to ten execution groups.

Execution groups in the DCC editor

Execution groups are groups of blocks. The blocks of an execution group are started in a defined sequence at a specified time and are calculated cyclically one after the other within a specified sampling time.

In the DCC editor a maximum of ten execution groups (execution group 1 to 10) can be defined per drive object (DO) and thereby per basic chart (see also: SINAMICS system integration > Execution sequence, creating new execution groups). In the project navigator of STARTER / SCOUT (context menu of the chart, menu command **Set execution groups ...**) fixed or free execution groups of the drive object can be assigned to the previously defined execution groups.

Note

The **Interconnection with execution group**... command is only supported with DCC SIMOTION.

⚠ WARNING

Changing the assignment of an execution group

If the assignment of an execution group is changed in the **Set Execution Groups** window (or in parameter p21000[]), the affected execution group is initially logged off during time slice management and then logged on once again with the new assignment. The execution group is not calculated during the period between logging off and logging back on. The log-on and log-off take place in a background process of the drive unit; the duration is therefore not defined and is determined by the current CPU time load of the drive unit. (This affects the path of the output signal in the case of time-dependent blocks, e.g. the DIF differentiator.) Prior to the first calculation cycle after logging back on, internal status variables of the blocks are partially reset. For both of these reasons, this can result in jumps in the output signal of blocks, which for example can affect the torque/force setpoint and (in the case of operated axes) also the torque/actual force value. Logic signals can also acquire an unexpected state at this point of operation.

If the change to the execution group also results in a change to the sampling time, internal constants or factors are automatically adjusted for time-dependent blocks (BF, DCA, DIF, DT1, INT, MFP, PCL, PDE, PDF, PIC, PST, PT1, RGE, RGJ, WBG). If you use these blocks in the following execution groups, you must assign parameter p2048 the value of the isochronous master cycle clock:

- Receive AFTER IF1 PROFIdrive PZD
- Send BEFORE IF1 PROFIdrive PZD
- Receive AFTER IF1 PROFIdrive flexible PZD
- Receive AFTER IF2 PZD
- Send BEFORE IF2 PZD
- Receive AFTER IF2 flexible PZD

Note that the execution groups created in the chart are only visible in the **Set Execution Groups** window after the chart has been compiled.

Parameter r21002 displays the basic sampling time hardware.

Parameter r21003 displays the basic sampling time software.

For more detailed information on these parameters, see the online help for DCC parameters or the "DCC blocks" Function Manual.

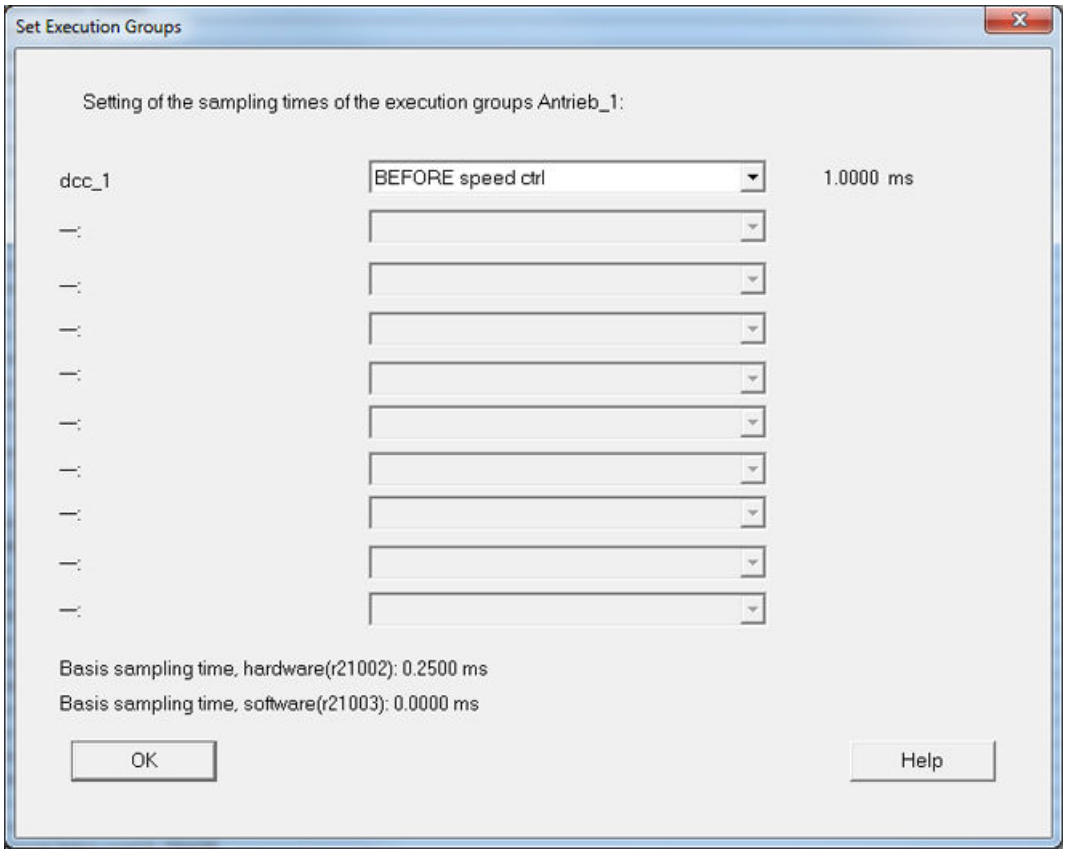

Figure 7-636 **Set Execution Groups** window

The execution groups created in the DCC editor must be assigned to the "Fixed execution groups" and the "Free execution groups" of the SINAMICS drive object.

Note

For parameter p21000 (Properties execution group) and, therefore, in the context menu of the "Set sampling times" chart, write access for the enabled controller is blocked in at least one drive axis or infeed. The old value automatically takes effect again in this case. If necessary, switch off all drive axes and infeeds, and make a new attempt.

Fixed execution groups

Fixed execution groups

A "fixed execution group" is called at a fixed position in the system execution using the sampling time of the corresponding system function.

The following fixed execution groups are available for SINAMICS as of FW Version 2.5:

- **Read in AFTER digital inputs**
  This execution group is called after the current values of the digital inputs have been read in on this drive object type and the corresponding binector outputs have been written.
  The sampling time of this execution group corresponds to the sampling time of the CU inputs/outputs (p0799) or the digital inputs/outputs of the TB30, TM31 and TM41 (p4099[0]).
- **Output BEFORE digital outputs**
  This execution group is called before the digital outputs are output on this drive object type.
  The sampling time of this execution group corresponds to the sampling time of the CU inputs/outputs (p0799) or the inputs/outputs of the TB30, TM31 and TM41 (p4099[0]).
- **Read in AFTER analog inputs**
  This execution group is called after the current values of the analog inputs have been read in on this drive object type and the corresponding binector outputs have been written.
  The sampling time of this execution group corresponds to the sampling time of the inputs/outputs of the TB30, TM31 and TM41 (p4099[1]).
- **Output BEFORE analog outputs**
  This execution group is called before writing is performed on the analog outputs.
  The sampling time of this execution group corresponds to the sampling time of the inputs/outputs of the TB30, TM31 and TM41 (p4099[1]).
- **BEFORE speed controller**
  This execution group is called before the speed controller additional setpoint values "n_reg n_set1" (p1155) and "n_reg n_set2" (p1160) are read into FP3080. The sampling time of the speed controller (p0115[1]) produces the call, but a minimum sampling time of 1 ms is required.
- **BEFORE speed setpoint channel**
  This execution group is called before function block diagrams 3010, 3020, 3030, 3040 and subsequent charts are calculated, if the setpoint channel has been activated (p0108.8 = 1). If no setpoint channel has been configured (p0108.8 = 0), calculation takes place before function block diagram 3095. The setpoint channel sampling time produces the call (p0115[3]).
- **BEFORE position controller**
  This execution group is called after the actual position value preparation (function block diagram 4010) has been calculated and before the position controller (function block diagrams 4015, 4020 and 4025) is calculated. The sampling time of this execution group corresponds to the sampling time of the position controller (p0115[4]).
- **BEFORE actual position value**
  This execution group is called before the actual position value preparation (function block diagram 4010) and the position controller (function block diagrams 4015, 4020, and 4025) are calculated. The sampling time of this execution group corresponds to the sampling time of the position controller (p0115[4]). (Available as of V4.3).
- **BEFORE basic positioner**
  This execution group is called before the basic positioner function module (function block diagrams 3610 to 3650) is calculated. The sampling time of this execution group corresponds to the sampling time of the basic positioner function module (p0115[5]).

- **BEFORE standard technology controller**
  This execution group is called before the technology controller function module is calculated (p0108.16 = 1) (function block diagrams 7950, 7954 and 7958). The sampling time of this execution group corresponds to the sampling time of the technology controller (p0115[6]).

- **Receive AFTER IF1 PROFIdrive PZD** [1)]
  This execution group is called after cyclic process data has been received via communication interface IF1 (e.g. via the integrated PROFIBUS interface) and output to connector outputs r2050[..], r2060[..], binector outputs r2090 - r2093 and connector binector transformers r2094 and r2095.
  The sampling time of this execution group corresponds to the PROFIdrive PZD sampling time.
  As of SINAMICS FW Version 2.5, communication interface IF1 (Interface 1) is always used by the PROFIBUS interface inside the CU or, if a CBE20 has been inserted in the option slot, PROFINET.
  Parameter p0092 can be used to set whether the utilization calculation (r9976) evaluates the execution group for isochronous operation (p0092 = 1) or non-isochronous operation (p0092 = 0) during SINAMICS ramp-up.
  Non-isochronous operation (r2043.1 = 0):
  For SINAMICS **software versions V2.5 and V2.6**, the PROFIBUS data is sent and received immediately after each other at the start of the IF1 PROFIdrive PZD sampling time.
  At the start of the IF1 PROFIdrive PZD sampling time set in p2048, the PROFIBUS data is sent first and then the process data received. In the case of non-isochronous cyclic communication at the IF1 communication interface, the execution group is cyclically calculated with the sampling time of the IF1 communication interface (p2048), i.e. after writing the connector outputs for the process data (PZD) r2050[..], r2060[..], r2090 - r2093 and after calculating the connector binector transformer r2094 and r2095.
  As of SINAMICS **software version V4.3**, the PROFIBUS data is received and sent at two separate times. The process data is received at the start of the IF1 PROFIdrive PZD sampling time set in p2048. In the case of non-isochronous cyclic communication at the IF1 communication interface, the execution group is cyclically calculated with the sampling time of the IF1 communication interface (p2048) after receiving the data, i.e. after writing the connector outputs for the process data (PZD) r2050[..], r2060[..], r2090 - r2093 and after calculating the connector binector transformer r2094 and r2095.
  For calculating the utilization of system r9976 correctly, p092 must be = 0 (== factory setting) in non-isochronous operation.
  Isochronous operation (r2043.1 = 1):
  In isochronous operation, the times at which the data is received from the master (T_o), the data is sent to the master (T_i) and the DP cycle time (T_{DP}) [3)] are configured in the master.
  Internally, the calls to T_o and T_i are realized using a state machine that is called cyclically with sampling time T_{Zu}, e.g. for standard servo drive objects with the current controller sampling time of 125 µs. The sampling time T_{Zu} = 125 µs, however, is at least as large as the largest current controller sampling time (e.g. for the vector, 250 µs, 375 µs or 500 µs).
  This means only integer multiples of T_{Zu} >= 125 µs can be set [3)] as times T_i and T_o for the drive.
  $\rightarrow T_i = n_i \bullet T_{Zu}$:

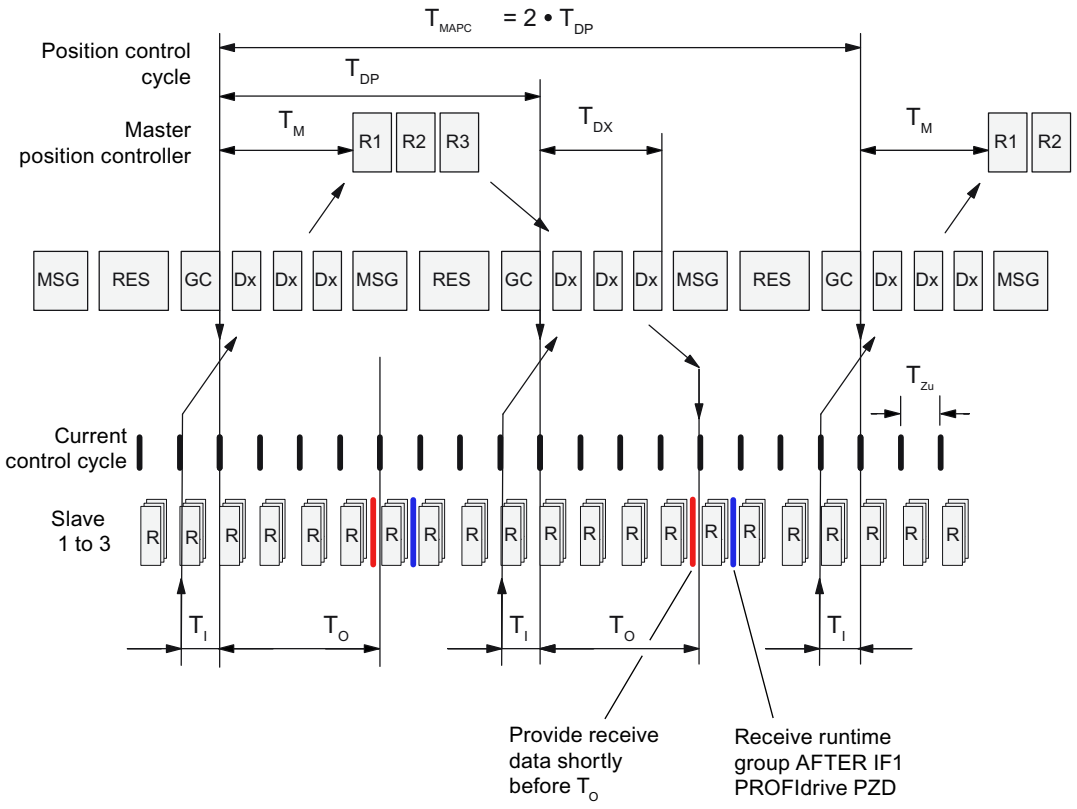

Figure 7-637 Calling the "Receive AFTER IF1 PROFIdrive PZD" or "Receive AFTER IF2 PROFIdrive PZD" execution group for isochronous PROFIBUS communication. See also [3)].

Receive data (sent by the master) is always processed and made available at the end of the sampling time (n_o -1) T_{Zu}, so that the received process data remains valid until the start of the next sampling period at the time $T_o = n_o \bullet T_{Zu}$ at r2050[..], r2060[..], r2090 - r2093. Thus, in the last sampling time T_{Zu} before T_o. The "Receive AFTER IF1 PROFIdrive PZD" execution group is then calculated in the following first sampling time T_{Zu} after T_o.

Note

Please take note that two connector-binector converters (function block diagram 2468: p2099, r2094, r2095) are NOT called synchronously in isochronous mode but may be processed within sampling time p2048 at any time depending on the computing time utilization.

The calculation must be completed within the sampling time T_{Zu}; otherwise, warning A01053 "System overload detected" or a time-slice overflow (F01205) will occur. For this reason, only the absolute minimum number of DCBs that are necessary for the required function should be calculated in this execution group.
The computing time available for this execution group decreases the more drive axes are calculated on the CU since the current controllers (and also the speed controller for the servo) of the drive axes are also calculated in the sampling time p0115[0] = T_{Zu} (>=125 µs).
If the utilization calculation is to be executed during ramp-up of the CU for isochronous operation (unfavorable case regarding degree of utilization), p092 = 1 must be set.
Otherwise (p092 = 0) the utilization in r9976 will be updated only after switchover to

isochronous operation. The increased maximum overall utilization in isochronous operation will be displayed only in r9976.
If you want to calculate a larger number of DCBs, please check whether you would not do better to configure this using the "Receive AFTER IF1 PROFIdr. flexible PZD" execution group.

Note

In the case of this execution group, please note that the higher computing time utilization that applies in isochronous operation is not actually taken into account in the utilization calculation until the time of the transition (specified by the PROFIBUS master) to isochronous operation. After the drive device has ramped up, this means the utilization of the complete system initially still lies within the valid range and it is only when the transition is made to isochronous operation that the drive device shuts down with fault F1054 "System limits exceeded".

- **Send BEFORE IF1 PROFIdrive PZD** [1)]
  This execution group is called before cyclic process data is sent via communication interface IF1 (e.g. the integrated PROFIBUS interface), i.e. before calculating the connector binector transformer p2080 – p2084 and reading in the connector inputs p2051[..], p2061[..].
  The sampling time of this execution group corresponds to the PROFIdrive PZD sampling time.
  As of SINAMICS firmware Version 2.5, communication interface IF1 is always used by the PROFIBUS interface inside the CU or, if a CBE20 is inserted in the option slot, PROFINET.
  Parameter p0092 can be used to set whether the utilization calculation (r9976) evaluates the execution group for isochronous operation (p0092 = 1) or non-isochronous operation (p0092 = 0) during SINAMICS ramp-up.
  Non-isochronous operation (r2043.1 = 0):
  For SINAMICS software versions **V2.5** and **V2.6**, the PROFIBUS data is sent and received (in this sequence) immediately after each other at the start of the IF1 PROFIdrive PZD sampling time.
  The "Send BEFORE IF1 PROFIdrive PZD" execution group is processed at the end of the IF1 PROFIdrive PZD sampling time before the data is sent at the start of the next sampling time. After computing the execution group, at the end of the sampling time, the connector binector transformer p2080 – p2084 is still calculated and the connector inputs p2051[..], p2061[..] read in. This means all send data is present completely at the end of the sampling time and will be sent at the start of the next sampling time.
  As of SINAMICS software version **V4.3**, the PROFIBUS data is received and sent at two separate times.
  The "Send BEFORE IF1 PROFIdrive PZD" execution group is processed at the end of the IF1 PROFIdrive PZD sampling time before the complete data is still sent at the end of the sampling time. For the non-isochronous (cyclical) communication at the communications interface IF1, the execution group is calculated cyclically with the sampling time of the interface IF1 (p2048) (before sending the data), i.e. also before calculating the connector binector transformer p2080 – p2084 and reading in the connector inputs p2051[..], p2061[..].
  For calculating the utilization of system r9976 correctly, p092 must be = 0 (== factory setting) in non-isochronous operation.
  Isochronous operation (r2043.1 = 1):
  In isochronous operation, the times at which the data is received from the master (T_o), and sent to the master (T_i) as well as the DP cycle time (T_{DP}) [3)] are configured in the master.
  Internally, the calls to T_o and T_i are realized using a state machine that is called cyclically with sampling time T_{Zu}, e.g. for standard servo drive objects with the current controller sampling time of 125 µs. The sampling time T_{Zu} = 125 µs, however, is at least as large as the largest current controller sampling time (e.g. for the vector 250 µs, 375 µs or 500 µs).
  This means only integer multiples of T_{Zu} >= 125 µs can be set [3)] as times T_i and T_o for the drive.

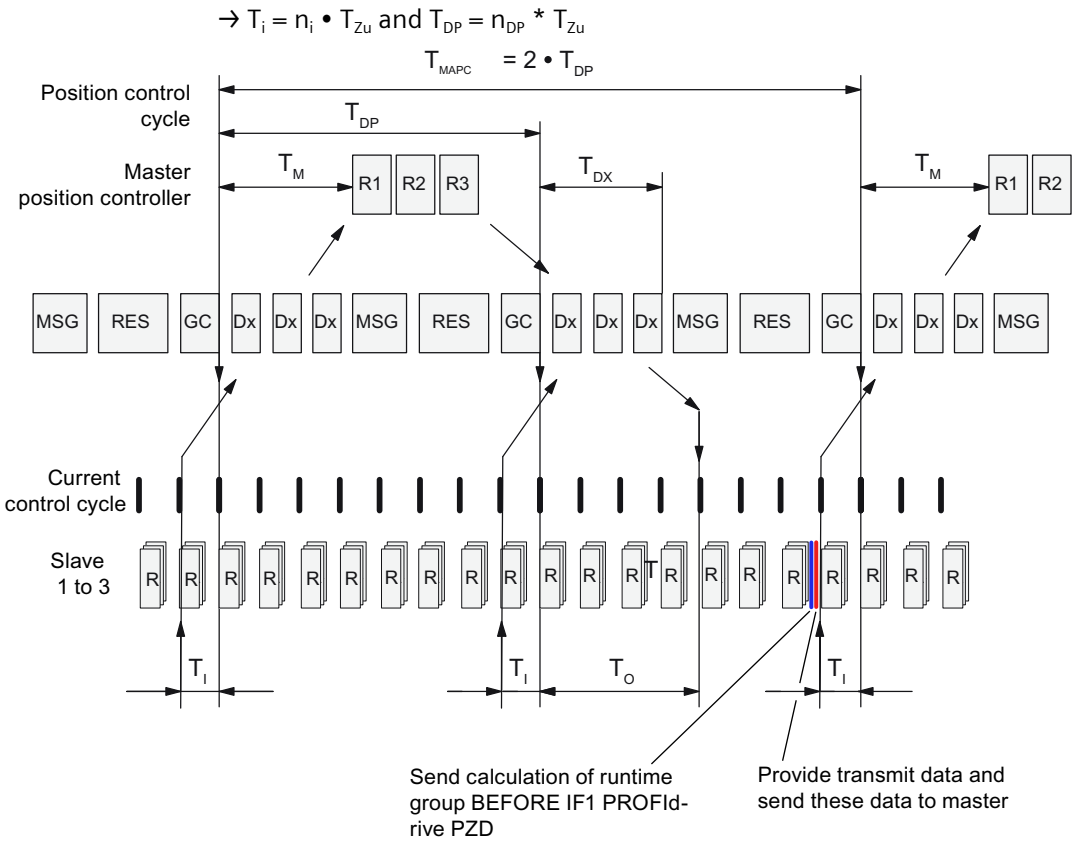

Figure 7-638 Calling the "Send BEFORE IF1 PROFIdrive PZD" or "Send BEFORE IF2 PROFIdrive PZD" execution group for isochronous PROFIBUS communication. See also [3)].

The "Send BEFORE IF1 PROFIdrive PZD" execution group is calculated in the last sampling time T_{Zu} before the data is sent to the master and before T_i and reading in the connector inputs p2051[..], p2061[..].

Note

Please note that five connector-binector converters (function block diagram 2472: p2080 ..., r2089) are also NOT called synchronously in isochronous operation but may be processed within sampling time p2048 at any time depending on the computing time utilization.

The calculation of the execution group must be completed within sampling time T_{Zu}]; otherwise, a fault F1054 "System limit exceeded" (V4.3), a warning A01053 "System overload measured" (V2.x) or a time-slice overflow (F01205) occurs. For this reason, only the absolute minimum number of DCBs that are necessary for the required function should be calculated in this execution group.
The computing time available for this execution group decreases as the number of drive axes calculated on the CU increases, since the current controller (and the speed controllers for the servo) of the drive axes are also calculated in sampling time p0115[0] = T_{Zu}.
If the utilization calculation during the ramp-up of the CU has already executed the isochronous operation (the more unfavorable configuration regarding the utilization of the CU), then p092 must be set to = 1. Otherwise (p092 = 0) the utilization in r9976 will be updated only after switchover to isochronous operation. The increased maximum overall utilization in isochronous operation will be displayed only in r9976.

Note

In the case of this execution group, please note that the higher computing time utilization that applies in isochronous operation is not actually taken into account in the utilization calculation until the time of the transition (specified by the PROFIBUS master) to isochronous operation. After the drive device has ramped up, this means the utilization of the complete system initially still lies within the valid range and it is only when the transition is made to isochronous operation that the drive device shuts down with fault F1054 "System limits exceeded".

- **Receive AFTER IF1 PROFIdr. flexible PZD** [1)]
  This execution group is called after cyclic process data has been received via communication interface IF1 (e.g. via the integrated PROFIBUS interface) and output to connector outputs r2050[..], r2060[..], binector outputs r2090 - r2093 and connector binector transformers r2094 and r2095.
  The sampling time of this execution group corresponds to the PROFIdrive PZD sampling time. The only difference from the Receive AFTER IF1 PROFIdrive PZD execution group is the way in which the execution group behaves in isochronous mode. Even in isochronous mode this execution group is called using the PROFIdrive PZD sampling time configured in the master as with any other sampling time. This means that initially all shorter sampling times are called at time T_o depending on the validity of the receive data (current controller; speed controller if applicable). This execution group is called first only when the T_{DP} sampling time starts to be processed. You basically do not know how often the shorter sampling times with higher priority of the current and speed controller are calculated before this execution group starts to be processed. In addition, processing of this execution group is interrupted due to shorter sampling times.
  This execution group should only be used if IF1 is usually operated in isochronous mode. The benefit of this execution group is that considerably more blocks can be calculated than in the Receive AFTER IF1 PROFIdrive PZD execution group because the calculation does not have to be completed after current controller sampling time p0115[0]. However (due to the higher priority and interruption caused by shorter sampling times), there is no longer a fixed synchronism between T_o and the time the execution group is called.

- **Receive AFTER IF2 PZD** [2)]
  The CAN bus interconnection CBC10, the CBE20, or the integrated PROFIBUS/PROFINET interface (see description p8839, p8815) on the CU can all serve as communications interface IF2. This execution group is available only on the CU_S, CU_G, CU_GM, CU_GL, SERVO, VECTOR, VECTORMV, VECTORSL and VECTOR_GL drive object types.
  Non-isochronous operation (PROFINET, PROFIBUS, or CAN bus):
  The execution group is called once the connectors r8850[..], r8860[..], r8890 - r8893 have been described with the receive data and the calculation of the connector-binector converters (function block diagram 2485.7: r8894 and r8895) has been executed. The sampling time of this execution group corresponds to the IF2 PZD sampling time in p8848.
  Isochronous operation (r2043.1 = 1):
  As of SINAMICS V4.4, isochronous PROFINET/PROFIBUS operation is also supported for the communications interface IF2. (See SINAMICS S120 Function Manual FH1 → Applications → Parallel operation of communications interfaces.)
  In isochronous operation, the times at which the data is received from the master (T_o), the data is sent to the master (T_i) and the DP cycle time (T_{DP}) [3)] are configured in the master. Internally, the calls to T_o and T_i are realized using a state machine that is called cyclically with sampling time T_{Zu}, e.g. for standard servo drive objects with the current controller sampling time of 125 µs. The sampling time T_{Zu} = 125 µs, however, is at least as large as the largest current controller sampling time (e.g. for the vector 250 µs, 375 µs, or 500 µs).
  This means only integer multiples of T_{Zu} >= 125 µs can be set as times T_i and T_o for the drive [3)].
  → $T_i = n_i \bullet T_{Zu}$ and $T_{DP} = n_{DP} * T_{Zu}$ See figure 3-2
  Receive data (sent by the master) is always processed and made available at the end of the sampling time (n_o -1) T_{Zu}, so that the received process data remains valid until the start of the next sampling period at the time $T_o = n_o \bullet T_{Zu}$ at r8850[..], r8860[..], r8890 - r8893 (function block diagram 2485). Thus, in the last sampling time T_{Zu} before T_o. The "Receive AFTER IF2 PZD" execution group is then calculated in the first sampling time T_{Zu} to follow T_o.

Note

Please take note that two connector-binector converters (function block diagram 2485: p8899, r8894, r8895) are NOT called synchronously in isochronous mode but may be processed within sampling time p8848 at any time depending on the computing time utilization.

The calculation must be completed within the sampling time T_{Zu}; otherwise, warning A01053 "System overload detected" or a time-slice overflow (F01205) will occur. For this reason, only the absolute minimum number of DCBs that are necessary for the required function should be calculated in this execution group. The computing time available for this execution group decreases as the number of drive axes calculated on the CU increases, since the current controllers (and also the speed controllers for the servo) of the drive axes are also calculated in the sampling time p0115[0] = T_{Zu} (>=125 µs). If the utilization calculation is to be executed during ramp-up of the CU for isochronous operation (unfavorable case regarding degree of utilization), p092 = 1 must be set. Otherwise (p092 = 0) the utilization in r9976 will be updated only after switchover to isochronous operation. The increased maximum overall utilization in isochronous operation will be displayed only in r9976. If you want to calculate a larger number of DCBs, please check whether you would not do better to configure this using the "Receive AFTER IF2 PROFIdr. flexible PZD" execution group.

Note

In the case of this execution group, please note that the higher computing time utilization that applies in isochronous operation is not actually taken into account in the utilization calculation until the time of the transition (specified by the PROFIBUS master) to isochronous operation. After the drive device has ramped up, this means the utilization of the complete system initially still lies within the valid range and it is only when the transition is made to isochronous operation that the drive device shuts down with fault F1054 "System limits exceeded".

- **Send BEFORE IF2 PZD** [2)]
  The CAN bus interconnection CBC10, the CBE20, or the integrated PROFIBUS/PROFINET interface (see description p8839, p8815) on the CU can all serve as communications interface IF2. This execution group is available only on the CU_S, CU_G, CU_GM, CU_GL, SERVO, VECTOR, VECTORMV, VECTORSL and VECTOR_GL drive object types.
  Non-isochronous operation (PROFINET, PROFIBUS, or CAN bus):
  The execution group is called before the binector connector transformers p8880 – p8884 are calculated and the before connector inputs p8851[..], p8861[..] with the send data are read. The sampling time of this execution group corresponds to the IF2 PZD sampling time in p8848. See function block diagrams 2487 and 2493.
  Isochronous operation (r2043.1 = 1):
  As of SINAMICS V4.4, isochronous PROFINET/PROFIBUS operation is also supported for the communications interface IF2.
  (See SINAMICS S120 Function Manual FH1 → Applications → Parallel operation of communications interfaces.)
  In isochronous operation, the times at which the data is received from the master (T_o), and sent to the master (T_i) as well as the DP cycle time (T_{DP}) [3)] are configured in the master. Internally, the calls to T_o and T_i are realized using a state machine that is called cyclically with sampling time T_{Zu}, e.g. for standard servo drive objects with the current controller sampling time of 125 µs. The sampling time T_{Zu} = 125 µs, however, is at least as large as the largest current controller sampling time (e.g. for the vector 250 µs, 375 µs, or 500 µs).
  This means only integer multiples of T_{Zu} >= 125 µs can be set as times T_i and T_o for the drive [3)].
  → $T_i = n_i \bullet T_{Zu}$ and $T_{DP} = n_{DP} * T_{Zu}$ See also figure 3-3
  The "Send BEFORE IF2 PZD" execution group is calculated in the last sampling time T_{Zu} before the data is sent to the master and before T_i and reading in the connector inputs p8851[..], p8861[..].

  Note

  Please note that five connector-binector converters (function block diagram 2489: p8880 ..., r8889) are NOT called synchronously in isochronous mode but may be processed within sampling time p8848 at any time depending on the computing time utilization.

  The calculation of the execution group must be completed within sampling time T_{Zu}]; otherwise, a fault F1054 "System limit exceeded" (V4.3), a warning A01053 "System overload measured" (V2.x) or a time-slice overflow (F01205) occurs. For this reason, only the absolute minimum number of DCBs that are necessary for the required function should be calculated in this execution group.
  The computing time available for this execution group decreases as the number of drive axes calculated on the CU increases, since the current controller (and the speed controllers for the servo) of the drive axes are also calculated in sampling time p0115[0] = T_{Zu}.
- **Receive AFTER IF2 flexible PZD** [1)]

This execution group is called after cyclic process data (PZD) has been received via communication interface IF2 (e.g. via the integrated PROFIBUS interface) and output to connector outputs r8850[..], r8860[..], binector outputs r8890 - r8893 and connector binector converters r8894 and r8895.
The sampling time of this execution group corresponds to the PROFIdrive PZD sampling time. The only difference from the Receive AFTER IF2 PROFIdrive PZD execution group is the way in which the execution group behaves in isochronous mode. Even in isochronous mode this execution group is called using the PROFIdrive PZD sampling time configured in the master as with any other sampling time. This means that initially all shorter sampling times are called at time T_o depending on the validity of the receive data (current controller; speed controller if applicable). This execution group is called first only when the T_{DP} sampling time starts to be processed. You basically do not know how often the shorter sampling times with higher priority of the current and speed controller are calculated before this execution group starts to be processed. In addition, processing of this execution group is interrupted due to shorter sampling times. This execution group should only be used if IF2 is usually operated in isochronous mode. The benefit of this execution group is that considerably more blocks can be calculated than in the Receive AFTER IF1 PROFIdrive PZD execution group because the calculation does not have to be completed after current controller sampling time p0115[0]. However (due to the higher priority and interruption caused by shorter sampling times), there is no longer a fixed synchronism between T_o and the time the execution group is called.

1) IF1 is the abbreviation for communication interface 1. With SINAMICS V2.5 and SIMOTION V4.1, this refers to the integrated PROFIBUS interface or - if a CBE20 has been inserted in the option slot - the PROFINET interface. IF1 supports the PROFIdrive profile and isochronous operation.
2) IF2 is the abbreviation for communication interface 2. IF2 of the CU320 and CU320-2 can only be used by the CAN bus if a CBC10 module has been inserted in the option slot and SINAMICS software as of V2.5 is used. The CBE20 or integrated PROFIBUS/PROFINET interface can be assigned to the IF2 via parameters (p8839, p8815). (See SINAMICS S120 Function Manual FH1 → Applications → Parallel operation of communications interfaces.) As of SINAMICS V4.4, isochronous mode is also supported on IF2.
3) For T_{DP}, T_i and T_o, the formulas and limit values listed in the Function Manual FH1→ Communication → Communication via PROFIBUS DP → Motion Control with PROFIBUS → "Time settings and Meanings" table apply.

The PROFIBUS functionalities described here also apply to PROFINET.

Not every fixed execution group is available on every drive object type. This means, for instance, that SERVO, VECTOR, VECTORMV... drive object types do not contain any digital or analog inputs; therefore, the fixed execution groups for the digital inputs/outputs and analog inputs/outputs are not available here.

Please ensure that the sampling time for DCC SINAMICS is restricted to below 1 ms. As a property of an execution group, select a fixed execution group in which the sampling time for the assigned system function is < 1 ms. This execution group will thus only be called with the sampling time of 1 ms, and will thereby deviate from the assigned system function. Fault F51004 (see r0947) is set to indicate this deviation. The fault value of the fault (r0949) + 1 gives the number of the execution group where the deviation has occurred.

Example for the automatic limitation of the sampling time:

On the SERVO drive object type, select "BEFORE speed controller" as a fixed execution group.
The associated system function is the speed controller.
The sampling time of the speed controller is p0115[1] = 125 µs in the factory setting of p0112 = 3.
In contrast to the sampling time of the speed controller, the sampling time of the DCC execution group is set automatically to 1 ms.
Also refer to the description of parameter p0112 in the SINAMICS S List Manual.

⚠ WARNING

In the case of an online change to the sampling time (execution group) the START method of the block is called. Initializations in the START method can result in jumps in the signal path.

Free execution groups

Free execution groups

The "free execution groups" are only defined by their sampling time (p21000 = 1 to 256 and p21000 = 1001 to 1096). The sampling times are provided centrally for all drive objects on a SINAMICS drive unit. A sampling time can be used simultaneously by several drive objects and several DCC execution groups. The sampling times are created in two different ways. The two methods have different limits for the maximum possible number of different sampling times.

- Free execution groups whose sampling times are created in the hardware:
  With the hardware sampling times, in p21000[0...9] each integer multiple of the basic sampling time (read-only in r21002) ranging from 1 * r21002 to 256 * r21002 can be generated with the following limits:
  - Minimum sampling time = 1 ms
  - Maximum sampling time = (r21003 - r21002) < r21003 (approx. 8 ms; on the D410 of the DP cycle).
  - On the D410 drive unit, r21003 always matches the DP cycle (PROFIBUS T_DP cycle clock) or with the send cycle clock for PROFINET. If 1 ms is configured as DP cycle / send cycle for PROFINET, this means no hardware sampling times (but only software sampling times) from DCC are used on this device.
  - The number of hardware sampling times on a drive device is limited. The number of still available hardware sampling times can be read from r7903 (as of SINAMICS V2.6). Further information is contained in Chapter DCC for SINAMICS → Overview → Computing time load, memory requirement and assignment of the HW sampling times → Number of possible different hardware sampling times (Page 5555).

    Note

    As regards offline configuration using STARTER commissioning software, values 0 - 256 can be entered in p21000[0..9], even if this violates the limits stated above for the hardware sampling times from 1 ms ... <r21003. This will only be detected once the Control Unit has been downloaded, and will result in the use of a replacement value and the F51004 fault. If the set value is too small, 1 ms will be set as substitute value; if it is too large, the next largest SW sampling time will be set.

  - On the drive objects of the CU, TB30, TM15 DIDO, TM 31 and TM41, the sampling time for additional functions p0115[0] = 4 ms is preset. If you want to configure a DCC execution group with a smaller sampling time on these drive objects, you should first set the sampling time for the additional functions p0115[0] on this drive object to the value of the smallest desired sampling time. To do this, p0009 = 3 must first be set. Only then is it possible to change p0115[0]. For the new value for p0115[0] to take effect, p0009 = 0 must be reset.
- Free execution groups whose sampling times are created in the software:
  The software sampling times are generated as an integer multiple of the basic value for software sampling times (read out in parameter r21003).
  The possible set values for the software sampling times (1 * r21003 - 96 * r21003) can be taken from the parameter description for p21000 (see Function Manual, *Description of the standard DCC blocks*, in the appendix in the *Parameters* section).

⚠ WARNING
The START method of the block is called for an online change to the sampling time (execution group). Initializations in the START method can result in jumps in the signal path.

Execution sequence order, creating new execution groups

When a CFC is created, a new execution group with the same name as the chart will be created automatically. All blocks that are inserted into the chart will be automatically assigned in the insertion sequence of this execution group.

The computing sequence of the blocks within the execution group is specified by the configuration. If no other execution sequence is specified by the user, the execution sequence corresponds to the insertion sequence of the blocks within an execution group.

If the execution sequence with this execution group is to be changed, new execution groups added or the assignment of blocks to the execution groups changed, these properties can be changed in the execution editor. To do this, go offline in the STARTER and then open the chart. In the DCC editor, the **execution sequence** button can be used to activate and deactivate the execution editor.

The center column of the execution editor contains the chart with its chart name. The execution group(s) are arranged hierarchically below. If you want to create additional execution groups, select the **Insert execution group...** item from the context menu of the chart (right-click the chart). The individual blocks can be moved between the execution groups or within an execution group using drag-and-drop. The details given in the Pos column (e.g. 1 / 2) correspond to the name in the bottom line in the right-hand part of the block header with a colored background. The 1st digit stands for the execution group (between 1... 10) and the 2nd digit for the sequence within the execution group. The execution sequence can be changed by dragging & dropping into the center column.

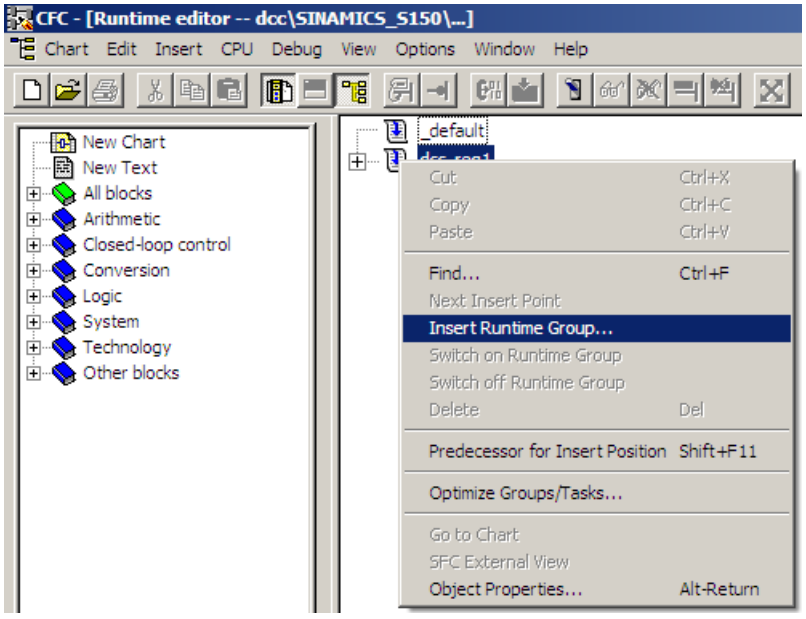

Figure 7-639 Context menu, **Insert execution group...**

Note

1. The assignment of identical names for DCCs in different drive objects is not permitted.
2. The assignment of identical names for execution groups in different drive objects is not permitted.

If the same fixed or free execution group of the drive object is assigned to several execution groups in the DCC editor, the execution groups of the DCC editor will be calculated in the sequence from top (calculated first) to bottom (calculated last) as shown in the "Set Execution Groups (Sampling Times)" window.

Creating customer-specific parameters ("declare")

The properties of the input and output connections of blocks can be edited in the DCC editor in the Properties window of the block connection. Input connections may not be interconnected in the default setting of the DCC editor. The Properties window of the connection is opened by double-clicking the connection or by selecting **Object properties** in the context menu of the connection.

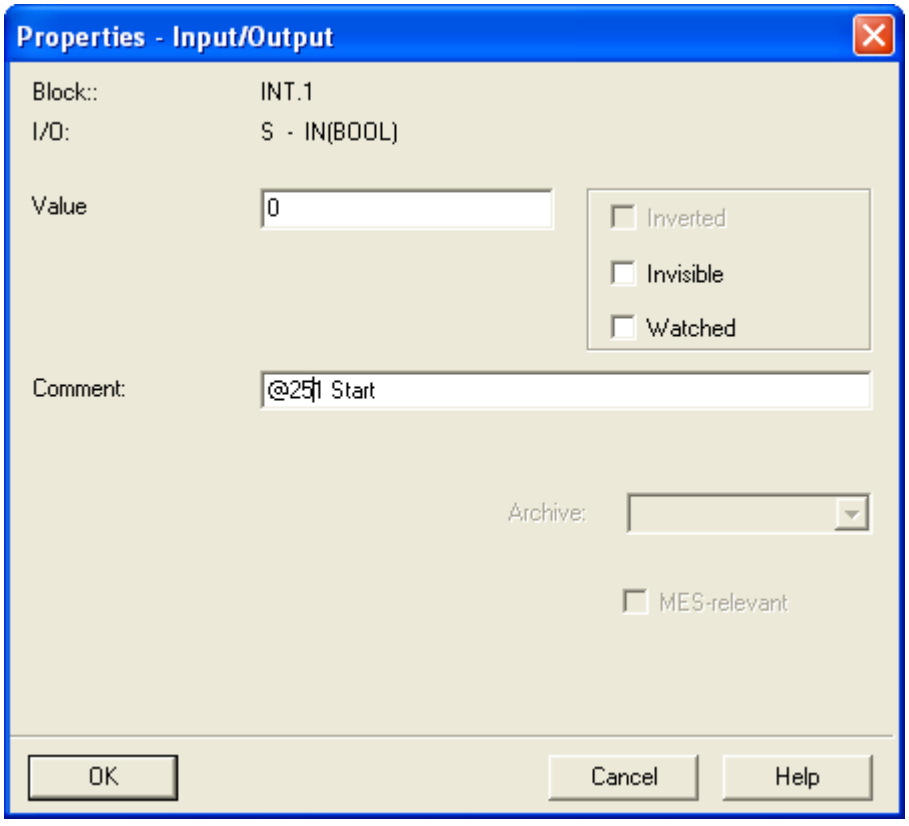

Figure 7-640 **Properties - Connection** window of the connection S (= Set) of the block INT (= INTegrator)

In SINAMICS, input and output connections of blocks can be published as parameters. "Publish" means that users create the parameters themselves (parameter numbers and parameter text). This is the prerequisite in order to interconnect the block connections using BICO parameters to the basic system in order to assign the values to the input connections using adjustable parameters and to monitor the values of the output connections using parameters. The parameter number 251 in the above figure and in the following figure is arbitrary.

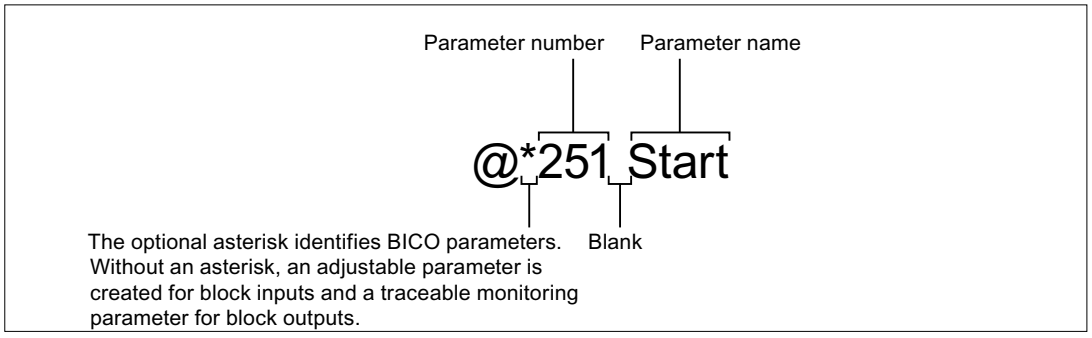

Figure 7-641 Structure of the block connection comment

The parameter name, which follows the parameter number separated by a space, is displayed in the STARTER expert list.

The data type of the published input/output is taken over by the block connection.

For the "publishing" of block inputs, a distinction must be made between adjustable parameters (without asterisk) and BICO parameters (with asterisk).

For the "publishing" of block outputs, the following distinction must be made:

- Without asterisk: pure monitoring parameter that cannot be interconnected and that can be recorded with the trace function.
- With asterisk: as for the case without asterisk, but additional interconnection possible.

Block inputs to be published may not be already interconnected in the default setting of the DCC editor. If necessary, an existing interconnection must first be deleted. To do this, click the interconnection in the chart to mark it and select **Delete interconnection(s)** in the context menu. In this DCC editor setting, the comment shown for a block input interconnected with a different block is always that of the connected block output.

If you want to remove this constraint, select **Options** > **Settings** > **Display ...** in the DCC editor and deactivate the **Interconnection comment** checkbox under **Parameters** and close the window with OK. Already interconnected block inputs can now be published without having to delete the interconnection first.

A parameter number may only be used just once in a chart. The DCC editor does not check when the parameter number is entered in the Properties window of the connection whether this parameter number is already used in the chart. The multiple use of the parameter numbers will be indicated as error only when the chart is compiled.

The parameter numbers of the charts are represented on the number range from p21500 to p25999 of the expert list of the STARTER. With each DCC chart, it is possible to specify where the parameter range of the chart is to begin. This can be performed in the **Parameters** tab in the Properties window of the chart in STARTER, using the parameter number base.

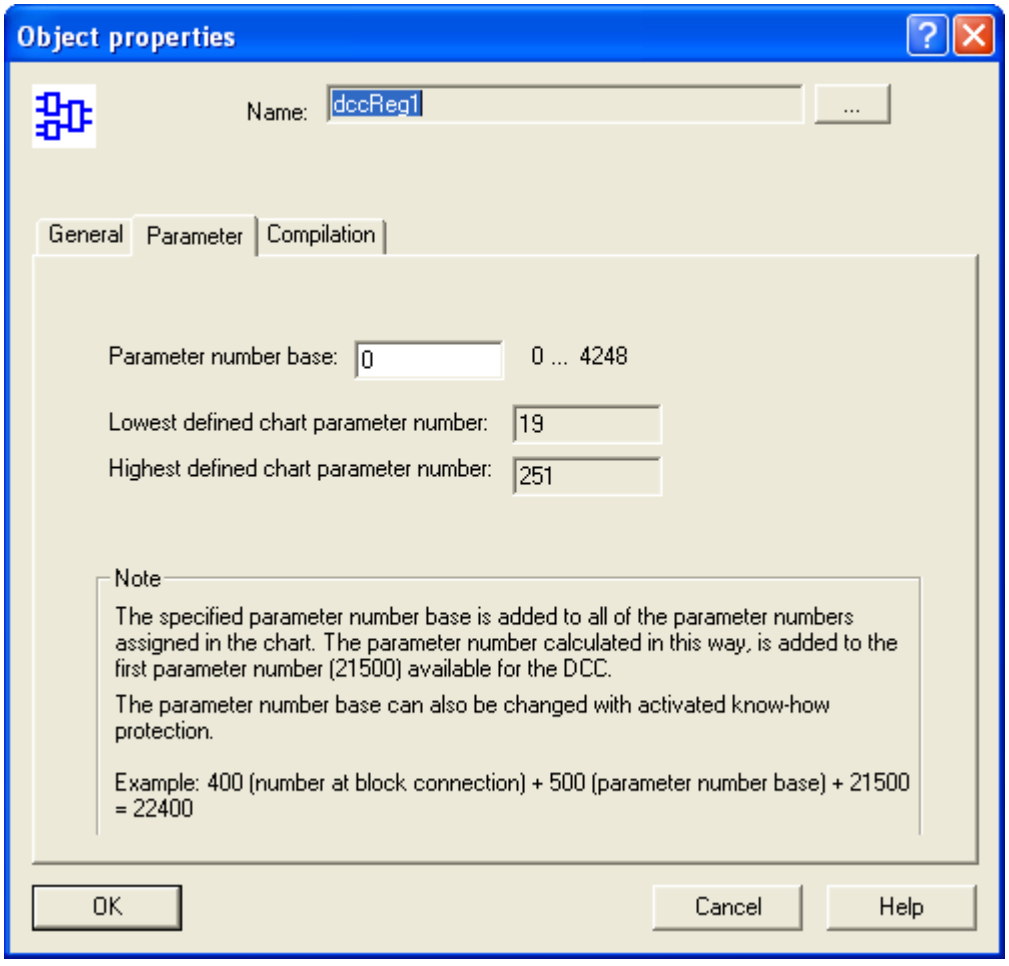

Figure 7-642 Properties window of the dccReg1 chart for setting the parameter number base

The parameter number in STARTER has the following form:

- Parameter number in the chart + base parameter number + 21500;
  where 21500 is the first parameter number available for DCC. The parameter number base must always be >= 0. The parameter number base can be changed.

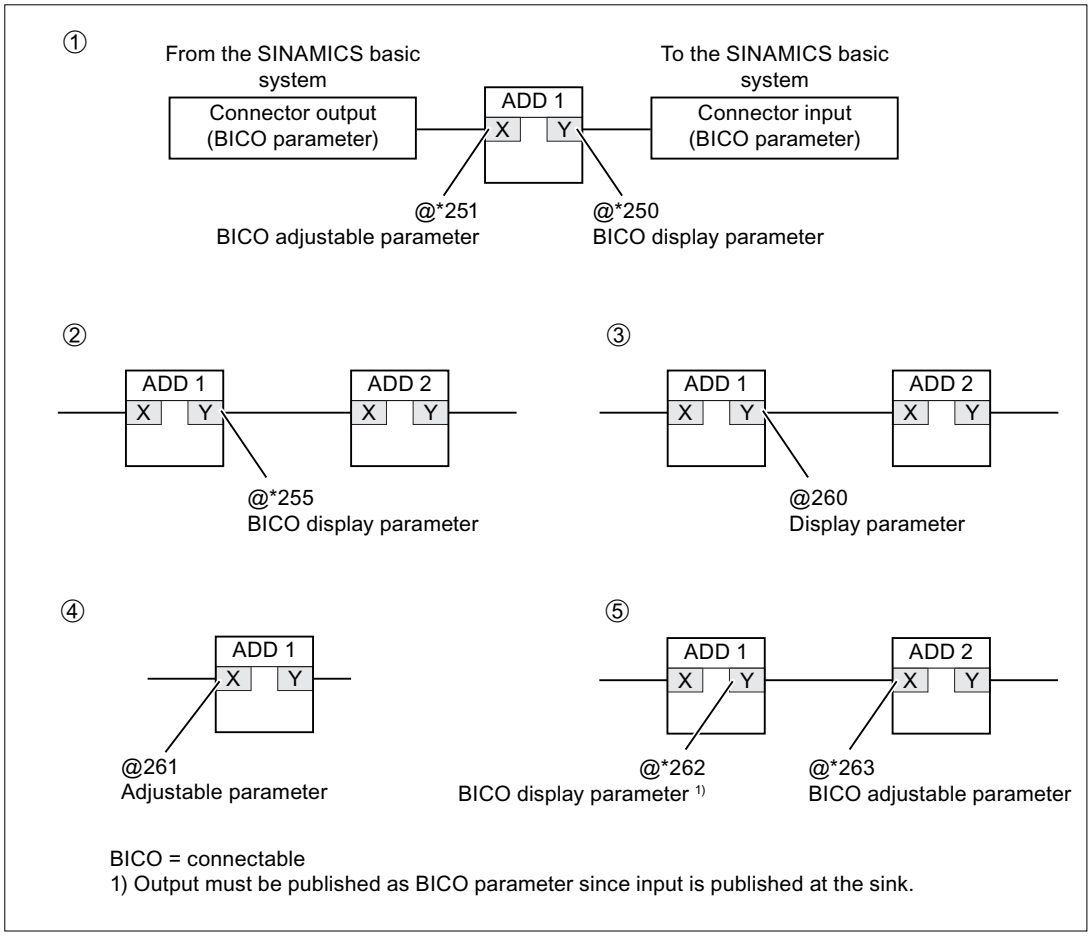

Figure 7-643 Examples of parameter definitions

Example 1: For an interconnection of the block connection with the SINAMICS basic system, the connection must be published as BICO parameter.

Example 2: Each block output connection can be published as BICO parameter. The signal on this output can be recorded with the trace.

Example 3: Each block output connection can be published as (not interconnectable with other BICO parameters) display parameter. The signal on this output can be recorded with the trace. The block input can be interconnected to every other non-published block input.

Example 4: The block input connection X of the ADD 1 block is published as adjustable parameter.

Example 5: Because the block input connection X of the ADD 2 is published as BICO parameter, the block output connection interconnected with it must also be published as BICO parameter. It is, however, possible in the DCC editor to interconnect ADD 1 Y with ADD 2 X when only the block input ADD 2 X is published. This results in an error message when the chart is compiled. The signal value of a block input published as BICO parameter cannot be recorded with the trace.

Note

No help function can be created for @parameters.

Display of the parameters

If the parameters configured on the block connections are to be displayed in the DCC editor, then select **Options** > **Settings** > **Display ...** and select **Comment** under **Connections**. The first eight characters of the comment are then displayed at the respective block connections in the block symbols.

Interconnection with SINAMICS parameters

You can interconnect with SINAMICS BICO parameters in the DCC editor.

Procedure

Interconnection can be performed as follows:

1. Creating customer-specific parameters ("Publishing", @ parameters); see Creating customer-specific parameters (Page 5543).

   Note

   In the DCC editor, block connections can initially be connected with the drive's BICO parameters without the need to publish them as parameters. However, this will cause errors when compiling the chart, since only block connections that have been published as @* parameters can be connected to the drive's BICO parameters.

2. Select the block connection to be interconnected.
3. Right-click and select **Interconnection with operand...** from the context menu. The **DCC Signal Selection** window appears.

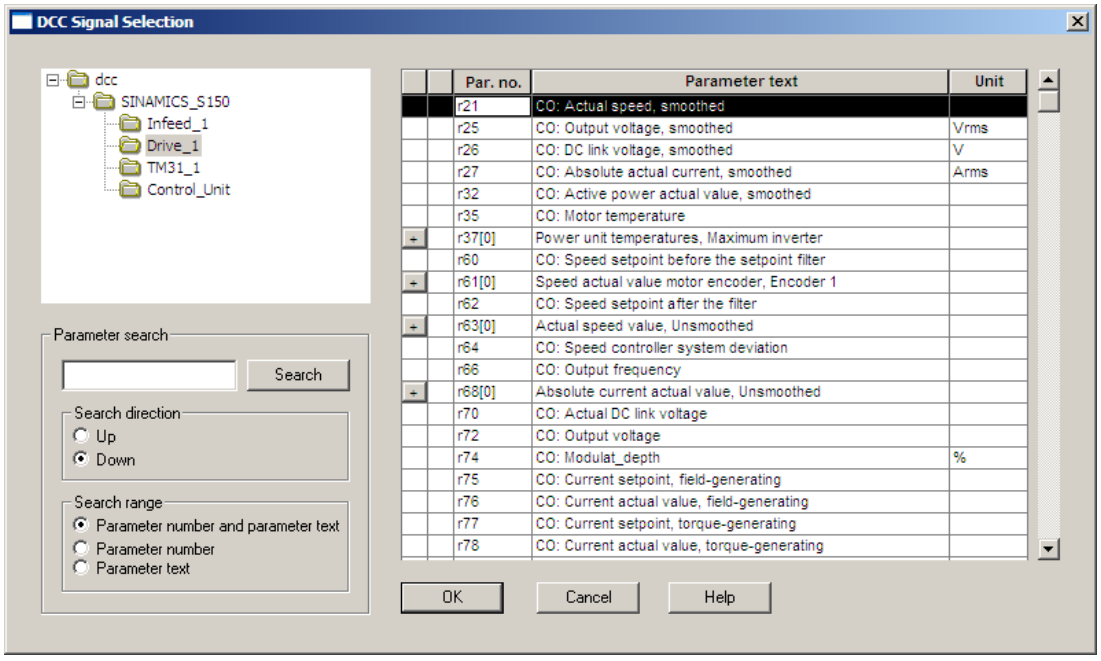

Figure 7-644 Signal selection

4. Select the parameter to be interconnected.
5. Click **OK** to close the window.

From this point on, the selected block connection is interconnected with the SINAMICS parameter and the parameter is displayed in the sheet bar of the DCC editor.

Note

BICO parameters defined in other DCC charts will not be displayed in the signal selection list.

DCC-local parameters can be directly interconnected in the CFC chart as an interconnection of block connections. This interconnection is then converted to a BICO interconnection.

Connections to BICO parameters in DCC charts on other DOs can be established graphically in the DCC editor using two charts open next to one another.

Note

With the BICO technology of the SINAMICS drive family you can interconnect BICO parameters with different data types, e.g. a BICO parameter of the FLOAT32 data type with a BICO parameter of the INT32 data type. In this case, the value range of the FLOAT32 data type exceeds the value range of the INT32 data type.

The SINAMICS basic system automatically ensures that in such cases the source parameters do not exceed the value ranges of the sinks.

You must explicitly ensure this restriction in the DCC chart for published BICO parameters, e.g. through an LIM block.

Computing time load, memory requirement and assignment of the HW sampling times

The following statements govern the use of DCC-SINAMICS on the SINAMICS S120, S150, G130, G150 and (on the SINAMICS_Integrated in) SIMOTION D4xx devices. Details about other devices are contained in the associated device documentation.

Computing time load for the SINAMICS V2.5 and V2.6 software versions

The processing of blocks requires computing time. This means with the computing of DCC execution groups, it is no longer possible to calculate the maximum quantity structure for drive objects of a CU3x0, D4xx and CX32.

The resulting computing time load is dependent on the following:

- Number of calculated execution groups
- Sampling time of execution groups
- Number of calculated blocks
- Calculated block types
- For some blocks, it depends on the parameterization (e.g. the setting of enable connections)

Parameter r9976 (system load; can be found on the CU's drive object) is available in the system as an online tool. The average value for the computing time load in r9976[1] should **always** be below 85.0%. Likewise, the maximum value for the computing time load in r9976[5] should **always** be below 85.0%. Exceeding the computing time load limit of 90% triggers warning A51003. The warning is reset if the computing time load falls below 88%.

The computing time load should not fall below the limit of 85.0% so that the response time of the STARTER/SCOUT engineering tool is not too greatly restricted.

If the computing time load increases to the point that it is no longer possible for all blocks and system functions assigned to a sampling time to be completed within this sampling time, the drive unit switches off and outputs fault F01205: "CU: Time-slice overflow".

Offline mode enables the SIZER engineering tool to make an approximate statement regarding whether a configuration can be calculated on a CU3x0 or D4xx. The additional computing time load is **not** taken into account by activating the DCCs.

Note

The computing time load reaches its maximum value when the following conditions are met:

- All necessary function modules are activated.
- All drives and infeeds are in the operational status.
- Closed-loop control in the final configuration is approved on all drives and infeeds.
- Configured isochronous data transfer is used.

The values displayed in r9976 are thoroughly smoothed internally. A change in the computing time load is therefore only displayed in full in r9976 after 2 - 3 minutes.

If, during OFFLINE configuration, it is not certain whether the limit value for the computing time load of 85% (r9976[1] and r9976[5]) will be adhered to, you can initially call the execution groups being used in a very large sampling time (e.g. 96 * r21003). After checking the actual system load in r9976, you can then gradually select execution groups with shorter sampling times right through to the execution group that is intended for the application in question.

During OFFLINE configuration, the following should be carried out:

- Activate all necessary function modules on the drive objects.
- Assign all necessary blocks to their execution groups.
- Establish all connections, both between the blocks and to the drive objects (as long as this still makes sense even if an increased sampling time is being used).

The following applies as a rough configuration aid to SERVO drives:

If one A-INF infeed is configured on a SINAMICS CU320 with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs) and three SERVO drive axes are configured with the speed and current controller sampling times set in the factory (p0112 = 3 == STANDARD → p0115[1] = p0115[0] =125 µs) and the function modules and without isochronous PROFIBUS/PROFINET communication set in the factory, one DCC chart with 50 blocks can be calculated on each of the three drive objects in an execution group with a sampling time of 2 ms.

The following (functional single) blocks have been used in a chart in this case:

AND, OR, XOR, NOT, BF, CTR, MUX8, NAND, NCM, SH_DW, ADD, SUB, MUL, DIV, AVA, MAS, MIS, PLI20, DEL, DEZ, SUB_D, SUB_I, MUL_D, MUL_I, DIV_D, DIV_I, AVA_D, SII, STM, DLB, DX8, DX8D, MFP, PCL, PDE, PDF, PST, RSR, DFR, BSW, NSW, LIM, PT1, INT, DIF, LVM, LIM_D, PC, PIC, RGE

In a sampling time of 1 ms, only around half the blocks can be calculated. Around twice as many can be calculated in a 4 ms sampling time.

A SERVO axis with standard sampling times omitted from the maximum configuration thus permits the use of approximately 50 blocks (of the above-mentioned types) for a sampling period of 2 ms.
Approximately 50 blocks (of the above-mentioned types) in an execution group increase the computing time load of the CU by approximately 11%.

The following applies as a rough configuration aid to VECTOR drives:

If one A-INF infeed is configured on a SINAMICS CU320 with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), two VECTOR drive axes are configured with the speed controller sampling times p0115[1] = 2000 µs and the current controller sampling times p0115[0] = 500 µs (p0115[2] = p0115[3] = p0115[4] = 2000 µs) and the function modules and without isochronous PROFIBUS/PROFINET communication set in the factory, one DCC chart with approx. 70 blocks (type selection, see above for SERVO) can be calculated on two drive objects in an execution group with a sampling time of 2 ms.
This means approx. 70 blocks (type selection, see above for SERVO) increase the computing time load by approx. 15%.

In a sampling time of 1 ms, only around half the blocks can be calculated. Around twice as many can be calculated in a 4 ms sampling time.

The following generally applies:

You can of course use any blocks you want in your project. Using other block types may produce other results in terms of the number of blocks that can be calculated and the computing time load. Blocks with a very extensive functionality of course require a greater computing time. Note that the computing time needed for some blocks also depends on the values configured at the connections, e.g. whether an enable connection is set.

When measuring the computing time load, all connections should therefore be set to their final configuration values wherever possible.

When commissioning a configuration, the current computing time load must always be checked online on the drive unit for compliance with the limits stated at the start for r9976[1] and r9976[5].

Computing time load as of software version V4.3

With software version SINAMICS V4.3, DCC is available for the new higher performance CU320-2 DP module. It is also available for the new modules CU310-2 DP, CU310-2 PN, and CU320-2 PN in the case of SINAMICS V4.4, and for SIMOTION D4x5-2. As of software V4.3, after a download (DL) or a parameter change (e.g. of the sampling time of a execution group), the control unit (CU) uses the configuration data to determine the expected computing time utilization (including the load due to DCCs) and indicates this for the complete system in parameter r9976 (the level of system utilization that can be found on the drive object of the CU). If the calculated average computing time utilization for the complete system r9976[1] or the maximum utilization in a sampling time r9976[5] (including interruptions due to shorter sampling times) exceeds the maximum value of 100.00%, this causes the setting of fault F1054 (CU: System limit exceeded). The fault F1054 causes all infeeds and drive axes calculated on the CU to be switched off. The utilization is calculated on the CU, i.e. the utilization values are displayed in the STARTER/SCOUT only in online mode.

The resulting computing time utilization caused by DCC depends on the following:

- Number of calculated execution groups
- Sampling time of the execution groups
- Number of calculated blocks
- Calculated block types
- Use of the execution groups "Receive AFTER IF1 PROFIdrive PZD ", "Send BEFORE IF1 PROFIdrive PZD", "Receive AFTER IF2 PROFIdrive PZD", and "Send BEFORE IF2 PROFIdrive PZD" of the bus configuration (isochronous/ not isochronous; see chapter Fixed execution groups (Page 5529))

The proportional computing time utilization caused by DCC is displayed on the drive objects on which DCCs are configured in the parameter r21005[0...9] for the execution groups 1 to 10 (as of SINAMICS V4.3). Note that the average computing time utilization for an execution group k can be calculated only when this is registered for cyclical processing (p21000[k-1] ≠ 0, in the STARTER/SCOUT in the context menu of the chart → Set sampling times).

In contrast to software versions V2.5 and V2.6, a parameter change (in online mode of the STARTER) that affects the computing time utilization (e.g. change of the sampling time of a DCC execution group) causes an immediate recalculation of r9976 (and r21005) by the drive device. For parameters that may only be changed in the device states C1 (commissioning 1) or C2 , i.e. may only be changed in STARTER/SCOUT offline mode (e.g. p0115), the new value of the computing time utilization in r9976 will be displayed only after the project download and the subsequent CU ramp-up.

As of V4.3, the permitted maximum value of the computing time utilization r9976 increases practically to 99.99%. (For values > 100.00%, fault F1054 will be set; this simultaneously causes an OFF2 on all drive objects of the CU.)

As rough configuration aid, the following is true for **SERVO** drives with the current controller sampling time p0115[0] = 125 µs and the speed controller sampling time p0115[1] = 125 µs:

1. If on a SINAMICS CU320-2 one A-INF infeed with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), **six SERVO drive axes** with the speed and current controller sampling times set in the factory (p0112 = 3 == STANDARD → p0115[1] = p0115[0] =125 µs), the function modules set in the factory setting, one TB30 [2)] and with isochronous PROFIBUS/PROFINET communication with $T_{\_DP}$ >= 2 ms are configured, one (1) DCC with approximately 50 blocks can be calculated in an execution group with a sampling time of 2 ms.
2. If on a SINAMICS CU320-2 one A-INF infeed with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), **5 SERVO drive axes** with the speed and current controller sampling times set in the factory (p0112 = 3 == STANDARD → p0115[1] = p0115[0] =125 µs), the function modules set in the factory setting, 1 TB30 [2)], 3 TM31 [2)] and isochronous PROFIBUS/PROFINET communication with T_{DP} >= 2 ms are configured, one (1) DCC chart with approximately 75 blocks can be calculated [1)] in an execution group with a sampling time of 2 ms.
3. For each additional omitted SERVO axis, approximately 75 additional blocks [1)] can be calculated in the sampling time of 2 ms.

As rough configuration aid, the following is true for **VECTOR** drives with the current controller sampling time p0115[0] = 500 µs and the speed controller sampling time p0115[1] = 2000 µs (p0115[3] = 2000 µs, p0115[4]=2000 µs):

For more than three VECTOR axes on a CU320-2, the current controller sampling time will be increased automatically to the value p0115[0] = 500 µs. This automatically increases the speed controller sampling time to 2 ms.

1. If, on a SINAMICS CU320-2, one A-INF infeed with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), **six VECTOR drive axes** with the current controller sampling times p0115[0] = 500 µs, the speed controller sampling time p0115[1] = 2000 µs, the functions and function modules set with the factory setting, one TB30 [2)] and with isochronous PROFIBUS/PROFINET communication with $T_{\_DP}$ >= 2 ms are configured, one (1) DCC with approximately 50 blocks can also be calculated in an execution group with the sampling time 2 ms.
2. If, on a SINAMICS CU320-2, one A-INF infeed with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), **five VECTOR drive axes** with the current controller sampling times p0115[0] = 500 µs, the speed controller sampling time p0115[1] = 2000 µs, the functions and function modules set with the factory setting, with isochronous PROFIBUS/PROFINET communication with $T_{\_DP}$ >= 2 ms, one TB30 [2)] and three TM31 [2)] are configured, one (1) DCC with approximately 75 blocks can also be calculated in an execution group with the sampling time 2 ms.
3. For each additional omitted VECTOR axis (with p0115[0] = 500 µs and p0115[1] = 2000 µs), approximately 75 additional blocks [1)] can be calculated in the sampling time of 2 ms.

As rough configuration aid, the following is true for **VECTOR** drives with the current controller sampling time p0115[0] = 250 µs and the speed controller sampling time p0115[1] = 1000 µs (p0115[3] = 1000 µs, p0115[4] = 1000 µs):

For up to three VECTOR axes on a CU320-2, the current controller sampling time and the speed controller sampling time have the values p0115[0] = 250 µs and 1 ms, respectively, in the factory setting.

1. If, on a SINAMICS CU320-2, one A-INF infeed with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), **three VECTOR drive axes** with the current controller sampling times p0115[0] = 250 µs, the speed controller sampling time p0115[1] = 1000 µs, the functions and function modules set with the factory setting, one TB30 [2)] and with isochronous PROFIBUS/PROFINET communication with $T_{\_DP}$ >= 2 ms are configured, one (1) DCC with approximately 50 blocks can also be calculated in an execution group with the sampling time 2 ms.
2. If, on a SINAMICS CU320-2, one A-INF infeed with the sampling times set in the factory (p0112 = 2 == LOW → p115[0] = 250 µs), **two VECTOR drive axes** with the current controller sampling times p0115[0] = 250 µs, the speed controller sampling time p0115[1] = 1000 µs, the functions and function modules set with the factory setting, with isochronous PROFIBUS/PROFINET communication with $T_{\_DP}$ >= 2 ms, one TB30 [2)] and three TM31 [2)] are configured, one (1) DCC with approximately 150 blocks can also be calculated in an execution group with the sampling time 2 ms.
3. For each additional omitted VECTOR axis (with p0115[0] = 250 µs and p0115[1] = 1000 µs), approximately 150 additional blocks [1)] can be calculated in the sampling time of 2 ms.

The following generally applies:

You can of course use any blocks you want in your project. The use of other block types may produce different results in terms of the number of blocks that can be calculated and the computing time utilization. Blocks with a very extensive functionality of course require a greater computing time.

1) The chart with 75 blocks consists of an execution group with the following blocks in the listed sequence:

AND, OR, XOR, NOT, BF, CTR, MUX8, NAND, NCM, SH_DW, ADD, SUB, MUL, DIV, AVA, MAS, MIS, PLI20, DEL, DEZ, SUB_D, SUB_I, MUL_D, MUL_I, DIV_D, DIV_I, AVA_D, SII, STM, DLB, DX8, DX8_D, MFP, PCL, PDE, PDF, PST, RSR, DFR, BSW, NSW, LIM, PT1, INT, DIF, LVM, LIM_D, PC, PIC, RGE, AND, OR, XOR, NOT, BF, CTR, MUX8, NAND, NCM, SH_DW, ADD, SUB, MUL, DIV,AVA, MAS, MIS, PLI20, DEL, DEZ, SUB_D, SUB_I, MUL_D, MUL_I, DIV_D.

The chart with 150 blocks consists of an execution group that contains the previously listed 75 blocks twice.

2) All sampling times (p4099[]) of the TB30 and the TM31 have the value 4 ms (factory setting).

Memory requirement

The blocks and @ parameters in the DCC charts require memory on the drive unit. To use DCC-SINAMICS, for SINAMICS G130, G150, S120, S120 Chassis, S120CM, S150 and SIMOTION D4x5, at least one drive axis must be excluded in comparison to the maximum possible configurations (1 ALM + 6 servo axes + TB30 or 1 ALM + 4 vector axes + TB30).

Maximum quantity structures with a topology of 5 servo or 3 vector axes with 1 ALM and 1 TB30			
Drive unit		**CU320**[2]	**SINAMICS Integrated on SIMOTION D4x5**
SINAMICS 2.6.1	**Blocks**[1]	350	-
	@Parameters[1]	350	-
SINAMICS 2.6.2	**Blocks**[1]	500	200
	@Parameters[1]	500	200

2) SINAMICS G130, G150, S120, S120 Chassis, S120CM, S150

Note

The specified maximum numbers for blocks and @parameters always apply for the entire drive unit and should be regarded as guide values. Only the factory-set function modules are active. The individual blocks and @parameters may be arbitrarily distributed across several charts. Conserving @parameters has little effect on the quantity structure of the blocks; the specified maximum numbers for the blocks should therefore not be exceeded.

Savings in further drive axes can increase the maximum limits by 50 blocks and 50 @parameters for each axis saved.

Maximum limits when just one axis is used (including 1 ALM + TB30)					
Drive unit		**CU320 and CU310[2] with 1 servo axis**	**CU320 and CU310[2] with 1 vector axis**	**SINAMICS Integrated[3] with one servo axis**	**SINAMICS Integrated[3] with one vector axis**
SINAMICS 2.6.1	**Blocks**[1]	550	450	-	-
	@Parameters[1]	550	450	-	-
SINAMICS 2.6.2	**Blocks**[1]	700	600	400	300
	@Parameters[1]	700	600	400	300

2) SINAMICS G130, G150, S120, S120 Chassis, S120CM, S150

3) S120i on D4x5

When expanding the topology on a drive unit with TMxx or DMC20 modules, one drive unit must be omitted for each additional TMxx module.
Please note when connecting CX32 modules to a D4x5 that memory and CPU time are also allocated for each CX32 on the D4x5. When using the DCC, another servo or vector axis must be omitted for every 2 CX32s (i.e. the axis must be omitted for the first CX32).

Example for SINAMICS 2.6.2:

D4x5 with 1 ALM + 4 servo axes + 2 CX32 + 1TB30 à
Permits DCC with 200 DCBs + 200 @parameters.

D4x5 with 1 ALM + 2 vector axes + 2 CX32 + 1TB30 à
Permits DCC with 200 DCBs + 200 @parameters.

When using DCC on the CX32 the same quantity structure applies as on the CU320.

Note

The final limits are determined by the total memory available on the drive unit and the computing time load. If the above-mentioned recommended maximum limits are exceeded, this can result in errors during upload or download (e.g. fault F1105 CU: insufficient memory) and the drive can no longer be switched on. If it is not possible to perform a new download with a suitably adjusted project, a power OFF/ON must be performed on the affected drive unit.

By activating additional function modules (e.g. basic positioner EPOS), additional memory is allocated and the specified maximum limits are decreased.

[1]) The charts for the above-specified quantity structures are formed from n x (chart1 + chart2): Chart1 contains 50 blocks (of the following types: AND, OR, XOR, NOT, BF, CTR, MUX8, NAND, NCM, SH_DW, ADD, SUB, MUL, DIV, AVA, MAS, MIS, PLI20, DEL, DEZ, SUB_D,SUB_I, MUL_D, MUL_I, DIV_D, DIV_I, AVA_D, SII, STM, DLB, DX8, DX8D, MFP, PCL, PDE, PDF, PST, RSR, DFR, BSW, NSW,LIM, PT1, INT, DIF, LVM, LIM_D, PC, PIC, RGE) with 50 @parameters and approx. 90 connections (from block connector to block connector).

Chart2 contains 50 blocks (of block types AND, OR, ADD, MUL, DIV, B_DW, B_W, BY_W, D_I, D_R, D_UI, D_US, DW_B, DW_R, DW_W, I_D, I_R, I_UD, I_US, N2_R,N4_R, R_D, R_DW, R_I, R_N2, R_N4, R_UD, R_UI, R_US, UD_I, UD_R, UI_R, US_D, US_I, US_R, W_B, W_BY, W_DW, WBG,DCA, INCO, OCA, TTCU, ADD, ADD_D, ADD_I, ADD_M, AVA, AVA_D, RSS), 50 @parameters and approx. 90 connections (from block connector to block connector)

For example, 350 blocks and 350 @parameters are compiled from 4 * chart1 + 3 * chart2.

Memory requirement as of software version SINAMICS V4.3

The blocks and @ parameters in the DCC charts require memory on the drive unit. A maximum of 1,500 blocks and 1,500 @ parameters may be configured in DCC SINAMICS with the modules CU320-2 DP, CU320-2 PN (V4.4 or higher), CU310-2 DP (V.4.4 or higher), and CU310-2 PN (V.4.4 or higher) on SINAMICS S120, S150, G130, and G150.

For SINAMICS_Integrated V4.4 or higher (V4.2 or higher with SIMOTION), a maximum of 1,500 blocks and 1,500 @ parameters may be configured on the D4x5-2 modules.

Number of possible different hardware sampling times

The sampling times for the execution groups can be selected in p21000[x] as a multiple of r21002 (basic sampling time of hardware time slices), a multiple of r21003 (basic sampling time of software time slices), or on the basis of the sampling time of a basic SINAMICS system function (e.g. when p21000[x] = 9003 == "before setpoint channel" from the sampling time of the setpoint channel p0115[3]).

Only sampling times can be set as hardware sampling times, for which the following applies:

1 ms <= T_sampling <= r21003 - r21002 in p21000[x]

Hardware sampling times, assignment, and number

The assignment of the available hardware sampling times is displayed in r21008[0...24] as follows (STARTER/SCOUT: in online mode only):

- Value = 0.0 --> sampling time not assigned
- Value != 0.0 (not equal to 0.0) --> sampling time in ms
- Value = 9.9999e + 006 --> sampling time not supported

During configuration, note that the number of different hardware sampling times (1 ms = cycle duration T_sampling <r21003 - r21002) used by the basic SINAMICS system, active function modules (see r108) and Drive Control Chart is restricted as follows:

- CU310, CU320, D4xx --> no. of hardware sampling times = 13
- CU320-2 DP with SINAMICS V4.3 and higher --> no. of hardware sampling times = 25
- CU310-2 DP, CU310-2 PN, and CU320-2 PN with SINAMICS V4.4 and higher --> no. of hardware sampling times = 25

- SINAMICS_Integrated on the D4x5-2 with SINAMICS V4.4 (contained in SIMOTION V4.2) and higher --> no. of hardware sampling times = 25
- CUD (SINAMICS DC MASTER) --> number of hardware sampling times = 11

Hardware sampling times, usage

A sampling time can be used simultaneously by more than one execution group of DCC, function modules and the basic SINAMICS system.

For this reason, the execution groups should ideally be registered to existing sampling times or, if it makes more sense in relation to the function, the execution group "Before setpoint channel" should be used.

For internal reasons, the drive unit always requires at least one (or more, depending on how the basic sampling times p0115[0] of the drive objects are parameterized) free hardware sampling time, which is why the current **Number of free hardware sampling times** can be read in **r7903** (as of SINAMICS V2.6).

DCC and FBLOCKS together must not use more than 5 different hardware sampling times on one drive unit. (This only refers to sampling times that deviate from the hardware sampling times already present in the basic system.)

Note

Note that a long-term trace registers a sampling time of 2 ms and the trace registers sampling times in accordance with the selected trace cycle clock. If these sampling times have not already been registered by the basic SINAMICS system, "Free blocks" (FBLOCKS), or Drive Control Chart (DCC), these functions require additional free hardware sampling times.

The registered hardware sampling times can be read (if the DCC is activated) in r21008[0...12].

The current number of free hardware sampling times is displayed in r7903 (as of SINAMICS V2.6).

Project download, error message, and procedure

If too many different hardware sampling times are configured offline, an error message is not output until the project is downloaded.

In this case, proceed as follows:

1. With the project in offline mode, set all the free execution groups to which hardware sampling times are assigned to software sampling times.
   - Hardware sampling times (DCC: p21000 < 256)
   - Software sampling times (DCC: p21000 >= 1001)
     The assignment of fixed execution groups (DCC: p21000 >= 2000) does not need to be changed because the fixed execution groups use the same sampling time as the assigned basic SINAMICS system function.
2. Download the project again.

3. Once the project has been downloaded and the Control Unit has ramped up, check:
   – r7903: Number of hardware sampling times still available
   – r21008: Hardware sampling times already registered by the basic SINAMICS system.
4. Adjust the execution group parameters accordingly.

Note

The number of different hardware sampling times possible on a Control Unit is restricted. For this reason, software sampling times (multiple of r21003) or, if necessary, the fixed execution group (p21000[0...9] ≥ 2000) should ideally be used.

Upgrading SINAMICS firmware

Upgrading firmware on the CF card

If you upgrade the SINAMICS firmware directly on the CF card and replace the USER directory, you must also replace the DCB libraries used in the DCC chart in the OEM directory.

For a detailed description of the procedure, please refer to the Function Manual*SINAMICS S120 Drive Functions*.

Updating the firmware via the Web server

For a detailed description of the procedure, please refer to the Function Manual*SINAMICS S120 Drive Functions*.

7.4.4.2 Working with DCC SINAMICS

Preliminary remarks on configuration

Preliminary remarks

The following is a brief explanation of what you will be configuring in this chart.

Configuration example

The requirement for this example is that there must be a STARTER or SCOUT version (≥ V4.1.2) suitable for your SINAMICS SW version (≥ V2.6) installed on your computer. The SINAMICS Support Package (SSP) V2.6 must also be installed. Your computer must also have a CFC license to use the DCC editor. You can install this license from the USB stick provided with the help of the Step7 Automation License Manager. A CU310 or CU320 is required with which STARTER/SCOUT can connect online, e.g. via PROFIBUS.

The configuration example deals with a straightforward oscillating circuit that creates sinusoidal oscillation at its output.

It will only take you a few minutes to create the chart; then you can execute it in test mode as a demonstration.

The following blocks are used:

- Two integrators (**INT**)
- One inverter (**SII**)

As indicated by the differential equation **f"(x) = - f(x)**, the oscillating circuit is comprised of two integrator blocks that are linked by negation.

The frequency of the oscillating circuit is determined by the integrating time constant at the integrators.

The oscillation amplitude is specified by the initial value at the integrator output.

Configuration example structure

The configuration example is divided into the following steps:

1. Creating a new project.
2. Inserting the DCC in the project.
3. Inserting blocks in a DCC.
4. Interconnecting blocks.
5. Parameterizing block connections in the chart.
6. Publishing block connections as parameters.
7. Setting execution sequence within an execution group
8. Compiling the DCC in the DCC editor.
9. Setting sampling time for an execution group
10. Loading the DCC technology option on to the drive unit's CF card.
11. Downloading the compiled DCC to the drive.
12. Displaying values at block connections online.
13. Recording signals from the DCC with the trace.
14. Archiving the project.
15. Creating documentation.

Creating a new project

- Create a new project in the SCOUT or STARTER engineering system, e.g. **dcc_ex**, see Creating a project (Page 5424).
- Create a new device. To do this, insert a "SINAMICS S120 CUxxx" in the STARTER or SCOUT by double-clicking the "Insert single drive unit" command. Select "xxx" to suit your existing hardware (CU320, CU310DP, CU310PN).
- You can now insert a chart.

Inserting a DCC

- Open up the tree structure in the project navigator to the control unit.
- Call **Insert DCC** below the control unit (double-click).

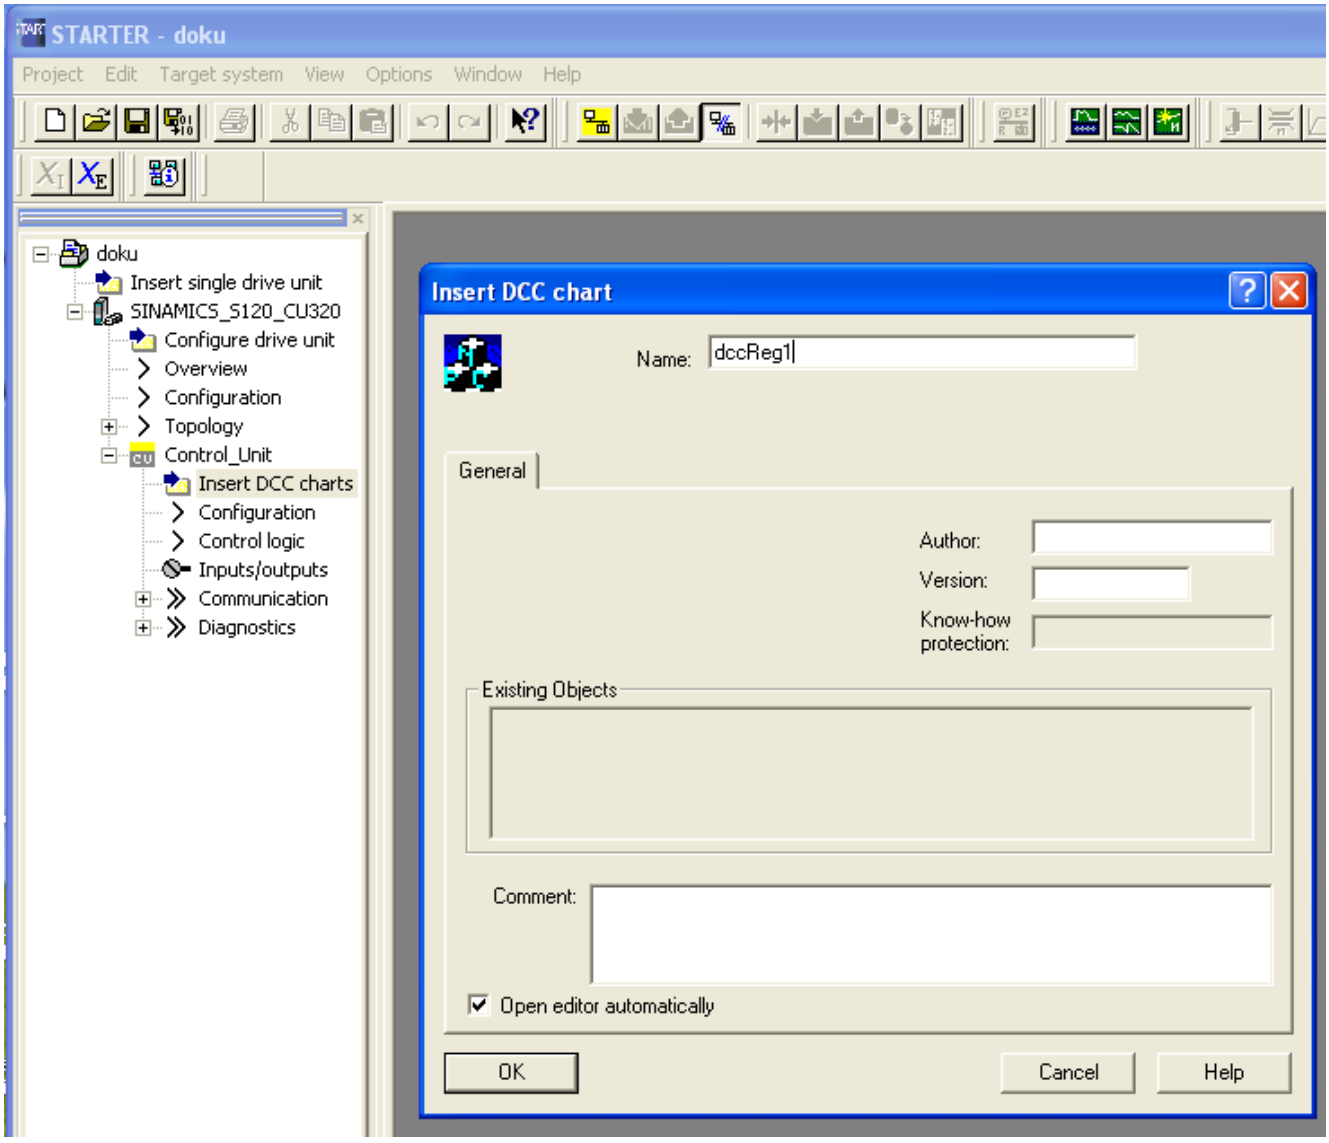

Figure 7-645 Inserting a DCC SINAMICS chart

- The **Insert DCC** window opens and you can enter a new name (of no more than 22 characters) for the chart (in our example *dccReg1*) and a comment. Please note that all characters after an underscore in the chart name can only be digits.
- Click OK to close the window. The DCC is opened when the **Open editor automatically** checkbox is activated
  Alternatively, you can open the chart at any time by double-clicking on the chart symbol in the project navigator.

- When first creating a chart in a project, you will be prompted to import a block library.

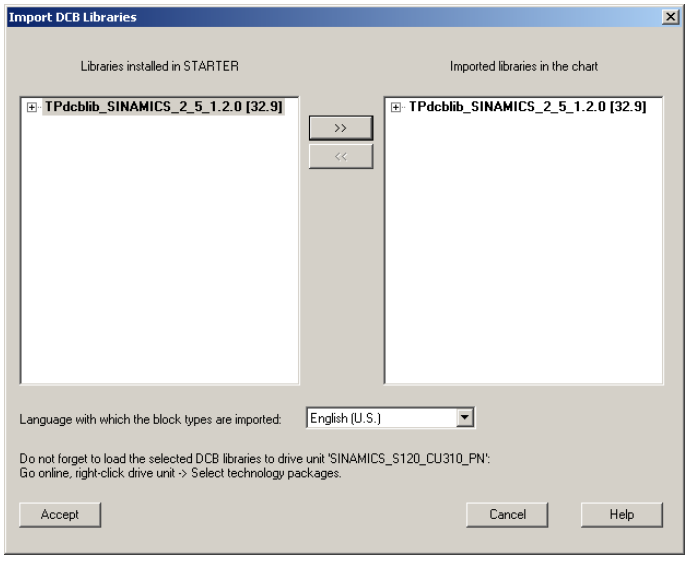

Figure 7-646 Importing a block library

- In the window **Import DCB Libraries**, select the block library in the left column **Libraries installed in STARTER.** Take the selected library into the right column by clicking the **>>** button.
- Close the window with the **Accept** command. The block library is loaded and the DCC editor opened with the chart.

The project structure has now been set up, a chart created and the block library loaded. All that remains is to create some activity within the chart, i.e. by inserting blocks and interconnecting them. Just one chart can be created for each drive object.

Inserting blocks

- Open a block family in the **Closed-loop control** family with the closed-loop control blocks.

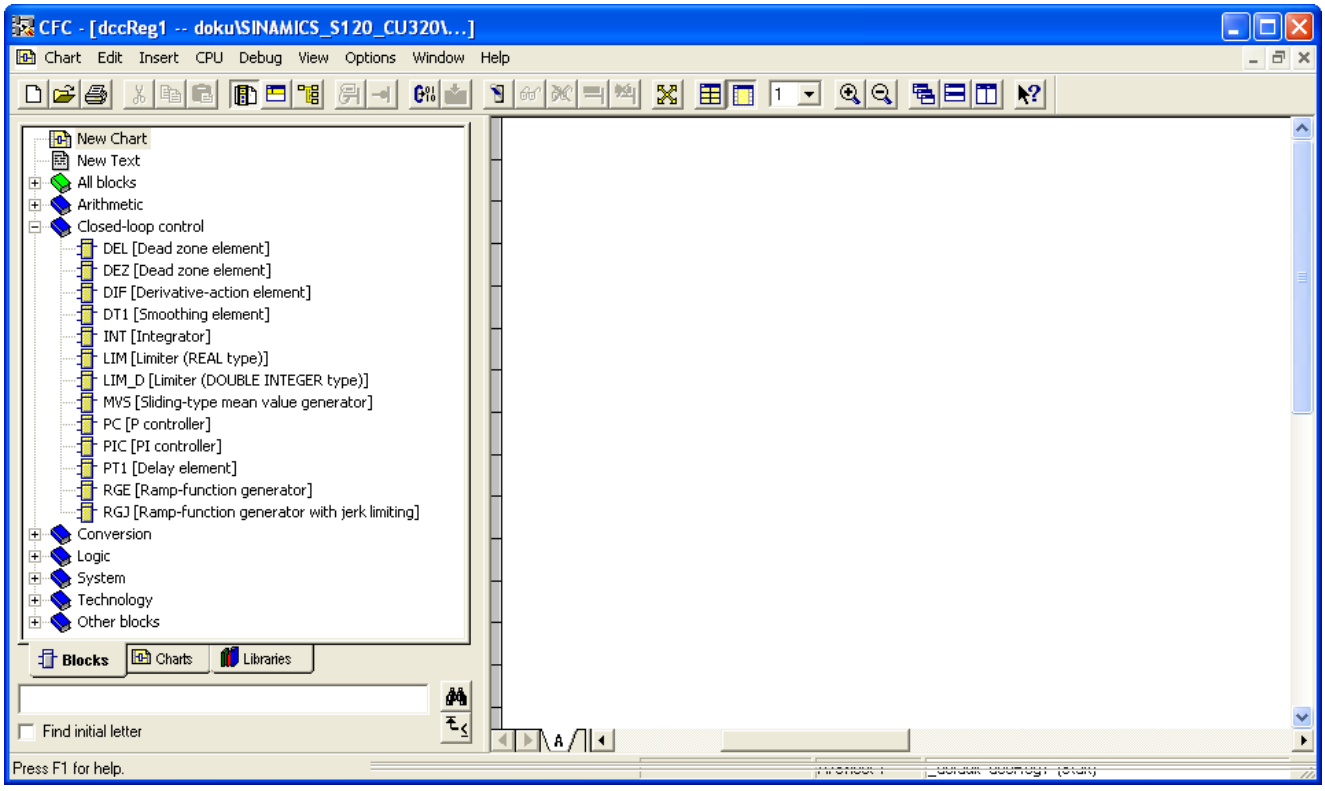

Figure 7-647 DCC editor with opened **Closed-Loop Control** DCB family

- Select the required block (e.g. INT) and insert it in the chart using drag-and-drop. Only the outline of the block in dashed lines is displayed during the copying procedure. Release the mouse button at the required point.

Note

If one block superimposes another block in the chart, the superimposed block will be displayed in gray and its connections will not be visible. You must reposition the blocks to ensure that all connections and block information are displayed.

Interconnecting blocks

Procedure

- Select the **Y** output of the first **INT**egrator, followed by the **X** input of the second **INT**egrator.
- Select the **Y** output of the second **INT**egrator, followed by the **X** input of the inverter (**SII**).
- Select the **Y** output of the inverter (**SII**), followed by the **X** input of the first **INT**egrator.

The autorouter creates the connecting lines from the outputs to the inputs and they are then interconnected.

Parameterizing block connections in the chart

For the first integrator INT 1/1, the following initial values should be assigned to the connections: LL = -10.0, LU = 10.0, SV = 2.0, Ti = 100 ms

For the second integrator INT 1/2, the following initial values should be assigned to the connections: LL = -10.0, LU = 10.0, Ti = 100 ms

To do this, open the **Properties - Connection** window of the respective block connection by double-clicking it. Enter the initial value for **Value** and click **OK** to close the window. Note that for the input of the values for Ti, the "ms" unit must follow the numeric value 100 without any spaces.

As the connections mentioned above are not interconnected, the entered values also remain valid after the initialization. The initialization of the block inputs and outputs is performed before the first cyclic call of the chart.

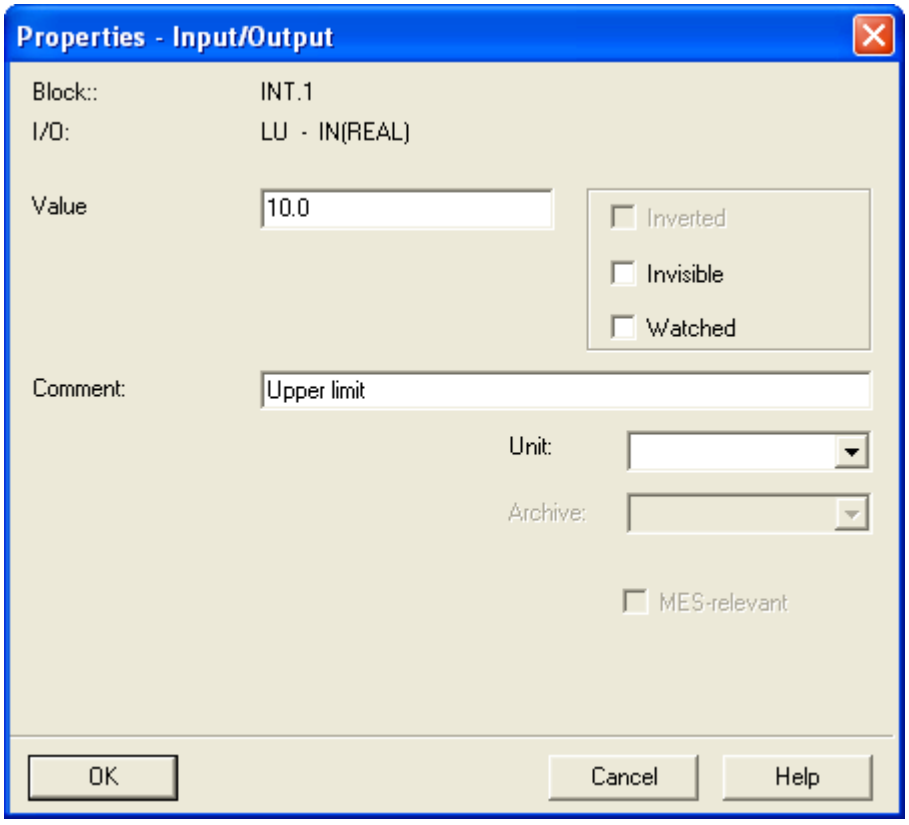

Figure 7-648 Properties window of the "LU" block connection

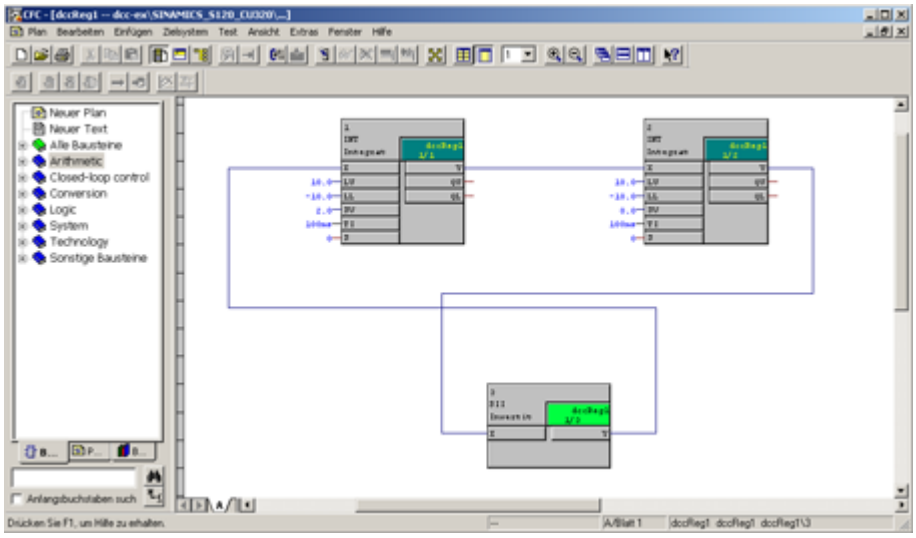

Figure 7-649 Chart "dccReg1" with interconnected blocks. Some connections have been assigned initial values that differ from the factory setting.

Publishing block connections as parameters

To be able to interconnect the output signal of the second (right-hand) integrator to the SINAMICS basic system, it must be published as an interconnectable parameters (i.e. as BICO parameter). To excite the oscillating circuit once, the integrator input of the first (left-hand) integrator must be published as adjustable parameter. The parameter numbers used in the following section have been chosen arbitrarily.

The Y connection of the second integrator is to be published as adjustable parameter. To do this, enter "@*20 output", for example, in the comment field in the Properties window (double-click connection Y). See Creating customer-specific parameters (Page 5543).

Enter "@1 start" in the comment field of connection S (set) of the first integrator. This publishes the block connection as adjustable parameter.

As the default setting of the parameter number base of a chart is always 0, when the chart is compiled, the new parameters r21501 and r21520 are created and displayed in the expert list of the CU drive object in STARTER.

Note

To make this assignment of the @ parameters to the connections in the chart visible, the display form of the connections in the DCC editor must be changed. To do this, open the **Display Settings** window in **Options > Settings > Display**, change there under **Connections** the display from **Name** to **Comment** and click **OK** to close the window.

The chart will then be compiled.

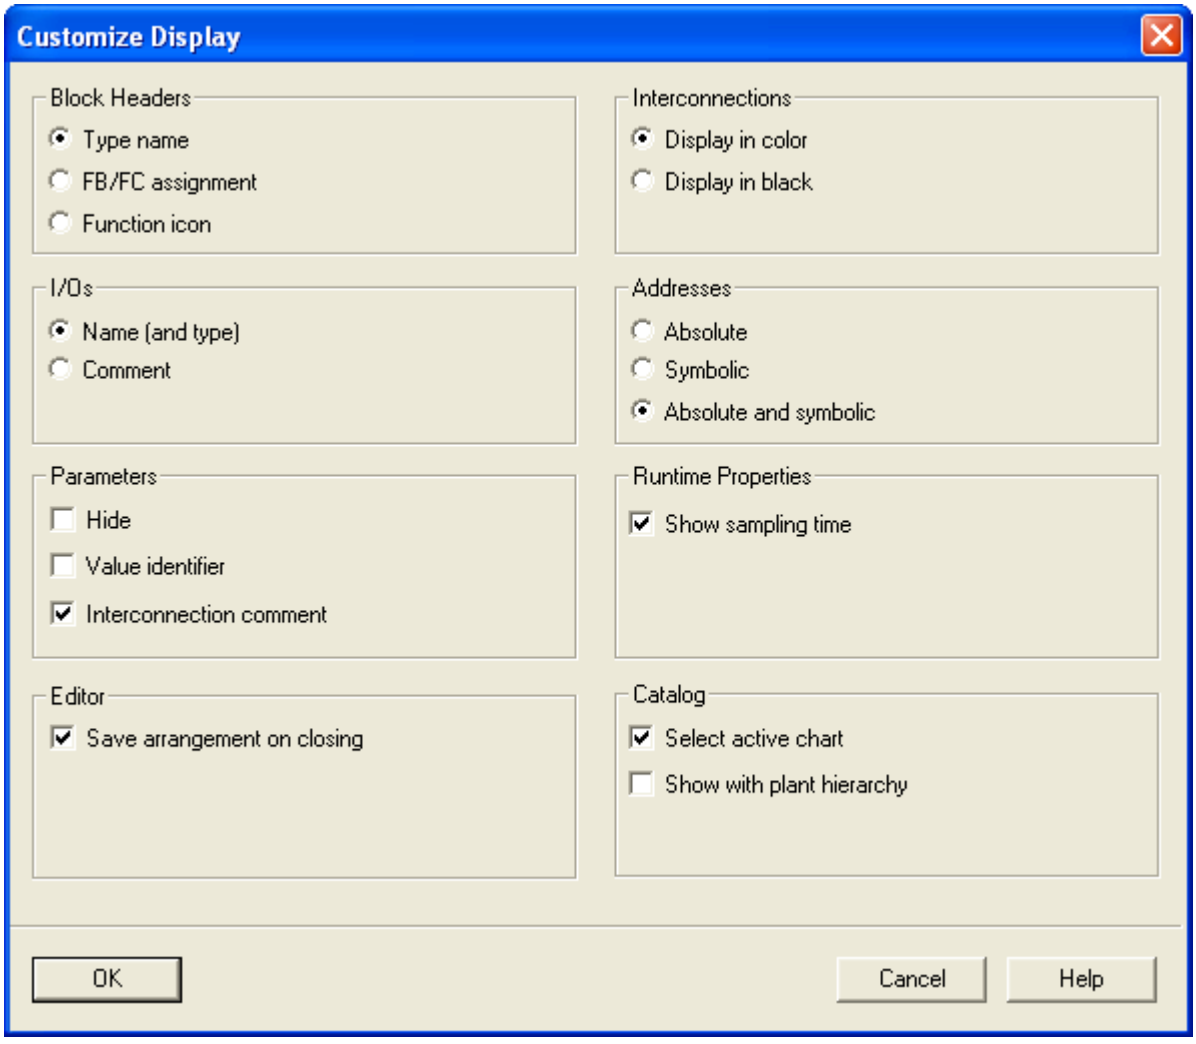

Figure 7-650 **Display Settings** window

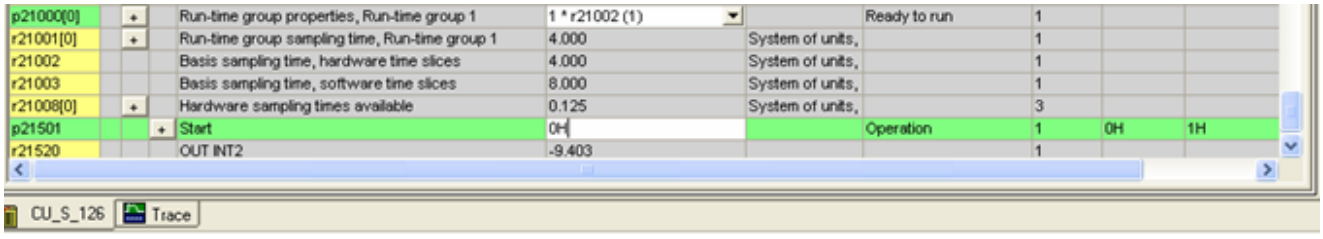

Figure 7-651 View from the expert list with the parameters defined in the DCC

Compiling the DCC chart in the DCC editor

Compiling

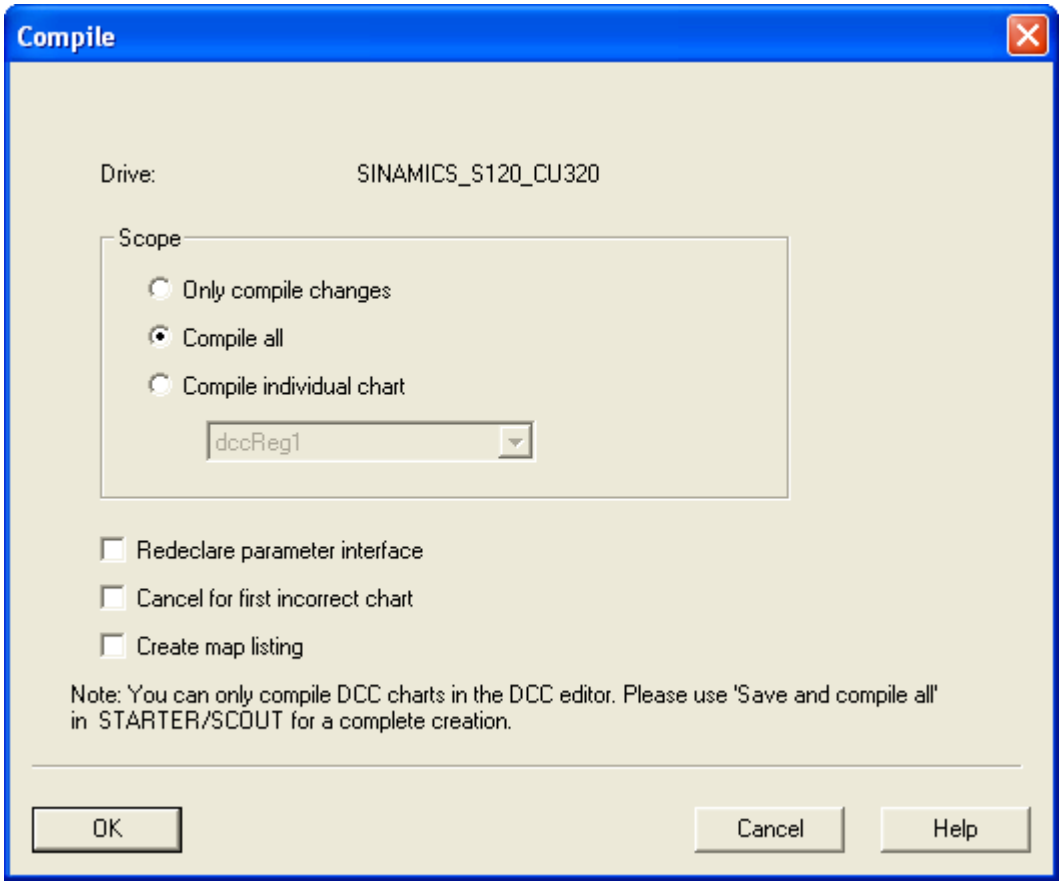

Figure 7-652 Compiling a dialog in the DCC editor

Before the first compilation from the DCC editor, the project must be saved once in STARTER (button).

You can begin compiling from the DCC editor with **Chart > Compile > Charts as program...** or via the button.

You can also start the compiling and saving of a project from the STARTER by clicking the button.

If errors occur during compilation, the **Logs** dialog box will automatically be displayed at the end of the procedure (just as in the case of the consistency check).

Compilation options

For detailed information about the compilation options, refer to Compiling (Page 5450).

After compilation

The compilation log is displayed after compilation. If error messages are displayed, the causes must be corrected before continuing.

Note

Once the DCC chart has been compiled, the interconnections from the DCC chart apply. For detailed information on accepting the interconnections from the expert list into the DCC chart, please refer to the section titled Reading back BICO interconnections and parameters (Page 5572).

Setting execution sequence within an execution group

These are automatically assigned to execution group 1 when the blocks are inserted in a new chart. Execution group 1 is automatically given the name of the chart. The sequence corresponds to the order in which they are inserted in the chart. The sequence can be displayed and edited in the execution editor. You can access the execution editor in the DCC editor via **Edit > Execution sequence** or with  . If an execution group (light blue folder) is selected in the center column in the tree structure, the blocks contained in the execution group are displayed in the right-hand column.

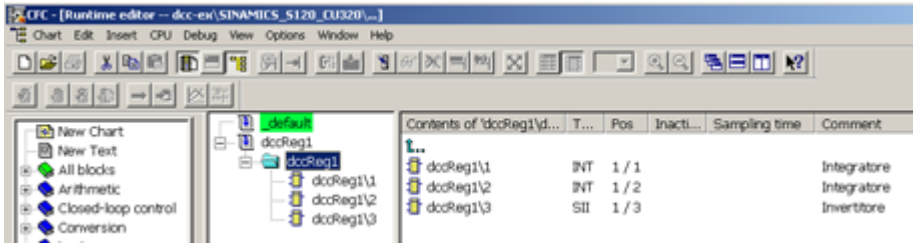

Figure 7-653 Execution editor with open execution group dccReg1

You can return to the DCC by selecting **Edit > Execution sequence** again or by clicking  again.

Setting sampling time for an execution group

The sampling time for an execution group is always set in the STARTER. The DCC you want is highlighted in the project navigator and the **Set execution groups** item called from the chart's context menu. The **Set Execution Groups** window opens.

Our chart was created on the CU drive object. r21002 = 4 ms in this case. A free execution group with a sampling time of 1*r21002 is set.

Note

In the offline mode of the STARTER / SCOUT V4.1.x, r21002 and r21003 are always displayed with the value. The r21002 value is identical with the p0115[0] value on the associated drive object.

When setting the sampling time, note that the minimum sampling time in the drive for DCC execution groups is 1 ms. Only times that are shorter than r21003 may be chosen as a multiple of r21002.

Please re-compile the chart once you have set the sampling time.

Loading the DCC technology option onto the CF card of the drive device

As of SINAMICS 4.3.1, the DCC technology package is located on the S120/S150 CompactFlash Card supplied from the factory for stand-alone drive units. With all other SINAMICS and SIMOTION D4xx CompactFlash Cards, the DCC technology package must be downloaded to the card by means of a technology package download

To load the technology package, call up SCOUT/STARTER and establish an online connection with the drive unit. SCOUT/STARTER is in online mode.

Then in the drive unit's context menu, select the **Select technology packages...** command.

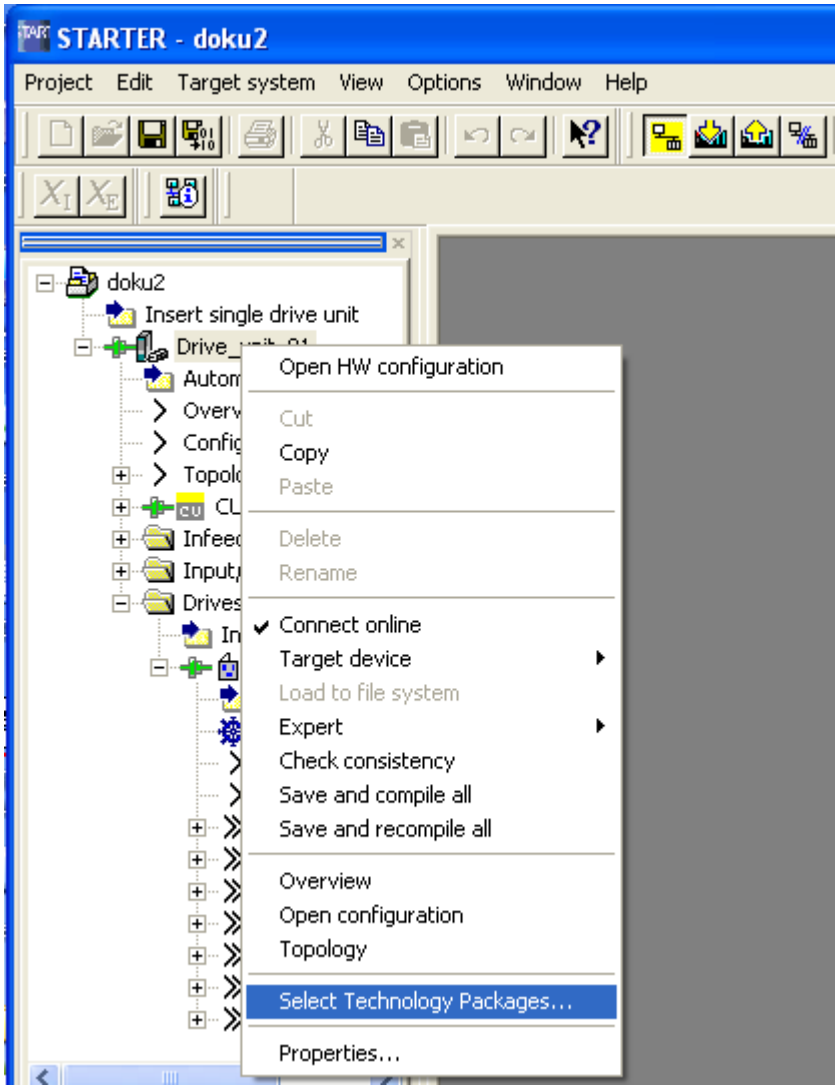

Figure 7-654 Context menu of the drive unit

In the **Select Technology Packages** window, select the desired block library and set **Download** for this library in the action column. Then click the **Perform actions** button in the bottom-right window above the progress bar. The label on the button changes to **Cancel**.

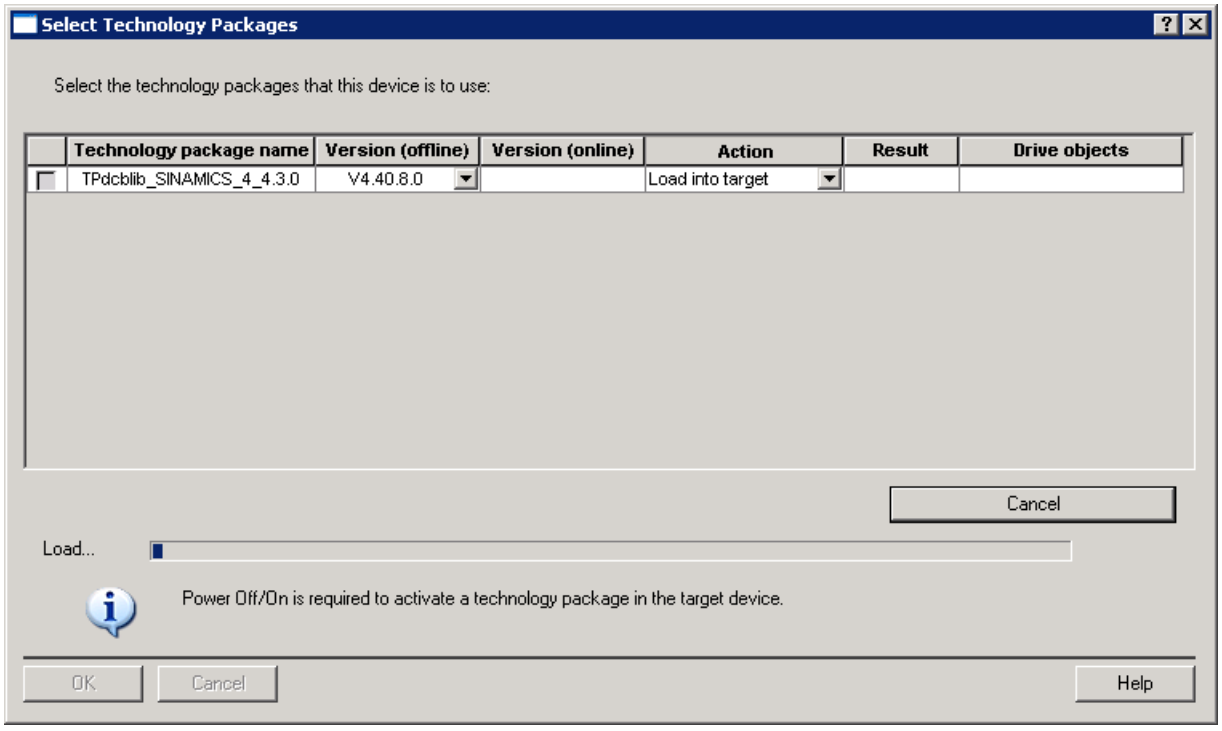

Figure 7-655 Select Technology Packages window

A progress bar shows how the downloading process is progressing. Once the downloading process is complete, the label on the button changes back to **Perform actions**.

The window is closed by double-clicking **OK**.

Note

Once the technology package has been downloaded, the drive unit has to be switched off and on again once. Only once the supply voltage to the CU and/or D4xx has been switched back on and it has been ramped up can DCCs be downloaded to the drive unit and run.

As of SINAMICS 4.4 and with the CU310-2 and CU320-2 modules, it is **not** necessary to switch off and restart the drive unit once the technology package has been downloaded. Once the technology package has been downloaded, an internal ramp-up process is performed automatically. DCC is loaded as part of this process.

When technology packages are deleted from the CompactFlash Card, all the DCC components of all the projects saved on it are deleted at the same time. As of SINAMICS V4.4 and with the CU310-2 and CU320-2 modules, an internal ramp-up process is then performed by the CU. This removes DCC from the CU memory.

Note

When downloading the technology package, as few people as possible should be connected to the bus, as the download time is significantly increased when multiple users are connected.

Downloading compiled DCC chart into the drive

To be able to execute the DCC program on a drive object, it must have first been downloaded to the drive unit. To do this, establish a connection to the drive unit and click the **Download** button in the Online/Offline Comparison window.

Downloading can take place in STARTER at any time via the **Download** function.

After the successful download, the DCC is calculated in cyclic operation on the CU drive object.

Displaying values of block connections online

As of SINAMICS V2.6 and SCOUT/STARTER V4.1.2, the DCC editor can display the values of block inputs and outputs online in test mode. The display is independent of whether a block input or output has been published as parameter. SCOUT/STARTER must be in online mode.

The signal value of block inputs (= connector inputs) published as BICO parameters cannot be displayed. Instead, the signal value of the supplying output can be displayed.

As soon as the test mode is exited again (e.g. by clicking ), the yellow fields with the value display disappear.

If you want to display the values of the connections logged on once for display, by selecting the test mode again, you must set **Test > Laboratory mode** in the DCC editor. This setting is only possible when the DCC editor is not in test mode.

In our example, the output values Y of the two integrators are to be displayed. To do this, open successively in the DCC editor with a double-click on the connection of the **Properties – Connection** window and with a mouse click set a tick for **For test** on the right-hand side in the middle. This registers these outputs for display in test mode. Then use **Test > Test mode** or Ctrl-T or  in the DCC editor to switch to test mode. The values of the two block outputs are highlighted in yellow and refreshed with a monitoring cycle of 2 seconds.

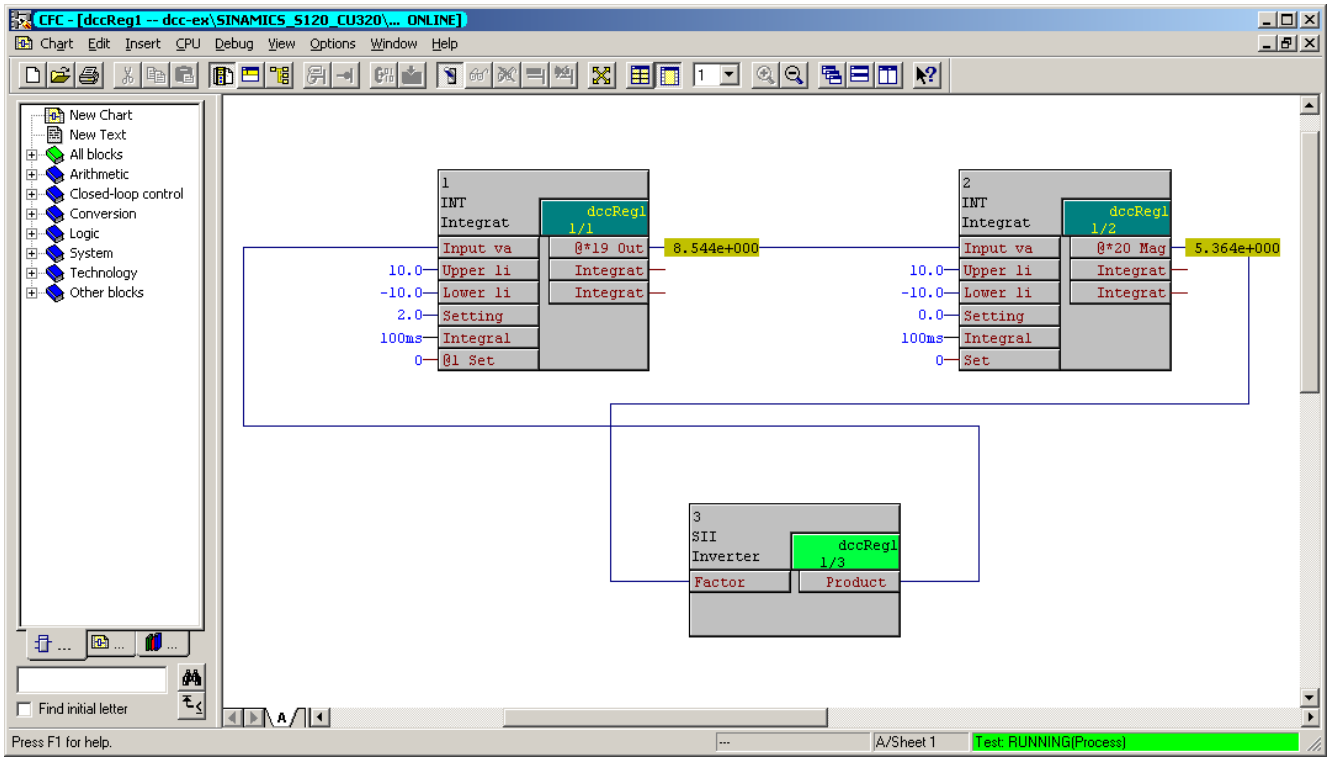

Figure 7-656 Display of the DCC dccReg1 in test mode

To make the oscillator vibrate, it must be excited once. To do this, set the p21501 parameter in the expert list of the STARTER once to "1" (the set value SV = 2.0 is applied at the output of the left-hand integrator) and then reset to "0". The oscillator vibrates and the output values of the integrators show changing values in the chart and in the expert list (r21520).

If you want to make further changes to the chart, you can exit the test mode with **Test > Test mode** or by clicking the button. It can take several seconds before the test mode of the DCC editor is exited.

If you want to display the values of further block connections in test mode, right-click the desired block connection and select **Log on connection** in the context menu.

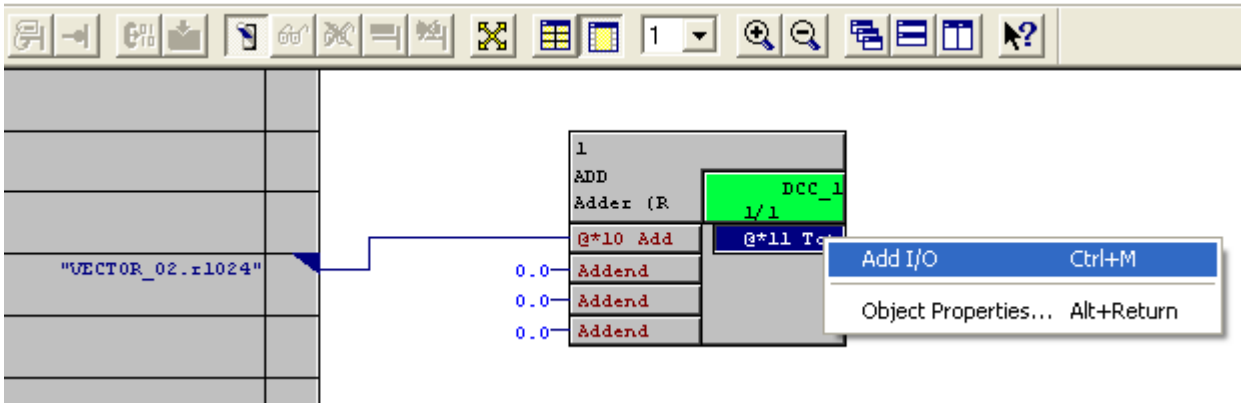

Figure 7-657 Log on connection context menu

If you want to display the signal value of a BICO output of the SINAMICS basic system, the signal value supplied to the DCC via the sheet bar cannot be displayed directly. In this case, an NOP_xx-

block with the correct data type is inserted. The signal value of the output of the NOP_xx- can then be displayed online.

Interconnection to the BICO parameters of the basic system in DCC SINAMICS

Procedure

You can make an interconnection to the BICO parameters of the basic system as follows:

1. Open the DCC chart.
2. Select the DCB connection to be interconnected.
3. Publish the selected connection as a BICO parameter (the comment for the connection must start with "@*", see Creating customer-specific parameters ("publishing") (Page 5543))
4. Right-click and select **Interconnection with operand...** from the context menu. The DCC Signal Selection window appears.
5. Select the parameter to be interconnected. Only those parameters are offered that are compatible according to the BICO interconnection rules. Further information on BICO interconnections can be found in the online help of STARTER/SCOUT under the BICO interconnections index entry.
6. Click OK to close the window.

The block connection is interconnected to the selected BICO parameter.

Note

The interconnected block connections must be published as BICO parameters for connections to signal outputs or signal inputs of the basic system.

The connection can first be made in the DCC editor without publishing the block connections. However, connecting an unpublished block connection to a BICO parameter of the basic system results in an error when compiling the chart.

Note

Interconnections with published block connections, which are established via the expert list, are not read back to the DCC editor. For this reason, subsequent compilation of the DCC chart will result in interconnections created previously in the expert list being overwritten again.

You can prevent interconnections from being overwritten by selecting **Chart -> Read back BICOs and parameters** in the open DCC chart in offline mode and then compiling the DCC chart.

Note

If **symbolic assignment** is enabled in the project, the **Standard/automatic** setting must be changed to **User-defined** in the **Telegram configuration** dialog box for the drive objects in which DCC is used.

The automatic telegram setting and automatic telegram extension must be deactivated.

Interconnection of different data types

When interconnecting to BICO parameters, the data types of the BICO parameter and pin may differ. In this case, you must ensure that the values are not outside the valid value range of the data types. Generally, the LIM DCC block should be connected between the input/output and the BICO parameter for this purpose.

If, for example, a block output with the REAL data type is connected to a BICO parameter of the UNSIGNED32 type, an exception error can occur when the value at the block output exceeds the value value range of an UNSIGNED32.

Deleting and moving BICO interconnections

When moving BICO interconnections, the signal can acquire the value 0 for a few cycles. The no longer interconnected input on the original connection is permanently assigned the value 0.

BICO interconnections and reading back parameters

To display up-to-date BICO interconnections, which have been changed online in the target device, in the DCC editor in online mode, the project must be read back from the target device.

It is also necessary to read back BICO interconnections and parameters to the DCC chart if these have been changed in the expert list. Unless these are read back, the configuration from/in the DCC chart is reactivated after a subsequent download.

Note

Implicit calling of the function "Read back BICO interconnections and parameters"

If drive objects are deleted, the function "Read back BICO interconnections and parameters" will be automatically called.

Procedure

BICO interconnections and parameter values changed subsequently can be read back from the target system via the DCC editor menu command **Chart -> Read back BICOs and parameters**. As of DCC Version 2.1, you can find this under **Options -> Read back BICOs and parameters**.

Input and output BICO interconnections are read back. The read back process always applies to all DCC charts of a device.

Requirements

- The structure of the block instances and interconnections must be the same both online and offline.
- The sources of the DCC chart must be available.

Note

It is not possible to read back BICO interconnections in the case of DCC charts that have been uploaded from a target device to an empty project.

Record with the trace signals from the DCC chart

The integrator output published as interconnectable parameter acts like any other connector output of the SINAMICS basic unit. This means this signal can also be recorded with the trace. The signal characteristic at block connections (that are not published as parameters) can still be recorded with the trace. The trace is called in STARTER with **Target system > Trace** or . In this example, the outputs of the two integrators in the DCC are recorded with a cycle clock of 1 ms. The output of the first (left-hand) integrator is to be recorded as first signal in the trace. The signal selection is opened with for this. Select the drive object on which the DCC is located (only CU_S_126). Open the directory tree and the dccReg1 chart is displayed. Open the directory tree of dccReg1 and the three blocks in the DCC are displayed. The desired connection is on block 1 (top left digit in the block symbol) of the dccReg1 chart. The designation of the connections in the signal selection of the trace is made up of the _ChartName_BlockNumber_, i.e. _dccReg1_1 in this case. The desired connection can now be selected in the list of block connections. The window is then closed by clicking **OK**. See the following figure.

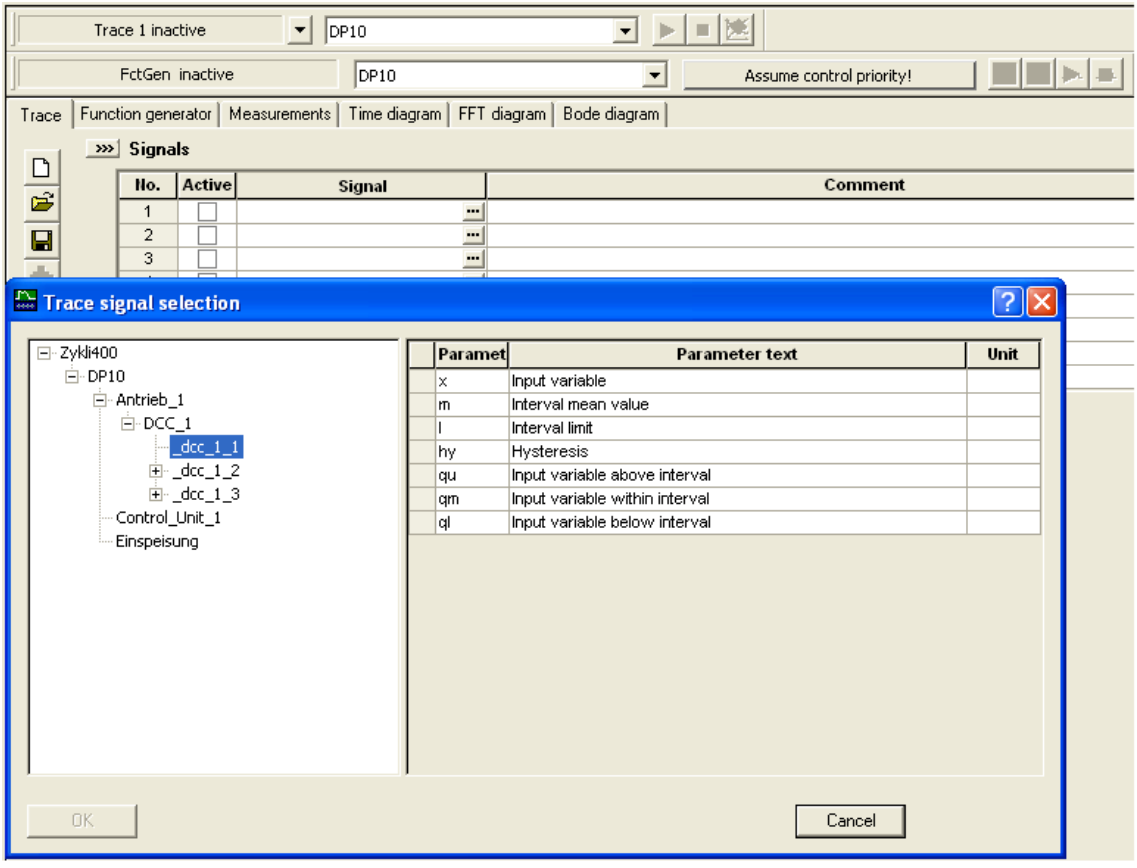

Figure 7-658 Trace signal selection for the block connections of the _dccreg1_1 block in the dccReg1 chart

The output of the second (right-hand) integrator is to be set as second signal. This block output is published as BICO parameter r21520. The recording can be started with the ▶ button.

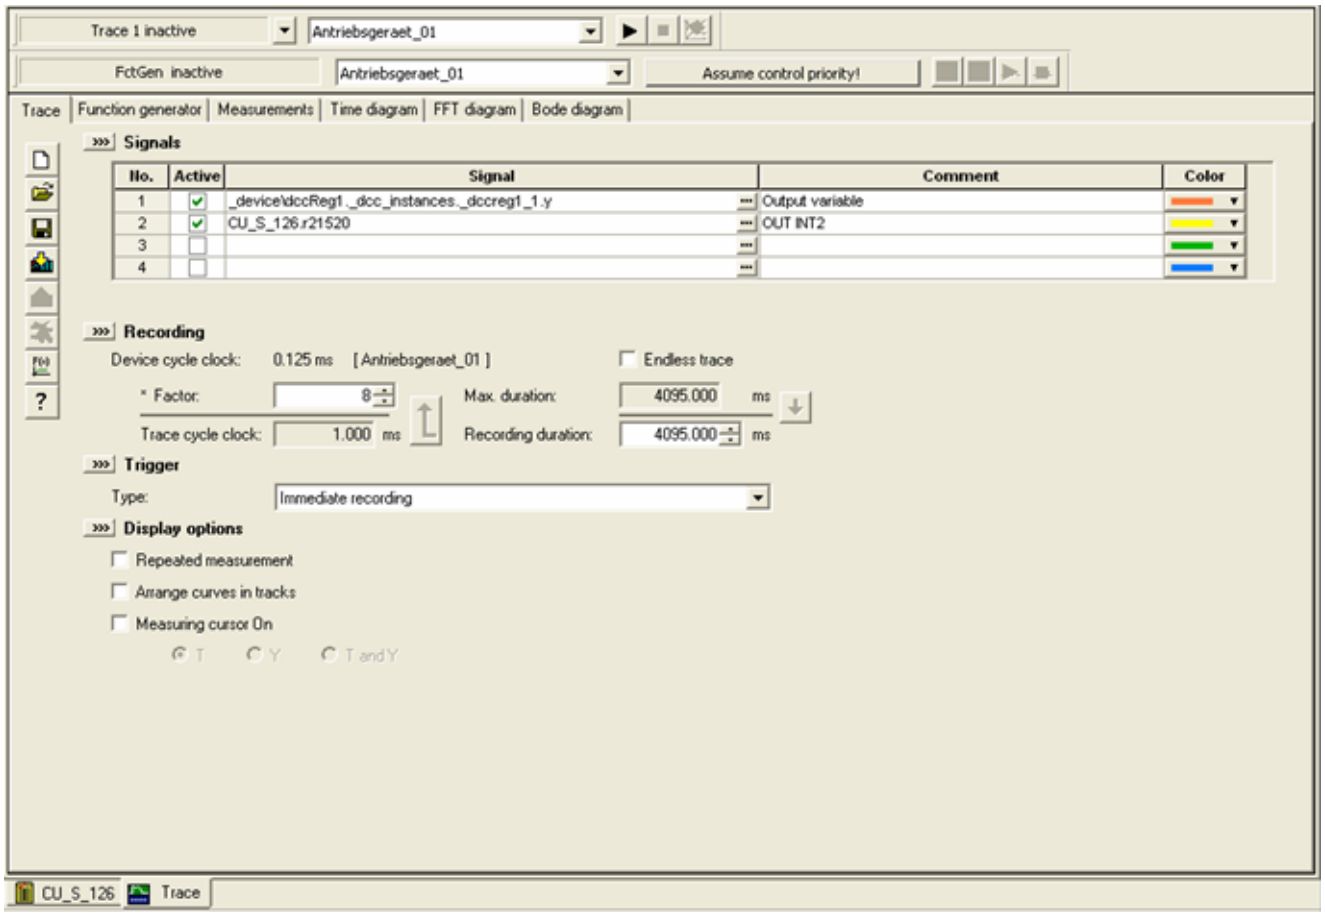

Figure 7-659 Parameterization of the trace

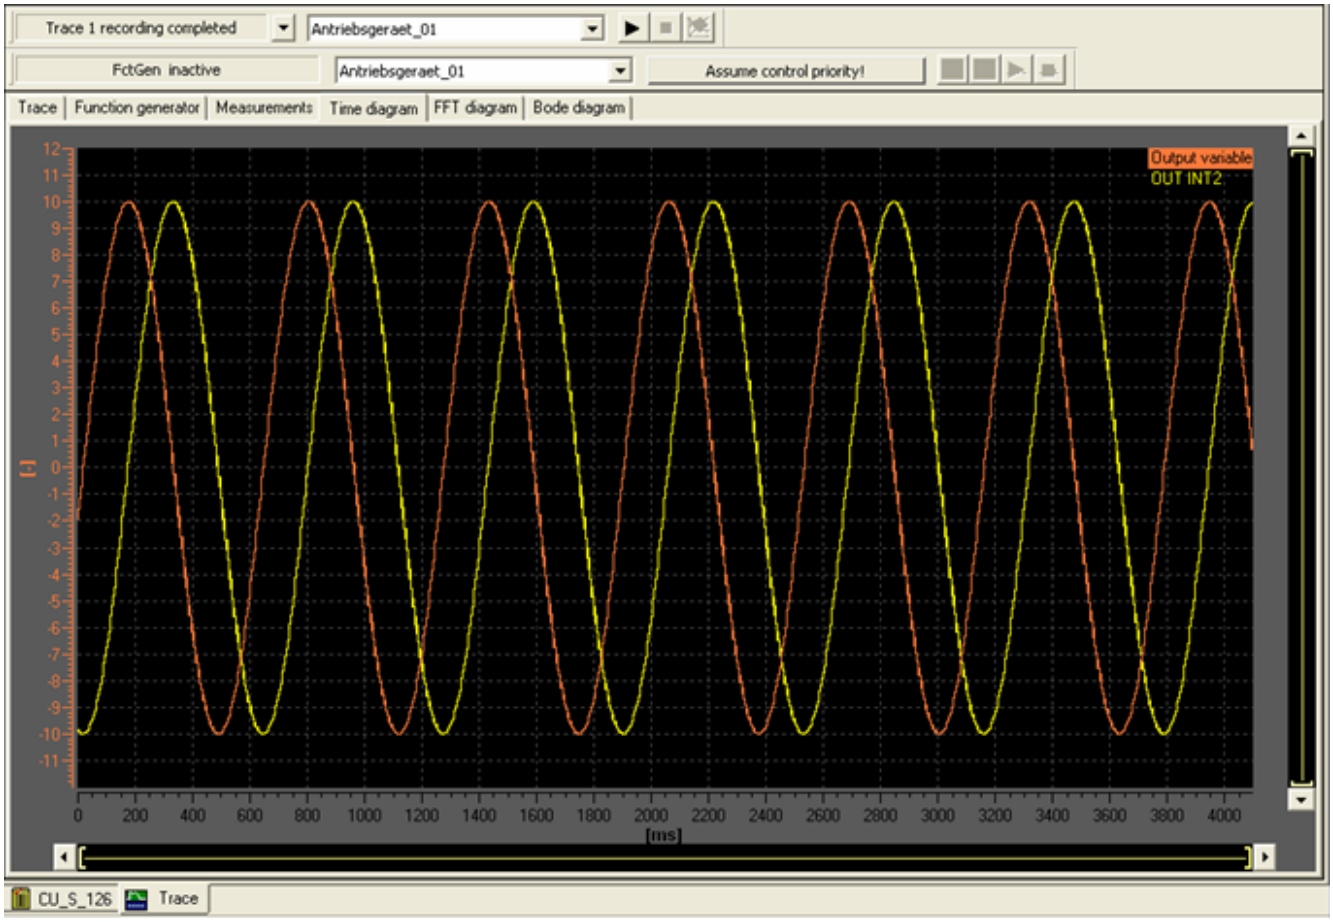

Figure 7-660 Display of the recorded signals as timing diagram

Note

When inserting block instances and connections online, the trace of the signal must be restarted.

Comparing DCC charts

For SINAMICS DCC charts on the drive object (DO) and in the DCC library, a detailed comparison of two DCC charts can be started in the project comparison as of STARTER V4.4 / SCOUT V4.4. The detailed comparison of the DCC charts can be started from the project comparison on the DCC chart.

The chart contents of two charts are compared on the basis of a chart source or compilation. The comparison result is displayed in tabular form. This feature is only available for SINAMICS DCC charts in SCOUT, not for SIMOTION DCC charts.

The detailed comparison can be started for the following comparison attributes:

- Source code (time stamp comparison)
- Blocks
- Interconnections

- Execution groups
- @ parameters and external references

The detailed comparison enables possible inconsistencies between the DCC charts to be precisely identified when going online or when activating the test mode.

The detailed comparison offers the following options:

- If the comparison attributes (source code, blocks, interconnections, execution groups, @parameters) are not consistent, a comparison result is provided with detailed information.
- Tabular list of the comparison result
- If the DCC charts are inconsistent, you can jump to the appropriate position in the DCC chart in order to avoid unnecessary searching in the DCC chart.
- As with the project comparison, the detailed comparison of DCC charts can be performed with the same comparison partners. This means that the detailed comparison can be performed between DCC charts and the project. The DCC charts and the project can be in the offline-offline or offline-online states respectively.
- The DCC libraries are also contained implicitly as "DCC chart" comparison object.

Further information on the DCC detailed comparison can be found in the Project Comparison Manual or in the STARTER/SCOUT online help (Project comparison index).

Archiving a project

If during or after the commissioning, you want to archive the project, including the DCCs, on a data carrier, this is possible with **Project > Archive** in STARTER.

Creating documentation

Complete documentation

The example has been successfully configured and tested. You can now create the complete documentation for your example.

Chart reference data

Alternatively, the chart reference data also displays the execution groups with the block types and the execution sequence. Use **Options > Chart reference data** in the DCC editor to open the **Chart Ref** window.

In the **Chart Ref** window, click the  button to also display the blocks in the configured execution groups. To begin printing, click: 

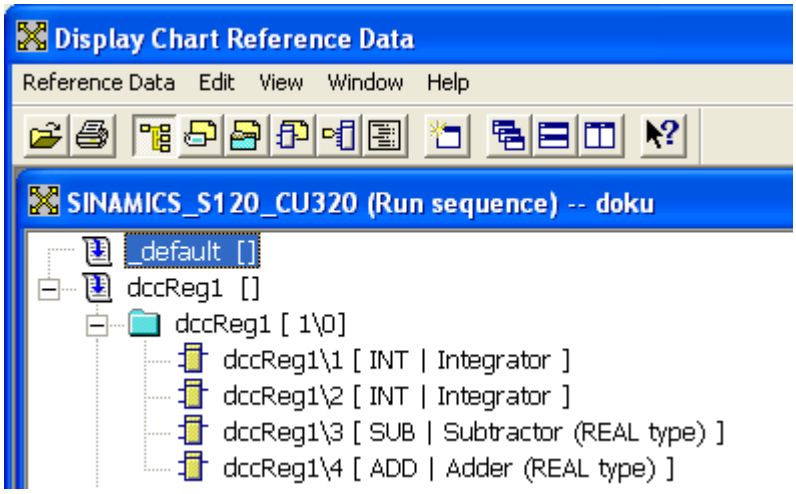

Figure 7-661 Chart Ref. window: Display chart reference data

Printing a chart

You should also print the chart to document the interconnection of the blocks. Because only one page was used on this chart, it suffices to print the current page. To begin printing, click: 

If your chart consists of several pages, we recommend that you print them individually in the page view. Click the  button to change to the page view.

Click  or  to customize the display so that all blocks are shown on a single page on the PC monitor.

Assignment of execution groups

To document the assignment of the execution groups, select the **Set execution groups** command in STARTER in the context menu of the chart. The **Set Execution Groups** window appears. Print a screenshot.

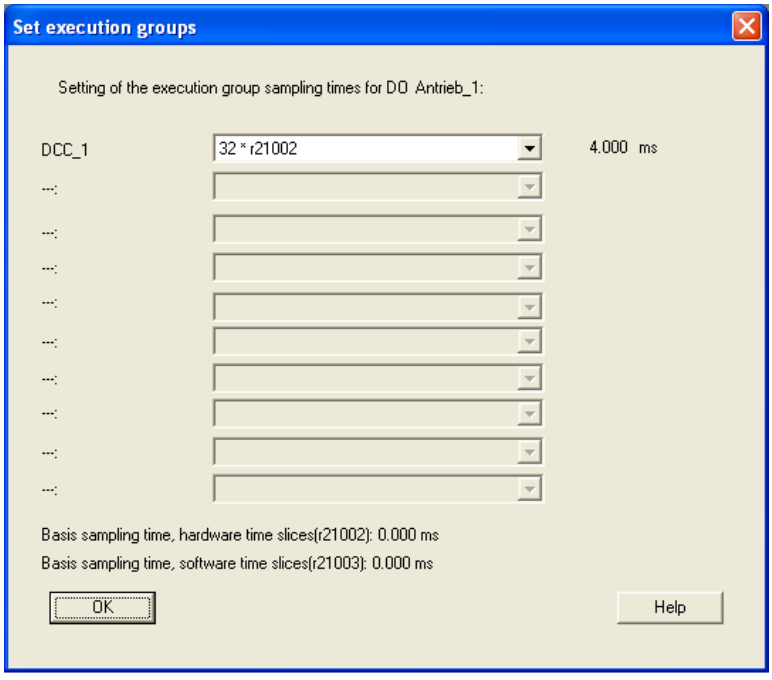

Figure 7-662 Set execution groups window

The change of the hardware r21002 basic sampling time displays the value for p0115[0] in the CU ramp-up of 1 ms. Here p0115[0] was changed from 4000 µs (factory setting) in offline mode to 1000 µs and then downloaded to the CU.

Update to a new SINAMICS version

When using DCC charts, the project must always be updated in the Engineering System and downloaded to the target device.

7.4.4.3 Connecting the DCC to the drive

Overview

Only DCB connections of a DCC chart declared as BICO parameters can be connected to the connector inputs (CI) and connector outputs (CO) of the drive.

All block connections of data type REAL that are published as BICO parameters are per-unit variables. This means that calculations are performed with per-unit signal values within DCC.

(1.0 corresponds to 100%). The conversion to the connector units of the drive is performed automatically.

With all other data types, no conversion to a per-unit variable takes place.

Calculating a DCC chart with per-unit variables

Example 1.1 (interconnecting input value)

Disconnect any online connection to the drive unit in STARTER.
– p1020 = 1 and
– p1021 = p1022 = p1023 = 0
(function block diagram 2505) are set on a drive object of the SERVO (the "Extended setpoint channel" function module must be activated) or VECTOR type. Fixed speed setpoint 1 (p1001 in function block diagram 3010) is then output on r1024 (Speed setpoint active).

The following are also set:
– p1001 = 1500 rpm and
– p2000 = 3000 rpm (reference speed).

Insert a DCC on the drive object.

Insert the ADD block in this chart. Connections X1 and Y of the ADD block are published as (interconnectable) BICO parameters.

Right-click twice on input X1. The context menu opens. Select **Interconnection to operand...**. In the signal selection window DCC now select r1024 (CO: actual speed value effective) and confirm with **OK**.

Compile the chart by selecting **Chart > Compile > Charts as program...**.

Select Set execution groups... in the context menu of the DCC, set the only execution group that is present, e.g. to 20 * r21003 and confirm with **OK**.

Go online with STARTER and download the project to the target system.

Then online in the DCC editor, switch the test mode on with **Test > Set test mode**. Now right-click the output of the adder and select **Log on connection** in the context menu.

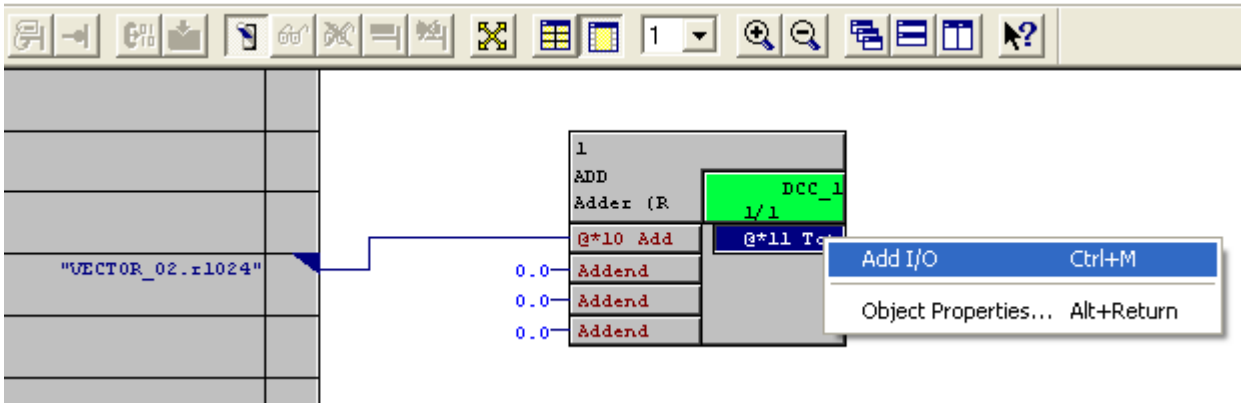

Figure 7-663 **Log on connection** context menu

The current output value (= per-unit speed setpoint = 1500 rpm / 3000 rpm = 0.5) is then displayed.

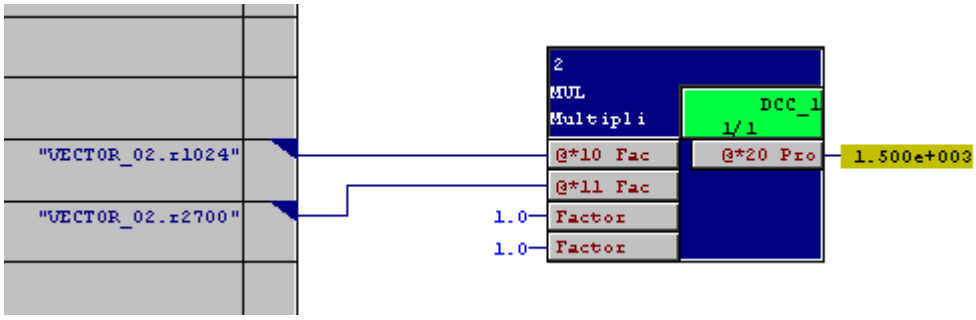

Figure 7-664 Connection value on example 1.1 is displayed

Example 1.2 (interconnecting the output value)

In the DCC chart, a value of e.g. 1.2 should be interconnected with the basic device. The value for this example will be configured as an initializing value to the X input of the NOP module. The module output (Y) has therefore the constant value 1.2, and will be configured as an interconnectable BICO parameter (@*20).

If a connector output of DCC is interconnected with the basic device, this will always be interpreted as a referred value of the basic system. The unit-related absolute value in the basic device now depends on which unit and therefore which reference variable the selected connector input has in the basic system:

When interconnecting the connector input for speed setpoint p1070 (function plan 3030), the referred output value from the DCC chart will automatically be multiplied with the reference variable "Reference speed" p2000 (in the example p2000 = 1500 min^{-1}). In the SINAMICS basic system, a speed setpoint of 1800 min-1 (= p2000 * 1.2 = 1500 min^{-1} * 1.2) will thus become effective.

For this reason, always take note in the case of BICO interconnections with the basic system if you work with absolute variables or with referred variables in DCC. Since the connector output of the DCC chart in the case of interconnection with a unit-related connector input of the basic system will always (internally) be multiplied with the reference variable (belonging to the unit).

Calculating a DCC chart with absolute variables

Example 2.1 (interconnecting input value)

If you want to work with absolute variables in the DCC (in our example using speed values), you have to convert the referenced value to which the variables are automatically converted by the drive into an absolute variable (in our example, a speed) using the reference variable. For DCC, the reference variables are provided as monitoring parameters r2700... r2707 which have no units and can be interconnected. Parameters r2700... r2707 have the special feature that the value is transferred 1:1 to DCC without being divided by the reference variable.

On SERVO type (the "Extended setpoint channel" function module must be activated) or VECTOR type drive objects,
– p1020 = 1 and

– p1021 = p1022 = p1023 = 0
(function block diagram 2505) are set. Fixed speed setpoint 1 (p1001 in function block diagram 3010) is then output on r1024 (speed setpoint active, function block diagram 3010).

The following are also set:
– p1001 = 1500 rpm and
– p2000 = 3000 rpm

r1024 (speed setpoint active, function block diagram 3010) then assumes the value 1500 rpm.

The interconnectable monitoring parameter for the r2700 reference speed indicates a value of 3000 in the expert system.

The multiplier MUL is dragged into the chart.

The 1st factor (X1) is published as a BICO parameter and interconnected with r1024. → Factor 1 = 0.5 (referenced speed setpoint active)

The 2nd factor (X2) is published as a BICO parameter and interconnected with r2700. → Factor 2 = 3000.0 (value of reference variable p2000)

At the multiplier output this results in:

0.5 * 3000.0 = 1500.0

The speed setpoint r1024 is available again in DCC in rpm.

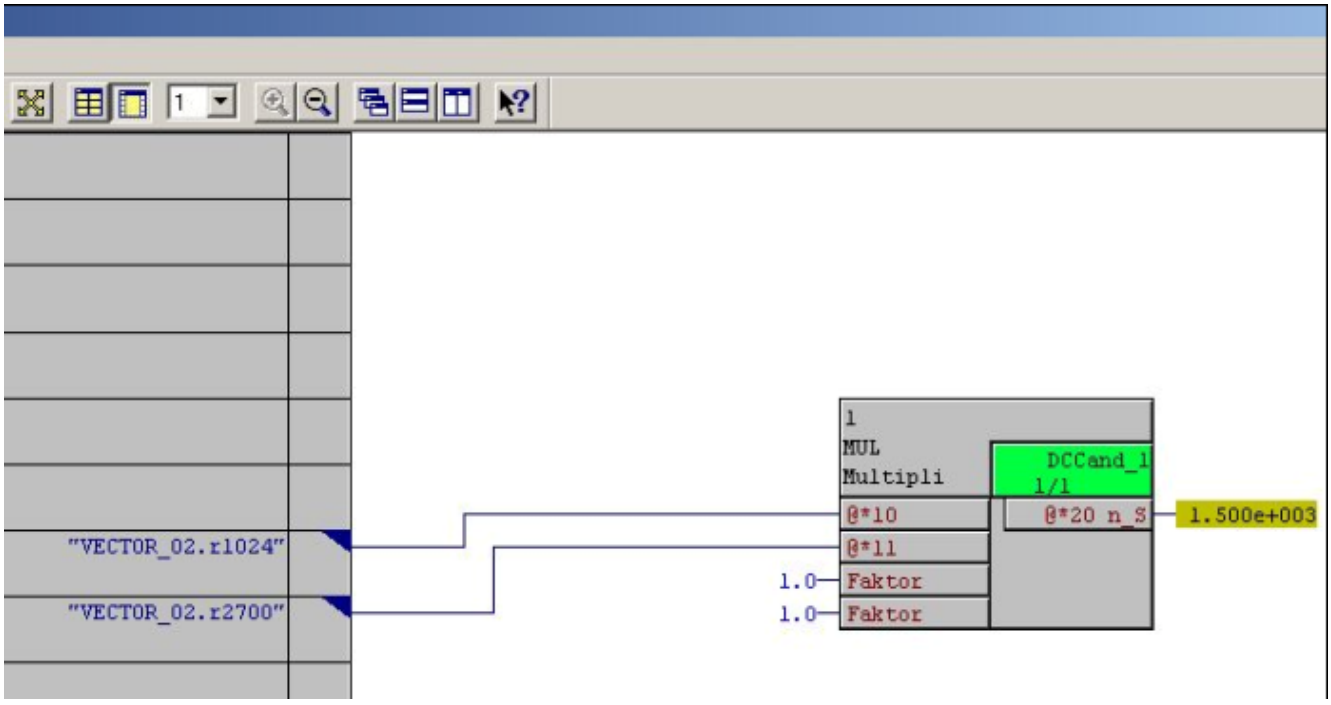

Figure 7-665 DCC for example 2.1 in online test mode

The block was automatically assigned to an execution group when inserted into the chart. The free execution group 20 * r21003 (selected at random) has been assigned to the execution group in the **Set execution group** menu.

Example 2.2 (interconnecting output value)

Absolute values are used in the DCC to calculate the torque in Nm units. The torque setpoint calculated is to be passed on to the "Extra torque M_extra 2" (p1513, function block diagram 6060) connector input. For this to happen, the absolute value must be converted into a referenced torque while still in the DCC. When connecting a real type (== floating point) connector output (CO) from the DCC with connector input (CI) p1513 M_extra 2 [torque in the Nm unit] on the drive, the automatic conversion in the BICO connection always assumes that DCC is providing a referenced signal.

Note

The LIM type block supplies the absolute torque of 0.204625 Nm calculated in the chart at its Y output. This absolute value is now divided by the reference variable for torque r2703 = 0.8185 Nm and the referenced torque value for interconnecting with the drive is thereby calculated. The referenced torque value is available at the block DIV's output and is published as BICO parameter r21530 (value = 0.2499 = 0.204625/0.8185). Block NOP1 has only been inserted so that the value of reference torque r2703 can be shown in the chart at its r21527 output published as a BICO parameter.

Monitoring parameter r1515 (total extra torque, function block diagram 6060) is only calculated if the speed controller is enabled and the drive is magnetized (r0056.4 = 1 = yes). (A machine must be connected to the motor modules and be running for this purpose.) Otherwise the value is set to zero.

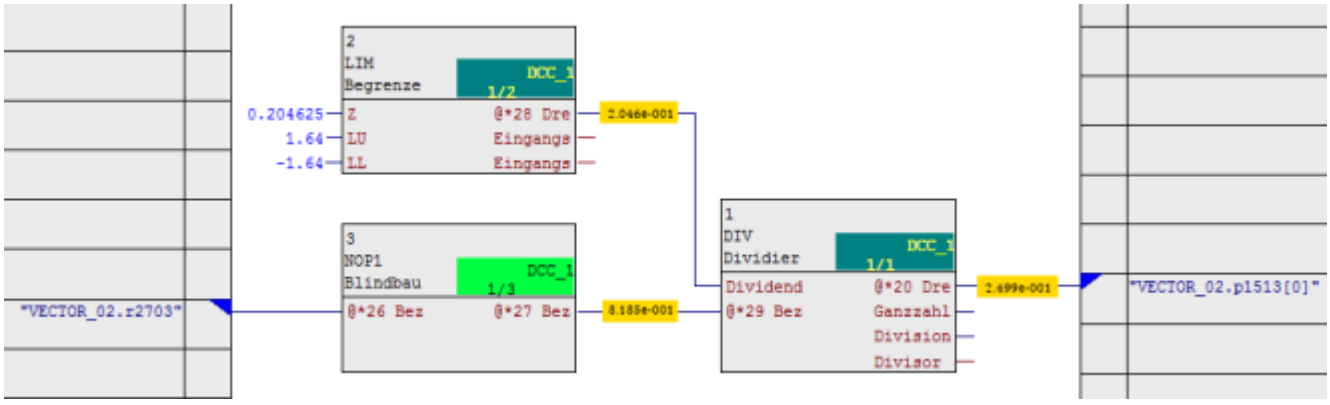

Figure 7-666 Interconnecting output value

Interconnecting DCC signals with communication interfaces IF1 and IF2

Preliminary remark

The basic system can be connected to process data interfaces IF1 and IF2 via free telegram configuration using BICO (p0922 = 999) or via (standard) telegrams depending on p0922. To interconnect with the basic system, the DCC connections needed must be published as BICO parameters. These DCC parameters should always be interconnected with the basic system in the DCC Editor by calling the context menu **Interconnection to operand**.

Interconnecting received process data with DCC

When interconnecting the received PZD data (see SINAMICS S Parameter Manual, function block diagrams 9206 and 9204), the particular way in which the connector outputs (COs) of PZD processing behave (for IF1 r2050, r2060 and for IF2 r8850 and r8860) should be noted. These COs (connector outputs) can either provide their signals in whole numbers (integers) or as floating point values (REAL). The data type provided is determined by the first signal linked to this CO. This can also be determined by a standard message frame having been selected (p0922 |= 999) on a drive object. The PZD COs are thereby automatically interconnected according to the definition of the message frame selected. This interconnection is not canceled when resetting p0922 = 999 == free message frame configuration with BICO.

p1070 = 2060[2] is set for example. r2060[2] (PZD received word 3 and 4) is thereby connected to the main setpoint (in function block diagram 3030) of a REAL variable of the basic system. This means that only connector inputs from DCC with the REAL signal data type can be interconnected on r2060[2].

Note

Connections to integer inputs can be made both online and offline in the DCC editor; a corresponding error message is only issued when the chart is downloaded.

Interconnecting sent process data with DCC

The send data is interconnected as with any other BICO connection.

Detailed descriptions about this topic are contained in the *SINAMICS S120 function manual*.

7.4.4.4 DCC SINAMICS specifications

Rules for assigning names in the DCC editor

Names are used for data exchange between SCOUT/STARTER and the DCC editor.

The names in the DCC editor must therefore abide by the following rules:

- Basic chart:
  - No keyword or previously defined name permitted
  - Must start with a letter or underscore
  - May contain numbers, letters, and underscores
  - An underscore must be followed by a number
- Subchart:
  - Must start with a letter
  - May contain numbers and letters
  - Underscores are not permitted
  - Keyword or previously defined name permitted
  - In the DCC editor, a check is performed to determine whether the name has previously been defined.
- Block instance:
  - Can start with a number
  - May contain numbers and letters
  - May not start with an underscore
  - Keyword or previously defined name permitted
  - In the DCC editor, a check is performed to determine whether the name has previously been defined.
- Execution group:
  - Keyword or previously defined name permitted
  - In the DCC editor, a check is performed to determine whether the name has previously been defined.
- BICO parameter:
  - No previously defined parameter numbers permitted
  - In the DCC editor, a check is performed to determine whether the parameter number has previously been defined.

Field/name lengths and conventions

Field/name lengths and conventions

Object	Length	Remark
Chart name	22 *)	May not contain the following characters: \ . : / * ? " < > | # % ( ) Use of the "_" character is subject to particular specifications.
Chart comment	255	All ANSI characters are permitted.
Execution group	22	Only letters, numbers and underscores may be used.
Block instance comment	80	All ANSI characters are permitted.
Parameter comment	80	All ANSI characters are permitted.
Block name (instance name)	16 *)	May not contain the following characters: \ . : / * ? " < > | # % Use of the "_" character is subject to particular specifications.
Global operand	Max. 49	Interconnection with BICO parameter.

*) The chart name and block name must jointly consist of a maximum of 24 characters, including separating characters.

Representation of the dynamic value display

The values are output next to the connections, according to their data type. They are displayed on the screen with a colored background.

Table 7-614 Representation of the dynamic value display

Representation	Meaning
Blue on white	Representation of the values in edit mode (offline)
Black asterisks on yellow	Values during transfer to the dynamic display
Black value on yellow	Representation of the values read from the drive object in test mode
#### on a red background	Representation of values while the dynamized values required from the drive object are missing (fault, overload)

7.4.5 DCC for SIMOTION

7.4.5.1 Overview

Introduction

This product brief is intended for experienced SIMOTION users who are not yet familiar with the DCC program package. Using a short example, you will find out how to create a project after starting up SIMOTION SCOUT, create a DCC chart, interconnect blocks, compile the chart, download it to the target device and test it online.

Note

In most cases, there are a number of options for working with the DCC editor (e.g. using the keyboard). In this example, the quickest or most suitable option is used. Apart from a few exceptions, no alternative methods of operation or procedures are explored here.

Software requirements

The software requirements for DCC are the same as those for SIMOTION SCOUT.

You require an appropriate license to use the DCC editor.

Please refer to the following table for information on which kernel version supports which DCB libraries.

Kernel version	DCB lib version
SIMOTION 4.1.5	4.1.2, 4.1.4, 4.1.5
SIMOTION 4.2	4.1.5, 4.2

SIMOTION system integration

Execution level, execution group and execution sequence

DCC tasks and execution groups

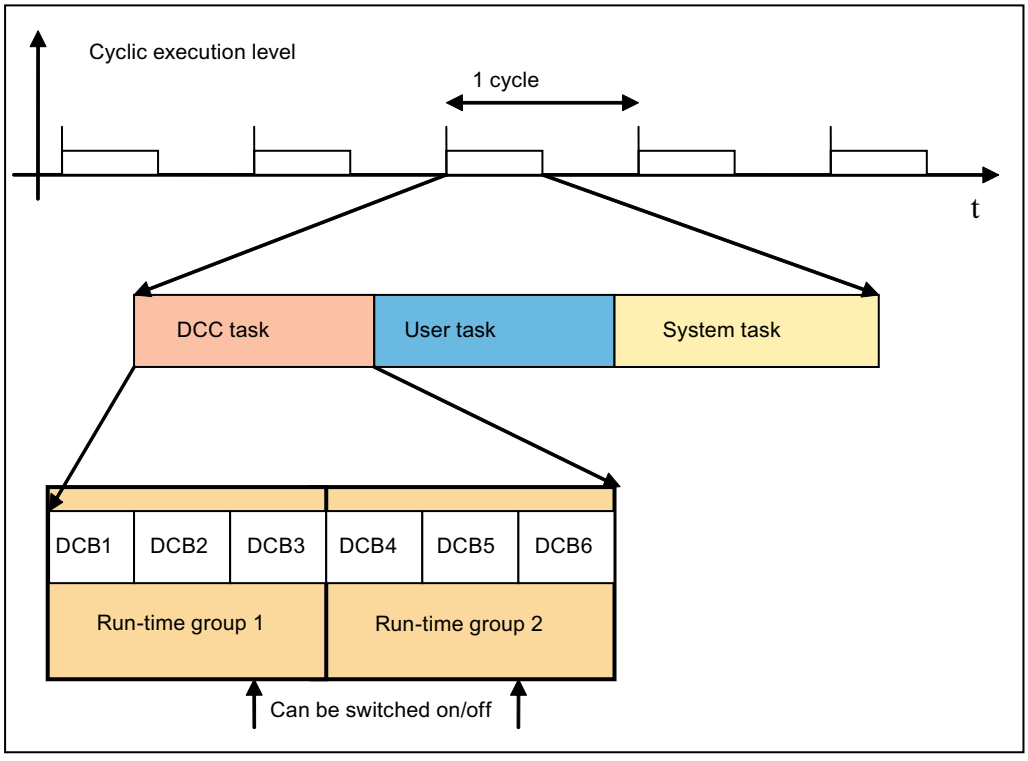

Figure 7-667 Sequence model for blocks

Tasks

A DCC task is available for the user programming in each of the five cyclic execution levels (in descending order of priority):

- T1: servodcc in the servo level
- T2: ipodcc in the IPO level
- T3: ipodcc_2 in the IPO_2 level
- T4: dccaux in the DCCAUX level
- T5: dccaux_2 in the DCCAUX_2 level

Further information on the execution system of SIMOTION can be found in Section *Execution system / tasks / system cycle clocks* of the *SIMOTION SCOUT Basic Functions* Function Manual.

Execution groups

The available tasks (sampling time and execution sequence in the system: T1 to T5) are assigned execution groups. The blocks are embedded into these execution groups. The execution groups therefore allow the task to be structured or divided as required by the user; e.g. dancer control, setpoint processing, etc. The execution groups are embedded sequentially into the blocks. **Only** blocks **from one** basic chart may be contained in an execution group.

You can use the "Enable" attribute to activate and deactivate an execution group. Normally, execution groups are processed in cycles; however, the enable attribute can be used for switching individual execution groups on and off.

A BOOL-type block output can be connected to enable an execution group or a block group. To do this, highlight the connection to be interconnected and select the **Interconnection with execution group**... command in the context menu.

Note

The **Interconnection with execution group**... command is only supported with DCC SIMOTION.

Execution sequence

For tasks: The execution sequence corresponds to the sequence in which execution groups and blocks are inserted within a task.

The same applies to groups: The sequence in which the individual blocks are inserted is the execution sequence within the execution group.

You can change the execution sequence.

Setting the system cycle clocks

The properties that determine the execution behavior of a task are configured in SIMOTION. You can carry out parameterization in the Properties dialog box of the CPU under **Expert execution system > Set system cycle clocks**.

No multiple insertion of blocks in different tasks

Inserting a block several times in different tasks is not permissible.

Changing the execution sequence

- Click **Edit > Execution sequence** or the  button.

The **Execution Sequence** window appears: In the left-hand side of the window, you will see the structure of the task. In the right-hand window, the content is displayed. The default integration position of the blocks is in cyclic task **T2**, in the default execution group that has the same name as the chart.

To move blocks that have already been inserted from task **T2** to higher-priority task **T1**:

- Double-click the **T2** symbol.
- The execution groups are displayed in the right-hand window:
  - When you highlight the execution group, the blocks it contains are displayed (including the chart/block name, comment and position).
  - Highlight the execution group that you want to move in task **T2** and use drag-and-drop to drag it to the task **T1** symbol in the left-hand window. The right-hand window is now empty.
  - When you double-click task **T1** to open it, the execution group that you have moved will be displayed there.
- Close the window via **Chart > Close** and proceed to the next step.

HMI variables (publishing of variables and @ variables)

HMI variables

You can declare block inputs and outputs as **HMI variables** and therefore generate a static interface for these for use in your system visualization. This interface is largely static from an HMI point of view, i.e. not every change made to the DCC configuration demands that the address information of the HMI system be reimported.

The memory image with the HMI variables is **not** automatically deleted during compilation. It is only deleted on request.

HMI variables that are removed from the DCC when the block that defined them is deleted remain in the memory image until **reorganization** is requested during compilation in the DCC.

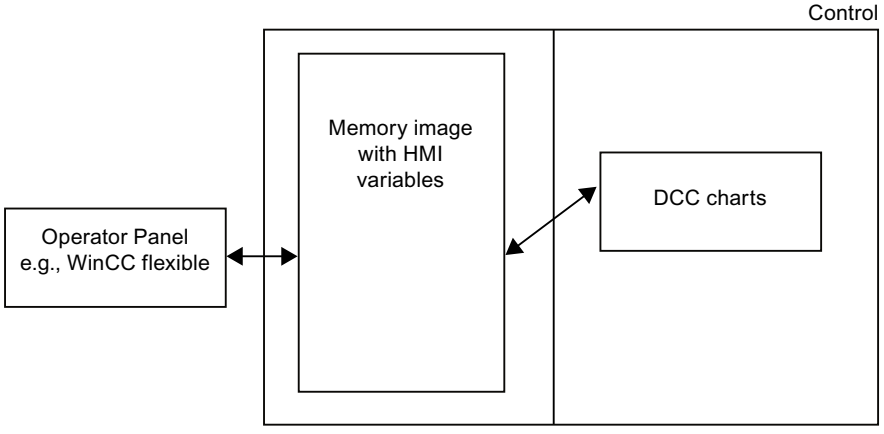

Figure 7-668 HMI variables

@ variables (SIMOTION)

Structure of the @ variables

In the comment, block inputs and outputs are published by the variable name preceded by @.

Table 7-615 Structure of comments in SIMOTION

Comment	Meaning
SIMOTION: @name <<variable comment>>	The connection is entered as an HMI variable in SIMOTION. Name is the part before the first blank (whereby you must adhere to the ST conventions (Page 5609)).

The text which follows the variable name (separated by a blank), is transferred as a variable comment. It is then displayed in the symbol browser. The variable identifier results from the variable name.

The data type of the published input/output is taken over by the block connection. Where necessary, it is mapped onto the appropriate data type of the engineering system.

No help function can be created for @ variables.

Exporting to WinCC

Procedure

A created DCC chart can be exported to WinCC, whereby the export specifications of the SIMOTION SCOUT also apply for DCC charts. However, for this to happen the OPC-XML export must be activated in the Properties dialog box of the chart in SIMOTION SCOUT.

In the engineering system, right-click the chart and select **Properties** in the context menu. The export is activated via **Enable OPC-XML** on the **Compiler** tab.

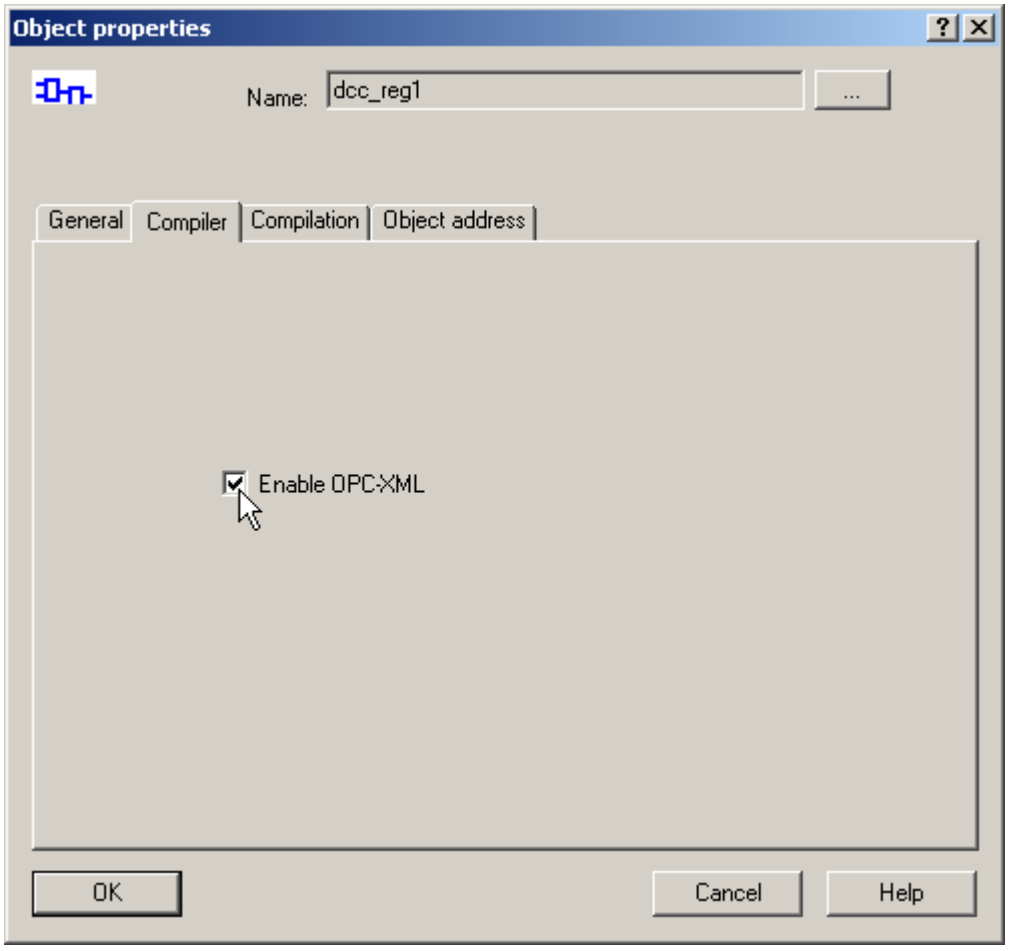

Figure 7-669 DCC chart properties - OPC-XML export

The export can be performed in SIMOTION SCOUT via **Options > Export OPC data**.

Interconnecting with SIMOTION variables

Interconnecting with SIMOTION variables

You can interconnect with global operands (SIMOTION variables) in the DCC editor.

Note

Please observe the Specifications for assigning names in DCC SIMOTION (Page 5609).

Procedure

Interconnection can be performed as follows:

1. Select the block connection to be interconnected.
2. Execute the **Insert > Interconnection to operand** command in the menu. The interconnection to a global operand can also be performed via the context menu of the block. The **Symbol Input Help** window appears.

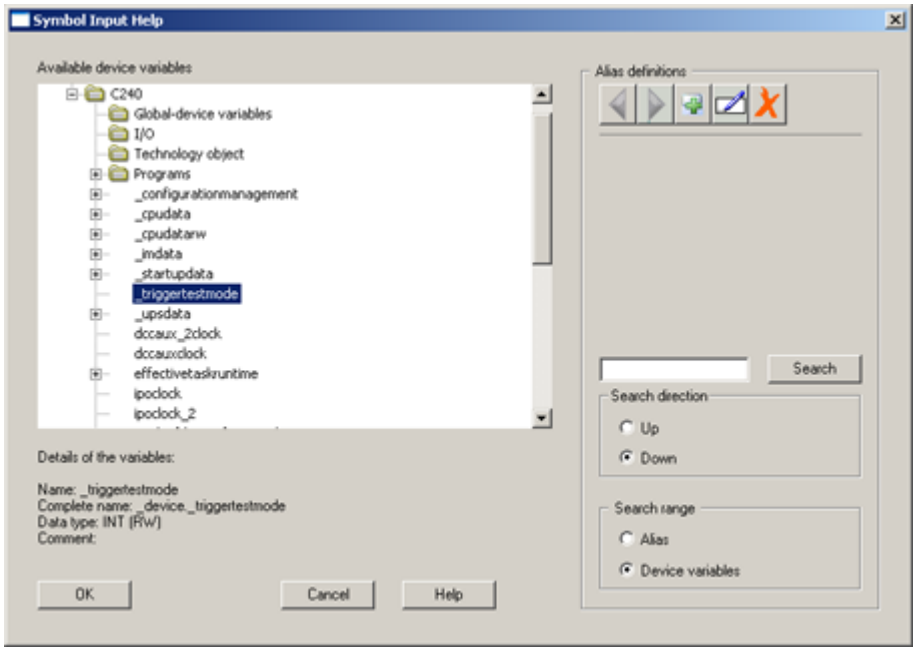

Figure 7-670 **Symbol Input Help** window

3. You can now navigate in the CPU or technology object assigned to the chart and select the device variable to be interconnected – the application highlights compatible device variables in bold-face type.
4. Click **OK** to close the window.

From this point on, the selected block connection is interconnected with the global operand and the global operand is represented by a sheet bar variable in the DCC editor.

Note

The global variables and the I/O variables must first be created and then the interconnection performed.

Note

You can search for a variable name or a parameter text in the search field of the **Symbol Input Help** dialog box.

Interconnection to array elements

You can interconnect array elements of ST programs in the DCC editor.

Procedure

Interconnection can be performed as follows:

1. Create a new ST program with an array variable in the SIMOTION SCOUT engineering system using the **Insert ST program** command.
2. Right-click and select **Interconnection with operand** from the context menu. The **Symbol Input Help** window appears.

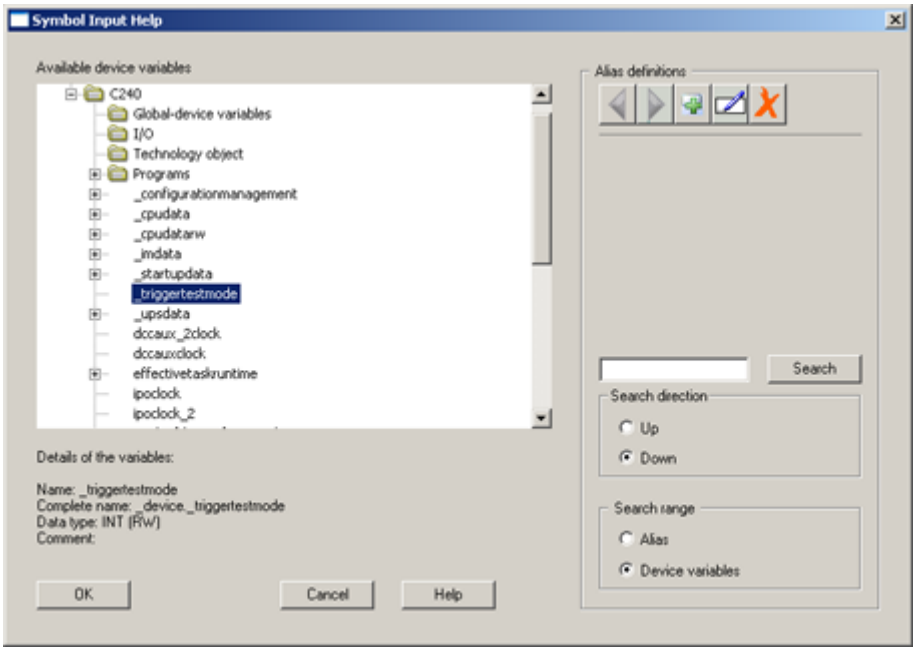

Figure 7-671 Symbol input help window

3. Select the array variable to be interconnected.
4. Enter the number of the array element to be interconnected.
5. Click **OK** to close the window.

From this point on, the selected block connection is interconnected with the array element and the array element is represented by a sheet bar variable in the DCC editor.

Alias parameter

You can assign alias identifiers in the DCC editor for variables. The reason for assigning an alias may be that a name is too long - the DCC editor only accepts a maximum of 49 characters for identifiers.

Procedure

An alias can be created as follows:

1. Right-click the block connection and select **Interconnection with operand** from the context menu. The **Symbol Input Help** window appears.
2. Select the connection that is to be defined by the alias.

3. Click the button from the alias definition area.

4. Enter the alias name in the entry field.
5. Close the window.

The alias has been successfully created and can now be used - the computer now resolves the alias as required, e.g. within the framework of the compilation.

DCC and SIMOTION trace

As accustomed with SIMOTION-based devices, you can trace each block connection as a variable or use it in the trigger condition in SCOUT.

7.4.5.2 Working with DCC SIMOTION

Preliminary remarks on configuration

Preliminary remarks

The following is a brief explanation of what you will be configuring in this chart.

Configuration example

The configuration example deals with a straightforward oscillating circuit that creates sinusoidal oscillation at its output.

It will only take you a few minutes to create the chart; then you can execute it in test mode as a demonstration.

The following blocks are used:

- Two integrators (**INT**)
- One inverter (**SII**)

As indicated by the differential equation **f"(x) = - f(x)**, the oscillating circuit is comprised of two integrator blocks that are linked by negation.

The frequency of the oscillating circuit is determined by the integrating time constant at the integrators.

The oscillation amplitude is specified by the initial value at the integrator output.

The DCC editor can be started via the SIMOTION SCOUT engineering system.

Configuration example structure

The configuration example is divided into the following steps:

1. Creating a new project
2. Inserting the DCC in the project
3. Inserting blocks in the DCC
4. Interconnecting blocks in the DCC
5. Compiling the DCC in the DCC editor
6. Downloading the compiled DCC program to a CPU
7. Starting the CPU
8. Switching between process and laboratory mode
9. Setting test mode and the test mode types
10. Monitoring values in laboratory and process modes
11. Logging on and logging off connections for monitoring
12. Using the "Enable" attribute for execution group control
13. Creating complete documentation for the example
14. Information on the chart reference data function

Creating a project

- Create a new project in the SIMOTION SCOUT engineering system, e.g. **dcc_ex**, see Creating a project (Page 5424).
- Create a new device, e.g. a D445, using **Create new device**.
- Select the package **TPdcblib_SIMOTION_4_2.3.0 [x.y]** and close the window.
- You can now insert a chart.

Inserting a chart

- In the project navigator, double-click **Insert DCC** under **Programs**.
- Now give your chart another new name. The text field for the DCC name is selected automatically and the cursor is activated.
- Edit the new name here: **dcc_reg1**.

- If the **Open editor automatically** option is activated, the DCC will be started automatically. Alternatively, you can open the DCC by double-clicking **dcc_reg1**.
- If a library has not yet been imported, at this point you will be prompted to import one: Select **TPdcblib_SIMOTION_4_2.3.0 [x.y]** in the left-hand window, then click **>>** and finally **Close**.

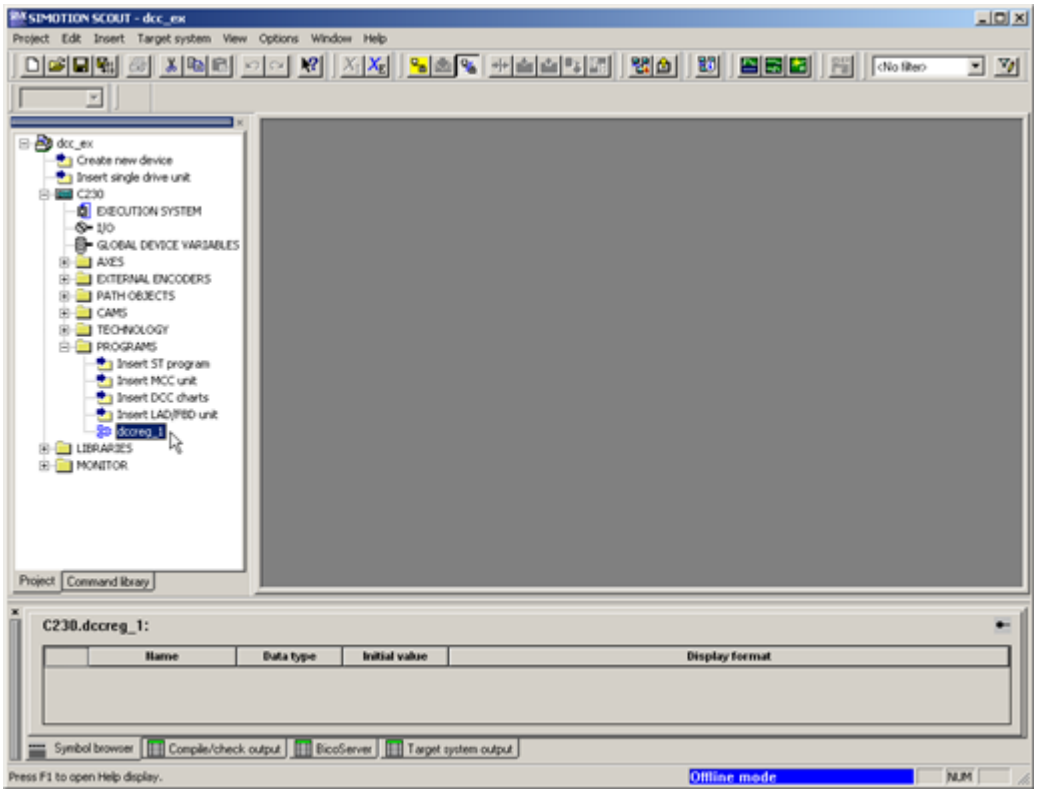

Figure 7-672 Inserting a chart

This creates the project structure and a chart. All that remains is to create some activity within the chart, i.e. by inserting blocks and interconnecting them.

Inserting blocks

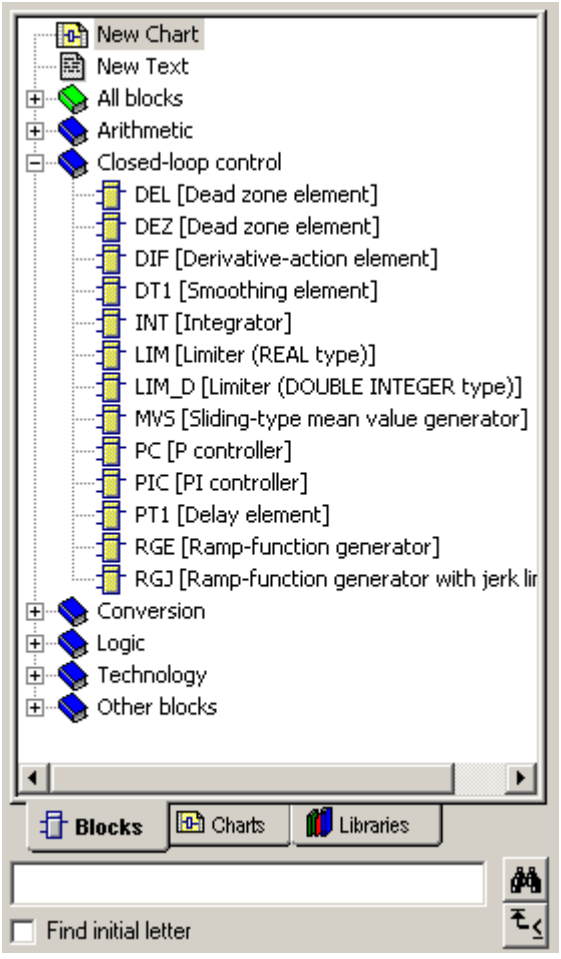

Figure 7-673 Inserting a block

- Open a block family in the **Closed-loop control** family with the closed-loop control blocks.
- Select the required block and insert it in the chart using drag-and-drop. Only the outline of the block in dashed lines is displayed during the copying procedure. Release the mouse button at the required point.
- To search for a block, enter its name in the input field of the block catalog and click the **binoculars** button. The search process begins. Once the block has been found, insert it in an empty space on the chart using drag-and-drop.

Note

If blocks are superimposed on the chart with other elements, such as other blocks or the sheet bar, the superimposed block will be displayed in gray and its connections will not be visible. You must reposition the blocks to ensure that all block information can be viewed.

Changing to the page view

To change to the page view from the overview representation, right-click an empty space in the chart and select **Display this page** in the context menu that appears. The names of the block connections are displayed in this enlarged view.

You can also switch to the page view and back to the overview again by double-clicking an empty area on a page.

Configuring the block display

You can change the display of the blocks. You can change the block width using **Options > Settings > Blocks / sheet bars width....** You can change the designation of the inputs and outputs of the blocks using **Options > Settings > Display** in the **Connections** submenu.

The block type can be displayed in the form of both text (name) and graphics (control symbol). This can be configured via **Options > Settings > Display** in the submenu **Block headers**.

Interconnecting blocks

Procedure

- Select the **Y** output of the first **INT**egrator, followed by the **X** input of the second **INT**egrator.
- Select the **Y** output of the second **INT**egrator, followed by the **X** input of the inverter (**SII**).
- Select the **Y** output of the inverter (**SII**), followed by the **X** input of the first **INT**egrator.

The autorouter creates the connecting lines from the outputs to the inputs and they are then interconnected.

Parameterizing block connections in the chart

For the first integrator INT 1/1, the following initial values should be assigned to the connections: LL = -10.0, LU = 10.0, SV = 2.0, Ti = 100 ms

For the second integrator INT 1/2, the following initial values should be assigned to the connections: LL = -10.0, LU = 10.0, Ti = 100 ms

To do this, open the **Properties - Connection** window of the associated block connection with a double-click. Enter the initial value for **Value** and click **OK** to close the window. Note that for the input of the values for Ti, the "ms" unit must follow the numeric value 100 without any spaces.

As the connections mentioned above are not interconnected, the entered values also remain valid during the cyclic processing of the chart.

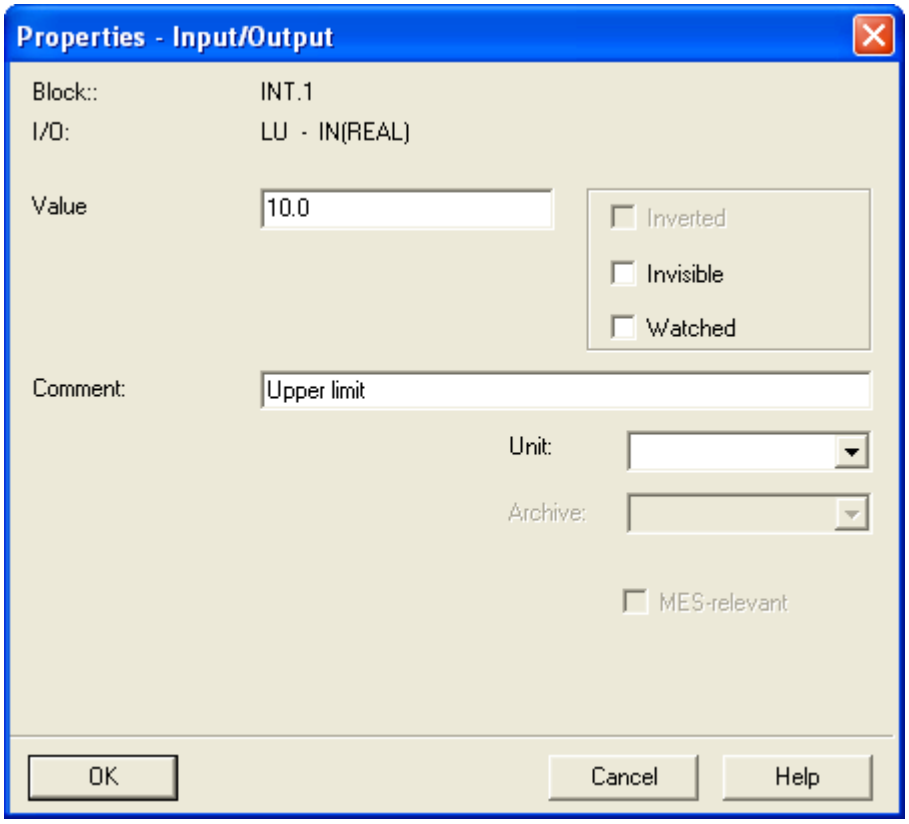

Figure 7-674 Properties window of the "LU" block connection

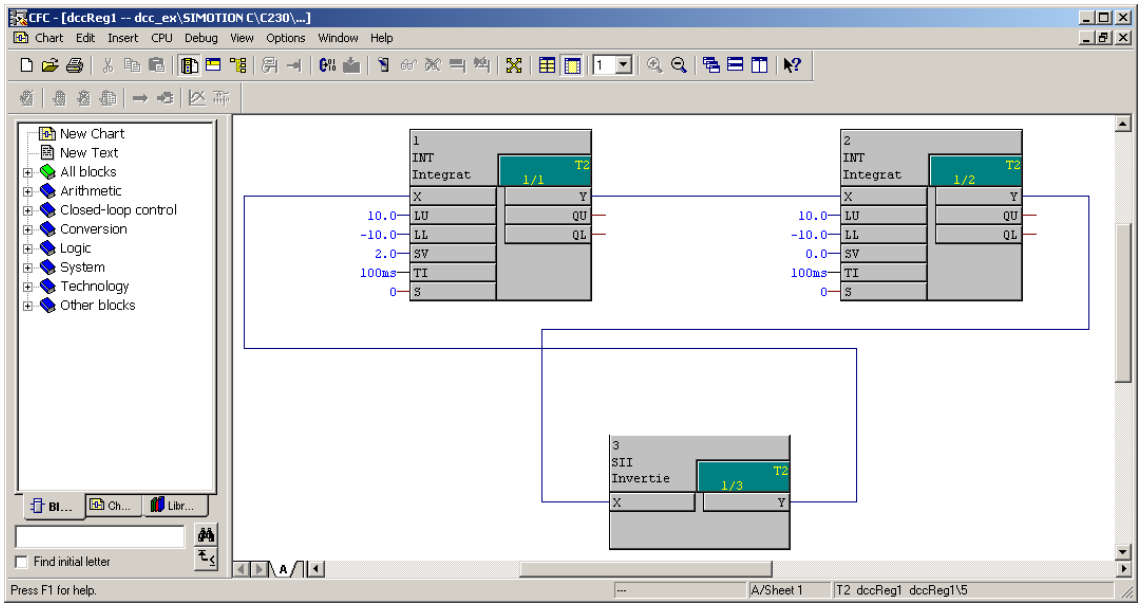

Figure 7-675 Chart "dccReg1" with interconnected blocks. Some connections have been assigned values that differ from the default values.

Structures for DCB block connections

As of DCC 2.1/SIMOTION RT 4.2, user-defined data types structured for DCC SIMOTION can be used for block connections. The structure definitions are taken from the DCC block library.

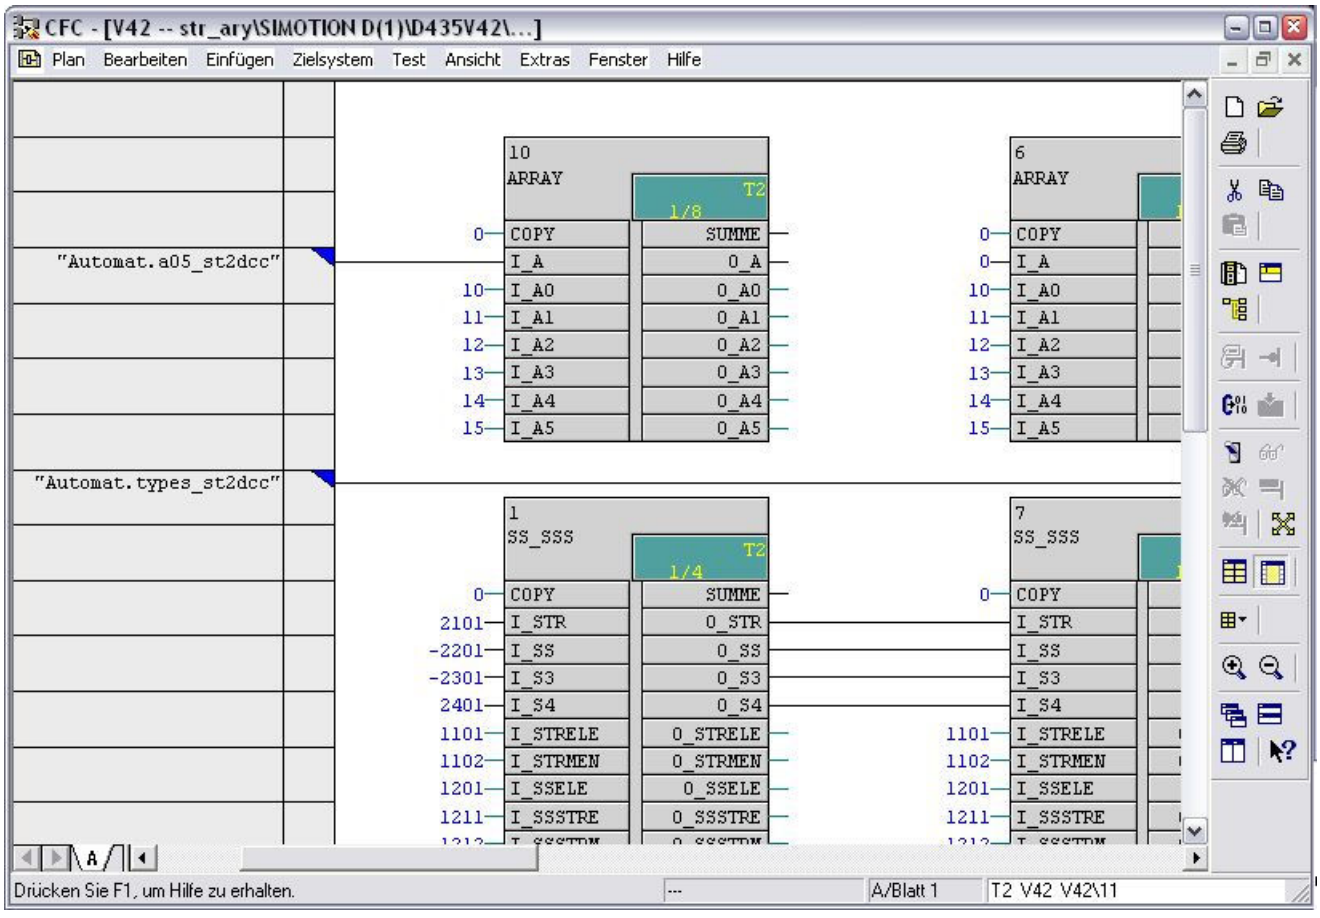

Figure 7-676 Interconnected structures

Purpose

Signals associated with one another from a technological perspective can be combined to form structures.

For example, this means that a setpoint, factor, and control signal can be transferred as related components of the same structure. The structure can be extended at block level; this means there is no need to make any changes in the DCC chart.

Creating structures

New structures can only be generated by blocks that have been created with the SIMOTION CLib Studio. Structures cannot be defined in the DCC editor.

Transferring structured block connections to/from TO variables

The structures must be the same in the DCB library and in the TP definition.

It is not possible to accept structures from TPs. The structure must be defined in the DCB block.

Assigning parameters for structured block inputs

An initialization value is pre-assigned to structured block inputs.

Call up the object properties for a structure or an elementary data type in the structure in order to edit them. Double-click the block connection to open the **Select structure element** dialog. Highlight the structure element you wish to edit and open the **Properties** dialog by either clicking the **Properties** button or double-clicking the structure element.

The **Properties** dialog can be called up in both edit mode and test mode.

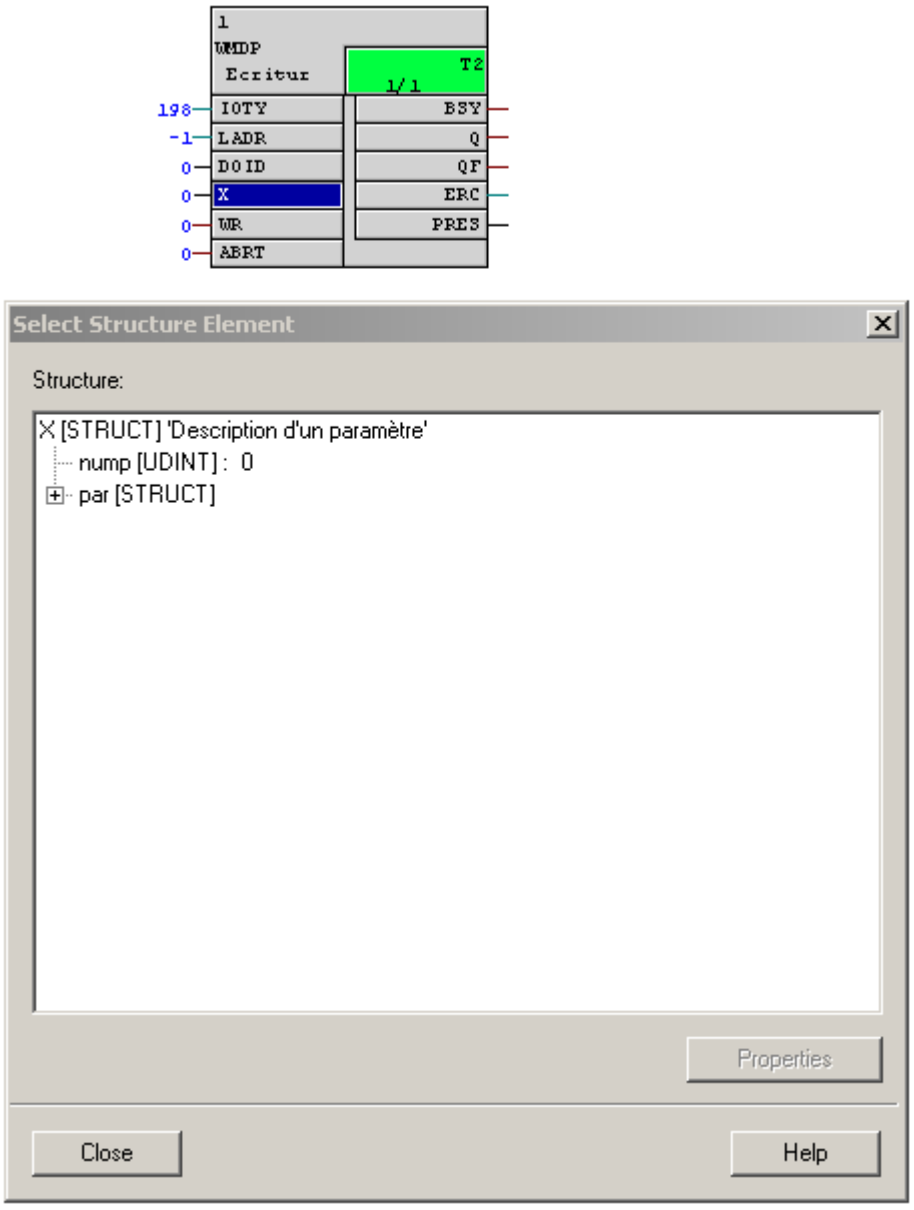

Figure 7-677 Assigning parameters for structured block connections

Arrays are represented by individual symbols for display in the CFC editor.

Example: FIELD|2|.

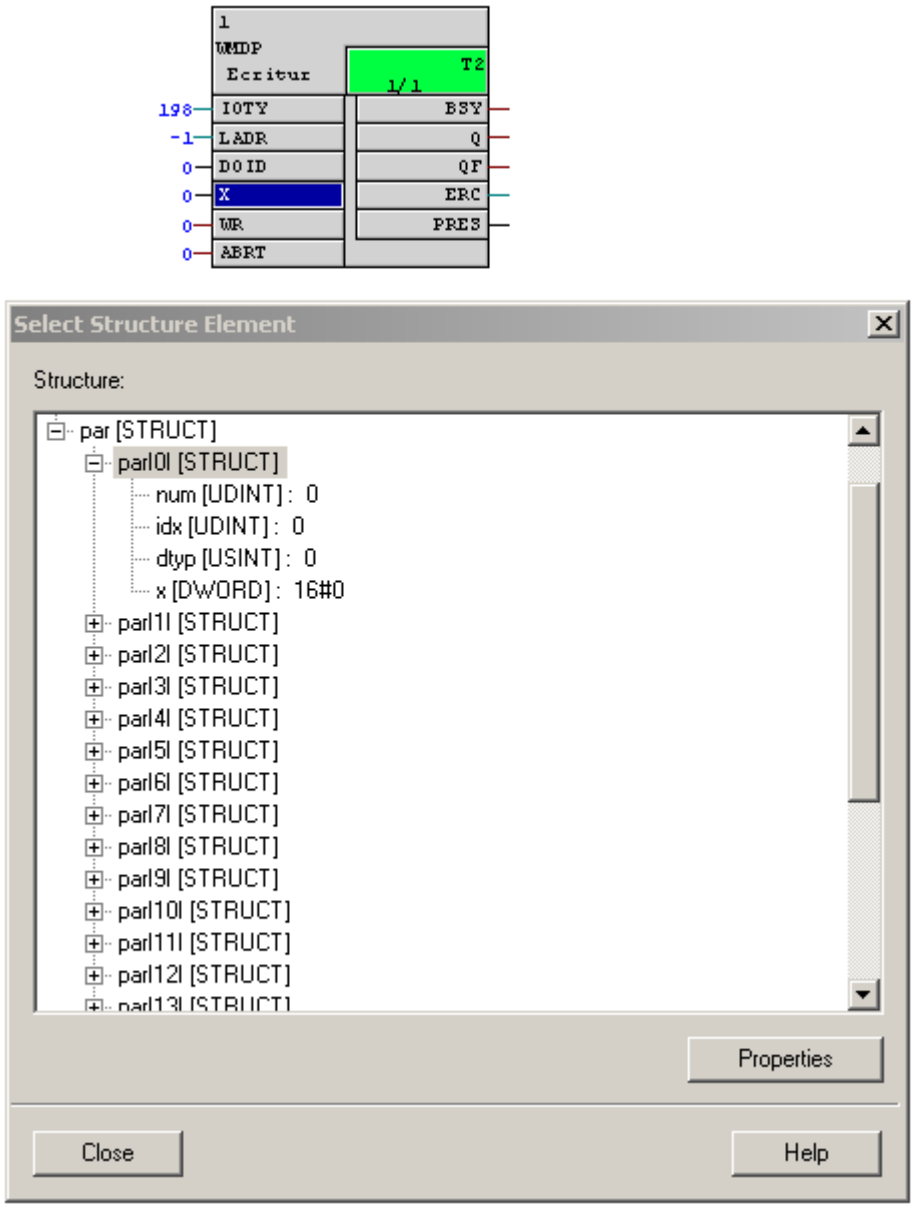

Figure 7-678 Assigning parameters for structured block connections

Double-clicking a structure element or clicking the **Properties** button opens a dialog box that is similar to the one for a block connection of an elementary data type.

Interconnecting structured block connections

Structured block connections are interconnected with the following in the editor:

- Connections of the same type from other CFC blocks
- Global variables of the same type
- TO variables of the same type
- IO arrays of the same length

Structured connections can only be interconnected as an entire unit.

It is not possible to interconnect individual structure elements.

You can monitor values using the dynamic display.

Structures can be interconnected when the name of the data type and the basic data type of the individual elements match. The interconnection rules of the DCC apply: DINT and DWORD are considered to be the same type.

Arrays can be interconnected when the basic data type and the dimension match.

With arrays of structures, the complete definition of the structure must be identical so that the connections can be interconnected.

Structures can only be monitored in the values table.

Interconnection of structured block connections to external variables

You can also interconnect structured block connections to external variables, e.g. a global variable of an ST block. However, as only structures from a DCBLib are valid, this library must be imported within the ST source file and the structure type from the DCBLib used for the global variable. The use of an identical reproduction within ST is not possible for an interconnection.

Example of an ST source file for the interconnection of input X of the RMDP DCC block

```
INTERFACE
    USEPACKAGE dcblib_simotion_4_3;
    VAR_GLOBAL
        x: DCB_RMDP_PAR;
    END_VAR
END_INTERFACE
```

An input or output parameter of a block (in this case RMDP) with the appropriate structure type can then be interconnected to the global ST variable via **Interconnection to operand...**. For subcharts, the input of the block must already have been interconnected previously to an input or output parameter of the subchart.

Publishing structured block connections

You can publish a structure element by entering a comment beginning with an @ sign at the structure element.

You can publish a block connection by entering a comment beginning with an @ sign at the block connection (top level). A structured variable is then created. The first identifier in the comment determines the variable identifier.

Note

DCB blocks with user-defined structures may only be edited as of SIMOTION 4.2.

Libraries with structures may not be generated for older SIMOTION versions.

Block types with user-defined structures may not be used in DCC SINAMICS.

Default connection values for delta downloads

Changes made to the default values of the block connections at a later date are only transferred to SIMOTION if the option highlighted in the following image is activated:

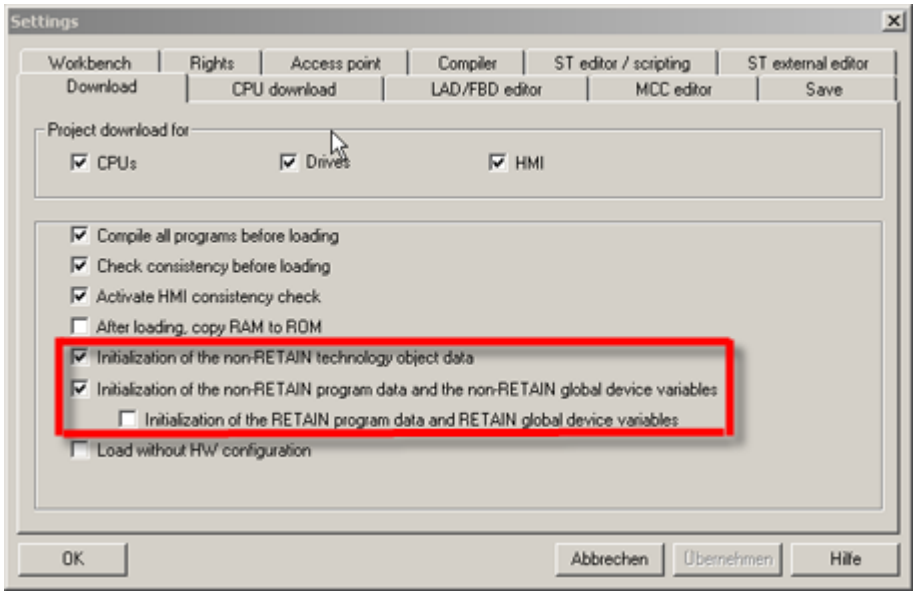

Figure 7-679 Settings for SIMOTION data transfer

Compiling the DCC in the DCC editor

Compiling

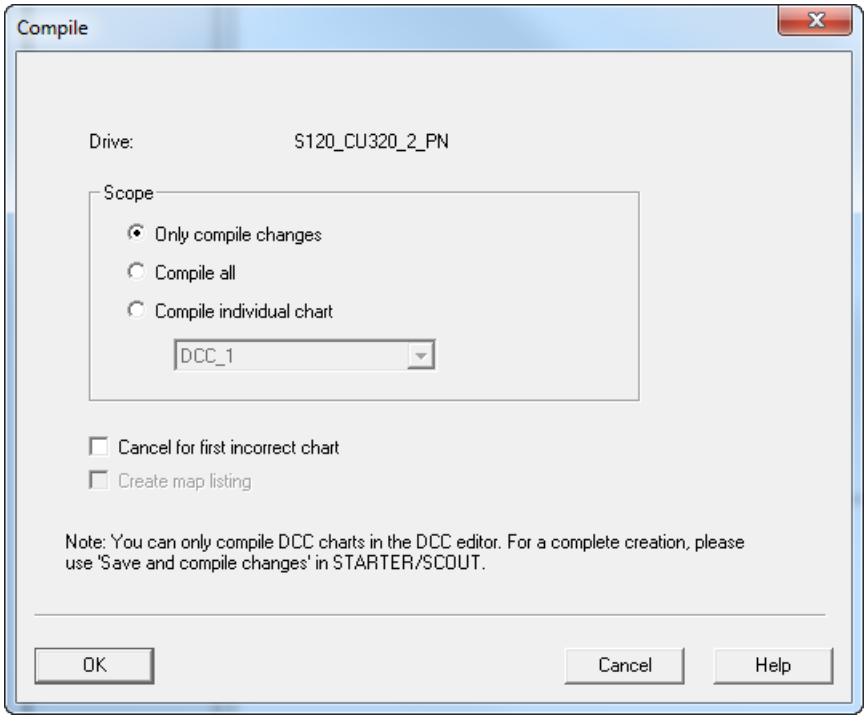

Figure 7-680 Compiling a dialog in the DCC editor

You can begin compiling with **Chart > Compile > Charts as program...** or via the button.

If errors occur during compilation, the **Logs** dialog box will automatically be displayed at the end of the procedure (just as in the case of the consistency check).

Note

You can check whether all the required block libraries and technology packages have been activated via the menu item **Options -> Block types**.

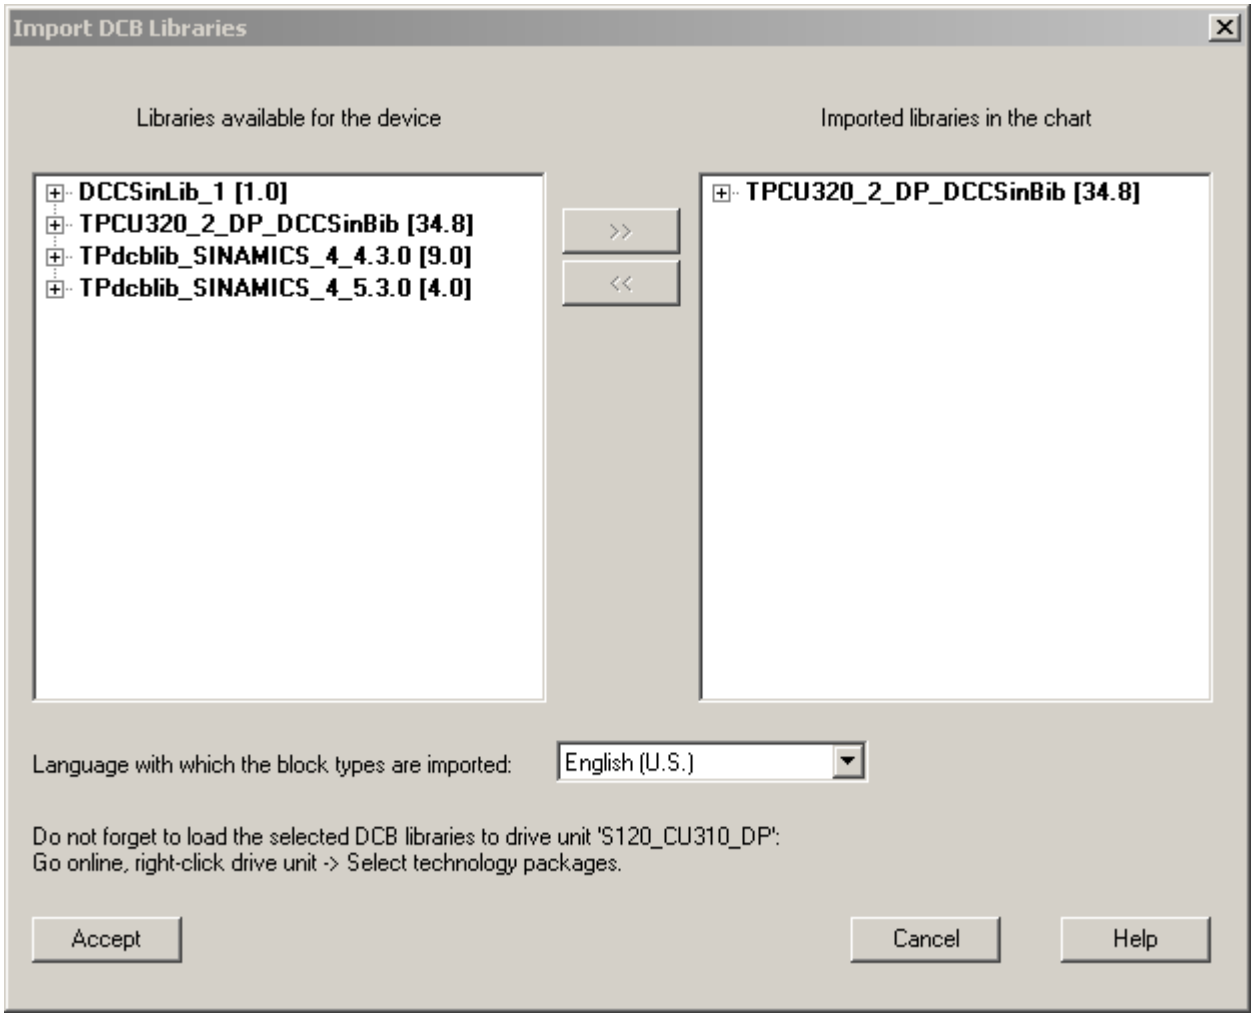

Figure 7-681 Updating the block library dialog

Compilation options

For detailed information about the compilation options, refer to Compiling (Page 5450).

Note

The **Reorganize HMI variable interface** option enables you to reassign the addresses for all @ variables currently defined in the chart. @ variables that are still available in the interface, but are no longer used in the charts, are deleted.

After compilation

On completion of the compilation procedure, a detailed compilation log appears.

- To access the relevant block that is causing an error, select the error line in the log and click **Go to**.
- The log can be called again at a later point via the menu **Options > Logs** and, if necessary, can also be printed out.

Loading the compiled DCC

To be able to operate the DCC program on a CPU, it must have first been downloaded to the CPU.

Downloading can only take place in SIMOTION SCOUT.

Note

The DCC editor assigns the configured DCBs to tasks T1 to T5 in the execution system.

Starting the CPU

To execute the DCC program, the CPU must be switched to RUN.

Enable attribute, execution groups

The "Enable" attribute enables or disables an execution group (enable = 1; disable = 0).

The "Enable" attribute is set to 1 by default. However, it can also be set dynamically. The output value of a block determines whether the group is to be enabled or disabled. To this end, you can interconnect the digital output of a block with the execution group.

Creating documentation

Complete documentation

The example has been successfully configured and tested. You can now create the complete documentation for your example.

Chart reference data

In this case, the chart reference data is the **block type cross references** and the **execution sequence**. In the toolbar, click: 

You can open the **Chart Ref: Display Chart Reference Data** window via **Options > Reference data** in the menu. In this window, you can use the buttons in the toolbar to create and display the relevant lists. To begin printing, click: 

Then close the dialog box with **Reference data > Exit**.

Note

The **Chart Ref: Display Chart Reference Data** window can only be opened when the window of the execution editor is not open.

Printing a chart

You also want to print the chart. Since only one page has been used on this chart, a single page display is recommended for printing. The chart is now set to **Page view**. To begin printing, click: 

If your chart consists of several pages, we recommend that you print them individually in the page view. Click the  button to change to the page view.

Click  or  to customize the display so that all DCBs are shown on a single page on the PC monitor.

Compiling the DCC in the DCC editor (Page 5606)

7.4.5.3 DCC SIMOTION specifications

Rules for assigning names in the DCC editor

Variables are used for data exchange between SCOUT and the DCC editor. The variable names used are subject to the same restrictions regarding names in SIMOTION.

Note

In the DCC editor, the length of the name is restricted to **a maximum of 49 characters**. In SIMOTION, however, longer names are supported. Where this arises, it is necessary to either use aliases or interpose ST variables.

The names in the DCC editor must therefore abide by the following rules:

- Basic chart:
  - No keyword or previously defined name permitted
  - Must start with a letter
  - May contain numbers, letters, and underscores
  - "_" must be followed by a number
- Subchart:
  - Must start with a letter
  - May contain numbers and letters
  - Underscores are not permitted
  - Keyword or previously defined name permitted (during compilation, a check is performed to determine whether this is unique)
  - During compilation in the DCC editor, the name is checked to determine whether it is unique
- Block instance:
  - Can start with a number
  - May contain numbers and letters
  - May not start with an underscore
  - Keyword or previously defined name permitted
  - In the DCC editor, a check is performed to determine whether the name has previously been defined
- Execution group:
  - Keyword or previously defined name permitted
  - In the DCC editor, a check is performed to determine whether the name has previously been defined
- Chart connection:
  - No keyword or previously defined name permitted
  - In the DCC editor, a check is performed to determine whether the name has previously been defined

Field/name lengths and conventions

Field/name lengths and conventions

Object	Length	Remark
Chart name	22 *)	May not contain the following characters: \ . : / * ? " < > | # % ( ) Use of the "_" character is subject to particular specifications.
Chart comment	255	All ANSI characters are permitted.
Execution group	22	Only letters, numbers and underscores may be used.
Block type	6	Determined by DCC.
Block instance comment	80	All ANSI characters are permitted.
Parameter comment	80	All ANSI characters are permitted.
Block name (instance name)	16 *)	May not contain the following characters: \ . : / * ? " < > | # % Use of the "_" character is subject to particular specifications.
Global operand	Max. 49	If names from SIMOTION are too long, an ALIAS must be defined.

*) The chart name and block name must jointly consist of a maximum of 24 characters, including separating characters.

See also

Rules for assigning names in the DCC editor (Page 5609)

Representation of the dynamic value display

The values are output next to the connections, according to their data type. They are displayed on the screen with a colored background.

Table 7-616 Representation of the dynamic value display

Representation	Meaning
Blue on white	Representation of the values in edit mode (offline)
Black asterisks on yellow	Values during transfer to the dynamic display
Black value on yellow	Representation of the values read from the SIMOTION RT in test mode
#### on a red background	Representation of values while the dynamized values required from the SIMOTION RT are missing (fault, overload)

Displaying operands

When integrating OpenCFC into SIMOTION DCC, only symbolic operand names rather than absolute operand names may be used. The settings for displaying operands in the CFC Editor under **Options -> Settings -> Display ...** are ignored.

7.4.5.4 Faults and warnings

Notes on error message display

Notes on error message display

If an error message or warning appears in the DCC, there will be special characters that draw your attention to names or parts of names. You can double-click these characters to proceed directly to the relevant site of the error.

The characters have the following meanings:

- **Block instance or block input/block output**
  - Represented as:
    "\." <instance name> ["." <pin name>]
  - Example:
    Interconnection of "_device\ST_1.i" with "._DCC_6_CFC1_1.x_1" cannot be achieved; invalid type
- **Interconnection to chart connections**
  - Represented as:
    "<" <variable name> ">"
  - Example:
    The input connection DCC_5\<interconn_add_1_x_1> from the chart 'DCC_5' is not interconnected with a sink.
- **Execution level/execution group**
  - Represented as:
    "{" <group name> "}"
  - Example:
    Empty execution group {EG}

Note

Error analysis when a DCB block crashes

If a DCB block crashes during operation, information about the cause and the block instance can be found in the device diagnostics buffer in SIMOTION. With this information, you can contact the creator of the block library, remove the relevant block instance or change the parameterization.

7.4.6 Appendix

7.4.6.1 List of abbreviations

Abbreviation	Description
(G)UI	(**G**rapical) **U**ser **I**nterface
Connection	General term for block input or block output
BI parameter	**B**inector **I**nput parameter. The parameter is used for the interconnection of a binector to a sink signal that can only have the states 0 or 1
BICO	**Bi**nector-**Co**nnector that designates an interconnectable parameter in the drive
BO parameter	Binector parameter (also **B**inector **O**utput parameter). The parameter can be used as a binary signal source (0 or 1)
CFC	**D**rive **C**ontrol **C**hart
CI parameter	**C**onnector **I**nput parameter. The parameter is used for the interconnection of a connector to a sink signal
CO parameter	Connector parameter (also **C**onnector **O**utput parameter). The parameter can be used as a signal source
CSV	**C**omma **S**eparated **V**alue, text format for column-oriented data
DCB	**D**rive **C**ontrol **B**lock
DCC	**D**rive **C**ontrol **C**hart
DO	**D**rive **O**bject
ELF file	File coded in **E**xecutable **L**inkable **F**ormat
FEAT	**Feat**ure document
ITCP	**I**nstance, **T**ime slice, **C**onnection and **P**arameter/Variable
MBCS	**M**ulti-**B**yte **C**haracter **S**et, corresponds to UTF-8
MDI	**M**ultiple-**D**ocument **I**nterface – an application with several windows
OEM	**O**riginal **E**quipment **M**anufacturer
TP	**T**echnology **P**ackage

7.4.6.2 Glossary

Execution level	Interface to the execution system used for the execution of blocks.
Execution group	Execution groups are used for structuring or subdividing execution levels. The blocks and/or charts are integrated sequentially into the execution groups. SIMOTION only: Execution groups, for example, can be switched on and off separately through a connection to a block output (data type BOOL). When an execution group is switched off, all blocks/charts contained therein are no longer calculated.
Execution sequence	Sequence in which the blocks should be calculated in an execution level or execution group

User library	A user library which contains block libraries. As the blocks are based on charts, they can be handled individually in this case.
Output connections	The output connections can be interconnected to other inputs or assigned an initialization value. The value is then active at this connection when the block is calculated in the INIT mode for the first time. This is useful, for example, when a specific value is to be assigned to the output connection of a flip-flop block or a controller block.
HMI variables	You can declare block inputs and outputs as **HMI variables** and therefore generate a static interface for these for use in your system visualization.
Basic library	A library that has been created in C, e.g. with the aid of a DCB tool. Such a library is a closed unit, i.e. a DCB cannot, for example, be separated from a library in order to transfer it to another block. The supplied DCBLIB is an example.
Basic chart	The chart that is visible and can be managed in STEP 7 or SCOUT/STARTER. All other charts, i.e. chart partitions or sub-charts can only be managed in the DCC editor. Only the term chart is used in the following.
Block help	Detailed information about a certain block type can be obtained by selecting the block and pressing the F1 key.
Block type library	Consists of the description of the block types contained in the library and the object file that implements the blocks, e.g. ELF.
INIT mode	Initialization, ramp-up
RUN mode	Cyclic operation
DCB library	A user-defined DCB is created from a chart.
DCB studio	Development environment for the programming of C block libraries.
DCB viewer	You can read the descriptions of the individual block types in the DCB viewer during the configuration in the DCC editor. The DCB viewer is opened by selecting a block and pressing the F1 key.
Input connections	The input connections can be parameterized with constants by the project engineer or interconnected to other block outputs. When the DCB blocks are called, the inputs and outputs have already been assigned default values that can be changed when required.
Creation mode	DCCs can be edited in creation mode.
Freely defined parameters	@ parameters and @ technology connectors. Interface defined for the parameterization by the user in the form of parameter numbers that can be defined as ALIAS for block inputs and block outputs.
Global operands	Global operands are connection partners for block inputs/outputs with which DCB blocks can read and write information from the system environment.

Hierarchical chart or also subchart	A chart (subchart) can be inserted in another chart (chart-in-chart-technique). Hierarchical structures can be formed here. Each inserted chart can be opened and, like every other chart, edited further and therefore changed individually. A chart can be encapsulated for further use, i.e. chart connections added. Which block connections are provided at the chart connections can also be specified individually.
Comments	Each block connection of the CFC page can have a comment added.
Connector	If no more lines can be drawn because the page is too full, the CFC inserts a connector at the block/chart connection and a number in the sheet bar. The corresponding connectors are assigned the same reference number. If several interconnections that cannot be displayed all start at one output, they are all assigned the same reference number. You can recognize the connection point location through the varying representation of the connector. For details, refer to the CFC help.
Laboratory mode	The blocks are automatically monitored in laboratory mode (display of the current values of the block/chart connections logged on for testing).
Offline	Project is processed without a connection to the device.
Online	Project is processed with a connection to the device.
Online RUN, or pulse enable at the drive	Project is processed with a connection to the device and the device is in open-loop or closed-loop control.
Parameterization	Instead of an interconnection, a constant different than the default can be parameterized at each input or output.
Process mode	The blocks are not automatically monitored in process mode (display of the current values of the block/chart connections logged on for testing) so that the additional load is very small.
Sheet bars	The sheet bars on the left and right sides of a CFC page contain the references to the interconnected objects, e.g. other blocks or execution groups, that are not on the current page. They also contain the number of the connector (breakpoint) when the connection line to the sheet bar cannot be drawn because the page is too full.
Technology package	A technology package (the DCBLIB) contains technology objects (DCB) that are capable of being instantiated.
Chart partition	Each chart comprises up to 26 chart partitions ("A".."Z"). Each chart partition consists of up to six DIN A4 pages. A newly created chart only contains chart partition "A".
Test mode	Test mode can be used to debug the DCCs.
Text interconnections	Are used to split projects into separate, configurable units and define an "open" interconnection between charts. A text interconnection can only be at a block/chart input and always references a block or chart output in CFC. The text interconnection is an "open" interconnection until it becomes a "real" interconnection upon closing. A closable text interconnection is the addressing of an input by means of a character string, which identifies a specific interconnection source (output) via the path specification (chart/block.connection).

Trace	The signals of the block outputs can be recorded with the trace function.
Trend display	In test mode with SIMOTION, you can use the value and trend display to analyze the input and output values of blocks.
Typical	DCB library
Overflow pages	Overflow pages are created automatically when more sheet bar entries are generated than can be displayed on a page. An overflow page consists solely of the sheet bars and contains no further objects.
Interconnecting	The term interconnecting means: The connection of a block output to another DCB block input on the same device Interconnections of a block output to an execution group. SIMOTION only Interconnection of a block output to a global operand or a global operand to a DCB block input. A global operand can be the following: The name of a SIMOTION variable. The name of a SINAMICS parameter (can also be performed implicitly through the interconnection to a SB).
Workbench	The workbench is the navigation center for the individual engineering steps and is used for the centralized creation and management of projects. It provides a uniform, function-oriented, consistent, filterable view of all data and programs, even in distributed systems.

8.1 Description of the DCC standard blocks

Preface

SIMOTION documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.3.1:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

SINAMICS documentation

The SINAMICS documentation is organized into two parts:

- General documentation/catalogs
- Manufacturer/service documentation

An overview of the current documentation in the available languages can be found on the Internet:

http://www.siemens.com/motioncontrol

Select the menu items "Support" --> "Technical Documentation" --> "Overview of Publications."

Information on the range of training courses and FAQs (Frequently Asked Questions) is available on the Internet:

http://www.siemens.com/motioncontrol

Select the menu item "Support".

Further documentation for the DCC editor

- SINAMICS/SIMOTION DCC Editor Description

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (finding and searching in manuals/information)

http://www.siemens.com/motioncontrol/docu

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and on the Service&Support pages under **Product Support**:

http://support.automation.siemens.com

Technical Support

Country-specific telephone numbers for technical support are available on the internet under **Contact**:

http://www.siemens.com/automation/service&support

Compliance with the General Data Protection Regulation

Siemens respects the principles of data privacy, in particular the data minimization rules (privacy by design).

For the product SINAMICS DCC this means:

The product stores personal data only in the project. The user is therefore responsible for ensuring compliance with the statutory data protection provisions. This applies in particular to the transfer of projects. If the user links this data with other data (e.g. shift plans) or if he/she stores person-related data on the same data medium (e.g. hard disk), thus personalizing this data, he/she has to ensure compliance with the applicable data protection stipulations.

The following data must be taken into account.

- Windows login
  In the standard configuration, the product saves the login details of the Windows user together with technical function data (e.g. time stamp) in the project. The specified data is saved in order to trace changes in large configurations.
  With SINAMICS DCC, a personal reference can be established via the project and all elements contained in it (e.g. charts).
  The specified data can be viewed in the properties of the project and the elements in SINAMICS DCC (property "Author") and subsequently changed, with the exception of the last modification of the project.

For the above-mentioned point, the details of the functions mentioned in the respective chapter in the information system of SINAMICS DCC must be observed.

By generating the login or username, personal data can be pseudonymized for the functions. Deleting the project will cause all personal data saved within it to be deleted too.

8.1.1 Safety instructions and industrial security

8.1.1.1 Fundamental safety instructions

General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

If the safety instructions and residual risks in the associated hardware documentation are not observed, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

Warranty and liability for application examples

Application examples are not binding and do not claim to be complete regarding configuration, equipment or any eventuality which may arise. Application examples do not represent specific customer solutions, but are only intended to provide support for typical tasks.

As the user you yourself are responsible for ensuring that the products described are operated correctly. Application examples do not relieve you of your responsibility for safe handling when using, installing, operating and maintaining the equipment.

Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the Internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit:

Industrial security (http://www.siemens.com/industrialsecurity)

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed at:

Industrial security (http://www.siemens.com/industrialsecurity)

Further information is provided on the Internet:

Industrial Security Configuration Manual (https://support.industry.siemens.com/cs/ww/en/view/108862708)

⚠ WARNING

Unsafe operating states resulting from software manipulation

Software manipulations (e.g. viruses, trojans, malware or worms) can cause unsafe operating states in your system that may lead to death, serious injury, and property damage.

- Keep the software up to date.
- Incorporate the automation and drive components into a holistic, state-of-the-art industrial security concept for the installation or machine.
- Make sure that you include all installed products into the holistic industrial security concept.
- Protect files stored on exchangeable storage media from malicious software by with suitable protection measures, e.g. virus scanners.
- Protect the drive against unauthorized changes by activating the "know-how protection" drive function.

8.1.1.2 Use write and know-how protection

Prevent unauthorized changes by means of know-how protection

⚠ WARNING

Danger to life through manipulation of DCC charts and DCC libraries

The use of unprotected DCCs and DCC libraries entails a higher risk of manipulation of DCCs, DCC libraries and backup files.

- Protect important DCC charts and DCC libraries by using **know-how protection programs** or via the **know-how protection for drive units** in the SCOUT/STARTER. You can prevent manipulation by assigning a strong password.
- For **know-how protection programs** and **the know-how protection of drive units**, use passwords which include at least eight characters, upper and lower cases, numbers and special characters.
- Make sure that only authorized personnel can access the passwords.
- Protect the backup files on your file system using a write protection.

8.1.1.3 Industrial Security Configuration Manual

Manual on industrial security

Further information can be found in the configuration manual "Industrial Security" for SINAMICS, SINUMERIK and SIMOTION at Security Manual (https://support.industry.siemens.com/cs/document/108862708/sinumerik-simotion-sinamics-industrial-security?dti=0&lc=en-DE).

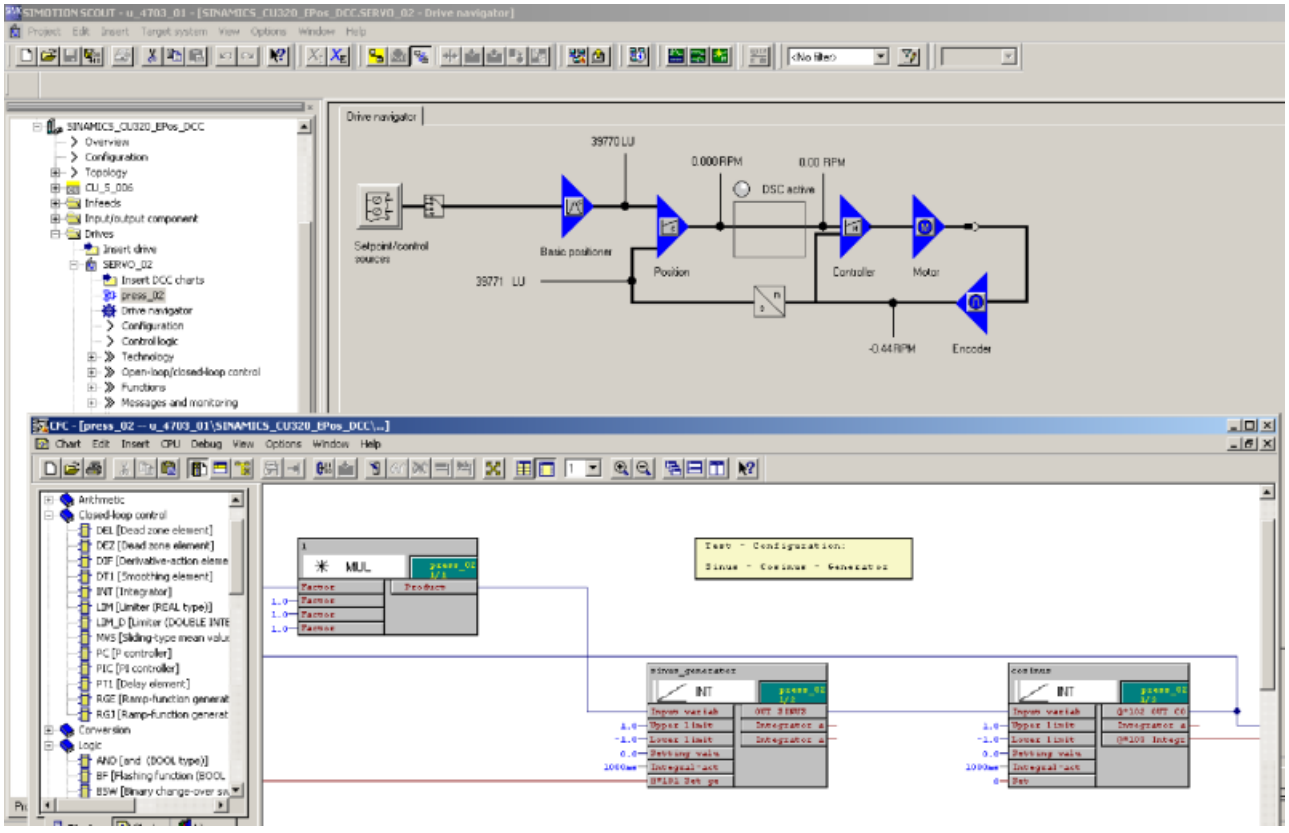
Note in particular the explanations on the cell protection concept in Section "General security measures - Network segmentation".

8.1.2 Introduction

8.1.2.1 Introduction to the Drive Control Chart (DCC)

Drive Control Chart (DCC) for SINAMICS and SIMOTION means graphic configuration and expansion of the device functionality by means of freely available control, calculation and logic blocks.

Drive Control Chart (DCC) expands the facility for the simplest possible configuring of technological functions both for the SIMOTION motion control system and the SINAMICS drive system. This opens up a new dimension for users for adapting the specified systems to the specific functions of their machines. DCC has no restriction with regard to the number of usable functions; this is only limited by the performance capability of the target platform.



The user-friendly DCC Editor enables easy graphics-based configuration, allows control loop structures to be clearly represented and provides a high degree of reusability of diagrams that have already been created.

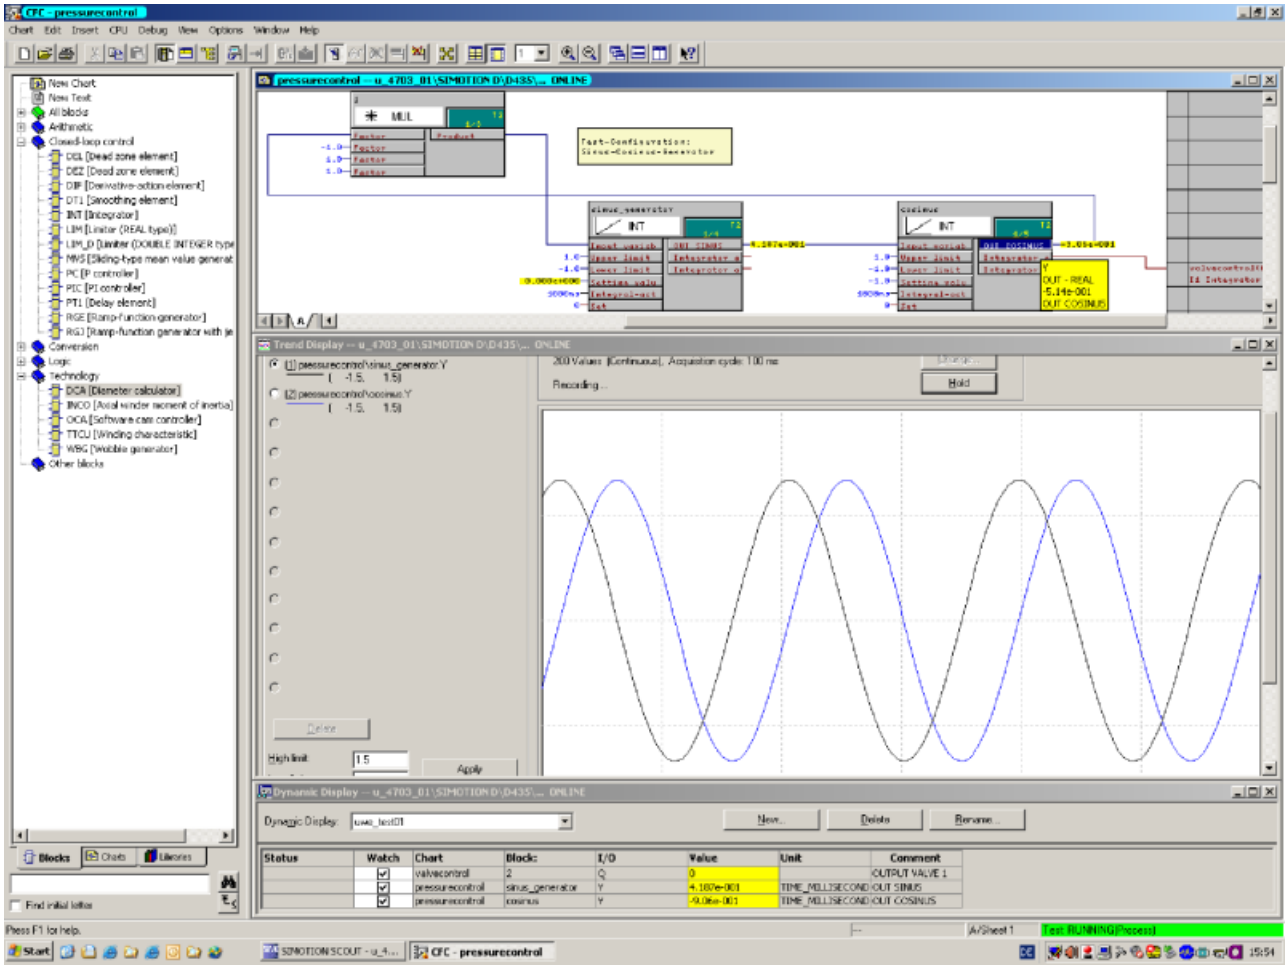
The open-loop and closed-loop control functionality is defined by using multi-instance-capable blocks (Drive Control Blocks - DCBs) from a predefined library (DCB library) that are selected and graphically linked by dragging and dropping. Test and diagnostic functions allow the program behavior to be verified and, in the case of a fault, the cause identified.

The block library contains a large selection of control, arithmetic and logic blocks as well as extensive open-loop and closed-loop control functions.

All commonly used logic functions are available for selection (AND, XOR, On/Off delay, RS flip-flop, counters, etc.) for the logic operation, evaluation and acquisition of binary signals. Numerous calculation functions, such as summation, division and minimum/maximum evaluation are available for monitoring and evaluating numeric variables. In addition to the drive control, axial winder functions, PI controllers, ramp-function generators or sweep generators can be configured simply and without problem.

Almost unlimited programming of control structures is possible in conjunction with the SIMOTION motion control system. These can then be combined with other program sections to form an overall program.

Drive Control Chart for SINAMICS drives also provides a convenient basis for resolving drive-related open-loop and closed-loop control tasks directly in the converter. This results in further adaptability of SINAMICS for the tasks set. Local data processing in the drive supports the implementation of modular machine concepts and results in an increase in the overall machine performance.



8.1.2.2 Libraries

Blocks are located in libraries that are imported as technology packages in the DCC editor.

There are two different libraries:

1. The SIMOTION library contains the SIMOTION blocks identified in this document.
2. The SINAMICS library contains the SINAMICS blocks identified in this document.

To find out which of the blocks described here are available within SIMOTION and/or SINAMICS, you can use both the overview in Appendix A3 and the sections on block descriptions.

Compatibility

SIMOTION

The compatibility of the standard library for the SIMOTION devices is described on the SIMOTION SCOUT DVD and at the following link on the Internet:

SIMOTION compatibility list (https://support.industry.siemens.com/cs/ww/en/view/18857317)

SINAMICS

The following standard libraries are executable with SINAMICS V5.1:

- SINAMICS V5.1 (dcblibV3_0_sinamics5_1)
- SINAMICS V4.8 (dcblibV3_0_sinamics4_8)
- SINAMICS V4.7 (dcblibV3_0_sinamics4_7)
- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

The following standard libraries are executable with SINAMICS V4.8:

- SINAMICS V4.8 (dcblibV3_0_sinamics4_8)
- SINAMICS V4.7 (dcblibV3_0_sinamics4_7)
- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

The following standard libraries are executable with SINAMICS V4.7:

- SINAMICS V4.7 (dcblibV3_0_sinamics4_7)
- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

The following standard libraries are executable with SINAMICS V4.6:

- SINAMICS V4.6 (dcblibV3_0_sinamics4_6)
- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V4.5, the following standard libraries are executable:

- SINAMICS V4.5 (dcblibV3_0_sinamics4_5)
- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V4.4, the following standard libraries are executable:

- SINAMICS V4.4 (dcblibV3_0_sinamics4_4)
- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V4.3.x, the following standard libraries are executable:

- SINAMICS V4.3 (dcblibV2_0_sinamics4_3)

With SINAMICS V2.6.x, the following standard libraries are executable:

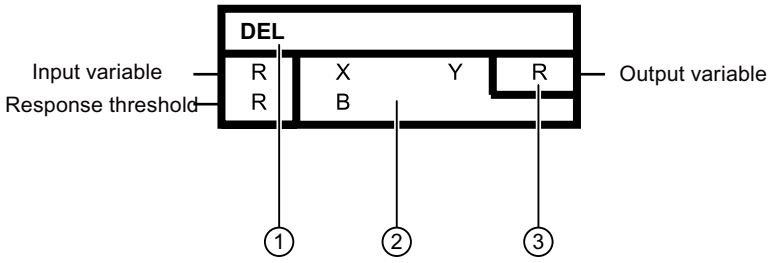
- SINAMICS V2.6 (dcblibV2_0_sinamics2_6)

With SINAMICS V2.5.SP1, the following standard libraries are executable:

- SINAMICS V2.5 (dcblibV2_0_sinamics2_5_1)

8.1.2.3 Nomenclature of the blocks

A block is displayed as follows:



① Block designator
② Connection designator
③ Connection data type

It is identified using the following attributes:

Block designator

Each data type has its own block type. To simplify differentiation between the blocks for various data types with the same functionality, these are provided with a postfix corresponding to the data type, whereby postfix is not usually used for the Real and Bool data types (e.g. MUL_I: Integer-type multiplier, MUL: Real-type multiplier). The following table lists commonly used extensions:

Table 8-1 Block designator

Postfix for block designator	Data type of the input/output variable
_I	Integer
_D	Double_Integer
_W	Word
_R	Real (optional)
_B	Bool (optional)
_SI	Short Integer
_M	Modulo
_BY	Byte
_UI	Unsigned Integer
_US	Unsigned Short Integer
_UD	Unsigned Double Integer

Postfix for block designator	Data type of the input/output variable
_DW	Double Word
_LR	Long Real

Connection designator

- To identify a field from the input or output variable, the designator is extended by an index beginning with 1 (e.g. X1, X2, X3, etc.).
- With a generic number of inputs (e.g. ADD), the connection name is indexed beginning with 1 (e.g. X1, X2, X3, etc.).

The following table shows an overview of common connection designators:

Table 8-2 Connection designator

Connection designator	Use
X, X1, X2...	Numeric input variable
Y, Y1, Y2...	Numeric output variable
I, I1, I2...	Binary input variable
Q, Q1, Q2...	Binary output variable
IS	Bit string input (Word)
QS	Bit string output (Word)

If further inputs and outputs are used along with the primary input and output variables (e.g. limit values, time data, substitute values, status displays), the designators from the pool of the primary input/output variables are not used. The following table shows the preferred designators for secondary variables:

Connection designator	Use
LU	Input: Upper limit
LL	Input: Lower limit
SV	Input: Setting value
S	Input: Setting the setting value
R	Input: Resetting the setting value
QU	Output: Upper limit reached
QL	Output: Lower limit reached
QF	Output: Fault flag
QE	Output Y equals input X
QN	Inverted binary variable

Connection data type

The abbreviated designators of the data types are listed in the following table:

Abbreviation	Bit width	Data type according to IEC 61131-3	Description
BO	1	BOOL	BOOLEAN
BY	8	BYTE	Bit string, Unsigned Integer

Abbreviation	Bit width	Data type according to IEC 61131-3	Description
SI	8	SINT	Signed Short Integer
DI	32	DINT	Signed Double Integer
DW	32	DWORD	Bit string, Unsigned Integer
I	16	INT	Signed Integer
R	32	REAL	Floating Point Single Precision acc. to IEEE 754
LR	64	LREAL	Floating Point Double Precision according to IEEE 754
T	32	SDTIME	Floating Point Single Precision according to IEEE754
W	16	WORD	Bit string, Unsigned Integer
AID	32	-	Alarm ID

8.1.2.4 Block connections

Block connections display the interface of the DCBs, via which interconnection between the blocks can be performed. A distinction is made between

- Block output
- Block input

here, and these have the following properties:

- Inputs are positioned on the left of the block and are the target of an interconnection
- Outputs are positioned on the right of the block and are the source of an interconnection

8.1.2.5 Byte ordering

When interconnecting the blocks, the byte ordering of the data does not have to be taken into consideration. During data type conversions and arithmetic operations, the byte ordering of the target system is implicitly taken into consideration. Any byte swapping required for handling data beyond the system boundaries is carried out by the system (e.g. byte swapping may have to be carried out in Big Endian format before transferring data via PROFIBUS).

8.1.2.6 Direct interconnection of different data types

When interconnecting blocks, the target and source must be of the same data type. If the data types are different, there are special conversion blocks available which allow the data type to be converted.

The following permissible implicit conversions are an exception. The table below lists the permissible conversions.

The following data types, which can be interconnected without a conversion block, are another exception. In this case, the binary value of the output variable is transferred unchanged as the input variable.

Table 8-3 Conversions

Input	Output	Description
WORD	INT	Interconnection of a word variable to an integer variable
INT	WORD	Interconnection of an integer variable to a word variable
DWORD	DINT	Interconnection of a double word variable to a double integer variable
DINT	DWORD	Interconnection of a double integer variable to a double word variable
BYTE	SINT	Interconnection of a byte variable to a short integer variable
SINT	BYTE	Interconnection of a short integer variable to a byte variable
USINT	BYTE	Interconnection of an unsigned short integer variable to a byte variable
BYTE	USINT	Interconnection of a byte variable to an unsigned short integer variable
USINT	SINT	Interconnection of an unsigned short integer variable to a short integer variable
SINT	USINT	Interconnection of a short integer variable to an unsigned short integer variable
UINT	WORD	Interconnection of an unsigned integer variable to a word variable
WORD	UINT	Interconnection of a word variable to an unsigned integer variable
UINT	INT	Interconnection of an unsigned integer variable to an integer variable
INT	UINT	Interconnection of an integer variable to an unsigned integer variable
UDINT	DWORD	Interconnection of an unsigned double integer variable to a double word variable
DWORD	UDINT	Interconnection of a double word variable to an unsigned double integer variable
UDINT	DINT	Interconnection of an unsigned double integer variable to a double integer variable
DINT	UDINT	Interconnection of a double integer variable to an unsigned double integer variable
SDTIME	REAL	Interconnection of an SDTime variable to a real variable

8.1.2.7 Initialization of the blocks

Initialization determines the starting condition of the block. It is carried out by the system before the cyclical processing[1)] of the block. The sequence for initializing the individual blocks is implemented according to the configured priority and process sequence. At the time of initialization, the configured interconnections and constants for a block are already active. At this point, the values from the interconnection source are already available in a block. Should a block behave in a special way during initialization, this is described in the respective block description under "Initialization". In the case of initialization, the blocks must be assigned in a time slice (SINAMICS) or to a task (SIMOTION).

[1)] As of SIMOTION 4.1 SP2, initialization is performed during a STOP/RUN transition (SIMOTION) or during the transition to cyclical operation (SINAMICS).

8.1.2.8 Implementing complex functions in a sample configuration

Sample configurations are available for the "convenient ramp-function generator" and "technology controller". These are based on the "free blocks" of the SIMOVERT MASTERDRIVES frequency converter series.

The functionality of the convenient ramp-function generator is implemented by interconnecting individual DCBs. They are provided in the form of a sample configuration.

Notes relating to the technology controller

- The smoothing filters cannot be deactivated using the time constant T = 0, as the time constant is limited to the sampling time of the block. The filters must be deactivated explicitly by a signal. The corresponding binary input must be provided in the sample configuration.
- The D component cannot be deactivated using the delay time Tv = 0. This must be deactivated explicitly by a binary signal. The corresponding binary input must be provided in the sample configuration.
- The I component cannot be deactivated using Tn = 0. For this, the I component of PIC must be reset explicitly using SV = 0 and S = 1.

Note

Here, you should now also use the advantage of DCC and configure/transfer only the blocks that are required, i.e. not fall back on the sample configurations from the outset and start with the basic blocks, such as RGJ (ramp-function generator with rounding) or PIC (PI controller) and expand, if necessary.

Import sample configuration

The sample configuration is archived in the form of exported DCC charts as of SCOUT/STARTER version V4.3.

SIMOTION

In order to import the DCC chart in SCOUT, a SIMOTION device needs to be present in the project. In the Programs folder, select the path of the exported DCC chart via the shortcut menu Expert -> Import object. The files can usually be found under the following path:

C:\Program Files\Siemens\Step7\Examples\dcc\SIMOTION

SINAMICS

To import the DCC chart in SCOUT/STARTER, an S120 drive unit with a drive object (DO) must be present in the project. On the drive object, select the path of the exported DCC chart via the shortcut menu Expert -> Import object. The files can usually be found under the following path:

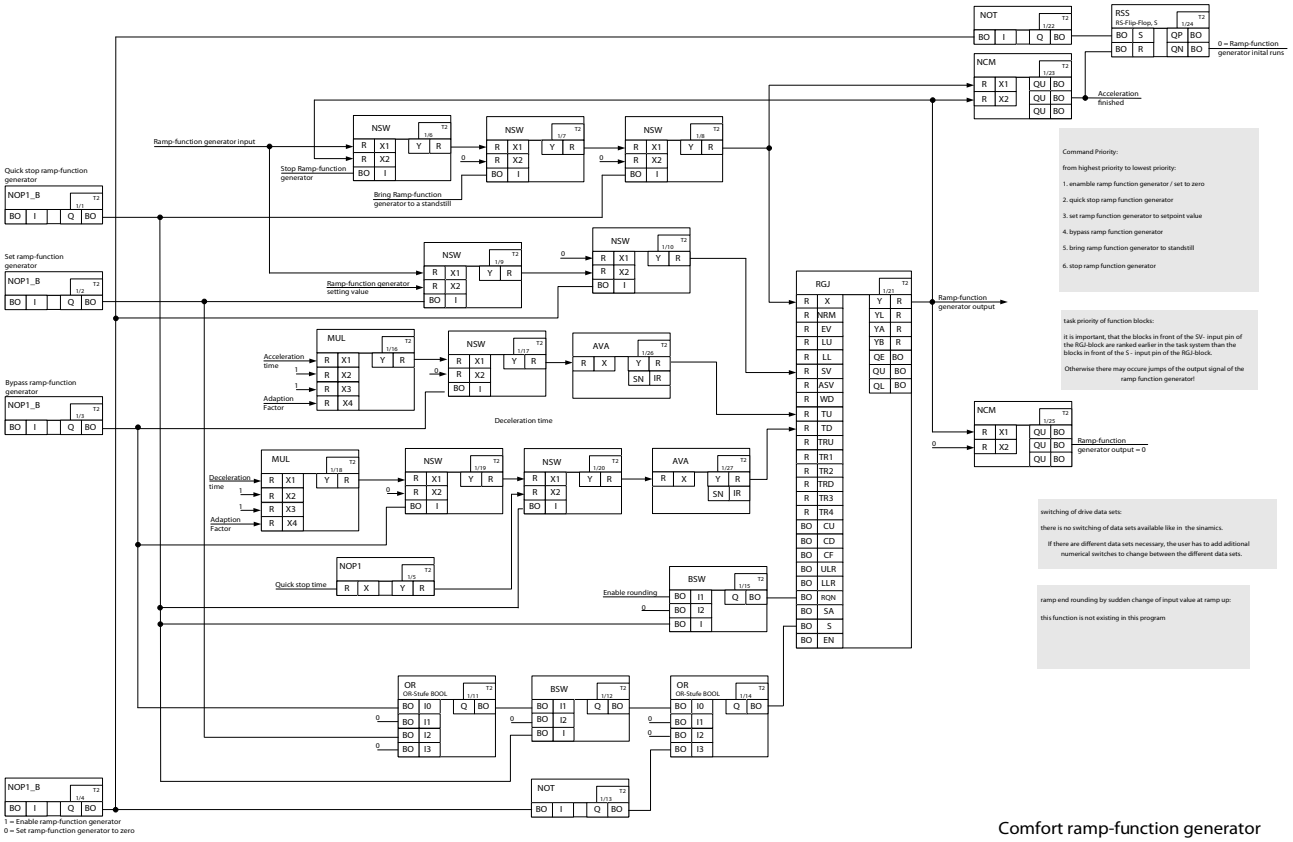
C:\Program Files\Siemens\Step7\Examples\dcc\SINAMICS

Up to SCOUT/STARTER version V4.3, the sample configuration was archived as a project export under the following path:

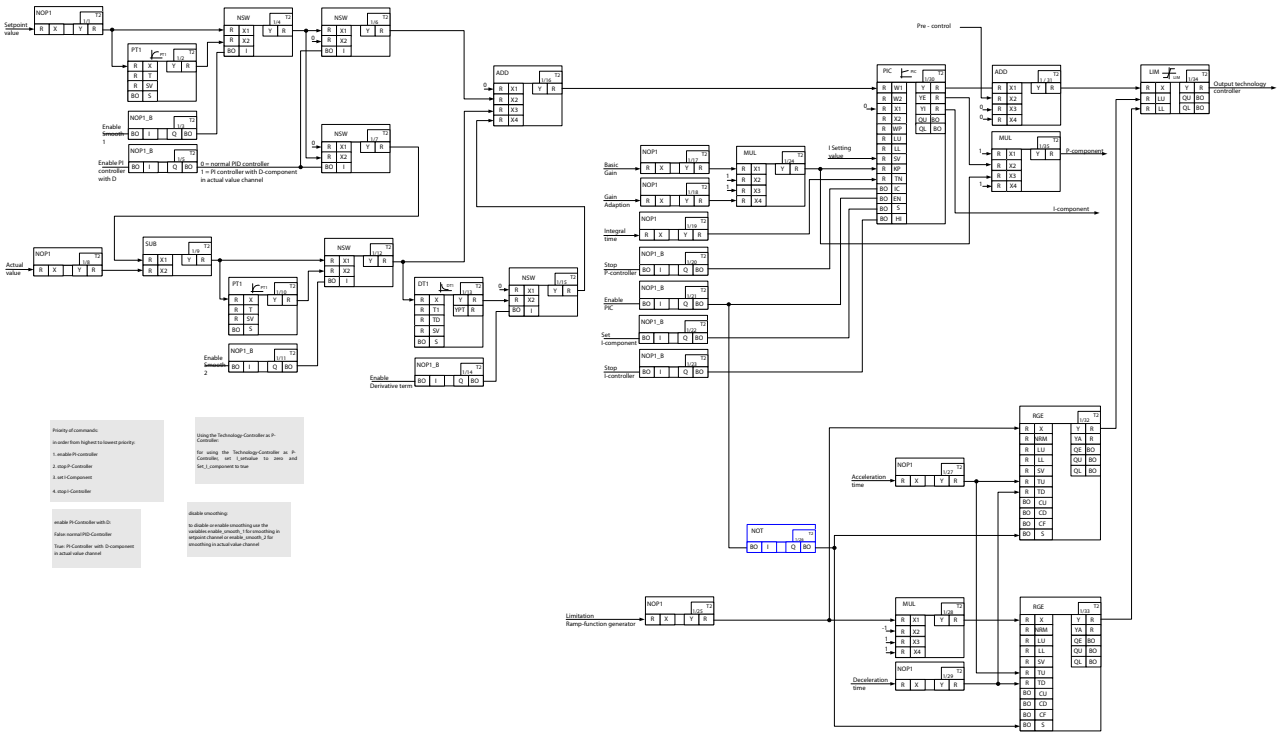
C:\Program Files\Siemens\Step7\Examples\dcc\Examples_CRGE_TCLR.xml

Note

The sample project has been created on the basis of a SCOUT project and thus contains both the configurations for SINAMICS_Integrated and SINAMICS standalone / CU320. When importing the sample project with STARTER (stand-alone), the SIMOTION components are naturally rejected; the CU320 components, however, continue to be accurately imported and are reproducible.



Comfort ramp-function generator



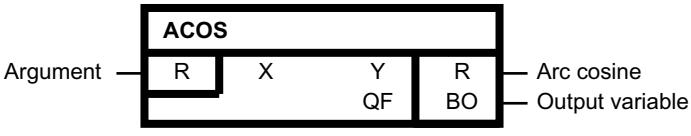
Technology Controller

8.1.3 Arithmetic

8.1.3.1 ACOS

Arc cosine function

Symbol



Brief description

Determination of the arc cosine value for an argument

Method of operation

The block determines the associated arc cosine value in radian measure for an argument to be entered at input X and outputs the result at output Y.

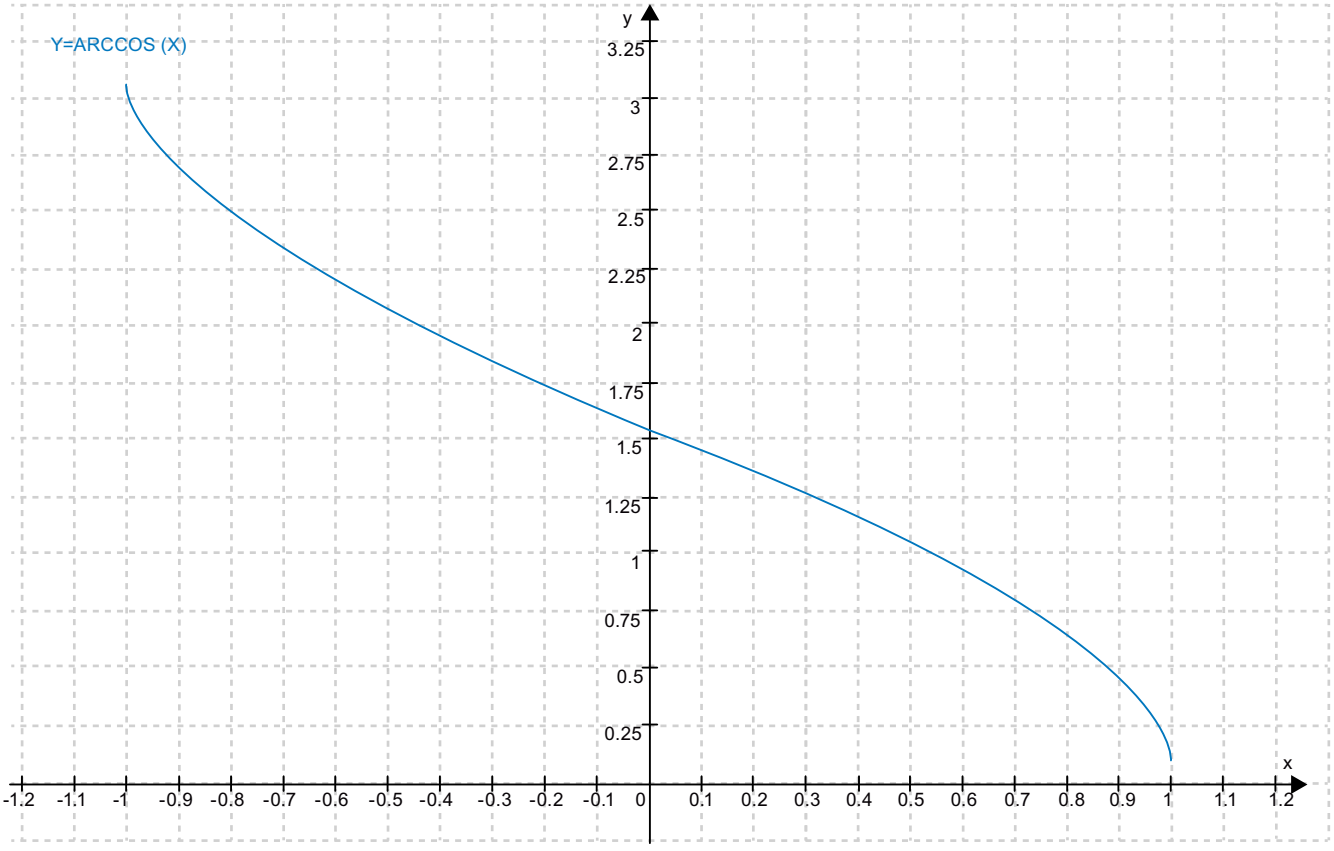
Y = arccos X

Permitted input range: -1.0 <= X <= +1.0

Output range: 0.0 <= Y <= ∏

If the argument lies outside of the permitted input range, output Y is limited to ∏ (when X < -1.0) or 0.0 (when X > +1.0) and binary output QF = 1 is set at the same time.

Transfer function



Block connections

Block connection	Description	Default	Value range	Attrib-utes
X	Argument	0.0	REAL	
Y	Arc cosine	∏/2	REAL	
QF	Output variable	0	0/1

Special characteristics	X comprises up to four inputs (X1 to X4)

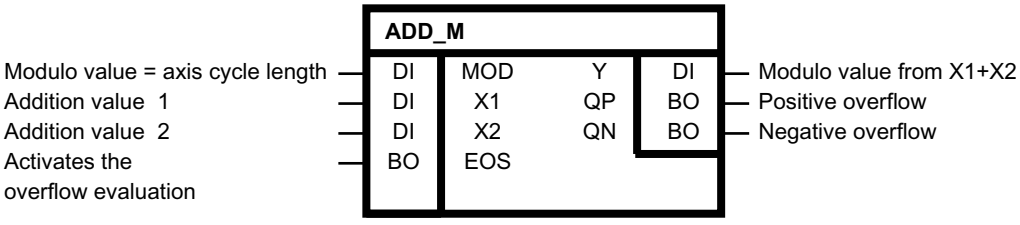
8.1.3.5 ADD_M

Modulo adder for addition in correct axis cycle

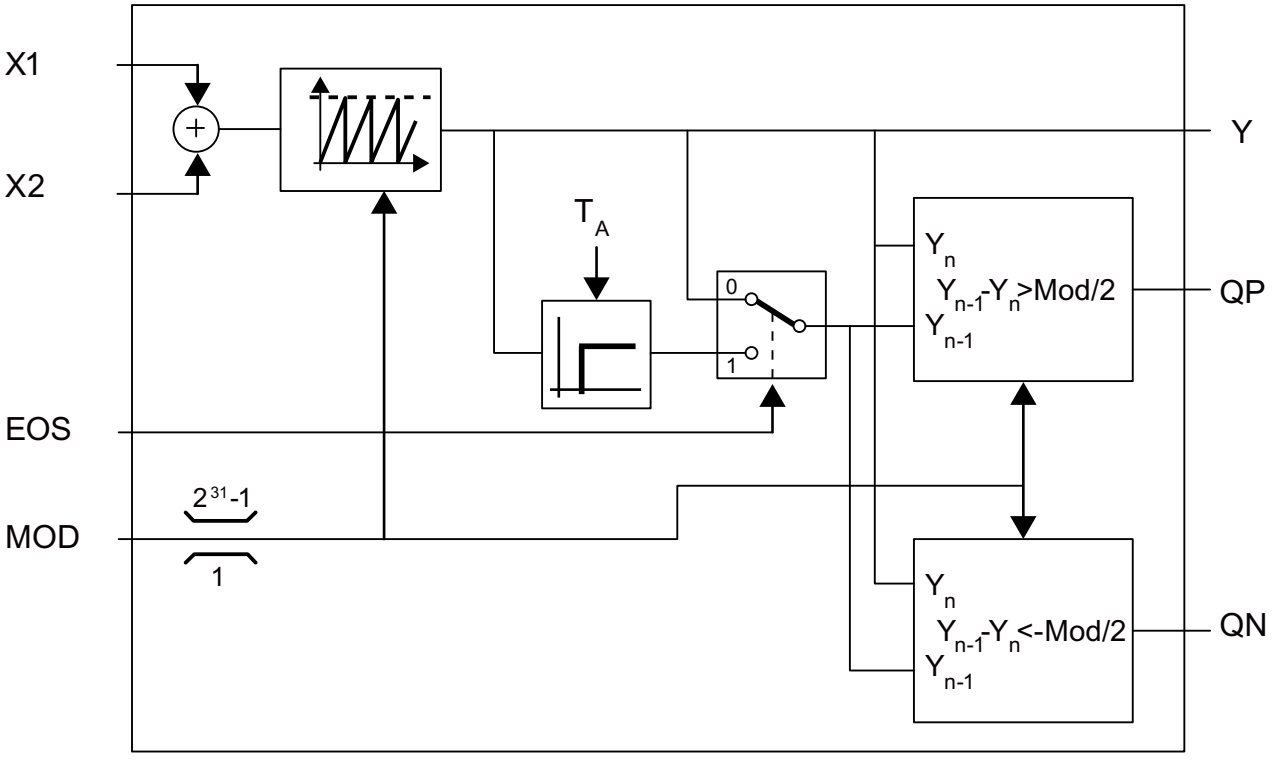
Symbol



Brief description

The ADD_M block is used to add position values. It can be used to "add up" offsets for position setpoints or for dead time compensation in the real master.

Block diagram



Method of operation

This block adds the input values X1 and X2. A modulo value can be specified at the MOD input. The module value must be in the range of 1 to 2^{31}-1 and is applied to the sum of X1 and X2. Thus, the result Y of the modulo operation is always in the band from 0 to MOD.

The EOS input can be used to activate an overflow evaluation. When EOS = 1:

Positive overflow: QP = Y_{n-1}-Y_n> MOD/2

Negative overflow: QN = $Y_{n-1} - Y_n < -MOD/2$

When EOS = 0: QP = 0; QN = 0

This enables the overflow evaluation to be deactivated when setting offsets. When the modulo value is changed, the overflow evaluation is switched off for one cycle.

Block connections

Block connection	Description	Default	Value range	Attributes
MOD	Modulo value = axis cycle length	1	DINT	
X1	Addition value 1	0	DINT	
X2	Addition value 2	0	DINT	
EOS	Activates the overflow evaluation	0	0/1	
Y	Modulo value from X1+X2	0	DINT	
QP	Positive overflow	0	0/1	
QN	Negative overflow	0	0/1

Special characteristics	-

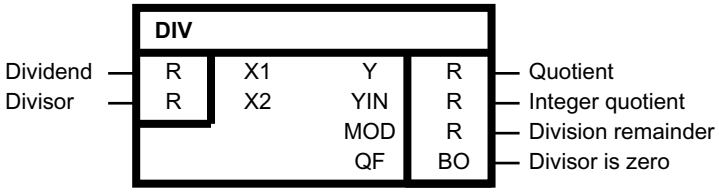
8.1.3.11 DIV

Divider (REAL type)

Symbol



Brief description

Divider with two real-type inputs

Method of operation

The block divides the value entered at connection X1 by the value entered at connection X2.

The result is output at outputs Y, YIN, and MOD:

- The Y output contains the quotient with integer places and decimal places
- The YIN output contains the integer quotient
- The MOD output contains the division remainder (absolute residual value)

The Y output is limited to a range of approximately -3.4 E38 to +3.4 E38.

$$Y = \frac{X1}{X2}$$

MOD = (Y – YIN) * X2

If the output value Y violates the permissible value range of -3.402823 E38 to 3.402823 E38 (because the divisor X2 is very small or zero), then the limit value of the output range is output at connection Y with the correct sign. The binary output QF=1 is set at the same time. If X2 is zero, then the outputs YIN and MOD retain their last values.

With division of 0/0, the block output Y remains unchanged. The binary output QF is set to 1. With a division by zero, output MOD retains its last value.

Truth table(s)

The following truth table lists the block responses in the cases specified above.

X1/X2	Y	YIN	MOD	OF
X/0	Limit value with correct sign	YIN n-1	MOD n-1	1
0/0	Y n-1	YIN n-1	MOD n-1	1
0/X	0	0	0	0

Block connections

Block connection	Description	Default	Value range	Attributes
X1	Dividend	0.0	REAL	
X2	Divisor	1	REAL	
Y	Quotient	0.0	REAL	
YIN	Integer quotient	0.0	REAL	
MOD	Division remainder	0.0	REAL	
QF	Divisor is zero	0	0/1	

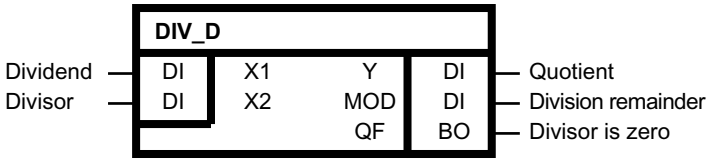
Configuration data

SIMOTION	✓
SINAMICS	✓
Can be inserted online	Yes
Special characteristics	-

8.1.3.12 DIV_D

Divider (double integer type)

Symbol



Brief description

Divider with two inputs of the double integer type

Method of operation

The block divides the value entered at connection X1 by the value entered at connection X2 taking account of the sign. The quotient, limited to the range of -2147483648 (2^{31}) to 2147483647 (2^{31} -1), is output at connection Y.

$$Y = \frac{X1}{X2}$$

The division remainder is output at connection MOD. The sign of the division remainder MOD matches that of dividend X1.

MOD = X1 MOD X2

When output value Y exceeds the permissible range of -2147483648 (2^{31}) to +2147483647 (2^{31}-1) (because divisor X2 is zero), then the limit value of the output range with the correct sign is output at connection Y. The binary output QF = 1 is set at the same time.

With division of 0/0, the block output Y remains unchanged. The binary output QF is set to 1. With a division by zero, output MOD retains its last value.

Truth table(s)

The following truth table lists the block responses in the cases specified above.

X1/X2	Y	MOD	OF
X/0	Limit value with correct sign	MOD n-1	1
0/0	Y n-1	MOD n-1	1
0/X	0	0	0

Block connections

Block connection	Description	Default	Value range	Attributes
X1	Dividend	0	DINT	
X2	Divisor	1	DINT	
Y	Quotient	0	DINT	
MOD	Division remainder	0	DINT	
QF	Divisor is zero	0	0/1

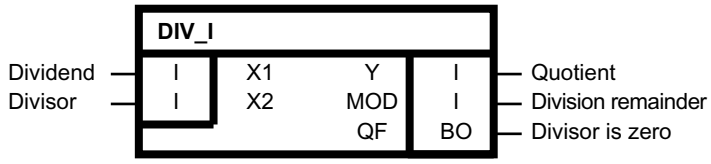
8.1.3.13 DIV_I

Divider (integer type)

Symbol



Brief description

Divider with two integer-type inputs

Method of operation

The block divides the value entered at connection X1 by the value entered at connection X2 taking account of the sign. The quotient is limited to the range of -32768 to +32767 and output at connection Y.

$$Y = \frac{X1}{X2}$$

The division remainder is output at connection MOD. The sign of the division remainder MOD matches that of dividend X1.

MOD = X1 MOD X2

When output value Y exceeds the permissible range of -32768 to +32767 (because the divisor is zero), then the limit value of the output range with the correct sign is output at connection Y. The binary output QF = 1 is set at the same time.

With division of 0/0, the block output Y remains unchanged. The binary output QF is set to 1. With a division by zero, output MOD retains its last value.

Truth table(s)

The following truth table lists the block responses in the cases specified above.

X1/X2	Y	MOD	OF
X/0	Limit value with correct sign	MOD n-1	1
0/0	Y n-1	MOD n-1	1
0/X	0	0	0

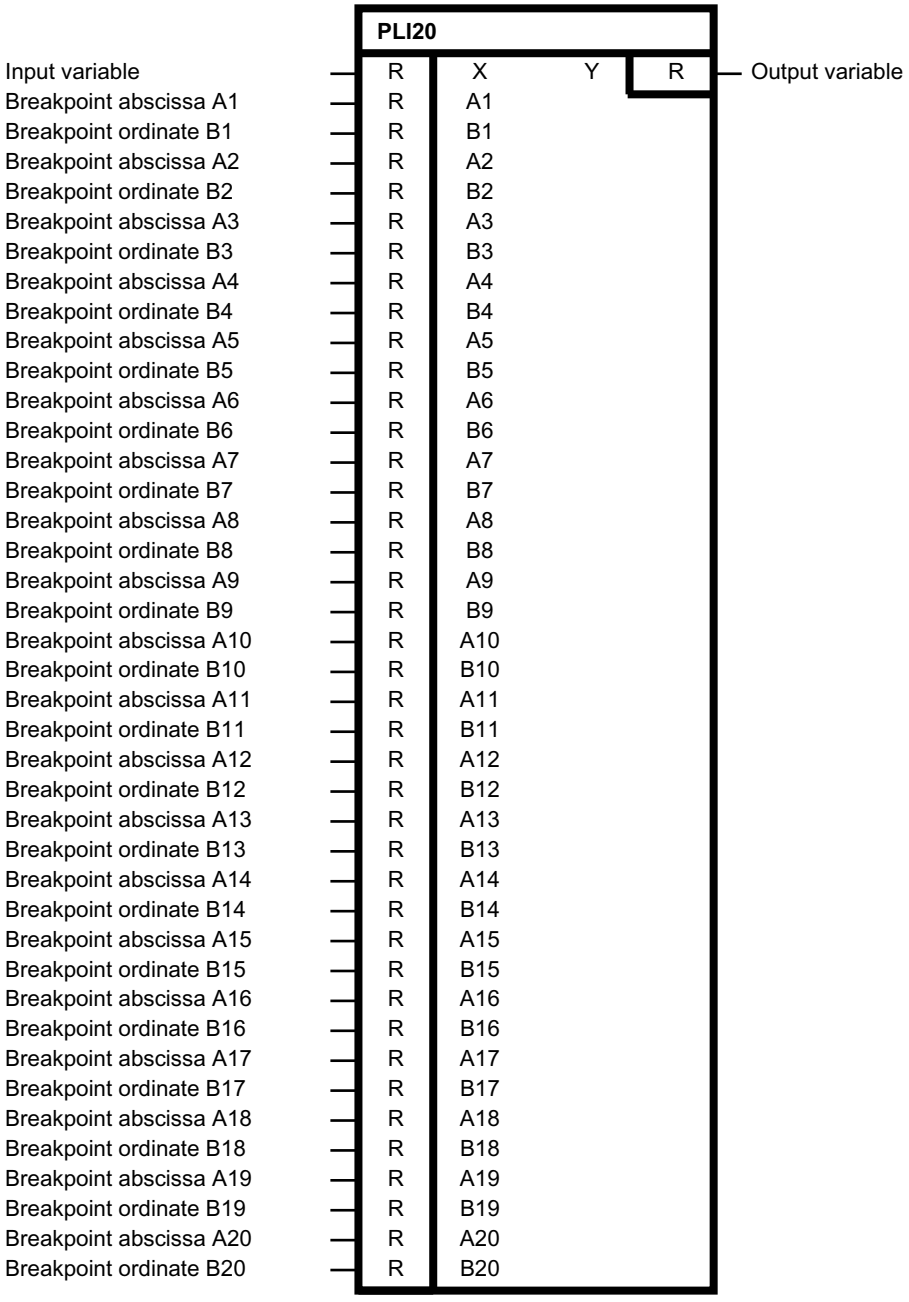
8.1.3.19 PLI20

Polyline, 20 breakpoints

Symbol



Brief description

Block of the REAL type

- For linearization of characteristic curves
- For simulation of non-linear transfer elements
- For controller gain defined in sections

Method of operation

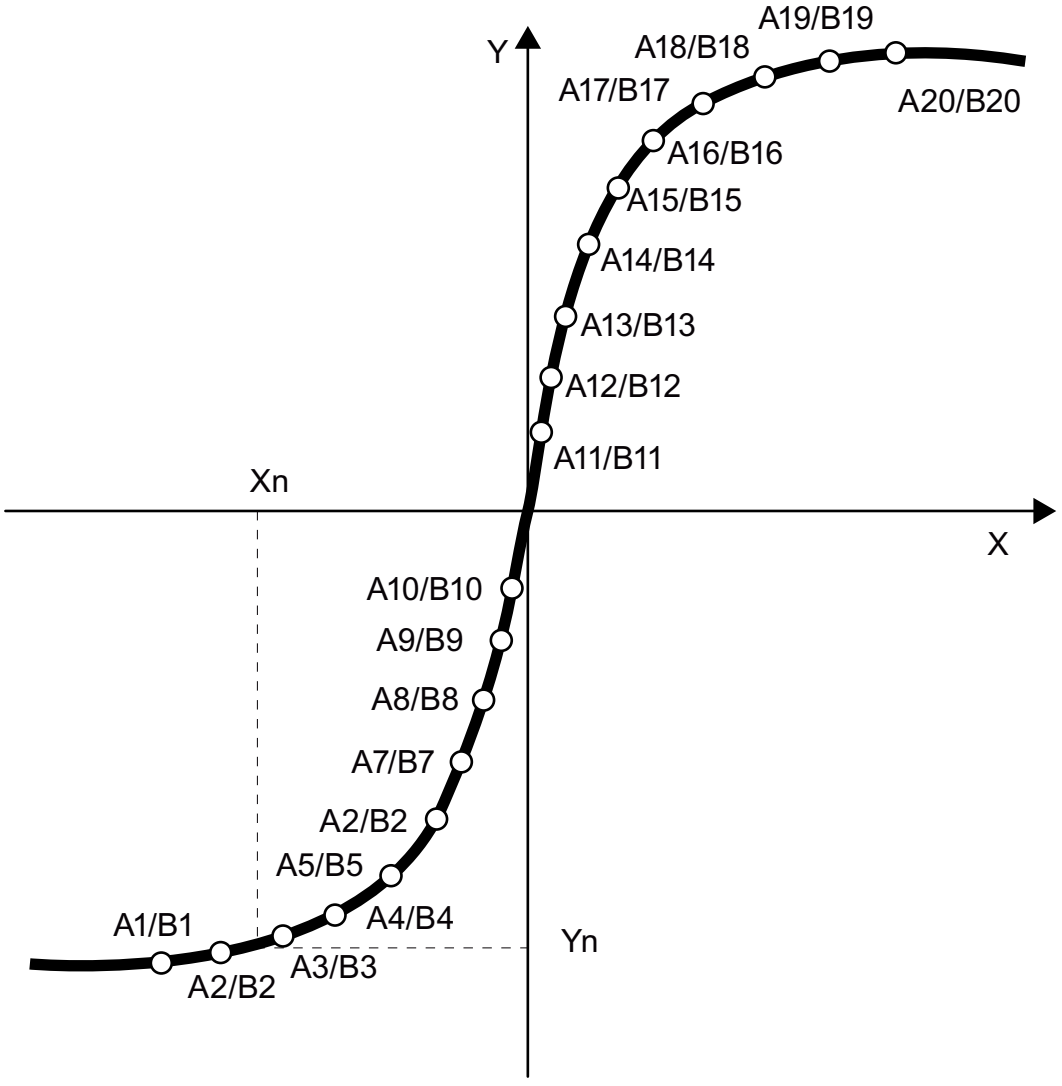
- The block adapts output variable Y arbitrarily to input variable X by means of up to 20 breakpoints in four quadrants.
- Interpolation is carried out linearly between the breakpoints. Outside of A1 and A20, the characteristic curve runs horizontally.

Configuration notes

During configuration, you must ensure that the values of A1 to A20 are sorted in ascending order otherwise incorrect values are output. The ordinate values B1 to B20 can be selected arbitrarily, i.e. irrespective of the preceding value.

If breakpoints are not needed (e.g. as of A16/B16), the following abscissas and ordinates (A16/B16 to A20/B20) must be assigned the same values as A15/B15.

Example



Simulation of the magnetization characteristic curve

Subtractor with two inputs of the INTEGER type

Method of operation

- The block subtracts the value entered at connection X2 from the value entered at connection X1, taking account of the sign. The result, limited to a range of approximately -32768 to 32767, is output at output Y.
- Y= X1-X2

Block connections

Block connection	Description	Default	Value range	Attributes
X1	Minuend	0	INT	
X2	Subtrahend	0	INT	
Y	Difference	0	INT

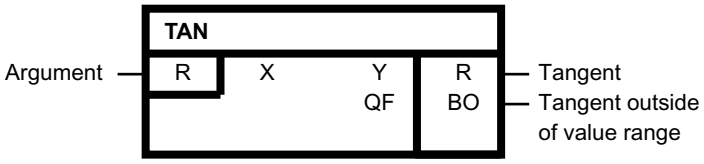
8.1.3.26 TAN

Tangent

Symbol



Brief description

Determination of the tangent value for an angle

Method of operation

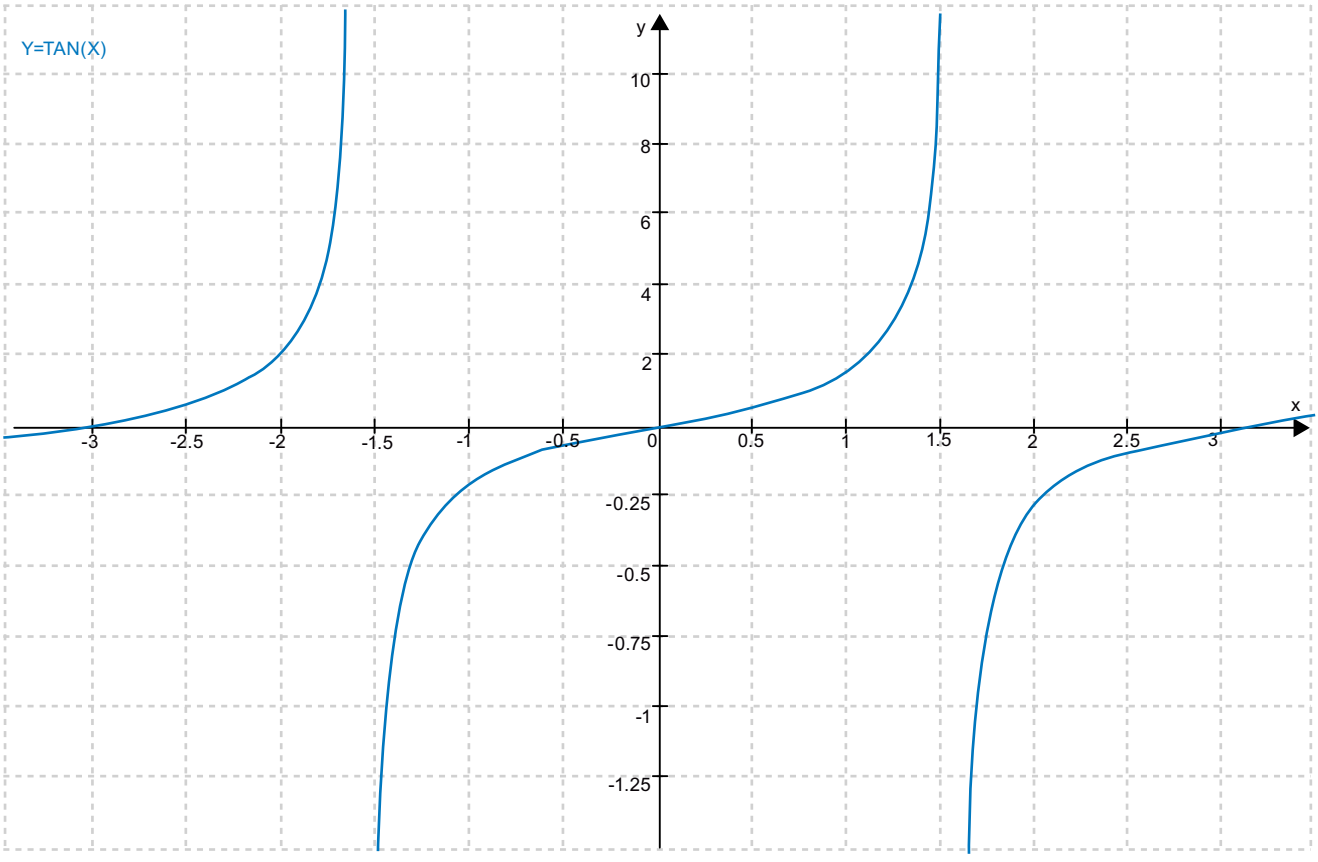
The block determines the associated tangent value in radian measure for an argument to be entered at input X and outputs the result at output Y.

Y = tan X

Output range: -3.402823 E38 to 3.402823 E38

If the tangent value determined lies outside of the range of -3.402823 E38 to 3.402823 E38, the block output Y is limited to -3.402823 E38 or +3.402823 E38, and the binary output QF = 1 is set at the same time.

Transfer function



Block connections

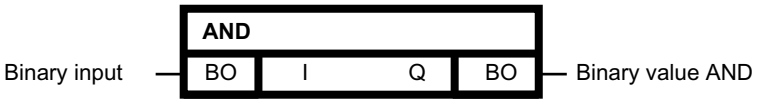
8.1.4 Logic

8.1.4.1 AND

Logic AND operation (BOOL type)

Symbol



Brief description

AND block with up to four inputs of the BOOL type

Method of operation

The block combines the binary values at the inputs I 1-4 to a logic AND and outputs the result at its binary output Q.

$Q = I_{01} \wedge ... \wedge I_{04}$

Output Q = 1, when the value 1 is present at all generic inputs I1 to I4. In all other cases, output Q = 0.

Truth table(s)

Input				Output
I01	I02	I03	I04	Q
0	*	*	*	0
*	0	*	*	0
*	*	0	*	0
*	*	*	0	0
1	1	1	1	1

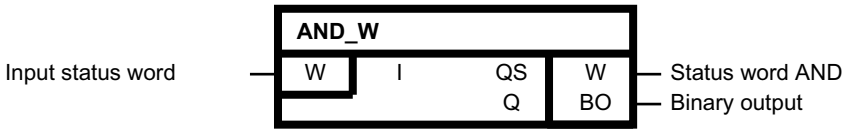
Special characteristics	I comprises up to four connections (I1 to I4)

8.1.4.2 AND_W

Logic AND operation (WORD type)

Symbol



Brief description

AND_W block with up to four inputs of the WORD type

Method of operation

16 binary states are combined in a status word.

This function block links the status words I_{01} to I_{16} bit-by-bit according to the logic AND function. The corresponding bits of status word AND are then set at block output QS.

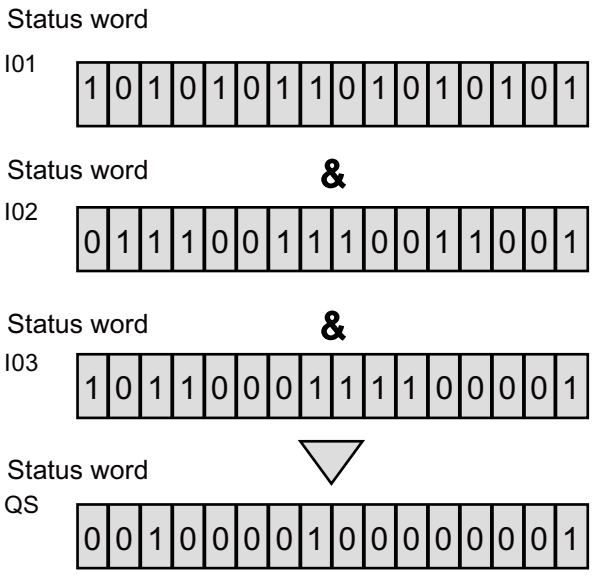
The following applies for bit k of status word AND:

$$QS_k = I_{01k} \wedge .. \wedge I_{nnk}, k = 1...16$$

A bit of the AND status word is equal to 0 when at least one of the equivalent bits on the block inputs I1 to I4 is equal to 0.

The binary output Q is 1 if at least one bit of the status word AND is equal to 1.

Following state diagram (for 3 inputs)



Block connections

Block connection	Description	Default	Value range	Attributes
I	Input status word	16#FFFF	WORD	
QS	Status word AND	16#0000	WORD	
Q	Binary output	0	0/1	

Configuration data

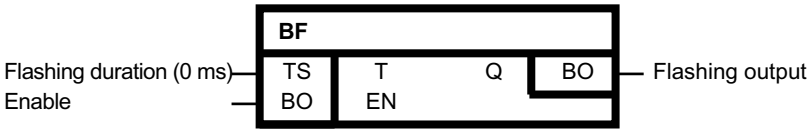
8.1.4.3 BF

Flashing function (BOOL type)

Symbol



Brief description

Block of the BOOL type

- For controlling signal encoders
- As clock generator

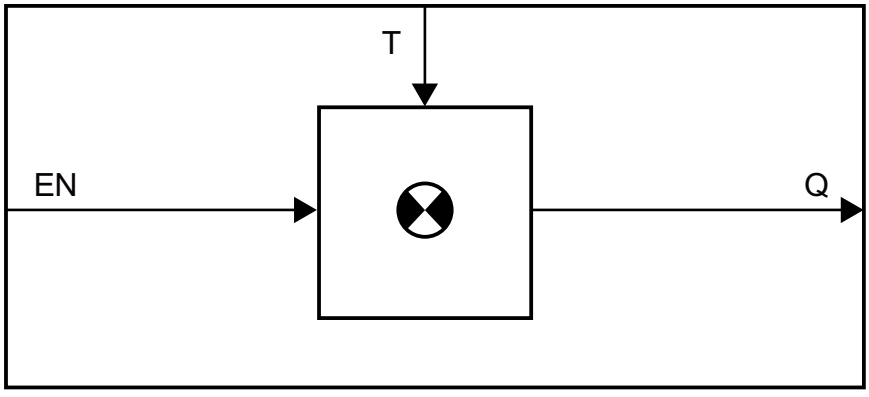
Method of operation

This block sets its output Q alternately to 1 and 0 at a frequency of interval T, as long as input EN = 1.

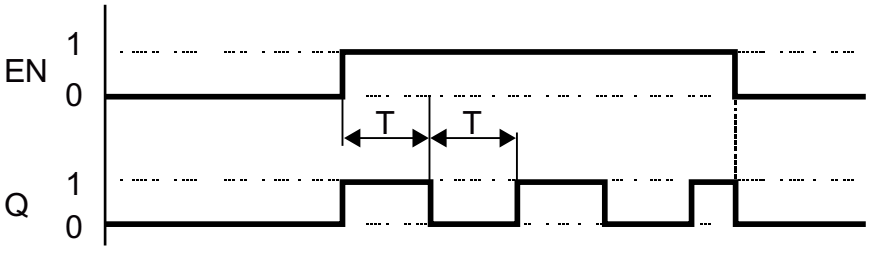
If enable input EN = 0, then output Q = 0.

In this case, T is both the light duration and the dark duration.

Block diagram



Time diagram



Flashing pulse Q subject to flashing duration T and the enable EN

Block connections

Block connection	Description	Default	Value range	Attributes
T	Flashing duration (0 ms)	0	SDTIME	
EN	Enable	0	0/1

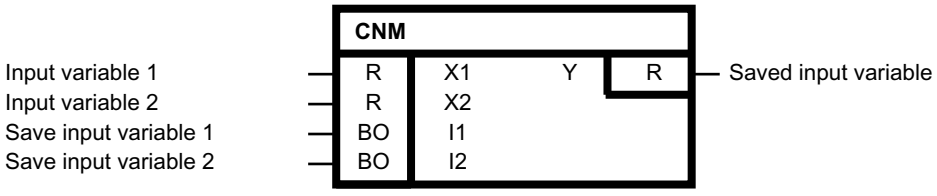
8.1.4.6 CNM

Controllable numeric memory (REAL type)

Symbol



Brief description

Block of the REAL type for saving an instantaneous input value (sample-and-hold function) with

- Selectable input
- Selectable save time
- Rising edge-initiated triggering

The blocks CNM_I and CNM_ D fulfill the same function. They only differ in the data type used.

Method of operation

On a rising edge at I1, X1 is switched through to output Y.

On a rising edge at I2, X2 is switched through to output Y.

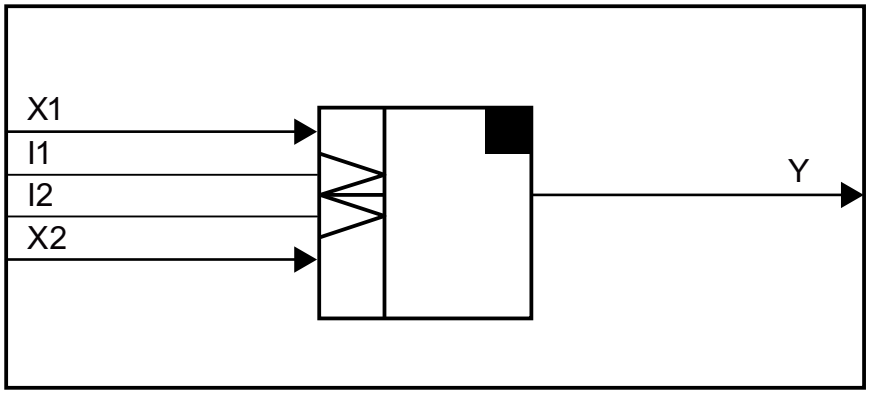
The saved input variable remains pending on Y until the next rising edge at I1 or I2 switches through the next instantaneous value.

In the case of a simultaneous rising edge at I1 and I2, I1 receives priority, and X1 is switched through to Y.

Initialization

If input I1 or I2 receives the value 1 during initialization of an upstream output, the block does not detect a positive edge during the first cyclic pass. Otherwise, the block detects a positive edge during the first cyclic pass. In START mode (edge memory bit), the values for I1 and I2 are stored temporarily.

Block diagram



Truth table(s)

Input		Output Y at the time of triggering
I1	I2	
*	*	$Y_n = Y_{n-1}$
*	0 -> 1	$Y_n = X2_n$
0 -> 1	*	$Y_n = X1_n$

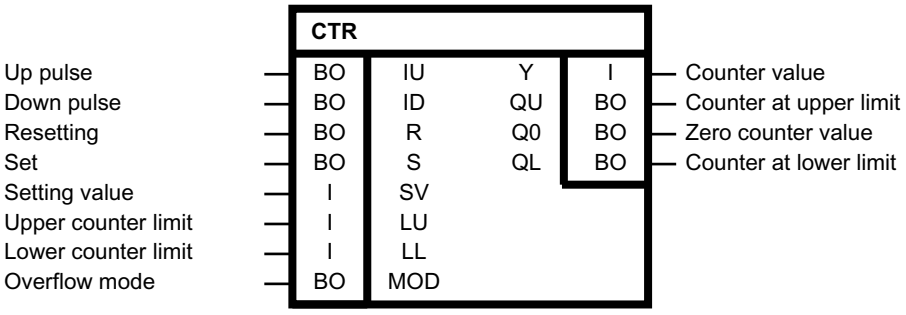
8.1.4.9 CTR

Counter (BOOL type)

Symbol



Brief description

Block for counting up and down with the following counter functions:

- Set counter to zero
- Hold counter at zero (disable)
- Set counter to initial value

Independent setting of upper and lower counter limit.

Method of operation

This block forms an edge-triggered up-down counter. With a rising edge of a pulse at input IU, the counter value is incremented.

With a rising edge of a pulse at input ID, the counter value is decremented. The counter value is present at output Y. Controlling the counter (see also truth table). With S=1, the counter value Y can be preset with the set value SV.

However, the reset input R has priority over the set input. As long as R is logic 1, Y is held at 0. The counter is disabled. If Y is not in the counting range between LL and LU, the output is set to the active limit value when R = 1.

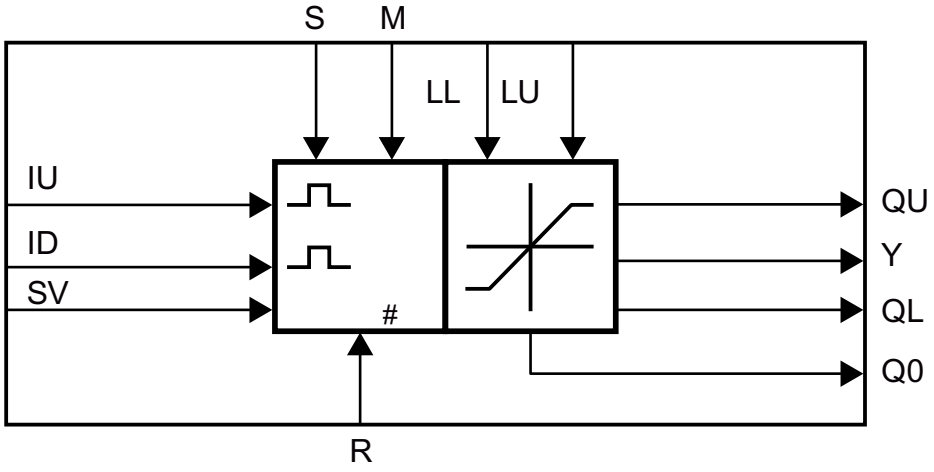
The working area of the counter can be specified via LU (upper counter limit value) or LL (lower counter limit value).

The setting value (SV) is in the range from LL >= SV >= LU.

MOD=0	When these limits are reached, the counter stops counting and the display QU (counter at upper limit) or QL (counter at lower limit) is set.
MOD=1	When the upper limit (LU) is reached, the counter value is set to the lower limit when the next Up pulse occurs; QU = 1 indicates positive overflow for a cycle.
	When the lower limit (LL) is reached, the counter value is set to the upper limit when the next Down pulse occurs; QL = 1 indicates negative overflow for a cycle.

When the counter value is zero, the output Q0 is set to 1.

Block diagram



Truth table(s)

Binary command	Binary command	Counter value Y
S	R	
0	0	Y is retained
0	1	Y is reset
1	0	Y = SV (set value)
1	1	Y is reset

Counter value when set/reset command is given

Initialization

The initialization defines the start value for the first cyclic pass. If input ID or IU is preset with 1, the block cannot detect a positive edge during the first cyclic pass.

Boundary conditions:

- LL <= Y <= LU for LL <LU
- Y = LU for LL >= LU

Block connections

Block connection	Description	Default	Value range	Attrib-utes
IU	Up pulse	0	0/1	
ID	Down pulse	0	0/1

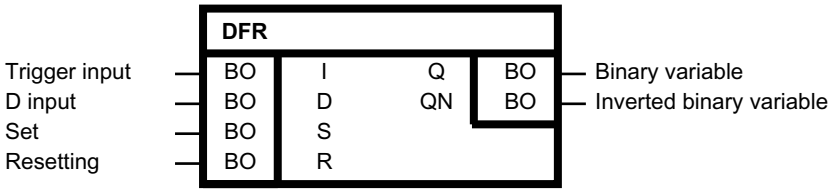
8.1.4.10 DFR

Reset-dominant D-type flip-flop (BOOL type)

Symbol



Brief description

Block of the BOOL type for use as reset-dominant D-type flip-flop

Method of operation

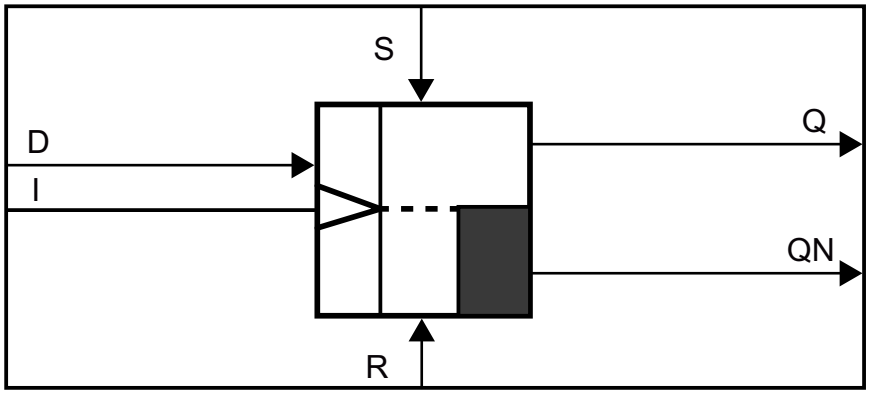
If the two inputs S and R are logic 0, the D input information is switched through to output Q on a rising edge at trigger input I. Output QN always has the value inverse to Q. With logic 1 at input S, output Q is set to logic 1. If input R is set to logic 1, then output Q is set to logic 0. If both inputs are logic 0, then Q does not change. However, if the two inputs S and R are logic 1, then Q is logic 0, since the reset input dominates.

Initialization

If input I receives the value 1 during initialization from an upstream output, the block does not detect a positive edge during the first cyclic pass.

Otherwise, the block detects a positive edge during the first cyclic pass. In START mode, the value for I is stored temporarily.

Block diagram



Truth table(s)

D	I	Binary command		Output states	
		S	R	Q	QN
0	0 -> 1	0	0	0	1
1	0 -> 1	0	0	1	0
*	1 -> 0	0	0	Q_{n-1}	Q_{n-1}

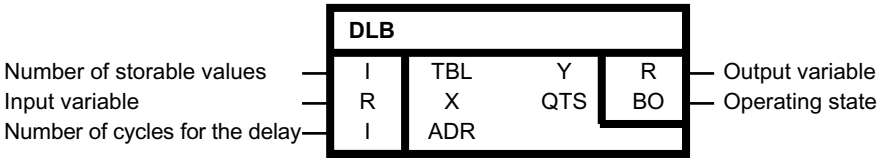
8.1.4.12 DLB

Delay element (REAL type)

Symbol



Brief description

Block of the REAL type for the output of an input variable which is delayed by a specifiable number of sampling times.

Method of operation

If the operating state is QTS = 1, the block contains a delay memory of the TBL variable. The input variable specified at input X is output after a delay as output variable Y. The delay is specified by the integer multiple ADR of the sampling time (time slice in which the block is calculated). When operating mode QTS = 0, the delay memory is not activated. In this case, the input variable specified at input X is output immediately as output variable Y.

Initialization

During initialization, the delay memory is requested for the purpose of acquiring TBL input variables. The delay memory can contain a maximum of 1000 values. If TBL < 0, TBL is limited to 0. QTS = 1 indicates that the delay memory requested in TBL is available. QTS = 0 indicates that the system was not able to make the memory available, due to a lack of resources, or a TBL value > 1000 has been defined. In this case, output Y is corrected to input X during cyclic operation.

Block connections

Block connection	Description	Default	Value range	Attributes
TBL	Number of storable values	100	0...1000	
X	Input variable	0.0	REAL	
ADR	Number of cycles for the delay	0	0...1000

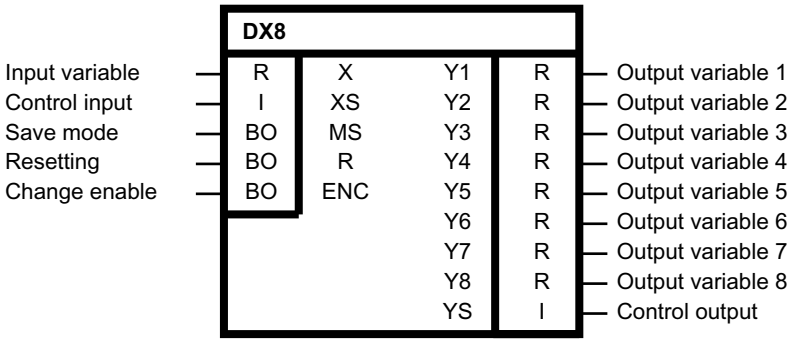
8.1.4.13 DX8

Demultiplexer, eight outputs, cascadable (REAL type)

Symbol



Brief description

Block of the REAL type for demultiplex operation. This block is cascadable.

Method of operation

Depending on ENC, R, MS and XS = 1 to 8, the block switches through its input X to one of the eight selectable outputs Y1 to Y8 (example: XS = 3 means Y3 = X).

When XS = 0 or XS >= 9, none of the block inputs Y1 to Y8 is selected. Non-selected outputs are either set to zero or retain their previous value until the next change.

The following priority sequence applies for the control inputs:

ENC before R before MS

When ENC = 0, all outputs Y1 to Y8 remain unchanged, regardless of R and MS.

When ENC = 1, outputs Y1 to Y8 are enabled for change.

When R = 1, all outputs Y1 to Y8 receive the value 0, irrespective of MS.

When MS = 0 (non-latching mode), all outputs Y1 to Y8 not selected by XS receive the value 0.

When MS = 1 (storing mode), all outputs not selected by XS remain unchanged.

Truth table(s)

ENC	R	MS	XS	Outputs Y1 to Y8
0	*	*	*	The previous values are retained
1	1	*	*	Y1 to Y8 = 0
1	0	0	1 <= XS <= 8	• Selected output = X • Output not selected = 0
1	0	0	XS = 0 or XS >= 9	Y1 to Y8 = 0
1	0	1	1 <= XS <= 8	• Selected output = X • Outputs not selected remain unchanged
1	0	1	XS = 0 or XS >= 9	All previous values remain unchanged

Cascading

The block output YS must be connected to the block input XS of the following block.

For XS = 0 to 8, YS = 0

When XS > 8: YS = XS-8

(use for cascading)

Block connections

Block connection	Description	Default	Value range	Attrib-utes

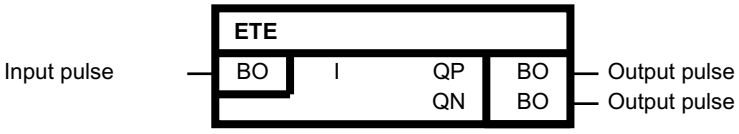
8.1.4.16 ETE

Edge evaluator (BOOL type)

Symbol



Brief description

Edge evaluation

Method of operation

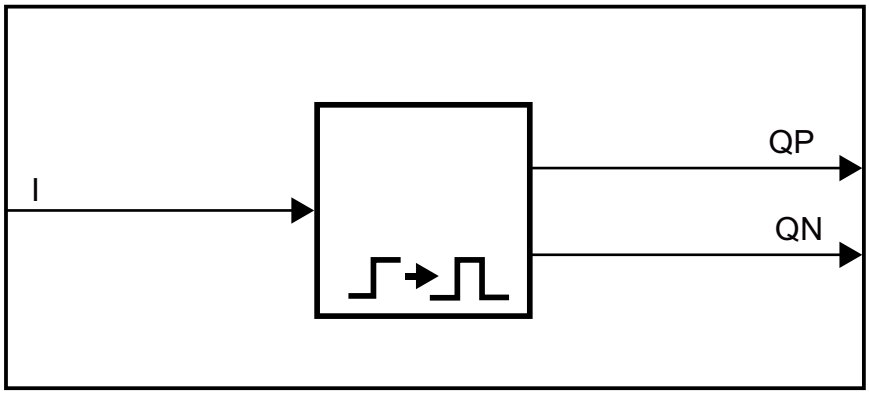
This block detects a signal change at input I. With a positive edge (0→1) at input I, output QP = 1 is set for scan time TA.

With a negative edge (1→0) at input I, output QN = 1 is set for scan time TA.

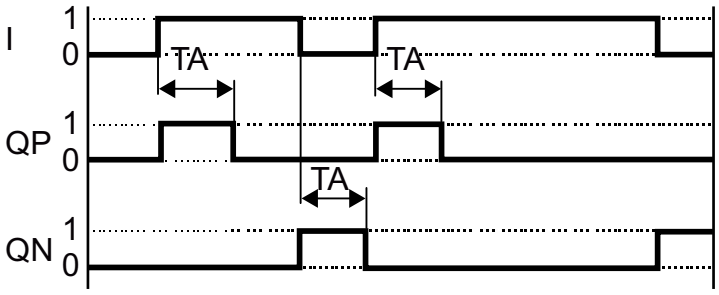
Initialization

The initialization defines the start value for the first cyclic pass. If input I receives the value 1 during initialization of an upstream block, the block cannot detect a positive edge during the first cyclic pass. If input I receives the value 0 during initialization of an upstream block, the block cannot detect a negative edge during the first cyclic pass.

Block diagram



Time diagram



Output pulses QP and QN as a function of scan time TA and input pulse I

Block connections

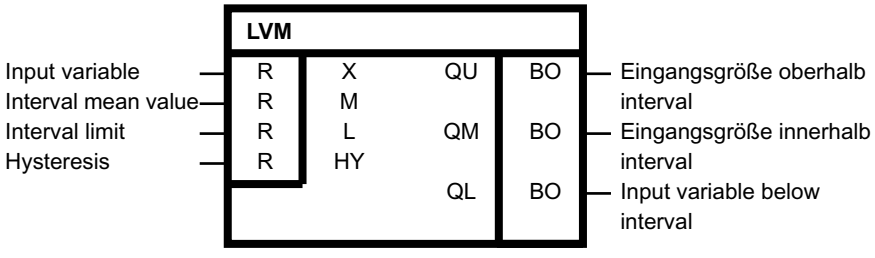
Double-sided limit monitor with hysteresis (BOOL type)

Symbol



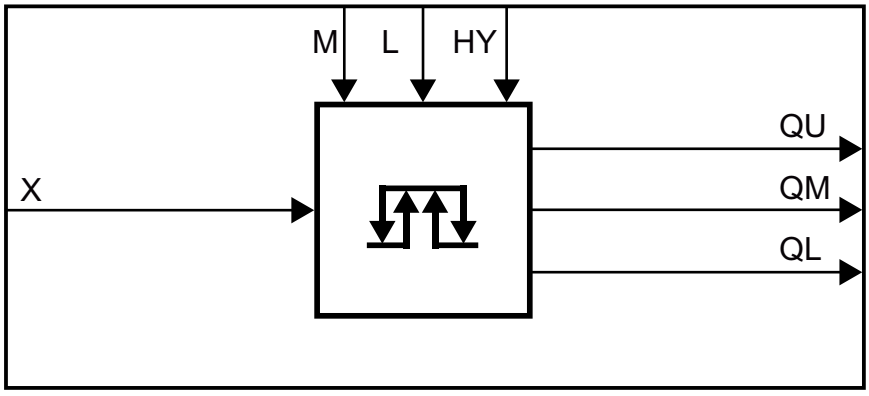
Brief description

- The block of the BOOL type monitors an input variable through comparison with selectable reference variables.
- Can be used for monitoring setpoints, actual values and measured values, as well as for the suppression of frequent switching (chatter).
- The block provides a window discriminator function.

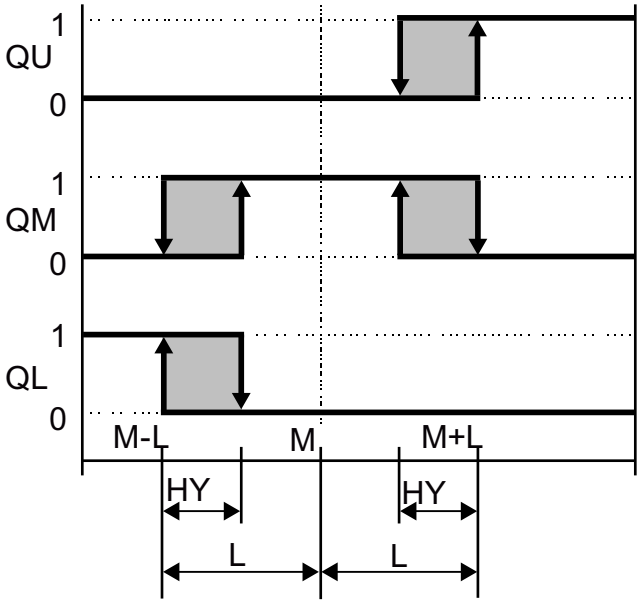
Method of operation

The block calculates an intermediate value based on a transmission characteristic (see Transmission characteristic) with hysteresis. This intermediate value is compared with the interval limits, and the result is output at outputs QU, QM, and QL. The transfer characteristic is configured with the values for the mean value M, the interval limit L and the hysteresis HY.

Block diagram



Transfer function



Block connections

Block connection	Description	Default	Value range	Attributes
X	Input variable	0.0	REAL	
M	Interval mean value	0.0	REAL	
L	Interval limit	0.0	REAL	
HY	Hysteresis	0.0	REAL	
QU	Input variable above the interval	0	0/1	
QM	Input variable above the interval	0	0/1	
QL	Input variable above the interval	0	0/1

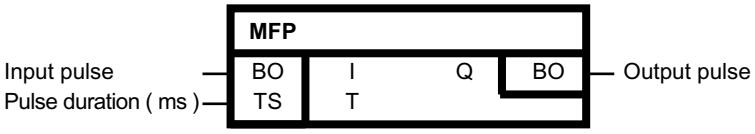
8.1.4.18 MFP

Pulse generator (BOOL type)

Symbol



Brief description

- Timer for generating a pulse with a fixed duration.
- Used as a pulse-contracting or pulse-stretching monoflop.

Method of operation

The rising edge of a pulse at input I sets output Q to 1 for the pulse duration T. The pulse generator cannot be retriggered. When T=0, a pulse duration of 1 cycle is active.

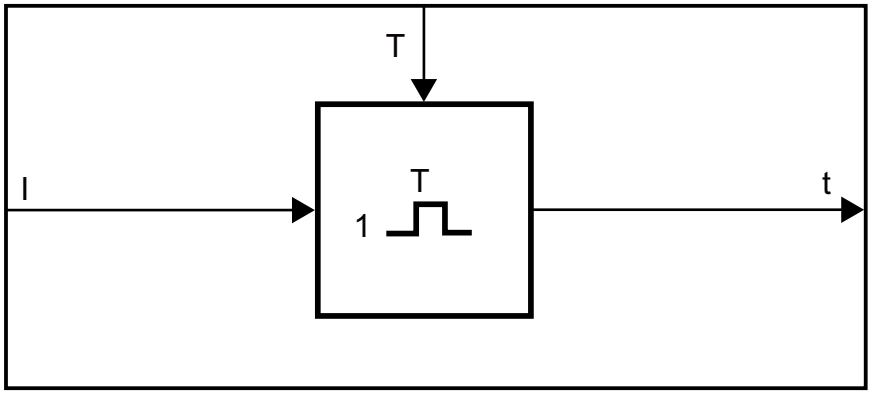
Initialization

The initialization defines the start value for the first cyclic pass.

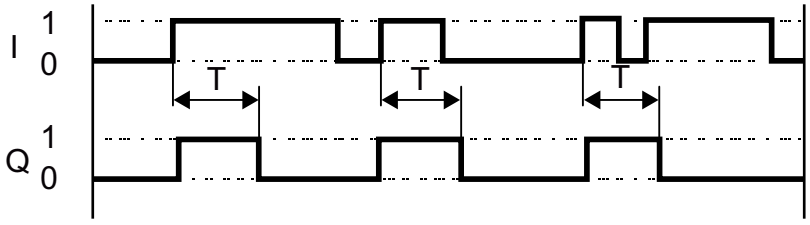
If input I receives the value 1 during initialization from the upstream block output, the block cannot detect a positive edge during the first cyclic pass.

If output Q receives the default value 1, output Q = 1 is set after initialization for the pulse duration T.

Block diagram



Time diagram



Output pulse Q as a function of pulse duration T and input pulse I

Block connections

Block connection	Description	Default	Value range	Attributes

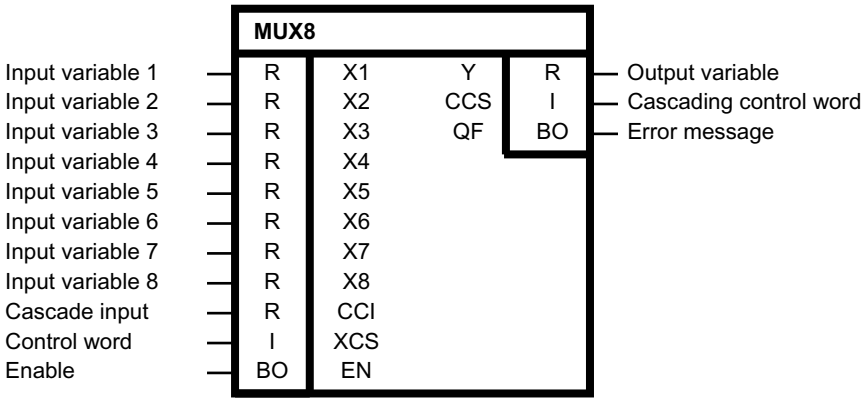
8.1.4.19 MUX8

Multiplexer, cascadable (REAL type)

Symbol



Brief description

Block of the REAL type for 8-fold multiplex operation. This block is cascadable.

Method of operation

This block outputs the value of the cascading input CCI at output Y as long as the enable input EN is logic 0.

When EN is logic 1, one of the input variables X1 to X8 is switched through to output Y as long as the 16-bit control word XCS assumes a value between 1 and 8.

If the value of the input XCS > 8, output Y assumes the value 0, and output QF becomes logic 1. The cascading control word assumes the value CCS = XCS-8, see truth table.

The outputs Y, CCS, and QF can be used to cascade the blocks. In this case, output Y of the first block is connected to input CCI of the downstream multiplexer, output CCS to the following XCS, and output QF to the following input EN.

Method of operation

16 binary states are combined in a status word.

The block combines the status words I1 to I4 bit-by-bit according to the logic OR function.

The result is given to the block output QS (status word OR).

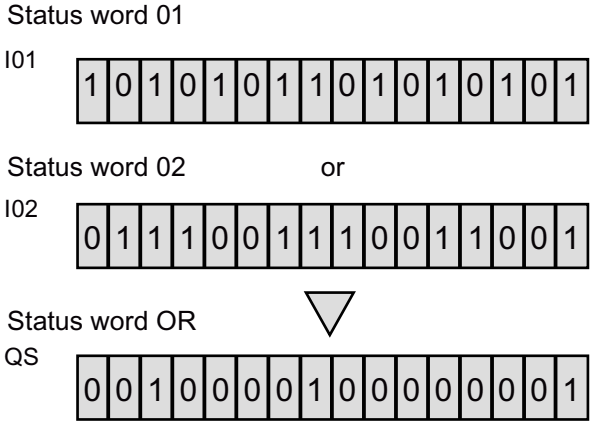
The following applies for bit k of status word OR:

$QS_k = I02_k \vee I02_k, \quad k = 1...16$

A bit of the OR status word is equal to 1 when at least one of the equivalent bits on the block inputs I1 to I4 is equal to 1.

The binary output Q is 1 if at least one bit of the status word OR is equal to 1.

Following state diagram (for 3 inputs)



Block connections

Block connection	Description	Default	Value range	Attrib-utes

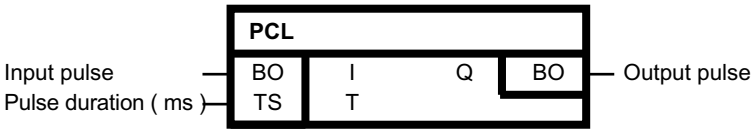
Special characteristics	I comprises up to four connections (I1 to I4)

8.1.4.42 PCL

Pulse shortener (BOOL type)

Symbol



Brief description

Timer for limiting the pulse duration

Method of operation

The rising edge of a pulse at input I sets output Q to 1. Output Q becomes 0 when input I = 0 or pulse duration T has expired. When T=0, a pulse duration of 1 cycle is active.

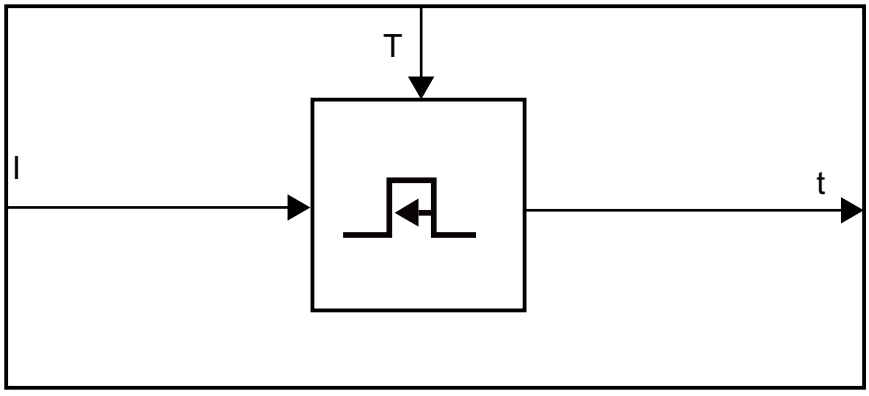
Initialization

The initialization defines the start value for the first cyclic pass.

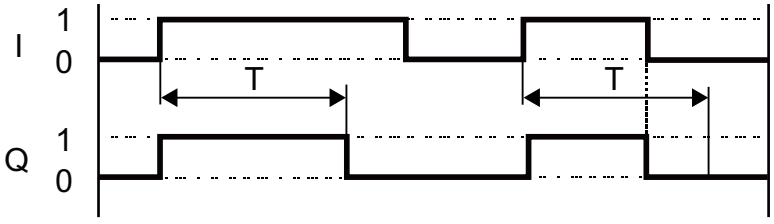
If input I receives the value 1 during initialization from the upstream block output, the block cannot detect a positive edge during the first cyclic pass.

If output Q receives the default value 1, output Q = 1 is set after initialization for the pulse duration T.

Block diagram



Time diagram



Output pulse Q as a function of pulse duration T and input pulse I

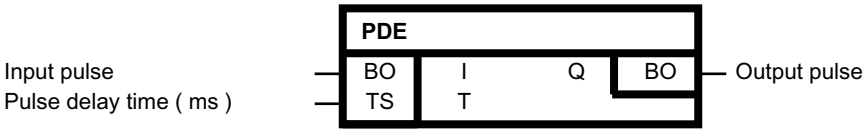
8.1.4.43 PDE

Switch-on delay (BOOL type)

Symbol



Brief description

BOOL-type timer with on-delay

Method of operation

The pulse delay time at the input T is taken over with the rising edge at input I. After this time has elapsed, output Q is set to 1.

Output Q becomes 0 when I = 0.

If the duration of input pulse I is less than pulse delay time T, then Q remains at 0.

If time T is so long that the maximum value that can be displayed internally (T/ta as 32-bit value, where ta = sampling time) is exceeded, the maximum value is set (e.g. when ta = 1 ms, approx. 50 days).

When T=0, a pulse delay time of 1 cycle is active.

Method of operation

The initialization defines the start value for the first cyclic pass.

If input I receives the value 1 during initialization from the upstream block output, the block cannot detect a positive edge during the first cyclic pass. The pulse delay time T is therefore not taken over in the first cyclic pass with I = 1, the specified time from the initialization remains effective.

If output Q receives a value of 1 during initialization, then output Q = 1 is set immediately after initialization when I = 1.

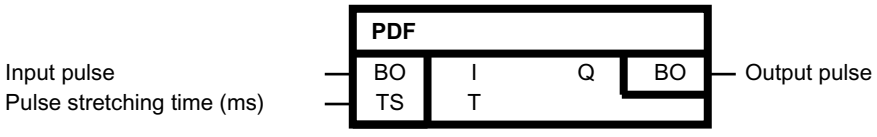
8.1.4.44 PDF

Switch-off delay (BOOL type)

Symbol



Brief description

BOOL-type timer with off-delay

Method of operation

The falling edge of a pulse at block input I resets output Q to 0 after pulse stretching time T.

Output Q becomes 1 when I = 1.

Output Q becomes 0 when input pulse I = 0 and the off-delay time T has expired.

If input I is reset to 1 before time T expires, then output Q remains at 1.

When T=0, a pulse stretching time of 1 cycle is active.

Initialization

The initialization defines the start value for the first cyclic pass.

If input I receives the value 1 during initialization from the upstream block output, the block cannot detect a negative edge during the first cyclic pass.

If output Q receives the value 1 during initialization, output Q = 1 is set after initialization for the pulse stretching time T.

Block diagram

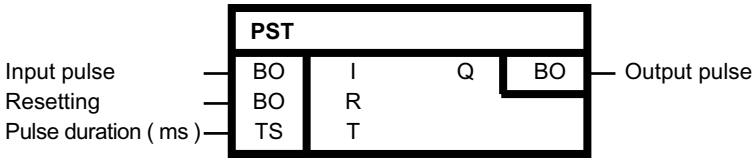
Pulse stretching block (BOOL type)

Symbol



Brief description

Block for the generation of a pulse with a minimum duration and with additional reset input.

Method of operation

The rising edge of a pulse at input I sets output Q to 1.

Output Q does not fall back to 0 until input pulse I = 0 and the pulse duration T has expired.

Output Q can be set to zero at any time by means of the reset input R with R = 1.

When T=0, a pulse duration of 1 cycle is active.

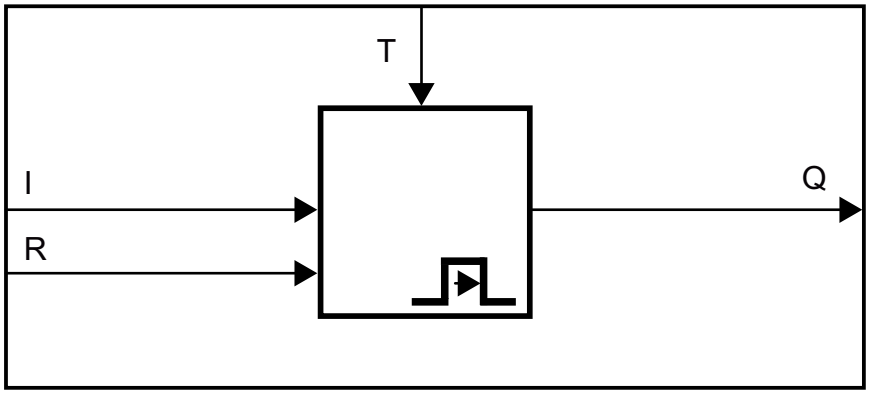
Initialization

The initialization defines the start value for the first cyclic pass.

If input I receives the value 1 during initialization from the upstream block output, the block cannot detect a positive edge during the first cyclic pass.

If output Q receives the value 1 during initialization, output Q = 1 is set after initialization for the pulse duration T.

Block diagram



Time diagram

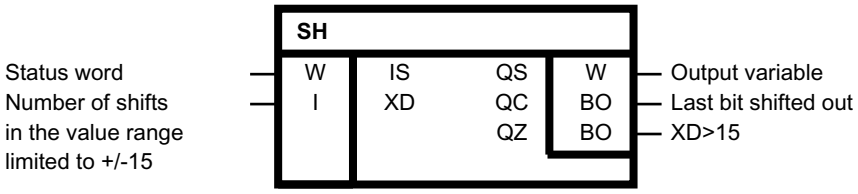
Shift block (WORD type)

Symbol



Brief description

The block of the WORD type shifts a status word bit-by-bit to the left or right.

Method of operation

The block shifts the status word present at input IS bit-by-bit by the number of positions specified at input XD.

New positions created by the shifting are filled with zeros irrespective of the shift direction.

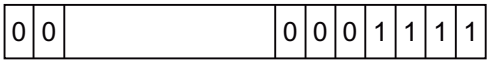
The last bit shifted out is output on output QC. When XD = 0, QC = 0 is always true. When |XD| > 15, QC = 0, QS = 0 and QZ = 1 are always true.

Shift to the left - example:

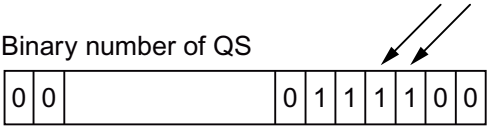
XD = 2; IS = 15

-> QS = 60; QC = 0

Binary number of IS



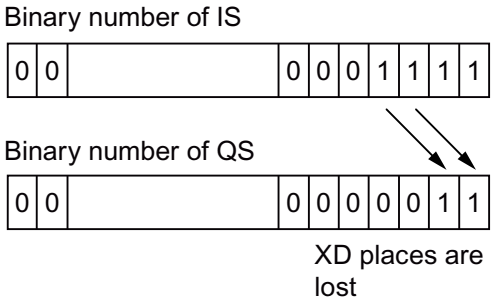
Binary number of QS



Shift to the right - example:

XD = -2; IS = 15

-> QS = 3 (remainder is omitted); QC = 1



Block connections

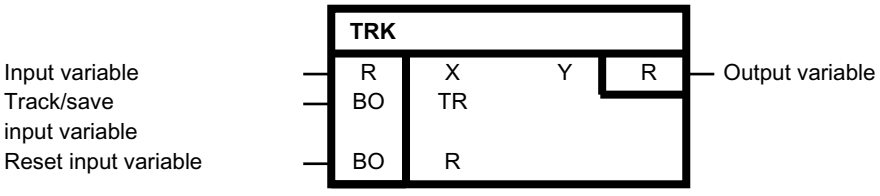
8.1.4.50 TRK

Tracking/memory element (REAL type)

Symbol



Brief description

Block of the REAL type for saving a current input value with the following properties:

- Edge-controlled latch functions for the input value
- Level-controlled correction of the output value

Method of operation

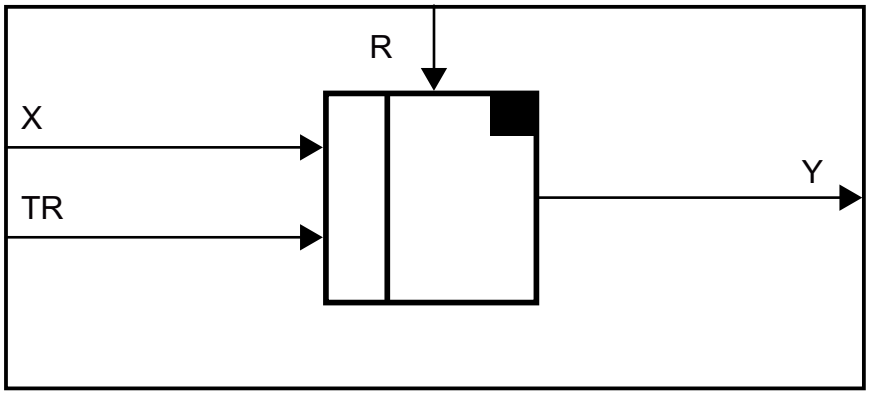
TRACK	TR = 1	Direct tracking of output value Y = X.
	TR = 1-> 0	With a negative edge at TR, the current input variable is saved and output on output Y.
	TR = 0	The value at output Y does not change.
RESET	R = 1	Output Y is reset to 0. The reset input is dominant.

Initialization

If input TR receives the value 1 during initialization of an upstream block output, a negative edge can be detected during the first cyclic pass. In START mode, the value for TR is stored temporarily.

If input TR receives the value 0 during initialization of the upstream block output, the block cannot detect a negative edge during the first cyclic pass.

Block diagram



Truth table(s)

Input		Output Y at the time of triggering

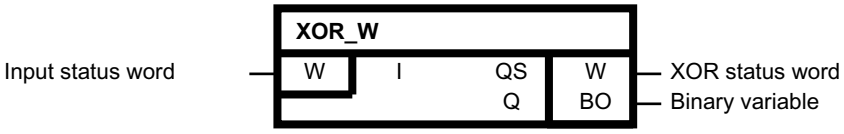
8.1.4.53 XOR_W

Logic exclusive OR operation (WORD type)

Symbol



Brief description

XOR block with up to four inputs of the WORD type

Method of operation

The block combines the status words I1 to I4 bit-by-bit according to the logic exclusive OR function.

The result is given to the block output QS (status word XOR).

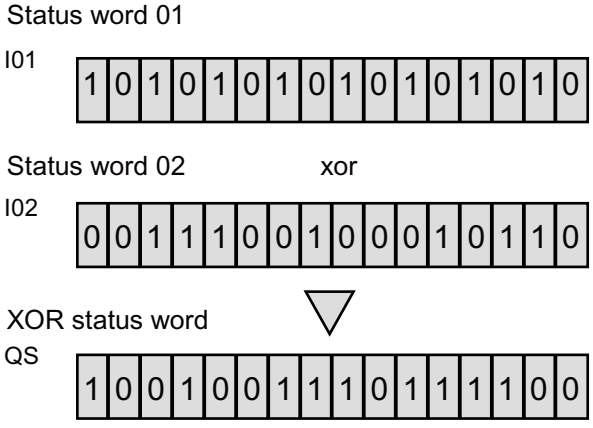
The following applies for bit k of status word XOR:

$$QS_k = (\overline{I01_k} \wedge I02_k) \vee (I01_k \wedge \overline{I02_k}), k = 1...16$$

A bit of status word XOR equals 1 if an odd number of the equivalent bits at the generic block inputs I1 to I4 equals 1.

The binary output Q is 1 if at least one bit of the status word XOR is equal to 1.

Following state diagram (for 3 inputs)



Block connections

Block connection	Description	Default	Value range	Attributes

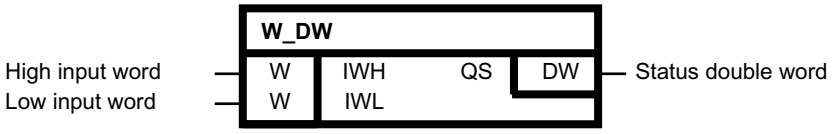
8.1.5.48 W_DW

Status word to status double word converter

Symbol



Brief description

Two 16-bit words are copied to one 32-bit double word.

Method of operation

The input variables are mapped according to the formula

$QS = (IWL + IWH) * 2^{16}$

to output QS.

Block connections

Block connection	Description	Default	Value range	Attrib-utes
IWH	High input word	16#0000	WORD	
IWH	Low input word	16#0000	WORD	
QS	Status double word	16#00000000	DWORD

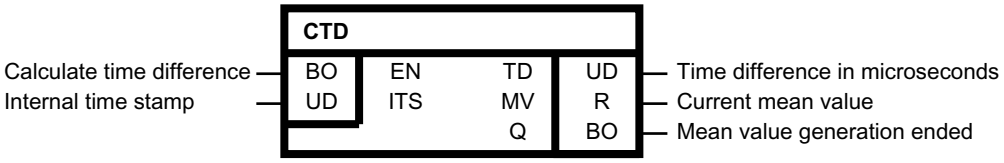
Special character-istics	-

8.1.6 System

8.1.6.1 CTD

Time difference determination from an internal time stamp

Symbol



Brief description

Block for determining a time difference in microseconds.

Method of operation

If EN = 1, the time difference relative to time stamp ITS is determined and output at output TD. Time stamp ITS must be determined beforehand with block GTS. A positive edge at EN starts the mean value generation of TD, and the output is output at MV. After 10000 mean value determinations, the mean value generation ends and output Q is set to 1. If input EN = 0 is set, the mean value generation and output Q is reset. Outputs TD and MV retain their last value.

Block connections

Block connection	Description	Default	Value range	Attributes
EN	Calculate time difference	0	0/1	
ITS	Internal time stamp	0	UDINT	
TD	Time difference in microseconds	0	UDINT	
MV	Current mean value	0	REAL	
Q	Mean value generation ended	0	0/1

8.1.6.2 GTS

Reads out a time stamp

Symbol

Brief description

Blocks for reading out an internal time stamp for determination of runtimes. The determined time stamp can then be indicated at the CTD block for calculating a time difference in microseconds.

Method of operation

If EN = 1, an internal time stamp is determined and output at output TS. If EN = 0 is predefined, the last determined time stamp is output at TS.

Block connections

Block connection	Description	Default	Value range	Attributes
EN	Output time stamp	0	0/1	
ITS	Internal time stamp	0	UDINT

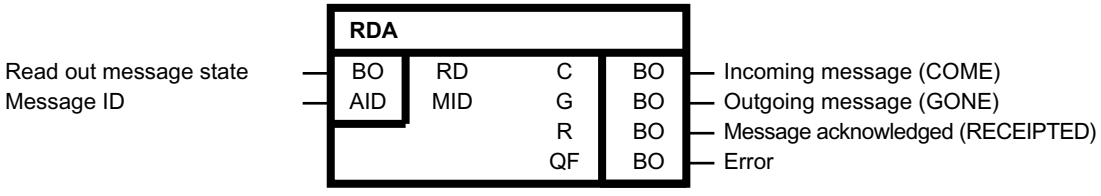
8.1.6.4 RDA

Reads out a message

Symbol



Brief description

The block reads the state of a message and its acknowledgement state.

Method of operation

- The message is configured in SIMOTION SCOUT and referenced via a project-wide unique ID.
- Input MID contains the message ID, e.g. _alarm.Message.

- The state of the message is determined as long as input RD=1.
- A change of the message ID is possible. The state of the message ID specified at input MID is read out in each cycle.
- The outputs display the state of the message. The following combinations are possible:

C (incoming message)	G (outgoing message)	R (message acknowledged)	Meaning
0	1	0	Outgoing message, not acknowledged
1	0	0	Incoming message, not acknowledged
1	0	1	Incoming message, acknowledged
0	0	0	Message not in the message buffer *)

*) Message not in the message buffer - there are three options:

- Message never triggered.
- Message triggered via AlarmS, but also sent.
- Message triggered via _AlarmSq, sent and acknowledged at the display device.

The outputs are refreshed as long as RD=1. With RD=0, the last state of the message buffer is retained. Output Q is set when an error occurs, e.g. message ID not configured.

Block connections

Block connection	Description	Default	Value range	Attributes
RD	Read out message state	0	0/1	
MID	Message ID	STRUCTALARMID#NIL	StructAlarmId	
C	Incoming message (COME)	0	0/1	
G	Outgoing message (GONE)	0	0/1	
R	Message acknowledged (RECEIPTED)	0	0/1	
QF	Error	0	0/1

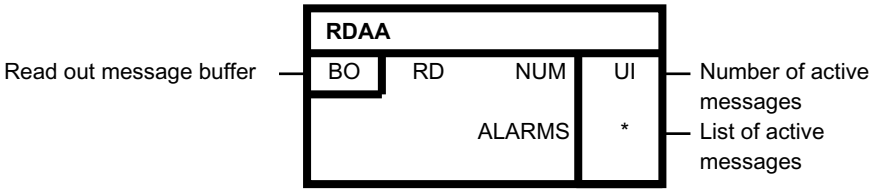
8.1.6.5 RDAA

Reads out all messages

Symbol



Brief description

The list of active messages in the SIMOTION target device is read out.

Method of operation

- The reading out of all active messages is initiated with a rising edge at input RD.
- The number of active messages is returned at NUM output.
- A field of up to 40 active messages is displayed at the ALARMS output.
  The following is displayed for each alarm:
  - The message ID
  - The identifier for message not acknowledgeable (0), acknowledgeable message (1)
  - The state of the alarm: OUTGOING_ALARM (0), INCOMING_ALARM (1)
- The outputs are refreshed as long as RD=1. With RD=0, the last state of the message buffer is retained.

Block connections

Block connection	Description	Default	Value range	Attributes
RD	Read out message buffer	0	0/1	
NUM	Number of active messages	0	0..40	
ALARMS	List of active messages			
ALARMS[]	Up to 40 messages can be active	0		
ALARMS[].Id	Message ID	STRUCTALAR-MID#NIL	StructAlarmId	
ALARMS[].type	Corresponds to enumAlarmIdType (0: ALARM_S, 1: ALARM_SQ)	0	0/1

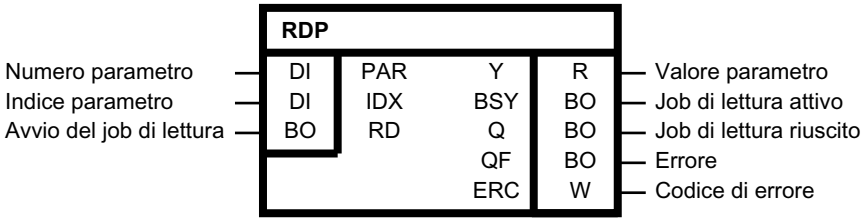
8.1.6.6 RDP

Reads drive parameters (REAL type)

Symbol



Brief description

The block enables the asynchronous reading of drive parameters of the REAL type on the local drive object.

Method of operation

The parameter number and the index of the parameter to be read must be specified at inputs PAR and IDX, respectively. If a parameter is not indexed, IDX = 0 must be set. The parameter is always read on the drive object on which the chart with the block is calculated. It is not possible to access parameters on several drive objects.

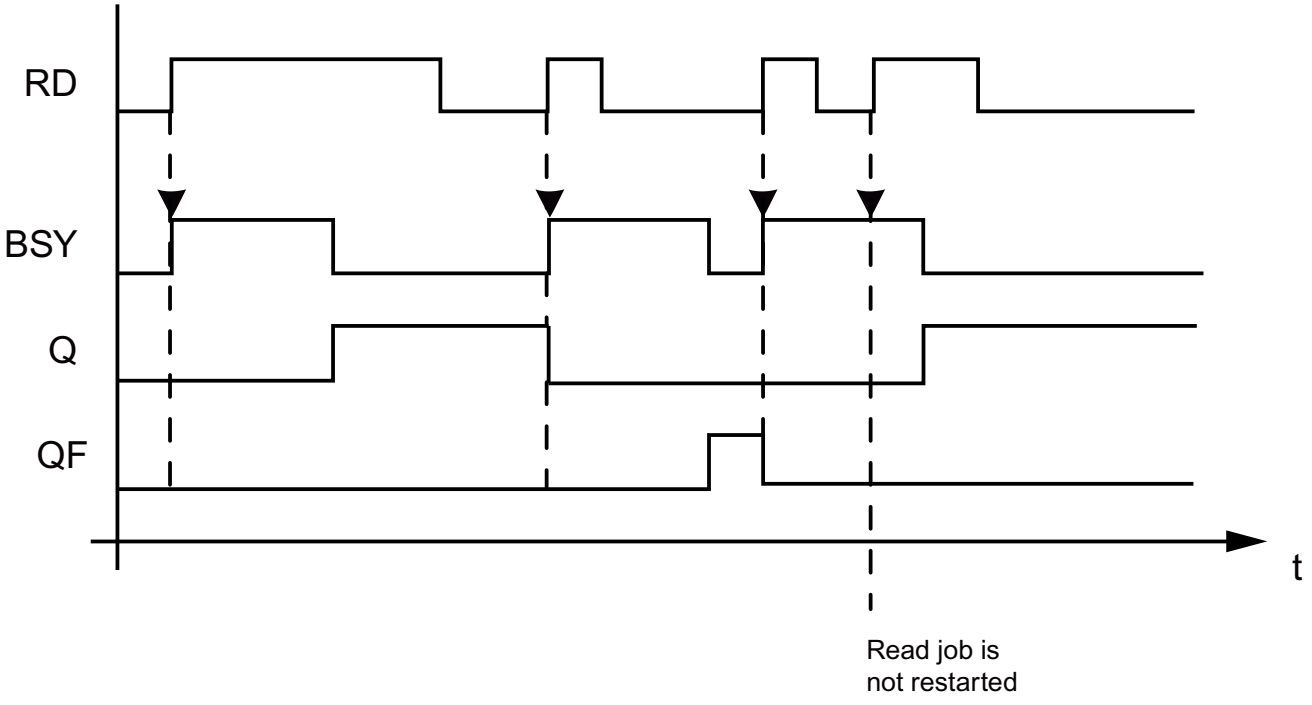
The asynchronous read job is started on a positive edge at input RD. As long as the job is active, the BSY flag is set. The number of cycles for a parameter access is dependent on the system utilization and can vary from job to job. During an active read job, any additional positive edges at input RD are ignored.

Output Q = 1 indicates that the parameter has been read successfully and the value is available at output Y. Y holds its value until a new value has been read. If an error occurs during an access, this is signaled with QF = 1. Output Y retains its last value.

For error diagnostics, the error code ERC can be evaluated. ERC corresponds to the error code for parameter accesses according to PROVIdrive DPV1. The possible error codes can be found in Appendix A.2 of this document or in the SINAMICS Function Manual FH1 in Section PROFIBUS DP / PROFINET IO Communication and there in the Subsection Communication according to PROFIdrive → Acyclic communication → Configuration of the jobs and responses in Table Error values in DPV1 parameter responses.

ERC is only valid as long as QF = 1.

Time diagram



Quantity framework

Any number of asynchronous jobs of different block instances can be issued in parallel. Each block instance can only process one job.

Block connections

Block connection	Description	Default	Value range	Attrib-utes

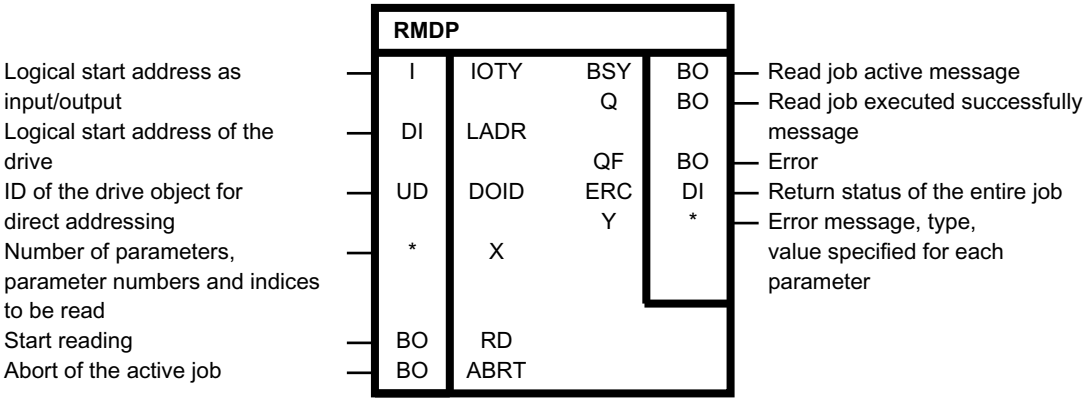
8.1.6.12 RMDP

Reads drive parameters from the controller

Symbol



Brief description

The RMDP block enables up to 39 SINAMICS parameters to be read from the DCC SIMOTION program. Only SINAMICS drives are supported. For error diagnostics, the error code ERC can be evaluated. ERC corresponds to the error code for parameter accesses according to PROVIdrive DPV1. The possible error codes can be found in Appendix A.2 of this document or in the SIMOTION Communication System Manual in Section PROFIdrive and there in the Subsection Acyclic communication (Base Mode Parameter Access) → Error evaluation in table Error codes in Base Mode Parameter Access responses.

The RMDP block is available as of SIMOTION V4.2.

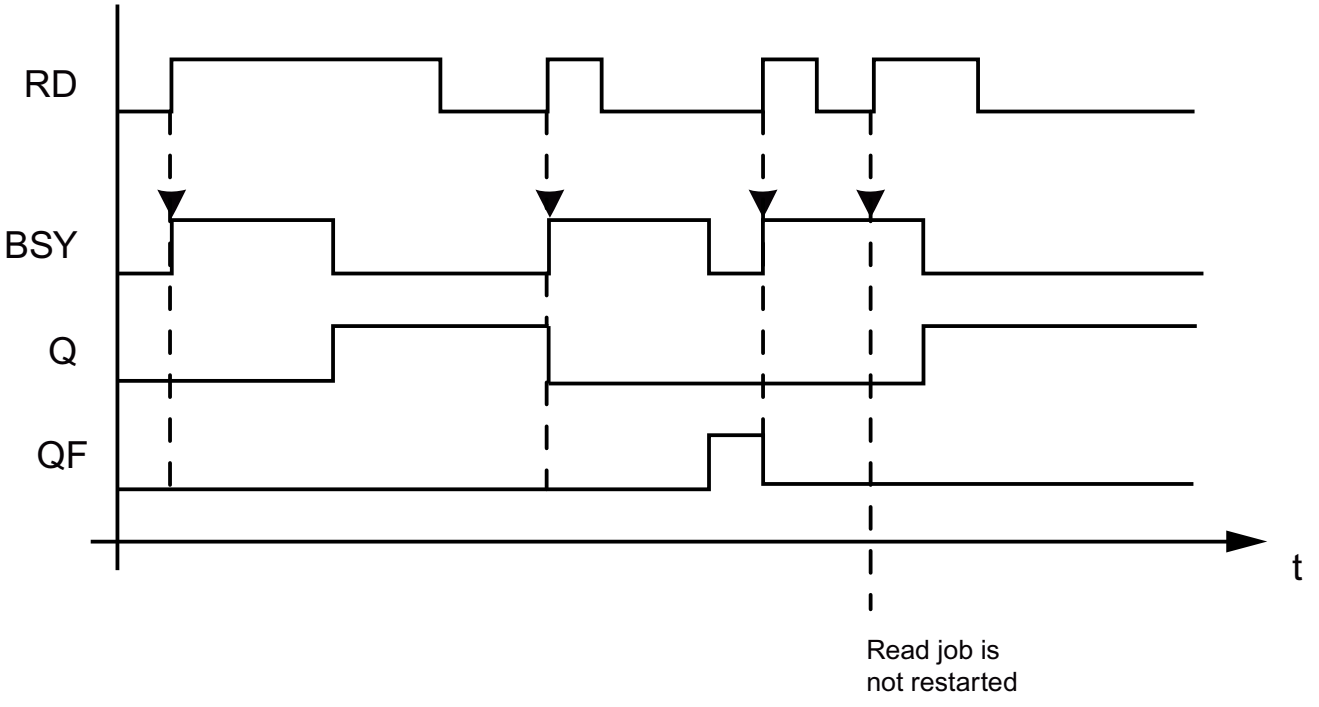
Method of operation

First the block inputs for addressing the drive are entered as well as the selection of the parameters to be read. The asynchronous read job is started by the positive edge at input RD. As long as the job is active, the BSY flag is set. The number of cycles for a parameter access is dependent on the system utilization and communication load and can vary from job to job. During an active read job, any additional positive edges at input RD are ignored. The actual reading/writing of the parameters is not performed in the DCC task. The block instance only controls the communication command. The results of the read/write job must be polled at the block outputs in the following task cycles. The evaluation is performed via global variables or user-defined block types. Output Q = 1 indicates that the parameters have been read successfully and the values are available at output Y. Y retains its value until a new job has been completed successfully. If an error occurs during an access, this is signaled with QF = 1. Output Y retains its last value. For error diagnostics, the error code ERC can be evaluated.

If the entire job is successful (output Q=1) and individual jobs are not successful (ERC not equal to 0), the values that are read from the drive are displayed. The other parameters with ERC = 0 have been read error-free.

The error status of the individual read jobs can be evaluated on the parameter-specific return value PRES. An active job is aborted with the positive edge on the ABRT input. The ABRT signal must have the value 1 for at least one cycle.

Time diagram



Brief description

The block enables up to 39 SINAMICS parameters to be read.

Data set 47 is always read out for PROFIBUS (external or integrated) irrespective of whether the function is called with a valid (0>=doId<=254) or invalid 'doId' (doId=255).

Two data sets are available for PROFINET:

- Base Mode Parameter Access - local (data set 0xB02E)
- Base Mode Parameter Access - global (data set 0xB02F)

Data set 0xB02E is used for SIMOTION if either no 'dold' or an invalid 'dold' (dold=255) is specified in the function. Access to the appropriate DO is then performed via the Parameter Access Point (PAP). Either the PAP address can be specified directly or the log. address of the cyclic data (e.g. 256 for a DO axis) can be specified. SIMOTION then determines the corresponding PAP from this address before accessing the correct address. PAP must always be at subslot 1 (HW Config configuration).

Data set 0xB02F is used if a valid 'dold' (0>=doId<=254) is entered. Any valid PAP or address can be specified because the assignment is only performed via the 'doId'.

Description of the block inputs

'IOTY' input/output assignment of the logical start address of the drive.
With 198: INPUT, the logical address of the drive is in the input range.
With 199: OUTPUT, the logical address of the drive is in the output range.
Diagnostic addresses are always of type INPUT.

'LADR': Specification of the logical start address of the drive. If the optional parameter DOID is also used, any arbitrary address of the station (preferably the diagnostics address of the station) can be specified.
With PROFINET, parameter access is via the Parameter Access Point (PAP) of a drive object.
As an alternative to the logical start address of the drive, specification of the diagnostic address of the associated PAP is recommended.

'DOID': For the direct addressing of a drive object. The DOID can be unspecified or specified as invalid (>254) under the following conditions:

- Access via the DOID is not supported by the DP slave / IO device (P978 is not implemented).
- Data set 0xB02F is not supported (PROFINET only).
- Access is to be via the parameter access point of a DO (PROFINET only).

'X': The parameters to be read are specified under input X.

'X.NUMP': Number of parameters to be read.

'X.PAR[].NUM': Specifies the parameter numbers from which the values are to be read.

'X.PAR[].IDX': Parameter index; for indexed values, 0 means index 0. For non-indexed values, parameter index 0 must be specified.

'RD': Start read job

'ABRT': Abort active job

Description of the block inputs

'Q': Job completed without errors.

'QF': Job completed with errors.

'ERC': Corresponds to the values of the return value 'functionResult' of the _readDriveMultiParameter function.

'Y': Description of the parameter values. An error code, the data type and the value are read out for each parameter. Further information on the return value parameterResult can be found in the SIMOTION List Manual System Functions/Variables Devices → System Functions - Devices 1 → _readDriveMultiParameterDescription

'Y[].PRES': Corresponds to the parameter-specific return value. Coding corresponds to the return parameter parameterResult of the _readDriveMultiParameter ST function. Further information on the return parameter parameterResult can be found in the SIMOTION List Manual System Functions/Variables Devices → System Functions - Devices 1 → _readDriveMultiParameterDescription

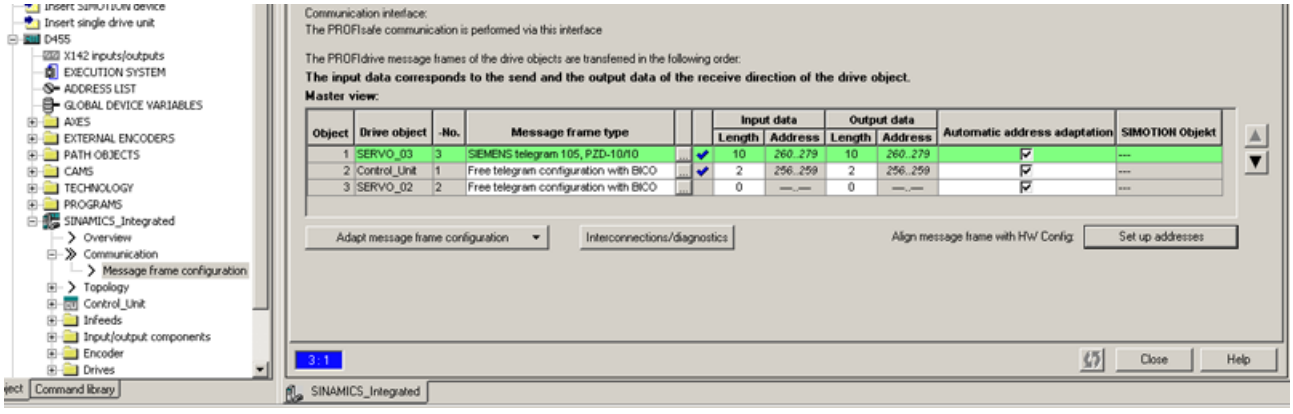
'Y[].DTYP': Returns the data type of the parameter (for the coding, see PROFIdrive profile).

'Y[].VAL': Parameter values read from the drive; the data type results from the returned data type. A conversion block must be called for different data types. When accessing REAL parameters, the conversion is performed via the conversion block DW_R.

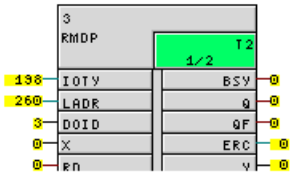
Parameterization example

In order to be able to write certain parameters of a drive object (in the example: SERVO_03), proceed as follows:

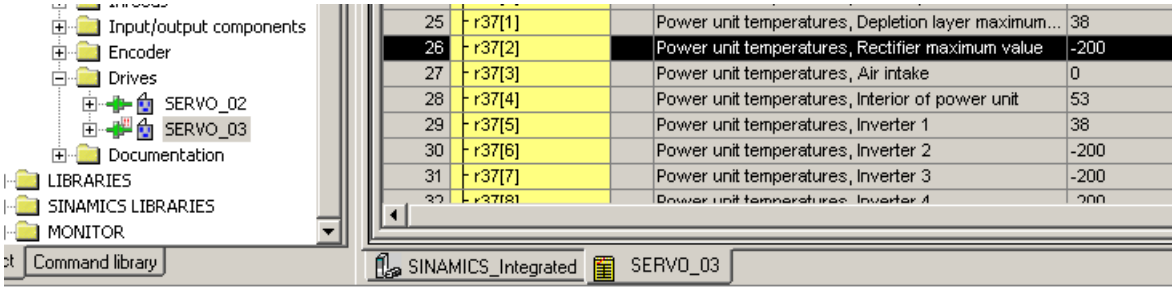
First set the correct telegram configuration.



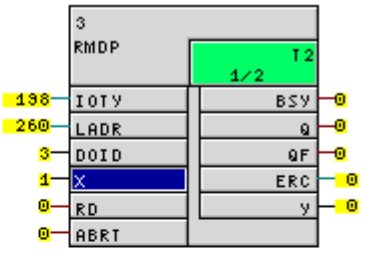
Then set the desired DO address in the RMDP block. To do this, set the block input 'LADR' to the address (260) set in the telegram and the block input 'DOID' to the number (3) set in the telegram.

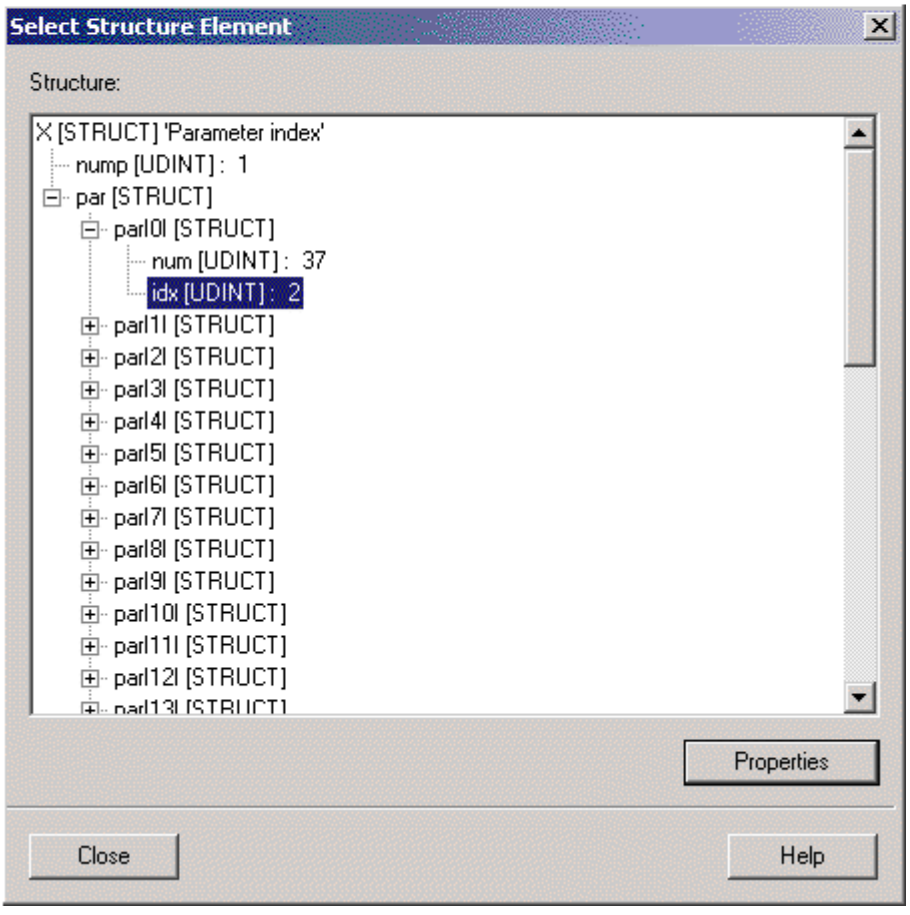


Select the parameters to be read at block input 'X', e.g. r37(2) power unit temperatures, rectifier maximum value in the expert list.

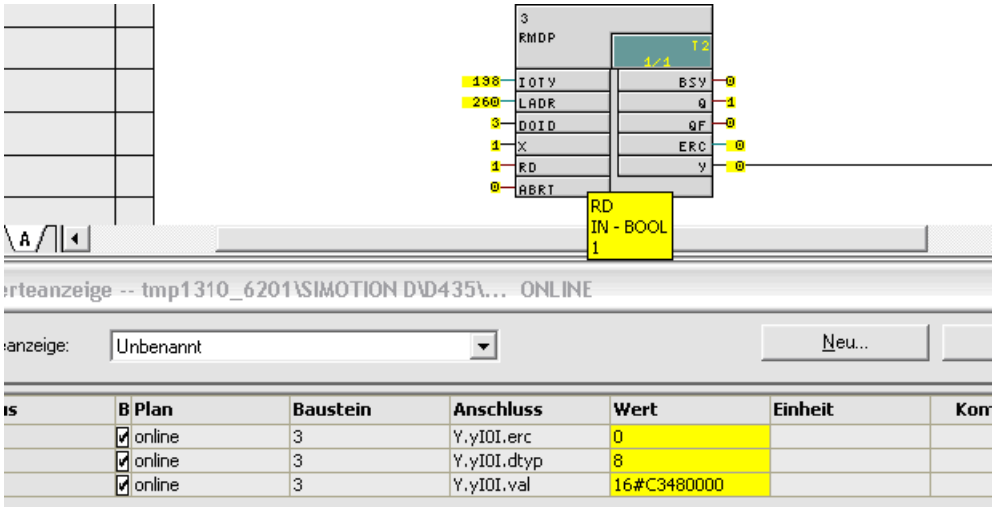


To do this, double-click block input 'X', select the first structure element and enter the parameter number (37) at 'num' and the index (2) at 'idx'.





Then set the block input 'RD' to 1 to start the reading.



Block connections

Block connection	Description	Default	Value range	Attributes
IOTY	Logical start address as input/ output	0	0: Invalid 198: Input address 199: Output address	
LADR	Logical start address of the drive	-1	DINT	
DOID	ID of the drive object for direct addressing	255	0 .. 254, 255: Invalid	
X	Number of parameters, parameter numbers and indices to be read			
X.NUMP	Number of parameters to be read	1	1..39	
X.PAR	Description of a parameter			
X.PAR[].NUM	Parameter number	1	1..65535	
X.PAR[].IDX	Parameter index	0	0..65535	
RD	Start reading	0	0/1	
ABRT	Abort of the active job	0	0/1	
BSY	Read job active message	0	0/1	
Q	Read job executed successfully message	0	0/1

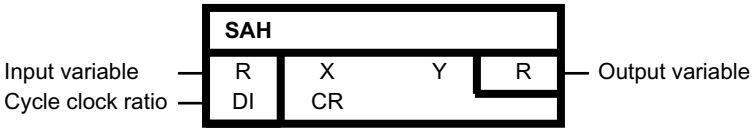
Sample & hold (REAL type)

Symbol



Brief description

Sample & hold block for equidistant value transfer (REAL type) between blocks with different scanning procedures.

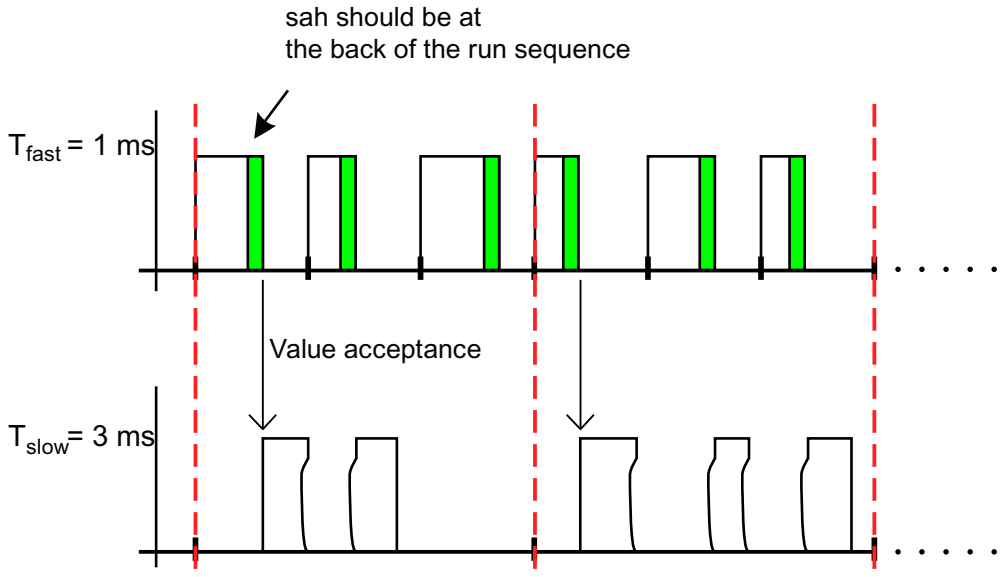
Method of operation

The value of the input variable X is taken over in the output variable Y in every CR cycle. The value transfer cycle clock is synchronized with the cycle control point of the execution system. The cycle control point defines the cycle clock in which all sampling times of the execution system are restarted.

A value transfer takes place every CR cycle clock relative to the cycle control point. The absolute value of CR is always generated for the cycle clock ratio. In the special case of CR = 0, the block behaves as for CR = 1. The block must always be configured in the faster sampling time. If the value from the slower scan time is transferred, it should be at the very beginning of the run sequence. If the value is to taken from the faster into the slower sampling time, the block should be computed last in the execution sequence.

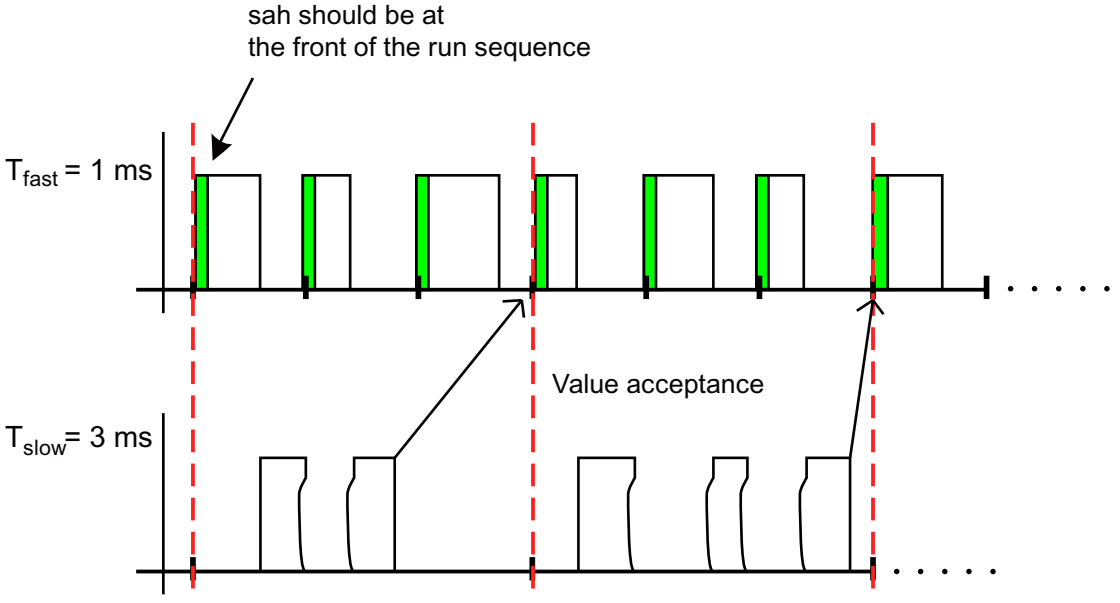
The following figure shows the transfer of values from a 1 ms level to a 3 ms level. The time diagram is shown for the calculation of the execution group.

$$CR = \frac{3ms}{1ms} = 3$$



The following figure shows the transfer of values from a 3 ms level to a 1 ms level. The time diagram is shown for the calculation of the execution group.

$$CR = \frac{3ms}{1ms} = 3$$



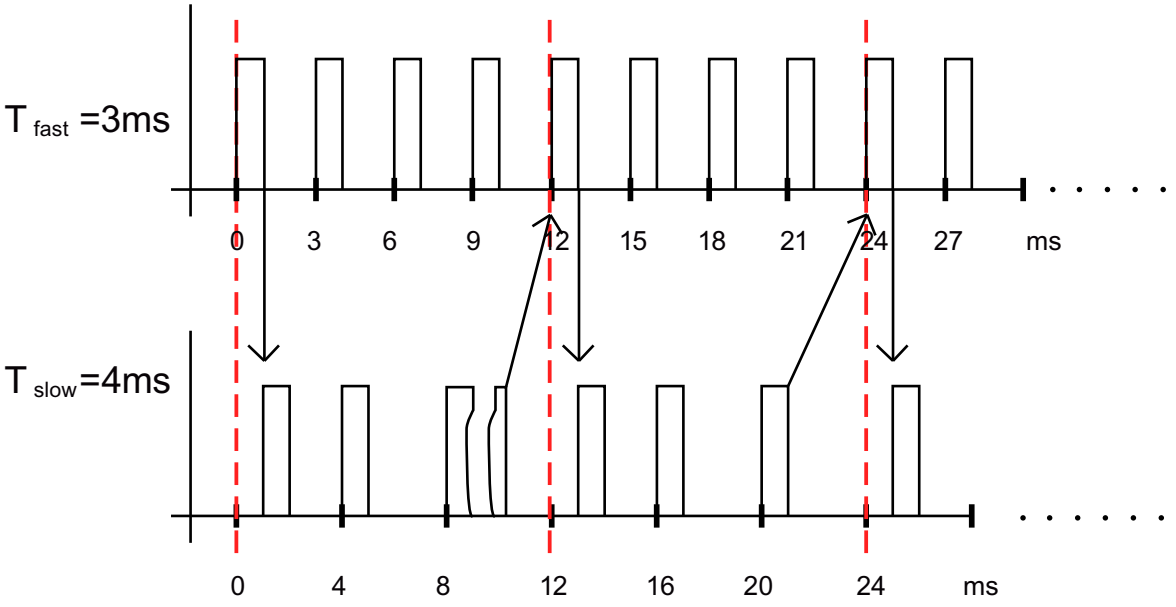
If the slower scan time is not a multiple of the faster scan time, the value can only be transferred consistently if both scanning procedures are restarted synchronously after CR cycles. This corresponds to the least common multiple of both scan times. CR is then calculated as follows:

$$CR = \frac{g\left(T_{fast}, T_{slow}\right)}{T_{fast}}$$

$g(T_{fast}, T_{slow})$: least common multiple

The following shows the value transfer for $T_{fast} = 3$ ms and $T_{slow} = 4$ ms. The value transfer is made in both directions.

$$CR = \frac{g(3ms, 4ms)}{3ms} = \frac{12ms}{3ms} = 4$$



To enable values to be transferred at an optimal speed, it is recommended that the slower scan time is always a multiple of the faster scan time.

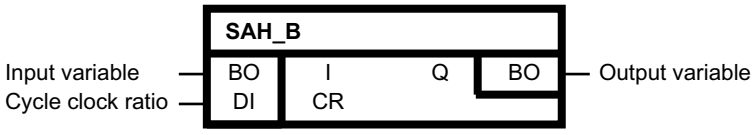
Sample & hold (BOOL type)

Symbol



Brief description

Sample & hold block for equidistant value transfer (BOOL type) between blocks with different scanning procedures.

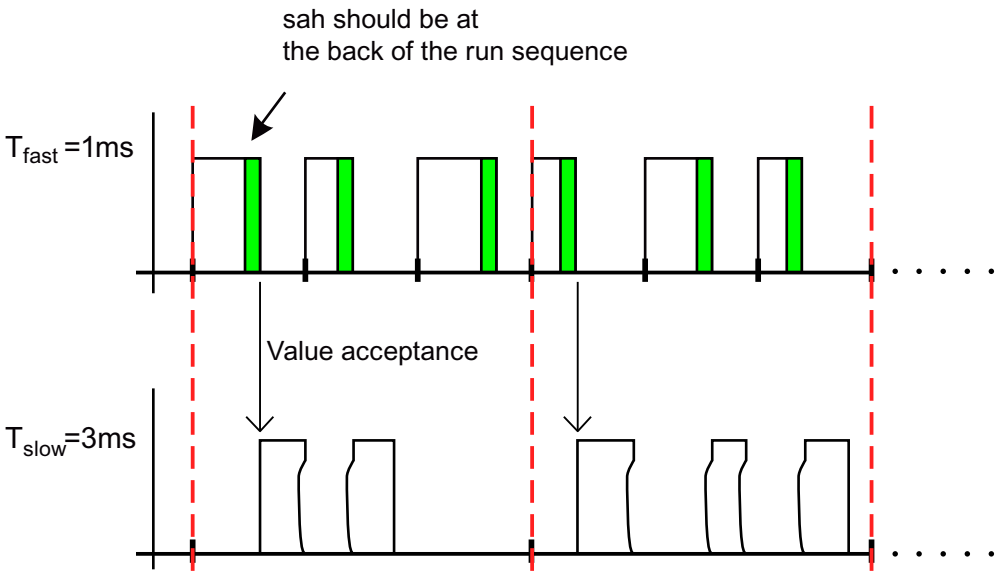
Method of operation

The value of the input variable I is taken over in the output variable Q in every CR cycle. The value transfer cycle clock is synchronized with the cycle control point of the execution system. The cycle control point defines the cycle clock in which all sampling times of the execution system are restarted.

A value transfer takes place every CR cycle clock relative to the cycle control point. The absolute value of CR is always generated for the cycle clock ratio. In the special case of CR = 0, the block behaves as for CR = 1. The block must always be configured in the faster sampling time. If the value from the slower scan time is transferred, it should be at the very beginning of the run sequence. If the value is to taken from the faster into the slower sampling time, the block should be computed last in the execution sequence.

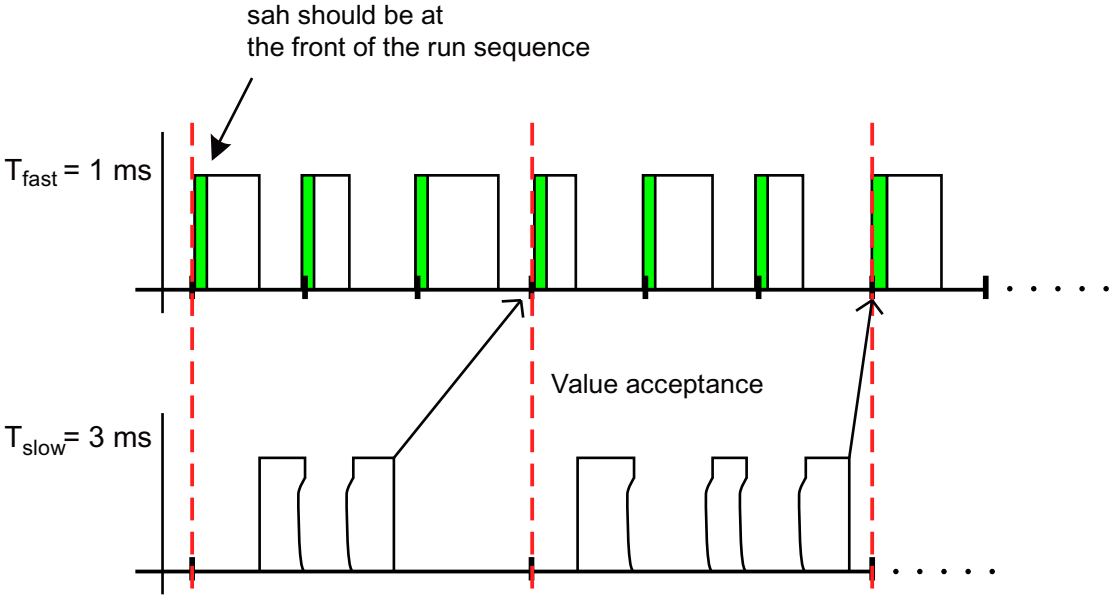
The following figure shows the transfer of values from a 1 ms level to a 3 ms level. The time diagram is shown for the calculation of the execution group.

$$CR = \frac{3ms}{1ms} = 3$$



The following figure shows the transfer of values from a 3 ms level to a 1 ms level. The time diagram is shown for the calculation of the execution group.

$$CR = \frac{3ms}{1ms} = 3$$



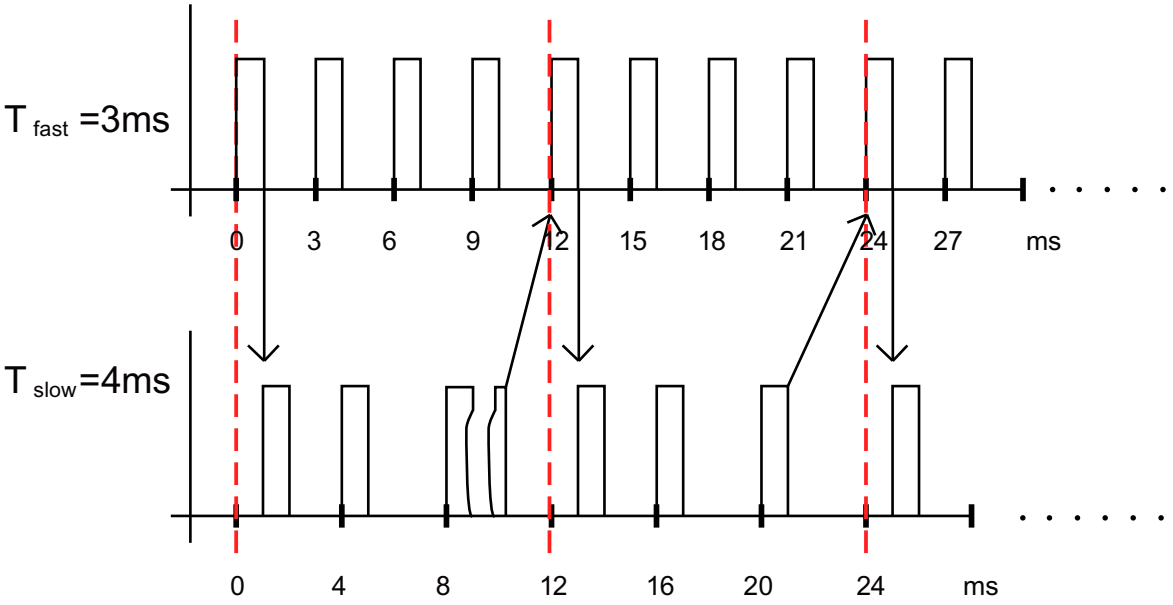
If the slower scan time is not a multiple of the faster scan time, the value can only be transferred consistently if both scanning procedures are restarted synchronously after CR cycles. This corresponds to the least common multiple of both scan times. CR is then calculated as follows:

$$CR = \frac{g\left(T_{fast}, T_{slow}\right)}{T_{fast}}$$

g(T_{fast},T_{slow}): least common multiple

The following shows the value transfer for T_{fast} = 3 ms and T_{slow} = 4 ms. The value transfer is made in both directions.

$$CR = \frac{g(3ms, 4ms)}{3ms} = \frac{12ms}{3ms} = 4$$



To enable values to be transferred at an optimal speed, it is recommended that the slower scan time is always a multiple of the faster scan time.

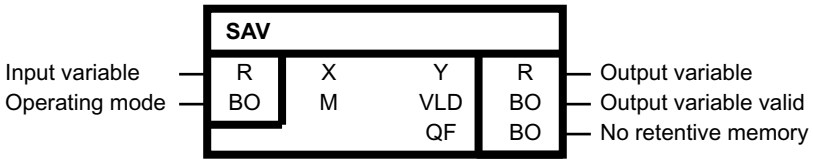
8.1.6.18 SAV

Value buffering (REAL type)

Symbol



Brief description

SAV (Save) enables retentive storage of a REAL-type input variable.

Method of operation

The block is a retentive read/write memory for a REAL value.

The saved value of a SAV block is not retained when:

- The retentive memory on the target device has been cleared through a user action.
- The chart on which the block was configured, has been deleted and the change transferred to the target device.
- The block has been deleted and the change transferred to the target system.
- The instance name of a block has been changed and transferred to the target system.

The value is retained when:

- The instance name does not change during a download.
- The target device ramps up without configuration data on the memory card. The memory of the missing SAV blocks is only released after a download. In this way, the data is also retained when the firmware is updated.
- Another SAV block has been added or removed.
- A download of the configuration is performed after an update of the DCBLIB.
- Another DO has been added or removed and downloaded to the target device.
- Another chart has been added or removed and downloaded to the target device.
- The target device ramps up with the same configuration as before the power failure.

The block is only active when a 0 on output QF indicates that retentive memory space is available on the target device for storing the input values.

The block mode is set at input M:

Write mode (M =1)

- Input variable X is written cyclically to output Y.
- In addition, input variable X is transferred to the system for retentive storage. In so doing, an already saved value is overwritten.

Read mode (M = 0)

- The current saved value is output at output Y. The values at input X are not saved.
- Output VLD = 1 indicates the validity of Y. If the retentive memory of the system was recreated when the block is initialized, VLD = 0. In this case, Y is invalid and contains its default value. The status of VLD changes to 1 the first time a value is written (M = 1).

Initialization

The assignment between the SAV block and the value in the retentive memory is performed via the instance name of the block. The unique instance name is automatically generated by the DCC editor when the block is inserted in a chart. The instance name is made up of the call path of the block as follows:

(Chart name)/(Name of subchart 1)/(Name of subchart 2)/../(Name of the block)

The instance name could look like this:

DCC_1/CFC1/CFC2/CFC3/SAV1

Chart name	DCC_1
Name of subchart 1	CFC1
Name of subchart 2	CFC2
Name of subchart 3	CFC3
Name of the block	SAV1

This instance name controls whether output Y is initialized with its default value or outputs the last saved value in the INIT mode. A check is made on the target device whether a retentive value has been saved for this instance name of the block. If this is not the case, the system recreates the memory space, the default value of output variable Y is transferred to the system for retentive storage and VLD is set to 0. If a retentive value has been saved for the instance name, it is read and written to output Y and status VLD = 1 is output.

If no retentive memory is available for the block, output QF = 1 is set.

Block connections

Block connection	Description	Default	Value range	Attrib-utes
X	Input variable	0.0	REAL	
M	Operating mode	0	0/1	
Y	Output variable	0.0	REAL	
VLD	Output variable valid	0	0/1	
QF	No retentive memory	0	0/1	

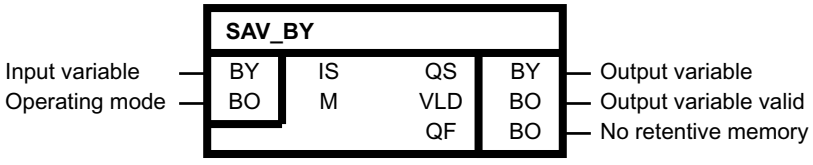
Configuration data

SIMOTION	✓
SINAMICS	✓
Can be inserted on-line	No
Special characteristics	A maximum of ten blocks can be used for the retentive storage (SAV, SAV_BY, SAV_I, SAV_D) for each SINAMICS or SINAMICS INTEGRATED drive unit. Retentive memory is available for a maximum of 40 bytes of user data. As of STARTER/SCOUT V4.2, the number of blocks is only checked in the consistency check (menu "Project -> Check consistency" or "Check consistency" in the shortcut menu of the drive unit).

8.1.6.19 SAV_BY

Value buffering (BYTE type)

Symbol



Brief description

SAV_BY (Save) enables retentive storage of a BYTE-type input variable.

Method of operation

The block is a retentive read/write memory for a BYTE value.

The saved value of a SAV block is not retained when:

- The retentive memory on the target device has been cleared through a user action.
- The chart on which the block was configured, has been deleted and the change transferred to the target device.
- The block has been deleted and the change transferred to the target system.
- The instance name of a block has been changed and transferred to the target system.

The value is retained when:

- The instance name does not change during a download.
- The target device ramps up without configuration data on the memory card. The memory of the missing SAV blocks is only released after a download. In this way, the data is also retained when the firmware is updated.
- Another SAV block has been added or removed.

- A download of the configuration is performed after an update of the DCBLIB.
- Another DO has been added or removed and downloaded to the target device.
- Another chart has been added or removed and downloaded to the target device.
- The target device ramps up with the same configuration as before the power failure.

The block is only active when a 0 on output QF indicates that retentive memory space is available on the target device for storing the input values.

The block mode is set at input M:

Write mode (M =1)

- Input variable IS is written cyclically to output QS.
- Input variable IS is also transferred to the system for retentive storage. In so doing, an already saved value is overwritten.

Read mode (M = 0)

- The currently saved value is output at output QS. The values at input IS are not saved
- Output VLD = 1 displays the validity of QS. If the retentive memory of the system was recreated when the block is initialized, VLD = 0. In this case, QS is invalid and contains its default value. The status of VLD changes to 1 the first time a value is written (M = 1).

Initialization

The assignment between the SAV block and the value in the retentive memory is performed via the instance name of the block. The unique instance name is automatically generated by the DCC editor when the block is inserted in a chart. The instance name is made up of the call path of the block as follows:

(Chart name)/(Name of subchart 1)/(Name of subchart 2)/../(Name of the block)

The instance name could look like this:

DCC_1/CFC1/CFC2/CFC3/SAV1

Chart name	DCC_1
Name of subchart 1	CFC1
Name of subchart 2	CFC2
Name of subchart 3	CFC3
Name of the block	SAV1

This instance name controls whether output QS is initialized with its default value or outputs the last saved value in the INIT mode. A check is made on the target device whether a retentive value has been saved for this instance name of the block. If not, the memory space is recreated by the system, the default value of the output variable QS transferred to the system for retentive storage, and VLD = 0 set. If a retentive value has been saved for the instance name, this is read, written to output QS, and the status VLD = 1 output.

If no retentive memory is available for the block, output QF = 1 is set.

Block connections

Block connection	Description	Default	Value range	Attributes
IS	Input variable	16#00	BYTE	
M	Operating mode	0	0/1	
QS	Output variable	16#00	BYTE	
VLD	Output variable valid	0	0/1	
QF	No retentive memory	0	0/1	

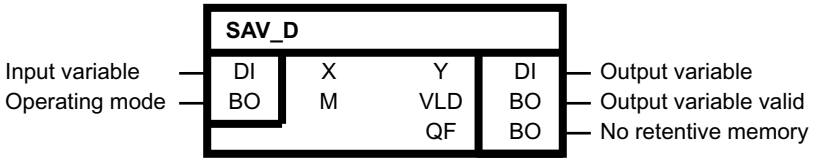
Configuration data

SIMOTION	✓
SINAMICS	✓
Can be inserted online	No
Special characteristics	A maximum of ten blocks can be used for the retentive storage (SAV, SAV_BY, SAV_I, SAV_D) for each SINAMICS or SINAMICS INTEGRATED drive unit. Retentive memory is available for a maximum of 40 bytes of user data. As of STARTER/SCOUT V4.2, the number of blocks is only checked in the consistency check (menu "Project -> Check consistency" or "Check consistency" in the shortcut menu of the drive unit).

8.1.6.20 SAV_D

Value buffering (DOUBLE INTEGER type)

Symbol



Brief description

SAV_D (Save) enables retentive storage of a DOUBLE INTEGER-type input variable.

Method of operation

The block is a retentive read/write memory for a DOUBLE INTEGER value.

The saved value of a SAV block is not retained when:

- The retentive memory on the target device has been cleared through a user action.
- The chart on which the block was configured, has been deleted and the change transferred to the target device.

- The block has been deleted and the change transferred to the target system.
- The instance name of a block has been changed and transferred to the target system.

The value is retained when:

- The instance name does not change during a download.
- The target device ramps up without configuration data on the memory card. The memory of the missing SAV blocks is only released after a download. In this way, the data is also retained when the firmware is updated.
- Another SAV block has been added or removed.
- A download of the configuration is performed after an update of the DCBLIB.
- Another DO has been added or removed and downloaded to the target device.
- Another chart has been added or removed and downloaded to the target device.
- The target device ramps up with the same configuration as before the power failure.

The block is only active when a 0 on output QF indicates that retentive memory space is available on the target device for storing the input values.

The block mode is set at input M:

Write mode (M =1)

- Input variable X is written cyclically to output Y.
- In addition, input variable X is transferred to the system for retentive storage. In so doing, an already saved value is overwritten.

Read mode (M = 0)

- The current saved value is output at output Y. The values at input X are not saved.
- Output VLD = 1 indicates the validity of Y. If the retentive memory of the system was recreated when the block is initialized, VLD = 0. In this case, Y is invalid and contains its default value. The status of VLD changes to 1 the first time a value is written (M = 1).

Initialization

The assignment between the SAV block and the value in the retentive memory is performed via the instance name of the block. The unique instance name is automatically generated by the DCC editor when the block is inserted in a chart. The instance name is made up of the call path of the block as follows:

(Chart name)/(Name of subchart 1)/(Name of subchart 2)/../(Name of the block)

The instance name could look like this:

DCC_1/CFC1/CFC2/CFC3/SAV1

Chart name	DCC_1
Name of subchart 1	CFC1
Name of subchart 2	CFC2

Name of subchart 3	CFC3
Name of the block	SAV1

This instance name controls whether output Y is initialized with its default value or outputs the last saved value in the INIT mode. A check is made on the target device whether a retentive value has been saved for this instance name of the block. If this is not the case, the system recreates the memory space, the default value of output variable Y is transferred to the system for retentive storage and VLD is set to 0. If a retentive value has been saved for the instance name, it is read and written to output Y and status VLD = 1 is output.

If no retentive memory is available for the block, output QF = 1 is set.

Block connections

Block connection	Description	Default	Value range	Attributes
X	Input variable	0	DINT	
M	Operating mode	0	0/1	
Y	Output variable	0	DINT	
VLD	Output variable valid	0	0/1	
QF	No retentive memory	0	0/1

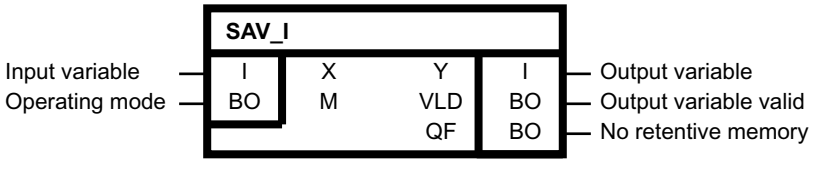
As of STARTER/SCOUT V4.2, the number of blocks is only checked in the consistency check (menu "Project -> Check consistency" or "Check consistency" in the shortcut menu of the drive unit).

8.1.6.21 SAV_I

Value buffering (INTEGER type)

Symbol



Brief description

SAV_I (Save) enables retentive storage of an INTEGER-type input variable.

Method of operation

The block is a retentive read/write memory for an INTEGER value.

The saved value of a SAV block is not retained when:

- The retentive memory on the target device has been cleared through a user action.
- The chart on which the block was configured, has been deleted and the change transferred to the target device.
- The block has been deleted and the change transferred to the target system.
- The instance name of a block has been changed and transferred to the target system.

The value is retained when:

- The instance name does not change during a download.
- The target device ramps up without configuration data on the memory card. The memory of the missing SAV blocks is only released after a download. In this way, the data is also retained when the firmware is updated.
- Another SAV block has been added or removed.
- A download of the configuration is performed after an update of the DCBLIB.
- Another DO has been added or removed and downloaded to the target device.
- Another chart has been added or removed and downloaded to the target device.
- The target device ramps up with the same configuration as before the power failure.

The block is only active when a 0 on output QF indicates that retentive memory space is available on the target device for storing the input values.

The block mode is set at input M:

Write mode (M =1)

- Input variable X is written cyclically to output Y.
- In addition, input variable X is transferred to the system for retentive storage. In so doing, an already saved value is overwritten.

Read mode (M = 0)

- The current saved value is output at output Y. The values at input X are not saved.
- Output VLD = 1 indicates the validity of Y. If the retentive memory of the system was recreated when the block is initialized, VLD = 0. In this case, Y is invalid and contains its default value. The status of VLD changes to 1 the first time a value is written (M = 1).

Initialization

The assignment between the SAV block and the value in the retentive memory is performed via the instance name of the block. The unique instance name is automatically generated by the DCC editor when the block is inserted in a chart. The instance name is made up of the call path of the block as follows:

(Chart name)/(Name of subchart 1)/(Name of subchart 2)/../(Name of the block)

The instance name could look like this:

DCC_1/CFC1/CFC2/CFC3/SAV1

Chart name	DCC_1
Name of subchart 1	CFC1
Name of subchart 2	CFC2
Name of subchart 3	CFC3
Name of the block	SAV1

This instance name controls whether output Y is initialized with its default value or outputs the last saved value in the INIT mode. A check is made on the target device whether a retentive value has been saved for this instance name of the block. If this is not the case, the system recreates the memory space, the default value of output variable Y is transferred to the system for retentive storage and VLD is set to 0. If a retentive value has been saved for the instance name, it is read and written to output Y and status VLD = 1 is output.

If no retentive memory is available for the block, output QF = 1 is set.

Block connections

Block connection	Description	Default	Value range	Attributes
X	Input variable	0	INT	
M	Operating mode	0	0/1

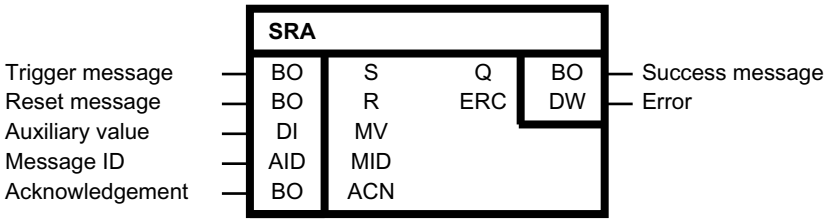
As of STARTER/SCOUT V4.2, the number of blocks is only checked in the consistency check (menu "Project -> Check consistency" or "Check consistency" in the shortcut menu of the drive unit).

8.1.6.22 SRA

Triggers/resets a message

Symbol



Brief description

A message configured in SCOUT can be triggered or reset with the SRA (Set Alarm) block. The message is sent to the HMI and entered in the message buffer in the SIMOTION target device. The message buffer contains all active messages. The SRA block is configured for multiple instantiation. There can be several block instances that trigger the same message number.

Method of operation

- The message configured in SCOUT is entered at the MID message number.
- Input ACN =1 indicates that it is an acknowledgeable message. In this case, the message also only disappears after a reset when it has been acknowledged by the user on the HMI. ACN = 0 is configured for messages that cannot be acknowledged.
- A process value / auxiliary value must be entered at parameter MV if this has been specified in the configuration in SCOUT. A numerical value of the DINT type can be configured.
  The auxiliary value is inserted in the message text with a special syntax during the configuration of the messages: The call of a process value starts with @ and ends with @. The parameters in between indicate the output of the value and its format.
  Only auxiliary values of the DINT type are possible for messages triggered with the SRA block. For detailed information on the syntax of auxiliary values in the message configuration, refer to the SIMOTION SCOUT online help.
- The message is triggered with a rising edge at input S. If the block is called with a new message number with 1 at input S, then the message is also triggered. Up to 40 messages can be entered in the message buffer. If the block SRA is activated with rising edge at input S at full message buffer, the block will be acknowledged with the error message. The message is not entered.
- The message is reset with a rising edge at input R.
- If a rising edge is set at both inputs S and R during a call, R takes priority, i.e. the message is reset.

- Output Q = 1 indicates that the parameter has been successfully set or reset. The outputs are set again with a rising edge at input S or R.
- With Q = 0, output ERC displays an error code that specifies the reason why the message could not be issued:
  The specified values can be displayed as OR logic operation between the constants.

Error code	Meaning
16#00 00	No error. For an incoming message, an entry is made in the message list. The entry is deleted from the message list for an outgoing message.
16#80 01	Message name not permitted.
16#80 02	Message loss through overflow. All 40 entries of the message list are occupied. An entry has not been made in the message list.
16#80 03	Message loss through overflow (signal not sent yet, signal overflow). Send buffer for notification of the clients is still occupied by the last event. An entry has not been made in the message list. An error might also occur if function calls with rising and falling edge follow in quick succession.
16#80 04	Double message, message rejected (call with message came or went two times in succession). An entry has not been made in the message list.
16#80 05	No display device reported. A message is still entered in the list.
16#80 07	No job has been started yet with this message name (first call with S = FALSE). Falling edge (outgoing message) arrived without prior rising edge (incoming message) An entry has not been made in the message list.
16#80 08	A message with this ID is already active in the message buffer. The message occurs when a message with the ID is in the message buffer and the same ID is set again. A new message buffer entry is not generated.
16#80 09	Internal error
16#80 10	Entry was rejected; message acknowledgment memory full.

Block connections

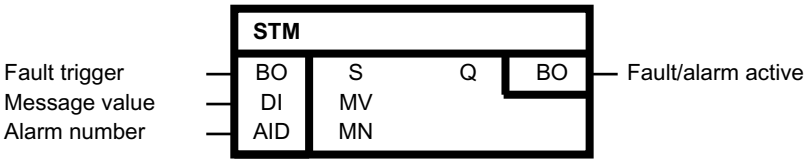
8.1.6.23 STM

Fault/alarm trigger

Symbol



Brief description

A predefined message (fault or alarm) can be triggered on the DO with the STM (Set Message) block. The fault is displayed (e.g. STARTER, AOP) and entered in the fault buffer or alarm buffer of the DO. The following specifications apply to this block type:

- The message number (fault/alarm number) assigned to an instance must be in the range 51050 to 51069 (default value is 51050).
- A message number can be repeated at multiple instances in the DO (message can be issued from different instances). However, for performance reasons, the STM block is not designed for multiple instantiation. The figure below shows the resulting behavior when there is multiple instantiation with the same message number for a fault on the same DO. Without additional RC circuitry, the block instances with the same message number are not coordinated (in any case, this would not be possible if the instances were running in different scan times). For this reason, we recommend assigning a unique message number in the DO for each instance.
- The message text is predefined and cannot be changed (see table below).
- The message type cannot be changed (a fault cannot be redefined to an alarm, or vice versa).

- The default setting for the fault response is OFF2. This can be changed in the SINAMICS basic system parameter:
  - p2100[0..19] "Set fault number for fault response" and
  - p2101[0..19] "Fault response setting"
- The default setting for the acknowledgement mode is IMMEDIATE. This can be changed in the SINAMICS basic system parameter:
  - p2126[0..19] "Setting fault number for acknowledge mode" and
  - p2127[0..19] "Acknowledgement mode setting"

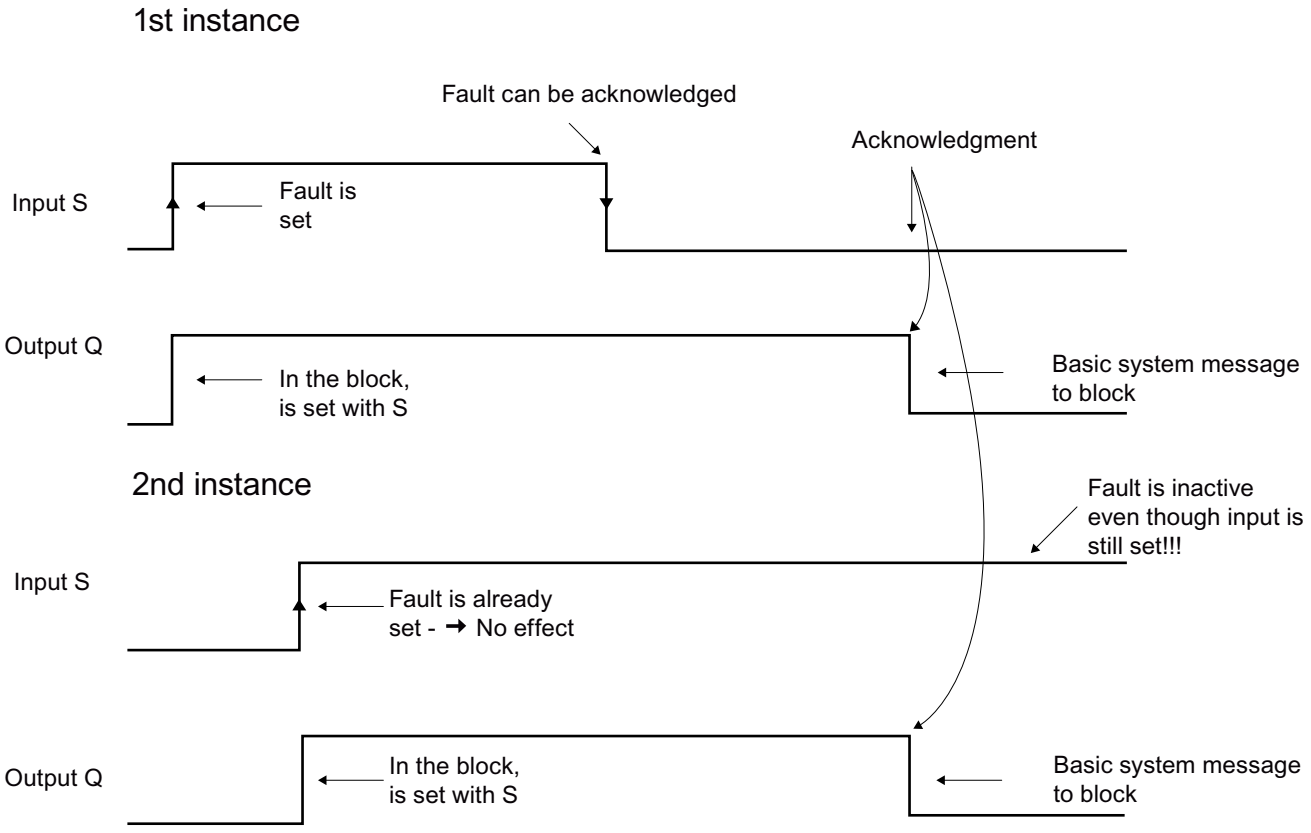
The table below specifies the default settings for the attributes. Possible options for the various settings can be found in the user documentation:

Message type	Alarm number	Reaction	Acknowledgment	Message text
Fault (cannot be changed)	F51050 - F51059	OFF2 (can be changed via p2100/p2101)	IMMEDIATE (can be changed via p2126/ p2127)	DCC: Fault F5105x Additional value: %d(x:= 0 to 9)
Alarm (cannot be changed)	A51060 - A51069			DCC: Alarm A5106x Additional value: %d(x:= 0 to 9)

Method of operation

The number of the fault to be triggered (F51050 - F51059) must be specified at input MN. A positive edge at input S triggers a fault at the DO. This is entered in the fault buffer of the DO and the specified response at the DO is executed. By doing this, output Q is set by the block. Output Q remains set as long as the fault is active. After a negative edge at input S, the fault can be acknowledged according to the acknowledgement attribute of the message (analog system faults: see first instance in figure below).

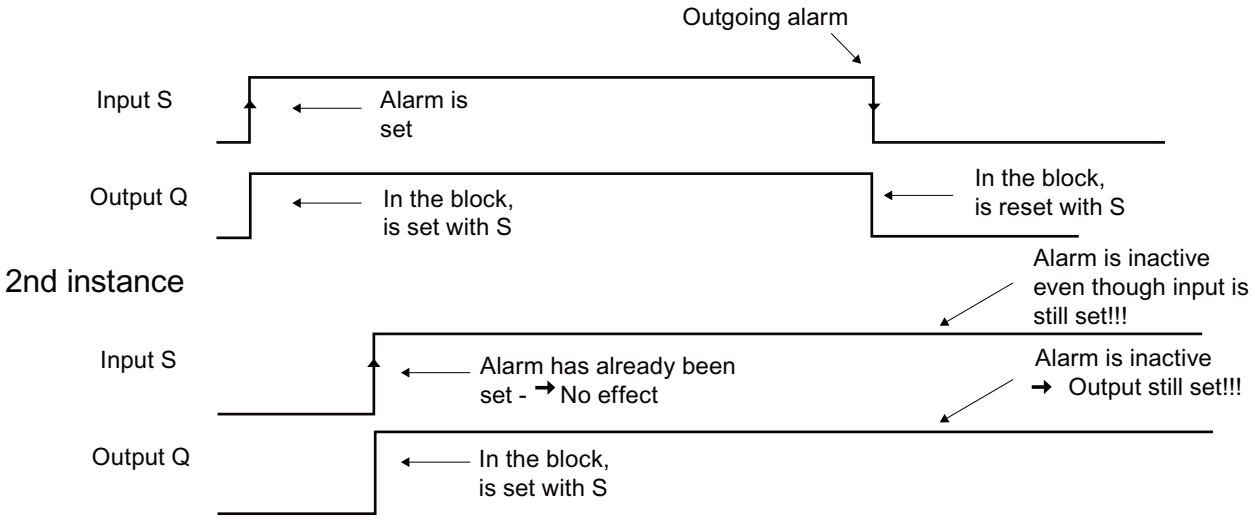
Input MV can be used to add additional information (fault value) for the fault. The value is transferred to input S when the fault is triggered on a positive edge and is entered in the fault buffer of the DO.



Example of two-fold instantiation with the same fault number on one DO (without additional RC circuitry)

Method of operation

The number of the alarm to be triggered (A51060 - A51069) must be specified at input MN. A positive edge at input S triggers the alarm assigned to the block. This is entered in the alarm buffer of the DO. In so doing, output Q is set. The output remains set as long as the alarm is active. Alarms are self-acknowledging and are acknowledged when input S is reset (see figure below). Input MV can be used to provide additional information (alarm value) for the alarm, which is also entered in the alarm buffer.



Example of two-fold instantiation with the same alarm number at one DO (without additional RC circuitry)

Block connections

Block connection	Description	Default	Value range	Attributes
S	Fault trigger	0	0/1	
MV	Message value	0	DINT

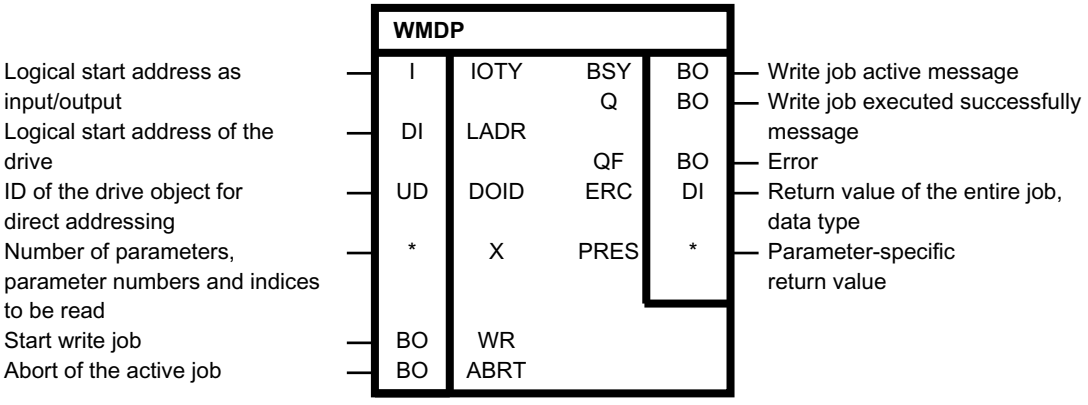
8.1.6.24 WMDP

Writes drive parameters from the controller

Symbol



Brief description

The WMDP block enables up to 23 SINAMICS parameters to be written from the DCC SIMOTION program. Only SINAMICS drives are supported. For error diagnostics, the error code ERC can be evaluated. ERC corresponds to the error code for parameter access according to PROVIdrive DPV1. The possible error codes can be found in Appendix A.2 of this document or in the SIMOTION Communication System Manual in Section PROFIdrive and there in the Subsection Acyclic communication (Base Mode Parameter Access) → Error evaluation in table Error codes in Base Mode Parameter Access responses.

The WMDP block is available as of SIMOTION V4.2.

Method of operation

First the block inputs for addressing the drive as well as the selection of the parameters and values to be written are entered. If a parameter is not indexed, IDX = 0 must be set. The asynchronous write job is started with the positive edge at input WR. As long as the job is active, the BSY flag is set. The number of cycles for a parameter access is dependent on the system utilization and communication load and can vary from job to job. During an active write job, any additional positive edges at input WR are ignored. The actual reading/writing of the parameters is not performed in the DCC task. The block instance only controls the communication command. The results of the read/write job must be polled at the block outputs in the following task cycles. The evaluation is performed via global variables or user-defined block types. Output Q = 1 indicates that the parameter has been successfully written. If an error occurs during an access, this is signaled with QF = 1. For error diagnostics, the error code ERC can be evaluated.

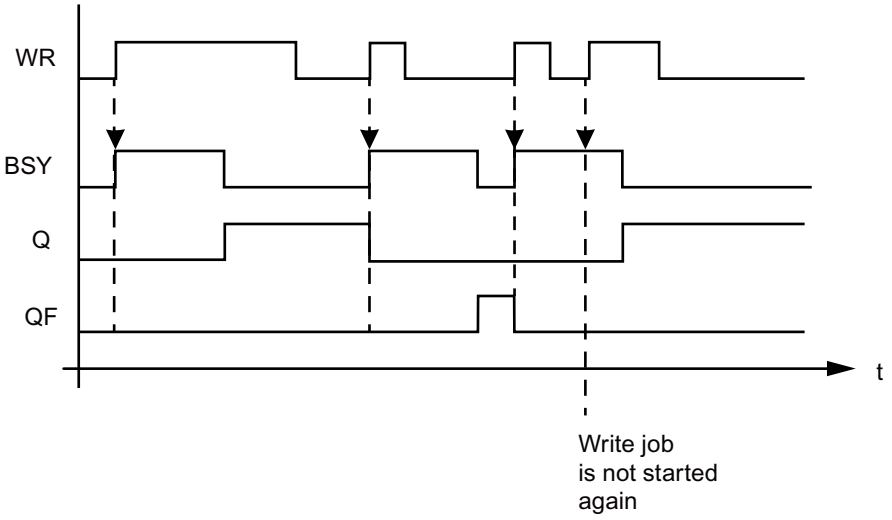
Despite the overall status Q =1, the writing of individual parameters may have been aborted with error. Write jobs for which there is no error in PRES, have been executed.

The error status of the individual write jobs can be evaluated on the parameter-specific return value PRES. An active job is aborted with the positive edge on the ABRT input. The ABRT signal must have the value 1 for at least one cycle.

Brief description

The block enables up to 23 SINAMICS parameters to be written.

Time diagram



Data set 47 is always read out for PROFIBUS (external or integrated) irrespective of whether the function is called with a valid (0>=doid<=254) or invalid 'doid' (doid=255).

Two data sets are available for PROFINET:

- Base Mode Parameter Access - local (data set 0xB02E)
- Base Mode Parameter Access - global (data set 0xB02F)

Data set 0xB02E is used for SIMOTION if either no 'doid' or an invalid 'doid' (doid=255) is specified in the function. Access to the appropriate DO is then performed via the Parameter Access Point (PAP). Either the PAP address can be specified directly or the log. address of the cyclic data (e.g. 256 for a DO axis) can be specified. SIMOTION then determines the corresponding PAP from this address before accessing the correct address. PAP must always be at subslot 1 (HW Config configuration).

Data set 0xB02F is used if a valid 'doid' (0>=doid<=254) is entered. Any valid PAP or address can be specified because the assignment is only performed via the 'doid'.

Description of the block inputs

'IOTY' input/output assignment of the logical start address of the drive.
With 198: INPUT, the logical address of the drive is in the input range.
With 199: OUTPUT, the logical address of the drive is in the output range.
Diagnostics addresses are always of the INPUT type.

'LADR': Specification of the logical start address of the drive. If the optional parameter DOID is also used, any arbitrary address of the station (preferably the diagnostics address of the station) can be specified.
With PROFINET, parameter access is via the Parameter Access Point (PAP) of a drive object.
As an alternative to the logical start address of the drive, specification of the diagnostic address of the associated PAP is recommended.

'DOID': For the direct addressing of a drive object. The DOID can be unspecified or specified as invalid (>254) under the following conditions:

- Access via the DOID is not supported by the DP slave / IO device (P978 is not implemented).
- Data set 0xB02F is not supported (PROFINET only).
- Access is to be via the parameter access point of a DO (PROFINET only).

'X.NUMP': Number of parameters to be written.

'X.PAR.NUM': Specifies the parameter numbers from which the values are to be written.

'X.PAR.IDX': Parameter index; for indexed values, 0 means index 0. For non-indexed values, parameter index 0 must be specified.

'X.PAR.DTYP' specifies the parameter data type (for the coding, see PROFIdrive profile). The data type must match the type of the parameter in the drive. The block performs the data type-specific transfer. If the specified data type does not match the actual data type of the parameter in SINAMICS, an error status is returned.

'X.PAR.X': Data to be written to the drive, DWORD. Conversion blocks are required for different data types. Conversion block R_DW should be used to write a REAL parameter. Conversion block B_DW should be used to write a BYTE parameter.

'WR': Start write job

'ABRT': Abort active job

Description of the block outputs

'Q': Job completed without errors.

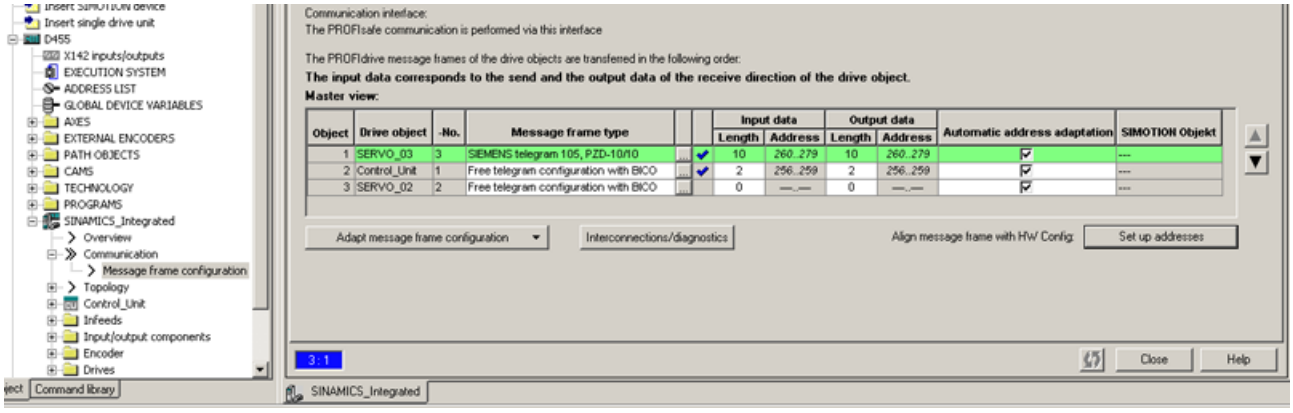
'QF': Job completed with errors.

'ERC': Corresponds to the values of the return value 'functionResult' of the _writeDriveMultiParameter function.

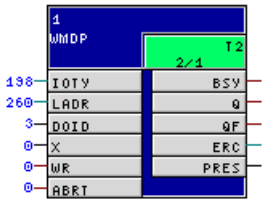
Parameterization example

In order to be able to write certain parameters of a drive object (in the example: SERVO_03), proceed as follows:

First set the correct telegram configuration.

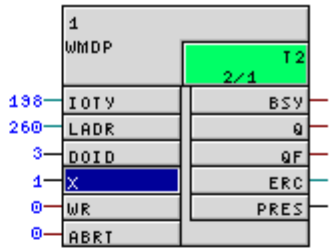


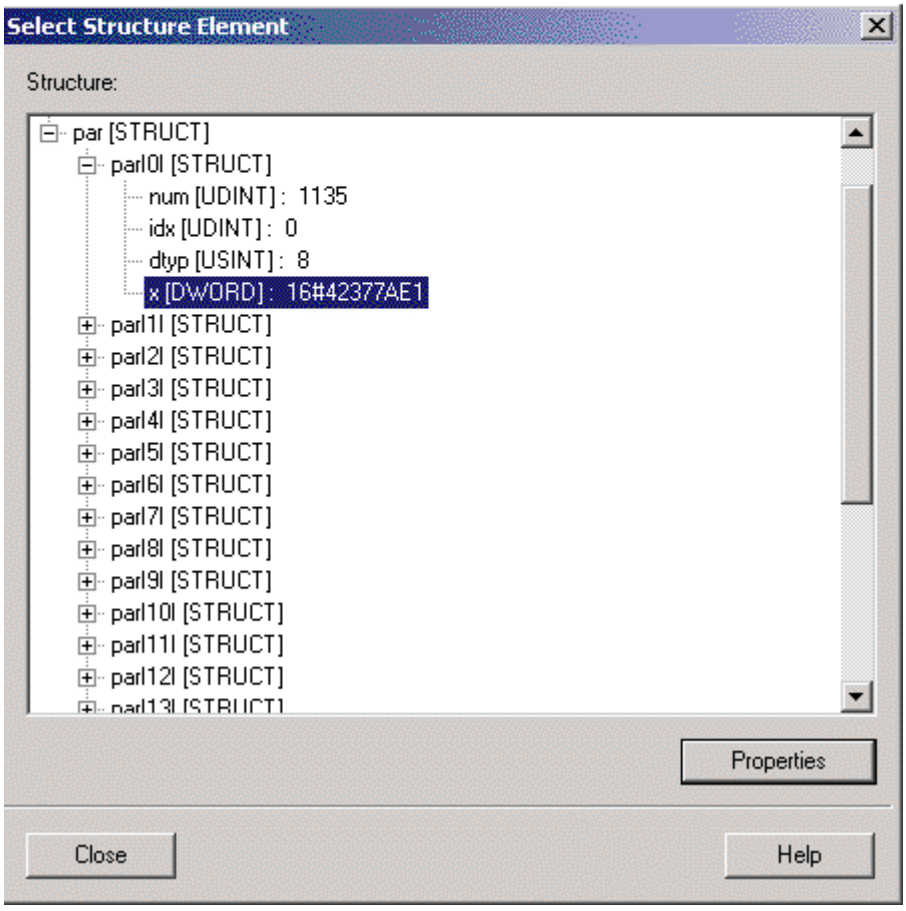
Then set the desired DO address in the WMDP block. To do this, set the block input 'LADR' to the address (260) set in the telegram and the block input 'DOID' to the number (3) set in the telegram.



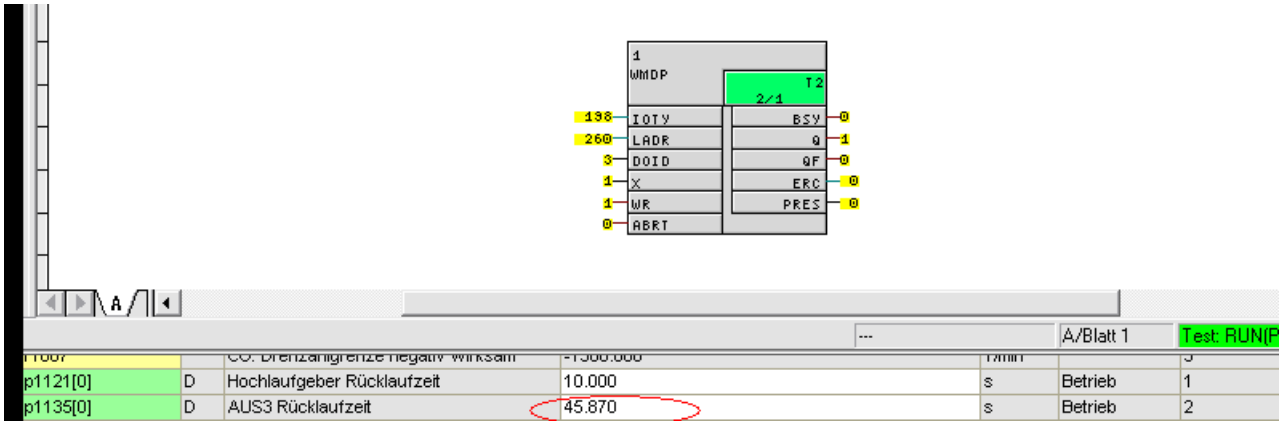
Select the parameters to be written at block input 'X', e.g. P1135(0) OFF3 ramp-down time.

To do this, double-click block input 'X', select the first structure element and enter the parameter number (1135) at 'num' and the index (0) at 'idx'. Enter the data type at 'dtyp'. It must correspond to the data type of the parameter, in our case 8 (floating-point). Enter the value 16#42377AE1 as DWORD at 'x'. The coding of the data types can be found in the SIMOTION List Manual 'System Functions/Variables Devices → System Functions - Devices 1 → _readDriveMultiParameterDescription'.





Then set the block input 'WR' to 1 to start the writing. The result can be viewed in the expert list.



Block connections

Block connection	Description	Default	Value range	Attributes
IOTY	Logical start address as input/ output	0	0: Invalid 198: Input address 199: Output address	
LADR	Logical start address of the drive	-1	DINT	
DOID	ID of the drive object for direct addressing	255	0 .. 254, 255: Invalid	
X	Number of parameters, parameter numbers and indices to be read	1		
X.NUMP	Number of parameters to be written	0	1..23	
X.PAR	Description of a parameter	0		
X.PAR.NUM	Number of the parameter	0	1..65535	
X.PAR.IDX	Index of the parameter	0	1..65535	
X.PAR.DTYP	Data type of the parameter to be written	0	USINT	
X.PAR.X	Value of the parameter	0	DWORD	
WR	Start write job	0	0/1	
ABRT	Abort of the active job	0	0/1	
BSY	Write job active message	0	0/1	
Q	Write job executed successfully message	0	0/1	
QF	Error	0	0/1	
ERC	Return value of the entire job, data type	16#0000	DWORD

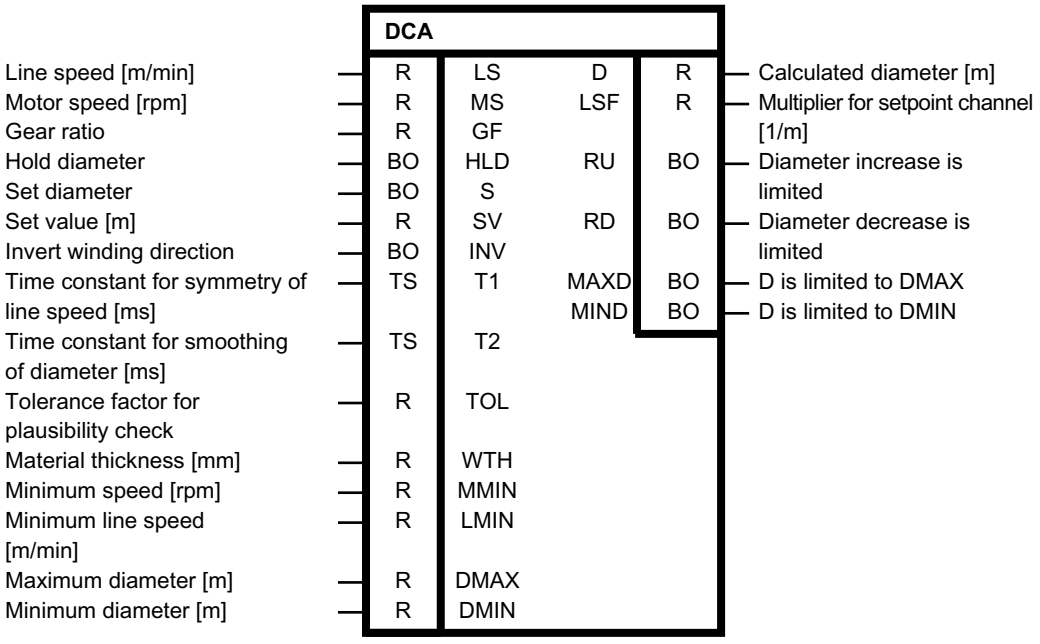
8.1.7 Technology

8.1.7.1 DCA

Diameter calculator

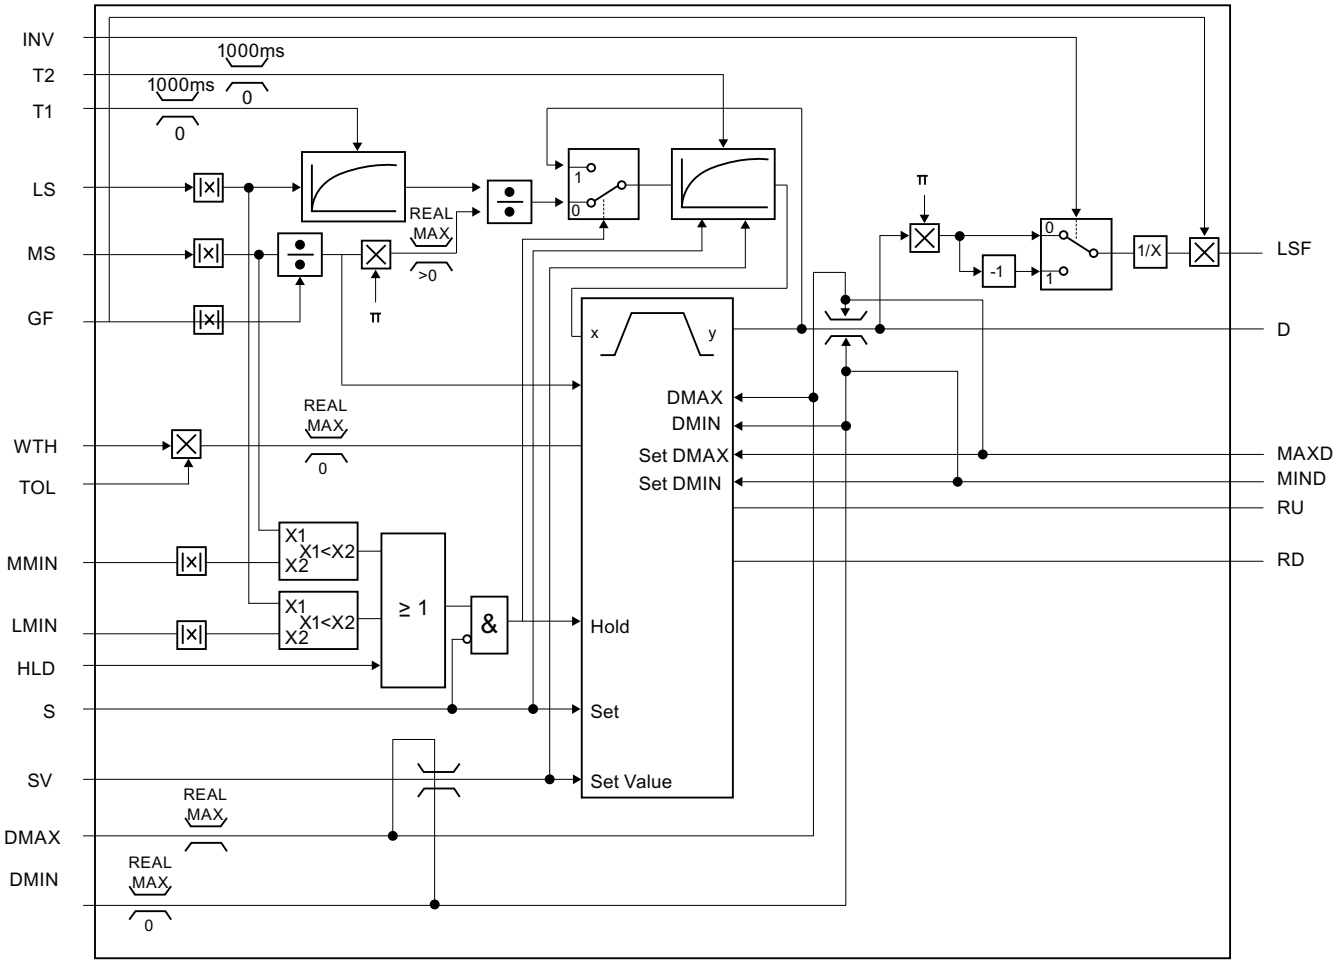
Symbol



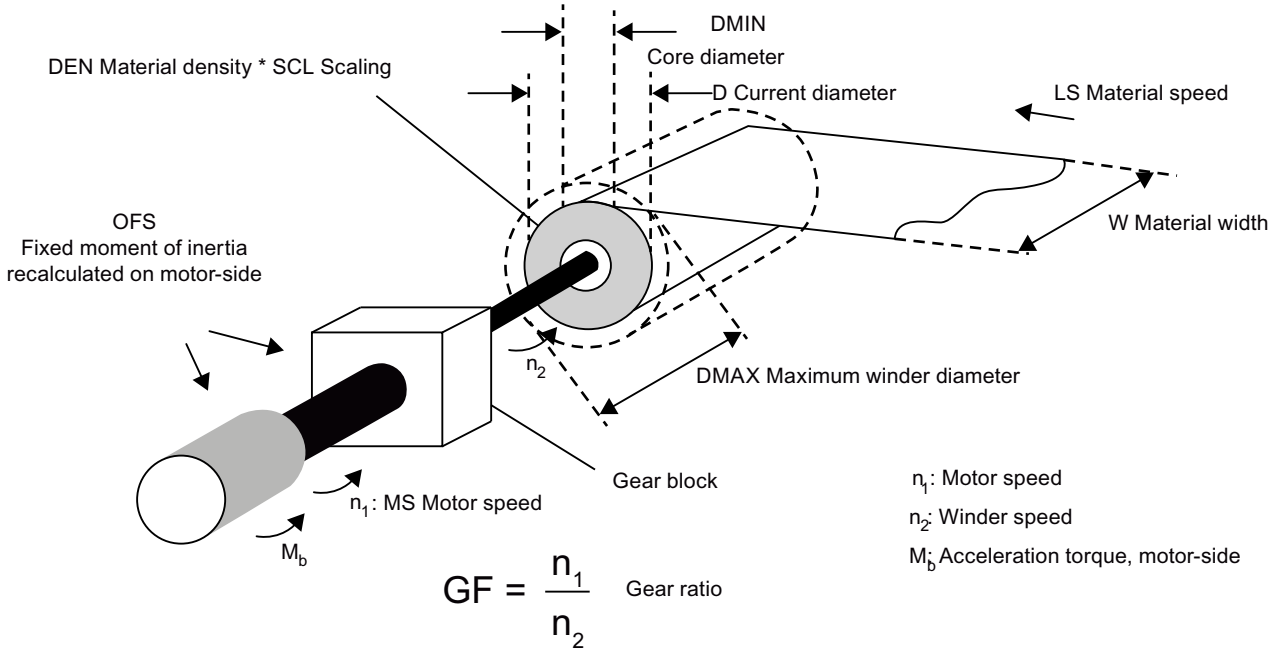
Brief description

Technological block for axial winder applications. It is used to determine the current diameter of an axial winder based on the line speed and the motor speed. The calculated diameter is checked for plausibility.

Block diagram



Method of operation



The block cyclically calculates the diameter of an axial winder on the basis of the current line speed and the motor speed, which have to be supplied via the LS and MS inputs. The current motor speed is indicated at input MS. With deceleration time T1, the path velocity can be decelerated relative to the motor speed.

The current diameter is then calculated using the following formula:

$$\text{Diameter} = \frac{\text{Line speed} \cdot \text{Gear ratio}}{\text{Motor speed} \cdot \pi}$$

The result can then be smoothed again using a smoothing element with time constant T2. The smoothing filters T1 and T2 have PT1 behavior. If time constant T1 or T2 = 0, the input value of the smoothing is written directly to the output. The diameter is only calculated if the path velocity LS or motor speed MS is greater than the threshold value LMIN or MMIN, respectively. Otherwise, the last calculated diameter value is held. In this case, smoothing T2 switches over to the fed-back diameter D. It is also possible to trigger holding of diameter D directly by setting input HLD = 1. Input SV can be used to assign a preset value to the diameter; this diameter is applied when S =1. Smoothing element T2 is also initialized with this value. When S = 0, the diameter calculation and smoothing T2 is enabled again. Setting the diameter has precedence over holding.

After smoothing element T2, the calculated diameter is checked for plausibility and corrected if a violation is identified. This test function is equivalent to that of a single ramp-function generator. The ramp-up time or ramp-down time is calculated dynamically from the material thickness WTH, tolerance factor TOL, and the winding speed. When material thickness WTH = 0, the plausibility check has no effect.

The maximum diameter change ΔD_{max} per scan interval is determined as follows:

$$\Delta D_{max} = TOL \cdot 2 \cdot \frac{MS}{60 \cdot GF} \cdot \frac{WTH}{1000} \cdot T_A$$

with:

ΔD_{max}	Maximum diameter change [m] per scan interval
TOL	Tolerance factor
MS	Motor speed [rpm]
GF	Gear ratio
WTH	Material thickness [mm]
T_A	Block sampling time [s]

The resulting diameter D is limited as follows:

$D_n \leq D_{n-1} + \Delta Dmax_n$; for D_n(unlimited)$\geq D_{n-1}$ (ramp-up limiting)

$D_n \geq D_{n-1} - \Delta Dmax_n$; for D_n(unlimited)$\leq D_{n-1}$ (ramp-down limiting)

Output RU (ramp-up limiting) or RD (ramp-down limiting) is set in order to signal externally that limiting is in effect. If limiting is no longer in effect, the corresponding output is reset to zero. When Hold = 1 or Set = 1, both outputs are reset. When the diameter is set, the ramp-function generator has no effect. The plausibility check is a downstream limiter. If the current diameter is limited to DMAX, output MAXD = 1 is set. If the current diameter is limited to DMIN, this is signaled at output MIND. If limiting is active, the ramp-function generator is corrected with the active limit value in order to avoid anti-windup. In this case, the following applies to the next ramp-function generator cycle:

$D_{n-1} = DMAX_{n-1}$ if diameter is limited to DMAX

$D_{n-1} = DMIN_{n-1}$ if diameter is limited to DMIN

Output LSF cyclically supplies a multiplication factor for the setpoint channel in order to calculate the speed setpoint of the motor from the current path velocity. If the INV input is set to the value 1, the winding direction is inverted.

Block connections

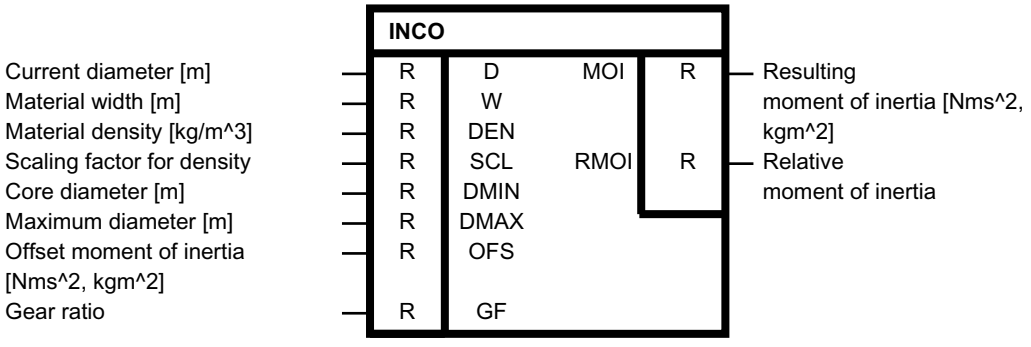
8.1.7.2 INCO

Axial winder moment of inertia

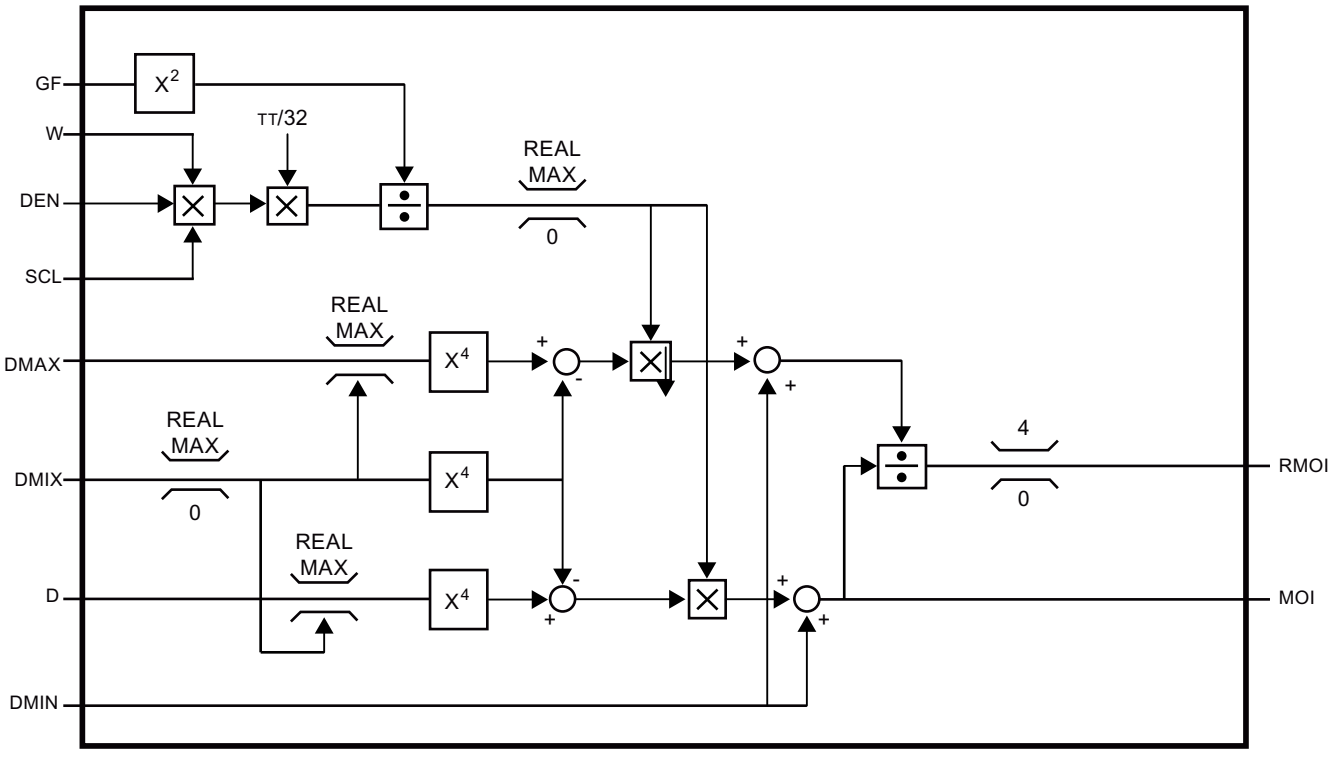
Symbol



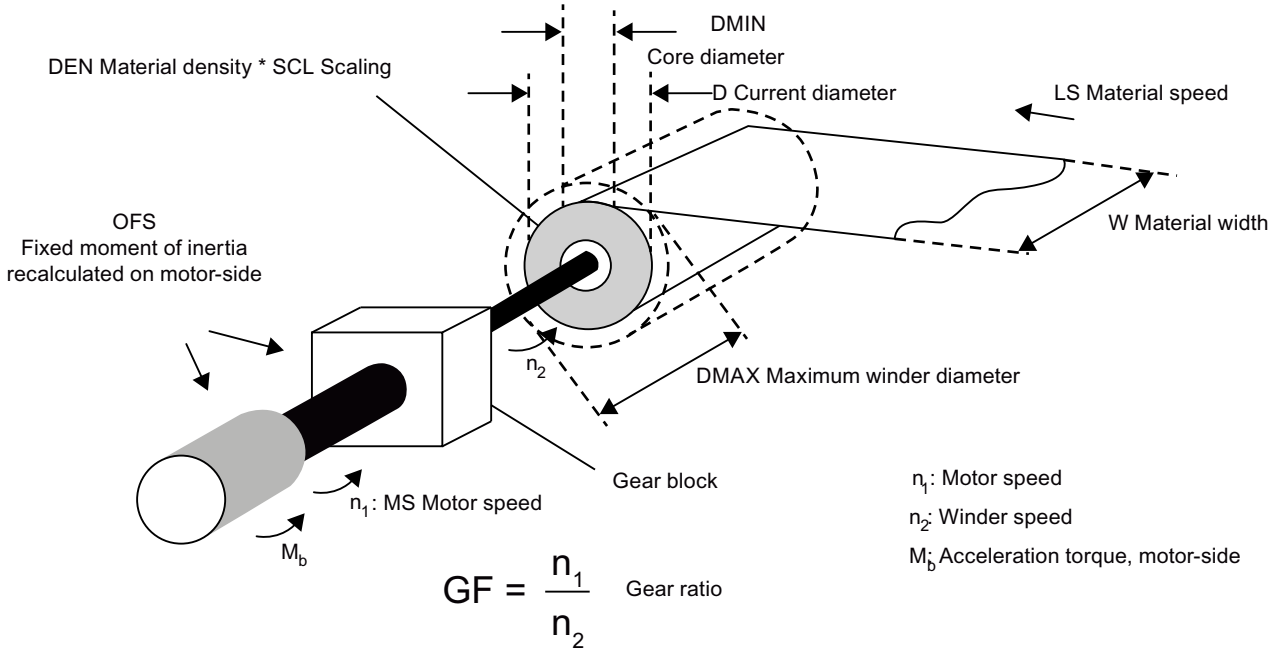
Brief description

Technological block for axial winder applications. It is used for determining the moment of inertia of a winder, which is used to derive a torque feedforward control.

Block diagram



Method of operation



The block calculates the motor-side moment of inertia of an axial winder. Input variable D specifies the current diameter [m] of the winding. The density [kg/m3] of the winder can be specified via DEN, and a correction factor for the density can be specified via SCL. Input variable DMIN [m] is used to specify the diameter of the winding core or the minimum diameter of the wound material. In order to calculate the relative moment of inertia RMOI for an adaptation Kp of the speed controller, the block requires the maximum moment of inertia of the layout. To calculate this, the maximum winding diameter must be specified at input DMAX [m]. The total static moment of inertia (motor, empty winder and, if required, gearbox) relative to the motor side can be specified via input OFS [Nms2, kgm2]. The transmission ratio is specified at input GF. The current moment of inertia of the entire winder layout relative to the motor side is output at output MOI.

Block connections

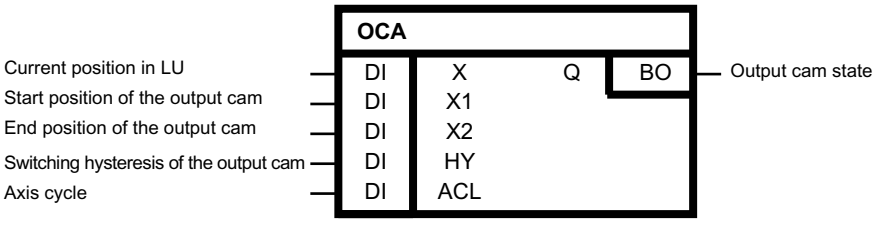
Software cam controller

Symbol

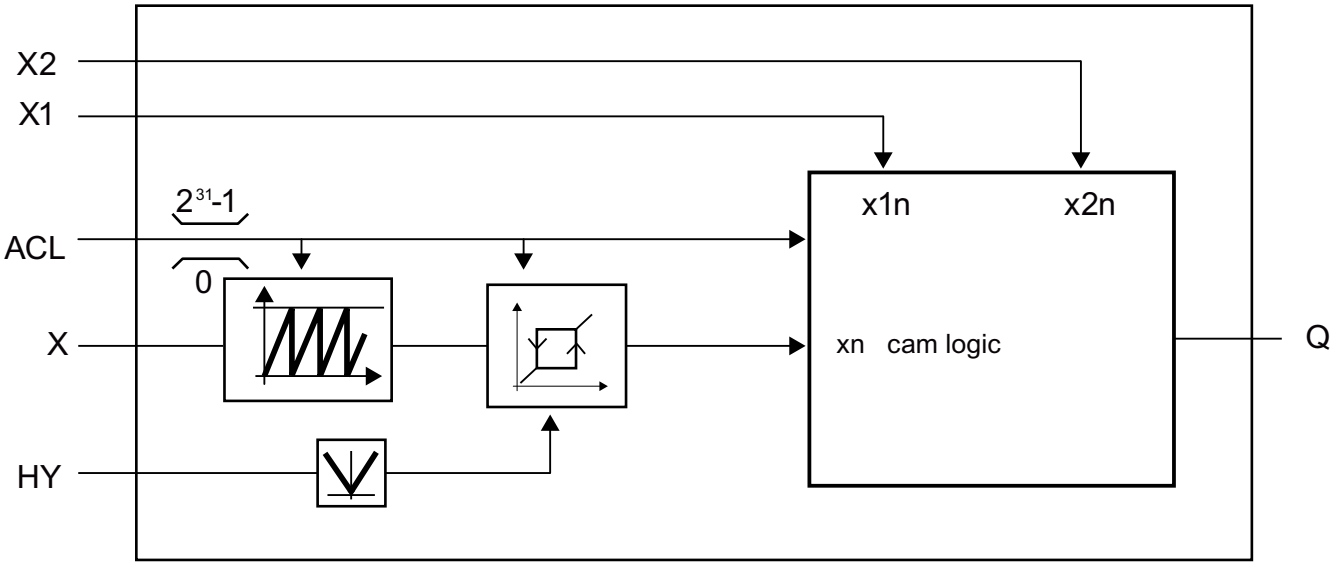


Brief description

Software cam controller with the following features:

- Position-based cam.
- Switch-on/switch-off positions can be changed dynamically.
- Adjustable hysteresis for actual-value-related output cam.

Block diagram



Method of operation

The switch-on position of the position-based cam in the positive direction and the switch-off position in the negative direction is specified via input X1 [LU]. X2 [LU] specifies the switch-off position in the positive direction or the switch-on position in the negative direction. In order to be able to drive the cam controller with modulo axes, the axis cycle can be specified at input ACL. If ACL = 0, there is no internal modulo correction. A hysteresis band for input X can be set via HY. This means that switching operations do not occur when actual value-related output cams are at a standstill.

The hysteresis is used to avoid unwanted switch-on and switch-off operations of the output cam during actual value noise. After a switching operation, switching is only possible again for a direction reversal when the hysteresis range is exited.

The cam logic makes the following evaluation:

Non-modulo axis (ACL = 0)

x1n < x2n	Q = (x1n ≤ xn) AND (x2n > xn)
x1n ≥ x2n	Q = 0

Modulo axis (ACL <> 0):

x1n < x2n	Q = (x1n ≤ xn) AND (x2n > xn)
x1n > x2n	Q = (x1n ≤ xn) OR (x2n > xn)
x1n = x2n	Q = 0

Block connections

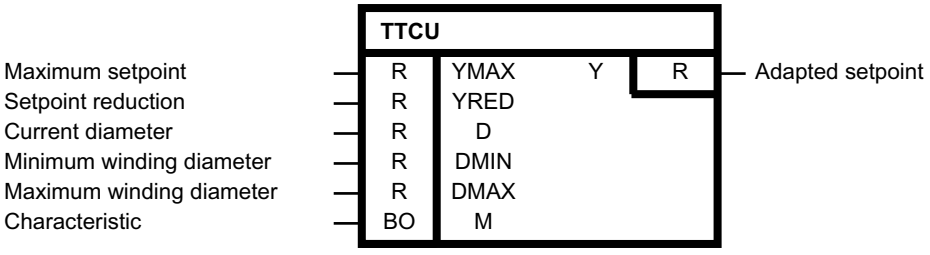
Winding harshness characteristic

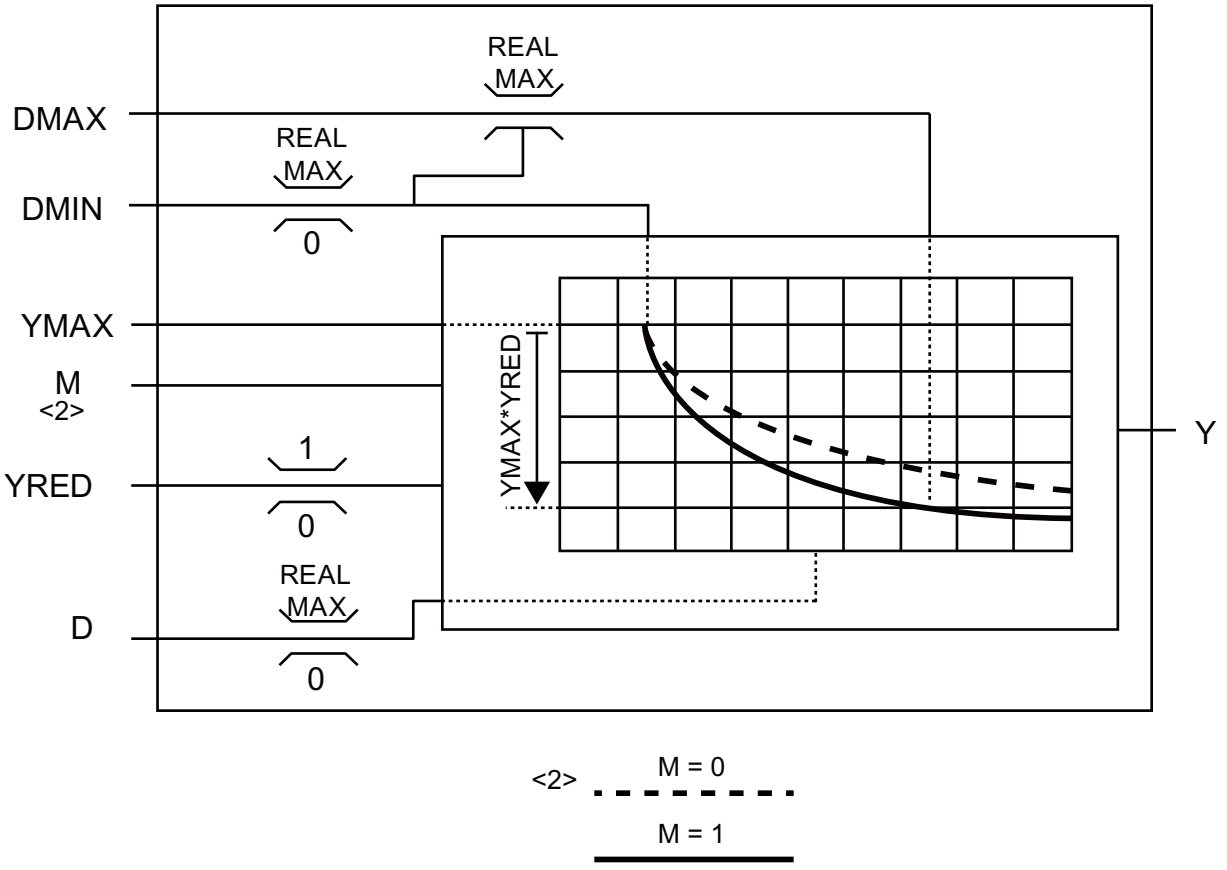
Symbol



Brief description

Adaptation of a setpoint according to the specified characteristic. The block used for winder applications to determine the tension setpoint depending on the current winder diameter.

Block diagram



Method of operation

The reduction of the characteristic starts when D > DMIN is true. Input variable YRED specifies the degree of reduction relative to input variable YMAX. Input M can be used to preselect a characteristic that defines the reduction behavior of the output variable as the input variable increases. If M = 0 has been preselected, the characteristic is reduced asymptotically by the factor YMAX*YRED. In this case, input variable DMAX is not taken into account. If M =1 has been preselected, input variable DMAX can be used to specify at which input variable D = DMAX the characteristic runs through YMAX- YMAX*YRED.

The calculation of the characteristic is specified as follows:

D ≤ DMIN is true

$$Y = YMAX$$

D > DMIN and M = 0 (reaching of the reduction factor for D→∞)

$$Y = YMAX\left(1 - YRED\left(1 - \frac{DMIN}{D}\right)\right)$$

D > DMIN and M = 1 (attainment of reduction factor for D = DMAX)

$$DMAX > DMIN : Y = YMAX \left(1 - YRED \frac{DMAX}{DMAX - DMIN} \left(1 - \frac{DMIN}{D}\right)\right)$$

$$DMAX = DMIN : Y = YMAX \left(1 - YRED\right)$$

Block connections

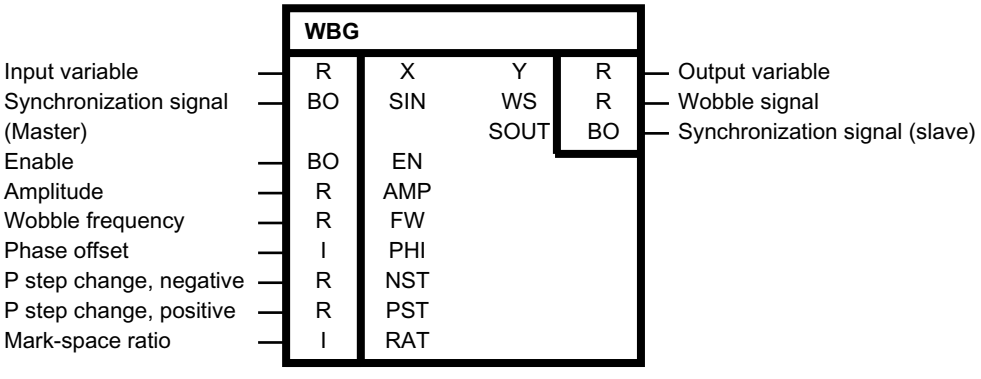
8.1.7.5 WBG

Wobble generator

Symbol

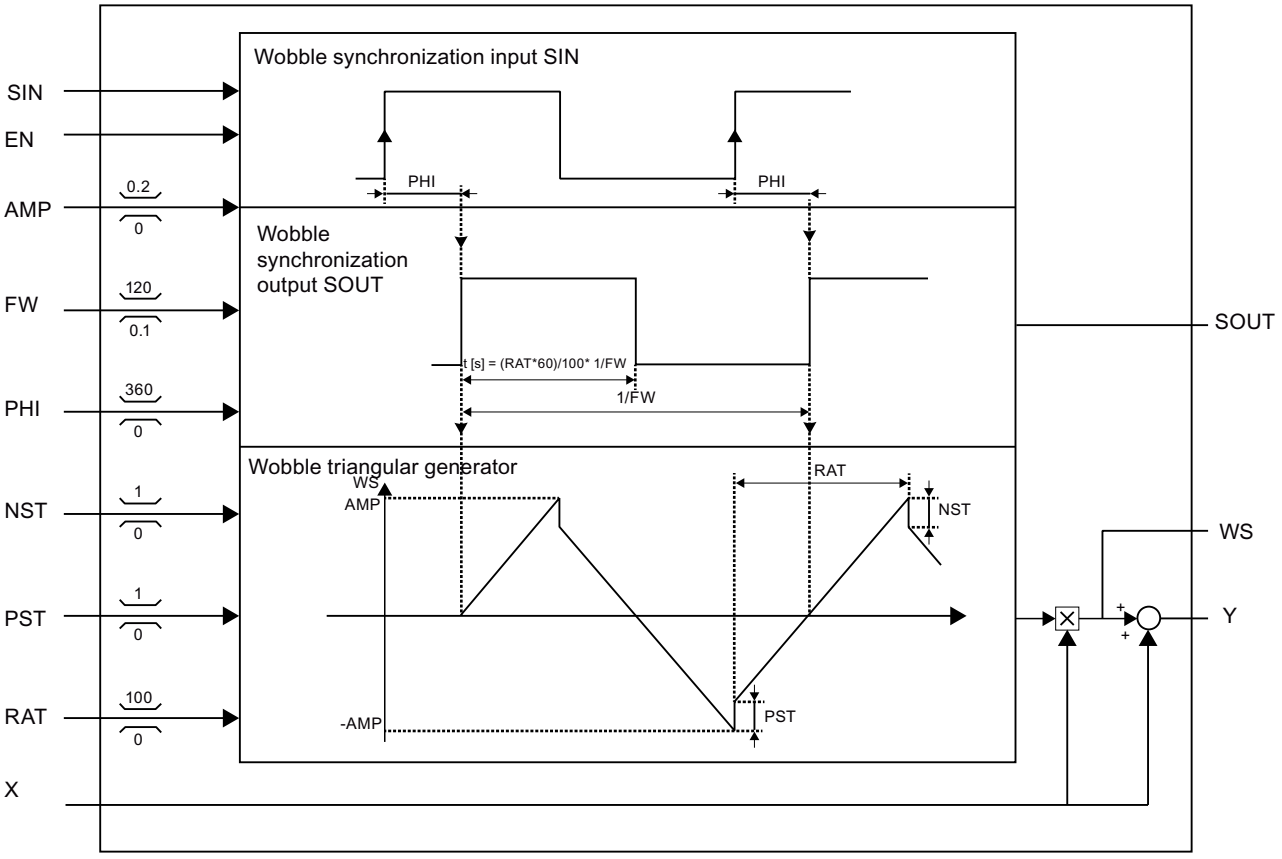


Brief description

Triangular generator with adjustable frequency and amplitude for imprinting of "faults" on traversing drives for winding up textile threads. This generator has the following features:

- Positive and negative P step change, can be adjusted separately.
- Synchronization to a master drive with an adjustable phase shift.
- Enable input.

Block diagram



Method of operation

The wobble generator is enabled with EN = 1. This triggers the output of wobble signal WS and synchronization signal SOUT. The signal generation always starts with a positive zero crossover or with a positive edge of synchronization output SOUT. If EN is reset, wobble generation continues up to the next zero crossover of WS. The generator is then disabled and SOUT = 0 is set. Input PHI (0-360°) enables a phase shift between the positive edge of the synchronization input SIN to be set along with the start of the wobble signal. The signal is then generated for a signal period. For continuous signal generation, SIN must be used periodically as a trigger. If the generation of the preceding signal period is still running at a new start time, this generation is canceled. Special case PHI = 360 enables free-running wobble generation to be activated. The signal generation runs periodically and is decoupled from synchronization input SIN. The wobble signal is injected into input x and output at output Y.

Attributes of the wobble signal

Input	Value range	Description
AMP	0..0.2	Relative amplitude of the wobble signal
FW	0.1..120 rpm	Frequency of the wobble signal
PHI	0..360°	Phase shift of wobble signal relative to a positive edge at synchronization input SIN
NST	0.0..1.0	Relative, negative step change of wobble signal at the end of the positive signal edge
PST	0.0..1.0	Relative, positive step change of wobble signal at the end of the negative signal edge
RAT	0..100%	Ratio of rising signal edge / signal period

Effective amplitude(WS) = ABS(X) * AMP

Effective negative step change = -ABS(X) * AMP * NST

Effective positive step change = ABS(X) * AMP * PST

Ratio of rising edge / falling edge = RAT/(100-RAT)

If the attributes of the wobble signal are changed dynamically, the changed attributes take effect at the start of a new signal period (positive zero crossover).

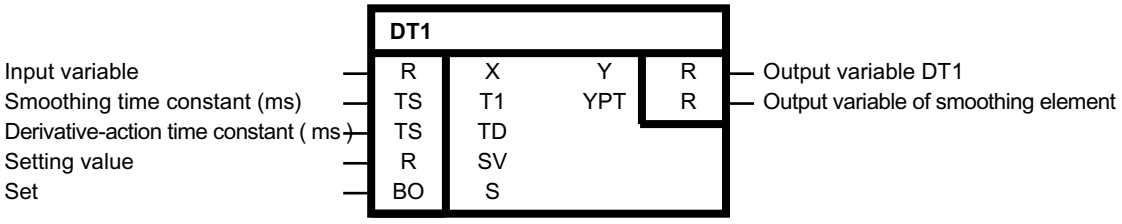
8.1.8.4 DT1

Smoothing element

Symbol



Brief description

Block with derivative-action response and smoothing. The DT1 output can be set.

Method of operation

Setting function not active (S = 0)

Input variable X (dynamically delayed by smoothing time constant T1), is given to a derivative-action element and block output YPT.

Output variable Y of the entire DT1 element is proportional to the change velocity of YPT (differential quotient), multiplied by the derivative-action time constant TD.

T1 determines the steepness of the decline of the output variable. It specifies the time at which the transfer function fell to 37% of X-TD/T1 after smoothing and differentiation. If T1/TA is sufficiently large (T1/TA>10), the transfer function corresponds to the characteristic curve of

$Y(t) = X \cdot (TD/T1) \cdot e^{-t/T1}$

with $t = n \cdot TA$

Algorithm:

$$Y_n = \frac{TD}{T1} \cdot (X_n - YPT_{n-1})$$

$$YPT_n = YPT_{n-1} + \frac{TA}{T1} \cdot (X_n - YPT_{n-1})$$

YPT_n	Value of YPT in scan interval n
Y_n	Value of Y in scan interval n
X_n	Value of X in scan interval n
YPT_{n-1}	Value of YPT in scan interval n-1

The larger T1/TA is, the smaller is the amplitude change on Y and YPT from one sampling time to the next. TA is the sampling time in which the block is configured. The larger that TD/TA is, the larger the amplitude change on Y from one sampling time to the next. TD and T1 are limited internally: TD >= 0, T1 >= TA.

Setting function active (S = 1)

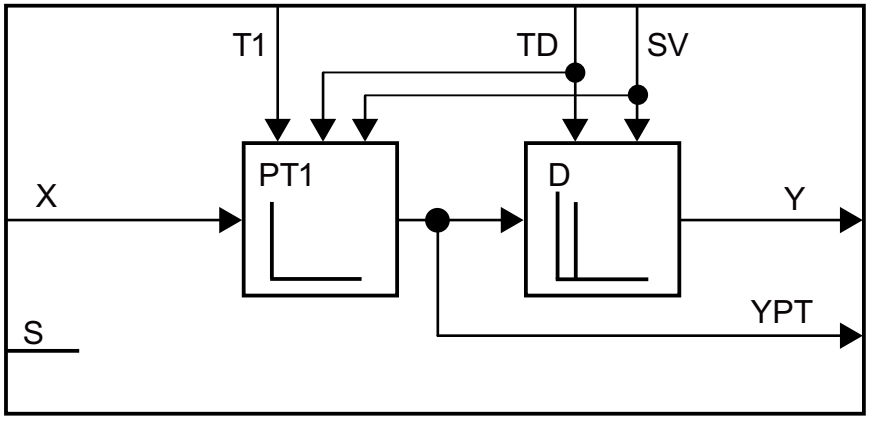
With active setting function, the setting value SV is applied at the dt1 output Y (Y=SV), the following results for the output of the smoothing element:

$$YPT_n = X_n - \frac{T1}{TD} \cdot SV_n$$

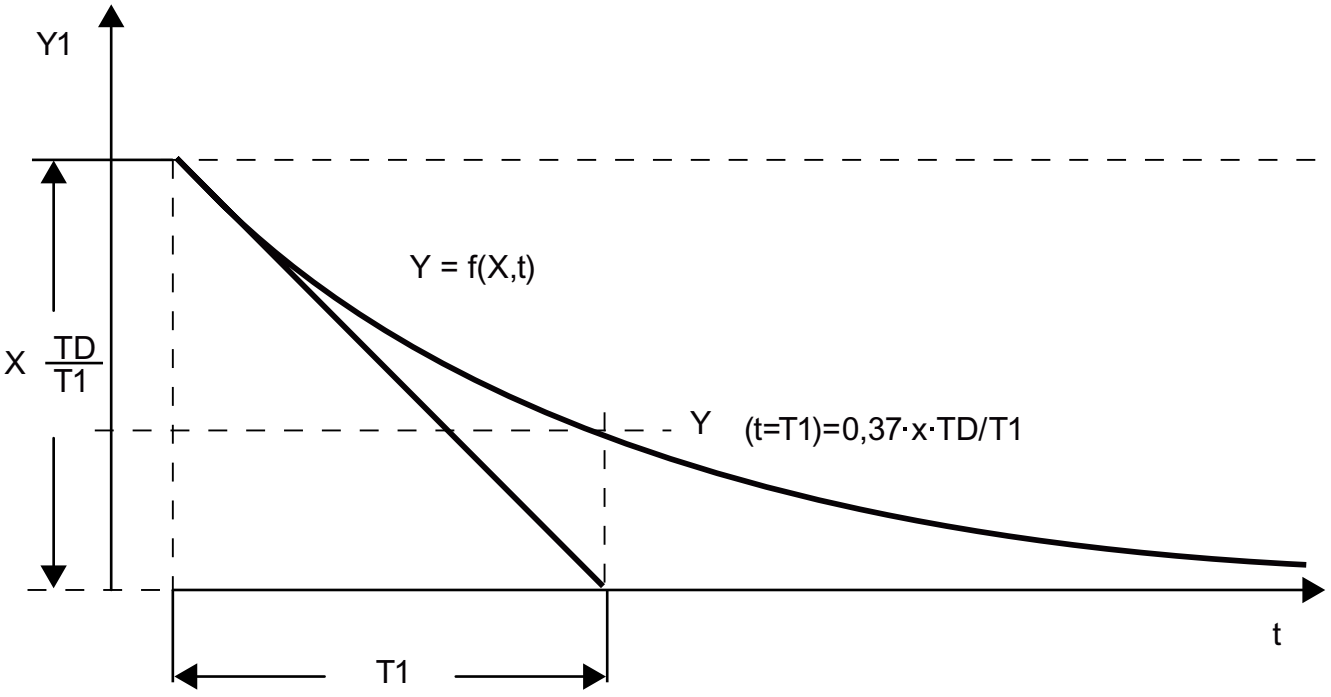
for $TD \neq 0$

The internal limitations for T1 and TD apply in this case. When TD=0, the output variables remain unchanged, as long as S=1.

Block diagram



XY diagram



Initialization

If input S is logic 1 at the initialization, the setting value SV is applied at output Y and YPT = T1/TD*(X-SV) set.

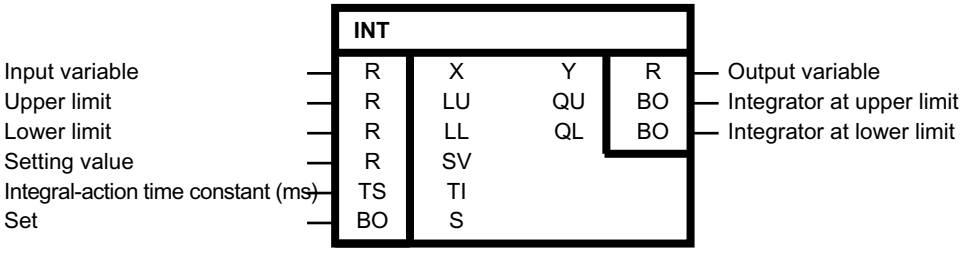
8.1.8.5 INT

Integrator

Symbol



Brief description

- Block with integral behavior
- Set initial value
- Adjustable integral-action time constant
- Adjustable limits
- For normal integrator mode, a positive limit value must be specified for LU and a negative limit value for LL

Method of operation

The change in output variable Y is proportional to input variable X and inversely proportional to the integral-action time constant TI.

The output Y of the integrator can be limited via the inputs LU and LL. If the output reaches one of the two limits, a message is sent via the outputs QU or QL. If LL >= LU, then output Y = LU.

The calculation of the discrete values (TA is the sampling time in which the block is configured) is performed according to the following algorithm:

Algorithm:

$$Y_n = Y_{n-1} + \frac{TA}{TI} \cdot X_n$$

Y_n	Value of Y in scan interval n
Y_{n-1}	Value of Y in scan interval n-1
X_n	Value of X in scan interval n

When S = 1, the output variable Y is set to the setting value SV. Two functions can be realized via S:

Track integrator (Y = SV)

The binary input is S = 1 and the setting value SV is changed. If applicable, the output makes a jump to the setting value immediately after the setting operation.

Set integrator to initial value SV

S is switched to 1. S is then set to 0, and the integrator starts from SV in the direction specified by the polarity of input variable X.

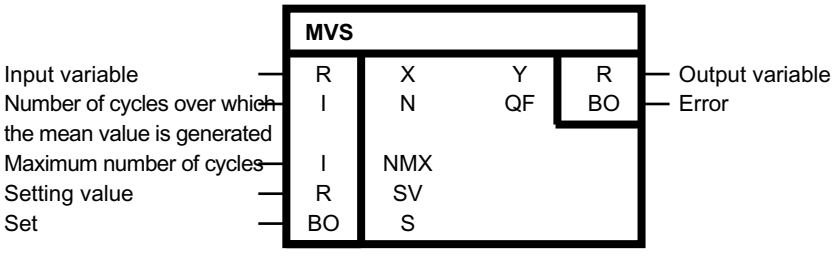
8.1.8.8 MVS

Sliding-type mean value generator

Symbol



Brief description

The block calculates a sliding-type mean value via the input variable X.

Method of operation

The mean value is generated over the last N cycles.

$$Y_k = \frac{1}{N} \cdot \sum_{i=k-(N-1)}^{k} X_i$$

X_k = X in cycle k

k = 0 is the current cycle

The number of cycles can be changed in the range $1 \leq N \leq NMX$. The maximum number of cycles is specified through NMX and cannot be changed during operation. The block limits input N to

the range of 1 ≤ N ≤ NMX. The buffer for the input values is always filled up to NMAX, irrespective of N. In this way, the block can re-determine the current mean value via all variables when there is a change in the window length.

The mean value is set to set value SV as long as S = 1.

Initialization

At the initialization, NMX is used to specify the maximum size of the mean value buffer for the X values. For this reason, NMX should be set to the maximum value of N required under operating conditions. The value of NMX is limited to the range of values between 1 and 1,000. If there is not enough memory for NMX on the target device, or if NMX is limited, output QF is set to 1 and output Y retains its default value during cyclic operation. As NMX cannot be changed dynamically during operation, NMX should be specified as a constant.

Application areas

The block can be used as ramp-function generator or filter block for the mean value generation. It acts as a low pass and band-stop filter for frequencies f_k.

$$f_k = \frac{k}{N \cdot T_A}$$

k = 1, 2, ...

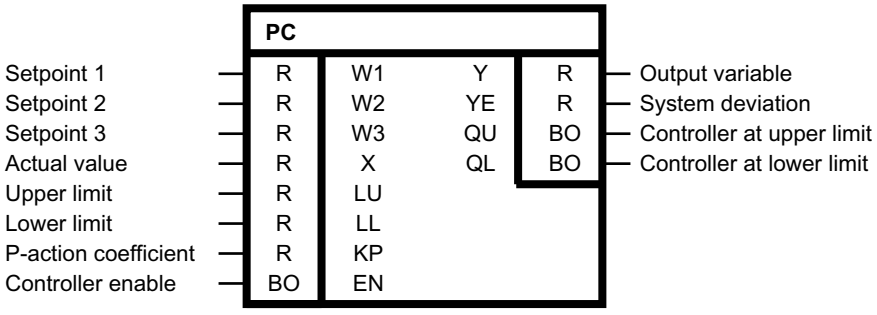
P controller

Symbol



Brief description

- P controller with 3 setpoint inputs and 1 actual value input
- Sign reversal of actual value in block
- Indication when set limits are reached
- For normal controller operation, a positive limit value must be specified for LU and a negative limit value for LL.

Method of operation

The three setpoints W1, W2, and W3 are added and the actual value X is subtracted from the setpoint total. The result YE is multiplied by the proportional coefficient KP and given to output Y.

Algorithm:

$Y = KP \cdot YE = KP \cdot (W1 + W2 + W3 - X)$

$YE = W1 + W2 + W3 - X$

The system deviation YE is always calculated, irrespective of the operating mode, and is lead out separately.

The output Y of the controller can be limited via the inputs LU and LL. If the output Y reaches one of the two limits, a message is sent via the outputs QU and QL. If LL >= LU, then output Y = LU.

The controller is enabled with EN = 1. If EN = 0, the output variable Y is set to zero. The controller is disabled. The binary outputs QU and QL are treated in this case as if KP*YE equaled zero.

The controller operates inverted when a negative KP value is selected (inversion amplifier).

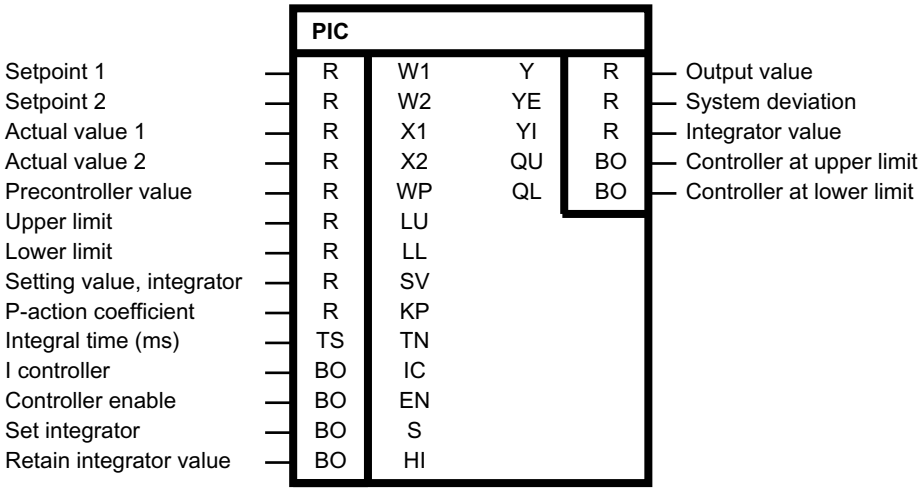
8.1.8.10 PIC

PI controller

Symbol



Brief description

- Universal PI controller, can be switched to P controller or I controller modes. Can be used as a speed controller or a primary controller. Suitable for dynamic override control

Flexible integrator functions:

- Set initial value ⇒ Load SV to integrator
- Retain current value of integrator ⇒ P controller
- Integrator control by SV
- Integrator control by controller limiting
- Gain shutdown ⇒ I controller

Overall controller functions:

- Independent setting and modification of the following variables during operation:
  - Proportional coefficient KP
  - Integral action time TN
  - Controller limits LU and LL
  - Precontroller value WP, e.g. for acceleration injection
  - Second actual value input X2, e.g. for droop injection
- Indication when set limits are reached

Method of operation

The actual value total (X1+X2) is subtracted from the setpoint total (W1+W2) according to the equation:

YE = (W1 + W2) - (X1 + X2)

The result, system deviation YE, is then multiplied by the adjustable proportional coefficient KP. The product is carried to the output summation device and the integrator. The adjustable integral time TN determines the integration behavior of the controller. The change in output variable YI is proportional to input variable KP*YE and inversely proportional to the integral-action time TN. The integrator value YI is also given to the output summation device. Another value with the correct sign can be added to output value Y via input WP.

Discrete values are calculated according to the algorithm:

Algorithm:

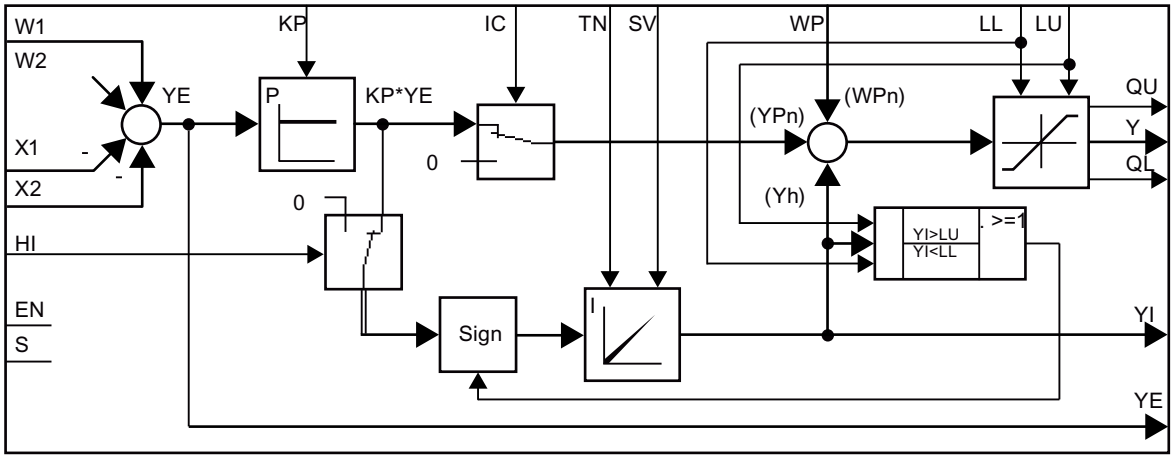
$$Y_n = Y_{n-1} + KP \cdot \left[\left(1 + \frac{TA}{TN} \right) \cdot YE_n - YE_{n-1} \right]$$

With the boundary conditions: LL<Y<LU and LL<LU

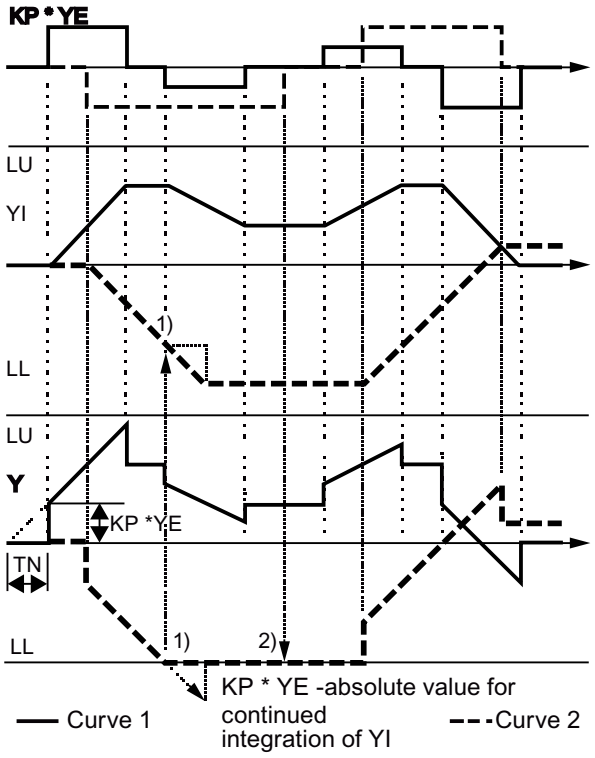
Y_n	Value of Y in scan interval n
Y_{n-1}	Value of Y in scan interval n-1

TA is the sampling time in which the block is configured.

Block diagram



XY diagram



Curves 1 and 2 show the characteristic of Y and YI during YE jumps:

- Curve 1, normal operation, no limiting
- Curve 2, with use of limiting (e.g. LL)

For 2) a decay of YE*KP is expected, but this is canceled by the continued integration in 1).

Operating modes and control of the controller

Output value Y and integrator value YI of the controller can be limited via the inputs LU and LL. When the set limits are reached by output variable Y, a message is issued with QU = 1 of QL = 1.

The following priority sequence applies for the control inputs:

EN before IC before S before HI.

Command input at the control inputs:

Control input	Value	Functions
EN	1	Controller enable
IC	1	Change-over from PI controller to I controller
S	1	Accept integrator setting value, do not integrate
HI	1	Retain integrator output YI, do not integrate

The combination of commands at the control inputs and the possible operating modes can be found in the truth tables.

In normal controller operation, LL <= 0 <= LU and LL < Yn < LU. However, other settings, explained below, are possible. To this end, the algorithm is converted appropriately:

$Y_n = KP \cdot YE_n + YI_n + WP_n$

There are 5 different operating conditions in conjunction with LU and LL:

No.	Condition	Y_n
LL < LU		
1	$LL < KP*YE_n + YI_n + WP_n < LU$	$KP*YE_n+YI_n+WP_n$
2	$KP*YE_n + YI_n + WP_n >= LU$	LU
3	$KP*YE_n + Y_n + WP_n <= LL$	LL
LL=LU		
4	None	LU
LL > LU		
5	None	LU

Integrator control by own limiting

If output Y comes up against one of the set limitations LL or LU during the control process, integrator YI will continue to run if applicable, until it comes up against the limitation itself and is retained there.

If the controller is at the limit and the limit value is changed, output Y momentarily assumes the new value as long as an override is defined. However, the integrator is updated to the new limiting value at change velocity YIn.

Section 2: Characteristic with LLn < LLn-1 according to operating condition 3

Section 3: Characteristic with LLn > LLn-1 according to operating condition 3, for

limit shift relative to the control direction with

sign inversion at the integrator input

Section 4: Characteristic with LLn > LUn according to operating condition 5

1) Jump by KP*YE, because the integrator was run up to the limit.

Change-over from PI mode to I mode

When EN = 1 and IC = 1, the P component is retained at 0, and the controller is switched from PI mode to I mode. Output Y assumes integrator value YI. If this occurs during the control process, then a jump by -KP*YE will occur at output Y During a reset to IC = 0, the P component is reset to the current value of KP*YE. The controller again exhibits PI behavior. If this occurs during the control process, then a jump by KP * YE will occur at output Y.

Change-over from PI mode to P mode

If block inputs EN = 1 and HI = 1, the integrator YI is retained, and a bumpless controller change-over takes place from PI mode to P mode. YI continues to act as an addend on output Y.

During a reset to HI = 0, the integrator is enabled again. The controller again exhibits PI behavior.

Transfer functions

Transfer functions during changeover without controller override: Examples for EN=1∧S=0

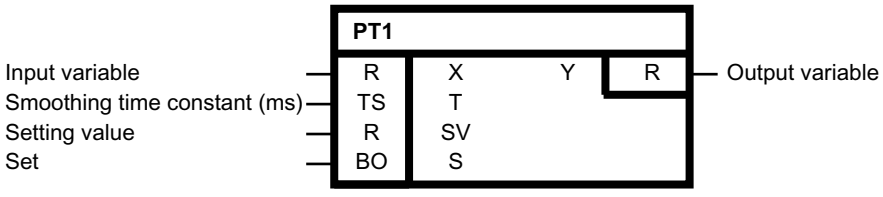
Delay element

Symbol



Brief description

- First-order delay element with setting function
- Use as smoothing element

Method of operation

Setting function not active (S = 0)

Input variable X, dynamically delayed by smoothing time constant T, is given to output Y.

T determines the steepness of the rise of the output variable. It indicates the time at which the transfer function has risen to 63% of its end value.

After t = 3T, the transfer function reaches approximately 95% of its end value.

The internally fixed proportional gain is 1 and does not vary.

If T/TA (T/TA > 10) is sufficiently large, the transfer function corresponds to the characteristic of

$Y(t) = X \cdot (1-e^{-t/T})$

with t = n * TA.

Discrete values are calculated according to the algorithm:

Algorithm:

$$Y_n = Y_{n-1} + \frac{TA}{T} \cdot (X_n - Y_{n-1})$$

Y_n	Value of Y in scan interval n
Y_{n-1}	Value of Y in scan interval n-1
X_n	Value of X in scan interval n

Setting function active (S = 1)

When the setting function is active, the actual setting value SVn is accepted at the output variable: Yn = SVn

Block diagram

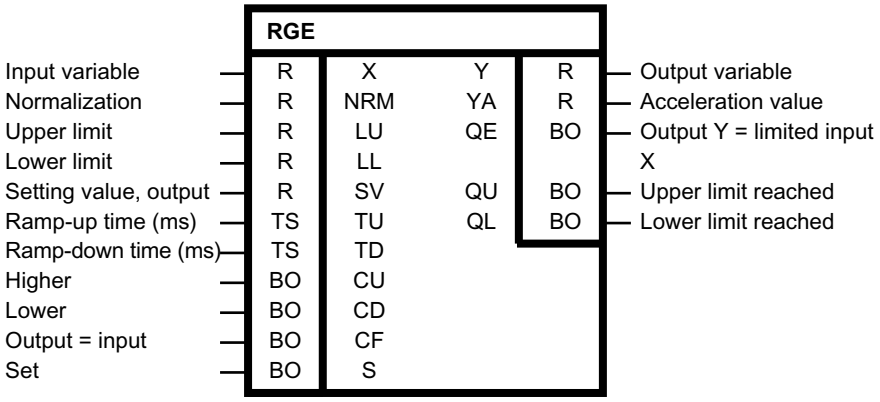
8.1.8.12 RGE

Ramp-function generator

Symbol



Brief description

- Ramp-function generator for limiting the change velocity of input variable X
- Output variable can be limited

Independent setting and modification of the following variables during operation:

- Ramp-up and ramp-down time
- Output limits LU and LL
- Setting value

Flexible ramp-function generator functions:

- Integrating correction to setpoint X
- Setting of initial value for ramp-function generator output (-> load SV to integrator)
- Integrating increase and decrease of ramp-function generator output

Method of operation

The block contains an integrator with two integration time constants that can be set separately. Output Y changes according to the algorithm:

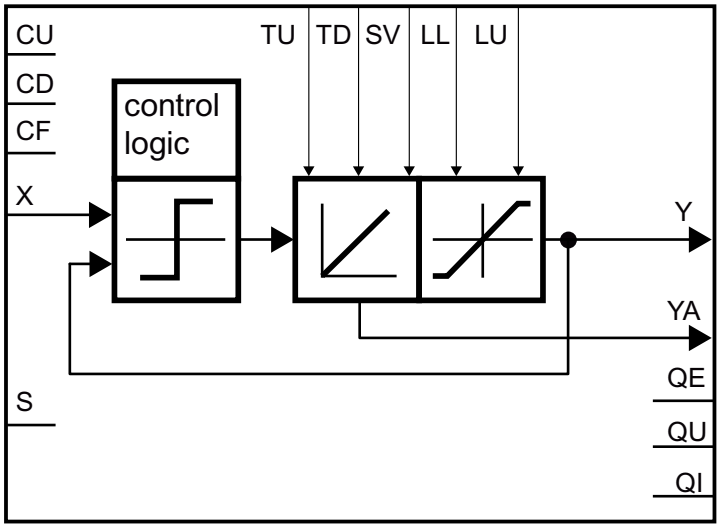
$Y_n = Y_{n-1}+YA_n$

The acceleration value YA is calculated separately for the ramp up and ramp down and is output on an output.

The process in which output value Y moves away from zero is called ramp up.

The process in which output value Y moves toward zero is called ramp down.

Block diagram



The following applies for the ramp up acceleration value:

$$YA = \frac{TA}{TU} \cdot NRM \text{ for } Y > 0$$

$$YA = -\frac{TA}{TU} \cdot NRM \text{ for } Y < 0$$

The following applies for the ramp down acceleration value:

$$YA = -\frac{TA}{TD} \cdot NRM \text{ for } Y > 0$$

$$YA = \frac{TA}{TD} \cdot NRM \text{ for } Y < 0$$

The change-over between ramp up time and ramp down time takes place during a direction change or at the zero crossover of the transfer function.

The operating mode is predefined by means of control logic, depending on the logic states of the control inputs S, CF, CU, and CD.

The output variable can be limited by means of the inputs LU and LL. When the set limits are reached by Y, the binary outputs QU or QL are set to 1. The binary output QE becomes 1 when Y = X.

Ramp-up time and ramp-down time

The ramp-up time TU is the time in which the absolute value of the output variable increases by NRM.

The ramp-down time TD is the time in which the absolute value of the output variable decreases by NRM. Ramp up time and ramp down time can be selected differently.

The smaller TA/TU or TA/TD is, the smaller is the amplitude change on Y from one scan time to the next. TA is the scan time in which the block is processed.

The following priority sequence applies for the control inputs:

S before CF before CU and CD.

Function of control inputs:

S=1	Load setting value SV in integrator; do not integrate.
CF=1	Correct output Y to setpoint X with integration.
CU=1	Correct output Y in the direction LU with integration
CD=1	Correct output Y in the direction LL with integration

Operating modes and control of the ramp-function generator

The combination of commands at the control inputs and the possible operating modes can be found in the truth tables.

In normal ramp-up mode, LL <= 0 <= LU and LL< Yn < LU. However, other settings, explained below, are possible.

The following applies to the setting LL >= LU: The LU limit is dominant over the LL limit.

Behavior of the integrator at the limitation

If output Y comes up against one of the set limits LL or LU during the control process, the integrator value is retained. The output value Y is then kept constant until the integrator value leaves the limit due to changes in the input variables.

If the integrator is at the limit and the limit value is changed, the integrator behaves differently depending on the direction of the limit value change.

If the absolute value of a limit value is increased and it has been defined in the control logic that the ramp-function generator should run in the same direction, the integrator continues to integrate from the previously held value according to the set ramp up time, until the output once again comes up against the limit value.

If the absolute value of the limit value is reduced, the integrator integrates from the previously held value according to the set ramp down time, until the output again reaches the limit value.

TU and TD are limited internally: TU >= TA, TD >= TA

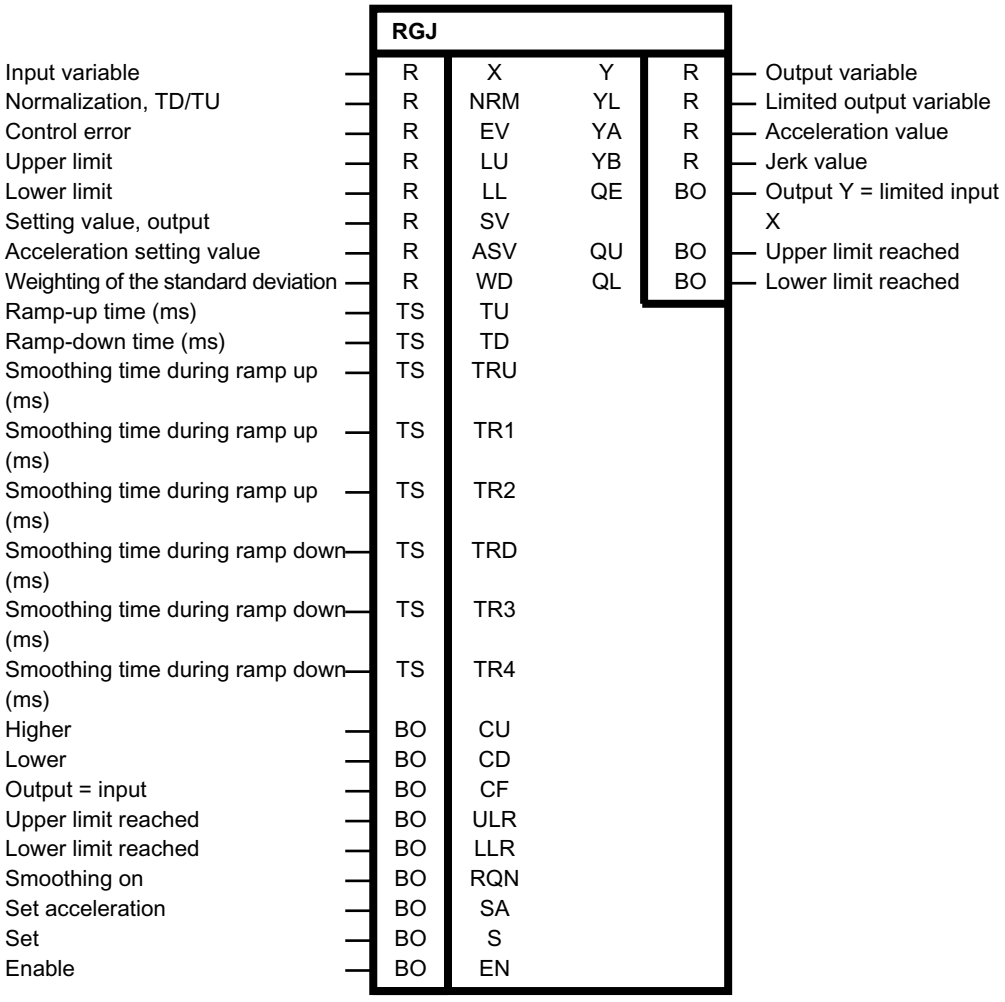
Ramp-function generator with jerk limiting

Symbol



Brief description

- Ramp-function generator with jerk limiting and correction
- Ramp-function generator functions
- Set output Y or acceleration YA
- Correct ramp-function generator output to setpoint X with integration and jerk limiting
- Integrating increase and decrease of ramp-function generator output
- Correction of the ramp-function generator according to the system deviation of a lower-level controller during limiting

Method of operation

The block limits the acceleration (change in velocity) and the jerk (change in acceleration) of setpoints.

The following algorithms apply:

$$Y_n = Y_{n-1} + YA_n$$

$$YA_n = YA_{n-1} + YB_n$$

Acceleration value YA and jerk YB are calculated separately for ramp up and ramp down. This requires configuration of the time values ramp up time TU and smoothing time during ramp up TRU as well as ramp down TD and smoothing time during ramp down TRD.

The following applies for the acceleration value YA outside of the smoothing time during ramp up:

$$YA = YA_{max} = \frac{TA}{TU} \cdot NRM \text{ for } Y > 0$$

$$YA = YA_{max} = -\frac{TA}{TU} \cdot NRM \text{ for } Y < 0$$

The following applies for the acceleration value YA outside the smoothing time during ramp-down:

$$YA = YA_{max} = -\frac{TA}{TD} \cdot NRM \text{ for } Y > 0$$

$$YA = YA_{max} = \frac{TA}{TD} \cdot NRM \text{ for } Y < 0$$

The following applies for the jerk value YB during the smoothing time during ramp up:

$$YB = \frac{TA \cdot YA_{max}}{TRU}$$

or

$$YB = \frac{TA \cdot YA_{max}}{TR1} \quad YB = \frac{TA \cdot YA_{max}}{TR2}$$

The following applies for the jerk value YB during the smoothing time during ramp down:

$$YB = \frac{TA \cdot YA_{max}}{TRD}$$

or

$$YB = \frac{TA \cdot YA_{max}}{TR3} \quad YB = \frac{TA \cdot YA_{max}}{TR4}$$

The operating mode is predefined by means of control logic, depending on the logic states of the binary variables EN, S, SA, CF, CU, and CD.

Input variable X and thus indirectly output variable Y are limited by means of the block inputs LU and LL. When the set limits are reached by Y, a message is issued to the binary outputs with QU = 1 or QL = 1.

Binary output QE becomes 1 when output variable Y equals the limited value of input variable X.

A ramp up process is subdivided into three phases:

Phase 1

When setpoint X increases, the maximum jerk YB (depending on TRU or TR1) is defined in the first part. Thus, the acceleration increases proportionally over time; in this smoothing phase, output Y rises quadratically over time.

Phase 2

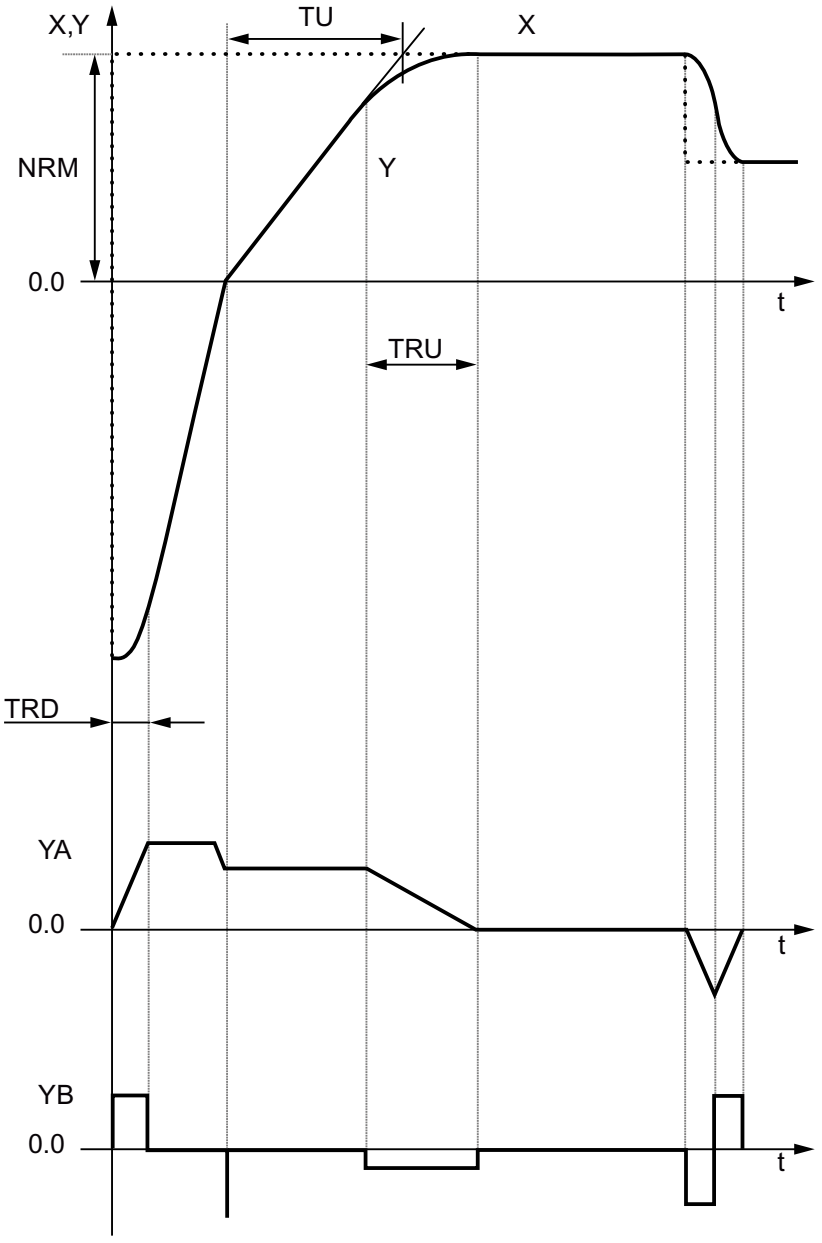
Once the maximum acceleration YA has been reached according to the defined ramp-up time TU, the acceleration is constant. Output variable Y rises proportionally over time.

Phase 3

In the third part, the acceleration is decreased proportionally over time. In this smoothing phase, output variable Y approaches input variable X on YB quadratically over time (depending on TRU or TR2).

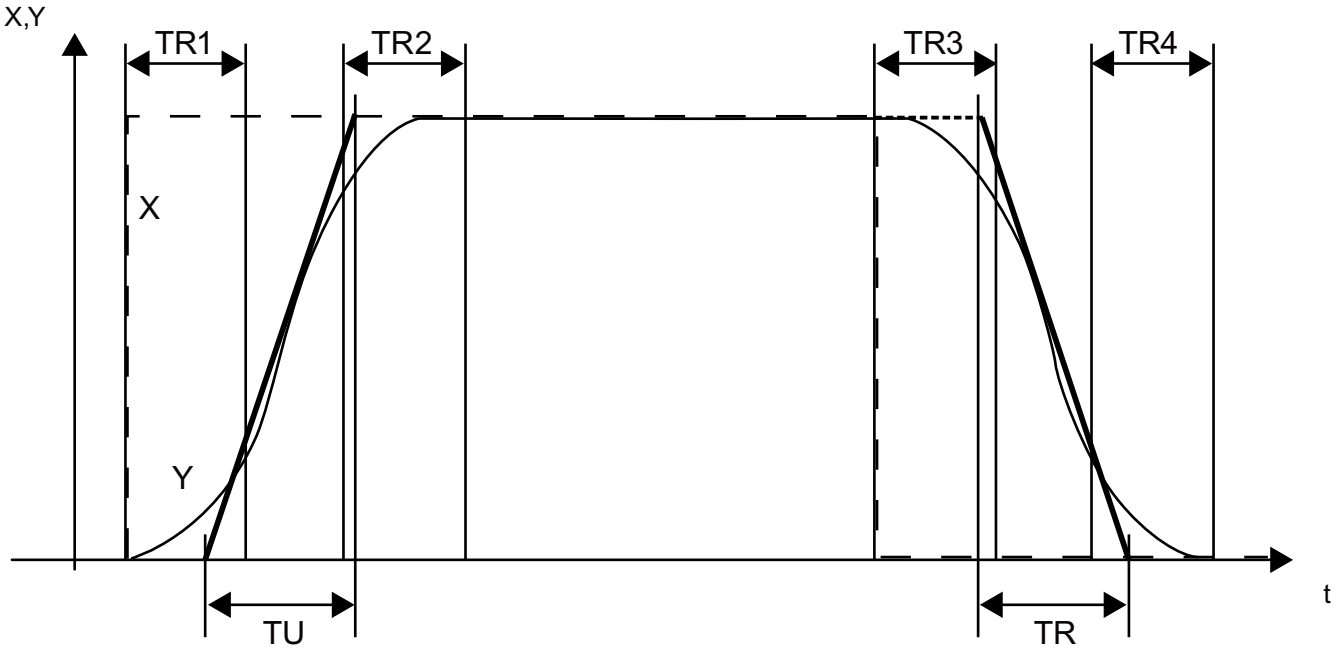
A ramp-down process proceeds analogously.

Transfer function



Ramp-up and ramp-down (not true to scale)

Rounding times if TRU = 00.0 ms and TRD = 0.0 ms:



Ramp-up and ramp-down (not true to scale)

Ramp-up time and ramp-down time

The ramp-up time TU is defined as the time in which the value of the output variable increases proportionally over time by the value NRM.

The ramp-down time TD is defined as the time in which the value of the output variable decreases proportionally over time by the value NRM.

Ramp up time and ramp down time can be selected differently.

Smoothing time during ramp up and ramp down

The smoothing time is defined as the time in which the output variable reaches the maximum acceleration value starting from a constant initial value. During this time, the jerk value is constant and not equal to zero (compare with phase 1).

The smoothing time is also defined as the time in which the output variable reaches a constant final value starting from its maximum acceleration value (compare with phase 3). The smoothing time is defined with TRU or TR1 and TR2 during a ramp-up process and with TRD or TR3 and TR4 during a ramp-down process.

Each time the setpoint changes direction, the system switches from ramp-up to ramp-down or from ramp-down to ramp-up with the associated smoothing processes, depending on the initial position. The same applies accordingly when the ramp-up or ramp-down time is changes during operation.

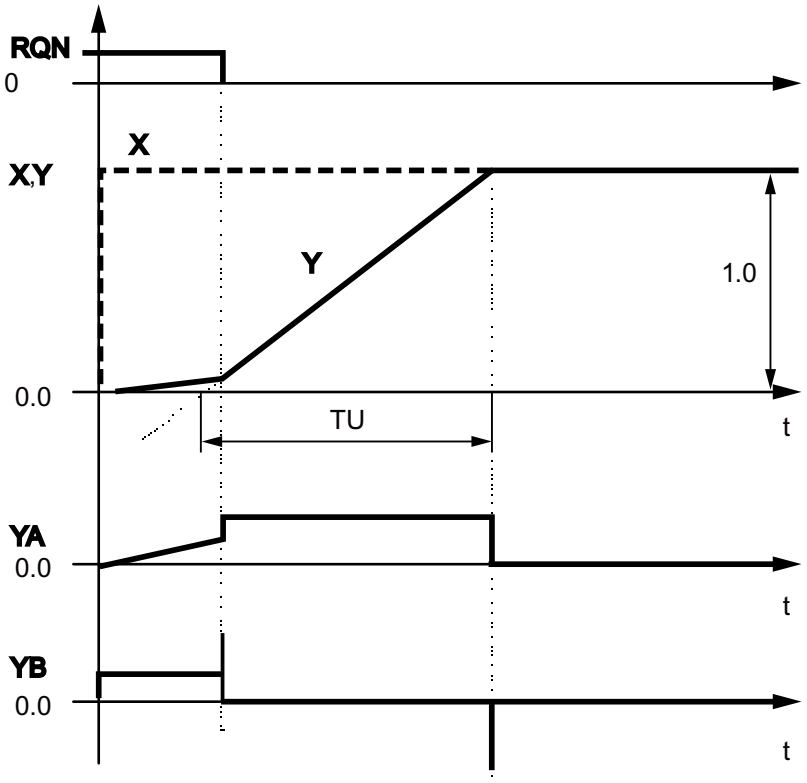
If a ramp-up follows a ramp-down whereby TRD and TD are small and TRU and TU are large, YA is reduced during the ramp-down to the extent that no overshooting occurs in the following ramp-up as long as the target value (X, LL, or LU) and the ramp-function generator times (TU, TD, TRU, TRD) do not change.

If the smoothing (RQN=0) and the correction (ULR=LLR=0) are switched off, then the RGJ block behaves the same as the RGE block.

Enabling smoothing (jerk limitation)

Smoothing is active during ramp up and ramp down when RQN=1.

Transfer function: Switching off smoothing during ramp up



Smoothing is off when RQN = 0. Ramp up/down takes place according to the ramp-up/ramp-down time specified in TU or TD.

When the jerk limiting is switched off during the smoothing time, the remaining ramp up/down also occurs with the ramp-up/ramp-down time specified in TU or TD.

"Smoothing off" mode

If you want to operate the block in this mode, proceed as follows:

- Set the connections TRU, TR1, TR2, TRD, TR3, and TR4 to "0" (all smoothing times are "0").
- Set the RQN connection to "1" ("Smoothing on" mode).

With these settings, the RGJ block behaves as described in the "Smoothing off" mode (RQN = 0).

Operating modes and control of the ramp-function generator

The control inputs are defined as follows:

EN=1	Enable ramp-function generator
S=1	Set output Y to setting value SV; do not integrate

SA=1	Set acceleration YA to setting value ASV; do not integrate
CF=1	Correct output Y to setpoint X with integration.
CU=1	Correct output Y in the direction LU with integration
CD=1	Correct output Y in the direction LL with integration

Correction of the ramp-function generator

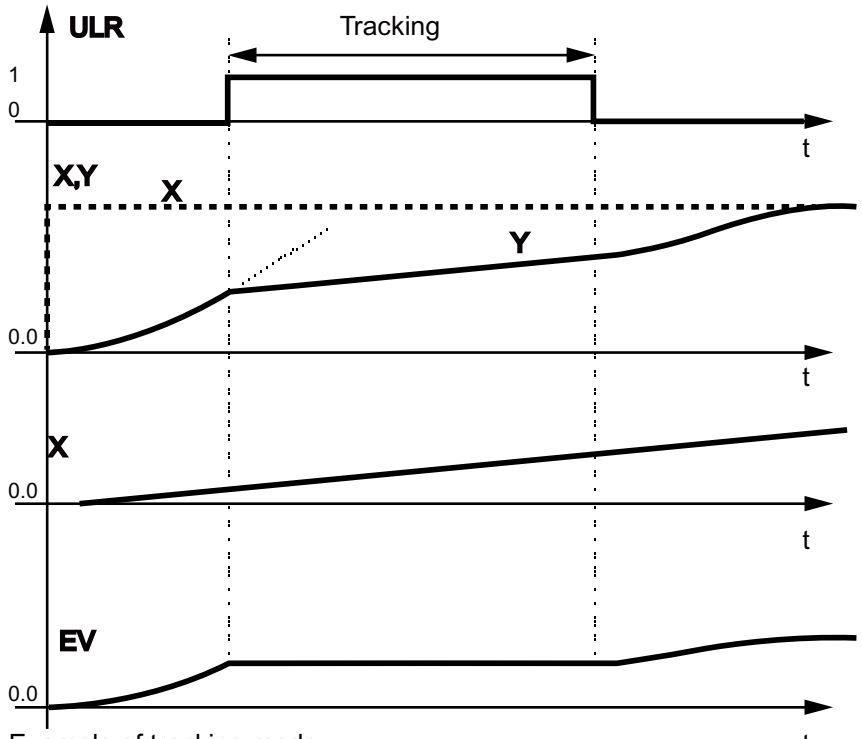
In general, output Y of the ramp-function generator is carried as a setpoint to a lower-level control loop (e.g. speed controller).

If this controller reaches the limit because of a change (e.g. during a ramp-up), the ramp-function generator may not increase the output in accordance to the ramp-up times. In this case, output Y is corrected using the system deviation EV and the weighting factor WD:

$Y_n = Y_{n-1}-EV_n+WD \cdot EV_k$

$_n$= scan interval n

$_k$= the time at which the controller first reaches the limit (0 -> 1 edge on ULR or LLR)



Example of tracking mode

In general, this correction can only be used for "classic control loops" (e.g. PI speed controllers). The controller limits must be set correctly (e.g. equal to the current limits).

Generally, WD is 1.01 to 1.1 (> 1.0!). Jerk limiting is not active during the correction.

The binary outputs of the controller ("Upper/lower limit reached") are returned to the binary inputs ULR or LLR. When the limit is reached, one of the two binary inputs ULR = 1 or LLR = 1 is set via the feedback on the RGJ block, and therefore the correction activated.

If the correction is not to be used, ULR and LLR must be set to 0.

8.1.9 Messages and parameters

8.1.9.1 Messages

All objects: DCC, DCC_DC

F51000 DCC: Logon of the run-time group with sampling time management rejected

Message value: -
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: IMMEDIATELY
Cause: The OA application "Drive Control Chart" (DCC) attempted to log on a sampling time that cannot be implemented with the sampling time management of the basic SINAMICS system. The logon was rejected.
Remedy: Try to assign this run-time group another fixed or free run-time group.
The assignment is set in STARTER in the context menu of the DCC chart via sampling times.
Then compile the chart and download it again into the drive unit.

F51001 DCC: No further hardware sampling times available

Message value: %1

Message class: General drive fault (19)

Drive object: All objects

Reaction: NONE

Acknowledge: IMMEDIATELY

Cause: The drive unit can no longer provide any additional hardware sampling times, whose sampling time deviates from the sampling times.already logged on.

Remedy: The fault can be immediately acknowledged, as the system run-time group 0 (corresponds to "Do not calculate") was assigned in p21000[x].

Fault value (r0949, interpret hexadecimal):

yyyyxxxx hex

yyyy: The upper 16 bits of the fault value specify the number of the drive object.

xxxx: The lower 16 bits specify the index of the run-time group in p21000.

Note:

In window "Set run-time groups" in the context menu of the chart, p21000[0] is the topmost entry and p21000[9] the lowest entry.

The current assignment of hardware sampling times can be read-out in r21008.

F51004 DCC: Sampling time of the free run-time group differs at download

Message value: %1

Message class: General drive fault (19)

Drive object: All objects

Reaction: NONE

Acknowledge: IMMEDIATELY

Cause: In the STARTER/SCOUT project that was downloaded, the hardware sampling time of a free run-time group (1 <= p21000[i] <= 256) was set to a value that was either too low or too high. The sampling time must be between 1 ms and the value (r21003 - r21002).

If the sampling time of the selected free run-time group is < 1 ms, the equivalent value of 1 ms is used.

If the value >= r21003, then the sampling time is set to the next higher or the same software sampling time >= r21003. In order to prevent the fault the calculated software sampling time can be set in the run-time group (1001 <= p21000[i] <= 1096).

The free run-time group involved is assigned as a minimum to one block.

If this fault still occurs during download after the selection in p21000[i] in the project has been corrected, please check which run-time group is involved on the basis of the fault value (r0949). Only one F51004 fault is signaled at a time, even if several run-time groups have been incorrectly parameterized in p21000[].

Fault value (r0949, decimal interpretation):

Number of the p21000 index of the run-time group where the sampling time was incorrectly set.

Number of the run-time group = fault value + 1

Note:

With SIMOTION D410, r21003 (unlike all the other Control Units) is automatically set the same as the PROFIBUS sampling time.

Remedy: Correctly set the sampling time of the run-time group or remove all of the blocks from the run-time group.

F51005 DCC: Sampling time of the fixed run-time group differs online

Message value: %1

Message class: General drive fault (19)

Drive object: All objects

Reaction: NONE

Acknowledge: IMMEDIATELY

Cause: Generally, the sampling times of the fixed run-time groups correspond to the sampling times of the associated system function (e.g. the sampling time of the fixed run-time group "BEFORE speed controller" generally corresponds to the sampling of the speed controller p0115[1]).
The sampling time of a system function online was set to a lower value (e.g. with p0112, p0115, p0799, p4099) than the smallest permissible sampling time that is allowed for the fixed run-time group belonging to this system function (1 ms). The sampling time is set to 1 ms. The fixed run-time group involved is assigned as a minimum to one block.
Fault value (r0949, decimal interpretation):
Number of the p21000 index of the run-time group where the sampling time was incorrectly set.
Number of the run-time group = fault value + 1

Remedy: Using parameter p0112 or p0115, increase the sampling time of the system function to the minimum permissible sampling time for the run-time groups of 1 ms or remove all of the blocks from the run-time group.

F51006 DCC: Sampling time of the fixed run-time group differs at download

Message value: %1

Message class: General drive fault (19)

Drive object: All objects

Reaction: NONE

Acknowledge: IMMEDIATELY

Cause: Generally, the sampling times of the fixed run-time groups correspond to the sampling times of the associated system function (e.g. the sampling time of the fixed run-time group "BEFORE speed controller" generally corresponds to the sampling of the speed controller p0115[1]).
During a download, the sampling time of a system function was set to a lower value (p0112, p0115) than the smallest permissible sampling time that is allowed for the fixed run-time group belonging to this system function (1 ms). The sampling time is set to the smallest possible value (r21002 on the drive object).
Fault value (r0949, decimal interpretation):
Number of the p21000 index of the run-time group where the sampling time was incorrectly set.
Number of the run-time group = fault value + 1

Remedy: Using parameter p0112 or p0115, increase the sampling time of the system function to the minimum permissible sampling time for the run-time groups of 1 ms or remove all of the blocks from the run-time group.

F51008 DCC: No NVRAM available

Message value: %1

Message class: General drive fault (19)

Drive object: All objects

Reaction: OFF2

Acknowledge: IMMEDIATELY

Cause: The DCC project contains at least one block that requires remanent memory from the basic SINAMICS system (e.g. SAV, SAV_BY, SAV_D, SAV_I). The request for remanent memory was rejected by the basic SINAMICS system.
Fault value (r0949, decimal interpretation):
0: There is no more free remanent memory available on the drive unit.
1: The EPROM data of the drive unit indicates that there is no remanent memory on the module.

Remedy: For fault value = 0:
- Deactivate other applications on the drive unit that use remanent memory.
- Do not use blocks that require remanent memory in your DCC charts.
For fault value = 1:
- For modules D425 or D435, use hardware version D or higher.
Note:
You can read out the hardware version using SCOUT in online mode under Target system --> Device diagnostics --> tab "General" in the lower window, 3rd column in the line of the CPU.

F51009 DCC: Project data and block library are incompatible

Message value: -

Message class: General drive fault (19)
Drive object: All objects
Reaction: OFF2
Acknowledge: IMMEDIATELY
Cause: The block library and the saved or downloaded project data are incompatible.
Remedy: Make sure that the block library and project data match.
- Update the block library in SINAMICS by downloading the technology package.
or
- Update the project data in the DCC Editor by importing the correct block library.

A51032 DCC: Internal measurement active

Message value: -
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: A Siemens internal measurement has been activated.
Remedy: Carry out a POWER ON (switch off/on) for the Control Unit involved.

F51033 Licensing DCC application not sufficient

Message value: -
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: IMMEDIATELY
Cause: There is a license error in a DCB block.
Remedy: -Obtain the necessary license.
-Later licensing is not possible online via p9920, 9921.

F51034 DCC: block runtimes are not measured

Message value: -
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: IMMEDIATELY
Cause: A block library created with DCB Studio contains blocks for which the runtime has not been measured. Contact the person that created the library.
Remedy:

F51035 DCC: DCC configuration error

Message value: -
Message class: General drive fault (19)
Drive object: All objects
Reaction: OFF2
Acknowledge: IMMEDIATELY
Cause: An error has occurred when powering up from a DCC configuration.

Remedy: - evaluate fault buffer (r0945).
- carry out a POWER ON for all components
(switch-off/switch-on)
- if required, check the data on the non-volatile memory (e.g. memory card).
- upgrade firmware to later version.
- contact the Hotline.

F51050 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51051 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51052 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)

Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51053 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51054 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51055 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects

Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51056 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51057 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51058 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)

Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

F51059 DCC: Fault initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: Infeed: OFF2 (NONE, OFF1)
Servo: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Vector: OFF2 (ENCODER, IASC/DCBRK, NONE, OFF1, OFF3, STOP2)
Chopper: OFF2 (NONE)
Hla: OFF2 (ENCODER, NONE, OFF1, OFF3, STOP2)
Acknowledge: IMMEDIATELY (POWER ON)
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Fault value (r0949, decimal interpretation):
The configured message value is displayed in r0949.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51060 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51061 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE

Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51062 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51063 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51064 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51065 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects

Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51066 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51067 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51068 DCC: alarm initiated by "Drive Control Chart"

Message value: %1
Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

A51069 DCC: alarm initiated by "Drive Control Chart"

Message value: %1

Message class: General drive fault (19)
Drive object: All objects
Reaction: NONE
Acknowledge: NONE
Cause: "Drive Control Chart" (DCC) has initiated this message via the block "Set Message" (STM) or via a block (SINAMICS DCB Extension) generated using SINAMICS DCB Studio.
Alarm value (r2124, interpret decimal):
The configured message value is displayed in r2124.
Remedy: This message was configured with "Drive Control Chart" (DCC).
The cause and remedy depend on the project and should be described in the corresponding project documentation.

8.1.9.2 Parameters

Version: 5200300

All objects: DCC, DCC_DC

p21000[0...9] Run-time group properties / RTG property

DCC

Can be changed: T	**Calculated:** -	**Access level:** 1
Data type: Integer16	**Dynamic index:** -	**Function diagram:** -
P-Group: -	**Unit group:** -	**Unit selection:** -
Not for motor type: -	**Scaling:** -	**Expert list:** 1
Min:	**Max:**	**Factory setting:**
0	4005	0

Description: Allocates properties to run-time groups 1 to 10.
This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.
The index x + 1 of p21000 corresponds to the number of the run-time group:
- p21000[0] is used to set the property of the run-time group 1
...
- p21000[9] is used to set the property of the run-time group 10

Value:
0: Do not calculate run-time group
1: T = 1 * r21002
2: T = 2 * r21002
3: T = 3 * r21002

Recommendation: On the drive objects of CU, TB30, TM15DI_DO, TM31, TM41, TM120, the sampling time for supplementary functions is preset to p0115[0] = 4 ms. If you wish to configure a DCC run-time group with a shorter sampling time on these drive objects, then you should first set the sampling time for supplementary functions p0115[0] on this drive object to the value of the shortest sampling time required.

Index: [0] = Run-time group 1
[1] = Run-time group 2
[2] = Run-time group 3
[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

For value = 4002, 4003, 4005 (IF2 run-time group):

On devices where IF2 does not exist (D4xx, CU310), when selecting the run-time groups that involve IF2, the corresponding run-time group for IF1 is automatically logged on.

Description: Allocates properties to run-time groups 1 to 10.

This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.

The index x + 1 of p21000 corresponds to the number of the run-time group:

- p21000[0] is used to set the property of the run-time group 1

...

- p21000[9] is used to set the property of the run-time group 10

Value:

0:	Do not calculate run-time group

Recommendation: On the drive objects of CU, TB30, TM15DI_DO, TM31, TM41, TM120, the sampling time for supplementary functions is preset to p0115[0] = 4 ms. If you wish to configure a DCC run-time group with a shorter sampling time on these drive objects, then you should first set the sampling time for supplementary functions p0115[0] on this drive object to the value of the shortest sampling time required.

Index: [0] = Run-time group 1
[1] = Run-time group 2
[2] = Run-time group 3
[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

p21000[0...9] Run-time group properties / RTG property

All objects	**Can be changed:** T	**Calculated:** -	**Access level:** 1
	Data type: Integer16	**Dynamic index:** -	**Function diagram:** -
	P-Group: -	**Unit group:** -	**Unit selection:** -
	Not for motor type: -	**Scaling:** -	**Expert list:** 1
	Min:	**Max:**	**Factory setting:**
	0	4005	0

Description: Allocates properties to run-time groups 1 to 10.

This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.

The index x + 1 of p21000 corresponds to the number of the run-time group:

- p21000[0] is used to set the property of the run-time group 1

...

- p21000[9] is used to set the property of the run-time group 10

Value:

[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

For value = 4002, 4003, 4005 (IF2 run-time group):

On devices where IF2 does not exist (D4xx, CU310), when selecting the run-time groups that involve IF2, the corresponding run-time group for IF1 is automatically logged on.

[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION
The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

For value = 4002, 4003, 4005 (IF2 run-time group):

On devices where IF2 does not exist (D4xx, CU310), when selecting the run-time groups that involve IF2, the corresponding run-time group for IF1 is automatically logged on.

Recommendation: On the drive objects of CU, TB30, TM15DI_DO, TM31, TM41, TM120, the sampling time for supplementary functions is preset to p0115[0] = 4 ms. If you wish to configure a DCC run-time group with a shorter sampling time on these drive objects, then you should first set the sampling time for supplementary functions p0115[0] on this drive object to the value of the shortest sampling time required.

Index: [0] = Run-time group 1
[1] = Run-time group 2
[2] = Run-time group 3
[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

For value = 4002, 4003, 4005 (IF2 run-time group):

On devices where IF2 does not exist (D4xx, CU310), when selecting the run-time groups that involve IF2, the corresponding run-time group for IF1 is automatically logged on.

Description: Allocates properties to run-time groups 1 to 10.

This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.

The index x + 1 of p21000 corresponds to the number of the run-time group:

- p21000[0] is used to set the property of the run-time group 1

...

- p21000[9] is used to set the property of the run-time group 10

Value:

0: Do not calculate run-time group

Recommendation: On the drive objects of CU, TB30, TM15DI_DO, TM31, TM41, TM120, the sampling time for supplementary functions is preset to p0115[0] = 4 ms. If you wish to configure a DCC run-time group with a shorter sampling time on these drive objects, then you should first set the sampling time for supplementary functions p0115[0] on this drive object to the value of the shortest sampling time required.

Index: [0] = Run-time group 1
[1] = Run-time group 2
[2] = Run-time group 3
[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

For value = 4002, 4003, 4005 (IF2 run-time group):

On devices where IF2 does not exist (D4xx, CU310), when selecting the run-time groups that involve IF2, the corresponding run-time group for IF1 is automatically logged on.

Description: Allocates properties to run-time groups 1 to 10.

This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.

The index x + 1 of p21000 corresponds to the number of the run-time group:

- p21000[0] is used to set the property of the run-time group 1

...

- p21000[9] is used to set the property of the run-time group 10

Value:

0:	Do not calculate run-time group

[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):
This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:
1 ms <= T_sample < r21003.
At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.
For value > 2000 (fixed run-time group):
The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.
Example:
"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

p21000[0...9] Run-time group properties / RTG property

Description: Allocates properties to run-time groups 1 to 10.
This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.
The index x + 1 of p21000 corresponds to the number of the run-time group:
- p21000[0] is used to set the property of the run-time group 1
...
- p21000[9] is used to set the property of the run-time group 10

Description: Allocates properties to run-time groups 1 to 10.
This property comprises the sampling time and, for p21000[x] >= 2000, the instant of the call within the sampling time.
The index x + 1 of p21000 corresponds to the number of the run-time group:
- p21000[0] is used to set the property of the run-time group 1
...
- p21000[9] is used to set the property of the run-time group 10

Value:
0: Do not calculate run-time group
1: T = 1 * r21002
2: T = 2 * r21002
3: T = 3 * r21002

Recommendation: On the drive objects of CU, TB30, TM15DI_DO, TM31, TM41, TM120, the sampling time for supplementary functions is preset to p0115[0] = 4 ms. If you wish to configure a DCC run-time group with a shorter sampling time on these drive objects, then you should first set the sampling time for supplementary functions p0115[0] on this drive object to the value of the shortest sampling time required.

Index: [0] = Run-time group 1
[1] = Run-time group 2
[2] = Run-time group 3
[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):

This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:

1 ms <= T_sample < r21003.

At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.

For value > 2000 (fixed run-time group):

The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.

Example:

"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

4004: Receive AFTER IF1 PROFIdrive flexible PZD

Recommendation: On the drive objects of CU, TB30, TM15DI_DO, TM31, TM41, TM120, the sampling time for supplementary functions is preset to p0115[0] = 4 ms. If you wish to configure a DCC run-time group with a shorter sampling time on these drive objects, then you should first set the sampling time for supplementary functions p0115[0] on this drive object to the value of the shortest sampling time required.

Index: [0] = Run-time group 1

[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Dependency: See also: r7903, r21008

⚠ CAUTION

The properties of the run-time groups must not be changed during operation as this could result in discontinuous signal transitions.

Note

For value = 1 ... 256 (free run-time group):
This selection value can only be selected online if the following applies for sampling time T_sample of this run-time group:
1 ms <= T_sample < r21003.
At download, a value that violates this condition is not rejected, but a permissible equivalent value is set automatically and fault F51004 is output.
For value > 2000 (fixed run-time group):
The fixed run-time groups p21000[x] >= 2000 log on with the sampling time of the associated basic system function, subject to a minimum sampling time of 1 ms. If, as a result of this limit, the actual sampling time deviates from the sampling time of the basic system function, then fault F51005 (during F51006 download) is output. In this case, another run-time group with a sampling time >= 1 ms should be selected. When selecting the fixed run-time groups, a check is not made as to whether the associated system block exists.
Example:
"BEFORE speed setpoint channel" means before function charts 3010, 3020, 3030, 3040, etc. are calculated, if the setpoint channel is activated. If, e.g. for SERVO, a setpoint channel has not been configured (p0108.8 = 0), the calculation is made before function chart 3095.

r21001[0...9] **Run-time group sampling time / RTG sampling time**

Not for motor type: -	**Scaling:** -	**Expert list:** 1
Min:	**Max:**	**Factory setting:**
- [ms]	- [ms]	- [ms]

Description: Displays the basis sampling time effective at this drive object for p21000 = 1002 to 1096 as factor.
Sampling time T = (p21000 - 1000) * r21003

Dependency: Ensure that the basis sampling time on the SIMOTION D410 for the software time slices is always the same as the configured PROFIBUS/PROFINET clock cycle.

r21005[0...9] **Computing time load of the run-time group / RTG load**

All objects

Can be changed: -	**Calculated:** -	**Access level:** 3
Data type: FloatingPoint32	**Dynamic index:** -	**Function diagram:** -
P-Group: -	**Unit group:** -	**Unit selection:** -
Not for motor type: -	**Scaling:** -	**Expert list:** 1
Min:	**Max:**	**Factory setting:**
- [%]	- [%]	- [%]

Description: Share of the computing time load with which the DCC run-time group contributes to the utilization of the sampling time during which it is called.

Index: [0] = Run-time group 1
[1] = Run-time group 2
[2] = Run-time group 3
[3] = Run-time group 4
[4] = Run-time group 5
[5] = Run-time group 6
[6] = Run-time group 7
[7] = Run-time group 8
[8] = Run-time group 9
[9] = Run-time group 10

Note
The computing time load can only be displayed for the run-time groups which are logged on (p21000[x] > 0). The value for the computing time load is calculated in the drive unit based on the project loaded plus DCC chart. Therefore, the values r21005[x] are not available in the offline mode of the SCOUT/STARTER.

In r21005 the computing time load is displayed, with which the DCC runtime group utilizes the sampling time in which it is called. The runtime groups "Receive AFTER IF1 PROFIdrive PZD" (p21000 = 4000), "Send BEFORE IF1 PROFIdrive PZD" (p21000 = 4001), "Receive BEFORE IF2 PZD" (p21000 = 4002) and "Send BEFORE IF2 PZD" (p21000 = 4003) are called in the isochronous mode and in the non-isochronous mode, in different sampling times.
In the non-isochronous mode, these are IF1 / IF2 PZD sampling time (p2048 for p21000 = 4000 or 4001, p8848 for p21000 = 4002 or 4003). In the isochronous mode, this is the current controller sampling time (p115[0]) which is periodically called with the isochronous bus cycle time. The computing time load displayed in r21005 is always calculated for the (more unfavorable) case of isochronous operation. This is why this value does not (always) act to the full amount on the computing time load of the complete system.

r21008[0...31] Hardware sampling times available / HW t_samp

All objects

Can be changed: -	**Calculated:** -	**Access level:** 3
Data type: FloatingPoint32	**Dynamic index:** -	**Function diagram:** -
P-Group: -	**Unit group:** -	**Unit selection:** -
Not for motor type: -	**Scaling:** -	**Expert list:** 1
Min:	**Max:**	**Factory setting:**
- [ms]	- [ms]	- [ms]

Description: Displays the assignment of the available hardware sampling times of the drive unit.
The designated sampling times are those created as a multiple of the hardware basis sampling time (r21002) and which are always < r21003.

[29] = Hardware 30
[30] = Hardware 31
[31] = Hardware 32

Dependency:
See also: r7903, p21000
See also: F51001

NOTICE
For internal purposes, the drive unit always requires several free hardware sampling times. Therefore the current number of free hardware sampling times can be read out in r7903. If r7903=0, no additional sampling time different from r21008[0...31] may be provided from the Control Unit. When selecting in this state, if a run-time group with a sampling time < r21003 (p21000 <= 255) is selected in p21000, only run-time groups whose sampling time is already provided in r21008[0...31] may be selected.

Note
A sampling time that is provided can be simultaneously used by system functions, several FBLOCK run-time groups and several DCC run-time groups.
The sampling time of run-time groups that have been assigned to the PROFIBUS run-time groups (p21000 = 4000 ... 4004) is not displayed in r21008. For this sampling time, one of the internally and permanently assigned hardware sampling times is used.
If the value of r21008[x] != 0 (not equal to 0), then the sampling time is specified in ms.
If the value of r21008[x] = 0, this sampling time can still be freely assigned. It should be noted that the basic system requires several freely assignable hardware sampling times for internal functions. The number of hardware sampling times that can still be freely assigned can be read out in r7903.
If the value r21008[x] = 99999.00000, this hardware sampling time is not supported.

p21031 Computing time measurement, blocks / Comp_ti_meas block

All objects

Can be changed: T, U	**Calculated:** -	**Access level:** 4
Data type: Unsigned32	**Dynamic index:** -	**Function diagram:** -
P-Group: -	**Unit group:** -	**Unit selection:** -
Not for motor type: -	**Scaling:** -	**Expert list:** 1
Min:	**Max:**	**Factory setting:**
0	4294967295	0

Description: Sets the number of the run-time group to be measured 1 ... 10.
This starts measurement of the entire run-time group and the individual blocks.
At the end of the measurement the parameter is reset automatically to 0.

⚠ DANGER

During this measurement, the run-time group n is logged off and on again twice for the purpose of time slice management. Since this procedure runs in a background task, the run-time group is not calculated for an indefinite period on two occasions. This can lead to freezing or jumps in signal values. Logical signals can assume unexpected values. This measurement must therefore never be carried out when an application is running!

Note
The run-time group to be measured has to be logged on.
Only one measurement can take place at a time.
The results are displayed in parameters r21035, r21036, r21037.

Description: In the block run-time measurements, the block run-times are measured. R21039 indicates whether the measurement is the first or a subsequent call.

If the block type occurs only once in the run-time group, only the measured value for the first run will be supplied.

The parameter is designed for the measurement of 50 block instances

	-	-	-

Description:
Library ID of the measured block (block run-time measurement via parameter p21031).
Measurements with blocks from different libraries can thereby be carried out in one run-time group.
The blocks are measured in the same sequence as they have been programmed in the execution sequence.
The parameter is designed for the measurement of 50 block instances

8.1.10 Appendix

8.1.10.1 Data types

The table lists the data types relevant for the DCBLIB.

Table 8-4 Overview: Data types of the block connections

Abbreviation	Data width	Data type according to IEC 61131-3	Postfix for DCB identifier	PIN designator ○ Input ○ Output	Can be connected with data type	Description
BO/B	1 bit	BOOL	_B*	I, I1, I2,.... Q, Q1, Q2;....	BOOL	Bool
BY	8 bit	BYTE	_BY	IS QS	BY, SINT, USINT	Bit string
W	16 bit	WORD	_W		WORD, INT, UINT	Bit string
DW	32 bit	DWORD	_DW		DWORD, DINT, UDINT	Bit string
SI	8 bit	SINT	_SI	X, X1, X2, ... Y, Y1, Y2, ...	SINT, USINT, BY	Signed Short Integer
I	16 bit	INT	_I		INT, UINT, WORD	Signed Integer
DI/D	32 bit	DINT	_D		DINT, UDINT, DWORD	Signed Double Integer
US	8 bit	USINT	_US		SINT, USINT, BY	Unsigned Short Integer
UI	16 bit	UINT	_UI		INT, UINT, WORD	Unsigned Integer
UD	32 bit	UDINT	_UD		DINT, UDINT, DWORD	Unsigned Double Integer
R	32 bit	REAL	_R*		REAL, SDTIME	Floating Point Single Precision according to IEEE 754
LR	64 bit	LREAL	_LR		LREAL	Floating Point Double Precision according to IEEE 754
TS	32 bit	(SDTIME)	-	-	SDTIME, REAL	The SDTIME data type is derived from the REAL data type, 1.0 corresponds to 1.0 ms. Negative values are not defined.
AID	32 bit	-	-	-	DINT, UDINT, DWORD	Alarm ID
*	-	Block-defined	-	-	See DCC editor description	See DCC editor description

The table lists the fields for DPV1 parameter job and response.

Table 8-5 Overview: Fields in DPV1 parameter job and response

Field	Data type	Values	Remark
Job reference	Unsigned8	0x01 to 0xFF	
	Unique identification of the job/response pair for the master. The master changes the job reference with each new job. The slave mirrors the job reference in its response.		
Job identifier	Unsigned8	0x010x02	Read job Write job
	Specifies the type of job. In the case of a write job, the changes are made in the volatile memory (RAM). A save operation is needed in order to transfer the modified data to the non-volatile memory (p0971, p0977).		
Response ID	Unsigned8	0x010x020x810x82	Read job (+) write job (+) read job (-) write job (-)
	Mirrors the job identifier and specifies whether job execution was positive or negative. Negative means: The job could not be carried out totally or partly. For each subresponse, the error values are transferred instead of the values.		
Drive object number	Unsigned8	0x01 to 0x27	Number 1 ... 39 Limited by DPV1 telegram length
	Defines the number of adjoining areas for the parameter address and/or parameter value for multi-parameter jobs. The number of parameters = 1 for single jobs.		
Attribute	Unsigned8	0x100x200x30	Value Description Text (not implemented)
	Type of parameter element accessed		
Number of elements	Unsigned8	0x000x01 ... 0x75	Special function Number 1 ... 117 Limited by DPV1 telegram length
	Number of array elements accessed		
Parameter number	Unsigned16	0x0001 to 0xFFFF	No. 1 to 65535
	Addresses the parameter accessed		
Subindex	Unsigned16	0x0000 to 0xFFFF	No. 0 to 65535
	Addresses the first array element of the parameter accessed		

Field	Data type	Values	Remark
Format	Unsigned8	0x020x030x040x050x060x070x08 Other values 0x400x410x420x430x44	Integer8 data type Integer16 data type Integer32 data type Unsigned8 data type Unsigned16 data type Unsigned32 data type Floating-point data type See PROFIdrive PROFILE v3.1 Zero (without values as a positive subresponse of a write request) Byte Word Double Word Error
	The format and number specify the adjoining space containing values in the telegram. For write access, it is preferable to specify data types according to the PROFIdrive profile. Bytes, words, and double words are also possible as a substitute.		
Number of values	Unsigned8	0x00 to 0xEA	Number 0 ... 234 Limited by DPV1 telegram length
	Specifies the number of subsequent values.		
Error values	Unsigned16	0x0000 to 0x00FF	Meaning of the error values, see Appendix A.2
	The error values in the event of a negative response. If the values make up an odd number of bytes, a zero byte is attached. This ensures the integrity of the word structure of the telegram.		
Values	Unsigned16	0x0000 to 0x00FF	
	The values of the parameter for read or write access. If the values make up an odd number of bytes, a zero byte is attached. This ensures the integrity of the word structure of the telegram.		

8.1.10.2 Error values in PROFIdrive parameter responses, data types

Table 8-6 Error values in DPV1 parameter responses

Error value	Meaning	Remark	Additional info
0x00	Illegal parameter number.	Access to a parameter that does not exist.	-
0x01	Parameter value cannot be changed.	Modification access to a parameter value that cannot be changed.	Subindex
0x02	Lower or upper value limit exceeded.	Modification access with value outside value limits.	Subindex
0x03	Invalid subindex.	Access to a subindex that does not exist.	Subindex
0x04	No array.	Access with subindex to an unindexed parameter.	-
0x05	Wrong data type.	Modification access with a value that does not match the data type of the parameter.	-

Error value	Meaning	Remark	Additional info
0x06	Illegal set operation (only reset permitted).	Modification access with a value not equal to 0 in a case where this is not permitted.	Subindex
0x07	Description element cannot be changed.	Modification access to a description element that cannot be changed.	Subindex
0x09	No description data available	Access to a description that does not exist (the parameter value exists).	-
0x0B	No parameter change rights.	Modification access with no parameter change rights.	-
0x0F	No text array available.	Access to a text array that does not exist (the parameter value exists).	-
0x11	Request cannot be executed due to operating status.	Access is temporarily not possible for unspecified reasons.	-
0x14	Illegal value.	Modification access with a value that is within the limits but is illegal for other permanent reasons (parameter with defined individual values).	Subindex
0x15	Response too long.	The length of the present response exceeds the maximum transfer length.	-
0x16	Illegal parameter address.	Illegal or unsupported value for attribute, number of elements, parameter number, subindex or a combination of these.	-
0x17	Illegal format.	Write request: illegal or unsupported parameter data format.	-
0x18	Number of values inconsistent.	Write request: a mismatch exists between the number of values in the parameter data and the number of elements in the parameter address.	-
0x19	Drive object does not exist.	You have attempted to access a drive object that does not exist.	-
0x20	The text element of the parameter cannot be changed.	-	-
0x21	BMP service is not supported; invalid request ID.	-	-
0x22	Multi-parameter accessing is not supported.	-	-
0x65	Parameter presently deactivated.	Access to a parameter that, although available, is currently inactive (e.g. n control set and access to parameter from V/f control).	-
0x6B	Parameter %s [%s]: No write access for the enabled controller.	-	-
0x6C	Parameter %s [%s]: Unit unknown.	-	-
0x6D	Parameter %s [%s]: Write access only in the commissioning state, encoder (p0010 = 4).	-	-
0x6E	Parameter %s [%s]: Write access only in the commissioning state, motor (p0010 = 3).	-	-
0x6F	Parameter %s [%s]: Write access only in the commissioning state, power unit (p0010 = 2).	-	-
0x70	Parameter %s [%s]: Write access only in the quick commissioning mode (p0010 = 1).	-	-

Error value	Meaning	Remark	Additional info
0x71	Parameter %s [%s]: Write access only in the ready mode (p0010 = 0).	-	-
0x72	Parameter %s [%s]: Write access only in the commissioning state, parameter reset (p0010 = 30).	-	-
0x73	Parameter %s [%s]: Write access only in the commissioning state, Safety (p0010 = 95).	-	-
0x74	Parameter %s [%s]: Write access only in the commissioning state, tech. application/units (p0010 = 5).	-	-
0x75	Parameter %s [%s]: Write access only in the commissioning state (p0010 not equal to 0).	-	-
0x76	Parameter %s [%s]: Write access only in the commissioning state, download (p0010 = 29).	-	-
0x77	Parameter %s [%s] must not be written during download.	-	-
0x78	Parameter %s [%s]: Write access only in the commissioning state, drive configuration (device: p0009 = 3).	-	-
0x79	Parameter %s [%s]: Write access only in the commissioning state, define drive type (device: p0009 = 2).	-	-
0x7A	Parameter %s [%s]: Write access only in the commissioning state, data set basis configuration (device: p0009 = 4).	-	-
0x7B	Parameter %s [%s]: Write access only in the commissioning state, device configuration (device: p0009 = 1).	-	-
0x7C	Parameter %s [%s]: Write access only in the commissioning state, device download (device: p0009 = 29).	-	-
0x7D	Parameter %s [%s]: Write access only in the commissioning state, device parameter reset (device: p0009 = 30).	-	-
0x7E	Parameter %s [%s]: Write access only in the commissioning state, device ready (device: p0009 = 0).	-	-
0x7F	Parameter %s [%s]: Write access only in the commissioning state, device (device: p0009 not equal to 0).	-	-
0x81	Parameter %s [%s] must not be written during download.	-	-
0x82	Transfer of the control authority (master) is inhibited by BI: p0806.	-	-
0x83	Parameter %s [%s]: Requested BICO interconnection not possible.	BICO output does not supply float values. The BICO input, however, requires a float value.	-
0x84	Parameter %s [%s]: Parameter change inhibited (refer to p0300, p0400, p0922).	-	-
0x85	Parameter %s [%s]: Access method not defined.	-	-

Error value	Meaning	Remark	Additional info
0xC8	Below currently valid limit.	Modification request for a value that, although within "absolute" limits, is below the currently valid lower limit.	-
0xC9	Above currently valid limit.	Modification request for a value that, although within "absolute" limits, is above the currently valid lower limit (e.g. governed by the current converter rating).	-
0xCC	Write access not permitted.	Write access is not permitted because an access code is not available.	-
0xFF	Successful read/write operation.	The value has been successfully read or written.	-

8.1.10.3 Block overview

The version as of which they are available must be specified for new blocks.

Block	Description	SIMOTION	SINAMICS
ACOS	Arc cosine function	x	
ADD	Adder (REAL type)	x	x
ADD_D	Adder (double integer type)	x	x
ADD_I	Adder (integer type)	x	x
ADD_M	Modulo adder for addition in correct axis cycle	x	x
AND	Logic AND operation (BOOL type)	x	x
AND_W	Logic AND operation (WORD type)	x	
ASIN	Arc sine function	x	
ATAN	Arc tangent function	x	
AVA	Absolute value generator, with sign evaluation	x	x
AVA_D	Absolute value generator (double integer)	x	x
BF	Flashing function (BOOL type)	x	x
BF_W	Flashing function for status word (WORD type)	x	
BSW	Binary change-over switch (BOOL type)	x	x
BY_B	Status byte to eight binary variables converter	x	
BY_W	Status byte to status word converter	x	x
B_BY	Eight binary variables to status byte converter	x	
B_DW	32 binary variables to status double word converter	x	x
B_W	16 binary variables to status word converter	x	x
CNM	Controllable numeric memory (REAL type)	x	x
CNM_D	Controllable numeric memory (DOUBLE INTEGER type)	x	x
CNM_I	Controllable numeric memory (INTEGER type)	x	x
COS	Cosine function	x	V4.4
CTD	Time difference determination from an internal time stamp	x	
CTR	Counter (BOOL type)	x	x
DCA	Diameter calculator	x	x
DEL	Dead zone element	x	x

Block	Description	SIMOTION	SINAMICS
DEZ	Dead zone element	x	x
DFR	Reset-dominant D-type flip-flop (BOOL type)	x	x
DFR_W	Reset-dominant D-type flip-flop (WORD type)	x	
DIF	Derivative action element	x	x
DIV	Divider (REAL type)	x	x
DIV_D	Divider (double integer type)	x	x
DIV_I	Divider (integer type)	x	x
DLB	Delay element (REAL type)	x	x
DT1	Smoothing element	x	x
DW_B	Status double word to 32 binary variables converter	x	x
DW_R	Acceptance of bit string as REAL value	x	x
DW_W	Status double word to status word converter	x	x
DX8	Demultiplexer, eight outputs, cascadable (REAL type)	x	x
DX8_D	Demultiplexer, eight outputs, cascadable (DOUBLE INTEGER type)	x	x
DX8_I	Demultiplexer, eight outputs, cascadable (INTEGER type)	x	x
D_I	DOUBLE INTEGER to INTEGER converter	x	x
D_R	DOUBLE INTEGER to REAL converter	x	x
D_SI	DOUBLE INTEGER to SHORT INTEGER converter	x	
D_UI	DOUBLE INTEGER to UNSIGNED INTEGER converter	x	x
D_US	DOUBLE INTEGER to UNSIGNED SHORT INTEGER converter	x	x
ETE	Edge evaluator (BOOL type)	x	x
GTS	Reads out a time stamp	x	
INCO	Axial winder moment of inertia	x	x
INT	Integrator	x	x
I_D	INTEGER to DOUBLE INTEGER converter	x	x
I_R	INTEGER to REAL converter	x	x
I_SI	INTEGER to SHORT INTEGER converter	x	
I_UD	INTEGER to UNSIGNED DOUBLE INTEGER converter	x	x
I_US	INTEGER to UNSIGNED SHORT INTEGER converter	x	x
LIM	Limiter (REAL type)	x	x
LIM_D	Limiter (DOUBLE INTEGER type)	x	x
LR_R	LONG REAL to REAL converter	x	
LVM	Double-sided limit monitor with hysteresis (BOOL type)	x	x
MAS	Maximum evaluator	x	x
MFP	Pulse generator (BOOL type)	x	x
MIS	Minimum evaluator	x	x
MUL	Multiplier (REAL type)	x	x
MUL_D	Multiplier (double integer type)	x	x
MUL_I	Multiplier (integer type)	x	x
MUX8	Multiplexer, cascadable (REAL type)	x	x
MUX8_D	Multiplexer, cascadable (DOUBLE-INTEGER type)	x	x
MUX8_I	Multiplexer, cascadable (INTEGER type)	x	x
MVS	Sliding-type mean value generator	x	x

Block	Description	SIMOTION	SINAMICS
N2_R	16-bit fixed-point format (N2) to REAL converter	x	x
N4_R	32-bit fixed-point format (N4) to REAL converter	x	x
NAND	Logic AND operation (BOOL type)	x	x
NCM	Numeric comparator (REAL type)	x	x
NCM_D	Numeric comparator (DOUBLE INTEGER type)	x	x
NCM_I	Numeric comparator (INTEGER type)	x	x
NOP1	Dummy block (REAL type)	x	x
NOP1_B	Dummy block (BOOL type)	x	x
NOP1_D	Dummy block (DOUBLE INTEGER type)	x	x
NOP1_I	Dummy block (INT type)	x	x
NOP8	Dummy block (REAL type)	x	x
NOP8_B	Dummy block (BOOL type)	x	x
NOP8_D	Dummy block (DOUBLE INTEGER type)	x	x
NOP8_I	Dummy block (INTEGER type)	x	x
NOR	Logic OR operation (BOOL type)	x	x
NOT	Inverter (BOOL type)	x	x
NOT_W	Status word inverter (WORD type)	x	
NSW	Numeric change-over switch (REAL type)	x	x
NSW_D	Numeric change-over switch (DOUBLE INTEGER type)	x	x
NSW_I	Numeric change-over switch (INTEGER type)	x	x
OCA	Software cam controller	x	x
OR	Logic OR operation (BOOL type)	x	x
OR_W	Logic OR operation (WORD type)	x	
PC	P controller	x	x
PCL	Pulse shortener (BOOL type)	x	x
PDE	Switch-on delay (BOOL type)	x	x
PDF	Switch-off delay (BOOL type)	x	x
PIC	PI controller	x	x
PLI20	Polyline, 20 breakpoints	x	x
PST	Pulse stretching block (BOOL type)	x	x
PT1	Delay element	x	x
RAA	Reset all messages	V4.3	
RDA	Reads out a message	V4.3	
RDAA	Reads out all messages	V4.3	
RDP	Reads drive parameters (REAL type)		x
RDP_D	Reads drive parameters (DOUBLE INTEGER type)		x
RDP_I	Reads drive parameters (INTEGER type)		x
RDP_UD	Reads drive parameters (UNSIGNED DOUBLE INTEGER type)		x
RDP_UI	Reads drive parameters (UNSIGNED INTEGER type)		x
RDP_US	Reads drive parameters (UNSIGNED SHORT INTEGER type)		x
RGE	Ramp-function generator	x	x
RGJ	Ramp-function generator with jerk limiting	x	x
RMDP	Reads drive parameters from the controller	V4.2	

Block	Description	SIMOTION	SINAMICS
RSR	RS flip-flop, R-dominant (BOOL type)	x	x
RSS	RS flip-flop, S-dominant (BOOL type)	x	x
R_D	REAL to DOUBLE INTEGER converter	x	x
R_DW	Acceptance of bit string as DWORD	x	x
R_I	REAL to INTEGER converter	x	x
R_LR	REAL to LONG REAL converter	x	
R_N2	REAL to 16-bit fixed-point format (N2) converter	x	x
R_N4	REAL to 32-bit fixed-point format (N4) converter	x	x
R_SI	REAL to SHORT INTEGER converter	x	
R_UD	REAL to UNSIGNED DOUBLE INTEGER converter	x	x
R_UI	REAL to UNSIGNED INTEGER converter	x	x
R_US	REAL to UNSIGNED SHORT INTEGER converter	x	x
SAH	Sample & hold (REAL type)		x
SAH_B	Sample & hold (BOOL type)		x
SAH_BY	Sample & hold (BYTE type)		x
SAH_D	Sample & hold (DOUBLE INTEGER type)		x
SAH_I	Sample & hold (INTEGER type)		x
SAV	Value buffering (REAL type)	x	x
SAV_BY	Value buffering (BYTE type)	x	x
SAV_D	Value buffering (DOUBLE INTEGER type)	x	x
SAV_I	Value buffering (INTEGER type)	x	x
SH	Shift block (WORD type)	x	
SH_DW	Shift block (DWORD type)	x	x
SII	Inverter	x	x
SIN	Sine function	x	V4.4
SI_D	SHORT INTEGER to DOUBLE INTEGER converter	x	
SI_I	SHORT INTEGER to INTEGER converter	x	
SI_R	SHORT INTEGER to REAL converter	x	
SI_UD	SHORT INTEGER to UNSIGNED DOUBLE INTEGER converter	x	
SI_UI	SHORT INTEGER to UNSIGNED INTEGER converter	x	
SQR	Square-root extractor	x	
SRA	Triggers/resets a message	V4.3	
STM	Fault/alarm trigger		x
SUB	Subtractor (REAL type)	x	x
SUB_D	Subtractor (DOUBLE INTEGER type)	x	x
SUB_I	Subtractor (INTEGER type)	x	x
TAN	Tangent	x	
TRK	Tracking/memory element (REAL type)	x	x
TRK_D	Tracking/memory element (DOUBLE INTEGER type)	x	x
TTCU	Winding harshness characteristic	x	x
UD_I	UNSIGNED DOUBLE INTEGER to INTEGER converter	x	x
UD_R	UNSIGNED DOUBLE INTEGER to REAL converter	x	x
UD_SI	UNSIGNED DOUBLE INTEGER to SHORT INTEGER converter	x	

Block	Description	SIMOTION	SINAMICS
UI_D	UNSIGNED INTEGER to DOUBLE INTEGER converter	x	x
UI_R	UNSIGNED INTEGER to REAL converter	x	x
UI_SI	UNSIGNED INTEGER to SHORT INTEGER converter	x	
US_D	UNSIGNED SHORT INTEGER to DOUBLE INTEGER converter	x	x
US_I	UNSIGNED SHORT INTEGER to INTEGER converter	x	x
US_R	UNSIGNED SHORT INTEGER to REAL converter	x	x
WBG	Wobble generator	x	x
WMDP	Writes drive parameters from the controller	V4.2	
WRP	Writes drive parameters (REAL type)		x
WRP_D	Writes drive parameters (DOUBLE INTEGER type)		x
WRP_I	Writes drive parameters (INTEGER type)		x
WRP_UD	Writes drive parameters (UNSIGNED DOUBLE INTEGER type)		x
WRP_UI	Writes drive parameters (UNSIGNED INTEGER type)		x
WRP_US	Writes drive parameters (UNSIGNED SHORT INTEGER type)		x
W_B	Status word to 16 binary variables converter	x	x
W_BY	Status word to status byte converter	x	x
W_DW	Status word to status double word converter	x	x
XOR	Logic exclusive OR operation (BOOL type)	x	x
XOR_W	Logic exclusive OR operation (WORD type)	x	

8.2 Supplement to SIMODRIVE POSMO A Positioning Motor

Introduction

Contents of the function manual

This **document** is part of the **SIMOTION Programming - References documentation package**.

This documentation serves as a supplement to the documentation on SIMODRIVE POSMO A in the *Distributed Positioning Motor on PROFIBUS DP* user manual.

This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

This manual describes how you can use function blocks to control and assign parameters for a POSMO A drive from a SIMOTION program.

This manual describes differences in handling that arise when controlling and assigning parameters for a POSMO A drive from the SIMOTION system as compared to the SIMATIC system.

Function block

The function blocks for communication between the SIMOTION system and the distributed SIMODRIVE POSMO A positioning motor are part of the program library of the "SIMOTION SCOUT" engineering system.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

http://www.siemens.com/motioncontrol/docu

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

http://www.siemens.com/mdm

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

8.2.1 Fundamental safety instructions

8.2.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.2.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.2.2 Description

8.2.2.1 General

Overview

SIMODRIVE POSMO A is an intelligent distributed positioning drive on the PROFIBUS DP field bus (DP standard slave).

The power unit and all of the motion control are located in the motor.

All of the signals and data for commissioning and operating the drive are transferred via the PROFIBUS DP.

The operating energy is supplied by a 24 VDC connection (for a 75 W motor) or a 48 VDC connection (for a 300 W motor).

The integrated positioning functionality is suitable for a variety of simple single-axis applications, such as adjusting endstops and formats.

Note

Hardware and software requirements

The following requirements apply for the functionalities described in this manual:

- Hardware release POSMO A 75 W: As of O
- Software release POSMO A 75 W: As of V3.0
- Hardware release POSMO A 300 W: As of G
- Software release POSMO A 300 W: As of V3.0

POSMO A positioning motors with different hardware and software requirements can be controlled with function blocks integrated in SIMOTION SCOUT V4.1. The functionality is restricted by the hardware/software release of the POSMO A positioning motor used.

Requirement

The following software versions are required for the standard functions described in this documentation:

- SIMOTION SCOUT V4.1 or higher
- SIMOTION Kernel V4.1 or higher
- SIMOTION technology packages V4.1 or higher

Communication

The PROFIBUS DP field bus allows rapid cyclical data exchange between the DP slave (POSMO A) and the higher-level DP master (SIMOTION hardware platform, such as SIMOTION C2xx).

Further information

Note

For more information, refer to the "Product brief" section of the *Distributed Positioning Motor on PROFIBUS DP* user manual.

This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Installation and connection

For a description of how to install and connect a SIMODRIVE POSMO A and points you must be aware of when doing so, refer to the "Installation and connection" section of the *Distributed Positioning Motor on PROFIBUS DP* user manual.

On the SIMOTION device (hardware platform), connect SIMODRIVE POSMO A to one of the PROFIBUS DP interfaces.

The following figure shows how to connect a SIMODRIVE POSMO A drive to a SIMOTION hardware platform (such as SIMOTION C2xx).

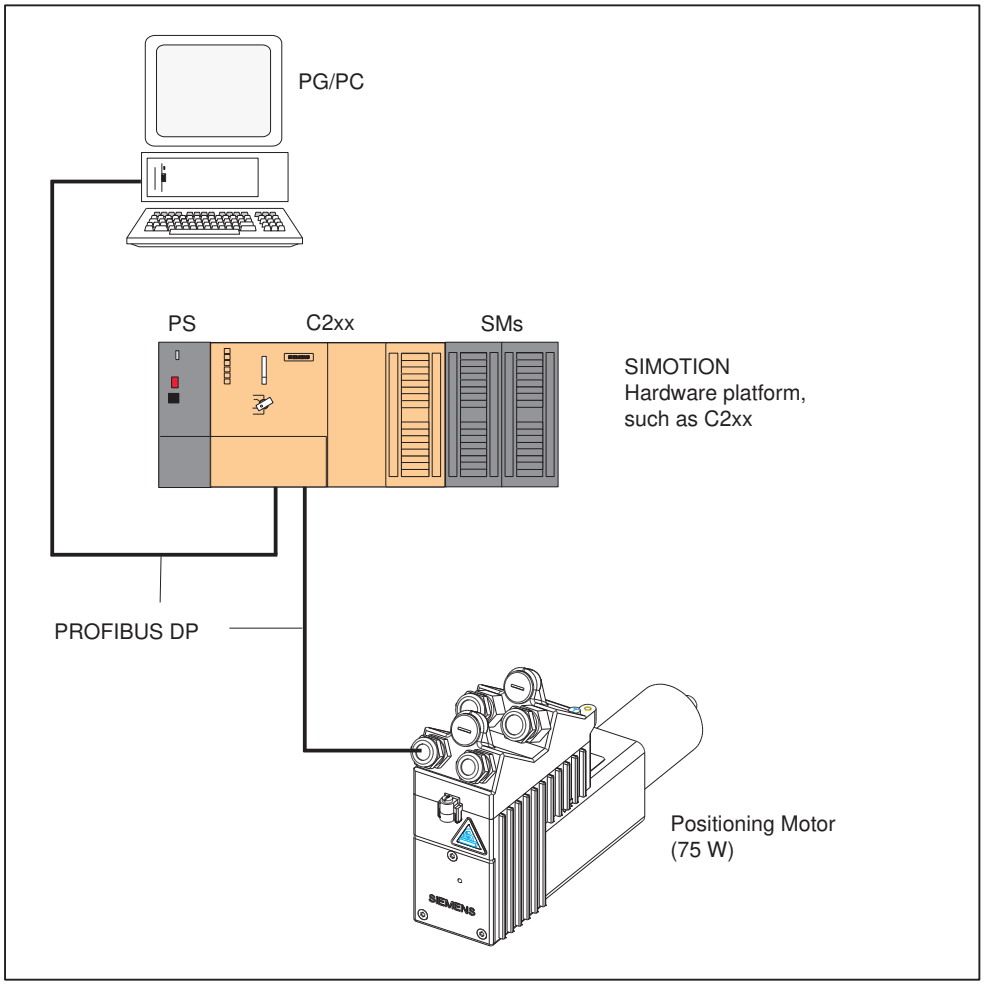

Figure 8-2 Connection of SIMODRIVE POSMO A to the SIMOTION C2xx hardware platform

8.2.2.2 Installation and startup

Overview

You must perform the following steps to commission the SIMODRIVE POSMO A and control it from the SIMOTION system:

1. Mount and wire the SIMODRIVE POSMO A positioning motor.
2. Set the PROFIBUS DP node address on the connection cover of the SIMODRIVE POSMO A.
3. Switch on the terminating resistor at the first and last bus node.

Note

For steps 1 to 3, refer to *Section "Installation and Connection"* of the *Distributed Positioning Motor on PROFIBUS DP* user manual.

4. You can use any of the following to commission the SIMODRIVE POSMO A:
   - C1 master "SIMODRIVE POSMO A PROFIBUS MASTER"
   - Commissioning tool "SimoCom A"

     Note

     Refer to the *Distributed Positioning Motor on PROFIBUS DP* user manual, *Section "Commissioning of DP Master"*.

   - "Drive ES" tool. This tool includes "SimoCom A"

     Note

     Refer to the *Drive ES Basic* function description.

5. Insert the SIMODRIVE POSMO A into the SIMOTION project (refer to Section Inserting a SIMODRIVE POSMO A positioning motor into a SIMOTION project (Page 6047)).
6. Control the SIMODRIVE POSMO A from the SIMOTION system using function blocks, see Section Function blocks (Page 6049).

Note

Refer to the *Distributed Positioning Motor on PROFIBUS DP* user manual for more information on the following topics:

- Axis commissioning
- Communication via PROFIBUS DP
- Description of functions
- Error handling and diagnostics
- Assembly and service

8.2.2.3 Inserting a SIMODRIVE POSMO A positioning motor into a SIMOTION project

Requirement

The following requirements must be met:

1. You have created a project in SIMOTION SCOUT and have inserted a rack with a SIMOTION hardware platform in the hardware configuration.
2. You have configured a PROFIBUS subnet.

Note

For information on creating a project and configuring a PROFIBUS subnet, refer to the online help for SIMOTION SCOUT.

Inserting SIMODRIVE POSMO A

To integrate the SIMODRIVE POSMO A into the PROFIBUS subnet of your project, proceed as follows:

1. In SIMOTION SCOUT, open the **User Projects** dialog box with the **Project > Open** menu command. In this dialog box, select your project and confirm your choice with **OK**.
2. Open **HW Config** (by double-clicking the SIMOTION device in the project navigator of SIMOTION SCOUT).
3. In the **HW Config** window, open the **hardware catalog** with the **View > Catalog** menu command.
4. In the hardware catalog, open the **PROFIBUS DP** folder and the **SIMODRIVE** subfolder and select **SIMODRIVE POSMO A**.
5. Use a drag-and-drop operation to move the SIMODRIVE POSMO A onto the PROFIBUS subnet of your project.
   The **Properties - PROFIBUS Interface SIMODRIVE POSMO A** dialog box is displayed. In this dialog box, you select the address you set in the connection cover of POSMO A (see *Section "Installation and Connection" of the Distributed Positioning Motor on PROFIBUS DP* user manual) and confirm with **OK**.
   The SIMODRIVE POSMO A positioning motor you have selected is inserted into the project.
6. Input and output addresses of the POSMO A.
   When you insert the POSMO A into your SIMOTION project, the input and output addresses are assigned default values. You can see these values when you select the inserted POSMO A. You can read the input and output addresses in the lower part of the **HW Config** window. You must create these addresses as I/O variables in the symbol browser before calling the function blocks; see Section Creating I/O Variables (Page 6048).

8.2.2.4 Integrating the function blocks in the user project

Creating the instance of the FBs in the user project

The function blocks are part of the program library of the SIMOTION SCOUT engineering system. For working with the blocks, an instance has to be created in the user project for each function block used and if using the **_POSMOA_rwAllParameter** function block, a variable of type **Struct_POSMOA_params**.

Example:

```
VAR_GLOBAL
...
 myPosmoAControl        : _POSMOA_control;         // FB for controlling of POSMO A
 myPosmoArwParameter    : _POSMOA_rwParameter;     // FB for handling single parameter
 myPosmoArwAllParameter : _POSMOA_rwAllParameter;  // FB for handling parameterset
 myAllParaPosmoA        : Struct_POSMOA_params;    // Variable for structure of all
                                                   // parameters POSMO A
...
END_VAR
```

Call (LAD representation)

The LAD representation of the individual function blocks can be found in the respective function block descriptions.

Example of an application

The application example is contained on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

8.2.2.5 Creating I/O Variables

Overview

Communication between the SIMOTION hardware platform and the SIMODRIVE POSMO A takes place through direct access to the I/O. I/O variables are used to address the direct read/write access to the I/O.

You can freely assign the names of I/O variables in SIMOTION SCOUT. You must define the I/O variables as ARRAY [0..7] and [0..3] of BYTE. You assign the address settings in the hardware configuration to these I/O variables.

The names of the I/O inputs must be transferred to the function blocks as call parameters. The prepared data for the I/O outputs are provided by the function block as in/out parameters. The

in/out parameters must be be supplied with variables of type ARRAY [0..7] of BYTE and [0..3] of BYTE. Once the block has been called, these variables must be assigned to the I/O variables for the I/O outputs; see call example in Section Calling function blocks (Page 6071).

Note

The variable for supplying the in/out parameters must not be created as a temporary variable (VAR_TEMP or local variable of a function).

The following example shows how to assign the module addresses to the I/O variables in SIMOTION SCOUT.

	Name	I/O address	Read only	Data type	Field length
1	⊞ mypkwin	PIB 256		Array	8
2	⊞ mypzdin	PIB 264		Array	4
3	⊞ mypkwout	PQW 256	☐	Array	8
4	⊞ mypzdout	PQW 264	☐	Array	4

Figure 8-3 Address assignment in SIMOTION SCOUT

Each input and output address has a range of 8 bytes (which corresponds to the parameter identifier value (PKW) range of POSMO A) and a range of 4 bytes (which corresponds to the process data (PZD) range of POSMO A).

Note

For additional information, refer to:

- *SIMOTION SCOUT* online help
- Programming Manual of the corresponding programming language, e.g.:
  - *SIMOTION ST, Structured Text* Programming Manual
  - *SIMOTION MCC, Motion Control Chart Programming Manual*
  - *SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram Programming Manual*

These documents are shipped with SIMOTION SCOUT in electronic form!

8.2.3 Function blocks

8.2.3.1 Overview of function blocks

This section contains a description of all of the function blocks (FBs) and the data structure you need for communication between a SIMOTION hardware platform and the SIMODRIVE POSMO A.

The function blocks form the software interface between the SIMOTION system and the SIMODRIVE POSMO A positioning motor.

These function blocks make it easier to control and assign parameters for a SIMODRIVE POSMO A positioning motor from the SIMOTION program.

For example, you can assign parameters for a POSMO A without being familiar with PROFIBUS parameter formats and request specifiers.

The function blocks must be called repeatedly (in cycles) from the user program.

The following function blocks are available:

- Function block _POSMOA_control (Page 6050)
- Function block _POSMOA_nControl (Page 6057) (V4.1 and higher):
- Function block _POSMOA_rwParameter (Page 6062)
- Function block _POSMOA_rwAllParameter (Page 6065)

Note

For the complete control and communication of the SIMODRIVE POSMO A from the SIMOTION program, an instance must be created for each **_POSMOA_rwParameter** and **_POSMOA_rwAllParameter** function block and, depending on the parameterized operating mode (speed or position control mode), an instance of the **_POSMOA_control** or **_POSMOA_nControl** function block.

Note

If the SIMODRIVE POSMO A is disconnected and then reconnected to the power system, any MDI traversing block data (see the table titled "Parameters of the _POSMOA_control function block") that had been transferred previously must be transferred to the POSMO A again.

8.2.3.2 Function block _POSMOA_control

Task

You can control the connected SIMODRIVE POSMO A with the **_POSMOA_control** function block.

The functions are as follows:

- Initialize
  Sets the drive in "ready to operate" mode.
  Requirements:
  - A drive fault has not been signaled (**driveError** = FALSE)
  - Fault acknowledgement is not active (**resetError** = FALSE)
- Referencing
  Sets the home position for the drive.
- Tippen
  The drive travels at a controlled speed in a plus or minus direction.
- Program execution
  Starts, stops, or aborts a single block addressed by **blockNumber** or a block within the program.

- MDI
  The drive travels at the assigned speed and acceleration to an assigned position.
  The MDI parameters are transferred in block 3.
  The MDI block can be started with **blockNumber** = 3 and **start** = TRUE.
- Fault acknowledgement
  Acknowledges a fault in the drive.

  Note

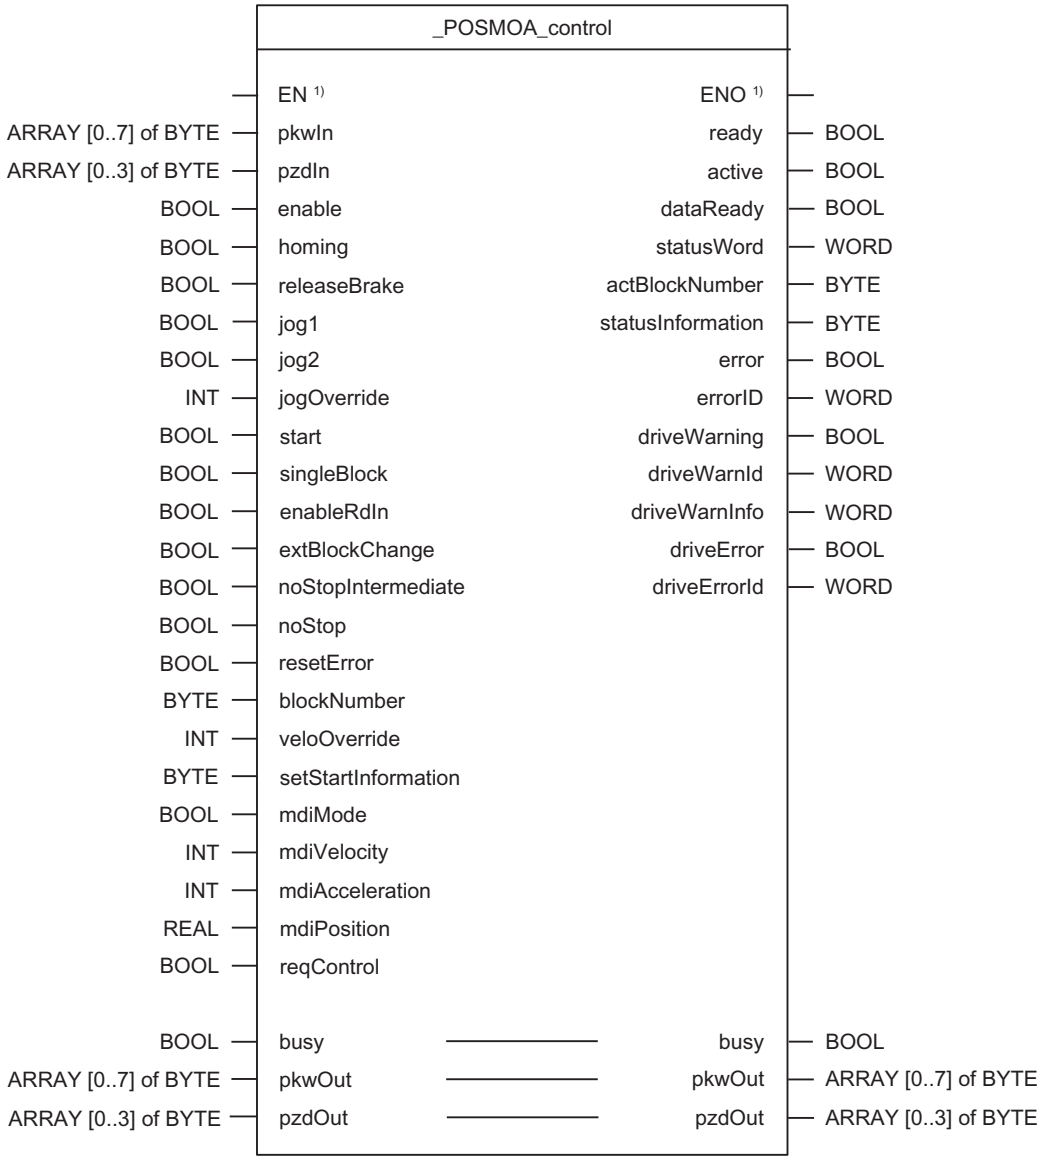
  A fault must be acknowledged before the drive can move. This requires that parameter **enable** = TRUE.

- Automatic single-block operation/automatic control

Checkback signals are as follows:

- Current traversing block
- Data Set Ready
- Warning and fault information
- Complete status (status word and checkback signal byte)
- Data transfer status

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Note

The SIMOTION identifiers have changed as of V4.0.

You can find a comparison of SIMOTION and SIMATIC names in the Appendix SIMOTION and SIMATIC names (Page 6081).

The **busy** parameter must **not** be overwritten by the user. It is supplied and checked by the function block, and must be supplied with a global variable created by the user only when the respective function block is called. This parameter coordinates the individual function blocks for the POSMO A. This ensures that no more than one function block can access a POSMO A at the same time.

Table 8-7 Parameters of the _POSMOA_control function block

Name	P type [1]	Data type	Default	Meaning
pkwIn	IN	ARRAY [0..7] of BYTE	8(16#00)	Transfer I/O inputs of POSMO A to FB
pzdIn	IN	ARRAY [0..3] of BYTE	4(16#00)	Transfer I/O inputs of POSMO A to FB
enable	IN	BOOL	FALSE	Sets drive to ready for operation The drive is now ready for operation provided there are no faults.
homing	IN	BOOL	FALSE	Sets the home position This signal must be present for at least 50 ms.
releaseBrake [4]	IN	BOOL	FALSE	= TRUE: Release holding brake = FALSE: Brake sequence control effective
jog1	IN	BOOL	FALSE	Selection of jog 1 If jog 1 and 2 are set simultaneously, a warning is issued and the drive does not move.
jog2	IN	BOOL	FALSE	Selection of jog 2 If jog 1 and 2 are set simultaneously, a warning is issued and the drive does not move.
jogOverride [3]	IN	INT	20	Speed override of jogging (0 to 100%) The override can also be changed during travel.
veloOverride [3]	IN	INT	20	Velocity override (0 to 100%) This override can also be changed during travel.
start	IN	BOOL	FALSE	= edge FALSE → TRUE: The traversing block specified in **blockNumber** is started. Once a block has been selected in **blockNumber**, the **start** parameter cannot be set until the next block call.
singleBlock[4]	IN	BOOL	FALSE	= TRUE: Automatic single block. Each block has to be re-started. = FALSE: AUTOMATIC mode
enableRdIn[4]	IN	BOOL	TRUE	= TRUE: Read-in enable. Next block is enabled for execution. = FALSE: Read-in disable

Name	P type [1]	Data type	Default	Meaning
extBlockChange [4]	IN	BOOL	FALSE	= Edge FALSE → TRUE: The active block is interrupted and the next block is selected. = FALSE: No external block change
noStopIntermediate	IN	BOOL	FALSE	= TRUE: No intermediate stop or block in intermediate stop is resumed = FALSE: Intermediate stop Interruption of current travel request**start** is not accepted
noStop	IN	BOOL	FALSE	= TRUE: No stop = FALSE: Stop Abort of current travel request If **start** parameter is set at the same time, **start** is not accepted.
blockNumber	IN	BYTE	16#00	Traversing block numbers 3 to 27 Single block or program **blockNumber** = 3 → MDI operation
resetError	IN	BOOL	FALSE	Acknowledges fault 1. Remedy cause of fault. 2. FALSE → TRUE edge 3. Parameter must remain set to TRUE until **driveError** = FALSE.
setStartInformation	IN	BYTE	16#00	Start byte Bit combination transmitted to the drive as an additional start requirement. [2]
mdiMode [3]	IN	BOOL	FALSE	= TRUE: MDI relative The value in the **mdiPosition** parameter is evaluated relative to the current position = FALSE: MDI absolute The value in the **mdiPosition** parameter is evaluated in absolute terms relative to the drive zero position set by homing.
mdiVelocity [3]	IN	INT	0	Velocity of MDI travel (0 to 100%)
mdiAcceleration [3]	IN	INT	0	Acceleration of MDI travel (0 to 100%)
mdiPosition [3]	IN	REAL	0	Target position of MDI travel Value range: $-2 \cdot 10^5$ to $2 \cdot 10^5$
reqControl [4]	IN	BOOL	FALSE	Control requested by the open-loop control p701 = 1: Message frame substitution active = TRUE: PROFIBUS data are taken over by the POSMO A = FALSE: Data from the PROFIBUS are frozen; the data last received are used p701 = 0: Message frame substitution inactive. Behavior as for POSMO A before software version V3.0
pkwOut	IN/OUT	ARRAY [0..7] of BYTE	-	Prepared FB data for I/O outputs of the POSMO A
pzdOut	IN/OUT	ARRAY [0..3] of BYTE	-	Prepared FB data for I/O outputs of the POSMO A
busy	IN/OUT	BOOL	-	Coordination of the FBs
ready	OUT	BOOL	FALSE	Drive ready for operation Logic operation: Status word bits 2 to 0 [2]

Name	P type [1]	Data type	Default	Meaning
active	OUT	BOOL	FALSE	= TRUE: Axis in motion
dataReady [4]	OUT	BOOL	FALSE	Several cycles are required for the transfer , for example, of **mdiPosition** and **jogOverride** = TRUE: Data transfer completed (e.g. **mdiPosition**, **jogOverride**,...) = FALSE: Data transfer in progress (ramp-up time) or data transfer not yet started
statusWord	OUT	WORD	16#0000	Read out of status word [2]
actBlockNumber	OUT	BYTE	16#00	Readout of current block number
statusInformation	OUT	BYTE	16#00	Checkback signal byte Bit combination as additional status signal. [2]
driveWarning	OUT	BOOL	FALSE	A drive warning is pending (refer to parameter **driveWarnId**).
driveWarnId	OUT	WORD	16#0000	Reason for the warning Bit format Value corresponds to parameter 953 (warnings) [2]
driveWarnInfo [4]	OUT	WORD	16#0000	Warnings or supplementary information, corresponds to p954 of the POSMO A
driveError	OUT	BOOL	FALSE	A drive error is pending (refer to the **driveErrorId** parameter)
driveErrorId	OUT	WORD	16#0000	Reason for the error Bit format Value corresponds to parameter 947 (errors) [2]
error	OUT	BOOL	FALSE	= TRUE: Request completed with error (refer to the **errorID** parameter)
errorID	OUT	WORD	16#0000	Number of the parameter assignment error signaled by the drive (parameter identifier value (PKW) range) [2]

[1] Parameter types: IN = input parameter, OUT = output parameter, IN/OUT = in/out parameter

[2] See *Distributed Positioning Motor on PROFIBUS DP* user manual

[3] This parameter is only transferred when the value of the parameter changes.

[4] As of SIMOTION V4.1, this parameter is part of the **_POSMOA_control** FB and can only be operated with POSMO A as of software version V3.0.

Message frame substitution (POSMO A as of software version V3.0)

For specific applications it is necessary that under no circumstances the drive comes undesirably to a standstill or the drive state can be configured to "freeze" to run-down the master (SIMOTION device).

The "Message frame substitution" function can be activated with the **reqControl** input parameter using software version V3.0 or higher of the POSMO A, with parameter **p701** = **TRUE** set.

The process data sent by the SIMOTION device are taken over by the POSMO A with **reqControl** = **TRUE**. When the transition from **TRUE** to **FALSE** occurs on the **reqControl** input parameter, the

POSMO A uses the process data received most recently (control word, block selection and start byte). If parameter **P701** = **FALSE**, the status of the **reqControl** input parameter is not evaluated.

Note

The "Message frame substitution" function takes immediate effect when p701 = 1.

Make sure that it is possible to shut down the drive at any time using an EMERGENCY STOP.

For additional information, refer to the SIMODRIVE POSMO A user manual, *Distributed Positioning Motor on PROFIBUS DP*.

Task integration (call)

The **_POSMOA_control** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in synchronous tasks (e.g. **IPOSynchronousTask**) is not recommended for runtime reasons.

Note

The functionality of the **_POSMOA_control** FB has been expanded with V4.1. To enable you to use the newly implemented functions, you must add the new input parameters when calling the **_POSMOA_control** FB.

If you want to work with the previous functions (< V4.1), you can leave out the new input parameters with a detailed notation when calling the FB.

Error messages, faults and warnings

The **TRUE** value at the **error** output parameter indicates a parameterization error. The **errorID** output parameter provides more detailed information on the parameterization error that has occurred or has been signaled by POSMO A. Parameterization errors do not need to be acknowledged. Changed parameters (e.g. ramp-up time) can be transferred again.

Faults on the POSMO A are signaled in the **driveError** output parameter with the value **TRUE**. The reason for the fault can be read out in the **driveErrorId** output parameter (value corresponds to P947). Drive faults have to be acknowledged and must be reset in the **resetError** input parameter with the rising edge!

Warnings pending from the POSMO A and the associated information are output in the **driveWarning**, **driveWarnId** (value corresponds to P953) and **driveWarnInfo** (value corresponds to P954) output parameters.

8.2.3.3 Function block _POSMOA_nControl

Task

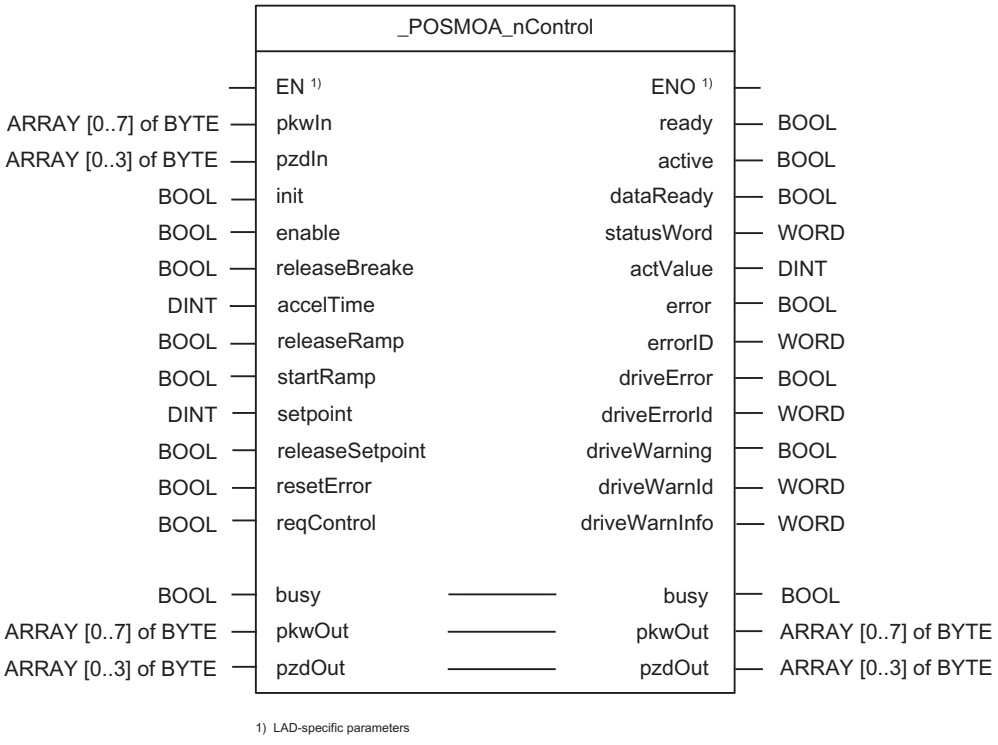
You can control the connected SIMODRIVE POSMO A in speed-controlled mode with the **_POSMOA_nControl** function block.

Note

The **_POSMOA_nControl** function block is contained in SIMOTION SCOUT as of V4.1.

The technology objects (TOs) cannot be used to operate the POSMO A via the speed setpoint interface.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Note

The **busy** parameter must **not** be overwritten by the user. It is supplied and checked by the function block, and must be supplied with a global variable created by the user only when the respective function block is called. This parameter coordinates the individual function blocks for the POSMO A. This ensures that no more than one function block can access a POSMO A at the same time.

Table 8-8 Parameters of the _POSMOA_nControl function block

Name	P type [1)]	Data type	Default	Meaning
pkwIn	IN	ARRAY[0..7] of BYTE	8(16#00)	Transfer I/O inputs of POSMO A to **_POSMOA_nControl** FB
pzdIn	IN	ARRAY[0..3] of BYTE	4(16#00)	Transfer I/O inputs of POSMO A to FB
init	IN	BOOL	FALSE	= TRUE: Sets the drive to "Ready to start" STW = 0x040E
enable	IN	BOOL	FALSE	= TRUE: Sets the drive to "Ready for operation" The drive is now ready for operation (provided there are no errors).
releaseBrake	IN	BOOL	FALSE	= TRUE: Release holding brake = FALSE: Brake sequence control effective
accelTime	IN	DINT	0	Ramp-up/ramp-down time [ms] During this time, the setpoint is adjusted in speed-controlled mode as follows: • Ramp-up: From zero to the maximum permissible actual speed • Ramp-down: From the maximum permissible actual speed to zero
releaseRamp	IN	BOOL	FALSE	= TRUE: Release ramp-function generator output
startRamp	IN	BOOL	FALSE	= Edge FALSE → TRUE: Start ramp-function generator
setpoint	IN	INT	0	Speed setpoint
releaseSetpoint	IN	BOOL	FALSE	Setpoint release **=** TRUE: Setpoint released
resetError	IN	BOOL	FALSE	Acknowledge error 1. Remedy cause of error 2. FALSE → TRUE edge 3. Parameter must remain set to TRUE until **driveError** = FALSE.
reqControl	IN	BOOL	FALSE	Control requested by the open-loop control p701 = 1: Message frame substitution active = TRUE: PROFIBUS data are taken over by the POSMO A = FALSE: Data from the PROFIBUS are frozen; the most recent data received are used p701 = 0: Message frame substitution inactive. Behavior as with POSMO A before software version V3.0
busy	IN/OUT	BOOL	-	Coordination of the function blocks

Name	P type [1]	Data type	Default	Meaning
pkwOut	IN/OUT	ARRAY[0..7] of BYTE	-	Prepared FB data for I/O outputs of the POSMO A (parameter identifier value interface)
pzdOut	IN/OUT	ARRAY[0..3] of BYTE	-	Prepared FB data for I/O outputs of the POSMO A (process data interface)
ready	OUT	BOOL	FALSE	Drive ready for operation, AND operation: Status word bit 2, bit 1, bit 0
active	OUT	BOOL	FALSE	= TRUE: Drive traveling (n > 0)
dataReady	OUT	BOOL	FALSE	Several cycles are required for transferring the ramp-up time, for example. Completion of the data transfer is indicated by a rising edge. = TRUE: Data transfer finished, data have been transferred = FALSE: Data transfer in progress (e.g. ramp-up time)
statusWord	OUT	WORD	16#0000	Display of status word
actValue	OUT	DINT	0	Actual speed
error	OUT	BOOL	FALSE	= TRUE: Request completed with error (refer to the **errorID** parameter)
errorID	OUT	WORD	16#0000	Number of the parameter assignment error signaled by the drive (parameter identifier value (PKW) range) [2]
driveError	OUT	BOOL	FALSE	Drive error is pending
driveErrorId	OUT	WORD	16#0000	Reason for the error Bit format Value corresponds to parameter 947 (errors) [2]
driveWarning	OUT	BOOL	FALSE	A drive warning is pending (refer to parameter **driveWarnId**).
driveWarnId	OUT	WORD	16#0000	Reason for the warning Bit format Value corresponds to parameter 953 (warnings) [2]
driveWarnInfo	OUT	WORD	16#0000	Supplementary information for warnings (for POSMO A, firmware version 1.4 and higher) Bit format The value corresponds to P954, (supplementary information for warnings)

[1] Parameter types: IN = input parameter, OUT = output parameter, IN/OUT = in/out parameter

[2] See *Distributed Positioning Motor on PROFIBUS DP* user manual

Function description

The POSMO A is set to the "ready to start" state (control word 0x040E) with the **TRUE** level on the **init** input parameter. The "ready to start" state is displayed in the output parameter **statusWord**, bit 0 = **TRUE**. When the transition from **FALSE** to **TRUE** level occurs at the input parameter **enable**, the drive is set to "ready for operation". The POSMO A changes to the "ready for operation" state, which can be read out on the output parameter **ready** = **TRUE**. Traversing is started when the input parameters **enableSetpoint** = **TRUE**, **enableRamp** = **TRUE**, (enable ramp-function generator) **execRamp** = **TRUE** (start ramp-function generator) with a positive edge, and **setpoint** > 0.

The order in which the input parameters **enable**, **enableSetpoint**, **enableRamp**, and **execRamp** are set for starting traversing is at the user's discretion. The input parameters

specified above have equal status. Traversing stops when the input parameters **enable**, **enableSetpoint**, **enableRamp**, and **execRamp** are reset.

Transferring parameters (e.g. ramp-up time - input parameter **accelTime**) requires several task cycles. If a new value is parameterized at the **accelTime** input parameter, the output parameter **dataReady** is set to **FALSE**. Any pending parameter errors (output parameter **error** = **TRUE**) are reset. Data transfer is performed as soon as the in/out parameter **busy** = **FALSE**. If data transmission was active when the **accelTime** input parameter was newly parameterized (e.g. read parameter with **_POSMOA_rwParameter** FB), data transfer is suspended until **busy** = **FALSE**. The value which was parameterized when **busy** = **TRUE** changed to **busy** = **FALSE** at the input parameter **accelTime** is transferred. Completion of data transfer is displayed with a rising edge at the output parameter **dataReady** and stays at **TRUE** until the next data transfer is started.

Message frame substitution (POSMO A, software version V3.0 and higher)

With certain applications, it is essential that the drive be prevented from coming to an undesirable standstill under all circumstances, or that "freezing" of the drive status can be configured for the purpose of shutting down the master (SIMOTION device).

The "Message frame substitution" function can be activated with the **reqControl** input parameter as of software version V3.0 of the POSMO A with set parameter **p701** = **TRUE**.

The process data sent by the SIMOTION device are taken over by the POSMO A with **reqControl** = **TRUE**. With the transition from **TRUE** to **FALSE** on the **reqControl** input parameter, the POSMO A uses the process data received last (control word, block selection and start byte). If parameter **P701** = **FALSE**, the status of the **reqControl** input parameter is not evaluated.

Note

The "Message frame substitution" function takes effect immediately with p701 = 1!

Make sure that the drive can be shut down at any time by an EMERGENCY STOP.

For more information, refer to the SIMODRIVE POSMO A user manual, *Distributed Positioning Motor on PROFIBUS DP*.

Graphical overview of the functionality

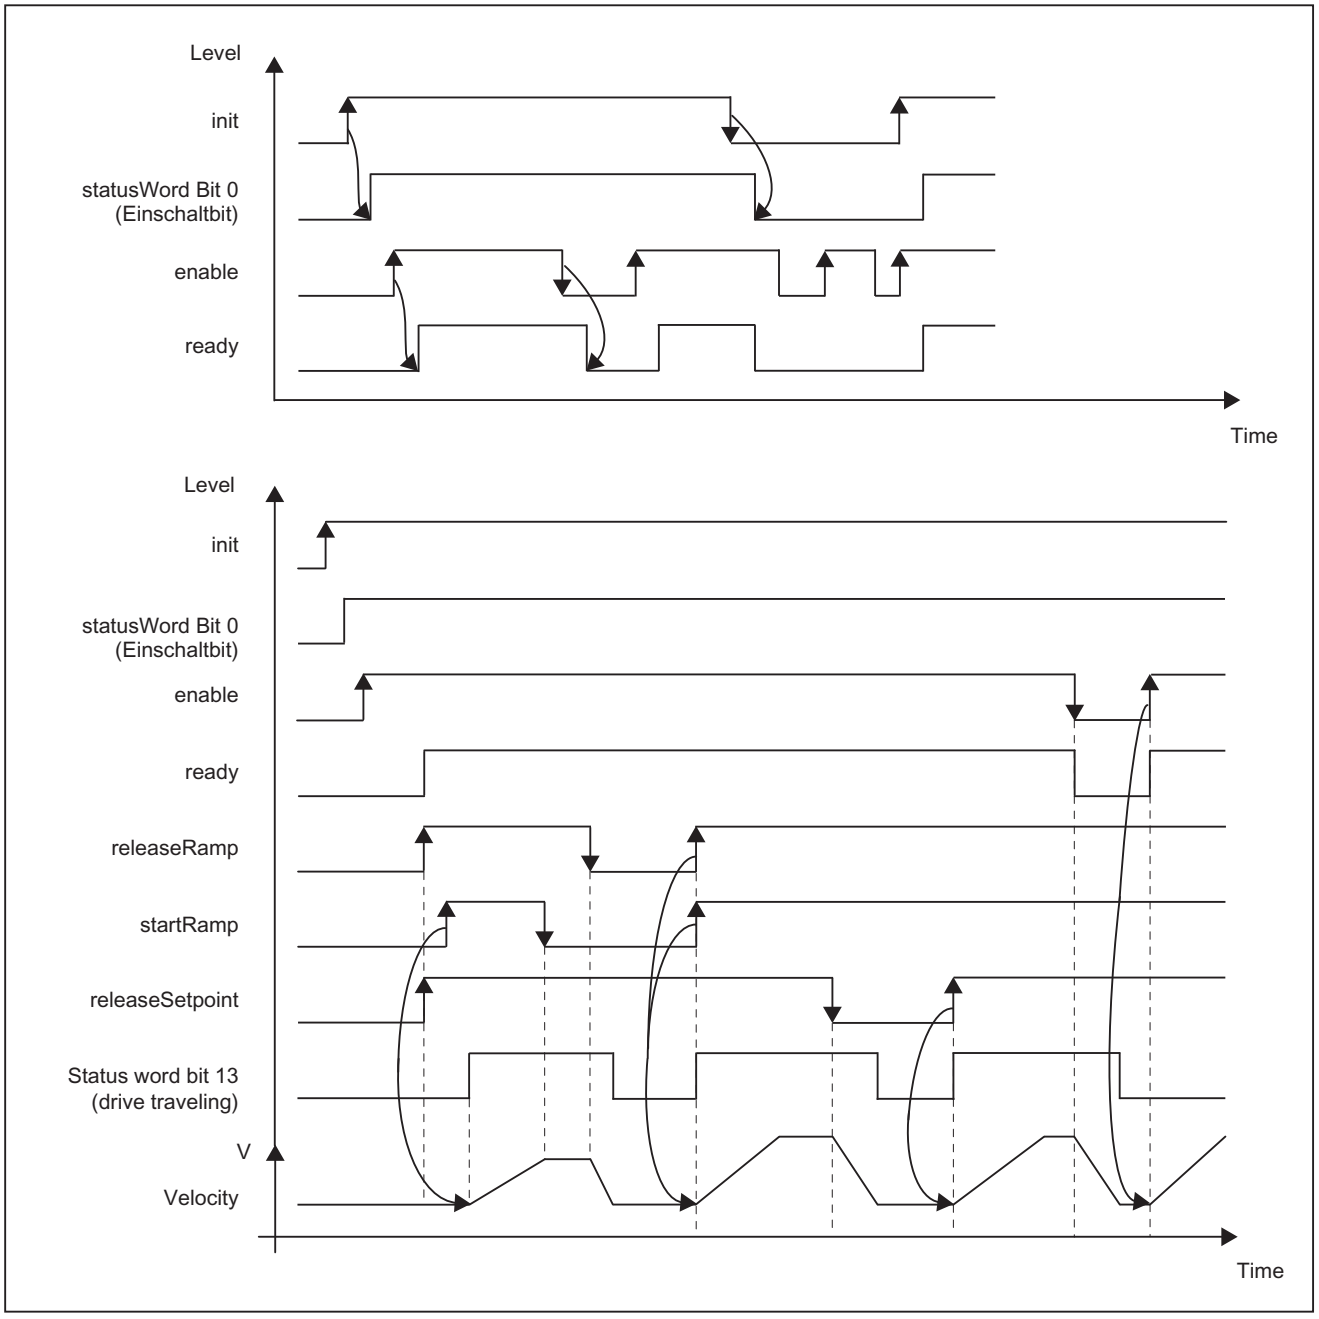


Figure 8-4 Signal propagation diagram

Task integration (call)

The **_POSMOA_nControl** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in synchronous tasks (e.g. **IPOSynchronousTask**) is not recommended for runtime reasons.

Error messages, errors, and warnings

The **TRUE** value at the **error** output parameter indicates a parameterization error. The **errorID** output parameter provides more detailed information on the parameterization error that has occurred. Parameterization errors do not need to be acknowledged. Parameters that have been changed (e.g. ramp-up time) can be transferred again.

Errors in the POSMO A are signaled in the **driveError** output parameter with the value **TRUE**. The reason for the error can be read out in the **driveErrorId** output parameter (value corresponds to P947). Drive errors have to be acknowledged and must be reset in the **resetError** input parameter with a rising edge.

Warnings from the POSMO A that are pending, and their associated information, are output in the **driveWarning**, **driveWarnId** (value corresponds to P953), and **driveWarnInfo** (value corresponds to P954) output parameters.

8.2.3.4 Function block _POSMOA_rwParameter

Task

The **_POSMOA_rwParameter** function block enables parameters to be assigned for the connected SIMODRIVE POSMO A.

The functions are as follows:

- Reading a parameter: Provides the value of the specified parameter.
- Writing a parameter value: Sets the specified parameter to the specified value.
- Loading factory settings: Resets the parameter configuration to the factory settings.
- Saving a parameter: Saves the current parameter configuration in non-volatile memory.

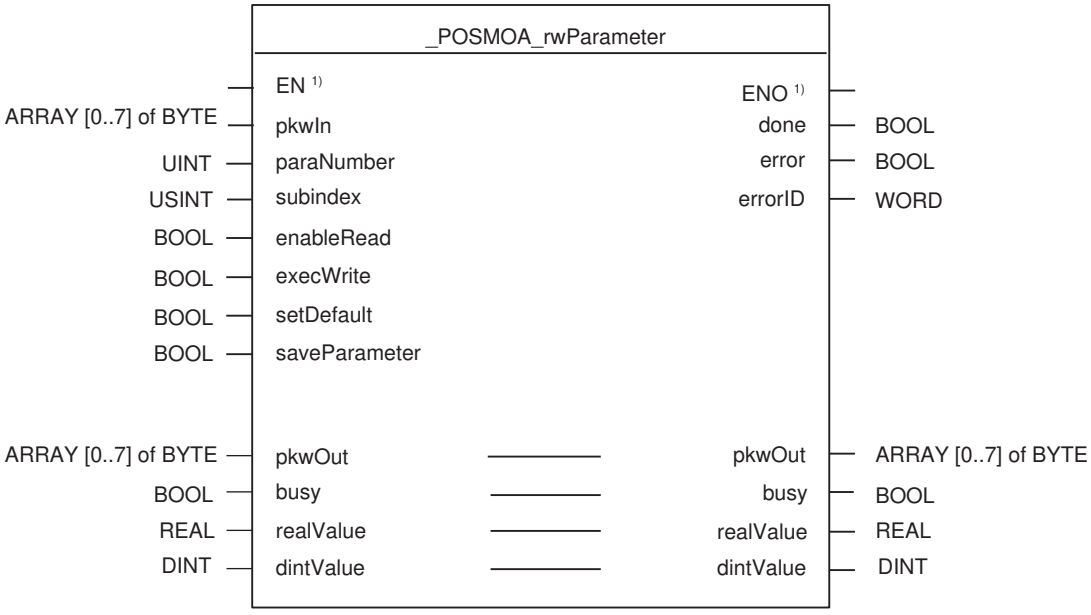
The following parameters can be read/written with this function block:

Parameter numbers	Read from POSMO A	Write to POSMO A (positioning mode)	Write to POSMO A (speed-controlled mode)
1...5	Yes	Yes	Yes
6...7	Yes	Yes	No
9...23	Yes	Yes	Yes
24	Yes	Yes	No
25...38	Yes	Yes	Yes
39...53	Yes	No	No
54	Yes	Yes	Yes
55	Yes	No	No
56...61	Yes	Yes	Yes
62	Yes	No	No
80:28...87:28	Yes	Yes	Yes
99:21	Yes	Yes	Yes
100	Yes	Yes	No
101:11	Yes	Yes	No
700 [1)]	Yes	Yes	Yes

Parameter numbers	Read from POSMO A	Write to POSMO A (positioning mode)	Write to POSMO A (speed-controlled mode)
701 [1]	Yes	Yes	Yes
880 [1]	Yes	Yes	Yes
918...928	No	No	No
930	Yes	No	No
947...954	No	No	No
964:8	Yes	No	No
967...990:78	No	No	No
1426 [1]	Yes	Yes	Yes
1427 [1]	Yes	Yes	Yes

[1] This parameter is new or extended with SIMOTION V4.1.

Call (LAD representation)



[1] LAD-specific parameters

Parameter description

Note

The SIMOTION identifiers have changed as of V4.0.

You can find a comparison of SIMOTION and SIMATIC names in the Appendix SIMOTION and SIMATIC names (Page 6081).

The **busy** parameter must **not** be overwritten by the user. It is supplied and checked by the function block, and must be supplied with a global variable created by the user only when the respective function block is called. This parameter coordinates the individual function blocks for the POSMO A. This ensures that no more than one function block can access a POSMO A at the same time.

Table 8-9 Parameters of the _POSMOA_rwParameter function block

Name	P type [1]	Data type	Default	Meaning
pkwIn	IN	ARRAY [0..7] of BYTE	8(16#00)	Transfer I/O inputs of POSMO A to FB
paraNumber	IN	UINT	0	Parameter number to be read or written
subindex	IN	USINT	0	Subindex = 0 for parameters with no index This value is the array index for parameters with an array. [2]
enableRead	IN	BOOL	FALSE	= TRUE: Reads parameter cyclically = edge FALSE → TRUE: Reads parameter one time
execWrite	IN	BOOL	FALSE	= edge FALSE → TRUE: Writes parameter When set simultaneously with **enableRead**, read is executed.
setDefault	IN	BOOL	FALSE	= edge FALSE → TRUE: Loads factory settings When set simultaneously with **enableRead**, read is executed.
saveParameter	IN	BOOL	FALSE	= edge FALSE → TRUE: Saves parameter When set simultaneously with **enableRead**, read is executed.
pkwOut	IN/OUT	ARRAY [0..7] of BYTE	-	Prepared FB data transferred to the I/O outputs of the POSMO A
busy	IN/OUT	BOOL	-	Coordination of the FBs
realValue	IN/OUT	REAL	-	Write → value to be written (data types C4 and N2) [2] Read → value to be read (data types C4 and N2) [2]
dintValue	IN/OUT	DINT	-	Write → value to be written (data types I2, T2, V2 and T4) [2] Read → value to be read (data types I2, T2, V2 and T4) [2]
done	OUT	BOOL	FALSE	= TRUE: When current request has been completed = FALSE: There is no request pending, or a request is being executed.
error	OUT	BOOL	FALSE	= TRUE: Request completed with error (refer to the **errorID** parameter)
errorID	OUT	WORD	16#0000	Number of the parameter assignment error signaled by the drive (parameter identifier value (PKW) range) [2]

[1] Parameter types: IN = input parameter, OUT = output parameter, IN/OUT = in/out parameter

[2] See *Distributed Positioning Motor on PROFIBUS DP* user manual

Task integration (call)

The **_POSMOA_rwParameter** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in synchronous tasks (e.g. **IPOSynchronousTask**) is not recommended for runtime reasons.

Fault messages

The **TRUE** value at the **error** output parameter indicates a parameterization error. The **errorID** output parameter provides more detailed information on the parameterization error that has occurred or has been signaled by POSMO A. Parameterization errors do not need to be acknowledged. Changed parameters (e.g. ramp-up time) can be transferred again.

8.2.3.5 Function block _POSMOA_rwAllParameter

Task

The **_POSMOA_rwAllParameter** function block enables reading and writing of the parameter block of the connected SIMODRIVE POSMO A.

The data to be read or written are saved in a variable created by the user with the **Struct_POSMOA_params** data structure when the associated function block instance is called.

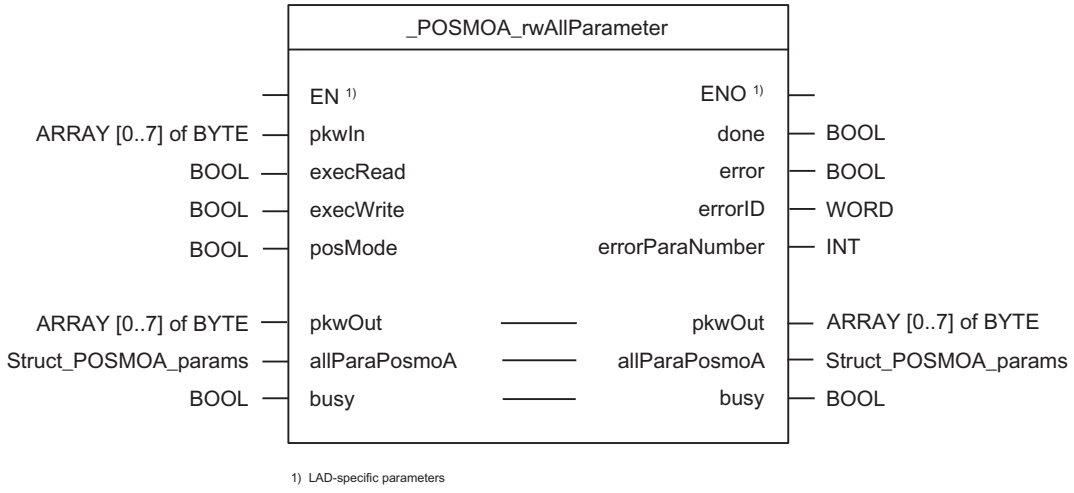
The following parameters are read/written with this function block:

Parameter numbers	Read from POSMO A	Write to POSMO A (positioning mode)	Write to POSMO A (speed-controlled mode)
1...5	Yes	Yes	Yes
6...7	Yes	Yes	No
9...23	Yes	Yes	Yes
24	Yes	Yes	No
25...38	Yes	Yes	Yes
39...53	Yes	No	No
54	Yes	Yes	Yes
55	Yes	No	No
56...61	Yes	Yes	Yes
62	Yes	No	No
80:28...87:28	Yes	Yes	Yes
99:21	Yes	Yes	Yes
100	Yes	Yes	No
101:11	Yes	Yes	No
700 [1)]	Yes	Yes	Yes
701 [1)]	Yes	Yes	Yes
880 [1)]	Yes	Yes	Yes
918...928	No	No	No
930	Yes	No	No

Parameter numbers	Read from POSMO A	Write to POSMO A (positioning mode)	Write to POSMO A (speed-controlled mode)
947...954	No	No	No
964:8	Yes	No	No
967...990:116	No	No	No
1426 [1)]	Yes	Yes	Yes
1427 [1)]	Yes	Yes	Yes

[1)] This parameter is new or extended with SIMOTION V4.1.

Call (LAD representation)



Parameter description

Note

The SIMOTION identifiers have changed as of V4.0.

You can find a comparison of SIMOTION and SIMATIC names in the Appendix SIMOTION and SIMATIC names (Page 6081).

The **busy** parameter must **not** be overwritten by the user. It is supplied and checked by the function block, and must be supplied with a global variable created by the user only when the respective function block is called. This parameter coordinates the individual function blocks for the POSMO A. This ensures that no more than one function block can access a POSMO A at the same time.

Table 8-10 Parameters of the _POSMOA_rwAllParameter function block

Name	P type [1]	Data type	Default	Meaning
pkwIn	IN	ARRAY [0..7] of BYTE	8(16#00)	Transfer I/O inputs of POSMO A to FB
execRead	IN	BOOL	FALSE	= edge FALSE → TRUE: Reads all data one time The start takes place on a positive edge.
execWrite	IN	BOOL	FALSE	= edge FALSE → TRUE: Writes all data one time The start takes place on a positive edge.
posMode [3]	IN	BOOL	TRUE	= TRUE: Positioning mode of the POSMO A = FALSE: Speed-controlled mode
pkwOut	IN/OUT	ARRAY [0..7] of BYTE	-	Prepared FB data for I/O outputs of the POSMO A
allParaPosmoA	IN/OUT	Struct_POS-MOA_params	-	Data structure for all parameters of the POSMO A
busy	IN/OUT	BOOL	-	Coordination of the FBs
done	OUT	BOOL	FALSE	= TRUE: When current request has been completed = FALSE: There is no request pending, or a request is being executed.
error	OUT	BOOL	FALSE	= TRUE: Request completed with error (refer to the **errorID** parameter)
errorID	OUT	WORD	16#0000	Number of the parameter assignment error signaled by the drive (parameter identifier value (PKW) range) [2]
errorParaNumber	OUT	INT	0	Number of the parameter that caused the error [2]

[1] Parameter types: IN = input parameter, OUT = output parameter, IN/OUT = in/out parameter

[2] See *Distributed Positioning Motor on PROFIBUS DP* user manual

[3] As of SIMOTION V4.1, this parameter is part of the **_POSMOA_rwAllParameter** FB and can only be operated with POSMO A software version 3.0 and higher.

Data structure of Struct_POSMOA_params

The data structure of type **Struct_POSMOA_params** contains all of the parameters for controlling the SIMODRIVE POSMO A.

This data structure is used by the **_POSMOA_rwAllParameter** function block. Self-defined variables of data type **Struct_POSMOA_params** are used to access data structure elements.

The following table contains the **Struct_POSMOA_params** data structure.

Note

The SIMOTION identifiers have changed as of V4.0.

You can find a comparison of SIMOTION and SIMATIC names in the Appendix SIMOTION and SIMATIC names (Page 6081).

p84	ARRAY[0..27] of DINT	28(0)	Timer value for traversing blocks 1 to 27	r/w
p85	ARRAY[0..27] of REAL	28(0.0)	Signaling position for traversing blocks 1 to 27	r/w
p86	ARRAY[0..27] of INT	28(0)	SMStart MMStart for traversing blocks 1 to 27	r/w
p87	ARRAY[0..27] of INT	28(0)	MMStop MMPos for traversing blocks 1 to 27	r/w
p99	ARRAY[0..20] of INT	13,18,23,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0	Program management (see *Distributed Positioning Motor on PROFIBUS DP* user manual)	r/w
p100	INT	0	Control word simulation	r/w
p101	ARRAY[0..10] of INT	10(0)	Blocks 1 to 10 of the data structure for the POSMO A parameters	r/w
p700 [2]	INT	2	Operating mode 1 = speed-controlled mode 2 = positioning mode	r/w
p701 [2]	INT	0	Message frame substitution	r/w
p880 [2]	REAL	4096	Normalizing of the speed at the gear output when a setpoint of 4096 decimal is specified via the control word (STW)	r/w

Name	Type	Initial value	Comment	r/w [1]
p930	INT	0	Current mode 1 = speed-controlled mode 2 = positioning mode	r
p964	ARRAY[0..7] of INT	8(0)	Drive identification	r
p1426 [2]	REAL	100	Tolerance band for actual speed value	r/w
p1427 [2]	INT	0	Delay time for "Ramp-up completed" signal	r/w

[1] r - read, w - write

[2] This parameter is new or extended with SIMOTION V4.1.

Structure of "Array_POSMOA_prgCtrlInfo"

"Array_POSMOA_prgCtrlInfo" contains the program control word. Here, you can define the behavior of a traversing block (see *Distributed Positioning Motor on PROFIBUS DP* user manual).

Table 8-12 Structure of Array_POSMOA_prgCtrlInfo

Array element	Data type	Initial value	Comment
0	BOOL	TRUE	Type of motion
1	BOOL	TRUE	Type of positioning
2	BOOL	FALSE	Type of timer
3	BOOL	FALSE	Connection between timer and start byte
4	BOOL	FALSE	Program return
5	BOOL	FALSE	Type of traversing
6	BOOL	FALSE	Invert start byte condition
7	BOOL	FALSE	SM start type
8	BOOL	FALSE	Program stop
9	BOOL	FALSE	Set actual value

Task integration (call)

The **_POSMOA_rwAllParameter** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in synchronous tasks (e.g. **IPOSynchronousTask**) is not recommended for runtime reasons.

Note

The functionality of the **_POSMOA_rwAllParameter** FB has been expanded with V4.1. To enable you to use the newly implemented functionality, you must add the new **posMode** input parameter when calling the **_POSMOA_rwAllParameter** FB.

If you want to work with the previous functionality (< V4.1), you can leave out the new input parameter with a detailed notation when calling the FB.

Fault messages

The **TRUE** value at the **error** output parameter indicates a parameterization error. The **errorID** output parameter contains more detailed information on the parameterization error that has occurred or has been signaled by POSMO A. The **errorParaNumber** output parameter supplies the number of the parameter that has caused the error.

Parameterization errors do not need to be acknowledged. Changed parameters (e.g. ramp-up time) can be transferred again.

8.2.3.6 Calling function blocks

In order to be able to work with the function blocks in your user program, proceed as follows (The numbers shown in the following program segment correspond to the steps below.):

1. Create the function block instances (see the following program segment, e.g. create instance for the **_POSMOA_control** function block).
2. Create a variable for the data structure (for FB **_POSMOA_rwAllParameter** only).
3. Create an array for the in/out parameters of the FB.
4. Call instance of the function block.
5. Transfer input parameters.
6. The output parameters of the FB are accessed with <instance name of FB>. <name of output parameter>.
7. Data prepared by the FB for the I/O outputs are assigned to the I/O variables from the array created in step 3 (see the following program segment).

Note

If you want to control more than one SIMODRIVE POSMO A, you must create a new variable for the data structure (FB **_POSMOA_rwAllParameter**) and FB instances with new names for each POSMO A you use.

Call example

```
UNIT E_posmoA;

INTERFACE

// Definition of global variables for demo program
 VAR_GLOBAL
```

```
  myPosmoAControl  : _POSMOA_control;   // create "_POSMOA_control" instance                    (1)
  myEnable         : BOOL;              // enable posmoA
  myHoming         : BOOL;              // homing posmoA
  myJogPositive    : BOOL;              // jog positive posmoA
  myJogNegative    : BOOL;              // jog negative posmoA
  myBusy           : BOOL;              // coordination bit
  myError          : BOOL;              // variable created by user for accessing
                                        // an output variable of the function block
 END_VAR

 PROGRAM ExamplePosmoA;                 // Program of BackgroundTask
END_INTERFACE

IMPLEMENTATION

PROGRAM ExamplePosmoA                   // Program of BackgroundTask
  VAR
  //    temporary array for outputs of FBs                                                    (3)
        tmpPkwOutput : ARRAY[0..7] of BYTE;
        tmpPzdOutput : ARRAY[0..3] of BYTE;
  END_VAR

// INSTANCE CALL of FB _POSMOA_control                                                       (4)
    myPosmoAControl  (    pkwIn    := myPkwIn,                                            (5)
                          pzdIn    := myPzdIn,
                          enable   := myEnable,
                          homing   := myHoming,
                          jog1     := myJogNegative,
                          jog2     := myJogPositive,
                          busy     := myBusy,
                          pkwOut   := tmpPkwOutput,
                          pzdOut   := tmpPzdOutput
                     );
// an output variable in the "_POSMOA_control" function block is assigned to a              (6)
// "myError" variable created by the user.
    myError := myPosmoAControl.error;

// Assignment of intermediate buffer byte arrays to I/O addresses
    myPkwOut := tmpPkwOutput;                                                              (7)
    myPzdOut := tmpPzdOutput;

END_PROGRAM             // ExamplePosmoA
END_IMPLEMENTATION
```

Note

The ExamplePosmoA program must be assigned in the execution system.

8.2.4 Application example

8.2.4.1 General information on the application example

Task

The application example shows how POSMO A can be controlled with the help of the function blocks and how POSMO A drive parameters can be read and written.

Ther is a command interface **enumCommands** for starting the desired action, e.g. jogging.

The **Struct_checkbacks** data structure shows the status of the actions and additional information.

The following operating modes and functionalities are implemented:

- Homing
  Option: "Approach using visual axis marking and assign actual value"
- Jogging
  Move in positive or negative direction
- MDI
  Travel to the required position
- Parameter handling
  - Write or read individual parameters
  - Save all parameters in the EEPROM of the POSMO A
- Read out current actual position
- The current actual position of the POSMO A is read cyclically in jog mode and in MDI and stored in a variable.

Hardware platform

The application example is available for various SIMOTION hardware platforms.

Note

If the application example is not available for your SIMOTION hardware platform, you must adapt the hardware configuration.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. The configuration in the example can be adapted to suit the available hardware (commission drive, PROFIBUS DP address).
2. The hardware configuration can be adapted to the example (commission drive, PROFIBUS DP address).

Note

Please observe the drive documentation when commissioning the drive.
This documentation is included in the SIMOTION SCOUT scope of delivery in electronic format.

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

1. De-archive and open the project containing the application example.
2. Check the hardware configuration: PROFIBUS DP addresses.
3. Save and compile the example project. You can then download the example to the SIMOTION device and switch to **RUN** mode.

Additional handling steps for the example are carried out using the Enums in the symbol browser within the **myCommand** structure. This requires that the "E_posmoA" element be selected from the **Programs** container in the project navigator.

Values from the "Control value" column are assigned to the corresponding variables by clicking **Immediate control**.

Error messages

Pending errors and warnings (for example, reading during jogging or of individual parameter) are displayed in the following variables:

- myCheckbacks.error = TRUE
  An error has occurred (request canceled; a POSMO A error is pending).
- myCheckbacks.ctrlErrorID
  Error specification of the **_POSMOA_control** function block. Number of the parameter assignment error signaled by POSMO A.
- myCheckbacks.driveErrorID
  Error specification of POSMO A
  Reason for an error signaled by POSMO A
- myCheckbacks.rwErrorID
  Error specification of the **_POSMOA_rwParameter** function block. Error has occurred during reading or writing.

- myCheckbacks.driveWarning = TRUE
  POSMO A warning is pending.
- myCheckbacks.driveWarningID = TRUE
  Warning number of an alarm signaled by POSMO A.

8.2.4.2 Operator control and monitoring of the application example in the detail view

POSMO A will be automatically initialized when your SIMOTION hardware platform changes from STOP to RUN mode. The POSMO A provides feedback that the drive is ready to operate with the following variable:

- myCheckbacks.driveReady = TRUE

Select operating mode

You can choose between "Jog", "Homing", "MDI", or "Parameter handling" modes. This is done via the **myCommand** variable.

"Jog" mode

In the "Jog" mode, the POSMO A can be moved in positive and negative direction.

"Jogging" is implemented with the following parameter settings on the instance created of the **_POSMOA_control** function block:

- jogOverride = 100
- veloOverride = 100
- noStopIntermediate = TRUE — No intermediate stop
- noStop = TRUE — No stop

In the "Control value" column of the symbol browser, select the check boxes for the following variables and select the values to be assigned.

- myCommand = START_JOG_POSITIVE — Jogging in positive direction
- myCommand = START_JOG_NEGATIVE — Jogging in negative direction

Clicking on **Immediate control** assigns the value to the variable, and the POSMO A is moved in the respective direction.

The current "Jog" state can be read in the symbol browser as follows:

- myCheckbacks.actCommand = JOG_POSITIVE_ACTIVE
  Jogging in positive direction activated
- myCheckbacks.actCommand = JOG_NEGATIVE_ACTIVE
  Jogging in negative direction activated
- myCheckbacks.jogPositiveBusy = TRUE
  POSMO A moves in position direction
- myCheckbacks.jogNegativeBusy = TRUE
  POSMO A moves in negative direction

The current actual position of POSMO A can be read in the symbol browser in the **myCheckbacks.actPosition** variable.

Note

The "Jog" mode may be terminated only after the POSMO A is stopped (myCommand = STOP)!

"Homing" mode

The "approach using visual axis marking and assign actual value" options have been implemented. For homing, POSMO A must be switched to closed-loop control and zero speed. The actual value (parameter 40 of POSMO A) can be set via the "Parameter handling", write individual parameter operating mode.

In the "Control value" column of the symbol browser, select the check boxes for the following variables and select the values to be assigned.

- myCommand = START_HOMING

Clicking **Immediate control** assigns the value to the variable, and the POSMO A is homed to the value set in parameter 40 of POSMO A.

Note

For more information on the homing of the POSMO A, refer to the *Distributed Positioning Motor on PROFIBUS DP* user manual.

This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

The current "Homing" state can be read in the symbol browser as follows:

- myCheckbacks.actCommand = HOMING_ACTIVE
  Homing activated
- myCheckbacks.actCommand = NO_COMMAND_ACTIVE
  myCheckbacks.done = TRUE
  Homing completed without error

"MDI" mode

Requirement: The POSMO A is homed!

In the "MDI" mode, one MDI block absolute can be moved.

"Jogging" of the MDI block is implemented with the following parameter settings on the instance created of the **_POSMOA_control** function block:

- mdiMode = FALSE MDI absolute
- mdiVelocity = 100
- mdiAcceleration = 100
- veloOverride = 100

- noStopIntermediate = TRUE — No intermediate stop
- noStop = TRUE — No stop

The target position of the MDI block is specified in the **myAbsolutePosition** variable.

In the "Control value" column of the symbol browser, select the check boxes for the following variables and select the values to be assigned.

- myCommand = START_MDI_BLOCK_ABSOLUTE
- myAbsolutePosition = ... The target position of the MDI block is specified here. (Default = 0.0)

Clicking on **Immediate control** assigns the values to the variables, and the POSMO A moves the MDI block absolute.

The current state of the "MDI" mode can be read in the symbol browser as follows:

- myCheckbacks.actCommand = MDI_BLOCK_ACTIVE
  Move MDI block absolute activated
- myCheckbacks.actCommand = NO_COMMAND_ACTIVE
- myCheckbacks.done = TRUE
- myCheckbacks.positionReached = TRUE
  MDI block traversed without error

The current actual position of POSMO A can be read in the symbol browser, from the **myCheckbacks.actPosition** variable.

Note

The "MDI" mode may be terminated only after the POSMO A is stopped (myCommand = STOP)!

"Parameter handling" mode

In the "Parameter handling" mode you can read and write individual parameters and save all parameters in the EEPROM of POSMO A.

Read individual parameter

In the **myRdParaNumber** variable you state the parameter you want to read. In the **myRdSubIndex** variable, you state the subindex for the parameter you wish to read (indexed parameters only).

In the "Control value" column of the symbol browser, select the check boxes for the following variables and select the values to be assigned.

- myCommand = READ_ONE_PARAMETER
  Read individual parameter
- myRdParaNumber = ...
  You state the number of the parameter to be read here.
- myRdSubIndex = ...
  You state the subindex of the parameter to be read here (for indexed parameters only)

The value read is saved in the **myReadValue** variable.

Write individual parameter

In the **myWrParaNumber** variable you state the parameter you want to write. In the **myWrSubIndex** variable, you state the subindex for the parameter you wish to write (indexed parameters only).

In the **myWrRealValue** variable (data types C4 and N2) [2)] or **myWrDintValue** (data types I2, T2, V2, and T4) [2)], you state the value for the parameter to be written.

In the "Control value" column of the symbol browser, select both the check boxes for the following variables and the values to be assigned.

- myCommand = WRITE_ONE_PARAMETER
  Write individual parameter
- myWrParaNumber = ...
  You state the number of the parameter to be written here.
- myWrSubIndex = ...
  You state the subindex of the parameter to be written here (for indexed parameters only)
- myWrRealValue = ...
  You state the value of the parameter to be written here (data types C4 and N2) [2)].
- myWrDintValue = ...
  Here, you state the value of the parameter to be written (data types I2, T2, V2, and T4) [2)].

[2)] Refer to the *Distributed Positioning Motor on PROFIBUS DP* user manual.
This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Saving all parameters in the EEPROM

In the "Control value" column of the symbol browser, select the check boxes for the following variables and select the values to be assigned.

Clicking **Immediate control** assigns the value to the variable; this activates saving of all parameters in the EEPROM.

- myCommand = SAVE_PARAMETER Saving all parameters in the EEPROM

The current "Parameter handling" state can be read in the symbol browser as follows:

- myCheckbacks.actCommand = READ_PARA_ACTIVE
  Read individual parameter activated
- myCheckbacks.actCommand = WRITE_PARA_ACTIVE
  Write individual parameter activated

- myCheckbacks.actCommand = SAVE_PARAMETER_ACTIVE
  Save all parameters of the POSMO A activated
- myCheckbacks.actCommand = NO_COMMAND_ACTIVE
  myCheckbacks.done = TRUE
  Parameter handling completed without error

Acknowledging faults on POSMO A

Faults on POSMO A are acknowledged as follows:

- myCommand = RESET_ERRORS

The current fault acknowledgement state can be read in the symbol browser as follows:

- myCheckbacks.actCommand = RESET_ERRORS_ACTIVE
  Fault acknowledgement active
- myCheckbacks.actCommand = NO_COMMAND_ACTIVE
  myCheckbacks.done = TRUE
  Fault acknowledgement completed

Note

A POSMO A fault can only be acknowledged successfully when the cause of the error no longer exists.

8.2.4.3 Variables used in application example

Table 8-13 Overview of the variables used

Symbol	Data type	Initial value	Meaning
myCommand	enumCommands	NO_COMMAND	Command interface
myCheckbacks	Struct_Checkbacks	NO_COMMAND_ACTIVE	Command status Additional information

Table 8-14 Overview of the enums enumCommands

Symbol	Enum Value	Meaning
START_HOMING	0	Start homing of POSMO A
START_JOG_NEGATIVE	1	Start jogging in negative direction
START_JOG_POSITIVE	2	Start jogging in positive direction
START_MDI_BLOCK_ABSOLUTE	3	Start moving MDI block absolute
STOP	4	Stop all actions
RESET_ERRORS	5	Acknowledge faults on POSMO A
READ_ONE_PARAMETER	6	Start reading individual parameter
WRITE_ONE_PARAMETER	7	Start writing individual parameter

Symbol	Enum Value	Meaning
SAVE_PARAMETER	8	Save all parameters in the EEPROM of POSMO A
NO_COMMAND	9	No action to be carried out

Table 8-15 Overview of the enums enumActCommand

Symbol	Enum Value	Meaning
HOMING_ACTIVE	0	Homing of POSMO A activated
JOG_NEGATIVE_ACTIVE	1	Jogging in negative direction activated
JOG_POSITIVE_ACTIVE	2	Jogging in positive direction activated
MDI_BLOCK_ACTIVE	3	Moving MDI block absolute activated
STOP_ACTIVE	4	Stop all actions activated
RESET_ERRORS_ACTIVE	5	Acknowledge faults on POSMO A active
READ_PARA_ACTIVE	6	Read individual parameter active
WRITE_PARA_ACTIVE	7	Write individual parameter active
SAVE_PARAMETER_ACTIVE	8	Save all parameters in the EEPROM of POSMO A active
NO_COMMAND_ACTIVE	9	No action active

Table 8-16 Data structure Struct_checkbacks

Symbol	Data type	Meaning
actCommand	enumActCommand	Enums active actions
done	BOOL	Action completed
driveReady	BOOL	Drive (POSMO A) ready for operation
jogPositiveBusy	BOOL	Jogging positive active
jogNegativeBusy	BOOL	Jogging negative active
actPosition	REAL	Current actual position of POSMO A
positionReached	BOOL	Position when moving MDI block absolute reached
error	BOOL	Error has occurred (request canceled; a POSMO A error is pending)
ctrlErrorID	WORD	Error specification of the **_POSMOA_control** block. Number of the parameter assignment error signaled by POSMO A
driveErrorID	WORD	Error specification of the POSMO A Reason for an error signaled by POSMO A
rwErrorID	WORD	Error specification of the **_POSMOA_rwParameter** block. Error during reading or writing has occurred
driveWarning	BOOL	POSMO A warning is pending
driveWarningID	WORD	Warning number

8.2.5 Appendix

8.2.5.1 SIMOTION and SIMATIC names

The table below contains a comparison of SIMOTION and SIMATIC names.

Table 8-17 SIMOTION and SIMATIC names for SIMODRIVE POSMO A

Name in the SIMOTION system as of V4.1 (command library in SCOUT)	Name in the SIMATIC system	Name in the SIMOTION system up to V3.2 (SIMOTION function library)
Function block parameters		
_POSMOA_control	**FB 10**	**_FB_posmoA_control**
pkwIn	I_O_address	PKWInputInterface
pzdIn	I_O_address	PZDInputInterface
enable	Initialization	initialize
homing	Referencing	homing
releaseBrake	Brake_release	-

8.2.5.2 List of abbreviations

Table 8-18 Abbreviations

Abbreviation	Meaning
DC	Direct current
DP	Distributed I/O
EEPROM	Electrically Erasable Programmable Read-Only Memory
ES	SIMOTION SCOUT
FB	Function block
FW	Firmware
HW	Hardware

Abbreviation	Meaning
IN	Input parameters
IN/OUT	In/out parameter
LAD	Ladder diagram
MDI	**M**anual **D**ata **I**nput
OUT	Output parameters
PIV	Parameter identification value: Parameter part of a PPO
POSMO A	**Pos**itioning **Mo**tor **A**ctuator
PPO	**P**arameter **P**rocess data **O**bject: Cyclic data message frame when transferring data with PROFIBUS DP and the "variable-speed drives" profile
PZD	Process data: Process data part of a PPO
ST	Structured text
STW	Control word
SW	Software
TO	Technology object

8.3 Reading and Writing Drive Data

Preface

Contents of Function Manual

This **document** is part of the **SIMOTION Programming - References documentation package**.

The manual describes how you can use a function block to read and write drive parameters using the PIV (Parameter Identification Value) interface.

Function block

The function block for the "Reading and Writing of Drive Data" for SIMOTION is part of the command library of the "SIMOTION SCOUT" engineering system.

Information in this manual

The following describes the purpose and objectives of the manual:

- General
  This chapter presents information on commissioning the drives, assigning parameters to the PROFIBUS DP interface, and integrating the function block into the SIMOTION system.
- Function blocks
  This chapter describes the function block for reading and writing drive data in connection with the SIMOTION system.
- Index to locate information

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

8.3.1 Fundamental safety instructions

8.3.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.3.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.3.2 Description

8.3.2.1 General

Overview

Siemens offers a wide spectrum of drives with a graduated range of power ratings.

Of this extensive selection of drives, the SIMOTION Motion Control System supports the SIMODRIVE 611 universal, SIMOVERT MASTERDRIVES MC and POSMO CA/CD/SI drives, as well as other drives.

Coupling via PROFIBUS DP enables the drive system and the SIMOTION system to exchange all of their data over this link.

Requirement

The following software versions are required for the standard functions described in this documentation:

- SIMOTION SCOUT V4.0 or higher
- SIMOTION Kernel V4.0 or higher
- SIMOTION technology packages V4.0 or higher

Communication

The PROFIBUS DP field bus allows rapid cyclical data exchange between the DP slave (drive) and the higher-level DP master (SIMOTION hardware platform, such as SIMOTION C2xx).

Note

The **_RWPAR_cyclic** function block described in this documentation enables you to read or write the individual parameters of a drive. In so doing, the parameter channel is transferred in the cyclic message frame. This requires that the relevant drive supports data exchange via the parameter identifier value (PIV) interface, as defined in the **PROFIdrive V2 Drive Profile** (1997).

For drives that support the parameter channel according to the **PROFIdrive V3.1 Drive Profile** (parameter requests are transferred with acyclic DP-V1 message frames), the corresponding system functions are available in SIMOTION:

- **_readDriveParameterDescription**: This function enables the descriptive data of a drive parameter to be read out.
- **_readDriveParameter**: This function enables a drive parameter to be read.
- **_writeDriveParameter**: This function enables a drive parameter to be written.
- **_readDriveFaults**: This function enables the current fault buffer entry in the drive to be read.
- **_readDriveMultiParameterDescription**: This function enables multiple parameter descriptions to be read.
- **_readDriveMultiParameter**: This function enables multiple parameters to be read.
- **_writeDriveMultiParameter**: This function enables multiple parameters to be written.

Further information is contained in the **SIMOTION C2xx / P350 / D4xx System Function/ Variables** lists manual. These documents are shipped with SIMOTION SCOUT in electronic form!

The SIMODRIVE 611 universal, SIMOVERT MASTERDRIVES, MICROMASTER MM4, and POSMO CA/ CD/SI drives support both the PIV interface as well as the acyclic parameter channel. SINAMICS devices support only the acyclic PROFIdrive parameter channel.

8.3.2.2 Start-up and Parameterization of PROFIBUS DP Interface

Requirement

The following requirements must be met:

1. You have created a project in SIMOTION SCOUT and have inserted a rack with a SIMOTION hardware platform in the hardware configuration.
2. You have configured a PROFIBUS subnet.
3. You have commissioned the drive(s) and inserted them in your SIMOTION project.
4. You have configured the drive(s) as a PROFIBUS slave and have assigned parameters for the PROFIBUS DP interface.
5. PIV slot
   If the message frame set during configuration of the drive as a PROFIBUS slave (HW Config > DP slave properties > Configuration tab) does not contain a PIV component, then one PIV slot must be configured for each axis (slot 4 for single-axis drives; slots 4 and 8 for double-axis drives).
   Refer to the figure: "Addresses (PIV slot) in SIMOTION SCOUT"
   Note:
   For SIMOVERT MASTERDRIVES MC, a message frame with a PIV component must be set.

Note

For instructions on creating a project, configuring a PROFIBUS subnet, and inserting a drive in the project, refer to the online help for *SIMOTION SCOUT*.

For additional information, e.g. about commissioning, refer to the user manuals of the installed drives.

8.3.2.3 Integrating the function block in the user project

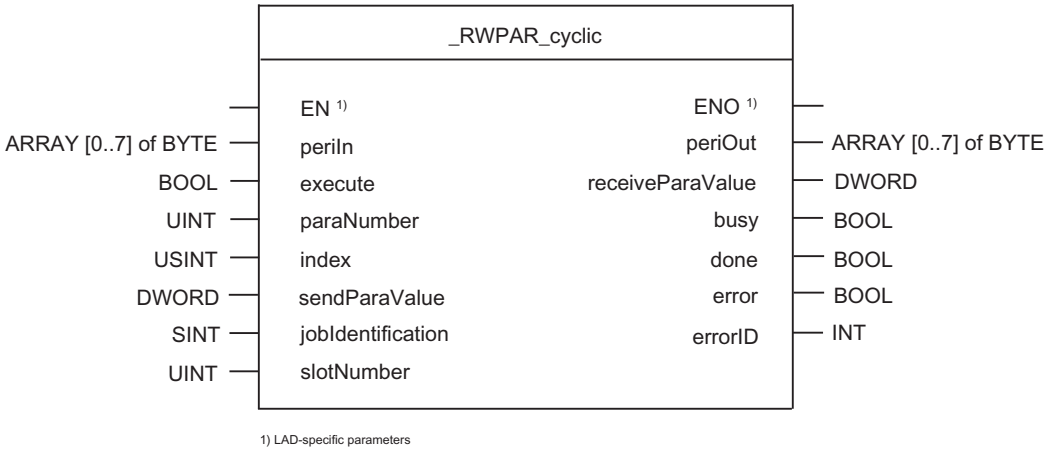
Creating the instance of the FBs in the user project

The function block is part of the command library of the "SIMOTION SCOUT" engineering system. To work with the block, an instance must first be created in the user project.

Example:

```
VAR_GLOBAL
...
  myInstRWParCyclicAxis1: _RWPAR_cyclic ;   // create "_RWPAR_cyclic"
                                             // instance
...
END_VAR
```

Call (LAD representation)



Application example

The application example is included on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

8.3.2.4 Creating I/O Variables

Overview

To read and write drive parameters by means of the PIV interface, you must define I/O variables in SIMOTION SCOUT.

Communication between the SIMOTION device and the drive takes place by means of direct I/O access when data are exchanged over the PIV interface. I/O variables are used to address the direct read/write access to the I/O.

You can freely assign the names of I/O variables in SIMOTION SCOUT. I/O variables must be specified as ARRAY [0..7] of BYTE. You assign addresses set in the hardware configuration (PIV slot) to these I/O variables.

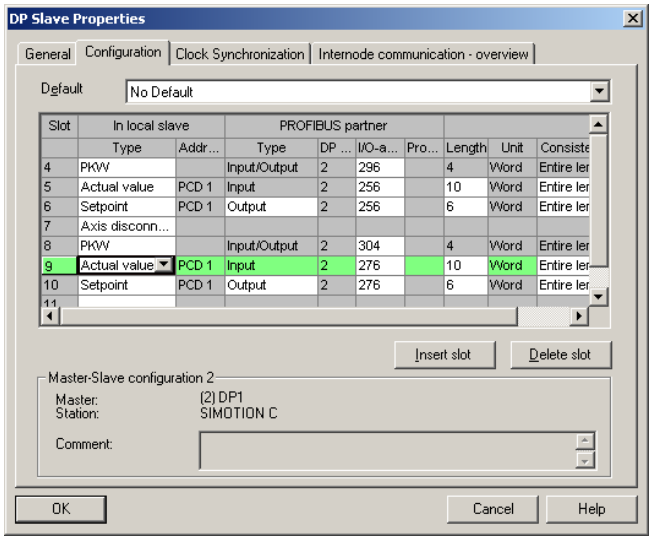


Figure 8-5 Addresses (PIV slot) in SIMOTION SCOUT

The names of the I/O inputs must be transferred to the function block as a call parameter (inputInterface). The data prepared for the I/O outputs are made available as output parameters by the FB and must be assigned to the corresponding I/O variables (see call example in the "Calling the Function Block" section).

The following example shows how to assign the module addresses to the I/O variables in SIMOTION SCOUT.

	Name	I/O address	Read only	Data type	Field length
1	myperipheralinputaxis1	PIB 296		Array	8
2	myperipheraloutputaxis1	PQB 296	☐	Array	8
3	myperipheralinputaxis2	PIB 304		Array	8
4	myperipheraloutputaxis2	PQB 304	☐	Array	8

Figure 8-6 Address assignment in SIMOTION SCOUT

Input addresses and output addresses have a range of 8 bytes each (corresponding to the PIV range of the drive).

Note

For additional information, refer to:

- *SIMOTION SCOUT* online help
- Programming manual of the corresponding programming language, e.g.:
  - *SIMOTION ST, Structured Text* programming manual
  - *SIMOTION MCC, Motion Control Chart* programming manual
  - *SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram* programming manual

These documents are shipped with SIMOTION SCOUT in electronic form!

8.3.3 Function block

8.3.3.1 Overview

This section contains a description of the function block (FB) required to read and write drive data between a SIMOTION device and the drive.

This function block makes it easier to read and write drive parameters from a SIMOTION program over the PIV interface of a drive.

The **_RWPAR_cyclic** function block must be called repeatedly (cyclically) from the user program.

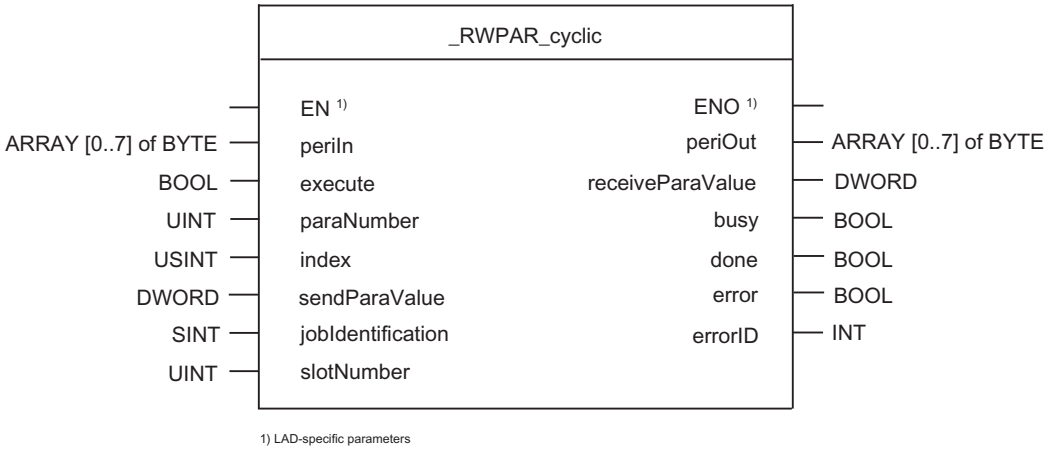
8.3.3.2 _RWPAR_cyclic function block

Task

The **_RWPAR_cyclic** function block enables you to read or write the individual parameters of a drive.

For this purpose, the relevant drive must support the mechanism of data exchange via the PIV interface.

Call (LAD representation)



_RWPAR_cyclic FB parameters

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the designations up to V3.2 / from V4.0 is contained in the "List of parameters" table in Appendix A.

Table 8-19 _RWPAR_cyclic FB parameters

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
periIn	IN	ARRAY [0 to 7] of BYTE	Transfers I/O inputs of drive to FB	I/O variable of the I/O inputs of the drive transferred to the FB	Checked
execute	IN	BOOL	FALSE → TRUE edge Start request	Entered	Checked
paraNumber	IN	UINT	Parameter to be read or written [2]	Entered	Checked
index	IN	USINT	Subindex for parameter to be read or written	Entered	Checked
sendParaValue	IN	DWORD	Value of parameter to be written	Entered	Checked
jobIdentification	IN	SINT	Request identifier [2]	Entered	Checked
slotNumber	IN	UINT	PIV slot number [2]	Entered	Checked
periOut	OUT	ARRAY [0 to 7] of BYTE	Prepared FB data for I/O outputs of drive	Checked and entered on the I/O variable for the I/O outputs	Entered
receiveParaValue	OUT	DWORD	Value of read parameter	Checked	Entered
busy	OUT	BOOL	= TRUE: A request is being processed = FALSE: No request has been received	Checked	Entered
done	OUT	BOOL	= TRUE: If current request is done, only one cycle is active = FALSE: There is no request pending, or a request is being executed.	Checked	Entered
error	OUT	BOOL	= TRUE: Request terminated with error (see **errorID** parameter) - only one cycle is active	Checked	Entered
errorID	OUT	INT	Error specification [2] only one cycle is active	Checked	Entered

[1] Parameter types: IN = input parameter, OUT = output parameter

[2)]See user manuals for relevant drives (PIV range)

Note

If **errorID** = 201, an incorrect slot was configured
Remedy: Check and modify slot configuration!

If **errorID** = 301, transfer of the request was aborted because no correct response data has been received from the drive after 1000 function block call cycles.
Remedy: Repeat request, check communication link if necessary!

If **errorID** = 302, parameter change rights do not exist for the relevant drive
Remedy: Set the parameter change rights and repeat the request.

If you want to read and write indexed parameters for SIMODRIVE 611 universal and SIMODRIVE POSMO CD, CA and SI, you must set bit 11 in the P879 parameter to "1".

For information about drive parameters and their formats and data types, refer to the user manuals for the installed drives.

Function description

This function block processes the PIV interface (4 words wide) in a cyclic message frame.

A complete request (**paraNumber**, **index**, **sendParaValue**, **jobIdentification**) is processed. Consistent data transfer is ensured by the byte ARRAY mechanism for I/O inputs and outputs. A new request is accepted through a positive edge at the **execute** parameter of the block. A **busy** parameter at the block indicates that request processing is in progress. A new request cannot be started until processing of the previous request is finished (**done** = **TRUE**). Any errors are indicated in the **error** and **errorID** parameters.

Signal sequence diagram

The following figure shows the behavior of the parameters of the **_RWPAR_cyclic** function block

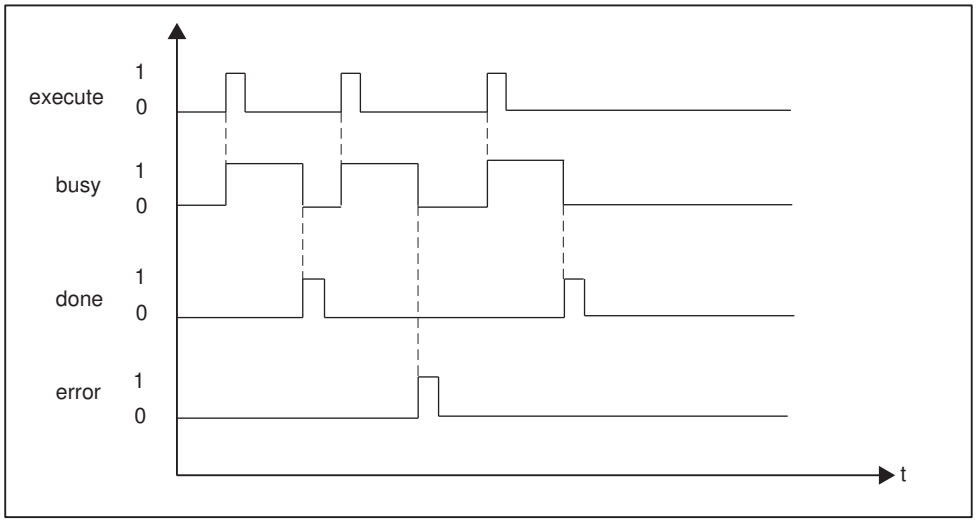


Figure 8-7 _RWPAR_cyclic FB signal sequence diagram

Task integration (call)

The **_RWPAR_cyclic** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

8.3.3.3 Calling the function block

In order to work with the function block in your user program, proceed as follows (the numbers shown in the following program snippet correspond to the steps below):

1. Create an instance of the function block.
2. Call instance of the function block.
3. Transfer input parameters.
4. The output parameters of the function block are accessed with <instance name of FB>.<name of output parameter>.
5. The data for the I/O outputs prepared by the FB are assigned to the I/O variables.

Note

If you want to read or write parameters from multiple drives, you must create an FB instance with a new name for each drive.

Call example

```
UNIT E_rwPar;
```

```
INTERFACE                                                                    (1)
  VAR_GLOBAL
    myInstRWParCyclicAxis1: _RWPAR_cyclic;    // create "_RWPAR_cyclic" instance
    myTransferError        : WORD :=16#0000;   // displays error number of
                                               // data transfer
    myWrOneParaToAxis1     : BOOL :=FALSE;     // starts the transmission of
                                               // proportional gain
                                               // (non indexed parameter) to Axis1
  END_VAR

  PROGRAM ExampleRWParameter;

END_INTERFACE

IMPLEMENTATION

  PROGRAM ExampleRWParameter                   // program of BackgroundTask

  VAR
    mySlotNumberAxis1        : UINT ;
    myStartParamAxis1        : BOOL :=FALSE;   // start flag for data transmission
                                               //of axis 1
    myParaNumAxis1           : UINT  :=0;
    myIndexAxis1             : USINT := 0;
    mySendParaValueAxis1     : DWORD :=16#0000;
    myJobIdentificationAxis1 : SINT := 0;
  END_VAR

    // call instance from standard FB "_RWPAR_cyclic" to proceed data transfer  (2)
    myInstRWParCyclicAxis1( periIn            := myPeripheralInputAxis1,
                            slotNumber        := mySlotNumberAxis1,            (3)
                            execute           := myStartParamAxis1,
                            paraNumber        := myParaNumAxis1,
                            index             := myIndexAxis1,
                            sendParaValue     := mySendParaValueAxis1,
                            jobIdentification := myJobIdentificationAxis1 );
    // copy error code                                                          (4)
    myTransferError:= myInstRWParCyclicAxis1.errorID;

    // write peripheral outputs                                                 (5)
    myPeripheralOutputAxis1 := myInstRWParCyclicAxis1.periOut;

END_PROGRAM

END_IMPLEMENTATION
```

Note

The ExampleRWParameter program must be assigned in the execution system.

8.3.4 Example of an application

8.3.4.1 General

The call example above shows how to read and write a variety of drive parameters from a SIMOTION program in a system with a SIMODRIVE 611 universal double-axis module. The parameters are written either individually or as a group to the 1st and 2nd axis on the double-axis module. Drive parameters are read:

- once from the 1st axis of the double-axis module
- cyclically from the 2nd axis of the double-axis module

Hardware platform

The application example is available for various SIMOTION hardware platforms.

Note

If the application example is not available for your hardware platform, you have to adapt the hardware configuration.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. The configuration in the example can be adapted to the available hardware (commission drive, PROFIBUS DP address).
2. The hardware configuration can be adapted to the example (commission drive, PROFIBUS DP address).

   Note

   For commissioning the drive, please observe the drive documentation!
   This documentation is included in the SIMOTION SCOUT scope of supply as electronic documentation!

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the axis configuration: PROFIBUS DP addresses.
3. Save and compile the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

Variables used in application example

Symbol	Data type	Meaning	Actions performed by user	Actions performed by example
myWrOneParaToAxis1	BOOL	Transfers the P-gain of the speed controller to Axis 1 (edge-triggered)	Set Reset (on error)	Reset
myWrIndexedParaToAxis1	BOOL	Transfers the ramp-up time of parameter block 1 of Axis 2 - indexed parameter (edge-triggered)	Set Reset (on error)	Reset
myWrThreeParaToAxis1	BOOL	Transfers a set of 3 parameters to Axis 1 (edge-triggered)	Set Reset (on error)	Reset
myWrOneParaToAxis2	BOOL	Transfers the P-gain of the speed controller to Axis 2 (edge-triggered)	Set Reset (on error)	Reset
myRdThreeParaAxis1	BOOL	Reads 3 parameters from axis 1 once	Set Reset (on error)	Reset
myRdIndexedParaAxis1	BOOL	Reads the ramp-up time of parameter block 1 of Axis 1 - indexed parameter (edge-triggered)	Set Reset (on error)	Reset
myRdThreeParaCyclicAxis2	BOOL	Reads 3 parameters from axis 2 cyclically	Set Reset	Read Reset (on error)
myTransferError	INT	Contains the error identifier (**errorID**) of the **_RWPAR_cyclic** FB	Read	Written
myReadCyclicActive	BOOL	= TRUE: cyclical reading of parameters is active	Read	Written

8.3.4.2 Sequence of the application example

This application example illustrates how to read and write the drive parameters for a SIMODRIVE 611 universal double-axis module using the **_RWPAR_cyclic**function block. On the basis of five different parameterized calls of the **_RWPAR_cyclic** FB, drive parameters will be written to the 2 axes of the double-axis module or will be read discretely or cyclically.

Start the transfer operation by setting the global variables (e.g., "myWrOneParaToAxis1" to transfer the P-gain of the speed controller to Axis 1) in the symbol browser and pressing the "Immediate control" button. Once the parameters have been transferred successfully, the variables will be reset by the application example. However, if any transfer errors have occurred, the global variables will not be reset automatically by the application example. In this case, you must reset the global variables (to "FALSE") in the symbol browser yourself. The error ID is saved in the "myTransferError" global variable and displayed in the symbol browser of SIMOTION SCOUT.

The drive parameters are stored in the following structures:

Table 8-20 Overview of the data structures for the drive parameters

Data structure	Meaning
structParameterAxis1	Drive parameters for axis 1
writeParameter	Substructure for the drive parameters to be written for axis 1
readParameter	Substructure for the drive parameters of axis 1 to be read
structParameterAxis2	Drive parameters for axis 2
writeParameter	Substructure for the drive parameters to be written for axis 2
readParameter	Substructure for the drive parameters of axis 2 to be read

Before initiating the transfer, you can modify the values of the drive parameters to be written in the symbol browser and activate them using the "Immediate control" button.

8.3.4.3 Error messages

Any transfer errors that occur are stored in the "myTransferError" global variable and displayed in the symbol browser of SIMOTION SCOUT.

Note

If **myTransferError** = 201, an incorrect slot was configured
Remedy: Check and modify slot configuration!

If **myTransferError** = 301, transfer of the request was aborted because no correct response data have been received from the drive after 1,000 function block call cycles.
Remedy: Repeat request, check communication link if necessary!

If **myTransferError** = 302, parameter change rights do not exist for the relevant drive
Remedy: Set the parameter change rights and repeat the request.

If you want to read and write indexed parameters for SIMODRIVE 611 universal and SIMODRIVE POSMO CD, CA and SI, you must set bit 11 in the P879 parameter to "1".

For information about drive parameters and their formats and data types, as well as a detailed description of the error ID, refer the the *SIMODRIVE 611 universal (PIV range)* function description.
This documentation is included as electronic documentation with the supplied SIMOTION SCOUT!

8.3.5 Appendix

8.3.5.1 List of parameters

A comparison of the SIMOTION identifiers up to V3.2/as of V4.0 is shown in the table below.

Table 8-21 List of parameters

Name in the SIMOTION system as of V4.0 (program library in SCOUT)	**Name in the SIMOTION system up to V3.2 (SIMOTION function library)**
Function block parameters	
_RWPAR_cyclic	**_FB_rwPar_cyclic**
periIn	inputInterface
execute	execute
paraNumber	parameterNumber
index	index
sendParaValue	sendParameterValue
jobIdentification	jobIdentification
slotNumber	slotNumber
periOut	outputInterface
receiveParaValue	receiveParameterValue
busy	busy
done	done
error	error
errorID	errorID

8.4 Standard function for SINAMICS S120 line modules

Foreword

Contents of the function manual

This **document** is part of the **SIMOTION programming references documentation package**.

Function block

The **_LineModule_control** function block is part of the command library of the "SIMOTION SCOUT" engineering system.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

8.4.1 Fundamental safety instructions

8.4.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.4.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.4.2 Description

8.4.2.1 General

The **_LineModule_control** function block can only be used in the SIMOTION system

- For the SIMOTION D4x5/D4x5-2 hardware platform or
- For the SIMOTION C, P, and D hardware platforms with a subordinate SINAMICS S120 CU320/CU320-2

in conjunction with a SINAMICS S120 infeed (Line Module) with a DRIVE-CLiQ connection.

From SIMOTION V4.2 onward, the symbolic assignment is activated as standard for newly created projects. For this purpose, no telegrams must be configured for the infeed. If the symbolic assignment is deactivated, SIEMENS telegram 370 must be configured.

The following software versions are required for the standard function described in this documentation:

- SIMOTION SCOUT V4.2 or higher
- SIMOTION Kernel V4.2 or higher

Note

For versions earlier than V4.2, a function block can be found in "SIMOTION Utilities & Applications" for controlling SINAMICS S120 Line Modules (under **Applications > Cross-Sector Applications > Function Block for Controlling Line Modules**).

"SIMOTION Utilities & Applications" is provided free of charge and as part of the SIMOTION SCOUT scope of delivery.

8.4.2.2 Product description

You can use the **_LineModule_control** function block to switch on and off all SINAMICS S120 Line Modules with DRIVE-CLiQ connections from SIMOTION, as well as to perform straightforward diagnostics tasks.

The following infeeds are supported by the **_LineModule_control** function block:

- Active Line Modules (ALM)
- Basic Line Modules (BLM)
- Smart Line Modules (SLM)

The **_LineModule_control** function block is provided for communication between the higher-level SIMOTION control and SINAMICS S120 Line Modules using the command library of the SIMOTION SCOUT engineering system.

The function block is described in this manual.

Note

Line Modules (Active Line Modules, Basic Line Modules, Smart Line Modules) of different types must not be operated simultaneously on the same DC link.

Note

For explanations relating to the status and control word of SINAMICS S120 Line Modules, refer to the

- *SINAMICS S120 Drive Functions* Function Manual
- *SIMOTION D4x5* Commissioning and Hardware Installation Manual

These documents are provided as part of the SIMOTION SCOUT scope of delivery in electronic format.

8.4.3 Parameter assignment / addressing

8.4.3.1 Overview

Communication between the SIMOTION device and the Line Module takes place via the internal PROFIBUS DP (for SIMOTION D4x5/D4x5-2) or the external PROFIBUS DP or PROFINET (for SIMOTION C, P, D with subordinate SINAMICS S120 CU320/CU320-2).

From SIMOTION V4.2 onward, the symbolic assignment is activated as standard for newly created projects. For this purpose, no message frames must be configured for the infeed.

If the symbolic assignment is deactivated, SIEMENS message frame 370 must be configured for use of the **_LineModule_control** function block function. Addresses from 256 are recommended for configuring the Line Modules, where I/O variables are used for the write and read I/O access procedures.

8.4.3.2 Addressing the Line Module for SINAMICS S120

Creating I/O variables

In the SIMOTION user project, two I/O variables with the configured Line Module I/O addresses must be created for the purpose of reading the status word (ZSW) and writing the control word (STW) of the configured Line Module.

The I/O variables must be created in the symbol browser in SIMOTION SCOUT. You are free to choose any names for them. The following shows an example of an Active Line Module created as I/O variable **myperiInAlm** and **myperiOutAlm** . These are also used in the application example: refer to the chapter titled Example of an application (Page 6122).

Activated symbolic assignment

In the case of **activated symbolic assignment,** create the I/O variables in the address list as follows:

1. Create two I/O variables in the address list (e. g. **myperiInAlm** and **myperiOutAlm**), see Figure "Assigning an I/O variable".
2. The status word must be assigned to the I/O variable **myperiInALM**. For this purpose, select the entry "IN" as the I/O address and under data type select the entry "empty" or WORD. In the "Assignment" column, click on the "**...**" button.

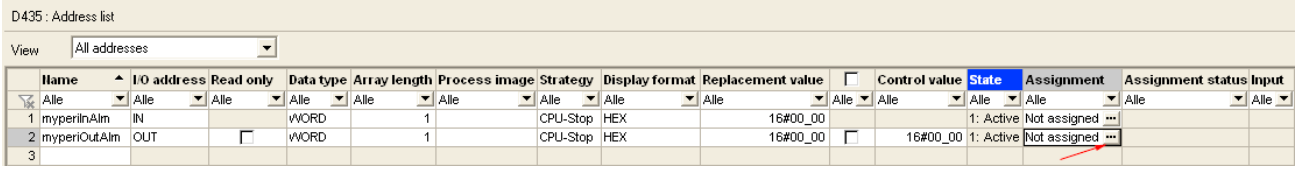

Figure 8-8 Assigning an I/O variable

The "Assigning myperiInALM" window opens.

3. Highlight the status word under infeed and confirm by pressing "OK".

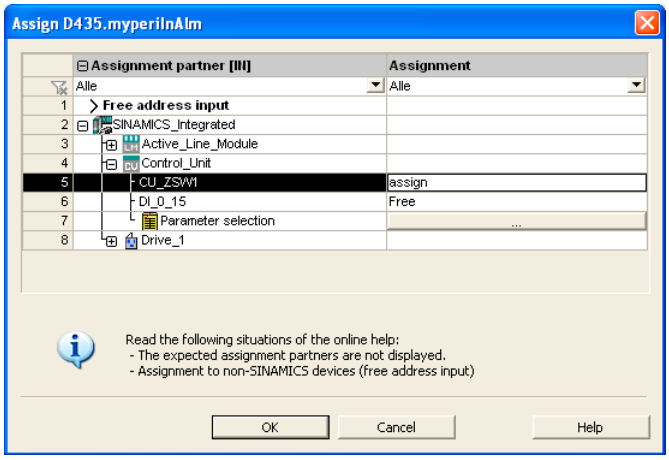

Figure 8-9 Highlighting the status word

The I/O variable is assigned to the status word.

4. Repeat steps 2 to 3 for assigning the control word with the I/O variable **myperiOutAlm**. The I/O variables are now assigned to the status and control word.

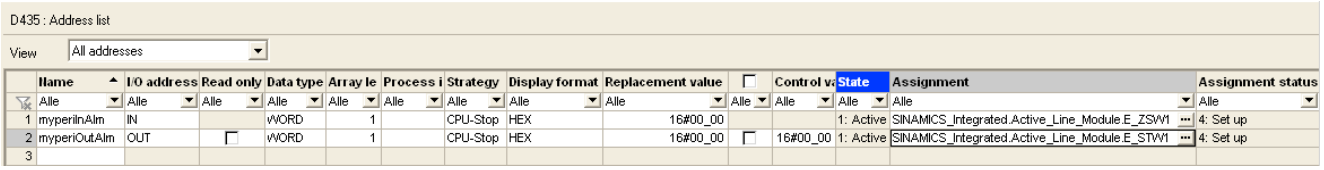

Figure 8-10 Assigned I/O variables in the address list

Continue with the chapter entitled Parameter transfer at FB _LineModule_control (Page 6109).

Deactivated symbolic assignment

In the case of **deactivated symbolic assignment,** proceed as follows to determine the addresses of the Line Module:

1. In the project navigator, double-click "Communication" followed by "Message frame configuration" underneath the SINAMICS drive unit.
2. The "PZD message frames" window opens. Check whether message frame 370 is selected for the infeed. Click on "Set up address". The assigned addresses of the message frames are then displayed. Select the start address for the input data (see figure below).

Example

Determining the addresses from the message frame configuration of the SINAMICS drive unit (using an ALM as an example):

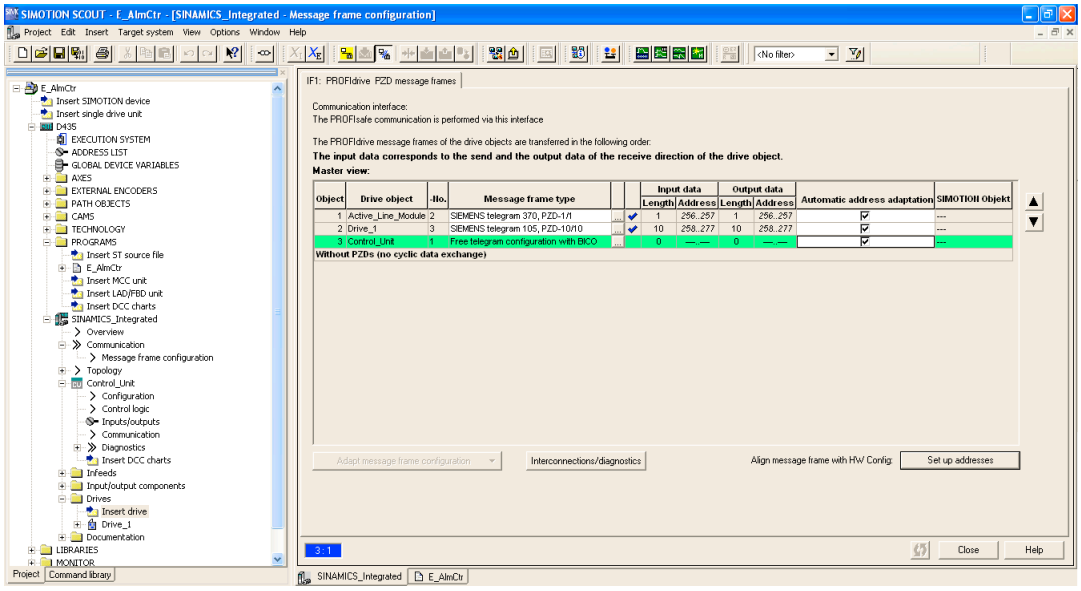

Figure 8-11 Message frame configuration addresses

Creating the I/O variables in the symbol browser:

	Name	I/O address	Read only	Data type	Array length	Process image	Strategy	Display	Replacement value		Control value
	Alle	Alle	Alle	Alle	Alle	Alle	Alle	Alle	Alle	All	Alle
1	myperiInAlm	PIW 256		WORD	1		CPU-Stop	HEX	16#00_00		
2	myperiOutAlm	PQW 256		WORD	1		CPU-Stop	HEX	16#00_00		16#00_00
3											

Figure 8-12 Addressing with I/O variables (example)

Note

Make sure that the addresses are accepted correctly from the message frame configuration. In your user project, when the **_LineModule_control** FB is called you must assign these two I/O variables to the **periIn** and **periOut** input/output parameters. Only once you have done this will the Line Module status word that has been read be transferred to the FB, and the output data prepared by the FB for the control word be transferred to the Line Module.

8.4.3.3 Parameter transfer at FB _LineModule_control

The I/O variable for the I/O inputs (status word) must be transferred to the **periIn** input parameter.

The prepared data for the I/O outputs (control word) are supplied by the **_LineModule_control** FB at the **periOut** output parameter. The **periOut** output parameter must be assigned to the I/O variable for the I/O outputs.

At the **typeLM** input parameter, specify the type of Line Module to be controlled.

8.4.4 Programming

8.4.4.1 _LineModule_control function block

Overview of _LineModule_control FB

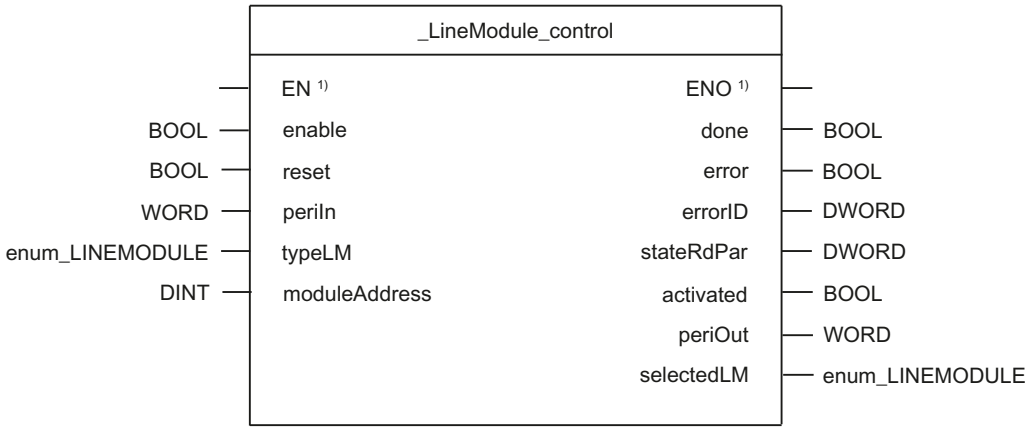
Task

You can use the **_LineModule_control** FB to switch on and off infeeds (Line Modules) for SINAMICS S120 with a DRIVE-CLiQ connection via your user program.
The **_LineModule_control** FB transfers the commands to the selected Line Module, reads the response data provided, and monitors the status signals from the Line Module.

Note

From SIMOTION V4.2 onward, the symbolic assignment is activated as standard for newly created projects. For this purpose, no message frames must be configured for the infeed. If the symbolic assignment is deactivated, SIEMENS message frame 370 must be configured.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

The table below contains all the parameters of the **_LineModule_control** FB.

Table 8-22 Parameters of the _LineModule_control FB

Name	P type [1)]	Data type	Default	Meaning
enable	IN	BOOL	FALSE	Switch line module on/off **TRUE** = Depending on the **typeLM** input parameter, the line module type is determined and the line module is then switched on (FALSE → TRUE status change) **FALSE** = Switch off
reset	IN	BOOL	FALSE	Acknowledge pending errors with rising edge
periIn	IN	WORD	16#0000	The I/O variable for the status word read from the line module is assigned to this input parameter, see Section Parameter assignment / addressing (Page 6107)
typeLM	IN	enum_ LINEMODULE	NOT_DEFINED	• Selection of line module to be controlled: ACTIVE_LINE_MODULE = 1 SMART_LINE_MODULE = 2 BASIC_LINE_MODULE = 3 • Automatic detection of line module type: AUTO_DETECT = 4 (only recommended in exceptional cases) The typeLM input parameter can only be changed when the line module is switched off. If the **typeLM** input parameter is changed in the activated state, there is no reaction. Only after deactivation (enable=FALSE) and subsequent activation (enable=TRUE) is the value in the **typeLM** input parameter taken over.
moduleAddress	IN	DINT	0	Logical address of the line module Only required if **typeLM** = AUTO_DETECT.
done	OUT	BOOL	FALSE	Job completed without errors. Signal present for just one cycle.
error	OUT	BOOL	FALSE	Line module error status **TRUE** = error during the request processing
errorID	OUT	DWORD	16#00000000	Specification of the error For **error** = **TRUE**, the **errorID** parameter contains the error information (refer to the "Error messages" table)
stateRdPar	OUT	DWORD	16#00000000	Error messages or status messages of system function _readDriveParameter() Only relevant if **typeLM** = AUTO_DETECT.
activated	OUT	BOOL	FALSE	Line module operating state: **TRUE** = line module switched on **FALSE** = line module switched off

Name	P type [1)]	Data type	Default	Meaning
periOut	OUT	WORD	16#0000	This output parameter must be linked with the I/O variable for the line module control word; refer to Section Parameter assignment / addressing (Page 6107).
selectedLM	OUT	enum_ LINEMODULE	NOT_DEFINED	Selected or automatically detected line module: • NOT_DEFINED = 0: – If the readDriveParameter() system function was not completed without errors. – If no line module type was selected at the **typeLM** input parameter on a rising edge at the **enable** input parameter. The **activated** output parameter is also set to FALSE in this status. • ACTIVE_LINE_MODULE = 1 • SMART_LINE_MODULE = 2 • BASIC_LINE_MODULE = 3

[1)] Parameter types: IN = input parameter, OUT = output parameter

Function description

At the **typeLM** input parameter, specify the type of Line Module to be controlled. In exceptional cases, e.g. generic blocks for modular machines, automatic detection of the Line Module can also be configured.

At the **selectedLM** output parameter, the selected Line Module or the Line Module determined in the **_LineModule_control** FB is displayed.

A rising edge at the **enable** input parameter switches on the Line Module.

The switch from TRUE to FALSE at the **enable** input parameter switches off the Line Module. Errors present at the **error** output parameter must be acknowledged with a rising edge at the **reset** input parameter. Only the error is acknowledged. Once the error has been successfully acknowledged, the Line Module must be switched on again using a rising edge on the **enable** input parameter. The Line Module will not be switched on if errors are present (**error** = TRUE) while there is a rising edge at the **enable** input parameter. The error must be acknowledged first.

The error reset and the enable can also be executed together. Setting **enable** and **reset** from FALSE to TRUE simultaneously first acknowledges a pending error and then switches on the Line Module.

- If an error has been acknowledged with **reset** = TRUE and no others errors are pending, **error** = FALSE and **errorID** = 0.
- If an error is still present, **error** = TRUE remains and the **errorID** will be updated.

Manual selection of the Line Module

Select the Line Module to be controlled via the parameter **typeLM** :

- **typeLM** = ACTIVE_LINE_MODULE
- **typeLM** = SMART_LINE_MODULE
- **typeLM** = BASIC_LINE_MODULE

If no errors are present, the Line Module selected at the **typeLM** input parameter will be switched on when there is a rising edge at the **enable** input parameter.
The **_LineModule_control** FB does not check the selected Line Module. The _readDriveParameter() system function is not called in the **_LineModule_control** FB. The FB does not evaluate the **moduleAddress** input parameter in this case.

Automatic detection of the Line Module (only in exceptional cases)

General information

In exceptional cases, e.g. generic blocks for modular machines, automatic detection of the Line Module type can be configured:

typeLM = AUTO_DETECT

Note

When using this function, you must take potential programming conflicts with other parallel DPV1 jobs into account, e.g. from the library functions used. Manual selection is recommended for familiar Line Module types.

If the user sets the **typeLM** input parameter to AUTO_DETECT, the **_LineModule_control** FB automatically detects the type of Line Module once when there is a rising edge at the **enable** input parameter. In this mode, the _readDriveParameter() system function is called internally in the FB and the type of Line Module is determined by means of a parameter request. For this function, the configured Line Module address must also be specified at the **moduleAddress** input parameter (see Section "Determining the Logical Address of the Line Module"). Otherwise, the _readDriveParameter() system function called by the **_LineModule_control** FB will signal an error. In the case of error "50001" at the **errorID** output parameter, the **stateRdPar** output parameter will contain specific information on the error from the _readDriveParameter() system function.

Note

You must ensure that only one parameter request is ever active for each drive unit (e.g. SINAMICS Integrated, CU320, CX32). Otherwise, conflicts with other DPV1 jobs may arise, e.g. from the library functions used. Any additional requests sent to the same drive unit will be rejected with the error 16#FFFF81C7 (on output parameter functionResult of the parameter job or on output parameter **stateRdPar** of the **_LineModule_control** FB).

In the case of automatic Line Module detection, no parameter requests from the user program may be active at the drive unit of the Line Module when there is a rising edge at the **enable** input

parameter. If the Line Module type cannot be determined automatically, an error is generated and the Line Module is not switched on.

You can recognize an active parameter request in the **_LineModule_control** FB from the values 0x00007001 or 0x00007002 in the **stateRdPar** output parameter.

The values 0x0000000 or FFFF8xxx (parameter request aborted with an error) in the **stateRdPar** output parameter indicate that the **_LineModule_control** FB is not processing any parameter requests internally.

For additional information on acyclic reading and writing of parameters (using DP-V1 services) with the _readDriveParameter() system function, please refer to the *SIMOTION Communication* System Manual, as well as the *SIMOTION D4x5* Commissioning and Hardware Installation Manual, Section "Acyclic communication with the drive".

Effect of the _readDriveParameter() system function in the _LineModule_control FB

The _readDriveParameter() system function enables the **_LineModule_control** FB to determine the type of Line Module when **typeLM** is set to AUTO_DETECT. For this purpose, the system function reads out parameter r107 of the Line Module. Parameter r107 indicates the Line Module type.

The parameter is read out once before the start of the Line Module switch-on sequence.

Once the Line Module type has been successfully read out, the switch-on sequence is executed.

If the Line Module type is read out incorrectly, the **error** output parameter is set to TRUE, the **selectedLM** output parameter is set to NOT_DEFINED, and the switch-on sequence is not started. Additionally, more detailed information on the error is specified in the **errorID** and **stateRdPar** output parameters.

Requirement for reading out the Line Module type/call:

The _readDriveParameter() system function call starts when there is a rising edge at the **enable** input parameter and **typeLM** is set to AUTO_DETECT for the **_LineModule_control** FB. The system function is called repeatedly until either 0x00000000 (OK) or 0xFFFF8xxx (parameter request aborted with error) is signaled at its output parameter, functionResult.

During the read process, the values 0x00007001 (first call) or 0x00007002 (intermediate call) are output (parameter request active).

All values of the functionResult output parameter of system function _readDriveParameter() are output in exactly the same format at the **stateRdPar** output parameter of the **_LineModule_control** FB. The error functionResult = 0xFFFF81C7 (parameter request active) is an exception to this rule. This error is only output once a timeout has expired at the output parameters of the **_LineModule_control FB** (see the "Timeout behavior" description below).

You can use the **stateRdPar** output parameter to execute (start/end) reading of the internal FB parameters.

Timeout behavior in relation to the _readDriveParameter() system function:

If a parameter request from a user or from the SIMOTION device is already active at the Line Module (functionResult = 0xFFFF81C7 error message), the parameter is read out repeatedly within a timeout period of 1 s.

The **stateRdPar** output parameter of the **_LineModule_control** FB remains at value 0x00007002 during the repeated readout process taking place within the timeout.

The parameter is only read again if there is a functionResult = 0xFFFF81C7 error. If the system function signals any other errors, an error is output immediately at the **_LineModule_control** FB and the parameter reading process is aborted with the **_readDriveParameter** system function.

If the functionResult = 0xFFFF81C7 error is still present once the timeout period has elapsed, the following error is output at the output parameters of the **_LineModule_control** FB:

error = TRUE
errorID = 50001
stateRdPar = 0xFFFF81C7
selectedLM = NOT_DEFINED

Output parameters in relation to the _readDriveParameter() system function:

Table 8-23 Output parameters in relation to _readDriveParameter():

Parameters of the _LineModule_control FB	Task
stateRdPar	Output the functionResult output parameter of the _readDriveParameter() system function
selectedLM	Output the Line Module type determined If a parameter has been assigned incorrectly (e.g. the wrong module address) or an error occurs during parameter reading, this output parameter will be set to NOT_DEFINED.

Determining the logical address of the Line Module

If you are using the automatic detection method, you need to assign a value for the module address (logical address) of the Line Module at the **moduleAddress** input parameter of the **_LineModule_control** FB (see Chapter Determining the module address (Page 6115)).

Determining the module address

To select a diagnostic interrupt in the PeripheralFaultTask, the module address (logical address) of the Line Module must be determined and made readily available in a variable.

In the case of activated symbolic assignment, determine the module address using the system function **_getLogicalAddressOfIoVariable** from the name of the I/O variable for the status or control word of the Line Module.

In the case of deactivated symbolic assignment, proceed in the same way as for determining the addresses of I/O variables, but this time determine the module address for the status and control word of the Line Module. Use the same address value (start address of input data) in the same way as for I/O variables for the status and control word of the Line Module, see Addressing the Line Module for SINAMICS S120 (Page 6107).

Graphical overview of the functionality

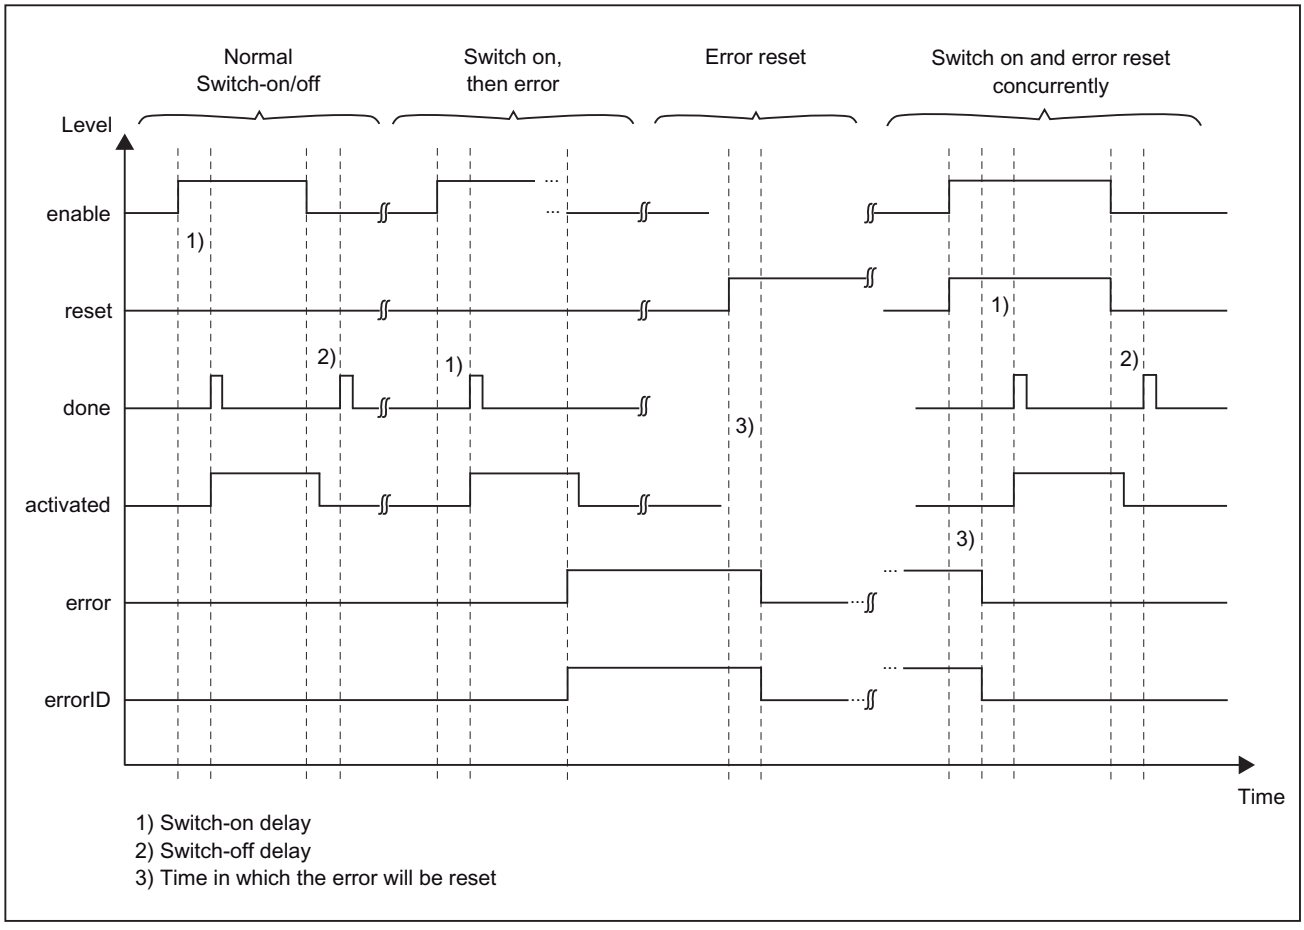


Figure 8-13 Signal propagation diagram

Task integration (call)

The **_LineModule_control** FB is designed to be called in a cyclic task and must be called in this task during each task pass. Processing a job can take several cycles. The user decides which cyclic task of the **_LineModule_control** FB the call is made in. No restrictions are applied with respect to the functionality of the **_LineModule_control** FB.

8.4.4.2 Calling the function block

Procedure

Proceed as follows to work with the **_LineModule_control** function block in your user project (the numbers shown in the program segment below correspond to the steps listed):

1. Create an instance of the **_LineModule_control** function block.
2. Call the function block instance and transfer input parameters.

3. The output parameters of the function block are accessed with <instance name of FB>.<name of output parameter>.
4. The data for the I/O outputs (control word of the Active Line Module) prepared by the FB must be assigned by the user program to the I/O variables for the purpose of writing the control word. It is recommended that you use the _setSafeValue system function for this assignment task.

Note

The program segment is an extract from the application example supplied. The application example is included on the "SIMOTION Utilities & Applications" DVD and is available for various SIMOTION hardware platforms.

"SIMOTION Utilities & Applications" is provided free of charge and as part of the SIMOTION SCOUT scope of delivery.

Note

For additional information, see the following sources:

- *SIMOTION SCOUT* online help
- Programming manual of the corresponding programming language, e.g.:
  - *SIMOTION ST*, *Structured Text* programming manual
  - *SIMOTION MCC*, *Motion Control Chart* programming manual
  - *SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram* Programming Manual

These documents are provided as part of the SIMOTION SCOUT scope of delivery in electronic format.

END_IMPLEMENTATION
```

8.4.4.3 Error messages

The value **TRUE** at the **error** output parameter indicates an error status in the Line Module. More details of the error are provided at the **errorID** output parameter. The assignment of the error cause is made in this output parameter.

If an internal Line Module (200xx group) fault occurs, the user must read out the exact cause using the appropriate SIMOTION system functions, e.g. **_readDriveFaults**.

For a detailed description of the system functions, refer to the *SIMOTION System Functions/ Variables Device* Parameter Manual. This document is provided as part of the SIMOTION SCOUT scope of delivery in electronic format.

Error groups

The errors signaled in the **errorID** output parameter may be allocated to the following error groups:

Group 100xx:	A time-out is present. The Line Module does not respond to the **_LineModule_control** FB commands, or responds too late.
Group 200xx:	An internal Line Module fault is present. "Fault active" bit of the Line Module status word = **TRUE** The exact cause of the error must be read out using the appropriate SIMOTION system functions (e.g. **_readDriveFaults**).
Group 300xx:	The Line Module has withdrawn the "Controlled by PLC" bit in the status word during operation.
Group 400xx:	An error occurred during a **reset**.
Group 500xx:	An error occurred during the execution of the _readDriveParameter() system function used internally by the **_LineModule_control** FB. More detailed error information can be obtained from the **statusRdPar** output parameter.

Error messages

Note

Statuses S1 to S4 are contained in the **errorID** output parameter while the Line Module is in the process of being switched on or off.

You can find the meanings of the statuses (S1 to S4) described in the table below in the Appendix Flow diagrams for switching the Line Modules on and off (Page 6125).

For explanations relating to the status and control word of SINAMICS S120 Line Modules, refer to the

- *SINAMICS S120 Drive Functions* Function Manual
- *SIMOTION D4x5* Commissioning and Hardware Installation Manual

These documents are provided as part of the SIMOTION SCOUT scope of delivery in electronic format.

The error groups and error messages listed below are to be viewed as being in decimal format.

Table 8-24 Error messages

Error no. (errorID), decimal	**Meaning**
100xx	Timeout during the status transition of the Line Module. • 1000x: Time-out when switching on: Status x (S1...S4) was not attained. • 100x0: Time-out when switching off: Status x (S1...S4) was not attained. **Example:** 10030: Time-out error when switching off. Status S3 was either not attained at all or attained too late.
200xx	The Line Module reports an internal fault using the "Fault active" bit of the status word. • 2000x: Internal fault when switching on: Status x (S1...S4) was not attained. • 200x0: Internal fault when switching off: Status x (S1...S4) was not attained. **Example:** 20002: Internal fault when switching on: In status S2. The exact cause of the error must be read out using the appropriate SIMOTION system functions (e.g. _readDriveFaults).
30000	While there was a rising edge on the **enable** input parameter, the "Controlled by PLC" bit in the status word of the Line Module was set to **FALSE**. This means that the command could not be performed.
300xx	The Line Module has reset the "Controlled by PLC" bit in the status word. The FB resets all bits in the Line Module control word and waits for new commands. • 3000x: The "Controlled by PLC" bit in the status word was reset to Status x (S1...S4) when switching on. • 300x0: The "Controlled by PLC" bit in the status word was reset during operation or when switching off to Status x (S1...S4). **Example:** 30002: The "Controlled by PLC" bit in the status word was reset during switching on to Status S2.
40001	While there was a rising edge on the **reset**input parameter, the "Controlled by PLC" bit in the status word of the Line Module was set to **FALSE**. This means that the command could not be performed.
40003	While there was a rising edge on the **reset** input parameter, the Line Module did not reset the "Fault active" bit in the status word, even though the "Acknowledge error" bit was set in the control word.
50001	Only relevant if input parameter **typeLM** = AUTO_DETECT An error occurred during the execution of the _readDriveParameter() system function. Evaluate the **statusRdPar** output parameter. Information on the errors can be found in the *SIMOTION System Functions/Variables Device* List Manual.

Error correction

Use the methods outlined below to correct pending errors.

Table 8-25 Information on correcting pending errors

Check the diagnostics LEDs on the Line Module and all SINAMICS components. • Check the RDY LED. • Check the DC-LINK LED. For descriptions of all the LEDs, please refer to the *SINAMICS S120 Booksize Power Units* Manual.
Check the communication between SIMOTION and the connected Line Module. Has SIEMENS message frame 370 been configured for the connected Line Module? See Section Parameter assignment / addressing (Page 6107)
Check the programming for the _LineModule_control FB. • Does the symbol browser in your project contain one I/O variable for reading the status word and one for writing the control word? • Is the I/O variable for reading the status word assigned to input parameter **periIn**of the **_LineModule_control** FB? • Is output parameter **periOut** assigned to the I/O variable for writing the control word after the **_LineModule_control** FB is called? • Is the **_LineModule_control** FB called in a cyclic task and run during each cycle? See Section Parameter assignment / addressing (Page 6107)
Check whether the connected Line Module has signaled any errors. • Check the error messages in the "Alarms" window of SIMOTION SCOUT. • In the Line Module expert list, check the error messages in the following parameters: p945 (fault code) p947 (fault number) p2131 (current fault code) • Check the error messages via the user program, using the _readDriveFaults() system function. For information on the causes of the errors read and how to remedy them, please refer to the *SINAMICS S* List Manual and the *SIMOTION SCOUT* online help. On SIMOTION Utilities & Applications, you will also find a DPV1 library containing a function block for reading drive fault and warning messages. SIMOTION Utilities & Applications is provided as part of the SIMOTION SCOUT scope of delivery.
Check the entries in the SINAMICS diagnostics buffer (D4x5 SINAMICS Integrated/CX32: SIMOTION V4.1 SP2 and higher; CU320: SINAMICS Firmware V2.6 and higher) 1. Right-click the SINAMICS device in the SIMOTION SCOUT project navigator. 2. Select "Target device" > "Device Diagnostics" from the context menu and open the "Diagnostics buffer" tab.

Check the status of the SINAMICS drive. **Line Module:** 1. Open the Line Module expert list in SIMOTION SCOUT. 2. Check the following parameters: r2 (status display) p10 = 0 (commissioning parameter filter) r46 (missing enables) **Control Unit:** 1. Open the Control Unit expert list in SIMOTION SCOUT. 2. Check the following parameters: r2 (status display) p9 = 0 (device commissioning parameter filter)
Check the Line Module wiring. • Check the supply voltage for the connected Line Module. • Check the supply voltage at the EP terminals. • Check the DRIVE-CLiQ topology. • Check the wiring of the Active Interface Module (if present).

8.4.5 Example of an application

8.4.5.1 General

Task

The application example shows:

- How you can use the **_LineModule_control** FB to switch a Line Module on and off. This is shown using the example of an ALM.
- How error statuses are signaled by the **_LineModule_control** FB, and how you can reset the errors.
- Additional ALM diagnostic information.

The application example contains the following programs:

Table 8-26 Application example programs

Program	Task	Meaning
StartUpALM	StartupTask	Program for start-up
PeripheralFaultALM	PeripheralFaultTask	Program for handling diagnostic alarms
BackGrndALM	BackgroundTask	Program for switching the ALM on and off

Structure of the example

In the application example, an Active Line Module (ALM) is used as the infeed. The application example is structured as follows:

- Type declarations
- Variable definitions
- Variable initialization
- Switch-on sequence
- Switch-off sequence
- Evaluation of diagnostic alarms in the **PeripheralFaultTask**

Hardware platform

The application example is available for various SIMOTION hardware platforms.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" DVD. "SIMOTION Utilities & Applications" is provided free of charge and as part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the axis configuration:
3. If necessary, modify the example project.
4. Save and compile the example project. You can then download the example to the SIMOTION device and switch to RUN mode.

Adapting the application example

The address of the Line Module in the frame configuration must match the addresses of the I/O variables in the application example. To enable selection of a diagnostic interrupt in the PeripheralFaultTask, the address of the Line Module must be adapted in a subsequent variable.

You must adapt the following settings where necessary:

- Address of I/O variables **myperiInAlm** and **myperiOutAlm** (default: 256), see Chapter Addressing the Line Module for SINAMICS S120 (Page 6107)
- **myAlmModuleAddress**(default: 256)
  In the case of activated symbolic assignment, determine the module address via the system function **_getLogicalAddressOfIoVariable**, see Chapter Determining the module address (Page 6115).

8.4.5.2 Sequence of the application example

Relevant variables in the application example

Table 8-27 Overview of the relevant variables

Variable	Data type	Initial value	Meaning
mySwitchOn	BOOL	FALSE	**TRUE** = Start the switch-on sequence
mySwitchOff	BOOL	FALSE	**TRUE** = Start the switch-off sequence
myFirstRun	BOOL	TRUE	**TRUE** = Initialize the variables
myError	BOOL	FALSE	**TRUE** = Error on ALM or error during switching on/off
myErrorId	DWORD	16#00000000	Error specification
myDiagnosticAlarm	BOOL	FALSE	**TRUE** = Diagnostic alarm present on ALM
myProcessAlarm	BOOL	FALSE	**TRUE** = process alarm present
myAlmCtrl_In	Struct_AlmControlIn	-	Structure for input parameter of the **_LineModule_control** FB
myAlmCtrl_Out	Struct_AlmControlOut	-	Structure for output parameter of the **_LineModule_control** FB
myperiInAlm	WORD	16#0000	I/O variable with ALM address for status word
myperiOutAlm	WORD	16#0000	I/O variable with ALM address for control word
myAlmModuleAddress	DINT	256	ALM address for selection of diagnostic alarm in **PeripheralFaultTask**
myPftTsi	Struct_PeripheralFaultTaskTsi	-	Task start information for **PeripheralFaultTask**

StartUpALM program

In the StartUpAlm program, a flag for the initial run is set and then evaluated in the BackgroundTask. This allows for the implementation of a standard start-up sequence for not only the STOP – RUN transition, but also an appropriate user request.

BackGrndALM program

The BackGrndALM program contains 2 program sequences for switching the Active Line Module on and off. In both sequences, the switch-on/switch-off procedure is monitored for errors and tested to ensure it has completed successfully.

The switch-on procedure for the ALM is initiated using a positive edge on the **mySwitchOn** variable. The steps that follow involve testing the switch-on procedure to ensure it has completed successfully and checking it for errors. The **mySwitchOn** variable is set to FALSE once the switch-on procedure has begun.

The switch-off procedure for the ALM is initiated using a positive edge on the **mySwitchOff** variable. The value of the **mySwitchOff** variable is then set to FALSE. The step that follows involves testing the procedure to ensure it has completed successfully and checking it for errors.

Any errors that occurred during processing are displayed in the **myError** and **myErrorId** global variables and can be reset using the **myAlmCtrl_In.reset** variable.

PeripheralFaultALM program

If the module triggering an error is the ALM, the start information for the **PeripheralFaultTask** is written to the **myPftTsi** global variable. If the start information evaluation produces a diagnostic or process alarm signaled by the ALM, this is displayed in the **myDiagnosticAlarm** or **myProcessAlarm** global variable.

8.4.6 Appendix

8.4.6.1 Flow diagrams for switching the Line Modules on and off

Overview

The flow diagrams below describe the statuses (S1 to S4) present while the Line Module is ramping up.

The Line Modules are switched off using the same procedure used to switch them on, but in the reverse order.

Note

For explanations relating to the status and control word of SINAMICS S120 Line Modules, refer to the

- *SINAMICS S120 Drive Functions* Function Manual
- *SIMOTION D4x5* Commissioning and Hardware Installation Manual

These documents are provided as part of the SIMOTION SCOUT scope of delivery in electronic format.

Flow diagram for switching on the Active Line Module (ALM)

8.4.6.2 List of abbreviations / acronyms

Table 8-28 Abbreviations

Abbreviation	Meaning
ALM	Active Line Module
BLM	Basic Line Module
DRIVE-CLiQ	DRIVE Component Link with IQ
FB	Function block
IN	Input parameters
I/O	Input/output
LAD	Ladder diagram
LED	Light Emitting Diode
OUT	Output parameter
PLC	Programmable Logic Controller
PZD	Process data
SLM	Smart Line Module
STW	Control word
ZSW	Status word

8.5 Supplement to the CP 340 and CP 341 Modules

Preface

Contents of the function manual

This **document** is part of the **SIMOTION Programming References documentation package**.

This manual is a supplement to the following SIMATIC manuals:

- CP 340 Point-to-Point Communication, *Installation and Parameter Assignment*
- CP 341 Point-to-Point Communication, *Installation and Parameter Assignment*

These documents are included in the SIMOTION SCOUT scope of supply as electronic documentation!

This manual supplement will help you to integrate and start up the CP 340 and CP 341 communication processors in a SIMOTION system.

Differences in handling which result from the software architecture of a SIMOTION system as compared to the software architecture of a SIMATIC system will be described.

Function blocks

The function blocks for communication between the SIMOTION system and the CP 340 and CP 341 modules are part of the program library of the "SIMOTION SCOUT" engineering system.

Sections in this manual

The following chapters of this manual describe the function blocks (FBs) and data structures used in a SIMOTION system.

- General
  This chapter describes the differences and similarities in operation of the various CP modules.
- CP 340 function blocks
  This chapter describes the function blocks required for communication between a SIMOTION system and a CP 340.
- CP 341 function blocks
  This chapter describes the function blocks required for communication between a SIMOTION system and a CP 341.
- Alarm processing
  This chapter describes the differences in alarm processing in the SIMOTION system compared to the SIMATIC system.
- SIMATIC and SIMOTION Names
  This appendix contains a comparison of SIMATIC and SIMOTION names.
- The index allows you to locate information quickly.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

http://www.siemens.com/motioncontrol/docu

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

8.5.1 Fundamental safety instructions

8.5.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.5.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.5.2 Description

8.5.2.1 General

This chapter describes the general differences between SIMOTION and SIMATIC systems in terms of the operation of the CP 340 / CP 341 communications processors and in terms of data transfer.

Note

This manual is a supplement to SIMATIC manuals *CP 340 Point-to-Point Connection, Installation and Parameter Assignment/CP 341 Point-to-Point Connection, Installation and Parameter Assignment*.

These documents are shipped with SIMOTION SCOUT in electronic form!

The following software versions are required for the standard functions described in this documentation:

- SIMOTION SCOUT V4.2 or higher
- SIMOTION Kernel V4.2 or higher

8.5.2.2 Product description

The communications processor (CP) enables data to be exchanged between your SIMOTION system and another communications partner.

Function blocks are required for data exchange between the SIMOTION device and the communications processors. The function blocks for the SIMOTION system are described in this manual; these function blocks are handled differently than the function blocks for SIMATIC S7.

Functionality of the CP 340 / CP 341

The functionality of the function blocks and the CPs in a SIMOTION system is the same as in the SIMATIC S7 with the exception of special protocols for the CP 341.

The special protocols for "Modbus Slave", "Modbus Master" and "Data Highway" for the CP 341 are **not** currently supported by SIMOTION function blocks. For detailed information, see the "CP 340 function blocks" and "CP 341 function blocks" chapters.

Possible applications

In addition to the possible applications described in SIMATIC manuals *CP 340 Point-to-Point Connection, Installation and Parameter Assignment and CP 341 Point-to-Point Connection, Installation and Parameter Assignment*, these communications processors (CPs) can also be used in a SIMOTION system. The communications processors can be used as centralized modules (on the SIMOTION C2xx only) or as distributed modules (SIMOTION C2xx, SIMOTION P350 and SIMOTION D4xx).

More than one CP 340/CP 341 can be used on one SIMOTION device.

The figure below shows the connection of an ET 200M distributed I/O device with IM 153-1 and CP 340 or CP 341 to a SIMOTION device (e.g. SIMOTION C2xx).

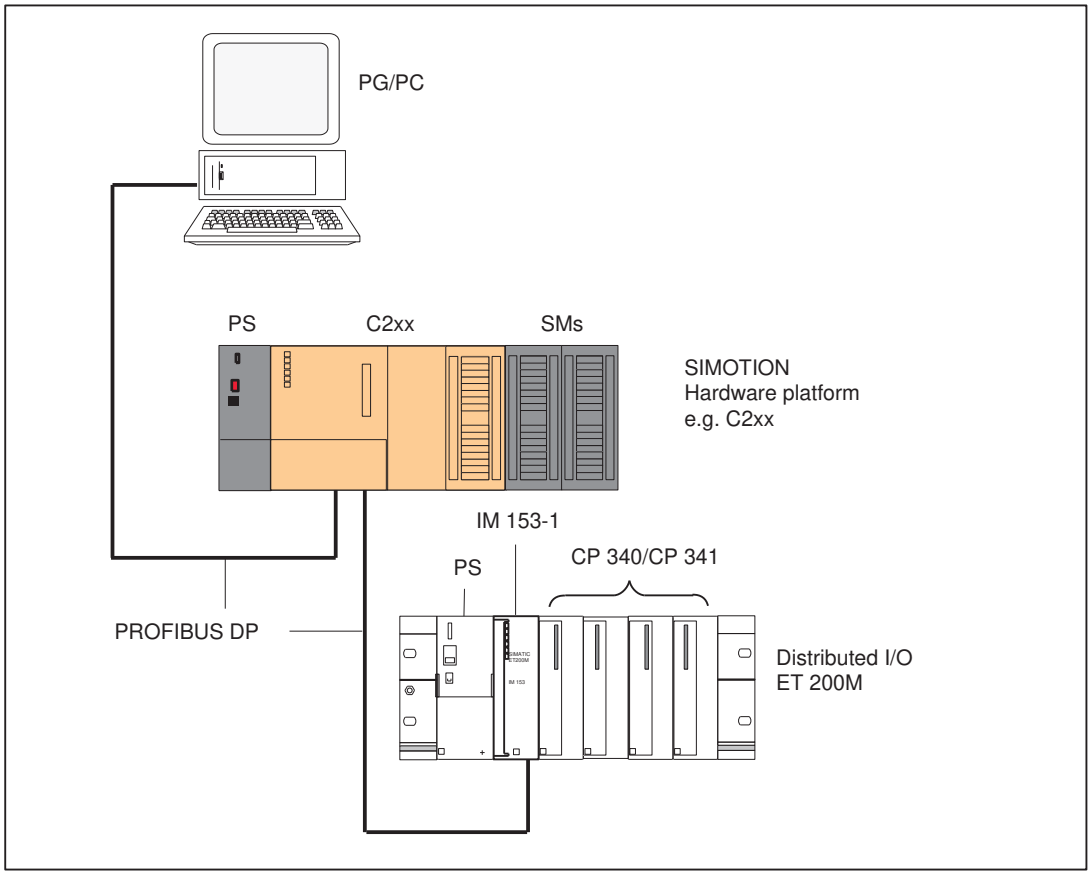

Figure 8-17 Connection of an ET 200M distributed I/O device with IM 153-1 and CP 340 or CP 341 to a SIMOTION C2xx (example of distributed application)

8.5.2.3 Setup and connection

Overview

The following sequence of operations is required to commission the CP 340/CP 341 and operate it under the control of the SIMOTION system:

Distributed application (SIMOTION C2xx, SIMOTION P350, and SIMOTION D4xx)

1. Assemble and install the cables for the ET 200M distributed I/O device complete with power supply (PS), interface module (IM) and communications processor (CP).
2. Establish the PROFIBUS connection between the ET 200M and the SIMOTION device.
3. Set the PROFIBUS DP node address on the IM.
4. Switch on the terminating resistor at the first and last bus node.

Note

For steps 1 to 4, refer to the *ET 200M Distributed I/O* manual.

This documentation is included in the SIMOTION SCOUT scope of supply as electronic documentation!

5. For inserting the communications processors CP 340 or CP 341 into the SIMOTION project, see Chapter Integrating the communications processors in the SIMOTION project (Page 6136).
6. Assign parameters for the CP 340/CP 341 communications processors.
   The SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment and CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manuals contain a description of how to install the parameter assignment interface for the CP 340 and 341 and how to assign parameters for the communications processors.
7. For integrating function blocks into the SIMOTION project, see Chapter Integrating the function blocks in the user project (Page 6137).

Centralized application (SIMOTION C2xx only)

1. For information on planning the mechanical installation and preparing and mounting the SIMOTION components, refer to the *SIMOTION C2xx* operating instructions and the *SIMATIC S7-300 Automation System, Software Installation* manual.
   These documents are shipped with SIMOTION SCOUT in electronic form!
2. To continue, refer to steps 5 to 7 for distributed application.

8.5.2.4 Integrating the communications processors in the SIMOTION project

Requirement

The following requirements must be met when networking with PROFIBUS:

1. You have created a project in SIMOTION SCOUT and have inserted a rack with a SIMOTION hardware platform in the hardware configuration.
2. You have configured a PROFIBUS subnet (for distributed use only).

Note

For how to create a project and configure a PROFIBUS subnet, refer to the online help of *SIMOTION SCOUT*.

The following requirements must be met when with PROFINET:

1. You have created a project in SIMOTION SCOUT and have inserted and configured a rack with a PROFINET-compatible SIMOTION device in the hardware configuration.
2. You have configured a PROFINET IO System (for distributed use only).

Note

For how to create a project and configure a PROFINET IO system, refer to the online help of *SIMOTION SCOUT*.

Inserting the CP 340/CP 341 (distributed application)

The description below is an example of networking via PROFIBUS.

1. In SIMOTION SCOUT, open the **User Projects** dialog box with the **Project > Open** menu command. In this dialog box, select your project and confirm your choice with **OK**.
2. Open **HW Config**.
3. In the **HW Config** window, open the **hardware catalog** with the **View > Catalog** menu command.
4. Open the **PROFIBUS DP** folder and the **ET 200M** subfolder in the hardware catalog. Select, for example, the **IM 153-1 interface module** (Article No.: 6ES7 153-1AA03-0XB0 or a successor module).
5. Use a drag-and-drop operation to place the IM 153-1 I/O device on the PROFIBUS subnet of your project. The **Properties - PROFIBUS IM 153-1 Interface** dialog box opens. In this dialog box, select the address you set on the IM 153-1 (see *ET 200M Distributed I/O Device* manual) and confirm with **OK**.
   The selected IM 153-1 I/O device is inserted in the project.

6. The inserted I/O device must now be fitted with your project modules. To do this, open the **CP 300** subfolder below the selected I/O device in the hardware catalog and select the relevant **CP modules**.

   Note

   Diagnostic alarms are not enabled by default. Activate the alarms for each module in the **Properties** dialog box.

7. **Save** and **compile** your project.

8.5.2.5 Integrating the function blocks in the user project

Creating an instance of the FBs in the user project

The function blocks are part of the program library of the SIMOTION SCOUT engineering system. For working with the blocks, an instance has to be created in the user project for each function block used.

Example:

```
VAR_GLOBAL
...
  myInstCP340Send  : _CP340_send;  // create FB instance
  myInstCP341Send  : _CP341_send;  // create FB instance
...
END_VAR
```

Call (LAD representation)

The LAD representation of the individual function blocks can be found in the respective function block descriptions.

Example of an application

The application example is included on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

8.5.2.6 Creating I/O variables

Overview

Communication between the SIMOTION device and the CP 340 and CP 341 takes place by means of direct I/O access and data set transfer. For data set transfer, the module address is transferred to the FB as an input parameter. I/O variables are used to address the direct read/write access to the I/O.

You can freely assign the names of I/O variables in SIMOTION SCOUT. I/O variables must be specified as ARRAY [0..15] of BYTE. You assign the address settings in the hardware configuration to these I/O variables.

The names of the I/O inputs must be transferred to the function blocks as call parameters (**periIn**). The prepared data for the I/O outputs are provided by the FB as in/out parameters (**periOut**). The in/out parameter must be supplied with a variable of type ARRAY [0..15] of BYTE. After the block is called, this variable must be assigned to the I/O variables for the I/O outputs (see Chapter Calling the CP 340 function blocks (Page 6167)).

Note

The variable for supplying the in/out parameters must not be created as a temporary variable (VAR_TEMP or local variable of a function).

The following example shows how to assign the module addresses to the I/O variables in SIMOTION SCOUT.

	Name	I/O address	Read only	Data type	Field length
1	⊞ myperipheralinputcp340	PIB 256		Array	16
2	⊞ myperipheraloutputcp340	PQB 256	☐	Array	16
3	⊞ myperipheralinputcp341	PIB 272		Array	16
4	⊞ myperipheraloutputcp341	PQB 272	☐	Array	16

Figure 8-18 Address assignment in SIMOTION SCOUT for two CP modules

Note

For additional information, see the following sources:

- *SIMOTION SCOUT* online help
- Programming Manual of the corresponding programming language, e.g.:
  - *SIMOTION ST, Structured Text* programming manual
  - *SIMOTION MCC, Motion Control Chart* programming manual
  - *SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram* programming manual

These documents are included in the SIMOTION SCOUT scope of delivery as electronic documentation.

8.5.3 CP 340 function blocks

8.5.3.1 Overview of the function blocks of the CP 340

This chapter contains a description of all of the function blocks (FBs) and the data structure required for communication between a SIMOTION device and a CP 340.

The function blocks form the software interface between the SIMOTION device and the CPs. They must be called repeatedly (in cycles) from the user program.

The following function blocks are available:

- _CP340_send function block (Page 6139)
- _CP340_receive function block (Page 6143)
- _CP340_printer function block (Page 6147)
- _CP340_getV24Signals function block (Page 6164)
- _CP340_setV24Signals function block (Page 6166)

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6231) in the table "SIMOTION and SIMATIC CP 340 identifiers".

SIMOTION SCOUT contains all of the required FBs and the **Struct_CP340_printData** data structure (for **_CP340_printer** function block only) of the CP 340. The function blocks can be used to control one or more CP 340 modules.

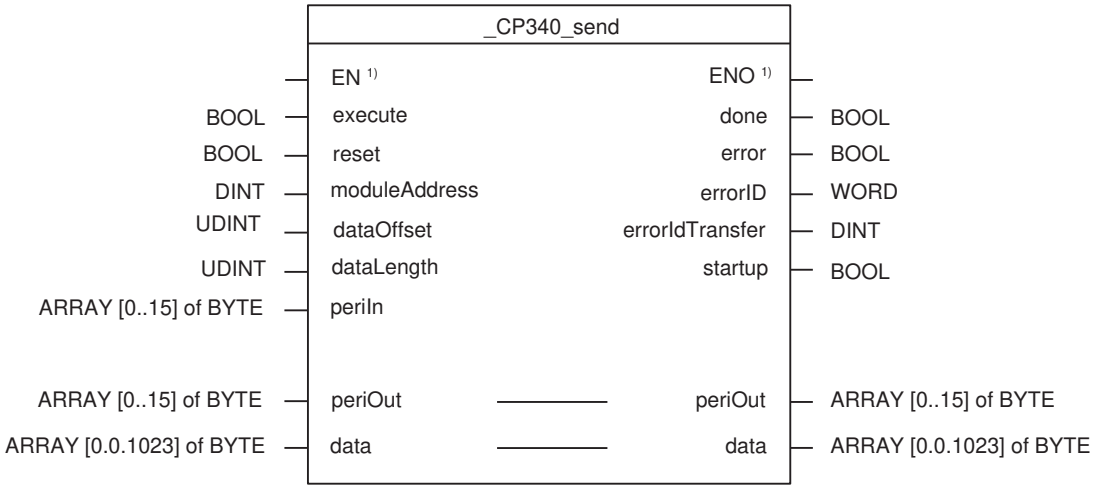
8.5.3.2 _CP340_send function block

Function

The **_CP340_send** function block enables you to send data from the **data** send array to a communications partner. You have 1,024 bytes available for this.

For the transfer, you can use the 3964 (R) protocol or ASCII driver.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-29 Parameters of the _CP340_send FB

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
execute	IN	BOOL	Initiates job on positive edge	Entered	Checked
reset	IN	BOOL	Cancels job	Entered	Checked
moduleAddress	IN	DINT	Module address of the CP for data set transfer (from HW Config)	Entered	Checked
dataOffset	IN	UDINT	Offset of the first element to be sent	Entered	Checked
dataLength	IN	UDINT	Number of elements to be sent	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
periOut	IN/OUT	ARRAY[0..15] of BYTE	Prepared FB data for the I/O outputs of the CP 2)	Checked and transferred to the I/O variable for the I/O outputs	Entered
data	IN/OUT	ARRAY[0..1023] of BYTE	Send data array	Entered	Checked
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered
errorID	OUT	WORD	Error specification For **error** = TRUE, the error information (event class and number) is displayed in the **errorID** parameter. 3)	Checked	Entered

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
errorIdTransfer	OUT	DINT	Error during data transfer between the CP and the SIMOTION device (detailed error diagnostics if 16#1E0F is present in the **errorID** parameter [4])	Checked	Entered
startup	OUT	BOOL	Indicates CP startup	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 340.

[3] For error information, refer to the SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 340"

[4] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

Signal sequence diagram of the _CP340_send FB

The following figure illustrates the behavior of the **done** and **error** parameters according to the input circuit of **execute** and **reset**.

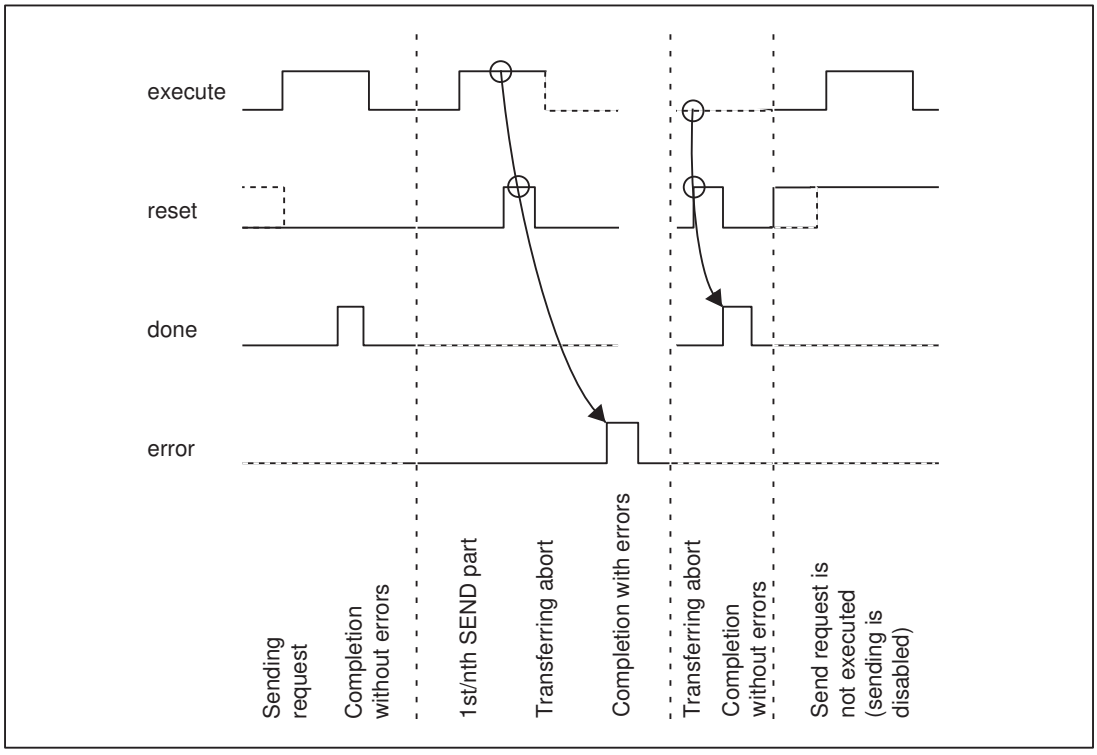


Figure 8-19 Signal sequence diagram of the _CP340_send FB

Note

The **execute** input is edge-triggered. The send job starts when there is a positive edge at the **execute** input.

Task integration (call)

The **_CP340_send** function block must be called cyclically in the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

The SIMOTION device sends data to a communications partner

The **_CP340_send** function block transfers a data block that is specified by the following parameters to the CP 340:

- **data** corresponds to the data array containing the send data
- **dataOffset** corresponds to the array index containing the first send byte
- **dataLength** corresponds to the amount of data to be sent in bytes

The **_CP340_send** FB must be called repeatedly by a program. The send job can only be executed by cyclically calling the send FB.

A positive edge at the **execute** input initiates the transfer. A data transfer operation can run over several calls, depending on the amount of data involved.

The active transfer job can be canceled by setting the **reset** parameter to "TRUE". This will reset the **_CP340_send** FB to its initial state. The send operation will remain disabled as long as the signal state at the **reset** parameter is "TRUE".

The **moduleAddress** parameter specifies the module address of the CP 340 being addressed.

Status and error display on the _CP340_send FB

The **done** output indicates that the job has been completed without errors. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/number is displayed in the **errorID** output (see "Parameters of the _CP340_send FB" table). If no errors have occurred, **errorID** has a value of 0. **Done** and **error**/**errorID** are also displayed for **reset** of the **_CP340_send** FB. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

The **done**, **error, errorID**, and **errorIdTransfer** parameters are available for one block call only.

Note

There is no parameter check for the **_CP340_send** function block. Incorrect parameterization of this block may cause the SIMOTION device to switch to "STOP" mode.

Before the CP 340 can process an initiated job following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP-SIMOTION startup mechanism of the **_CP340_send** FB must be complete. Any jobs initiated in the meantime will not be lost. They are transferred to the CP 340 once the startup coordination has finished.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

Assignment in the data area

The data to be sent is transferred to the **_CP340_send** FB in the **data** parameter (VAR_IN_OUT) as ARRAY of BYTE. At the beginning of the send operation, the data is copied to a local variable of the FB and transferred from there to the CP 340.

Note

Once the data have been entered in the static memory of the send FB, you can modify the variable created in the **data** parameter. This does not affect the data to be sent.

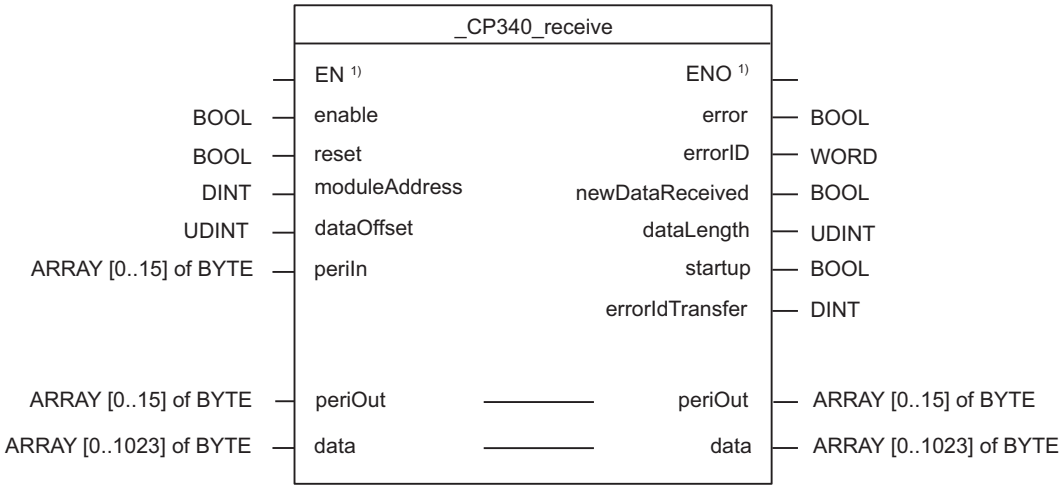
8.5.3.3 _CP340_receive function block

Function

The **_CP340_receive** function block enables you to receive data from a communications partner in the **data** receive field. You have 1,024 bytes available for this.

For the transfer, you can use the 3964 (R) protocol or ASCII driver.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-30 Parameters of the _CP340_receive FB

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
enable	IN	BOOL	Receive enable	Entered	Checked
reset	IN	BOOL	Cancels job	Entered	Checked
moduleAddress	IN	DINT	Module address of the CP for data set transfer (from HW Config)	Entered	Checked
dataOffset	IN	UDINT	Offset of the first element to be received	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
periOut	IN/OUT	ARRAY[0..15] of BYTE	Prepared FB data for the I/O outputs of the CP 2)	Checked and transferred to the I/O variable for the I/O outputs	Entered
data	IN/OUT	ARRAY[0..1023] of BYTE	Receive data array	Checked	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered
errorID	OUT	WORD	Error specification For **error**=TRUE, the error information (event class and number) is displayed in the **errorID** parameter.3)	Checked	Entered
newDataReceived	OUT	BOOL	Receive new data	Checked	Entered
dataLength	OUT	UDINT	Quantity of data received	Checked	Entered

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
startup	OUT	BOOL	Indicates CP startup	Checked	Entered
errorIdTransfer	OUT	DINT	Error during data transfer between the CP and the SIMOTION device (precise error diagnostics if 16#1E0F is present in the **errorID** parameter [4])	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 340.

[3] For error information, refer to the SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 340".

[4] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

Signal sequence diagram of the _CP340_receive FB

The following figure illustrates the behavior of the **newDataReceived**, **dataLength**, and **error** parameters according to the input circuit of **enable** and **reset**.

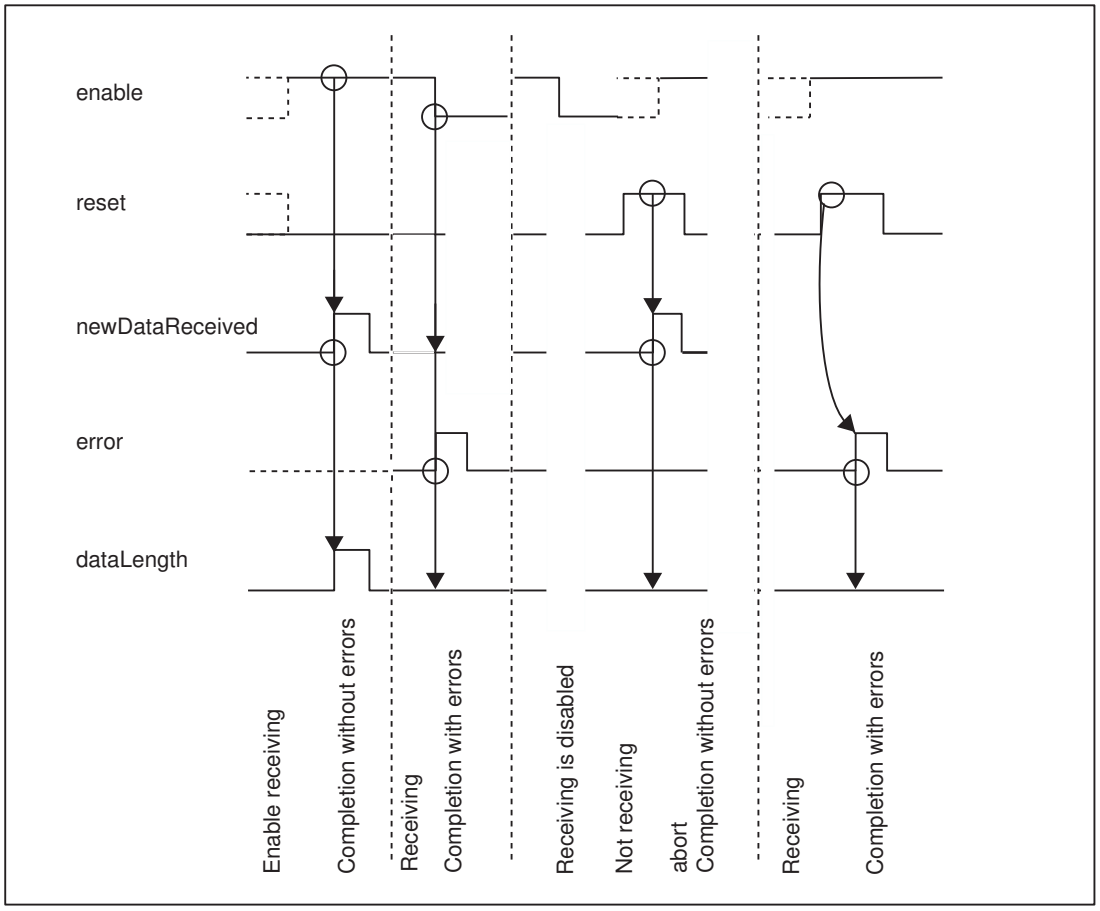


Figure 8-20 Signal sequence diagram of the _CP340_receive FB

Task integration (call)

The **_CP340_receive** function block must be called cyclically in the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

SIMOTION device receives data from a communications partner

The **_CP340_receive** FB transfers a data block that is specified by the **data** and **dataOffset** parameters from the CP 340 to a SIMOTION device. The **_CP340_receive** function block must be called repeatedly by a program. The receive job can only be executed by cyclically calling the receive FB.

Receiving of data is enabled with static signal state "TRUE" in the **enable** parameter. An active data transfer can be canceled with signal state "FALSE" in the **enable** parameter. The canceled receive job is terminated with an error message (**errorID** output). The receive operation will

remain disabled as long as the signal state at the **enable** parameter is "FALSE". A data transfer operation can run over several calls, depending on the amount of data involved.

The active transfer job can be canceled by setting the **reset** parameter to "TRUE". This will reset the **_CP340_receive** FB to its initial state. The receive operation will remain disabled as long as the signal state at the **reset** parameter is "TRUE".

The **moduleAddress** parameter specifies the module address of the CP 340 being addressed for the data set transfer.

Status and error display on the _CP340_receive FB

The **newDataReceived** output indicates that new data have been received without errors. The amount of data received is indicated in the **dataLength** parameter. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/number is displayed in the **errorID** output (see "Parameters of the _CP340_receive FB" table). If no error has occurred, **errorID** has the value "0". **newDataReceived** and **error**/**errorID** will also be output when the **_CP340_receive** FB is **reset**. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

The **newDataReceived**, **dataLength, error, errorID**, and **errorIdTransfer** parameters are available for one block passage only.

Note

There is no parameter check for the **_CP340_receive** function block. Incorrect parameterization of this block may cause the SIMOTION device to switch to STOP mode.

Before a job from the CP 340 can be received following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP SIMOTION startup mechanism of the **_CP340_receive**FB must be complete.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

Assignment in the data area

During the receive operation, the data to be received is stored temporarily in the FB. Once data transmission from the CP 340 to the SIMOTION device has been completed, the data is made available in the **data** parameter (VAR_IN_OUT) of the **_CP340_receive** FB.

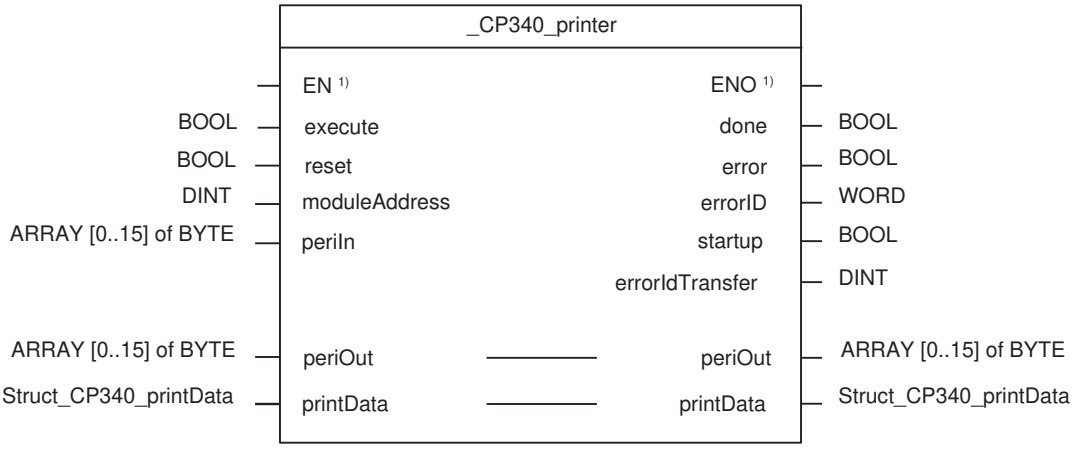
8.5.3.4 _CP340_printer function block

Description of the _CP340_printer FB

Function

The **_CP340_printer** function block is used to send data of type **Struct_CP340_printData** from the printer memory area to a serial printer. For example, the **_CP340_printer** function block might send a process message to the CP 340. The CP 340 prints out the process message on the connected printer.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-31 Parameters of the _CP340_printer FB

Name	P type 1)	Data type	Comment	Actions performed by user	Actions performed by block
execute	IN	BOOL	Initiates job on positive edge	Entered	Checked
reset	IN	BOOL	Cancels job	Entered	Checked
moduleAddress	IN	DINT	Module address of the CP for data set transfer (from HW Config)	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
periOut	IN/OUT	ARRAY[0..15] of BYTE	Prepared FB data for the I/O outputs of the CP 2)	Checked and transferred to the I/O variable for the I/O outputs	Entered
printData	IN/OUT	**Struct_CP340_printData**	Send data array (data to be printed)	Entered	Checked
Struct_CP340_printData (data structure) 5)					
variable		ARRAY[0..3] of Struct_CP340_dataRecord	Variable to be printed	Entered	Checked
format		ARRAY[0..150] of BYTE	Format string	Entered	Checked
Struct_CP340_dataRecord (data structure) 5)					
dataLength		UDINT	Quantity of data	Entered	Checked
data		ARRAY[0..31] of BYTE	Print data	Entered	Checked

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered
errorID	OUT	WORD	Error specification For **error**=TRUE, the error information (event class and number) is displayed in the **errorID** parameter.[3]	Checked	Entered
startup	OUT	BOOL	Indicates CP startup	Checked	Entered
errorIdTransfer	OUT	DINT	Error during data transfer to the CP (precise error diagnostics if 16#1E0F is present at the **errorID** parameter [4])	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 340.

[3] For error information, refer to the SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 340".

[4] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

[5] See "Message text structure", print storage area structure example

Signal sequence diagram of the _CP340_printer FB

The following figure illustrates the behavior of the **done** and **error** parameters according to the input circuit of **execute** and **reset**.

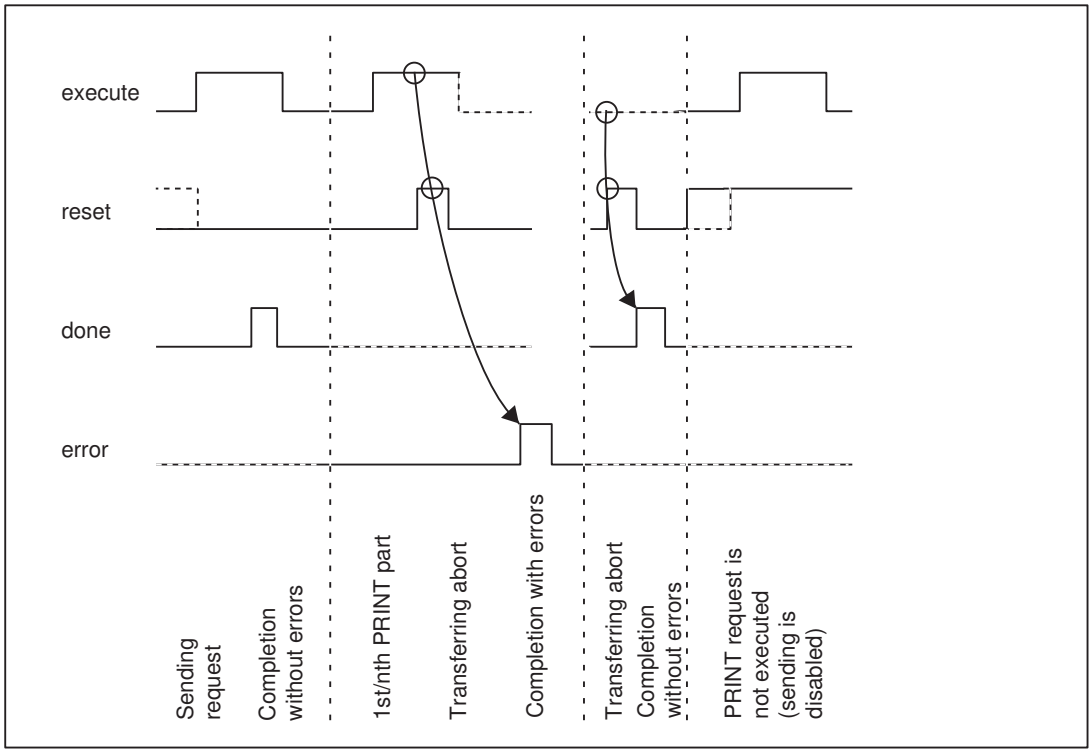


Figure 8-21 Signal sequence diagram of the _CP340_printer FB

Note

The **execute** input is edge-triggered. The send job starts when there is a positive edge at the **execute** input.

Task integration (call)

The **_CP340_printer** function block must be called cyclically in the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

The **_CP340_printer** function block is called repeatedly by a program. The print job can only be executed by cyclically calling the print FB.

A positive edge at the **execute** input initiates the transfer of the message text. A data transfer operation can run over several calls (program cycles), depending on the amount of data involved.

The active transfer job can be canceled by setting the **reset** parameter to "TRUE". This will reset the **_CP340_printer** FB to its initial state. The sending of print jobs will remain disabled as long as the signal state at the **reset** parameter is TRUE.

The **moduleAddress** parameter specifies the module address of the CP 340 being addressed for the data set transfer.

For call examples for the **_CP340_printer** FB, see Chapter CP 340 print call examples (Page 6160).

Status and error display on the _CP340_printer FB

The **done** output parameter indicates that the job has been completed without errors. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/ number is displayed in the **errorID** output parameter (see "Parameters of the CP340_printer FB" table). If no errors have occurred, **errorID** has a value of 0. **Done** and **error/errorID** are also displayed for **reset** of the **_CP340_printer** FB. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

The **done**, **error, errorID**, and **errorIdTransfer** parameters are available for one block call only.

Note

There is no parameter check for the **_CP340_printer** function block. Incorrect parameterization of this block may cause the SIMOTION device to switch to "STOP" mode. Before the CP 340 can process an initiated job following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP-SIMOTION startup mechanism of the **_CP340_printer** FB must be complete. Any jobs initiated in the meantime will not be lost. They are transferred to the CP 340 once the startup coordination has finished.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

Assignment in the data area

The print data is transferred to the **_CP340_printer** FB as a data structure of type **Struct_CP340_printData** and copied to a local variable of the FB at the beginning of the print operation.

Structure of printer memory of type Struct_CP340_printData

The four variables to be printed and the format string must be entered in a variable with the following data type:

Example:

```
Struct_CP340_dataRecord     : STRUCT
     dataLength : UDINT;                        // Data quantity
     data       : ARRAY [0..31] of BYTE;        // Data field
END_STRUCT

Struct_CP340_printData    : STRUCT
     variable   : ARRAY [0..3] of Struct_CP340_dataRecord;  // 1st to 4th variable
     format     : ARRAY [0..150] of BYTE;                   // Format string
END_STRUCT
```

The first variable to be printed corresponds to the **variable [0]** element, the second variable to be printed corresponds to the **variable [1]** element, etc. The number of bytes to be printed per variable is limited to 32. The data for variable **i** must be placed in variable [**i-1**].data[0..31]. The number of bytes to be printed must be entered in the **variable [i-1].dataLength** element.

The format string corresponds to the **format** element. The format string must be structured as follows (refer to the SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment* manual):

- Specification of string length in **format [0]**
- Specification of individual characters in **format [1 to 150]**

Note

If the maximum length is exceeded, the print job is canceled and event number 16#1E41 is indicated at the **errorID** parameter output of the **_CP340_printer** FB.

Entering variables and message texts in the printer memory area

Before the data transfer to the CP 340 begins, the variable values to be printed must be entered **byte by byte and in the proper format** in the **variable[].data** element of the data structure of type **Struct_CP340_printData** (see item 2 in the example below). The number of bytes for each variable (variable length) must be assigned to the **variable.datalength** element (e.g. WORD type variable - variable.datalength:=2). An entry corresponding to the data type of the value must be made in the **format** element for each value entered in the **variable** element. (e.g. WORD type variable - %I). The total length of the entries in the **format** element must be assigned to the **format[0]** element.

You configure message texts with the CP 340 "point-to-point connection" parameter assignment interface. Once the hardware configuration has been downloaded to the SIMOTION device, the message texts are stored in the CP 340. The message texts that have been saved can be selected with corresponding entries in the **variable** and **format** elements.

Note

You can use supplemental function blocks (see Chapter supplemental function blocks (Page 6154)) to enter values into the printer memory area and to select message texts.

Example:

- Print message text no. 3 (stored in CP 340).
  Configured message text: "This is message text no. 3"

```
myPrintData.variable[0].datalength := 1;
myPrintData.variable[0].data[0]    := 3;   // Message text no. 3
```

```
myPrintData.format[0]     :=2;      // Format string length
myPrintData.format[1]     :=16#25;  // "%" Format specification for message
text
myPrintData.format[1]     :=16#4E   // "N" Format specification for message
text
```

- Print message text no. 4 with a WORD-type variable.

```
Configured message text   : "This is message text no. %I"
Printed text          : "This is message text no. 4"

myPrintData.variable[0].datalength := 1;
myPrintData.variable[0].data[0]    := 4;  // Message text no.4

myPrintData.variable[1].datalength := 2;  // 2 Byte data type WORD
myPrintData.variable[1].data[0]    := 0   // High - Byte
myPrintData.variable[1].data[1]    := 4   // Low - Byte
myPrintData.format[0]              := 4;  // Format string length
myPrintData.format[1]          := 16#25;  // ASCII code "%" format
specification
myPrintData.format[2]          := 16#4E;  // ASCII code "N" format
specification
                                          // for message text
myPrintData.format[3]          := 16#25;  // ASCII code "%" format
specification
myPrintData.format[4]          := 16#49;  // ASCII code "I" format
specification
                                          // for integer
```

Notes on handling

The format string entry in the "format" field must be hexadecimal.

Example:
% corresponds to 25 hex in the IBM character set,
N (message text output) corresponds to 4E hex in the IBM character set.
(see Hardware configuration > Character set)

Data types DATE, TIME, DATE_AND_TIME_OF_DAY and TIME_OF_DAY are not supported. The date information must be entered as a DWORD or WORD in the printer data structure.

Representation type "A" (German date format):
//datefrg:=4018 (01.01.2001) and 4199 (01.07.2001)
printData.variable[0].datalength:=2;
printData.variable[0].data[0]:=WORD_TO_BYTE(SHR(datefrg,8));
printData.variable[0].data[1]:=WORD_TO_BYTE(SHR(datefrg,0));

Representation type "F":
The value to be printed must be in floating point format (mantissa/exponent) (see call example 2, Chapter CP 340 print call examples (Page 6160))

Representation type "C":
If variable[ ].datalength:=1 in the printer data structure, the characters will be printed horizontally.
If variable[ ].datalength:=2 (3,4) in the printer data structure, the characters will be printed vertically.

Representation type "X":
For CP 340 RS232, product version E08 and higher, representation type "X" (binary) outputs the values correctly on a serial printer.

Disconnected printer
The communications link is not monitored for printers even if alarm generation is enabled in HW Config of STEP 7.

Example:

- A break in the connection between the printer and the CP 340 triggers neither an error nor a diagnostic alarm.
- Nor are they triggered if a print job is started but no printer is connected.

Note

The code in examples 1, 2, and 3 (see Chapter CP 340 print call examples (Page 6160)) can be transferred to the SIMOTION SCOUT editor with **Copy** and **Paste**.

supplemental function blocks

Function

Supplemental function blocks are provided for entering variables of various data types as well as for entering message texts into data structure **Struct_CP340_printData**. You enter the value of the variables **byte by byte** and **in the proper format** in the **variable** element of the printer memory area and, optionally, in the **format** element. When numbers are entered for message texts, one entry is made in each of the **format** and **variable** elements. The method of representation for the variables in printed text and the method of entry in the format string can be selected by means of parameters.

The following supplemental function blocks are available:

- **_CP340_realToPrintData**
  Entry of a number of data type REAL into data structure **Struct_CP340_printData**
- **_CP340_dwordToPrintData**
  Entry of a number of data type DWORD into data structure **Struct_CP340_printData**
- **_CP340_wordToPrintData**
  Entry of a number of data type WORD into data structure **Struct_CP340_printData**
- **_CP340_byteToPrintData**
  Entry of a number of data type BYTE into data structure **Struct_CP340_printData**
- **_CP340_dintToPrintData**
  Entry of a number of data type DINT into data structure **Struct_CP340_printData**

- **_CP340_intToPrintData**
  Entry of a number of data type INT into data structure **Struct_CP340_printData**
- **_CP340_printMsgText**
  Selection of message texts stored in the CP 340

Note

SINT and USINT data types can be entered into data structure **Struct_CP340_printData** with the **_CP340_intToPrintData** function block. Type conversion is implicit.

Parameter description

Table 8-32 _CP340_byteToPrintData, _CP340_wordToPrintData, _CP340_dwordToPrintData parameters

Name	P type [1)]	Data type	Comment	Actions performed by user	Actions performed by block
execute	IN	BOOL	Edge-triggered job initiation	Entered	Checked
data	IN	BYTE/WORD/ DWORD	Variable/value to be entered in the data structure.	Entered	Checked
numVariable	IN	INT	Number of the variable in which the entry is to be made. 1≤ **numVariable** ≤ 4	Entered	Checked

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
entryFormatString	IN	ENUM	Method of entry in the format string and method of representation of the value in the **data** parameter.	Entered	Checked
		CP_REPLACE_WITH_SIGN	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: signed integer		
		CP_REPLACE_WITHOUT_SIGN	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: unsigned integer		
		CP_REPLACE_BINARY	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: binary		
		CP_ADD_WITHOUT_SIGN	Entry is added to the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: unsigned integer		
		CP_ADD_WITH_SIGN	Entry is added to the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: signed integer		
		CP_NO_ENTRY	No entry in the substructure of the format string		
entryAtByteNumber	IN	USINT	Specifies the byte at which the entry is to begin in the substructure of the format string. **entryAtByteNumber** = 0 Entry is made after the last entry found	Entered	Checked
printData	IN/OUT	Struct_CP340_printData	Data structure for the printer data	No actions	Enters values
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors (permissible value range exceeded)	Checked	Entered

error	OUT	BOOL	Job completed with errors (permissible value range exceeded)	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Task integration (call)

The supplemental blocks must be called in the **BackgroundTask** or the **TimerInterruptTask**.

For call examples for the **_CP340_printer** FB, see Chapter CP 340 print call examples (Page 6160).

Status and error indicators

The **done** output indicates that the job has been completed without errors. The **error** output indicates that an error has occurred.

The **done** and **error** parameters are available for one block call only.

CP 340 print call examples

Call example 1

```
UNIT E1CP340p;

INTERFACE
VAR_GLOBAL
  myPreparePrintData          : BOOL;               // Initiate prepare print request
  myRequestPrint              : BOOL;               // Initiate transfer to printer
  myReset                     : BOOL;               // Abort print
  myActualLevel               : REAL := 5.67;       // actual value "level"

```

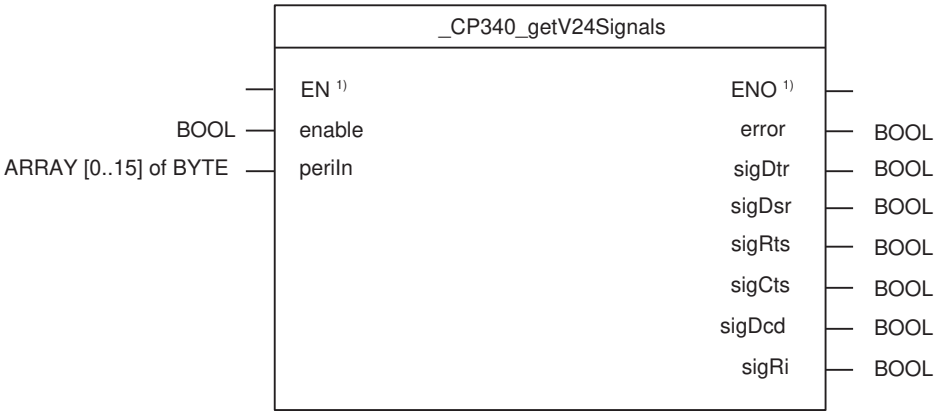
8.5.3.5 _CP340_getV24Signals function block

Function

The **_CP340_getV24Signals** function block reads the RS-232-C accompanying signals from the CP 340 and makes them available to the user in the block parameters. The functionality of the **_CP340_getV24Signals** FB can only be used if a parameterized ASCII driver is specified.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-36 Parameters of the _CP340_getV24Signals FB

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
enable	IN	BOOL	Block enable	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
error	OUT	BOOL	Job completed with errors	Checked	Entered
sigDtr	OUT	BOOL	Data terminal ready	Checked	Entered
sigDsr	OUT	BOOL	Data set ready	Checked	Entered
sigRts	OUT	BOOL	Request to send	Checked	Entered
sigCts	OUT	BOOL	Clear to send	Checked	Entered
sigDcd	OUT	BOOL	Data carrier detected	Checked	Entered
sigRi	OUT	BOOL	Ring Indicator	Checked	Entered

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Task integration (call)

The **_CP340_getV24Signals** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. For runtime reasons, calling the FB in the **IPOSynchronousTask** is not recommended.
The RS 232C accompanying signals will be updated with each FB call (cyclical polling). The CP 340 updates the status of the inputs/outputs in a time base of 20 ms.

Note

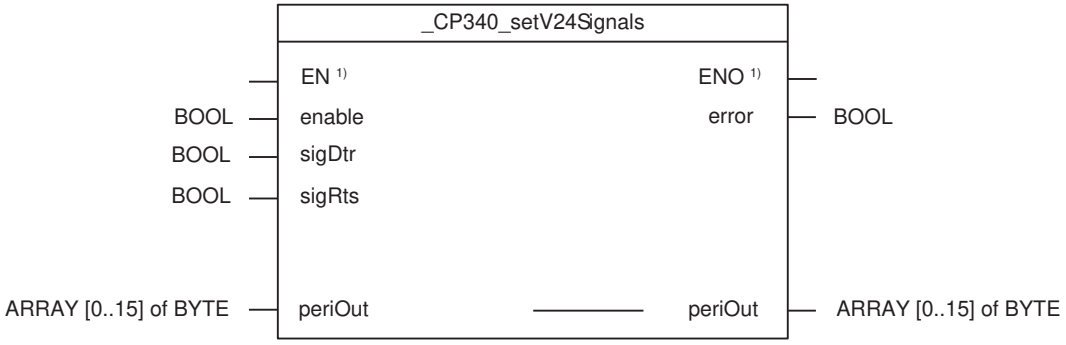
A minimum pulse duration is necessary to detect a signal change. Determining factors are the cycle time (SIMOTION device), the update time on the CP 340, and the response time of the communications partner.

8.5.3.6 _CP340_setV24Signals function block

Function

The **_CP340_setV24Signals** function block can be used to set or reset RS 232C accompanying signals. The functionality of the **_CP340_setV24Signals** FB can only be used if a parameterized ASCII driver is specified.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-37 Parameters of the _CP340_setV24Signals FB

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
enable	IN	BOOL	Block enable	Entered	Checked
sigDtr	IN	BOOL	Data terminal ready	Entered	Checked
sigRts	IN	BOOL	Request to send	Entered	Checked

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
periOut	IN/OUT	ARRAY[0..15] of BYTE	Prepared FB data for the I/O outputs of the CP [2]	Checked and transferred to the I/O variable for the I/O outputs	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 340.

Task integration (call)

The **_CP340_setV24Signals** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

8.5.3.7 Calling the CP 340 function blocks

In order to be able to work with the function blocks in your user project, proceed as follows (the numbers shown in the following program segment correspond to the steps below):

1. Create the function block instance (see the following program segment, e.g. create instance for the **_CP340_send** FB).
2. Create a variable for the data structure (for FB **_CP340_printer** only).
3. Create an array for the in/out parameters of the FB.
4. Call instance of the function block.
5. Transfer input parameters.
6. The output parameters of the FB are accessed with <instance name of FB>. <name of the output parameter>.
7. Data prepared by the FB for the I/O outputs are assigned to the array of the I/O variable created in step 3.

Note

The CP 340 call example is an extract from the supplied E_CP340 application example, which is included on the "SIMOTION Utilities & Applications" CD-ROM.

If you wish to control multiple CP 340 devices, you must create a new variable for the data structure and FB instances with a new name for each CP 340 you implement.

Call example for CP 340

```
UNIT E_CP340;

INTERFACE
```

```
  VAR_GLOBAL
   myExecSendCP340      : BOOL;                    // Trigger send task
   myModuleAddrCP340    : DINT:=256;               // module address
   mySendDataArrayCP340 : ARRAY [0..1023] OF BYTE; // Send data array 1024 bytes
   myInstCP340Send      : _CP340_send;             // Create instance of FB                    (1)
  END_VAR

  PROGRAM ExampleCP340;          // Program in BackgroundTask

END_INTERFACE

IMPLEMENTATION
  VAR_GLOBAL
   MyResetSend          : BOOL;                    // Cancel send order
  END_VAR

  VAR
   MyCPOutputArray      : ARRAY [0..15] OF BYTE;   // Array for CP output data                 (3)
  END_VAR

  VAR_TEMP
   MyDataLengthSend     : UDINT;             // Length of data to be sent
   MyDataOffsetSend     : UDINT;             // Offset of first byte to be sent
  END_VAR

   // CALL FB INSTANCE TO SEND                                                                 (4)
   myInstCP340Send (                                                                           (5)
          execute       := myExecSendCP340,         // Trigger order
          reset         := myResetSend,             // Order cancellation
          moduleAddress := myModuleAddrCP340,       // Module address
          dataOffset    := myDataOffsetSend,        // Data offset
          dataLength    := myDataLengthSend,        // Number of data to be sent
          periIn        := myPeripheralInputCP340,  // I/O variable of I/O inputs
          periOut       := myCPOutputArray,         // Output data array
          data          := mySendDataArrayCP340     // Send data array
          );

   myStateStartUpCP340  := myInstCP340Send.startUp; // Module start-up status                (6)

   // TRANSFER DATA TO CP340
   myPeripheralOutputCP340 := myCPOutputArray;  // Assign array for CP output data

END_PROGRAM                                     // ExampleCP340                             (7)
```

```
END_IMPLEMENTATION
```

Note

The PROGRAM "ExampleCP340" must be assigned in the execution system.

8.5.3.8 Data consistency

When sending data

Once a job is initiated by a positive edge at the **execute** input, the data to be sent is copied to the static memory area of the send FB. This means that once the FB call has ended, the send data array can be written to again for the next send request on a positive edge. The data are retained as consistent data within the send FB.

Note

During the copy operation to the static memory area of the FB, data consistency cannot be guaranteed if the send/receive data areas are accessed in a higher priority task.

When receiving data

Once the receive request is complete, the data are copied over to the receive buffer in a block from the static memory area of the receive FB. This means that once the FB call has ended, either all data are entered in the receive buffer (**newDataReceived** = TRUE) or no data are entered in the receive buffer (**newDataReceived** = FALSE).

Note

During the copy operation from the static memory area of the receive FB, data consistency cannot be guaranteed if the send/receive data areas are accessed in a higher priority task.

When printing

The data in the **printData** parameter in the static memory area of the FB are copied when a positive edge occurs at the **execute** input of the **_CP340_printer** FB. This means that once the FB call has ended, you can write to the variable and the format string for the next print request.

8.5.3.9 Application Examples

sending and receiving with CP 340

Function

This example shows how to:

- use the **_CP340_send** function block to send data from the Send data array to a communications partner.
- use the **_CP340_receive** function block to receive data in the receive data array.

In the example program, the CP 340 is used both as sender and as receiver. This requires the jumpering of the send and receive lines (PIN 2 and PIN 3 on the RS232 interface) and the "ASCII" setting in the parameter assignment tool. The **_CP340_send** FB is used to transfer the send data to the CP module. This sends the data using the RS232 interface. The jumpered send and receive line means that the data to be sent is read immediately by the CP module. The **_CP340_receive** FB reads the received data from the CP module and copies these data to the receive data array.

This example requires proper installation of the parameter assignment tool, as described in the SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment* manual.

Hardware platform

The application example is available for various SIMOTION hardware platforms. You must adapt the example for centralized applications with SIMOTION C.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Assigning module parameters

Proceed as follows:

1. Open your project in SIMOTION SCOUT.
2. Open the hardware configuration in SIMOTION SCOUT.
3. Configure your hardware station with a CP 340 module.
4. Double-click the **CP 340** to open the **Properties** dialog box for this module. Click the **Parameter** button to launch the parameter assignment tool of the CP 340 module.
5. The "ASCII" protocol must be selected in the protocol selection box.
   The standard settings of the ASCII protocol suffices for the application example.
6. Jumper the send and receive line (PIN 2/PIN 3) of the RS232 interface.
7. Apply your settings in the parameter assignment interface with the **File > Save** menu command, and close the interface with the **File > Exit** menu command. Close the Properties window for the CP 340 module by clicking the **OK** button.

8. Save the hardware configuration with the **Station > Save and compile** menu command.
9. Download the hardware configuration with the **Target system > Download to module** menu command.
   The red "SF" LED on the IM 153 turns on and then off if the assigned module parameters have been downloaded without errors.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. You can adapt the configuration in the example to the available hardware (e.g. PROFIBUS DP address).
2. You can adapt the configuration of the hardware to the example (e.g. PROFIBUS DP address).

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and is included in the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the axis configuration: PROFIBUS DP addresses.
3. Check the module addresses (hardware configuration) against the I/O addresses of the controller in SIMOTION SCOUT and module address in the program (myModuleAddrCP340).
4. **Save** and **compile** the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

Sequence of the application example

Table 8-38 Input icons used

Symbol	Data type	Designation
mySelectPointToPointCP340	BOOL	Select point-to-point connection
myExecSendCP340	BOOL	Start send job
mySendOrder1	BOOL	Select send: Job 1
mySendOrder2	BOOL	Select send: Job 2
mySendOrder3	BOOL	Select send: Job 3
myResetSend	BOOL	Cancel send job
myEnableToReceive	BOOL	Receive enable
myReceiveOrder1	BOOL	Select receive: Job 1
myReceiveOrder2	BOOL	Select receive: Job 2
myReceiveOrder3	BOOL	Select receive: Job 3
myResetReceive	BOOL	Cancel receive job
myModuleAddrCP340	DINT	CP 340 module address, default 256

Symbol	Data type	Designation
mySendDataArrayCP340	ARRAY[0..1023] of BYTE	Send data array
myReceiveDataArrayCP340	ARRAY[0..1023] of BYTE	Receive data array

Table 8-39 Output symbols used

Symbol	Data type	Designation
mySendDone	BOOL	Send: Completed
mySendError	BOOL	Send: Error display
mySendErrorNumber	WORD	Send: Error status
mySendTransErrorNumber	DINT	Send: Error status transfer
myNewDataReceived	BOOL	Receive: New data have been received
myReceiveError	BOOL	Receive: Error display
myReceiveErrorNumber	WORD	Receive: Error status
myReceiveTransErrorNumber	DINT	Receive: Error status transfer
myStateStartupCP340	BOOL	CP 340 startup status FALSE = startup completed
myDiagnosticAlarm	BOOL	TRUE = diagnostic alarm present on the CP 340
myProcessAlarm	BOOL	TRUE = process alarm present on the CP340
myAlarmInterrupt	UDINT	Type of the alarm (process, diagnostic alarm)
myLogBaseAddrIn	DINT	Module address
myLogBaseAddrOut	DINT	
myLogAddress	DINT	Diagnostic address
myAlarmDetails	DWORD	Alarm information

Note

You can either monitor and control the input and output variables used in the programming example in the INTERFACE area of the unit (under VAR_GLOBAL) using the symbol browser, or you can assign real inputs and outputs to the input and output variables in your user program.

For the "point-to-point connection" application example, set the "mySelectPointToPointCP340" input to "TRUE". This requires that the "E_CP340p" element be selected in the "PROGRAMS" folder in the project navigator. This will call function blocks contained in the application example.

Receiving data:

To receive data, you must set the "myEnableToReceive" variable to "TRUE" (static signal). If receive jobs 1 and 3 are enabled ("myReceiveOrder1" = TRUE and "myReceiveOrder3" = TRUE), the data is stored in the "myReceiveDataArrayCP340" data array starting with the "myReceiveDataArrayCP340[0]" array element (data offset is 0). If job 2 is enabled ("myReceiveOrder2" = TRUE), the data is stored in the "receiveDataArray" data array starting with the "myReceiveDataArrayCP340[20]" array element (data offset is 20).
If "myNewDataReceived" = TRUE, this indicates that new data has been received. This signal is present for one cycle only.
If an error occurred during the transfer ("myReceiveError" = TRUE), the error code is stored in the "myReceiveErrorNumber" variable. If error code 16#1E0F is present in "myReceiveErrorNumber", an error occurred during the data transfer. The transfer error code is stored in the

"myReceiveTransErrorNumber" variable. The error signals are deleted when you set input "myResetReceive" = TRUE.

Sending data:

You can use the "mySendOrder1", "mySendOrder2" and "mySendOrder3" inputs to select between three send jobs:

- Job 1 sends 10 bytes of data from the "mySendDataArrayCP340" data array from array element "mySendDataArrayCP340[0]" to "mySendDataArrayCP340[9]"
- Job 2 sends 20 bytes of data from the "mySendDataArrayCP340" data array from array element "mySendDataArrayCP340[20]" to "mySendDataArrayCP340[39]"
- Job 3 sends 1024 bytes of data from the "mySendDataArrayCP340" data array.

The data is sent to the communications partner if the "myExecSendCP340" input detects a signal change from "FALSE" to "TRUE" (positive edge).
If output signal "mySendDone" = TRUE, the send job has been completed. A new job can be sent if the "myExecSendCP340" input signal detects another signal change from FALSE to TRUE. If an error occurred during the transfer ("mySendError" = TRUE), the error code is stored in the "mySendErrorNumber" variable. If error code 16#1E0F is present in "mySendErrorNumber" , an error occurred during the data transfer. The transfer error code is stored in the "mySendTransErrorNumber" variable. The error signals are deleted when you set input "myExecSendCP340" = FALSE.

When the signal state at the "myResetSend" or "myResetReceive" input is set to "TRUE", the send job or receive job is canceled, respectively. If the signal state remains "TRUE", sending and receiving of data is disabled.

Note

Proper data transfer can be observed as follows:

- The "TxD" and "RxD" LEDs on the CP module illuminate.
- Output parameter (_CP_send FBs) **done** = TRUE or **NewDataReceived** = TRUE

Printing with CP 340

Function

The example shows how to use the **_CP340_printer** function block to send **Struct_CP340_printData** type data from the print memory area to a serial printer. For more information, see Chapter _CP340_printer function block (Page 6147).

In the example program, text examples with and without variables, date specifications, and line and page feeds are output to the printer by means of the CP 340.

This example requires proper installation of the parameter assignment tool, as described in the SIMATIC *CP 340 Point-to-Point Connection, Installation and Parameter Assignment* manual.

Hardware platform

The application example is available for various SIMOTION hardware platforms.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Assigning module parameters

Proceed as follows:

1. Open your project in SIMOTION SCOUT.
2. Open the hardware configuration in SIMOTION SCOUT.
3. Configure your hardware station with a CP 340 module.
4. Double-click the **CP 340** to open the **Properties** dialog box for this module. Click the **Parameter** button to launch the parameter assignment tool of the CP 340 module.
5. The "PRINTER" protocol must be selected in the protocol selection box.
6. Open the protocol properties by selecting the **Edit > Go to protocol** menu command and the **Edit > Open object** menu command.
7. Select the following setting in the **Protocol** dialog box (all other settings remain unchanged):
   - **Baud rate: 9600 bits/s**
   - **Data flow control: none**
   - **Data bits: 8**
   - **Stop bits: 1**
   - **Parity: even**

   Confirm your selection with **OK**.
8. To edit the message texts, double-click the **Messages** icon to open the relevant dialog box. In the next dialog box, click the **SDB** button.
9. Under "Edit Message", enter a number on the left and the text on the right, as follows:
   - 1 System level log
   - 2 Date:
   - 3 Level %I I reached at %Z (time)

   Confirm your selection with **OK**.
10. To edit the page layout, double-click the **Page Layout** icon to open the relevant dialog box.

11. Select the following settings in this dialog box:
    - **Left-hand margin: 3**
    - **Lines per page: 20**
    - **Separators / end of line: CR LF**
    - **Header lines: Example: Printing with the CP 340 for SIMOTION**
    - **Page footers: page %P**

    Confirm your selection with **OK**.
12. The default settings for the "IBM" character set remain selected under "Font" and "Control Characters".
13. Apply your settings in the parameter assignment interface with the **File > Save** menu command, and close the interface with the **File > Exit** menu command. Click **OK** to close the Properties window for the CP 340 module.
14. Save the hardware configuration with the **Station > Save and compile** menu command.
15. Download the hardware configuration with the **Target system > Download to module** menu command.
    The red "SF" LED on the IM 153 turns on and then off if the assigned module parameters have been downloaded without errors.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. You can adapt the configuration in the example to the available hardware (e.g. PROFIBUS DP address).
2. You can adapt the configuration of the hardware to the example (e.g. PROFIBUS DP address).

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example
2. Check the axis configuration: PROFIBUS DP addresses
3. Check the module addresses (hardware configuration) against the I/O addresses of the controller in SIMOTION SCOUT and the module addresses in the program (myModuleAddr_1)
4. Save and compile the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

Sequence of the application example

Further steps for executing the example are performed in the symbol browser using the "myPrintSelect" variable. This requires that the "E_CP340p" element be selected in the "PROGRAMS" folder in the project navigator.

The program resets the "myPrintSelect" variable autonomously; this can be seen in the "Status Value" column in the symbol browser.

This application example shows you how to use the _FB_CP340.print function block to send data from the send data array to a serial printer.

The following texts can be printed with the example program:

1. Print new page with header:
   "Example: Printing with the CP 340 for SIMOTION"
2. Print new line and five line feeds
3. Print message text without variables and two line feeds:
   "System level log"
4. Message text, two tabs and WORD variable for German date format.
   "Date:"
   "Date: 01.01.2001"
5. Message text with time of day and quantity (DWORD variable and DINT variable) and six line feeds
   "Level %I I was reached at %Z (time)"
   "Level 3000 I was reached at 08:45:04.018 (time)"
6. Print footer with conversion instruction for page number
   "Page: %P"
   "Page: 1"

To print out all the lines from the example, select the check box for "myPrintSelect" and set ALL_PRINT in the "Control Value" column in the symbol browser.

Click "Immediate control" to assign the value ALL_PRINT to the variable and to print the example.

Other settings can be assigned to the "myPrintSelect" variable:

"DATE_PRINT"	Output "Date: 01.01.2001"
"REPORT_TEXT_PRINT"	Output "Level 3000 reached at 08:45:04.018"
"NO_PRINT"	No output made

The date, time, and level quantity can be changed using the following variables:

- myDateGermany
- myTimeValue,
- myQuantity

Utilized control variables

Table 8-40 Utilized control variables

Symbol	Data type	Initial value	Designation
myPrintSelect	EnumPrintSelect	NO_PRINT	Selection of printer output
myDateGermany	WORD	4018	Date: 01.01.2001
myTimeValue	DWORD	31504018	Time: 08:45:04.018
myQuantity	DINT	3000	Quantity: 3000
myModuleAddr_1	DINT	256	Module address

Pending errors are indicated by the following variables:

Table 8-41 Variables used for displaying errors

Symbol	Data type	Initial value	Designation
myDiagnosticAlarm	BOOL		Diagnostic interrupt
myProcessAlarm	BOOL		Process interrupt
myErrorNumberprinter	WORD		Error code
myTransErrorNumberprinter	DINT		Transfer error number
myStopPrinter	BOOL	FALSE	Cancel print

Note

The active transfer job can be canceled by setting the "myStopPrinter" variable to "TRUE". The **_CP340_printer** FB is reset to its initial state.

The sending of print jobs will remain disabled as long as the signal state of the "myStopPrinter" variable is "TRUE".

8.5.4 CP 341 function blocks

8.5.4.1 Overview of the function blocks of the CP 341

This chapter contains a description of all of the function blocks (FBs) and the data structure required for communication between a SIMOTION device and a CP 341.

The function blocks form the software interface between the SIMOTION device and the CPs. They must be called repeatedly (in cycles) from the user program.

The following function blocks are available:

- _CP341_send function block (Page 6178)
- _CP341_receive function block (Page 6190)
- _CP341_printer function block (Page 6200)

- _CP341_getV24Signals function block (Page 6217)
- _CP341_setV24Signals function block (Page 6219)

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6231) in the table "SIMOTION and SIMATIC identifiers CP 341".

SIMOTION SCOUT contains all of the required function blocks and the **Struct_CP341_CI512Data** data structure (for RK 512 computer link only) of the CP 341. The function blocks can be used to control one or more CP 341 modules.

8.5.4.2 _CP341_send function block

Description of the _CP341_send FB

Function

The **_CP341_send** function block enables you to send data from the send data array to a communications partner (3964(R) protocol, RK 512 protocol, ASCII driver) or to fetch data from a communications partner and store it there (RK 512). You have 4,096 bytes available for this.

Task integration (call)

The **_CP341_send** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

Application with 3964(R) protocol or ASCII driver

The SIMOTION device sends data to a communications partner

The **_CP341_send** function block transfers a data block that is specified by the following parameters to the CP 341:

- **data** corresponds to the data array containing the send data
- **dataOffset** corresponds to the array index containing the first send byte
- **dataLength** corresponds to the amount of data to be sent in bytes

The **_CP341_send** function block is called repeatedly by a program. The send job can only be executed by cyclically calling the send FB.

A positive edge at the **execute** input initiates the transfer. A data transfer operation can run over several calls, depending on the amount of data involved.

The active transfer job can be canceled by setting the **reset** parameter to "TRUE". This will reset the **_CP341_send** FB to its initial state. The send operation will remain disabled as long as the signal state at the **reset** parameter is "TRUE".

The **moduleAddress** parameter specifies the module address of the CP 341 being addressed.

Status and error display on the _CP341_send FB

The **done** output indicates that the job has been completed without errors. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/number is displayed in the **errorID** output (see "Parameters of the _CP341_send FB" table (3964 (R) procedure or ASCII driver application)"). If no errors have occurred, **errorID** has a value of 0. **Done** and **error**/**errorID** are also displayed on **reset** of the **_CP341_send** function block. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

Parameters **done**, **error,errorID**, and **errorIdTransfer** are present for one block call only.

Note

There is no parameter check for the **_CP341_send** function block. Incorrect parameterization of this block may cause the SIMOTION device to switch to "STOP" mode.

Before the CP 341 can process an initiated job following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP-SIMOTION startup mechanism of the **_CP341_send** FB must be complete. Any jobs initiated in the meantime will not be lost. They are transferred to the CP 341 once the startup coordination has finished.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

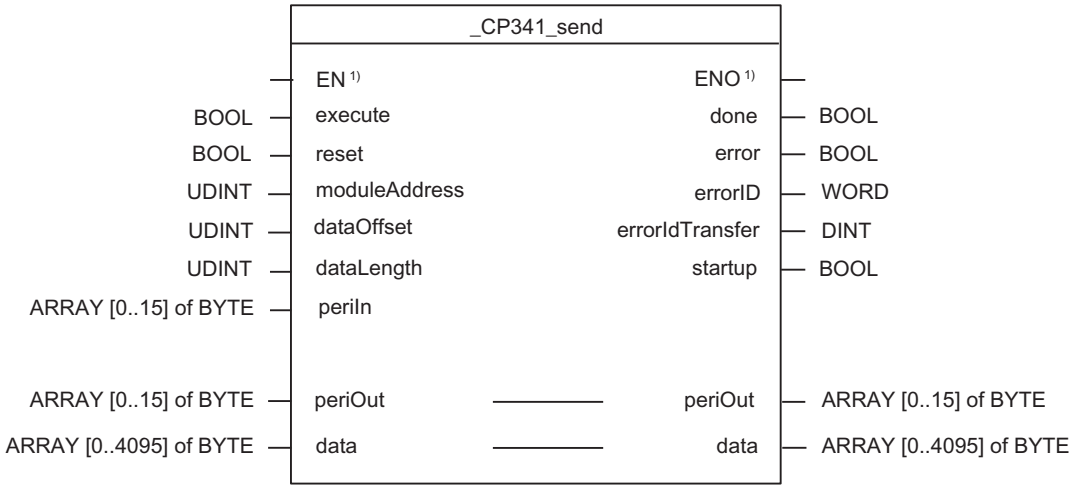
Assignment in the data area

The data to be sent are transferred to the **_CP341_send** FB in the **data** parameter (VAR_IN_OUT) as ARRAY of BYTE. At the beginning of the send operation, the data is copied to the FB and transferred from there to the CP 341.

Note

Once the data have been entered in the static memory of the send FB, you can modify the variable created in the **data** parameter. This does not affect the data to be sent.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-42 Parameters of the _CP341_send FB (application with 3964(R) protocol or ASCII driver)

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
execute	IN	BOOL	Initiates job on positive edge	Entered	Checked
reset	IN	BOOL	Cancels job	Entered	Checked
moduleAddress	IN	DINT	Module address of the CP for data set transfer (from HW Config)	Entered	Checked
dataOffset	IN	UDINT	First element to be sent	Entered	Checked
dataLength 2)	IN	UDINT	Number of elements to be sent	Entered	Checked
periIn	IN	ARRAY [0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
periOut	IN/OUT	ARRAY [0..15] of BYTE	Prepared FB data for the I/O outputs of the CP 3)	Checked and transferred to the I/O variable for the I/O outputs	Entered
data	IN/OUT	ARRAY[0..4095] of BYTE	Send data array	Entered and checked	Entered
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered
errorID	OUT	WORD	Error specification For **error** = TRUE, the error information (event class and number) is displayed in the **errorID** parameter. 4)	Checked	Entered

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
errorIdTransfer	OUT	DINT	Error during data transfer to the CP (precise error diagnostics if 16#1E0F is present at the **errorID** parameter [5])	Checked	Entered
startup	OUT	BOOL	Indicates CP startup	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] If an application uses earlier CP 341 versions with a maximum telegram length of 1 kB, only the maximum value of 1,024 can be set at the **dataLength** input parameter.

[3] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY [0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 341.

[4] For error information, refer to the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 341".

[5] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

Signal sequence diagram of the _CP341_send FB

The following figure illustrates the behavior of the **done** and **error** parameters according to the input circuit of **execute** and **reset**.

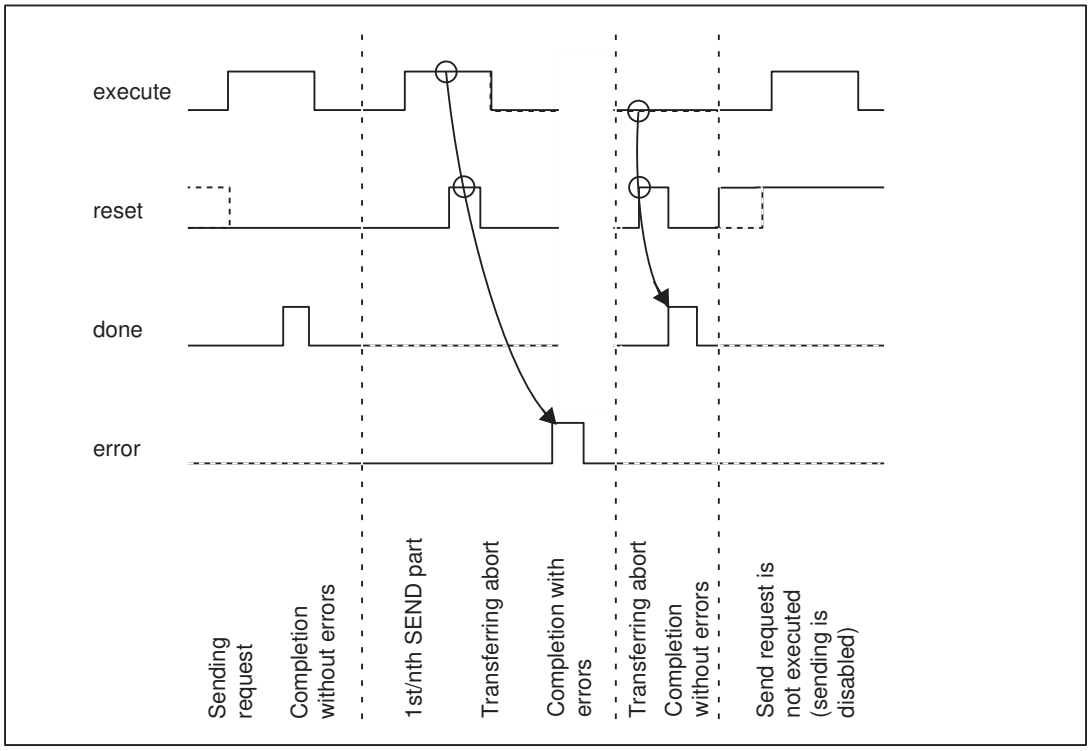


Figure 8-22 Signal sequence diagram of the _CP341_send FB

Note

The **execute** input is edge-triggered. The send job starts when there is a positive edge at the **execute** input.

Application with RK 512 computer interfacing

Sending data with the _CP341_send FB: SIMOTION with SIMOTION

Note

The handling of the **_CP341_send** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMOTION** communication.

You can send data to a communications partner by specifying 'SEND_CP' in the **mode** parameter.

A positive edge at the **execute** input initiates the data transfer. A data transfer operation can run over several calls (program cycles), depending on the amount of data involved.

The **moduleAddress** parameter specifies the module address of the CP that is to be used for the data transfer.

The data to be sent is specified in the following parameters:

- **data** indicates the data array containing the send data.
- **dataOffset** corresponds to the array index containing the first send byte.
- **dataLength** corresponds to the amount of data to be sent in bytes.

You must also indicate where the data is to be entered on the receiver.

- The **remoteCpuId** parameter specifies the number of the receiver (relevant for multiprocessor communication only).
- **remoteDataType** specifies the memory area where the data will be entered on the receiver (if the communications partner is a SIMOTION device, 68 must always be entered).

- **remoteMemIndex** specifies the memory index where the receive data will be entered. **RemoteMemIndex** = 0 is not permissible. An error message will be generated.
- **remoteDataOffset** specifies the array index in which the first receive byte is to be entered.

Note

The above parameters relate to a variable addressed specifically by the receiver. The receiver specifies the variable in which the data will be entered.

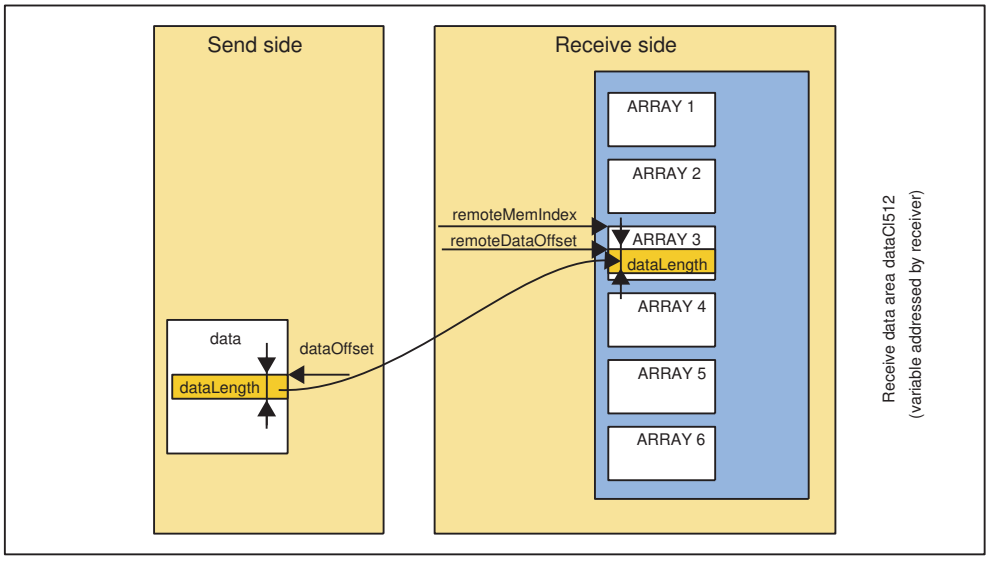

Figure 8-23 Send data _FB_P_Send: SIMOTION with SIMOTION

The communication flag bit (see Chapter Special features related to data transfer (Page 6223)), which is checked in the receiver before the send job is initiated and set once the send job is complete, is specified with parameters **remoteComFlagByte** (array index containing the communication flag bit) and **remoteComFlagBit** (bit position of the communication flag bit).

Special features for sending data

Assigning 255 to the **remoteComFlagByte** parameter will disable the communication flag functionality.

Sending data with the _CP341_send FB: SIMOTION with SIMATIC

Note

The handling of the **_CP341_send** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMATIC** communication.

You can send data to a communications partner by specifying 'SEND_CP' in the **mode** parameter.

A positive edge at the **execute** input initiates the data transfer. A data transfer operation can run over several calls (program cycles), depending on the amount of data involved.

The **moduleAddress** parameter specifies the module address of the CP that is to be used for the data transfer.

The data to be sent is specified in the following parameters:

- **data** indicates the data array containing the send data.
- **dataOffset** corresponds to the array index containing the first send byte.
- **dataLength** corresponds to the amount of data to be sent in bytes.

You must also indicate where the data is to be entered on the receiver.

- The **remoteCpuId** parameter specifies the number of the receiver (relevant for multiprocessor communication only).
- **remoteDataType** indicates the memory area where data will be entered on the receiver.
  - Data block = 68
  - Extended data block = 88
  - Flag = 77
  - Input = 69
  - Output = 65
  - Counter = 90
  - Timer = 84
- **remoteMemIndex** specifies the number of the data block or extended data block where the receive data will be entered. It has no relevance for all other receive areas. **RemoteMemIndex** = 0 is not permissible. An error message will be generated.
- **remoteDataOffset** specifies the array index in which the first receive byte is to be entered.

The communication flag bit (see Chapter Special features related to data transfer (Page 6223)), which is checked in the receiver before the send job is initiated and set once the send job is complete, is specified with parameters **remoteComFlagByte** (array index containing the communication flag bit) and **remoteComFlagBit** (bit position of the communication flag bit) in the SIMATIC flag area.

Special features for sending data

Assigning 255 to the **remoteComFlagByte** parameter will disable the communication flag functionality.

The signal sequence diagram of the **_CP341_send** FB can be found in Chapter Description of the _CP341_send FB (Page 6178).

Fetching data with the _CP341_send FB: SIMOTION with SIMOTION

Note

The handling of the **_CP341_send** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMOTION** communication.

You can fetch data from a communications partner by specifying "FETCH_CP" in the **mode** parameter.

A positive edge at the **execute** input initiates the data transfer. A data transfer operation can run over several calls (program cycles), depending on the amount of data involved.

The **moduleAddress** parameter specifies the module address of the CP that is to be used for the data transfer.

You must also indicate where the data are to be fetched on the receiver.

- The **remoteCpuId** parameter specifies the number of the receiver (relevant for multiprocessor communication only).
- **remoteDataType** specifies the memory area where the data will be fetched on the receiver (if the communications partner is a SIMOTION device, 68 must always be entered).
- **remoteMemIndex** specifies the memory index where the data will be fetched. **RemoteMemIndex** = 0 is not permissible. An error message will be generated.
- **remoteDataOffset** specifies the array index where the first byte is to be fetched.

Note

The above parameters relate to a variable addressed specifically by the communications partner. They specify the variable from which the data will be fetched.

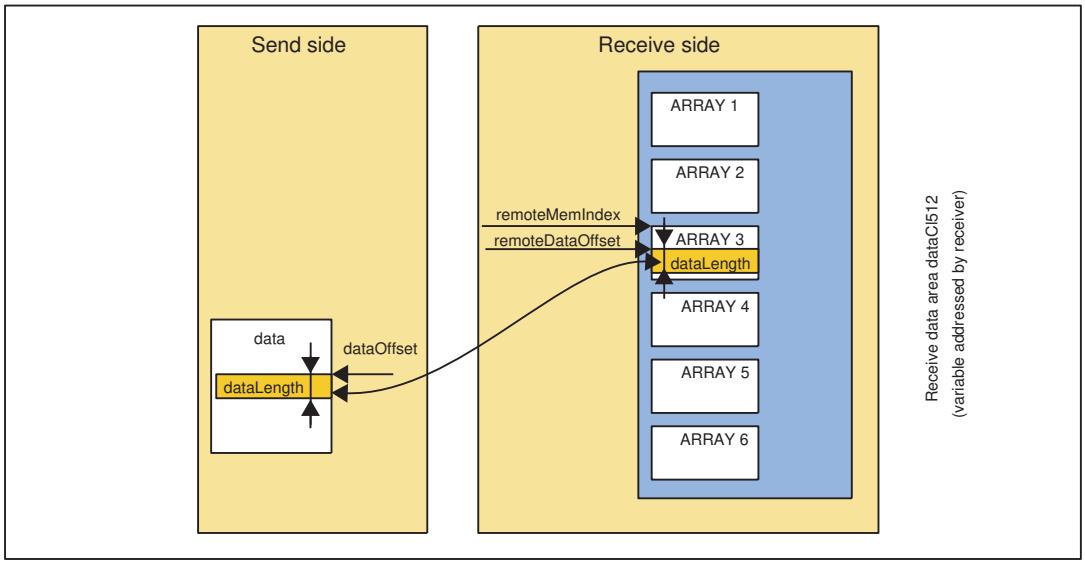

Figure 8-24 Fetch data _P_Send FB: SIMOTION with SIMOTION

The following parameters are used to specify where the fetched data will be saved:

- **data** corresponds to the data array in which the requested data will be entered.
- **dataOffset** corresponds to the array index in which the first fetched data byte will be entered.
- **dataLength** corresponds to the amount of data to be fetched in bytes.

The communication flag bit (see Chapter Special features related to data transfer (Page 6223)), which is checked in the receiver before the send job is initiated and set once the fetch job is complete, is specified with parameters **remoteComFlagByte** (array index containing the communication flag bit) and **remoteComFlagBit** (bit position of the communication flag bit).

Special features for fetching data

Assigning 255 to the **remoteComFlagByte** parameter will disable the communication flag functionality.

Fetching data with the _CP341_send FB: SIMOTION with SIMATIC

Note

The handling of the **_CP341_send** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMATIC** communication.

You can fetch data from a communications partner by specifying "FETCH_CP" in the **mode** parameter.

A positive edge at the **execute** input initiates the data transfer. A data transfer operation can run over several calls (program cycles), depending on the amount of data involved.

The **moduleAddress** parameter specifies the module address of the CP that is to be used for the data transfer.

You must also indicate where the data is to be fetched on the communications partner.

- **remoteCpuId** specifies the number of the communications partner (relevant for multiprocessor communication only).
- **remoteDataType** specifies the memory area where the data will be fetched on the communications partner.
  - Data block = 68
  - Extended data block = 88
  - Flag = 77
  - Input = 69
  - Output = 65
  - Counter = 90
  - Timer = 84

- **remoteMemIndex** specifies the number of the data block or extended data block where the receive data will be fetched.
  RemoteMemIndex = 0 is not permissible. An error message will be generated.
- **remoteDataOffset** specifies the array index where the first byte is to be fetched.

The following parameters are used to specify where the fetched data will be saved:

- **data** corresponds to the data array in which the requested data will be entered.
- **dataOffset** corresponds to the array index in which the first fetched data byte will be entered.
- **dataLength** corresponds to the amount of data to be fetched in bytes.

The communication flag bit (see Chapter Special features related to data transfer (Page 6223)), which is checked in the communications partner before the send job is initiated and set once the send job is complete, is specified with parameters **remoteComFlagByte** (array index containing the communication flag bit) and **remoteComFlagBit** (bit position of the communication flag bit) in the SIMATIC communication flag area.

Special features for fetching data

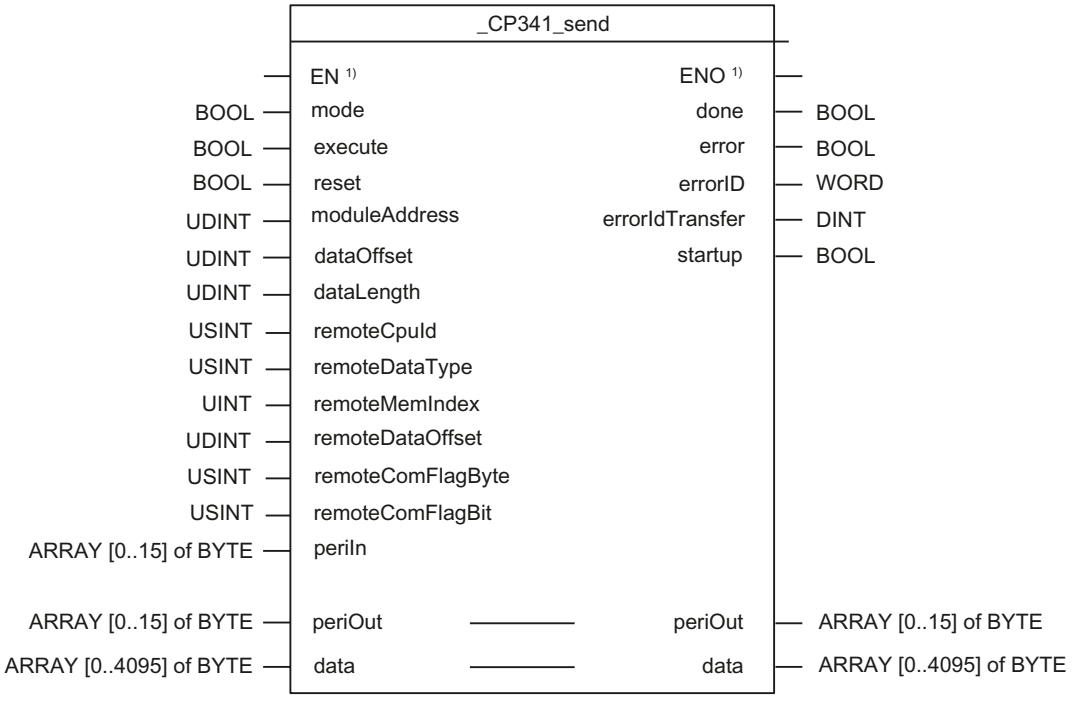
Assigning 255 to the **remoteComFlagByte** parameter will disable the communication flag functionality.

The signal sequence diagram of the **_CP341_send** FB can be found in Chapter Description of the _CP341_send FB (Page 6178).

Assignment in the data area

During the receive operation, the data to be received are stored temporarily in a local ARRAY. Once the data transfer from the CP 341 to the SIMOTION device is complete, the data is made available in the **data** (VAR_IN_OUT) parameter of the **_CP341_send** FB.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-43 Parameters of the _CP341_send FB (application with RK 512 computer link)

Name	P type 1)	Data type	Comment	Actions performed by user	Actions performed by block
mode	IN	EnumSendFetch	SEND_CP: Sends data FETCH_CP: Fetches data from the communications partner	Entered	Checked
execute	IN	BOOL	Initiates job on positive edge	Entered	Checked
reset	IN	BOOL	Cancels job	Entered	Checked
moduleAddress	IN	DINT	Module address of the CP for data set transfer (found in **HW Config**)	Entered	Checked
dataOffset	IN	UDINT	First element to be sent	Entered	Checked
dataLength	IN	UDINT	Number of elements to be sent	Entered	Checked
remoteCpuId	IN	USINT	Number of the remote communications partner	Entered	Checked
remoteDataType	IN	USINT	Area type in the remote communications partner	Entered	Checked

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block

remoteDataOffset	IN	UDINT	First element in the remote communications partner	Entered	Checked
remoteComFlag-Byte	IN	USINT	Communication flag index in the local communications partner	Entered	Checked
remoteComFlagBit	IN	USINT	Communication flag bit no. in the local communications partner	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
periOut	IN/OUT	ARRAY[0..15] of BYTE	Prepared FB data for the I/O outputs of the CP [3]	Checked and transferred to the I/O variable for the I/O outputs	Entered
data	IN/OUT	ARRAY[0..4095] of BYTE	Send data array Receive data for parameter **mode =** FETCH_CP	Entered and checked	Entered
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered
errorID	OUT	WORD	Error specification For **error**=TRUE, the error information (event class and number) is displayed in the **errorID** parameter.[4]	Checked	Entered
errorIdTransfer	OUT	DINT	Error during data transfer to the CP (precise error diagnostics if 16#1E0F is present at the **errorID** parameter [5])	Checked	Entered
startup	OUT	BOOL	Indicates CP startup	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **remoteMemIndex** = 0 is not permissible. An error message will be generated.

[3] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 341.

[4] For error information, refer to the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 341"

[5] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

8.5.4.3 _CP341_receive function block

Description of the _CP341_receive FB

Function

The **_CP341_receive** function block enables you to receive data from a communications partner in the receive data array (3964(R) protocol, ASCII driver, RK 512) or to make data available for the communications partner (RK 512). Each data array depends on the type of protocol used. If you are using the 3964(R) protocol or ASCII driver, the receive data array is **dataCI3964**. For an RK 512 computer link, the data array is **dataCI512**. In both cases, 4,096 bytes are available. From the **dataCI512** data array, data is also made available for the communications partner.

Task integration (call)

The **_CP341_receive** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

Application with 3964(R) protocol or ASCII driver

SIMOTION device receives data from a communications partner

The **_CP341_receive** function block transfers a data block that is specified by the **dataCI3964** and **dataOffset** parameters from the CP 341 to a SIMOTION device. The **_CP341_receive** function block is called repeatedly by a program. The receive job can only be executed by cyclically calling the receive FB.

Receiving of data is enabled with static signal state "TRUE" in the **enable** parameter. An active data transfer can be canceled with signal state "FALSE" in the **enable** parameter. The canceled receive job is terminated with an error message at the **errorID** output. The receive operation will remain disabled as long as the signal state at the **enable** parameter is "FALSE". A data transfer operation can run over several calls, depending on the amount of data involved.

The active transfer job can be canceled by setting the **reset** parameter to "TRUE". This will reset the **_CP341_receive** FB to its initial state. The receive operation will remain disabled as long as the signal state at the **reset** parameter is "TRUE".

The **moduleAddress** parameter specifies the module address of the CP 341 being addressed.

Status and error display on the _CP341_receive FB

The **newDataReceived** output indicates that the job has been completed without errors. The amount of data received is indicated in the **dataLength** parameter. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/number is displayed in the **errorID** output (see "Parameters of the _CP341_receive FB" table (3964 (R) procedure or ASCII driver)"). If no error has occurred, **errorID** has the value "0".
newDataReceived and **error**/**errorID** will also be output when the **_CP341_receive** FB is **reset**. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

The **newDataReceived**, **dataLength, error, errorID**, and **errorIdTransfer** parameters are available for one block call only.

Note

There is no parameter check for the **_CP341_receive** FB. Incorrect parameterization of this block may cause the SIMOTION device to switch to "STOP" mode.

Before a job from the CP 341 can be received following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP-SIMOTION startup mechanism of the **_CP341_receive** FB must be complete.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

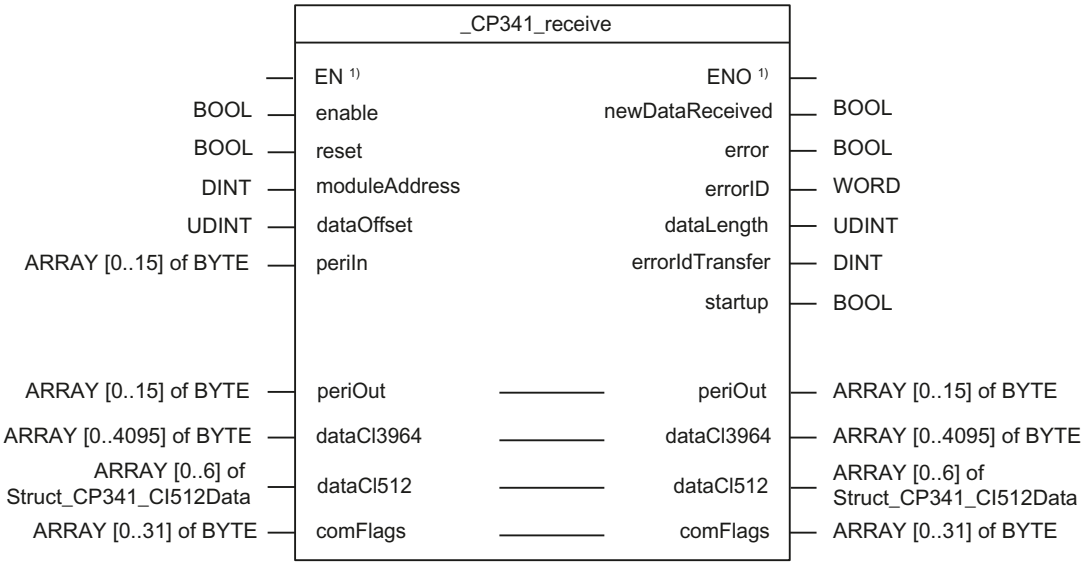
Assignment in the data area

During the receive operation, the data to be received are stored temporarily in a local ARRAY. Once the data transfer from the CP 341 to the SIMOTION device is complete, the data are made available in the **dataCI3964** (VAR_IN_OUT) parameter of the **_CP341_receive** FB.

Note

To ensure data consistency, do not access the receive data array until all the data has been received (**newDataReceived** = TRUE).

Call (LAD representation)



1) LAD-specific parameters

Parameters of the _CP341_receive FB (3964(R) protocol or ASCII driver)

Table 8-44 Parameters of the _CP341_receive FB (3964(R) protocol or ASCII driver)

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
enable	IN	BOOL	Receive enable	Entered	Checked
reset	IN	BOOL	Cancels job	Entered	Checked
moduleAddress	IN	DINT	Module address of the CP for data set transfer (from HW Config)	Entered	Checked
dataOffset	IN	UDINT	First element to be received	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
periOut	IN/OUT	ARRAY[0..15] of BYTE	Prepared FB data for the I/O outputs of the CP [2]	Checked and transferred to the I/O variable for the I/O outputs	Entered
dataCl3964	IN/OUT	ARRAY[0..4095] of BYTE	Receive data array	Entered and checked	Entered
dataCl512	IN/OUT	ARRAY[0..6] of 'Struct_CP341_Cl512Data'	Data area for RK 512 two-dimensional array [3]	Entered and checked	Checked
comFlags	IN/OUT	ARRAY[0..31] of BYTE	Communication flag area for RK 512	Entered and checked	Entered
newDataReceived	OUT	BOOL	New data have been received	Checked	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered
dataLength	OUT	UDINT	Quantity of data received	Checked	Entered
errorID	OUT	WORD	Error specification For **error**=TRUE, the error information (event class and number) is displayed in the **status** parameter.[4]	Checked	Entered
errorIdTransfer	OUT	DINT	Error during data transfer to the CP (precise error diagnostics if 16#1E0F is present at the **errorID** parameter [5])	Checked	Entered
startup	OUT	BOOL	Indicates CP startup	Checked	Entered

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

2) **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 341.

3) No data can be exchanged in array index **dataCl512[0]**.

4) For error information, refer to the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 341"

5) For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

Signal sequence diagram of the _CP341_receive FB

The following figure illustrates the behavior of the **newDataReceived**, **dataLength**, and **error** parameters according to the input circuit of **enable** and **reset**.

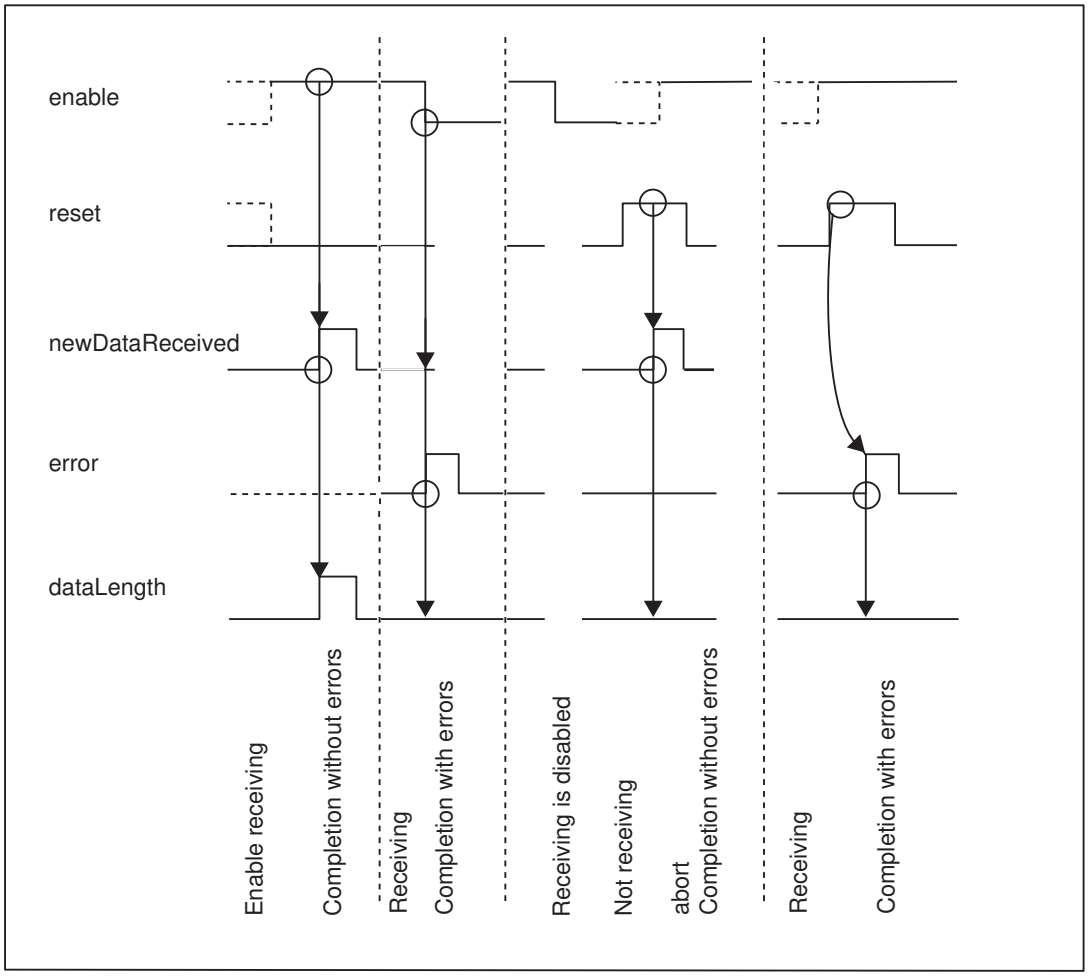


Figure 8-25 Signal sequence diagram of the _CP341_receive FB

Application with RK 512 computer interfacing

Receiving data with the _CP341_receive FB: SIMOTION with SIMOTION

Note

The handling of the **_CP341_receive** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMOTION** communication.

The data to be received will be entered in a variable created in the **dataCl512** parameter. The communications partner specifies where the receive data will be entered in the variable. The information about the entry location is output at the following output parameters.

- **localCpuId** specifies the number of the receiver (relevant for multiprocessor communication only).
- **localDataType** specifies the memory area where the receive data have been entered (irrelevant for SIMOTION with SIMOTION communication).
- **localMemIndex** specifies the memory index where the receive data have been entered.
- **localDataOffset** specifies the array index where the first receive byte has been entered.
- **dataLength** corresponds to the amount of data received in bytes.

A static "TRUE" signal state in the **enable** parameter enables a check to determine whether data are to be read from the CP 341. An active data transfer can be canceled with signal state "FALSE" in the **enable** parameter. The canceled receive job is terminated with an error message at the **errorID** output. The receive operation will remain disabled as long as the signal state at the **enable** parameter is "FALSE". A data transfer operation can run over several calls, depending on the amount of data involved.

The **moduleAddress** parameter specifies the module address of the CP that is to be used for the data transfer.

The communication flag area (see Chapter Special features related to data transfer (Page 6223)) is specified by a variable created in the **comFlags** parameter. The communication flag bit, which was checked in the receiver before the send job was initiated and was set after the send job was finished, is indicated at output parameters **localComFlagByte** (array index containing the communication flag bit) and **localComFlagBit** (bit position of communication flag bit).

Special features for receiving data

Assigning 255 to the **localComFlagByte** parameter will disable the communication flag functionality.

Receiving data with the _CP341_receive FB: SIMOTION with SIMATIC

Note

The handling of the **_CP341_receive** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMATIC** communication.

The communications partner on the SIMATIC side must set the input parameters according to the SIMOTION description.

Signal sequence diagram of the _CP341_receive FB

The following figure illustrates the behavior of the **newDataReceived, dataLength**, and **error** parameters according to the input circuit of **enable** and **reset**.

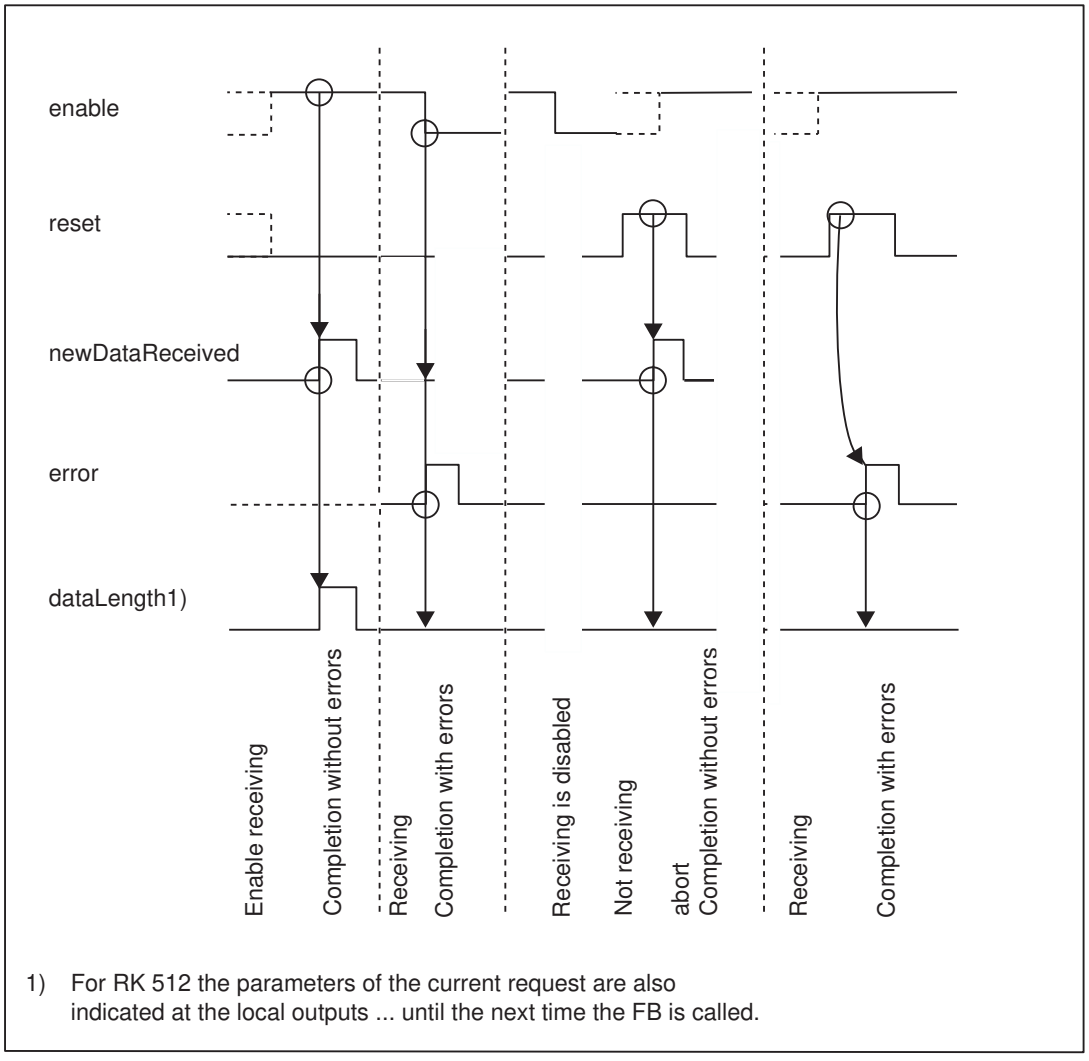

Figure 8-26 Signal sequence diagram of the _CP341_receive - receive data FB

Providing data with the _CP341_receive FB: SIMOTION with SIMOTION

Note

The handling of the **_CP341_receive** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMOTION** communication.

Function block processing is enabled with static signal state "TRUE" in the **enable** parameter. An active data transfer can be canceled with signal state "FALSE" in the **enable** parameter. The

canceled fetch job is terminated with an error message at the **errorID** output. Data cannot be provided as long as the signal state at the **enable** parameter is "FALSE". A data transfer operation can run over several calls, depending on the amount of data involved.

The **moduleAddress** parameter specifies the module address of the CP that is to be used for the data transfer.

The data to be provided are entered in a variable created in the **dataCl512** parameter. The communications partner specifies which data is to be fetched from the variable. The information about the fetched data is output in the following output parameters.

- **localCpuId** specifies the number of the communications partner providing the data (relevant for multiprocessor communication only).
- **localDataType** specifies the memory area where the data was fetched (irrelevant for SIMOTION).
- **localMemIndex** specifies the memory index where the data were fetched.
- **localDataOffset** specifies the array index where the first data byte was fetched.
- **dataLength** corresponds to the amount of data sent in bytes.

Special features for providing data

Assigning 255 to the **localComFlagByte** parameter will disable the communication flag functionality.

Providing data with the _CP341_receive FB: SIMOTION with SIMATIC

Note

The handling of the **_CP341_receive** FB differs according to whether data is to be exchanged with a **SIMOTION System** or a **SIMATIC System**.

The parameter assignment is described below for a function block for **SIMOTION with SIMATIC** communication.

The communications partner on the SIMATIC side must specify the input parameters according to the SIMOTION description.

Signal sequence diagram of the _CP341_receive FB

The following figure illustrates the behavior of the **newDataReceived, dataLength**, and **error** parameters according to the input circuit of **enable** and **reset**.

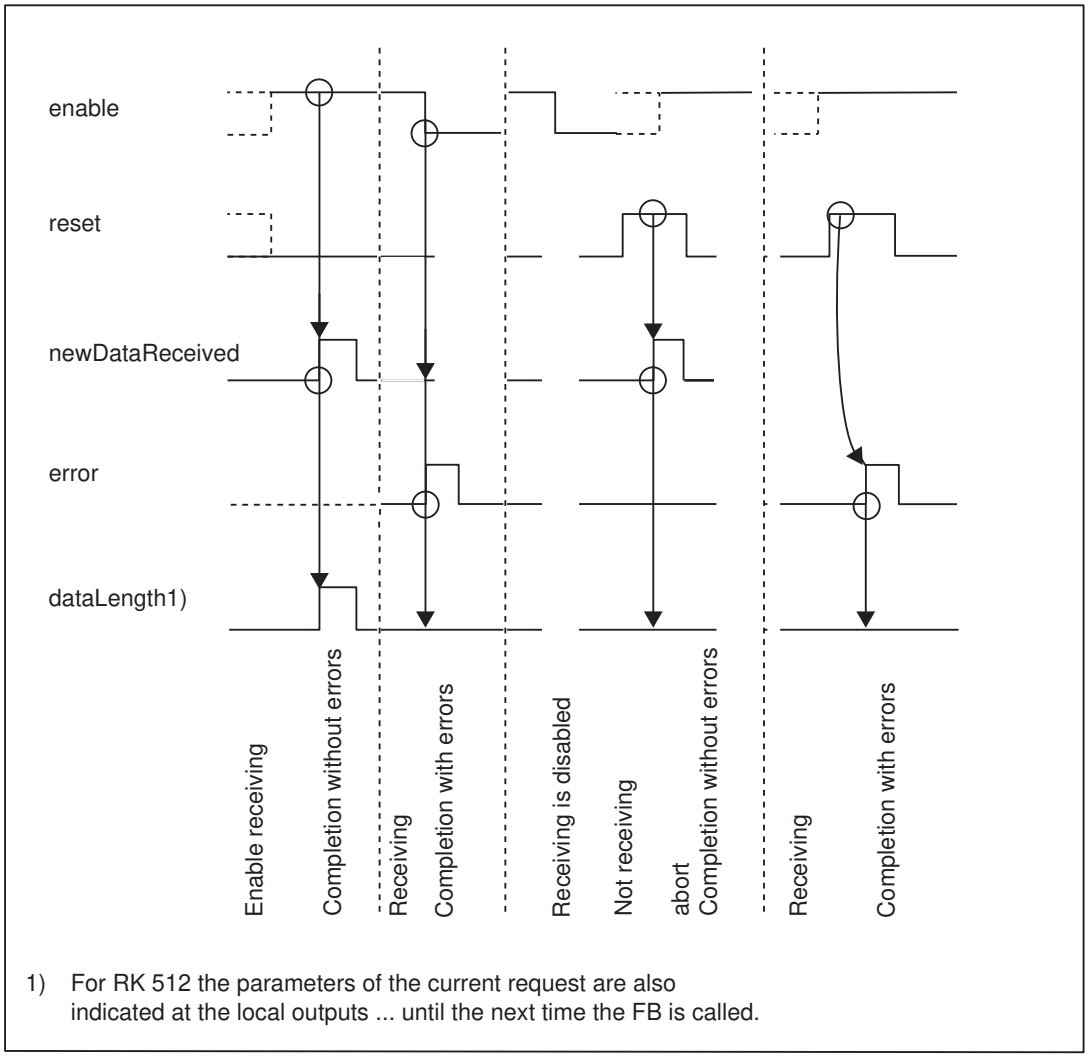

Figure 8-27 Signal sequence diagram of the _CP341_receive - providing data FB

Error display on the _CP341_receive FB

The **newDataReceived** output parameter indicates that the job has been completed without errors. The amount of data received is indicated in the **dataLength** parameter. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/number is displayed in the **errorID** output parameter (see "Parameters of the _CP341_receive FB" table (application with RK 512 computer link)"). If no errors have occurred, **errorID** has a value of 0. The **newDataReceived** and **error**/**errorID** parameters are also displayed on **reset** of the **_CP341_receive** FB. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

The **newDataReceived**, **dataLength, error, errorID**, and **errorIdTransfer** parameters are available for one block passage only.

Note

There is no parameter check for the **_CP341_receive** FB. Incorrect parameterization of this block may cause the SIMOTION device to switch to "STOP" mode.

Before a job from the CP 341 can be received following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP-SIMOTION startup mechanism of the **_CP341_receive** FB must be complete.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

Assignment in the data area

During the receive operation, the data to be received is stored temporarily in the **_CP341_receive** FB. Once the data transfer from the CP 341 to the SIMOTION device is complete, the data are made available in the **dataCI512** (VAR_IN_OUT) parameter of the **_CP341_receive** FB.

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] No data can be exchanged in array index **dataCl512[0]**.

[3] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 341.

[4] For error information, refer to the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 341".

[5] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

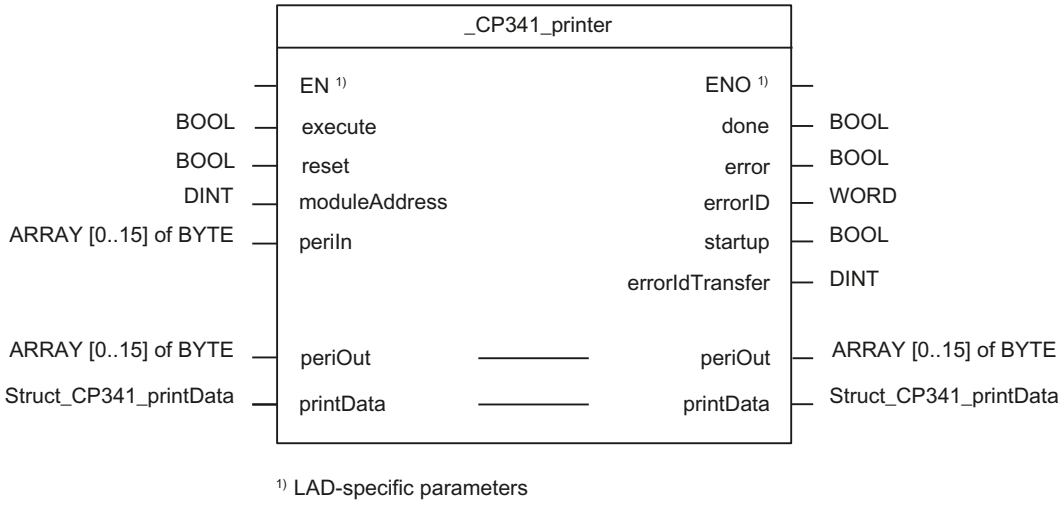
8.5.4.4 _CP341_printer function block

Description of the _CP341_printer FB

Function

The **_CP341_printer** function block is used to send data of type **Struct_CP341_printData** from the printer memory area to a serial printer. For example, the **_CP341_printer** function block might send a process message to the CP 341. The CP 341 prints out the process message on the connected printer.

Call (LAD representation)



1) LAD-specific parameters

startup	OUT	BOOL	Indicates CP startup	Checked	Entered
errorIdTransfer	OUT	DINT	Error during data transfer to the CP (precise error diagnostics if 16#1E0F is present at the **errorID** parameter [4])	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 341.

[3] For error information, refer to the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manual, Chapter "Diagnostics with the CP 341".

[4] For a more detailed description (_readRecord and _writeRecord), see *SIMOTION System Function/Variable Devices* Parameter Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation.

[5] See "Message text structure", print storage area structure example

Signal sequence diagram of the _CP341_printer FB

The following figure illustrates the behavior of the **done** and **error** parameters according to the input circuit of **execute** and **reset**.

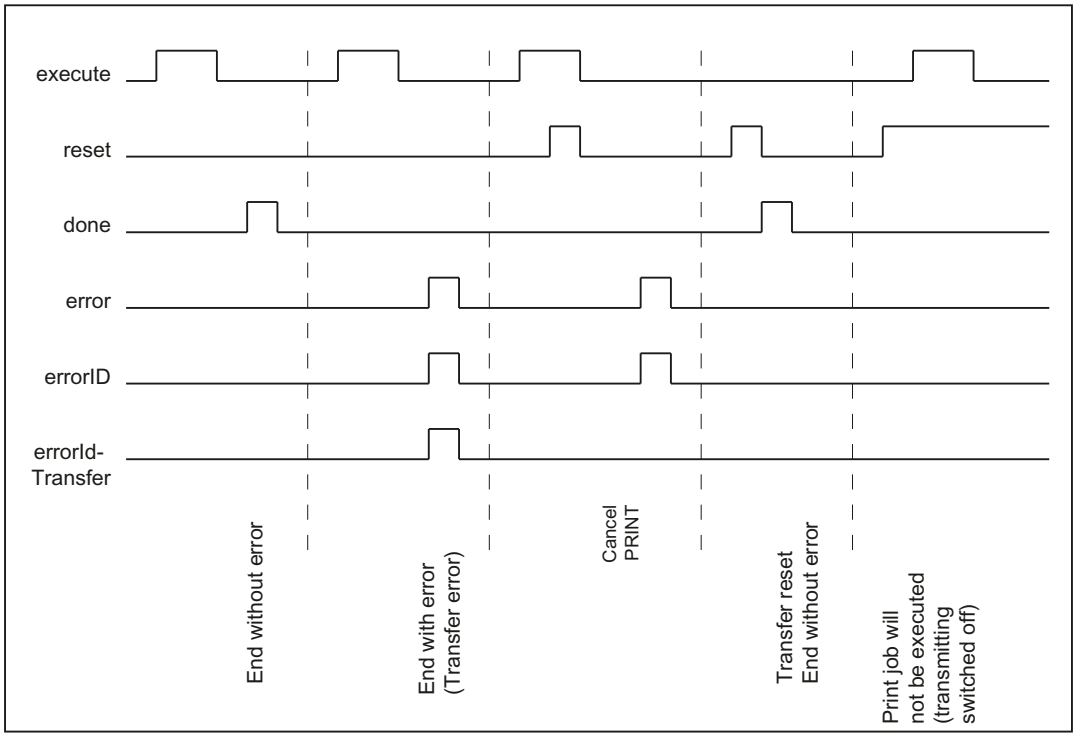

Figure 8-28 Signal sequence diagram of the _CP341_printer FB

Note

The **execute** input is edge-triggered. The send job starts when there is a positive edge at the **execute** input.

Task integration (call)

The **_CP341_printer** function block must be called cyclically in the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

The **_CP341_printer** function block is called repeatedly by a program. The print job can only be executed by cyclically calling the print FB.

A positive edge at the **execute** input initiates the transfer of the message text. A data transfer operation can run over several calls (program cycles), depending on the amount of data involved.

The active transfer job can be canceled by setting the **reset** parameter to "TRUE". This will reset the **_CP341_printer** FB to its initial state. The sending of print jobs will remain disabled as long as the signal state at the **reset** parameter is TRUE.

The **moduleAddress** parameter specifies the module address of the CP 341 being addressed for the data set transfer.

For call examples for the **_CP341_printer** FB, see Chapter CP 341 print call examples (Page 6213).

Status and error display on the _CP341_printer FB

The **done** output parameter indicates that the job has been completed without errors. The **error** output indicates that an error has occurred. If an error occurs, the corresponding event class/ number is displayed in the **errorID** output parameter (see "Parameters of the CP341_printer FB" table). If no errors have occurred, **errorID** has a value of 0. **Done** and **error/errorID** are also output for **reset** of the **_CP341_printer** FB. When 16#1E0F is displayed in the **errorID** parameter, a detailed error description is also output via the **errorIdTransfer** parameter.

The **done**, **error, errorID**, and **errorIdTransfer** parameters are available for one block call only.

Note

There is no parameter check for the **_CP341_printer** function block. Incorrect parameterization of this block may cause the SIMOTION device to switch to "STOP" mode. Before the CP 341 can process an initiated job following a transition of the SIMOTION device from "STOP" to "RUN" mode, the CP-SIMOTION startup mechanism of the **_CP341_printer** FB must be complete. Any jobs initiated in the meantime will not be lost. They are transferred to the CP 341 once the startup coordination has finished.

The end of the startup coordination is indicated in output parameter **startup** = FALSE.

Assignment in the data area

The print data is transferred to the **_CP341_printer** FB as a data structure of type **Struct_CP341_printData** and copied to a local variable of the FB at the beginning of the print operation.

Structure of printer memory of type Struct_CP341_printData

The four variables to be printed and the format string must be entered in a variable with the following data type:

Example:

```
Struct_CP341_dataRecord     : STRUCT
     dataLength : UDINT;                        // Data quantity
     data       : ARRAY [0..31] of BYTE;        // Data field
END_STRUCT

Struct_CP341_printData    : STRUCT
     variable   : ARRAY [0..3] of Struct_CP341_dataRecord;  // 1st to 4th variable
     format     : ARRAY [0..150] of BYTE;                   // Format string
END_STRUCT
```

The first variable to be printed corresponds to the **variable [0]** element, the second variable to be printed corresponds to the **variable [1]** element, etc. The number of bytes to be printed per variable is limited to 32. The data for variable **i** must be placed in **variable [i-1].data[0..31]**. The number of bytes to be printed must be entered in the **variable [i-1].dataLength** element.

The format string corresponds to the format element. The format string must be structured as follows (refer to the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* Manual):

- Specification of string length in **format [0]**
- Specification of individual characters in **format [1 to 150]**

Note

If the maximum length is exceeded, the print job is canceled and event number 16#1E41 is indicated at the **errorID** parameter output of the **_CP341_printer** FB.

Entering variables and message texts in the printer memory area

Before the data transfer to the CP 341 begins, the variable values to be printed must be entered **byte by byte and in the proper format** in the **variable[].data** element of the data structure of type **Struct_CP341_printData** (see item 2 in the example below). The number of bytes for each variable (variable length) must be assigned to the **variable.datalength** element (e.g. WORD type variable - variable.datalength:=2). An entry corresponding to the data type of the value must be made in the **format** element for each value entered in the **variable** element. (e.g. WORD type variable - %I). The total length of the entries in the **format** element must be assigned to the **format[0]** element.

You configure message texts with the CP 341 "point-to-point connection" parameter assignment interface. Once the hardware configuration has been downloaded to the SIMOTION device, the message texts are stored in the CP 341. The message texts that have been saved can be selected with corresponding entries in the **variable** and **format** elements.

Note

You can use supplemental function blocks (see Chapter supplemental function blocks (Page 6207)) to enter values into the printer memory area and to select message texts.

Example:

- Print message text no. 3 (stored in CP 341).
  Configured message text: "This is message text no. 3"

```
myPrintData.variable[0].datalength := 2;   // Data type WORD
myPrintData.variable[0].data[0]    := 0;
myPrintData.variable[1].data[0]    := 3;   // Message text no. 3
```

```
myPrintData.format[0]     :=2;       // Format string length
myPrintData.format[1]     :=16#25;  // "%" Format specification for message
text
myPrintData.format[1]     :=16#4E   // "N" Format specification for message
text
```

- Print message text no. 4 with a WORD-type variable.

```
Configured message text   : "This is message text no. %I"
Printed text          : "This is message text no. 4"

myPrintData.variable[0].datalength := 2;  // Data type WORD
myPrintData.variable[0].data[0]    := 0;
myPrintData.variable[0].data[0]    := 4;  // Message text no.4

myPrintData.variable[1].datalength := 2;  // 2 Byte data type WORD
myPrintData.variable[1].data[0]    := 0   // High - Byte
myPrintData.variable[1].data[1]    := 4   // Low - Byte
myPrintData.format[0]              := 4;  // Format string length
myPrintData.format[1]          := 16#25;  // ASCII code "%" format
specification
myPrintData.format[2]          := 16#4E;  // ASCII code "N" format
specification
                                          // for message text
myPrintData.format[3]          := 16#25;  // ASCII code "%" format
specification
myPrintData.format[4]          := 16#49;  // ASCII code "I" format
specification
                                          // for integer
```

Notes on handling

The format string entry in the "format" field must be hexadecimal.

Example:
% corresponds to 25 hex in the IBM character set,
N (message text output) corresponds to 4E hex in the IBM character set.
(see Hardware configuration > Character set)

Data types DATE, TIME, DATE_AND_TIME_OF_DAY and TIME_OF_DAY are not supported. The date information must be entered as a DWORD or WORD in the printer data structure.

Representation type "A" (German date format):
//datefrg:=4018 (01.01.2001) and 4199 (01.07.2001)
printData.variable[0].datalength:=2;
printData.variable[0].data[0]:=WORD_TO_BYTE(SHR(datefrg,8));
printData.variable[0].data[1]:=WORD_TO_BYTE(SHR(datefrg,0));

Representation type "F":
The value to be printed must be in floating point format (mantissa/exponent) (see call example 2, Chapter CP 341 print call examples (Page 6213))

Representation type "C":
If variable[ ].datalength:=1 in the printer data structure, the characters will be printed horizontally.
If variable[ ].datalength:=2 (3,4) in the printer data structure, the characters will be printed vertically.

Representation type "X":
For CP 341 RS232, product version E08 and higher, representation type "X" (binary) outputs the values correctly on a serial printer.

Disconnected printer
The communications link is not monitored for printers even if alarm generation is enabled in HW Config of STEP 7.

Example:

- A break in the connection between the printer and the CP 341 triggers neither an error nor a diagnostic alarm.
- Nor are they triggered if a print job is started but no printer is connected.

Note

The code in examples 1, 2, and 3 (see Chapter CP 341 print call examples (Page 6213)) can be transferred to the SIMOTION SCOUT editor with **Copy** and **Paste**.

supplemental function blocks

Function

Supplemental function blocks are provided for entering variables of various data types as well as for entering message texts into data structure **Struct_CP341_printData**. You enter the value of the variables **byte by byte** and **in the proper format** in the **variable** element of the printer memory area and, optionally, in the **format** element. When numbers are entered for message texts, one entry is made in each of the **format** and **variable** elements. The method of representation for the variables in printed text and the method of entry in the format string can be selected by means of parameters.

The following supplemental function blocks are available:

- **_CP341_realToPrintData**
  Entry of a number of data type REAL into data structure **Struct_CP341_printData**
- **_CP341_dwordToPrintData**
  Entry of a number of data type DWORD into data structure **Struct_CP341_printData**
- **_CP341_wordToPrintData**
  Entry of a number of data type WORD into data structure **Struct_CP341_printData**
- **_CP341_byteToPrintData**
  Entry of a number of data type BYTE into data structure **Struct_CP341_printData**
- **_CP341_dintToPrintData**
  Entry of a number of data type DINT into data structure **Struct_CP341_printData**

- **_CP341_intToPrintData**
  Entry of a number of data type INT into data structure **Struct_CP341_printData**
- **_CP341_printMsgText**
  Selection of message texts stored in CP 341

Note

SINT and USINT data types can be entered into data structure **Struct_CP341_printData** with the **_CP341_intToPrintData** function block. Type conversion is implicit.

Parameter description

Table 8-47 _CP341_byteToPrintData, _CP341_wordToPrintData, _CP341_dwordToPrintData parameters

Name	P type [1)]	Data type	Comment	Actions performed by user	Actions performed by block
execute	IN	BOOL	Edge-triggered job initiation	Entered	Checked
data	IN	BYTE/WORD/ DWORD	Variable/value to be entered in the data structure.	Entered	Checked
numVariable	IN	INT	Number of the variable in which the entry is to be made. 1≤ **numVariable** ≤ 4	Entered	Checked

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
entryFormatString	IN	ENUM	Method of entry in the format string and method of representation of the value in the **data** parameter.	Entered	Checked
		CP_RE-PLACE_WITH_SIGN	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: signed integer		
		CP_RE-PLACE_WITH-OUT_SIGN	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: unsigned integer		
		CP_REPLACE_BINA-RY	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: binary		
		CP_ADD_WITH-OUT_SIGN	Entry is added to the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: unsigned integer		
		CP_ADD_WITH_SIG N	Entry is added to the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: signed integer		
		CP_NO_ENTRY	No entry in the substructure of the format string		
entryAtByteNum-ber	IN	USINT	Specifies the byte at which the entry is to begin in the substructure of the format string. **entryAtByteNumber** = 0 Entry is made after the last entry found	Entered	Checked
printData	IN/OUT	Struct_CP341_prin tData	Data structure for the printer data	No actions	Enters values
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors (permissible value range exceeded)	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Table 8-48 _CP341_realToPrintData

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
execute	IN	BOOL	Edge-triggered job initiation	Entered	Checked
data	IN	REAL	Variable/value to be entered in the data structure.	Entered	Checked
numVariable	IN	INT	Number of the variable in which the entry is to be made. 1 ≤ **numVariable** ≤ 4	Entered	Checked
entryFormatString	IN	ENUM	Method of entry in the format string and method of representation of the value in the **data** parameter.	Entered	Checked
		CP_REPLACE_WITHOUT_EXPONENT	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: floating-point		
		CP_REPLACE_WITH_EXPONENT	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: with exponent		
		CP_ADD_WITHOUT_EXPONENT	Entry is added in the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: floating-point		
		CP_ADD_WITH_EXPONENT	Entry is added in the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: with exponent		
		CP_NO_ENTRY	No entry in the substructure of the format string		
entryAtByteNumber	IN	USINT	Specifies the byte at which the entry is to begin in the substructure of the format string. **entryAtByteNumber** = 0 Entry is made after the last entry found	Entered	Checked
printData	IN/OUT	Struct_CP341_printData	Data structure for the printer data	No actions	Enters values
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors (permissible value range exceeded)	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
execute	IN	BOOL	Edge-triggered job initiation	Entered	Checked
data	IN	INT/DINT	Variable/value to be entered in the data structure.	Entered	Checked
numVariable	IN	INT	Number of the variable in which the entry is to be made. 1 ≤ **numVariable** ≤ 4	Entered	Checked
entryFormatString	IN	ENUM	Method of entry in the format string and method of representation of the value in the **data** parameter.	Entered	Checked
		CP_DEFAULT	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: signed integer		
		CP_ADD_TO_STRING	Entry is added to the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: signed integer		
		CP_NO_ENTRY	No entry in the substructure of the format string		
entryAtByteNumber	IN	USINT	Specifies the byte at which the entry is to begin in the substructure of the format string. **entryAtByteNumber** = 0 Entry is made after the last entry found	Entered	Checked
printData	IN/OUT	Struct_CP341_printData	Data structure for the printer data	No actions	Enters values
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors (permissible value range exceeded)	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Table 8-50 _CP341_printMsgText

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
execute	IN	BOOL	Edge-triggered job initiation	Entered	Checked
numMsgText	IN	USINT	Number of the message text (stored in the CP 341)	Entered	Checked

Name	P type [1]	Data type	Comment	Actions performed by user	Actions performed by block
numVariable	IN	INT	Number of the variable in which the entry is to be made. 1 ≤ **numVariable** ≤ 4	Entered	Checked
entryFormatString	IN	ENUM	Method of entry in the format string and method of representation of the value in the **data** parameter.	Entered	Checked
		CP_DEFAULT	Entry starting at byte 1 in the substructure of the format string; existing entries are overwritten. Method of representation: signed integer		
		CP_ADD_TO_STRING	Entry is added to the substructure of the format string, **entryAtByteNumber** parameter is evaluated. Method of representation: signed integer		
		CP_NO_ENTRY	No entry in the substructure of the format string		
entryAtByteNumber	IN	USINT	Specifies the byte at which the entry is to begin in the substructure of the format string **entryAtByteNumber** = 0 Entry is made after the last entry found	Entered	Checked
printData	IN/OUT	Struct_CP341_printData	Data structure for the printer data	No actions	Enters values
done	OUT	BOOL	Job completed without errors	Checked	Entered
error	OUT	BOOL	Job completed with errors (permissible value range exceeded)	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Task integration (call)

The supplemental blocks must be called in the **BackgroundTask** or the **TimerInterruptTask**.

For call examples for the **_CP341_printer** FB, see Chapter CP 341 print call examples (Page 6213).

Status and error indicators

The **done** output indicates that the job has been completed without errors. The **error** output indicates that an error has occurred.

The **done** and **error** parameters are available for one block call only.

CP 341 print call examples

Call example 1

```

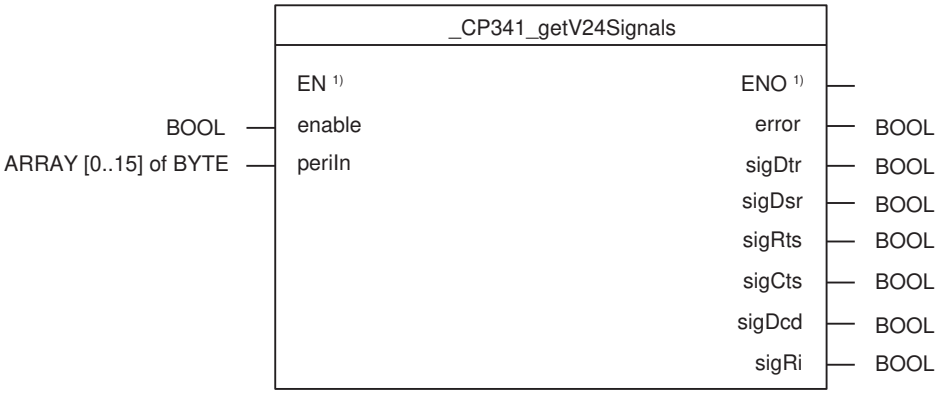
8.5.4.5 _CP341_getV24Signals function block

Function

The **_CP341_getV24Signals** function block reads the RS-232-C accompanying signals from the CP 341 and makes them available to the user in the block parameters. The functionality of the **_CP341_getV24Signals** FB can only be used if a parameterized ASCII driver is specified.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-51 Parameters of the _CP341_getV24Signals FB

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
enable	IN	BOOL	Block enable	Entered	Checked
periIn	IN	ARRAY[0..15] of BYTE	I/O inputs of the CP transferred to the FB	I/O variable of the I/O inputs of the CP transferred to the FB	Checked
error	OUT	BOOL	Job completed with errors	Checked	Entered
sigDtr	OUT	BOOL	Data terminal ready	Checked	Entered
sigDsr	OUT	BOOL	Data set ready	Checked	Entered
sigRts	OUT	BOOL	Request to send	Checked	Entered
sigCts	OUT	BOOL	Clear to send	Checked	Entered
sigCcd	OUT	BOOL	Data carrier detected	Checked	Entered
sigRi	OUT	BOOL	Ring Indicator	Checked	Entered

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Task integration (call)

The **_CP341_getV24Signals** function block must be called cyclically in the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

The RS 232C accompanying signals are updated each time the function is called (cyclic polling). The CP 341 updates the status of the inputs/outputs in a time base of 20 ms.

Note

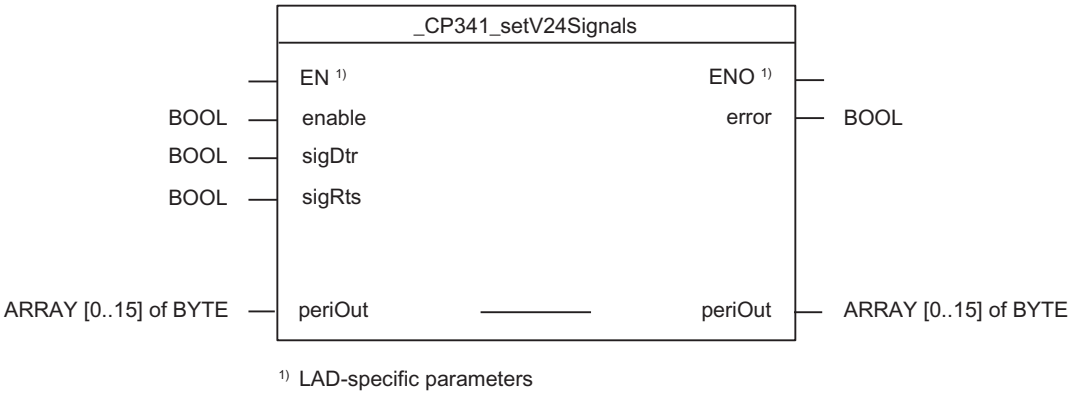
A minimum pulse duration is necessary to detect a signal change. Determining factors are the cycle time (SIMOTION device), the update time on the CP 341, and the response time of the communications partner.

8.5.4.6 _CP341_setV24Signals function block

Function

The **_CP341_setV24Signals** function block can be used to set or reset RS-232-C accompanying signals. The functionality of the **_CP341_setV24Signals** FB can only be used if a parameterized ASCII driver is specified.

Call (LAD representation)



Parameter description

Table 8-52 Parameters of the _CP341_setV24Signals FB

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
enable	IN	BOOL	Block enable	Entered	Checked
sigDtr	IN	BOOL	Data terminal ready	Entered	Checked
sigRts	IN	BOOL	Request to send	Entered	Checked

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
peri-Out	IN/OUT	ARRAY [0..15] of BYTE	Prepared FB data for the I/O outputs of the CP [2]	Checked and transferred to the I/O variables for the I/O outputs	Entered
error	OUT	BOOL	Job completed with errors	Checked	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with a variable of type **ARRAY[0..15] of BYTE**. Create a local or global variable in your program under **VAR** (do not create a temporary variable under VAR_TEMP). After the FB has been called, this variable must be assigned to the I/O variable for the I/O outputs of the module. See call example for CP 341.

Task integration (call)

The **_CP341_getV24Signals** function block must be called cyclically in the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

8.5.4.7 Calling the CP 341 function blocks

In order to be able to work with the function blocks in your user project, proceed as follows (the numbers shown in the following program segment correspond to the steps below):

1. Create the function block instance (see the following program segment, e.g. create instance for the **_CP341_send** FB).
2. Create a variable for the data structure (for RK 512 computer interfacing only).
3. Create an array for the in/out parameters of the FB.
4. Call instance of the function block.
5. Transfer input parameters.
6. The output parameters of the FB are accessed with <instance name of FB>.<name of output parameter>.
7. Data prepared by the FB for the I/O outputs are assigned to the array of the I/O variables created in step 3.

Note

The CP 341 call example is an extract from the supplied E_CP341 application example, which is included on the "SIMOTION Utilities & Applications" CD-ROM.

If you wish to control multiple CP 341 devices, you must create a new variable for the data structure and FB instances with a new name for each CP 341 you implement.

Call example for CP 341

```
UNIT E_CP341;

INTERFACE
```

```
VAR_GLOBAL
      myExecSendCP341      : BOOL;                    // Trigger send task
      myModuleAddrCP341    : DINT:=256;               // module address
      mySendDataArrayCP341 : ARRAY [0..4095] OF BYTE; // Send data array 4,096 bytes
      myInstCP341Send      : _CP341_send;             // Create instance of FB                    (1)
END_VAR

PROGRAM ExampleCP341;                                // Program in BackgroundTask

END_INTERFACE

IMPLEMENTATION
    VAR_GLOBAL
      MyResetSend          : BOOL;                    // Cancel send order
    END_VAR

PROGRAM ExampleCP341                                 // Program in BackgroundTask

// Variables used: see interface area under VAR_GLOBAL
VAR
    MyCPOutputArray       : ARRAY [0..15] OF BYTE;   // Array for CP output data                 (3)
END_VAR

VAR_TEMP
    MyDataLengthSend      : UDINT;            // Length of data to be sent
    MyDataOffsetSend      : UDINT;            // Offset of first byte to be sent
END_VAR

// CALL FB INSTANCE TO SEND
    myInstCP341Send (                                                                            (4)
        mode             := SEND_CP,                // Send data                                 (5)
        execute          := myExecSendCP341,        // Trigger order
        reset            := myResetSend,            // Order book
        moduleAddress    := myModuleAddrCP341,      // Module address
        dataOffset       := myDataOffsetSend,       // Offset
        dataLength       := myDataLengthSend,       // Number of data to be sent
        periIn           := myPeripheralInputCP341, // I/O variable of I/O inputs
        periOut          := myCPOutputArray,        // Data for I/O outputs
        data             := mySendDataArrayCP341    // Send data array
        );

    myStateStartUpCP341 := myInstCP341Send.startUp;  // Start-up status                          (6)

// TRANSFER DATA TO CP341
```

```
    myPeripheralOutputCP341  := myCPOutputArray;    // Array for output variables                (7)
                                                    // of I/O variables

END_PROGRAM               // ExampleCP341

END_IMPLEMENTATION
```

Note

The "ExampleCP341" program must be assigned in the execution system.

8.5.4.8 Data consistency

When sending data

Once a job is initiated by a positive edge at the **execute** input, the data to be sent is copied to the static memory area of the send FB. This means that once the FB call has ended, the send data array can be written to again for the next send request on a positive edge. The data are retained as consistent data within the send FB.

Note

During the copy operation to the static memory area of the FB, data consistency cannot be guaranteed if the send/receive data areas are accessed in a higher priority task.

When receiving data

Once the receive request is complete, the data are copied over to the receive buffer in a block from the static memory area of the receive FB. This means that when the FB call is complete, either all data (**newDataReceived** = TRUE) are entered in the receive buffer or no data (**newDataReceived** = FALSE) have been entered.

Note

During the copy operation from the static memory area of the receive FB, data consistency cannot be guaranteed if the send/receive data areas are accessed in a higher priority task.

8.5.4.9 Special features related to data transfer

Communication flag function with the CP 341

The communication flag functionality with respect to RK 512 computer interfacing is similar to that in the SIMATIC. Once data has been sent or fetched, a bit is set in the communications partner. This bit is checked when a new job is initiated. If it is set (= TRUE), the job is not processed. The communications partner must first reset this bit (= FALSE). The bit to be set or checked is specified by the requester FB (**_CP341_send**) in the **remoteComFlagByte** and **remoteComFlagBit** parameters.

SIMOTION ↔ SIMOTION

In the variable (ARRAY [0..31] of BYTE) created in the **comFlags** parameter, the bit position of the communication flag bit to be checked or set is specified as follows:

- **remoteComFlagByte** corresponds to the array index of the byte in which the bit is to be set/ checked.
- **remoteComFlagBit** corresponds to the bit position in the byte specified by the **remoteComFlagByte** parameter.

Note

The same variable must always be transferred at the **comFlags** parameter during the block call to ensure consistency of the communication flag bit.

SIMOTION ↔ SIMATIC

Communication flags are always stored in the flag area MB0 to MB254 in SIMATIC. The bit position of the communication flag bit to be checked or set is specified as follows:

- **remoteComFlagByte** corresponds to the flag byte in which the bit is to be set or checked (e.g. **remoteComFlagByte**=1 corresponds to MB1).
- **remoteComFlagBit** corresponds to the bit position in the byte specified by the **remoteComFlagByte** parameter.

Requests that can be processed simultaneously with the CP 341

The following function blocks may only be programmed once in your user program for each CP 341 communication processor used:

- _CP341_send FB
- _CP341_receive FB

Data transfer with the RK 512 computer interfacing

Data transfer options

Active jobs:

The **_CP341_send** function block enables you to issue active jobs to the CP 341 in the user program of the SIMOTION system. You can

- Send data from your automation system to a remote communications partner.
- Fetch data from a remote communications partner and store it in the send data array.

Note

If you fetch data from a CP 341, a **_CP341_receive** function block must be programmed for the communications partner.

Passive jobs:

The **_CP341_receive** function block enables you to use passive jobs to coordinate the reading of data on the CP 341 and make the data available. The communications partner is active. You can

- Enter data sent by the communications partner in the **dataCI512** receive data array.
- Make data available from **dataCI512** for a remote communications partner.

Special feature related to sending data

Note the following special features related to "sending" data:

- With RK 512, the amount of sent data must be an even number. If an odd value is specified for the length in the **dataLength** parameter, an additional filler byte with a value of "FALSE" will be transferred at the end of the data.
- With RK 512, any specified offset must be an even number. If an odd offset is specified, the data will be stored for the partner starting with the next smallest even offset.

8.5.4.10 Application example of the CP 341

Function

This example shows how to:

- use the **_CP341_send** function block to send data from the Send data array to a communications partner.
- use the **_CP341_receive** function block to receive data in the receive data array.

In the example program, the CP 341 is used both as the sender and receiver. This requires the jumpering of the send and receive lines (PIN 2 and PIN 3 on the RS232 interface) and the "ASCII" setting in the parameter assignment tool. The **_CP341_send** FB is used to transfer the send data to the CP module. This sends the data using the RS232 interface. The jumpered send and receive line means that the data to be sent is read immediately by the CP module. The **_CP341_receive** FB reads the received data from the CP module and copies these data to the receive data array.

This example requires proper installation of the parameter assignment tool, as described in the SIMATIC *CP 341 Point-to-Point Connection, Installation and Parameter Assignment* manual.

Hardware platform

The application example is available for various SIMOTION hardware platforms. You must adapt the example for centralized applications with SIMOTION C.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Assigning module parameters

Proceed as follows:

1. Open your project in SIMOTION SCOUT.
2. Open the hardware configuration in SIMOTION SCOUT.
3. Configure your hardware station with a CP 341 module.
4. Double-click the **CP 341** to open the "Properties" dialog box for this module. Click the "Parameters" button to launch the parameter assignment tool of the CP 341 module.
5. The "ASCII" protocol must be selected in the protocol selection box.
   The standard settings of the ASCII protocol suffices for the application example.
6. Jumper the send and receive line (PIN 2/PIN 3) of the RS232 interface.
7. Apply your settings in the parameter assignment interface with the "File" > "Save" menu command, and close the interface with the "File" > "Exit" menu command. Click "OK" to close the Properties window for the CP 341 module.
8. Save the hardware configuration with the "Station" > "Save and compile" menu command.
9. Download the hardware configuration with the "Target system" > "Download to module" menu command.
   The red "SF" LED on the IM 153 turns on and then off if the assigned module parameters have been downloaded without errors.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. You can adapt the configuration in the example to the available hardware (e.g. PROFIBUS DP address).
2. You can adapt the configuration of the hardware to the example (e.g. PROFIBUS DP address).

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the axis configuration: PROFIBUS DP addresses.
3. Check the module addresses (hardware configuration) against the I/O addresses of the controller in SIMOTION SCOUT and module address in the program (myModuleAddrCP341).
4. Save and compile the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

Sequence of the application example

Table 8-53 Input icons used

Symbol	Data type	Designation
mySelectPointToPointCP341	BOOL	Select point-to-point connection
myExecSendCP341	BOOL	Initiate send job
mySendOrder1	BOOL	Select send: Job 1
mySendOrder2	BOOL	Select send: Job 2
mySendOrder3	BOOL	Select send: Job 3
myResetSend	BOOL	Cancel send job
myEnableToReceive	BOOL	Receive enable
myReceiveOrder1	BOOL	Select receive: Job 1
myReceiveOrder2	BOOL	Select receive: Job 2
myReceiveOrder3	BOOL	Select receive: Job 3
myResetReceive	BOOL	Cancel receive job
myModuleAddrCP341	DINT	CP 341 module address, default 256
mySendDataArrayCP341	ARRAY[0..4095] of BYTE	Send data array
myReceiveDataArrayCP341	ARRAY[0..4095] of BYTE	Receive data array

Table 8-54 Output symbols used

Symbol	Data type	Designation
mySendDone	BOOL	Send: Completed
mySendError	BOOL	Send: Error display
mySendErrorNumber	WORD	Send: Error status
mySendTransErrorNumber	DINT	Send: Error status transfer
myNewDataReceived	BOOL	Receive: New data have been received
myReceiveError	BOOL	Receive: Error display
myReceiveErrorNumber	WORD	Receive: Error status
myReceiveTransErrorNumber	DINT	Receive: Error status transfer

Symbol	Data type	Designation
myStateStartupCP341	BOOL	CP 341 startup status FALSE = startup completed
myDiagnosticAlarm	BOOL	TRUE = diagnostic alarm present on the CP 341
myProcessAlarm	BOOL	TRUE = process alarm present on the CP341
myAlarmInterrupt	UDINT	Type of the alarm (process, diagnostic alarm)
myLogBaseAddrIn	DINT	Module address
myLogBaseAddrOut	DINT	
myLogAddress	DINT	Diagnostic address
myAlarmDetails	DWORD	Alarm information

Note

You can monitor and control the input and output variables used in the programming example in the INTERFACE area of the unit (under VAR_GLOBAL); alternatively, you can assign real inputs and outputs to the input and output variables in your user program.

For the "point-to-point connection" application example, set the "myselectPointToPointCP341" input to "TRUE". This will call function blocks contained in the application example.

Receiving data:

To receive data, you must set the "myEnableToReceive" variable to "TRUE" (static signal). If receive jobs 1 and 3 are enabled (myReceiveOrder1 = TRUE and "myReceiveOrder3" = TRUE), the data is stored in the "myReceiveDataArrayCP341" data array starting with the "myReceiveDataArrayCP341[0]" array element (data offset is 0). If job 2 is enabled ("myReceiveOrder2" = TRUE), the data is stored in the "myReceiveDataArrayCP341" data array starting with the "myReceiveDataArrayCP341[20]" array element (data offset is 20).
If "myNewDataReceived" = TRUE, this indicates that new data has been received. This signal is present for one cycle only.

If an error occurred during the transfer ("myReceiveError" = TRUE) the error code is stored in the "mySendErrorNumber" variable. If error code 16#1E0F is present in "myReceiveErrorNumber", an error occurred during the data transfer. The transfer error code is stored in the "myReceiveTransErrorNumber" variable. The error signals are reset when you set input "myResetReceive" = TRUE.

Sending data:

You can use the "mySendOrder1", "mySendOrder2" and "mySendOrder3" inputs to select between three send jobs:

- Job 1 sends 10 bytes of data from the "mySendDataArrayCP341" data array from array element "mySendDataArrayCP341[0]" to "mySendDataArrayCP341[9]"
- Job 2 sends 20 bytes of data from the "mySendDataArrayCP341" data array from array element "mySendDataArrayCP341[20]" to "mySendDataArrayCP341[39]"
- Job 3 sends 4,096 bytes of data from the "mySendDataArrayCP341" data array.

The data is sent to the communications partner if the "myExecSendCP341" input detects a signal change from "FALSE" to "TRUE" (positive edge).
If output signal "mySendDone" = TRUE, the send job has been completed. A new job can be sent if the "myExecSendCP341" input signal detects another signal change from FALSE to TRUE.

If an error occurred during the transfer ("mySendError" = TRUE), the error code is stored in the "mySendErrorNumber" variable. If error code 16#1E0F is present in "mySendErrorNumber", an error occurred during the data transfer. The transfer error code is stored in the "mySendTransErrorNumber" variable. The error signals are reset when you set input "myExecSendCP341" = FALSE.

When the signal state at the "myResetSend" or "myResetReceive" input is set to "TRUE", the send job or receive job is canceled, respectively. If the signal state remains "TRUE", sending and receiving of data is disabled.

Note

Proper data transfer can be observed as follows:

- The "TxD" and "RxD" LEDs on the CP module illuminate.
- Output parameter (_CP341_send FB) **done** = TRUE or **NewDataReceived** = TRUE

8.5.5 Alarm processing

Pending error messages are processed and evaluated differently in a SIMOTION system than in a SIMATIC system. Diagnostic alarms are not enabled by default. Enable the alarms for each module in the hardware configuration, see Chapter Integrating the communications processors in the SIMOTION project (Page 6136).

If you have parameterized diagnostic alarms, then you should program the alarm processing sequence according to the principle presented below.

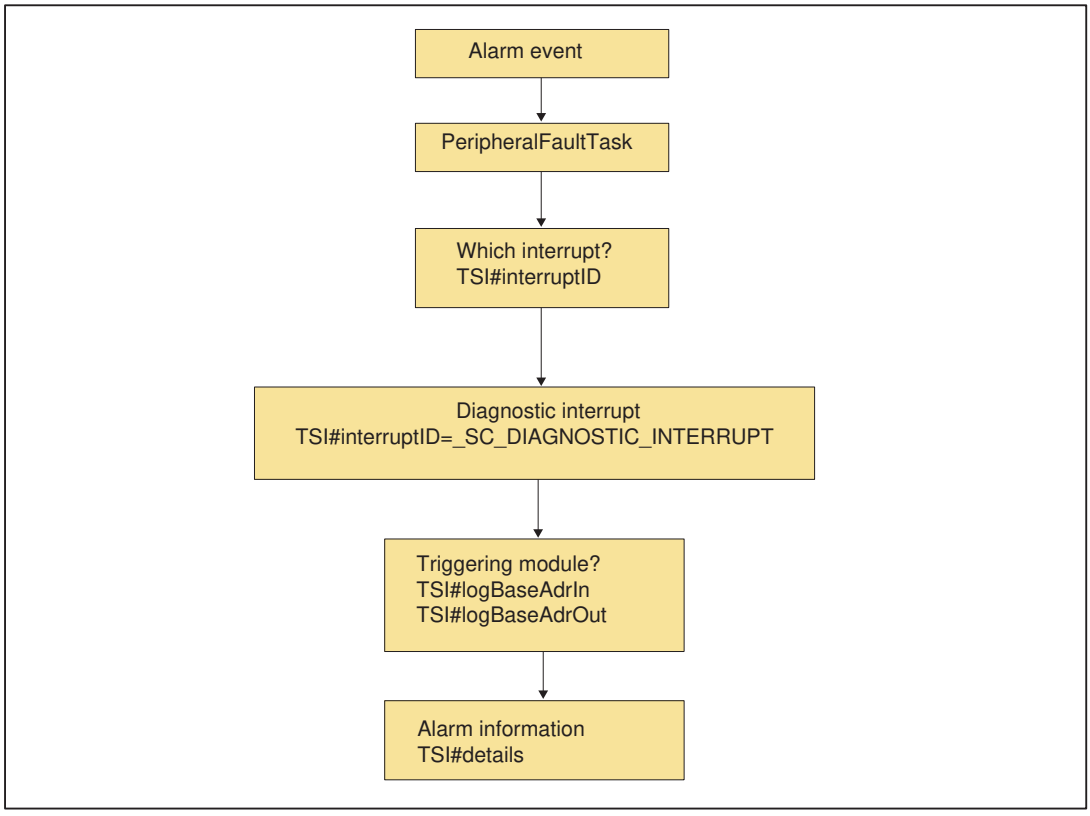


Figure 8-29 Alarm processing for CP 340 or CP 341

Alarm evaluation

Alarms originating from the I/O are evaluated in the **PeripheralFaultTask**. When the **PeripheralFaultTask** is started, the **Taskstartinfo** is made available, which you can evaluate in the user program.

The **Taskstartinfo** of **PeripheralFaultTask** is comparable to the local data of OB82 in the SIMATIC system.

Table 8-55 Meaning of the Taskstartinfo

Task	TSI		Remarks
PeripheralFaultTask	DT	TSI#startTime	Start time of the task
	UDINT	TSI#interruptID	Identifies the triggering event: • _SC_PROCESS_INTERRUPT • _SC_DIAGNOSTIC_INTERRUPT • _SC_STATION_DISCONNECTED • _SC_STATION_RECONNECTED
	DINT	TSI#logBaseAdrIn	Logical base address if a process alarm (PRAL) or a diagnostic alarm (DAL) was caused by an input area on the module, otherwise _SC_INVALID_ADDRESS
	DINT	TSI#logBaseAdrOut	Logical base address if a process alarm (PRAL) or a diagnostic alarm (DAL) was caused by an output area on the module, otherwise _SC_INVALID_ADDRESS
	DINT	TSI#logDiagAdr	Diagnostic address of a DP slave if the alarm was caused by a station failure or station recovery of an associated DP slave, otherwise _SC_INVALID_ADDRESS
	DWORD	TSI#details	Detail information (bit fields)

Definition of a diagnostic alarm

If the user program is to respond to an internal or external error, you can set the parameters for a diagnostic alarm that will interrupt the cyclical program of the SIMOTION device.

Events triggering a diagnostic alarm

The criteria (events) that trigger diagnostic alarms in a SIMOTION system are the same as in a SIMATIC system.

More detailed information is available in the following SIMATIC manuals: *CP 340 Point-to-Point Connection, Installation and Parameter Assignment and CP 341 Point-to-Point Connection, Installation and Parameter Assignment*.

Responses to a diagnostic alarm

If a diagnostic alarm occurs, the following take place:

- Diagnostic data are written to **TSI#details** variable in the Taskstartinfo of **PeripheralFaultTask**.
- In the **PeripheralFaultTask**, you can read out and save the 4 bytes of diagnostic data.
- The group error LED (SF) of the CP module lights up. The group error LED (SF) is extinguished as soon as the error has been remedied.

Bit assignment

The **TSI#details** variable is assigned in the same way as in a SIMATIC system.

Note

More information is available in the following SIMATIC manuals:

- *CP 340 Point-to-Point Connection, Installation and Parameter Assignment*
- *CP 341 Point-to-Point Connection, Installation and Parameter Assignment*

8.5.6 Appendices

8.5.6.1 SIMOTION and SIMATIC names

The tables below contain a comparison of SIMOTION and SIMATIC names.

Table 8-56 SIMOTION and SIMATIC names for CP 340

Name in the SIMOTION system as of V4.0 (command library in SCOUT)	Name in the SIMATIC system	Name in the SIMOTION system up to V3.2 (SIMOTION Function Library)

8.6 Supplement to the FM 350-1, FM 350-2, and FM 352 Modules

Preface

Contents of the function manual

This **document** is part of the **SIMOTION Programming - References documentation package**.

This documentation is a supplement to the following SIMATIC manuals:

- FM 350-1 Function Module, *Installation and Parameter Assignment*
- FM 350-2 Counter Module, *Installation and Parameter Assignment*
- FM 352 Electronic Cam Controller, *Installation and Parameter Assignment*

These documents are included in the SIMOTION SCOUT scope of delivery as electronic documentation.

This manual supplement will help you to correctly integrate and commission the FM 350-1, FM 350-2 and FM 352 modules in a SIMOTION system.

Differences in handling which result from the software architecture of a SIMOTION system as compared to the software architecture of a SIMATIC system will be described.

Function blocks

The function blocks required for communication between the SIMOTION system and the FM 350-1, FM 350-2 and FM 352 modules are included in the command library of the "SIMOTION SCOUT" engineering system.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P

- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

8.6.1 Fundamental safety instructions

8.6.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.6.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.6.2 Description

8.6.2.1 General part

This section describes the general similarities and differences in the operation of the function modules (FMs) in a SIMOTION system as compared to a SIMATIC system.

Note

This manual is a supplement to the following SIMATIC manuals:

- *FM 350–1 Function Module Installation and Parameter Assignment*
- *FM 350–2 Counter Function Module Installation and Parameter Assignment*
- *FM 352 Electronic Cam Controller, Installation and Parameter Assignment*

These documents are included in the SIMOTION SCOUT scope of delivery as electronic documentation!

The following software versions are required for the standard functions described in this documentation:

- SIMOTION SCOUT V4.2 or higher
- SIMOTION Kernel V4.2 or higher

8.6.2.2 Product description

FM 350-1 counter module

The FM 350-1 is a single-channel, high-speed counter module. The module can function in the following counter ranges:

- 0 to 2^{32} - 1
- -2^{31} to 2^{31} - 1

The maximum input frequency of the counter signals is up to 500 kHz depending on the encoder signal.

The FM 350-1 can be used for the following counting and measuring tasks:

- Continuous counting
- Single counting
- Periodic counting
- Frequency measurement
- Period measurement
- Speed measurement

You can start and stop the count or measurement process either via the user program (software gate) or via external signals (hardware gate).

From release 3 (Article No.: 6AG1350-1AH03-2AE0), you can also operate the FM 350-1 in a clock synchronized manner with a suitable interface module (IM) in the ET 200M system.

FM 350-2 counter module

The FM 350-2 is an 8-channel counter module with dosing functions. The module can function in the following counter ranges:

- -2^{31} to 2^{31} - 1

The maximum input frequency of the counter signals is up to 10 kHz per counter channel depending on the encoder signal.

The FM 350-2 can be used for the following tasks:

- Continuous counting up/down
- Single counting up/down
- Periodic counting up/down
- Frequency measurement
- Speed measurement
- Period measurement
- Dosing

You can start and stop the count either via the user program (software gate) or via external signals (hardware gate).

The counter, gate and direction signals can be connected directly to the module.

FM 352 electronic cam controller

The FM 352 is a single-channel electronic cam controller. It supports both rotary axes and linear axes. Initiators, incremental encoders or absolute encoders (SSI) can be connected for position sensing. As a slave, the FM 352 can also listen in on the SSI message frame of an absolute encoder.

Up to a maximum of 128 position-based or time-based cams can be parameterized. The position-based and time-based cams can be assigned to 32 cam tracks. The first 13 cam tracks are output via the digital outputs on the module.

Function blocks

Function blocks are required for controlling the function modules. The function blocks for the SIMOTION system are described in this manual.

Functionality of the function modules

The function blocks (FBs) and the function modules (FMs) have the same functionality in a SIMOTION system as in a SIMATIC S7 automation system. However, the execution of data transfers and the handling of FBs have been adapted to the given SIMOTION boundary conditions.

Possible applications

In addition to the possible applications described in the SIMATIC manuals, the FM 350-1, FM 350-2 and FM 352 function modules can also be used in a SIMOTION system. The function modules can be used as centralized modules (on the SIMOTION C2xx only) or as distributed modules (SIMOTION C2xx, SIMOTION P35x and SIMOTION D4xx).

Several FM 350-1, FM 350-2 and FM 352 modules can be operated on one SIMOTION device.

The following figure shows you how to connect an ET 200M distributed I/O device with IM 153-1 and FM 350-1 or FM 350-2 or FM 352 to a SIMOTION device (e.g. SIMOTION C2xx).

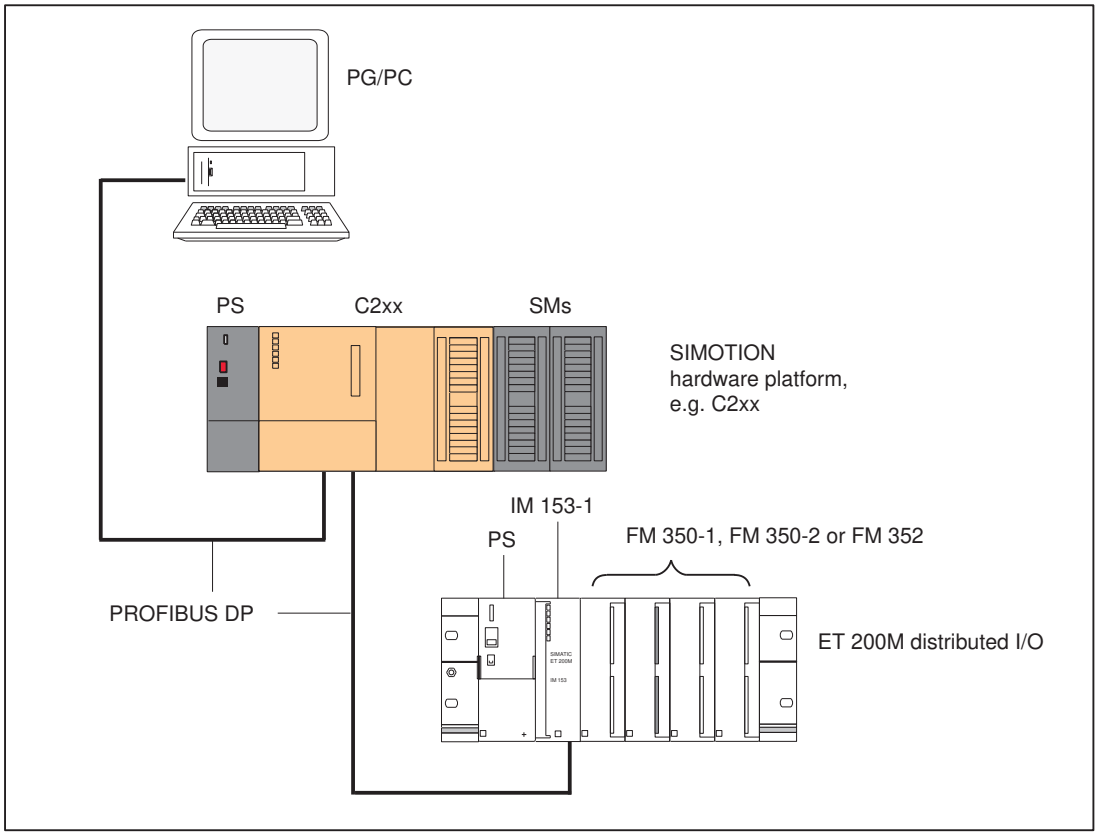

Figure 8-30 Connection of the FMs in an ET 200M to the SIMOTION C2xx device (example of distributed application)

8.6.2.3 Installation and connection

Overview

The following steps need to be carried out in order to commission the FM 350-1, FM 350-2 or FM 352 function modules and to control them from the SIMOTION system:

Distributed application (SIMOTION C2xx, SIMOTION P350, and SIMOTION D4xx)

1. Assemble and wire the ET 200M distributed I/O device complete with power supply (PS), interface module (IM) and function module (FM).
2. Establish the PROFIBUS connection between the ET 200M and the SIMOTION device.
3. Set the PROFIBUS DP node address on the IM.

4. Switch on the terminating resistor at the first and last bus node.

Note

For steps 1 to 4, refer to the *ET 200M Distributed I/O* manual.

This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

5. Insert the function modules FM 350-1 / FM 350-2 / FM 352 into the SIMOTION project, see chapter Inserting function modules into the SIMOTION project (Page 6244).
6. Assign parameters for the FM 350-1, FM 350-2 or FM 352 function module.
   The following SIMATIC manuals describe how to install the parameter assignment interfaces for the FMs and how to assign the module parameters:
   – For FM 350-1, refer to the *FM 350-1 Function Module, Installation and Parameter Assignment* manual.
   – For FM 350-2, refer to the *FM 350-2 Counter Module, Installation and Parameter Assignment* manual.
   – For FM 352, refer to the *FM 352 Electronic Cam Controller, Installation and Parameter Assignment* manual.
7. Link the function blocks to the SIMOTION project (refer to chapter Integrating the function blocks in the user project (Page 6245)).

Centralized application (SIMOTION C2xx only)

1. For information on planning the mechanical installation and preparing and mounting the SIMOTION components, refer to the *SIMOTION C2xx* operating instructions and the *SIMATIC S7-300 Automation System, software installation manual*.
   These documents are included in the SIMOTION SCOUT scope of delivery as electronic documentation!
2. To continue, refer to steps 5 to 7 for distributed application.

8.6.2.4 Inserting function modules into the SIMOTION project

Requirement

The following requirements must be met when networking with PROFIBUS:

1. You have created a project in SIMOTION SCOUT and have inserted a rack with a SIMOTION hardware platform in the hardware configuration.
2. You have configured a PROFIBUS subnet (for distributed use only).

Note

For how to create a project and configure a PROFIBUS subnet, refer to the online help of *SIMOTION SCOUT*.

The following requirements must be met when with PROFINET:

1. You have created a project in SIMOTION SCOUT and have inserted and configured a rack with a PROFINET-compatible SIMOTION device in the hardware configuration.
2. You have configured a PROFINET IO System (for distributed use only).

Note

For how to create a project and configure a PROFINET IO system, refer to the online help of *SIMOTION SCOUT*.

Inserting FM 350-1, FM 350-2 or FM 352 (distributed application)

The description below is an example of networking via PROFIBUS.

1. In SIMOTION SCOUT, open the **User Projects** dialog box with the **Project > Open** menu command. In this dialog box, select your project and confirm your choice with **OK**.
2. Open **HW Config**.
3. In the **HW Config** window, open the **hardware catalog** with the **View > Catalog** menu command.
4. Open the **PROFIBUS DP** folder and the **ET 200M** subfolder in the hardware catalog. Select, for example, the **IM 153-1 interface module** (Article No.: 6ES7 153-1AA03-0XB0 or a successor module).
5. Use a drag-and-drop operation to place the IM 153-1 I/O device on the PROFIBUS subnet of your project. The **Properties - PROFIBUS IM 153-1 Interface** dialog box opens. In this dialog box, select the address you set on the IM 153-1 (see *ET 200M Distributed I/O Device* manual) and confirm with **OK**.
   The selected IM 153-1 I/O device is inserted in the project.
6. The inserted I/O device must now be fitted with your project modules. To do this, open the **FM300** subfolder below the selected I/O device in the hardware catalog and select the relevant **FM modules**.

   Note

   By default, the diagnostic alarms and process alarms are not enabled. Activate the alarms for each module in the **Properties** dialog box.

7. **Save** and **compile** your project.

8.6.2.5 Integrating the function blocks in the user project

Creating the FBs instance in the user project

The function blocks are part of the command library of the SIMOTION SCOUT engineering system. For working with the blocks, an instance has to be created in the user project for each function block used.

Example:

```
VAR_GLOBAL
...
    myInstFM3502Ctrl    : _FM3502_control;    // create FB instance
    myInstFM3501Ctrl    : _FM3501_control2;   // create FB instance
    myInstFM352Ctrl     : _FM352_control;     // create FB instance
...
END_VAR
```

Call (LAD representation)

The LAD representation of the individual function blocks can be found in the respective function block descriptions.

Application example

The application example is included on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and is part of the SIMOTION SCOUT scope of delivery.

8.6.2.6 Creating I/O variables

Overview

Communication between the SIMOTION device and the FM 350-1, FM 350-2 and FM 352 takes place via direct I/O access and data set transfer. For data set transfer, the module address is transferred to the FB as an input parameter. I/O variables are used to address the direct read/write access to the I/O.

You can freely assign the names of I/O variables in SIMOTION SCOUT. I/O variables must be specified as ARRAY [0..15] of BYTE. You assign the address settings in the hardware configuration to these I/O variables.

The names of the I/O inputs must be transferred to the function blocks as call parameters (**periIn**). The prepared data for the I/O outputs are provided by the FB as in/out parameters (**periOut**). The in/out parameter must be supplied with a variable of type ARRAY [0..15] of BYTE. After the block is called, this variable must be assigned to the I/O variables for the I/O outputs (see call example in chapter "Calling the function blocks").

Note

The variable for supplying the in/out parameters **must not** be created as a temporary variable (VAR_TEMP or local variable of a function).

The following example shows how to assign the module addresses to the I/O variables in SIMOTION SCOUT.

	Name	I/O address	Read only	Data type	Field length
1	⊞ myperipheralinputfm3501	PIB 256		Array	16
2	⊞ myperipheraloutputfm3501	PQB 256	☐	Array	16

Figure 8-31 Address assignment in SIMOTION SCOUT

Note

For additional information, see the following sources:

- *SIMOTION SCOUT* online help
- Programming manual of the corresponding programming language, e.g.:
  - *SIMOTION ST, Structured Text* programming manual
  - *SIMOTION MCC, Motion Control Chart* programming manual
  - *SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram* programming manual

These documents are included in the SIMOTION SCOUT scope of delivery as electronic documentation!

8.6.3 Function blocks of the FM 350-1

8.6.3.1 Overview of the FM 350-1 function blocks

This section describes the function blocks (FBs) and the data structure required for parameter assignment, control and commissioning of the FM 350-1 module.

The function blocks form the software interface between the SIMOTION device and the FMs. They must be called repeatedly (in cycles) from the user program.

The following function blocks are available:

- Function block _FM3501_control2 (Page 6248)
- Function block _FM3501_diagnostic (Page 6252)

SIMOTION SCOUT contains all of the required FBs and data structure **Struct_FM3501_fmData** of the FM 350-1. The function blocks can be used to control one or more FM 350-1 modules.

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6310) in the table "SIMOTION and SIMATIC identifiers FM 350-1".

8.6.3.2 Function block _FM3501_control2

Introduction

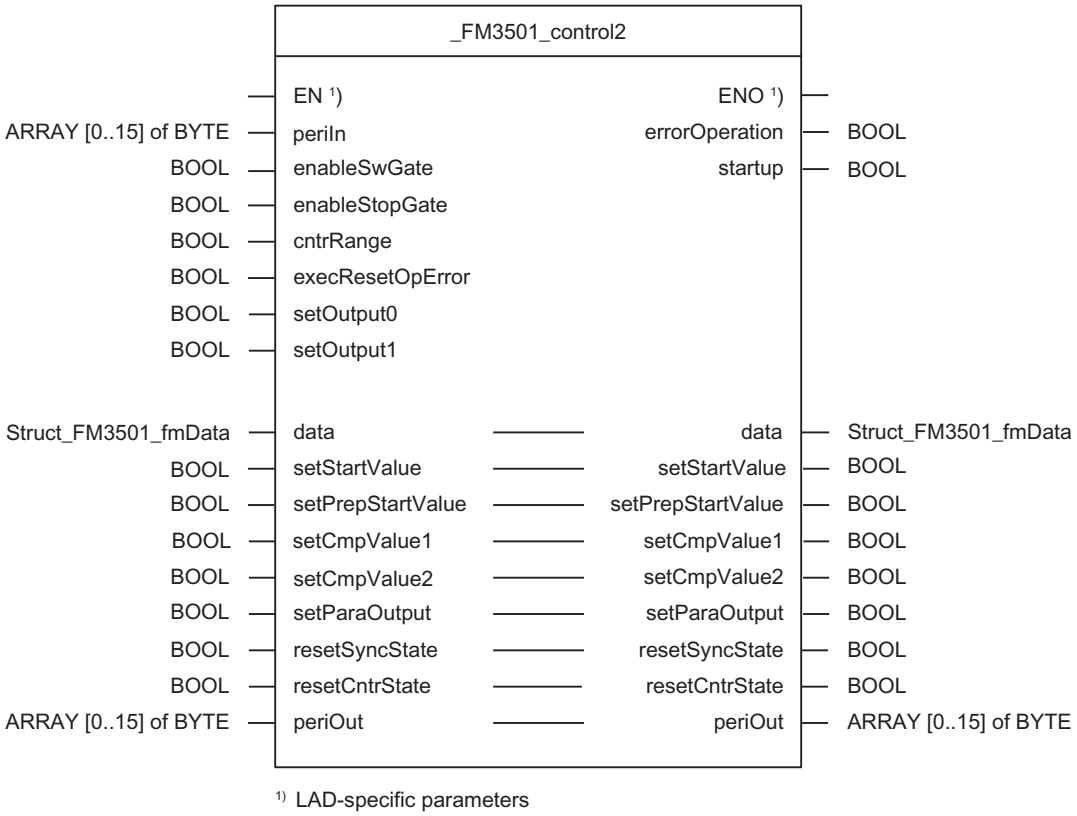
The **_FM3501_control2** function block can be used to control the module and to query the status of the FM 350-1.

Note

With SIMOTION V4.2 and higher, the **_FM3501_control2** function block with enhanced functions is available.

The **_FM3501_control** function block is still supported for compatibility reasons, although it does not enable the full scope of functions offered by the FM 350-1 to be activated.

Call (LAD representation)



1) LAD-specific parameters

Parameter description

Table 8-59 Parameters of the _FM3501_control2 function block

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
periIn	IN	ARRAY [0 to 15] of BYTE	Transfers I/O inputs of the FM to the FB	I/O variable of the I/O inputs of the FM transferred to the FB	Queried
enableSwGate	IN	BOOL	"SW gate (start/stop)" counter control bit	Sets and resets this	Queried
enableStopGate	IN	BOOL	"Stop gate" counter control bit	Sets and resets this	Queried
cntrRange	IN	BOOL	Counter range limit of the FM FALSE: $-2^{31} \leq$ count value $< 2^{31}-1$ TRUE: $0 \leq$ count value $< 2^{32}-1$	Sets and resets this	Queried
execResetOpError	IN	BOOL	Acknowledges operator error in the case of a rising edge	Sets and resets this	Queried
setOutput0	IN	BOOL	Setting/resetting of digital output DO0 of the FM 350-1	Sets and resets this	Queried
setOutput1	IN	BOOL	Setting/resetting of digital output DO1 of the FM 350-1	Sets and resets this	Queried
data	IN/OUT	Struct_FM3501 _fmData	Data structure	Entered and queried	Queried and entered
setStartValue	IN/OUT	BOOL	Count: Transfers "direct loading" trigger bit [2] Measuring: may not be used.	set	Queries and resets this
setPrepStartValue	IN/OUT	BOOL	Count: Transfers "preparatory loading" trigger bit [3] Measuring: Transmission of the lower limit	set	Queries and resets this
setCmpValue1	IN/OUT	BOOL	Count: Transfers "comparison value 1" trigger bit Measuring: Transmission of the upper limit	set	Queries and resets this
setCmpValue2	IN/OUT	BOOL	Count: Transfers "comparison value 2" trigger bit Measuring: Transmission of the update time	set	Queries and resets this

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
setParaOutput	IN/OUT	BOOL	Reassignment of parameters for behavior of digital outputs DO0 and DO1 of the FM 350-1, specification in following elements of data structure **Struct_FM3501_fmData**: configMeasOut0 configCntrOut0/ configCntrOut1 setCntrHyst setCntrPulse	set	Queries and resets this
resetSyncState	IN/OUT	BOOL	Deletes "synchronization" status bit	set	Queries and resets this
resetCntrState	IN/OUT	BOOL	Deletes "zero crossing" status bit	set	Queries and resets this
periOut	IN/OUT	ARRAY [0 to 15] of BYTE	Prepared data of the FB for the I/O outputs of the FM [4]	Queried and entered on the I/O variable for the I/O outputs	Entered
errorOperation	OUT	BOOL	An operator error has occurred	Queried	Sets and resets this
startup	OUT	BOOL	Indicates the startup of the FM	Queried	Entered

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] The **setStartValue** parameter specifies that the load value will be transferred to the load register and directly to the counter.

[3] The **setPrepStartValue** parameter specifies that the load value will be stored in the load register only. The load value in the load register will then be transferred at the next trigger (FM input "DI set" - set counter). The following must be satisfied:
- **enableReverseSetting = TRUE** (element of data structure **Struct_FM3501_fmData**) or
- **enableForwardSetting = TRUE** (element of data structure **Struct_FM3501_fmData**)

[4] **Note:** The **periOut** parameter must be supplied with an array of type **ARRAY [0 to 15] of BYTE**. Create a local or global array in your program under **VAR** (do not create a temporary array under VAR_TEMP). After the FB has been called, this array must be assigned to the I/O variable for the I/O outputs of the module. See FM 350-1 call example.

Functionality

The **_FM3501_control2** function block transfers data cyclically from a data structure of type **Struct_FM3501_fmData** to the FM 350-1. It also reads data from the FM 350-1 and enters this data in the elements of the data structure.

Note

Count:

The **cntrRange** input parameter must be set according to the assigned count range limits of the FM 350-1.

- **cntrRange** := **FALSE**, count range -231 ≤ count value < 231 - 1
  - loadValue1, cmpValue1_1, cmpValue2_1 are written from the FB to the FM
  - actValue1, actCntrValue1 are read from the FM
- **cntrRange** := **TRUE**, count range 0 ≤ count value < 232 - 1
  - loadValue2, cmpValue1_2, cmpValue2_2 are written from the FB to the FM
  - actValue2, actCntrValue2 are read from the FM

The same count ranges must be selected in the parameterization tools and in the data structure (**cntrRange**).

Measuring:

In measuring operating modes (frequency measurement, period measurement, speed measurement) the input parameter **cntrRange** := **TRUE** must be set.

Task integration (call)

The **_FM3501_control2** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

You can start a job for the FM 350-1 via the appropriate parameters **setStartValue**, **setPrepStartValue**, **setCmpValue1**, **setCmpValue2**, **setOutput0, setOutput1, setParaOutput**, **resetSyncState**, **resetCntrState**, **execResetOpError**, **enableStopGate**, or **enableSwGate**.

Depending on the job, the following values must be entered in the data structure before each call:

- during counting: the load value or the comparison value
- during measuring: the lower limit, the upper limit, or the update time
- when reassigning parameters for digital outputs: the specification of the behavior of the digital outputs

Once the job is carried out, the **_FM3501_control2** function block deletes any set in/out parameter (**setStartValue**, **setPrepStartValue**, **setCmpValue1**, **setCmpValue2**, **setParaOutput**, **resetSyncState**, or **resetCntrState**). This enables you to recognize that the job has been executed by the FM 350-1.

Startup behavior

As soon as the **_FM3501_control2** function block detects that the FM 350-1 is starting up, any pending job is deferred until after the startup is acknowledged. A startup of the FM 350-1 is indicated by output parameter **startup**=**TRUE**. Any deferred jobs are carried out once the startup is finished and are therefore not lost.

Error message during an FB call

If an error occurs during an FB call, it is indicated at the **errorOperation** block parameter. You can read out the error information in the **errorIdOperation** element of the data structure. You can acknowledge the error using the **execResetOpError** parameter.

Note

No new errors can be signaled until you have acknowledged the error.

Error numbers

The following error numbers can be displayed in the **errorIdOperation** element in the data structure.

Table 8-60 Error number assignment

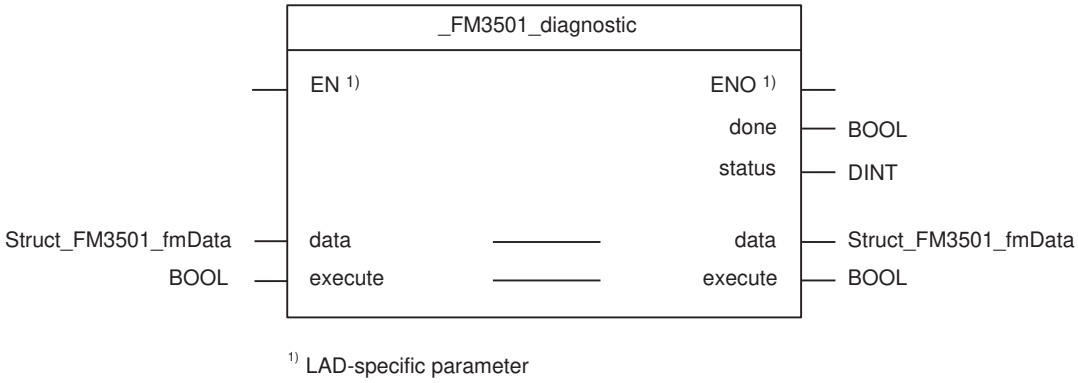
Error number	Meaning
0	No error
1	Operating mode cannot be started using the SW gate
2	Operating mode cannot be aborted
4	Only permitted if there is a pending output disable (OD)

8.6.3.3 Function block _FM3501_diagnostic

Introduction

The **_FM3501_diagnostic** function block enables you to read out the complete diagnostic data from the FM 350-1.

Call (LAD representation)



Parameter description

Table 8-61 Parameters of the _FM3501_diagnostic function block

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
data	IN/OUT	Struct_FM3501 _fmData	Data structure with counter data and diagnostic data	Entered and checked	Checked and entered
execute	IN/OUT	BOOL	Trigger bit for diagnostic data set	set	Checks and resets this
done	OUT	BOOL	Job completed without errors	Checked	Entered
status	OUT	DINT	Return value (error ID) 2) **_readRecord**	Checked	Entered

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

2) A detailed description is contained in the *SIMOTION System Function/Variables* parameter manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Functional description

Diagnostic data is read out from the **_FM3501_diagnostic** function block and made available in the associated **Struct_FM3501_fmData** data structure. The return value (error ID) can be read out at the **status** output parameter of the function block.

Sequence

Data is transferred as follows:

1. If in/out parameter **execute** = **TRUE** is set, the diagnostic data is read out from the FM 350-1.
2. The data are entered in data structure **data** of the **_FM3501_diagnostic** function block.

3. The return value (error ID) is copied to the **status** parameter of FB instance **_FM3501_diagnostic**.

Note

The return value (error ID) in the **status** parameter is present for one cycle only. The values 0x7001 and 0x7002 indicate that a data transfer has been initiated and is active.

4. As soon as the function has been executed, in/out parameter**execute** is reset.

Note

For the diagnostic sequence to be correct, the module address must be entered in the **moduleAddress** element of the data structure of type **Struct_FM3501_fmData**.

Task integration (call)

The **_FM3501_diagnostic** function block can be called in the **PeripheralFaultTask**, **BackgroundTask** or **TimerInterruptTask**. For performance reasons, the function block should not be called in the **PeripheralFaultTask**.

8.6.3.4 Data structure of the FM 350-1

Overview

The data structure of type **Struct_FM3501_fmData** contains the control and checkback signals of the FM 350-1 and the diagnostic data.

The data structure is used by the **_FM3501_control2** and **_FM3501_diagnostic** function blocks. Elements of the data structure are accessed using a variable of data type **Struct_FM3501_fmData**, which you must define yourself.

The **Struct_FM3501_fmData** data structure is shown in the table below.

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6310) in the table "SIMOTION and SIMATIC identifiers FM 350-1".

Table 8-62 Data structure of Struct_FM3501_fmData

[1] Variable for internal FB use (not relevant to users)

configMeasOut0 structure

In "Measuring" operating mode, the behavior of digital output DO0 for **setParaOutput = TRUE** is defined as follows in parameter **configMeasOut0**:

Table 8-63 configMeasOut0 structure

Bits 2 to 7	Bit 1	Bit 0	Behavior of digital output DO0
x	0	0	Inactive
x	0	1	Outside the limits
x	1	0	Below the lower limit
x	1	1	Above the upper limit

configCntrOut0/configCntrOut1 structure

In "Counting" operating mode, the behavior of digital outputs DO0 and DO1 for **setParaOutput = TRUE** is defined as follows in parameter **configCntrOut0/configCntrOut1**:

Table 8-64 configCntrOut0/configCntrOut1 structure

Bits 3 to 7	Bit 2	Bit 1	Bit 0	Behavior of digital outputs DO0/DO1
x	0	0	0	Inactive
x	0	0	1	Active within the range from comparison value to overflow
x	0	1	0	Active within the range from comparison value to underflow
x	0	1	1	Active on reaching the comparison value for pulse duration (up/down)
x	1	0	0	Active on reaching the comparison value for pulse duration up
x	1	0	1	Active on reaching the comparison value of pulse duration down

8.6.3.5 Calling function blocks

In order to be able to work with the function blocks in your user project, proceed as follows (the numbers shown in the following program segment correspond to the steps below):

1. Create the function block instance (see the following program segment, e.g. create instance for FB **_FM3501_control2**).
2. Set up variables for the data structure.
3. Create an array for the in/out parameters of the FB.
4. Call instance of the function block.
5. Transfer input parameters.

6. The output parameters of the FB are accessed with <instance name of FB>. <name of output parameter>.
7. Data prepared by the FB for the I/O outputs are assigned to the array of the I/O variables created in step 3.

Note

The call example is an extract from the E_FM3501 application example supplied, which can be found on the "SIMOTION Utilities & Applications" CD-ROM.

If you wish to control more than one FM 350-1, you must create a new variable for the data structure and FB instances with a new name for each FM 350-1 used.

Call example

```
UNIT E_FM3501;
INTERFACE
    VAR_GLOBAL
    myDataFM3501 : Struct_FM3501_fmData;      // Create variable of data structure              (2)
    // Following variables are - set by application to activate function;
    // - reset by FB to signal completion of function.

    MyLoadStartValue         : BOOL;             // Load load value directly
    MyLoadPrepareStartValue  : BOOL;             // Load load value in preparation
    ...

    // INPUT VARIABLES
    MySetSoftwareGate        : BOOL;             // Software gate
    MyStopGate               : BOOL;             // Stop gate
    ...

    // OUTPUT VARIABLES
    MyOperationError         : BOOL;             // Error in FB _FB_FM3501_control2
    MyStateFMStartup         : BOOL;             // Start-up status

    myInstFM3501Ctrl         : _FM3501_control2; // create FB instance                         (1)

    END_VAR

END_INTERFACE

IMPLEMENTATION

PROGRAM ExampleFM3501                            // Program in BackroundTask

VAR
```

```
    FMOutputArray      : ARRAY [0..15] of BYTE;  // Array for FM output data                    (3)
END_VAR

// CALL INSTANCE of _FM3501_control2                                                            (4)
  myInstFM3501Ctrl(
    EnableSwGate       := mySetSoftwareGate,        // Control software gate                    (5)
    EnableStopGate     := myStopGate,               // Control internal gate
    ExecResetOpError   := myResetError,             // Acknowledge operator error
    CntrRange          := TRUE,                     // Counter range
    setOutput0         := mySetOutput0,             // Control digital otput
    setOutput1         := mySetOutput1,             // Control digital otput
    PeriIn             := myPeripheralInputFM3501,  // input address
    Data               := myDataFM3501,             // Transfer data structure
    PeriOut            := FMOutputArray,            // FM output data array

  // following IN_OUT parameters are set by the application
  // and reset by the FB! (shake-hand-effect)
    SetStartValue      := myLoadStartValue,         // Load counter
    SetPrepStartValue  := myLoadPrepareStartValue,  // Load counter in preparation
    setCmpValue1       := myLoadComparisonValue1,   // Load new comparison value 1
    setCmpValue2       := myLoadComparisonValue2,   // Load new comparison value 2
    resetSyncState     := myResetSyncState,         // Reset synchronization bit
    resetCntrState     := myResetCounterState,      // Reset status bit
    setParaOutput      := mySetParaOutput           // set new configuration
                                                    // data of digital outputs
    );

// TRANSFER DATA TO FM
    myPeripheralOutputFM3501 := FMOutputArray;   // Assign array of FM output data             (7)
                                                 // to I/O variables

// EVALUATE AND DISPLAY STATUS MESSAGES
    MyStateFMStartup   := myInstFM3501Ctrl.startup;          // Start-up status               (6)
    MyOperationError   := myInstFM3501Ctrl.errorOperation;

END_PROGRAM           // ExampleFM3501
END_IMPLEMENTATION
```

Note

The PROGRAM ExampleFM3501 must be assigned in the execution system.

8.6.3.6 Application example for FM 350-1

Introduction

The following example uses the "Transfer load value to FM 350-1" and "Start counter" functions to show how the **_FM3501_control2** function block can be applied. This example is representative for all of the functions of this module. A call example for the **_FM3501_diagnostic** function block is located in the diagnostic section (PeripheralFaultTask).

Table 8-65 Input symbols used

Symbol	Data type	Description
myLoadStartValue	BOOL	Directly load the load value
myLoadPrepareStartValue	BOOL	Load the load value in preparation
myLoadComparisonValue1	BOOL	Transfer comparison value 1
myLoadComparisonValue2	BOOL	Transfer comparison value 2
myResetSyncState	BOOL	Reset the synchronization status bit
myResetCntrState	BOOL	Reset the status bit for zero crossing/overflow/underflow
mySetSoftwareGate	BOOL	Software gate
myEnableStopGate	BOOL	Stop gate
myResetError	BOOL	Acknowledge error
myResetDiagnosticAlarm	BOOL	Acknowledge diagnostic alarm
myResetProcessAlarm	BOOL	Acknowledge process alarm

Table 8-66 Output symbols used

Symbol	Data type	Description
myErrorOperation	BOOL	Error in the **_FM3501_control2** function block
myStateFMStartup	BOOL	Startup status
myLoadStartValueActive	BOOL	Load count value active
myLoadPrepareStartValueActive	BOOL	Load count value in preparation active
myLoadComparisonValue1Active	BOOL	Load comparison value 1 active
myLoadComparisonValue2Active	BOOL	Load comparison value 2 active
myResetSyncActive	BOOL	Reset synchronization status bit active
myResetCounterStateActive	BOOL	Reset zero crossing/overflow/underflow status bit active
myDiagnosticAlarm	BOOL	Receive diagnostic alarm
myProcessAlarm	BOOL	Receive process alarm
myStateCounter	BOOL	Counter running (opState)
myStateDirection	BOOL	Direction bit (opDirection)
myStateZeroCrossing	BOOL	Zero crossing
myCounterOverflow	BOOL	Counter overflow
myCounterUnterflow	BOOL	Counter underflow
myStateSwGate	BOOL	Software gate (stateSwGate)
myStateGate	BOOL	Internal gate (stateGate)

Note

Depending on the type of signal used, you should pay attention to the coding plug of the FM 350-1 (for example, position D for 24 V signals).

You can either monitor and modify the input and output variables used in the programming example in the INTERFACE section of the unit (under VAR_GLOBAL) using the symbol browser, or you can assign real inputs and outputs to the input and output variables in your unit.

Contents of example

When the **_FM3501_control2** function block is called, the control and checkback signals are exchanged cyclically between the SIMOTION device (C230-2, P350, D435) and the FM 350-1. All of the data that are relevant to the module are located in data structure "dataFM3501".

Depending on the configuration of the FM 350-1 (operating mode, use of gates, alarm configuration, etc.), the FM 350-1 counts the pulses at the wired encoder signal input if, for example, the value of the "myStateSwGate" input is "TRUE". The counting operation stops if input "myStateSwGate" = FALSE or if input "myEnableStopGate" = TRUE.

Transferring the load values

Two parameters are available for transferring the load value to the FM 350-1. When the **_FM3501_control2** FB is called, either the "myLoadStartValue" or "myLoadPrepareStartValue" parameter is selected on a rising edge. The "myLoadStartValue" parameter specifies that the load value will be transferred to the load register and directly to the counter (you must set input "myLoadStartValue" = TRUE).
The "myLoadPrepareStartValue" parameter specifies that the load value will be stored in the load register only (you must set trigger bit "myLoadPrepareStartValue" = TRUE in your user program). The load value in the load register is then transferred at the next event (FM input "DI set") that sets the counter.
The FB must be called until the FB has reset the selected trigger bit ("myLoadStartValue" or "myLoadPrepareStartValue").
The in/out parameter remains set while the transfer is active. If the trigger bit you set has been reset by the **_FM3501_control2** function block, the FM 350-1 has received the load value.

Loading comparison values

New comparison values are transferred to the FM by setting the "myLoadComparisonValue1" or "myLoadComparisonValue2" inputs (rising edge).

Deleting status bits

The synchronization status bit is reset by setting the "myResetSyncState" input (rising edge) and the zero crossing/overflow/underflow status bit is reset by setting the "myResetCntrState" input.

Process alarm / diagnostic alarm

If a process alarm or diagnostic alarm is triggered by the FM 350-1, this is indicated by the "myProcessAlarm" and "myDiagnosticAlarm" variable, respectively. If the "PeripheralFaultFM3501" program is integrated in the PeripheralFaultTask, this task is started and the most important task start information is stored temporarily in the "myAlarmDetails", "myIogAddressIn" and "myAlarmInterrupt" variables. If a diagnostic alarm has been signaled, the **_FM3501_diagnostic** FB is started, which reads out detailed diagnostic information from the module. These diagnostic data are then located in data structure "dataFM3501". Setting the

"myResetDiagnosticAlarm" input variable (to acknowledge a diagnostic alarm) or the "myResetProcessAlarm" input variable (to acknowledge a process alarm) acknowledges the respective alarms.

The respective states are signaled by the output variables used (see Table "Output symbols used").

Hardware platform

The application example is available for various SIMOTION hardware platforms and is intended for distributed use of the FM 350-1.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. You can adapt the configuration in the example to the available hardware (PROFIBUS DP address).
2. You can adapt the configuration of the hardware to the example (PROFIBUS DP address).

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and is part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the hardware configuration: PROFIBUS DP addresses.
3. Check the module addresses (hardware configuration) against the I/O addresses of the controller in SIMOTION SCOUT and module address in the program (dataFM3501.moduleAddress).
4. Save and compile the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

8.6.4 Function blocks of the FM 350-2

8.6.4.1 Overview of the FM 350-2 function blocks

This section describes the function blocks (FBs) and the data structure required for parameter assignment, control and commissioning of the FM 350-2 module.

The function blocks form the software interface between the SIMOTION device and the FMs. They must be called repeatedly (in cycles) from the user program.

The following function blocks are available:

- Function block _FM3502_control (Page 6264)
- Function block _FM3502_write (Page 6266)
- Function block _FM3502_read (Page 6267)
- Function block _FM3502_diagnostic (Page 6269)

SIMOTION SCOUT contains all of the required FBs and data structure **Struct_FM3502_fmData** of the FM 350-2. The function blocks can be used to control one or more FM 350-2 modules.

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6310) in the table "SIMOTION and SIMATIC identifiers FM 350-2".

Note

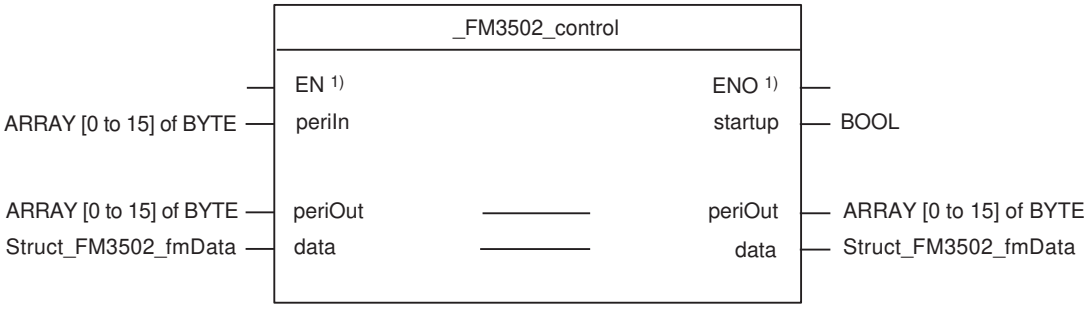
The online functions of the parameter assignment tool in STEP 7 **HW Config** can only be used for diagnostic purposes (read-only access to the module). Write access (control function) has no effect. The parameters set by the program can be read out using the parameter assignment tool.

8.6.4.2 Function block _FM3502_control

Introduction

The **_FM3502_control** function block can be used to control the module and to query the status of the FM 350-2.

Call (LAD representation)



1) LAD-specific parameter

Parameter description

Table 8-67 Parameters of the _FM3502_control function block

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
periIn	IN	ARRAY [0 to 15] of BYTE	Transfers I/O inputs of the FM to the FB	I/O variable of the I/O inputs of the FM transferred to the FB	Queried
periOut	IN/OUT	ARRAY [0 to 15] of BYTE	Prepared data of the FB for the I/O outputs of the FM [2]	Queried and entered on the I/O variable for the I/O outputs	Entered
data	IN/OUT	Struct_FM3502_fmData	Data structure with channel-specific data	Entered and queried	Queried and entered
startup	OUT	BOOL	Indicates the startup of the FM	Queried	Entered

[1] Parameter types: IN = input parameter, OUT = output parameter, IN/OUT = in/out parameter

[2] **Note:** The **periOut** parameter must be supplied with an array of type **ARRAY [0 to 15] of BYTE**. Create a local or global array in your program under **VAR** (do not create a temporary array under VAR_TEMP). After the FB has been called, this array must be assigned to the I/O variable for the I/O outputs of the module. See FM 350-2 call example!

Functional description

The **_FM3502_control** function block cyclically transfers the control signals from the **control** substructure of the data structure of type **Struct_FM3502_fmData** to the FM 350-2. In addition, it reads the checkback signals from the FM 350-2 and enters these into the **checkback** substructure of the data structure of type **Struct_FM3502_fmData**.

The **_FM3502_control** function block is absolutely essential for operation of the FM 350-2.

Task integration (call)

The**_FM3502_control** function block must be called cyclically via the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

Before the call, you enter the current control signals in the **control** substructure of the **Struct_FM3502_fmData** data structure. After the call, the checkback signals are updated in the **checkback** substructure of the data structure. They can then be processed further.

The **_FM3502_control** function block must be called cyclically for **each** FM 350-2 integrated in the project.

Startup behavior

The **_FM3502_control** function block performs startup coordination with the FM 350-2. A startup of the FM 350-2 is indicated by output parameter **startup** = **TRUE**.
After startup has been acknowledged, the control and checkback signals are exchanged with the FM 350-2.

8.6.4.3 Function block _FM3502_write

Introduction

The **_FM3502_write** function block executes write jobs (for example, loading count values and comparison values) to the FM 350-2.

Call (LAD representation)

1) LAD-specific parameter

Parameter description

Table 8-68 Parameters of the _FM3502_write function block

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
periIn	IN	ARRAY [0 to 15] of BYTE	Transfers I/O inputs of the FM to the FB	I/O variable of the I/O inputs of the FM transferred to the FB	Queried
periOut	IN/OUT	ARRAY [0 to 15] of BYTE	Prepared data of the FB for the I/O outputs of the FM 2)	Queried and entered on the I/O variable for the I/O outputs	Entered
data	IN/OUT	Struct_FM3502_fmData	Data structure with channel-specific data	Entered and queried	Queried and entered
error	OUT	BOOL	Job completed with errors	Queried	Entered
status	OUT	DINT	Error ID 3) **_writeRecord**	Queried	Entered

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

2) **Note:** The **periOut** parameter must be supplied with an array of type **ARRAY [0 to 15] of BYTE**. Create a local or global array in your program under **VAR** (do not create a temporary array under VAR_TEMP). After the FB has been called, this array must be assigned to the I/O variable for the I/O outputs of the module. See FM 350-2 call example!

3) A detailed description is contained in the *SIMOTION System Function/Variables* List Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Functional description

The **_FM3502_write** function block loads the counters and comparators of the FM 350-2 from the data structure of type **Struct_FM3502_fmData** by means of a write job.

The **_FM3502_write** function block should only be called when executing write jobs.

Task integration (call)

The **_FM3502_write** function block can be called via the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

Before executing a write job, you must supply the appropriate values in the data range associated with the write job. A write job is triggered by assigning the job number in the **write.execJobNumber** element. The **_FM3502_write** function block must continue to be called cyclically until the **write.execJobNumber** element is zero. The last write job must be complete before a new write job can be executed, i.e. **write.execJobNumber** is deleted.

Note

To ensure the correct sequence, the module address must be entered (in "general data") in the **moduleAddress** element of the data structure of type **Struct_FM3502_fmData**.

Startup behavior

The **_FM3502_write** function block does not perform startup coordination with the FM 350-2. During the startup phase, job execution is disabled. Any pending jobs are not lost, but they are not executed until the startup has been acknowledged.

Error message during a call

If an error occurs during a call, it is reported in the **status** output parameter.

Note

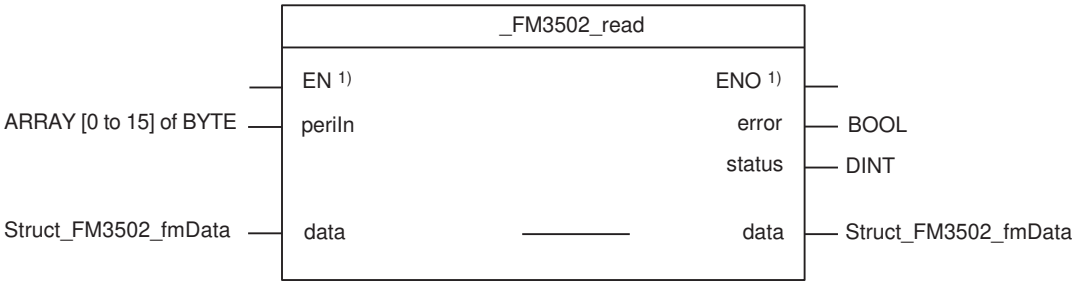
The return value (error ID) in the **status** parameter is present for one cycle only. The values 0x7001 and 0x7002 indicate that data transfer has been initiated and is active.

8.6.4.4 Function block _FM3502_read

Introduction

The **_FM3502_read** function block is used to read out the count values and measured values of the FM 350-2.

Call (LAD representation)



1) LAD-specific parameter

Parameter description

Table 8-69 Parameters of the _FM3502_read function block

Name	P type 1)	Data type	Meaning	Actions performed by user	Actions performed by block
periIn	IN	ARRAY [0 to 15] of BYTE	Transfers I/O inputs of the FM to the FB	I/O variable of the I/O inputs of the FM transferred to the FB	Queried
data	IN/OUT	Struct_FM3502_fmData	Data structure with channel-specific data	Entered and queried	Queried and entered
error	OUT	BOOL	Job completed with errors	Queried	Entered
status	OUT	DINT	Error ID 3) **_readRecord**	Queried	Entered

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

2) **Note:** The **periOut** parameter must be supplied with an array of type **ARRAY [0 to 15] of BYTE**. Create a local or global array in your program under **VAR** (do not create a temporary array under VAR_TEMP). After the FB has been called, this array must be assigned to the I/O variable for the I/O outputs of the module. See FM 350-2 call example!

3) A detailed description is contained in the *SIMOTION System Function/Variables list manual*. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Functional description

The **_FM3502_read** function block executes the read jobs entered in the **read.execJobNumber** element and transfers the read data to the data structure of type **Struct_FM3502_fmData**.

The **_FM3502_read** function block should only be called when executing read jobs.

Task integration (call)

The **_FM3502_read** function block can be called via the **BackgroundTask** or the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

A read job is triggered by assigning the job number in the **read.execJobNumber** element. The **_FM3502_read** function block must continue to be called cyclically until the

read.execJobNumber element is zero. The current read job must be complete before a new read job can be executed, i.e. **read.execJobNumber** is deleted.

Note

To ensure the correct sequence, the module address must be entered (in "general data") in the **moduleAddress** element of the data structure of type **Struct_FM3502_fmData**.

Startup behavior

The **_FM3502_read** function block does not perform startup coordination with the FM 350-2. During the startup phase, job execution is disabled. Any pending jobs are not lost, but they are not executed until the startup has been acknowledged.

Error message during a call

If an error occurs during a call, it is reported in the **status** output parameter.

Note

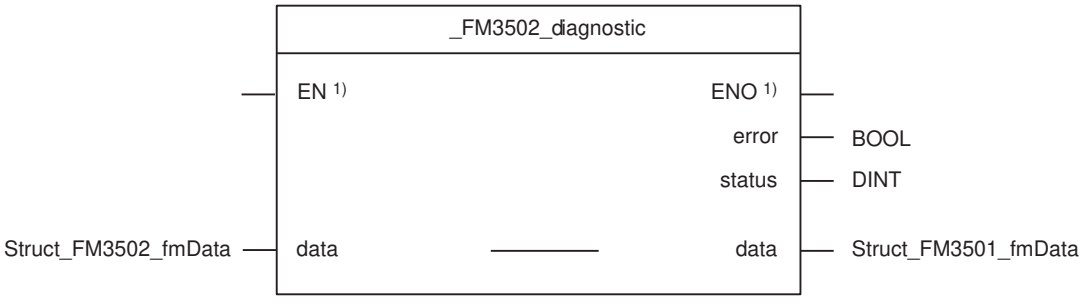
An error ID in **status** is present for one cycle only. The values 0x7001 and 0x7002 indicate that data transfer has been initiated and is active.

8.6.4.5 Function block _FM3502_diagnostic

Introduction

The **_FM3502_diagnostic** function block enables you to read out the complete diagnostic data from the FM 350-2.

Call (LAD representation)



1) LAD-specific parameter

Parameter description

Table 8-70 Parameters of the _FM3502_diagnostic function block

Name	P type [1]	Data type	Meaning	Actions performed by user	Actions performed by block
data	IN/OUT	Struct_FM3502_fmData	Data structure with channel-specific data	Entered and checked	Checked and entered
error	OUT	BOOL	Request completed with errors	Checked	Entered
status	OUT	DINT	Return value (error ID) [2] **_readRecord**	Checked	Entered

[1] Parameter types: IN = input parameter, OUT = output parameter, IN/OUT = in/out parameter

[2] A detailed description is contained in the *SIMOTION System Function/Variables* parameter manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Functional description

The entire diagnostic data are read out by the **_FM3502_diagnostic** function block and made available in the **diagnostic** substructure of the **Struct_FM3502_fmData** data structure.

The return value (error ID) can be read out at the **status** output parameter of the function block.

Sequence

Data is transferred as follows:

1. When the **_FM3502_diagnostic** function block is called, data transfer is enabled and the data are transferred. You can view the error ID at the **status** output parameter.

   Note

   The return value (error ID) in the **status** parameter is present for one cycle only. The values 0x7001 and 0x7002 indicate that a data transfer has been initiated and is active.

2. The data are entered in the data structure of type **Struct_FM3502_fmData**.
3. The return value (error ID) is provided at the **status** parameter of the **_FM3502_diagnostic** function block.
4. The reading out of diagnostic data is finished when **status** = 0 is signaled.

   Note

   To ensure the correct sequence, the module address must be entered (in "general data") in the **moduleAddress** element of the data structure of type **Struct_FM3502_fmData**.

Task integration (call)

The **_FM3502_diagnostic** function block can be called in the **PeripheralFaultTask**, **BackgroundTask** or **TimerInterruptTask**. For performance reasons, the function block should only be called in the **PeripheralFaultTask**.

8.6.4.6 Data structures of the FM 350-2

Overview

The data structure of type **Struct_FM3502_fmData** contains all data of the FM 350-2 relevant for operation, as well as diagnostic data.

The data structures are used by the the following function blocks: **_FM3502_control**, **_FM3502_write**, **_FM3502_read** and **_FM3502_diagnostic**. Elements in the data structure are accessed using a variable of data type **Struct_FM3502_fmData**, which you must define yourself.

The **Struct_FM3502_fmData** data structure is shown in the table below.

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6310) in the table "SIMOTION and SIMATIC identifiers FM 350-2".

[1)] Variable for internal FB use (not relevant to users)

8.6.4.7 Calling function blocks

In order to be able to work with the function blocks in your user project, proceed as follows (the numbers shown in the following program segment correspond to the steps below):

1. Create the function block instance (see the following program segment, e.g. create instance for FB **_FM3502_control**).
2. Set up variables for the data structure.
3. Create an array for the in/out parameters of the FB.
4. Call instance of the function block.
5. Transfer input parameters.
6. The output parameters of the FB are accessed with <instance name of FB>.<name of output parameter>.
7. Data prepared by the FB for the I/O outputs are assigned to the array of the I/O variables created in step 3.

Note

The call example is an extract from the supplied E_FM3502 application example, which is contained on the "SIMOTION Utilities & Applications" CD-ROM.

If you wish to control more than one FM 350-2, you must create a new variable for the data structure and FB instances with a new name for each FM 350-2 used.

Call example

```
UNIT E_FM3502;

INTERFACE
VAR_GLOBAL

    myDataFM3502        : Struct_FM3502_fmData;   // variable for data structure                (2)

    // OUTPUT VARIABLES
    myStateFMStartup    : BOOL;                   // Start-up status
    myInstFM3502Ctrl    : _FM3502_control;        // create FB instance                         (1)

END_VAR

END_INTERFACE

IMPLEMENTATION

PROGRAM ExampleFM3502                           // Program in BackgroundTask

// Variables used: see interface area under VAR_GLOBAL
VAR
```

```
    FMOutputArray      : ARRAY [0..15] of BYTE;    // Array for FM output data                (3)
END_VAR

// CALL INSTANCE of FB _FB_FM3502_control                                                      (4)
    myInstFM3502Ctrl
        (
        periIn         := myPeripheralInputFM3502,   // I/O variable of I/O inputs           (5)
        periOut        := FMOutputArray,             // FM output data array
        data           := myDataFM3502               // Data structure
        );

// TRANSFER DATA TO FM
    myPeripheralOutputFM3502   := FMOutputArray;     // Assign array of FM output           (7)
                                                     // data to I/O variable

    myStateFMStartup  := myInstFM3502Ctrl.startup;   // Start-up status                     (6)

END_PROGRAM                  // ExampleFM3502

END_IMPLEMENTATION
```

Note

The PROGRAM ExampleFM3502 must be assigned in the execution system.

8.6.4.8 Application example for FM 350-2

Introduction

In this example, the FM 350-2 counter module is used to solve two different tasks. Counter channels 0 and 1 will be used to control a filling unit. At the same time, a frequency measurement with limit value check will be performed using counter channel 4.

Filling unit

A box will be filled with a certain number of parts from a collection bin. Counter channel 0 counts 10 (0...9) parts and controls the filling valve. Counter channel 1 is used to control the motor that transports the boxes and to count the number of boxes. When the box is in the correct position, the valve is opened and the parts are filled into the box. When the specified number has been reached, the valve is closed and the box transport is initiated. Arriving parts are counted until the next box arrives.

While the box is being transported, a new number of parts can be specified.
The number of filled parts and the number of boxes can be monitored (in the symbol browser).

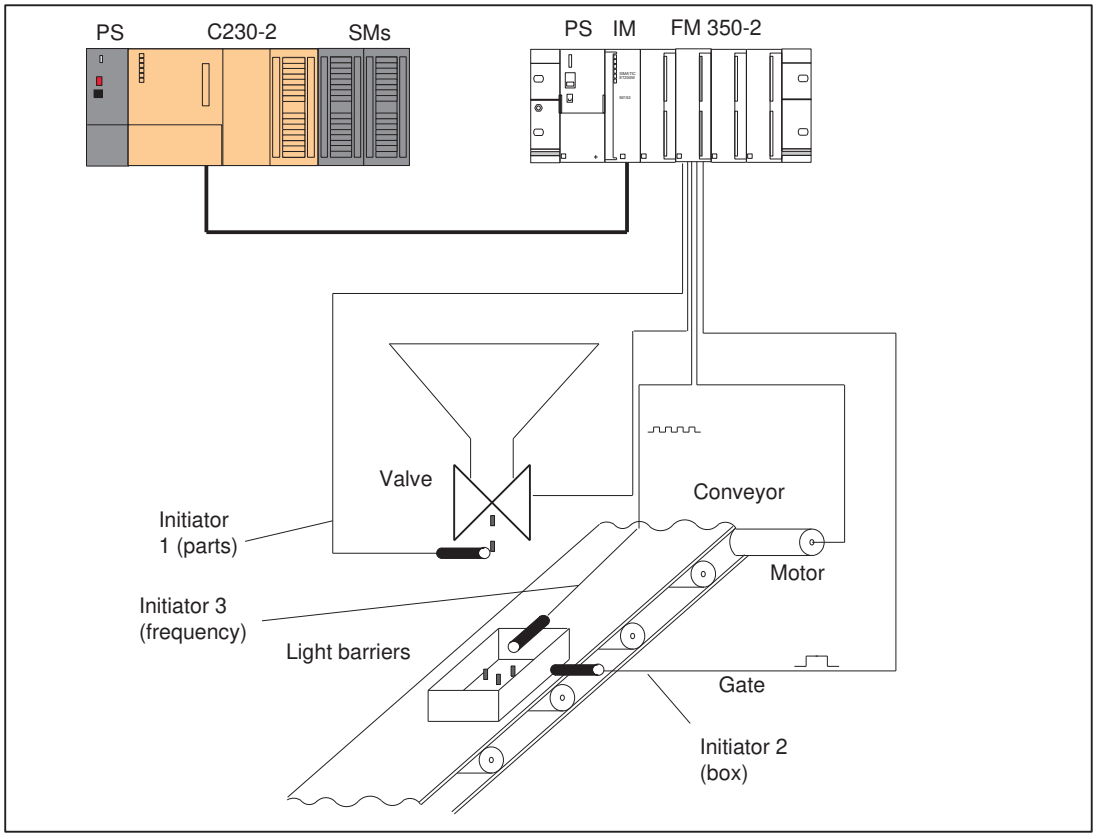

Figure 8-32 Example application for the FM 350-2

Frequency measurement

A frequency measurement (speed of falling parts) is made at counter channel 4 for frequencies up to 10 kHz. The measured frequency is subjected to a limit value check for the lower limit of 1 kHz and upper limit of 9 kHz. The status of the limit values, the measured frequency and the continuously counted pulses can be monitored (in the symbol browser).

FM 350-2 installation and wiring

Proceed as follows to install and wire the FM 350-2:

1. Insert the bus connector supplied with the FM 350-2 onto the bus plug.
2. Hook the FM 350-2 onto the rail, pivot the module downwards and bolt it into place (more detailed instructions can be found in SIMATIC manual *FM 350-2 Counter Module Installation and Parameter Assignment*).

3. Wire the front connector as shown below (a complete pin assignment for the front connector can be found in SIMATIC manual *FM 350-2 Installation and Parameter Assignment*).

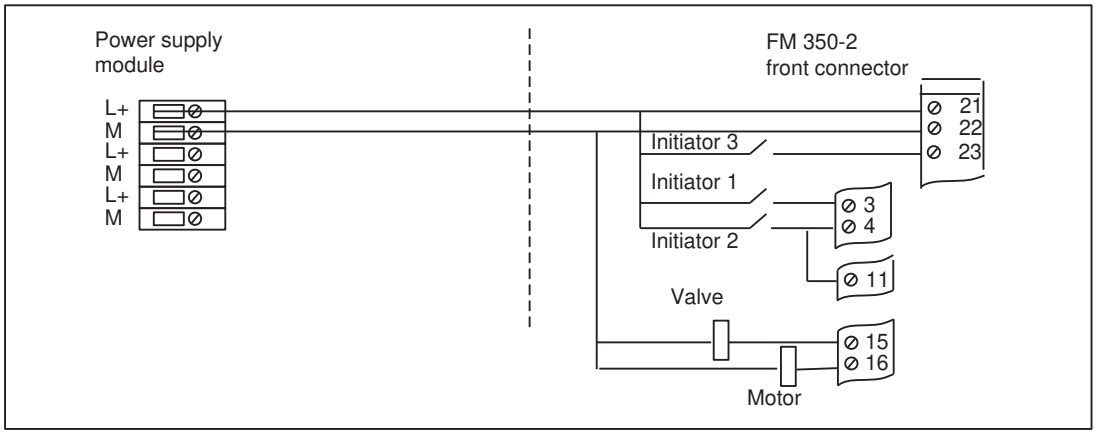

Figure 8-33 FM 350-2 installation and wiring

Terminal	Name	Meaning
21	L+	24 V power supply
22	M	Ground
23	A4	Frequency input from 24 V initiator 3
3	A0	Counter pulses for parts from 24 V initiator 1
4	A1	Counter pulses for boxes from 24 V initiator 2
11	I0	Box in position (HW gate) from terminal 4
15	Q0	Actuation of valve for filling parts
16	Q1	Actuation of the motor for box transport

4. Plug the front connector into the FM 350-2 and screw tightly.

Assigning module parameters

Proceed as follows:

1. Open your project in SIMOTION SCOUT.
2. Open the hardware configuration in SIMOTION SCOUT.
3. Configure your hardware station.
4. Double-click **FM350-2** to open the **Properties** dialog box for the module. There you will see the "General", "Addresses" and "Basic parameters" tabs for the module.
5. Click the Parameters button. The parameter assignment screen forms of the FM 350-2 will open. The parameters for encoders, operating modes, alarm enabling, and outputs are stored for every channel in these screen forms.
   Under the **Edit > Specify channels** menu command, you will find the global settings for all of the channels of the FM 350-2.

6. Change the following parameters:
   Specify channels:
   - Specify channels 0...7 as single counters!
   - For USER_TYP2, select data type DWORD and for channel 4, select the "Measured value" setting instead of "Counter value".

   Afterwards, click **OK** to confirm.
   Channel 0:
   - Mode: "Single counting" and activation of "Use hardware gate"
   - Under alarm enable, enter the comparison value "9" (10 parts) (all alarm enables alarms are deactivated).

   Channel 4:
   - Mode: "Frequency measurement" and x10 ms for time window "1"
   - Under alarm enable, enter "1000000" for the range underflow limit and "9000000" for the range overflow limit (all alarm enables are deactivated).
7. Transfer the parameter assignment for the FM 350-2 to the hardware configuration using the **File > Save** menu command and close the "FM350-2 Counter" window using the **File > Exit** menu command.
8. Save the hardware configuration with the **Station > Save and compile** menu command.
9. Download the hardware configuration with the **Target system > Download to module** menu command.
   The red "SF" LED of the FM 350-2 turns on and off after the module parameter assignment is downloaded without errors.

Hardware platform

The application example is available for various SIMOTION hardware platforms and is intended for distributed use of the FM 350-2.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. You can adapt the configuration in the example to the available hardware (PROFIBUS DP address).
2. You can adapt the configuration of the hardware to the example (PROFIBUS DP address).

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the hardware configuration: PROFIBUS DP addresses.
3. Check the module addresses (hardware configuration) against the I/O addresses of the controller in SIMOTION SCOUT and module address in the program (myDataFM3502.moduleAddress).
4. Save and compile the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

Input/output symbols

Table 8-72 Input symbols used

Symbol	Data type	Description
myStartFillup	BOOL	Start the filling unit
myMeasurementFrequency	BOOL	Start the frequency measurement
mySetNewCounterValue	BOOL	Start to load new quantity
myReadActualCounterValue	BOOL	Start to read current values
myChangeChannelActualValue	BOOL	Read selection of current values FALSE: Channels 0..3 TRUE: Channels 4..7
myNewQuantity	UINT	New quantity
myResetProcessAlarm	BOOL	Acknowledgement of process alarm
myResetDiagnosticAlarm	BOOL	Acknowledgement of diagnostic alarm

Table 8-73 Output symbols used

Symbol	Data type	Description
myStateLoad	BOOL	New quantity loaded
myErrorWrite	BOOL	Error when loading quantity
myErrorRead	BOOL	Error when reading current values
myCounterOverflow	BOOL	Upper frequency limit exceeded
myCounterUnderflow	BOOL	Lower frequency limit fallen below
myStateFMStartup	UINT	Startup status
myProcessAlarm	BOOL	Process alarm
myDiagnosticAlarm	BOOL	Diagnostic alarm

Note

You can either monitor and modify the input and output variables used in the programming example in the INTERFACE section of the unit (under VAR_GLOBAL) using the symbol browser, or you can assign real inputs and outputs to the input and output variables in your unit.

Filling unit application sequence

The sequence for the "Filling unit" application is reproduced below.

1. Start the filling unit application by setting the "myStartFillup" input.
   Output Q1 of the FM 350-2 is set to move the box into position.
2. Actuate 24 V initiator 2 (box in position/box counting pulses) when the box is in position.
   A "1" is displayed in data structure "myDataFM3502.checkback.opValue1" (number of boxes).
   Then the valve is opened via output Q0 of the FM 350-2, and the parts are counted. When you actuate 24 V initiator 1, the number of filled parts is incremented in "myDataFM3502.checkback.opValue0" (number of parts). When 10 parts are reached, the valve is closed and the box transport is activated. The process is repeated when the next box arrives.
   Proceed as follows to change the number of parts:
3. Enter the new quantity in the "myNewQuantity" input parameter as a control value and activate it. The new quantity is applied with "Immediate control".
4. Set the "mySetNewCounterValue" input to load the new quantity. The "mySetNewCounterValue" input evaluates the rising edge and only then starts a new write job (transfer of new parts is resumed only if the "mySetNewCounterValue" input was set to "FALSE" beforehand). If the new quantity is successfully loaded, the "myStateLoad" output is briefly set.

Frequency measurement application sequence

The sequence for the "Frequency measurement" application is reproduced below.

1. Start the frequency measurement application by setting the "myMeasurementFrequency" input.
2. Actuate 24 V initiator 3 (frequency input), for example, by connecting a frequency generator to it.
3. Set the "myChangeChannelActualValue" input and the "myReadActualCounterValue" input.
   As long as these inputs are set, the current values are displayed in data structures "myDataFM3502".counterValue4 to "myDataFM3502".measuringValue7.
   You have the option of reading the current values of counter channels 0 to 3 by deleting the "myChangeChannelActualValue" input.
   If the value drops below the lower frequency limit of 1 kHz, this is indicated at the"myCounterUnderflow" output.
   If the value exceeds the upper frequency limit of 9 kHz, this is indicated at the "myCounterOverflow" output.
   In addition, you can also read the current values (counter values and measured values) of counter channels 4 to 7.

Diagnostic alarm / process alarm

Incorrect wiring can cause errors, which the FM 350-2 displays using the "SF" group error LED and in the "myProcessAlarm" and "myDiagnosticAlarm" variables. In these cases, the FM 350-2 triggers a diagnostic alarm/process alarm, provided the basic parameters are set accordingly (alarm generation: YES; and alarm selection: diagnostic or diagnostic+process). If the "PeripheralFaultFM3502" program is integrated in the PeripheralFaultTask, this task is started and the most important task start information is stored temporarily in the "myAlarmDetails", "myLogBaseAddressIn" and "myAlarmInterrupt" variables.

If a diagnostic alarm has been signaled, the **_FM3502_diagnostic** FB is started, which reads out detailed diagnostic information from the module. These diagnostic data are then located in data structure "myDataFM3502". You can acknowledge the respective alarm by setting the "myResetDiagnosticAlarm" input variable (when acknowledging a diagnostic alarm) or "myResetProcessAlarm" input variable (when acknowledging a process alarm).

8.6.5 Function Blocks of the FM 352

8.6.5.1 Overview of the FM 352 function blocks

This section describes the function blocks (FBs) and the data structures required for parameter assignment, control and commissioning of the FM 352 module.

The function blocks form the software interface between the SIMOTION device and the FMs. They must be called repeatedly (in cycles) from the user program.

The following function blocks are available:

- Function block _FM352_initialize (Page 6284)
- Function block _FM352_control (Page 6285)
- Function block _FM352_diagnostic (Page 6287)

SIMOTION SCOUT contains all of the required FBs and data structures **Struct_FM352_ctrlData**, **Struct_FM352_diagData** and **Struct_FM352_paraData** of the FM 352. The function blocks can be used to control one or more FM 352 modules.

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC identifiers can be found in the appendix SIMOTION and SIMATIC names (Page 6310) in the table "SIMOTION and SIMATIC identifiers FM 352".

Note

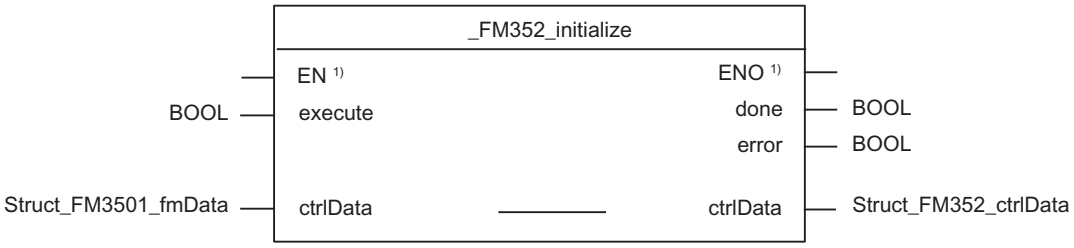
The online functions of the parameter assignment tool in STEP 7 **HW Config** can only be used for diagnostic purposes (read-only access to the module). Write access (control function) has no effect. The parameters set by the program can be read out using the parameter assignment tool.

8.6.5.2 Function block _FM352_initialize

Introduction

The **_FM352_initialize** function block allows you to initialize the channel data after startup of the FM 352 module.

Call (LAD representation)



Parameter description

Table 8-74 Parameters of the _FM352_initialize function block

Name	P type 1)	Data type	Meaning
execute	IN	BOOL	Activation
ctrlData	IN/OUT	Struct_FM352_ctrlData	Data structure with channel-specific data
done	OUT	BOOL	Function or job executed completely without errors
error	OUT	BOOL	Request completed with errors

1) Parameter types: IN/OUT = in/out parameter

Functional description

The _FM352_initialize function block initializes the channel data structure:

- Control signals
- Checkback signals
- Trigger bits, done bits and error bits of jobs
- Function switches and their done bits and error bits
- Job management and internal buffers for the **_FM352_control** function block

The data required for **_FM352_initialize** function block are transferred in variables of the data structure of type **Struct_FM352_ctrlData**.

Task integration (call)

The **_FB_FM352_initialize** function block must be run through after startup of the SIMOTION system. Therefore, you should call it in the **StartupTask** or in a self-programmed initialization phase of your user program. In this way you can ensure that your user program does not access outdated data.

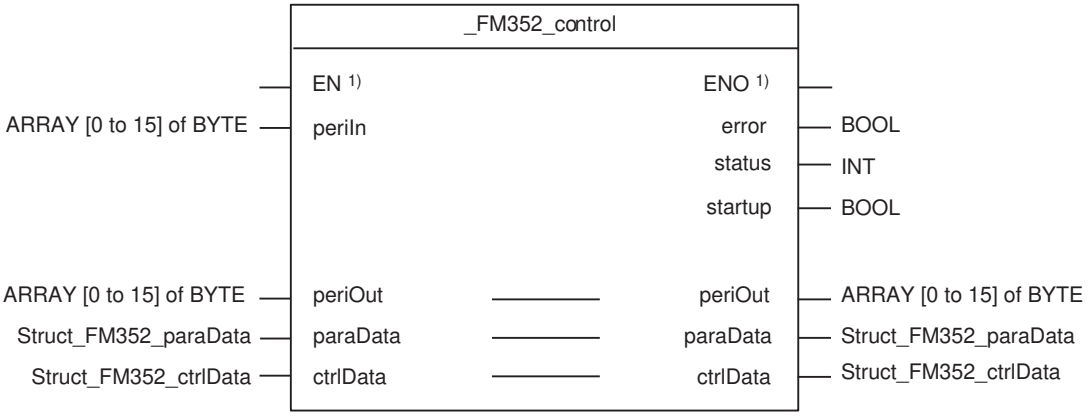
8.6.5.3 Function block _FM352_control

Introduction

The **_FM352_control** function block enables you to do the following:

- Write control signals and read out checkback signals from the FM 352
- Read and write parameters of the FM 352

Call (LAD representation)



1) LAD-specific parameter

Parameter description

Table 8-75 Parameters of the _FM352_control function block

Name	P type 1)	Data type	Meaning
periIn	IN	ARRAY [0 to 15] of BYTE	Transfers I/O variable of the I/O inputs of the FM to the FB
periOut	IN/OUT	ARRAY [0 to 15] of BYTE	Prepared data of the FB for the I/O outputs of the FM 2)
ctrlData	IN/OUT	Struct_FM352_ctrlData	Data structure with channel-specific data
paraData	IN/OUT	Struct_FM352_paraData	Data structure with machine data and output cam data
error	OUT	BOOL	Job completed with errors

Name	P type [1]	Data type	Meaning
status	OUT	INT	Status 0: FB inactive 1: FB active -1: Error
startup	OUT	BOOL	Indicates the startup of the FM

[1] Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

[2] **Note:** The **periOut** parameter must be supplied with an array of type **ARRAY [0 to 15] of BYTE**. Create a local or global array in your program under **VAR** (do not create a temporary array under VAR_TEMP). After the FB has been called, this array must be assigned to the I/O variable for the I/O outputs of the module. Call example for FM 352!

Functional description

The **_FM352_control** function block performs the following activities in the **BackgroundTask**:

- Reading checkback signals
  The FB reads all of the checkback signals of the FM 352 and enters them into the channel data structure. Because the control signals and jobs are not executed until after this step, the checkback signals reflect the status of the module before the block was called.
- Writing control signals
  The control signals entered in the channel data structure are transferred to the module. Enabling of output cam processing, however, is delayed as long as the trigger for a "Set reference point" job or "Write output cam data" job is set.
- Executing read/write jobs
  The jobs to be executed are specified in channel data structure **Struct_FM352_ctrlData** using "trigger bits". More than one job can be activated at the same time. The jobs are executed by the **_FM352_control** function block in the order received.

Task integration (call)

The **_FM352_control** function block must be called cyclically in the **BackgroundTask** or in the **TimerInterruptTask**. Calling in the **SystemInterruptTask** is not permitted. Read and write jobs are triggered by setting the corresponding trigger bits in the data structure. Calling the function block in the **IPOSynchronousTask** is not recommended for runtime reasons.

To ensure the proper sequence, the module address must be entered (under general data / version switches) in the **moduleAddress** element of the data structure of type **Struct_FM352_ctrlData**.

Startup behavior

The **_FM352_control** function block acknowledges the module startup. During this time, **status** and **jobBusy** = 1. During the startup phase, job execution is disabled. Any pending jobs are not lost and they will be executed after startup has been acknowledged.

Error message during a call

You can read out error information in the data structure in the **jobErrorId** element of the data structure of type **Struct_FM352_ctrlData**.

- The programming device or PC enables you to read out the diagnostic buffer via the parameter assignment interface using the **Test > Error evaluation** menu command.
  - You will find the error class and the error number along with plain text.
- You can evaluate errors in your program. The following means are available for this purpose:
  - Return values (**status**) of the integrated FBs as a group display for errors that occurred during execution of the FBs.
  - Error bits of the jobs as a group display for errors that occurred during execution of a job.
  - **dataError** error bit as a group display for an error that has been detected by the FM 352 during a write job.
  - Error ID in **jobErrorId** for the cause of the error during communication between FB and FM 352. The return values of system functions **_writeRecord** and **_readRecord** are entered in **jobErrorId**.
    Further information on the system functions is contained in the *SIMOTION System Function/Variables* List Manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!
  - **_FM352_diagnostic** function block for reading out the diagnostic buffer of the FM 352. Here you can obtain the causes for errors, for jobs and asynchronous events (operating errors, diagnostic errors).

Note

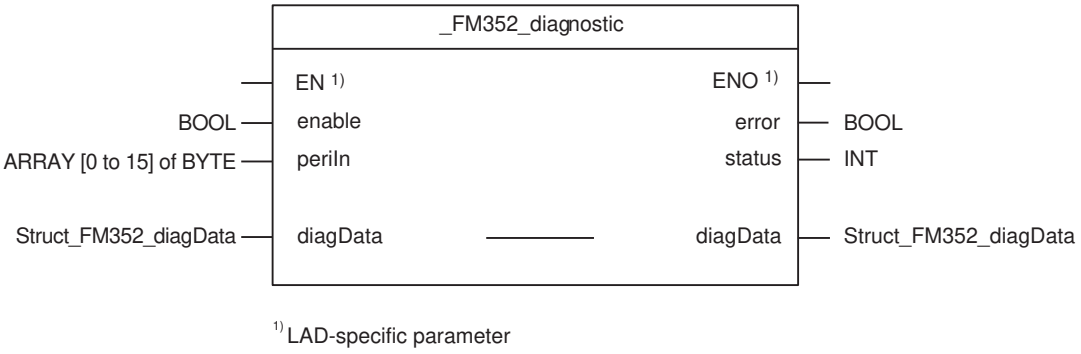
The return value (error ID) in the **status** parameter is present for one cycle only. The values 0x7001 and 0x7002 indicate that data transfer has been initiated and is active.

8.6.5.4 Function block _FM352_diagnostic

Introduction

The **_FM352_diagnostic** function block enables you to read out complete diagnostic data from the FM 352.

Call (LAD representation)



1) LAD-specific parameter

Parameter description

Table 8-76 Parameters of _FM352_diagnostic function block

Name	P type 1)	Data type	Comment
enable	IN	BOOL	Enable
periIn	IN	ARRAY [0..15] of BYTE	I/O variable for access to I/O inputs from the FM 352
diagData	IN/OUT	Struct_FM352_diagData	Data structure for diagnostic data
error	OUT	BOOL	Request completed with errors
status	OUT	INT	Return value 0 : FB inactive 1: FB reading data -1 : Error

1) Parameter types: IN = input parameters, OUT = output parameters, IN/OUT = in/out parameters

Functional description

The diagnostic data are read out by the **_FM352_diagnostic** function block and made available to you in the associated **Struct_FM352_diagData** data structure. The return value (error ID) can be read out at the **status** output parameter of the function block.

The **_FM352_diagnostic** function block reads the diagnostic data when checkback signal **diagDataChanged** = **TRUE** either automatically or per job (**diagInformation** = **TRUE**).

Sequence

The data are transferred as follows:

1. If the set trigger parameter **diagInformation** = TRUE or **diagDataChanged** = TRUE in the data structure of type **Struct_FM352_diagData**, the diagnostic data are read out from the FM 352.
2. The data are entered in the data structure of the **_FM352_diagnostic** function block.

3. The return value (error ID) is provided at the **status** output parameter of the **_FM352_diagnostic** function block.

Note

The return value (error ID) in the **status** parameter is present for one cycle only. The values 0x7001 and 0x7002 indicate that a data transfer has been initiated and is active.

4. As soon as the function has been executed, the trigger parameter is signaled as finished by the transfer.

Note

To ensure the proper sequence, the module address must be entered in the **moduleAddress** element of the data structure of type **Struct_FM352_diagData**.

Task integration (call)

The **_FM352_diagnostic** function block must be called in the **BackgroundTask** or **TimerInterruptTask**. An additional call in the **SystemInterruptTask** is not permitted. At least two calls (cycles) are required for complete execution of the function. For performance reasons, the function block should only be called in the **PeripheralFaultTask**.

Job

You can read the diagnostic buffer independent of a new entry by setting the **diagInformation** trigger bit. After the diagnostic buffer is read, the trigger bit is set to **FALSE**.

Error message during a call

If an error occurs during a call, it is reported in the **status** output parameter (= -1). The return value of the **_readRecord** system function is entered in the **jobErrorId** element of the data structure of type **Struct_FM352_diagData**.

Further information on the system function is contained in the *SIMOTION System Function/ Variables* parameter manual. This documentation is included in the SIMOTION SCOUT scope of delivery as electronic documentation!

Note

The error ID in the jobErrorId element and the **status** output parameter is present for one cycle.

8.6.5.5 Data structures of the FM 352

Overview of the FM 352 data structures

The data structures contain all data of the FM 352 relevant for operation, as well as diagnostic data. Three different data structures are provided as type declarations for the FM 352.

- Data structure of type Struct_FM352_ctrlData (Page 6290)
- Data structure of type Struct_FM352_diagData (Page 6298)
- Data structure of type Struct_FM352_paraData (Page 6296)

These data structures are used by the following function blocks: **_FM352_initialize**, **_FM352_control** and **_FM352_diagnostic**. The elements of the data structure are accessed using a variable of the appropriate data type, which is to be defined by the user.

Note

The SIMOTION identifiers have changed as of V4.0. A comparison of the SIMOTION and SIMATIC names of the "Data structure of Struct_FM352_ctrlData", "Data structure of Struct_FM352_paraData" and "Data structure of Struct_FM352_diagData" tables can be found in the appendix SIMOTION and SIMATIC names (Page 6310) in the table "SIMOTION and SIMATIC names for FM 352".

Struct_FM352_ctrlData

The **Struct_FM352_ctrlData** data structure is shown in the table below.

Table 8-77 Data structure of Struct_FM352_ctrlData

Struct_FM352_ctrlData			
Name	**Type**	**Initial value**	**Comment**
General data / version switches			
moduleAddress	INT	256	Module address
FmType	BOOL	TRUE	FM 352 V5.0 and higher
Control signals			
enableSimPositive	BOOL	FALSE	Simulation in positive direction
enableSimNegative	BOOL	FALSE	Simulation in negative direction
enableOutputCam	BOOL	FALSE	Output cam processing enabled
enableTrack0Counter	BOOL	FALSE	Counter function of counter output cam track 0 enabled
enableTrack1Counter	BOOL	FALSE	Counter function of counter output cam track 1 enabled
enableTrack	WORD	16#0000	Enable output cam tracks 0 to 15 Bit 0: Track 0
Checkback signals			

Struct_FM352_ctrlData			
Name	**Type**	**Initial value**	**Comment**
diagDataChanged	BOOL	FALSE	New entry in the diagnostic buffer of the FM 352 (can be read out with **_FM352_diagnostic**)
dataError	BOOL	FALSE	Data error (can be read out using the parameterization tool)
parameterized	BOOL	FALSE	Module parameterized
outputCamActive	BOOL	FALSE	Output cam processing running
synchronized	BOOL	FALSE	Axis is synchronized
measDone	BOOL	FALSE	Length measurement or edge detection is finished
dirNegative	BOOL	FALSE	Axis moving in a negative direction
dirPositive	BOOL	FALSE	Axis moving in a positive direction
hystZone	BOOL	FALSE	Axis is within the hysteresis range
floatActValue	BOOL	FALSE	Set actual value on-the-fly executed
actPosition	DINT	0	Current position of axis (cyclic updating)
trackSignals	DWORD	16#0000 0000	Current track signals of tracks 0 to 31 Bit 0: Track 0
Function switches			
enableEdgeDetection	BOOL	FALSE	Edge detection ON
enableSimulation	BOOL	FALSE	Simulation ON
enableLenMeasuring	BOOL	FALSE	Length measuring ON
execRetrigRefPoint	BOOL	FALSE	Retrigger reference point
switchOffSwLimit	BOOL	FALSE	Software limit switch disabled
Trigger bits for write jobs			
execWrMachineData	BOOL	FALSE	Write machine data
execWrActivateMData	BOOL	FALSE	Activate machine data
execWrActValueRevoke	BOOL	FALSE	Set actual value, undo on-the-fly actual value setting
execWrOutputCamData1	BOOL	FALSE	Write output cam data 1 (output cams 1 to 15)
execWrOutputCamData2	BOOL	FALSE	Write output cam data 2 (output cams 16 to 31)
execWrOutputCamData3	BOOL	FALSE	Write output cam data 3 (output cams 32 to 47)
execWrOutputCamData4	BOOL	FALSE	Write output cam data 4 (output cams 48 to 63)
execWrOutputCamData5	BOOL	FALSE	Write output cam data 5 (output cams 64 to 79)
execWrOutputCamData6	BOOL	FALSE	Write output cam data 6 (output cams 80 to 95)
execWrOutputCamData7	BOOL	FALSE	Write output cam data 7 (output cams 96 to 111)
execWrOutputCamData8	BOOL	FALSE	Write output cam data 8 (output cams 112 to 127)
execWrSetRefPoint	BOOL	FALSE	Set reference point coordinates
execWrActValue	BOOL	FALSE	Set actual value
execWrActValSetOnTheFly	BOOL	FALSE	Set actual value on-the-fly
execWrZeroOffset	BOOL	FALSE	Set zero point offset
execWrOutputCamEdge1	BOOL	FALSE	Write output cam edge setting (1 cam)
execWrOutputCamEdge16	BOOL	FALSE	Write settings for fast output cam change (16 output cams)

Struct_FM352_ctrlData			
Name	**Type**	**Initial value**	**Comment**
Trigger bits for read jobs			
execRdMachineData	BOOL	FALSE	Read machine data
execRdOutputCamData1	BOOL	FALSE	Read output cam data 1
execRdOutputCamData2	BOOL	FALSE	Read output cam data 2
execRdOutputCamData3	BOOL	FALSE	Read output cam data 3
execRdOutputCamData4	BOOL	FALSE	Read output cam data 4
execRdOutputCamData5	BOOL	FALSE	Read output cam data 5
execRdOutputCamData6	BOOL	FALSE	Read output cam data 6
execRdOutputCamData7	BOOL	FALSE	Read output cam data 7
execRdOutputCamData8	BOOL	FALSE	Read output cam data 8
execRdMeasValue	BOOL	FALSE	Read measured values
execRdCntrValueTrack	BOOL	FALSE	Read the count values of the counter cam tracks
execRdActPosition	BOOL	FALSE	Read position data and track data
execRdEncValue	BOOL	FALSE	Read encoder values
execRdOutputCamData	BOOL	FALSE	Read output cam data and track data
Done bits for function switches			
enableEdgeDetectDone	BOOL	FALSE	"Switch edge detection ON or OFF" completed
enableSimDone	BOOL	FALSE	"Switch simulation ON or OFF" completed
enableLenMeasDone	BOOL	FALSE	"Switch length measurement ON or OFF" completed
retrigRefPointDone	BOOL	FALSE	"Switch retrigger reference point ON or OFF" completed
switchOffSwLimDone	BOOL	FALSE	"Switch software limit switch ON or OFF" completed
Done bits for write jobs			
wrMdDone	BOOL	FALSE	"Write machine data" job completed
wrActivateMdDone	BOOL	FALSE	"Activate machine data" job completed
wrActValueRevokeDone	BOOL	FALSE	"Set actual value, undo on-the-fly actual value setting" completed

Struct_FM352_paraData

The **Struct_FM352_paraData** data structure is shown in the table below.

Table 8-78 Data structure Struct_FM352_paraData

Struct_FM352_paraData			
Name	**Type**	**Initial value**	**Comment**
Machine data			
xxxModuleType1 [1)]	BOOL	FALSE	0 for FM 352

Struct_FM352_paraData			
Name	**Type**	**Initial value**	**Comment**
enableProcessAlarm	BOOL	FALSE	Enable process alarm: Output cam ON/OFF
xxxModuleType2 [1)]	BOOL	FALSE	0 for FM 352
minEdgeDistance	DINT	0	Minimum edge distance for edge detection
unitDimension	DINT	1	Dimension system
axisType	DINT	0	Linear axis = 0 Rotary axis = 1
endRotAxis	DINT	100000	End of rotary axis
encType	DINT	1	Encoder type, message frame length
lenPerRevolution	DINT	80000	Length per encoder revolution
incPerRevolution	DINT	500	Increments per encoder revolution
cntOfRevolutions	DINT	1024	Number of encoder revolutions
baudRate	DINT	0	Transmission rate
refPoint	DINT	0	Home position coordinates
absEncOffset	DINT	0	Absolute encoder adjustment
refPointTrigMode	DINT	0	Reference point retrigger mode
cntrDirection	BOOL	FALSE	Counting direction: 0 = normal, 1 = inverted
openCircuit	BOOL	TRUE	Wire break monitoring
transmissionError	BOOL	TRUE	Message frame error monitoring
missingPulse	BOOL	TRUE	Missing pulse monitoring
swLimitStart	DINT	-100000000	Start of software limit switch
swLimitEnd	DINT	100000000	End of software limit switch
numOfOutputCamsToSet	DINT	0	Volume of project data: 0,1,2,3 = max. 16,32,64,128 output cams
hysteresis	DINT	0	Hysteresis
simSpeed	DINT	0	Simulation speed
ctrlTrackOutputs	WORD	16#0000	Track output actuation: 0 = electronic cam controller, 1 = SIMOTION device; Bit number = track number
enableInput3	BOOL	FALSE	Enable input I3
xxxEnableInput4..10 [1)]	BOOL	FALSE	Reserved
track0CntrOutputCam	BOOL	FALSE	Track 0 is the counter cam track
track1CntrOutputCam	BOOL	FALSE	Track 1 is the counter cam track
track2CntrOutputCam	BOOL	FALSE	Track 2 is the counter cam track
track0CntrLimit	DINT	2	Upper count value for counter cam track 0
track1CntrLimit	DINT	2	Upper count value for counter cam track 1
Output cam data for output cams 0 to 15 / 0 to 31 / 0 to 63 / 0 to 127 (data structure)			
outputCam	**ARRAY [0..127] of outputCamData**		Elements for output cam data
valid	BOOL	FALSE	Output cam valid
posForceDirection	BOOL	FALSE	Force direction positive (plus)
negForceDirection	BOOL	FALSE	Force direction negative (minus)

Struct_FM352_paraData			
Name	**Type**	**Initial value**	**Comment**
outputCamType	BOOL	FALSE	FALSE: Position-based cams, TRUE: Time-based output cam
switchOnAlarm	BOOL	FALSE	Process alarm while switching on
switchOffAlarm	BOOL	FALSE	Process alarm while switching off
trackNumber	BYTE	16#00	Track number
beginOutputCam	DINT	0	Beginning of output cam
endOutputCam	DINT	0	End of output cam / ON duration
actuationTime	UINT	0	Actuation time

[1)] Variable for FB-internal use (not relevant to users)

Struct_FM352_diagData

The **Struct_FM352_diagData** data structure is shown in the table below. This data structure contains the diagnostic data of the FM 352.

Table 8-79 Data structure Struct_FM352_diagData

Struct_FM352_diagData			
Name	**Type**	**Initial value**	**Comment**
moduleAddress	INT	256	Module address
jobErrorId	INT	0	Description of errors
jobBusy	BOOL	FALSE	At least one job running
diagInformation	BOOL	FALSE	Essential to read the diagnostic buffer
numOfValidEntries	INT	0	Number of valid entries in the list
Diagnostic data (data structure)			
diagnosticEntry	**ARRAY [1..4] of diagType**		Elements for diagnostic data
incomingAlarm	BOOL	FALSE	Event coming
internFault	BOOL	FALSE	Internal fault
extFault	BOOL	FALSE	External fault
faultClass	INT	0	Fault class
faultNumber	INT	0	Error code
chNumber	INT	0	Channel number
outputCamNumber	INT	0	Output cam numbers 0 to 127 with fault class = output cam data error
Variables for FB-internal use (not relevant to users)			
xxxDataSet	ARRAY [0..227] of BYTE		Internal use
xxxDiagnosis0	Struct_FM352_diagType	-	Internal use
xxxFeedback0	DWORD	16#00000000	Internal use
xxxNextOrder	INT	0	Internal use
xxxDataSetNumber	BYTE	16#00	Internal use
xxxDataSetLength	INT	0	Internal use

Struct_FM352_diagData			
Name	**Type**	**Initial value**	**Comment**
xxxCntOfBuffers	INT	0	Internal use
xxxEnableDataSet236	BOOL	FALSE	Internal use
xxxDataSet	BOOL	FALSE	Internal use

8.6.5.6 Calling function blocks

In order to be able to work with the function blocks in your user project, proceed as follows (the numbers shown in the following program segment correspond to the steps below):

1. Create the function block instance (see the following program segment, e.g. create instance for **FB_FM352_control**).
2. Set up variables for the data structure.
3. Create an array for the in/out parameters of the FB.
4. Call instance of the function block.
5. Transfer input parameters.
6. The output parameters of the FB are accessed with <instance name of FB>. <name of output parameter>.
7. Data prepared by the FB for the I/O outputs are assigned to the array of the I/O variables created in step 3.

Note

The call example is an extract from the supplied E_FM352 application example, which is contained on the "SIMOTION Utilities & Applications" CD-ROM.

If you wish to control more than one FM 352, you must create a new variable for the data structure and FB instances with a new name for every FM 352 used.

Call example

```
UNIT E_FM352;

INTERFACE
VAR_GLOBAL
  myDataFM352Ctrl       : Struct_FM352_ctrlData ;    // variable of data structure              (2)
  myDataFM352Parameter  : Struct_FM352_paraData ;    // variable of data structure
  myInstFM352Ctrl       : FM352_control ;            // create FB instance                      (1)
END_VAR

PROGRAM ExampleFM352;                                // program in background task

END_INTERFACE

IMPLEMENTATION
```

```
PROGRAM ExampleFM352

VAR
    FMOutputArray        : ARRAY [0..15] of BYTE;    // Array for FM output data                (3)
END_VAR

// CALL INSTANCE of FB _FB_FM352_control                                                        (4)

  myInstFM352Ctrl
    (
    periIn      := myPeripheralInputFM352,  // variable of I/O inputs                        (5)
    ctrlData    := myDataFM352Ctrl,         // variable with channel-specific data
    paraData    := myDataFM352Parameter,    // variable with machine and output
                                            // cam data
    periOut     := FMOutputArray            // FM output data array
    );

   // TRANSFER DATA TO FM
  myPeripheralOutputFM352  := FMOutputArray;    // Copy array of FM output                   (7)
                                                // data to I/O variables

  myStateFMStartup   := myInstFM352Ctrl. startup; // Start-up status                         (6)

END_PROGRAM                                       // ExampleFM352

END_IMPLEMENTATION
```

Note

The PROGRAM ExampleFM352 must be assigned in the execution system.

8.6.5.7 Application example for FM 352

Introduction

In this example you use a user program to control an output cam controller.

Once startup of the FM 352 is complete, the example program transfers stored machine data to the FM 352. The FM 352 is now parameterized for the application example. It then executes a series of steps in response to events.

Using the variable tables, you can specify events, monitor the reactions of the module and evaluate the diagnostic buffer.

This example will familiarize you with the following block options:

- Submitting several jobs at once
- Mixing read and write jobs
- Reading using a continuous job without waiting for the end of the job
- Evaluating the checkback signals of the block
- Evaluating the checkback signals for an individual job
- Centralized error evaluation by the **_FM352_diagnostic** function block at the end of the user program
- Evaluating the diagnostic buffer in conjunction with "dataError"

FM 352 installation and wiring

Connect the power supply to the front connector of the FM 352 at terminal 1 "L+" and terminal 2 "M" (24 V).

Assigning module parameters

Proceed as follows:

1. Open your project in SIMOTION SCOUT.
2. Open the hardware configuration in SIMOTION SCOUT.
3. Configure your hardware station.
4. You will find the FM 352 module under the corresponding ET 200M.
5. Save the hardware configuration with the **Station > Save and compile** menu command.
6. Download the hardware configuration with the **Target system > Download to module** menu command.
   The red "SF" LED on the FM 352 turns on and then off if the assigned module parameters have been downloaded without errors.

Hardware platform

The application example is available for various SIMOTION hardware platforms and is intended for distributed use of the FM 352.

Note

If the application example is not available for your hardware platform, you must adapt the hardware configuration.

Adapting the application example

The configuration in the example and your available hardware must be adapted.

The following options are available:

1. You can adapt the configuration in the example to the available hardware (PROFIBUS DP address).
2. You can adapt the configuration of the hardware to the example (PROFIBUS DP address).

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

1. Dearchive and open the project containing the application example.
2. Check the hardware configuration: PROFIBUS DP addresses.
3. Check the module addresses (hardware configuration) against the I/O addresses of the controller in SIMOTION SCOUT and module address in the program (myDataFM352Ctrl.moduleAddress).
4. Save and compile the example project. Then, you can download the example to the SIMOTION device and switch to **RUN** mode.

Default settings for machine and output cam data

The following FM 352 data are preset in the program and transferred to the FM at the start of the example (see Starting the example).

- Measuring system: Degrees (4 decimal places)
- Axis: Rotary axis:
  - End of rotary axis: 360.0000 degrees
  - Simulation speed: 360.0000 degrees/min
- Encoder: Monitoring: Switch off wire break and missing pulse
- Cams:

No.	Valid	Track	Type	Start [degrees]	End [degrees]	Time [ms]	Actuation time [ms]	Effective direction	Process alarm
0	x	0	Distance	0.0000	90.0000	-	0.0	Both	None
1	x	0	Distance	180.0000	270.0000	-	0.0	Both	None
2	x	1	Distance	0.0000	90.0000	-	2000.0	Both	None
3	x	1	Distance	180.0000	270.0000	-	2000.0	Both	None
4	x	2	Distance	130.0000	330.0000	-	0.0	Both	None
5	x	3	Distance	130.0000	330.0000	-	2000.0	Both	None

Application sequence

The SIMOTION device (C230-2, P350, D435) is in "RUN" mode. Create a watch table in your project and insert the values from tables "Current cam tracks and output cams", "Switch", "Current actual value" and "Error displays".

Default settings in the program

The following constants are defined in the **E_FM352** unit:

Table 8-80 Constants

Name	Data type	Control value	Meaning
myRefPoint	DINT	1000	Reference coordinate
myBeginOutputCam0	DINT	1470000	Beginning of output cam 0
myEndOutputCam0	DINT	1920000	End of output cam 0
myBeginOutputCam1	DINT	2000000	Beginning of output cam 1
myEndOutputCam1	DINT	3000000	End of output cam 1

Table 8-81 Current cam tracks and output cams

Name	Data type	Meaning
myDataFM352Ctrl.synchronized	BOOL	= TRUE if the axis is synchronized
myDataFM352Ctrl.outputCamActive	BOOL	Output cam processing running
myDataFM352Ctrl.trackSignalsCamActive	DWORD	Current track signals (tracks 0...31)
myDataFM352Ctrl.outputCamData00_31	DWORD	Output cam identifier bits for output cams 0 to 31
myDataFM352Parameter.outputCam[0].beginOutputCam	DINT	Beginning of output cam 0
myDataFM352Parameter. outputCam[0].endOutputCam	DINT	End of output cam 0
myDataFM352Parameter. outputCam[1].beginOutputCam	DINT	Beginning of output cam 1
myDataFM352Parameter. outputCam[1].endOutputCam	DINT	End of output cam 1

Table 8-82 Switch

Name	Data type	Control value	Meaning
mySwitch	BOOL	TRUE	Input for simulated switch

Table 8-83 Current actual value

Name	Data type	Meaning
myDataFM352Ctrl.actPosition	DINT	Current axis position
myStepNumber	INT	Step number

Table 8-84 Error displays

Name	Data type	Meaning
myError	BOOL	Group errors
myOutputCamError	BOOL	Output cam errors
myDataFM352Ctrl.jobErrorId	INT	Error code

Starting the example

Start the example by setting input **myExampleStart** = **TRUE**. Once the program has detected a rising edge at this input, all of the machine data and output cam data required for the example are transferred to the FM and an axis is then started in simulation. You can observe the changes in the actual position (myDataFM352Ctrl.actPosition), output cam data (myDataFM352Ctrl.outputCamData00_31) and track signals (myDataFM352Ctrl.trackSignals). You can also observe the step number of the step sequence (myStepNumber).

When output cam 4 is set (130 degrees), parameters for output cams 0 and 1 are reset to the default values (see Table "Constants"). You can see the change in the watch table.

The program then waits for an external event. Switch the simulated switch by setting **mySwitch** = **TRUE**. The output cam data revert back to the previous values.

After this pass, the sequence of steps is executed, the step number is -2 and the simulation is stopped.

Error assessment

If an error occurs during execution, the step sequence is stopped and the simulation is switched off. Step number -1 is entered.

User program (sequence steps)

The user program executes a sequence of steps as follows:

- **Step** 99: The program waits in cyclic processing mode for the example to start (StartupTask has been executed but "exampleStart" = FALSE).
- **Step** 0: The output cam controller is initialized. Associated data is set to the jobs that are to be executed when the module is restarted. Module restart can be triggered, for example, by a restart of the C230-2.
- **Step** 1: The program waits for the set jobs to be executed.
- **Step** 2: The program continuously reads the output cam ID bits and waits until output cam 4 is set.
- **Step** 3: Parameters for output cams 0 and 1 are reassigned. To enable you to observe the change, the output cam data are read out before and after the change and displayed in the watch table.
- **Step** 4: The program waits for the set jobs to be executed.
- **Step** 5: Here the program waits for "external" event "Switch ON" (mySwitch = TRUE), which you can set via the watch table.

- **Step** 6: When the event occurs, output cams 0 and 1 are reset to the value that was read out in the initialization step.
- **Step** 7: The program waits for the set jobs to be executed.

At the end of the sequence of steps, the instance of FB **_FM352_control** and the instance of FB **_FM352_diagnostic** are called.

If the diagnostics detected a message about invalid output cam data, the **myOutputCamError** output is set.

8.6.6 Alarm processing

8.6.6.1 Overview of alarm processing

Pending error messages are processed and evaluated differently in a SIMOTION system than in a SIMATIC system. By default, the diagnostic alarms and process alarms are not enabled. Activate the alarms for the relevant module in the hardware configuration (refer to Chapter Inserting function modules into the SIMOTION project (Page 6244)).

If you have parameterized process alarms and/or diagnostic alarms, program the alarm processing sequence in accordance with the flow diagram below.

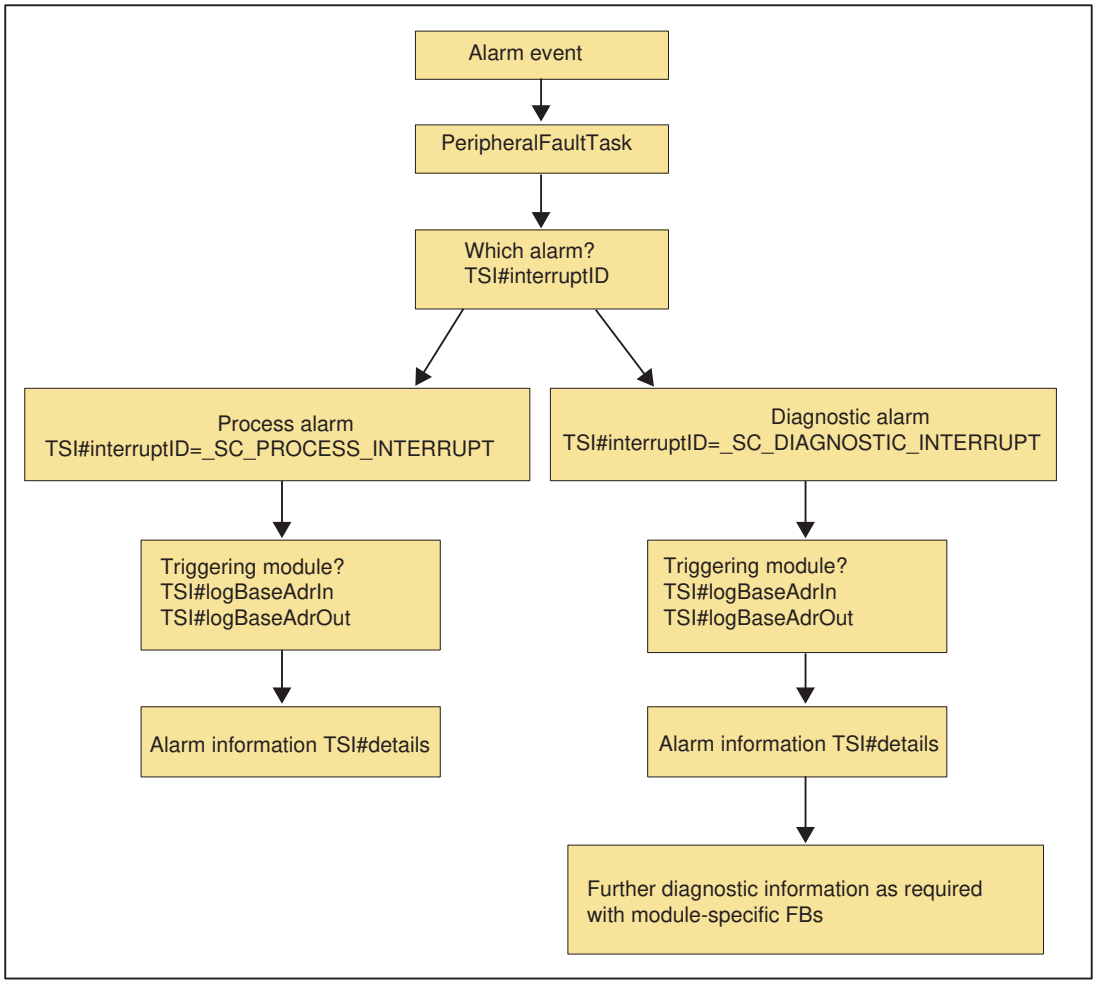

Figure 8-34 Alarm processing in the FM modules

Alarm evaluation

Alarms originating from the I/O are evaluated in the **PeripheralFaultTask**. When the **PeripheralFaultTask** is started, the **Taskstartinfo** is made available, which you can evaluate in the user program.

The **Taskstartinfo** of the **PeripheralFaultTask** is comparable to the local data of OB40 and OB82 in the SIMATIC system.

Table 8-85 Meaning of the Taskstartinfo

Task	TSI		Note
PeripheralFaultTask	DT	TSI#startTime	Start time of the task
	UDINT	TSI#interruptID	Identifies the triggering event: • _SC_PROCESS_INTERRUPT • _SC_DIAGNOSTIC_INTERRUPT • _SC_STATION_DISCONNECTED • _SC_STATION_RECONNECTED
	DINT	TSI#logBaseAdrIn	Logical base address if a process alarm (PRAL) or a diagnostic alarm (DAL) was caused by an input area on the module, otherwise _SC_INVALID_ADDRESS
	DINT	TSI#logBaseAdrOut	Logical base address if a process alarm (PRAL) or a diagnostic alarm (DAL) was caused by an output area on the module, otherwise _SC_INVALID_ADDRESS
	DINT	TSI#logDiagAdr	Diagnostic address of a DP slave if the alarm was caused by a station failure or station recovery of an associated DP slave, otherwise _SC_INVALID_ADDRESS
	DWORD	TSI#details	Detail information (bit fields)

8.6.6.2 Process alarms

For the FM modules, you can select which events will trigger a process alarm. The assignment can be made in the parameter assignment screen forms of the configuration package for each module.

Definition of a process alarm

If an event needs a response irrespective of the cycle of the SIMOTION device, the relevant FM module can trigger a process alarm.

Events that trigger a process alarm

The criteria (events) that trigger process alarms in a SIMOTION system are the same as those in a SIMATIC system.

For a more detailed description, refer to the
FM 350-1/FM 350-2/FM 352 Installation and Parameter SIMATIC manuals.

Reactions to a process alarm

A process alarm causes the following to occur:

- Process data are written in the **TSI#details** variable in the Taskstartinfo of **PeripheralFaultTask**.
- The SIMOTION device goes into STOP mode if a program has not been assigned in the **PeripheralFaultTask**.

Bit assignment

The **TSI#details** variable is assigned in the same way as in a SIMATIC system.

Note

More information is available in the following SIMATIC manuals:

- *FM 350-1 Function Module Installation and Parameter Assignment*
- *FM 350-2 Counter Function Module Installation and Parameter Assignment*
- *FM 352 Electronic Cam Controller Installation and Parameter Assignment*

Evaluation of process alarms in the FM

If a process alarm is triggered, the data in the Taskstartinfo of **PeripheralFaultTask** are written to the **TSI#details** variable and made available there.

Note

If an event occurs that should trigger a process alarm, but a previous identical event has not yet been acknowledged, a new alarm is not triggered. The new process alarm is lost.

Subject to parameter assignment, this can result in a diagnostic alarm ("Process alarm lost").

If < 2 ms elapse between two events that should normally both trigger a process alarm, the second process alarm is lost and no diagnostic alarm can be triggered (for FM 350-2 only).

The **TSI#details** variable is assigned in the same way as in a SIMATIC system.

8.6.6.3 Diagnostic alarms

Definition of a diagnostic alarm

If the user program is to respond to an internal or external error, you can set the parameters for a diagnostic alarm that will interrupt the cyclical program of the SIMOTION device.

Events that trigger a diagnostic alarm

The criteria (events) that trigger diagnostic alarms in a SIMOTION system are the same as in a SIMATIC system.

For a more detailed description, refer to the *FM 350-1/FM 350-2/FM 352, Installation and Parameter Assignment* SIMATIC manuals.

Responses to a diagnostic alarm

If a diagnostic alarm is issued, the following occurs:

- Diagnostic data are written to **TSI#details** variable in the Taskstartinfo of **PeripheralFaultTask**.
- The SIMOTION device goes into STOP mode if a program has not been assigned in the **PeripheralFaultTask**.
- You can use module-specific FBs to read additional diagnostic data in the **PeripheralFaultTask** or **BackgroundTask** according to FM type.
- The group error LED (SF) of the FM module lights up. The group error LED (SF) is extinguished as soon as the error has been remedied.

Bit assignment

The **TSI#details** variable is assigned in the same way as in a SIMATIC system.

Note

More information is available in the following SIMATIC manuals:

- *FM 350-1 Function Module Installation and Parameter Assignment*
- *FM 350-2 Counter Function Module Installation and Parameter Assignment*
- *FM 352 Electronic Cam Controller, Installation and Parameter Assignment*

Evaluation of diagnostic alarms

If a diagnostic alarm is triggered, the data in the Taskstartinfo of the **PeripheralFaultTask** are written to the **TSI#details** variable. The **PeripheralFaultTask** is called automatically and provides 4 bytes of diagnostic information for fast analysis. The contents of the diagnostic information are the same as in a SIMATIC system.

Additional information can be read out using module-specific FBs.

FM 350-1

FB **_FM3501_diagnostic** reads out 16 bytes of diagnostic data and makes them available in the data structure of type **Struct_FM3501_data**. The function block can be called in the **PeripheralFaultTask**, **BackgroundTask** or **TimerInterruptTask**.

FM 350-2

FB **_FM3502_diagnostic** reads out 16 bytes of diagnostic data and enters them in the **diagnostic** substructure of the data structure of type **Struct_FM3502_data**. The function block can be called in the **PeripheralFaultTask**, **BackgroundTask** or **TimerInterruptTask**.

FM 352

FB **_FM352_diagnostic** reads out all diagnostic data and enters them into the data structure of type **Struct_FM352_diagnosticData**. The FB must be called in the **BackgroundTask** or **TimerInterruptTask**.

8.6.7 Appendix

8.6.7.1 SIMOTION and SIMATIC names

The tables below contain a comparison of SIMOTION and SIMATIC names.

Table 8-86 SIMOTION and SIMATIC names for FM 350-1

Name in SIMOTION System, V4.0 and higher (command library in SCOUT)	Name in the SIMATIC system	Name in the SIMOTION system up to V3.2 (SIMOTION Function Library)
Function block parameters		
_FM3501_control2	**FC CNT_CTRL (FC 0)**	**_FB_FM3501_control**

8.7 Supplement for the ET 200S frequency converter

Preface

Contents of this Function Manual

This **document** is a component of the **SIMOTION Programming - References** documentation package.

This documentation is a supplement to the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions *(03/2005 Edition)*.

This documentation is supplied with the SIMOTION SCOUT in electronic form!

This manual describes how you can control the ET 200S frequency converter with the aid of the **_ET200S_FC_control** function block (Article No.: 6SL3244-0SA00-1AA**0**) from a SIMOTION device.

Function block

The **_ET200S_FC_control** function block is used for the communication between the SIMOTION system and the ET 200S frequency converter and is a component of the command library of the "SIMOTION SCOUT" engineering system.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

http://www.siemens.com/motioncontrol/docu

My Documentation Manager

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

8.7.1 Fundamental safety instructions

8.7.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.7.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.7.2 Description

8.7.2.1 General

Overview

This manual describes the differences in the operation of the ET 200S FC (FC = Frequency Converter) in the SIMOTION system compared with operation in the SIMATIC system.

Note

This manual is a supplement to the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).

This documentation is supplied with the SIMOTION SCOUT in electronic form!

Requirements

The following are required for the standard function described in this document:

- SIMOTION SCOUT, V4.1 SP1 or higher
- SIMOTION Kernel, V4.1 SP1 or higher
- ET 200S frequency converter with ICU24, software release V1.02 or higher

Note

The functions associated with the **_ET200S_FC_control** function block can only be used on the ET 200S frequency converter with ICU (Article No: 6SL3244-0SA00-1AA**0**).

8.7.2.2 Product description

ET 200S frequency converter

The ET 200S FC is a modular frequency converter that is completely embedded in the distributed I/O system of the ET 200S.

During generator operation of the connected motor, the ET 200S FC feeds back energy into the supply system.

Function block

The **_ET200S_FC_control** function block is provided for the cyclic communication and the parameter transfer of the ET 200S FC with SIMOTION. This function block is described in this manual.

Note

The **_ET200S_FC_control** function block **cannot** be used to control the ET 200S FC (Article No.: 6SL3244-0SA00-1AA**1**). Standard telegram 1 should be used for this frequency converter.

Functionality

The functionality of the **_ET200S_FC_control** function block and the ET 200S FC is the same as when used in the SIMATIC S7 automation system. There are differences in the execution of the data transfer and the handling of the FB.

Possible applications

The ET 200S FC can be operated in a distributed ET 200S station via PROFIBUS DP on a SIMOTION controller.

Several ET 200S frequency converters can be operated in one ET 200S station. The ET 200S interface module IM 151-1 is used for the connection to PROFIBUS DP.

The following figure shows a distributed configuration with SIMOTION C2xx.

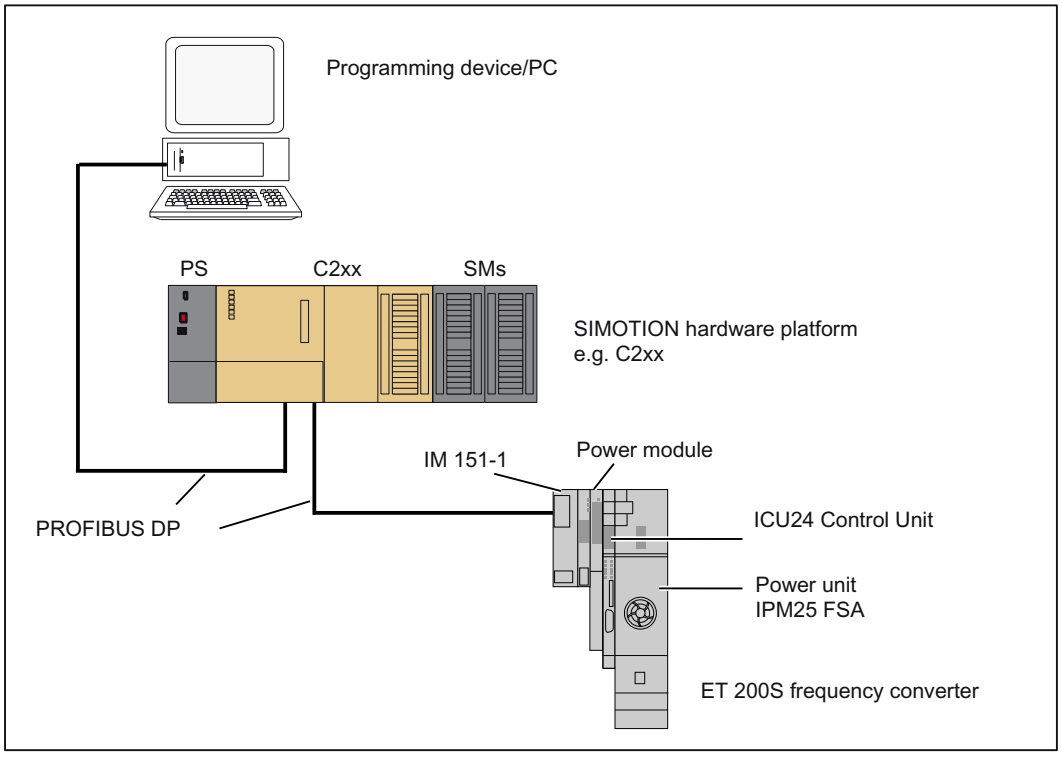

Figure 8-35 Connection of the ET 200S frequency converter to the SIMOTION C2xx device (example)

8.7.2.3 Installation and connection

You must perform the following steps to be able to operate the ET 200S frequency converter using the SIMOTION system:

1. Install and connect the ET 200S interface module (IM) with the components of the ET 200S FC.
2. Establish the PROFIBUS connection between the IM and the SIMOTION device.
3. Set the PROFIBUS DP node address on the IM.
4. Switch on the terminating resistor at the first and last bus node.

Note

The commissioning of the ET 200S frequency converter can be performed either via

- the STARTER functionality integrated in the SIMOTION SCOUT engineering system (via "Insert single drive"), or
- or the STARTER engineering software.

For a description of commissioning and steps 1 to 4, see the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).

5. Insert the ET 200S FC into the SIMOTION project (refer to Chapter Inserting the ET 200S frequency converter into a SIMOTION project (Page 6332)).
6. Parameterizing the ET 200S FC.
   To parameterize the module, go to **HW Config**. Double-click the relevant module to open the **Properties** dialog box. Select the **Parameters** tab to access the parameterization interface. There you can assign parameters for your module.
   See the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).
7. Link the function block to the SIMOTION project (refer to Chapter Integrating the function block in the user project (Page 6333)).

8.7.2.4 Inserting the ET 200S frequency converter into a SIMOTION project

Requirement

The following requirements must be met:

1. You have created a project in SIMOTION SCOUT and inserted a rack with a SIMOTION device in the hardware configuration.
2. You have configured a PROFIBUS subnet.

Note

For how to create a project and configure a PROFIBUS subnet, refer to the online help of *SIMOTION SCOUT*.

Inserting the frequency converter

1. In SIMOTION SCOUT, open the "User Projects" dialog box with the "Project" > "Open" menu command. In this dialog box, select your project and confirm with "OK".
2. Open **HW Config**.
3. In the "HW Config" window, open the **hardware catalog** with the "View" > "Catalog" menu command.
4. In the hardware catalog, open the "PROFIBUS DP" folder and the "ET 200S" subfolder and select, for example, the **IM 151-1 Standard** interface module (Article No.:6ES7 151-1AA04-0AB0 or follow-on module).
5. Use a drag-and-drop operation to place the "IM 151-1 Standard" interface module on the PROFIBUS subnet of your SIMOTION device.
   The "Properties - PROFIBUS IM 151-1 Standard Interface" dialog box opens. In this dialog box, select the address you set on the IM 151-1 (see *ET 200S Distributed I/O Device* Manual) and confirm your selection with "OK".
   The selected IM 151-1 Standard I/O device is inserted into the project.
6. The inserted I/O device still has to be equipped with the following modules: PM-D power module and ET 200S FC frequency converter, consisting of ICU24 closed-loop control module.
   Open the "Motor starter" folder and the "PM" subfolder under "IM 151-1 Standard" in the hardware catalog. Select the **PM-D 24VDC** power module.
   You insert the frequency converter by selecting in the hardware catalog under "IM151-1 Standard" (Article No.: 6ES7 151-1AA04-0AB0) in folder "Frequency converters" the closed-loop control module **ICU24** (Article No.: 6SL3244-0SA00-1AA0).

   Note

   You can disable or enable diagnostic alarms via parameter p8452 in the ET 200S frequency converter.
7. Save and compile your project.

8.7.3 Programming

8.7.3.1 Integrating the function block in the user project

Creating the FB instance in the user project

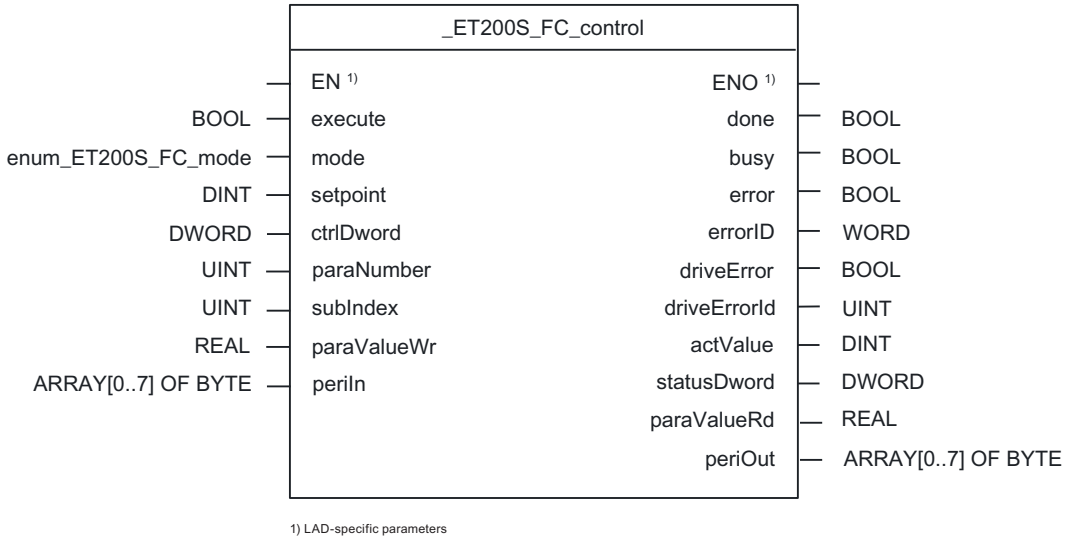
The **_ET200S_FC_control** function block is a component of the command library of the SIMOTION SCOUT engineering system. To work with the block, an instance of the function block must first be created in the user project.

Example:

```
VAR_GLOBAL
...
```

```
  myFC_control    : _ET200S_FC_control;   // create instance of FB _ET200S_FC_control
...
END_VAR
```

Call (LAD representation)



Application example

The application example is included on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge with SIMOTION SCOUT.

8.7.3.2 Addressing the ET 200S frequency converter

Overview

Communication between the SIMOTION device and the ET 200S FC takes place through direct access to the I/O. I/O variables are used to address the direct read/write access to the I/O.

Creating I/O variables

For the cyclic data transfer with the ET 200S frequency converter, you must create an I/O variable in the symbol browser for each I/O input and output. When creating the I/O variable, enter the configured address from the hardware configuration in the "I/O address" column (see example below). Enter a field length of 8 in the "Field length" column.

With these specifications, an I/O variable of type ARRAY[0..7] of BYTE is created in the SIMOTION project for cyclic data transfer.

Example:

Determining addresses from **HW Config**:

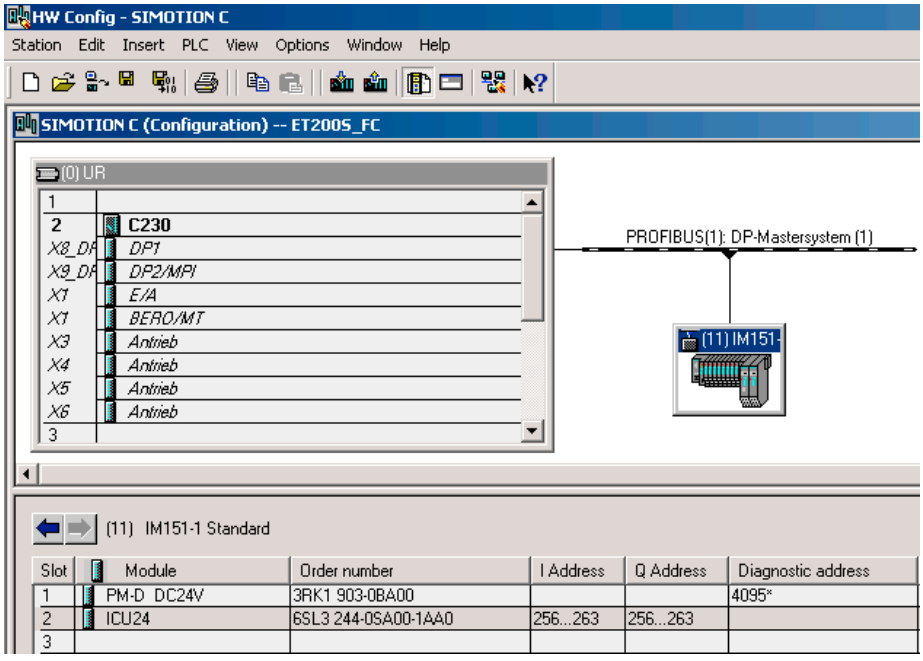


Figure 8-36 Addresses in HW Config

Creating the I/O variables in the symbol browser:

	Name	I/O address	Read only	Data type	Field length
1	myperiin	PIB 256		Array	8
2	myperiout	PQB 256	☐	Array	8

Figure 8-37 Addressing with I/O variable

The I/O addresses in the symbol browser shown in the figure have the following meanings:

- "PIB" = Peripheral Input Byte
- "PQB" = Peripheral Output Byte

Parameter transfer

The I/O variable for the I/O inputs is transferred to the **periIn** input parameter.

The prepared data for the I/O outputs are supplied by the function block at the **periOut** output parameter. The **periOut** output parameter must be assigned to the I/O variable for the I/O outputs.

Note

When booting the firmware of the ET 200S frequency converter from the MMC card, it may take more than 500 ms for the ET 200S frequency converter to ramp up.

To avoid I/O area access errors when the frequency converter has not yet ramped up, accesses to the I/O inputs and outputs of the frequency converter must be performed with the **_getSafeValue** and **_setSafeValue** system functions (see sample program **UNIT E_FC_ctr**).

Note

For additional information, refer to:

- SIMOTION SCOUT online help
- Programming Manuals for the relevant programming languages, such as:
  - SIMOTION ST, Structured Text Programming Manual
  - SIMOTION MCC, Motion Control Chart Programming Manual
  - SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram Programming Manual

These documents are shipped with SIMOTION SCOUT in electronic form.

8.7.4 Parameterization

8.7.4.1 Function block _ET200S_FC_control

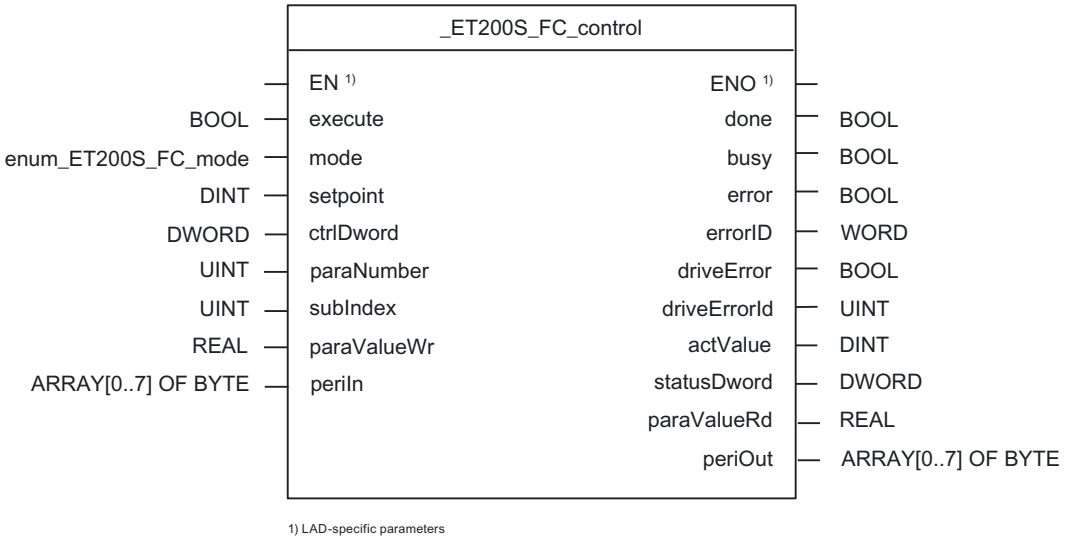
Task

You can control the ET 200S FC via your user program with the FB **_ET200S_FC_control**.

The FB **_ET200S_FC_control** supports the following functions:

- Drive control:
  - Sending control words
  - Receiving status words
- Diagnostics:
  - Displaying drive faults
  - Acknowledging drive errors
  - Displaying parameterization errors in the data exchange
- Reading and writing of drive parameters

Call (LAD representation)



Parameter description

The following table contains all the parameters of the function block **_ET200S_FC_control**.

Table 8-90 Parameters of the FB _ET200S_FC_control

Name	Type [1]	Data type	Default	Meaning
execute	IN	BOOL	FALSE	Start of a data transfer from/to the ET 200S FC with rising edge
mode	IN	enum_ET200S_FC_mode (READ, WRITE, DATA1, DATA2, RESET_ERR)	READ	Selection of data transfer type • READ: Read individual parameter • WRITE: Write individual parameter • DATA1: Data set 1 is set active (p0810 to 0.0) with rising edge on parameter **execute**. • DATA2: Data set 2 is set active (p0810 to 1.0) with rising edge on parameter **execute**. • RESET_ERR: Acknowledgement of parameterization and drive errors
periIn	IN	ARRAY [0 to 7] of BYTE	8 (16#00)	Transfer I/O inputs of ET 200S FC to FB
setpoint	IN	DINT	0	Normalized setpoint without units for the ET 200S FC, transferred cyclically [4]
ctrlDword	IN	DWORD	16#00000000	Control words (STW 1 and STW 2) of the ET 200S FC, transferred cyclically [5]
paraNumber	IN	UINT	0	Parameter number to be read or written
subIndex	IN	UINT	0	Index of an indexed parameter for the ET 200S FC
paraValueWr	IN	REAL	0.0	Parameter value to be written
done	OUT	BOOL	FALSE	**TRUE** = Read/write parameter was processed without errors

Name	Type [1]	Data type	Default	Meaning
busy	OUT	BOOL	FALSE	**TRUE** = Read/write parameter active
error	OUT	BOOL	FALSE	**TRUE** = parameterization error
errorID	OUT	WORD	16#0000	Error number of the parameterization error (error number 0..108, or 16#0000..16#006C) [3] **Note**: If **error** = **TRUE** and **errorID** = **16#0000**, the following error is pending: "Invalid parameter number"
driveError	OUT	BOOL	FALSE	**TRUE** = Drive error is pending (refer to the **driveErrorId** parameter)
driveErrorId	OUT	UINT	0	Reason for the error (decimal format) Value corresponds to parameter r0947 (errors) [2]
periOut	OUT	ARRAY [0 to 7] of BYTE	8 (16#00)	Prepared FB data for I/O outputs of the ET 200S FC
actValue	OUT	DINT	0	Display of the parameter value of p2051.1 (process data on field bus) [2]
statusDword	OUT	DWORD	16#00000000	Status words (ZSW 1 and ZSW 2) of the ET 200S FC [2]
paraValueRd	OUT	REAL	0.0	Read parameter value

[1] Parameter types: IN = input parameter, OUT = output parameter

[2] See the *SIMATIC ET 200S FC Frequency Converter* Parameter Manual (03/2005 Edition).

[3] See the *SIMATIC ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).

[4] Calculation in the converter:

$$\text{Converter set frequency} = \frac{\text{Value in setpoint} \cdot \text{reference frequency in drive parameter p2000}}{\text{Normalizing value}}$$

Example 1: - Normalizing value = 16,384 (4000 hex)
- p2000 = 50 Hz
- Desired set frequency = 20 Hz

$$\text{Setpoint} = \frac{20\ \text{Hz} \cdot 16{,}384}{50\ \text{Hz}} = 6{,}553$$

Example 2: - Normalizing value = 16,384 (4000 hex)
- Speed (50 Hz ≙ max. speed ≙ 1,350 rpm)
- Desired speed = 1,000 rpm

$$\text{Setpoint} = \frac{1{,}000\ \text{rpm} \cdot 16{,}384}{1{,}350\ \text{rpm}} = 12{,}136$$

Note

You can find the normalizing value in the *SIMATIC ET 200S FC Frequency Converter* Parameter Manual (03/2005 Edition) under parameter p2000.

The **execute** parameter is only used to start acyclic data transfer from/to the frequency converter.

When the frequency converter is switched on, the enables must be set in the control word and the setpoint (**setpoint**) takes immediate effect.

The effect of the control word depends on the parameterization in the frequency converter.

[5] Bit assignment of **ctrlDword** (control words 1 and 2 for the ET 200S FC):

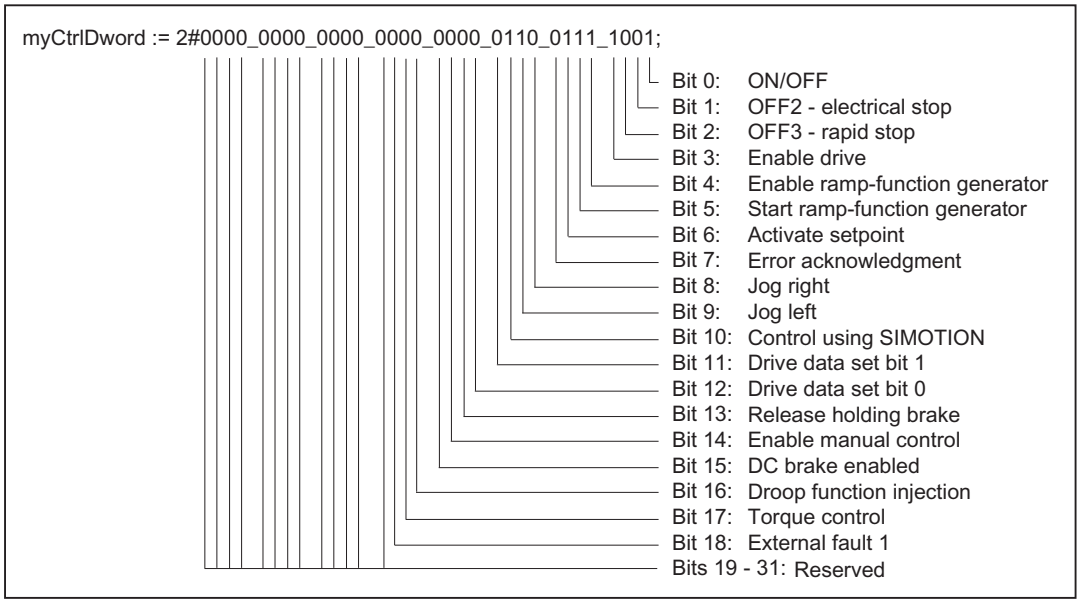


Figure 8-38 Meaning of control bits (in STW 1 and STW 2 for the ET 200S FC)

Description of functions

When the **_ET200S_FC_control** function block is called, the cyclic data is written and updated and jobs (such as reading/writing parameter) can be carried out.

The values in the input parameters **periIn**, **setpoint**, and **ctrlDword** are transmitted cyclically - regardless of the **busy**, **done**, **execute**, and **mode** parameters - and the output parameters **periOut**, **actValue**, and **statusDword** are updated cyclically.

Jobs are started with a rising edge on the input parameter **execute**. The type of data transfer is selected in the input parameter **mode**.

You can choose from the following options in the input parameter **mode**:

- READ: Individual parameters are read from the ET 200S FC (factory setting).
- WRITE: Individual parameters are written to the ET 200S FC.
- DATA1: The drive parameter p0810 is set to 0.0 (command data set 1 of the drive active).
- DATA2: The drive parameter p0810 is set to 1.0 (command data set 2 of the drive active).
- RESET_ERR: Resetting of parameterization and drive errors.

A job is started with a rising edge on the input parameter **execute** and the output parameters set to **done** = **FALSE** and **busy** = **TRUE**.

If **mode** = **WRITE** is selected, the parameters **paraNumber**, **subIndex**, and **paraValueWr** are accepted with a rising edge on the input parameter **execute**. An active data transfer is indicated by **busy** = **TRUE**. When a job is completed without errors, the following parameters are displayed: **busy** = **FALSE**, **done** = **TRUE**, and **error** = **FALSE**. When a job is completed with errors (parameterization errors), the following parameters are displayed: **busy** = **FALSE**, **done** = **FALSE**, and **error** = **TRUE**. The error number of the parameterization error is displayed in output parameter **errorID**. Parameterization errors are acknowledged with a rising edge on the input parameter **execute** and **mode** = **RESET_ERR** selected. If acknowledgement is successful, the output parameter is set to **done** = **TRUE** and the **error** and **errorID** parameters are reset.

The drive parameter p0810 is set to 0.0 (command data set 1 of the drive active) with a rising edge on the input parameter **execute** and **mode** = **DATA1** selected. This drive parameter is set to 1.0 (command data set 2 of the drive active) with a rising edge on the input parameter **execute** and **mode** = **DATA2** selected. This means that control command acceptance can be switched from "USS on RS232" to "Fieldbus", if the relevant P0700 setting is made.

Note

If another job (e.g. reading parameters when a write job is active) is started when **busy** = **TRUE**, this is disregarded. A new job is only executed when **busy** = **FALSE**.

Note

When booting the firmware of the ET 200S frequency converter from the MMC card, it may take more than 500 ms for the ET 200S frequency converter to ramp up.

To avoid I/O area access errors when the frequency converter has not yet ramped up, accesses to the I/O inputs and outputs of the frequency converter must be performed with the **_getSafeValue** and **_setSafeValue** system functions (see sample program **UNIT E_FC_ctr** on the "SIMOTION Utilities & Applications" CD-ROM).

Graphic overview of the functionality

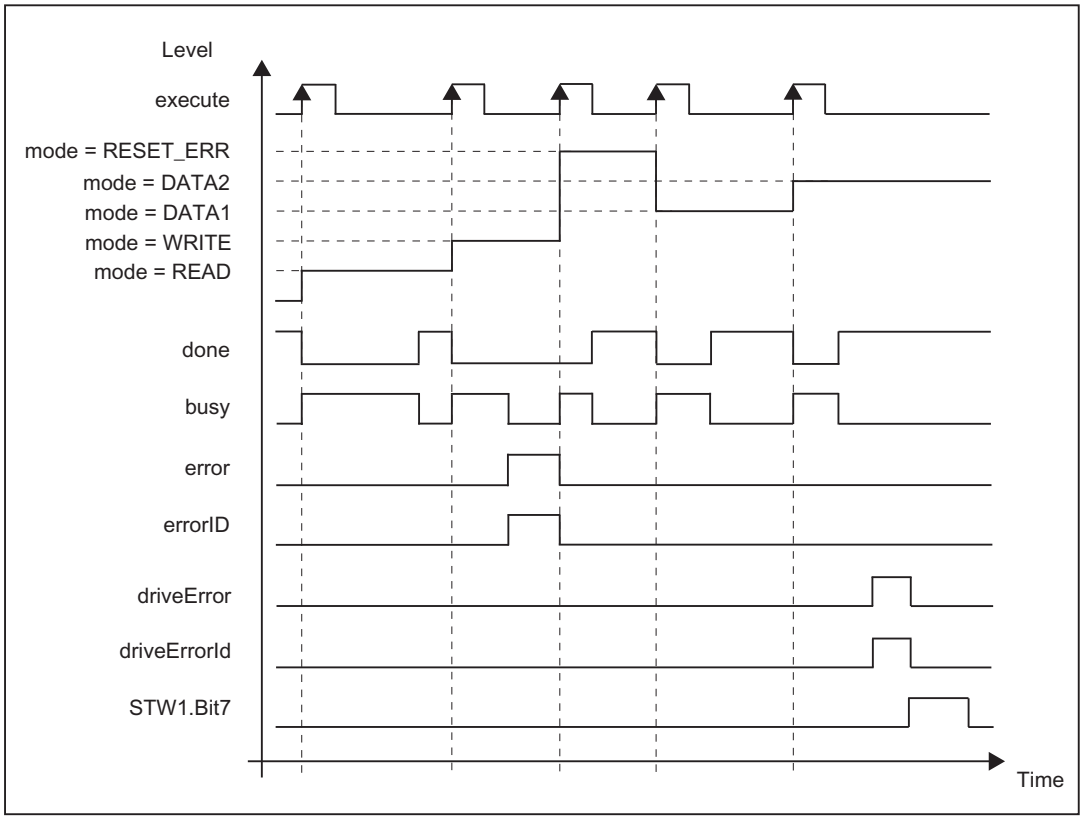

Figure 8-39 Signal propagation diagram

Task integration (call)

The **_ET200S_FC_control** FB is designed to be called in a cyclic task and must be called in this task during each task cycle. The execution of a job can take several cycles. The user decides which cyclical task the **_ET200S_FC_control** FB is called in. There are no restrictions with respect to this in the **_ET200S_FC_control** FB. The call can be performed in all cyclic tasks. A fixed time frame (e.g. **IPOSynchronousTask**) is not required for processing.

A separate instance of the **_ET200S_FC_control** function block must be created for the control and communication tasks of each frequency converter used.

Error messages

The drive errors of the ET 200S FC are output at the output parameters **driveError** and **driveErrorId** of the **_ET200S_FC_control** FB. The output parameter **driveErrorId** displays the associated error number (from r0947). For a description of the error numbers, see the *SIMATIC ET 200S FC Frequency Converter* Parameter Manual (03/2005 Edition).

Rectify the cause of the drive error. Drive errors are acknowledged with a rising edge on the input parameter **execute** and **mode** = **RESET_ERR** selected.

Parameterization errors are signaled at the output parameters **error** and **errorID** , and reset with a rising edge on input parameter **execute** and **mode** = **RESET_ERR** selected.

8.7.4.2 Calling the function block

Procedure

Proceed as follows to work with the **_ET200S_FC_control** function block in your user project (the numbers shown in the following program segment correspond to the steps listed below):

1. Create an instance of the function block.
2. Call instance of the function block.
3. Transfer input parameters.
4. The output parameters of the function block are accessed with <instance name of FB>.<name of output parameter>.
5. The data for the I/O outputs prepared by the FB are assigned to the I/O variables.

Note

The program segment is an extract from the supplied application example. The application example is included on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge with SIMOTION SCOUT.

If you want to control several frequency converters, you must create a new variable for the FB instances with a new name for each module used.

Separate data structures have been created for the input and output parameters in the example to provide a better overview.

Call example

```
UNIT E_FC_ctrl;

INTERFACE

TYPE
   ...                                    // see example
END_TYPE

VAR_GLOBAL
```

```
 myFC_control     : _ET200S_FC_control;     // create instance of FB _ET200S_FC_control          (1)
 myFC_control_In  : Struct_FC_control_In;   // input parameter of FB _ET200S_FC_control
 myFC_control_Out : Struct_FC_control_Out;  // output parameter of the FB _ET200S_FC_control
 myRetValSetSafe  : enumSetAndGetSafeValue; // return value from system function _setsafevalue

 ...                                        // see example

END_VAR

PROGRAM ExampleET200S_FC;                  // Program in BackgroundTask

END_INTERFACE

IMPLEMENTATION

PROGRAM ExampleET200S_FC
// Program in BackgroundTask
   // call _getSafeValue -> Test I/O-variables after powerOn Reset
   myRetValGetSafe := _getSafeValue (
    variable   := myPeriIn,
    accessMode := DEFAULT_VALUE,
    getValue   := myTmpPeriIn
   );
 IF (myRetValGetSafe = OK)                      // powerOn ready
 THEN
   // CALL FB INSTANCE
   myFC_control (                                                                             (2)
    periIn      := myTmpPeriIn,                // I/O peripheral input                       (3)
    execute     := myFC_control_In.execute,    // execute / start the data transfer
    mode        := myFC_control_In.mode,       // select the mode
    paraNumber  := myFC_control_In.paraNumber, // parameter number to read or write
    subIndex    := myFC_control_In.subIndex,   // index of the parameter
    paraValueWr := myFC_control_In.paraValueWr,// value of the parameter to write
    setpoint    := myFC_control_In.setpoint,   // set the setpoint
    ctrlDword   := myFC_control_In.ctrlDword   // set the control word
   );

  // get output parameter of the FB _ET200S_FC_control                                         (4)

  myFC_control_Out.error        := myFC_control.error;        // error occured
  myFC_control_Out.errorID      := myFC_control.errorID;      // number of error
  myFC_control_Out.driveError   := myFC_control.driveError;   // drive error
  myFC_control_Out.driveErrorId := myFC_control.driveErrorId; // number of the drive error
  myFC_control_Out.actValue     := myFC_control.actValue;     // per default the
                                                              // actual speed value
  myFC_control_Out.statusDword  := myFC_control.statusDword;  // the status word
  myFC_control_Out.paraValueRd  := myFC_control.paraValueRd;  // value of the
                                                              // parameter to read
 END_IF

  // write peripheral output                                                    (5
  myRetValSetSafe := _setSafeValue (                                            )
    variable   := myPeriOut,                                // I/O peripheral output
    value      := myFC_control.periOut,
    accessMode := NO_CHANGE
   );

END_PROGRAM                          // end Program in BackgroundTask

END_IMPLEMENTATION
```

8.7.5 Application example

8.7.5.1 General

Task

The application example shows how you can control the ET 200S frequency converter with the aid of the **_ET200S_FC_control** function block. You can carry out the following functions with this example:

- Reset parameterization and drive errors
- Read parameter
- Write parameter
- Activate command data set 1
- Activate command data set 2
- Start the motor at a specified speed
- Stop a running motor

Requirements

The following requirements must be met:

- You have commissioned the ET 200S frequency converter (Article No.: 6SL3244-0SA00-1AA**0**) with the connected motor.
  For information on commissioning the frequency converter, see the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).
  This document is supplied with SIMOTION SCOUT in electronic form.
- You have completed the addressing of the ET 200S frequency converter (refer to chapter Addressing the ET 200S frequency converter (Page 6334)).

Hardware platform

The application example is available for various SIMOTION hardware platforms.

Note

If the application example is not available for your SIMOTION hardware platform, you must adapt the hardware configuration.

Calling the application example

The application example can be found on the "SIMOTION Utilities & Applications" CD-ROM. The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge with SIMOTION SCOUT.

1. Dearchive and open the project containing the application example.
2. Check the hardware configuration, e.g. the PROFIBUS DP addresses.
3. **Save** and **compile** the example project. Then, you can download the example to the SIMOTION device and switch to RUN mode.

Adapting the application example

The configuration in the example and its available hardware must be adapted.

The following options are available:

1. You can adapt the configuration of the example to the available hardware.
2. You can adapt the configuration of the hardware to the example.

You can adapt the configuration in the example to the available hardware.

You have assigned a module address <> 256 in **HW Config**.

1. In the symbol browser, change the I/O address to the value you assigned in **HW Config**:

	Name	I/O address	Read only	Data type	Field length
1	⊞ myperiin	PIB 256		Array	8
2	⊞ myperiout	PQB 256	☐	Array	8

Figure 8-40 Adapting the I/O address

2. Enter the same value in the **myModuleAddr** variable of the application example.

Note

When booting the firmware of the ET 200S frequency converter from the MMC card, it may take more than 500 ms for the ET 200S frequency converter to ramp up.

To avoid I/O area access errors when the frequency converter has not yet ramped up, accesses to the I/O inputs and outputs of the frequency converter must be performed with the **_getSafeValue** and **_setSafeValue** system functions (see sample program **UNIT E_FC_ctrl** on the "SIMOTION Utilities & Applications" CD-ROM).

8.7.5.2 Sequence of the application example

Relevant variables in the application example

Table 8-91 Overview of the relevant variables

Symbol	Data type	Initial value	Meaning
myCommand	enumCommand (CMD_READ, CMD_WRITE, CMD_RESET_ERR, CMD_USE_DATA1, CMD_USE_DATA2, CMD_START, CMD_STOP)	CMD_READ	Selection of command to be executed
myCmdExecute	BOOL	FALSE	TRUE = Start selected command
myCmdDone	BOOL	FALSE	TRUE = Error-free command processing
myCmdError	INT	0	Error specification
myParaNumber	UINT	0	Number of parameter to be written
mySubIndex	UINT	0	Index of the parameter number
myParaValueWr	REAL	0.0	Parameter value to be written
myParaValueRd	REAL	0.0	Read parameter value
mySetpoint	INT	500	Speed specification in [rpm]
myMaxRevolution	INT	1,350	Maximum speed of the motor in [rpm]

Command processing

Proceed as follows to activate command processing in the sample program:

1. In the project navigator, under **Programs** select the **E_FC_ctrl Unit**.
2. Open the symbol browser in SIMOTION SCOUT.
3. Select a command in the symbol browser by setting the **myCommand** variable to the command to be executed.
4. Parameterize the command-specific variable.
5. Start the selected command by setting the **myCmdExecute** variable to **TRUE**.
6. Wait until error-free command execution is indicated by **myCmdDone** = **TRUE**. An error during command execution is specified in the **myCmdError** parameter.
7. You can now call additional commands.

The functions contained in the application example are described below.

Example: Resetting drive and parameterization errors

The function block displays drive errors at the output parameters **myFC_control.driveError** = **TRUE** and **myFC_control.driveErrorId** ≠ **16#0000**; these must be acknowledged before the next command is called. Drive errors are reset with bit 7 in the control word **ctrlDword**.

Parameterization errors are indicated at the output parameters **myFC_control.error** = **TRUE** and **myFC_control.errorID** = **16#0000**.

Example: You have set an invalid parameter number (**myParaNumber** = 9999).

To acknowledge the parameterization error, you must set the variables **myCommand** and **myCmdExecute** to **CMD_RESET_ERR** and **TRUE** respectively.
The output parameters are then reset with **myFC_control.error** = **FALSE** and **myFC_control.errorID** = **16#0000**.

Example: Read parameter

Proceed as follows to read a parameter:

1. Set the **myCommand** variable to **CMD_READ** in the symbol browser.
2. Assign the **myParaNumber** variable the parameter number to be read (e.g. "1120", startup time).
3. Set the **mySubIndex** variable to "0".
4. Start the command with **myCmdExecute** = **TRUE**.
   The parameter value read from the ET 200S FC is output in the **myParaValueRd** variable.

Example: Write parameter

Proceed as follows to write a parameter:

1. Set the **myCommand** variable to **CMD_WRITE** in the symbol browser.
2. Assign the **myParaNumber** variable the parameter number to be written (e.g. "1120", startup time).
3. Set the **mySubIndex** variable to "0".
4. Enter the parameter value to be written (e.g. "50") in the **myParaValueWr** variable.
5. Start the command with **myCmdExecute** = **TRUE**.
   The value entered in the **myParaValueWr** variable is transmitted to the ET 200S FC.

Example: Activate command data set 1

Proceed as follows to activate command data set 1:

1. Set the **myCommand** variable to **CMD_USE_DATA1** in the symbol browser.
2. Start the command with **myCmdExecute** = **TRUE**.

Example: Activate command data set 2

Proceed as follows to activate command data set 2:

1. Set the **myCommand** variable to **CMD_USE_DATA2** in the symbol browser.
2. Start the command with **myCmdExecute** = **TRUE**.

Example: Start the motor at a specified speed

Proceed as follows to get the connected motor to turn at a speed of 500 rpm:

1. Enter the value "500" in the **mySetpoint** variable.
2. Set the **myCommand** variable to **CMD_START** in the symbol browser.
3. Start the command with **myCmdExecute** = **TRUE**.
   The input parameter **myFC_Control_In.setpoint** is set to the speed parameterized in the **mySetpoint** variable accordingly and transferred to the input parameter **setpoint**.
   All enables in control word 1 are set. The motor starts to turn.
   After the speed parameterized in the **mySetpoint** variable is reached, the command is ended with **myCmdDone** = **TRUE**.

Note

When starting the motor with a rising edge on bit 0 in STW 1, bit 8 and bit 9 in STW 1 (jog right/left) must have the signal level **FALSE**.

Assignment of **ctrlDword** (STW 1 and STW 2 of ET 200S FC) when starting the motor:

`CMD_START : // start motor`	16#0000 047F hex or binary: 0000 01**00** 0111 111**1**
`CMD_JOG_RIGHT : // motor jog. Right`	16#0000 057E hex or binary: 0000 010**1** 0111 111**0**
`CMD_JOG_LEFT : // motor jog. Left`	16#0000 067E hex or binary: 0000 01**1**0 0111 111**0**

Example: Stop a running motor

Proceed as follows to stop a running motor:

1. Set the **myCommand** variable to **CMD_STOP** in the symbol browser.
2. Start the command with **myCmdExecute** = **TRUE**.
   Bit 0 in control word 1 (On/Off) is reset. The motor begins to stop.
   After reaching the actual speed < 1 rpm, the command is terminated with **myCmdDone** = **TRUE**.

Note

Bit 0, bit 8, and bit 9 in STW 1 must have the signal level **FALSE** when stopping a motor.

Assignment of **ctrlDword** (STW 1 and STW 2 of ET 200S FC) when stopping the motor:

`CMD_STOP : // stop motor`	16#0000 047E hex or binary: 0000 01**00** 0111 111**0**

8.7.6 Alarm processing

8.7.6.1 Overview

Sequence of the alarm processing

Pending error messages are processed and evaluated differently than in a SIMATIC system. Diagnostic alarms are not enabled by default. Activate the alarms for the relevant module in the hardware configuration (refer to Chapter Inserting the ET 200S frequency converter into a SIMOTION project (Page 6332)).

If you have parameterized diagnostic alarms, then you should program the alarm processing sequence according to the principle presented below.

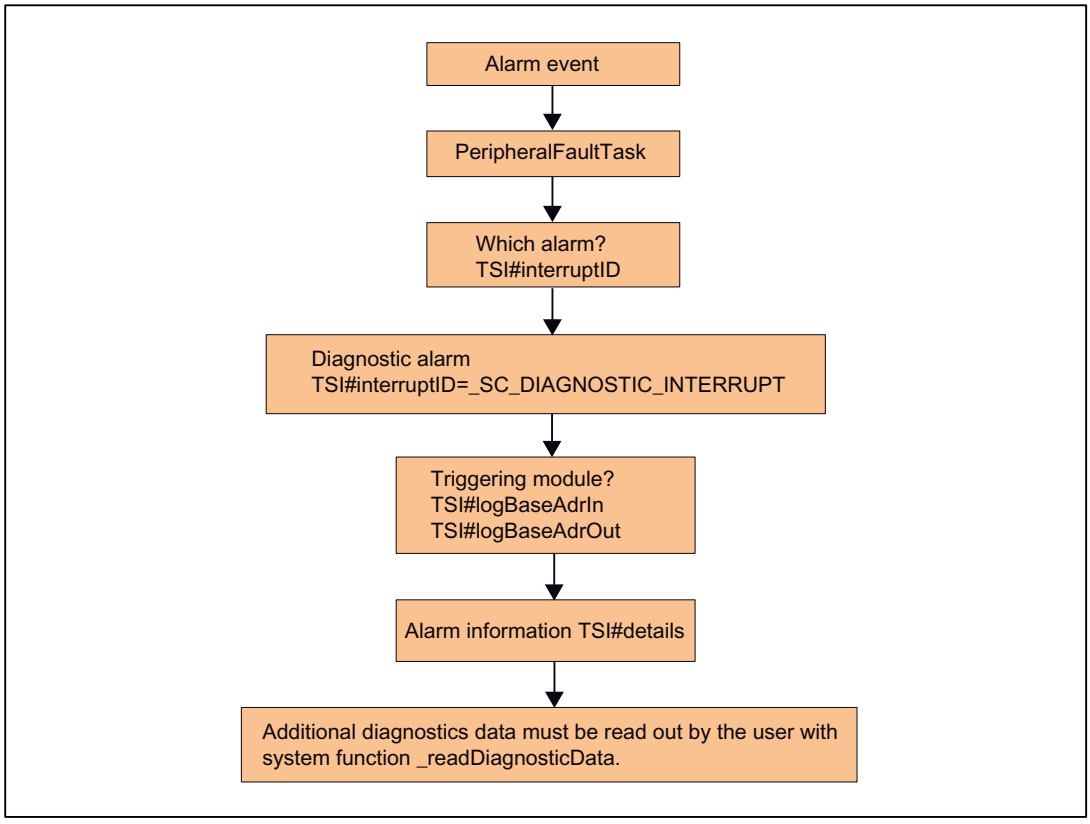

Figure 8-41 Alarm processing for the frequency converter

Additional references

A detailed description of the system functions can be found in the *SIMOTION System Function/ Variable Devices* Parameter Manual. This document is shipped with SIMOTION SCOUT in electronic form.

Detailed information on DP slave diagnostics can be found in the SIMATIC Manual titled *ET 200S Distributed I/O System*.

Alarm evaluation

Alarms sent by the I/O are evaluated in the **PeripheralFaultTask**. When the **PeripheralFaultTask** is started, the **Taskstartinfo** is made available; you must evaluate this in the user program. To do this, assign a program to the **PeripheralFaultTask** in the execution system (see sample program **Unit_E_FC_ctr**).

The **Taskstartinfo** of **PeripheralFaultTask** is comparable to the local data of OB 82 in the SIMATIC system.

Table 8-92 Meaning of the Taskstartinfo

Task	TSI		Meaning
PeripheralFaultTask	DT	TSI#startTime	Start time of the task
	UDINT	TSI#interruptID	Identifies the triggering event: • _SC_PROCESS_INTERRUPT • _SC_DIAGNOSTIC_INTERRUPT • _SC_STATION_DISCONNECTED • _SC_STATION_RECONNECTED
	DINT	TSI#logBaseAdrIn	Logical start address if a hardware interrupt (PRAL) or a diagnostic interrupt (DAL) was caused by an input range on the module, otherwise _SC_INVALID_ADDRESS
	DINT	TSI#logBaseAdrOut	Logical start address if a hardware interrupt (PRAL) or a diagnostic interrupt (DAL) was caused by an output range on the module, otherwise _SC_INVALID_ADDRESS
	DINT	TSI#logDiagAdr	Diagnostic address of a DP slave if the interrupt was caused by a CPU stop or recovery of the associated DP slave, otherwise _SC_INVALID_ADDRESS
	DWORD	TSI#details	Detail information (bit fields)

8.7.6.2 Diagnostic alarms

Diagnostic alarms enable operational messages (hardware faults) of the ET 200S FC to be detected in the SIMOTION device.

Definition of a diagnostic alarm

If the user program is to respond to an internal or external error, you can set the parameters for a diagnostic alarm that will interrupt program execution in the SIMOTION device.

Events that trigger a diagnostic alarm

The criteria (events) for triggering diagnostic alarms in a SIMOTION system correspond to those in a SIMATIC system.

For a more detailed description, refer to the section titled "Diagnostics and monitoring functions" in the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).

Responses to a diagnostic alarm

If a diagnostic alarm is issued, the following occurs:

1. The group error LED (SF) lights up on the ET 200S frequency converter.
2. Diagnostic data is written to the **TSI#details** variable in the Taskstartinfo of **PeripheralFaultTask**. The program assigned to the **PeripheralFaultTask** is executed.

3. The SIMOTION device goes into STOP mode if a program has not been assigned to the **PeripheralFaultTask**.
4. The group error LED (SF) goes out as soon as the error has been remedied.

Bit assignment

The **TS#details** variable is assigned in the same way as in a SIMATIC system.

Note

For a more detailed description, refer to the section titled "Diagnostics and monitoring functions" in the SIMATIC *ET 200S FC Frequency Converter* Operating Instructions (03/2005 Edition).

8.7.7 Appendix

8.7.7.1 SIMOTION and SIMATIC names

The table below contains a comparison of SIMOTION and SIMATIC names.

Name in the SIMOTION system, V4.1 and higher (command library in SCOUT)	**Name in the SIMATIC system**
Function block parameter	
_ET200S_FC_control	**ET200S_FC_DRIV**
execute	REQ
mode	-
periIn	-
setpoint	FREQ_SET
ctrlDword	CTRL
paraNumber	PAR_ADDRESS
subIndex	PAR_INDEX
paraValueWr	WRITE_DATA_VALUE
done	-
busy	BUSY
error	PAR_ERR
errorID	PAR_ERR_NO
driveError	ERR_NO_VALID
driveErrorId	ERR_NO
periOut	-
actValue	FREQ
statusDword	STAT
paraValueRd	READ_DATA_VALUE

8.7.7.2 List of abbreviations

Table 8-93 Abbreviations

Abbreviation	Meaning
DP	Distributed I/O
FB	Function Block
FC	**F**requency **C**onverter
IN	Input parameters
IM	Interface Module
I/O	Input/Output
LAD	Ladder diagram
LED	Light Emitting Diode
OUT	Output parameters
PG/PC	Programming Device / Personal Computer
PIB	Peripheral Input Byte
PM	Power Module
PQB	Peripheral Output Byte
PS	Power Supply
ST	Structured Text
STW	Control word
ZSW	Status word

8.8 Supplement to SIWAREX FTA Weighing Module

Preface

Contents of this Function Manual

This **document** is a component of the **SIMOTION Programming - References** documentation package.

This document is a supplement to the
"SIWAREX FTA Weighing Electronics for Automatic Scale" Manual.

This document is supplied in electronic format with SIMOTION SCOUT.

This manual tells you how you can control and assign parameters for a SIWAREX FTA weighing module from a SIMOTION device using the **_FTA_control** function block.

Function block

The **_FTA_control** function block for communication between the SIMOTION system and the SIWAREX FTA weighing module is a component of the command library of the "SIMOTION SCOUT" engineering system.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION V4.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Additional information

Click the following link to find information on the following topics:

- Ordering documentation / overview of documentation
- Additional links to download documents
- Using documentation online (find and search manuals/information)

http://www.siemens.com/motioncontrol/docu

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

http://www.siemens.com/mdm

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

http://support.automation.siemens.com

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

http://www.siemens.com/automation/service&support

8.8.1 Fundamental safety instructions

8.8.1.1 General safety instructions

⚠ WARNING

Risk of death if the safety instructions and remaining risks are not carefully observed

If the safety instructions and residual risks are not observed in the associated hardware documentation, accidents involving severe injuries or death can occur.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

⚠ WARNING

Danger to life or malfunctions of the machine as a result of incorrect or changed parameterization

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization (parameter assignments) against unauthorized access.
- Respond to possible malfunctions by applying suitable measures (e.g. EMERGENCY STOP or EMERGENCY OFF).

8.8.1.2 Industrial security

Note

Industrial security

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. For more information about industrial security, visit http://www.siemens.com/industrialsecurity.

To stay informed about product updates as they occur, sign up for a product-specific newsletter. For more information, visit http://support.automation.siemens.com

⚠ WARNING

Danger as a result of unsafe operating states resulting from software manipulation

Software manipulation (e.g. by viruses, Trojan horses, malware, worms) can cause unsafe operating states to develop in your installation which can lead to death, severe injuries and/or material damage.

- Keep the software up to date.
  Information and newsletters can be found at:
  http://support.automation.siemens.com
- Incorporate the automation and drive components into a state-of-the-art, integrated industrial security concept for the installation or machine.
  For more detailed information, go to:
  http://www.siemens.com/industrialsecurity
- Make sure that you include all installed products into the integrated industrial security concept.

8.8.2 Description

8.8.2.1 General

Overview

This manual describes the general differences and similarities of the SIWAREX FTA (**F**lexible **T**echnology, **A**utomatic Weighing Instrument) weighing module that result for data transfer and module diagnostics when the module is operated in a SIMOTION system as compared to a SIMATIC system.

The "Weight display with calibration capability" section also describes how the weight display with calibration capability is integrated in SIMOTION.

Note

This manual is a supplement to the *"SIWAREX FTA Electronic Weighing System for Automatic Scale"* Manual.

This document is supplied in electronic format with SIMOTION SCOUT.

Requirements

The following are required for the standard function described in this document:

- SIMOTION SCOUT, V4.1 or higher
- SIMOTION Kernel, V4.1 or higher
- SIWAREX FTA weighing module, firmware version V2.1.8 or higher

To first commission and test the SIWAREX FTA weighing module, you need the "SIWAREX FTA for SIMATIC S7 Configuration Package" CD-ROM. This CD-ROM is **not** supplied with SIMOTION SCOUT.

8.8.2.2 Product description

SIWAREX FTA is a versatile and flexible weighing module.

The primary task of the SIWAREX FTA weighing module consists of high-precision measurement of actual weight with up to three measurement ranges and precise control of weighing operations.

The SIWAREX FTA weighing module can be assigned parameters for the following operating modes:

- **N**on **A**utomatic **W**eighing **I**nstrument = NAWI
- **A**utomatic **W**eighing **I**nstrument = AWI
  - For gravimetric filling
  - For catch-weighing
  - For totalizing

Function block

The **_FTA_control** function block is provided for communication between the SIMOTION device and the SIWAREX FTA weighing module. This function block is described in this manual.

Functionality

The **_FTA_control** function block reads/writes cyclic data from/to the SIWAREX FTA weighing module. Data are also transferred acyclically from/to the weighing module upon request.

The functionality of the **_FTA_control** function block and the SIWAREX FTA weighing module is the same as when used in a SIMATIC S7 automation system. However, the execution of data transmission and the handling of the FB have been adapted to the given general SIMOTION conditions.

Possible applications

In addition to the possible applications described in the SIMATIC manuals, you can also use the SIWAREX FTA weighing module in a SIMOTION system. The SIWAREX FTA weighing module can be used for centralized applications (only on the SIMOTION C2xx) or distributed applications (SIMOTION C2xx, SIMOTION P350, and SIMOTION D4xx).

The following figure illustrates the connection of a distributed ET 200M I/O device with IM 153-1 and SIWAREX FTA to a SIMOTION device (e.g., C2xx).

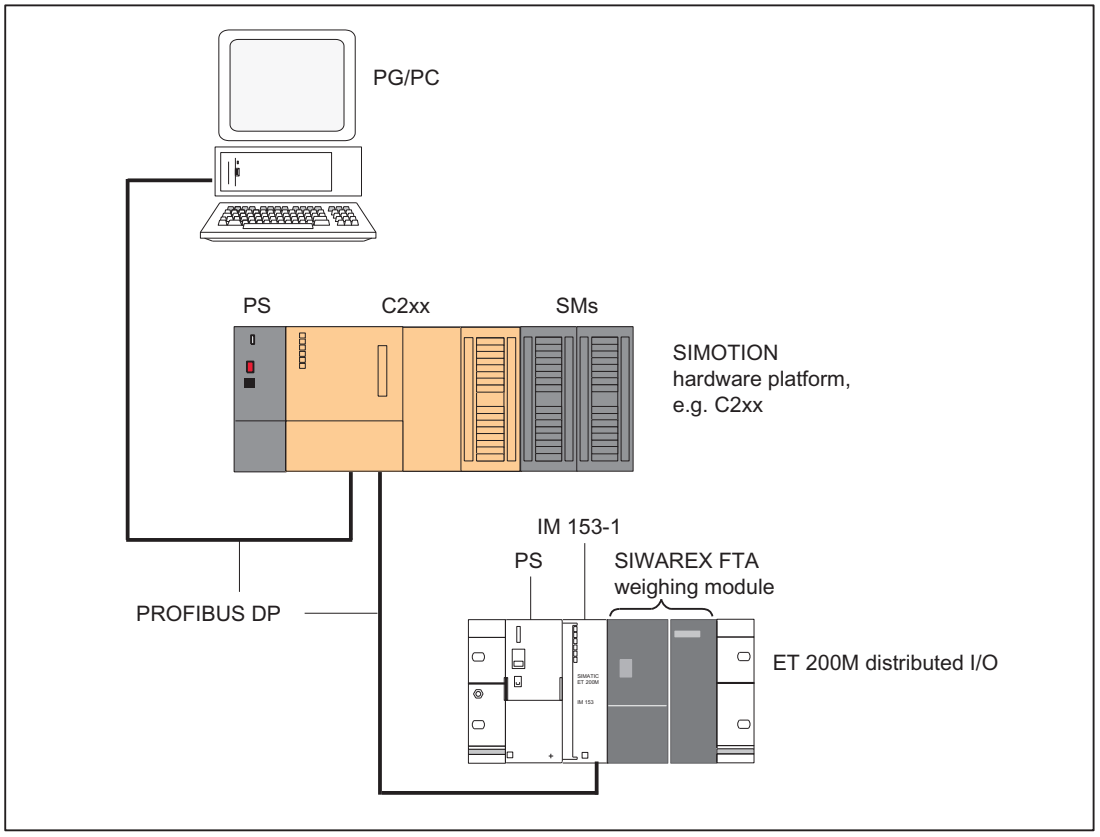

Figure 8-42 Connection of weighing module with an ET 200M to a SIMOTION C2xx device (example of distributed application)

8.8.2.3 Setup and connection

Overview

You must perform the following steps to commission the SIWAREX FTA weighing module and control it from the SIMOTION system.

Distributed application (SIMOTION C2xx, SIMOTION P350, and SIMOTION D4xx)

1. Assembly and wiring of ET 200M distributed I/O device with power supply (PS), interface module (IM), and weighing module.
2. Establish the PROFIBUS connection between the ET 200 M and the SIMOTION device.
3. Set the PROFIBUS DP node address on the IM.
4. Switch on the terminating resistor at the first and last bus node.
5. Insert the weigh beam in the SIMOTION project, see section Integrating the weighing module in a SIMOTION project (Page 6359).
6. Assign parameters to the weighing module using the SIWATOOL FTA program.
   Consult the *SIWAREX FTA Electronic Weighing System for Automatic Scale* Manual to learn how to install the SIWATOOL FTA parameterization tool and assign parameters to the weighing module.
7. Integrate the function block in the SIMOTION project, see section Integrating the function block in the user project (Page 6361).

Centralized application (SIMOTION C2xx only)

1. To learn how to configure the mechanical design and prepare and install the SIMOTION components, refer to *SIMOTION C* Operating Instructions and *SIMATIC Automation System S7-300, Software Installation* Manual .
   These documents are shipped with SIMOTION SCOUT in electronic form.
2. For the remaining steps, refer to steps 5 to 7 of the distributed application.

8.8.2.4 Integrating the weighing module in a SIMOTION project

Requirements

You have run the Hardware Support Package for installing the weighing module in the hardware catalog of SIMATIC Manager.

Note

This Hardware Support Package is included on the "SIWAREX FTA configuration package for SIMATIC S7" CD-ROM, which you need to configure the weighing module. This CD-ROM is **not** supplied with the SIWAREX FTA and must be ordered separately.

The following requirements must be met when networking with PROFIBUS:

1. You have created a project in SIMOTION SCOUT and inserted a rack with a SIMOTION device in the hardware configuration.
2. You have configured a PROFIBUS subnet (for distributed use only).

Note

For how to create a project and configure a PROFIBUS subnet, refer to the online help of *SIMOTION SCOUT*.

The following requirements must be met when with PROFINET:

1. You have created a project in SIMOTION SCOUT and inserted and configured a rack with a SIMOTION device capable of PROFINET in the hardware configuration.
2. You have configured a PROFINET IO System (for distributed use only).

Note

For how to create a project and configure a PROFINET IO system, refer to the online help of *SIMOTION SCOUT*.

Inserting the weighing module (distributed application)

The description below is an example of networking via PROFIBUS.

1. In SIMOTION SCOUT, open the **User Projects** dialog box with the **Project > Open** menu command. In this dialog box, select your project and confirm your choice with **OK**.
2. Open **HW Config**.
3. In the **HW Config** window, use the **View > Catalog** menu command to open the **Hardware Catalog**.
4. In the hardware catalog, open the **PROFIBUS DP** folder and the **ET 200M** subfolder and select, for example, the **IM 153-1 interface module** (Article No.: 6ES7 153-1AA03-0XB0 or a successor module).
5. Use a drag-and-drop operation to move the IM 153-1 I/O device to the PROFIBUS subnet of your project.
   The **Properties - PROFIBUS IM 153-1 Interface** dialog box opens. In this dialog box, select the address you set on the IM 153-1 (see *Distributed I/O Device ET 200M* Manual) and confirm your selection with **OK**.
   The selected IM 153-1 I/O device is inserted in the project.
6. The inserted I/O device must now be fitted with the module from your project. To do so, open the **Weighing Modules** subfolder under the selected I/O device in the hardware catalog, and select **SIWAREX FTA**.

Note

By default, the diagnostic alarms and process alarms are not enabled. Enable the alarms for the weighing module in the **Properties** dialog box.

7. **Save** and **compile** your project.

Inserting the weighing module (centralized application)

1. In SIMOTION SCOUT, open the **User Projects** dialog box with the **Project > Open** menu command. In this dialog box, select your project and confirm your choice with **OK**.
2. Open **HW Config**.
3. In the **HW Config** window, use the **View > Catalog** menu command to open the **Hardware Catalog**.
4. In the hardware catalog, open the **SIMATIC 300 > FM 300** folder followed by the **Weighing Modules** subfolder and select **SIWAREX FTA**.
5. Use a drag-and-drop operation to place the SIWAREX FTA weighing module into the SIMOTION device's rack.

   Note

   By default, the diagnostic alarms and process alarms are not enabled. Enable the alarms for the weighing module in the **Properties** dialog box.

6. **Save** and **compile** your project.

8.8.3 Programming

8.8.3.1 Integrating the function block in the user project

Creating the FB instance in the user project

The **_FTA_control** function block is a component of the command library of the SIMOTION SCOUT engineering system. In order to work with the block, you must create an instance of the function block and a **struct_FTA_scaleData** type variable in the user project.

Example:

```
VAR_GLOBAL
  myFTA_control  : _FTA_control;           // create instance of FB _FTA_control
  myScaleData    : struct_FTA_scaleData;   // structure with all scale data
END_VAR
```

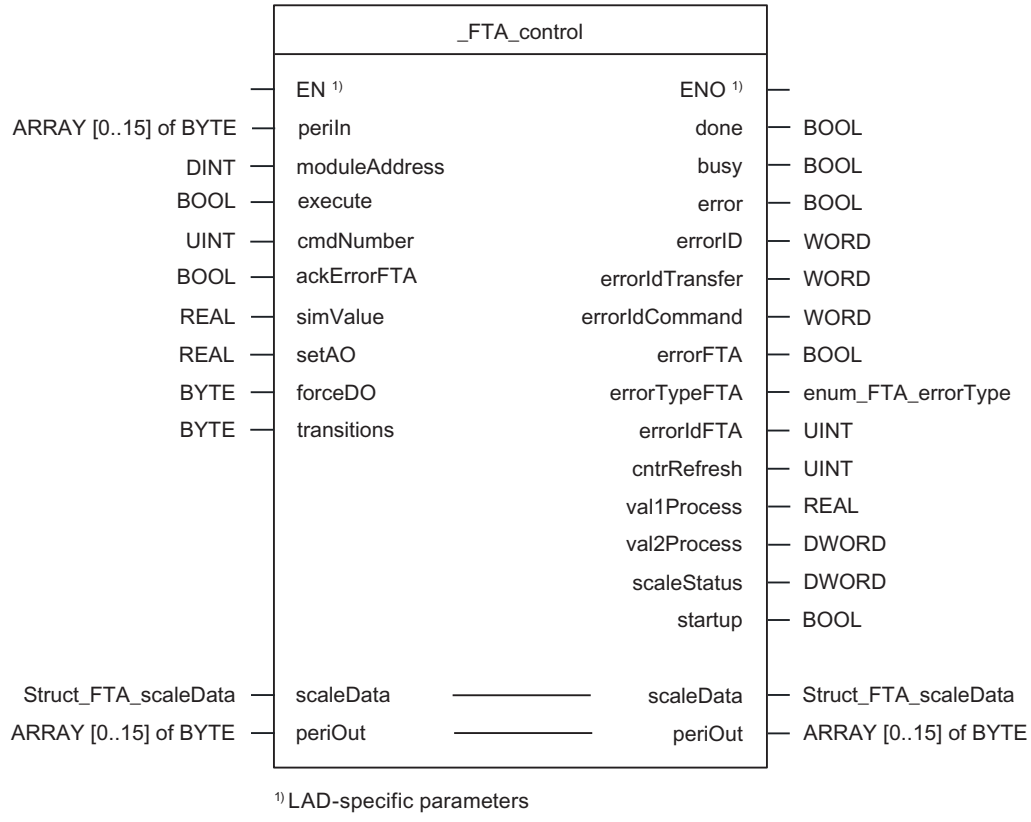
Note

If you want to control more than one weighing module, you must create

- a new variable for the data structure and
- an instance of the function block with a new name

in the user program for each weighing module used.

Call (LAD representation)



Application example

The application example is included on the "SIMOTION Utilities & Applications" CD-ROM and is available for various SIMOTION hardware platforms.

The "SIMOTION Utilities & Applications" CD-ROM is provided free of charge and part of the SIMOTION SCOUT scope of delivery.

8.8.3.2 Addressing the SIWAREX FTA weighing module

Overview

Communication between the SIMOTION device and the SIWAREX FTA weighing module takes place by means of direct I/O access and data record transfer.

Creating I/O variables

For cyclic data transfer, you must create one I/O variable for the I/O inputs and one I/O variable for the I/O outputs in the symbol browser. This I/O variable must have the address of the weighing module of data type BYTE and a field length of 16.

When creating the I/O variable, enter the configured address from the hardware configuration in the "I/O address" parameter (see example below).

Example

Determining addresses from **HW Config**:

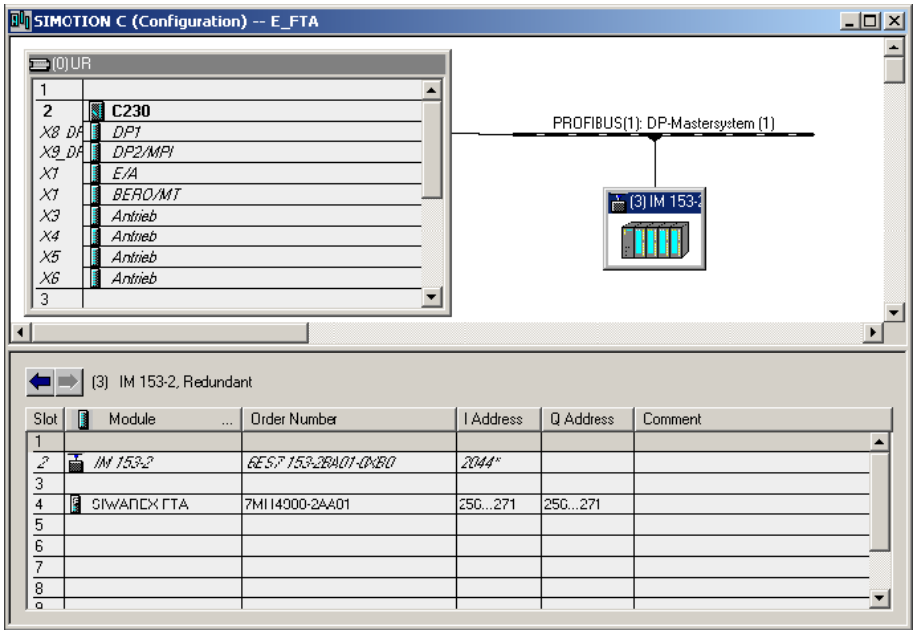


Figure 8-43 Addresses in HW Config

Creating the I/O variables in the symbol browser:

	Name	I/O address	Read only	Data type	Field length
1	myperiin	PIB 256		Array	16
2	myperiout	PQB 256		Array	16

Figure 8-44 Addressing with I/O variables

Parameter transfer

The I/O variable for the I/O inputs is transferred to the **periIn** input parameter.

The prepared data for the I/O outputs are supplied by the function block at the **periOut** output parameter. These data are assigned to the I/O variable for the I/O outputs.

Note

For additional information, refer to:

- SIMOTION SCOUT online help
- Programming Manuals for the relevant programming language, such as:
  - SIMOTION ST, Structured Text Programming Manual
  - SIMOTION MCC, Motion Control Chart Programming Manual
  - SIMOTION LAD/FBD, Ladder Diagram and Function Block Diagram Programming Manual

These documents are shipped with SIMOTION SCOUT in electronic form.

8.8.4 Parameter assignment

8.8.4.1 _FTA_control function block

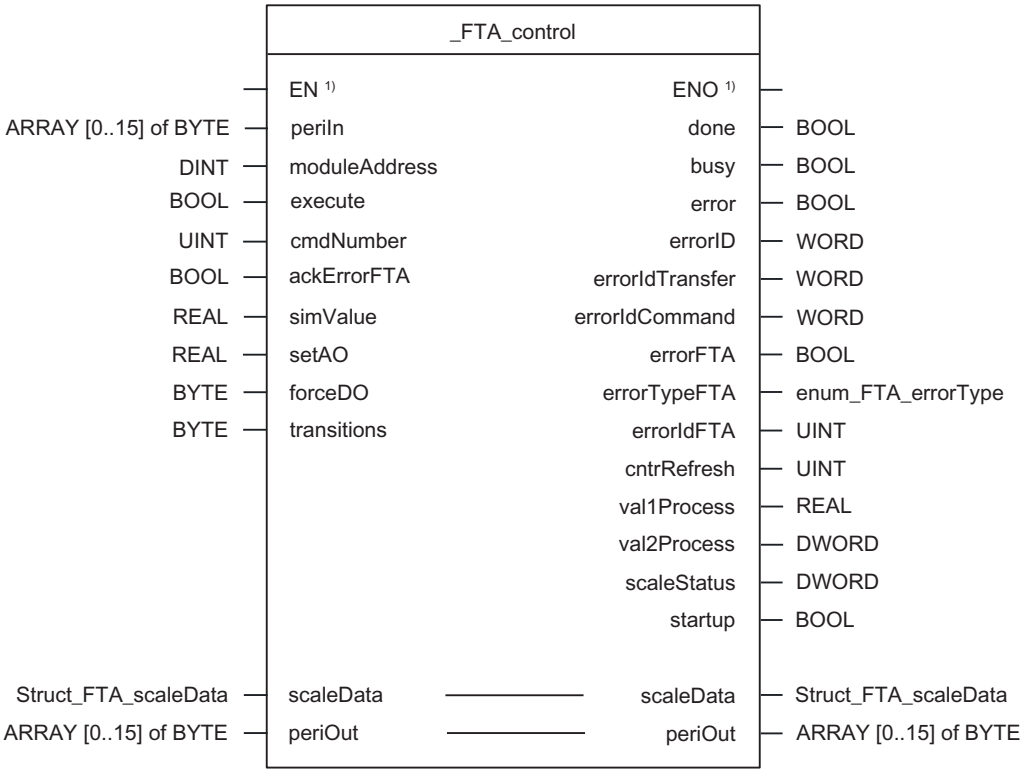
Task

The **_FTA_control** function block (FB) enables you to control the SIWAREX FTA weighing module in the SIMOTION automation system.

The **_FTA_control** FB writes process data cyclically to the weighing module and reads the status of the weighing module cyclically. The status is made available at the output parameters of the FB.

On request, the FB writes scale data to the weighing module and reads scale data and process status from the weighing module. The scale data and process status are stored by the function block in the **Struct_FTA_scaleData** data structure and read by the function block from this data structure.

Call (LAD representation)



Parameter description

The table below contains all parameters of the function block **_FTA_control**.

Table 8-94 Parameters of the _FTA_control function block

Name	Type[1)]	Data type	Default	Definition
periIn	IN	ARRAY [0 to 15] of BYTE	16 (16#00)	Transfers I/O inputs to **_FTA_control** function block
moduleAddress	IN	DINT	0	Module address from **HW Config**
execute	IN	BOOL	FALSE	Rising edge: the command entered in **cmdNumber** is executed.
cmdNumber	IN	UINT	0	Provides the command number The command is started using the **execute** parameter.
ackErrorFTA	IN	BOOL	FALSE	**TRUE** = acknowledgment of error of SIWAREX FTA weighing module waiting to be dealt with
simValue	IN	REAL	0.0	Value for weight simulation when simulation is enabled; selection is made in DR7
setAO	IN	REAL	0.0	Value specification for analog output of weighing module with master control of higher-level control; selection is made in DR7

Name	Type[1)]	Data type	Default	Definition
forceDO	IN	BYTE	16#00	Specifies digital outputs of weighing module with parameterized forced control; selection is made in DR7
transitions	IN	BYTE	16#00	Disables and enables weighing steps The bit numbers in the **transitions** byte correspond to the numbers of the weighing steps. Bit = **FALSE**: weighing step is executed Bit = **TRUE**: weighing step is not executed, and the system waits for the bit to be reset
scaleData	IN/OUT	**Struct_FTA_scaleData**		Data structure for the parameters of the SIWAREX FTA weighing module
periOut	IN/OUT	ARRAY [0 to 15] of BYTE	16 (16#00)	Prepared FB data for I/O outputs of SIWAREX FTA weighing module
done	OUT	BOOL	FALSE	**TRUE** = command execution completed without errors
busy	OUT	BOOL	FALSE	**TRUE** = command in progress
error	OUT	BOOL	FALSE	**TRUE** = **_FTA_control** FB has detected an error; error specified in **errorID**.
errorID	OUT	WORD	16#0000	Error specification For **error** = **TRUE**, the **errorID** output parameter contains the error information, see "Error messages"
errorIdTransfer	OUT	WORD	16#0000	Error specification for faults during data transfer with system functions **_writeRecord** / **_readRecord** [2)]
errorIdCommand	OUT	WORD	16#0000	Error number of data or operation error that has occurred. For a description of errors, see the SIWAREX FTA Manual *Electronic Weighing System for Automatic Scale*
errorFTA	OUT	BOOL	FALSE	**TRUE** = new error message in message buffer of SIWAREX FTA weighing module, error specification in **errorTypeFTA**
errorTypeFTA	OUT	Enum_FTA_ errorType (OP_ERROR, TECHNO_ERROR, DATA_ERROR)	0	Error specification When **errorFTA** = **TRUE**, parameter **errorTypeFTA** contains the error information type: • OP_ERROR: Operating message (error) • TECHNO_ERROR: technological error • DATA_ERROR: data or operation error
errorIdFTA	OUT	UINT	0	Message number, for a description of the signal, see the SIWAREX FTA Manual *Electronic Weighing System for Automatic Scale*

Name	Type[1)]	Data type	Default	Definition
cntrRefresh	OUT	UINT	0	Outputs the update number for the values in output parameters **val1Process** / **val2Process**. The SIWAREX FTA weighing module updates the values for the **val1Process** / **val2Process** parameters internally in a 10 ms cycle. Each time the values are updated, the weighing module increments the value for the **cntrRefresh** parameter. The **_FTA_control** function block reads the values in cycles from the weighing module in the time scale of the calling task (e.g. BackgroundTask) and updates the values in the output parameters **cntrRefresh**, **val1Process** / **val2Process**. The value in **cntrRefresh** can be used like a time stamp in the SIMOTION device.
val1Process	OUT	REAL	0.0	Outputs the selected process parameter (e.g. net weight); selection is made in DR7
val2Process	OUT	DWORD	16#00000000	Outputs the selected process parameter (e.g. AWI status); selection is made in DR7
scaleStatus	OUT	DWORD	16#00000000	Outputs the status of the non-automatic scale
startup	OUT	BOOL	FALSE	**TRUE** = restart of the SIWAREX FTA weighing module Communication and command execution are not possible

1) Parameter types: IN = input parameter, IN/OUT = in/out parameter, OUT = output parameter

2) Description of system functions **_writeRecord** and **_readRecord** see Parameter Manual *SIMOTION system functions/ variables for devices*. This documentation is included in the SIMOTION SCOUT scope of supply as electronic documentation!

Function description

When the **_FTA_control** FB is called, the cyclic data of the FB are read and written.

Command execution is started on a rising edge on input parameter **execute**. The command is selected by specifying the command number in input parameter **cmdNumber**. For the command groups with numbers 203 - 699, one or more data records (DR) are transferred to or read by the SIWAREX FTA weighing module. When a command is started, the output parameters **busy** = **TRUE** and **done** = **FALSE** are set. Output parameters **error**, **errorID**, **errorIdCommand**, and **errrorIdTransfer** are reset. When the command has been executed without errors, the following parameters are displayed: **busy** = **FALSE**, **done** = **TRUE**, and **error** = **FALSE**.

If an error occurs during command execution, the following output parameters are set **busy** = **FALSE**, **done** = **FALSE**, and **error** = **TRUE**. The error is specified in output parameters **errorID**, **errorIdTransfer**, and **errorIdCommand**.

A new command can only be started once execution of the commands is complete (**busy** = **FALSE**). If a new command is started while commands are being executed (**busy** = **TRUE**), the new command is ignored.

Note

You can find an overview of the command groups and commands in the appendix.

If the SIWAREX FTA weighing module generates a new error message, the following output parameter is set: **errorFTA** = **TRUE**. The error message is specified in output parameters **errorTypeFTA** and **errorIdFTA**. After the error message has been evaluated, it must be acknowledged with a rising edge on input parameter **ackErrorFTA** . The output parameters **errorFTA**, **errorTypeFTA** and **errorIdFTA** are reset by the **_FTA_control** function block in the process.

Graphic overview of the functionality

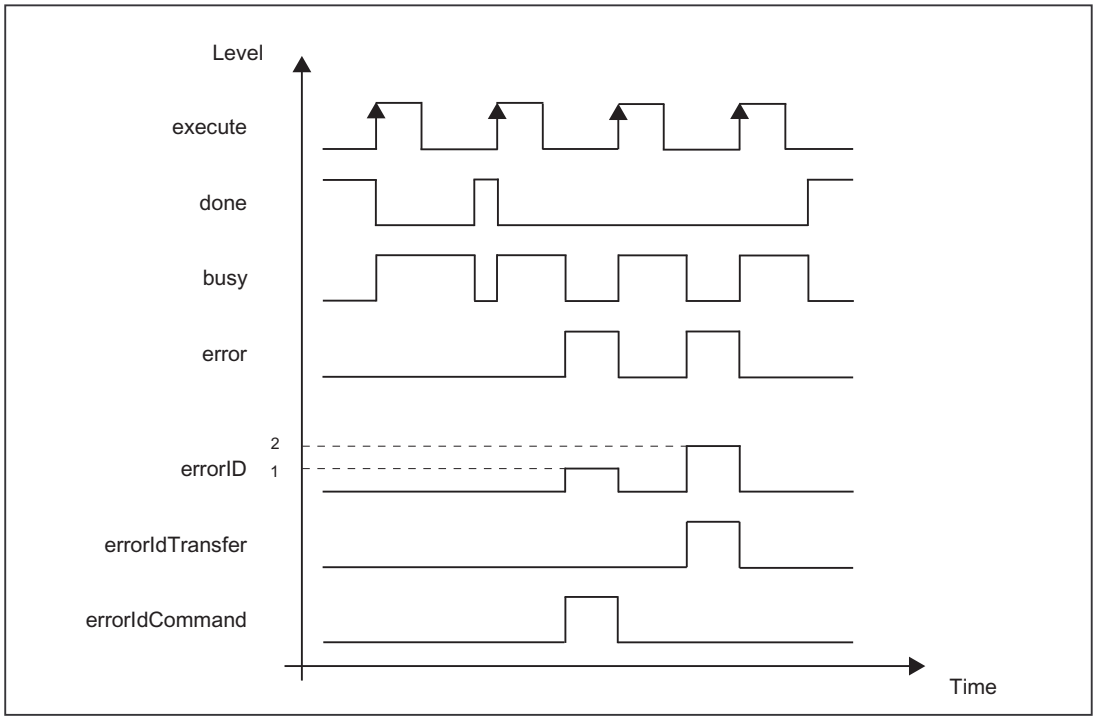


Figure 8-45 Command execution signal sequence diagram

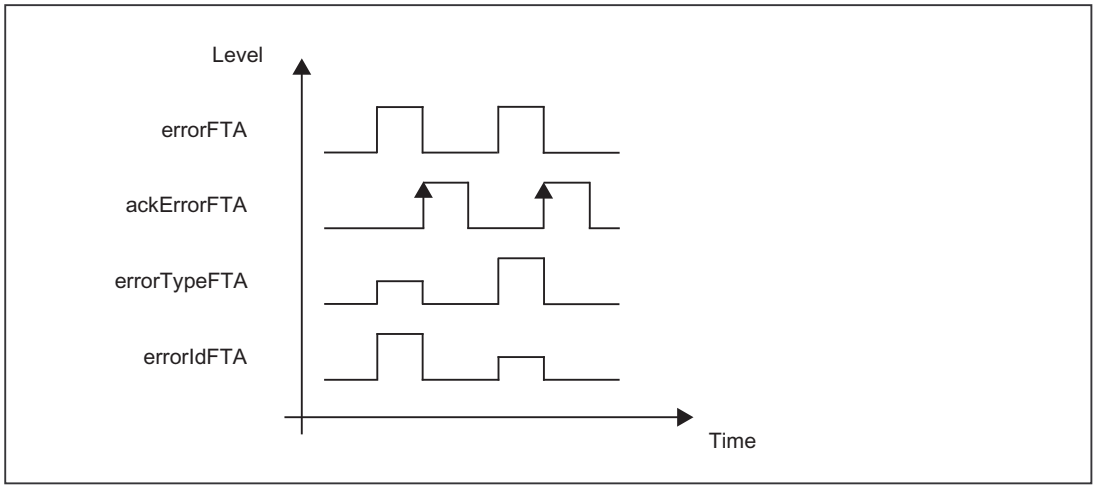

Figure 8-46 Messages signal sequence diagram

Task integration (call)

The **_FTA_control** function block is designed to be called in a cyclic task and must be called in this task during each task cycle. It may take several cycles for a task to be executed. The user decides which cyclic task of the **_FTA_control** function block the call is made in. No limitations are placed on the functionality of the **_FTA_control** function block. The call can be performed in all cyclic tasks. A fixed time scale (e.g. **IPOSynchronousTask**) is not required for the processing.

Error messages

When an error occurs, an error specification is displayed in output parameter **errorID**. If an error has not occurred, **errorID** has the value "16#0000". The **errorID** output parameter remains present until the error is corrected.

The **errorID** output parameter is reset with a rising edge on input parameter **execute**.

Table 8-95 Error numbers in output parameter errorID

Error no. errorID	Definition
Bit 0	Command terminated with error; data or operation error has occurred For error specification, see output parameter **errorIdCommand**
Bit 1	Error has occurred during call of system functions **_writeRecord** / **_readRecord** [1)] For error specification, see output parameter **errorIdTransfer**
Bit 2	Error during data record/command interpretation The specified data record or command number is incorrect.
Bit 3	Life bit error, SIWAREX FTA is not responding
Bit 4	I/O data could not be read out in this cycle
Bit 5	Active command aborted during restart of SIWAREX FTA weighing module
Bit 6	Reserve (use not permitted)
Bit 7	Reserve (use not permitted)
Bit 8	Reserve (use not permitted)
Bit 9	Reserve (use not permitted)
Bit 10	Reserve (use not permitted)
Bit 11	Reserve (use not permitted)
Bit 12	Reserve (use not permitted)
Bit 13	Reserve (use not permitted)
Bit 14	Reserve (use not permitted)
Bit 15	Reserve (use not permitted)

1) Description of system functions **_writeRecord** and **_readRecord** see Parameter Manual *SIMOTION system functions/variables for devices*. This documentation is included in the SIMOTION SCOUT scope of supply as electronic documentation!

When communication errors and command-execution faults occur, an error number is output in output parameters **errorIdTransfer** and **errorIdCommand**. Refer to the *SIWAREX FTA Electronic Weighing System for Automatic Scale* Manual for the meaning of the error numbers.

8.8.4.2 Data structures

Overview of data structures

Overview

The data structure of type **Struct_FTA_scaleData** contains all relevant data for operating the SIWAREX FTA weighing module. This data structure is used by the **_FTA_control** function block. The elements of the data structure are accessed by means of a user-defined variable of data type **Struct_FTA_scaleData** (see example below):

```
VAR
    myScaleData : Struct_FTA_scaleData;   // data structure with all scale data
END_VAR

PROGRAM
//...
    myScaleData.DR3.filtSequence := 1;   // write one element in DR3
//...
END_PROGRAM
```

Data records of the data structure

The table below contains all data records (DR) of the **Struct_FTA_scaleData** data structure which can be read and written by the SIMOTION device and the winccOcxWrite variable for the data transfer of the weight display with calibration capability.

Table 8-96 Data structure Struct_FTA_scaleData

Name	Data type	Definition
DR3	**Struct_FTA_DR3**	Data structure for DR3: Calibration parameter
DR4	**Struct_FTA_DR4**	Data structure for DR4: Basic parameter
DR7	**Struct_FTA_DR7**	Data structure for DR7: Interfaces
DR8	**Struct_FTA_DR8**	Data structure for DR8: Date/time
DR9	**Struct_FTA_DR9**	Data structure for DR9: information about the weighing module
DR15	**Struct_FTA_DR15**	Data structure for DR15: Tare input
DR16	**Struct_FTA_DR16**	Data structure for DR16: Weight simulation input
DR17	**Struct_FTA_DR17**	Data structure for DR17: Analog output control
DR18	**Struct_FTA_DR18**	Data structure for DR18: Remote display control
DR20	**Struct_FTA_DR20**	Data structure for DR20: Setpoint weight
DR21	**Struct_FTA_DR21**	Data structure for DR21: Load weight
DR22	**Struct_FTA_DR22**	Data structure for DR22: Weighing parameter 1
DR23	**Struct_FTA_DR23**	Data structure for DR23: Weighing parameter 2
DR26	**Struct_FTA_DR26**	Data structure for DR26: Internal process values 1

Name	Data type	Definition
DR30	**Struct_FTA_DR30**	Data structure for DR30: Process values 1
DR31	**Struct_FTA_DR31**	Data structure for DR31: Process values 2
DR32	**Struct_FTA_DR32**	Data structure for DR32: Statistical data
DR34	**Struct_FTA_DR34**	Data structure for DR34: ASCII weight value
DR35	**Struct_FTA_DR35**	Data structure for DR35: Value for display with calibration capability is encrypted
DR39	**Struct_FTA_DR39**	Data structure for DR39: Version ID of "SecureOCX" weight display with calibration capability
DR44	**Struct_FTA_DR44**	Data structure for DR44: Last log
DR45	**Struct_FTA_DR45**	Data structure for DR45: Variable for log
DR46	**Struct_FTA_DR46**	Data structure for DR46: Parameter for readout of logs stored on the micro memory card of the weighing module
DR47	**Struct_FTA_DR47**	Data structure for DR47: Log requested via DR46
DR123	**Struct_FTA_DR123**	Data structure for DR123: DR123 can be read out with the SIWATOOL FTA to determine which data are stored on the micro memory card. Based on this information, the user can read out specific recordings and logs.
winccOcxWrite	**DWORD**	Variable for the data transfer between the "SecureOCX" weight display with calibration capability and the SIWAREX FTA weighing module, see section Weight display with calibration capability (Page 6400).

The data records listed in the table are defined in greater detail below.

Struct_FTA_DR3

Description

Data structure **Struct_FTA_DR3** contains the calibration parameter of the SIWAREX FTA weighing module.

To learn how to perform the calibration, refer to the *"SIWAREX FTA Weighing Electronics for Automatic Scale"* Manual.

Parameters

The table below contains all parameters of the data structure **Struct_FTA_DR3**.

Table 8-97 Struct_FTA_DR3

Name	Data type	Default	Definition
Calibration			
calibDigits0	DINT	1.398.101	Calibration digits for the zero point
calibDigits1	DINT	15.379.113	Calibration digits for calibration weight 1
calibDigits2	DINT	0	Calibration digits for calibration weight 2
calibDigits3	DINT	0	Calibration digits for calibration weight 3
calibDigits4	DINT	0	Calibration digits for calibration weight 4

Name	Data type	Default	Definition
calibWeight1	REAL	100.0	Calibration weight 1
calibWeight2	REAL	0.0	Calibration weight 2
calibWeight3	REAL	0.0	Calibration weight 3
calibWeight4	REAL	0.0	Calibration weight 4
sigRange	BYTE	16#02	Characteristic value range 16#01 = characteristic value to 1 mV/V 16#02 = characteristic value to 2 mV/V 16#04 = characteristic value to 4 mV/V
Filter			
filtSequence	BYTE	16#00	Signal filter sequence The 8 bits in this byte have the following meaning: Bit 0 = 0: Averaging filter before digital filter Bit 0 = 1: Digital filter before averaging filter Bit 1-7: Not assigned
filtType	BYTE	16#00	Low-pass filter type 16#00 = critically damped 16#01 = Bessel filter 16#02 = Butterworth filter Other definitions not permitted.
filtCutOffFreq	USINT	16#04	Filter limit frequency (Hz) Specifies the response time of the scale to a measured value change 16#00 = no filter 16#01 = 20 Hz 16#02 = 10 Hz 16#03 = 5 Hz 16#04 = 2 Hz 16#05 = 1 Hz 16#06 = 0.5 Hz 16#07 = 0.2 Hz 16#08 = 0.1 Hz 16#09 = 0.05 Hz Other definitions not permitted.
filtDepth	INT	10	Depth of averaging filter Number of values for averaging [0 to 250] x 2.5 ms 0 = averaging filter deactivated
Calibration parameter 1			
scaleId	STRING[10]	'SIWAREX xx'	Scale name
numRanges	USINT	1	Number of scale ranges 1 = 1 range 2 = 2 ranges 3 = 3 ranges Other definitions not permitted.
scaleType	BOOL	FALSE	Scale type **FALSE** = multi-range scale **TRUE** = multi-resolution scale
setZeroPwrOn	BOOL	FALSE	**TRUE** = zero setting activated upon weighing module startup (power ON)

Name	Data type	Default	Definition
setZeroTare	BOOL	FALSE	**TRUE** = zero setting activated upon weighing module startup (power ON) and tare <> 0
setZeroAutomatic	BOOL	FALSE	**TRUE** = automatic zero correction switched on
setTareType	BOOL	FALSE	Tare selection **FALSE** = use subtractive tare equipment **TRUE** = use additive tare equipment
Calibration parameter 2			
minWeightRange1	REAL	1	Minimum weight for weighing range 1
maxWeightRange1	REAL	100.0	Maximum weight for weighing range 1
incRange1	REAL	0.02	Numerical increment for weighing range 1 Numerical increment for weighing range 1 ($1*10^k$, $2*10^k$, $5*10^k$, $-4 \leq k \leq 1$)
minWeightRange2	REAL	0.0	Minimum weight for weighing range 2
maxWeightRange2	REAL	0.0	Maximum weight for weighing range 2
incRange2	REAL	0.0	Numerical increment for weighing range 2 Numerical increment for weighing range 2 ($1*10^k$, $2*10^k$, $5*10^k$, $-4 \leq k \leq 1$)
minWeightRange3	REAL	0.0	Minimum weight for weighing range 3
maxWeightRange3	REAL	0.0	Maximum weight for weighing range 3
incRange3	REAL	0.0	Numerical increment for weighing range 3 Numerical increment for weighing range 3 ($1*10^k$, $2*10^k$, $5*10^k$, $-4 \leq k \leq 1$)
Calibration parameter 3			
standStillTime1	TIME	T#1s	Downtime If the fluctuation range of the weight during the downtime is less than the fluctuation range defined in the **standStillWeight1**parameter, the scale standstill signal is set to **TRUE**.
standStillWeight1	REAL	0.02	Fluctuation range of the weight for detection/generation of the scale standstill signal
timeOutStandStill1	TIME	T#2s	Maximum wait time for scale standstill If a scale standstill is not detected within this time, a technology message (output parameter **errorFTA**, **errorTypeFTA**, **errorIdFTA**) is output.
maxPosWeightPwrOn	BYTE	16#0A	Maximum positive weight in [% of WBmax] for zero setting after Power On, 16#0A ≙ 10 %
minNegWeightPwrOn	BYTE	16#0A	Maximum negative weight in [% of WBmax] for zero setting after Power On, 16#0A ≙ 10 %
maxPosWeightZero	BYTE	16#01	Maximum positive weight in [% of WBmax] for zero setting, 16#01 ≙ 1 %
minNegWeightZero	BYTE	16#03	Maximum negative weight in [% of WBmax] for zero setting, 16#03 ≙ 3 %
maxTare	BYTE	16#64	Maximum tare load in [% of WBmax] with respect to the maximum weighing range, 16#64 ≙ 100 %
setLCType	BYTE	16#00	Selection of load cell type

Name	Data type	Default	Definition
timeOutDigLC	INT	80	Monitoring time in [ms] for digital load cell If a weight message frame is not received within the monitoring time, the SIWAREX FTA weighing module generates an operating error.
setRestriction	STRING[4]	'----'	The entry 'OIML' activates restrictions/regulations for scales that require official calibration
weightUnit	STRING[4]	'kg--'	Unit of mass (for example, t, kg, g)
Calibration parameter 4			
standStillTime2	TIME	T#1s	Downtime If the fluctuation range of the weight during the downtime is less than the fluctuation range defined in the **standStillWeight2**parameter, the scale standstill signal is set to **TRUE**.
standStillWeight2	REAL	0.02	Fluctuation range of the weight for detection/generation of the scale standstill signal
timeOutStandStill2	TIME	T#500ms	Maximum wait time for scale standstill If a scale standstill is not detected within this time, a technology message (output parameter **errorFTA**, **errorTypeFTA**, **errorIdFTA**) is output.
standStillWeight3	REAL	0.02	Fluctuation range of the weight for detection/generation of the scale standstill signal
standStillTime3	TIME	T#1s	Downtime If the fluctuation range of the weight during the downtime is less than the fluctuation range defined in the **standStillWeight3**parameter, the scale standstill signal is set to **TRUE**.
timeOutStandStill3	TIME	T#500ms	Maximum wait time for scale standstill If a scale standstill is not detected within this time, a technology message (output parameter **errorFTA**, **errorTypeFTA**, **errorIdFTA**) is output.
minDosingValTot	REAL	100	Smallest set weight for weight totalizing
incTotalizing	REAL	0.1	Scale interval for weight totalizing
xxxReserve0	Real	0.0	Reserve (use not permitted)
xxxReserve1	Byte	16#00	Reserve (use not permitted)
xxxReserve2	Byte	16#00	Reserve (use not permitted)

Struct_FTA_DR4

Overview

Data structure **Struct_FTA_DR4** contains the basic parameters of the SIWAREX FTA weighing module. These basic parameters determine additional characteristics that are responsible for scale performance.

Parameter description

The table below contains all parameters of the data structure **Struct_FTA_DR4**.

Table 8-98 Struct_FTA_DR4

Name	Data type	Default	Definition
Operating mode / logs			
scaleMode	BYTE	16#03	Scale mode, selection of weighing program 16#00 = weighing (additive) 16#01 = weighing (subtractive) 16#02 = dosing (additive), subsequent emptying 16#03 = dosing (additive), without subsequent emptying 16#04 = dosing (subtractive), without subsequent emptying 16#05 = check 16#06 = dosing (tare reweighing), cumulating 16#07 = dosing (additive)/(big bag) 16#08 = dosing (subtractive)/(big bag) 16#09 = dosing (subtractive), subsequent emptying Other definitions not permitted.
xxxReserve0	BYTE	16#00	Reserve (use not permitted)
xxxReserve1	WORD	16#0000	Reserve (use not permitted)
timeOutLogOutput	TIME	T#2s	Monitoring time in [ms] for output of log data to a connected printer.
selectLogOutput	BYTE	16#01	Selection of device for log output Bit 0 = 0: Log output to RS232 interface Bit 0 = 1: Log output to micro memory card (MMC)
xxxReserve2	BYTE	16#00	Reserve (use not permitted)
Limit values			
baseWeightLimit1	BOOL	FALSE	Base weight for limit value 1 **TRUE** = basis for limit value 1 is gross weight of scale **FALSE** = basis for limit value 1 is net weight of scale
baseWeightLimit2	BOOL	FALSE	Base weight for limit value 2 **TRUE** = basis for limit value 2 is gross weight of scale **FALSE** = basis for limit value 2 is net weight of scale
xxxReserve3	BOOL	FALSE	Reserve (use not permitted)
baseEmptyRange	BOOL	FALSE	Base weight for empty range monitoring **FALSE** = basis for empty range is gross weight of scale **TRUE** = basis for empty range is net weight of scale
xxxReserve4	BYTE	16#00	Reserve (use not permitted)
emptyRange	REAL	1.0	Empty range
limit1On	REAL	1.0	Start-up weight limit value 1
limit1Off	REAL	1.1	Shut-down weight limit value 1
limit2On	REAL	50.0	Start-up weight limit value 2
limit2Off	REAL	49.0	Shut-down weight limit value 2
limit3On	REAL	99.0	Start-up weight limit value 3
limit3Off	REAL	98.0	Shut-down weight limit value 3
Flow			

Name	Data type	Default	Definition
minFlowLimit1	REAL	0.0	Limit value 1 for minimum flow rate 0.0 = no limit value in effect >0.0 = minimum flow rate in [1/s]
minFlowLimit2	REAL	0.0	Limit value 2 for minimum flow rate 0.0 = no limit value in effect >0.0 = minimum flow rate in [1/s]
filtDepthMinFlow	BYTE	16#05	Filter depth of mean value filter for flow rate calculation [0..255] * 10 ms, 16#05 ≙ 5 * 10 ms = 50 ms
xxxReserve5	BYTE	16#00	Reserve (use not permitted)

Struct_FTA_DR7

Overview

Data structure **Struct_FTA_DR7** contains the parameters that determine the behavior of the SIWAREX FTA weighing module at the interfaces.

Parameter description

The table below contains all parameters of the data structure **Struct_FTA_DR7**.

Table 8-99 Struct_FTA_DR7

Name	Data type	Default	Definition
Interface to SIMOTION device			
xxxReserve0	BYTE	16#00	Reserve (use not permitted)
srcWeightSim	BYTE	16#00	Weight simulation source 16#00 = weight simulation is inactive 16#01 = weight simulation value from SIMOTION (defined externally via DR 16) 16#02 = weight simulation value from RS232
deciDigitsProcVal	BYTE	16#03	Number of decimal places/decade used for rounding the decimal places of process values (REAL weight values) 16#00 = rounding to 0 decimal places 16#01 = rounding to 1 decimal place 16#02 = rounding to 2 decimal places 16#03 = rounding to 3 decimal places 16#04 = rounding to 4 decimal places 16#05 = rounding to 5 decimal places 16#06 = rounding to 6 decimal places
xxxReserve1	BYTE	16#00	Reserve (use not permitted)
enableForceDO	BOOL	FALSE	**TRUE** = forced control of outputs possible in service mode
indexProcessValue1	BYTE	16#02	Selection of process value 1 from list at output parameter **val1Process** of function block **_FTA_control** for fast output to the SIMOTION device, 16#02 ≙ "Net weight (process value)" see AppendixSelection list for process values (Page 6412)

Name	Data type	Default	Definition
indexProcessValue2	BYTE	16#1E	Selection of process value 2 from list at output parameter **val2Process** of function block **_FTA_control** for fast output to the SIMOTION device, 16#1E ≙ "AWI status" see AppendixSelection list for process values (Page 6412)
xxxReserve2	BYTE	16#00	Reserve (use not permitted)
SIMOTION alarms			
defProcessAlarm0	WORD	16#0000	Definition of process alarm 0 16#0000 = no triggering of process alarms Range of values 16#0001 - 16#00FF: Number of technology error Range of values 16#0100 - 16#013F: 16#0100...16#011F ≙ bit no. NAWI status bit coming 16#0120...16#013F ≙ bit no. AWI status bit coming Range of values 16#0200 - 16#023F: 16#0200...16#021F ≙ bit no. NAWI status bit going 16#0220...16#023F ≙ bit no. AWI status bit going
defProcessAlarm1	WORD	16#0000	Definition of process alarm 1 (see **defProcessAlarm0**)
defProcessAlarm2	WORD	16#0000	Definition of process alarm 2 (see **defProcessAlarm0**)
defProcessAlarm3	WORD	16#0000	Definition of process alarm 3 (see **defProcessAlarm0**)
defProcessAlarm4	WORD	16#0000	Definition of process alarm 4 (see **defProcessAlarm0**)
defProcessAlarm5	WORD	16#0000	Definition of process alarm 5 (see **defProcessAlarm0**)
defProcessAlarm6	WORD	16#0000	Definition of process alarm 6 (see **defProcessAlarm0**)
defProcessAlarm7	WORD	16#0000	Definition of process alarm 7 (see **defProcessAlarm0**)
timeOutLifeBit	TIME	T#0ms	Sign-of-life monitoring in higher-level control 0ms = sign-of-life monitoring switched off
Analog output			
weightAOZero	REAL	0.0	Weight for zero point (0 or 4 mA)
weightAOEnd	REAL	0.0	Weight for end value (20 mA)
weightAOonOD	REAL	0.0	Substitute value for analog output for CPU-STOP (OS, output disable)
srcAO	BYTE	16#00	Source for the analog output 16#00 = SIMOTION control signals 16#01 = external default value via DR17 16#02 = gross 16#03 = net 16#04 = coarse/fine default values
rangeAO	BOOL	FALSE	Current range for the analog output **TRUE** = 0 to 20 mA **FALSE** = 4 to 20 mA
RS232			
printerBdRate	BYTE	16#03	RS232 - printer baud rate 16#00 = 1200 bit/s 16#01 = 2400 bit/s 16#02 = 4800 bit/s 16#03 = 9600 bit/s

Name	Data type	Default	Definition
setXonXoff	BOOL	TRUE	Transfer control for the RS232 interfaces **TRUE** = XON/XOFF transfer control ON **FALSE** = XON/XOFF transfer control OFF
setRtsCts	BOOL	FALSE	Transfer control for the RS232 interfaces **TRUE** = CTS/RTS transfer control ON **FALSE** = CTS/RTS transfer control OFF
RS485			
setRS485Prot	BYTE	16#00	R485 log selection 16#00 = no device 16#01 = SIEBERT display S11 16#02 = reserve 16#03 = SIEBERT display S102
digitsRemDisplay	BYTE	16#00	Decimal place for remote display (0 to 4)
rs485BdRate	BYTE	16#03	RS485 baud rate 16#00 = 1200 bit/s 16#01 = 2400 bit/s 16#02 = 4800 bit/s 16#03 = 9600 bit/s 16#04 = 19200 bit/s 16#05 = 38400 bit/s
rs485Parity	BOOL	FALSE	RS485 bit parity **TRUE** = odd **FALSE** = even
rs485NumDataBits	BOOL	TRUE	RS485- data bits **TRUE** = 8 data bits **FALSE** = 7 data bits
rs485NumStopBits	BOOL	FALSE	RS485- stop bits **TRUE** = 2 stop bits **FALSE** = 1 stop bit
Digital outputs			
defDO1	BYTE	16#FF	Definition of digital output 1 Range of values 16#00 - 16#3F 16#00...16#1F = bit no. NAWI status bit 16#20...16#3F = bit no. AWI status bit 16#FD = start of cyclic transfer of measurement, digital load cell 16#FE = stop of cyclic transfer of measurement, digital load cell 16#FF = output always inactive Range of values 16#40... 16#FC not permitted!
defDO2	BYTE	16#FF	Definition of digital output 2 (see **defDO1**)
defDO3	BYTE	16#FF	Definition of digital output 3 (see **defDO1**)
defDO4	BYTE	16#FF	Definition of digital output 4 (see **defDO1**)
defDO5	BYTE	16#FF	Definition of digital output 5 (see **defDO1**)
defDO6	BYTE	16#FF	Definition of digital output 6 (see **defDO1**)
defDO7	BYTE	16#FF	Definition of digital output 7 (see **defDO1**)
defDO8	BYTE	16#FF	Definition of digital output 8 (see **defDO1**)

Name	Data type	Default	Definition
lowActiveDO1	BOOL	FALSE	Level definition of digital output 1 **TRUE** = output low active **FALSE** = output high active
lowActiveDO2	BOOL	FALSE	Level definition of digital output 2 **TRUE** = output low active **FALSE** = output high active
lowActiveDO3	BOOL	FALSE	Level definition of digital output 3 **TRUE** = output low active **FALSE** = output high active
lowActiveDO4	BOOL	FALSE	Level definition of digital output 4 **TRUE** = output low active **FALSE** = output high active
lowActiveDO5	BOOL	FALSE	Level definition of digital output 5 **TRUE** = output low active **FALSE** = output high active
lowActiveDO6	BOOL	FALSE	Level definition of digital output 6 **TRUE** = output low active **FALSE** = output high active
lowActiveDO7	BOOL	FALSE	Level definition of digital output 7 **TRUE** = output low active **FALSE** = output high active
lowActiveDO8	BOOL	FALSE	Level definition of digital output 8 **TRUE** = output low active **FALSE** = output high active
DO1onOD	BOOL	FALSE	Substitute value for digital output 1 for CPU STOP (OD) or error
DO2onOD	BOOL	FALSE	Substitute value for digital output 2 for CPU STOP (OD) or error
DO3onOD	BOOL	FALSE	Substitute value for digital output 3 for CPU STOP (OD) or error
DO4onOD	BOOL	FALSE	Substitute value for digital output 4 for CPU STOP (OD) or error
DO5onOD	BOOL	FALSE	Substitute value for digital output 5 for CPU STOP (OD) or error
DO6onOD	BOOL	FALSE	Substitute value for digital output 6 for CPU STOP (OD) or error
DO7onOD	BOOL	FALSE	Substitute value for digital output 7 for CPU STOP (OD) or error
DO8onOD	BOOL	FALSE	Substitute value for digital output 8 for CPU STOP (OD) or error
enableDOonError	BOOL	FALSE	Activate substitute value output for fault condition **TRUE** = substitute value for fault condition enabled **FALSE** = substitute value for fault condition disabled
xxxReserve3	BYTE	16#00	Reserve (use not permitted)
Digital inputs			
defDI1	BYTE	16#00	Definition of digital input 1 16#00 = no command 16#01... 16#FE = command code 16#FF = step enabling (see DR23, step control weighing parameters)
defDI2	BYTE	16#00	Definition of digital input 2 (see **defDI1**)
defDI3	BYTE	16#00	Definition of digital input 3 (see **defDI1**)
defDI4	BYTE	16#00	Definition of digital input 4 (see **defDI1**)
defDI5	BYTE	16#00	Definition of digital input 5 (see **defDI1**)

Name	Data type	Default	Definition
defDI6	BYTE	16#00	Definition of digital input 6 (see **defDI1**)
defDI7	BYTE	16#00	Definition of digital input 7 (see **defDI1**)
lowActiveDI1	BOOL	FALSE	Level definition of digital input 1 **TRUE** = input low active **FALSE** = input high active
lowActiveDI2	BOOL	FALSE	Level definition of digital input 2 (see **lowActiveDI1**)
lowActiveDI3	BOOL	FALSE	Level definition of digital input 3 (see **lowActiveDI1**)
lowActiveDI4	BOOL	FALSE	Level definition of digital input 4 (see **lowActiveDI1**)
lowActiveDI5	BOOL	FALSE	Level definition of digital input 5 (see **lowActiveDI1**)
lowActiveDI6	BOOL	FALSE	Level definition of digital input 6 (see **lowActiveDI1**)
lowActiveDI7	BOOL	FALSE	Level definition of digital input 7 (see **lowActiveDI1**)
measTimeForCntr	TIME	T#999ms	Measuring time for pulse input/counter input
xxxReserve4	DWORD	16#0000 0000	Reserve (use not permitted)
MMC parameters			
modeLogOverflow	BOOL	TRUE	Behavior during log overflow (MMC card full) **TRUE** = overwrite oldest entries when MMC memory is full **FALSE** = stop logging with MMC memory is full
modeTraceOverflow	BOOL	TRUE	Behavior during trace overflow (MMC card full) **TRUE** = overwrite oldest trace data when MMC card is full **FALSE** = trace data cannot be overwritten
traceDataToMMC	BOOL	FALSE	Trace data memory location **TRUE** = store trace data on MMC **FALSE** = store trace data in RAM
traceSizeMMC	BYTE	16#32	Memory segment on MMC for trace function in [%], 16#32 ≙ 50 % Up to 100%; however, the sum of the trace function and logs cannot exceed 100%
logSizeMMC	BYTE	16#32	Memory segment on MMC for logs in [%], 16#32 ≙ 50 % Up to 100%; however, the sum of the trace function and logs cannot exceed 100%
traceCycle	BYTE	16#01	Recording cycle for trace function in [ms] 1 to n x 10 ms

Struct_FTA_DR8

Overview

You can set the date and time on the module using the **Struct_FTA_DR8** data structure.

Note

If necessary, the current date and time can be read from data record DR31, **actDataAndTime** element.

Parameter description

Table 8-100 Struct_FTA_DR8

Name	Data type	Default	Definition
dateAndTime	DATE_AND_TIME	DT#1992-01-01-0:0:0.0	Date and time for the SIWAREX FTA weighing module (write)

Struct_FTA_DR9

Overview

Data structure **Struct_FTA_DR9** contains information about the SIWAREX FTA weighing module. These parameters are read-only.

Parameter description

The table below contains all parameters of the data structure **Struct_FTA_DR9**.

Table 8-101 Struct_FTA_DR9

Name	Data type	Default	Definition
Module information			
crcCheckSumFw	DWORD	16#00000000	Firmware checksum
lenFw	DWORD	16#00000000	Firmware length in bytes
moduleInfo	STRING[26]	' '	Siemens AG module serial number
moduleName	STRING[10]	' '	Module name
application	ARRAY[1..8] OF STRING[4]	[' ', ' ', ' ', ' ', ' ', ' ', ' ', ' ']	Application identification
fileName	STRING[20]	'NAWI'	File name
typeVersion	BYTE	16#00	Version type 16#42 = 'B' = Lab status 16#50 = 'P' = Pilot 16#52 = 'R' = Release 16#53 = 'S' = Special status 16#56 = 'V' = Version 16#4B = 'K' = Revision status
fctVersion	USINT	0	Function status Major function changes or calibration-related changes (0 to 99)
dataStructVersion	USINT	0	Data record structure version Identifies changes in the data record structure (0 to 99)
corrVersion	USINT	0	Revision status Small changes or error corrections (0 to 99)
dateCreation	STRING[10]	' '	Creation date
timeCreation	STRING[8]	' '	Creation time

Name	Data type	Default	Definition
bootVersion	UINT	16#00	Bootloader version
scaleType	STRING[4]	'AWI' or 'NAWI'	AWI - Automatic Weighing Instrument NAWI - Non Automatic Weighing Instrument
xxxReserve1	WORD	16#0000	Reserve (use not permitted)

Struct_FTA_DR15

Description

Data structure **Struct_FTA_DR15** is used for external tare weight definition.

Parameters

Table 8-102 Struct_FTA_DR15

Name	Data type	Default	Definition
tareSetValue	REAL	0.0	External tare weight definition

Struct_FTA_DR16

Description

Data structure **Struct_FTA_DR16** is used for entering a weight simulation. The requirement for this is that the data structure **Struct_FTA_DR16** has been defined as the source for the weight simulation.

Parameters

Table 8-103 Struct_FTA_DR16

Name	Data type	Default	Definition
weightSimValue	REAL	0.0	Default value for weight simulation This value is used in place of the gross weight, for example, during testing.

Struct_FTA_DR17

Description

Data structure **Struct_FTA_DR17** is used with a predefined weight value to control the analog output. The requirement for this is that the data structure **Struct_FTA_DR17** has been defined in the data structure **Struct_FTA_DR7** as the source for controlling the analog output.

Parameters

Table 8-104 Struct_FTA_DR17

Name	Data type	Default	Definition
setAO	REAL	0.0	External definition for the analog output

Struct_FTA_DR18

Description

Data structure **Struct_FTA_DR18** is a structure for direct control of the remote display.

Parameters

Table 8-105 Struct_FTA_DR18

Name	Data type	Default	Definition
setValRemDisplay	REAL	0.0	External definition for the remote display

Struct_FTA_DR20

Description

Data structure **Struct_FTA_DR20** sends the setpoint weight for a weighing procedure to the SIWAREX FTA.

Parameters

Table 8-106 Struct_FTA_DR20

Name	Data type	Default	Definition
dosingSetpoint	REAL	50.0	Setpoint weight for the weighing operation

Struct_FTA_DR21

Description

The total amount of the material to be loaded is specified in loading mode. Data structure **Struct_FTA_DR21** sends the load setpoint weight for a weighing operation to the SIWAREX FTA.

Parameters

Table 8-107 Struct_FTA_DR21

Name	Data type	Default	Definition
loadingSetpoint	REAL	1000.0	Load quantity/total setpoint weight for loading mode

Struct_FTA_DR22

Description

Data structure **Struct_FTA_DR22** contains the weighing parameters. In general, the weighing parameters change when the material is changed and must be resent to the SIWAREX FTA weighing module.

Parameters

The table below contains all parameters of the data structure **Struct_FTA_DR22**.

Table 8-108 Struct_FTA_DR22

Name	Data type	Default	Definition
Weighing parameter 1			
maxDosingTime	TIME	T#0ms	Maximum dosing time 0ms = deactivated
inFlightWeight	REAL	1	In-flight weight Amount that is still trailing (in-flight) after the fine signal has been switched off
fineWeight	REAL	20	Fine weight Amount to be dosed during the fine signal
switchOffCorr	REAL	0.0	Switch-off compensation value Additional positive/negative offset of the fine-signal switch-off point
timePreDosing	TIME	T#0ms	Pre-dosing time 0 = deactivated > 0 = pre-dosing time
upperTolValTO1	REAL	0.2	Upper tolerance limit 1 (value of the permissible positive deviation from the setpoint weight)
lowerTolValTU1	REAL	0.2	Lower tolerance limit 1 (value of the permissible negative deviation from the setpoint weight)
upperTolValTO2	REAL	0.5	Value of upper tolerance limit 2 **upperTolValTO2** must be larger than **upperTolValTO1**
lowerTolValTU2	REAL	0.5	Value of lower tolerance limit 2 **lowerTolValTU2** must be larger than **lowerTolValTU1**

Struct_FTA_DR23

Description

The weighing parameters contained in data structure **Struct_FTA_DR23** are typical scale parameters that do not depend greatly on material properties.

Parameters

The table below contains all parameters of the data structure **Struct_FTA_DR23**.

Table 8-109 Struct_FTA_DR23

Name	Data type	Default	Definition
Weighing parameter 2			
selectText	BYTE	16#01	Text selection for automatic logging 16#00 = no automatic logging after weighing 16#01 = automatic logging with text 1 16#02 = automatic logging with text 2 16#03 = automatic logging with text 3 16#04 = automatic logging with text 4
xxxReserve1	BYTE	16#00	Reserve (use not permitted)
xxxReserve2	WORD	16#0000	Reserve (use not permitted)
maxSetpointDosing	REAL	90.0	Maximum setpoint weight for single dosing
disableTimeCoarse	TIME	T#500ms	Inhibit time coarse 0ms = deactivated After the coarse signal is switched on, weight evaluation is suspended for the specified time.
disableTimeFine	TIME	T#500ms	Inhibit time fine 0ms = deactivated After the coarse signal is switched off, weight evaluation is suspended for the specified time.
disableTimeCompare	TIME	T#0ms	Inhibit time for setpoint-actual comparison After the inhibit time is initiated by command, the current weight monitoring is suspended for the specified time during the weighing procedure.
valAOCoarse	BYTE	16#3C	Default value in [%] for analog output when coarse signal is active, 16#3C ≙ 60 %
valAOFine	BYTE	16#14	Default value in [%] for analog output when fine signal is active, 16#14 ≙ 20 %
filtTypeDosing	BYTE	16#00	Filter type for dosage control 16#00 = critically damped 16#01 = Bessel filter 16#02 = Butterworth filter Other definitions not permitted.

Name	Data type	Default	Definition
filtCutOffFreq	BYTE	16#04	Dosing filter limit frequency 16#00: No filter 16#01: fg = 20 Hz 16#02: fg = 10 Hz 16#03: fg = 5 Hz 16#04: fg = 2 Hz 16#05: fg = 1 Hz 16#06: fg = 0.5 Hz 16#07: fg = 0.2 Hz 16#08: fg = 0.1 Hz 16#09: fg = 0.05 Hz Other definitions not permitted.
Taring/zeroing			
modeZeroTare	BYTE	16#02	Tare/zeroing mode 16#00 = do not tare or zero when starting scale 16#01 = set to zero 16#02 = tare 16#03 = tare with mean value 16#04 = tare with external tare input Other definitions not permitted.
