Memory analysis mode provides a tool for estimating memory requirements. However, the information in the output file is only the result of the measurement in the most recently run program, and does not indicate the exact memory requirement of the JamaicaVM. Running programs following this can, therefore, result in a larger memory requirement due to external influences (different data, different scheduling of threads due to temporal influences, etc.). For safety reasons, approx. 20 % more memory than is actually required should be available.

Information relating to the memory requirement is written to the output file (see Output file JCONSOLE.TXT (Page 3949)).

This parameter determines the accuracy of the memory analysis as a percentage, i.e. if 10 is specified, the maximum memory requirement specified is accurate to within 10%. Consequently, the results of the analysis may then be up to 10 % higher than the memory that is actually required. However, the analysis slows down the execution of Java programs. If the value is zero, no analysis is carried out.

Default: 0

HOME

Mapped onto the "user.home" Java system property.

Default: B:/USER/SIMOTION/HMI/JAVA/FSROOT/

CURRENTDIR

Mapped onto the "user.dir" Java system property.

"user.dir" is the current working directory for all Java programs. In particular, both the configuration file for the InvocationManager and the Java libraries containing the user programs to be started automatically must be in this directory.

Default: B:/USER/SIMOTION/HMI/JAVA/PROG/

TEMPDIR

Mapped onto the "java.io.tmpdir" Java system property.

Default: A:/

BOOTCLASSPATH

Bootclasspath for the JamaicaVM. The JamaicaVM has the actual system classes "on-board". However, the Java library containing the InvocationManager and the API for data access and logging must be specified. When specifying several libraries, the libraries must be separated by semicolons.

The file name and the path must be specified.

Default: B:/SIEMENS/SIMOTION/SIMOTION.JAR

CLASSPATH

Additionally required Java libraries can be specified here using the CLASSPATH parameter.

If several libraries are specified, they must be separated using dash-points.

In the case of CLASSPATH, the file name and the path must be specified.

Default: No default value

MAINCLASSNAME

Name of the Java program that is executed when the JamaicaVM is started up.

The default SIMOTION Java start class (i.e. the InvocationManager) executes the user programs in accordance with the settings specified in JINVOKE.XML.

For this reason, if required the InvocationManager can be abandoned and a user program executed immediately instead. Arguments cannot be specified.

Default: com.siemens.ad.SIMOTION.invocation.InvocationManager

DEBUGGER

Setting options for the debugger

Several parameters are possible for setting the debugger. These parameters must be formulated in a line, like individual assignments (param=value) in each case. If several parameters are specified, they must each be separated by a comma.

The possible specifications are **address**, **suspend** and **server**, followed by the detailed description in each case.

address

If debugger mode is activated, the address used by the debugger must be specified. The target system is operated as standard as the debugging server. The address then only describes the relevant port number.

suspend

This parameter is optional. The parameter determines whether or not the JamaicaVM waits for a debugger to connect with it before running the Java applications. The possible values for the parameter are 'y' or 'n'.

The default value is 'y'. This means, if debugger mode is activated, the JamaicaVM waits as standard until a debugger has connected to it before running the applications. Different debugger frontends can handle connection buildup to the JamaicaVM differently.

For example, when using Eclipse at the start of the debugging session after connection buildup, any set breakpoints and the command for running the Java application are sent simultaneously. In this case, it is necessary, for example, to set desired breakpoints before starting the debugging session so that they take effect immediately when the debugging session is started.

server

This parameter is optional and determines whether or not the target system is to be operated as the debugging server. The possible values for the parameter are 'y' or 'n'.

The default value is 'y'. The target system is then operated as the debugging server. If debugger mode is active, the JamaicaVM opens a remote debugging server port.

By specifying 'n', the target system is operated as the debugging client. The JamaicaVM attempts to establish the network connection to a debugging server. The address specification must additionally include the TCP/IP address of the debugging server. The format is then:
`<TCP/IP address>:<port number>.`

Examples:
`DEBUGGER=suspend=n,address=8000`

The debugger is activated and opens the remote debugging port with the port number 8000. When the JamaicaVM is started up, it does not wait to run the Java applications.

`DEBUGGER=suspend=y,server=n,address=192.168.214.2:8000`

The debugger is activated and attempts to establish the network connection to the specified address. When the JamaicaVM is started up, it waits before running the Java applications.

If the specification is missing, debugger mode is not activated.

Default: No default value (debugger not activated)

Example

Example

Setting the memory size for the JamaicaVM and the current working directory for all Java programs.

```
SIMOTIONVM_HEAPSIZE=4500000
CURRENTDIR=B:/JAVA
```

Note

To determine the memory size required by the JamaicaVM, see also setting option SIMOTIONVM_ANALYSE (Page 3945).

Transferring user programs to the target system

Transfer via FTP is an extremely user-friendly option for transferring the user program from the development computer to the target system in the form of a Java library (JAR or ZIP file). (An FTP server is normally active on the target system).

All you need to do is ensure that "binary mode" is always set, so that the file will be transferred securely. Otherwise, the file could become changed during transmission. This will mean that classes within the Java library cannot be found.

Diagnostics buffer entry

A diagnostics buffer entry is created for errors that prevent the JamaicaVM from starting up.

The diagnostics buffer entry is only generated in the target system. The diagnostics buffer entry is not generated in tests on a development computer.

The diagnostics buffer entry contains a note if a problem arises when starting the JamaicaVM. In addition, the diagnostics buffer entry contains a simple error number for roughly determining the cause of the error.

Table 6-62 Possible error numbers

Error number	Error cause
1	The JCONSOLE.TXT output file could not be initialized.
2	The VMCONFIG.INI configuration file contains an invalid setting.
3	Error while starting the JamaicaVM (memory could not be reserved, insufficient memory for starting up, start class not found, etc.).

If error number 1 appears, the file system must be checked.

If error numbers 2 and 3 appear, the exact description of the error cause can be found in the JCONSOLE.TXT output file.

The error can subsequently be eliminated by adjusting the configuration of the JamaicaVM (see JamaicaVM configuration (VMCONFIG.INI) (Page 3945)).

Output file JCONSOLE.TXT

The output file JCONSOLE.TXT is only generated in the target system. This file is not generated in tests on a development computer.

All internal outputs of the JamaicaVM (such as information on the start settings, error messages, information after it has been exited, etc.) are written to a file.

This output file is called JCONSOLE.TXT. It is recreated each time the entire system is started up, and always in directory /USER/SIMOTION/HMI/SYSLOG/ of drive B:.

The output resembles a ring buffer. This means, if the maximum size of 128 KB is exceeded, a start is made again at the beginning of the file. The most recent entry is always followed by the character string $$END$$ to make it easy to find the entry. The character string serves as a separator between the old and new entries.

A typical example of the content of this output file:

```
jvmCreate
jamaica_main_task_entry: coming up
jamaica_main_task_entry: processing jvm configuration
SIMOTIONVM_HEAPSIZE = 4194304
SIMOTIONVM_NUMUSERTHREADS = 4
SIMOTIONVM_STACKSIZE = 40000
SIMOTIONVM_ANALYSE = 0
HOME = B:/USER/SIMOTION/HMI/JAVA/FSROOT/
CURRENTDIR = B:/USER/SIMOTION/HMI/JAVA/PROG/
TEMPDIR = A:/
BOOTCLASSPATH = B:/SIEMENS/SIMOTION/SIMOTION.JAR;
CLASSPATH =
MAINCLASSNAME = com.siemens.ad.SIMOTION.invocation.InvocationManager
jamaica_main_task_entry: waiting for prepared worker tasks
jamaica_main_task_entry: going to startup JamaicaVM:
jamaica
-Xbootclasspath:B:/SIEMENS/SIMOTION/SIMOTION.JAR;
com.siemens.ad.SIMOTION.invocation.InvocationManager
InvocationManager enters main...
Current working directory is: B:/
OK - starting user program
OK - starting user program
$$END$$
```

The example shows the following:

- The outputs for the power-up phase of SIMOTION Java
- The corresponding JamaicaVM parameters, the actual start of the JamaicaVM and the InvocationManager
- Including the start of two user programs.

More detailed InvocationManager outputs, e.g. which user programs have been started up, are output via logging (in accordance with the settings made in LOGGING element (Page 3941)).

The output file can be transferred for viewing from the target system to the development computer using FTP (an FTP server is normally active on the target system).

Information on the JamaicaVM memory requirement

If the JamaicaVM is operated in memory analysis mode via the SIMOTIONVM_ANALYSE setting (see also SIMOTIONVM_ANALYSE (Page 3945)), information on the maximum amount of memory required during a cycle is also written to the output file after the JamaicaVM has been exited.

The output might look like this:

```
### Application used at most 3773001 bytes for the Java heap
(accuracy 10%).
```

```
### Non-Java heap memory used: 209404 bytes.
###
###                     Worst case allocation overhead:
###     heapSize        dynamic GC      static GC
###     12954k          6               3
###     10854k          7               4
###     9509k           8               4
###     8598k           9               4
###     7929k           10              4
###     7028k           12              5
###     6461k           14              5
###     6054k           16              6
###     5762k           18              6
###     5537k           20              7
###     5218k           24              8
###     5003k           28              9
###     4851k           32              10
###     4731k           36              11
###     4639k           40              12
###     4504k           48              14
###     4411k           56              17
###     4345k           64              19
###     4188k           96              27
###     4112k           128              36
###     4035k           192             53
###     4000k           256             69
###     3965k           384             100
```

In this case, the minimum heap size is 3965 KB. The JamaicaVM could thus also be operated with a heap size of 4060160 bytes. The second column shows that in the worst-case scenario 384 allocation steps could be required to allocate an object. If, on the other hand, a 4035 KB heap were available, the worst-case scenario would involve 192 allocation steps.

The memory requirement is made up of 3773001 bytes for the actual Java heap and 209404 bytes for the "non-Java heap".

All objects managed by the garbage collector, and also internal objects of the VM, are stored on the Java heap. The non-Java heap contains the stacks and the static structures.

Interactive InvocationManager interface

Overview

The interactive InvocationManager interface allows user programs to be tested repeatedly without the need, for example, to exit the JamaicaVM each time.

The relevant commands for this can be sent to the InvocationManager via a socket connection.

A typical "development cycle" might progress as follows:

- Create Java library with user program on development computer
- Store Java library with user program on target system

- Open Java library via InvocationManager request
- Start user program via InvocationManager request
- Once the user program has been exited, the Java library can be closed by means of an InvocationManager request and then recreated, once expansions have been made on the development computer. Following this, it can be updated on the target system (e.g. via FTP transfer) and reopened, and the user program can be started up.

The InvocationManager protocol

All parts of a request must be separated by/ended with a line feed character (0x0A). It is crucial that you do not forget the final line feed character. The InvocationManager waits until it receives the line feed character before executing the request. If the socket connection was terminated before that, the InvocationManager terminates processing of the request.

A request must begin with one of the following keywords:

- cmd... followed by the actual command and, if applicable, its parameters
- job... followed by the class name, method name, and arguments (optional)
- task... followed by the class name, method name, and arguments (optional)

Commands

openArchive

This command opens the relevant Java library.

The command must be followed by the name of the Java library to be opened.

The name specification can be either absolute or relative.

If the specification is relative, i.e. only the file name is specified without the path, the file itself must be in the current working directory (see CURRENTDIR (Page 3945))

Only one Java library can be opened via the interactive interface at any one time. Before the specified Java library is opened, any other Java library that may currently be open is closed automatically.

closeArchive

This command closes the Java library that is currently open.

setLoggingLevel

The command must be followed by the name of the new logging level.

For the correct name, see DEFAULT_LEVEL (Page 3941).

This command can be used during runtime to change the appropriate logging level for the InvocationManager logging outputs.

exit

This command is used to exit the InvocationManager.

By exiting the InvocationManager, the JamaicaVM is also exited, but only if no other user program is active.

job/task requests

Both types of request enable a user program to be executed. The only difference lies in how the response sent to the client is handled.

The method to be called must be declared as public static, and must accept a string array as a single argument. Any value can be returned for the method.

The "job" type of request is intended for user programs with a "function result" (i.e. the method called supplies a result object, preferably after a relatively short runtime). With a "job" request, the InvocationManager holds off on sending the response until the method called returns, converts the result object into a string, and sends this string to the client. If the method does not supply a result object (e.g. a method with a void return type), the default response is sent to the client
OK - request finished

.

The "task" type of request is intended for user programs without a "function result" (these may have an extremely long runtime, or may never end). With a "task" request, the InvocationManager sends the default response to the client immediately before the relevant method is called
OK - starting user program

It then terminates the socket connection. If the client receives the response, it is guaranteed that the specified class has been successfully loaded and that the specified method is also available. However, a direct function result is not available.

If errors occur, the InvocationManager sends the relevant error message to the client as a response.

Once the response has been sent, the InvocationManager terminates the socket connection.

Note

The user program is started in a separate Java thread in the case of both request types. This means that the InvocationManager itself does not block any requests while the user program is running, but can instead continue to receive further requests at the same time.

Sample requests

Open Java library USERPROG.JAR.

```
cmd\nopenArchive\nUSERPROG.JAR\n
```

Load the `MyClass` Java class and execute the `runIt` method with arguments `aArgument1` and `aArgument2` ("zipped" as a string array).

```
job\nMyClass\nrunIt\naArgument1\naArgument2\n\n
```

Note

The two line feed characters at the end of the request must be available. An "empty argument" indicates the end of the argument list to the InvocationManager.

Sample programs

In addition to the documentation, sample programs in Java source code format are available as basic help methods (see Scope of delivery (Page 3913)).

Examples of data access, file functions, marshalling, and multithreading are available.

Examples of implementing tools, such as an InvocationManager client and a UDP logging host, are also available.

com/siemens/ad/SIMOTION/demo/da/NVRAMDemo.java

Example of using persistent data (stored in the NVRAM)

com/siemens/ad/SIMOTION/demo/da/Simple.java

Example of simple data access

com/siemens/ad/SIMOTION/demo/da/STVariable.java

Example of accessing variables for an ST program

com/siemens/ad/SIMOTION/demo/da/SystemVariable.java

Example of accessing system variables

com/siemens/ad/SIMOTION/demo/da/VariableBrowser.java

Example of browsing variables, including how to determine the data type of scalar variables using RTVariableANY

com/siemens/ad/SIMOTION/demo/da/VariableProperties.java

Example of reading variable properties.

com/siemens/ad/SIMOTION/demo/drive/DriveAccess.java

Example of how parameters, their description, and the error buffer of a drive can be accessed.

Note

For the demo program to process successfully, not only is a relevant project required on the target system, but also an addressable drive that is connected to the target system. The example requires a SINAMICS at the logic address 258.

com/siemens/ad/SIMOTION/demo/file/Simple.java

Example of file access; in particular, how file names can evolve independently of a platform

com/siemens/ad/SIMOTION/demo/invocation/InvocationClient.java

Example of how requests are sent to the InvocationManager

com/siemens/ad/SIMOTION/demo/marshalling/Receiver.java

Example of how the values of the Java variables can be set on the basis of the raw data received (UDP data telegram).

com/siemens/ad/SIMOTION/demo/marshalling/UDPRawDataSender.java

Utility program which can be used to send raw data to the marshaling receiver for testing purposes.

com/siemens/ad/SIMOTION/demo/log/UDPLoggingHost.java

Example of how the logging outputs can be received and output via UDP.

com/siemens/ad/SIMOTION/demo/sys/DeviceFunctions.java

Example of how device functions can be called

com/siemens/ad/SIMOTION/demo/sys/SystemFunctions.java

Example of how system functions of a TO can be called

com/siemens/ad/SIMOTION/demo/thread/Simple.java

Example of a user program with several threads. The main thread creates and starts a worker thread, which sends data cyclically to a UDP receiver.

At the same time, the main thread waits at a UDP socket for incoming data. When data is received, the main thread stops the worker thread and also stops itself.

Note

The UDPLoggingHost can be used as a UDP receiver and the UDPRawDataSender as a UDP sender (for the purpose of sending the stop request to the sample program). All you need to do is adapt the connection information (if applicable).

Format of logging outputs

The format of the logging outputs is as follows:

```
<Timestamp> | <LoggingLevel> | <LogTopic> | <LogMessage>
```

Timestamp

Time at which the logging output was created, in milliseconds from 1/1/1970, 00:00.

LoggingLevel

LoggingLevel that was specified with the logging output.

LoggingTopic

LoggingTopic that was specified when the logger was created. This allows logging outputs from different user programs to be distinguished from one another.

LoggingMessage

Message that was specified with the logging output.

If an exception (Java exception) is logged, the message also contains the description of the exception, including the stack trace information (only when automatic logging of the stack trace information is activated; see PRINT_STACKTRACE (Page 3941)).

Example

Below is an example of the program lines:

```
static final String APP_NAME = "Simple";

    public static void main( String [] args )
    {
        Logger vLogger = Logger.getLogger( APP_NAME );
        vLogger.log( Logger.INFO, "Starting up" );
        vLogger.log( Logger.INFO,
                     "CurrentDirectory is: " +
                      System.getProperty( "user.dir" ) );
```

and the relevant log outputs for a user program:

```
694224004323 | INFO | Simple | Starting up
694224004323 | INFO | Simple | CurrentDirectory is: B:/
```

Restarting the JamaicaVM

When the last Java thread has ended, the JamaicaVM will also stop.

To restart the JamaicaVM, the jvmrestart.mwsl program can be restarted via the Web browser:

```
<!DOCTYPE html>
<html>
  <head>
    <meta charset="ISO-8859-1">
    <title>Call JVMRESTART with CSRF Token</title>
  </head>
  <body>
    <a href="http://192.168.0.1/JApp/jvmRestart?<%=SingleUseToken
%>">http://192.168.0.1/JApp/jvmRestart</a>
  </body>
</html>
```

The IP address 192.168.0.1 must be changed in accordance with the own configuration.

The CSRF protection is implemented for this link by using the Server Side Include < %=SingleUseToken%>. The <%=SingleUseToken%> tag is resolved into a string such as: "SingleUseToken=i9/mSm1Bvc+BkNgOWNE+4FYTRNk=". The first "=" is followed by the token, but only if a user is logged on. The SSI <%RawSingleUseToken%> can be used for applications in which only the pure token value is to be used (e.g. within an HTML form "<form>"):

```
<html>
 <head>
  <meta charset="ISO-8859-1">
  <title>Call JVMRESTART with CSRF Token</title>
 </head>
<body>
<form method="get" action="/JApp/jvmRestart" >
<!-- CSRF Token input _must_ be at 1. place in form !!! -->
        <input type="hidden" name="SingleUseToken" value="<%=RawSingleUseToken%>"/>
        <input type="submit" value="Restart JVM now"/>
</form>
</body>
</html>
```

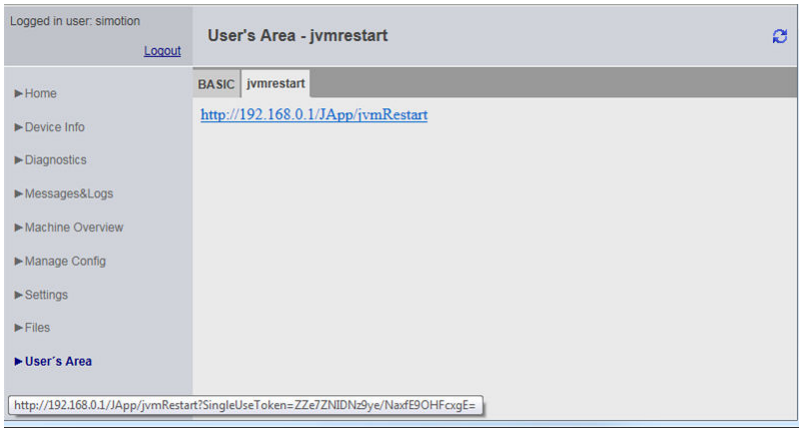

Figure 6-154 Restart JamaicaVM

Further information can be found in the *CSRF protection* chapter in the *SIMOTION IT Diagnostics and Configuration* manual.

If the CSRF token is not used, the browser outputs an error message.

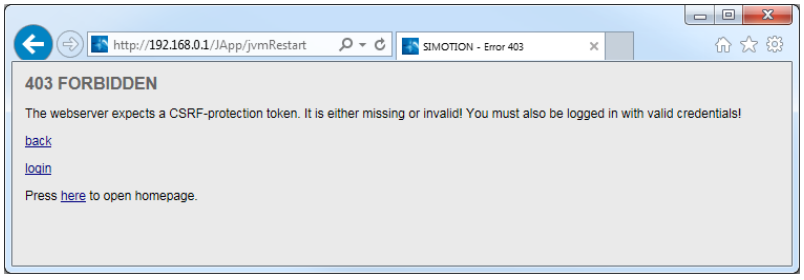

Figure 6-155 New restart of the JamaicaVM without CSRF token

Call of jvmRestart up to V5.2

In the older versions, a direct start of jvmRestart in the browser is possible.
`http://<host>/JApp/jvmRestart`

Note

Restart of the JamaicaVM is not forced by calling `jvmRestart`. A restart will only be successful if the JamaicaVM has shut down in the correct manner.

6.4.4.2 SIMOTION IT Servlets

Scope of functions implemented

"Java™ Servlet Specification, V2.2" supports SIMOTION IT Servlets.

However, not all of the concepts from the standard servlet API are implemented in SIMOTION IT Servlets.

The following are implemented:

- Differentiation between type of request (GET, POST)
- Access to all parameters of the request (from both the URL and form data)
- Access to the content of the request
- Access to the request header
- Specification of the response status
- Specification of the response header
- Writing of the response content
- Logging
- Initialization parameters from configuration file for servlets
- Servlet context with attribute management and initialization parameters

These enable the implementation of fully-fledged servlets, including structure and entry form editing features (e.g. for web browsers).

The section titled Implementing the servlet API (Page 3960) contains a detailed description of the functions implemented.

More advanced concepts such as the following are not implemented:

- Support for HTTP sessions
- Support for RequestDispatcher
- Support for security functionality
- Access to client information (remote host, etc.)
- Internationalization (only the ISO-8859-1 character set is available)
- Java server pages

Note

Security functionality

An authentication feature is implemented within the connection to the SIMOTION web server, which enables you to limit access to servlets as standard in the interests of security.

However, the Java security functions defined within the servlet API (such as the role-based security concept) are not implemented.

Scope of delivery

The following files are integral parts of SIMOTION IT Servlets:

File name	Description
svltapi.jar	Java library containing the standard servlet API.
svltimpl.jar	Java library containing the implementation of the servlet container.
simotion_servlets_doc.zip	Online documentation of the servlet API (HTML format).
simotion_servlets_demo.zip	Java source code for sample servlet.
JSERVER.XML	Sample servlet configuration file.

Implementing the servlet API

SIMOTION IT Servlets supports the "Java™ Servlet Specification, V2.2".

For the servlet API itself, the relevant implementation of the "Apache Jakarta Project" is used. This has been developed by the Apache Software Foundation (http://www.apache.org/ (http://www.apache.org/)) and does not provide support for Java Server Pages.

Essentially, this means that unless Java Server Pages need to be supported, all of the specified interfaces and classes for the servlet API are available. Additionally, the online documentation for the servlet API provides full descriptions of all the interfaces and classes it contains.

Certain interfaces, as well as certain interface methods, are not supported in the first version of SIMOTION IT Servlets, as they are not required for simple servlets.

Generally speaking, methods referred to in the servlet specification as "deprecated" (meaning that they are outdated and should no longer be used) are not supported.

If certain interface methods are not supported, calling them will trigger an exception of type "UnsupportedOperationException".

The table below provides both a detailed list of what is included in the servlet API and a description of the scope of functions implemented in SIMOTION servlets.

javax.servlet package	
	RequestDispatcher Not implemented
	ServletConfig Fully implemented
	ServletContext The following methods are implemented: public int getMajorVersion() public int getMinorVersion() public void log(String msg) public void log(String msg, Throwable throwable) public String getServerInfo() public String getInitParameter(String name) public Object getAttribute(String name) public Enumeration getAttributeNames() public void setAttribute(String name, Object object) public void removeAttribute(String name) public String getContextPath()

	ServletRequest The following methods are implemented: public int getContentLength() public String getContentType() public ServletInputStream getInputStream() throws IOException public String getParameter(String name) public Enumeration getParameterNames() public String[] getParameterValues(String name) public String getProtocol() public String getServerName()
	ServletResponse The following methods are implemented: public ServletOutputStream getOutputStream() throws IOException public void setContentType(String type) public void reset() public boolean isCommitted() public void flushBuffer() throws IOException
	SingleThreadModel Already implemented as appropriate in servlet API
	GenericServlet Already implemented as appropriate in servlet API
	ServletInputStream Fully implemented
	ServletOutputStream Fully implemented
	ServletException Already implemented as appropriate in servlet API
	UnavailableException Already implemented as appropriate in servlet API
javax.servlet.http package	
	HttpServletRequest The following methods are implemented: public Cookie[] getCookies() public long getDateHeader(String name) public String getHeader(String name) public Enumeration getHeaderNames() public int getIntHeader(String name) public String getMethod() public String getContextPath() public String getPathInfo() public String getQueryString() public String getRequestURI() public String getServletPath()

	HttpServletResponse The following methods are implemented: public void addCookie(Cookie cookie) public boolean containsHeader(String name) public void sendError(int sc, String msg) throws IOException public void sendError(int sc) throws IOException public void setDateHeader(String name, long date) public void setHeader(String name, String value) public void setIntHeader(String name, int value) public void setStatus(int sc)
	HttpSession Not implemented
	HttpSessionBindingListener Not implemented
	HttpSessionContext Not implemented
	Cookie Already implemented as appropriate in servlet API
	HttpServlet Already implemented as appropriate in servlet API
	HttpSessionBindingEvent Already implemented as appropriate in servlet API
	HttpUtils Already implemented as appropriate in servlet API
javax.servlet.jsp package This package (along with its subpackages) is not included in SIMOTION servlets.	

Creating user servlets

User servlets are created on a development computer.

To enable the Java compiler to find the classes referenced within the servlet API, the relevant Java library must be specified during compilation.

For example:
```
javac –classpath svltapi.jar ...
```

If classes are referenced by the SIMOTION API, it is also necessary to specify the relevant Java library during compilation.

For example:
```
javac –classpath svltapi.jar;simotion.jar ...
```

Remark:

The separator within the CLASSPATH specification is platform-specific. If a Windows development computer is used, the separator is the semicolon, as in the above example. On a Unix development computer, a colon must be used.

To ensure that the user servlet will not use any Java system classes that are not available within the SIMOTION IT Virtual Machine runtime environment, during compilation the Java library can also be specified with the system classes as a reference.

For example
```
javac –bootclasspath simotion_systemclasses.jar –classpath
svltapi.jar ...
```

Following compilation, all of the user program classes must be zipped into a Java library.

For example:
```
jar –cvf testsvlt.jar ...
```

Following this, the Java library can be transferred to the target system along with the user servlet and loaded by the servlet container.

Configuration file (JSERVER.XML)

The configuration file JSERVER.XML contains the settings for the SIMOTION IT Servlet container and the servlets to be loaded.

XML notation must be used for the structure of the configuration file. A simple XML parser (Nano/XML/Lite) is integrated in SIMOTION IT Virtual Machine that is perfectly adequate for editing the configuration file.

Before storing the configuration file on the target system, you are advised to display it in a web browser, for instance, so that any syntax errors can be made immediately apparent (if the configuration file has not been created using a special XML editor). NanoXML, in particular, deals with error messages very economically.

The individual XML configuration file elements are described below:

<table>
<tr><td colspan="2">ROOT element
SIMSERV must be used as the root element:
<pre><?xml version="1.0" standalone="yes"?>
<SIMSERV>
  <!—Initialization parameter of context -->
  <INITPARAM NAME="AParameter" VALUE="aValue"/>
  <!-- SERVLET elements, for example, are listed here -->
</SIMSERV></pre>All other elements must then be specified within the ROOT element.
The example above contains just one initialization parameter, as described below.</td></tr>
<tr><td colspan="2">INITPARAM element
The ROOT element can contain any number of INITPARAM elements. These initialization parameters can be queried from servlets using the Servlet Context,
meaning that they are available for all servlets.
The following attributes are evaluated:</td></tr>
<tr><td></td><td>NAME
Name of the initialization parameter.
If this attribute is missing, the element will not be evaluated any further.</td></tr>
<tr><td></td><td>VALUE
Value of the initialization parameter.
If this attribute is missing, the empty string is used as the value.</td></tr>
</table>

SERVLET element A SERVLET element contains information about the servlet to be loaded. The name of the Java class that implements the servlet and the path (part of the URL following the ContextPath) under which the servlet is to be registered must be specified for a servlet that is to be loaded. You can specify several SERVLET elements. meaning that it is possible to load several servlets. The following attributes are evaluated:	
	LIBRARY Name of the Java library (JAR or ZIP file) that contains the servlet. The name specification can be either absolute or relative. If the specification is relative, i.e. only the file name is specified without the path, the file itself must be in the current working directory. Specifying this is optional. If no Java library is specified, the Java class for the servlet must be located in the CLASSPATH.
	CLASSNAME Name of the Java class for the servlet.
	PATH Path under which the servlet is to be registered within the ServletContext.
	NAME Name of the servlet. Providing a name is optional and serves a purely informational purpose (the getServletName() method returns the name). If no specification is made, the name of the Java class is used as the servlet name.
	INITPARAM element A SERVLET element can contain any number of INITPARAM elements. There initialization parameters can be queried within the servlet by means of the servlet configuration, and apply to this servlet only. In terms of structure, the INITPARAM element for servlets is identical to the one for the ServletContext (see INITPARAM element).

An example of SERVLET elements

In this example, two servlets are loaded.

Java class MyServlet is loaded from the MYSVLT.JAR Java archive and registered under /myServlet within the ServletContext. The servlet can query the two initialization parameters. The name of the servlet matches that of the Java class.

A client references the servlet via http://<host>/servlet/myServlet.

The Java class TestServlet is loaded via the system class loader and registers within the ServletContext under the path /test . In this case, the Java class TestServlet must be located in the CLASSPATH of SIMOTION IT Virtual Machine.

The servlet has no initialization parameters. The name of the servlet is "A test servlet".

A client references the servlet via http://<host>/servlet/test

```
<SERVLET LIBRARY="MYSVLT.JAR" CLASSNAME="MyServlet" PATH="/
myServlet">
 <INITPARAM NAME="AParameter" VALUE="aValue"/>
 <INITPARAM NAME="AnotherParameter" VALUE="anotherValue"/>
</SERVLET>
```

```
<SERVLET CLASSNAME="TestServlet" PATH="/test"  NAME="A test servlet"/
>
```

Sample servlet and configuration

A sample servlet in Java source code format is included in the scope of delivery as a basic help method. Sample configuration JSERVER.XML may be used accordingly.

DemoServlet.java

The following section contains an example illustrating the basic principles of how a client request is edited within a concrete servlet.

```
/*
 * ================================================================
 * A simple servlet to demonstrate how to build a user-servlet.
 *
 * The servlet generates some "plain-text" only.
 *
 * Copyright (C) 2004 Siemens AG. All rights reserved.
 * ================================================================
 */
// Necessary servlet API
import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;
// Possible io exceptions
import java.io.IOException;
import java.io.PrintWriter;
/*
 * A simple servlet, which generates only a textual response.
 */
public class DemoServlet extends HttpServlet
{
    /*
     * Generate response for a GET-Request.
     */
    public void doGet( HttpServletRequest request,
                       HttpServletResponse response )
                throws ServletException, IOException
    {
        // "request" could be used to query additional
        // information
        // e.g. parameters ...

        // Set ContentType of the response
        response.setContentType("text/plain");

        // Obtain PrintWriter for writing response
        PrintWriter out = response.getWriter();
```

```
        // Write response
        out.println("Hello SIMOTION Servlets!");
    }
}
```

The sample servlet only generates simple text and does not require any parameters.

A servlet that wishes to have an entry form displayed in a browser generates the form in HTML and writes it to the browser as a response to a GET request. In order to edit the entry form, this type of servlet implements editing for the POST request as well, evaluates the form parameters within this, and generates a relevant response again.

JSERVER.XML

The configuration file supplied shows how the sample servlet can be loaded and how a DumpServlet contained in SIMOTION IT Servlets can be activated. This is useful for the purpose of viewing the current initialization parameters in the ServletContext.

```
<?xml version="1.0" standalone="yes"?>
<SIMSERV>

  <!-- Example of a SIMOTION IT Servlets configuration -->

  <!-- ServletContext parameters -->

  <INITPARAM NAME="ContextParam1" VALUE="ContextValue1"/>
  <INITPARAM NAME="ContextParam2" VALUE="ContextValue2"/>

  <!--
   The previously compiled demo servlet is loaded
   and must be zipped into SVLTDEMO.JAR and stored
   on the target system.
   The demo servlet is registered for path
   /demo, and can, therefore, by accessed by the client via http://
<host>/servlet/demo
  -->

  <SERVLET LIBRARY="SVLTDEMO.JAR" CLASSNAME="DemoServlet"
           PATH="/demo" NAME="Demo-Servlet"/>

  <!--
   No LIBRARY needs to be specified for the DumpServlet included as
standard.
   By way of a response, the DumpServlet provides information about
the current request and initialization
   parameters for the context and servlet (if specified),
   and can be registered for simple checking of the context
initialization parameters,
   for example.
   The dump servlet is registered for path
   /dump/*, for example, and can, therefore, be accessed by the
client via http://<host>/servlet/dump
   or even http://<host>/servlet/dump/APathInfo
```

```
  -->

  <SERVLET CLASSNAME="com.siemens.ad.SIMOTION.servlets.DumpServlet"
           PATH="/dump/*" NAME="Sample DumpServlet">
      <INITPARAM NAME="ServletParam1" VALUE="ServletValue1"/>
      <INITPARAM NAME="ServletParam2" VALUE="ServletValue2"/>
  </SERVLET>

</SIMSERV>
```

Restart of the servlet container

To stop the ServletContainer by calling an URL on the server, the so-called AdminServlet, a system servlet, must be loaded in the configuration file jserver.xml.

```
   <SERVLET
CLASSNAME="com.siemens.ad.SIMOTION.servlets.impl.AdminServlet"
            PATH="/admin/*" NAME="AdminServlet" />
```

The servlet is then registered on the subpath: "admin" and it knows the command (written as an http parameter):

```
   Action=StopContainer
```

By calling the URL

`<host><simotion-servlet-prefix>/admin?Action=StopContainer` (an HTTP-GET request is output)

the servlet container can be stopped.

The servlet restarts if the SIMOTION VM is restarted. This is done by calling the URL:

```
   <host><simotion-servlet-prefix>/JApp/jvmRestart
```

SIMOTION Programming 7

7.1 SIMOTION MCC Motion Control Chart

Preface

Scope

This document is part of the **SIMOTION Programming** documentation package.

This document applies to SIMOTION SCOUT, the engineering system of the SIMOTION product family in product version V5.3 in conjunction with:

- A SIMOTION device with the following versions of a SIMOTION Kernel:
  - V5.3
  - V5.2
  - V5.1
  - V4.5
  - V4.4
  - V4.3
  - V4.2
  - V4.1 [1]
  - V4.0 [1]
  - V3.2 [1]

  [1] V4.5 is the last product version of SIMOTION SCOUT that will support these versions of the SIMOTION Kernel.
- The relevant version of the following SIMOTION Technology Packages, depending on the kernel:
  - Cam
  - Path (Kernel as of V4.1)
  - Cam_ext
  - TControl

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.3:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

7.1.1 Fundamental safety instructions

7.1.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

7.1.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

7.1.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

7.1.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

7.1.2 Description

7.1.2.1 Overview

This chapter introduces the MCC (Motion Control Chart) graphical programming language and also describes the programming principles and procedures involved.

7.1.2.2 Introduction to MCC (Motion Control Chart)

MCC is a graphical programming language which has been designed to reduce the complexity of automating production machines.

Many production machines are very complex. They require a control system (SIMOTION) that is capable of handling motion control and technologies with a wide variety of motion functions, as well as PLC functions, arithmetic functions, and data management tasks.

MCC is the neutral description tool represented as a flowchart. This flowchart is referred to as "MCC chart" in this document. MCC provides you with all of the descriptive symbols you will need to define your automation task quickly and efficiently. It also offers a wide range of tools for structuring large-scale automation jobs.

With an MCC chart, you can create a program, a function block, or a function that complies with IEC 61131-3.

An MCC unit may contain no MCC charts, or one or more MCC charts. All the MCC charts contained in an MCC unit access the same data storage area.

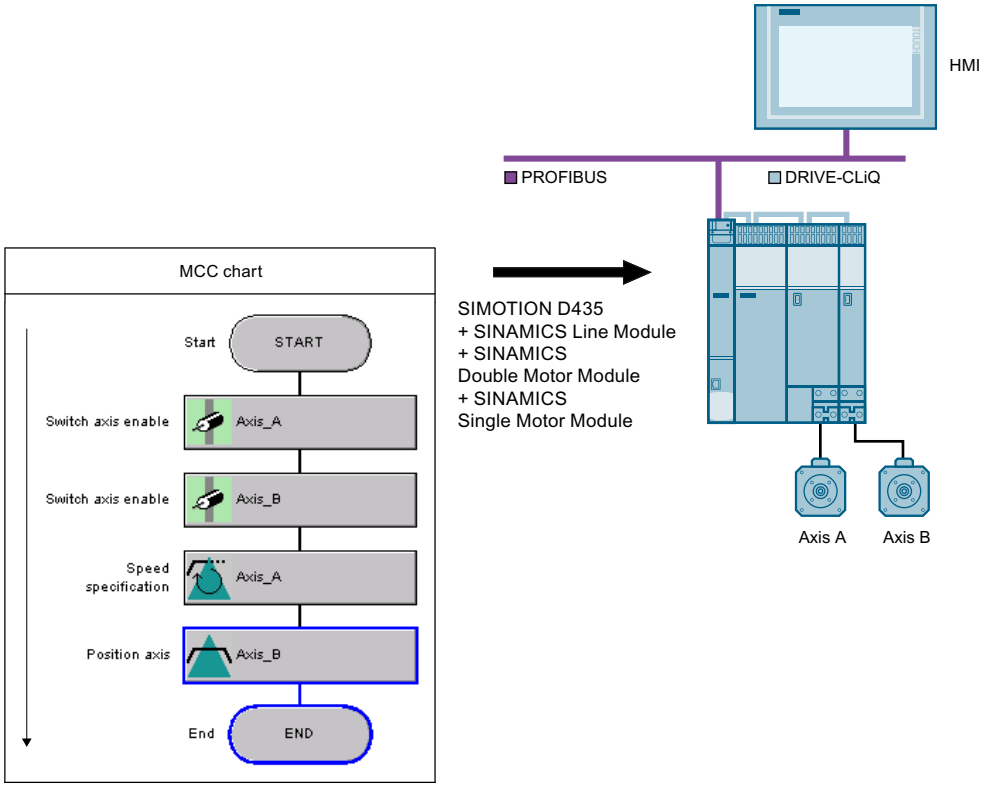

Figure 7-1 MCC for automating production machines

Application of MCC

MCC facilitates automation by offering the following features:

- The motion sequences on the machine can be easily programmed and are clearly defined.
- The programmer's logic is supported.
- Structured programming available through use of subprograms and modular creation of commands and library functions.
- Wait commands for quick responses to events.
- Simultaneous starting of axes.
- Online functions allow tracking of the program execution (program execution monitoring and breakpoints).
- Integrated online help.

These features help the inexperienced programmer to achieve results fast and let the experienced programmer create complex programs more efficiently.

7.1.2.3 Principles of programming

The SIMOTION motion control system offers powerful functions for motion control in production machines. As a graphical programming language, MCC helps you to formulate process and motion sequences easily by creating a sequence of graphical MCC commands.

The characteristics of every MCC command can be assigned individually. Control structures such as IF commands make for easy implementation of alternative branches.

The flowchart format makes it easy to follow the logical execution sequence. Furthermore, each MCC command has its own graphic design, making the functionality of each action within an MCC chart immediately evident. Consequently, the system greatly facilitates the programming of automation tasks and enhances readability. Supplementary online functions enable you to locate errors quickly or simply help you to keep track of the current states.

7.1.2.4 Procedure for programming

Let us look at an example of how MCC programming works.

Function

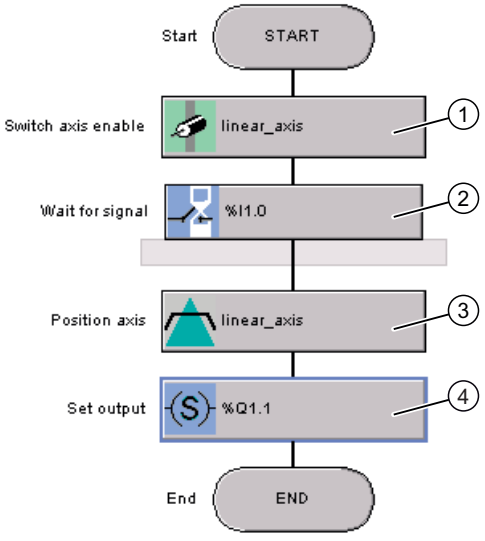
When you press a key, an axis will travel to position 1,000 mm at a velocity of 100 mm/s. Once this position has been reached, an output is to be set (for example, lamp ON).

This task is now broken down into several subtasks:

- Set axis enable signals
- Wait until the key is pressed
- Traverse axis to position
- Set output when motion ends

An MCC command is available for each of the listed subtasks. Each command is represented by a rectangular symbol in MCC. The parameters for individual commands (position = 1000, input = 1.0, etc.) are entered using a command dialog box. This opens when you double-click the command.

This example deals only with the MCC programming aspect. For this reason, information about the keys, axis, and lamp should already be available to the control system.



① Set enables:
drive enable, pulse enable, position controller enable
② Wait until the key with input I1.0 is pressed
③ Traverse the axis to position at the specified speed
④ Activate output Q1.1 for a lamp

Figure 7-2 MCC chart for example task

7.1.3 Software interface

7.1.3.1 User interface in MCC editor

This chapter describes the various operating features offered by the MCC editor. The user interface is graphically displayed and described.

7.1.3.2 Representation of MCC chart and MCC source file in Workbench

The Workbench is divided into 3 main windows:

- Project navigator: Displays the project structure
- Working area: Displays the MCC chart or MCC unit and parameter screen forms
- Detail view: Displays the variables, alarms, error messages, etc., depending on which element is selected in the project navigator

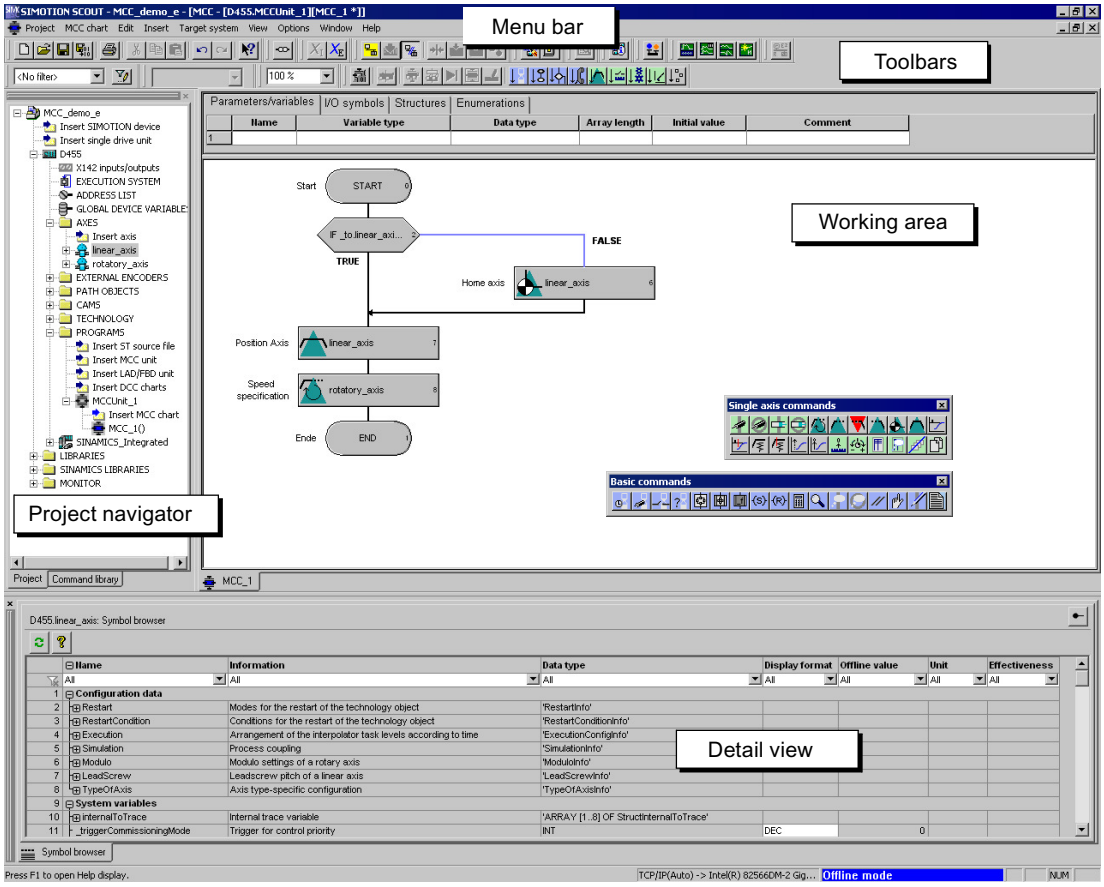


Figure 7-3 Workbench view

For additional information on using the Workbench:

- Maximizing working area and detail view
- Zooming in and out of an MCC chart
- Moving the MCC chart or MCC unit to the foreground
- Hiding and displaying the declaration table
- Enlarging/reducing the declaration table

Maximizing working area and detail view

The windows working area and detail view can be set to maximum zoom.

Select **View > Maximize working area** or **View > Maximize detail view** from the menu.

Zooming in and out of an MCC chart

There are various options available for changing the size of an MCC chart, i.e. the size of the command icons:

- Changing the zoom factor via the **Zoom factor** combo box.
  Select a factor from the list, or enter an integer value of your own choice.
- Press the **Ctrl** key while moving the mouse wheel.

The zoom factor selected applies to the declaration table and the MCC chart.

The changes always apply to the currently selected MCC chart.

Moving the MCC chart or MCC unit to the foreground

If several MCC charts or MCC units are open in the working area, they will be cascaded in most cases. Therefore, only the top window will be visible.

You can use different methods to move concealed windows to the foreground:

- By selecting the appropriate tab below the working window
- By selecting the appropriate name in the Window menu

Hiding and displaying the declaration table

If you need more space, you can completely hide the declaration table of an MCC chart.

- Double-click the separation line.

In order to display the declaration line again, double-click the separation line again.

Enlarging/reducing the declaration table

- Move the pointer over the separation line until it turns into a double line.
- Keep pressing the left mouse button while you move the separation line:
  - Up, to reduce the declaration area
  - Down, to enlarge the declaration area

7.1.3.3 Operator input options

The MCC editor provides the programmer with a variety of different operator input options. Alternatives for executing individual operator inputs include the following:

- Via the menu bar
- Via the context menu
- Via the toolbar

- Via key combinations
- Texts and variables can be moved into the input field using a drag and drop operation.

Menu bar

There are two separate menu bars for the MCC unit and the MCC chart. Each contains a complete set of action commands.

The appropriate menu bar is displayed for the active window in the working area.

Context menu

The context menu of an MCC chart opened in the working area contains the complete range of commands, see Inserting commands (Page 4013).

To use the context menu for an object, proceed as follows:

1. Select the appropriate object with the left mouse button.
2. Briefly click the right mouse button.
3. Left-click the appropriate menu item.

Note

In this document, work steps and action commands are executed wherever possible via the context menu. However, some action commands can only be executed via the menu bar or toolbar.

Toolbar

The toolbars contain important operator input options, for saving or pasting commands, for example. The toolbars can be positioned as required within the Workbench.

Using the menu **View > Toolbars**, you can display or hide these.

The MCC editor toolbar contains the full range of MCC commands. The list of commands is displayed when you place the cursor on the appropriate button, see Inserting commands (Page 4013).

Key combination

You can input commands quickly in the MCC editor using key combinations. The key combinations available in the MCC editor are listed in the appendix titled Key combinations (Page 4574).

The online help system is called up with Shift+F1 or F1.

Drag and drop

Variables can be moved from the detail view (*Symbol browser* tab) to the input field using a drag and drop operation.

Left-click the line number of the variable you wish to move. The line with the variable is selected. Keeping the left mouse button pressed, drag the line number into the input field of the parameter screen form. As soon as you release the left mouse button, the variable will be inserted at the appropriate position.

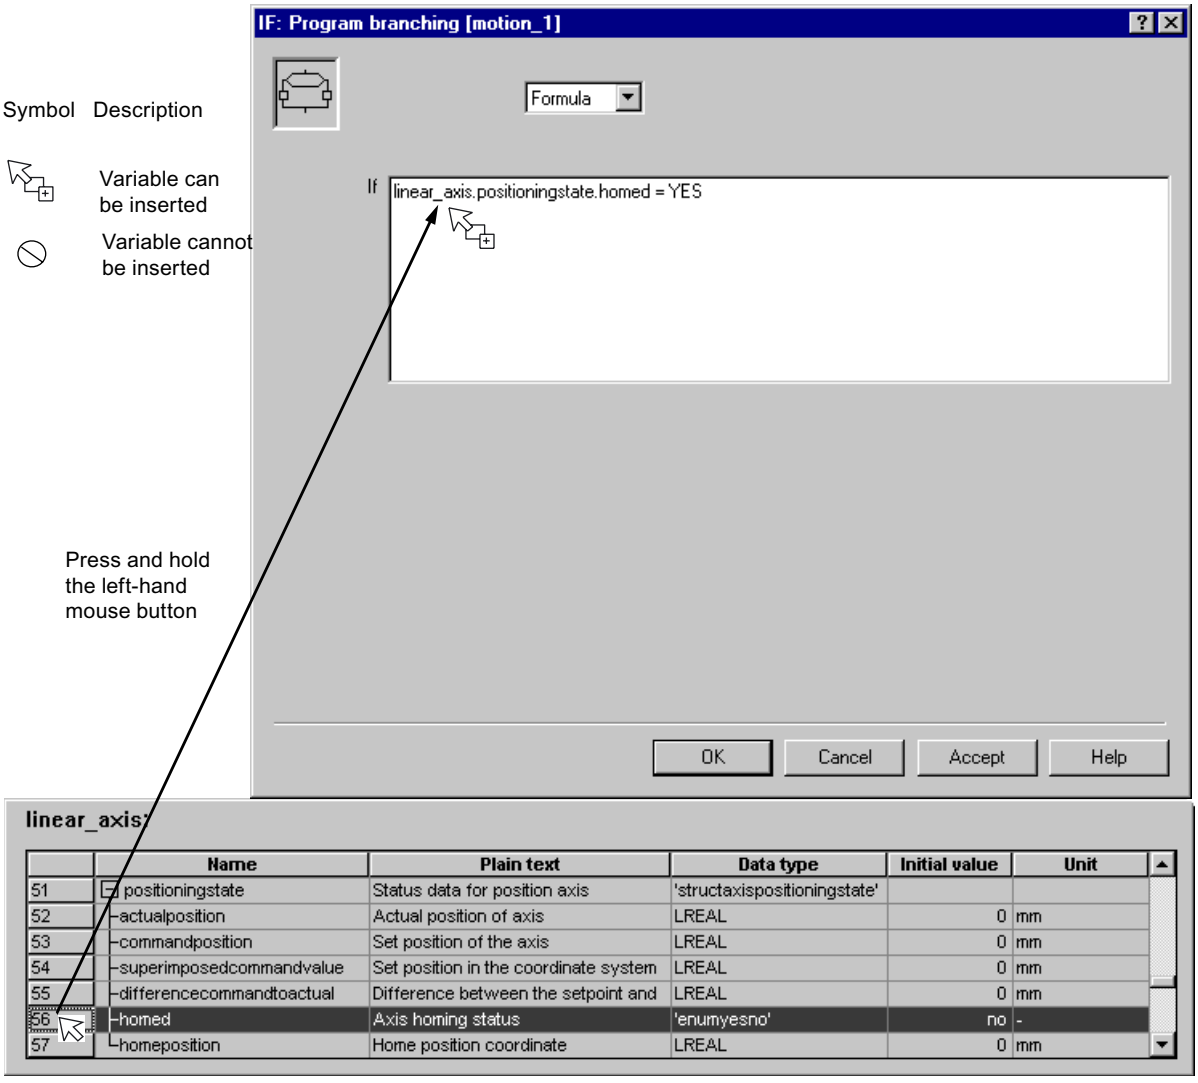

Figure 7-4 Inserting a variable using drag and drop

Automatic completion (Autocomplete)

In the MCC editor, you can automatically complete identifiers. A drop-down list box with identifiers that begin with the previously entered characters will be displayed. This operates on a context-sensitive basis, whereby the expected type for the identifier being sought and its visibility in the current program context determine which entries are displayed as options in the drop-down list box.

Depending on the context, the entries displayed in the drop-down list box are filtered and sorted:

- The filtering process may determine, for example, that only structure components are displayed for a structure.
- Entries are sorted according to their relevance to the context, with the more relevant identifiers appearing higher in the list (e.g. local variables are listed before global variables).

With MCC units and MCC charts, the identifiers can be completed automatically in the following input fields/editable drop-down list boxes:

- Declaration table of the MCC unit
  - "Variable type" column
  - "Data type" column
  - "Type" column
- Declaration table of the MCC chart
  - "Variable type" column
  - "Data type" column
- IF, WHILE, UNTIL, synchronous start MCC commands:
  - Condition in the Formula programming language
- FOR MCC command
  - "Variable" input field (completing a variable name)
  - "Start", "End", and "Increment" input field (completing an identifier within an expression)
- ST zoom MCC command
  - Editing in the ST programming language is supported here, so that automatic completion works the same as with the ST editor.
- Variable assignment MCC command
  - "Variable" column (completing a variable name)
  - "Expression" column (completing an identifier within an expression)
- Subprogram call MCC command
  - "Subprogram" editable drop-down list box
    A connection to the program source (if required) is automatically set up when the subprogram is selected.
  - "Library" editable drop-down list box
    A connection to the library (if required) is automatically set up when the subprogram is selected.
  - "Instance" editable drop-down list box
  - "Value" column
    A connection to the program source/library (if required) is automatically set up when the subprogram is selected.

- System function call MCC command
  - "System function" input field
  - "Return value" input field
  - "Value" column
- Input fields/editable drop-down list boxes in the parameter screen forms for the MCC commands
  All inputs in the input fields/editable drop-down list boxes of the parameter screen forms are supported by automatic completion.

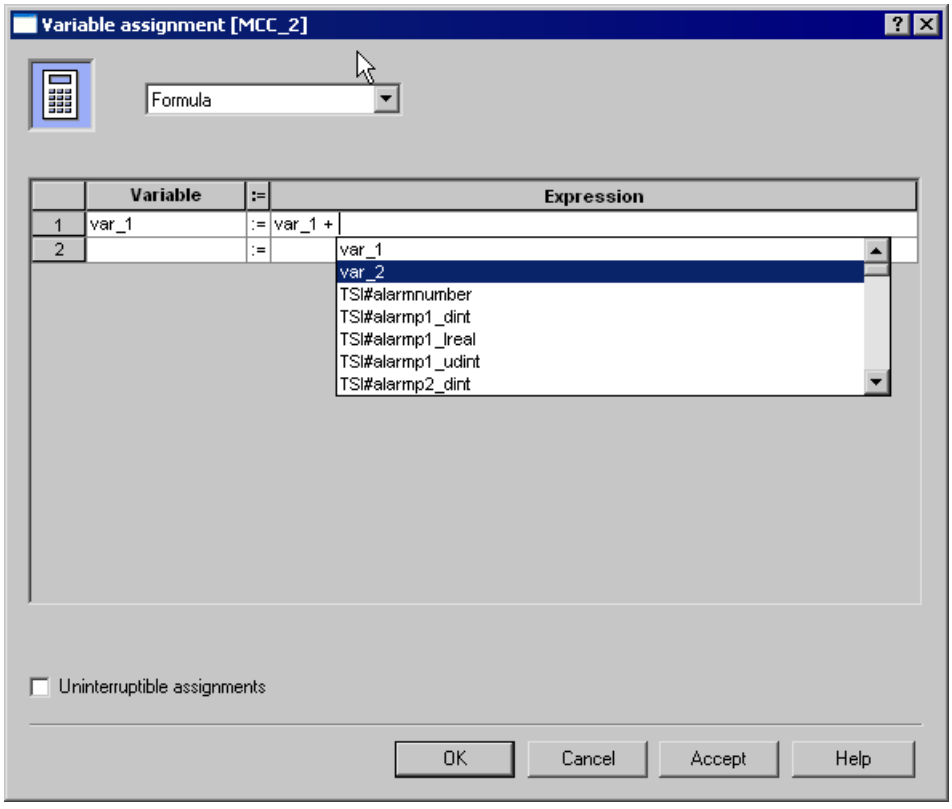

Figure 7-5 Automatic completion of an identifier within an expression

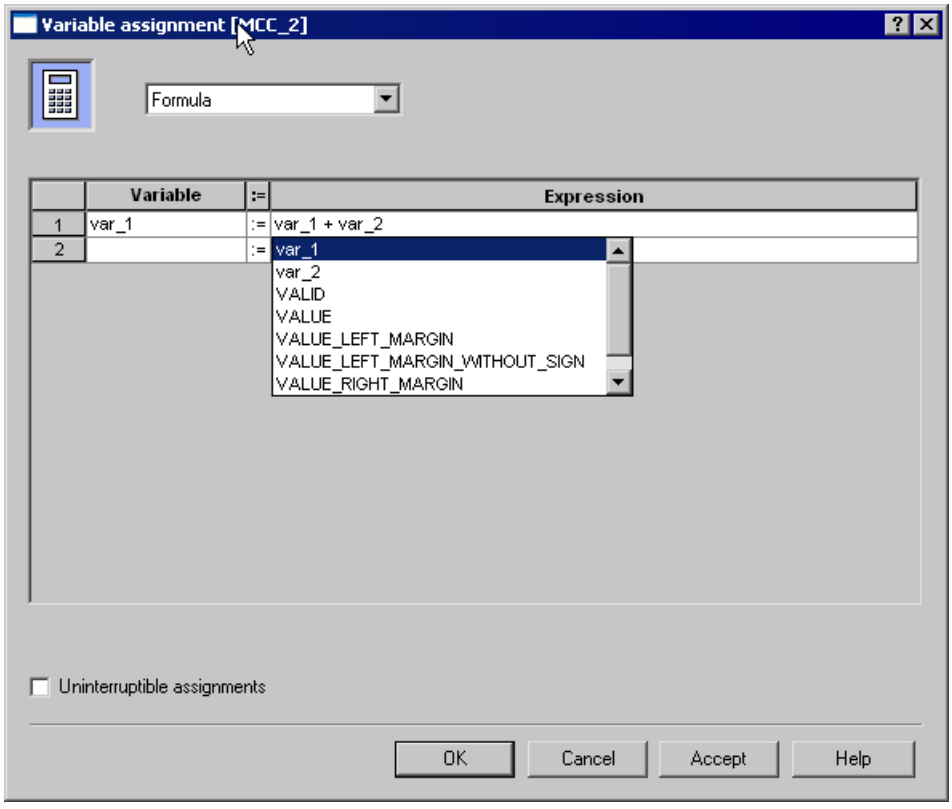

Figure 7-6 Replacing an identifier with another identifier

Procedure

To complete an identifier automatically (Autocomplete), proceed as follows:

1. Write the first characters of the identifier (e.g. the first letters of a word) in the input field/ editable drop-down list box. Alternatively, you can place the cursor anywhere in an existing identifier.
2. Press the **Ctrl+space** key combination.
   A drop-down list box opens containing the filtered/sorted identifiers for the current context. The identifiers listed start with the characters input so far or the characters up to where the cursor is positioned within an existing identifier.

   Note

   When the drop-down list box has been expanded and is editable (by clicking the ▾ symbol), automatic completion is already activated.

3. Expand or refine the options displayed:
   - Enter additional characters.
   - Delete characters.
   - Move the cursor with the left/right arrow keys.

4. Select the required identifier with the up/down arrow keys.
5. Press the **Return** key.
   The identifier is accepted by the input field/editable drop-down list box and the current word is overwritten.

Note

If only a single identifier is offered for selection, the selection window will not be opened and the identifier completed immediately.

Functional description

The following identifiers that begin with the specified characters will be offered:

- ST expressions
- ST program sections
- Identifiers from the command library
- Library, unit, POU, or system function names
- For technology objects including their system variables and configuration data
- Identifiers for the relevant MCC unit / MCC chart:
  - Program organization units (POU)
  - Data types
  - Variables and constants
  - Structure elements
- Identifiers from imported program sources

Note

Identifiers from the relevant MCC unit / MCC chart or from imported program sources will only be displayed correctly if the corresponding program source has been compiled.

The display operates on a context-sensitive basis, i.e. only those types of identifiers that are appropriate at the associated location of the MCC unit / MCC chart are offered:

- Within a declaration table, data types and variable types only
- Within a program organization unit (POU), no data types
- For a structure, structure components only (e.g. var_struct.xx)

7.1.3.4 Settings for the MCC editor

You can adjust important properties of the MCC editor to suit your individual requirements.

1. Select the menu **Options > Settings**.
   The **Settings** dialog box opens.
2. Select the **MCC editor** tab.
3. Make the required settings here.
4. Click **OK** or **Accept** to confirm.

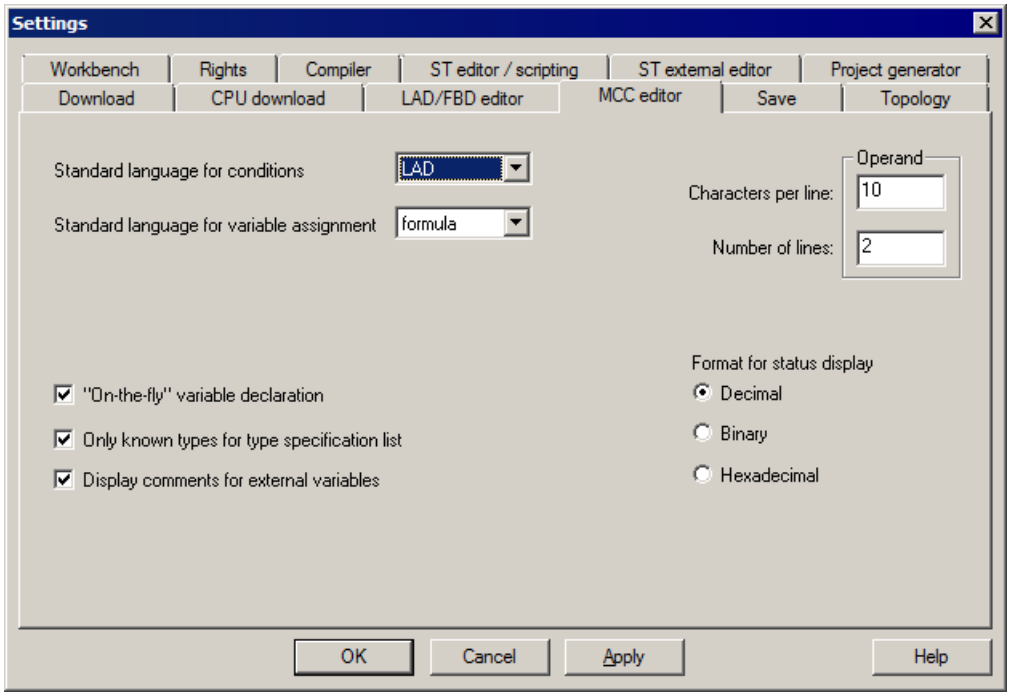

Figure 7-7 Settings for the MCC editor

The table below contains a description of the individual parameters.

Table 7-1 MCC editor parameter settings

Parameter	Description
Standard language for conditions	In the case of conditions, you can define the language set on opening. Possible settings are LAD, FBD, or Formula.
Standard language for variable assignment	In the case of a variable assignment, you can define the language set on opening. Possible settings are LAD, FBD, or Formula.
"On-the-fly" variable declaration	If this is active, a dialog box appears when an unknown symbol is input in the parameter screen form for an MCC command. You can perform the variables declaration in this box (see Defining global user variable and local variable in the Variables declaration dialog box ("on-the-fly" variables declaration)) (Page 4067).

Parameter	Description
Only known types if type lists exist	You can choose which function blocks are displayed as data types in the declaration tables for the MCC units and MCC charts: • When the checkbox is activated, the declaration table contains only function blocks that are defined in the same MCC unit or in linked source files or libraries (see Connections to other program sources or to libraries (Page 4114)). • When the checkbox is deactivated, the declaration table contains all function blocks defined in the project.
Display comments for external variables	If activated, the comments specified in the declaration table are displayed in the MCC editor for variables. The comment is displayed in a tool tip at the point where the variable is being used within the parameter screen form for an MCC command. This also applies to external variables declared in another MCC unit or LAD/FBD source file and connected to the current MCC unit. The other MCC unit or LAD/FBD source file needs to have been recompiled beforehand. Comments for variables declared in ST source files cannot be displayed. This also applies to variables of other source files connected to the current MCC unit via an ST source file.
Operand	You can change the options for displaying the operand in the case of conditions or variable assignments (Page 4152) for the LAD and FBD languages by entering the **Number of characters per line** and the **Number of lines** for the Operand field.
Format for status display	Format in which the variable values with bit data type are displayed for program status (Page 4542) and variable status (Page 4530).

7.1.3.5 Calling up the online help

The online help can provide assistance for many of the operating steps.

Call up the online help using either the:

- **Help** menu
  - Help topics
  - Context-sensitive help
  - Getting Started
- Using the **Help** button in an open parameter screen form
- Using the **F1** button for general help
- Using keystroke combination **Shift+F1** for context-sensitive help

7.1.4 MCC Source Files and MCC Charts

This chapter describes how to create and work with an MCC unit containing MCC charts.

7.1.4.1 General

MCC units are assigned to the SIMOTION device on which the programs (MCC charts) contained in the MCC unit will subsequently be run (e.g. SIMOTION D455-2). They are stored in the project navigator under the SIMOTION device in the PROGRAMS folder.

MCC charts are the individual program organization units (program, function, function block) in an MCC unit. They are stored under the MCC unit in the project navigator.

Note

ST source files, LAD/FBD units and DCC charts are also stored in the **PROGRAMS** folder under the SIMOTION device.

For a description of the SIMOTION ST (Structured Text) programming language, refer to the SIMOTION ST Programming and Operating Manual.

For a description of the SIMOTION LAD (Ladder Diagram) and SIMOTION FBD (Function Block Diagram) programming languages, refer to the SIMOTION LAD/FBD Programming and Operating Manual.

7.1.4.2 Inserting and managing MCC source files

Inserting a new MCC source file

MCC units are assigned to the SIMOTION device on which the programs (MCC charts) contained in the unit will subsequently be run (e.g. SIMOTION D455-2). They are stored in the project navigator under the SIMOTION device in the PROGRAMS folder.

The individual program organization units (POU, MCC charts) are stored under an MCC unit.

You can insert a new MCC unit in the following ways:

- In the project navigator: in the **PROGRAMS** folder using the **Insert MCC unit** element
- Select the **PROGRAMS** folder in the project navigator followed by **Insert > Program > MCC unit**
- Select the **PROGRAMS** folder in the project navigator followed by **Insert new object > MCC unit** in the context menu

Procedure

To insert a new MCC unit using the context menu, proceed as follows:

1. Open the appropriate SIMOTION device in the project navigator.
2. Select the **PROGRAMS** folder.
3. Select the **Insert new object > MCC unit** context menu.

4. Enter the name of the MCC unit.
   The names of program sources must comply with the rules for identifiers (Page 4047): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters.
   The permissible length of the name depends on the SIMOTION Kernel version:
   - SIMOTION Kernel as of version V4.1: Maximum 128 characters.
   - SIMOTION Kernel up to version V4.0: Maximum 8 characters.

   Names must be unique within the SIMOTION device. Protected or reserved identifiers are not permitted.
   Existing program sources (e.g. ST source files, MCC units) are displayed.
5. If necessary, select the **Compiler** tab and make any local compiler settings; see Local compiler settings (Page 3997).
6. You can also enter an author, version, and a comment.
7. Activate the **Open editor automatically** checkbox.
8. Confirm with **OK**.

Note

When you click **OK**, the MCC unit will only be transferred to the project. The data, together with the project, is only saved to the data carrier if you select, for example, **Project > Save**, **Project > Save and compile changes**, or **Project > Save and recompile all**.

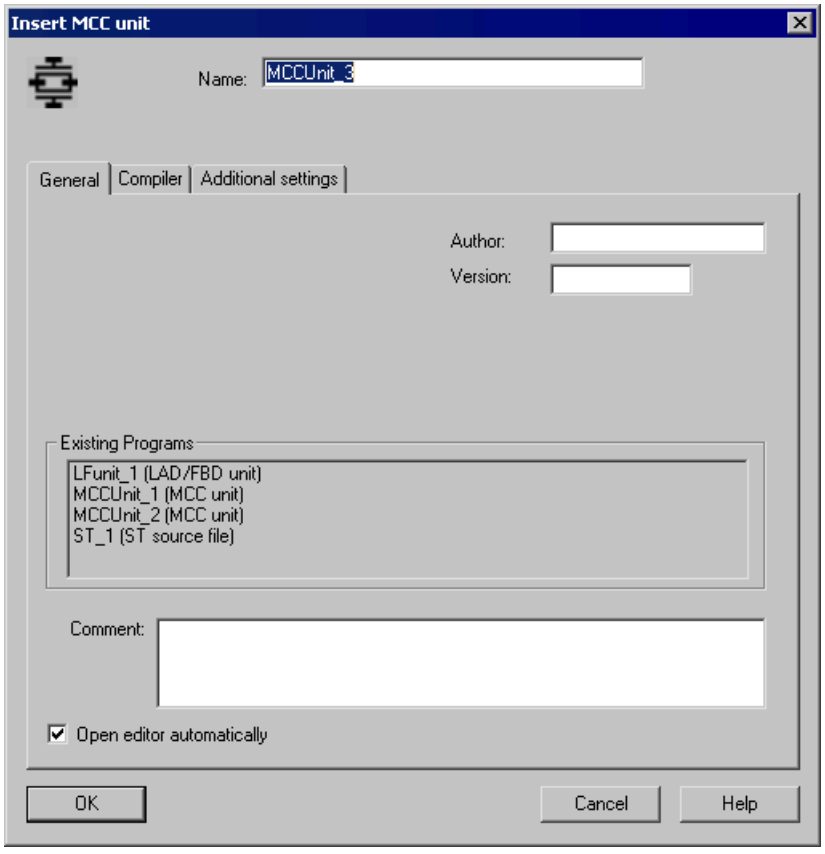

Figure 7-8 Creation dialog for a new MCC unit

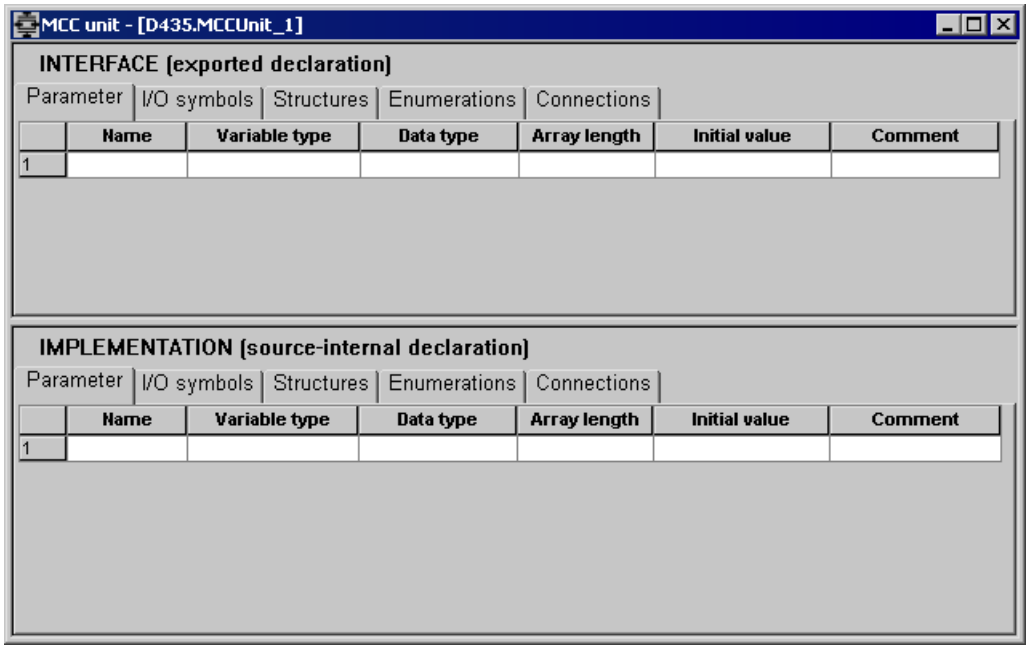

Figure 7-9 New MCC unit (declaration table for the interface and implementation sections)

Opening existing MCC source files

Procedure

To open an MCC unit:

1. Open the subtree of the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder.
3. Select the required MCC unit.
4. Select the **Open** context menu.
5. Only for MCC units with know-how protection (Page 3992):
   If the MCC unit (or a chart for this unit) is not already open and the login assigned to the MCC unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (until the unit and all its charts are closed).
   - If required, activate the "Use login as a standard login" checkbox.
     You will be logged in with this login and can now open additional units to which the same login is assigned without having to re-enter the password.

The MCC unit (declaration table) is opened in the working window. Multiple units can be opened.

Note

You can also double-click the required MCC unit to open it.

Transferring and compiling an MCC source file

Procedure:

1. To transfer an MCC unit with its associated MCC charts to the project and start its compilation, proceed as follows:
2. Make sure that the MCC unit or one of the associated MCC charts is the active window in the Workbench.
   Select one of the following menu commands:
   - **Accept and compile** button in the **MCC unit** or **MCC editor** toolbar
   - **MCC unit > Accept and compile** menu item or **MCC chart > Accept and compile** menu item

Alternative way of saving and compiling:

- Select the MCC unit or an MCC chart in the project navigator; then, in the context menu, select **Accept and compile**.

Note

The **Accept and compile** command transfers the changes in the MCC unit and associated MCC charts to the project only. The data, together with the project, is only saved to the data carrier if you select **Project > Save**, **Project > Save and compile changes**, or **Project > Save and recompile all**.

As of Version V4.2 of SIMOTION SCOUT, you no longer need to observe the POU order in the MCC unit, although the following exception applies:

When a project is saved in a format older than Version V4.2 of SIMOTION SCOUT, the MCC chart order in the MCC unit is of relevance as far as compilation is concerned. A subprogram (function, function block, or program ("program in program")) must be defined before it is used. This is the case when the MCC chart of the subprogram appears above the chart in which it is used in the project navigator. If necessary, resort the charts (see Subprogram call of function (FC) (Page 4129)).

Before saving a project in a format older than Version 4.2, you can check the project for downward compatibility (including the correct order of the POUs) via **Project > Old project format > Check the project for downward compatibility**.

You can also save (export) an MCC unit outside the project (see Exporting and importing MCC units (Page 3992)).

Error messages and warnings relating to compilation are displayed in the Compile/check output tab in the detail view.

Note

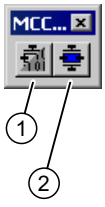
If certain commands (for example, Synchronous Start, Uninterruptible Variable Assignment) are included in the MCC chart, *UserInterruptTask_1* must be configured in the execution system in order to ensure error-free compilation. You must program the error reactions to these commands in *UserInterruptTask_1*.

If you receive an applicable error message, proceed as follows:

1. Insert an MCC chart for a program, and program the appropriate error reactions.
2. Assign the program to *UserInterruptTask_1*.

MCC unit toolbar

This toolbar contains important command buttons for an MCC unit:



① Accept and compile
② Insert MCC chart

Figure 7-10 MCC unit toolbar

This toolbar is active if an MMC unit is visible in the foreground of the Workbench working area.

Closing an open MCC source file

To close an open MCC unit in the working window, do one of the following:

- Click the **x** button in the header
- Select the **MCC unit > Close** menu command
- Select the **Window > Close all windows** menu command

If the changes have not yet been saved in the project, you can save or cancel them, or abort the close operation.

Cutting, copying, and deleting an MCC source file

You can cut or copy an MCC source file and all of its associated MCC charts and paste them under the same or a different SIMOTION device.

If the MCC source file is deleted after it is copied, its data will also be deleted from the clipboard and the MCC source file can no longer be inserted.

Note

When an MCC unit or MCC chart is copied under a SIMOTION device with an earlier version of SIMOTION Kernel, the reliability of commands and their parameterization is only checked when the MCC chart is opened or when the MCC unit or the project is compiled.

Procedure

Follow these steps:

1. Select the MCC source file in the project navigator.
2. In the context menu, select the appropriate item (**Cut**, **Copy**, or **Delete**).

Pasting a cut or copied MCC source file

Procedure

To insert a cut or copied MCC unit, proceed as follows:

1. Under the SIMOTION device, select the **PROGRAMS** folder.
2. In the context menu, select **Paste**.
   The MCC unit is inserted (with a different name, if necessary).
3. Change the name, if necessary (see Renaming MCC source files (Page 3995)).

Note

When an MCC unit or MCC chart is copied under a SIMOTION device with an earlier version of SIMOTION Kernel, the reliability of commands and their parameterization is only checked when the MCC chart is opened or when the MCC unit or the project is compiled.

Know-how protection for MCC source files

You can protect MCC units from access by unauthorized third parties. Protected MCC units and all associated MCC charts can only be opened or exported as ST source files when the password is entered.

The SIMOTION online help provides additional information on know-how protection.

Note

If you export in XML format, the MCC units are exported in an encrypted format. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

Exporting and importing an MCC source file

The export and import functions offer you the option of saving an MCC unit outside the project on your hard disk so that you can copy it from there into another project.

You can export an MCC unit as a text file for the SIMOTION ST (Structured Text) programming language. You can either import this file as an ST source file or edit it with any ASCII editor.

You can also export/import an MCC unit as an encoded XML file.

Exporting an MCC source file as an ST source file

You can export an MCC unit as a text file for the SIMOTION ST (Structured Text) programming language. You can either import this file as an ST source file or edit it with any ASCII editor.

Procedure

Follow these steps to export an MCC unit as an ST source file in ASCII format:

1. Open the MCC unit (Page 3989), entering the password if necessary (for MCC units with know-how protection (Page 3992)).
2. Make sure the declaration table for the MCC unit is the active window.
3. Select the **MCC unit > Export as ST** menu command.
4. Enter the path and file name for the ST source file and click **Save** to confirm.

The MCC unit is saved as an ST source file in ASCII format; the file name is given the default extension *.st

Alternatively, you can also proceed as follows:

1. Select the MCC unit in the project navigator.
2. Select the **Export as ST** context menu.
3. Only for MCC units with know-how protection (Page 3992) and which are not already open: If the MCC unit (or a program of this unit) is not already open and the login assigned to the MCC unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (for this export).
   - If required, activate the **Use login as a standard login** checkbox.
     You will be logged in with this login and can now export or open additional units to which the same login is assigned without having to re-enter the password.
4. Enter the path and file name for the ST source file and click **Save** to confirm.

Note

Text files for the ST programming language cannot be imported as MCC units.

An MCC unit with know-how protection is exported without protection.

Exporting an MCC source file in XML format

Procedure

This operation allows you to save an MCC unit in encoded form in a directory outside the project.

1. Select the MCC unit in the project navigator.
2. Select the **Expert > Save project and export object** context menu.
3. Select the directory for the XML export and confirm with **OK**.

Note

Know-how-protected MCC units can also be exported in XML format. The know-how protection is retained when the files are imported. The MCC units are exported in encrypted format. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

Importing an MCC source file from XML data

Procedure

This operation allows you to import MCC source files that were exported as encoded files in XML format.

1. In the project navigator, select the **PROGRAMS** folder.
2. In the context menu, select the **Import object** command.
3. Select the XML data to be imported.

The entire project is saved and recompiled.

Note

Individual objects (e.g. MCC source files) from a project that was exported as XML data cannot be imported selectively.

Properties of an MCC source file

Procedure

1. Under the SIMOTION device, open the **PROGRAMS** folder.
2. Select the required MCC unit.
3. Select the **Edit > Object properties** menu command.
4. If necessary, select further tabs to make local settings (only valid for this MCC unit):
   - **General** tab: General details on the MCC unit, e.g. time stamp of the last change, storage location of the project (see figure).
   - **Compiler** tab: Local settings of the compiler (Page 3997) for code generation and message display.
   - **Additional settings** tab: Display of the compiler options in accordance with the current compiler settings (refer to SIMOTION ST Programming and Operating Manual).
   - **Compilation** tab: Display of the compiler options the last time the MCC unit was compiled (refer to SIMOTION ST Programming and Operating Manual).
   - **Object address** tab: Set the internal object address of the MCC unit. The object addresses of the other program sources are displayed.

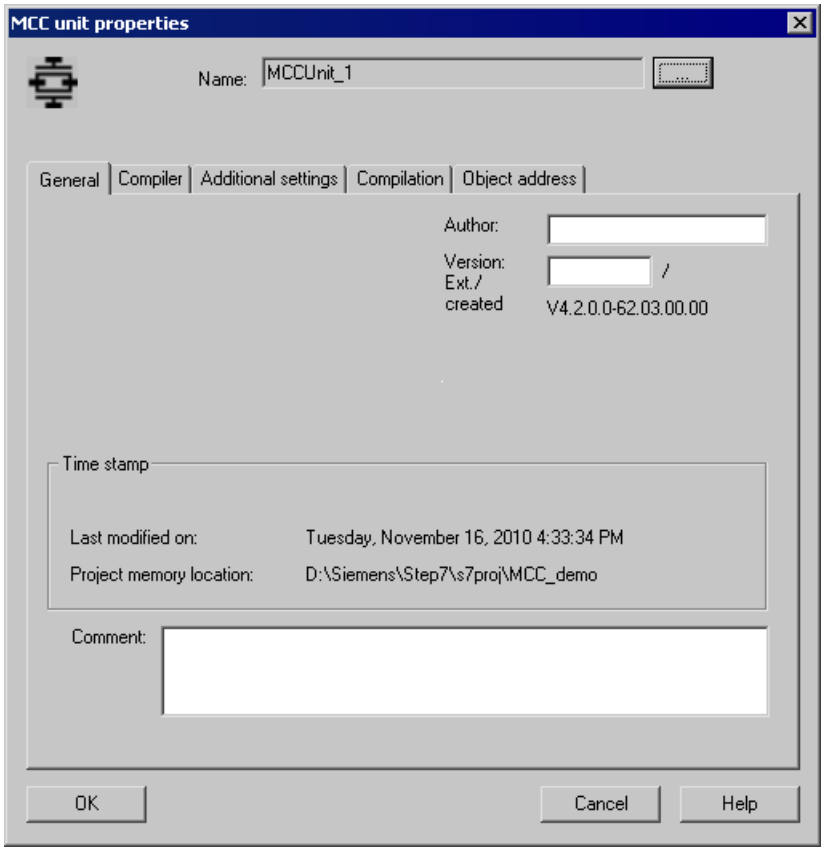


Figure 7-11 Properties of an MCC unit

Renaming MCC source files

To rename an MCC source file, proceed as follows:

1. Open the Properties window of the MCC source file.
2. Click ... .
3. Click **OK** to confirm.

using test functions

You can make use of various test functions during program execution. Additional code must be generated for some test functions (e.g. program status, single step or trace). You enter these settings in the compiler options:

1. Select the **Compiler** tab.
2. Make the necessary settings (see Local compiler settings (Page 3997)).

These functions facilitate debugging of your program.

Configuring compiler settings

You can configure the compiler settings as follows:

- Globally for the SIMOTION project, always valid for all programming languages, see Global settings of the compiler (Page 3996)
- Locally for an individual MCC source file within the SIMOTION project, see Local settings of the compiler (Page 3997)

Global compiler settings

The global settings are always valid for all programming languages within the SIMOTION project. If there are global settings which only apply to specific programming languages, this is specified on the **Compiler** tab.

Procedure

1. Select the menu **Options > Settings**.
2. Select the **Compiler** tab.
3. Make the settings in accordance with the parameter description in the SIMOTION ST Programming and Operating Manual.
4. Confirm with **OK**.

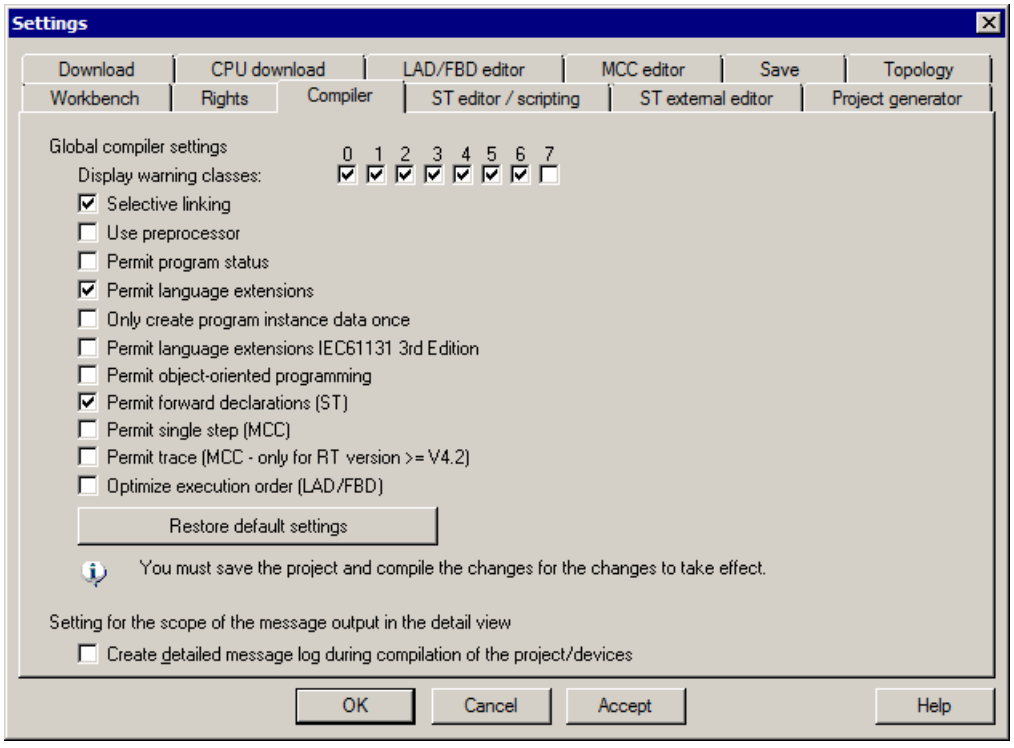

Figure 7-12 Global compiler settings

Parameter

For a description of the parameters of the global compiler settings, refer to SIMOTION ST Programming and Operating Manual.

Local compiler settings

Local settings are configured individually for each MCC source file; local settings overwrite global settings.

Procedure

To select the compiler options, proceed as follows:

1. Open the Properties window for the MCC source file, see Properties of an MCC source file (Page 3994).
2. Select the **Compiler** tab.
3. Define the settings according to the following table.
4. Click **OK** to confirm.

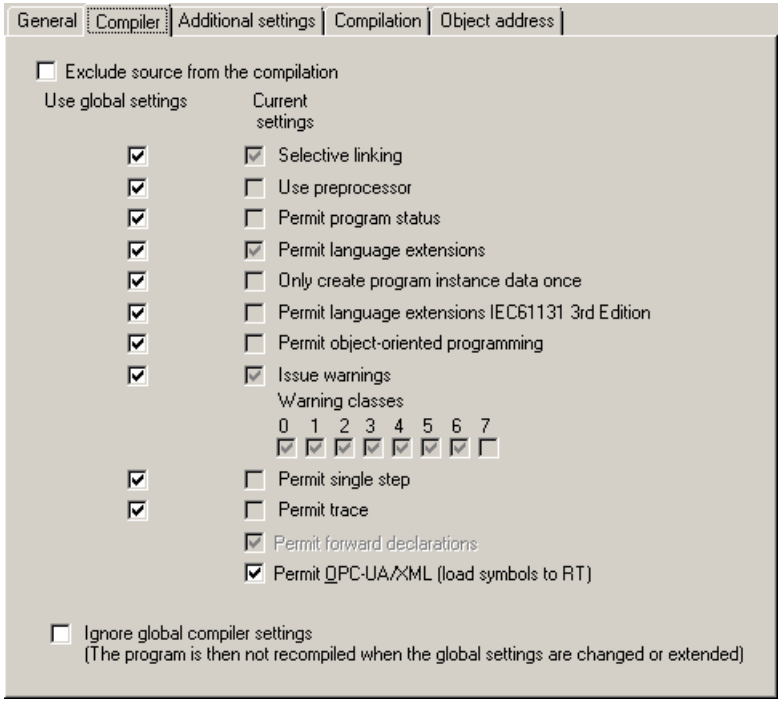

Figure 7-13 Local compiler settings for MCC source files in the Properties window

The current compiler options (the combination of global and local compiler settings which currently applies) for the program source are displayed on the **Additional settings** tab. The compiler options used the last time the program source was compiled can be seen on the **Compilation** tab.

The SIMOTION ST Programming and Operating Manual contains further information on what the compiler options mean.

Table 7-2 Local compiler settings

Parameter	Description
Exclude the source from the compilation	**Active**: This source is not compiled upon compilation of the project, the device or the library (e.g. Menu **Project > Save and recompile all**). The source is marked accordingly in the project navigator. Corresponding information is provided upon compilation. **Inactive** (standard): The source is compiled upon compilation of the project, the device or the library.
Use global settings	This checkbox is available for every parameter which also has a global setting. This is where you define whether the global settings are adopted or whether the local settings will apply. See the description under Effectiveness of global or local settings in the SIMOTION ST Programming and Operating Manual. Use the second checkbox or the other checkboxes for the relevant parameters (described below) to define the local settings.
Selective linking[1]	**Active**: Unused code is removed from the executable program. **Inactive**: Unused code is retained in the executable program. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).
Use preprocessor[1]	**Active**: Preprocessor is used, see SIMOTION ST Programming and Operating Manual. **Inactive**: Preprocessor is not used. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).
Enable program status[1]	**Active**: Additional program code is generated to enable monitoring of program variables (including local variables). **Inactive**: Program status not possible. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Program status (Page 4542).
Permit language extensions[1]	**Active**: Language elements are permitted that do not comply with IEC 61131-3. • Direct bit access to variables of a bit data type, see the SIMOTION ST Programming and Operating Manual. • Accessing the input parameter of a function block when outside the function block, see the SIMOTION ST Programming and Operating Manual. • Calling a program while in a different program, see the SIMOTION ST Programming and Operating Manual. **Inactive**: Only language elements are permitted that comply with IEC 61131-3. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).

Parameter	Description
Only create program instance data once[1]	**Active**: The local variables of a program are only stored once in the user memory of the unit. This setting is required when calling a program while in a different program, see the SIMOTION ST Programming and Operating Manual. **Inactive**: The local variables of a program are stored according to the task assignment in the user memory of the associated task. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Memory areas for the variable types in the SIMOTION ST Programming and Operating Manual. For further information, refer to the SIMOTION Basic Functions Function Manual.
Permit language extensions, IEC61131 3rd edition[1]	**Active**: Additional language elements can be used in accordance with IEC 61131-3 3rd edition. The corresponding keywords are locked as reserved or protected identifiers. • Nested block comments (e.g. in the ST magnifying glass (Page 4188)) • MCC command Continue (Page 4217) • Standard-compliant system functions LOWER_BOUND and UPPER_BOUND for determining the limits of a dynamic ARRAY • Additional system functions: – FROM_BIG_ENDIAN – FROM_LITTLE_ENDIAN – IS_VALID – TO_BIG_ENDIAN – TO_LITTLE_ENDIAN **Inactive**: The additional language elements cannot be used. The corresponding keywords are not locked. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). **Note** When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.
Permit object-oriented programming[1]	**Active**: The keywords for object-oriented programming according to IEC 61131-3 3rd edition are locked as reserved or protected identifiers. General references (Page 4086) can also be formed. **Inactive** (standard): The keywords for object-oriented programming are not locked. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). **Note** Independently of the setting the program organization units created in ST sources using object-oriented programming (e.g. classes, methods) can be used in this source. No program organization units can be created in MCC using object-oriented programming. When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

Parameter	Description
Issue warnings Warning classes[1]	In addition to error messages, the compiler can issue warnings and information. You can set the scope of the warning messages to be issued. "Issue warnings" checkbox: **Active**: The compiler issues the warnings and information according to the warning class selection that follows. **Inactive**: The compiler suppresses all warnings and information concerning this source file. The checkboxes for the warning classes are hidden. **Gray background** (display only): Operating on a global setting basis, the compiler always issues warnings and information in accordance with the global warning class selection shown below (if "Use global settings" = active). "Warning classes" checkboxes (only if "Issue warnings" = active): **Active**: The compiler issues warnings and information for the selected class. **Inactive**: The compiler suppresses warnings and information for the associated class. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See also Meaning of the warning classes in the SIMOTION ST Programming and Operating Manual.
Permit single step[1]	**Active**: An additional program code is created, which enables individual program steps to be monitored. **Inactive**: Single step is not possible. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). This function facilitates debugging of your program. See Tracking individual program steps (Page 4534).
Permit trace[1]	Only as of version V4.2 of the SIMOTION Kernel. **Active**: An additional program code is created, which enables monitoring of the program execution in program branches which are executed cyclically. **Inactive**: Trace is not possible. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). This function facilitates debugging of your program. See Tracking program execution using the trace (Page 4538).
Permit forward declarations	Forward declarations enable you to use program organization units (POUs) before they are completely defined. See the SIMOTION ST Programming and Operating Manual. This setting is always **active**. Forward declarations are always permitted for the MCC programming language.
Permit OPC-UA / -XML (load symbols to RT)	**Active:** Symbol information for the unit variables of the MCC source file is available in the SIMOTION device. This is required for: • The *_exportUnitDataSet* and *_importUnitDataSet* functions; see the SIMOTION Basic Functions Function Manual • The watch function of IT DIAG **Inactive:** Symbol information is not created.

Parameter	Description
Ignore global compiler settings (The program is not compiled again if the global settings are changed or extended.)	**Active:** The global settings of the compiler are ineffective for all parameters. The "Use global settings" checkboxes cannot be selected and are grayed out. When changing the global compiler settings, the MCC source is not recompiled. **Inactive:** The checkboxes "Use Global Settings" can be selected for all parameters and are presented against a white background. These checkboxes specify whether the global properties are taken over for the corresponding parameters. See the description under Effectiveness of global or local settings in the SIMOTION ST Programming and Operating Manual.
[1] Global setting is also possible (**Options > Settings > Compiler** menu), see Global compiler settings (Page 3996). See also the description on Effectiveness of global or local compiler settings in the SIMOTION ST Programming and Operating Manual.	

7.1.4.3 Inserting and managing MCC charts

MCC charts are displayed in the project navigator under the respective MCC source file.

Inserting a new MCC chart

You can insert a new MCC chart for an existing MCC unit in any of the following ways (see Insert new MCC unit (Page 3986)):

- In the project navigator: Below an MCC unit using the **Insert MCC chart** command
- Select the required MCC unit in the project navigator followed by **Paste > Program > MCC chart**
- Open the required MCC unit and select the **Insert MCC chart** symbol in the **MCC unit** toolbar

Procedure

To insert a new MCC chart into an existing MCC unit via the menu, proceed as follows:

1. Open the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder.
3. Select the relevant MCC unit in the project navigator.
4. Select **Paste > Program > MCC chart**.
5. Enter the name of the MCC chart.
   The names for MCC charts must comply with the Rules for identifiers (Page 4047): They are made up of letters (A ... Z, a ... z), digits (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters. Protected or reserved identifiers are not permitted.
   The permissible length of the name is 25 characters.
   The names must be unique within the MCC unit. The names of all exportable program organization units (POUs) must also be unique within the SIMOTION device. The names of all MCC charts of the program source as well as the names of all exportable POUs of the device are displayed.

6. Optionally enter the identifier of an object-oriented namespace.
   Identifiers for namespaces must comply with the Rules for identifiers (Page 4047) (see above).
   When an identifier is entered, the MCC chart is assigned to the specified namespace.
   The compiler option (Page 3996) "Permit object-oriented programming" must be activated.
   For further information on object-oriented namespaces, see the appropriate section in the SIMOTION ST Programming and Operating Manual.
7. For creation type, select **Program**. For creation types *Function* and *Function block*, see Subprogram (Page 4117).
8. Activate the **Exportable** checkbox if you would also like the program to be available in other program sources (LAD/FBD, MCC or ST source files) or in the execution system (see Assigning programs to a task (Page 4514)).
9. You can also enter an author, version, and a comment.
10. Activate the **Open editor automatically** checkbox.
11. Confirm with **OK**.

Note

When you click **OK**, the MCC chart will only be transferred to the project. The data, together with the project, is only saved to the data carrier if you select, for example, **Project > Save**, **Project > Save and compile changes**, or **Project > Save and recompile all**.

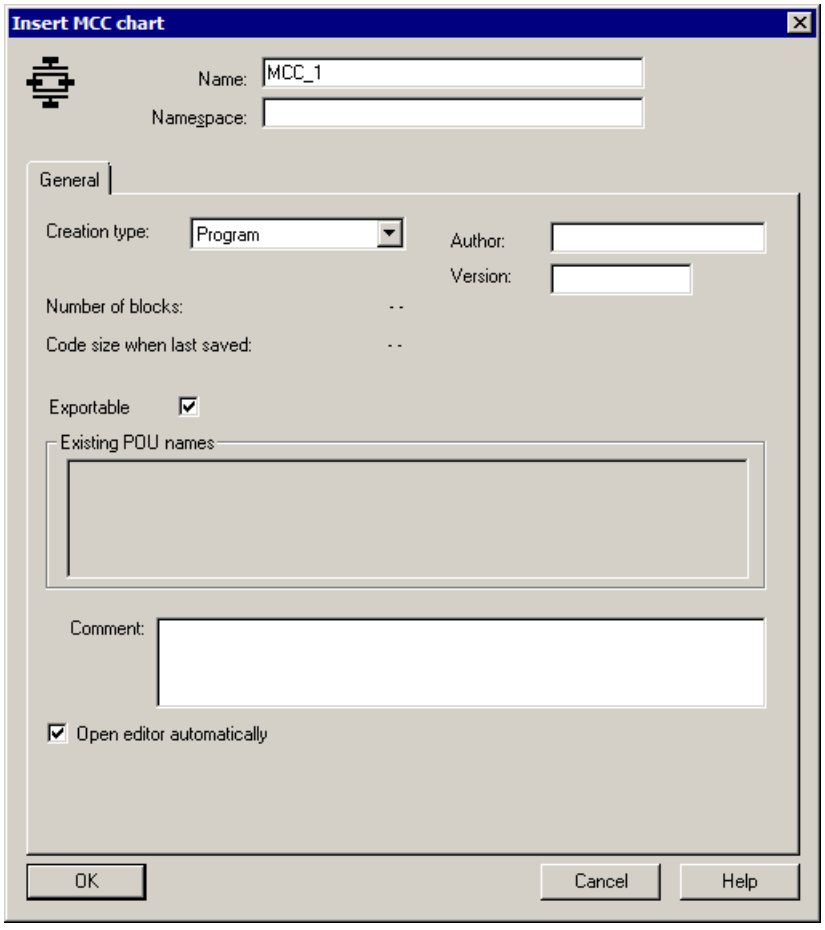

Figure 7-14 Dialog box for creating a new MCC chart

Note

Existing POE names are only displayed if the check box "Show existing POE names (insert dialog POE for LAD/FBD and MCC)" is set in the Settings > Workbench. If there are a large number of POEs in the project, it is recommended to deselect this option, as the computer memory for the process may not be sufficient to refresh the display.

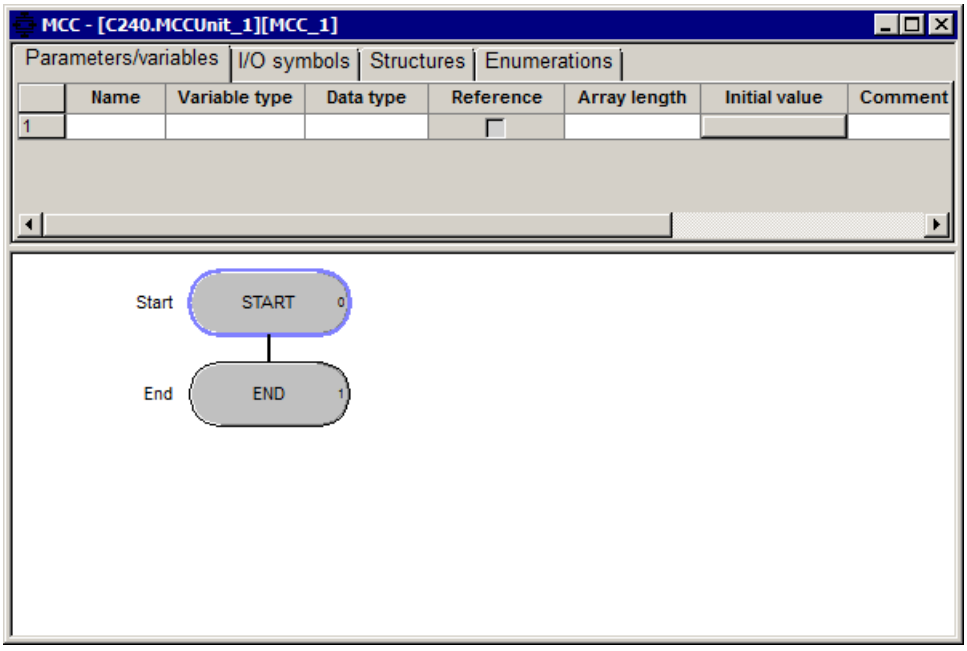

Figure 7-15 New MCC chart with declaration table and starting and end nodes

Opening an existing MCC chart

All MCC charts for an MCC unit are located in the project navigator below the relevant MCC unit.

Procedure

To open an MCC chart, do one of the following:

1. Open the subtree of the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder.
3. Open the MCC unit containing the required MCC chart.
4. Select the required MCC chart.
5. Select the **Open** context menu.
6. Only for charts below MCC units with know-how protection (Page 3992):
   If the MCC unit (or a chart for this unit) is not already open and the login assigned to the MCC unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (until the unit and all its charts are closed).
   - If required, activate the "Use login as a standard login" checkbox.
     You will be logged in with this login and can now open additional units to which the same login is assigned without having to re-enter the password.

The MCC chart is opened in the working window. Multiple MCC charts can be opened.

Note

You can also double-click the required MCC chart to open it.

Transferring and compiling an MCC chart

You cannot compile an MCC chart independently. The MCC source file is always compiled with all of its associated MCC charts (see Transferring and compiling an MCC source file (Page 3989)).

Closing an open MCC chart

To close an open MCC chart in the working window, do one of the following:

- Click the x button in the header
- Select the **MCC chart > Close** menu command
- Select the **Window > Close All Windows** menu command

If the changes have not yet been saved in the project, you can save or cancel them, or abort the close operation.

Cutting, copying, and deleting an MCC chart

You can cut or copy an MCC chart and paste it under the same or a different MCC source file (as well as under a different SIMOTION device).

An MCC chart that has been deleted can no longer be pasted.

Note

When an MCC unit or MCC chart is copied under a SIMOTION device with an earlier version of SIMOTION Kernel, the reliability of commands and their parameterization is only checked when the MCC chart is opened or when the MCC unit or the project is compiled.

Procedure

Follow these steps:

1. Select the MCC chart in the project navigator.
2. In the context menu, select the appropriate item (**Cut**, **Copy**, or **Delete**).

Pasting a cut or copied MCC chart

Procedure

Proceed as follows to paste a cut or copied MCC chart:

1. Select an MCC source file in the project navigator.
2. In the context menu, select **Insert**.
   The MCC chart is inserted with a different name.
3. Change the name, if necessary (see Renaming MCC charts (Page 4009)).

Note

When an MCC unit or MCC chart is copied under a SIMOTION device with an earlier version of SIMOTION Kernel, the reliability of commands and their parameterization is only checked when the MCC chart is opened or when the MCC unit or the project is compiled.

Specifying the order of MCC charts in the MCC source file

As of Version V4.2 of SIMOTION SCOUT, the user no longer needs to respect the POE order in the MCC unit, as the order no longer has any significance in terms of the ability to perform compilation. The only reason to change the POE order is to ensure the POEs are arranged in a more logical way from the user's perspective.

Exception

When a project is saved in a format older than Version V4.2 of SIMOTION SCOUT, the MCC chart order in the MCC unit is of relevance as far as compilation is concerned. A subroutine (function, function block, or program ("program in program")) must be defined before it is used. This is the case when the MCC chart of the subroutine appears above the chart in which it is used in the project navigator. If necessary, reorder the charts (see Subroutine call of function (FC) (Page 4129)).

Before saving a project in a format older than Version 4.2, you can check the project for downward compatibility (including the correct order of the POUs) via **Project > Old project format > Check the project for downward compatibility**.

Procedure

To change the order:

1. Select an MCC chart in the project navigator.
2. In the shortcut menu, select **Up/Down**.

Exporting and importing an MCC chart

The export and import functions offer you the option of saving an MCC chart outside the project on your hard disk so that you can copy it from there into another project.

If you have exported an MCC chart using an older software version, it can be imported and processed with any of the later software versions.

Exporting an MCC chart in XML format

You can use an XML export to save individual MCC units in a directory outside the project, independently of any particular version or platform.

Procedure

To export an MCC chart in XML format, proceed as follows:

1. Select the MCC chart in the project navigator.
2. Select the **Export as XML** command in the context menu.
3. Only for MCC charts in MCC units with know-how protection (Page 3992) and which are not already open:
   If the associated MCC unit (or a program of this unit) is not already open and the login assigned to the MCC unit is not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this chart is temporarily canceled (for this export).
   - If required, activate the **Use login as a standard login** checkbox.
     You will be logged in with this login and can now export or open additional units to which the same login is assigned without having to re-enter the password.
4. Enter the path and file name for the XML export and click **Save** to confirm.

The MCC chart is saved as XML format; the file name is given the default extension *.xml

Note

An MCC chart with know-how protection is exported without protection.

Importing an MCC chart from XML data

This operation allows you to import an MCC chart that was exported as a decoded file in XML format.

Procedure

1. Select the MCC unit in the project navigator.
2. In the context menu, select the **Import MCC chart > From MCC format** command.
3. Select the XML data to be imported.

Note

Individual objects (e.g. MCC charts) that were exported as XML data cannot be imported selectively.

Importing an MCC chart

This operation imports an MCC chart that was exported as an MCC chart in an earlier version of SIMOTION SCOUT into an existing MCC unit.

Note

An MCC chart cannot be exported into the corresponding format in the current version of SIMOTION SCOUT.

Procedure

1. Select the relevant MCC source file in the project navigator.
2. In the context menu, select **Import MCC Chart > From MCC Format**.
3. Select the directory and file name (name.mcc).
   The dialog window for inserting an MCC chart is displayed.
4. Enter the name of the MCC chart in the project.

If the existing technology objects do not match the MCC chart to be imported, it is possible to create them later.

Properties of an MCC chart

Procedure

The properties of an MCC chart are already defined when you insert it. However, these properties can be viewed and modified by doing the following:

1. Select the MCC chart in the project navigator.
2. In the shortcut menu, select **Properties**.
   The **MCC chart properties** dialog box opens.

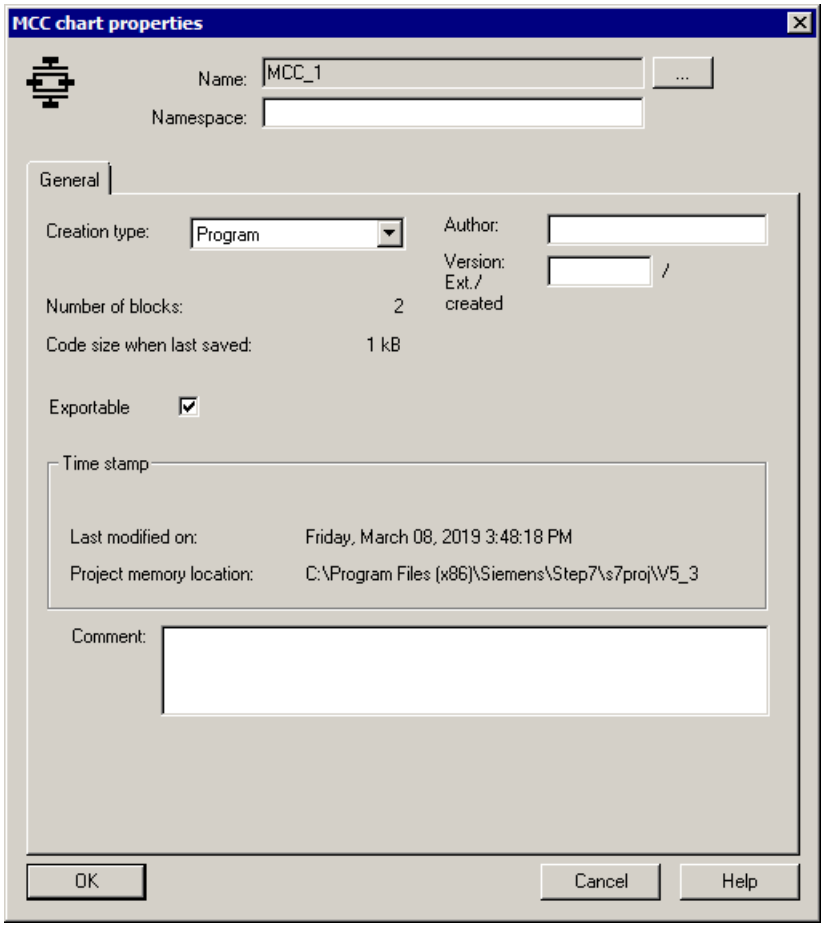

Figure 7-16 Properties of an MCC chart

Renaming MCC charts

To change the name of an MCC chart, proceed as follows:

1. Open the Properties window of the MCC chart.
2. Click ... .
3. Enter the new name for the MCC chart (see Rules for identifiers (Page 4047)).
4. Click **OK** to confirm.

Assigning an MCC chart to an object-oriented namespace

Proceed as follows to assign an MCC chart to an object-oriented namespace:

1. Open the Properties window of the MCC chart.
2. Enter the identifier of an object-oriented namespace in the **Namespace** field. Identifiers for namespaces must comply with the Rules for identifiers (Page 4047).
3. Confirm with **OK**.

When an identifier is entered, the MCC chart is assigned to the specified namespace. The compiler option (Page 3996) "Permit object-oriented programming" must be activated.

For further information on object-oriented namespaces, see the appropriate section in the SIMOTION ST Programming and Operating Manual.

Changing the creation type of the MCC chart

To change the creation type of an MCC chart, proceed as follows:

1. Open the Properties window of the MCC chart.
2. Select the new creation type (**Program**, **Function** or **Function block**).
3. Click **OK** to confirm.

Changing usability in other program sources (export capability)

To change the export capability of an MCC chart, proceed as follows:

1. Open the Properties window of the MCC chart.
2. If required, activate the **Exportable** checkbox.
   With activated checkbox, the MCC chart can be used in other program sources (e.g. MCC units, ST source files). A program can be assigned to a task only when this checkbox is activated (see assigning programs to a task (Page 4514)).
   When the checkbox is deactivated, the MCC chart can only be used in the associated MCC unit.
3. Click **OK** to confirm.

MCC chart overview

As the width and height of MCC charts are capable of exceeding the size of the editor window, you can create a separate overview window for every MCC chart. You can move this overview window outside of the Workbench, e.g. to a second monitor. You can gain an aerial view of the MCC chart by adjusting the size of the window and the zoom factor.

Call up overview window

Requirement: The MCC chart must be opened in the editor and be in the foreground of the working range.

Proceed as follows to open the overview window (alternatives):

- Select the **MCC chart > Overview** menu command.
- Select **Overview** from the shortcut menu.
- Press the CTRL+SHIFT+O shortcut key.

The Overview window opens; it is specific to the relevant MCC chart.

Using the Overview window

You can move the window on the screen as you wish and move it outside of the Workbench e.g. to a second screen. You can maximize or minimize the window as you wish by dragging the edges of the window.

The window is merely an overview. It cannot be used for editing the MCC chart, e.g. for selecting or editing commands. The MCC command currently selected in the editor is marked in blue.

You can change the representation size of the chart gradually using the  and  buttons.

If the "Editor frame" check box is enabled the area of the MCC chart visible in the editor is marked by a black frame.

Process for modules, see Module formation (Page 4019):

- When opening the module (in the Editor shortcut menu **Edit modules > Zoom into module**): A new "Levels" tab is opened in the overview window.
- When closing the module (in the Editor shortcut menu **Edit modules > Zoom out of module**): The last tab opened in the overview window is closed.

The overview window is also closed when the MCC chart is closed.

7.1.5 Programming in MCC

This chapter contains detailed instructions on how to program in the MCC language.

7.1.5.1 Principles of programming

General principles of programming

Every new MCC chart already contains a starting and an end node. You program commands and instructions between these two nodes. The commands you program are executed from the starting node in the direction of the end node.

Motion commands

Motion commands are executed based the transition behavior and step enabling conditions that are selected in the parameter screen forms.

Motion commands can be issued from all tasks.

The overall status of an axis motion is recorded in the system and can be queried at any time using system variables. A command can be waiting, active, or inactive.

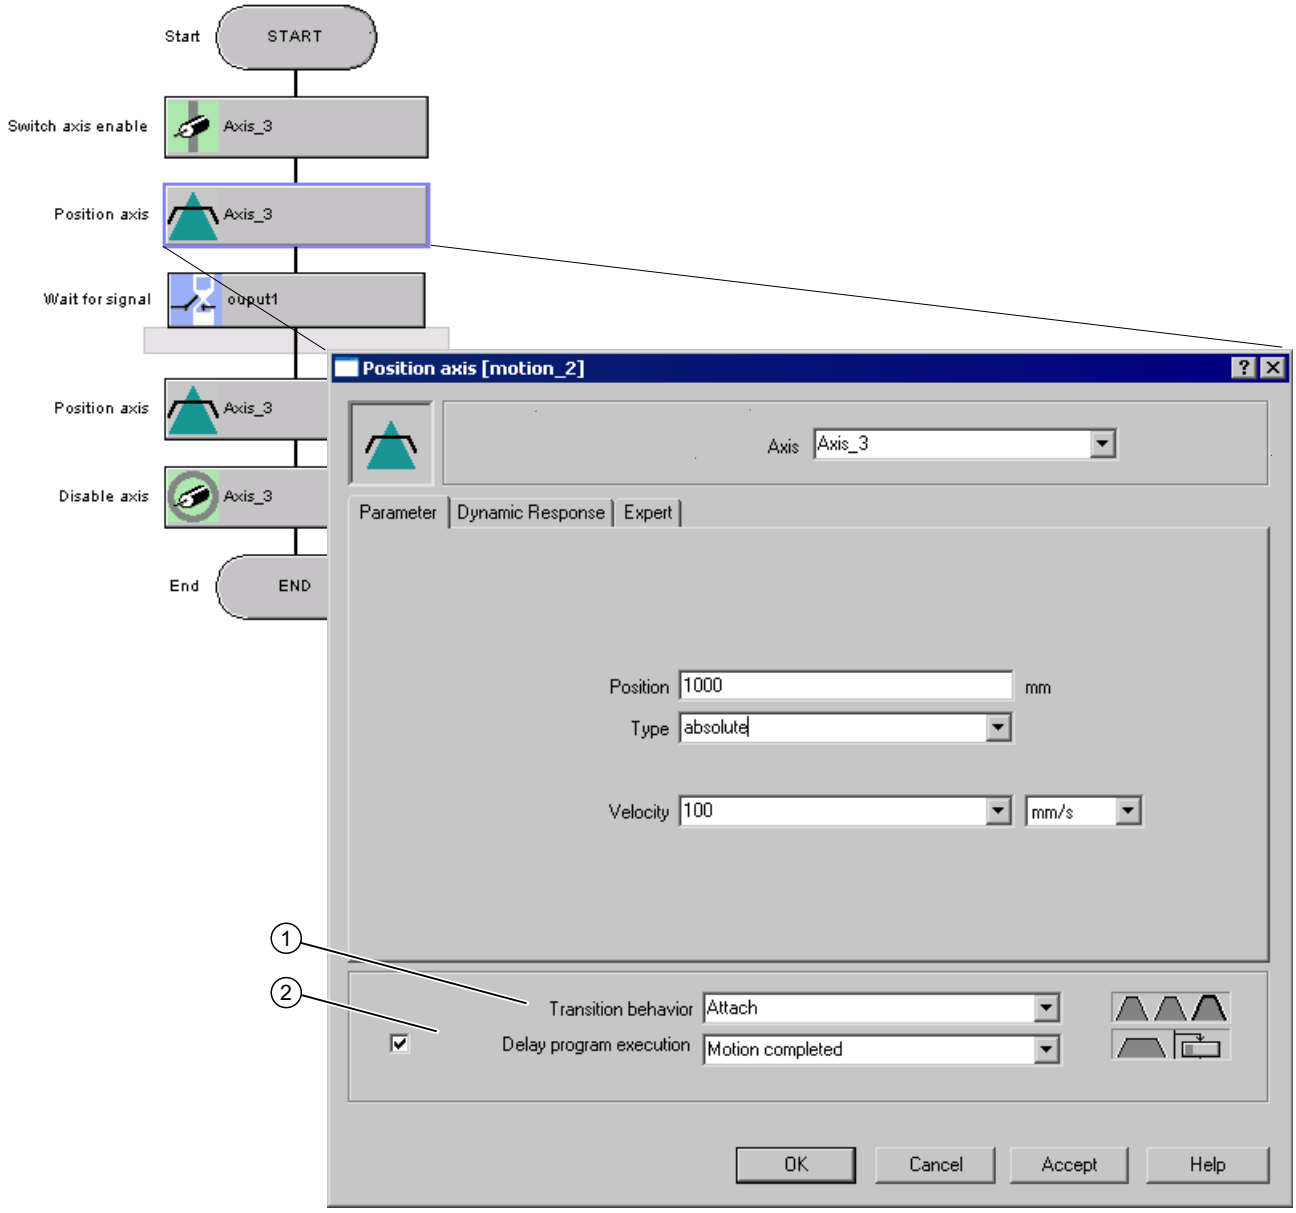
wait commands

Execution of the task is delayed until the programmed event (that is, the condition) occurs. The program is not executed again cyclically, and the task does not require any processor time. All other tasks continue to run unaffected.

The events are scanned in the interpolator cycle clock (IPO cycle clock). If the appropriate event occurs, the highest-priority task in its own level is continued. In the case of MotionTasks, the subsequent motion command is executed in the following IPO cycle clock.

Simplified example of programming principles

Axis_3 will move to absolute position 1,000 mm at a velocity of 100 mm/s. As soon as output 1 is switched, axis_3 will move back to position 0 mm.



① Attach transition behavior:
After switching the axis enable, the program switches to the positioning command.

② Delay program execution:
The next command is started when the axis motion has ended.

Figure 7-17 Example of programming principles

7.1.5.2 Managing MCC commands

inserting commands

You can insert commands into the MCC chart using one of the following:

- The context menu or
- MCC editor toolbar
- **MCC chart > Paste** menu command

Context menu

The context menu of an MCC chart opened in the working area contains the complete range of commands. The commands are divided into the same command groups as for the MCC editor function bar, but without the **Important commands** command group.

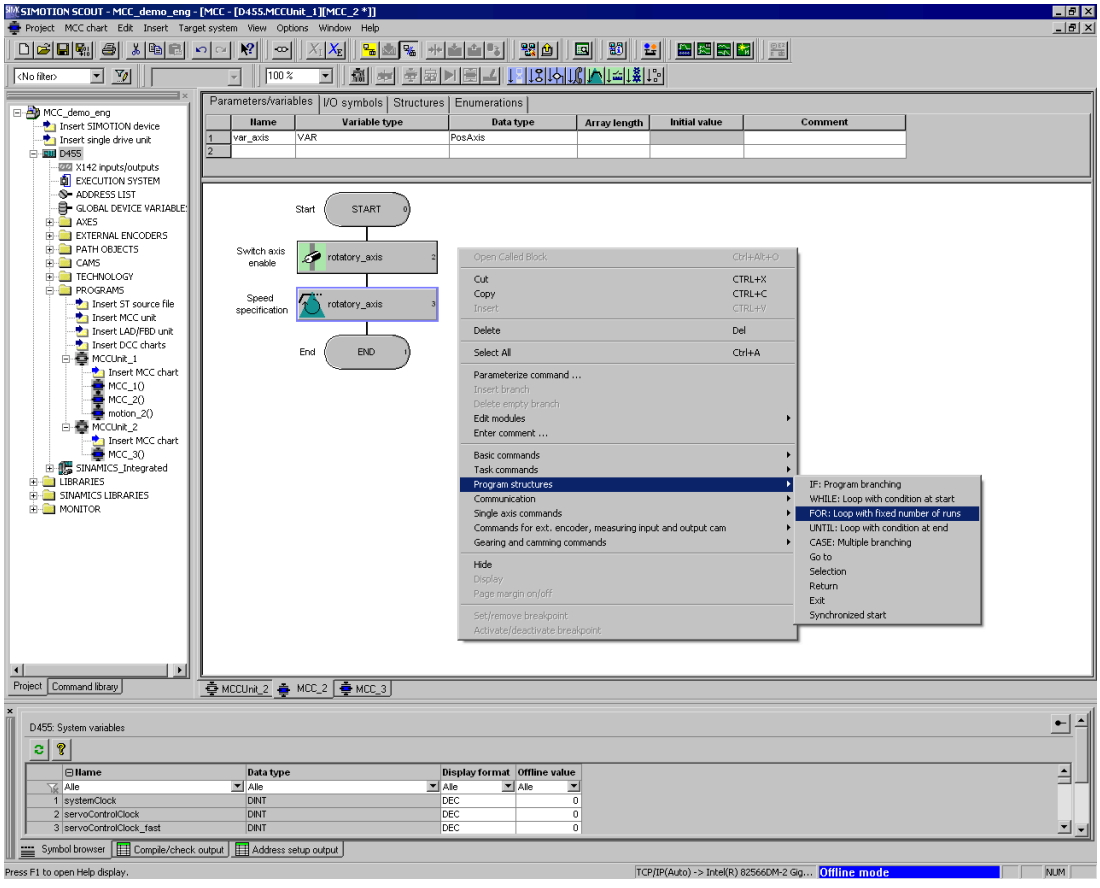


Figure 7-18 MCC editor context menu

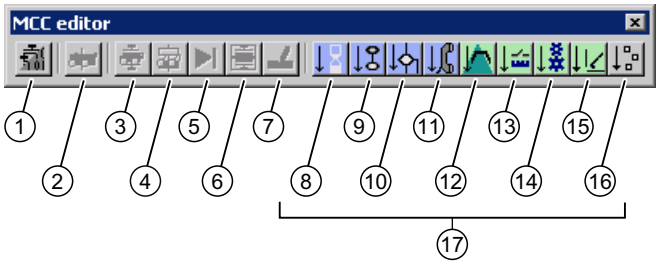
Note

The selection of command groups or command lists available in the context menu depends on which technology packages are currently selected for the SIMOTION device. To select the required technology packages, highlight the relevant SIMOTION device in the project navigator and choose the **Select technology packages** command in the context menu.

MCC editor toolbar

This toolbar contains important programming command buttons (for example, Insert MCC chart, Accept and compile, and Monitor) together with the complete range of commands. The commands are subdivided into command groups.



①	Accept and compile	⑩	Program structures
②	Program status	⑪	Communication
③	Monitoring	⑫	Single axis commands
④	Single-step	⑬	Commands for external encoders, measuring inputs and output cams
⑤	Next step	⑭	Commands for synchronous operation and camming
⑥	Trace on/off	⑮	Commands for path interpolation
⑦	Rerecord trace	⑯	Important commands
⑧	Basic commands	⑰	Command groups
⑨	Task commands		

Figure 7-19 MCC editor toolbar

Each of these groups is represented by a button on the toolbar. The list of commands is displayed when you move the cursor over the button; you can insert the appropriate command by clicking it with the left mouse button.

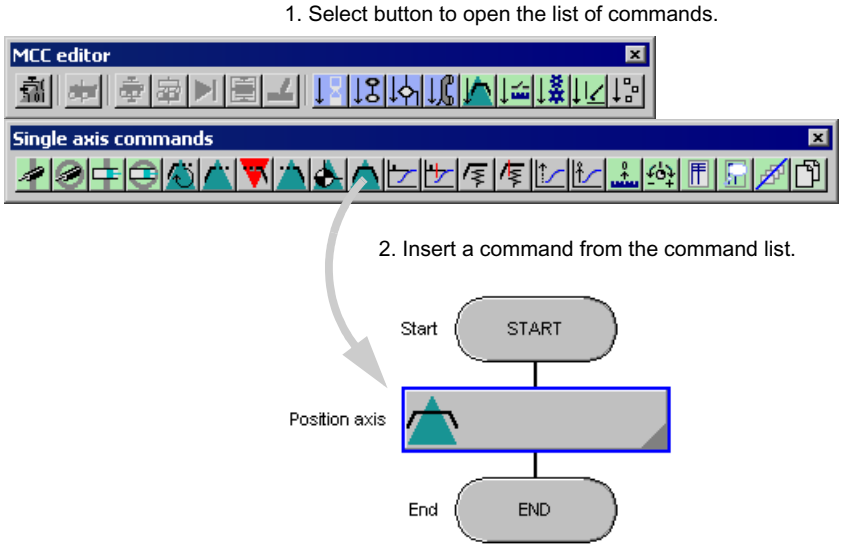


Figure 7-20 Inserting a command from the MCC editor toolbar

The command selected by clicking is always inserted after the selected command.

You can detach the displayed command list using the cursor and place it anywhere on the screen. It will then be easily accessible while you are creating your program.

If all of the command lists have been detached, every command can be inserted in the MCC chart with one click. The figure below shows a working window with an MCC chart and opened command lists.

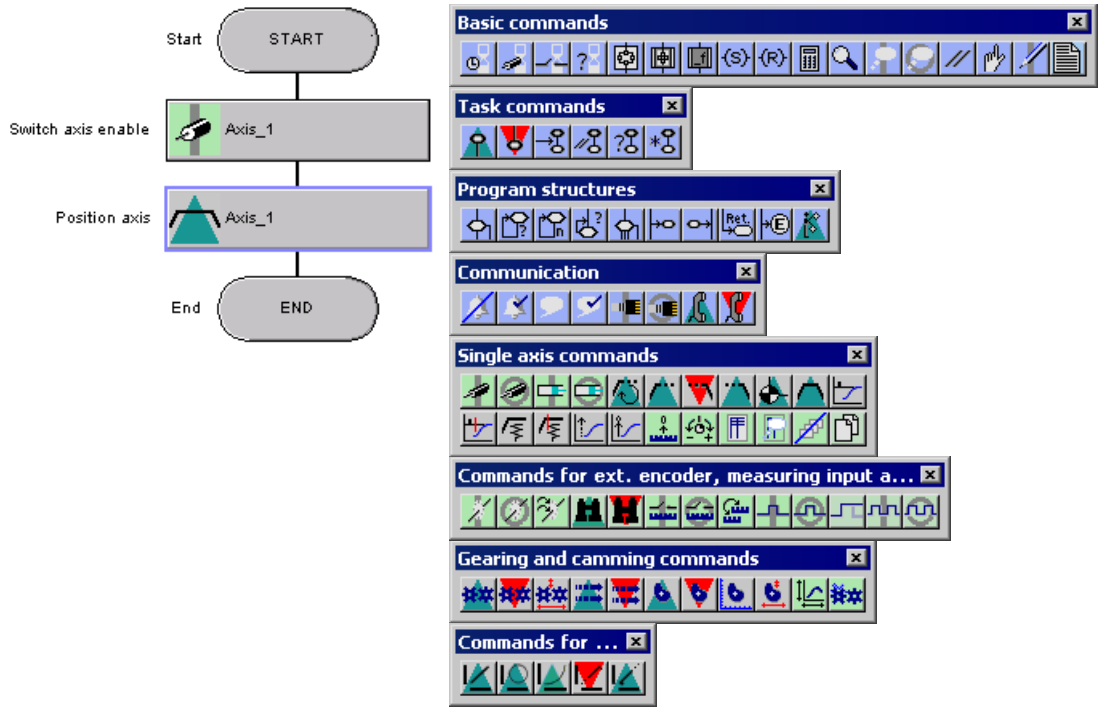

Figure 7-21 Opened command lists in the Workbench making every command available with one click

Note

The selection of command groups or command lists available for the MCC editor toolbar depends on which technology packages are currently selected for the SIMOTION device. To select the required technology packages, highlight the relevant SIMOTION device in the project navigator and choose the **Select technology packages** command in the context menu.

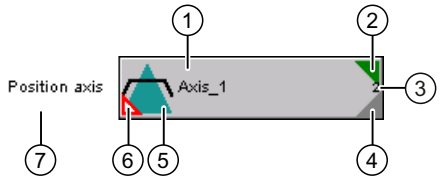
For example, the **Commands for path interpolation** list is only available in the PATH and CAM_EXT technology packages as of Version 4.1.

Representation of commands in the MCC chart

Commands are represented as a rectangular block. The starting and end nodes are oval, the conditions are diamond-shaped. All commands are assigned a symbol that graphically represents the command function. The commands are also color-coded:

Color	Commands
Light blue background	Basic commands, task commands. Communication
Light green background	Commands for technology objects that are not motion commands
Green	Motion commands for starting a movement
Red	Motion commands for stopping a movement

The figure below shows how most of the commands are represented in an MCC chart. The symbolic representation of commands makes it immediately obvious that axis_1 is being positioned. You can modify the brief comment if desired.



① Name of the technology object, e.g., axis name

② Marking:
Command comment present

③ Serial numbers for the command

④ Marking:
Command has not been parameterized yet or has been assigned incorrect parameters

⑤ Positioning the symbol

⑥ Hold point set

⑦ Brief comment

Figure 7-22 Representation of a motion command in the MCC chart

Brief comment

The brief comment is used to document the MCC chart or the command. It is preset with the name of the relevant command. Clicking the text allows you to change it, if necessary.

There is no maximum text length. The text length that can be displayed on the screen is dependent on the following factors:

- Font size and type
- Screen resolution

Command comment

You can enter an additional comment for each command:

- Select the required command in the MCC chart.
- In the context menu, select **Enter comment**.
- Enter the text of the comment in the displayed window.
- Click **OK** to confirm.

If a command comment is present, a green indicator appears at the top right of the command.

If you place the cursor above the command in the MCC chart, the comment is displayed via a tool tip.

Comment block

In addition, there is also a separate command for entering comments (see Comment block (Page 4197)).

Translating comments

Brief comments and command comments can be translated into various languages and displayed.

To do so, use the **Project > Language-Dependent Texts** menu command. Select **MCC comments** as the text source.

The remaining steps are outlined in the online help.

Numbering of commands

When a command is inserted, it is automatically assigned a serial number. This number is unique and is used to identify the command, for example, in the cross-reference list.

Note

The user is not able to change this number.

A number that is freed up after deletion of a command is reassigned only after the MCC chart has been saved and closed and then reopened.

Selecting commands

If you wish to copy a command, for example, you must select it beforehand.

You select a command by clicking it. You can select several commands by moving the cursor over them with the left mouse button depressed. If you wish to select all of the commands, choose **Select all** in the context menu.

Selected commands are identified by a thick blue border; in addition, the border of the last selected command flashes.

Hiding and displaying commands

You can hide commands for test purposes; hidden commands are excluded from the code generation process and are unavailable for selection.

Follow these steps:

1. Select the commands you want to hide.
2. On the shortcut menu, select **Mask Out**.

If you hide a control structure, all of the commands it contains and their parameters are also hidden.

To show hidden commands again, proceed as follows:

1. Select the commands you want to show.
2. On the shortcut menu, select **Display**.

Copying, deleting, cutting, or pasting commands

The functions **Copy**, **Delete** etc. can be selected either from the context menu or the **Edit** menu.

If you copy or cut a command and then paste it, the programmed parameters are also copied or cut and pasted. You can also paste the copied command into other MCC charts.

You cannot paste a command that has been deleted.

Note

If you delete a command by mistake, you can undo the delete operation. Select the **Edit > Undo** menu command.

If you copy a control structure, all of the commands it contains and their parameters are also copied. The same applies when **Delete**, **Cut**, or **Paste** is used.

Undo/redo

All actions can be undone in reverse order. Select the **Edit > Undo** menu command or the **Undo** button.

Note

The following actions cannot be undone:

- Save
- Accept and compile

If you want to redo one or more undone actions, use the **Edit > Redo** menu command or the **Redo** button.

Module creation

Modules are used to structure the MCC chart. Modules comprise a number of interrelated commands that are joined to make one single command. This feature allows even complex MCC charts to be structured in a clear, easily readable fashion.

A module can contain all types of commands. You can also nest modules and copy them for multiple use in different charts.

Command sequences that are to be used in several MCC charts must be swapped out as subprograms (Page 4117).

Procedure for creating a module

You can use two different methods to create a module:

- You can insert an empty module using the appropriate MCC editor toolbar command. You can then open the module by double-clicking it or using the context menu, and program the commands.
- You can use the context menu command directly to combine existing commands in the MCC chart to form a module:
  Select the required commands (**Shift** + press and hold the left mouse button and move the cursor over the MCC commands to be selected) and create the module via the context menu **Edit modules > Create module**.

Opening and closing a module

The module opens when you double-click the module command or select **Edit modules >Zoom in to module** in the context menu.

Close the module again by selecting **Edit modules > Zoom out of module** in the context menu.

Change the name of the module

Change the name of a created module by selecting **Edit module > Set name of module** in the context menu.

Canceling a module

You can cancel a created module by selecting **Edit modules > Cancel module** in the context menu. The commands previously grouped in the module are then displayed in the MCC chart instead of the module command.

Changing the module structure

If you want to change the module structure, cancel existing modules and create new ones.

Note

In offline mode, the changes to the module structure (creating or canceling modules) affect the project. If taken into the project, the MCC unit must be compiled again.

In online mode, a change to the module structure only affects the display, and the MCC unit does not have to be compiled again. Only when online mode is exited, are the changes to the module structure taken into the project and a new compilation is required.

7.1.5.3 Processing MCC commands

Assigning command parameters

All commands are assigned parameters in parameter screen forms. The structure of the parameter screen forms varies depending on the command.

Opening the parameter screen form

To open a parameter screen form, double-click the command or select **Parameterize command** in the context menu. You can open and edit any number of parameter screen forms from the same or different charts.

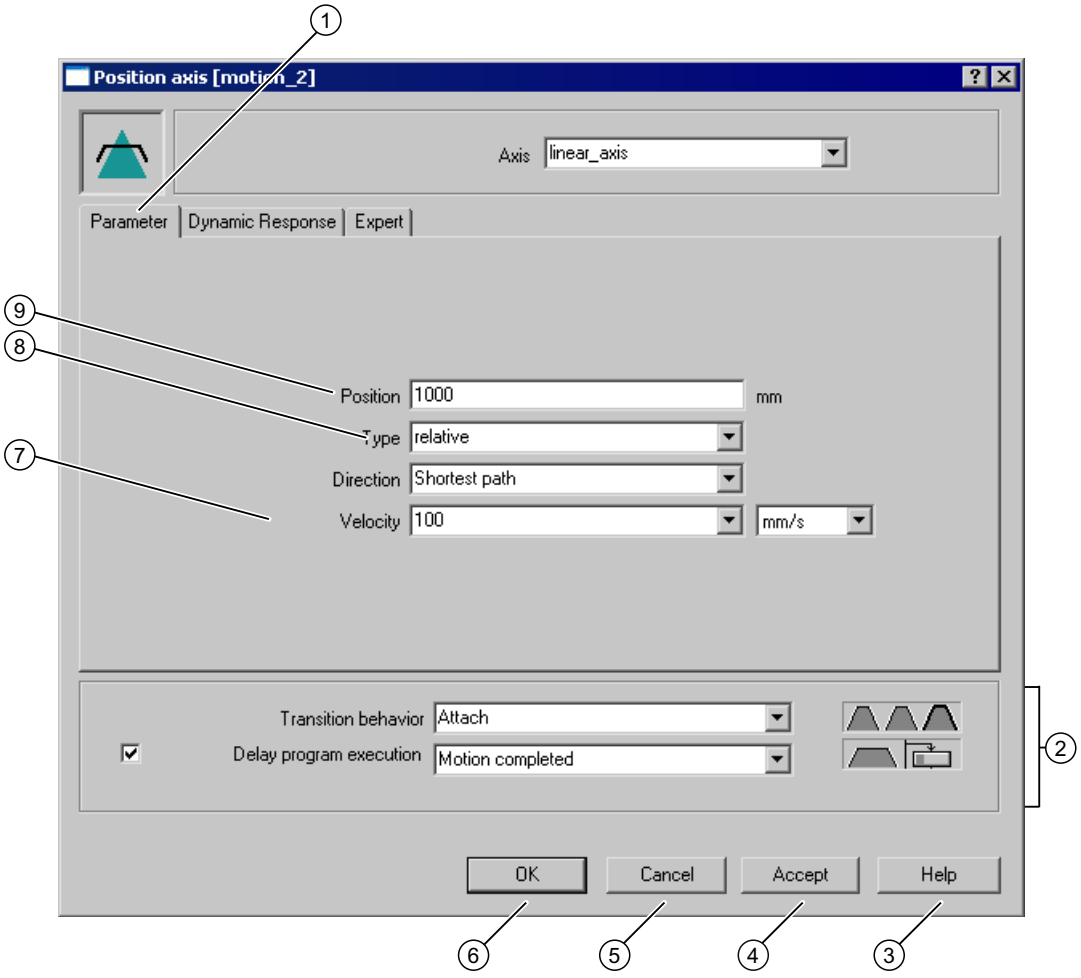
Changes in the symbol browser and in the project structure and commissioning are possible while a parameter screen form is open.

Structure of parameter screen forms for motion commands

The axis that is to be moved or stopped must always be specified in the top half of the box.

The center section contains different input fields and selection lists relating to the axis motion or stop commands. For reasons of clarity, this section contains several tabs. You need only assign the parameters in the first tab to obtain an executable command. All of the other tabs are optional and designed for special settings (such as jerk, acceleration, velocity profile, etc.).

The lower half of the box contains the settings for the transition behavior of the previous command and the step enabling condition for the next command.



①	Tab	⑥	Apply the parameter assignment and close the screen form
②	Transition behavior and step enabling condition	⑦	Editable selection list
③	Online help	⑧	Selection list (combo box)
④	Apply the parameter assignment	⑨	Input field
⑤	Close the screen form (discard the parameter assignment)		

Figure 7-23 Parameter screen form for a motion command

If there are many commands, the layout of the parameter screen form (presentation and selection options) depends on:

- Configuration data and system variables of the selected technology object, see Expert tab (Page 4034).
- Entries you have already made in the parameter screen form. Read the note about the table in Selection list (combo box) (Page 4022).

Structure of parameter screen forms for conditions and branches

You can program conditions and branches in the MCC editor using the LAD, FBD, or Formula languages, see LAD/FBD/formula (Page 4152).

Input fields and selection lists

Input field

Each input field must contain one of the following entries:

- Value
  In many cases, the entered value is checked for a maximum value that was specified during configuration of the technology object. This value is displayed in the tool tip.
- Unit variables (of the MCC source file) and global device variables or I/O variables
  These can be moved from the symbol browser to the input field with a drag-and-drop operation (see Formula (Page 4158)).
- Local variables of the MCC chart
- Formula
  You can drag-and-drop system functions and operators from the command library (see Using the command library (Page 4161)). When a system function is inserted, an automatic reliability check is performed within the relevant context (e.g. data type suitability).

Selection list (combo box)

Combo boxes provide different selection options. Frequently occurring selection options are listed in the following table below.

Table 7-3 Common selection options in combo boxes

Selectable options	Meaning
Default	The default value in the associated system variable is used. Default values can be defined during configuration of the technology object (see SIMOTION Basic Functions Function Manual). The "Set Axis Parameter" (Page 4325) command is used to change frequently used default Axis values.
Last programmed	The last programmed value is entered.
Last programmed velocity	For velocities only: The last programmed velocity is applied. For superimposed motion, the velocity of the base motion and the superimposition are added up.
Current	For velocities only: The active axis velocity is applied. Use for on-the-fly transitions and substitute motions.

Note

Not all of the options listed here are available in every case.

Note the following regarding the "default" and "last programmed" selection options: If the display of additional fields in the parameter screen form depends on this entry, these fields may not be displayed or some selection options may not be available.

Extension of the selection options by variables

You can extend the specified selection options in a selection list by defining variables of the appropriate data type in the declaration table of the MCC unit or the MCC chart. The names of the variables are also offered in the selection list.

- In selection lists for technology objects:
  Define a variable of the data type of the corresponding technology object (see Using a variable of the technology object data type (Page 4024)). The data type of the technology object (Page 4060) to be used is displayed in the tooltip of the selection list.
- In selection lists with enumeration elements:
  Define a variable of the corresponding enumeration data type. The enumeration data type to be used is displayed in the tool tip of the selection list.
  The variable can be assigned an element of the enumeration data type.
  A list of the elements of the respective enumeration data type is contained in the description of the relevant system function for the respective MCC command, see, for example Technology Packages, System Functions List Manual. The relevant system function is also specified for every MCC command in the Description of the MCC commands (Page 4173).

You can also declare the variables "on-the-fly". Enter the identifier of the variables in the combo box and press the **Return** key. For this, see Defining variables in the Variable declaration dialog box ("on-the-fly" variable declaration) (Page 4067).

Editable selection list (editable combo box)

Editable selection lists combine the properties of a Selection list (combo box) (Page 4022) and an Input field (Page 4022). They are used to input the numerical values of physical quantities (e.g. position, velocity). They are always linked to a unit of measure.

The input field of the editable selection list is associated with a numeric data type (usually LREAL). This is displayed in the tooltip.

- Select an entry from the selection options offered.
  You can select from the following:
  - For various enumeration elements, see Selection list (combo box) (Page 4022).
    These enumeration elements cannot be extended by variables.
  - All variables that are of the numeric data type of the input field and are effective in the MCC chart.
    Here, you select the variable that contains the numerical value of the physical quantity.
    You can define additional variables in the declaration tables or "on-the-fly" (Page 4067).

or

- Enter the value directly in the same way as in an entry field (Page 4022) (as a value or formula). To do this, select the entry in the selection list and overwrite it.

Note

When you select "**%**" in the "**Unit**" selection field: note that the value entered represents a percentage of the associated default value.

Unit

Here you can select what the value in the adjacent editable selection list represents. The following are available:

- The unit of the physical quantity defined during configuration of the technology object
  The value in the adjacent field represents a physical quantity with the indicated unit.
- "%" (percentage)
  The value in the adjacent field represents a percentage of the associated default value.

Assigning a technology object or a technology object-type variable to a command

Using a technology object

One or more technology objects (TOs) can be assigned to the command via its parameter screen form. Either a technology object which is already configured in the project navigation or a technology object-type variable can be assigned.

Assigning a technology object

A technology object which has already been configured (e.g. a linear axis with an incremental encoder) can be assigned to a command via its parameter screen form. Specific configuration data from the technology object is used to influence the design and/or selection options in the parameter screen form.

This relevant configuration data is displayed on the "Expert" tab in the "TO properties" list and saved in the command.

By assigning a technology object, the values displayed in the "TO properties" list on the "Expert" tab are fixed entries in the parameter screen form and cannot be changed.

Using a technology object-type variable

Assigning a technology object-type variable

Defining a technology object-type variable only serves to create a reference to a technology object.

As a place holder for a technology object, the variable can be assigned to a command via its parameter screen form. A technology object is only assigned to variables during the runtime of a program.

The variable defaults which influence the design and/or selection options in the parameter screen form are displayed in the "TO properties" list in the "Expert" (Page 4034) tab.

Through the assignment of a variable, the TO properties values shown in the "TO properties" list in the "Expert" tab are not fixed entries in the parameter screen form and can be changed in the parameter screen form.

However, these TO properties only appear in the parameter screen form and do not exist as the configuration data/system variables of a technology object. The command only receives the configuration data/system variables of a technology object if the technology object is assigned to the variable during the program runtime.

Example of an absolute encoder

A "posAxis" (position axis)-type variable is defined and assigned to the MCC "Home axis" command via its parameter screen form. An axis which is configured on the SIMOTION device, with an absolute encoder, is assigned to the variable as a technology object during the program runtime. Therefore, the parameter screen form must be adapted accordingly in the "Expert" (Page 4034) tab in order to select the "Absolute encoder adjustment" or "Absolute encoder calibration with specification of the position value" homing types.

Procedure

1. Define a technology object-type variable in the MCC chart declaration table by specifying the "posAxis" data type (see Description of the technology objects data types (Page 4060)). This means that a position axis-type technology object can be assigned to the variable during the program runtime.

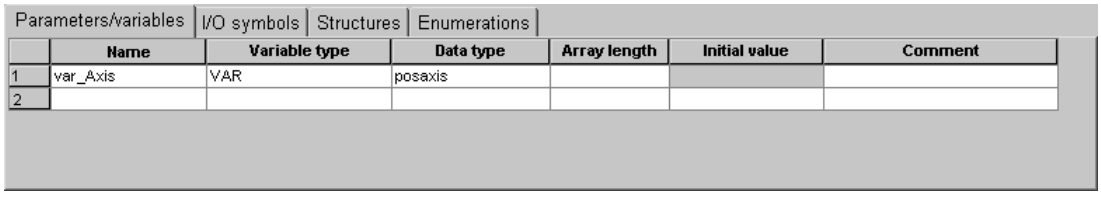


Figure 7-24 Defining a technology object-type variable in the declaration table

2. Insert the "Home axis" command into the MCC chart.
3. Double-click on the command.
   The parameter screen form opens.
4. Select the defined variable in the "Axis" dialog box.
   The variable is thus assigned to the command as a place holder for a position axis. Since a variable has been assigned to the command, and not a technology object, the TO properties, e.g. the encoder type, can be changed on the "Expert" tab.

5. Select the "Expert" tab.
   The variable defaults that influence the parameter screen form (design and/or selection options) are displayed in the "TO properties" list. For example, the "Incremental" default value appears in the "Value" column for the encoder type, i.e. an incremental encoder is preset. Based on the default "Incremental", only the homing types for an incremental encoder are available for selection in the "Homing type" dialog box in the "Parameters" tab. In order to select the homing types for an absolute encoder, the encoder type must be changed to absolute encoder beforehand.

6. In the "TO properties" list, select the entry "Absolute" or "Absolute cyclic" in the encoder type row from the drop-down list in the "Value" column.
   The encoder type is changed from incremental encoder to absolute encoder.

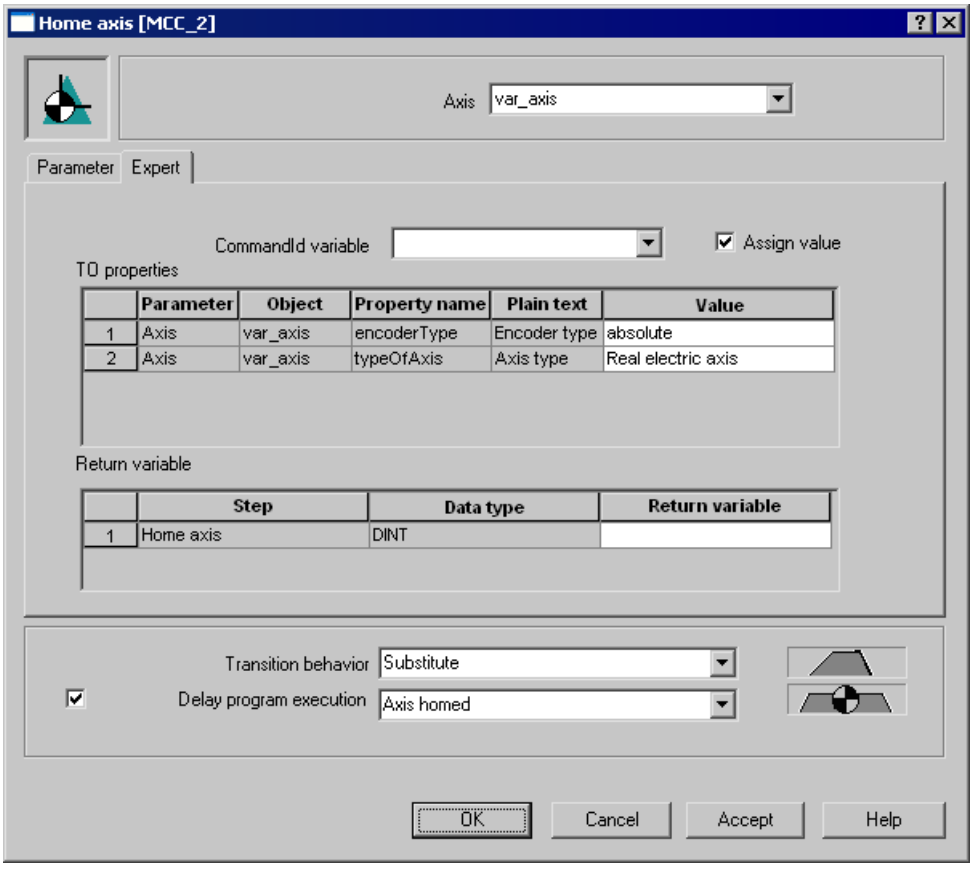

Figure 7-25 Selecting an absolute encoder via the Expert tab

7. Select the "Parameters" tab.
   The only options available for selection now in the "Homing type" dialog box are the "Absolute encoder adjustment" or "Absolute encoder calibration with specification of the position value" homing types.

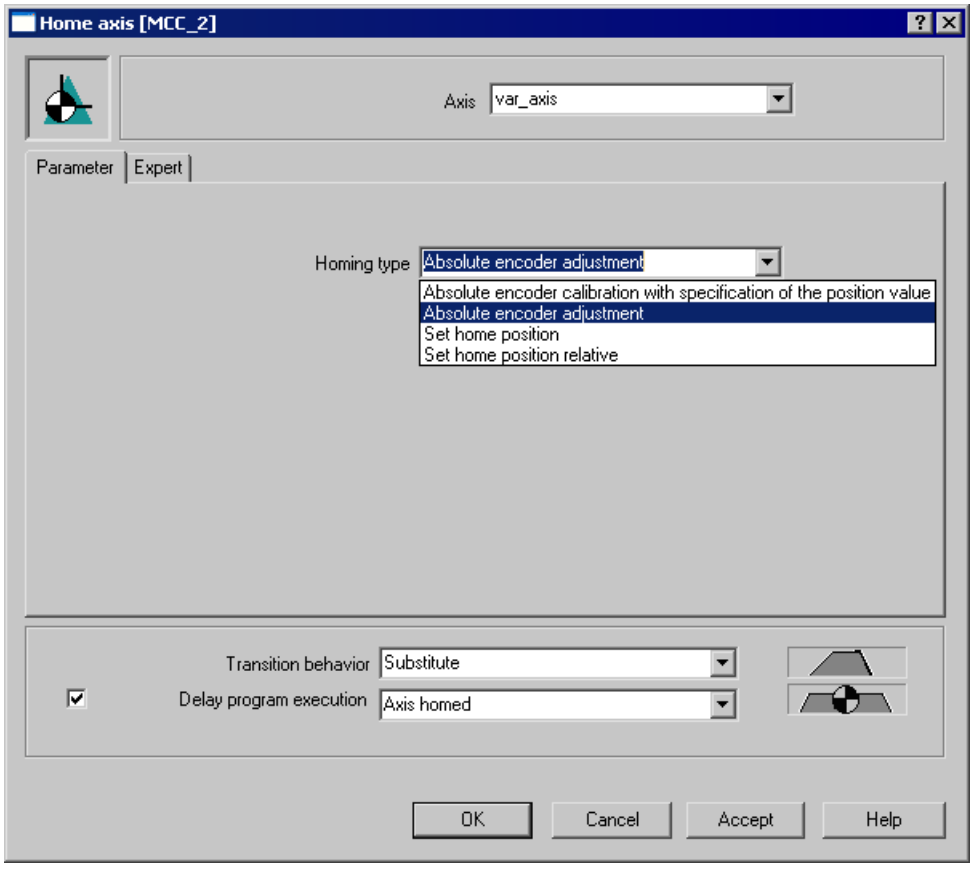

Figure 7-26 "Absolute encoder adjustment" homing type

Example of time-based cams

An "outputCamType" (output cam)-type variable is defined and assigned to the MCC "Switch output cam on" command via its parameter screen form. A time-based cam on a rotary axis which is configured on the SIMOTION device is assigned to the variable as a technology object during the program runtime. Therefore, the parameter screen form has to be adapted accordingly in the "Expert" (Page 4034) tab.

Procedure

1. Define a technology object-type variable in the MCC chart declaration table by specifying the "outputCamType" data type (see Description of the technology objects data types (Page 4060)). This means that an "output cam"-type technology object can be assigned to the variable during the program runtime.

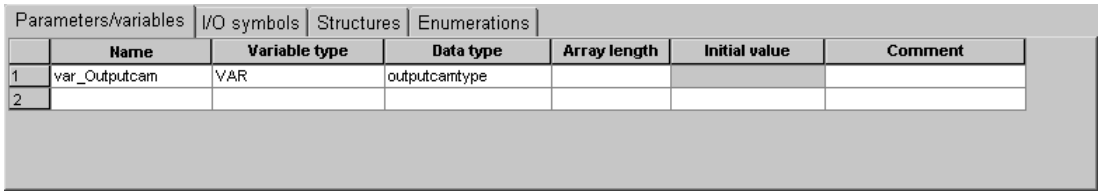

Figure 7-27 Defining a technology object-type variable in the declaration table

2. Insert the "Switch output cam on" command into the MCC chart.
3. Double-click on the command.
   The parameter screen form opens.
4. Select the entry "<Reference>" in the "Axis/encoder" dialog box, as the output cam is predefined as a reference (variable), and not as a technology object.
   Thus, the variable is assigned to the command as a place holder for an output cam in the "Output cam" dialog box. Since a variable has been assigned to the command, and not a technology object, the TO properties, e.g. the output cam type, can be changed on the "Expert" tab.

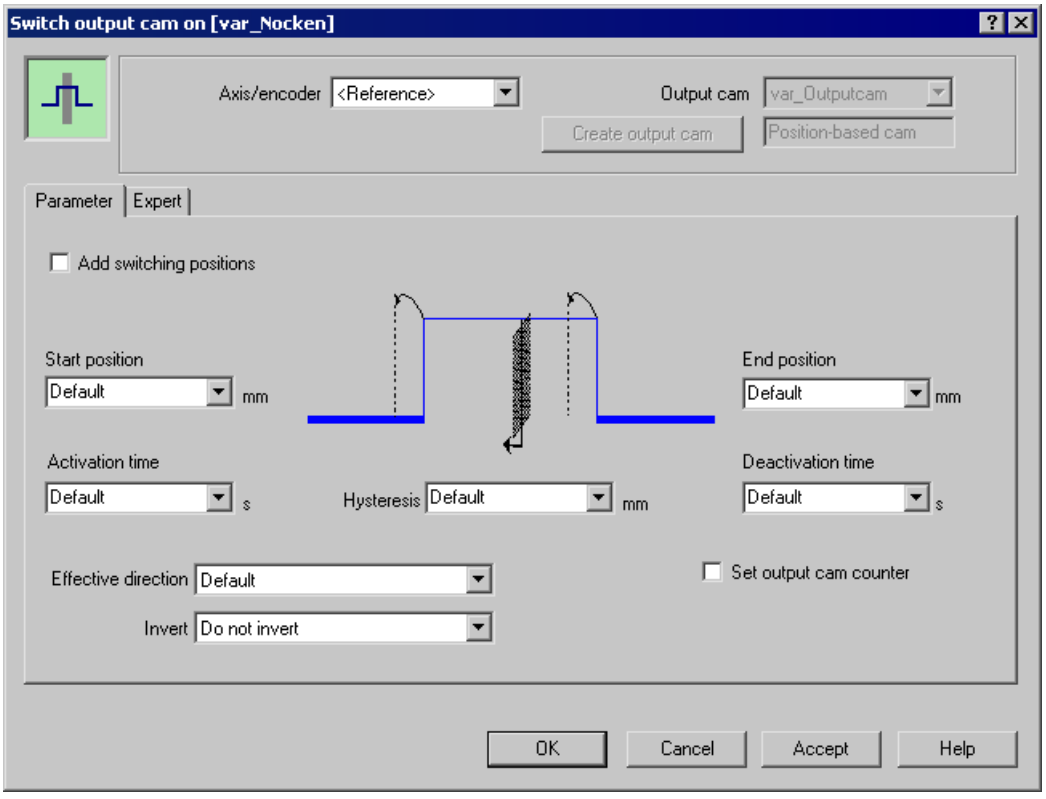

Figure 7-28 Parameter screen form: Switch output cam on for linear axis and position-based cam

5. Select the "Expert" tab.
   The variable defaults that influence the parameter screen form (design and/or selection options) are displayed in the "TO properties" list. For example, the "Position-based cam" default value appears in the "Value" column for the output cam type, i.e. a position-based cam is preset.
6. In the "TO properties" list, select the entry "Time-based cam" in the output cam type row from the drop-down list in the "Value" column.
   The output cam type is changed from position-based cam to time-based cam.
7. In the "TO properties" list, select the entry "Rotary axis" in the axis type row from the drop-down list in the "Value" column.
   The axis type is changed from linear axis to rotary axis.
8. Select the "Parameters" tab.
   The information displayed here has changed markedly because the parameters are now shown for a rotary axis and for a time-based cam.

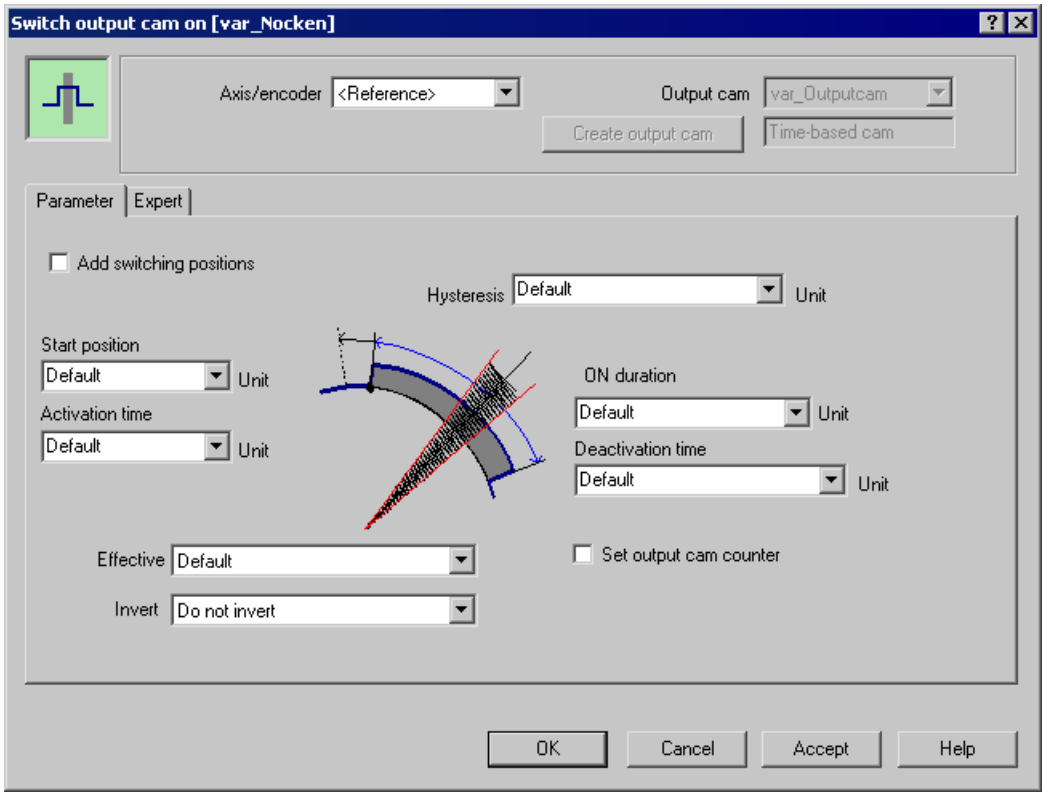

Figure 7-29 Parameter screen form: Switch output cam on for rotary axis and time-based cam

Dynamics tab

The parameter dialog boxes for most of the motion commands include a **Dynamic response** tab. Here you can specify the velocity profile type and the associated values for acceleration, deceleration, and jerk.

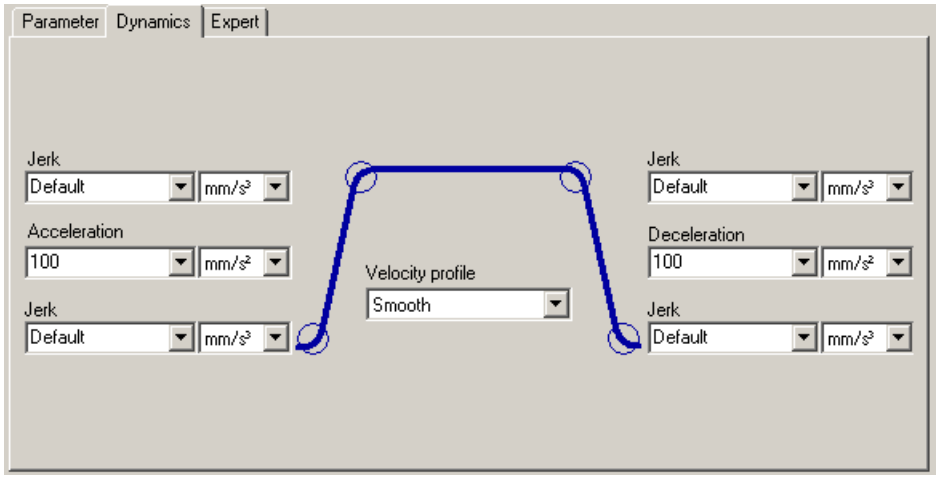

Figure 7-30 Dynamic response tab for motion commands

Overview of parameters

Table 7-4 Overview of parameters for Dynamic response tab

Field/Button	Explanation/Instructions
Velocity profile	The velocity profile is used to specify the transitions between the individual motion phases. The velocity profile influences the motion transitions as follows: • At the start and end of the acceleration phase, the transition to the constant acceleration or constant velocity phase • At the start and end of the deceleration phase, the transition to the constant deceleration or constant velocity phase Select the velocity profile. **Trapezoidal** A trapezoidal velocity profile is in effect for the command. Only the acceleration and deceleration can be programmed. **Constant** The velocity profile with smooth acceleration characteristic is in effect for the command. The change in acceleration/deceleration (jerk) can be verified. With the "Gearing on" (Page 4385) command, a constant velocity profile only takes effect if configuration data syncingMotion.smoothAbsoluteSynchronization = YES is set. **Default** **Last programmed** See Selection list (combo box) (Page 4022). The system variable for the default is given together with the description of each command.
Acceleration	The acceleration value during the constant acceleration phase. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** **Last programmed** See Selection list (combo box) (Page 4022). The meaning depends on the acceleration model used, which can be selected via the configuration data TypeOfAxis.DecodingConfig.directionDynamic: • **Non-direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = NO (default) The value causes acceleration in the motion of the axis, independent of the direction of motion. • **Direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = YES The value causes acceleration when the direction of rotation is positive and deceleration when the direction of rotation is negative. For additional information on specifying the acceleration and deceleration (acceleration model), see the TO Axis Electric/Hydraulic Function Manual. The system variable for the default is given together with the description of each command.

Field/Button	Explanation/Instructions
Deceleration	Deceleration value during the constant deceleration phase Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** **Last programmed** See Selection list (combo box) (Page 4022). The meaning depends on the acceleration model used, which can be selected via the configuration data TypeOfAxis.DecodingConfig.directionDynamic: • **Non-direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = NO (default) The value causes deceleration in the motion of the axis, independent of the direction of motion. • **Direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = YES The value causes deceleration when the direction of rotation is positive and acceleration when the direction of rotation is negative. For additional information on specifying the acceleration and deceleration (acceleration model), see the TO Axis Electric/Hydraulic Function Manual. The system variable for the default is given together with the description of each command.
Jerk	Only active with constant velocity profile. Change in acceleration or deceleration • At acceleration start • At acceleration end • At deceleration start • At deceleration end Irrespective of the acceleration model selected, the two jerk values for acceleration and deceleration always relate to the parameter (acceleration or deceleration) to which they are assigned via the **Dynamic response** tab. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** **Last programmed** See Selection list (combo box) (Page 4022). The system variable for the default is given together with the description of each command.
Velocity	Not always included on the **Dynamic response** tab. Velocity value during the constant velocity phase Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** **Last programmed velocity** **Current** See Selection list (combo box) (Page 4022). The system variable for the default is given together with the description of each command.

Field/Button	Explanation/Instructions
Constant traversing time	Only for the "Start axis position-controlled" (Page 4277) and "Speed specification" (Page 4273) commands. A time limit can be programmed for this command. • Activate the checkbox if the movement of the axis is to be time limited. If you do not activate the checkbox, the axis moves until it receives a new command. • Enter the duration of the constant motion phase (from the end of acceleration up to the start of deceleration). At the end of this time, the axis is decelerated until its speed reaches 0. If no time is specified, then the axis moves until it receives a new command. See also input field (Page 4022).
Time for deceleration	Only for the "Stop axis" (Page 4281) command. Duration of braking operation for a quick stop within a defined time period Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4022). **Default** **Last programmed** See Selection list (combo box) (Page 4022). System variable for default: userDefaultDynamics.stopTime

Expert tab

The parameter screen forms for many motion commands contain an **Expert** tab. The content of this tab depends on the motion command:

- You can define the variable for the CommandID.
- You can view configuration data or system variables that affect the parameter screen form, see Using a variable of the technology object data type (Page 4024).
- You can define the variable to which the return value is written (return variable).

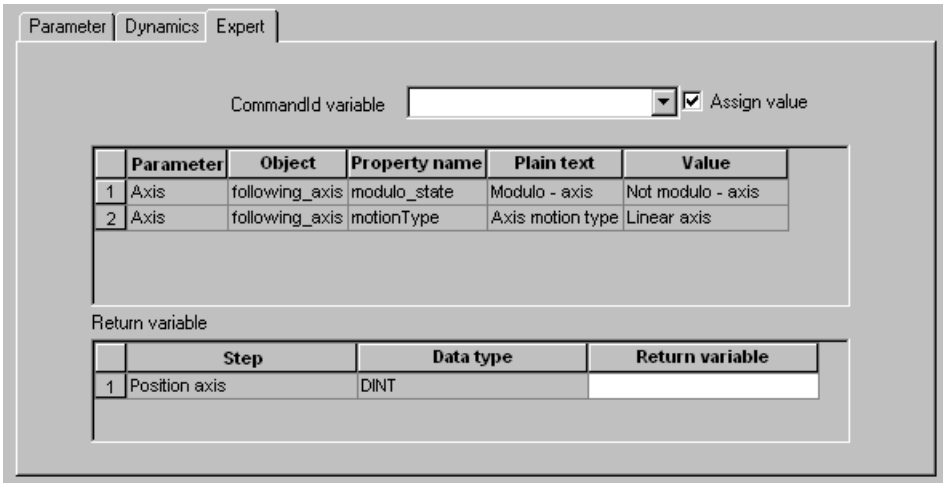

Figure 7-31 Expert tab for motion commands

Overview of parameters

Table 7-5 Overview of parameters for Expert tab

Field/Button	Explanation/Instructions
CommandID variable	The status of many motion commands can be tracked using the unique, project-wide CommandId. • If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable. The variables of this data type that were declared previously in the MCC unit or MCC chart are available for selection. – When the **Assign value** checkbox is activated, a unique project-wide CommandId is automatically generated, stored in the variables, and transferred to the command. You can use the stored CommandId to track the command status until the command has been completed properly or has been aborted. – When the **Assign value** checkbox is cleared, only the variable is transferred to the command. You must take steps to ensure that a unique project-wide CommandId is stored in the variable. You obtain the CommandId with the _getCommandId system function. In addition, you can buffer the CommandId in this case so that it is available even after the command has been completed. • If you leave the field empty, the CommandID is not assigned to any variables; this means that you cannot access the CommandID (default). When the field is empty, the **Assign value** checkbox must be activated.
TO properties	The technology object configuration data or system variables that affect the parameter screen form (presentation or selection options) are displayed in the "TO properties" list (see "TO properties list" table below). If you have selected a technology object-type variable (see Description of the technology object data types (Page 4060)) as the technology object (e.g. in a library), you can select a value in order to adapt the parameter screen form to the properties of the technology object. See Using a technology object-type variable (Page 4024). This selection does not change the configuration data or system variables of the technology object.
Return variable	Many commands are mapped onto one or more system functions (command steps). These usually have a return value that provides information to the user on the result of the system function. For each command step, you can specify a return variable in which the respective return value is stored: • When you enter the name of a variable of the specified data type, the return value of the command step is stored in this variable. The variables of this data type that were declared previously in the MCC unit or MCC chart are available for selection. A reference to the documentation describing the meaning of the individual values is given for each command. • If you leave the field empty, the return value of the command step is assigned to an internal variable that you cannot access (default). See also Relevant system function, system variable or command in the ST programming language (Page 4039) and Return values (Page 4039).

Table 7-6 TO properties list

Field/Button	Explanation/Instructions
Parameter	Indicates the name of the field for the technology object whose configuration data or system variables affect the parameter dialog box.
Object	Indicates the technology object selected in the parameter dialog box.
Property Name	Indicates the configuration data or system variable affecting the parameter dialog box.
Plain text	Indicates the meaning of the configuration data or system variable.
Value	The behavior depends on whether the technology object is defined on the SIMOTION device or whether it is a variable of the data type of a technology object: • If the technology object is defined on the SIMOTION device: The value defined during configuration is indicated. • If the technology object is a variable of the data type of a technology object: You can select a value from among the values of the enumeration data type of the configuration data or the system variable. The parameter dialog box is presented according to the selected value. This selection does not affect the configuration data or system variables of the technology object.

Transition behavior and step enabling condition

The transition behavior for all motion commands must be indicated by the motion command that is currently active on the axis. The transition behavior always relates to motion commands on the same axis irrespective of the program that issued the commands.

You can also program a step enabling condition to the next command in the flow chart.

Transition behavior from the currently active motion command

For motion commands, you specify the transition behavior from the command that is currently active on the axis. The table shows the transition behavior of the currently active command on the axis (thick line = programmed command, thin line = active command on the axis):

Transition behavior	Graph	Description
Substitute		The programmed command is executed immediately. The active command is aborted.
Attach		The programmed motion is attached to the active motion for this axis. Pending commands will be executed.
Attach and delete existing command		The programmed motion is attached to the active motion for this axis. Pending commands will be discarded.

Transition behavior	Graph	Description
Blending		The transition from the velocity of the active command to that of the programmed command takes place smoothly when deceleration begins in the active command. Therefore the active command should be programmed with step enabling condition **Start of deceleration phase**.
Superimpose		The programmed and active motions are superimposed. The command does not affect superimposed motions that are already active. The motion is started immediately.

Note

Not all of the options listed here are available in every case.

Delay program execution (step enabling condition)

This checkbox determines when the next command is to be executed. MCC is optimized for sequential programming; therefore, this checkbox is activated by default.

If the checkbox is clear ( graphic), the next command in the chart is started immediately after the current command or, where applicable, not until the command has been entered in the command buffer, see the detailed description in the "Overview of parameters" table for the relevant MCC command (Page 4173).

The table shows the step enabling conditions for the subsequent command when the checkbox is activated (trapezoid = current command, "MCC command" symbol = next command):

Wait for ...	Graph	Description
Motion start Interpolation start		The next command is started when the interpolation for the currently programmed motion begins.
Acceleration end		The next command is started when the acceleration phase for the active motion ends.
Speed/velocity reached		The next command is started when the speed/velocity for the active motion is reached.
Start of deceleration phase Deceleration start		The next command is started when the deceleration phase for the active motion begins.
End of setpoint interpolation		The next command is started when setpoint interpolation for the active motion has ended.
Motion is finished Axis stopped		The next command is started when the active motion has been completed (e.g. the minimum dwell time of the actual value in the configured position window around the target position has elapsed).
When clamping value is reached		The next command is started when the clamping value for the active motion is reached.
When command is completed or aborted		The next command is started when the current command is completed or aborted.

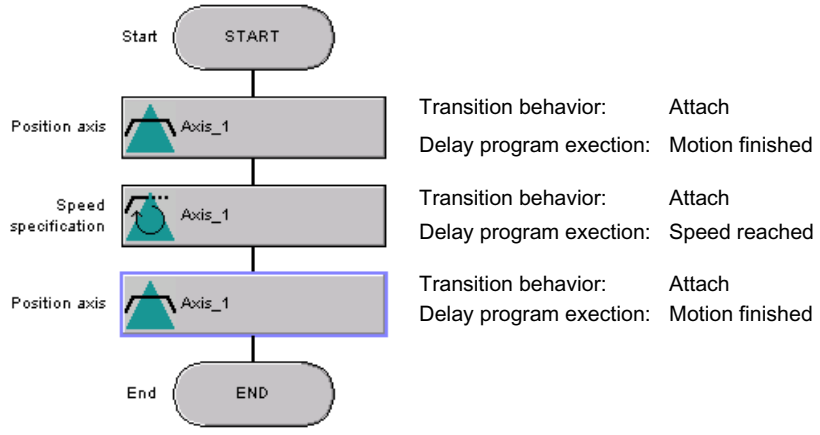
Wait for ...	Graph	Description
As soon as torque is limited		The next command is started as soon as torque limiting is triggered.
As soon as torque limitation is switched off		The next command is started as soon as torque limitation is switched off.
Axis synchronized		The next command is started when the axis is synchronized for the active motion.
Axis homed		The next command is started when the zero mark is detected for the active homing motion.

Note

Not all of the options listed here are available in every case.

You can query the current status of the axis by means of system variables. For a selection with corresponding values, see Axis status (Page 4177).

Example of transition behavior and step enabling condition



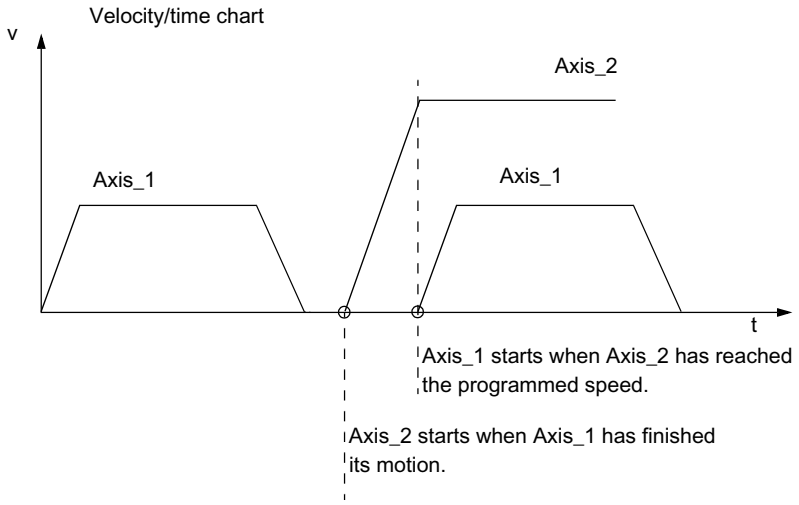


Figure 7-32 Example of transition behavior and step enabling condition

Note

The status of a motion command can be queried using the CommandID variables, see Expert tab (Page 4034). This may be necessary, in particular, if a transition to the next command is made before a motion has been completed (**Delay program execution** parameter is deactivated or set to an appropriate value, such as Motion Start, Velocity Reached).

The following system functions can be used for this purpose:

- For querying single axis commands:
  _getStateOfAxisCommand
  _getMotionStateOfAxisCommand
- For querying commands for synchronous operation and camming:
  _getStateOfFollowingObjectCommand
  _getMotionStateOfFollowingObjectCommand

For a description of the functions, refer to the SIMOTION Cam Technology Package, System Functions, List Manual.

ST commands can be programmed using the "System function call" (Page 4185) or "ST zoom" (Page 4188) command, for example.

Closing the parameter screen form

Click **OK** to close the parameter dialog box.

The syntax of the assigned command is checked when you close the screen form. Any errors are displayed.

Note

When a syntax check is performed on an MCC command, the declaration table in the MCC chart and the MCC source file are also read. Inconsistent data within the declaration tables may, therefore, cause unexpected error messages during parameter assignment.

Relevant system function, system variable, or command in the ST programming language

Each MCC command is mapped to a system function, an ST programming language command, or a value assignment to a system variable. This is specified for each MCC command.

For system function, the way in which the parameters of the MCC command are assigned to the parameters of the system function is also specified.

Return values

Many commands are mapped onto one or more system functions (command steps). These usually have a return value that provides information to the user on the result of the system function.

For these MCC commands, you can specify a return variable in which the respective return value is stored for each command step in the "Expert" tab (Page 4034):

- When you enter the name of a variable of the specified data type, the return value of the command step is stored in this variable. The variables of this data type that were declared previously in the MCC unit or MCC chart are available for selection.
  A reference to the documentation describing the meaning of the individual values is given for each command.
- If you leave the field empty, the return value of the command step is assigned to an internal variable that you cannot access (default).

Return value for the system functions of the technology packages

The return values for the system functions of the Cam, Path and Cam_EXT technology packages are described in the table.

Table 7-7 Description of return value for Cam, Path and Cam_EXT technology package functions

Error code	Meaning
0	No error
1	Invalid command parameter
2	Invalid range information in command parameters
3	Command aborted
4	Unknown command
5	Command cannot be executed due to current object state
6	Command aborted due to termination of user task
7	Command rejected due to suspension of command interpretation of the addressed technology object
8	Command aborted due to full command buffer
9	Insufficient memory
10	A connection to a technology object required for this operation does not exist
11	No object configuration
12	The error to be reset cannot be reset due to its configuration
13	Axis is not homed
14	Measurement job on virtual axis not possible
15	Ambiguous commandId
16	Command not implemented
17	Read access denied
18	Write access denied
19	Command argument not supported
20	The cam has already been interpolated and cannot be manipulated
21	The interpolation condition was violated
22	The programmed jerk is 0
23	The alarm to be deleted is not present
24	Command not possible on a virtual axis
25	A synchronized start of this command is not possible

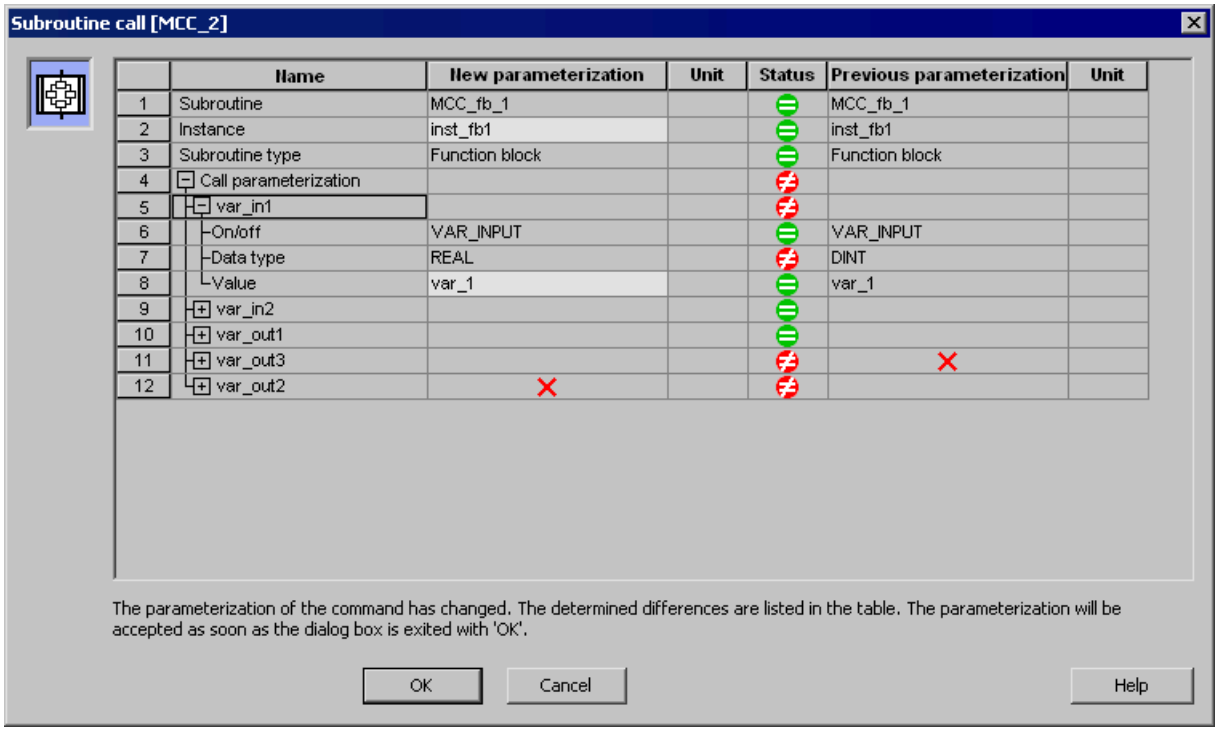
Error code	Meaning
26	Higher-level command was aborted because it is not permitted by the active command
27	Time exceeded during communication with the drive
28	Actual values are not valid
29	This command cannot be executed when velocity control is active
30	This command cannot be executed when position control is active
31	This command cannot be executed in torque-reduced operation or during travel to fixed limit stop
32	This command can only be executed when force/pressure control is active
33	This command cannot be executed when force/pressure control is active
34	This command can only be executed when pressure limiting is active
35	Master values are not valid
36	Slave values are not valid
37	No slave value can be determined for a master value
38	No master value can be determined for a slave value
39	This command cannot be executed when synchronous operation is inactive
40	This command cannot be executed because of a synchronization error.
41	The command cannot be executed when gearing or camming is active.
42	This command cannot be executed when camming is inactive
43	This command can only be used for an interpolated cam
44	This command cannot be executed when pressure limiting is active
45	Insufficient interpolation points are available to interpolate the cam
46	The specified path point cannot be reached due to restrictions of the kinematics.
47	Path axis values are not valid.
48	Maximum number of active commands exceeded.
49	Command only possible on a CPU local technology object
50	The command cannot be selected in this technology object configuration.
51	The multiple instantiation of the PLCopen function block on a technology object is not permitted.
52	No entry with the specified ID found.
53	The number of cam interpolation points exceeds the configured maximum limit.
≥ 10000	Internal error.

Updating a command in the event of parameterization changes

The MCC editor can provide support if the current parameterization for an MCC command differs from that saved in the MCC chart. This may happen, for example, in the following cases:

- For the "subroutine call" command:
  The parameterization of the subroutine (e.g. function or function block) called has changed, for example:
  - Additional or deleted parameters
  - Changed identifiers of parameters or their data types
- For motion commands:
  - Changes to the technology object's configuration data or system variables affecting the layout or selection options of the parameter screen form (e.g. linear axis/rotary axis, position-based cam/uni-directional output cam), see Using the technology object (Page 4024)
  - Expansions of a command's function (e.g. new parameters, new selection options)
    This may be the case, for example, when the device is being upgraded to a new version of SIMOTION Kernel or when an MCC chart or MCC unit is being copied from an earlier project.

A comparison screen form opens, as well as the parameter screen form, when parameters are reassigned for the relevant MCC command. This comparison screen form lists the previous parameterization (e.g. parameter identifiers, data types) and the new parameterization in a tabular format. Graphical symbols in the "Status" column highlight the differences and similarities. The symbol in the relevant column indicates that parameters or parameter properties are missing. You can also assign new values to parameters in the "New parameterization" column.



The new parameterization (parameter and parameter property) matches the old one.

The new parameterization (parameter or parameter property) differs from the old one.

Parameter or parameter property is missing for the relevant parameterization.

Figure 7-33 Comparison screen form for changed parameterization

Procedure

Proceed as follows if the parameterization for an MCC command has changed and the comparison screen form opens as well as the parameter screen form:

1. Look for the ≠ and ✕ symbols to help you find the parameterization differences in the comparison screen form.
   If necessary, open the subtree for a parameter to find out more details.
2. If necessary, assign new values to the parameters.
3. Click **OK** to confirm.
   The new parameterization and the assignments you have made are accepted by the parameter screen form.
   (The existing parameterization for the command is retained if you click **Cancel**.)
4. Check the parameterization in the parameter screen form once more.
5. Click **OK** to confirm.
   The changed parameterization is accepted by the MCC chart.

Note

Once you have had the changed parameterization accepted by the parameter screen form and then the MCC chart, the comparison screen form will not appear the next time the parameter screen form is opened.

7.1.5.4 General information about variables and data types

Overview of variable types

The following table shows all the variable types available for programming with ST.

- System variables of the SIMOTION device and the technology objects
- Global user variables (I/O variables, device-global variables, unit variables)
- Local user variables (variables within a program, a function, or a function block)

System variables

Variable type	Meaning
System variables of the SIMOTION device	Each SIMOTION device and technology object has specific system variables. These can be accessed as follows: • Within the SIMOTION device from all programs • From HMI devices You can monitor system variables in the symbol browser.
System variables of technology objects	

Global user variables

Variable type	Meaning
I/O variables	You can assign symbolic variable names to the I/O addresses of the SIMOTION device or the peripherals. This allows you to have the following direct accesses to the I/O: • Within the SIMOTION device from all programs • From HMI devices You create these variables in the symbol browser after you have selected the I/O element in the project navigator. You can monitor I/O variables in the symbol browser.
Global device variables	User-defined variables which can be accessed by all SIMOTION device programs and HMI devices. You create these variables in the symbol browser after you have selected the GLOBAL DEVICE VARIABLES element in the project navigator. Global device variables can be defined as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor global device variables in the symbol browser.
Unit variables	User-defined variables that all programs (programs, function blocks, and functions) can access within a unit (source file). You declare these variables in the declaration table of the source file: • In the interface section: These variables are exported and can be used in other units (e.g. ST source files, MCC source files, LAD/FBD source files) after a connection has been defined (Page 4115). They are also available on HMI devices as standard. • In the implementation section: You can only access these variables within the source file. You can declare unit variables as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor unit variables in the symbol browser.

Local user variables

Variable type	Meaning
	User-defined variables that can only be accessed within the program/chart (program, function, function block) in which they were defined.
Variable of a program (program variable)	Variable is declared in a program. The variable can only be accessed within this program. A differentiation is made between static and temporary variables: • Static variables are initialized according to the memory area in which they are stored. Specify this memory area by means of a compiler option. By default, the static variables are initialized depending on the task to which the program is assigned (see *SIMOTION Basic Functions* Function Manual). You can monitor static variables in the symbol browser. • Temporary variables are initialized every time the program in a task is called. Temporary variables cannot be monitored in the symbol browser.

Variable type	Meaning
Variable of a function (FC variable)	Variable is declared in a function (FC). The variable can only be accessed within this function. FC variables are temporary; they are initialized each time the FC is called. They cannot be monitored in the symbol browser.
Variable of a function block (FB variable)	Variable is declared in a function (FB). The variable can only be accessed within this function block. A differentiation is made between static and temporary variables: • Static variables retain their value when the FB terminates. They are initialized only when the instance of the FB is initialized; this depends on the variable type with which the instance of the FB was declared. You can monitor static variables in the symbol browser. • Temporary variables lose their value when the FB terminates. The next time the FB is called, they are reinitialized. Temporary variables cannot be monitored in the symbol browser.

Scope of the declarations

Scope of variable and data type declarations according to location of declaration

Location of declaration	What can be declared here	Scope
Symbol browser	• Global device variables • I/O variables	The declared variables are valid in all units (e.g., ST source files, MCC source files, LAD/FBD source files) of the SIMOTION device. All programs, function blocks, and functions in all units of the device can access the variables.
Interface section of the unit[1]	• Unit variables • Data types • Symbolic accesses to the fixed process image of the BackgroundTask	The declared variables, data types, etc., are valid in the entire unit (e.g., ST source file, MCC source file, LAD/FBD source file); all programs, function blocks, and functions within the unit can access them. In addition, they are also available in other units after connection (see Define connections (Page 4115)).
Implementation section of the unit[1]	• Unit variables • Data types • Symbolic accesses to the fixed process image of the BackgroundTask	The declared variables, data types, etc., are valid in the entire unit (e.g., ST source file, MCC source file, LAD/FBD source file); all programs, function blocks, and functions within the source file can access them.
POU (program/ function block/ function)[2]	• Local variables • Data types • Symbolic accesses to the fixed process image of the BackgroundTask	The declared variables, data types, etc., can only be accessed within the POU in which they were declared.

[1] MCC and LAD/FBD programming languages: in the declaration table of the respective source file.

[2] MCC and LAD/FBD programming languages: in the declaration table of the respective chart/program.

Rules for identifiers

Names for variables, data types, charts/programs must comply with the following rules for identifiers:

1. They are made up of letters (A to Z, a to z), numbers (0 to 9), and underscores (_).
2. The first character must be a letter or underscore.
3. This can be followed by as many letters, digits or underscores as needed in any order.
4. Exception: You must not use more than one underscore in succession.
5. Both upper- and lower-case letters are allowed. No distinction is made between upper- and lower-case notation (thus, for example, Anna and AnNa are regarded as identical).

Note

Reserved identifiers

Reserved identifiers may only be used as predefined. You may not declare a variable or data type with the name of a reserved identifier.

There is no distinction between upper- and lower-case notation.

You can find a list of all the identifiers whose meanings are predefined in SIMOTION in the SIMOTION Basic Functions Function Manual.

Note

Identifiers for SIMOTION devices

Identifiers for SIMOTION devices do not have to comply with rules specified above. When used in SIMOTION SCOUT they must be enclosed in double inverted commas (", ASCII code $22). See the SIMOTION ST Programming and Operating Manual.

Frequently used arrays in declarations

Reference (as of kernel V4.5)

References can be formed as of version V4.5 SIMOTION Kernel. The compiler option (Page 3996) "Object-oriented programming" must also be activated.

By activating the **Reference** checkbox, you specify that the declared variable (or the component of a structure) contains the reference to the specified data type. This means that the variable can contain address information for a variable of the specified data type.

The following are permitted as data types to which references can be formed:

- Elementary data types (e.g. INT, DINT, REAL, WORD, TIME, STRING)
- User-defined data types (UDT)
- System data types
- Function blocks, provided they contain at least one static variable
- Classes (from ST sources)

No references can be formed to the following data types because references exist already:

- Technology object data types
- Object-oriented interfaces (from ST sources)
- General references
- I/O references (from ST sources)

Array length and array element

A field is a chain of variables of the same type that can be addressed with the same name and different indices.

You can define the variable as a field [0...N-1] by entering a field length N. You have the following options for entering the field length:

- You can enter a constant positive integer value.
- You can enter a value range with ".." separating the min. and max. values.
- You can enter a constant expression of data type DINT (or of a data type which is implicitly convertible to DINT).

If the field is empty, a single variable is set up rather than a field.

Example definition of an field in the declaration table

	Name	Variable type	Data type	Array length	Initial value	Comment
1	const_1	VAR_GLOBAL CONSTANT	INT		11	constant
2	const_2	VAR_GLOBAL CONSTANT	INT		5	constant
3	array_4	VAR_GLOBAL	INT	11	11(5)	specification of the array length by value
4	array_5	VAR_GLOBAL	INT	const_1	11(5)	specification of the array length by constant expression
5	array_6	VAR_GLOBAL	INT	-5 .. 5	11(5)	specification of the array length by range of values
6	array_7	VAR_GLOBAL	INT	const_2 .. 3 * const_2	11(5)	specification of the array length by range of values as constant expression
7						

Figure 7-34 Defining the length of a field

Example of use of field elements in a variable assignment

	Variable	:=	Expression
1	array_1[0]	:=	4
2	array_2[3]	:=	array_2[4]
3		:=	

Figure 7-35 Use of field elements in a variable assignment

Initial value

You can specify an initialization value in this column. The field cannot be edited, but is provided as button.

1. Click the button. A window opens:

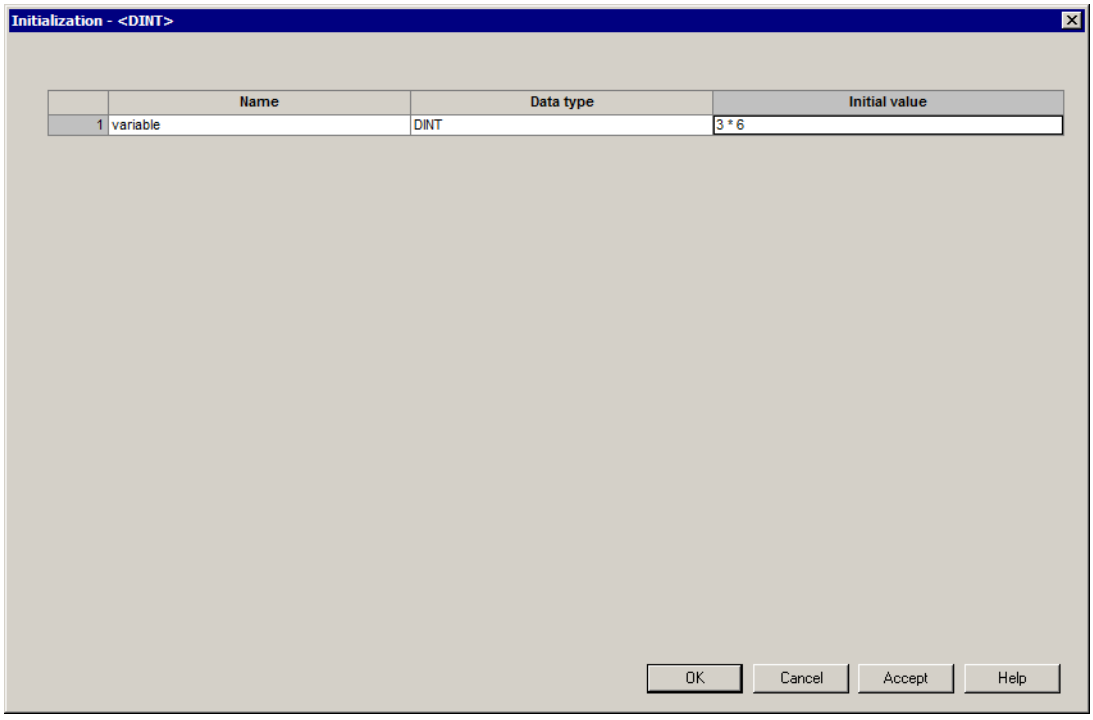


Figure 7-36 Definition an initialization value

2. Enter the initialization value in the **Initial value** column.
   You can specify this initialization value as a constant or as an expression. The following are permissible:
   - Constants
   - Arithmetic operations
   - Bit slice and data conversion functions
3. Confirm with **OK**.

Variables of a technology object data type cannot be assigned an initialization value. They are always initialized by the compiler with TO#NIL.

Initialization of arrays

Per default, the compiler assigns all array elements the initialization value of the data type. The initialization values can be changed by specifying an array initialization list according to the following example.

Table 7-8 Preassignment of array elements

10(1)	10 array elements [0..9] are pre-assigned the same value "1".
1,2,3,4,5	5 array elements [0..4] are pre-assigned different values "1", "2", "3", "4" and "5".
5(3),10(99),3(7),2(1)	The following array elements are pre-assigned the following values: • Five array elements [0..4] with the same value "3". • 10 array elements [5..14] with the same value "99". • 3 array elements [15..17] with the same value "7". • 2 array elements [18..19] with the same value "1".

Definition of these initialization values in the declaration table:

	Name	Variable type	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	array_1	VAR_GLOBAL	INT		10	10(1)	all array elements equal
2	array_1_	VAR_GLOBAL	INT		5	1, 2, 3, 4, 5	all array elements diverse
3	array_1_	VAR_GLOBAL	INT		20	5(3), 10(99), 3(7), 2(1)	several array elements respectively equal
4							

Figure 7-37 Definition of the initialization values of an array

Initialization of structures

Per default, the compiler assigns all components of a structure the initialization value of their data type. By specifying an initial value for a component, its initialization can be changed.

When using the structure in another declaration (e.g. variable or structure definition), the initialization values of individual components can be changed by assigning a structure initialization list, enclosed in round brackets ( ), in accordance with the following example.

	Structure name	Element name	Data type	Array length	Initial value	Comment
1	type_struct_1	s11	INT		1	
2		s12	DINT	3	3(2)	
3		s13	UDINT		3	
4	type_struct_2	s21	LREAL		3.0	
5		s22	DWORD		16#0000_FFFF	
6	type_struct_3	s31	type_struct_1		(s11 := 10, s12 := [3(20)])	
7		s32	type_struct_2		(s22 := 16#0000_00FF)	
8		s33	REAL		10.0 / 3.0	
9						

Figure 7-38 Definition of the initialization values of a structure

Instance-specific initialization of classes and function blocks

For the instance formation of classes and function blocks created during the object-oriented programming, variables declared as VAR OVERRIDE or VAR PUBLIC can be initialized instance-specific. The initialization values specified for the definition of the associated program organization unit (POU) are overwritten.

Proceed as follows to initialize the instance variables instance-specific:

1. Click the button in the **Initial value** column. A window opens.

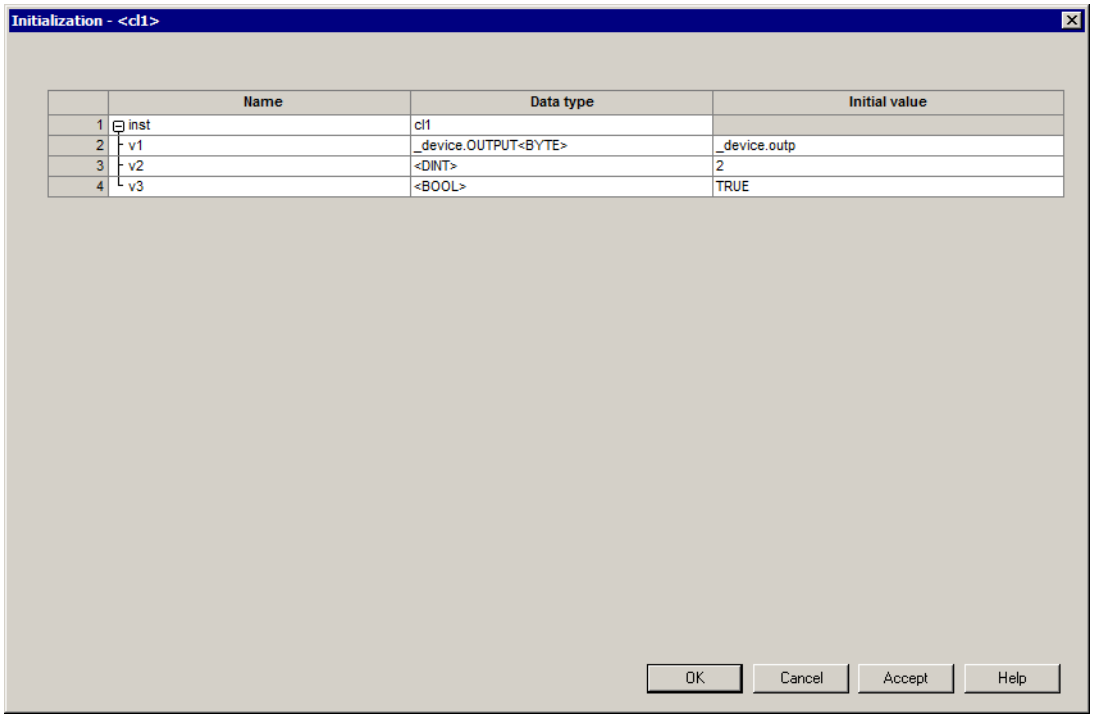

Figure 7-39 Definition of the initialization values of a class or function block

   Variables that must be initialized are already displayed in this window with their name and data type; the associated line is color-highlighted.

2. You can add additional lines for variables whose initialization is optional:
   - Click the number in line 1 and select **Add new line** in the context menu.
   - Enter the name of the variable. The data type is then initialized automatically.
3. Enter the initialization values of the associated variables.
4. Click **OK** to confirm.

Comments

A comment can be entered in this column. It may contain any characters or special characters.

Sorting in the declaration tables

You can specify a sorting order for a column in the declaration tables. The lines of the declaration table are arranged so that the entries (character strings) of the relevant column are sorted according to the sorting criterion. The characters are sorted according to their ANSI code; the sorting is not case-sensitive.

The following sorting criteria are available:

- **Sort in ascending order**
  Alphabetic sorting is ascending order (0 ... 9, a ...z).
- **Sort in descending order**
  Alphabetic sorting is descending order (z ... a, 9 ... 0).
- **Original order**
  No sorting. The lines of the declaration table are arranged in the order of declaration.

As long as the sorting order is not accepted (see below), the following applies:

- The sorting only affects the display. The data storage remains unchanged.
- The declaration table is saved in the original order.
- The compiler processes the declaration table in the original order.

Special features when sorting structures and enumerations

When sorting structures (Page 4058) and enumerations (Page 4059), the following applies:

- When sorting according to the **Structure name** or **Enumeration name** column:
  - The structures or enumerations are sorted according to their names.
  - The elements of these structures and enumerations remain in their original order.
- When sorting according to the other columns:
  - The structures and enumerations remain in their original order.
  - The elements within the structures and enumerations are sorted.

Special feature of pragma lines

For the declaration tables of a unit (interface section and implementation section), the following applies:

If in the declaration of unit variables (Page 4064) (Parameters tab), pragma lines (Page 4070) are available, the lines are sorted between the individual pragma lines.

Note

In the sorted view of a declaration table, the following is not possible:

- Insertion of new elements (e.g. variables, structures, enumerations as well as elements of structures and enumerations).
- Insertion of new or copied lines.
- Insertion of pragma lines.

Procedure

To sort the entries of the declaration table:

- Double-click the appropriate column header.
  The sorting changes between the sorting criteria.
  A double-click in another column header results sorting in ascending order according to this column.
- Or alternatively:
  - Move the cursor to the appropriate column header.
  - Select the sorting criterion in the context menu

  The sorting is performed according to the selected sorting criterion.
  The original order can only be selected in the context menu of a sorted column.

Accepting the sorting order

Proceed as follows:

1. Move the cursor to an arbitrary column header.
2. Select **Accept sorting order** in the context menu.

The sorting order is taken over as original order.

Note

Observe the following when accepting the sorting order in a declaration table:

- No "Undo" possible.
- The data storage and the declaration order are changed.
- The corresponding unit is changed and must be compiled again.
- The compiler processes the declaration table in the changed order.
- The relevant variable blocks are initialized during the download of the unit.
- HMI-relevant data is no longer consistent.

7.1.5.5 Data types

Data types

A data type is used to determine how the value of a variable or constant in a program source is to be used.

The following data types are available to the user:

- Elementary data types (Page 4054)
- User-defined data types (UDT) (Page 4057)
  - Enumerations
  - Structures (Struct)

- Technology object data types (Page 4060)
- System data types (Page 4061)

Elementary data types

Elementary data types define the structure of data that cannot be broken down into smaller units. An elementary data type describes a memory area with a fixed length and stands for bit data, integers, floating-point numbers, duration, time, date and character strings.

All the elementary data types are listed in the table below:

Table 7-9 Bit widths and value ranges of the elementary data types

Type		Reserv. word	Bit width	Range of values
Bit data type Data of this type uses either 1 bit, 8 bits, 16 bits, or 32 bits. The initialization value of a variable of this data type is 0.				
	Bit	BOOL	1	0, 1 or FALSE, TRUE
	Byte	BYTE	8	16#0 to 16#FF
	Word	WORD	16	16#0 to 16#FFFF
	Double word	DWORD	32	16#0 to 16#FFFF_FFFF
Numeric types These data types are available for processing numeric values. The initialization value of a variable of this data type is 0 (all integers) or 0.0 (all floating-point numbers).				
	Short integer	SINT	8	-128 to 127 (-2**7 to 2**7-1)
	Unsigned short integer	USINT	8	0 to 255 (0 to 2**8-1)
	Integer	INT	16	-32_768 to 32_767 (-2**15 to 2**15-1)
	Unsigned integer	UINT	16	0 to 65_535 (0 to 2**16-1)
	Double integer	DINT	32	-2_147_483_648 to 2_147_483_647 (-2**31 to 2**31-1)
	Unsigned double integer	UDINT	32	0 to 4_294_967_295 (0 to 2**32-1)
	Floating-point number (per IEEE -754)	REAL	32	-3.402_823_466E+38 to -1.175_494_351E-38, 0.0, +1.175_494_351E-38 to +3.402_823_466E+38 Accuracy: 23-bit mantissa (corresponds to 6 decimal places), 8-bit exponent, 1-bit sign.
	Long floating-point number (in accordance with IEEE-754)	LREAL	64	-1.797_693_134_862_315_7E+308 to -2.225_073_858_507_201_4E-308, 0.0, +2.225_073_858_507_201_4E-308 to +1.797_693_134_862_315_7E+308 Accuracy: 52-bit mantissa (corresponds to 15 decimal places), 11-bit exponent, 1-bit sign.
Time types These data types are used to represent various date and time values.				

Type		Reserv. word	Bit width	Range of values
	Duration in increments of 1 ms	TIME	32	T#0d_0h_0m_0s_0ms to T#49d_17h_2m_47s_295ms Maximum of 2 digits for the values day, hour, minute, second and a maximum of 3 digits for milliseconds Initialization with T#0d_0h_0m_0s_0ms
	Date in increments of 1 day	DATE	32	D#1992-01-01 to D#2200-12-31 Leap years are taken into account, year has four digits, month and day are two digits each Initialization with D#0001-01-01
	Time of day in increments of 1 ms	TIME_OF_DAY (TOD)	32	TOD#0:0:0.0 to TOD#23:59:59.999 Maximum of two digits for the values hour, minute, second and maximum of three digits for milliseconds Initialization with TOD#0:0:0.0
	Date and time	DATE_AND_TIME (DT)	64	DT#1992-01-01-0:0:0.0 to DT#2200-12-31-23:59:59.999 DATE_AND_TIME consists of the data types DATE and TIME Initialization with DT#0001-01-01-0:0:0.0
String type Data of this type represents character strings, in which each character is encoded with the specified number of bytes. The length of the string can be defined at the declaration. Indicate the length in "[" and "]", e.g. STRING[100]. The default setting consists of 80 characters. The number of assigned (initialized) characters can be less than the declared length.				
	String with 1 byte/character	STRING	8	You may use all the characters in the extended ASCII character set (ASCII code $00 to $FF). Default ' ' (empty string)

Note

During variable export to other systems, the value ranges of the corresponding data types in the target system must be taken into account.

Elementary system data types (Page 4057)

Value range limits of elementary data types

The value range limits of certain elementary data types are available as constants.

Table 7-10 Symbolic constants for the value range limits of elementary data types

Symbolic constant	Data type	Value	Hex notation
SINT#MIN	SINT	-128	16#80
SINT#MAX	SINT	127	16#7F
INT#MIN	INT	-32768	16#8000

Symbolic constant	Data type	Value	Hex notation
INT#MAX	INT	32767	16#7FFF
DINT#MIN	DINT	-2147483648	16#8000_0000
DINT#MAX	DINT	2147483647	16#7FFF_FFFF
USINT#MIN	USINT	0	16#00
USINT#MAX	USINT	255	16#FF
UINT#MIN	UINT	0	16#0000
UINT#MAX	UINT	65535	16#FFFF
UDINT#MIN	UDINT	0	16#0000_0000
UDINT#MAX	UDINT	4294967295	16#FFFF_FFFF
T#MIN TIME#MIN	TIME	T#0ms	16#0000_0000[1]
T#MAX TIME#MAX	TIME	T#49d_17h_2m_47s_295ms	16#FFFF_FFFF[1]
TOD#MIN TIME_OF_DAY#MIN	TOD	TOD#00:00:00.000	16#0000_0000[1]
TOD#MAX TIME_OF_DAY#MAX	TOD	TOD#23:59:59.999	16#0526_5BFF[1]
[1] Internal display only			

General data types

General data types are often used for the input and output parameters of system functions and system function blocks. The subroutine can be called with variables of each data type that is contained in the general data type.

The following table lists the available general data types:

Table 7-11 General data types

General data type	Data types contained
ANY_BIT	BOOL, BYTE, WORD, DWORD
ANY_INT	SINT, INT, DINT, USINT, UINT, UDINT
ANY_REAL	REAL, LREAL
ANY_NUM	ANY_INT, ANY_REAL
ANY_DATE	DATE, TIME_OF_DAY (TOD), DATE_AND_TIME (DT)
ANY_ELEMENTARY	ANY_BIT, ANY_NUM, ANY_DATE, TIME, STRING
ANY	ANY_ELEMENTARY, user-defined data types (UDT), system data types, data types of the technology objects

Note

You **cannot** use general data types as type identifiers in variable or type declarations.

The general data type is retained when a user-defined data type (UDT) is derived directly from an elementary data type (only possible with the SIMOTION ST programming language).

Elementary system data types

In the SIMOTION system, the data types specified in the table are treated in a similar way to the elementary data types. They are used with many system functions.

Table 7-12 Elementary system data types and their use

Identifier	Bit width	Use
StructAlarmId	32	Data type of the alarmId for the project-wide unique identification of the messages. The alarmId is used for the message generation. Please refer to the *SIMOTION Basic Functions* Function Manual. Initialization with STRUCTALARMID#NIL
StructTaskId	32	Data type of the taskId for the project-wide unique identification of the tasks in the execution system. Please refer to the *SIMOTION Basic Functions* Function Manual. Initialization with STRUCTTASKID#NIL

Table 7-13 Symbolic constants for invalid values of elementary system data types

Symbolic constant	Data type	Meaning
STRUCTALARMID#NIL	StructAlarmId	Invalid AlarmId
STRUCTTASKID#NIL	StructTaskId	Invalid TaskId

User-defined data types (UDT)

Defining user-defined data types (UDT)

You can create user-defined data types in units and programs/charts:

- Structures (Page 4058)
- Enumerations (Page 4059)

The scope of the data type declaration (Page 4058) depends on the location of the declaration.

Scope of the data type declaration

You create derived data types in the declaration tables of the source file or the program/chart. The scope of the data type declaration depends on the location of the declaration.

- In the declaration table of the unit, **Interface (exported declaration)** section:
  The data type is valid for the entire source file; all programs/charts (programs, function blocks, and functions) within the source file can access the data type.
  These variables are also available, if appropriately connected (see Define connections (Page 4115)), in other source files (or other units).
- In the declaration table of the unit, **Implementation (unit-internal declaration)** section:
  The data type is valid in the source file; all programs/charts (programs, function blocks, and functions) within the source file can access the data type.
- In the declaration table of the program/chart:
  The data type can only be accessed within the program/chart in which it is declared.

Defining structures

You define structures in the declaration tables of the unit or the program/chart. The scope of the structures depends on the location of the declaration.

To define structures, proceed as follows:

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Structures** tab.
3. Enter the name of the structure.
4. In the same line, enter:
   - The name of the first component in the **Element name** field.
   - Data type of the component.
     You can select already defined data types.
     See also:
     Elementary data types (Page 4054).
     User-defined data types (Page 4057).
     Technology object data types (Page 4060).
     System data types (Page 4061).
   - Activating the optional **Reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 4047).
   - Optional array length (to define the array size).
     See also: Array length and array element (Page 4048).
   - Optional initial value (initialization value).
     See also: Initial value (Page 4049).
   - Optional comment.
     See also: Comment (Page 4051).

5. Enter additional elements of the structure in the following lines; leave the **Structure name** field empty.
6. Begin the definition of the new structure by entering a new name in the **Structure name** field.

Example

This example shows the definition of a structure with three components:

	Structure name	Element name	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	t_struct	comp_1	INT	☐			
2		comp_2	REAL	☐	5	3(2), 2(3)	
3		compp_3	STRING	☐		'Example'	
4				☐			

Figure 7-40 Definition of a structure

Defining enumerations

You define **enumerations** in the declaration tables of the unit or the program/chart. The scope (Page 4058) of the enumerations depends on the location of the declaration.

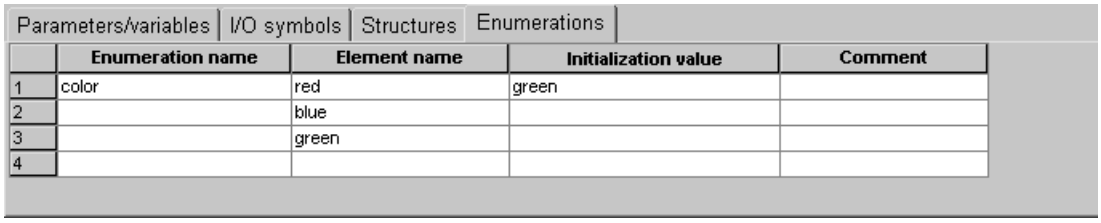
To define enumerations, proceed as follows:

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Enumerations** tab.
3. Enter the name of the enumeration.
4. In the same line, enter:
   - The name of the first element
   - Optionally, the initialization value of the enumeration data type
5. Enter additional elements of the enumeration in the following lines; leave the **Enumeration name** field empty.
6. You begin the definition of the new enumeration by entering a new name in the **Enumeration name** field.

Example

This example shows the definition of an enumeration data type with the name **Color** and the enumeration elements **Red**, **Blue**, and **Green**, as well as the initialization value (initial value) **Green**.

If no initialization value is entered during the enumeration definition (data type declaration), the first value of the enumeration is assigned to the data type. In this example, this means **Red** would be used for the initialization because it is defined as the first enumeration element.



Parameters/variables | I/O symbols | Structures | Enumerations

	Enumeration name	Element name	Initialization value	Comment
1	color	red	green	
2		blue		
3		green		
4				

Figure 7-41 Definition of an enumeration data type

Technology object data types

Description of the technology object data types

You can declare variables with the data type of a technology object (TO). The following table shows the data types for the available technology objects in the individual technology packages.

For example, you can declare a variable with the data type *posaxis* and assign it an appropriate instance of a position axis. Such a variable is often referred to as a reference.

Table 7-14 Data types of technology objects (TO data type)

Technology object	Data type	Contained in the technology package
Drive axis	DriveAxis	CAM, PATH[1], CAM_EXT
External encoder	ExternalEncoderType	CAM, PATH[1], CAM_EXT
Measuring input	MeasuringInputType	CAM, PATH[1], CAM_EXT
Output cam	OutputCamType	CAM, PATH[1], CAM_EXT
Cam track	_CamTrackType	CAM, PATH[1], CAM_EXT
Position axis	PosAxis	CAM, PATH[1], CAM_EXT
Following axis	FollowingAxis	CAM, PATH[1], CAM_EXT
Following object	FollowingObjectType	CAM, PATH[1], CAM_EXT
Cam	CamType	CAM, PATH[1], CAM_EXT
Path axis[1]	_PathAxis	PATH[1], CAM_EXT
Path object[1]	_PathObjectType	PATH[1], CAM_EXT
Fixed gear	_FixedGearType	CAM_EXT
Addition object	_AdditionObjectType	CAM_EXT
Formula object	_FormulaObjectType	CAM_EXT
Sensor	_SensorType	CAM_EXT
Controller object	_ControllerObjectType	CAM_EXT
Temperature channel	TemperatureControllerType	TControl
General data type, to which every TO can be assigned	ANYOBJECT	

[1] Available as of version V4.1.

You can access the elements of technology objects (configuration data and system variables) via structures (see SIMOTION Basic Functions Function Manual).

Table 7-15 Symbolic constants for invalid values of technology object data types

Symbolic constant	Data type	Meaning
TO#NIL	ANYOBJECT	Invalid technology object

Inheritance of the properties for axes

Inheritance for axes means that all of the data types, system variables and functions of the TO driveAxis are fully included in the TO positionAxis. Similarly, the position axis is fully included in the TO synchronizedAxis, the following axis in the TO pathAxis. This has, for example, the following effects:

- If a function or a function block expects an input parameter of the driveAxis data type, you can also use a position axis or a synchronized axis or a path axis when calling.
- If a function or a function block expects an input parameter of the posAxis data type, you can also use a synchronized axis or a path axis when calling.

System data types

There are a number of system data types available that you can use without a previous declaration. And, each imported technology packages provides a library of system data types.

Additional system data types (primarily enumeration and STRUCT data types) can be found

- In parameters for the general standard functions (see SIMOTION Basic Functions Function Manual)
- In parameters for the general standard function blocks (see SIMOTION Basic Functions Function Manual)
- In system variables of the SIMOTION devices (see relevant parameter manuals)
- In parameters for the system functions of the SIMOTION devices (see relevant parameter manuals)
- In system variables and configuration data of the technology objects (see relevant parameter manuals)
- In parameters for the system functions of the technology objects (see relevant parameter manuals)

7.1.5.6 Variables

Variables are an important component of programming and provide structure to programs. They are placeholders which can be assigned values that can be accessed several times in the program.

Variables have:

- A specific initialization behavior and scope of validity
- A data type and operations which are defined for that data type

User and system variables are differentiated. User variables can be defined by the user. System variables are provided by the system.

Keywords for variable types

The various keywords for variable types are shown in the following table.

Description of keywords for variable types

Keyword	Description	Use
Global user variables (declared in the interface or implementation section of the unit[1])		
VAR_GLOBAL	Unit variable; can be accessed by all POUs within the source file. If the variable was declared in the interface section, it can be used in another source file once a connection has been defined in its declaration table (see Define connections (Page 4115)).	FB, FC, program
VAR_GLOBAL RETAIN	Retentive unit variable; retained during power outage.	FB, FC, program
VAR_GLOBAL CONSTANT	Unit constant; cannot be changed from the program.	FB, FC, program
Local user variables (declared within a POU[2])		
VAR	Local variable (static for FB and program, temporary for FC)	FB, FC, program
VAR_TEMP	Temporary local variable	FB, FC, program
VAR_INPUT	Input parameters: Local variable; value is supplied from external source and can only be read in the FB or FC.	FB, FC
VAR_OUTPUT	Output parameters: Local variable; value is sent to an external destination by the FB. It can be read as an instance variable after being called by the FB (FB instance name.variable name).	FB, FC
VAR_IN_OUT	In/out parameter; the FB or FC accesses this variable directly (by means of a reference) and can change it directly.	FB, FC
VAR OVERRIDE	Static variable whose initialization value can be overwritten for an instance formation. The compiler option (Page 3994) "Permit object-oriented programming" must be activated.	FB
VAR CONSTANT	Local constant; cannot be changed from the program.	FB, FC, program
[1] MCC and LAD/FBD programming languages: in the declaration table of the associated source file. [2] MCC and LAD/FBD programming languages: in the declaration table of the associated chart/program.		

Defining variables

Variables are defined in the symbol browser or in the declaration table of the source file or chart/program. The following table provides an overview of where the relevant variable is defined.

Definition of variables

Variable type	Defined in...
Global device user variables	Symbol browser
unit variable	Declaration table of the source file as VAR_GLOBAL, VAR_GLOBAL RETAIN or VAR_GLOBAL CONSTANT
Local variable	Declaration table of the program/chart as: • VAR, VAR_TEMP, or VAR CONSTANT • Additionally for function blocks as VAR_INPUT, VAR_OUTPUT, VAR_IN_OUT • Additionally for functions as VAR_INPUT, VAR_IN_OUT
I/O variable	Symbol browser
Symbolic access to the fixed process image of the BackgroundTask	• Declaration table of the source file • Declaration table of the program/chart (programs and FB only)

Use of global device variables

Global device variables are user-defined variables that you can access from all program sources (e.g. ST source files, MCC source files) of a SIMOTION device.

Global device variables are created in the symbol browser tab of the detail view; to do this, you must be working in offline mode.

Here is a brief overview of the procedure:

1. In the project navigator of SIMOTION SCOUT, select the **GLOBAL DEVICE VARIABLES** element in the SIMOTION device subtree.
2. In the detail view, select the **Symbol browser** tab and scroll down to the end of the variable table (empty row).
3. In the last (empty) row of the table, enter or select the following:
   - **Name** of variable
   - **Data type** of variable (only elementary data types are permitted)
4. Optionally, you can make the following entries:
   - Activation of **Retain** checkbox (This declares the variable as retentive, so that its value will be retained after a power failure.)
   - **Field length** (array size)
   - **Initial value** (if array, for each element)
   - **Display format** (if array, for each element)

You can now access this variable using the symbol browser or any program of the SIMOTION device.

In ST source files, you can use a global device variable, just like any other variable.

Note

If you have declared unit variables or local variables of the same name (e.g. *var-name*), specify the global device variable with *_device.var-name*.

An alternative to global device variables is the declaration of unit variables in a separate unit, which is imported into other units. This has the following advantages:

1. Variable structures can be used.
2. The initialization of the variables during the STOP-RUN transition is possible (via Program in StartupTask).
3. For newly created global unit variables, a download in RUN is also possible.

Please refer to the SIMOTION Basic Functions Function Manual.

Declaring a unit variable in the source file

The unit variable is declared in the unit. The scope of validity of the variable is dependent on the section of the declaration table in which the variable is declared:

- In the interface section of the declaration table (INTERFACE):
  The unit variable is valid for the entire unit; all programs/charts (programs, function blocks, and functions) within the unit can access the unit variable. It is exported and can be used in other source files or units (e.g. ST source files, MCC units, LAD/FBD units) after a connection has been defined (Page 4115). It is also available on HMI devices as standard. The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.
- In the implementation section of the declaration table (IMPLEMENTATION):
  The unit variable is valid in the unit only; all programs/charts (programs, function blocks, and functions) within the unit can access the unit variable.

If you insert pragma lines (Page 4070) into the declaration table, you can split the unit variables into data blocks with a separate version code (Page 4081). You can also use the pragma lines to define a separate initialization behavior (Page 4076) for each of these data blocks and change the defaults for HMI export (Page 4082).

Proceed as follows; the unit (declaration table) is open, see Open existing program source (Page 3989):

1. In the declaration table, select the section for the desired scope.
2. Then select the **Parameters** tab.
3. Enter:
   - Name of the variable.
   - Variable type.
     See also: Keywords for variable types (Page 4062).
   - Data type of the variables.
     You can select already defined data types.
     See also: Data types (Page 4053).
   - Activating the optional **Reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 4047).
   - Optional array length (to define the array size).
     See also: Array length and array element (Page 4048).
   - Optional initial value (initialization value).
     See also: Initial value (Page 4049).
   - Optional comment.
     See also: Comment (Page 4051).

The variable is then declared and can be used immediately within the unit.

Note

Outside the unit (e.g. in the symbol browser), the variable is only available after the unit has been compiled.

INTERFACE (exported declaration)

Parameter | I/O symbols | Structures | Enumerations | Connections

	Name	Variable type	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	var_in1	VAR_GLOBAL	REAL	☐			
2				☐			

IMPLEMENTATION (source-internal declaration)

Parameter | I/O symbols | Structures | Enumerations | Connections

	Name	Variable type	Data type	Reference	Array length	Initial value	Comment [English (United States)]
1	var_in2	VAR_GLOBAL	BOOL	☐			
2	var_out	VAR_GLOBAL	INT	☐	10		
3				☐			

Figure 7-42 Example: Declaring a unit variable in the unit

Note

The declaration table of the unit is read each time parameters are assigned for a command. Inconsistent data within the declaration table may, therefore, cause unexpected error messages during parameter assignment.

Declaring local variables

A local variable can only be accessed within the program/chart (program, function, function block) in which it is declared.

We distinguish between the following:

- Static variables:
  Static variables retain their value over all passes of the unit section (block memory).
- Temporary variables:
  Temporary variables are initialized each time the unit section is called again.

See also: Initialization of local variables (Page 4077).

If you insert a pragma line (Page 4070) at the start of the declaration table, you can influence the initialization of static variables of programs (Page 4078).

Proceed as follows; the program/chart with the declaration table is open (see Open existing program source (Page 3989)):

1. In the declaration table, select the **Parameters/Variables** tab.
2. Enter:
   - Name of the variable.
   - Variable type for variables.
     See also: Keywords for variable types (Page 4062).
   - Data type of the variables.
     You can select already defined data types.
     See also: Data types (Page 4053).
   - Activating the optional **Reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 4047).
   - Optional array length (to define the array size).
     See also: Array length and array element (Page 4048).
   - Optional initial value (initialization value).
     See also: Initial value (Page 4049).
   - Optional comment.
     See also: Comment (Page 4051).

The variable is now declared and can be used immediately.

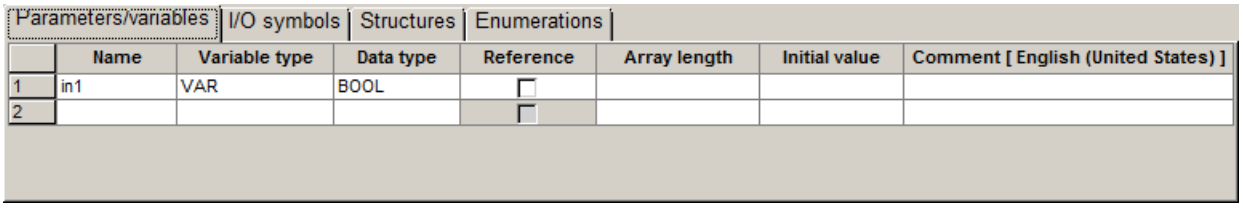


Figure 7-43 Example: Declaring a local variable in the chart/program

Note

The declaration table of the program/chart is read each time parameters are assigned for a command. Inconsistent data within the declaration table may, therefore, cause unexpected error messages during parameter assignment.

Defining variables in the Variable declaration dialog box ("on-the-fly" variable declaration)

As soon as you enter an unknown variable in the parameter screen form for an MCC command or an LAD/FBD graphic, the **Variable declaration** dialog box appears.

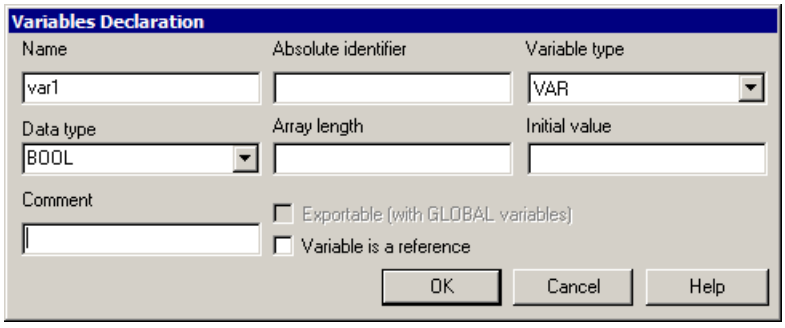

Figure 7-44 Variable declaration dialog box

Note

In order for the **Variable declaration** dialog box to appear, the **on-the-fly variable declaration** checkbox must be activated in the **Settings** dialog box.

Procedure

To define variables "on-the-fly" in the **Variable declaration** dialog box, proceed as follows:

1. Enter only the name of the variables in an input field of the parameter screen for an MCC command or LAD/FBD graphic and press the **Return** key.
   If the entered identifier is not a valid variable name, the dialog box **Variable declaration** appears.
2. Enter:
   - Another variable name, if required.
   - The **Data type** of the variables
     Available for selection are all elementary data types (Page 4054) and, where appropriate, the data type suitable for the input field.
     Select the data type or enter the identifier of a data type.
   - The **variable type**.
     Available for selection are all permitted keywords for variable types (Page 4062).
     Select the variable type.
     If you select a global variable type (e.g. VAR_GLOBAL), the checkbox **Exportable** becomes active.
   - The **Absolute identifier** for access to the fixed process image of the background task (Page 4103).
     You can only enter the identifier for the absolute access to the fixed process image of the background task if you have selected a data type that is included in the general data types (Page 4056) ANY_BIT or ANY_INT.
     Enter the absolute identifier according to the Syntax (Page 4110).
     The variable is displayed in the register **I/O symbols** of the declaration table.
   - Optional **array length**.
     Here, you specify the size of the array.
     Not available if an absolute identifier is entered.
     See also: Array length and array element (Page 4048).
   - Optional **initial value** (initialization value).
     Not available if an absolute identifier is entered.
     See also: Initial value (Page 4049).
   - Optional **comment**.
     See also:Comment (Page 4051).
   - Optionally, activate the **Variable is a reference** checkbox to declare a general reference to the data type.
     See also: Reference (Page 4047).

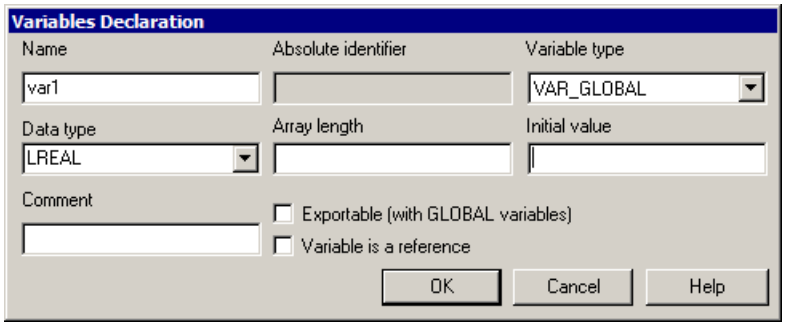

Figure 7-45 Example: Variable declaration

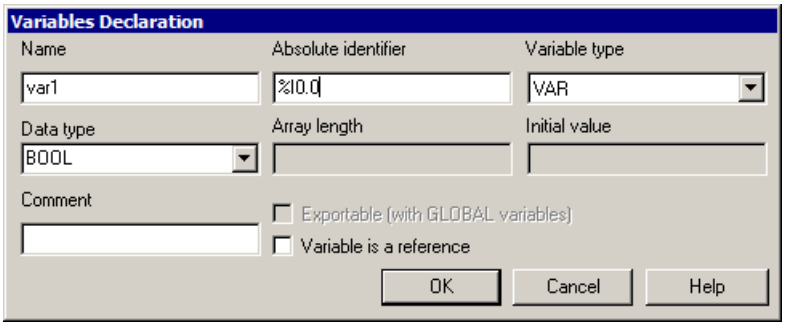

Figure 7-46 Example: Variable declaration (absolute name)

3. Confirm with **OK**.

Result

The variable is defined and entered in the declaration table of the source or the MCC chart or the LAD/FBD program, depending on the selected variable type and the **Exportable checkbox:**

- With local variables (e.g. VAR), the **Exportable** checkbox has a gray background and the new variable is entered in the declaration table of the MCC chart or the LAD/FBD program.
- With global variables (e.g. VAR_GLOBAL), the **Exportable** checkbox is shown activated:
  - If the **Exportable** checkbox is activated, the new variable is entered in the implementation section of the unit's declaration table.
  - If the **Exportable** checkbox is not activated, the new variable is entered in the interface section of the unit's declaration table.

Note

If you leave the **Variable declaration** dialog box by clicking **Cancel**, your input remains as it is, and the variable is not created.

Pasting pragma lines during variable definition

Pragma lines in declaration tables have the following function:

- In declaration tables of units (declaration of unit variables):
  Pragma lines in the interface section or implementation section of the declaration table split the variables of the respective section into different subsections:
  - The 1st subsection begins at the start of the relevant table and finishes at the 1st Pragma line.
  - All the other subsections start at one pragma line and finish at the next (or at the end of the table if starting at the last pragma line).

  Within these subsections of the table, each of the variables declared with VAR_GLOBAL or VAR_GLOBAL RETAIN forms a data block with a separate version code (Page 4081). If the version code is changed, only the data block concerned will be initialized during a download. Configure the pragma line in order to change the initialization behavior or the HMI export of the next data block (see following Section *Pragmas in the declaration tables of the unit variables*).
- In the declaration table of a program/chart (declaration of local variables):
  Line 1 may only contain one pragma line for changing the initialization behavior of programs' static variables (see the section titled *Pragmas in the declaration tables for local variables* later in this document).

Note

The SIMOTION Kernel version partially determines the effectiveness of pragma lines. This is specified for individual parameters.

Inserting a pragma line

To insert a pragma line into the declaration table, proceed as follows:

1. Select the **Parameters** tab (for unit variables) or **Parameters/variables** tab (for local variables).
2. In the declaration table, set the cursor to the number of the line at which a new data block is to be started.
   Only line 1 can be used in the declaration table for local variables.
3. Select the **Insert pragma line** context menu.
   A new line containing the **Pragmas** button only is inserted above the line.
4. Left-click the **Pragmas** button.
   A window containing configuration options for the relevant declaration table opens.
5. Enter the settings.
6. Confirm with **OK**.

Pragmas in the declaration tables for unit variables

A pragma line has been inserted into the declaration table for unit variables. If you click the "Pragmas" button in the table, the following window appears:

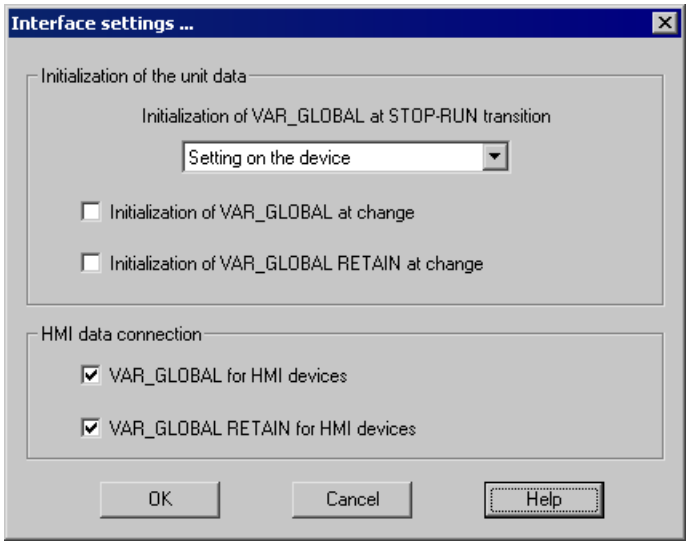

Figure 7-47 Pragma settings in the declaration table for unit variables (e.g. interface section)

This window is for making the settings below. These influence the data block following the pragma line:

Table 7-16 Parameters for pragma settings in the declaration table for unit variables

Parameter		Description
Initialization of unit data		
	Initialization of VAR_GLOBAL during STOP-RUN transition	Only as of version V4.1 of the SIMOTION Kernel. This setting determines whether the next data block of the non-retentive unit variables is initialized during the transition from STOP to RUN operating state. **Setting on the device** (standard): • As of version V4.2 of the SIMOTION Kernel: The setting made on the SIMOTION device applies. • Up to version V4.1 of the SIMOTION Kernel: Variables are **not** initialized. **Always**: Variables are initialized. **Never**: Variables are **not** initialized.
	Initialization of VAR_GLOBAL during a change	This setting determines whether a download for the next data block of the non-retentive unit variables can be performed in RUN if the version code has changed. **Active**: A download in RUN is possible. **Inactive** (standard): A download in RUN is **not** possible.
	Initialization of VAR_GLOBAL RETAIN during a change	This setting determines whether a download for the next data block of the retentive unit variables can be performed in RUN if the version code has changed. **Active**: A download in RUN is possible. **Inactive** (standard): A download in RUN is **not** possible.
HMI data connection		

Parameter		Description
		Use the settings below to change which unit variables are available on which HMI devices by default. Detailed description of the HMI export, in particular the effect of the settings depending on SIMOTION Kernel version: see Variables and HMI devices (Page 4082).
	VAR_GLOBAL for HMI devices	**Active** (standard in the interface section): The next data block of the non-retentive unit variables is available on HMI devices. **Inactive** (standard in the implementation section): The next data block of the non-retentive unit variables is **not** available on HMI devices.
	VAR_GLOBAL RETAIN for HMI devices	**Active** (standard in the interface section): The next data block of the retentive unit variables is available on HMI devices. **Inactive** (standard in the implementation section): The next data block of the retentive unit variables is **not** available on HMI devices.

Pragmas in the declaration tables for local variables

A pragma line has been inserted into line 1 of the declaration table for local variables. If you click the "Pragmas" button in the table, the following window appears:

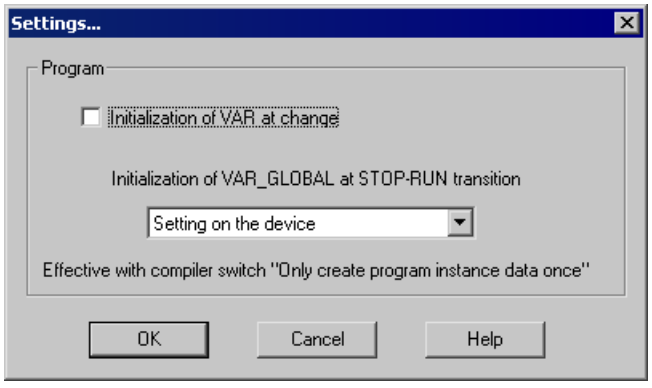

Figure 7-48 Pragma settings in the declaration table for local variables

You can make the following settings in this window:

Note

These settings only take effect in the following scenarios:

1. The "Only create program instance data once" compiler option is active on the higher-level unit.
2. The creation type of the program/chart is "Program".

Table 7-17 Parameters for pragma settings in the declaration table for local variables

Parameter	Description
Initialization of VAR during a change	This setting determines whether a download for the next static variables can be performed in RUN if the version code has changed. **Active**: A download in RUN is possible. **Inactive** (standard): A download in RUN is **not** possible.
Initialization of VAR during STOP-RUN transition	Only as of version V4.1 of the SIMOTION Kernel. This setting determines whether the next static variables are initialized during the transition from STOP to RUN operating state. **Setting on the device** (standard): • As of version V4.2 of the SIMOTION Kernel: The setting made on the SIMOTION device applies. • Up to version V4.1 of the SIMOTION Kernel: Variables are **not** initialized. **Always**: Variables are initialized. **Never**: Variables are **not** initialized.

Time of the variable initialization

The timing of the variable initialization is determined by:

- Memory area to which the variable is assigned
- Operator actions (e.g. source file download to the target system)
- Execution behavior of the task (sequential, cyclic) to which the program was assigned.

All variable types and the timing of their variable initialization are shown in the following tables. You will find basic information about tasks in the *SIMOTION Basic Functions* Function Manual.

The behavior for variable initialization during download can be set: To do this, as a default setting select the **Options > Settings** menu and the **Download** tab or define the setting during the current download.

Note

You can upload values of unit variables or global device variables from the SIMOTION device into SIMOTION SCOUT and save them in XML format.

1. Save the required data segments of the unit variables or global device variables as a data set with the function *_saveUnitDataSet*.
2. Use the **Save variables** function in SIMOTION SCOUT.

You can use the **Restore variables** function to download these data sets and variables back to the SIMOTION device.

For more information, refer to the SIMOTION SCOUT Configuration Manual.

This makes it possible, for example, to obtain this data, even if it is initialized by a project download or if it becomes unusable (e.g. due to a version change of SIMOTION SCOUT).

Version ID of global variables and their initialization during download (Page 4081)

Initialization of retentive global variables

Retentive variables retain their last value after a loss of power. All other data is reinitialized when the device is switched on again.

Retentive global variables are initialized:

- When the backup or buffer for retentive data fails.
- When a memory reset (MRES) is performed.
- With the restart function (Del. SRAM) in SIMOTION P320 or P350.
- By applying the *_resetUnitData* function, possible selectively for different data segments of the retentive data.
- When a download is performed according to the following description.
- With a firmware update (upgrade) or activation of a kernel in accordance with the following description.

Behavior during download

Table 7-18 Initializing retentive global variables during download

Variable type	Time of the variable initialization
Retentive global device variables	The behavior during the download depends on the *Initialization of retentive program data and retentive global device variables* setting[1]: • **Yes**[2]: All retentive global device variables are initialized. • **No**[3]: The retentive global device variables are only initialized if their version code is changed. See: Version code of global variables and their initialization during download (Page 4081).
Retentive unit variables	The behavior during the download depends on the *Initialization of retentive program data and retentive global device variables* setting[1]: • **Yes**[2]: All retentive unit variables (all units) are initialized. • **No**[3]: A data block (= declaration block)[4] of the retentive unit variables in the interface or implementation section is only initialized[5] if its version code is changed. See: Version code of global variables and their initialization during download (Page 4081).

[1] Default setting in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding check box is active.

[3] The corresponding check box is inactive.

[4] With the **SIMOTION ST** programming language:
A data block of the retentive unit variables corresponds to a VAR_GLOBAL RETAIN/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** and **SIMOTION LAD/FBD** programming languages:
A data block of the retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL RETAIN in the interface section or implementation section of the declaration table: Pragma lines (Page 4070) within a section of the declaration table separate the variables into different data blocks.

[5] Initialization of a changed data block also occurs during a download in RUN mode, provided the following condition is fulfilled:
With the **SIMOTION ST** programming language
The following attribute has been specified within a pragma: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line (Page 4070) is inserted in the declaration table with the following check box enabled in this line: *Initialization of VAR_GLOBAL RETAIN during a change*. All the variables declared with VAR_GLOBAL RETAIN up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see the SIMOTION Basic Functions Function Manual.

Behavior during upgrade or configuration change

When the SIMOTION device is upgraded to a new version of the SIMOTION Kernel or if the configuration is changed, the retentive variables are initialized as described below:

Table 7-19 Initialization of retentive global variables during upgrade or configuration change

Variable type	Time of the variable initialization
Retentive global device variables	This data is always initialized.
Retentive unit variables	This data can be retained. See section "Retaining retentive data" in the "Basic Functions for Modular Machines" Function Manual.

Initialization of non-retentive global variables

Non-retentive global variables lose their value during power outages. They are initialized:

- During the initialization of retentive global variables (Page 4074), e.g. during a firmware update or overall reset (MRES).
- During switch-on.
- By applying the *_resetUnitData* function, possible selectively for different data segments of the non-retentive data.
- During a download as described in the following table.
- During the transition from STOP to RUN mode as described at the end of the section.

Behavior during download

Table 7-20 Initializing non-retentive global variables during download

Variable type	Time of the variable initialization
Non-retentive global device variables	The behavior during the download depends on the *Initialization of non-retentive program data and non-retentive global device variables* setting[1]: • **Yes**[2]: All non-retentive global device variables are initialized. • **No**[3]: The non-retentive global device variables are only initialized if their version code is changed. See: Version code of global variables and their initialization during download (Page 4081).
Non-retentive unit variables	The behavior during the download depends on the *Initialization of non-retentive program data and non-retentive global device variables* setting[1]: • **Yes**[2]: All non-retentive unit variables (all units) are initialized. • **No**[3]: A data block (= declaration block)[4] of the non-retentive unit variables in the interface or implementation section is only initialized[5] if its version code is changed. See: Version code of global variables and their initialization during download (Page 4081).

[1] Default in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding check box is active.

[3] The corresponding check box is inactive.

[4] With the **SIMOTION ST** programming language:
A data block of the non-retentive unit variables corresponds to a VAR_GLOBAL/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A data block of the non-retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL in the interface section or implementation section of the declaration table: Pragma lines (Page 4070) within a section of the declaration table separate the variables into different data blocks.

[5] Initialization of a changed data block also occurs during a download in RUN, provided the following condition is fulfilled:
With the **SIMOTION ST**
programming language: The following attribute has been specified within a pragma in the relevant declaration block: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line (Page 4070) has been pasted into the declaration table and the following check box is activated: *Initialization of VAR_GLOBAL during a change*. All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see SIMOTION Basic Functions Function Manual.

Behavior during STOP-RUN transition

The values of non-retentive global variables are retained by default during the transition from STOP to RUN mode.

You can, however, make a setting whereby the non-retentive global variables are initialized during the STOP-RUN transition:

- **As of Version V4.2 of the SIMOTION Kernel**, by activating the **Initialization of non-retentive global variables and program data during STOP-RUN transition** checkbox on the SIMOTION device.
  With non-retentive unit variables, this setting can be overwritten by a pragma or pragma line (Page 4070) in the relevant data blocks of the program sources.
- **As of Version V4.1 of the SIMOTION Kernel**, by a pragma or pragma line in the relevant data blocks of the program sources (only with non-retentive unit variables):
  - With the **SIMOTION ST** programming language:
    Specify the following attribute within a pragma in the relevant VAR_GLOBAL/END_VAR declaration block: { BlockInit_OnDeviceRun := ALWAYS; }
  - With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
    Paste a pragma line (Page 4070) with the following setting into the declaration table: "*Initialization during STOP-RUN transition* = **Always**". All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block which is initialized during the STOP-RUN transition.

Note

With SIMOTION devices up to SIMOTION Kernel Version V4.0, non-retentive global variables are never initialized during the STOP-RUN transition.

Initialization of local variables

Local variables are initialized:

- For the initialization of retentive unit variables (Page 4074).
- For the initialization of non-retentive unit variables (Page 4076).
- Also, according to the following description:

Table 7-21 Initialization of local variables

Variable type	Time of the variable initialization
Local program variables	Local variables of programs are initialized differently: • Static variables (VAR) are initialized according to the memory area in which they are stored. See: Initialization of static program variables (Page 4078). • Temporary variables (VAR_TEMP) are initialized every time the program of the task is called.
Local variables of function blocks (FB)	Local variables of function blocks are initialized differently: • Static variables (VAR, VAR_IN, VAR_OUT) are only initialized when the FB instance is initialized. See: Initialization of instances of function blocks (FBs) (Page 4079). • Temporary variables (VAR_TEMP) are initialized every time the FB instance is called.
Local variables of functions (FC)	Local variables of functions are temporary and are initialized every time the function is called.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 4148) function.

Initialization of static program variables

The following versions affect the following static variables:

- Local variables of a unit program declared with VAR
- Function block instances declared with VAR within a unit program, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT).

The initialization behavior is determined by the memory area in which the static variables are stored. This is determined by the "Only create program instance data once" (Page 3996) compiler option.

- For the deactivated "Only create program instance data once" compiler option (default):
  The static variables are stored in the user memory of each task which is assigned to the program.
  The initialization of the variables thus depends on the execution behavior of the task to which the program is assigned (see SIMOTION Basic Functions Function Manual):
  - Sequential tasks (MotionTasks, UserInterruptTasks, SystemInterruptTasks, StartupTask, ShutdownTask): The static variables are initialized every time the task is started.
  - Cyclic tasks (BackgroundTask, SynchronousTasks, TimerInterruptTasks): The static variables are only initialized only during the transition from STOP to RUN operating state.
- For the activated "Only create program instance data once" compiler option:
  This setting is necessary, for example, if a program is to be called within a program.
  The static variables of all programs from the program source (unit) involved are only stored once in the user memory of the unit.
  They are thus initialized together with the non-retentive unit variables, see Initialization of non-retentive global variables (Page 4076).
  They are not initialized by default during the transition from STOP to RUN operating state.
  You can, however, make a setting whereby they are initialized during the STOP-RUN transition:
  - **As of version V4.2 of the SIMOTION Kernel**, by activating the **Initialization of non-retentive global variables and program data during STOP-RUN transition** checkbox on the SIMOTION device.
    This setting can be overwritten by a pragma or pragma line (Page 4070) in the data block of the relevant program organization unit (POU).
  - **As of version V4.1 of the SIMOTION Kernel**, by a pragma or pragma line in the data block of the relevant program organization unit (POU):
    With the **SIMOTION ST** programming language:
    Specify the following attribute within a pragma in the VAR/END_VAR declaration block:
    { BlockInit_OnDeviceRun := ALWAYS; }
    With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
    The declaration table starts with a pragma line (Page 4070) containing the following setting: "*Initialization during STOP-RUN transition* = **Always**". All the variables declared with VAR in the table are initialized during the STOP-RUN transition.

Initialization of instances of function blocks (FBs) or classes

The initialization of a function block instance (Page 4133) or a class instance (as of version V4.5 of the SIMOTION Kernel) (Page 4140) is determined by the location of its declaration:

- Global declaration (within VAR_GLOBAL/END_VAR in the interface of implementation section):
  Initialization as for a non-retentive unit variable, see Initialization of non-retentive global variables (Page 4076).
- Local declaration in a program (within VAR / END_VAR):
  Initialization as for static variables of programs, see Initialization of static variables of programs (Page 4078).

- Local declaration in a function block (within VAR / END_VAR):
  Initialization as for an instance of this function block.
- Declaration as in/out parameter in a function block or a function (within VAR_IN_OUT / END_VAR):
  For the initialization of the POU, only the reference (pointer) will be initialized with the instance of the function block remaining unchanged.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 4148) function.

Initialization of system variables of technology objects

The system variables of a technology object are usually not retentive. Depending on the technology object, a few system variables are stored in the retentive memory area (e.g. absolute encoder calibration).

The initialization behavior (except in the case of download) is the same as for retentive and non-retentive global variables. See Initialization of retentive global variables (Page 4074) and Initialization of non-retentive global variables (Page 4076).

The behavior during the download is shown below for:

- Non-retentive system variables
- Retentive system variables

Table 7-22 Initializing technology object system variables during download

Variable type	Time of the variable initialization
Non-retentive system variables	Behavior during download, depending on the *Initialization of all non-retentive data for technology objects* setting[1]: • **Yes**[2]: All technology objects are initialized. – All technology objects are restructured and all non-retentive system variables are initialized. – All technological alarms are cleared. • **No**[3]: Only technology objects changed in SIMOTION SCOUT are initialized. – The technology objects in question are restructured and all non-retentive system variables are initialized. – All alarms that are pending on the relevant technology objects are cleared. – If an alarm that can only be acknowledged with *Power On* is pending on a technology object that will not be initialized, the download is aborted.
Retentive system variables	Only if a technology object was changed in SIMOTION SCOUT, will its retentive system variables be initialized. The retentive system variables of all other technology objects are retained (e.g. absolute encoder calibration).

[1] Default in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding checkbox is active.

[3] The corresponding checkbox is inactive.

Version ID of global variables and their initialization during download

Table 7-23 Version code of global variables and their initialization during download

Data segment		Description of version code
Global device variables		
	Retentive global device variables Non-retentive global device variables	• Separate version code for each data segment of the global device variables. • The version code of the data segment changes for: – Add or remove a variable within the data segment – Change of the identifier or the data type of a variable within the data segment • This version code does not change on: – Changes in the other data segment – Changes to initialization values[1] • During downloading[2], the rule is: This data segment is only initialized when the version code of a data segment is changed.
Unit variables of a unit		
	Retentive unit variables in the interface section Retentive unit variables in the implementation section Non-retentive unit variables in the interface section Non-retentive unit variables in the implementation section	• Several data blocks (= declaration blocks)[3] are possible in each data segment. • **Separate version code** for each data block. • The version code of the data block changes for: – Add or remove a variable in the associated declaration block – Change of variable sequence in the relevant declaration block – Change of the identifier or the data type of a variable in the associated declaration block – Change of a data type definition (from a separate or imported[4] unit) used in the associated declaration block – Add or remove declaration blocks within the same data segment **before** the associated declaration block • This version code does not change on: – Add or remove declaration blocks in other data segments – Add or remove declaration blocks within the same data segment **after** the associated declaration block – Changes in other data blocks – Changes to initialization values[1] – Changes to data type definitions that are not used in the associated data block – Changes to functions • During downloading[2], the rule is: This data block is only initialized when the version code of a data block is changed[5]. • Functions for data backup and initialization take into account the version code of the data blocks.
Retentive variables of function blocks and classes (The instances are declared as non-retentive unit variables)		

Data segment		Description of version code
	Non-retentive unit variables in the interface section	Only as of version V4.5 of the SIMOTION Kernel. • The retentive variables of all instances within a declaration block (VAR_GLOBAL / END_VAR) are summarized as a separate retentive data block • to which a separate version code is assigned. • The version code of this retentive data block changes: – The data structure of the retentive local variables for the instances within the declaration block changes. – The sequence of the declaration blocks (VAR_GLOBAL / END_VAR) within the program source changes. • During downloading[2], the rule is: This data block is only initialized when the version code of a data block is changed[5]. • Functions for data backup and initialization take into account the version code of the data blocks.
	Non-retentive unit variables in the implementation section	

[1] Changed initialization values are not effective until the data block or data segment in question is initialized.

[2] If *Initialization of retentive program data and retentive global device variables* = No and *Initialization of non-retentive program data and non-retentive global device variables* = No.
In the case of other settings: See the sections "Initialization of retentive global variables (Page 4074)" and "Initialization of non-retentive global variables (Page 4076)".

[3] With the **SIMOTION ST** programming language:
A data block corresponds to a VAR_GLOBAL/END_VAR or VAR_GLOBAL RETAIN/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A data block of the non-retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL or VAR_GLOBAL RETAIN in the interface section or implementation section of the declaration table: Pragma lines (Page 4070) within a section of the declaration table separate the variables into different data blocks.

[4] The use of units depends on the programming language, refer to the relevant section (Page 4115).

[5] Initialization of a changed data block also occurs during a download in RUN mode, provided that the following condition is fulfilled:
With the **SIMOTION ST** programming language
The following attribute has been specified within a pragma: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line (Page 4070) is inserted in the declaration table with the following check box enabled in this line: *Initialization of VAR_GLOBAL during a change*. All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see SIMOTION Basic Functions Function Manual.

Variables and HMI devices

Exported variables

The following variables are exported to HMI devices where they are available:

- System variables of the SIMOTION device
- System variables of technology objects
- I/O variables
- Global device variables

- Retentive and non-retentive unit variables of the interface section (default setting).
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes.
  - In the SIMOTION MCC and SIMOTION LAD/FBD programming languages:
    For the variable declarations following a pragma line (Page 4070), if you deactivate the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* parameters in this pragma line.

  The unit variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.
- Non-retentive static variables (VAR) of programs provided that the compiler option "Only create program instance data once" is activated
- Non-retentive static variables (VAR) of function blocks
  This is the default setting when the compiler option "Permit object-oriented programming" is enabled. Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.
  The pragma is not evaluated if the compiler option "Permit object-oriented programming" is **not** activated. The export behavior cannot be changed.
- Non-retentive public variables (VAR PUBLIC) of classes (default setting, as of version V4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.

Note

The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.

The effect of the `{ HMI_Export := FALSE; }` / `{ HMI_Export := TRUE; }` pragma (or the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* settings in a pragma line) depends on the SIMOTION Kernel version:

- As of Version V4.1 of the SIMOTION Kernel:
  The pragma affects the export of the corresponding declaration block to HMI devices **and** the structure of the HMI address space:
  - Only those variables in declaration blocks exported to HMI devices occupy the HMI address space.
  - Within the HMI address space, the variables are arranged according to order of their declaration.
- Up to Version V4.0 of the SIMOTION Kernel:
  The pragma affects **only** the export of the corresponding declaration block to HMI devices. The HMI address space is also occupied by unit variables of the interface section whose declaration blocks are not assigned to HMI devices.
  Within the HMI address space, the variables are sorted in the following order:
  - Retentive unit variables of the interface section (exported and not exported).
  - Retentive unit variables of the implementation section (only exported).
  - Non-retentive unit variables of the interface section (exported and not exported).
  - Non-retentive unit variables of the implementation section (only exported).

  Within these segments, the variables are arranged according to order of their declaration.

Non-exported variables

The following variables are **not** exported to HMI devices and are **not** available there:

- Retentive and non-retentive unit variables of the implementation section (default setting)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`
    See also Controlling compiler with attributes.
  - In the SIMOTION MCC and SIMOTION LAD/FBD programming languages:
    For the variable declarations following a pragma line (Page 4070), if you activate the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* parameters in this pragma line.

  The unit variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
- Local variables (VAR, VAR_TEMP) of functions or methods
- Temporary variables (VAR_TEMP) of programs, function blocks or classes
- Retentive local variables (VAR RETAIN) of programs (as of version 4.5 of the SIMOTION Kernel)

- Retentive local variables (VAR RETAIN) of function blocks (as of version 4.5 of the SIMOTION Kernel)
  This is the default setting when the compiler option "Permit object-oriented programming" is enabled. Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
  The pragma is not evaluated if the compiler option "Permit object-oriented programming" is **not** activated. The export behavior cannot be changed.
- Retentive local variables (VAR RETAIN) of classes (default setting, as of version 4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
- Non-retentive static variables (VAR) of programs provided that the compiler option "Only create program instance data once" is **not** activated
- Non-retentive protected or private variables (VAR, VAR PROTECTED, VAR PRIVATE) of classes (default setting, as of version V4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes.

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.

Example for the SIMOTION ST programming language

Table 7-24 Example for the control of the HMI export with the corresponding pragma

```
INTERFACE
    VAR_GLOBAL
        // HMI export
        x1 : DINT;
    END_VAR
    VAR_GLOBAL
        { HMI_Export := FALSE; }
        // No HMI export
        x2 : DINT;
    END_VAR
    // ...
END_INTERFACE

IMPLEMENTATION
    VAR_GLOBAL
        // No HMI export
        y1 : DINT;
    END_VAR
    VAR_GLOBAL
        { HMI_Export := TRUE; }
        // HMI export
        y2 : DINT;
    END_VAR
    // ...
END_IMPLEMENTATION
```

7.1.5.7 General references (as of kernel V4.5)

Defining general references

General references contain the address assignment to a variable or an instance of a function block or class:

General references require a SIMOTION Kernel as of version V4.5. The compiler option (Page 3996) "Permit object-oriented programming" also must be activated.

References can be defined as variables or elements of structures.

To do this, activate the **Reference** checkbox in the **Parameters/variables** or **Structures** tab in the declaration table of the program source or program organization unit. The declaration is also possible as array element. See also the description for the "Reference (Page 4047)" checkbox.

This creates the "Reference to data type" (REF_TO *data_type*) that can contain the address to an existing data type (reference data type).

The following are permitted as data types to which references can be formed:

- Elementary data types (e.g. INT, DINT, REAL, WORD, TIME, STRING)
- User-defined data types (UDT)
- System data types

- Function blocks, provided they contain at least one static variable
- Classes (from ST sources)

No references can be formed to the following data types because references exist already:

- Technology object data types
- Object-oriented interfaces (from ST sources)
- General references
- I/O references (from ST sources)

Variables of general references can be declared in the interface and implementation sections as well as in all program organization units and classes. The data type to be referenced must be declared beforehand and lie within the scope of the POU. The declaration as element of a structure or an ARRAY is also possible.

All variable types for the relevant program organization unit are permitted with the exception of:

- VAR_IN_OUT.
  Arrays, structures, function blocks or classes that contain general references may nonetheless be transferred as VAR_IN_OUT.
- VAR RETAIN or VAR_GLOBAL RETAIN is not permitted.
  However, structures that contain at least one element other than reference types (general references, data types of the technology objects, object-oriented interfaces), can be stored retentive.
- VAR CONSTANT or VAR_GLOBAL CONSTANT is not meaningful.
  General references must be initialized with "NULL".

Forming general references

A reference to a variable is formed with the REF standard function (in := *var_name*). This function is described in detail in the "SIMOTION Basic Functions" Function Manual.

The REF function can be used on the following variables:

- Retentive and non-retentive unit variables or instances of classes or function blocks or their elements declared as such.
- In methods within classes or function blocks:
  - Static variables (VAR) of the higher-level class or function block (including instance variables for classes or function blocks).
  - The THIS keyword. Enables access to the instance variable of the higher-level class or function block.
- In function blocks:
  - Static variables (VAR) of the function block (including instance variables of classes or function blocks).
  - The THIS keyword. Permits access to the instance variable of the function block.

The variable must be able to be read and written.

Not permitted are:

- Variables of technology object data types
- Variables of object-oriented interfaces
- Variables of general references
- Retentive local variables within classes or function blocks
- I/O variables
- Global device variables
- Constants

The return value has the data type "Reference to the data type of the input parameter *in*". The return value can be assigned with the assignment operator ":=" to a variable that has REF_TO *type* data type. A data type conversion is not possible.

Note

Note for instances of function blocks that are passed as in/out parameter (VAR_IN_OUT):

- The REF function cannot be used for static variables (VAR) of function blocks imported from technology packages or device-independent libraries.

The restriction does not apply to class instances.

Operations with general references

Assignment operator ":="

For the assignment of a reference variable, the address of the variable rather than the variable value is passed. Consequently, the reference data types must be identical on both sides of the operator. No implicit data type conversion is possible.

The only exception is for references to classes. A reference to a derived class of a reference to the base class can be assigned here.

For the assignment, no check is made for the validity of the reference; the assignment is always possible.

An explicit assignment with NULL is also possible.

The validity of references should be checked by comparing with NULL before use.

Dereferencing with operator "^"

The reference content can be accessed with the postfix operator "^", e.g. *ref_var*^.

If the reference does not contain a valid value at runtime, the processing task is aborted and the ExecutionFaultTask called.

Before access, a check for validity by comparison with NULL is recommended.

Multilevel dereferencing is possible, e.g. reference to a structure that contains further references. Dereferenced variables can be used anywhere in expressions.

If a method is called via a reference to a class or function block, the class or function block must be dereferenced.

Dereferenced values cannot be used as actual parameters for the _releaseSemaphore() and _testandSetSemaphore() system functions.

Dynamic type conversion with the operator "?="

The operator "?=" can be used for dynamic type conversion only with references to classes and with interface variables (variables for object-oriented interfaces). It supports the following variants:

- Assignment between references to classes.
- Assignment of a reference to a class for an interface variable.
  Whereby, the reference to a class must be specified with the dereferencing operator "^".
- Assignment of an interface variable for a reference to a class.
- Assignment between interface variables

A dynamic type conversion is performed if the following two conditions are satisfied:

1. The variable to the right of the operator contains the reference to the instance of a class.
2. For the variable to the left of the operator, the following applies:
   - The variable is an interface variable:
     The object-oriented interface that this variable has as data type must implement the class on the right-hand side.
   - The variable is a reference to a class:
     This class corresponds to the class on the right-hand side or is a base class for this class.

In this case, the reference on the right-hand side is converted and transferred to the left-hand side.

If the type conversion fails, the variable on the left-hand side contains the "NULL" value.

Comparison operators

Only the comparison operators "=" and "<>" can be used to check for equality or inequality.

The operators ">", "<", ">=", "<=" as well as the MIN and MAX standard functions are not permitted.

7.1.5.8 Access to inputs and outputs (process image, I/O variables)

Overview of access to inputs and outputs

SIMOTION provides several possibilities to access the device inputs and outputs of the SIMOTION device as well as the central and distributed I/O:

- Via direct access with I/O variables
  Direct access is used to access the corresponding I/O address directly.
  Define an I/O variable (name and I/O address) without assigning a task to it. The entire address space of the SIMOTION device can be used.
  It is preferable to use direct access with sequential programming (in MotionTasks); access to current input and output values at a particular point in time is especially important in this case.
  Further information: Direct access and process image of the cyclic tasks (Page 4094).
- Via the process image of cyclic tasks using I/O variables
  The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming).
  Define an I/O variable (name and I/O address) and assign a task to it. The entire address range of the SIMOTION device can be used.
  Direct access to this I/O variable is still possible: Specify direct access with *_direct.var-name*.
  Further information: Direct access and process image of the cyclic tasks (Page 4094).
- Using the fixed process image of the BackgroundTask
  The process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device, on which a subset of the I/O address space of the SIMOTION device is mirrored. The mirror image is refreshed with the BackgroundTask and is consistent throughout the entire cycle. This process image is used preferentially when programming the BackgroundTask (cyclic programming).
  The address range 0 .. 63 can be used. Exception: I/O addresses that are accessed using the process image of the cyclic task can only be used with the setting “Common process image” (Page 4105) (as of Kernel V4.2).
  Further information: Access to the fixed process image of the BackgroundTask (Page 4103).

A comparison of the most important properties is contained in "Important properties of direct access and process image" (Page 4091).

You can use I/O variables like any other variable, see "Access I/O variables" (Page 4113).

Note

An access via the process image is more efficient than direct access.

Important features of direct access and process image access

Table 7-25 Important properties of direct access and process image access

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
Permissible address range	Entire address range of the SIMOTION device **Exception**: I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously (example: PIW63 or PQD62 are not permitted).		Addresses 0 .. 63. **Exception**: Up to version V4.1 of the SIMOTION Kernel or the "Separate process image" setting, addresses used for the process image of the cyclic tasks are not permitted.
Address configuration	Necessary. The addresses used must be present in the I/O and appropriately configured. The "Rules for I/O addresses for direct access and the process image of the cyclic tasks" (Page 4097) must be observed.		Not necessary. Addresses that are not present in the I/O or have not been configured can also be used.
Assigned task	None.	Cyclic task for selection: • SynchronousTasks, • TimerInterruptTasks, • BackgroundTask.	BackgroundTask.
Memory area for process images	-	Depends on the SIMOTON Kernel version: • Up to version V4.1: Separate memory areas in all cases • As of version V4.2: Option to select a common memory area	

<table>
<tr><th></th><th>Direct access</th><th>Access to process image of cyclic tasks</th><th>Access to fixed process image of the BackgroundTask</th></tr>

Error during generation of process image, alternative reactions available: • CPU stop[5] • Substitute value • Last value See SIMOTION Basic Functions Description of Functions.	Error during generation of process image, reaction: CPU stop[5] **Exception**: If a direct access has been created at the same address, the behavior set there applies.
Access			
• In the RUN operating state	Without any restrictions.	Without any restrictions.	Without any restrictions.
• During the StartupTask	Possible with restrictions: • Inputs can be read. • Outputs are not written until StartupTask is complete.	Possible with restrictions: • Inputs are read at the start of the StartupTask. • Outputs are not written until StartupTask is complete.	Possible with restrictions: • Inputs are read at the start of the StartupTask. • Outputs are not written until StartupTask is complete.

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
• During the ShutdownTask	Without any restrictions.	Possible with restrictions: • Inputs retain status of last update • Outputs are no longer written.	Possible with restrictions: • Inputs retain status of last update • Outputs are no longer written.

[1] A SIMOTION device is considered isochronous if at least one PROFIBUS DP or PROFINET interface is operated isochronously (constant bus cycle time). For SIMOTION D there is an exception with the DP Integrated interface to which the SINAMICS Integrated is connected.

[2]The following SIMOTION devices are updated in the Servo_fast cycle or IPO_fast cycle, if the cycles are configured: D445-2 DP/PN, D455-2 DP/PN (as of version V4.2) and D435-2 DP/PN (as of version V4.3).

3 IPO or IPO_2 adjustable, see “Setting system cycle clocks" section in the Basic Functions Function Manual.

[4] Call the ExecutionFaultTask.

[5] Call the PeripheralFaultTask.

Direct access and process image of cyclic tasks

Property

Direct access to inputs and outputs and access to the process image of the cyclic task always take place via I/O variables. The entire address range of the SIMOTION device (Page 4096) can be used.

A comparison of the most important properties, including in comparison to the fixed process image of the BackgroundTask (Page 4103) is contained in "Important properties of direct access and process image" (Page 4091).

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4097).

It is particularly important that every address used in an I/O variable is available in the I/O and configured; each byte in the address range may be assigned to no more than one I/O variable (does not apply to access with data type BOOL).

A detailed status of I/O variables (Page 4101) can be read as of version V4.2 of the SIMOTION Kernel, for example, in order to check the availability of the I/O variables.

Direct access

Direct access is used to access the corresponding I/O address directly. Direct access is used primarily for sequential programming (in MotionTasks). The access to the current value of the inputs and outputs at a specific time is particularly important.

For direct access, you define an I/O variable (Page 4098) without assigning it a task.

Process image of the cyclic task

The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming). The consistency during the complete cycle of the task is particularly important.

For the process image of the cyclical task you define an I/O variable (Page 4098) and assign it a task.

Direct access to this I/O variable is still possible: Specify direct access with *_direct.var-name*.

Note

An access via the process image is more efficient than direct access.

Additional properties as of version V4.2 of the SIMOTION Kernel

As of version V4.2 of the SIMOTION Kernel, direct access to inputs/outputs and the process image of the cyclic tasks offers additional properties:

- As far as the process image of the cyclic tasks is concerned, a common memory area with the fixed process image of the BackgroundTask can be set (standard with newly created devices)
- As far as the process image of the cyclic tasks is concerned, I/O variables for inputs can be written to (i.e. they can be assigned values).
- A detailed status of I/O variables (Page 4101) can be read, for example, in order to check the availability of the I/O variables.

Memory area with the fixed process image of the BackgroundTask

- **As of version V4.2 of the SIMOTION Kernel**, selecting a "Common process image" setting on the device ensures the memory area for the fixed process image of the BackgroundTask is a subset of the memory area for the process image of the cyclic tasks.
- **Up to version V4.1 of the SIMOTION Kernel** or the "Separate process image" setting on the device (as of version V4.2 of the SIMOTION Kernel), the fixed process image of the BackgroundTask and the process image of the cyclic tasks occupy different memory areas.

Note

If (and only if) you are also using the fixed process image of the BackgroundTask, it is important to consider the effects of the "Common process image" or "Separate process image" settings on the fixed process image of the BackgroundTask (Page 4103).

Table 7-26 Effect of "Common process image" or "Separate process image" settings on the process image of the cyclic tasks

	Common process image	Separate process image
Availability	Only available as of version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard for newly created devices	Up to version V4.1 of the SIMOTION Kernel applies: • System characteristic, not configurable. The following applies as of version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard with device upgrades
Download of new or changed I/O variables	Only possible in STOP mode.	Only possible in STOP mode.
Byte order when forming the process image and during access	Depends on connected I/O	
Effects on the fixed process image of the BackgroundTask	See the relevant table in "Access to the fixed process image of the BackgroundTask" (Page 4104).	
Further information	Common process image (Page 4105)	Separate process image (Page 4107)

Address range of the SIMOTION devices

The address range of the SIMOTION devices is specified in the following table according to the version of the SIMOTION Kernel concerned. The complete address range can be used for direct access and process image of the cyclical tasks.

Table 7-27 Address range of the SIMOTION devices according to the version of the SIMOTION Kernel

SIMOTION device	Address range for SIMOTION Kernel version					
	V3.2	V4.0	V4.1	4.2	V4.3	As of V4.4
C230-2	0 .. 2047 [3]	0 .. 2047 [3]	0 .. 2047 [3]	–	–	–
C240	–	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]
C240 PN [1]	–	–	0 .. 4095 [4]	0 .. 4095 [4]	0 .. 4095 [4]	0 .. 4095 [4]
D410 DP	–	–	0 .. 8191 [3]	0 .. 8191 [3]	0 .. 8191 [3]	–
D410 PN	–	–	0 .. 8191 [4]	0 .. 8191 [4]	0 .. 8191 [4]	–
D410-2	–	–	–	–	0 .. 8191 [3 4]	0 .. 8191 [3 4]
D425	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D425-2	–	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D435	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D435-2	–	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D445	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–	–
D445-1 [1]	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D445-2	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D455-2	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]
P320 [2]	–	–	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	–

SIMOTION device	Address range for SIMOTION Kernel version					
	V3.2	V4.0	V4.1	4.2	V4.3	As of V4.4
P320-4	–	–	–	–	–	0 .. 4095 [3]
P350	0 .. 2047 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	–

[1] Available as of V4.1 SP2 HF4

[2] Available as of V4.1 SP5

[3] For distributed I/O (over PROFIBUS DP), the transmission volume is restricted to 1024 bytes per PROFIBUS DP line.

[4] For distributed I/O (over PROFINET), the transmission volume is restricted to 4,096 bytes per PROFINET segment.

Rules for I/O addresses for direct access and the process image of the cyclical tasks

Note

You must observe the following rules for the I/O variable addresses for direct access and the process image of the cyclic task (Page 4094). Compliance with the rules is checked during the consistency check of the SIMOTION project (e.g. during the download).

1. Addresses used for I/O variables must be present in the I/O and configured appropriately in the HW Config.
2. I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously.
   The following I/O addresses are not permitted:
   - Inputs: PIW63, PID61, PID62, PID63
   - Outputs: PQW63, PQD61, PQD62, PQD63
3. All addresses of an I/O variable comprising more than one byte (e.g. WORD, ARRAY data type) must be within a continuous address range configured in HW Config, e.g. within the address range (slot or subslot) of *one* I/O module.
4. An I/O address (input or output) can only be used by a single I/O variable of data type BYTE, WORD or DWORD or an array of these data types. Access to individual bits with I/O variables of data type BOOL is possible.
5. If several processes (e.g. I/O variable, technology object, PROFIdrive telegram) access an I/O address, the following applies:
   - Only a single process can have write access to an I/O address of an output (BYTE, WORD or DWORD data type).
     Read access to an output with an I/O variable that is used by another process for write access, is possible.
   - All processes must use the same data type (BYTE, WORD, DWORD or ARRAY of these data types) to access this I/O address. Access to individual bits is possible irrespective of this. Please be aware of the following, for example, if you wish to use an I/O variable to read the PROFIdrive telegram transferred to or from the drive: The length of the I/O variable must match the length of the telegram.
   - Write access to different bits of an address is possible from several processes; however, write access with the data types BYTE, WORD or DWORD is then not possible.

Note

These rules do not apply to accesses to the fixed process image of the BackgroundTask (Page 4103). These accesses are not taken into account during the consistency check of the project (e.g. during download).

Creating I/O variables for direct access or process image of cyclic tasks

Create I/O variables for direct access or a process image of the cyclic tasks in the address list of the detail view.

This is only possible in offline mode.

Here is a brief overview of the procedure:

1. Select the "Address list" tab in the detail view and choose the SIMOTION device
   or
   In the project navigator of SIMOTION SCOUT, double-click the "ADDRESS LIST" element in the SIMOTION device subtree.
2. Select the line before which you want to insert the I/O variable and, from the context menu, select **Insert new line**
   or
   Scroll to the end of the table of variables (empty line).
3. In the empty row of the table, enter or select the following:
   - Names of the **I/O variables**
   - **I/O address**
     Select the "IN" or "OUT" entries if you wish to assign symbols to the I/O variable (input or output). As of Version V4.2 of the SIMOTION Kernel the symbolic assignment must be activated, menu **Project > Use symbolic assignment**.
     Or enter a fixed address according to "Syntax for entering I/O addresses" (Page 4100).
   - Optional for outputs:
     Activate the **Read only** checkbox if you only want to have read access to the output. You can then read an output that is already being written by another process (e.g. output of an output cam, PROFIdrive telegram).
     A read-only output variable cannot be assigned to the process image of a cyclic task.
   - **Data type** of the variables in accordance with "Possible data types of the I/O variables" (Page 4101).

4. Optionally, you can also enter or select the following (not for data type BOOL):
   - **Array length** (array size).
   - **Process image** or direct access:
     Can only be assigned if the **Read only** checkbox is deactivated.
     For process image, select the cyclic task to which you want to assign the I/O variable. To select a task, it must have been activated in the execution system.
     For direct access, select the blank entry.
   - **Strategy** for behavior in the event of an error, see SIMOTION Basic Functions Function Manual.
   - **Display format** (if array, for each element), when you monitor the variable in the address list
   - **Substitute value** (if array, for each element).
5. Only if you have selected "IN" or "OUT" as the I/O address (symbolic assignment).
   - In the **Assignment** column, click the **[...]** button.
     A window opens displaying the possible assignment targets of the SIMOTION device and, if necessary, of SINAMICS Integrated. Only those assignment targets are displayed that match the data direction (input/output) and data type.
   - Select the assignment target.
     The **Assignment status** column indicates whether the assignment was successful or not.

   For details regarding symbolic assignment, refer to the SIMOTION Basic Functions Function Manual.

You can now access this variable using the address list or any program of the SIMOTION device.

Details on how to manage the address list can be found in the online help.

Note

Note the following for the process image for cyclic tasks:

- A variable can only be assigned to one task.
- Each byte of an input or output can only be assigned to one I/O variable.

In the case of data type BOOL, please note:

- The process image for cyclic tasks and a strategy for errors cannot be defined. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access or CPU stop).
- The individual bits of an I/O variable can also be accessed using the bit access functions.

Take care when making changes within the I/O variables (e.g. inserting and deleting I/O variables, changing names and addresses):

- In some cases the internal addressing of other I/O variables may change, making all I/O variables inconsistent.
- If this happens, all program sources that contain accesses to I/O variables must be recompiled.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and then use them in your program sources (e.g. ST sources, MCC sources, LAD/FBD sources).

Outputs can be read and written to, but inputs can only be read.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables" (Page 4113).

Syntax for entering I/O addresses

Syntax

For the input of the I/O address for the definition of an I/O variable for direct access or process image of cyclical tasks (Page 4094), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

Table 7-28 Syntax for the input of the I/O addresses for direct access or process image of the cyclic tasks

Data type	Syntax for		Permissible address range					
	Input	Output	Direct access		Process image		e.g. direct access D435 V4.1	
BOOL	PIn.x	PQn.x	n: x:	0 .. *MaxAddr* 0 .. 7		-[1]	n: x:	0 .. 16383 0 .. 7
BYTE	PIBn	PQBn	n:	0 .. *MaxAddr*	n:	0 .. *MaxAddr*	n:	0 .. 16383
WORD	PIWn	PQWn	n:	0 .. 62 64 .. *MaxAddr* - 1	n:	0 .. 62 64 .. *MaxAddr* - 1	n:	0 .. 62 64 .. 16382
DWORD	PIDn	PQDn	n:	0 .. 60 64 .. *MaxAddr* - 3	n:	0 .. 60 64 .. *MaxAddr* - 3	n:	0 .. 60 64 .. 16380
n = logical address x = bit number								
MaxAddr =	Maximum I/O address of the SIMOTION device depending on the SIMOTION Kernel version, see Address range of the SIMOTION devices (Page 4096).							
[1] For data type BOOL, it is not possible to define the process image for cyclic tasks. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access).								

Examples

Input at logic address 1022, WORD data type: **PIW1022**.

Output at logical address 63, bit 3, BOOL data type: **PQ63.3**.

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4097).

Possible data types of I/O variables

The following data types can be assigned to the I/O variables for direct access and process image of the cyclical tasks (Page 4094). The width of the data type must correspond to the data type width of the I/O address.

If you assign a numeric data type to the I/O variables, you can access these variables as integer.

Table 7-29 Possible data types of the I/O variables for direct access and the process image of the cyclical tasks

Data type of I/O address	Possible data types for I/O variables
BOOL (PIn.x, PQn.x)	BOOL
BYTE (PIBn, PQBn)	BYTE, SINT, USINT
WORD (PIWn, PQWn)	WORD, INT, UINT
DWORD (PIDn, PQDn)	DWORD, DINT, UDINT

For details of the data type of the I/O address, see also "Syntax for entering I/O addresses" (Page 4100).

Detailed status of the I/O variables (as of Kernel V4.2)

As of version V4.2 of the SIMOTION Kernel, the status of an I/O variable can be queried using *_quality.var-name*, for example, in order to check the availability of the I/O variables. It is supplied as an OR logic operation of the following status values in the DWORD data type and can be assigned to an appropriate variable, for example. The value 16#0000_0000 indicates the connected I/O are operating without error.

The same value is supplied for every I/O variable within an address range (slot or subslot) configured in HW Config.

Table 7-30 Meanings of status values of I/O variables

Value (DWORD)	Bit x = 1	Meaning
16#0000_0000	-	No error occurred.
16#0000_0001	0	**Maintenance required** The connected module signals that it requires maintenance. The component needs to be checked within a foreseeable period (e.g. the printer cartridge must be changed within a period of several days).
16#0000_0002	1	**Maintenance demanded** The connected module demands maintenance. The component needs to be checked soon (e.g. the printer cartridge must be changed immediately).
16#0000_0004	2	**Warning pending** (drive warning, TM17 warning, etc.) The connected module has signaled a warning. This has been entered in the diagnostics buffer. The precise cause can be determined from the documentation for the relevant module.
16#0000_0008	3	**Fault pending** (diagnostic interrupt, drive fault, TM17 fault, etc.) The connected module has signaled an error. This has been entered in the diagnostics buffer. The precise cause can be determined from the documentation for the relevant module.

Value (DWORD)	Bit x = 1	Meaning
16#0000_0010	4	**This parameter assignment does not match the parameter assignment being compared.** A difference was detected when this parameter assignment was compared with the parameter assignment of the connected module. As such, the required functionality cannot be guaranteed. Remedy: Save the project and compile changes, reload both application and counterpart.
16#0000_0020	5	**Application and counterpart are not isochronous** (error involving the dynamic life-sign). Certain telegrams (axis, synchronous operation, output cam, measuring input telegrams) are synchronized by exchanging cyclic life-signs. Errors are detected when the cyclic life-sign is checked. This invalidates the data in the telegram. Remedy: Await synchronization, check the parameter assignment (e.g. does the master application cycle set on the device in HW Config match the position control cycle clock), save the project and compile changes, reload both application and counterpart.
16#0000_0040	6	**I/O cannot be used synchronously in all cycles.** A fast application cycle (Servo_fast) and a slow application cycle (Servo) are running asynchronously in relation to one another. The I/O can only be used synchronously in the cycles associated with the bus cycle. Access from other cycles is asynchronous and inconsistent. Remedy: Call the _synchronizeDpInterfaces() function.
16#0000_0080	7	**I/O cannot be used synchronously** The SIMOTION control is the sync slave on a bus. The bus connection is running synchronously in relation to the sync master, but is not yet running synchronously in relation to the application cycles of the SIMOTION control. Access to the I/O is asynchronous and inconsistent. Remedy: Call the _synchronizeDpInterfaces() function.
16#0000_0100	8	**Bus connection (sync slave) is not isochronous in relation to the sync master.** The SIMOTION control is the sync slave on a bus and has not yet synchronized its bus connection with the sync master. The isochronous I/O on this bus cannot be used yet. Remedy: Switch on/connect the sync master.
16#0000_0200	9	**DP station is deactivated.** The partner module has been deactivated. Remedy: Activate the partner module (_activateDpSlave() function).
16#0000_0400	10	**The partner of the inputs (e.g. I-device, I-slave) is in STOP.** The connected module is in STOP mode and not sending any new data as a result. Remedy: Switch the connected module to RUN.
16#0000_0800	11	**PROFINET: Failure detected by submodule** (e.g. channel error) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0000_1000	12	**PROFINET: Failure detected by module** (e.g. submodule failed, removed, etc.) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0000_2000	13	**PROFINET: Failure detected by device** (e.g. device in STOP, module removed, etc.) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config

Value (DWORD)	Bit x = 1	Meaning
16#0000_4000	14	**PROFINET: Failure detected by controller** (e.g. not connected, etc.) There is no connection to a partner on PROFINET. Possible cause: Partner is switched off, cable pulled out, incorrect parameter assignment for connection Troubleshooting: Best to use the PROFINET topology editor in HW Config.
16#0000_8000	15	**Slot/subslot is not connected** (disconnection alarm). The connection to the connected device is OK. The error must be searched for in the connected device (e.g. module/submodule removed). Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0001_0000	16	**Device is not connected** (station failure). There is no connection to a partner. Possible cause: Partner is switched off, cable pulled out.
16#0002_0000	17	**Substitute value behavior during access** There is no connection to the counterpart (sum signal from bits 9 to 16), i.e. there is no valid input data or the output data is not reaching the terminal. The substitute value behavior set (substitute value, last value) takes effect during direct access to this address or during process image updates.
16#4000_0000	30	**Diagnostics address only** No cyclic I/O data is configured for this address. It is possible, however, to query submodule diagnostic information.
16#8000_0000	31	**Address gap** There is no hardware configured for this logical address.

Access to fixed process image of the BackgroundTask

The fixed process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device on which a subset of the I/O address space of the SIMOTION device is mirrored. Preferably, it should be used for programming the BackgroundTask (cyclic programming) as it is consistent throughout the entire cycle.

The size of the fixed process image of the BackgroundTask for all SIMOTION devices is 64 bytes (address range 0 .. 63).

Note

The fixed process image of the BackgroundTask can be used to access addresses that are not available in the I/O or not configured in HW Config. These are treated like normal memory addresses.

Memory area

- **As of Version V4.2 of the SIMOTION Kernel**, selecting a "Common process image" setting on the device ensures the memory area for the fixed process image of the BackgroundTask is a subset of the memory area for the process image of the cyclic tasks.
  I/O addresses can be read and written to using both the fixed process image of the BackgroundTask and the process image of the cyclic tasks.
- **With Version V4.1 and lower of the SIMOTION Kernel** or the "Separate process image" setting on the device (as of Version V4.2 of the SIMOTION Kernel), the fixed process image of the BackgroundTask and the process image of the cyclic tasks occupy different memory areas. I/O addresses accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask. They are treated like normal memory addresses.

Table 7-31 Effect of "Common process image" or "Separate process image" settings on the fixed process image of the BackgroundTask

	Common process image	Separate process image
Availability	Only available as of Version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard for newly created devices	Version V4.1 and lower of the SIMOTION Kernel applies: • System characteristic, not configurable The following applies as of Version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard with device upgrades
Memory area	Subset of the memory area for the process image of the cyclic tasks	Separate memory area for the process image of the cyclic tasks
Using I/O addresses accessed using the process image of the cyclic tasks	Possible. Updates use the configured cyclic tasks.	Not supported. The addresses are treated like normal memory addresses.
Byte order when forming the process image	As supplied by the I/O	Always Big Endian
Byte order when accessing the process image	Always Big Endian	Always Big Endian
Access to I/O operating in the Little Endian byte order	Same result as during direct access or for the process image of cyclic tasks (apart from WORD or DWORD data types).	Results differ depending on the I/O variables created for direct access.
Effects on the process image of the cyclic tasks	See the relevant table in "Direct access and process image of the cyclic tasks (Page 4096)".	
Further information	Common process image (Page 4105)	Separate process image (Page 4107)

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

A comparison of the most important properties in comparison to the direct access and process image of the cyclic tasks (Page 4094) is contained in "Important properties of direct access and process image" (Page 4091).

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4097) do **not** apply. Access to the fixed process image of the BackgroundTask is not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

You can access the fixed process image of the BackgroundTask by means of:

- Using an absolute PI access (Page 4109): The absolute PI access identifier contains the address of the input/output and the data type.
- Using a symbolic PI access (Page 4111): You declare a variable that references the relevant absolute PI access:
  - A unit variable
  - A static local variable in a program.
- Using an I/O variable (Page 4113): In the symbol browser, you define a valid I/O variable for the entire device that references the corresponding absolute PI access.

Common process image (as of Kernel V4.2)

As of Version V4.2 of the SIMOTION Kernel, the "Common process image" setting can be selected on the SIMOTION device. This means addresses 0 .. 63 of the process image of the cyclic tasks and the fixed process image of the BackgroundTask occupy the same memory area.

This is the default for SIMOTION devices newly created in the project as of Version V4.2.

Property of the common process image

1. The memory area for the fixed process image of the BackgroundTask (Page 4103) is a subset of the memory area for the process image of the cyclic tasks (Page 4094).
2. This means I/O addresses already accessed using the process image of the cyclic tasks may also continue to be used for the fixed process image of the BackgroundTask. Updates, however, use the configured cyclic tasks.
3. The following applies when forming the fixed process image of the BackgroundTask:
   The byte order is the same as supplied by the I/O:
   - Big Endian, e.g. for I/O via PROFIBUS DP, PROFINET, P-Bus, DRIVE-CLiQ
   - Little Endian, e.g. for onboard I/O of C240, C240 PN SIMOTION devices

   Any I/O variable created for the relevant addresses for the purpose of direct access or the process image of the cyclic tasks has no effect on the byte order.

4. Access to the fixed process image of the BackgroundTask always takes place using the Big Endian byte order.
5. These last two properties (nos. 3 and 4) affect access to inputs and outputs operating with the Little Endian byte order (e.g. onboard I/O of C240, C240 PN SIMOTION devices).
   If the fixed process image of the BackgroundTask is used for access, this leads to the following behavior, regardless of whether I/O variables have been created for the relevant addresses for the purpose of direct access or the process image of the cyclic tasks:
   - Access to individual bytes always supplies the same result via an I/O variable or the fixed process image of the BackgroundTask.
   - With the fixed process image of the BackgroundTask, bytes only change places if data type WORD is used for access.

   Please also refer to the example below.

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

Example for common process image: Access to I/O operating with the Little Endian byte order

The digital inputs of the C240 SIMOTION device operate with the Little Endian byte order and occupy addresses 66 (bits 0 ..7) and 67 (bits 0.. 3) by default. The start address is changed to 60 in HW Config to ensure it is in the range occupied by the fixed process image of the BackgroundTask. Addresses 60 and 61 are now accessed using various I/O variables and the process image of the BackgroundTask.

The following three scenarios are considered, which differ in terms of whether and which I/O variables are created for direct access or the process image of the cyclic tasks:

1. Scenario A:
   No I/O variables are created for addresses 60 and 61.
2. Scenario B:
   Two I/O variables with data type BYTE are created for addresses 60 and 61: io_byte_60 (PIB60) and io_byte_61 (PIB61).
3. Scenario C:
   For adresss 60, **one I/O-Variable** with data type WORD is created; this also covers address 61: io_word_60 (PIW60).

Two additional I/O variables are also created in each of the three scenarios, making it possible to access bit 3: io_bit_60_3 (PI60.3) and io_bit_61_3 (PI61.3).

The table below lists which values are generated with the following access types:

- Direct access or access to the process image of the cyclic tasks:
  - Access to individual bytes or the word using the relevant I/O variables
  - Access to each individual byte using the _getInOutByte function (direct access only)
  - Access to the respective bit 3 using the relevant I/O variables
- Access to the fixed process image of the BackgroundTask:
  - Access to individual bytes using an absolute name
  - Access to the word using an absolute name
  - Access to the respective bit 3 using an absolute name

Table 7-32 "Common process image" setting (as of Kernel V4.2): Different types of access to the process images of an input operating with the Little Endian byte order

	Access using	**Scenario A** [1]	**Scenario B** [1]	**Scenario C** [1]
Direct access or access to the process image of the cyclic tasks	io_byte_60 (PIB60)	-	16#08	-
	io_byte_61 (PIB61)	-	16#00	-
	io_word_60 (PIW60)	-	-	16#0008
	_getInOutByte (IN, 60)	16#08	16#08	16#08
	_getInOutByte (IN, 61)	16#00	16#00	16#00
	io_bit_60_3 (PI60.3)	TRUE	TRUE	TRUE
	io_bit_61_3 (PI61.3)	FALSE	FALSE	FALSE
Access to the fixed process image of the BackgroundTask	%IB60	16#08	16#08	16#08
	%IB61	16#00	16#00	16#00
	%IW60	**16#0800** [2]	**16#0800** [2]	**16#0800** [2]
	%I60.3	TRUE	TRUE	TRUE
	%I61.3	FALSE	FALSE	FALSE

[1] Scenarios A, B, or C determine whether and which I/O variables are created for direct access or the process image of the cyclic tasks; see the explanation provided in the body of the document.

[2] The two bytes in the word change places, as a value saved in the Little Endian byte order is being read using Big Endian.

Separate process image (up to Kernel V4.1)

With Version V4.1 and below of the SIMOTION Kernel, the process image of the cyclic task and the fixed process image of the BackgroundTask are stored in different memory areas (separate process image).

As of Version V4.2 of the SIMOTION Kernel, the "Separate process image" setting can be selected on the SIMOTION device. This setting ensures there is compatibility with earlier Kernel versions.

It is the default for SIMOTION devices upgraded to Version V4.2 or higher.

Property of the separate process image

1. The fixed process image of the BackgroundTask (Page 4103) and the process image of the cyclic tasks (Page 4094) are stored in different memory areas.
2. This means I/O addresses that are already accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask. They are treated like normal memory addresses.
3. I/O variables for direct access influence the fixed process image of the BackgroundTask:
   – The fixed process image of the BackgroundTask is always formed for the relevant addresses in the Big Endian byte order.
4. Access to the fixed process image of the BackgroundTask always takes place using the Big Endian byte order.
5. These last two properties (nos. 3 and 4) affect access to inputs and outputs operating with the Little Endian byte order (e.g. onboard I/O of C230-2, C240, C240 PN SIMOTION devices). If an I/O variable is created for the relevant addresses for the purpose of direct access using data type WORD and access takes place using the fixed process image of the BackgroundTask, this leads to the following behavior:
   – Access with the data type WORD supplies the same result via the I/O variable and the fixed process image of the BackgroundTask.
   – Access to individual bytes using the _getInOutByte function (see SIMOTION Basic Functions Function Manual) supplies these in the Little Endian order.
   – Access to the individual bytes or bits with the fixed process image of the BackgroundTask supplies these in the Big Endian order.

   Please also refer to the example below.

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

Example for separate process image: Access to I/O operating with the Little Endian byte order

The digital inputs of the C240 SIMOTION device operate with the Little Endian byte order and occupy addresses 66 (bits 0 ..7) and 67 (bits 0.. 3) by default. The start address is changed to 60 in HW Config to ensure it is in the range occupied by the fixed process image of the BackgroundTask. Addresses 60 and 61 are now accessed using various I/O variables and the process image of the BackgroundTask.

The following three scenarios are considered, which differ in terms of whether and which I/O variables are created for direct access:

1. Scenario A:
   No I/O variables are created for addresses 60 and 61.
2. Scenario B:
   Two I/O variables with data type BYTE are created for addresses 60 and 61: io_byte_60 (PIB60) and io_byte_61 (PIB61).
3. Scenario C:
   For adresss 60, **one I/O-Variable** with data type WORD is created; this also covers address 61: io_word_60 (PIW60).

Two additional I/O variables are also created in each of the three scenarios, making it possible to access bit 3: io_bit_60_3 (PI60.3) and io_bit_61_3 (PI61.3).

The table below lists which values are generated with the following access types:

- Direct access:
  - Access to individual bytes or the word using the relevant I/O variables
  - Access to each individual byte using the _getInOutByte function
  - Access to the respective bit 3 using the relevant I/O variables
- Access to the fixed process image of the BackgroundTask:
  - Access to individual bytes using an absolute name
  - Access to the word using an absolute name
  - Access to the respective bit 3 using an absolute name

Table 7-33 "Separate process image" setting or Kernel up to Version V4.1: Different types of access to the process images of an input operating with the Little Endian byte order

	Access using	**Scenario A** [1]	**Scenario B** [1]	**Scenario C** [1]
Direct access	io_byte_60 (PIB60)	-	16#08	-
	io_byte_61 (PIB61)	-	16#00	-
	io_word_60 (PIW60)	-	-	16#0008
	_getInOutByte (IN, 60)	16#08	16#08	16#08
	_getInOutByte (IN, 61)	16#00	16#00	16#00
	io_bit_60_3 (PI60.3)	TRUE	TRUE	TRUE
	io_bit_61_3 (PI61.3)	FALSE	FALSE	FALSE
Access to the fixed process image of the BackgroundTask	%IB60	16#08	16#08	**16#00** [3]
	%IB61	16#00	16#00	**16#08** [3]
	%IW60	**16#0800** [2]	**16#0800** [2]	16#0008
	%I60.3	TRUE	TRUE	**FALSE** [3]
	%I61.3	FALSE	FALSE	**TRUE** [3]

[1] Scenarios A, B, or C determine whether and which I/O variables are created for direct access; see the explanation provided in the body of the document.

[2] The two bytes in the word change places, as a value saved in the Little Endian order is being read using Big Endian.

[3] The two adjacent bytes change places, as the relevant word is saved in the Big Endian order.

Absolute access to the fixed process image of the BackgroundTask (absolute PI access)

You make absolute access to the fixed process image of the BackgroundTask (Page 4103) by directly using the identifier for the address (with implicit data type). The syntax of the identifier (Page 4110) is described in the following section.

You can use the identifier for the absolute PI access in the same manner as a normal variable.

Note

Outputs can be read and written to, but inputs can only be read.

Syntax for the identifier for an absolute process image access

For the absolute access to the fixed process image of the BackgroundTask (Page 4109), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

You also use these identifiers:

- For the declaration of a symbolic access to the fixed process image of the BackgroundTask (Page 4111).
- For the creation of an I/O variables for accessing the fixed process image of the BackgroundTask (Page 4113).

Table 7-34 Syntax for the identifier for an absolute process image access

Data type	Syntax for		Permissible address range	
	Input	Output		
BOOL	%In.x or %IXn.x [1]	%Qn.x or %QXn.x[1]	n: x:	0 .. 63 [2] 0 .. 7
BYTE	%IBn	%QBn	n:	0 .. 63 [2]
WORD	%IWn	%QWn	n:	0 .. 63 [2]
DWORD	%IDn	%QDn	n:	0 .. 63 [2]
n = logical address x = bit number				
[1] The syntax %IXn.x or %QXn.x is not permitted when defining I/O variables. [2] For a separate process image (Page 4107), the following applies: No addresses that are used in the process image of the cyclic tasks. See note below.				

Examples

Input at logic address 62, WORD data type: **%IW62**.

Output at logical address 63, bit 3, BOOL data type: **%Q63.3**.

Note

Up to Version V4.1 of the SIMOTION Kernel or the "Separate process image" (Page 4107) setting on the device (as of Version V4.2 of the SIMOTION Kernel), the following applies:

- Addresses accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask.

This restriction no longer applies as of Version V4.2 of the SIMOTION Kernel or with the "Common process image" (Page 4105) setting on the device.

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4097) do **not** apply. Access to the fixed process image of the BackgroundTask is not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

Defining symbolic access to the fixed process image of the BackgroundTask

You create symbolic access to the fixed process image of the BackgroundTask in the declaration tables of the source file, MCC chart, or LAD/FBD program (only in the case of programs). The scope of the symbolic process image access is dependent on the location of the declaration:

- In the interface section of the declaration table of the source file (INTERFACE):
  Symbolic process image access behaves like a unit variable; it is valid for the entire source file; all MCC charts or LAD/FBD programs (programs, function blocks, and functions) within the source file can access the process image.
  In addition, these variables are available on HMI devices and, once connected, in other source files (or other units), as well.
  The total size of all unit variables in the interface section is limited to 64 Kbytes.
- In the implementation section of the declaration table of the source file (IMPLEMENTATION):
  Symbolic process image access behaves like a unit variable; it is only valid in the source file; all MCC charts or LAD/FBD programs (programs, function blocks, and functions) within the source file can access it.
- In the declaration table for the MCC chart or LAD/FBD program (only in the case of programs):
  Symbolic process image access behaves like a local variable; it can only be accessed within the MCC chart or LAD/FBD program in which it is declared.
  No symbolic process image access can be declared in functions or function blocks.

Proceed as follows; the source file or the MCC chart or LAD/FBD program (in the case of programs only) with the declaration table is opened:

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the I/O Symbols tab.
3. Enter:
   - Name of symbol (variable name)
   - For Absolute ID, the identifier of the absolute process image access (Page 4110).
   - Data type of symbol (Page 4112) (this must agree with the length of the process image access).

Possible data types for symbolic PI access

In the following cases, a data type that differs from that of the absolute PI access can be assigned to the fixed process image of the BackgroundTask (Page 4103). The data type width must correspond to the data type width of the absolute PI access.

- For the declaration of a symbolic PI access (Page 4111).
- For the creation of an I/O variable (Page 4113).

If you assign a numeric data type to the symbolic PI access or to the I/O variables, you can access these variables as integer.

Table 7-35 Possible data types for symbolic PI access

Data type of the absolute PI access	Possible data types of the symbolic PI access
BOOL (%In.x, %IXn.x, %Qn.x. %QXn.x)	BOOL
BYTE (%IBn, %QBn)	BYTE, SINT, USINT
WORD (%IWn, %QWn)	WORD, INT, UINT
DWORD (%IDn, %PQDn)	DWORD, DINT, UDINT

For the data type of the absolute PI access, see also "Syntax for the identifier for an absolute PI access (Page 4110)".

Example: Defining symbolic access to the fixed process image of the BackgroundTask

Parameters/variables | I/O symbols | Structures | Enumerations

	Name	Absolute identifier	Data type	Comment
1	input_1	%IB62	SINT	
2	output_1	%QB62	BYTE	
3				

Figure 7-49 Example: Defining symbolic access to the fixed process image of the BackgroundTask

Creating an I/O variable for access to the fixed process image of the BackgroundTask

You create I/O variables for access to the fixed process image for the background task in the symbol browser in the detail view; you must be in offline mode to do this.

Here is a brief overview of the procedure:

1. Select the "Address list" tab in the detail view and choose the SIMOTION device
   or
   In the project navigator of SIMOTION SCOUT, double-click the "ADDRESS LIST" element in the SIMOTION device subtree.
2. Select the line before which you want to insert the I/O variable and, from the context menu, select Insert new line
   or
   Scroll to the end of the table of variables (empty line).
3. In the detail view, select the Symbol browser tab and scroll down to the end of the variable table (empty row).
4. In the empty row of the table, enter or select the following:
   - **Name** of variable.
   - Under **I/O address**, the absolute PI access according to the "Syntax for the identifier for an absolute PI access" (Page 4110)
     (exception: The syntax %IXn.x or %QXn.x is not permitted for data type BOOL).
   - **Data type** of the I/O variables according to the "Possible data types of the symbolic PI access" (Page 4112).
5. Select optionally the display format used to monitor the variable in the symbol browser.

You can now access this variable using the address list or any program of the SIMOTION device.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and use them in your program sources.

Note that you can read and write outputs but you can only read inputs.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables" (Page 4113).

Accessing I/O variables

You have created an I/O variable for:

- Direct access or process image of the cyclic tasks (Page 4094).
- Access to the fixed process image of the BackgroundTask (Page 4103).

You can use this I/O variable just like any other variable.

Note

Consistency is only ensured for elementary data types.

When using arrays, the user is responsible for ensuring data consistency.

Note

If you have declared unit variables or local variables of the same name (e.g. *var-name*), specify the I/O variable using *_device.var-name* (predefined name space, see the "Predefined name spaces" table in "Name spaces").

It is possible to directly access an I/O variable that you created as a process image of a cyclic task. Specify direct access with *_direct.var-name* or *_device._direct.var-name*.

If you want to deviate from the default behavior when errors occur during variable access, you can use the _getSafeValue and _setSafeValue functions (see *SIMOTION Basic Functions* Function Manual).

For Errors associated with access to I/O variables, see *SIMOTION Basic Functions* Function Manual.

7.1.5.9 Connections to other program source files or libraries

In the declaration table of a unit, you can define connections to:

- LAD/FBD units under the same SIMOTION device
- MCC units under the same SIMOTION device
- ST source files under the same SIMOTION device
- Libraries

This will then allow you to access the following in this unit:

- For connected program sources (Page 4115), the following items which are defined there
  - Functions
  - Function blocks
  - Classes and methods contained therein (only for ST source files)
  - Programs (optional)
  - Unit variables
  - User-defined data types (structures, enumerations)
  - Symbolic accesses to the fixed process image of the BackgroundTask
- For connected libraries (Page 4116), the following items which are defined there
  - Functions
  - Function blocks
  - Classes and methods contained therein (only for ST libraries)
  - Programs (optional)
  - User-defined data types (structures, enumerations)

Program sources and libraries must be compiled beforehand.

For information about the library concept, see also the SIMOTION ST Programming Manual.

Note

Libraries can be created in all programming languages (MCC, ST, or LAD/FBD).

Defining connections

Procedure for defining connections to other program sources (units)

Connections to other units (program sources) are defined in the declaration table of the source file. The mode of action of a connection is dependent on the section of the declaration table in which it is defined.

- In the interface section of the declaration table:
  The imported functions, variables, etc., will continue to be exported to other units and to HMI devices. This can lead to name conflicts.
  This setting is necessary, for example, if unit variables are declared in the interface section of the source file with a data type that is defined in the imported program source.
- In the implementation section of the declaration table:
  The imported functions, variables, etc. will no longer be exported.
  This setting is usually sufficient.

Proceed as follows; the source file (declaration table) is open (see Open existing program sources (Page 3989)):

1. In the declaration table, select the section for the desired mode of action.
2. Select the **Connections** tab.
3. For the connection type, select: **Program/Unit**
4. In the same line, select the name of the unit to be connected:
   Units (program sources) must be compiled beforehand.

Procedure for defining connections to libraries

Connections to libraries are defined in the declaration table of the source file.

Proceed as follows; the unit (declaration table) is open, see Open existing program sources (Page 3989):

1. In the interface section of the declaration table, select the **Connections** tab.
2. For the connection type, select: **Library**.
3. In the same line, select the name of the library to be connected.
   Libraries must be compiled beforehand.
4. Optionally, you can define a name space for libraries, see Using name space (Page 4116):
   To do this, enter a name under **Name space**.

Note

When programming the "Subprogram call" command (see Inserting and parameterizing subroutine calls (Page 4121)) with a library function or a library function block, the connection to the library is automatically entered into the declaration table of the program source.

Using the name space

You can optionally assign a namespace to every connected library. You define the designation of the namespace when connecting the library (see How to define connections to libraries (Page 4116)).

It is important to specify the namespace if the current LAD/FBD program / MCC chart or program source contains variables, data types, functions, or function blocks with the same name as the connected library. The namespace will then allow you specific access to the variables, data types, functions, or function blocks in the library. This can also resolve naming conflicts between connected libraries.

If you wish to use variables, data types, functions, or function blocks from the connected library in a command in the LAD/FBD program or MCC chart, insert the designation of the namespace in front of the variable name, etc., from the library and separate them with a period (for example, namespace.var_name, namespace.fc_name).

Predefined namespaces

Namespaces are predefined for device-specific and project-specific variables, direct accesses to I/O variables, and variables of TaskId and AlarmId in the following table: If necessary, write their designation before the variable name, separated by a period, e.g. *_device.var_name* or *_task.task_name*.

Table 7-36 Predefined namespaces

Namespace	Description
_alarm	For AlarmId: The _alarm.name variable contains the AlarmId of the message with the name identifier – see SIMOTION Basic Functions Function Manual.
_device	For device-specific variables (global device user variables, I/O variables, system variables, and system variables of the SIMOTION device)
_direct	For direct access to I/O variables – see Direct access and process image of the cyclic tasks (Page 4094). Local namespace for _device. Nesting as in _device._direct.*name* is permitted.
_project	For names of SIMOTION devices in the project; only used with technology objects on other devices. With unique project-wide names of technology objects, used also for these names and their system variables
_quality	As of Version V4.2 of the SIMOTION Kernel: For the detailed status of I/O variables (Page 4101). A value with data type DWORD is supplied. Local namespace for _device. Nesting as in _device._quality.*name* is permitted.
_task	For TaskID: The _task.name variable contains the TaskId of the task with the *name* identifier – see SIMOTION Basic Functions Function Manual.
_to	For technology objects configured on the SIMOTION device and their system variables and configuration data Not for system functions and data types of the technology objects. In this case, use the user-defined namespace for the imported technology package, if necessary.

Object-oriented namespaces

You can assign functions, function blocks or programs to an object-oriented namespace. Enter the identifier of the object-oriented namespace when creating (Page 4001) or in the Properties window (Page 4008) of the respective program organization unit (POU). The compiler option (Page 3996) "Permit object-oriented programming" must be activated.

A POU within the namespace can only be accessed from a POU outside the namespace when the identifier of the namespace is added as prefix to the identifier of the POU, separated by a dot.

In the project navigator, the POU is shown as subelement of the namespace below the program source.

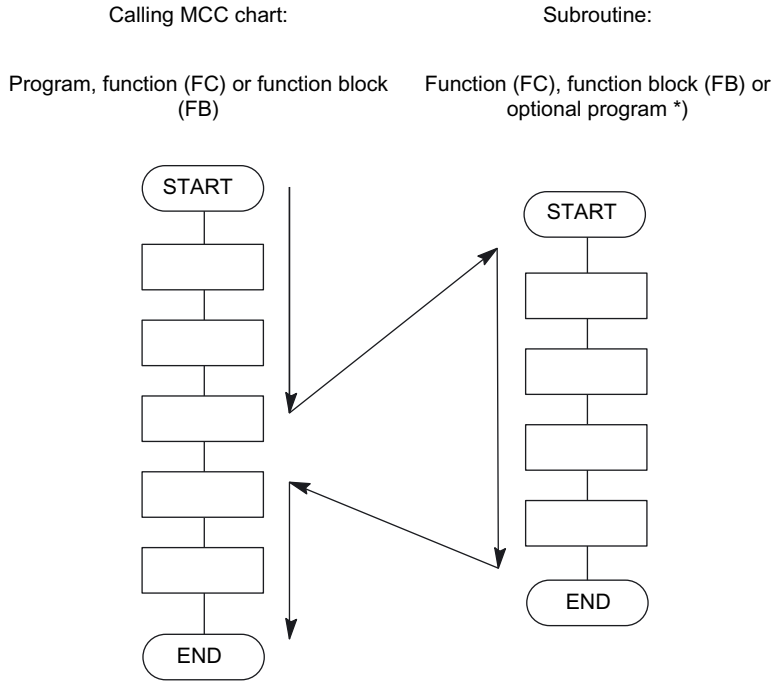
7.1.5.10 Subroutine

Universal, reusable sections of a program can be created in the form of subroutines.

When a subroutine is called, the program branches from the current task into the subroutine. The commands in the subroutine are executed. The program then jumps back to the previously active task.

Subroutines can be called any number of times by one or more MCC programs of the SIMOTION device.

Example of executing a subroutine



*) A program can be called as a subroutine by another program or function block (FB) ("program in program"). Specific compiler options must be set for this (see below).

Figure 7-50 Execution of a subroutine

Subroutine as a function (FC), function block (FB), or program (optional)

The creation type of a subroutine can be a function (FC), a function block (FB) or, as an option, a program ("program in program").

- Function
  A function (FC) is a subroutine without static data, that is, all local variables lose their value when the function has been executed. They are re-initialized when the function is next started.
  Data are transferred to the function using input or in/out parameters; the output of a function value (return value) is also possible.
- Function block
  A function block (FB) is a subroutine with static data, that is, local variables retain their value after the function block has been executed. Only variables that have been explicitly declared as temporary lose their value.
  An instance has to be defined before using an FB: Define a variable (VAR or VAR_GLOBAL) and enter the name of the FB as data type. The FB static data is saved in this instance. You can define several FB instances; each instance is independent from the others.
  The static data of an FB instance remain stored until the instance is next called; they are reinitialized when the variable type of the FB instance is initialized again (see Initialization of instances of function blocks (FB) (Page 4079)).
  Data are transferred to the FB using input parameters or in/out parameters; the data are returned from the FB using in/out or output parameters.
- Program ("program in program")
  You also have the option of calling a program within a different program or a function block. This requires the following compiler options to be activated (see Global compiler settings (Page 3996) and Local compiler settings (Page 3997)):
  - "Permit language extensions" for the program source of the calling program or function block and
  - "Only create program instance data once" for the program source of the called program. The static data of the called program is stored in the user memory of the program source (unit) of said called program.

  Most of the programming work involved in assigning the programs to the tasks can be performed by calling up programs within another program. In the execution system, only one associated calling program needs to be assigned to the tasks concerned.
  A program is called without parameters or return values.
  Further information on calling a program within a program can be found in the SIMOTION ST Programming and Operating Manual.

Note

The activated "Only create program instance data once" compiler option causes:

- The static variables of the programs (program instance data) to be stored in the user memory of the program source (unit) (see the SIMOTION ST Programming and Operating Manual). This also causes the initialization behavior to change (see the SIMOTION ST Programming and Operating Manual).
- All called programs with the same name use the same program instance data.

Exchange of information between the subroutine and calling program

Function (FC) and function block (FB) as a subroutine

Information is exchanged between the subroutine and the calling program using transfer parameters or global variables (e.g. unit variables).

Transfer parameters can be input, input/output or output parameters. They are defined in the declaration table for the subroutine (MCC chart):

- Input parameters: As variable type VAR_INPUT
- In/out parameter: As variable type VAR_IN_OUT
- Output parameter (for FB only): As variable type VAR_OUTPUT

For functions, a function value can be returned; you specify the data type of the return value when you insert (create) the function (see Insert function (FC) or function block (FB) (Page 4120)).

You assign current values to the input and/or in/out parameters when you call the subroutine (FC or FB instance). You may only assign user-defined variables to the in/out parameters of an FB because the called FB accesses the assigned variables directly and can therefore change them.

The output parameters of an FB can be read-accessed as often as required in the calling program.

A function does not formally contain any output parameters, since the result of the function can in this case be assigned to the return value of the function.

See also the examples of functions (Page 4128) and function blocks (Page 4132).

Program as subroutine ("program in program")

A program is called without parameters or return values. This means that information can only be exchanged between the calling program and the called program (subroutine) using global variables (e.g. unit variables).

See also

Inserting a subroutine call into the MCC chart and assigning parameters (Page 4121)

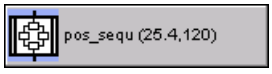
Inserting a function (FC) or function block (FB)

The creation dialog is similar to that of an MCC program:

1. The MCC unit must already exist (see Inserting an MCC unit (Page 3986)).
2. Select the relevant MCC unit in the project navigator.

3. Select the **Insert > Program > MCC chart** command from the menu.
   The input screen form opens.
   - Enter the name of the MCC chart.
     Names for MCC charts must comply with the Rules for identifiers (Page 4047): They are made up of letters (A ... Z, a ... z), digits (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters. Protected or reserved identifiers are not permitted.
     The permissible length of the name is 25 characters.
     The names must be unique within the MCC unit. The names of all exportable program organization units (POUs) must also be unique within the SIMOTION device. The names of all MCC charts of the program source as well as the names of all exportable POUs of the device are displayed.
   - Optionally enter the identifier of an object-oriented namespace.
     Identifiers for namespaces must comply with the Rules for identifiers (Page 4047) (see above).
     When an identifier is entered, the MCC chart is assigned to the specified namespace.
     The compiler option (Page 3996) "Permit object-oriented programming" must be activated. For further information on object-oriented namespaces, see the appropriate section in the SIMOTION ST Programming and Operating Manual.
   - For the creation type, select **Function** or **Function block**.
   - With creation type Function only:
     Select the data type of the return value as the return type (<--> for no return value).
   - Activate the **Exportable** checkbox if the function or function block is to be used in other program sources (LAD/FBD unit, MCC unit or ST source files).
     If the checkbox is deactivated, the MCC chart can only be used in the associated MCC unit (see also Changing usability in other charts (export capability) (Page 4010)).
   - You can also enter an author, version, and a comment.
   - Click **OK** to confirm.
4. Program the instructions in the function or function block.
   Assign an expression to the return value of a function (= function name) or to the output parameters of a function block.
5. Accept and compile the MCC unit. The subprogram you have created will then be displayed in the list.

Inserting a subroutine call into the MCC chart and assigning parameters



The Subprogram call command is available on the MCC editor toolbar (Basic commands command list).

You can use this command to call:

- Functions or function blocks of the same MCC source file or a different program source file (e.g., MCC source file, ST source file).
- Library functions or library function blocks from a program library.

- Optional programs (of the same MCC unit or a different program source) or library programs (from a program library). Specific compiler options must be set for this; see Parameter overview (Page 4124).
  A program can be called within a different program or a function block (FB).
- Public methods (access identifier PUBLIC) within classes or function blocks that are declared in ST source files or libraries. You can only generate methods and classes in the Structured Text (ST) programming language (object-oriented programming).
  The use of methods in classes requires a SIMOTION Kernel as of version V4.5.

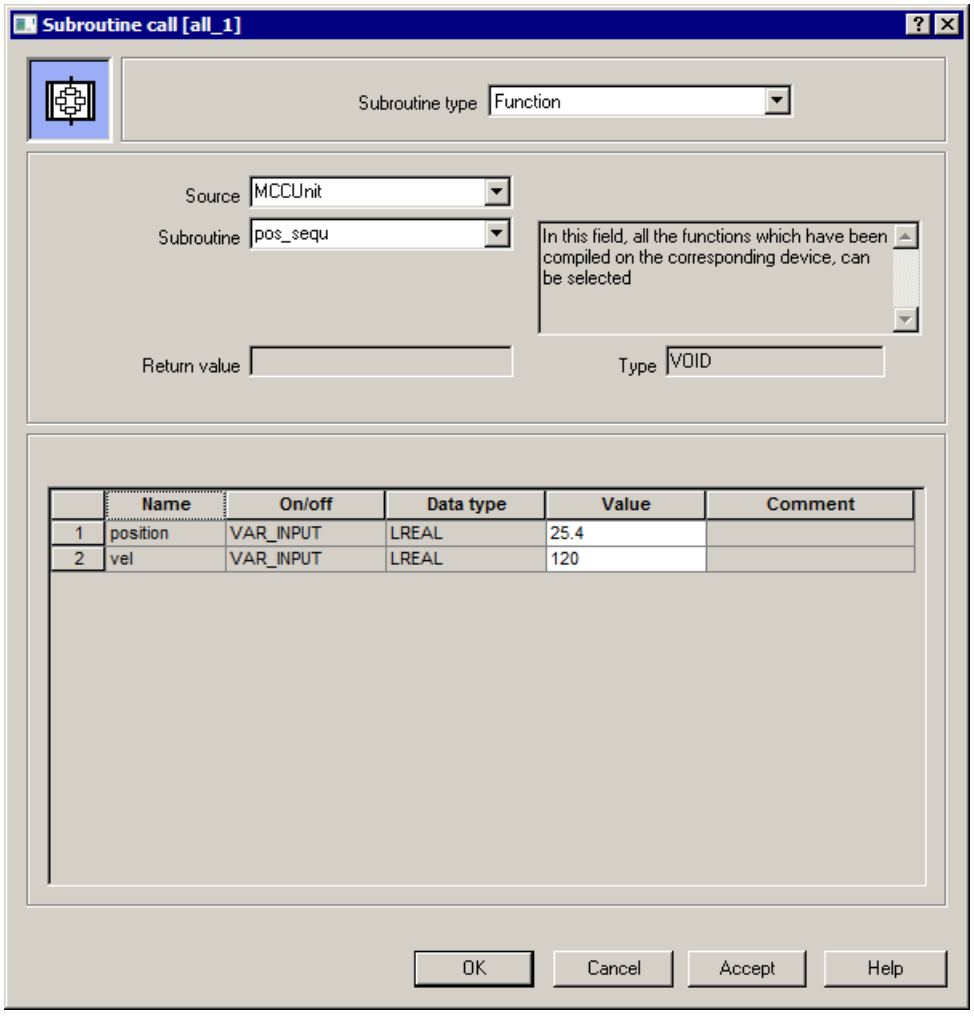


Figure 7-51 Subprogram call for a function

Note

Saving a project in a format older than Version V4.2 of SIMOTION SCOUT

Pay attention to the order of the MCC charts in an MCC unit. A subprogram (function, function block, or program ("program in program")) must be defined before it is used. This is the case when the MCC chart of the subprogram appears above the chart in which it is used in the project navigator If necessary, reorder the charts.

See also: Subprogram call of function (FC) (Page 4129)

Overview of subprogram call parameters

You can set the following parameters:

Table 7-37 Overview of subprogram call parameters

Field/button	Meaning/instruction
Subprogram type	Here, select the subprogram type. **Function** (default value) A function is a subprogram that has no memory beyond the call. In other words, the data is lost once the function has run and the output parameters and return value have been transferred. A function can also have a return value (function value) in addition to input, in/out and output parameters. **Function block** A function block is a subprogram which has a memory beyond the call. In other words, the values of the function block are retained after it has run. Variables of the data type for this function block must be declared. These variables are identified as instances of the function block; they include the memory of the function block beyond the calls. A function block only has input, in/out and output parameters but does not have a return value. The output parameters of the function block can be accessed even at a later time (after the function block has run) at the function block instance. **Library function** Function from library **Library function block** Function block from the library **Program** ("program in program") You also have the option of calling a program within a different program or a function block. This requires the following compiler options to be activated, see Global compiler settings (Page 3996) and Local compiler settings (Page 3997): • "Permit language extensions" for the program source of the calling program or function block and • "Only create program instance data once" for the program source of the called program. The static data of the called program is stored in the user memory of the program source (unit) of the called program. The same program instance data is used every time the program is called. A program is called without parameters or return values. **Library program** Program from library. The same restrictions apply as when calling a program. The static data for the called program is stored once in the user memory of the device that the library program was called on. The same program instance data is used every time the program is called on the same device.

Field/button	Meaning/instruction
Subprogram type (continued)	**Method** You can call up methods that have been defined in ST source files (object-oriented programming): • SIMOTION Kernel as of version V4.5: Methods that have been defined within classes or object-oriented interfaces. • Irrespective of the SIMOTON Kernel version: Methods that have been defined within function blocks. Activating the following compiler option is recommended, see Global settings of the compiler (Page 3996) and Local settings of the compiler (Page 3997): • "Permit object-oriented programming" for the MCC unit of the MCC chart being called. You cannot generate any methods in the MCC programming language. **Library method** (as of kernel V4.5) Method from library. The same restrictions apply as when calling a method.
Source	With "Function", "Function Block", "Program" or "Method" subprogram types only. All program sources for the SIMOTION device are displayed in the drop-down list. Select the program source which contains the subprogram.
Library	With "Library function", "Library function block", "Library program" or "Library method" subprogram types only. All libraries available in the project are displayed in the drop-down list box. Select the library which contains the subprogram.
Subprogram	With the following subprogram types only: • "Function" or "Library function" • "Function block" or "Library function block" • "Program" or "Library program" The drop-down list displays all of the subprograms for the selected subprogram type available in the selected program source or library. For subprogram assigned to an object-oriented namespace, the identifier of the namespace is added as a prefix, separated by a dot. Select the subprogram to be called. **Note** The functions, function blocks and programs themselves can be generated in every available programming language. They must be available in compiled form. A connection to the program source (if required) is automatically set up when the subprogram is selected. Library functions, function blocks and programs can be generated in every available programming language. A connection to the library (if required) is automatically set up when the subprogram is selected.
Program organization unit type	With "Method" or "Library method" subprogram types only. Select the program organization unit (POU) from which a method is to be called. The following are available: **Class** (default value) **Interface** **Function block** Classes, object-oriented interfaces and function blocks with methods can only be generated in the Structured Text (ST) programming language.

Field/button	Meaning/instruction
POU name	With "Method" or "Library method" subprogram types only. The drop-down list displays all of the program organization units (POUs) of the selected source or library and of the selected type. For POUs assigned to an object-oriented namespace, the identifier of the namespace is added as a prefix, separated by a dot. Select the name of the POU from which a method is to be called.
Instance	With "Function Block", "Library function block", "Method" or "Library method" subprogram types only. • The following applies to "Function block" or "Library function block" subprogram types: Select the name of the function block instance or enter it here. The instance contains the memory of the function block in the form of instance data. You define the instance as a variable whose data type is the name of the function block in one of the following ways: – in the declaration table of the MCC unit as VAR_GLOBAL or – in the declaration table of the MCC chart as VAR. • The following applies to "Method" or "Library method" subprogram types: – With POU type "Class" or "Function block" Select the name of the class or function block instance to which the method belongs or enter it here. The instance contains the memory of the class or the function block in the form of instance data. – With POU type "Interface" Select the name of the variable of the object-oriented interface to which the method belongs or enter it here. Before the subprogram call for an instance this variable must be assigned to a class which implements the instance. A corresponding test can be initiated before calling the method by selecting the "Test call to NULL" checkbox. You define the instance as a variable whose data type is the name of the class, the object-oriented interface or the function block in one of the following ways: – in the declaration table of the MCC unit as VAR_GLOBAL or – in the declaration table of the MCC chart as VAR.
Method	With "Method" or "Library method" subprogram types only. The drop-down list displays all of the public methods for the selected program organization unit (class, interface, function block). Select or enter the method to be called. A connection to the program source or library (if required) is automatically set up when the subprogram is selected.
Test call to NULL	With "Method" or "Library method" subprogram types **and** POU type "Interface". Activate the checkbox if the method is just to be called, if the variable for the object-oriented interface for an instance has been assigned to an implemented class.
Return value	With "Function", "Library function", "Method" or "Library method" subprogram types: Here, you enter the variable in which the return value is to be stored. The type of variable must match the return value type.
Type	With "Function", "Library function", "Method" or "Library method" subprogram types: The data type of the return value is displayed.
List of transfer parameters	
Name	The name of the transfer parameter is displayed here.

Field/button	Meaning/instruction
On/off	The variable type of the transfer parameter is displayed here. **VAR_INPUT** Input parameters (for functions, function blocks and methods) **VAR_IN_OUT** In/out parameters (for functions, function blocks and methods) **VAR_OUTPUT** Output parameters (for functions, function blocks and methods)
Data type	The data type of the transfer parameter is displayed here.
Value	Mandatory parameters are marked with "<???>" and optional parameters with "...". • The following applies to functions (FC) and methods: – Input parameters without a declared initial value and in/out parameters are mandatory parameters. – Input parameters with a declared initial value and output parameters are optional parameters. A subprogram call will only be functional if all the mandatory parameters are set. • The following applies to function blocks (FB): All parameters are optional. • The following applies to programs ("program in program"): No parameters present. Here, you assign current variables or values to the transfer parameters: • Input parameter (variable type VAR_INPUT): Here, you enter a variable name or an expression. The assignment of system variables or I/O variables is permissible; type transformations are possible. • In/out parameter (variable type VAR_IN): Enter a variable name; it must be directly writable and readable. System variables of SIMOTION devices and technology objects are not permitted nor are I/O variables. The data type of the in/out parameter must correspond to that of the assigned variables; application of type transformation functions is not possible. • Output parameter (variable type VAR_OUTPUT): The assignment of an output parameter to a variable is optional. – The following applies to function blocks: You can also access an output parameter after executing the function block. – The following applies to functions and methods: The values for the output parameters are lost after executing the function or method unless they have been assigned in the parameter screen. When assigned in this parameter screen form: Enter a variable name. The data type of the output parameter must correspond to that of the assigned variables; the application of type transformation functions is not possible.
Comment	The comment for the transfer parameters is displayed here.

Note

When selecting the subprogram type, the distinction as to whether the subprogram is defined on the device or in a library (e.g. function / library function), is only an aid in the selection of the respective subprogram. It has no effect on the code generation.

This way you can subsequently move the source of a subprogram from the device to a connected library (Page 4116) without changing the parameters of the "Subprogram call" command. The MCC unit is still compiled correctly.

If you parameterize the "Subprogram" command again, you may receive an error message that the subprogram has been deleted or renamed. Close the error message and select the new subprogram type (e.g. library function) and the library which contains the subprogram.

A check as to whether an identifier of a subprogram is hidden by an identifier with the same name in the MCC unit, is not performed. You can avoid name conflicts by using namespaces (Page 4116).

Example: Function (FC)

You want to create a subprogram with a circumference calculation for a circle. The calculation is performed in a function (FC). This is named Circumference.

The circle circumference calculation can thus be called as a subprogram by any task.

Formula for circumference calculation: Circumference = PI * 2 * radius

You define the Radius and PI variables in the declaration table of the function.

Creating and programming the function (FC)

1. In the **PROGRAMS** folder in the project navigator, open the MCC source file in which you want to create the function.
2. In the MCC source file, double-click on the entry **Insert MCC chart** and enter the following parameters in the open **Insert MCC chart** dialog window:
   - Enter the name **Circumference**.
   - For creation type, select **Function**.
   - For return type (data type of return value), select **REAL**.
   - Click **OK** to confirm.
3. In the declaration table, define the input parameter **radius** and the constant **PI** (see figure).
4. Program the variable assignment for the return value (see figure).
5. Accept and compile the MCC source file.

You have now finished programming the **Circumference** function.

	Name	Variable type	Data type	Array length	Initial value	Comment
1	radius	VAR_INPUT	REAL			
2	PI	VAR CONSTANT	REAL		3.14159	
3						

Figure 7-52 Declaring variables (e.g., input parameters) in the MCC chart

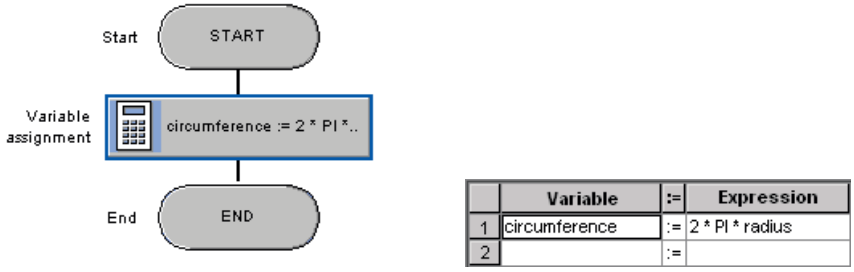

Figure 7-53 Programming the Circumference subroutine (e.g. assignment to a return value)

Subroutine call of function (FC)

The function (FC) is called from a program in the example.

Procedure

To call the function (FC) in a program, proceed as follows:

1. Create an MCC chart as a program in the same MCC unit (see Inserting a new MCC chart (Page 4001)).
2. In the MCC unit or MCC chart, declare the following (see figure):
   - The **mycircum** variable. The return value of the "Circumference" function is assigned to this variable.
   - The **myradius** variable. This variable contains the radius and is assigned to the input parameter "Radius" of the "Circumference" function.

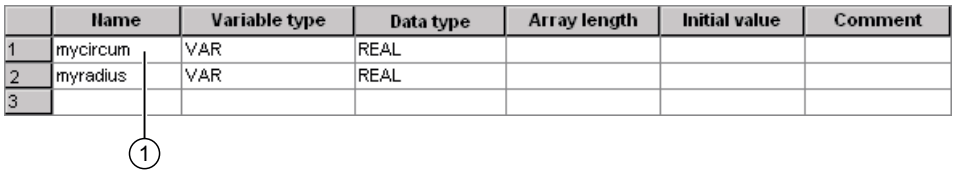
   Note that the validity range of the variables is dependent on the declaration location (see Defining variables (Page 4062)).
3. Insert the **Subprogram call** command.
4. Assign parameters in the parameter screen form (see figure).

   Note

   Mandatory parameters are marked with "<???>" and optional parameters with "...". A subprogram call will only be functional if all the mandatory parameters are set.

5. Accept and compile the MCC unit.

You have now finished programming the subprogram call.



① You can continue to use the mycircum variable in the program.

Figure 7-54 Declaring a variable in the MCC chart

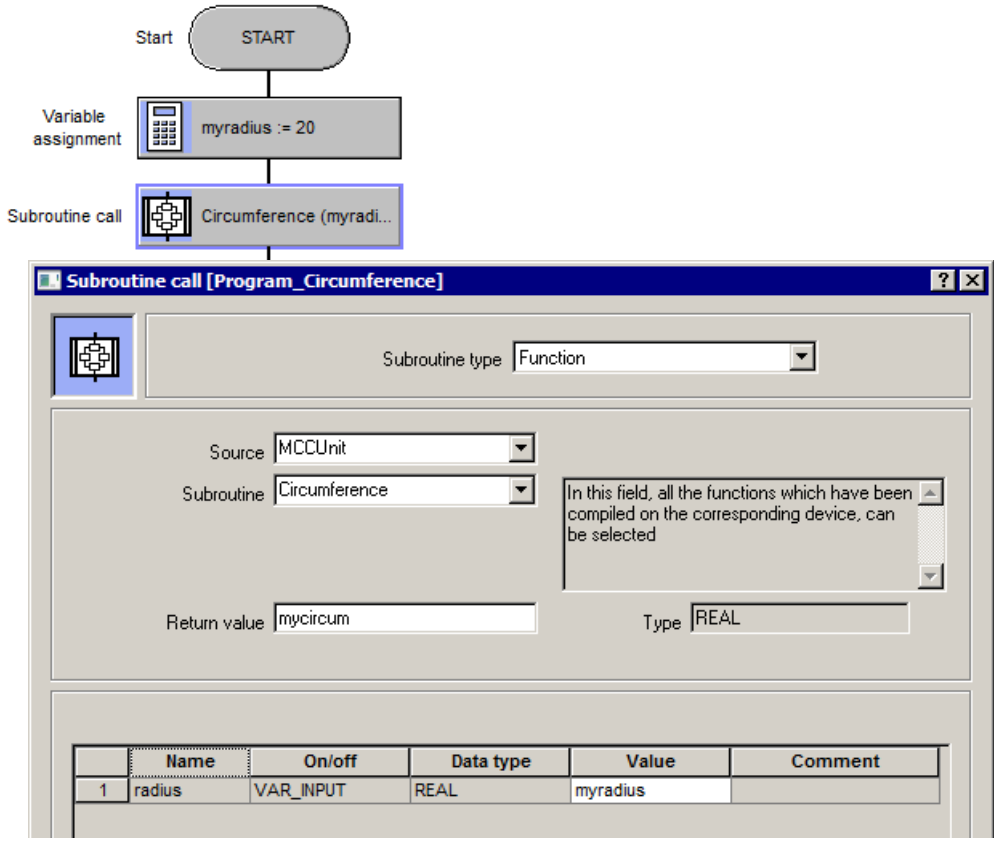


Figure 7-55 Opened parameter screen form for the subprogram call

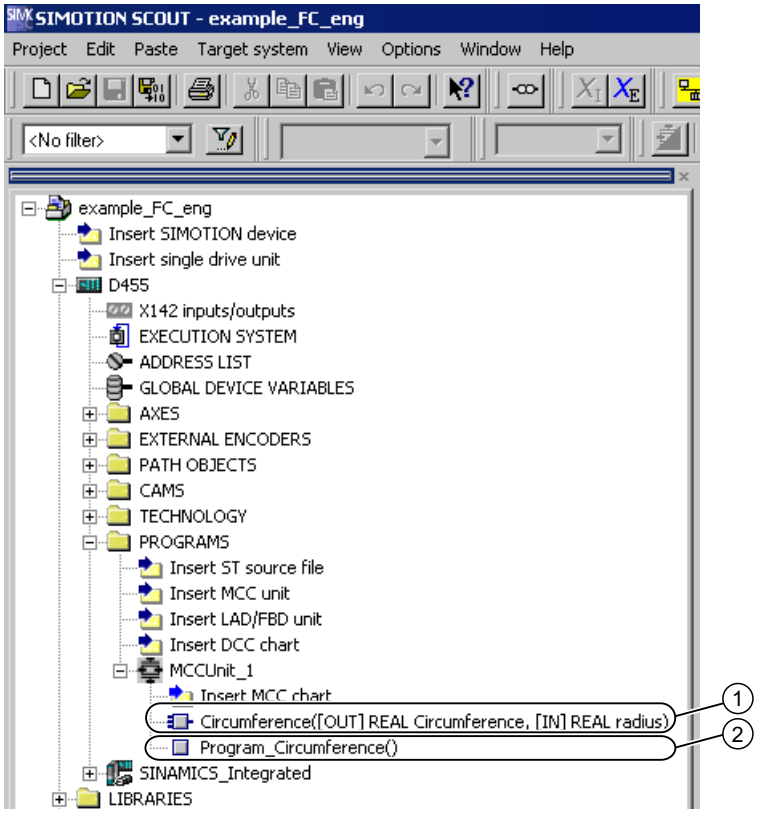
Note

Saving a project in a format older than Version V4.2 of SIMOTION SCOUT

Pay attention to the order of the MCC charts in the MCC unit (see figure below). A subprogram (function or function block) must be defined before it is used. This is the case when the MCC chart of the subprogram appears above the chart in which it is used in the project navigator.

As far as the example described here is concerned, the MCC chart with the function must appear in the project navigator above the chart containing the program with the subprogram call. If necessary, rearrange the charts by selecting the relevant MCC chart in the project navigator and selecting the command **Down** or **Up** in the context menu.



① MCC chart with the function

② MCC chart containing the program with the subprogram call

Figure 7-56 Sequence of the MCC charts

Opening the function (FC) directly following the subroutine call

You can open subroutines directly following their respective subroutine call via the context menu:

- This works regardless of the programming language (ST, MCC, LAD/FBD) used to create the subroutine.
- The subroutine opens in a separate editor or an editor already opened for the subroutine is moved to the foreground.

A subroutine may be a:

- User-defined FC
- User-defined FB
- User-defined program called as a subroutine ("program in program")
- Library function
- Library function block
- Library program called as a subroutine ("program in program")

Procedure

To open the function (FC) directly following the subroutine call, proceed as follows:

1. In the MCC chart, select the **Subroutine call** command used to call the function (FC).
2. Select the **Open called block** command in the context menu (Ctrl+Alt+O hotkey).
   The function (FC) opens in a separate editor or an editor already opened for the function (FC) is moved to the foreground.

Note

If the function (FC) called has not yet been created, the **Open called block** command appears inactive (grayed out) in the context menu.

Note

If the function (FC) called is in a program source with know-how protection, the steps required when opening the protected program source directly must also be performed here (see Know-how protection for MCC units (Page 3992)).

Example: Function block (FB)

You want to calculate a following error. The calculation is performed in a function block (FB) named FollError. The following error calculation can thus be called as a subprogram by any task.

Formula for following error calculation: Difference = Specified position – Actual position

Define the required input and output parameters Set position, Actual position, and Difference (with the other variables, if necessary) in the MCC chart (function block) or MCC unit.

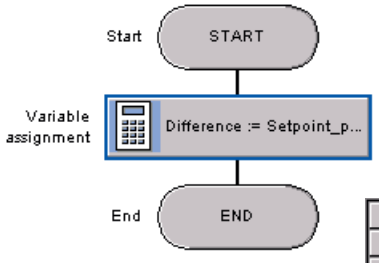
Creating and programming the function block (FB)

1. In the **PROGRAMS** folder in the project navigator, open the MCC source file in which you want to create the function block.
2. In the MCC source file, double-click on the entry **Insert MCC chart** and enter the following parameters in the open **Insert MCC chart** dialog window:
   - Enter the name **FollError**.
   - For creation type, select **Function block**.
   - Click **OK** to confirm.
3. In the declaration table, define the variables (e.g. input and output parameters; see figure).
4. The following error is calculated in a variable assignment (see figure).
5. Accept and compile the MCC source file.

You have now finished programming the **"FollError"** function block.

	Name	Variable type	Data type	Array length	Initial value	Comment
1	Setpoint_position	VAR_INPUT	LREAL			
2	Actual_position	VAR_INPUT	LREAL			
3	Difference	VAR_OUTPUT	LREAL			
4						

Figure 7-57 Declaring variables (e.g. input and output parameters) in the MCC chart



Formula language

	Variable	:=	Expression
1	Difference	:=	Setpoint_position - Actual_position
2		:=	

Figure 7-58 Programming a variable assignment

Subroutine call of function block (FB)

In this example, the function block (FB) is called from a program.

1. Generate an MCC chart as a program, see Insert new MCC chart (Page 4001).
2. Create a function block instance.
   – In the MCC source file or MCC chart, declare the instances of the function block along with the variables.

   Note that the validity range of the instance and variables is dependent on the declaration location (see Define variables (Page 4062)).
3. Call the function block:
   – Program the **Subroutine call** command.
4. After executing an instance of the function block, you can access the output parameters at any location in the calling program.
   – Program the **Variable assignment** command.
5. Accept and compile the program.

You have now finished programming the subroutine call.

Creating a function block instance

Before you can use a function block, you must define an instance. Each instance of an FB is independent of the others; once an instance has ended, its static variables remain stored.

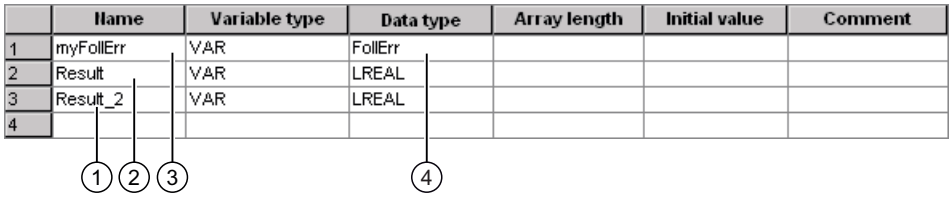
You define the instances of an FB in the declaration table of the MCC source file or MCC chart. The scope of the instance declaration is dependent on the location of the declaration:

- In the interface section of the declaration table of the MCC source file:
  The instance behaves like a unit variable; it is valid for the entire MCC source file; all MCC charts (programs, function blocks, and functions) within the MCC source file can access the instance.
  The instance is also available:
  - On HMI devices.
  - In other MCC source files (or other units) once connected, see "How to define connections to other units (program sources)" (Page 4115).

  The total size of all unit variables in the interface section is limited to 64 Kbytes.
- In the implementation section of the declaration table of the MCC source file:
  The instance behaves like a unit variable that is valid only for the MCC source file; all MCC charts (programs, function blocks, and functions) within the MCC source file can access the instance.
- In the declaration table of the MCC chart (for programs and function blocks only):
  The instance behaves like a local variable; it can only be accessed within the MCC chart in which it is declared.

Proceed as follows; the MCC source file or the MCC chart with the declaration table is open, see "Open existing MCC source files" (Page 3989) or "Open existing MCC chart" (Page 4004):

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Parameters** tab.
3. Enter or select the following:
   - **Name** of instance (variable name – see Rules for identifiers (Page 4047))
   - **Variable type** VAR or VAR_GLOBAL, depending on the declaration location (in MCC chart or MCC source file, respectively)
   - Designation of the function block as **data type**.
4. Declare the other variables.



① The output parameter Difference is assigned to the variable Result_2 during subsequent program runtime. You can use the Result_2 variable for other purposes in the program.

② The output parameter Difference is assigned to the variable Result in the subroutine call. You can use the Result variable for other purposes in the program.

③ Creating an instance

④ Select the required FB as the data type.

The created function blocks are offered as data types in the drop-down list box depending on the MCC editor settings (Page 3984):

- Only function blocks with the same program source or from connected program sources or libraries
- All function blocks defined in the project

Figure 7-59 Define an instance of the function block and variables in the MCC chart or MCC source file

Programming the subroutine call of the function block

1. Insert the Subroutine Call command in the MCC chart.
2. Program the command as follows:
   - For subroutine type, select **Function block**.
   - Select the designation of the function block as the subroutine.
     The input, in/out parameters and output parameters for the FB are displayed.
   - Enter the instance defined in the declaration table in the **Instance** field.
3. Assign the current values to the transfer parameters:
   - Input parameters: Variable or expression
   - In/out parameter: Directly readable/writable variable
   - Output parameter (optional): Variable

   You can paste unit and system variables from the detail view using a drag-and-drop operation.

   Note

   Mandatory parameters are marked with "<???>" and optional parameters with "...". Function blocks (FBs) only have optional parameters.

4. Click **OK** to confirm.

Note

Saving a project in a format older than Version V4.2 of SIMOTION SCOUT

Pay attention to the order of the MCC charts in an MCC unit. A subroutine (function or function block) must be defined before it is used. This is the case when the MCC chart of the subroutine appears above the chart in which it is used in the project navigator. If necessary, reorder the charts.

See also: Subprogram call of function (FC) (Page 4129)

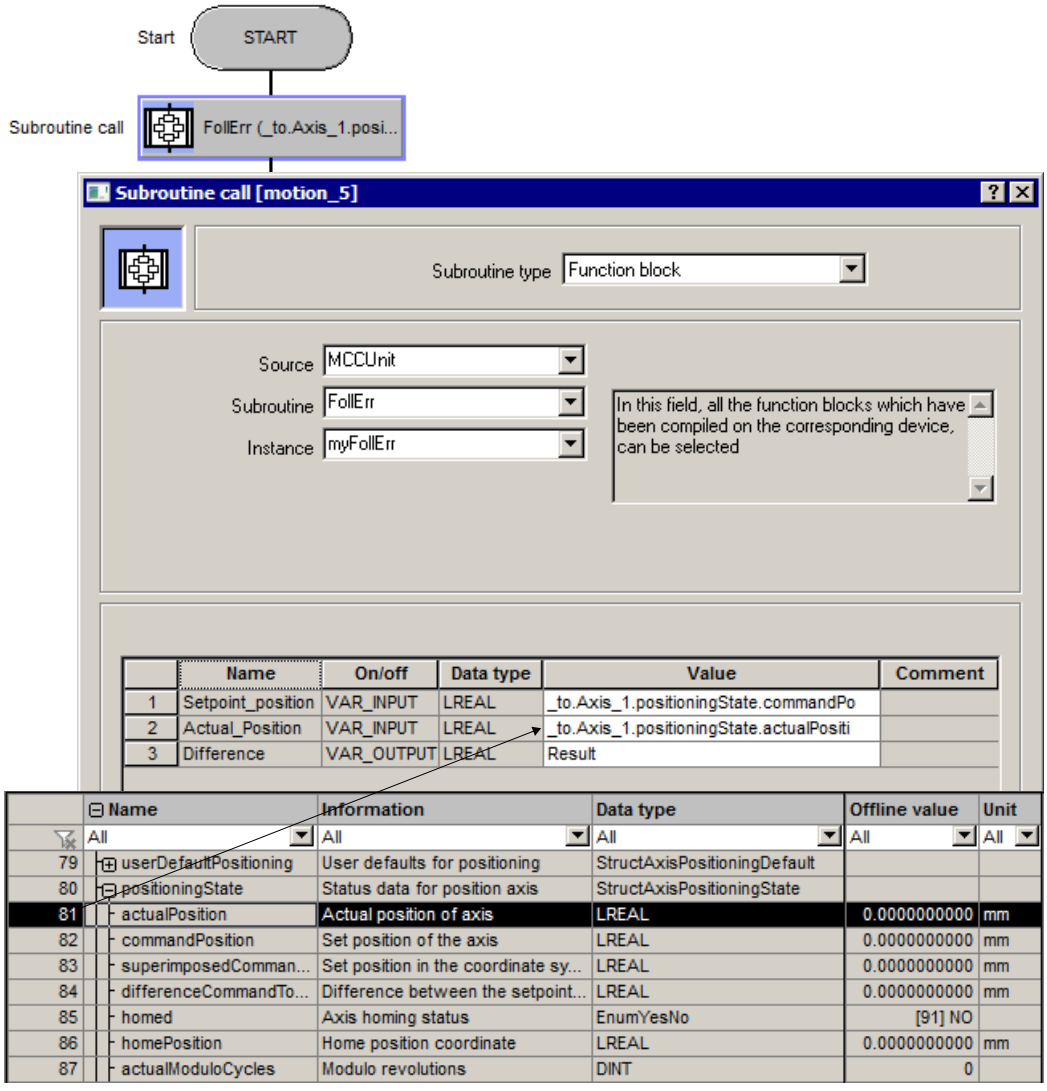


Figure 7-60 Opened parameter screen form for the subroutine call

Opening the function block (FB) directly following the subroutine call

You can open subprograms directly from their respective subprogram call using the context menu:

- This works regardless of the programming language (ST, MCC, LAD/FBD) used to create the subprogram.
- The subprogram opens in a separate editor or an editor already opened for the subprogram is moved to the foreground.

A subprogram may be a:

- User-defined FC
- User-defined FB
- User-defined program called as a subprogram ("program in program")
- Library function
- Library function block
- Library program called as a subprogram ("program in program")
- Class method
- Interface method

Procedure

To open the function block (FB) directly following the subprogram call, proceed as follows:

1. In the MCC chart, select the **Subprogram call** command used to call the function block (FB).
2. Select the **Open called block** command in the context menu (Ctrl+Alt+O hotkey).
   The function block (FB) opens in a separate editor, or an editor already opened for the function block (FB) is moved to the foreground.

Note

If the function block (FB) called has not yet been created, the **Open called block** command appears inactive (grayed out) in the context menu.

Note

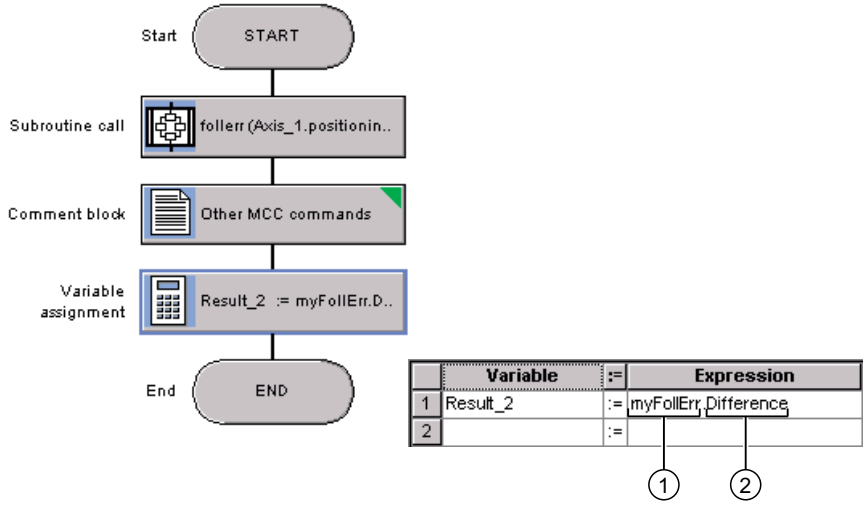
If the function block (FB) called is in a program source with know-how protection, the steps required when opening the protected program source directly must also be performed here. See Know-how protection for MCC units (Page 3992).

Accessing the output parameters of the function block retrospectively

After an instance of the function block has been executed, the static variables of the function block (including the output parameters) are retained. You can access the output parameters at any point in the calling program.

If you have defined the FB instance as VAR_GLOBAL, you can also access the output parameter in other MCC charts.

1. Insert the **Variable assignment** command in the MCC chart.
2. Program the command (see figure).
3. Click **OK** to confirm.



① Name of the FB instance ② Output parameter

Figure 7-61 Programming a variable assignment

Example: Method

In MCC charts you can call up public methods which have been defined in ST source files within classes and function blocks.

You can use methods in function blocks irrespective of the SIMOTION Kernel version.

Methods in classes can only be used in SIMOTION Kernel as of version V4.5.

No classes or methods can be defined in the MCC programming language itself. The same applies to methods within function blocks.

Requirement

In an ST source file the COUNTER class is defined with both public methods UP and DOWN: Both methods increment or decrement an internal counter variable until either the maximum value or minimum value is reached.

- The UP method has the following interface:
  - Input parameter INC with data type INT and initial value 1.
    You enter the increment here (standard = 1).
  - Output parameter QU with data type BOOL and initial value FALSE.
    The maximum value is reached when QU = TRUE.
  - Return value with data type INT.
    The return value shows the latest status for the internal counter variables.
- The DOWN method has the following interface:
  - Input parameter DEC with data type INT and initial value 1.
    You enter the increment here (standard = 1).
  - Output parameter QU with data type BOOL and initial value TRUE.
    The minimum value is reached when QU = FALSE.
  - Return value with data type INT.
    The return value shows the latest status for the internal counter variables.

The maximum value and minimum value for the counting range are stipulated in the private variables MAX_Val and MIN_Val for the class. They are pre-assigned with 100 or 0 respectively as standard. However, the initial values can be overwritten with the declaration of an instance for this class.

Subprogram call of the method

The method is called from a program in the example.

1. Generate an MCC chart as a program, see Insert new MCC chart (Page 4001).
2. Create an instance for the higher-level class or function block.
   - In the MCC source file or MCC chart, declare the instance of the class or the function block along with the variables, see: Creating an instance for the class or the function block (Page 4140).

   Note that the validity range of the instance and variables is dependent on the declaration location (see Define variables (Page 4062)).
3. Call the method:
   - Program the **Subprogram call** command, see: Programming the subprogram call of the method (Page 4141).
4. Accept and compile the program.

You have now finished programming the subroutine call.

Creating an instance for the class or the function block

Before you can use a method, you must define an instance for the higher-level class or the higher-level function block. Each instance of a class or FB is independent of the others; once an instance has ended, its static variables remain stored.

You define the instances of a class or FB in the declaration table of the MCC source file or MCC chart. The scope of the instance declaration is dependent on the location of the declaration:

- In the interface section of the declaration table of the MCC source file:
  The instance behaves like a unit variable; it is valid for the entire MCC source file; all MCC charts (programs, function blocks, and functions) within the MCC source file can access the instance.
  The instance is also available:
  - On HMI devices.
  - In other MCC source files (or other units) once connected, see "How to define connections to other units (program sources)" (Page 4115).

  The total size of all unit variables in the interface section is limited to 64 Kbytes.
- In the implementation section of the declaration table of the MCC source file:
  The instance behaves like a unit variable that is valid only for the MCC source file; all MCC charts (programs, function blocks, and functions) within the MCC source file can access the instance.
- In the declaration table of the MCC chart (for programs and function blocks only):
  The instance behaves like a local variable; it can only be accessed within the MCC chart in which it is declared.

Proceed as follows; the MCC source file or the MCC chart with the declaration table is open, see "Open existing MCC source files" (Page 3989) or "Open existing MCC chart" (Page 4004):

1. Select the declaration table and, if applicable, the section of the declaration table for the desired scope.
2. Select the **Parameters** tab.
3. Enter or select the following:
   - **Name** of instance (variable name – see Rules for identifiers (Page 4047))
   - **Variable type** VAR or VAR_GLOBAL, depending on the declaration location (in MCC chart or MCC source file, respectively)
   - Designation of the function block as **data type**.
4. Declare the other variables.

Programming the subprogram call of the method

1. Insert the Subroutine Call command in the MCC chart.
2. Program the command as follows:
   - Select **Method** as the subprogram type.
     The classes or function blocks exported from ST source files are displayed with their public methods in the following format: *Class_Name.Method_Name* or FB_name.Methods
   - Select the designation of the class with its method as the subprogram.
     The input, in/out parameters and output parameters for the method are displayed.
   - Enter the instance for the higher-level class or the higher-level function block defined in the declaration table in the **Instance** field.
   - Enter the variable assigned the return value after the method has ended in the **Return value** field.

3. Assign the current values to the transfer parameters:
   - Input parameters: Variable or expression
   - In/out parameter: Directly readable/writable variable
   - Output parameter (optional): Variable

   You can paste unit and system variables from the detail view using a drag-and-drop operation.

Note

Mandatory parameters are marked with "<???>" and optional parameters with "...".

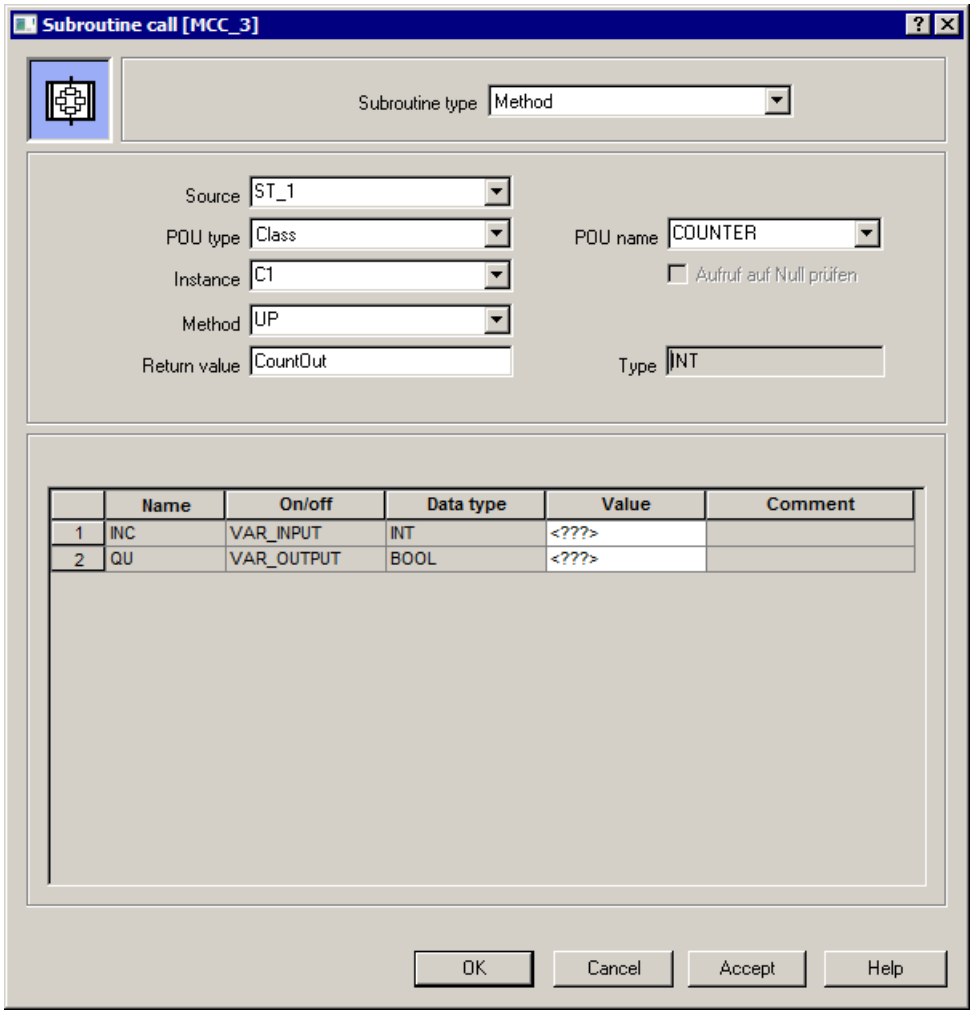


Figure 7-62 Subprogram call for a method

4. Click **OK** to confirm.

Note

Saving a project in a format older than Version V4.5 of SIMOTION SCOUT

Projects in which classes and their methods are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

The following program uses the COUNTER program which was declared in the ST source file ST_1, see requirements in "Example:Methods" (Page 4138). It calls the methods UP and DOWN defined in this class. A C1 instance for the COUNTER class was declared for this; provided that the upper value is not reached (UpValreached = FALSE), the Method COUNTER.UP is called, otherwise the Method COUNTER.DOWN is called until the lower limit value is reached.

This program must be assigned to a cyclic task of the execution system (e.g.: BackgroundTask).

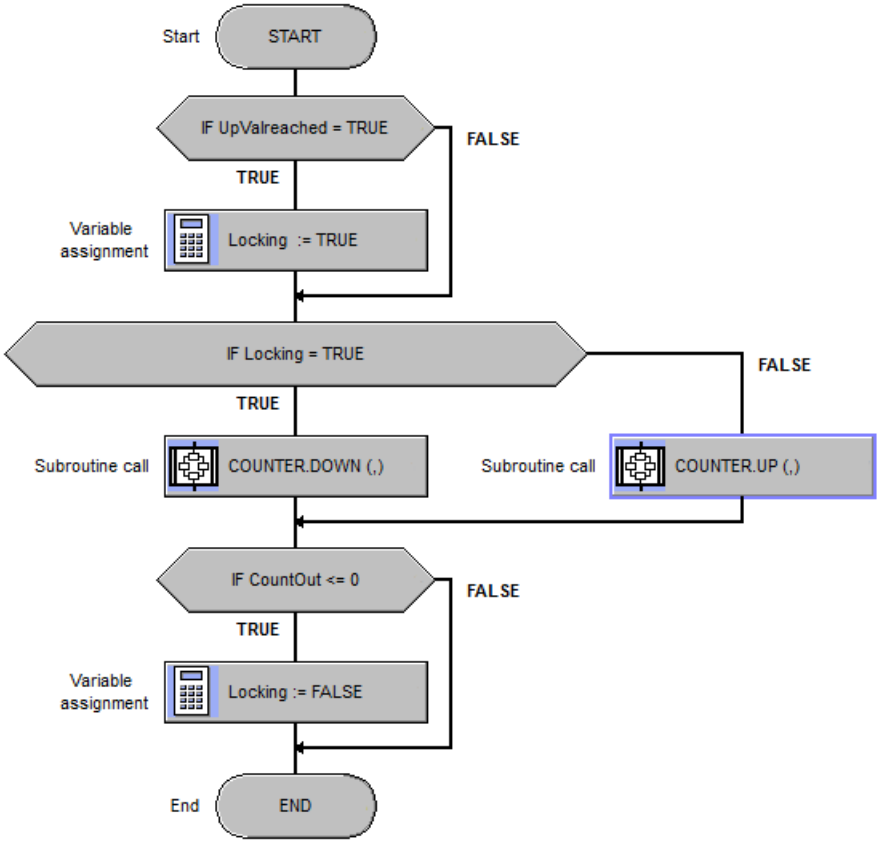

Figure 7-63 Example: Call of the methods in the COUNTER class

7.1.5.11 Reference data

The reference data provide you with an overview of:

- on utilized identifiers with information about their declaration and use (Cross-reference list (Page 4144)).
- on function calls and their nesting (Program structure (Page 4148))
- on the memory requirement for various data areas of the program sources (Code attributes (Page 4150))

Cross reference list

The cross-reference list shows all identifiers in program sources (e.g. ST source files, MCC units):

- Declared as variables, data types, or program organization units (program, function, function block)
- Used as previously defined types in declarations
- Used as variables in the statement section of a program organization unit.

Generating and updating a cross-reference list

Initially, the cross-reference list is generated automatically when opening. Open a cross-reference list, e.g. after selecting an ST source file or library via the **Edit > Display reference data > Cross-references** menu. After changes, the update is partly performed automatically and can always be triggered manually in the detail view via the  button. When updating via the button, a check is performed as to whether a compilation is required. If a compilation is required, this is indicated by a yellow triangle next to the button.

Update of the cross-reference list when selecting a program

The list is updated automatically when opening the selected program. The local defined identifiers are therefore up-to-date.

External identifiers in the program are not updated when opening.

The opened cross-reference list is also updated automatically when compiling the program.

Update of the cross-reference list when selecting a tree (CPU, project, library, program folder)

The cross-reference list is generated automatically when opening the first time. There is no automatic update when opened again.

Note

An error-free compilation is required for a correct, consistent display of the reference data. If required, compile the project, the CPU, the program or the library first.

Example: Cross-reference tab in detail view

	Name	Type	Declaration	Use	Path specification	Range	Language	Line/block
149	instanzvariable_fb	fb_2	kfquelle_1 (UNIT)	CALL	C230\KFQuelle_1	PROGRAM kopfup_3	ST	40

Figure 7-64 Cross-reference tab in detail view

Content of the cross-reference list

The cross-reference list contains all the identifiers assigned to the element selected in the project navigator. The applications for the identifiers are also listed in a table:

Details of how to work with the cross-reference list are provided in the section titled "Working with the cross-reference list".

Table 7-38 Meanings of columns and selected entries in the cross-reference list

Column	Entry in column	Meaning
Name		Identifier name
Type		Identifier type
	Name	• Data type of a variable (e.g. REAL, INT) • POU type (e.g. PROGRAM, FUNCTION)
	DERIVED	Derived data type
	DERIVED ANY_OBJECT	TO data type
	ARRAY ...	ARRAY data type
	ENUM ...	Enumerator data type
	STRUCT ...	STRUCT data type
Declaration		Location of declaration
	Name (UNIT)	Declaration in the program source *name*
	Name (LIB)	Declaration in the library *name*
	Name (TO)	System variable of the technology object *name*
	Name (TP)	Declaration in the default library specified: • Technology package *name* • std_fct = IEC library • device = device-specific library

Column	Entry in column	Meaning
	Name (DV)	Declaration on the SIMOTION device *name* (e.g. I/O variable or global device variable)
	_project	Declaration in the project (e.g. technology object)
	_device	Internal variable on the SIMOTION device (e.g. TaskStartInfo)
	_task	Task in the execution system
Use		Use of identifier
	CALL	Call as subprogram (static binding)
	CALL VTAB	Call of a method of the dynamic binding
	ENUM *name*	As element when declaring the enumerator data type *name*
	I/O	Declaration as I/O variable
	R	Read access
	R (TYPE)	As data type in a declaration
	R/W	Read and write access
	STRUCT *name*	As component when declaring the structure *name*
	TYPE	Declaration as data type or POU
	Variable type (e.g. VAR, VAR_GLOBAL)	Declaration as variable of the variable type specified
	W	Write access
Path specification		Path specification for the SIMOTION device or program source
	Name	SIMOTION device *name*
	Name1/*Name2*	• Program source *name2* on SIMOTION device *name1* • Program source *name2* in library *name1*
	Name/taskbind.hid	Execution system of the SIMOTION device *name*
Range		Range within the SIMOTION device or program source
	INTERFACE	Interface section of the program source
	POE type name (i.e. CLASS *name*, FUNCTION *name*, FUNCTION_BLOCK *name* INTERFACE *name* PROGRAM *name*)	Program Organization Unit (POU) *Name* within the program source. • In an MCC chart: Additional serial numbers for the command (block numbers) • In a LAD/FBD program: Additional serial numbers of the network
	I/O address	I/O variable
	METHOD *Name_1*::*Name_2*	Method *Name_2* within the class or the function block *Name_1*
	TASK *name*	Assignment for the task *name*
	UNIT	Implementation section of the program source, additional specification as POU to be made public in the interface section of the program source
	UNIT - IMPLEMENTATION	Implementation section of the program source
	_device	Global device variable

Column	Entry in column	Meaning
Language		Programming language of the program source
Line/Block		• In an ST source: Line number within the program source • In an MCC or LAD/FBD source: Relative line number within the command (block) or network. **Note** The absolute line number within the program source, which you need, for example, for the trace function "Trigger to code point", is obtained as follows: – Press the **Determine program line** button. – In the dialog box, press the button **Copy program line to the clipboard**.

Note

Single-step tracking and trace diagnostic functions in MCC programming

Additional variables and functions are created or used for these diagnostics functions:

- The variables TSI#dwuser_1 and TSI#dwuser_2 of the TaskStartInfo are used for the single-step tracking diagnostic function.
- Various internal functions and variables, whose identifier begins with an underscore, are automatically created by the compiler for the trace diagnostic function. The TSI#currentTaskId variable of the TaskStartInfo is also used.

With activated diagnostic function, these variables and functions are used for the control of the diagnostics function. These variables and functions must not be used in the user program.

Working with a cross-reference list

In the cross-reference list you are able to:

- Sort the column contents alphabetically:
  - To do this, click the header of the appropriate column.
- Search for an identifier or entry:
  - Click the "Search" button and enter the search term.
- Filter (Page 4148) the identifiers and entries displayed.
- Copy contents to the clipboard in order to paste them into a spreadsheet program, for example.
  - Select the appropriate lines and columns.
  - Press the CTRL+C shortcut.

- Print the content (**Project > Print**).
- Open the referenced program source and position the cursor on the relevant line of the ST source file (or MCC command or LAD/FBD element):
  - Double-click on the corresponding line in the cross-reference list.
    or
  - Place the cursor in the corresponding line of the cross-reference list and click the "Go to application" button.

Further details about working with cross-reference lists can be found in the online help.

Filtering the cross-reference list

You can filter the entries in the cross-reference list so that only relevant entries are displayed:

1. Click the "Filter settings" button.
   The "Filter Setting for Cross References" window will appear.
2. Activate the "Filter active" checkbox.
3. If you also want to display system variables and system functions:
   - Deactivate the "Display user-defined variables only" checkbox.
4. Set the desired filter criterion for the relevant columns:
   - Select the relevant entry from the drop-down list box or enter the criterion.
   - If you want to search for a character string within an entry: Deactivate the "Whole words only" checkbox.
5. Confirm with **OK**.

The contents of the cross-reference list will reflect the filter settings selected.

Note

A filter is automatically activated after the cross-reference list has been created.

Program structure

The program structure contains all the function calls and their nesting within a selected element.

You can display the program structure selectively for:

- An individual program source (e.g. ST source file, MCC unit, LAD/FBD source file)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Proceed as follows:

1. In the project navigator, select the element for which you want to display the program structure.
2. Select the **Edit > Display reference data > Program structure** menu command.
   The cross-reference tab is replaced by the program structure tab in the detail view.

Note

The display data is updated every time the program structure is opened.

You can update the detail view of an opened program structure with the F5 key.

Example: Program Structure tab in the detail view

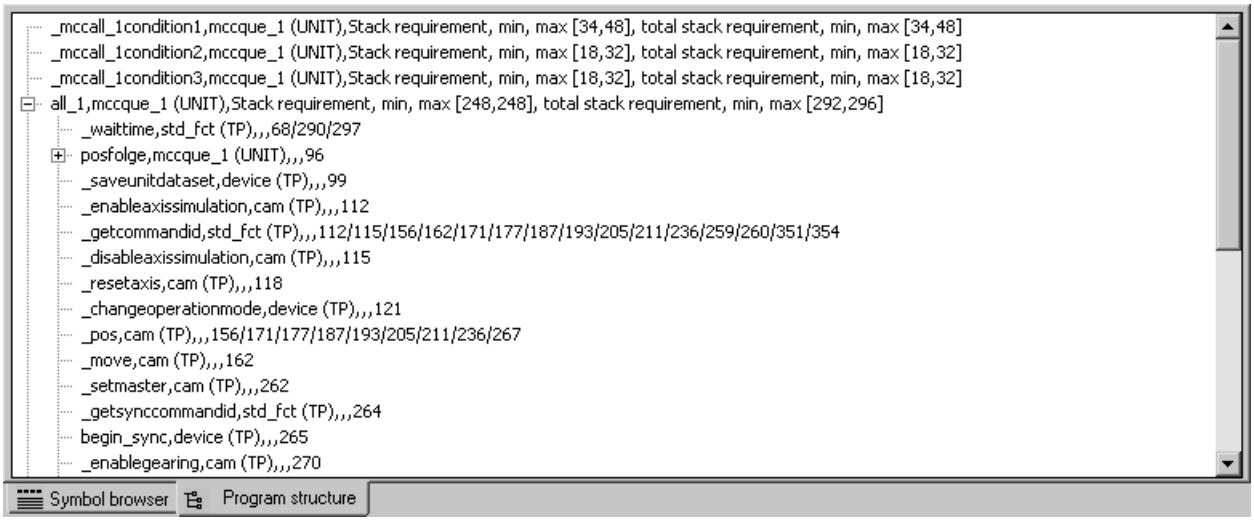

Figure 7-65 Example of a program structure

Content of the program structure

A tree structure appears, showing:

- as base respectively
  - the program organization units (programs, functions, function blocks) declared in the program source, or
  - the execution system tasks used
- below these, the subroutines referenced in this program organization unit or task.

For structure of the entries, see table:

Table 7-39 Elements of the display for the program structure

Element	Description
Base (declared POU or task used))	List separated by a comma • Identifier of the program organization unit (POU) or task The specification *Name_1::Name_2* means: Method *Name_2* within the class or the function block *Name_1*. • Identifier of the program source in which the POU or task was declared, with add-on [UNIT] • Minimum and maximum stack requirement (memory requirement of the POU or task on the local data stack), in bytes [Min, Max] • Minimum and maximum overall stack requirement (memory requirement of the POU or task on the local data stack including all called POUs), in bytes [Min, Max]
Referenced POU	List separated by a comma: • Identifier of called POU The specification *Name_1::Name_2* means: Method *Name_2* within the class or the function block *Name_1*. • Optionally: Identifier of the program source / technology package in which the POU was declared: Add-on (UNIT): User-defined program source Add-on (LIB): Library Add-on (TP): System function from technology package • with function blocks or methods only: Identifier of the instance of the function block or the higher-level class • with function blocks or methods only: Identifier of program source in which the instance of the function block or of the higher-level class was declared: Add-on (UNIT): User-defined program source Add-on (LIB): Library • Number of the line in the (compiled) source in which the POE is called; several line numbers are separated by "/".

Code attributes

You can find information on or the memory requirement of various data areas of the program sources under code attribute.

You can display the code attributes selectively for:

- An individual program source (e.g. ST source file, MCC unit, LAD/FBD source file)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Proceed as follows:

1. In the project navigator, select the element for which you want to display the code attributes.
2. Select the **Edit > Display reference data > Code attributes** menu command.
   The **Cross-references** tab is now replaced by the **Code attributes** tab in the detail view.

Note

The display data is updated every time the code attributes are opened.

You can update the detail view of the opened code attributes with the F5 key.

Code attribute contents

The following are displayed in a table for all selected program sources:

- Identifier of program source,
- Memory requirement, in bytes, for the following data areas of the program source:
  - **Dynamic data**: All unit variables (retentive and non-retentive, in the interface and implementation sections),
  - **Retain data**: Retentive unit variables in the interface and implementation section,
  - **Interface data**: Unit variables (retentive and non-retentive) in the interface section,
- the **Code size** during the last compilation in bytes,
- the **Number of referenced sources**:
  The maximum number of connected sources is displayed (including system libraries), regardless of whether they are downloaded to the target system at a later date.

Reference to variables

If you have selected the identifier of a variable in the open Editor window for each programming language, you can use the other places of use over the context menu to list or to skip these variables.

You select the identifier of a variable:

- In SIMOTION ST: In the Editor window of an ST source.
- In SIMOTION MCC: In the input field on the parameter screen of an open MCC command within an MCC chart
- In SIMOTION LAD/FBD: In the Editor window of a LAD/FBD program

An identifier is recognized as a variable under the following conditions:

1. The identifier is declared as a variable. The scope of the variable includes the respective window (ST source, MCC chart, LAD/FBD program).
2. The program source is compiled.
3. The variable is selected as follows (in an open parameter screen within an MCC chart):
   – The identifier is fully marked
   or
   – The cursor is within the identifier.

Note

In arrays and structures, only the variable can be selected, not a single element.

Using the **Go to** context menu, you have the following options:

- To jump to the next local place of use:
  Select the context menu **Go to > Local use >>**.
  The next place of use of the variables within the same Editor window (ST source, MCC chart, LAD/FBD program) is selected. In an MCC chart, the corresponding MCC command opens.
- Jump to the previous local place of use:
  Select the context menu **Go to > Local use <<**.
  The previous place of use of the variables within the same Editor window (ST source, MCC chart, LAD/FBD program) is selected. In an MCC chart, the corresponding MCC command opens.
- Jump to the declaration position:
  Select the context menu **Go to > Declaration position**.
  The declaration position of the variables is selected. The corresponding program source is opened, if necessary.
- List all places of use
  Select the context menu **Go to > Places of use ...**.
  In the detailed view, all places of use of the variables within their scope (including the declaration position) are listed The structure of this list is similar to the List of cross references (Page 4145).
  This is how you jump to a preferred place of use:
  – Double-click on the corresponding line.
  or
  – Place the cursor in the corresponding line and click the "Go to application" button.

7.1.5.12 LAD/FBD/formula

The creation language for a condition or variable assignment is either the ladder logic (LAD) or function block diagram (FBD) programming language, or a formula according to IEC61131-3. One of these programming languages can be selected as a standard language for conditions and variable assignments (see MCC editor settings (Page 3984)).

The language can be selected individually for the following commands:

- Variable assignment, see Variable assignment (Page 4187)
- Wait for condition, see Wait for condition (Page 4180)
- IF program branching, see IF: Program branching (Page 4206)
- WHILE loop with condition at the start, see WHILE: Loop with condition at the start (Page 4208)
- UNTIL loop with condition at the end, see UNTIL: Loop with condition at the end (Page 4211)
- Synchronous start, see Synchronous start (Page 4219)

You can switch between the different programming languages. A calculation programmed in LAD or FBD can be expanded in Formula in accordance with IEC61131-3. However, you can then only switch back to the LAD or FBD display if the expression can be displayed in these languages.

Note

If you have not yet programmed in these languages, you can find a brief description of how to do so in Appendix "Basic principles of LAD/FBD/Formula for MCC" (Page 4566).

Insert variable

You can insert variables from the detail view (Symbol browser tab) into the appropriate input field using a drag and drop operation.

Ladder diagram (LAD)

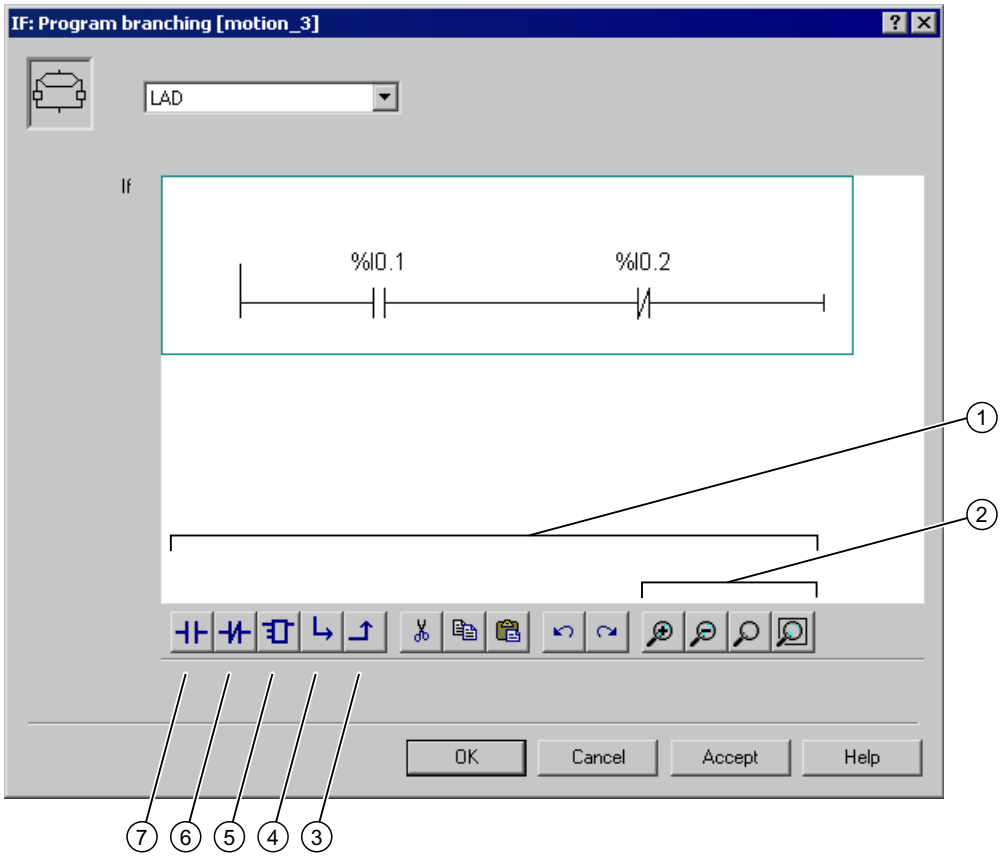
If you select the LAD language, an empty ladder diagram is initially opened.

New elements are inserted using the context menu commands or the buttons on the toolbar. New elements are always inserted after the selected element.

You can select individual elements using the cursor or the keyboard cursor keys. The selected element is displayed in blue.

Selected elements can be copied, pasted, cut, or deleted using the context menu.

Input screen form for ladder diagram



① Toolbar
② Enlarge/reduce the graphic display
③ Close branch
④ Open branch
⑤ Comparator
⑥ NC contact
⑦ NO contact

Figure 7-66 Input screen form for ladder diagram

Description of LAD elements

Description of normally open (NO) contact

NO contact	
Description	Signal = 1 if the operand has signal status 1. The operand specifies the bit or Boolean variable whose signal status is queried.
Data types	BOOL

Description of normally closed (NC) contact

NC contact	
Description	Signal = 1 if the operand has signal status 0. The operand specifies the bit or Boolean variable whose signal status is queried.
Data types	BOOL

Description of comparator

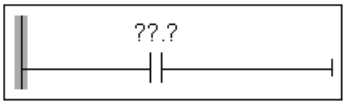
Comparator		
Description	Signal = 1 if the comparison of the two operands is true. Possible modes of comparison:	
	=	Equal to
	<>	Not equal to
	>	Greater than
	<	Less than
	>=	Greater than or equal to
	<=	Less than or equal to
Data types	SINT, INT, DINT, REAL, LREAL, BOOL, BYTE	
	SINT	8-bit integer comparator, Parameter: Byte
	INT	16-bit integer comparator, Parameter: Words
	DINT	32-bit integer comparator and time comparator, Parameter: Double words and times
	REAL	32-bit floating-point comparator, Parameter: Double words
	LREAL	64-bit floating-point comparator, Parameter: 64-bit floating point values

A detailed description of the elements can be found in Appendix "Ladder diagram (LAD) for MCC" (Page 4566).

Opens a branch

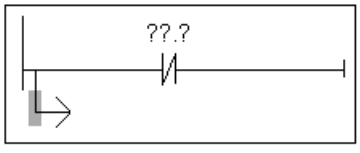
Procedure: Open branch

Use the cursor to select the position at which the branch is to be opened.



Open the branch using 

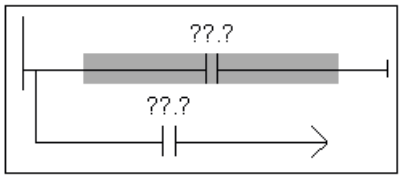
The branch is inserted after the selected element.



Closing a branch

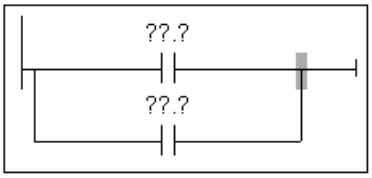
Procedure: Close branch

Use the cursor to select the position at which the branch must be closed.



Close the branch using 

The branch is closed after the selected element.



Function block diagram (FBD)

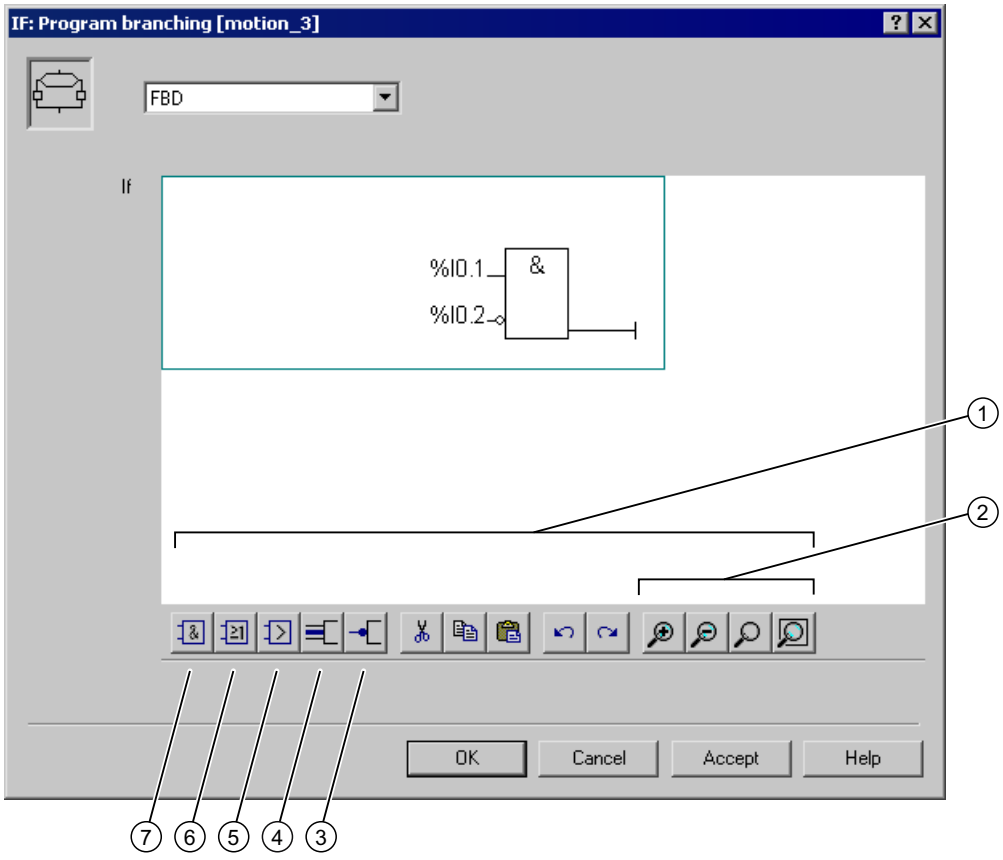
If you select the FBD language, an empty function block diagram is opened first.

New elements are inserted using the context menu commands or the buttons on the toolbar. New elements are always inserted after the selected element.

You can select individual elements using the cursor or the keyboard cursor keys. The selected element is displayed in blue.

Selected elements can be copied, pasted, cut, or deleted using the context menu.

Input screen form for function block diagram



① Toolbar
② Enlarge/reduce the graphic display
③ Negate input
④ Add input
⑤ Comparator
⑥ OR operation
⑦ AND operation

Figure 7-67 Input screen form for function block diagram

Description of FBD elements

Description of an AND operation

AND operation	
Description	The AND operation forms the signal states of two or more specified operands at the inputs of an AND box. If the signal status of all operands is 1, the condition is fulfilled and the result of the operation is 1. If the signal status of one operand is 0, the condition is not fulfilled and the result of the operation is 0.
Data types	BOOL

Description of an OR operation

OR operation	
Description	The OR operation forms the signal states of two or more specified operands at the inputs of an OR box. If the signal status of one operand is 1, the condition is fulfilled and the operation returns a result of 1. If the signal status of all operands is 0, the condition is not fulfilled and the result of the operation is 0.
Data types	BOOL

Description of comparator

Comparator	
Description	See Description of LAD elements (Page 4154).
Data types	See Description of LAD elements (Page 4154).

Description of Add input

Add input	
Description	An additional input is added to an AND or an OR operation.
Data types	----

Description of Negate input

Negate input	
Description	Signal is negated.
Data types	----

A detailed description of the elements can be found in Appendix "Function block diagram (FBD) for MCC" (Page 4569).

Formula

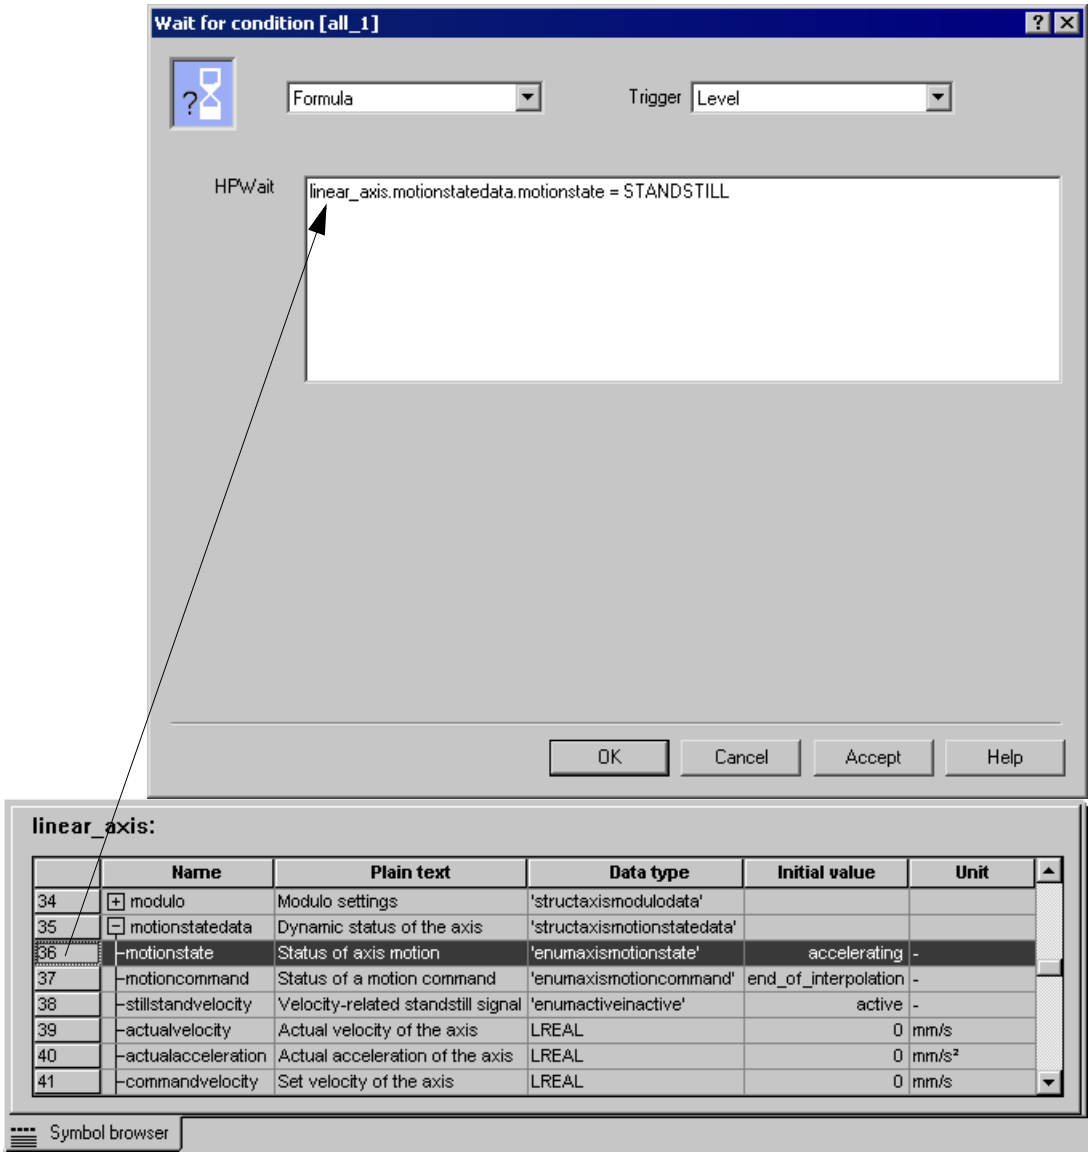
A condition or value can be programmed in Formula language.

You can move the operators you need from the Command library tab in the project navigator to the input field using a drag and drop operation.

The system variables are moved from the Symbol browser tab in the detail view to the input field using a drag and drop operation (see figure).

Closed block comments (* ... *) are permitted, line comments (starting with //) not. Use the command comment on the MCC command (**Enter comment ...** context menu), see also "Display of commands in the MCC chart" (Page 4016).

Programming a condition in the Formula language



A detailed description can be found in Appendix "Formula for MCC" (Page 4573).

7.1.5.13 Command library and system function

Command library

The command library is automatically displayed as a project navigator tab if you program the following commands:

- ST zoom
- System function call

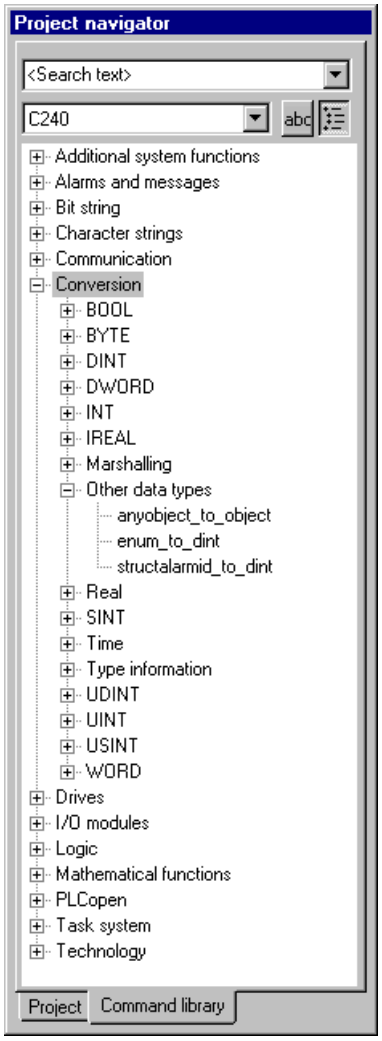


Figure 7-68 Command library tab of the project navigator

Note

You can move system functions from the command library to the parameter screen forms of the "ST zoom" and "System function call" commands using a drag-and-drop operation.

The command library stays open even when the programming window is closed.

Using the command library

Proceed as follows to insert operands or functions from the command library into a programming window:

Move the entry from the command library to the input field of the window using a drag-and-drop operation.

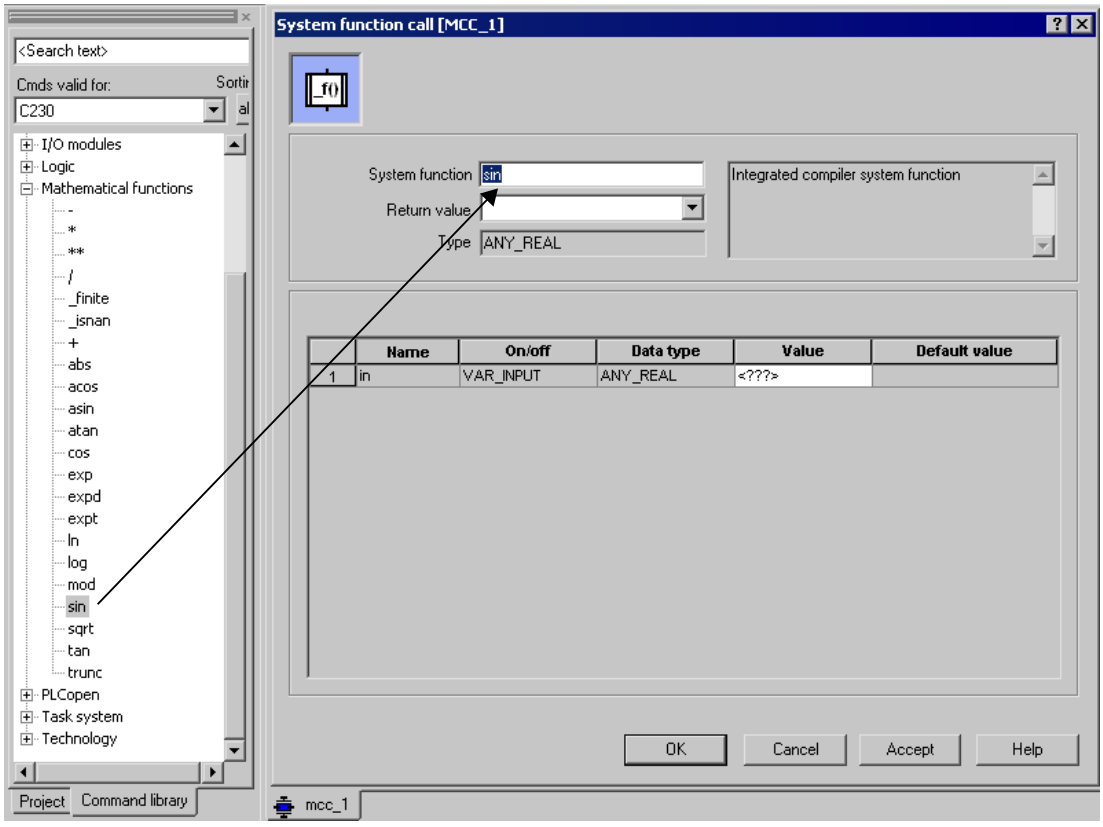

Figure 7-69 Inserting a command from the command library

Using the System function call command

The System function call command is available on the MCC editor toolbar (Basic commands command list). This command enables you to use any system functions and system function blocks in the MCC chart and to program their call conveniently.

When the command is called, the programmed system function or system function block is executed. Once the system function or system function block is executed, the execution of the MCC chart resumes after the command.

System function

The system function can be moved from the command library to the input field using a drag and drop operation or can be entered directly.

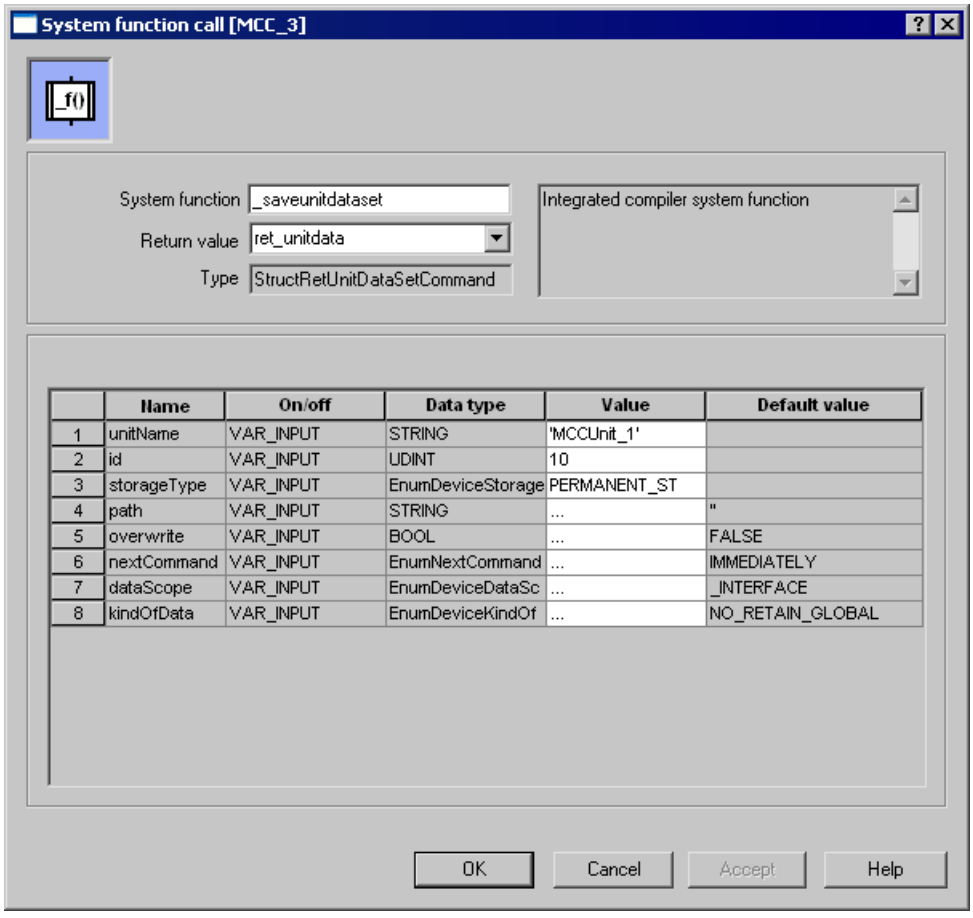
Return value

In the case of a system function, you specify the variable containing the return value of the function.

Instance

In the case of a system function block, you specify the instance. This instance has been declared as a variable beforehand (data type is the name of the system function block). See also Creating a function block instance.

Example of System function call



See also

Overview of parameters for System function call (Page 4163)

Overview of parameters for System function call

You can set the following parameters:

Table 7-40 Overview of parameters for System function call

Field/button	Meaning/instruction
System function	The desired system function can be selected from the command library. You can either enter the system function in the field or move it from the project navigator (command library) to the field using a drag and drop operation.
Return value	For a system function: Here, you enter the variable in which the return value is to be stored. The type of variable must match the return value type.
Type	For a system function: The data type of the return value is displayed.
Instance	For a system function block: Here, you enter the name of the system function block instance. The instance contains the memory of the function block in the form of instance data. Define the instance as VAR_GLOBAL in the declaration table of the MCC unit or VAR in the declaration table of the MCC chart.
List of transfer parameters	
Name	The name of the transfer parameter is displayed here.
On/off	The variable type of the transfer parameter is displayed here. **VAR_INPUT** Input parameter (for system functions and system function blocks) **VAR_IN_OUT** In/out parameter (for system function blocks only) **VAR_OUTPUT** Output parameter (for system function blocks only)
Data type	The data type of the transfer parameter is displayed here.

Field/button	Meaning/instruction
Value	Mandatory parameters are marked with "<???>" and optional parameters with "...". A system function call will only be functional if all the mandatory parameters are set. Here, you can assign current variables or values to the transfer parameters: • Input parameter (variable type VAR_INPUT): Here, you enter a variable name or an expression. The assignment of system variables or I/O variables is permissible; type transformations are possible. Optional input parameters are indicated by an entry in the **Default value** column. If no value has been transferred to it, it is automatically assigned the default value. • In/out parameter (variable type VAR_IN_OUT – for system function blocks only): Enter a variable name; it must be directly writable and readable. System variables of SIMOTION devices and technology objects are not permitted nor are I/O variables. The data type of the in/out parameter must correspond to that of the assigned variables; application of type transformation functions is not possible. • Output parameter (variable type VAR_OUTPUT – for system function blocks only): The assignment of an output parameter to a variable in this parameter screen form is optional; you can also access an output parameter after executing the function block. When assigned in this parameter screen form: Enter a variable name. The data type of the output parameter must correspond to that of the assigned variables; the application of type transformation functions is not possible.
Default value	Here, the default value is displayed for optional input parameters. If no value has been transferred to an optional input parameter, it is automatically assigned the default value.

7.1.5.14 MCC charts in libraries

Libraries provide you with user-defined types, unit variables, functions, and function blocks which you can use from any SIMOTION device.

Libraries can be written to in all available programming languages. They can be used in all program sources (e.g., MCC source files, ST source files).

In order to use a library in an MCC source file, you must link the library in the declaration table of the MCC source file (with specification of a name space, if necessary) (see How to define connections to libraries (Page 4116)).

You can obtain more details on inserting and managing libraries in the online help.

Using technology packages in libraries

Libraries can also contain the following:

- Commands that act on technology objects.
- Access to system variables of technology objects.

Note

Only variables of this data type (see Technology object data types (Page 4060)) are permitted as technology objects.

You specify the SIMOTION device and technology package for which the library is compiled in the object properties of the library:

1. Select the library in the project navigator.
2. Select the **Edit > Object Properties** menu command.
3. Then select the **Technology package** tab.
4. Select the SIMOTION devices (including the version number) and the technology packages for which the library is to be compiled.

Note

To compile a project without errors, observe the rules governing the selection of SIMOTION devices and technology packages in the following table.

Selection of devices and technology packages in a library

Selection	Description
Device-independent	You must also select: • The technology packages • The version number of the selected technology packages **Please note:** 1. The library is compiled without reference to a SIMOTION device. For this reason, the following must not be used: – System functions and system variables of SIMOTION devices – Version-dependent system functions of the SIMOTION ST programming language (see SIMOTION ST Programming Manual) Additional MCC commands (Page 4167) are not permitted. 2. The library is compiled precisely to the version selected. The use of system functions or variables which are not available in the selected version will result in a compilation error. 3. If a device-independent library is to be made available for another version it must be copied and inserted under a different name. This copy must be recompiled with a different version reference.
SIMOTION device including version (multiple selection possible)	Only those technology packages are displayed that are available for all of the selected devices. **Please note:** 1. The library is compiled for all of the selected devices and technology packages (of the selected device versions). 2. The use of system functions or variables which are not available for one of the selected devices, or the technology package of the respective device version, will result in a compilation error. 3. The library can only be used for the selected devices and technology packages. When you use the library in an MCC unit, the following is therefore checked: – Whether the library for the SIMOTION device (including version) that contains the MCC unit to be imported has been compiled. – Whether the technology package that is used on the SIMOTION device matches that of the library. Any inconsistencies will result in compilation errors.

Compiling a library

In libraries, you can use all MCC commands except for the ones listed in the table below. In addition, you are not permitted to access some variables; these variables are also listed in this table.

MCC commands and variable accesses not permitted in libraries

Table 7-41 Illegal MCC commands in libraries

In all libraries:

- Following MCC task command:
  - Determine TaskId (Page 4205)

See the SIMOTION ST Programming and Operating Manual.

Additional commands, if the library was compiled on a **device-independent** basis:

- Following MCC basic commands:
  - Change operating state (Page 4196)
  - Activate trace (Page 4197)
- All MCC task commands (Page 4198)
- Following MCC command for program structure:
  - Synchronous start (Page 4219)
- Following MCC commands for communication:
  - Incoming message (Page 4228)
  - Outgoing message (Page 4231)
  - Establish connection using TCP/IP (Page 4233)
  - Remove connection using TCP/IP (Page 4237)
  - Send data (Page 4239)
  - Receive data (Page 4246)
- System functions of SIMOTION devices (see List Manual for SIMOTION Devices).

Table 7-42 Illegal variable access in libraries

- Unit variables (retentive and non-retentive)
- Global device variables (retentive and non-retentive)
- I/O variables
- Instances of the technology objects and their system variables
- Variables of task names and configured messages (for name spaces _task and _alarm)
- If the library is not device-dependent (i.e. compiled without reference to a SIMOTION device or SIMOTION Kernel version):
  - System variables of SIMOTION devices (see List Manuals for SIMOTION Devices)
  - Configuration data of technology objects (see List Manual of Configuration Data for the Relevant SIMOTION Technology Package)

Compile a library as follows:

1. Select the library in the project navigator.
2. Select the SIMOTION devices and the technology packages for which the library is to be compiled (Menu **Edit > Object properties**, **Technology packages** tab - see Using technology packages in libraries (Page 4165))
3. Select the **Accept and compile** context menu.

7.1.5.15 Find and replace

The following options are available when searching for a given piece of text or for variables only:

- Find or find and replace in the entire project (project-wide search).
  This is described in detail in the Online help.

  Note

  Following a find and replace operation in the whole project, it may be necessary to compile the project, so as to update all symbol information.

- Find or find and replace in a certain program source or their subprograms (local search).
  The following is described in this manual:
  - Searching in an MCC unit or an MCC chart (Page 4168)
  - Searching and replacing in an MCC unit or an MCC chart (Page 4170)

  See the respective manuals for a description of the local search in the other programming languages.

Searching in an MCC unit or an MCC chart

Range of the local search

With local searching, only the contents of the window (MCC unit or MCC chart) in which the local search was triggered are searched.

- The following are searched in an MCC unit:
  - All tabs of the declaration table (INTERFACE and IMPLEMENTATION)

  The assigned MCC charts are **not** searched.
- The following are searched in an MCC chart:
  - All tabs of the declaration table
  - MCC commands (brief comments, input fields and selection lists of the parameter screen form, command comments)

The dialog box open during the local search is assigned to the respective window and is hidden when changing to another window and displayed again when returning.

Procedure

If you want to conduct local searching for arbitrary text in an MCC unit or MCC chart, proceed as follows:

1. Open the desired MCC unit (Page 3989) or the MCC chart (Page 4004).
2. In the menu, select **Edit > Find** (shortcut Ctrl+F).
   The **Find** dialog box opens.
   A character string selected in the MCC editor is automatically taken as a search term.
3. Enter the required search term in the **Find** input field.
   Wildcards such as "*" or "?" are not permitted.
4. If required, select a search option as well as the search direction (**Up**/**Down**).
   - If you activate the **Whole words only** checkbox, only a whole word is searched for.
   - If you activate the **Match case** checkbox, the search takes upper-/lower-case into account.
   - If you activate the **Variables only** checkbox, the search is performed only in fields that contain identifiers of variables.
5. Click the **Find next** button (shortcut F3).
   The search is started in the selected direction: The first matching text pattern is highlighted.
6. Click the **Find next** button again to display the next matching text pattern.

Note

You can also continue searching with F3 even when the dialog box is closed.

Displaying search results

- The relevant tab is automatically activated in a declaration table and the found search term is highlighted.
- The found search term is highlighted in the brief comment for an MCC command.
- The following applies for the parameter screen form of an MCC command:
  - The relevant tab is activated automatically. The found search term is highlighted in the input fields (not in selection lists).
  - If necessary, the parameter screen form of an MCC command that is not open is opened automatically and closed again at the first search result outside the MCC command. Changes to the command must be confirmed manually (**OK** or **Accept**).
- The following applies for the command comment of an MCC command:
  The **Enter Comment** dialog box is opened automatically and the found search term highlighted. When the first search result occurs outside the command comment, the dialog box closes automatically once more and the changes are saved.

The respective editor window can also be edited when the Find dialog box is open.

Finding and replacing in an MCC source file or an MCC chart

Introduction

The process of finding and replacing on a local basis works like local finding (Page 4168), but also makes it possible to specify an expression to replace a search term once found.

Procedure

If you want to conduct a local search for any text and replace it in an MCC source file or an MCC chart, proceed as follows:

1. Open the desired MCC source file (Page 3989) or the MCC chart (Page 4004).
2. In the menu, select **Edit > Replace** (shortcut Ctrl+H).
   The **Replace** dialog box opens.
   A character string selected in the MCC editor is automatically taken as a search term.
3. Enter the required search term in the **Find** input field.
   Wildcards such as "*" or "?" are not permitted.

   Note

   If you select a term in the MCC editor before opening the **Replace** dialog box, this is entered in the **Find** input field automatically.

4. If required, select a search option.
   - If you activate the **Whole words only** checkbox, the search looks for a whole word.
   - If the **Match case** checkbox is activated, the search takes account of uppercase and lowercase.
   - If you activate the **Variables only** checkbox, the search is performed only in fields that contain identifiers of variables.
5. Enter the expression that should replace the search term in the **Replace with** input field.
6. Click the **Find next** button (shortcut F3).
   The search begins in the **Down** direction and the first matching text pattern is highlighted. The **Replace** button also becomes active if a replacement is permitted at this position, see rules for replacing.
   - If you want to replace the search term found, click the **Replace** button.
     The search term found, now selected and displayed, is replaced and the next length of text to match the criteria is displayed.
   - If you do not want to replace the search term found, click the **Find next** button.
     The next length of text to match the criteria is displayed.

   With parameter screen forms, any replacements are taken over in the command. The syntax is checked when the parameter screen form is automatically closed. Errors are displayed in the detail view in the **Local replacement** tab. Also in the event of errors during the syntax check, the MCC command is closed and the local search continued.

Rules for replacing

When replacing, a check is made whether the resulting term after replacement is permitted in principle at this position, for example:

- For identifiers of variables and data types, a check is made whether the Rules for identifiers (Page 4047) have been observed.
- For selection fields (combo boxes), a check is made whether the resulting term is available as a selection option. Some examples are shown below:
  - In the declaration table of an MCC source file, VAR_GLOBAL cannot be replaced by VAR or VAR_TEMP.
  - A selection option in a selection field (combo box) in the parameter screen for an MCC command can only be replaced by a different selection option.
- Wildcards, such as " ... " or "???" generally cannot be replaced.

Note

If an item cannot be replaced at a particular position, the **Replace** button appears inactive (grayed out).

Further checks are not made, for example

- Whether variables or data types have already been defined.
- Whether there are further dependencies between fields and will be violated by the replacement.
- Whether the changes have an effect on the design of the parameter screen form (e.g. display or selection options for parameters).

In declaration tables, some columns are generally blocked for replacing, for example:

- The **Absolute identifier** column in the **I/O symbols** tab
- The **Type** column in the **Connections** tab

7.1.5.16 Print

The MCC source file or MCC chart displayed in the working window can be output to a printer.

1. Select the **Project > Print** menu command.
2. In the **Print project** window, select the print options (see table below):
   - When printing an MCC source file:
     Select print options for this MCC source file and each MCC chart it contains.
   - When printing an MCC chart:
     Select print options for this MCC chart.
3. Then, select:
   - **Print** if you want to output the result to the printer immediately
   - **Print preview** if you want to check the print result on the screen before printing

Print options for an MCC source file or MCC chart

Option	Meaning
Printing a declaration table (MCC source file and MCC chart)	When this check box is activated, the declaration table of the MCC source file or the MCC chart is printed. In the Select column below, select: **Default column widths** The table will be printed with the default column widths. **Scale column widths to screen** The table is printed with the column widths that were set in the declaration table window
Print chart (MCC chart only)	When this check box is activated, the selected MCC chart will be printed. Depending on the selected zoom factor, the printout can have multiple pages.
Printing the index page (MCC chart only)	When this check box is activated, an index page displaying the entire MCC chart on one page and the page boundaries of the individual pages is also printed. If the printout of the MCC chart consists of several pages, this will make it easier to read.
Display numbers of adjoining pages (MCC chart only)	When this check box is activated, the number of the next page will be printed on the margin of each page of a multi-page MCC chart printout.

Option	Meaning
Zoom (MCC chart only)	Select a zoom factor for the printout of the MCC chart: **Scale graphics to page width** The width of the MCC chart is scaled to the page width. Depending on the size, the chart may be divided vertically onto several pages. **Scale graphics to page height** The height of the MCC chart is scaled to the page height. Depending on the size, the chart may be divided horizontally onto several pages. **Scale graphics to one page** The height and width of the MCC chart are scaled to the page size. The chart is always presented on one page. **Graphic at 100%** The MCC chart will be printed in its original size. The chart can be divided onto several pages, both vertically and horizontally. **Apply zoom factor from screen** The MCC chart is printed with the zoom factor setting for its MCC editor window. The chart can be divided onto several pages, both vertically and horizontally.
Blank pages (MCC chart only)	If the printout of the MCC chart consists of several pages, blank pages can occur. In the Select column, select which blank pages should be printed: **Print all** All blank pages are printed. **Omit at end** Blank pages at the end of a series are not printed. If the Index page option is selected, the non printed pages are marked with an X on the index page. **Omit all** All blank pages (even in the middle of a series) are not printed. If the Index page option is selected, the non printed pages are marked with an X on the index page.

7.1.6 MCC commands

7.1.6.1 Basic commands

Wait time

Execution of the task is halted for the programmed time period.

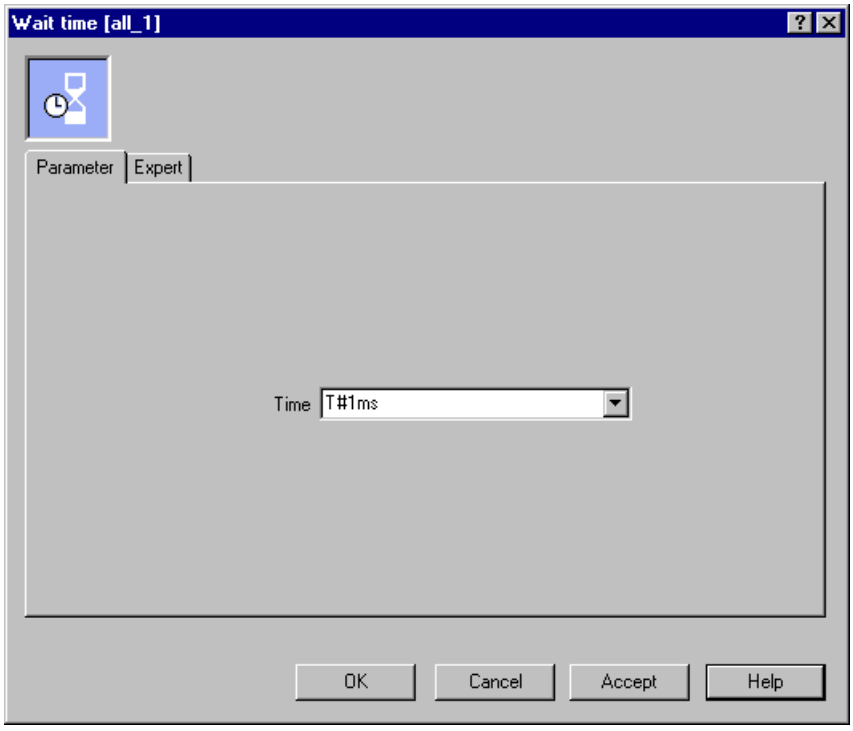


Figure 7-70 Parameter screen form: Wait time

Note

The command should be used in MotionTasks only; using it in cyclic tasks may lead to time monitoring errors!

- With SynchronousTasks: You can configure whether the time watchdog is suspended. Time monitoring is active by default.
  With IPOsynchronousTask, additionally take the following into account: UserInterruptTasks will no longer be started by their triggering event!
- With other cyclic tasks (BackgroundTask, TimerInterruptTasks): Time monitoring is always active.

Overview of parameters for Wait time

You can set the following parameters:

Table 7-43 Overview of parameters for Wait time

Field/Button	Explanation/instructions
Parameters tab	See Overview of parameters for Wait time - Parameters tab (Page 4175)
Expert **tab**	See Overview of parameters for Wait time - Expert tab (Page 4175)

Overview of parameters for Wait time - Parameters tab

Table 7-44 Overview of parameters for Wait time - Parameters tab

Field/Button	Explanation/instructions
Time	Enter the wait time here as a value or variable of type TIME. Granularity is 1 ms. The accuracy with which the time setting is applied is dependent on the clock grid in which the task is executed or, in the case of MotionTasks, on the interpolation cycle clock. If the wait time is 0, the task is continued without any interruption. **T#0ms** (default value) **T#0d_0h_0m_0s_0ms**

Overview of parameters for Wait time - Expert tab

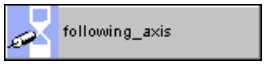
Table 7-45 Overview of parameters for Wait time - Expert tab

Field/Button	Explanation/instructions
	The **Expert** tab is described in detail in Overview of parameters for Expert tab (Page 4034).
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. Data type DINT, the value is always equal to 0.

Relevant system functions for Wait time

ST system function: _waitTime.

Wait for axis



Execution of the task is halted until the axis fulfills the programmed condition. Possible conditions are:

- **Axis status**: A status of the axis determined on the basis of system variables of the axis or the associated synchronous object (in the case of a synchronized axis)
- **Comparison value** : Comparison of a value of the axis (such as position, velocity) with a specified value

If both conditions are selected, they are combined using a logical AND.

The statuses and values of the axis relate to the total motion.

The condition is checked in the interpolator cycle clock. If the condition is fulfilled, the priority of the MotionTask is temporarily raised. The commands within the shaded area under the wait command are started in the next IPO cycle clock and executed with the highest priority.

Once the commands in the shaded area have been executed, the priority of the MotionTask is reset.

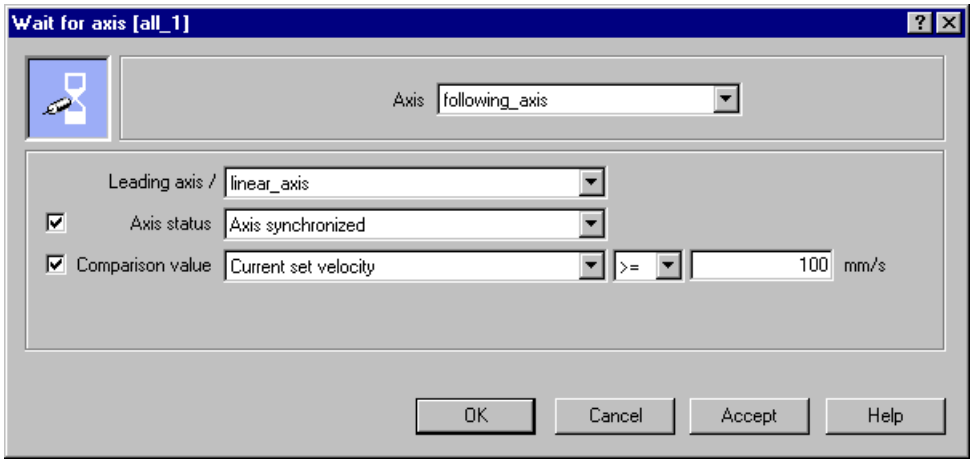


Figure 7-71 Parameter screen form: Wait for axis

Note

This command may only be programmed for MotionTasks.

Note

If you want to program a wait condition with axis statuses or axis values other than those provided in the selection lists:

Use the **Wait for condition** command and the corresponding system variables of the axis (see SIMOTION Cam Technology Package, System Variables Parameter Manual).

Overview of parameters for Wait for axis

You can set the following parameters:

Table 7-46 Overview of parameters for Wait for axis

Field/button	Meaning/instruction
Axis	Here, select the axis whose status or value you want to check. You can select from: • All axes that are configured on the device • All variables of the MCC chart with the following data types of technology objects, see Data types of technology objects (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.
Leading axis / encoder	Visible for all synchronous axes. **Note** The **Leading axis / encoder** selection is required only for synchronous axes with more than one synchronous object (superimposed synchronous motions). This input is ignored in the case of synchronous axes with only one synchronous object. By making this selection, you are indirectly selecting the synchronous object of the main motion or the superimposed motion.

Field/button	Meaning/instruction
Axis status	Here, you select an axis status as the condition • Select this checkbox if you want to evaluate the axis status. • Select the axis status. Different options are offered depending on the technology of the selected axis, see Axis status table (Page 4177).
Comparison value	Here, you select the comparison of an axis value as the condition. • Select this checkbox if you wish to compare an axis value. Possible axis values are shown in the subsequent selection list. • Select the axis value that you want to compare. Different options are offered depending on the technology of the selected axis. • Select the comparison operator, see Comparison operators for axis values table (Page 4178). • Enter the comparison value.
Tolerance	Only for comparisons for equality (=) or inequality (<>): Maximum absolute value of the permitted difference between the selected axis value and the programmed comparison value that will allow the equality condition to be satisfied.

Axis status

Axis status	Technology of the axis[1]	System variable and value
Axis moving at constant velocity	D, P, F	motionStateData.motionState = CONSTANT_MOVE
Axis in motion	D, P, F	motionStateData.motionCommand = IN_MOTION
Axis homed	P, F	positioningState.homed = YES
Axis at standstill (default value)	D, P, F	motionStateData.motionState = STANDSTILL Standstill monitoring is activated
Axis synchronized	G	syncState = YES (synchronous object)
Accelerating	D, P, F	motionStateData.motionState = ACCELERATING
Motion is finished	D, P, F	motionStateData.motionCommand = MOTION_DONE Axis is in the tolerance window and standstill monitoring is activated
Rotating	D, P, F	moveCommand.state <> INACTIVE The **Start axis position-controlled** or **Speed specification** command is active on the axis.
Synchronous operation active	G	state = GEARING (synchronous object) The **Gearing on** command is active on the axis.
Cam active	G	state = CAMMING (synchronous object) The **Cam on** command is active on the axis.
Quick stop active	D, P, F	stopEmergencyCommand = ACTIVE
Positioning	P, F	posCommand.state <> INACTIVE The **Position axis** command is active on the axis.
Simulation active	D, P, F	simulation = ACTIVE

Axis status	Technology of the axis[1]	System variable and value
Decelerating	D, P, F	motionStateData.motionState = DECELERATING
1) Technology of the axis D: Speed-controlled axis (driveAxis) P: Positioning axis (posAxis) G: Synchronous axis (followingAxis)		

Comparison operators for axis values

Operator	Condition satisfied if:
< (default value).	Selected axis value is less than the programmed comparison value.
<=	Selected axis value is less than or equal to the programmed comparison value.
<>	For position values only: The absolute value of the difference between the selected axis value and the programmed comparison value is greater than the specified tolerance.
=	For position values only: The absolute value of the difference between the selected axis value and the programmed comparison value is less than or equal to the specified tolerance.
>	Selected axis value is greater than the programmed comparison value.
>=	Selected axis value is greater than or equal to the programmed comparison value.

Relevant commands of the ST (Structured Text) programming language for Wait for axis

- EXPRESSION/END_EXPRESSION for formulation of the condition
- WAITFORCONDITION/END_WAITFORCONDITION

Wait for signal

Task execution is halted until the signal status at a digital input or output (data type BOOL) fulfills the programmed condition:

- Static 1 (TRUE) or 0 (FALSE)
- Rising or falling edge

The condition is checked in the interpolator cycle clock. If the condition is fulfilled, the priority of the MotionTask is temporarily raised. The commands within the shaded area under the wait command are started in the next IPO cycle clock and executed with the highest priority.

Once the commands in the shaded area have been executed, the priority of the MotionTask is reset.

The relevant digital input/output is specified as follows:

- Direct access and access to the process image of the cyclic task (Page 4094) (always via I/O variables of the BOOL data type).
- Following Access to the fixed process image of the BackgroundTask (Page 4103):
  - Absolute access to the fixed process image of the BackgroundTask (Page 4110) (BOOL data type).
  - Symbolic access to the fixed process image of the BackgroundTask (Page 4111) (BOOL data type that is defined in the interface section of the MCC unit declaration table.

Global device variables (Page 4063) of the BOOL data type can also be specified.

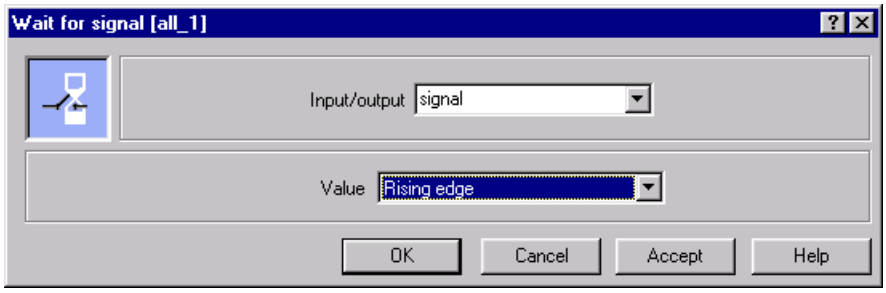

Figure 7-72 Parameter screen form for Wait for signal

Note

This command may only be programmed for MotionTasks.

Note

If you want to program a wait condition with I/O variables or process image accesses whose data type is not BOOL):

Use the "Wait for condition" (Page 4180) command.

Overview of parameters for Wait for signal

You can set the following parameters:

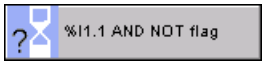
Table 7-47 Overview of parameters

Field/button	Meaning/instruction
Input/output	Here, you select the digital input or output to be evaluated for the wait condition. You can select from the following: • I/O variables (Page 4098) with BOOL data type. • Global device variables (Page 4063) with BOOL data type. • Symbolic access to the fixed process image of the BackgroundTask (Page 4111) with BOOL data type that has been defined in the interface section of the respective MCC unit declaration table. In addition, you can enter absolute process image access (Page 4110) with BOOL data type (e.g. %I10.0).
Value	Here, you can decide whether the condition evaluation is to be edge-triggered or level-triggered. **Rising edge** (default value) The condition is fulfilled if the input changes from 0 (FALSE) to 1 (TRUE). **Falling edge** The condition is fulfilled if the input changes from 1 (TRUE) to 0 (FALSE). **Level 'FALSE'** The condition is fulfilled if the input is static at 0 (FALSE). **Level 'TRUE'** The condition is fulfilled if the input is static at 1 (TRUE).

Relevant commands of the ST (Structured Text) programming language for Wait for signal

- EXPRESSION/END_EXPRESSION for formulation of the condition
- WAITFORCONDITION/END_WAITFORCONDITION

Wait for condition



Execution of the task is halted until the programmed condition is fulfilled.

If the condition is fulfilled, then the priority of the MotionTask is temporarily raised. The commands within the shaded area under the wait command are started in the next IPO cycle clock and executed with the highest priority.

Once the commands in the shaded area have been executed, the priority of the MotionTask is reset.

The condition can be composed of:

- Unit variables of the same MCC unit or imported program sources
- Global device variables
- Constants
- I/O variables and process image accesses (inputs)
- Operators

The expression may not contain:

- Function calls
- Local variables
- Grinding

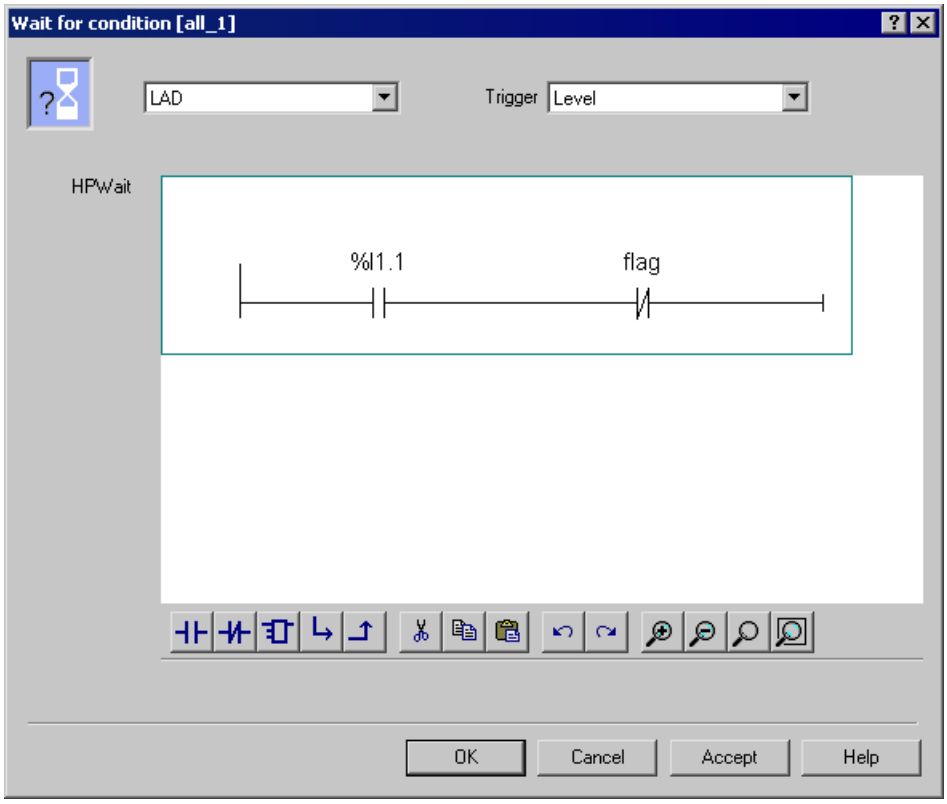


Figure 7-73 Parameter screen form: Wait for condition

Note

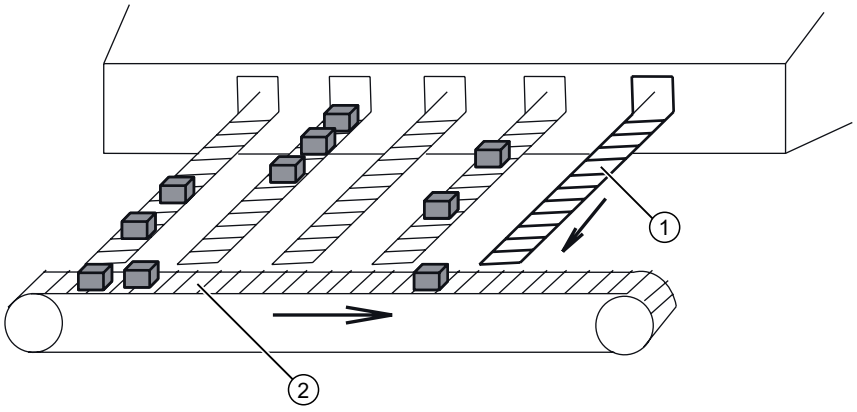
The Wait command may only be programmed for MotionTasks.

The condition is programmed in the ladder diagram (LAD), function block diagram (FBD), or Formula languages.

Example with Wait for condition

Task: A conveyor belt is in operation with several feeders. An additional new feeder must now be installed and programmed.

The packages will be moved onto the conveyor belt only if a package is present on the feeder and there is sufficient room for it on the conveyor belt.



① New feeder: Driven by axis_2

② Conveyor belt: Driven by axis_1

Figure 7-74 Installing and programming a new feeder

Solution

The conveyor belt is driven by axis_1 in position-controlled mode. The feeder unit is driven by axis_2. Two sensors are applied to input1 and input2. These monitor whether a package is on the feeder unit and whether there is sufficient room for it on the conveyor belt. If both are true, the feeder belt is moved (positioned relatively).

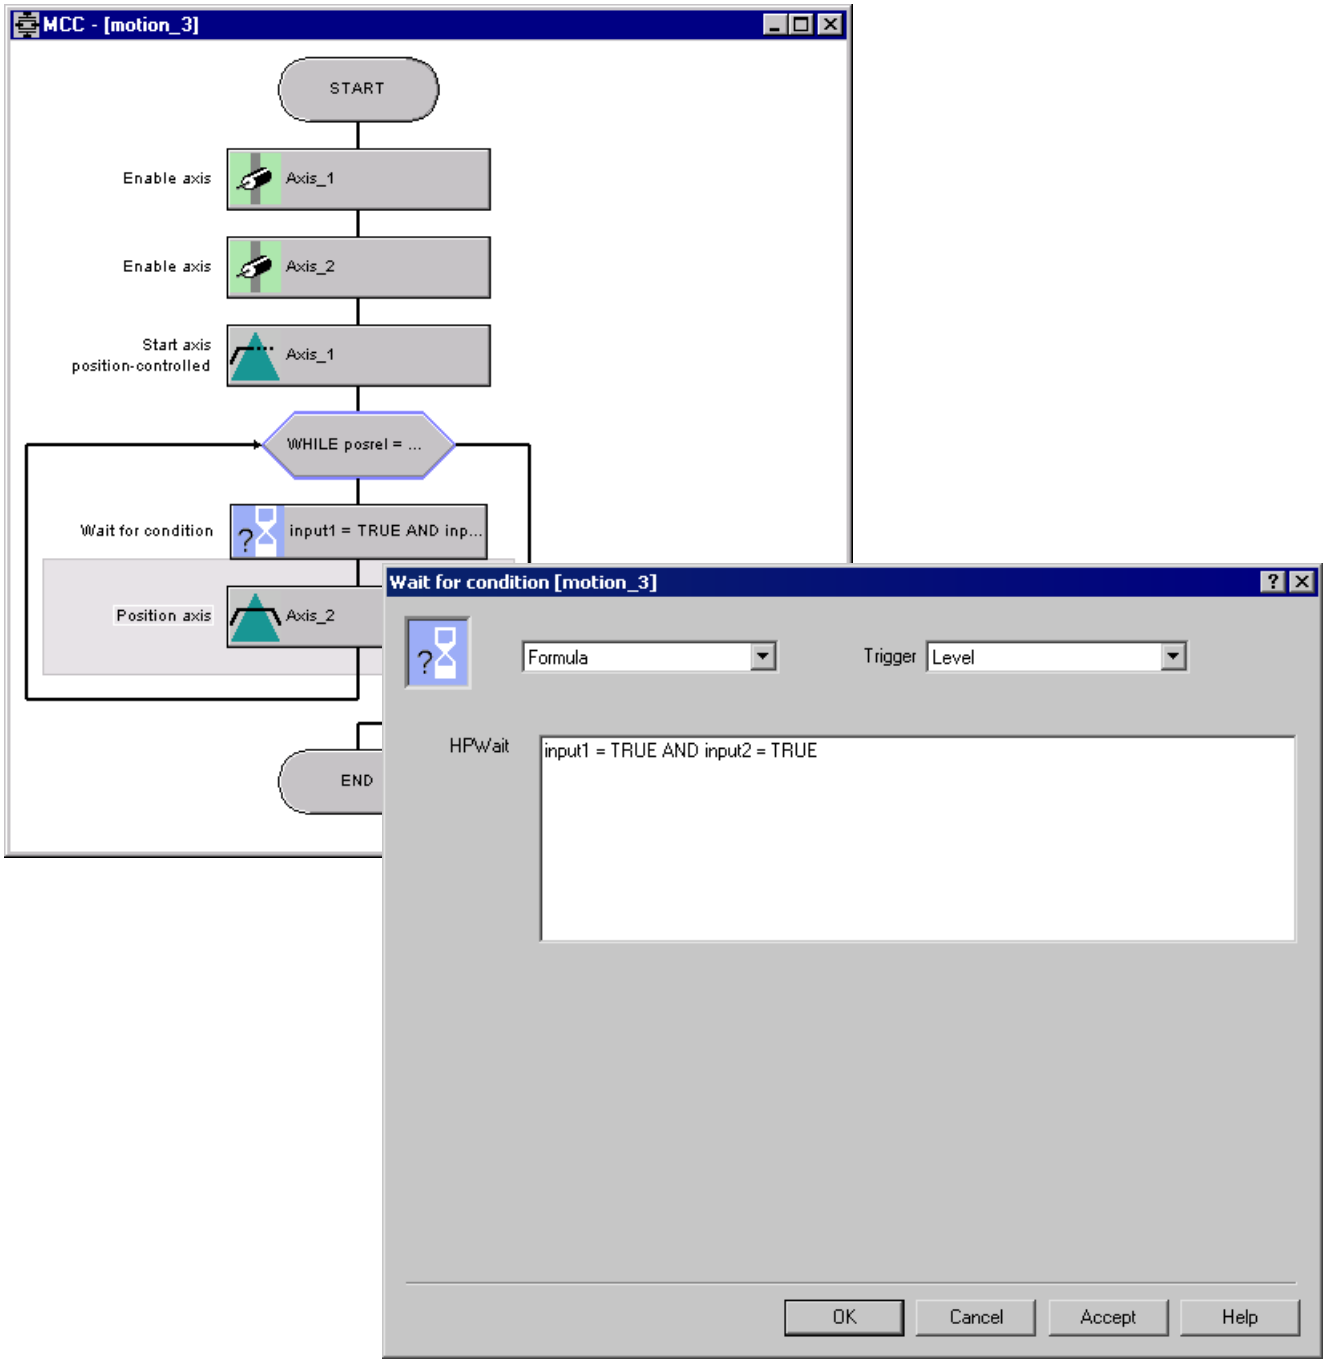


Figure 7-75 Section of MCC chart with open parameter screen form for Wait for condition command; if packages are on feeder belt, WHILE loop is executed (Posrel=True).

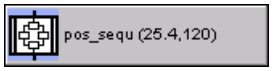
Relevant commands of the ST (Structured Text) programming language for Wait for condition

- EXPRESSION/END_EXPRESSION for formulation of the condition
- WAITFORCONDITION/END_WAITFORCONDITION

Module

Several commands are grouped in a module (see Module creation (Page 4019)).

Subroutine call



The **Subroutine call** command enables you to use user-defined functions and function blocks as well as library functions and library function blocks in the MCC chart and to program their call conveniently (see Insert and parameterize subroutine call in the MCC chart (Page 4121)).

As an option, you can also call user-defined programs ("program in program", see Subroutine (Page 4117)) or library programs.

When the command is called, the programmed function, function block or program is executed. Once the subroutine has been executed, execution of the MCC chart is resumed with the subsequent command.

Marking of mandatory parameters and optional parameters

In the parameter screen form for the command, mandatory parameters are marked with "<???>" and optional parameters with "...". A subroutine call will only be functional if all the mandatory parameters are set.

All the parameters shown are transfer parameters for the function or function block called, with function blocks (FBs) only having optional parameters. Called programs ("program in program") have no transfer parameters.

The following applies to the parameters of a function (FC):

- Transfer parameters without a declared initial value are shown as mandatory parameters
- Transfer parameters with a declared initial value are shown as optional parameters.

Opening user-defined FCs/FBs via the context menu

Regardless of the programming language (ST, MCC, LAD/FBD) in which they were created, called user-defined FCs/FBs/programs ("program in program") and library functions/library function blocks/library programs ("program in program") can be opened in a separate editor via the context menu directly following the subroutine call (see Opening the function (FC) directly following the subroutine call (Page 4131) or Opening the function block (FB) directly following the subroutine call (Page 4137)).

System function call

The **System function call** command enables you to use any system functions and system function blocks in the MCC chart and to program their call conveniently (see Using the system function call command (Page 4161)).

When the command is called, the programmed system function or system function block is executed. Once the system function or system function block is executed, the execution of the MCC chart resumes after the command.

In the parameter screen form for the command, mandatory parameters are marked with "<???>" and optional parameters with "...". A system function call will only be functional if all the mandatory parameters are set.

Set output

This command sets each bit of an output to 1.

Assigned values for Set output command according to data type

Data type	Assigned value	
		(decimal)
BOOL	TRUE	1
BYTE (SINT, USINT)	16#FF	–1 or 255
WORD (INT, UINT)	16#FFFF	–1 or 65535
DWORD (DINT, UDINT)	16#FFFFFFFF	–1 or 4294967295

If you wish to assign another value to the output, you must use the *Variable assignment* command.

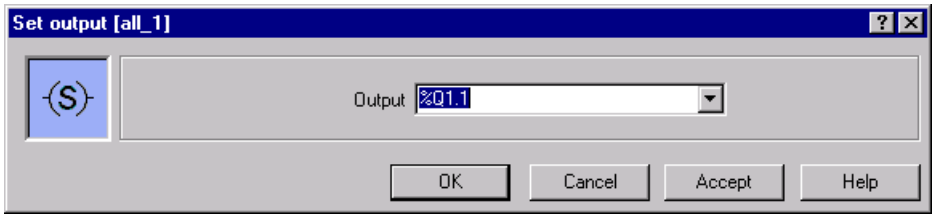


Figure 7-76 Parameter screen form: Set output

Overview of parameters for Set output

You can set the following parameters:

Table 7-48 Overview of parameters for Set output

Field/Button	Explanation/instructions
Output	Here, you select which output is to have its bits set to 1. You can select from the following (outputs only): I/O variables Symbolic accesses to the process image of the BackgroundTask In addition, you can enter absolute process image accesses (outputs). For information about absolute process image access, see Syntax for the identifier for absolute PI access.

Relevant commands of the ST (Structured Text) programming language for Set output

Value assignment to output

Reset output

This command sets each bit of an output to 0.

Table 7-49 Assigned values for Reset output command according to data type

Data type	Assigned value	
		(decimal)
BOOL	FALSE	0
BYTE (SINT, USINT)	16#0	0
WORD (INT, UINT)	16#0	0
DWORD (DINT, UDINT)	16#0	0

If you wish to assign another value to the output, you must use the **Variable assignment** command.

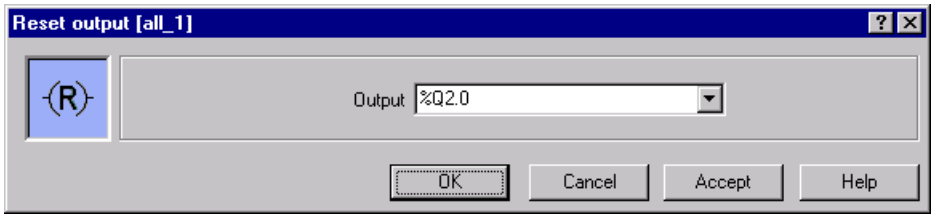

Figure 7-77 Parameter screen form: Reset output parameter

Overview of parameters for Reset output

You can set the following parameters:

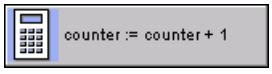
Table 7-50 Overview of parameters for Reset output

Field/Button	Explanation/instructions
Output	Here, you select which output is to have its bits set to 0. You can select from the following (outputs only): • I/O variables • Symbolic accesses to the process image of the BackgroundTask In addition, you can enter absolute process image accesses (outputs).

Relevant commands of the ST (Structured Text) programming language for Reset output

Value assignment to output

Variable assignment



You can use the Variable assignment command to assign values to user or system variables. The assignment takes place when the command is executed in the MCC chart.

A variable can be moved from the symbol browser to the input field with a drag and drop operation. Multiple variables can be assigned.

Note

Assignment is programmed in the ladder diagram (LAD) (Page 4153), function block diagram (FBD) (Page 4156) or Formula (Page 4158) languages.

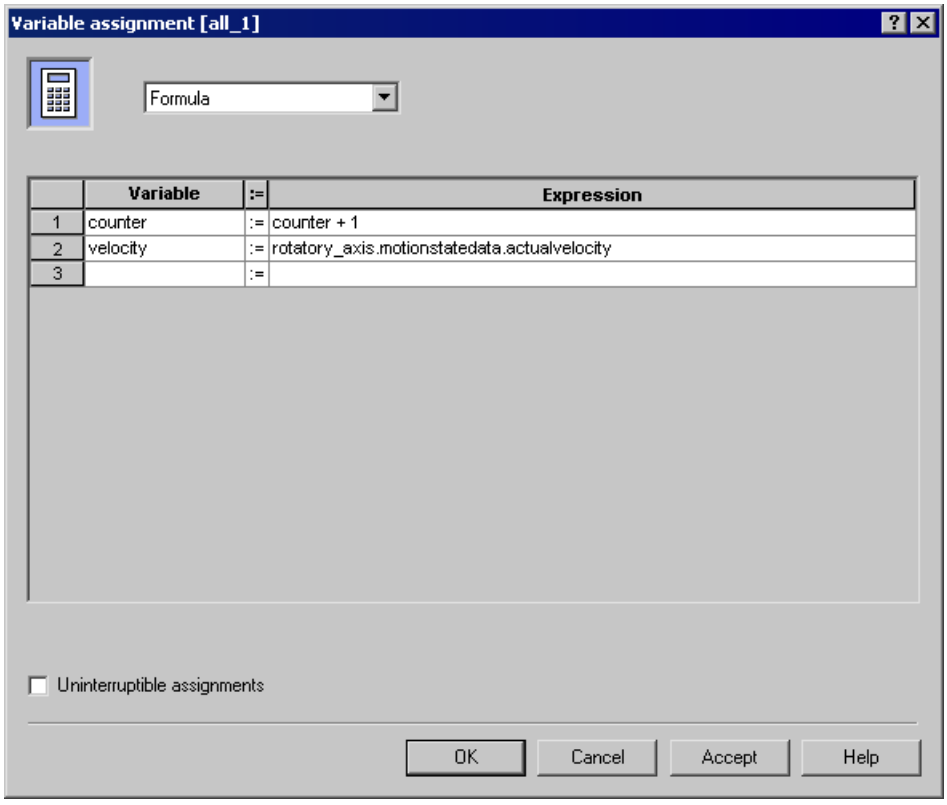


Figure 7-78 Parameter screen form with Formula language

Activate this checkbox if you want the data to be transferred without interruption by other tasks.

Note

If you activate the Uninterruptible assignments checkbox, you must set up UserInterruptTask_1 because the MCC calls this in the event of an error. You can program an error response in this task.

You can assign the following to a variable:

- A value (e.g.: a := 10, b := TRUE)
- Another variable (e.g.: c := d, e := f)
- A system variable (e.g.: axis_1.positioningstate.actualposition)
- An output variable of an FB
- The return value of a function (FC)
- An expression (e.g.: n := 2*h+10*m)

ST zoom

You can use this command to insert one or more ST commands in the MCC chart.

Enter the ST commands in the parameter screen form.

Note

Use shortcut keys Ctrl + TAB to enter a tab in the screen form.

Example with ST zoom

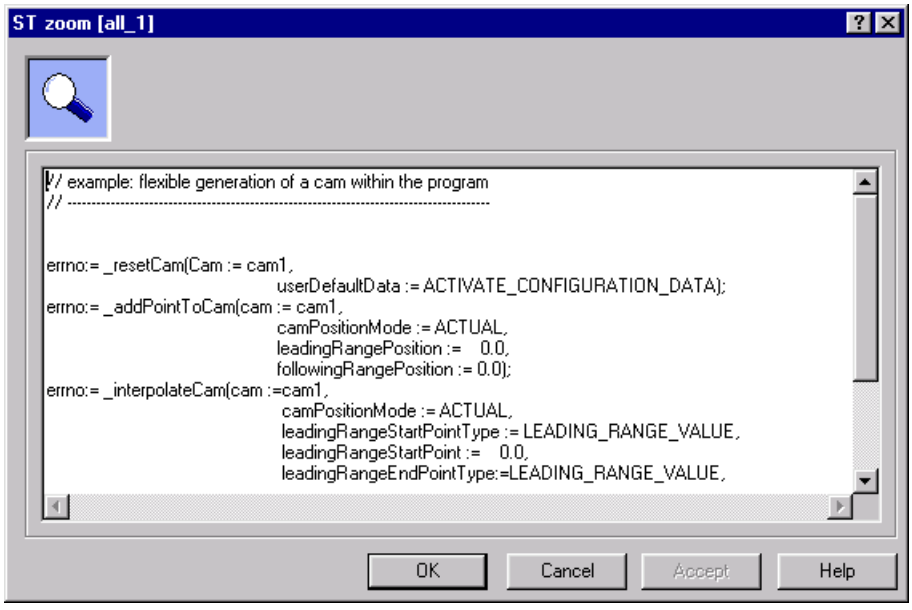

Figure 7-79 Parameter mask: ST zoom

Activate simulation for object

With this command, the selected technology objects (axes, output cams, measuring inputs, synchronous objects) are switched to simulation mode. The setpoint output for axes is suppressed. The output of output cams is not switched.

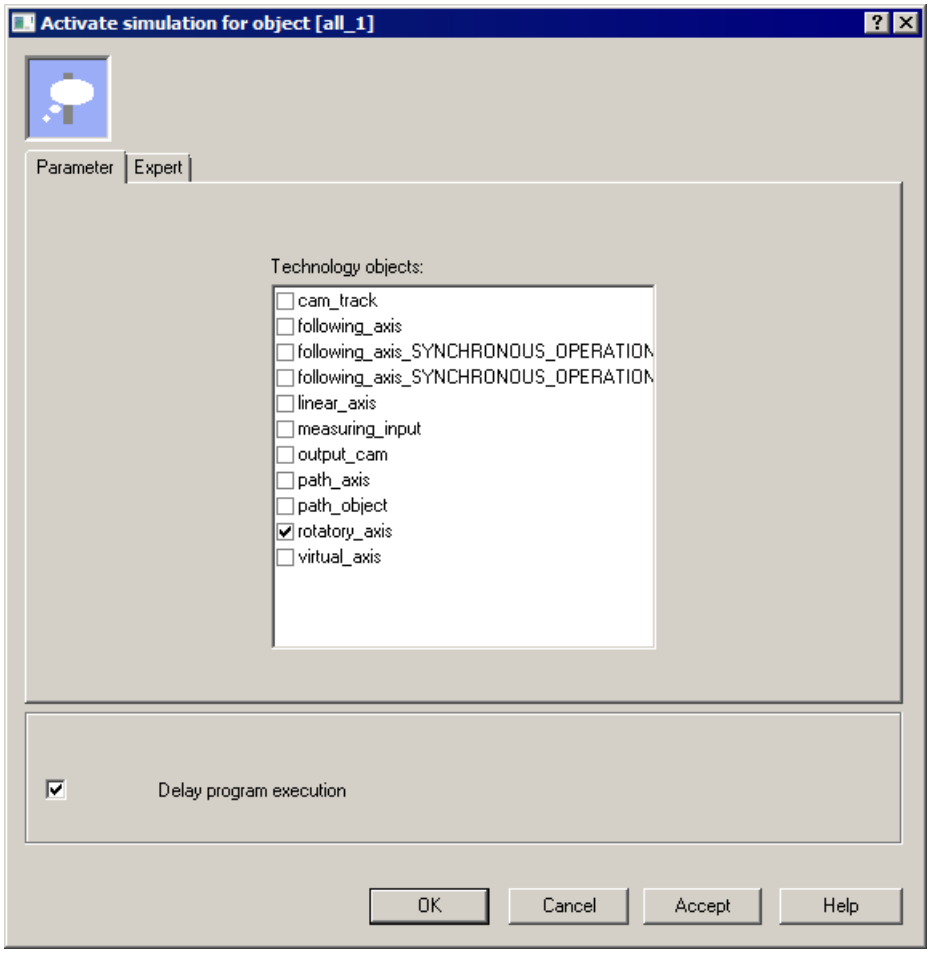

Figure 7-80 Parameter screen form: Activate simulation for object

Overview of parameters for Activate simulation for object

Field/button	Meaning/instruction
	The Expert tab is described in detail in Overview of parameters for Expert tab (Page 4034).
CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Relevant system functions for Activate simulation for object

Cam technology package:

- _enableAxisSimulation for speed-controlled axes, positioning axes and synchronous axes
- _enableCamTrackSimulation for cam tracks
- _enableFollowingObjectSimulation for synchronous objects
- _enableMeasuringInputSimulation for measuring inputs
- _enableOutputCamSimulation for output cams

Path technology package:

- _enableAxisSimulation for path axes
- _enablePathObjectSimulation for path objects

Deactivate simulation for object

With this command, the selected technology objects (e.g. axes, output cams, measuring inputs, synchronous objects) are switched from simulation mode to normal mode. The setpoint output for axes is activated. The cam output of the output cams is switched switched.

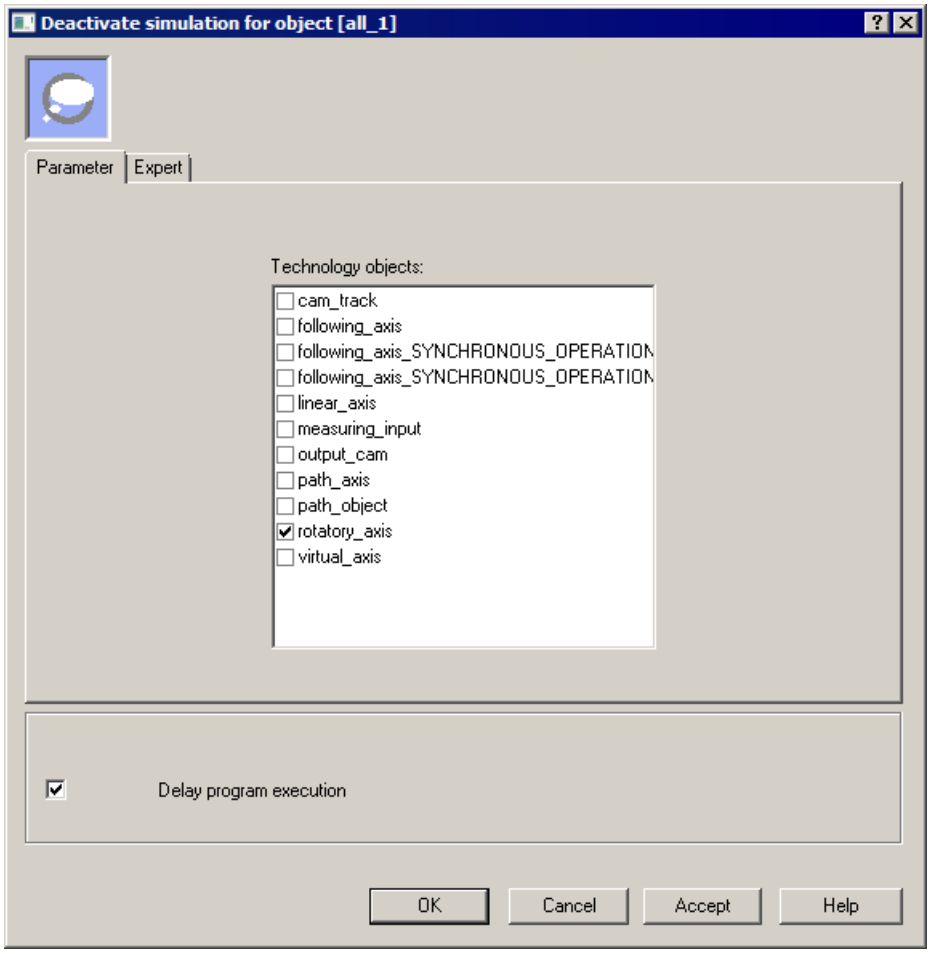

Figure 7-81 Parameter screen form: Deactivate simulation for object

CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Relevant system function for Deactivate simulation for object

Cam technology package:

- _disableAxisSimulation for speed-controlled axes, positioning axes and synchronous axes
- _disableCamTrackSimulation for cam tracks
- _disableFollowingObjectSimulation for synchronous objects
- _disableMeasuringInputSimulation for measuring inputs
- _disableOutputCamSimulation for output cams

Path technology package:

- _disableAxisSimulation for path axes
- _disablePathObjectSimulation for path objects

Reset object

The selected technology objects is reset to the initial state.

Optionally, the system variables of the selected technology objects can be reset to the configured default values.

You should use this command, for example, if an axis or a synchronous group is in an imprecisely defined state as the result of a programming or parameter assignment error.

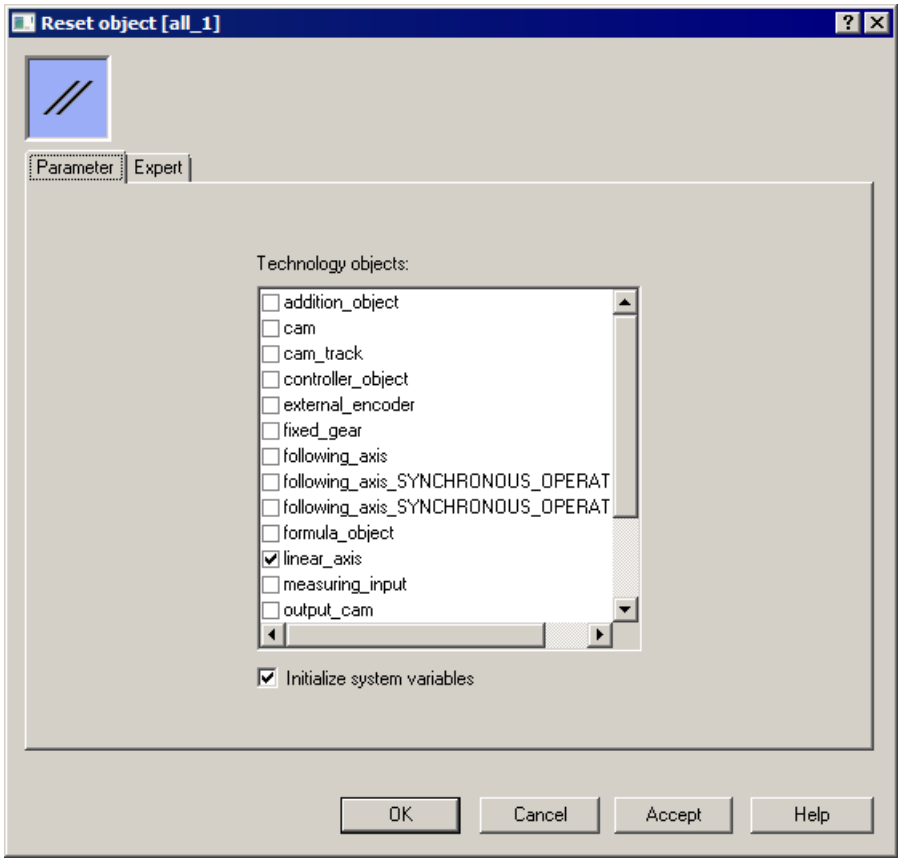

Figure 7-82 Parameter screen form: Reset object

Overview of parameters for Reset object

Parameters of the MCC command Reset object	**Parameter of the system functions _reset*TO***
Initialize system variables	userDefaultData

Change operating mode

You can use this command to place the SIMOTION device in STOP or STOP U mode.

Note

To place the SIMOTION device in RUN mode again, activate the software switch in SIMOTION SCOUT or the mode switch on the SIMOTION device.

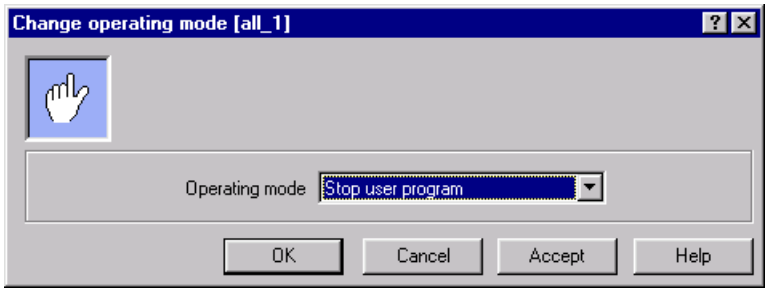

Figure 7-83 Parameter screen form: Change operating mode

Overview of parameters for Change operating mode

You can set the following parameters:

Table 7-61 Overview of parameters for Change operating mode

Field/Button	Explanation/instructions
Operating state	**STOP** STOP mode is selected. • Technology objects inactive (enables deleted, no axis motion) • User program is not executed • Loading a user program is possible • All system services are active (communication, etc.) • All analog and digital outputs set to 0 **STOP user program** STOPU mode is selected. • Technology objects active • Technology objects can execute jobs for testing and commissioning functions. • Otherwise identical to STOP mode

Relevant system functions for Change operating mode

System function of SIMOTION device: _changeOperationMode

Return value for Change operating mode

None.

Activate trace

This command enables you to log signal characteristics and axis status characteristics (see Activate trace (Page 4547)).

Comment block

You can use the comment block to structure the MCC chart and insert a comment anywhere within the program sequence. The size of the comment block is automatically adjusted to the size of the comment text. The block is displayed larger than normal command blocks in the chart.

If you place the cursor above the command in the MCC chart, the comment is displayed via a tool tip.

Example with Comment block

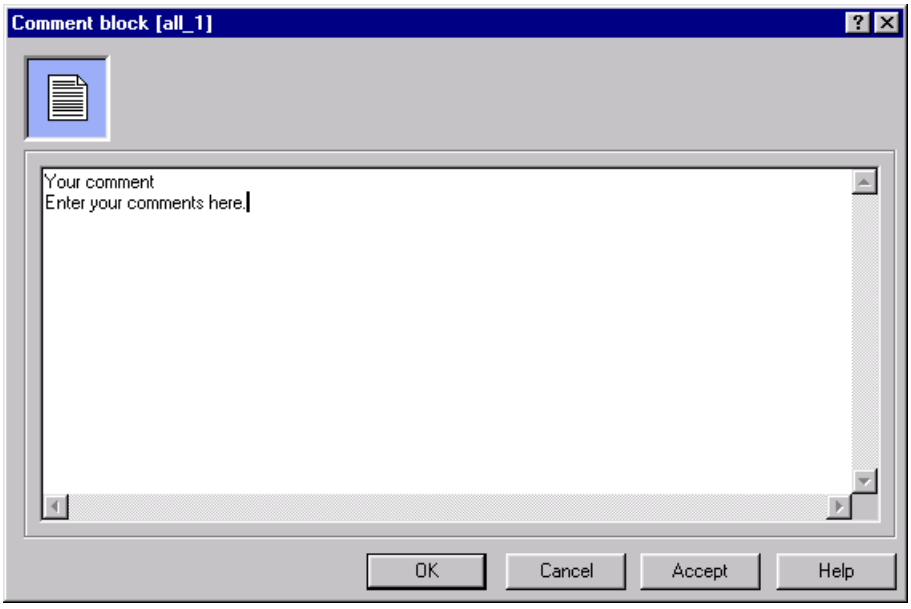

Figure 7-84 Parameter screen form: Comment block

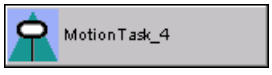
7.1.6.2 Task commands

Start task



This command starts a MotionTask with initialization of data.

Note

If the task is already active, it is stopped and restarted with data initialization.

The task to be started can be selected as follows:

- Using its name (as specified in the execution system)
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructTaskId
  This variable contains the TaskId that you obtained using the "Determine taskID" function.
  In this form, the command can be used in libraries.

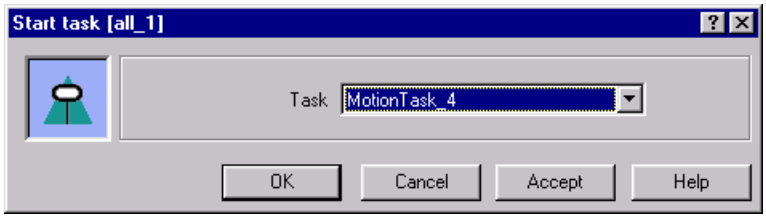


Figure 7-85 Parameter screen form: Start task

Note

This command may only be programmed for MotionTasks.

Call from the BackgroundTask

This command may be issued only once in the BackgroundTask. Otherwise, the selected MotionTask would be started at the beginning every time the BackgroundTask was executed.

To prevent this, you can query and evaluate the status of the MotionTask with the Task status command (see Example of use of Task status command (Page 4204)).

Overview of parameters for Start task

You can set the following parameters:

Table 7-62 Overview of parameters for Start task

Field/Button	Explanation/Instructions
Task	Select the task to be started. You can select from: • All MotionTasks (not in libraries) • All variables of data type StructTaskID declared in the MCC source file or MCC chart

Relevant system functions for Start task

ST system function: _restartTaskId

The _getTaskId system function is also called if the task was selected by name.

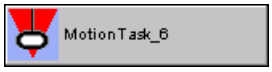
Return value for Start task

For ST system function _restartTaskId only:

The return value informs the user about the result of the command call (see description of the _restartTaskId function in the SIMOTION Basic Functions Function Manual).

Variable _MccRetDWORD with data type DWORD.

Interrupt task



The task is interrupted at its present position.

This command does not stop any axis motions that have already been started from this task.

Any active UserInterruptTask is stopped. If the condition for restarting this UserInterruptTask is true, it is not started nor is the fulfillment of the condition stored.

The task can be resumed with the "Continue task (Page 4201)" command.

The task to be interrupted can be selected as follows:

- Using its name (as specified in the execution system)
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructTaskId
  This variable contains the TaskId that you obtained using the "Determine taskID" function.
  In this form, the command can be used in libraries.

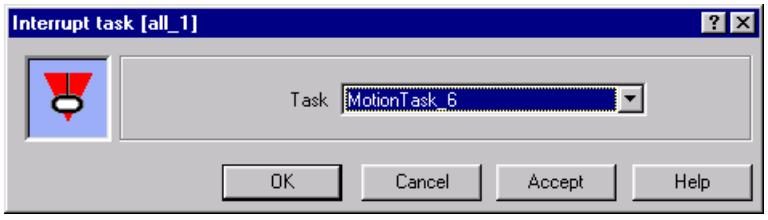


Figure 7-86 Parameter screen form: Interrupt task

Note

The command can be programmed for MotionTasks, UserInterruptTasks, and TimerInterruptTasks.

Overview of parameters for Interrupt task

You can set the following parameters:

Table 7-63 Overview of parameters for Interrupt task

Field/Button	Explanation/instructions
Task	Select the task to be interrupted. You can select from: • All MotionTasks (not in libraries) • UserInterruptTasks and TimerInterruptTasks configured on the device (not in libraries) • All variables of data type StructTaskId declared in the MCC source file or MCC chart

Relevant system functions for Interrupt task

ST system function: _suspendTaskId

The _getTaskId system function is also called if the task was selected by name.

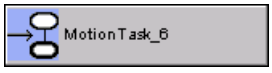
Return value for Interrupt task

For ST system function _suspendTaskId only:

The return value informs the user about the result of the command call (see description of the _suspendTaskId function in the SIMOTION Basic Functions Function Manual).

Variable _MccRetDWORD with data type DWORD.

Continue task



This command continues a task that was interrupted with the "Interrupt task (Page 4200)" command at the point it was interrupted.

Interrupted motions are not automatically continued. Resumption of interrupted motions must be programmed explicitly.

The task to be continued can be selected as follows:

- Using its name (as specified in the execution system)
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructTaskId
  This variable contains the TaskId that you obtained using the "Determine taskID" function.
  In this form, the command can be used in libraries.

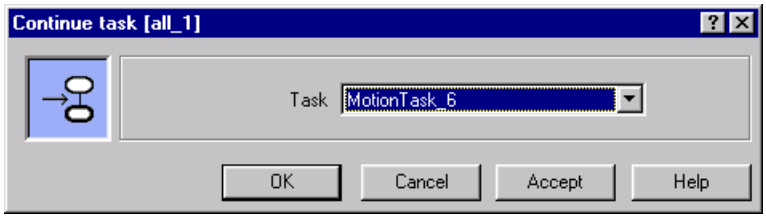


Figure 7-87 Parameter screen form: Continue task

Note

The command can be programmed for MotionTasks, UserInterruptTasks, and TimerInterruptTasks.

Overview of parameters for Continue task

You can set the following parameters:

Table 7-64 Parameter screen form for Continue task

Field/Button	Explanation/instructions
Task	Select the task to be continued. You can select from: • All MotionTasks (not in libraries) • UserInterruptTasks and TimerInterruptTasks configured on the device (not in libraries) • All variables of data type StructTaskID declared in the MCC source file or MCC chart

Relevant system functions for Continue task

ST system function: _resumeTaskId

The _getTaskId system function is also called if the task was selected by name.

Return value for Continue task

For ST system function _resumeTaskId only:

The return value informs the user about the result of the command call (see description of the _resumeTaskId function in the SIMOTION Basic Functions Function Manual).

Variable _MccRetDWORD with data type DWORD.

Reset task

This command stops a MotionTask. The initialization of the data can be restarted with the "Start task" command.

The task to be reset can be selected as follows:

- Using its name (as specified in the execution system)
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructTaskId
  This variable contains the TaskId that you obtained using the "Determine taskID" function.
  In this form, the command can be used in libraries.

Note

The "Reset task" and "Start task" commands cannot follow each other in direct succession. Instead, use only the "Start task" command.

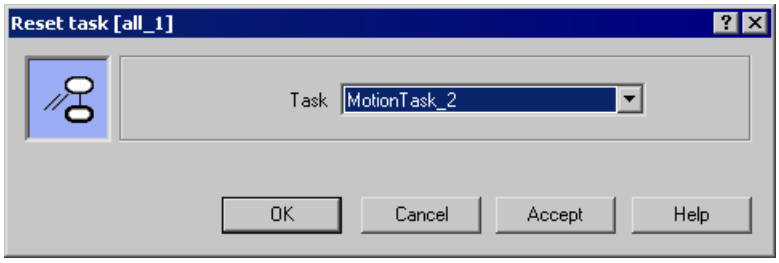

Figure 7-88 Parameter screen form: Reset task

Note

This command may only be programmed for MotionTasks.

Overview of parameters for Reset task

Table 7-65 Overview of parameters for Reset task

Field/Button	Explanation/instructions
Task	Select the task to be reset. You can select from: • All MotionTasks (not in libraries) • All variables of data type StructTaskID declared in the MCC source file or MCC chart

Relevant system functions for Reset task

ST system function: _resetTaskId

The _getTaskId system function is also called if the task was selected by name.

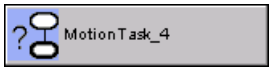
Return value for Reset task

For ST system function _resetTaskId only:

The return value informs the user about the result of the command call (see description of the _resetTaskId function in the SIMOTION Basic Functions Function Manual).

Variable _MccRetDWORD with data type DWORD.

Task status



This command returns the status of a task.

The task can be selected as follows:

- Using its name (as specified in the execution system)
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructTaskId
  This variable contains the TaskId that you obtained with the "Determine TaskId" function.
  In this form, the command can be used in libraries.

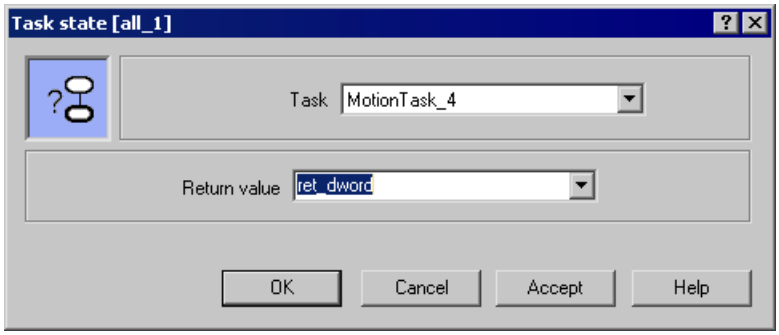


Figure 7-89 Parameter screen form: Task status

Note

The command can be programmed for MotionTasks, UserInterruptTasks, and TimerInterruptTasks.

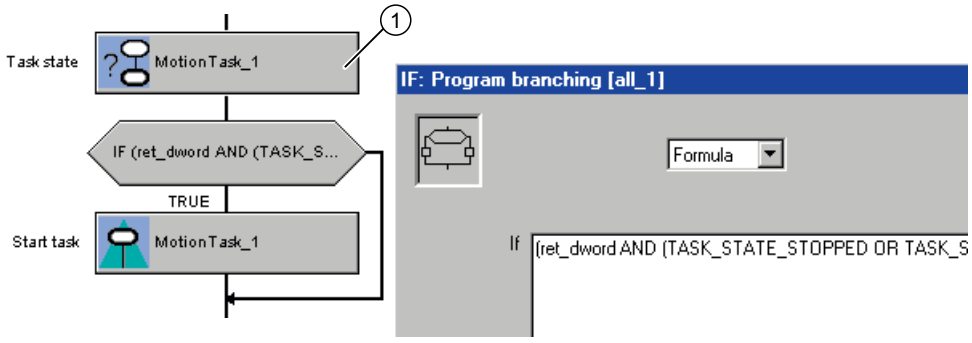
Overview of parameters for Task status

Table 7-66 Parameter screen form for Task status

Field/button	Meaning/instruction
Task	Select the task whose current state is to be determined. You can select from: • All MotionTasks (not in libraries) • UserInterruptTasks and TimerInterruptTasks configured on the device (not in libraries) • All variables of data type StructTaskID declared in the MCC unit or MCC chart
Return value	Here, you enter the return variable of type DWORD in which the task status will be stored as the command result (see description of the _getStateOfTaskId function in the SIMOTION Basic Functions Function Manual). This variable must be defined in a declaration table or the symbol browser.

Example of use of Task status command

In the following example, the task status of a MotionTask is queried to decide whether it can be started. The relevant bits of the return value are evaluated for this. If the result is positive, the MotionTask is started.



① The return value of the Task status command is stored in local variable ret_dword with data type DWORD. It indicates the status of MotionTask_1, which is then evaluated.

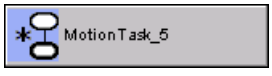
Figure 7-90 Example of a query whether a MotionTask can be started

Relevant system functions for Task status

ST system function: _getStateOfTaskId

The _getTaskId system function is also called if the task was selected by name.

Determine TaskId



This command generates a project-wide unique TaskId from the name of a task. This TaskId is assigned to a variable of data type StructTaskId.

This function must **not** be used in libraries.

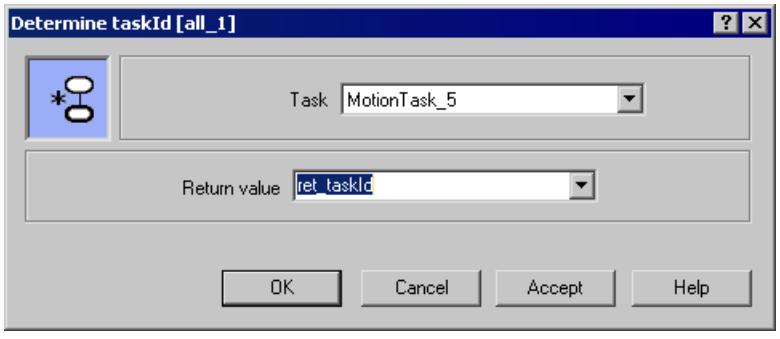


Figure 7-91 Parameter screen form: Determine TaskId

Note

The command can be programmed for MotionTasks, UserInterruptTasks, and TimerInterruptTasks.

Overview of parameters for Determine TaskId

You can set the following parameters:

Table 7-67 Overview of parameters for Determine TaskId

Field/Button	Explanation/instructions
Task	Select the name of the task whose project-wide unique TaskId is to be determined. You can select from: • All MotionTasks • UserInterruptTasks and TimerInterruptTasks configured on the device
Return value	Here, you enter the return variable of type StructTaskId in which the TaskId will be stored. This variable must be defined in a declaration table or the symbol browser.

Relevant system functions for Determine TaskId

ST system functions: _getTaskId.

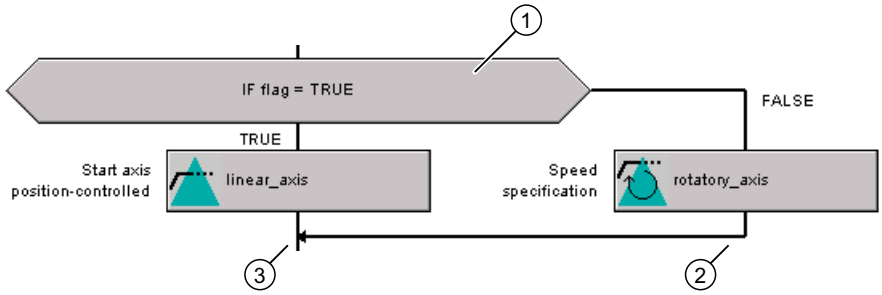
7.1.6.3 Program structures

IF: Program branching

A specified condition causes the program flow to branch to the TRUE branch or FALSE branch.

The program flow branches as follows:

- Condition is fulfilled: Execution continues down the TRUE path.
- Condition is not fulfilled: Execution continues down the FALSE path.



① Depending on the "flag" variables, either the linear axis or the rotary axis are started.
② Condition is not fulfilled.
③ Condition is fulfilled.

Figure 7-92 Example of a branch (IF) in a flowchart

Note

The condition is programmed in the ladder diagram (LAD) (Page 4153), function block diagram (FBD) (Page 4156) or Formula (Page 4158) languages.

Note on inserting the IF statement

The IF statement is normally inserted after the selected command. The two branches are empty.

If two or more commands are selected, the IF statement is inserted **before** the selected commands. The selected commands are automatically shifted to the TRUE branch; see figure below.

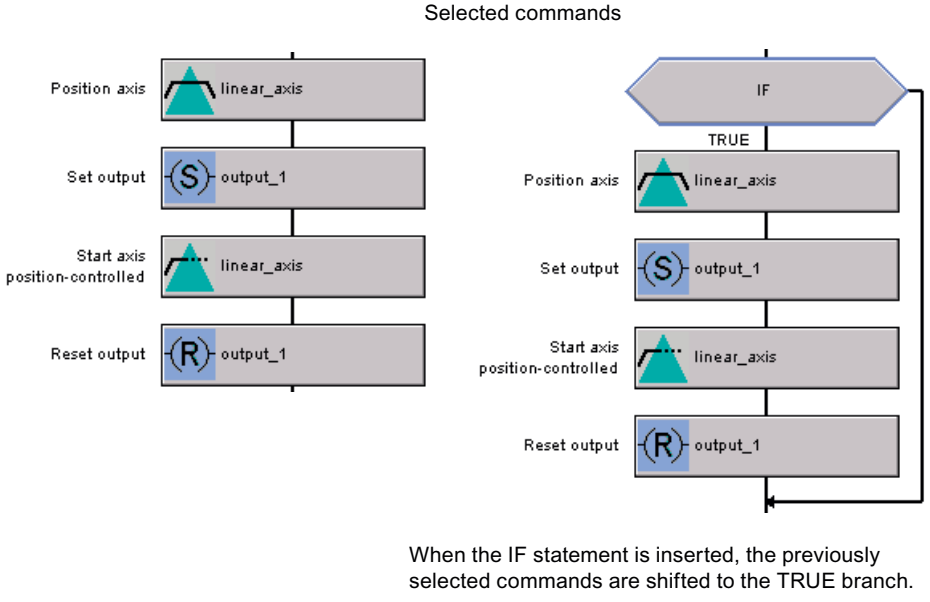


Figure 7-93 Inserting the IF statement when several commands are selected

Note on deleting/cutting or copying an IF statement

When you delete, cut, or copy an IF statement, the commands assigned in the branches are also deleted or copied.

If the commands within the control structure are not to be deleted or cut when the structure is deleted or cut, you must copy them first and repaste them outside the control structure.

Relevant commands of the ST (Structured Text) programming language for IF: Program branching

IF / ELSE / END_IF

WHILE: Loop with condition at the start

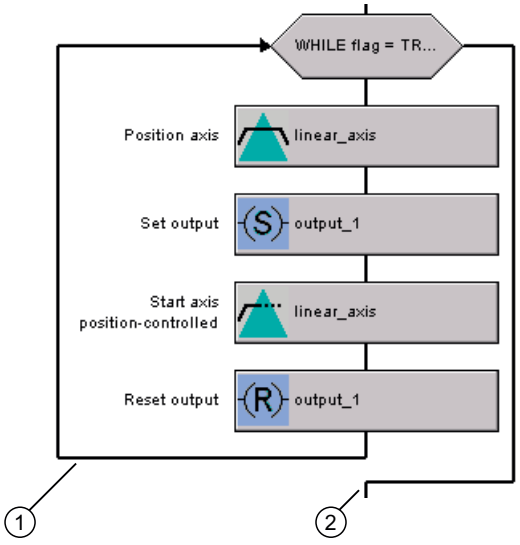
Commands programmed within the loop are executed as long as the loop condition is fulfilled.

The condition is programmed at the start of the loop.

When the WHILE command is reached, the program flow branches as follows:

- Condition is fulfilled: Program runs through loop.
- Condition is not fulfilled: Program continues.

Example of WHILE loop with condition at start



① Condition is fulfilled

② Condition is not fulfilled

Figure 7-94 Example of repetition with query at beginning (WHILE) in the flowchart

Note

The condition is programmed in the ladder diagram (LAD) (Page 4153), function block diagram (FBD) (Page 4156) or Formula (Page 4158) languages.

Refer to the notes regarding inserting (Page 4207), deleting, cutting, or copying of the IF statement (Page 4208); they apply analogously.

Relevant commands of the ST (Structured Text) programming language for WHILE: Loop with condition at the start

WHILE /END_WHILE

FOR: Loop with fixed number of runs

The FOR loop repeats a program section for a fixed number of runs. Once the loop has been run the specified number of times, the program continues.

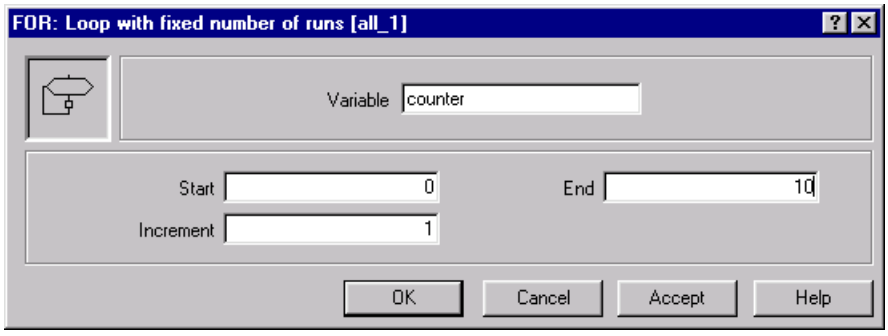


Figure 7-95 Parameter screen form: FOR statement

You use a FOR loop when the number of cycles is known at the programming stage.

If the number of cycles is not known, a loop with the WHILE (Page 4208) or UNTIL (Page 4211) command is more suitable.

Overview of parameters for FOR: Loop with fixed number of runs

You can set the following parameters:

Table 7-68 Overview of parameters for FOR loop with fixed number of runs

Field/button	Meaning/instruction
Variable	Enter the count variable for the FOR loop here. The variable must be of the SINT, USINT, INT, UINT or DINT data type. The variable name can be entered or moved from the declaration table using drag and drop.
Start	Enter the initial value of the count variable here. The count variable is set to the specified value at the first pass of the loop start. The initial value can be directly entered as a value or, alternatively, as a formula. Variables can be used. The expression must be of the count variables data type.
End	Enter the final value of the count variable here. The loop is executed repeatedly until the count variable exceeds the specified final value. The value can be directly entered as a value or, alternatively, as a formula. Variables can be used. The expression must be of the count variables data type.
Increment	Enter the increment here. The count variable is increased by the entered increment each time the loop is run. The value can be directly entered as a value or, alternatively, as a formula. Variables can be used. The expression must be of the count variables data type.

The values of these parameters must not be changed during the execution of the FOR loop.

Example of a FOR loop in a program

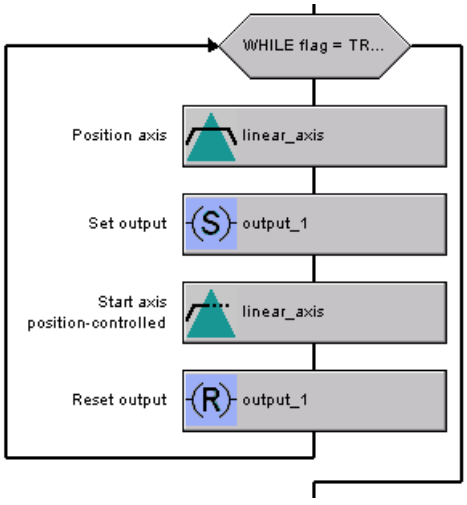

Figure 7-96 Example of a FOR loop in a program

Note

Refer to the notes regarding inserting (Page 4207), deleting, cutting, or copying of the IF statement (Page 4208); they apply analogously.

Example of a FOR statement

The program loop is to be executed 11 times. The variable must be defined and of the SINT, USINT, INT, UINT or DINT data type.

The parameter screen form is configured as shown in the figure below.

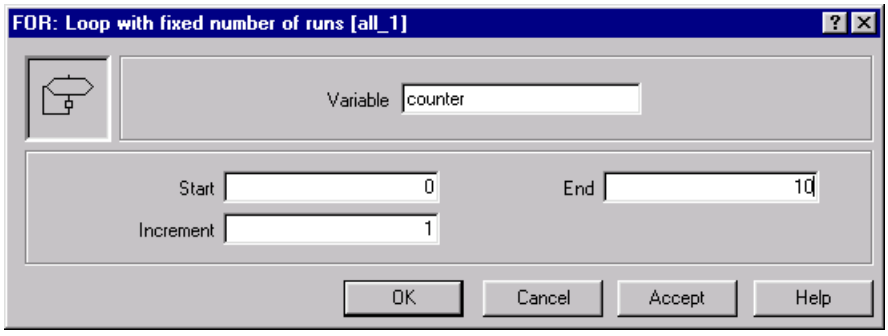

Figure 7-97 Example of a FOR statement

Relevant commands of the ST (Structured Text) programming language for FOR: Loop with fixed number of runs

FOR / END_FOR

UNTIL: Loop with condition at the end

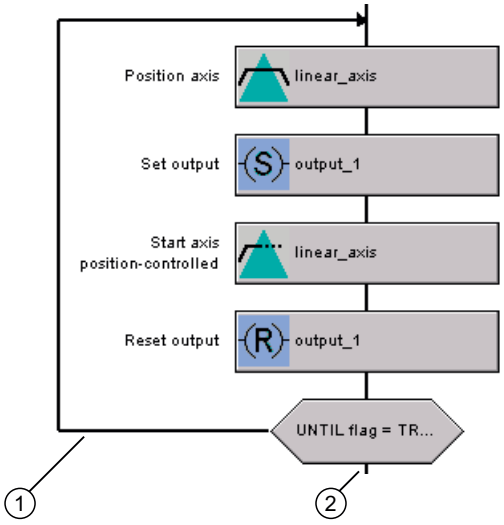
The commands programmed within the loop are executed **until** the loop condition is fulfilled.

The condition is programmed at the end of the loop. For this reason, the commands in the loop are executed at least once.

When the UNTIL command is reached, program flow branches as follows:

- Condition is not fulfilled: Program runs through loop.
- Condition is fulfilled: Program continues.

Example of UNTIL loop with condition at end



① Condition is not fulfilled

② Condition is fulfilled

Figure 7-98 Example of repetition with query at the end (UNTIL) in the flowchart

Note

The condition is programmed in the ladder diagram (LAD) (Page 4153), function block diagram (FBD) (Page 4156) or Formula (Page 4158) languages.

Refer to the notes regarding inserting (Page 4207), deleting, cutting, or copying of the IF statement (Page 4208); they apply analogously.

Relevant commands of the ST (Structured Text) programming language for UNTIL: Loop with condition at the end

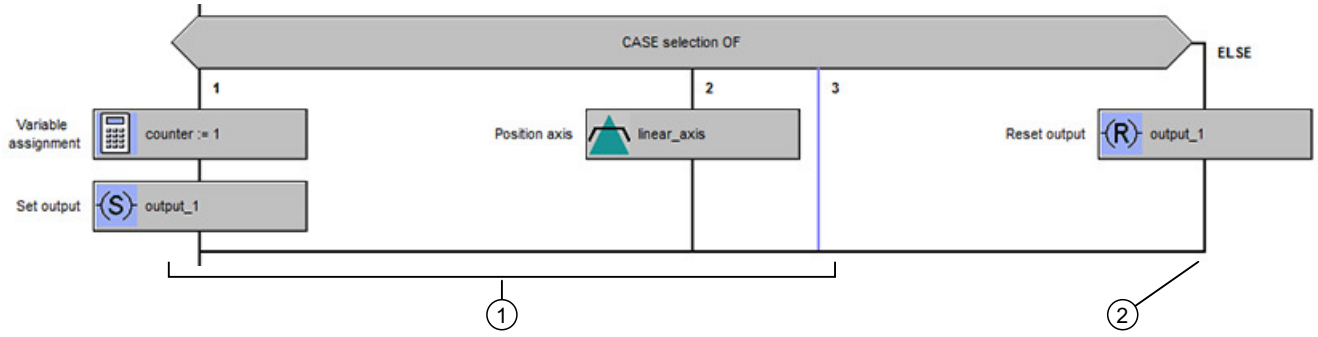
REPEAT / UNTIL / END_REPEAT

CASE: Multiple branching

Depending on the value of a variable, several alternative program branches may be executed. The following variable data types are permitted:

- General data type ANY_INT
- Any enumeration data type

Example of CASE Multiple branching



① Comparison value corresponds to one of the programmed constants

② Comparison value does not correspond to any of the programmed constants

Figure 7-99 Description of the variable and ELSE branch

Inserting a branch in the CASE statement

After insertion of this command, there are two program branches. To insert additional branches, proceed as follows:

- To insert a branch in the first position (left):
  Select the command, and select **Insert branch** from the context menu.
- To insert additional branches:
  Select the branch, and select **Insert branch** from the context menu.
  The branch is inserted on the right next to the selected branch.

Deleting a branch from the CASE statement

To delete a branch, proceed as follows:

1. Delete all commands from the branch.
2. Select the branch.
3. Select **Delete empty branch** from the context menu.

Comparison constant in the CASE statement

Overwrite the default ??? in every branch with a constant of the same data type as the variable. A value range can also be specified, for example, 1,2,3 or 4 to 10.

It is not possible to overwrite the default value in an ELSE branch.

The number of displayable characters for the comparison constant on a branch is limited. Long comparison constants are therefore shown in a shortened form with omission dots in the middle of the character string. However, the entire comparison constant is shown in the tooltip.

Overview of parameters for CASE: Multiple branching

You can set the following parameters:

Table 7-69 Overview of parameters for CASE multiple branching

Field/button	Meaning/instruction
Variable	Enter a variable of the following data types: • General data type ANY_INT • Any enumeration data type The variable name can be entered or moved from the symbol browser using a drag and drop operation. The CASE branch whose label is consistent with the variable content is executed. If the content of the variable does not match any of the constants or constant ranges, then the ELSE branch is executed.

Note

Refer to the notes regarding inserting (Page 4207), deleting, cutting, or copying of the IF statement (Page 4208); they apply analogously.

Relevant commands of the ST (Structured Text) programming language for CASE: Multiple branching

CASE / ELSE / END_CASE

Go to

You can program jumps within an MCC chart using the Go to command. A jump is defined as a jump label (Go to command) and a jump destination (Selection command), each with the same name. A circle symbol with a name marks the exit and entry point in each case. Several exit points with the same name can be programmed, but only one entry point.

The following jumps are illegal:

- Jumps to control structures
- Jumps out of the shaded area after a Wait command

After you have inserted a Go to command, you must enter the name of the jump destination. For this, double-click inside the circle.

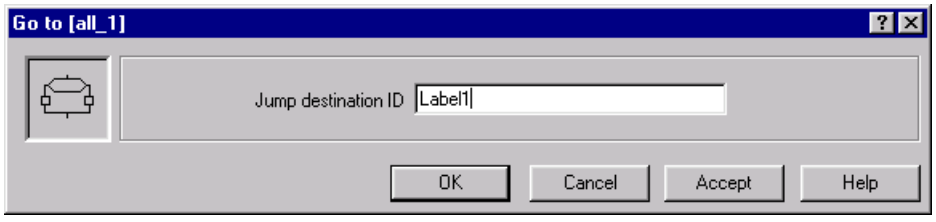


Figure 7-100 Parameter screen form: Go to

Overview of parameters for Go to

You can set the following parameters:

Table 7-70 Overview of parameters for Go to

Field/Button	Explanation/instructions
Jump destination ID	Enter the name of the jump destination. The name is made up of the following: • The first character is a letter or underscore symbol • The remaining characters are letters, underscore symbols, or digits It is irrelevant whether the letters are upper or lower case. The name must be identical to the newly assigned name for the jump label – see Selection (Page 4215) command.

Relevant commands of the ST (Structured Text) programming language for Go to:

GOTO

Selection

This command is used to identify the entry point for the Go To command. A jump is defined as a jump label (Go to command) and a jump destination (Selection command), each with the same name. A circle symbol with a name marks the exit and entry point in each case. Several exit points with the same name can be programmed, but only one entry point.

The following jumps are illegal:

- Jumps to control structures
- Jumps out of the shaded area after a Wait command

After you have inserted the Selection command, you must enter the name of the jump label. For this, double-click inside the circle.

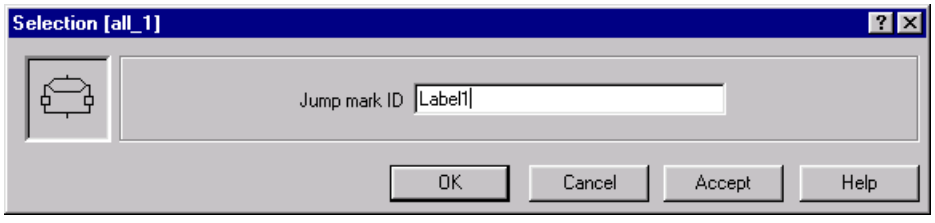

Figure 7-101 Parameter screen form: Selection (jump label)

Overview of parameters for Selection

You can set the following parameters:

Table 7-71 Overview of parameters for Selection

Field/Button	Explanation/instructions
Jump mark ID	Enter the name of the jump label. The name is made up of the following: • The first character is a letter or underscore symbol • The remaining characters are letters, underscore symbols, or digits It is irrelevant whether the letters are upper or lower case. The name must be identical to the newly assigned name for the jump destination – see Go to (Page 4214) command.

Relevant commands of the ST (Structured Text) programming language for Selection:

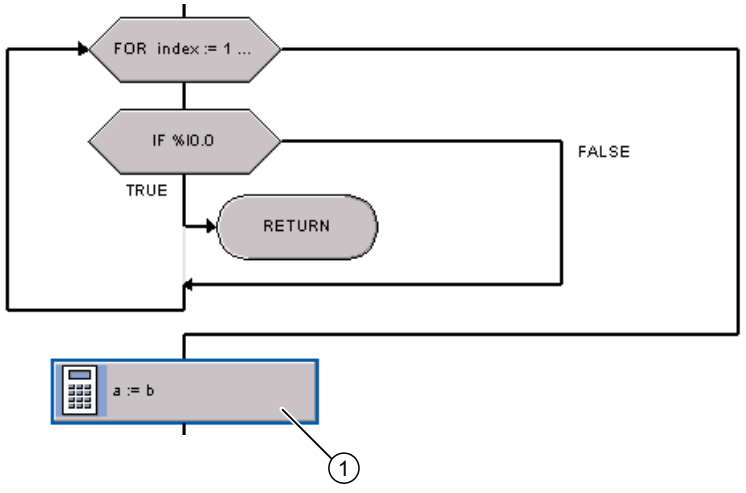
Definition of a jump label

Return

This command causes the MCC chart (program, function, function block) to end.

When a function or a function block is ended, program execution continues in the higher-level MCC chart (or program organization unit) after the position where the function or function block was called.

Example of Return



① The variable assignment is executed after the regular end of the FOR loop, but not after the execution of the Return command.

Figure 7-102 Example of Return

Relevant commands of the ST (Structured Text) programming language for Return:

RETURN

Exit

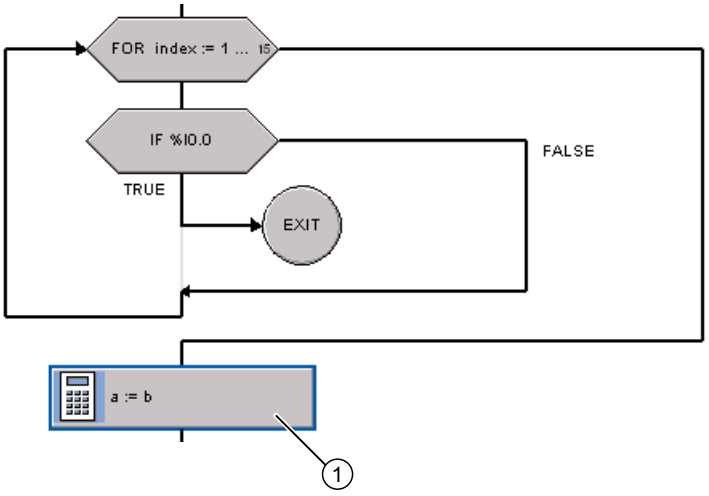
This command is permitted in the following program structures (loops):

- WHILE: Loop with condition at the start (Page 4208)
- FOR: Loop with fixed number of runs (Page 4209)
- UNTIL: Loop with condition at the end (Page 4211)

It enables the loop to be exited at any location without requiring the abort condition to be fulfilled.

The program is continued at the end of the loop.

Example of Exit



① The variable assignment is executed after the execution of the Exit command and the regular end of the FOR loop.

Figure 7-103 Example of Exit

Relevant commands of the ST (Structured Text) programming language for Exit:

EXIT

Continue

This command is only available if the compiler option **Language extensions IEC61131 3rd Edition** is enabled at the MCC source file, see Global settings of the compiler (Page 3996) and Local settings of the compiler (Page 3997).

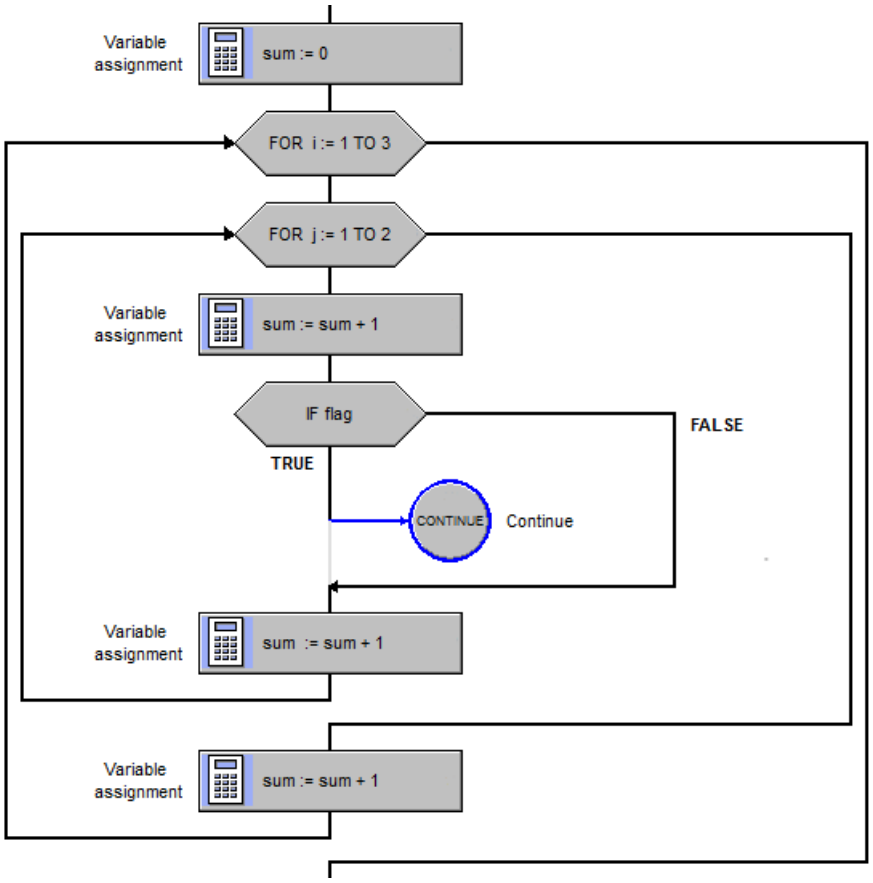
This command is permitted in the following program structures (loops):

- WHILE: Loop with condition at the start (Page 4208)
- FOR: Loop with fixed number of runs (Page 4209)
- UNTIL: Loop with condition at the end (Page 4211)

The command instigates a jump at the start of the loop.

- The condition is reviewed with the WHILE loop.
- The counter variable is incremented and compared with the full-scale value with the FOR loop.

Example for Continue



Value of the "sum" variable after the FOR loops have run

flag = FALSE: sum = 15

flag = TRUE: sum = 9

Figure 7-104 Example for Continue

Relevant commands of the ST (Structured Text) programming language for Continue

CONTINUE

Synchronous start

You can use this command to start several commands simultaneously. The permissible commands are listed in **Permissible commands**.

The next command is started once all the commands in the branches have been executed and ended. In addition, details of when a command is ended are entered in **Permissible commands**.

To check the correct completion of the synchronous start, you can query whether the commands, which were started synchronously, have been completed without error via the group variable _MccRetSyncStart. The group variable is set to not equal to 0 if a command within the synchronous start had a return value not equal to 0 (see SIMOTION Basic Functions Function Manual).

The following MCC sample program shows a synchronous start with two axes and subsequent query of the group variable _MccRetSyncStart. This is not equal to 0 when a command within the synchronous start had a return value not equal to 0.

There is no limit to the number of commands started simultaneously nor to the number of synchronous starts within an MCC chart.

This command should only be used in MotionTasks.

Note

When you use the Synchronous Start command, you must generate the UserInterruptTask_1 since this is called in the event of an error. You can program an error response in this task.

The task controller is temporarily shut down during the synchronous start. It is not restarted until the following conditions are met:

- All single-axis commands and synchronous operation and cam commands in the branches have been started
- All basic commands in the branches have been completed

Start interruptions by other tasks (except SynchronousTasks) are thus prevented. This can cause a timeout to occur in cyclic tasks (BackgroundTask, TimerInterruptTasks). This error can be detected and caught by programming the TimeFaultBackgroundTask or TimeFaultTask appropriately.

For information about execution levels and tasks, see Execution levels and tasks in SIMOTION in the SIMOTION ST Programming Manual.

Example: Synchronous start of three commands

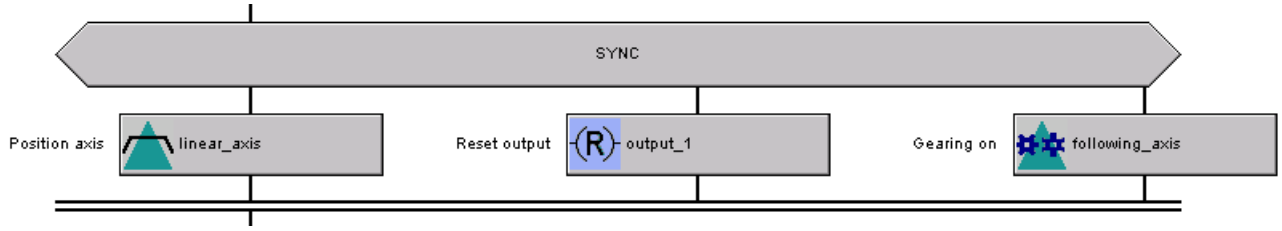


Figure 7-105 Synchronous start of three commands

Programming a condition

You can program a condition for the synchronous start. TRUE is the default setting when the command is called. This causes immediate synchronous start.

Programming a condition corresponds to the Wait for condition command. Consequently, you must note the following:

The condition can be composed of:

- Unit variables of the same MCC unit or imported program source files
- Global device variables
- Constants
- I/O variables and process image accesses (inputs)
- Operators

The expression may not contain:

- Function calls
- Local variables
- Loops

Note

The condition is programmed in the ladder diagram (LAD), function block diagram (FBD), or Formula languages.

Checkbox

If you activate the **Start command if condition is fulfilled** check box, the commands in the branches are not executed until the programmed condition is fulfilled.

Insert branch

After insertion of this command, there are two program branches. To insert additional branches, proceed as follows:

- To insert a branch in the first position (left):
  Select the command, and select **Insert branch** from the context menu.
- To insert additional branches:
  Select the branch, and select **Insert branch** from the context menu.
  The branch is inserted on the right next to the selected branch.

Deleting a branch

To delete a branch, proceed as follows:

1. Delete all commands from the branch.
2. Select the branch.
3. Select **Delete empty branch** from the context menu.

Permissible commands

The following table lists the commands permitted for the synchronous start.

Note

In the case of single axis commands and synchronous operation and cam commands, the synchronous start can only be guaranteed if the following two conditions are satisfied:

The commands embedded in the synchronous start must act on different axes.

The axes involved must be on the same ExecutionLevel (IPO or IPO_2).

The following table shows the permissible commands for a synchronous start with specification of timing for proper completion of commands; timing depends on whether an additional command is present on the relevant axis.

Table 7-72 Permissible commands for a synchronous start with specification of timing for proper completion of commands; timing depends on whether an additional command is present on the relevant axis

Permissible command	Timing for proper completion of command	
	Another command is present	No other command is present
Basic commands		
Subroutine call	-	-
Set output	-	-
Reset output	-	-
Variable assignment	-	-
Single axis commands		
Homed axis	Motion is finished	Motion is finished

Permissible command	Timing for proper completion of command	
	Another command is present	**No other command is present**
Start axis position-controlled	• With time specification: End of setpoint interpolation • Without time specification: Infinite	• With time specification: Motion is finished • Without time specification: Infinite
Speed preset	• With time specification: End of setpoint interpolation • Without time specification: Infinite	• With time specification: Standstill signal of axis • Without time specification: Infinite
Position axis	End of setpoint interpolation	Motion is finished
Time-dependent position profile	End of setpoint interpolation	Motion is finished
Time-dependent velocity profile	End of setpoint interpolation	• Speed-controlled (axis: Standstill signal of axis • Positioning axis or synchronous axis: Motion is finished
Stop axis	End of setpoint interpolation	• Speed-controlled (axis: Standstill signal of axis • Positioning axis or synchronous axis: Motion is finished
Commands for synchronous operation and camming		
Gearing on	Infinite	Infinite
Gearing off	End of setpoint interpolation	End of setpoint interpolation
Cam on	• Cyclic cam Infinite • Non-cyclic cam End of setpoint interpolation	• Cyclic cam Infinite • Non-cyclic cam End of setpoint interpolation
Cam off	End of setpoint interpolation	End of setpoint interpolation

Transition behavior

All single axis commands and commands for synchronous operation and camming embedded in the synchronous start are programmed with the **Substitute** transition behavior.

For the following commands, the **Superimpose** transition behavior can also be selected:

- Start axis position-controlled
- Speed preset
- Position axis
- Time-dependent position profile
- Time-dependent velocity profile

Step enabling condition

For each single axis command or command for synchronous operation and camming embedded in the synchronous start, the **Delay program execution** check box is activated. The user cannot change this setting. This indicates that once the synchronous start is executed, the MotionTask is placed in the waiting state until the last command enclosed within the synchronous start has been completed or aborted.

The timing for proper completion of a command depends on whether another axis command is pending, and is indicated in the table above in the Permissible commands section.

Deleting/cutting or copying

When you delete, cut, or copy the synchronous start command, any commands programmed in the branches are also deleted or copied.

Relevant system functions and commands of the ST (Structured Text) programming language for synchronous start

System functions of SIMOTION devices:

- BEGIN_SYNC / END_SYNC
- _disableScheduler / _enableScheduler
- _startSyncCommands

ST system function:

- _getSyncCommandId
- _waitTime

ST commands:

- EXPRESSION / END_EXPRESSION for formulation of the wait condition
- WAITFORCONDITION / END_WAITFORCONDITION

7.1.6.4 Communication

Acknowledge technology object alarms

This command acknowledges the pending technology alarms on one or more technology objects.

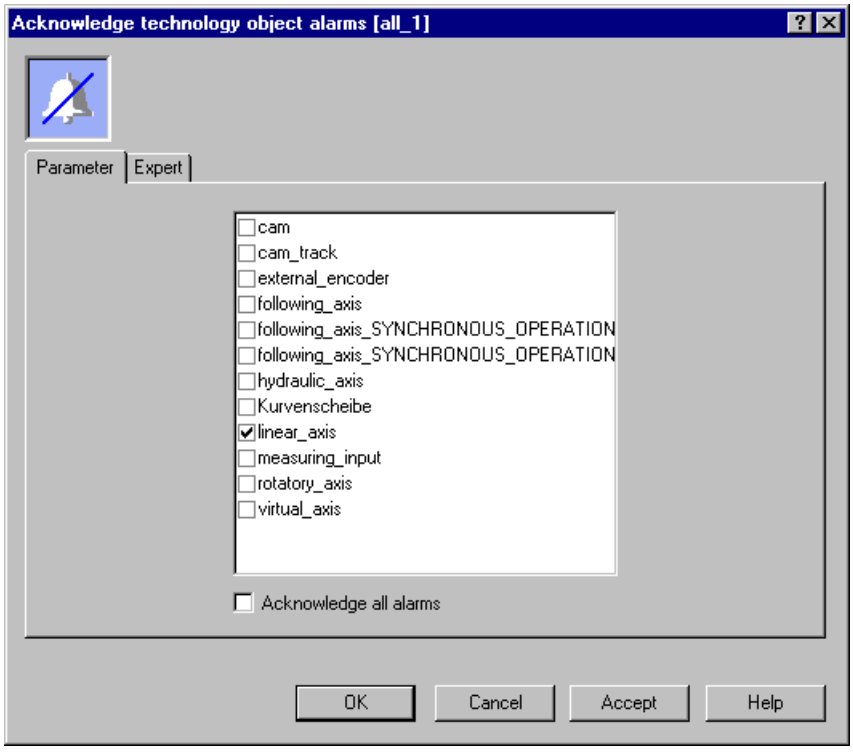

Figure 7-106 Parameter screen form: Acknowledge technology object alarms

Overview of parameters for Acknowledge technology object alarms

Table 7-73 Overview of parameters for Acknowledge technology object alarms

Field/Button	Explanation/instructions

Field/Button	Explanation/Instructions
Technology object	Here, you select the technology objects (axes, cams, etc.) whose alarms are to be acknowledged. You can select several objects simultaneously. The following are available: • All objects that are defined on the device • All variables with data types of technology objects declared in the MCC source file or MCC chart (see Technology object data types (Page 4060) table).
Acknowledge all alarms	Activate this check box if all alarms queued on the device are to be acknowledged.

Overview of parameters for Acknowledge technology object alarms - Expert tab

Table 7-75 Overview of parameters for Acknowledge technology object alarms - Expert tab

Field/Button	Explanation/Instructions
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. DINT data type. • When the **Acknowledge all alarms** check box is activated: The return value is always 0. • When the **Acknowledge all alarms** check box is cleared: For a description, see Return value for the system functions of the technology packages (Page 4040).

Relevant system functions for Acknowledge technology object alarms

When the **Acknowledge all alarms** check box is active:

- System function of SIMOTION devices
  - _resetTechnologicalErrors for resetting all objects

When the **Acknowledge all alarms** check box is cleared:

- Cam technology package:
  - _resetAxisError for drive axes, position axes, synchronized axes, and path axes
  - _resetCamError for cams
  - _resetCamTrackError for cam tracks
  - _resetExternalEncoderError for external encoders
  - _resetFollowingObjectError for synchronous objects
  - _resetMeasuringInputError for measuring inputs
  - _resetOutputCamError for output cams
- Path technology package:
  - _resetPathObjectError for path objects
- Cam_EXT technology package:
  - _resetAdditionObjectError for addition objects
  - _resetControllerObjectError for controller objects
  - _resetFixedGearError for fixed gear
  - _resetFormulaObjectError for formula objects
  - _resetSensorError for sensor objects
- TControl technology package:
  - _resetTControllerError for temperature channels

Each with parameter errorResetMode = ALL_ERRORS (default)

See also the **Acknowledge all alarms** field/button in the Overview of parameters for Acknowledge technology object alarms - Parameters tab (Page 4224) section.

Acknowledge specific technology object alarm

The command acknowledges all alarms or a specific alarm at a technology object.

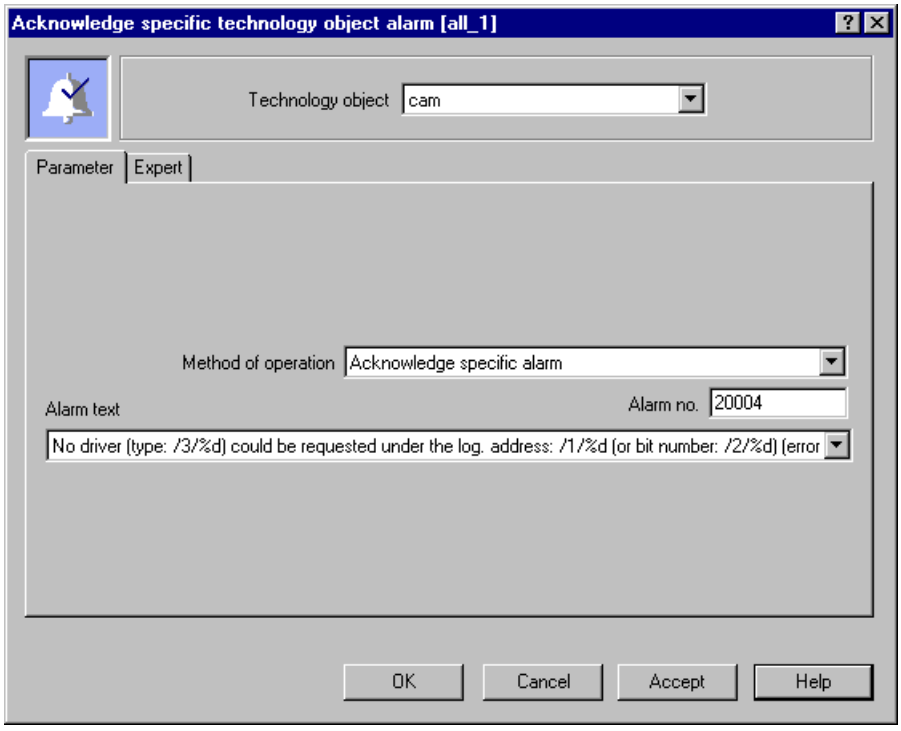

Figure 7-107 Parameter screen form: Acknowledge specific technology object alarm

Overview of parameters for Acknowledge specific technology object alarm

You can set the following parameters:

Table 7-76 Overview of parameters for Acknowledge specific technology object alarm

Field/Button	Explanation/instructions
Technology object	Here, you select the technology objects (axes, cams, etc.) whose alarms are to be acknowledged. You can select several objects simultaneously. The following are available: • All objects that are defined on the device • All variables with data types of technology objects declared in the MCC source file or MCC chart (see Technology object data types table).

- _resetFormulaObjectError for formula objects
- _resetSensorError for sensor objects

TControl technology package:

- _resetTControllerError for temperature channels

Each with parameter errorResetMode = SPECIFIC_ERROR

Incoming message

This command notifies configured nodes that a message has arrived.

The message can be selected as follows:

- By the name configured during message configuration (**Project > Messages > Configure** menu command).
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructAlarmId
  In this form, the command can be used in libraries.
  This variable contains the AlarmId of a configured message. You can obtain the AlarmId outside of libraries with _alarm.*Message* and assign to them a variable of data type StructAlarmId.

The message is sent to all of the configured nodes.

See the online help for information about message configuration.

If the specified message is already pending, then there is no change. The message is not reset.

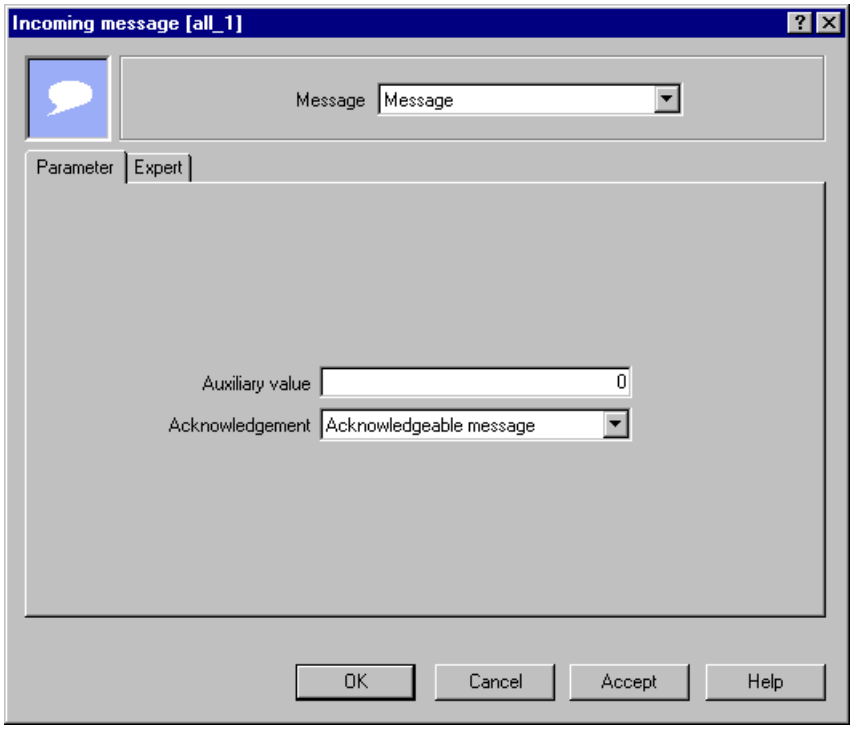

Figure 7-108 Parameter screen form: Incoming message

Overview of parameters for Incoming message

You can set the following parameters:

Table 7-79 Overview of parameters for Incoming message

Field/Button	Explanation/instructions
Alarm	Here you select the message. You can select from: • All configured messages (not in libraries). To configure new messages, select the **Project > Messages > Configure** menu command. • All variables of data type StructAlarmId declared in the MCC source file or MCC chart You can obtain the AlarmId of a configured message outside of libraries with _alarm.*Message* and assign to them a variable of data type StructAlarmId.
Parameters tab	See Overview of parameters for Incoming message - Parameter tab (Page 4230)
Expert tab	See Overview of parameters for Incoming message - Expert tab (Page 4230)

Overview of parameters for Incoming message - Parameters tab

Table 7-80 Overview of parameters for Incoming message - Parameters tab

Field / button	Meaning/instruction
Auxiliary value	Enter the auxiliary values for the message. The auxiliary value must be specified if auxiliary values have been defined during message configuration in SIMOTION SCOUT. • Irrespective of the SIMOTON Kernel version: 1 Auxiliary value possible, integer numbers, numbers with decimal points, and positive and negative values are permitted. Variables or constants of data types ANY_NUM or ANY_BIT can also be specified. • SIMOTION Kernel as of version V4.5: Up to 12 auxiliary values of data type BYTE (or SINT, USINT) possible, these are transferred in a field of 12 BYTE (ARRAY [0..11] OF BYTE). Auxiliary values with data types that include multiple bytes (e.g. WORD, DINT, REAL) are possible, these reduce the number of possible auxiliary values. The user must ensure that their values are saved in the permitted field elements in accordance with the big endian byte arrangement. The function AnyType_to_BigByteArray can be used for this, see Basic Functions Function Manual. For the arrangement of the auxiliary value in the byte field: see section "Example of messages with multiple auxiliary values (as of Kernel V4.5)" in the Basic Functions Function Manual.
Acknowledgment	Here, you select whether the message can be acknowledged. **Acknowledgeable message** (default value) acknowledgeable message: When the message arrives, the user must acknowledge it on the operator panel. **Message not acknowledgeable** Message not acknowledgeable: The message is visible until the program has issued an outgoing message.

Overview of parameters for Incoming message - Expert tab

Table 7-81 Overview of parameters for Incoming message - Expert tab

Field/button	Meaning/instruction
	The Expert tab is described in detail in Expert tab (Page 4034).
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DWORD; for a description, see _alarmSId and _alarmSqId functions in the SIMOTION Basic Functions Function Manual.

Relevant system functions for Incoming message

ST system functions:

- _alarmSId (for non-acknowledgeable message)
- _alarmSqId (for acknowledgeable message)

each with parameter sig:= TRUE

The _getAlarmId system function is also called if a configured message has been selected.

Outgoing message

This command notifies configured stations that a message is no longer pending.

The message can be selected as follows:

- By the name configured during message configuration (**Project > Messages > Configure** menu command).
  In this form, the command **cannot** be used in libraries.
- Using a variable of data type StructAlarmId
  In this form, the command can be used in libraries.
  This variable contains the AlarmId of a configured message. You can obtain the AlarmId outside of libraries with _alarm.*Message* and assign to them a variable of data type StructAlarmId.

Acknowledgeable messages can then be acknowledged on the OP.

See the online help for information about message configuration.

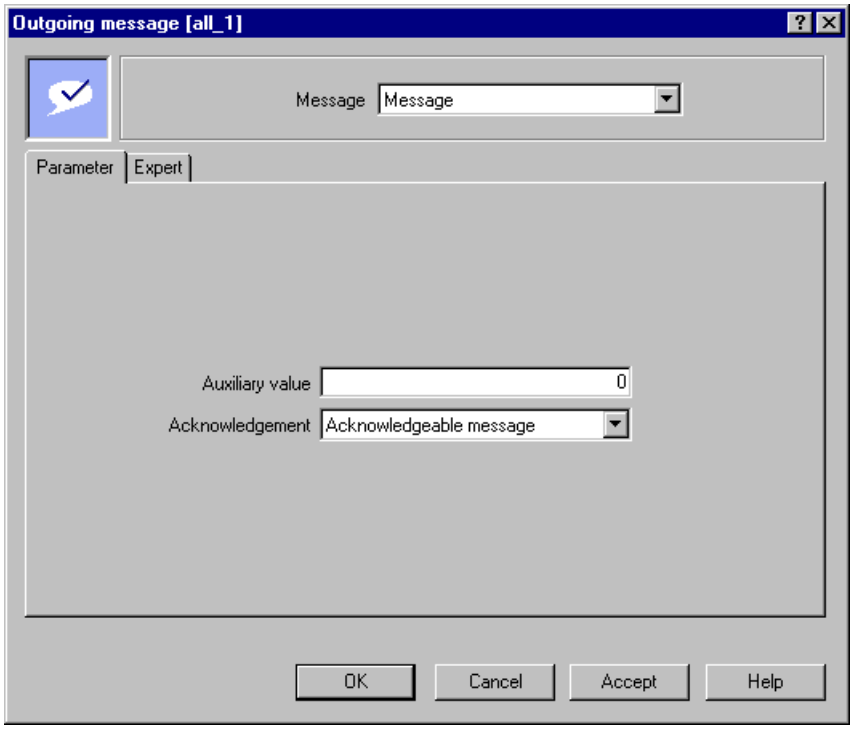

Figure 7-109 Parameter screen form: Outgoing message

Field/button	Meaning/instruction
	The Expert tab is described in detail in Expert tab (Page 4034).
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DWORD; for a description, see _alarmSId and _alarmSqId functions in the SIMOTION Basic Functions Function Manual.

Relevant system functions for Outgoing message

ST system functions:

- _alarmSId (for non-acknowledgeable message)
- _alarmSqId (for acknowledgeable message)

each with parameter sig:= FALSE

The _getAlarmId system function is also called if a configured message has been selected.

Establish connection using TCP/IP

Before you can use the TCP/IP protocol of the "Send data" (Page 4239) or "Receive data" (Page 4246) commands, you must establish the TCP/IP connection for both communication partners:

1. You specify one communications partner as the server.
   After the call, the command waits for a connection request at the specified port.
2. You specify the other communications partner as the client and specify the server it is to access.
   After the command is called, a connection to the server addressed by the IP address and port number is established.

The connection remains active until it is terminated by the "Remove connection via TCP/IP" (Page 4237) command.

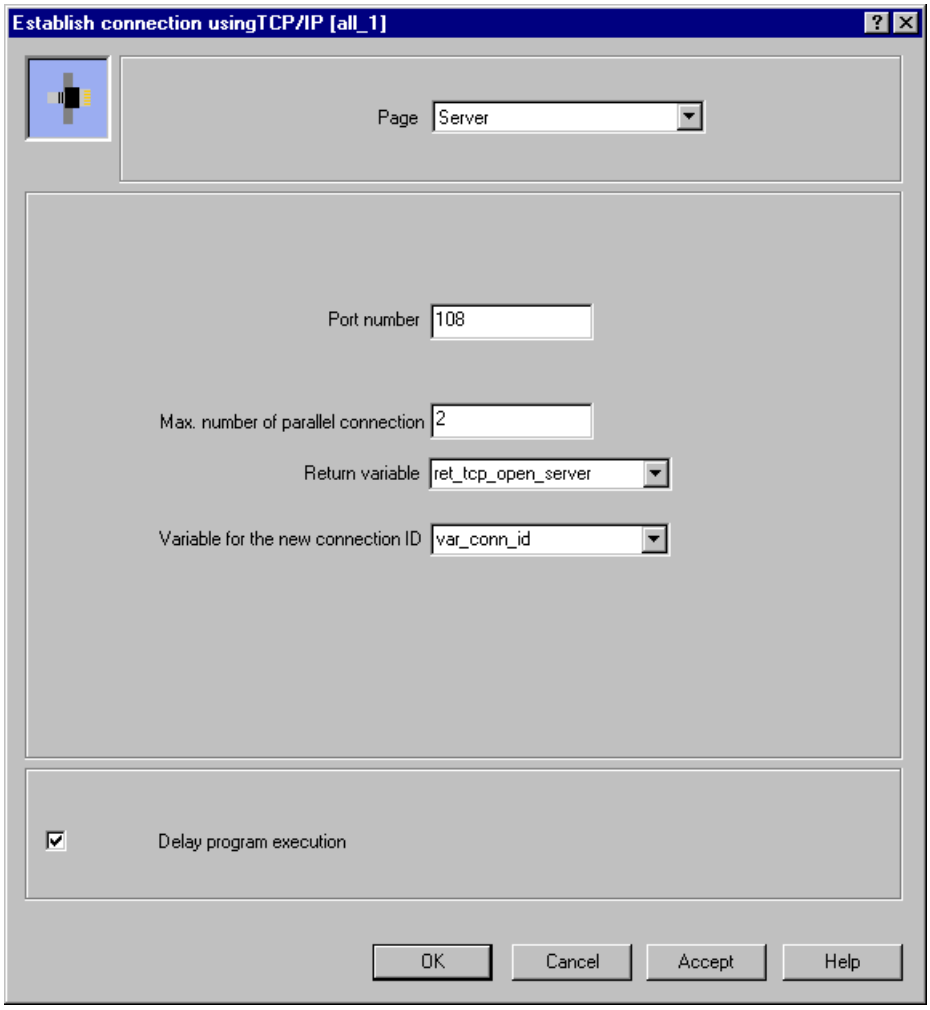

Figure 7-110 Parameter screen form: Establish connection via TCP/IP

Overview of parameters for Establish connection using TCP/IP

You can set the following parameters:

Table 7-85 Overview of parameters for Establish connection via TCP/IP

Field/button	Meaning/instruction
Page	Select whether the SIMOTION device is to act as a server or client in the TCP/IP connection. The parameter dialog box changes according to the selected value. **Server** The SIMOTION device acts as a server in the TCP/IP connection. **Client** The SIMOTION device acts as a client in the TCP/IP connection.
Parameters for	

Field/button		Meaning/instruction
	Page = Server	See Table "Overview of parameters for Establish connection via TCP/IP - Parameters for server"
	Page = Client	See Table "Overview of parameters for Establish connection via TCP/IP - Parameters for client"
Delay program execution		Activate the checkbox if execution of the following command should be delayed until this command has been completed. If the checkbox is not activated, the next command is executed immediately.

Table 7-86 Overview of parameters for Establish connection via TCP/IP - Parameters for server

Field/button	Meaning/instruction
Port number	Here, you enter the number of the port where the command waits for a connection request.
Max. number of parallel connection requests	Here, you enter the maximum number of parallel connection requests.
Return variable	Here, you enter the return variable of data type StructRetTcpOpenServer in which the error message and the connection parameters are stored. This variable must be defined in a declaration table. For the data type StructRetTcpOpenServer: See Return value for Establish connection via TCP/IP (Page 4237).
Variable for new connection ID	Here, you enter a variable of data type DINT. It contains the new connection ID. The value is identical to the connectionId component of the return variable.

Table 7-87 Overview of parameters for Establish connection via TCP/IP - Parameters for client

Field/button	Meaning/instruction
Port number	Here, you enter the port number of the client.
IP address of the server	Here, you enter the IP address of the server.
Port number of the server	Here, you enter the port number of the server.
Return variable	Here, you enter the return variable of data type StructRetTcpOpenClient in which the error message and the connection parameters are stored. This variable must be defined in a declaration table. For the data type StructRetTcpOpenClient: See Return value for Establish connection via TCP/IP (Page 4237).
Variable for new connection ID	Here, you enter a variable of data type DINT. It contains the new connection ID. The value is identical to the connectionId component of the return variable.

Relevant system functions for Establish connection using TCP/IP

System function of SIMOTION devices:

Return value for Establish connection using TCP/IP

The return value informs the user about the result of the command call and contains important connection parameters.

You must declare the return variable in a declaration table:

- If parameter **Page = Server** is selected:
  As variable of the StructRetTcpOpenServer data type.
- If parameter **Page = Client** is selected:
  As variable of the StructRetTcpOpenClient data type.

You select this variable in the **Return variable** parameter, see Overview of parameters for Establish connection via TCP/IP (Page 4234).

The following table lists the meaning of the individual elements of the StructRetTcpOpenServer and StructRetTcpOpenClient data types.

Table 7-90 Structure of the return value for Page = Server (TYPE StructRetTcpOpenServer)

Parameter (data type)	Meaning/values	Values
functionResult (DINT)	Error number	< **16#8000:** if command execution is okay >= **16#8000:** if an error has occurred See description for _tcpOpenServer command in the parameter manuals for the SIMOTION devices.
connectionId (DINT)	New connection ID	-
clientAddress (ARRAY [0..3] OF USINT)	IP address of the connecting client	-
clientPort (UINT)	Port number of the connecting client	-

Send data

This command sends data to a communications partner (such as a SIMATIC S7 station) using various protocols.

- XSend/XReceive protocol
  The connection to the communications partner is established via PROFIBUS or MPI and does not have to be configured.
  SIMOTION devices can send a maximum of 200 bytes in one unit; the actual user data length is dependent on the communications partner.
- UDP protocol
  The connection is established via Ethernet with the UDP protocol.
  SIMOTION devices can send a maximum of 1470 bytes in one unit; the actual user data length is dependent on the communications partner.
- TCP/IP protocol
  The connection is established via Ethernet with the TCP/IP protocol. You must have configured the TCP/IP connection beforehand. Use the "Establish connection via TCP/IP" (Page 4233) command.
  SIMOTION devices can send a maximum of 4096 bytes in one unit; the actual user data length is dependent on the communications partner.

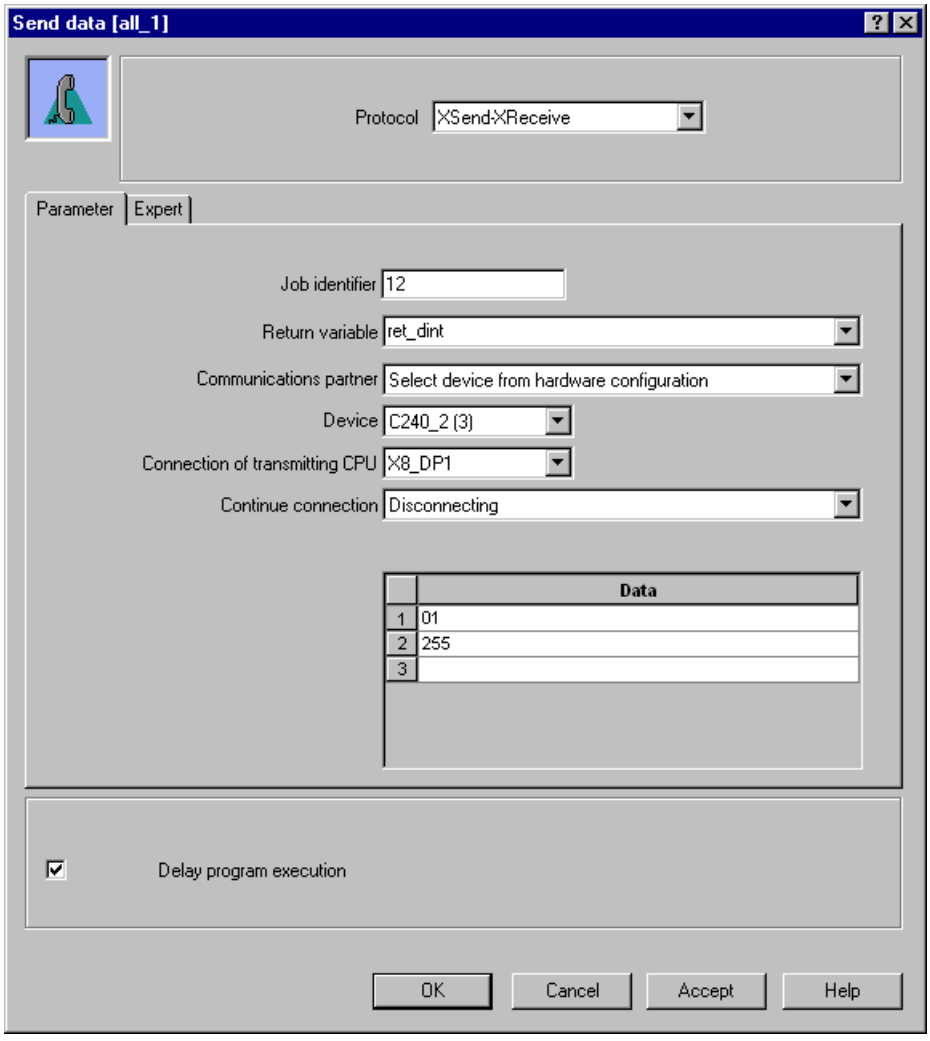

Figure 7-112 Parameter screen form: Send data

Overview of parameters for Send data

You can set the following parameters:

Table 7-95 Overview of parameters for Send data

Field/button	Meaning/instruction
Protocol	You can choose between the different protocols here. The parameter dialog box changes, accordingly. **XSend-XReceive** The connection is established via PROFIBUS or MPI. **UDP** The connection is established via Ethernet, and the UDP protocol is selected. **TCP/IP** The TCP/IP protocol is selected. You must have configured the TCP/IP connection beforehand. Use the "Establish connection via TCP/IP" (Page 4233) command.
Parameters tab	• For **Protocol = XSend-XReceive** See Table Overview of parameters for Send data - Parameters tab for Protocol = XSend-XReceive (Page 4241) • For **Protocol = UDP** See Table Overview of parameters for Send data - Parameters tab for Protocol = UDP (Page 4242) • For **Protocol = TCP/IP** See Table Overview of parameters for Send data - Parameters tab for Protocol = TCP/IP (Page 4243)
Expert tab	See Overview of parameters for Send data - Expert tab (Page 4243)
Delay program execution	Only when **Protocol = XSend-XReceive** or **Protocol = TCP/IP** is selected. • Activate the checkbox if you wish to delay execution of the following command until the current command has been completed. If the checkbox is not activated, the next command is executed immediately. If **Protocol = UDP** is selected, the next command is immediately processed.

Overview of parameters for Send data - Parameters tab

Table 7-96 Overview of parameters for Send data - Parameters tab for Protocol = XSend-XReceive

Field/button	Meaning/instruction
Job identifier	Enter the job identifier here. The data type is UDINT.
Return variable	If you enter the name of a variable of the data type DINT, you can use this variable to find out the result of the command call. This variable must be defined in a declaration table or the symbol browser. < **16#8000**: if command execution is okay **>= 16#8000**: if an error has occurred See description for _Xsend function in the List Manuals for the SIMOTION Devices.

Field/button	Meaning/instruction
Communications partner	Here, you select the communications partner to which you wish to send data. **Specify address directly** This setting enables you to enter the communications partner's address directly. Use this selection if the communications partner is not defined in the project (for example, SIMATIC S7 stations). **Select device from hardware configuration** (default value) This setting enables you to select a SIMOTION device from the current hardware configuration. This setting cannot be used in libraries.
Device	This selection is only active if **Select device from hardware configuration** is selected in the "Communications partner" selection field. Here, you select the receiving device. You can choose from all SIMOTION devices that can be reached directly by means of a PROFIBUS or MPI subnet.
Connection of transmitting CPU	This selection is only active if **Select device from hardware configuration** is selected in the "Communications partner" selection field. Here, you select the connection of the transmitting SIMOTION device. Once the receiving device (communications partner) is selected, the PROFIBUS or MPI connection of the transmitting SIMOTION device is offered.
Destination address of communications partner	This selection is active only if **Specify address directly** is active in the "Communications partner" list. Here, you enter the name of the variable in which the destination address of the communications partner is stored. You define the variable in a declaration table as StructXSendDestAddr (XSend-XReceive protocol).
Continue connection	Here, decide whether the connection should remain after data transfer. Select **Disconnecting** if the device in question is communicating with a large number of nodes. **Disconnecting** (default value) The connection is discontinued after the data transfer. **Connection remains active** The connection remains active after the data transfer.
Data	Enter the communication data here. You can enter up to 200 values. The data type must be BYTE; furthermore, variables of type BYTE can be entered.

Table 7-97 Overview of parameters for Send data - Parameters tab for Protocol = UDP

Field/button	Meaning/instruction
Port number of sender	Here, you enter the port number of the transmitting SIMOTION device.
IP address of receiver	Here, you enter the IP address of the receiver.
Port number of receiver	Here, you enter the port number of the receiver.

Field/button	Meaning/instruction
Socket lifetime	Here, decide whether the connection should remain after data transfer. Select Socket will be closed if the selected device communicates with many nodes. **Socket remains** (default value) The connection remains active after the data transfer. **Close socket** The connection is discontinued after the data transfer.
Data	Enter the communication data here. You can enter up to 1470 values. The data type must be BYTE; furthermore, variables of type BYTE can be entered.

Table 7-98 Overview of parameters for Send data – Parameters tab for Protocol = TCP/IP

Field/button	Meaning/instruction
Connection ID	Here, you enter the connection ID. This value was obtained when the TCP/IP connection was established with the "Establish connection via TCP/IP" (Page 4233) command.
Data	Enter the communication data here. You can enter up to 4096 values. The data type must be BYTE; furthermore, variables of type BYTE can be entered.

Overview of parameters for Send data - Expert tab

Table 7-99 Overview of parameters for Send data – Expert tab

Field/button	Meaning/instruction
	The Expert tab is described in detail in Expert tab (Page 4034).
CommandID variable	Only when **Protocol = XSend-XReceive** is selected If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	• When **Protocol = UDP** or **Protocol = TCP/IP** is selected If you enter the name of a variable of the data type DINT, you can use this variable to find out the result of the command call. < **16#8000:** if command execution is okay >= **16#8000:** if an error has occurred See description for _udpSend and _tcpSend functions in the parameter manuals for the SIMOTION devices. • When **Protocol = XSend-XReceive** is selected If you have specified a return variable in the Parameters (Page 4241) tab, it is displayed.

Querying the command status for Send data with XSend-XReceive protocol

When the XSend/XReceive protocol is used, you can query the status of the command on the basis of the CommandID variable using the _GetStateOfXCommand system function (see List Manuals for SIMOTION Devices). This is required, in particular, if the **Delay program execution** parameter is deactivated. In this way you can avoid an overflow of the send buffer due to multiple calls of the command.

ST commands can be programmed using the ST zoom (Page 4188), for example.

You cannot query the command status in the UDP or TCP/IP protocols.

Structure of destination address of the communications partner when address is entered directly (XSend-XReceive protocol)

When you enter the destination address of the communications partner directly in the XSend/XReceive protocol, you must declare a variable of data type StructXSendDestAddr in a declaration table or in the symbol browser.

The following table lists the meaning of the individual elements of these data types.

Table 7-100 Structure of the destination address of the communications partner when the address is entered directly (TYPE StructXSendDestAddr – XSend-XReceive protocol)

Parameter (data type)	Meaning	Values	
deviceId (USINT)	Point of the connection	C230-2, C240, C240 PN	**1** for X8 **2** for X9
		P350, P350-3	**1** for X101 **2** for X102
		D410 DP	**1** for X21
		D410-2 DP	**2** for X21 **1** for X24
		D410-2 DP/PN	**2** for X21
		D4x5, D4x5-2	**1** for X126 **2** for X136
remoteSubnetIdLength (USINT)	Length of the subnet dialog box	**0** for MPI, PROFIBUS	
remoteStaddrLength (USINT)	Length of the station address (station number) of the destination system.	**1** for MPI, PROFIBUS	
nextStaddrLength (USINT)	Length of the router address	**0** for MPI, PROFIBUS	
remoteSubnetId (ARRAY [0..5] OF USINT)	Subnet mask	(Irrelevant for MPI, PROFIBUS)	
remoteStaddr (ARRAY [0..5] OF USINT)	Station address of the destination system (actual destination address)	Node number for MPI, PROFIBUS: e.g. remoteStaddr[0] = 25	
nextStaddr (ARRAY [0..5] OF USINT)	Router address	(Irrelevant for MPI, PROFIBUS)

Receive data

This command is used to receive data from a communications partner (such as a SIMATIC S7 station) using various protocols.

- XSend-XReceive protocol
  The connection to the communications partner is established via PROFIBUS or MPI and does not have to be configured.
  SIMOTION devices can receive a maximum of 200 bytes in one unit; the actual user data length is dependent on the communications partner.
- UDP protocol
  The connection is established via Ethernet with the UDP protocol.
  SIMOTION devices can receive a maximum of 1470 bytes in one unit; the actual user data length is dependent on the communications partner.
- TCP/IP protocol
  The connection is established via Ethernet with the TCP/IP protocol. You must have configured the TCP/IP connection beforehand. Use the "Establish connection via TCP/IP" (Page 4233) command.
  SIMOTION devices can receive a maximum of 4096 bytes in one unit; the actual user data length is dependent on the communications partner.

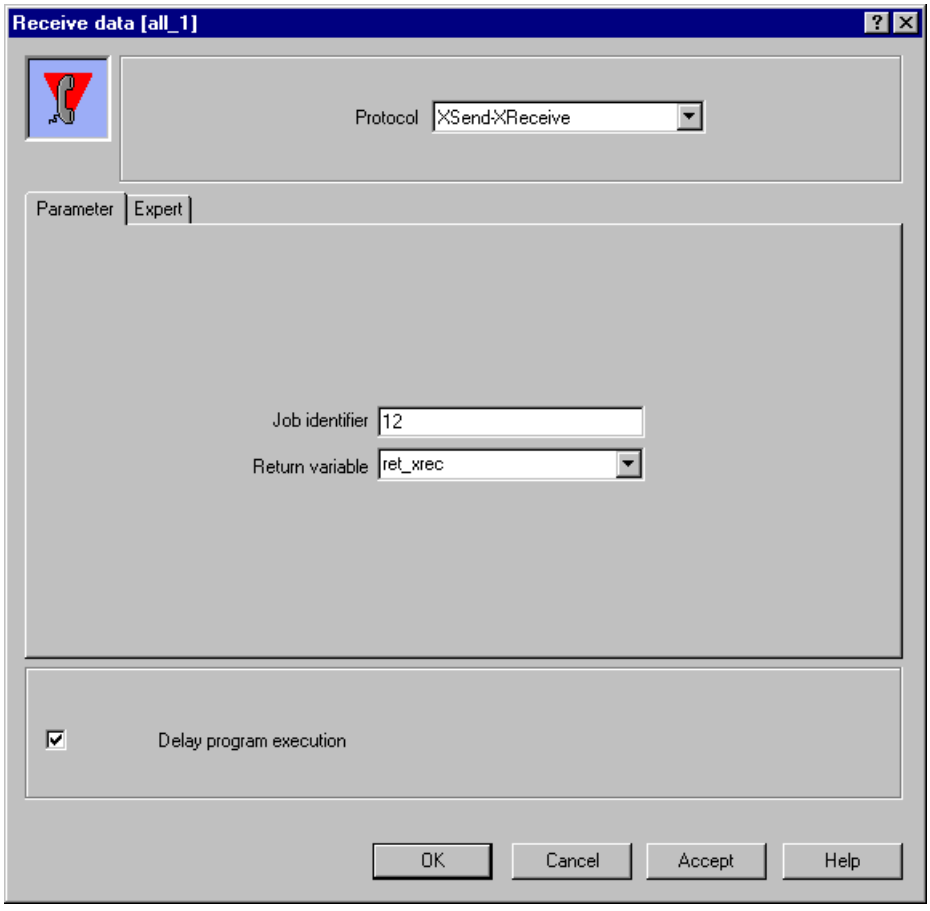

Figure 7-113 Parameter screen form: Receive data

Overview of parameters for Receive data

You can set the following parameters:

Table 7-104 Overview of parameters for Receive data

Field/button	Meaning/instruction
Protocol	You can choose between the different protocols here. The parameter dialog box changes, accordingly. **XSend-XReceive** The connection is established via PROFIBUS or MPI. **UDP** The connection is established via Ethernet, and the UDP protocol is selected. **TCP/IP** The TCP/IP protocol is selected. You must have configured the TCP/IP connection beforehand. Use the **Establish connection via TCP/IP** command.
Parameters tab	• For **Protocol = XSend-XReceive** See Table Overview of parameters for Receive data - Parameters tab for Protocol = XSend-XReceive (Page 4249) • For **Protocol = UDP** See Table Overview of parameters for Receive data - Parameters tab for Protocol = UDP (Page 4249) • For **Protocol = TCP/IP** See Table Overview of parameters for Receive data - Parameters tab for Protocol = TCP/IP (Page 4249)
Expert tab	See Overview of parameters for Receive data - Expert tab (Page 4250)
Delay program execution	Only when **Protocol = XSend-XReceive** or **Protocol = TCP/IP** is selected. • Activate the checkbox if execution of the following command should be delayed until this command has been completed. If the checkbox is not activated, the next command is executed immediately. Only when **Protocol = UDP** is selected • Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. **Synchronous** The next command is executed after the current command has been completed or aborted. **Abort** The active command is aborted if the port number is the same as that of the previous call of the command. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Receive data - Parameters tab

Return value for Receive data

The return value informs the user about the result of the command call and contains important connection parameters.

You must declare the return variable as a variable of the following data types in a declaration table or the symbol browser and specify it when assigning the command parameters.

- StructRetXReceive, if **Protocol = XSend-XReceive** is selected
- StructRetUdpReceive, if **Protocol = UDP** is selected
- StructRetTcpReceive, if **Protocol = TCP/IP** is selected

The following table lists the meaning of the individual elements of these data types.

Table 7-112 Structure of the return value (TYPE StructRetXReceive) for XSend-XReceive protocol

Parameter (data type)	Meaning/values	Values
functionResult (DINT)	Error number	**< 16#8000:** if command execution is okay **>= 16#8000:** if an error has occurred See description for _Xreceive command in the parameter manuals for the SIMOTION devices.
dataLength (UDINT)	Length of received data packet	
data (ARRAY [0..199] OF BYTE)	Received data	

Table 7-113 Structure of the return value (TYPE StructRetUdpReceive) for UDP protocol

Parameter (data type)	Meaning/values	Values
functionResult (DINT)	Error number	**< 16#8000:** if command execution is okay **>= 16#8000:** if an error has occurred See description for the _udpReceive command in the parameter manuals for the SIMOTION devices.
sourceAddress (ARRAY [0..3] OF USINT)	IP address of transmitter	
sourcePort (UINT)	Port number of transmitter	
dataLength (UDINT)	Length of received data packet	

Table 7-114 Structure of the return value (TYPE StructRetTcpReceive) for TCP/IP protocol

Parameter (data type)	Meaning/values	Values
functionResult (DINT)	Error number	**< 16#8000:** if command execution is okay >= **16#8000:** if an error has occurred See description for the _tcpReceive command in the parameter manuals for the SIMOTION devices.
dataLength (UDINT)	Length of received data packet	

7.1.6.5 Single axis commands

Switch axis enable

You use this command to switch the enables on an axis with an electric drive (for axes with a hydraulic drive, you use the Switch QF-axis enable function).

The force/pressure control can also be enabled or disabled on axes with force/pressure control.

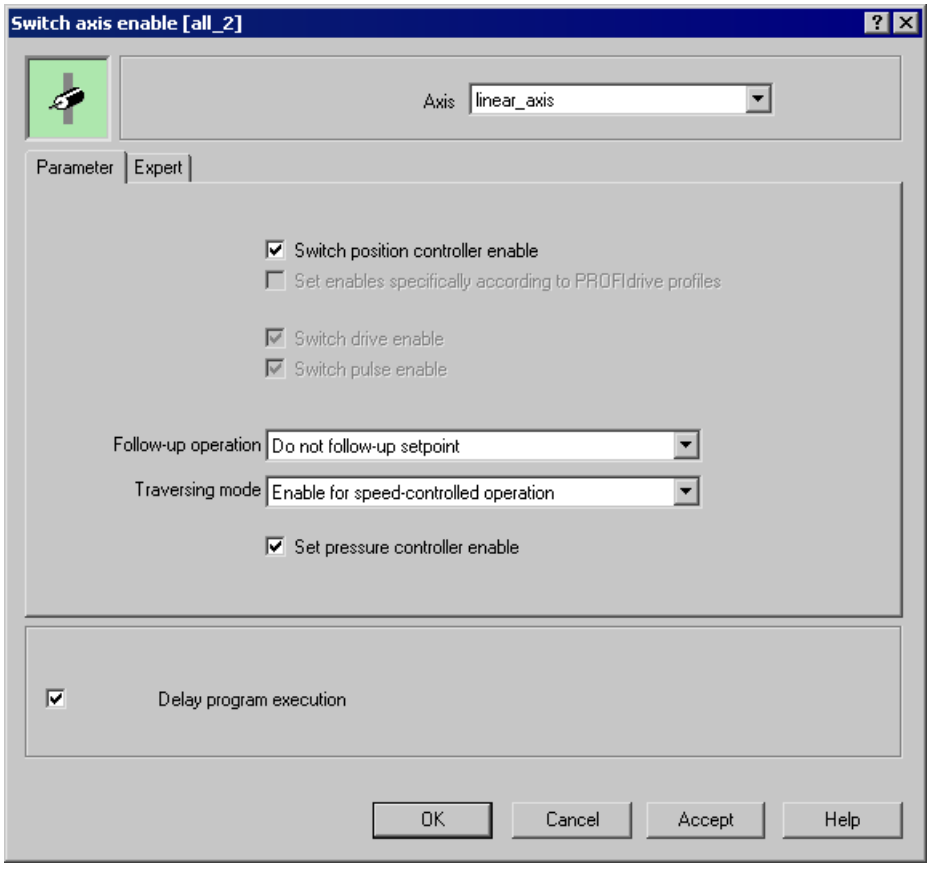

Figure 7-114 Parameter screen form: Switch axis enable

The following conditions must be fulfilled in order to execute motion commands on the axis:

1. Drive enable issued
2. Pulse enabled (power unit enabled)
3. Additional conditions for position, synchronized and path axes: Position controller enable is issued
4. Follow-up mode canceled

Until all conditions are fulfilled, the axis remains in follow-up mode (see Follow-up mode for various axis technologies).

The current status of enables can be accessed via system variables, which are specified in the description of the respective parameter.

Table 7-115 Follow-up mode for various axis technologies

Drive axis	**Position axis** **Synchronous axis** **Path axis**
Note Motion commands for the axis cannot be executed in follow-up mode.	
	The following applies to position control: Position control is canceled. The actual position value continues to be measured. The position setpoint is corrected to the current actual position value. **Note** Once follow-up mode is canceled, homing of the axis does not have to be repeated.
Current status for a real axis, indicating whether motion commands can be executed: System variable: control.	

For additional information on **axis enables**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Switch axis enable

Table 7-116 Overview of parameters for Switch axis enable

Field/button	**Meaning/instruction**
Axis	In Axis, select the axis for which the axis enable is to be switched. The list contains: • All axes with an electric drive that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.
Parameters tab	See Overview of parameters for Switch axis enable – Parameters tab (Page 4255)
Expert tab	See Overview of parameters for Switch axis enable – Expert tab (Page 4256)
Delay program execution	Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the command has been completed. If the checkbox is not activated, the next command is executed immediately.

Overview of parameters for Switch axis enable – Parameters tab

Table 7-117 Overview of parameters for Switch axis enable – Parameters tab

Field/button	Meaning/instruction
Switch position controller enable	Only for position, synchronized and path axes: Activate the checkbox if the position controller enable is to be switched. If the checkbox is activated: • The **Switch enables individually according to PROFIdrive profiles** checkbox is deactivated. • The **Switch drive enable** and **Switch pulse enable** checkboxes are activated. If the checkbox is not activated, the current status of the position controller enable is not changed. In the case of virtual axes, the position controller enable is always set, even if this checkbox has not been activated. The position controller enable must also be set if only speed-controlled operation has been selected for a position-controlled axis, see parameter **Traversing mode**. Current status of position controller enable for a real axis: System variable: servoMonitorings.controlState.
Switch enables individually according to PROFIdrive profiles	Activate the checkbox if you want to be able to switch enables individually in accordance with the PROFIdrive profile. If the checkbox is activated: • The **Switch drive enable** and **Switch pulse enable** checkboxes are hidden. • Seven check boxes are displayed for setting the individual bits of control word 1 (STW1) in accordance with PROFIdrive, see Meaning of bits of control word 1 (STW1) in accordance with PROFIdrive (Page 4257). – Activate the checkbox if you want to assign the corresponding enable. – Deactivate the checkbox if you want to retain the previous setting (enable assigned or not assigned) for the corresponding enable. All enables must be assigned for normal operation of the drive. If the checkbox is deactivated, the **Switch drive enable** and **Switch pulse enable** checkboxes are displayed.
Switch drive enable	Only if the **Switch enables individually according to PROFIdrive profiles** checkbox is deactivated. Activate the checkbox if the drive enable is to be switched. If the checkbox is not activated, the current status of the drive enable is not changed. Current status of drive enable for a real axis: System variable: actorMonitorings.driveState.
Switch pulse enable	Only if the **Switch enables individually according to PROFIdrive profiles** checkbox is deactivated. Activate the checkbox if the pulse enable (power enable) is to be switched. If the checkbox is not activated, the current status of the pulse enable is not changed. Current status of pulse enable for a real axis: System variable: actorMonitorings.power.

Field/button	Meaning/instruction
Follow-up mode	Here, you decide whether the axis is to be switched out of follow-up mode, see Table Follow-up mode for various axis technologies (Page 4257). **Do not follow up setpoint** (default value) Follow-up mode is disabled. Motion commands for the axis can be executed. In real axes, **Do not follow up setpoint** is only effective if all the other enables have been assigned. **Follow up setpoint** Follow-up mode is enabled. Motion commands for the axis cannot be executed. Current status for a real axis, indicating whether motion commands can be executed: System variable: control.
Traversing mode	**Maintain last setting** (default value) The axis is enabled with the most last set traversing mode (position and speed control). **Enable for speed- and position-controlled operation** The axis is enabled for speed- and position-controlled operation. This setting cannot be selected for drive axes. **Enable for speed-controlled operation** The axis is enabled for speed-controlled operation. If only speed-controlled operation is selected for a position-controlled axis the position controller enable still has to be set.
Set pressure controller enable	For axes with force/pressure control only. Activate the checkbox if you want to enable force/pressure control. If the checkbox is not activated, force/pressure control is disabled.

Remove axis enable

You use this command to remove the enables from an axis with an electric drive (for axes with a hydraulic drive, you use the Remove QF axis enable function).

The force/pressure control can also be disabled or enabled on axes with force/pressure control.

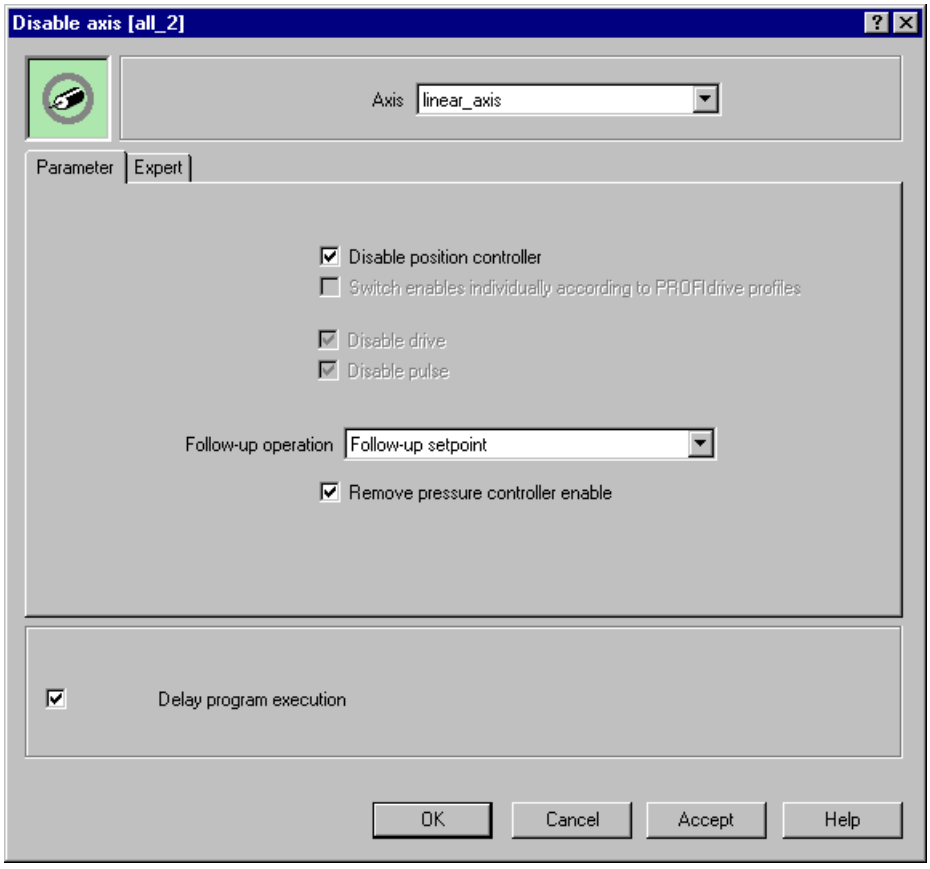

Figure 7-115 Parameter screen form: Remove axis enable

The following conditions must be fulfilled in order to execute motion commands on the axis:

1. Drive enable issued
2. Pulse enabled (power unit enabled)
3. Additional conditions for position, synchronized and path axes: Position controller enable is issued
4. Follow-up mode canceled

Until all conditions are fulfilled, the axis remains in follow-up mode (see Follow-up mode for various axis technologies (Page 4253) table).

The current status of enables can be accessed via system variables, which are specified in the description of the respective parameter (see Overview of parameters for Remove axis enable (Page 4259)).

For additional information on **axis enables**, see the TO Axis Electric/Hydraulic Function Manual.

Switch QF axis enable

You use this command to switch the enables on an axis with a hydraulic drive (for axes with an electric drive, you use the Switch axis enable function).

The force/pressure control can also be enabled or disabled on axes with force/pressure control.

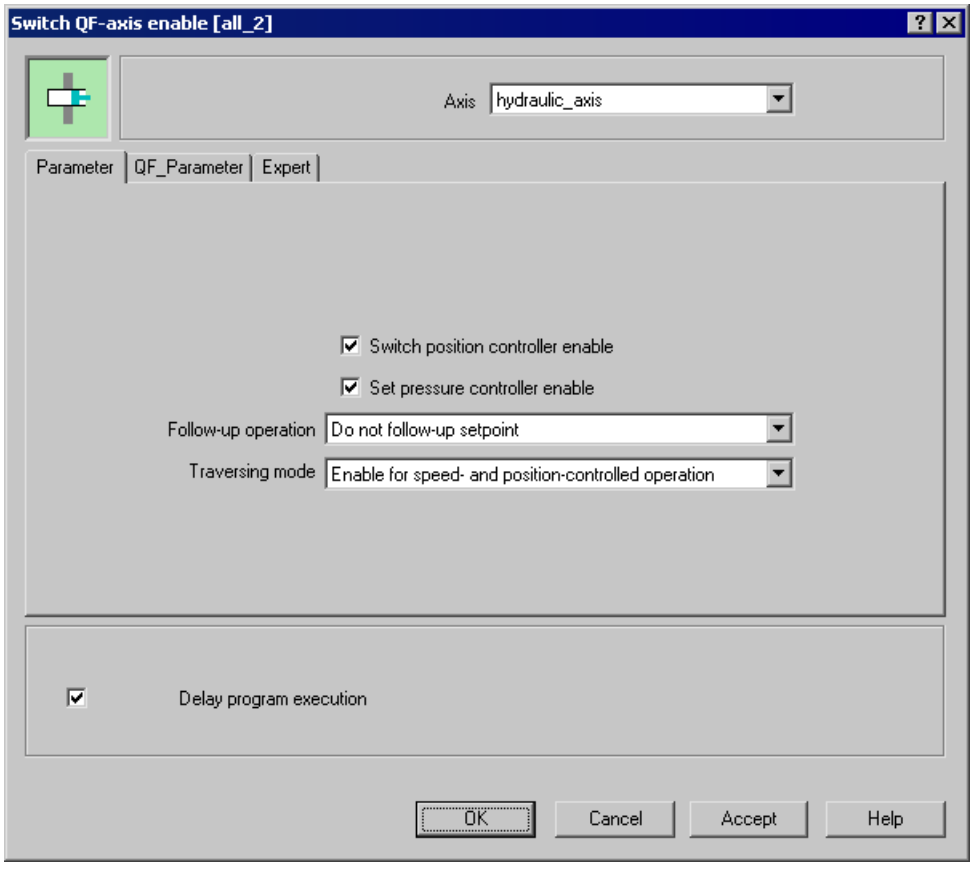

Figure 7-116 Parameter screen form: Switch QF axis enable

The following conditions must be fulfilled in order to execute motion commands on the axis:

1. If the Q-valve (actuator for volumetric flow) is assigned to multiple axes: Access to the Q-valve is ensured
2. Enable for the Q-valve is issued
3. Additional conditions for axes with force/pressure control by means of a pressure limitation valve (P-valve, actuator for force/pressure control):
   - If the pressure limitation valve is assigned to multiple axes: Access to the pressure limitation valve is ensured
   - Enable for the pressure limitation valve is issued
4. Additional conditions for position, synchronized and path axes: Position controller enable is issued
5. Follow-up mode canceled

Until all conditions are fulfilled, the axis remains in follow-up mode (see Follow-up mode for various axis technologies (Page 4253) table).

The current status of enables can be accessed via system variables, which are specified in the description of the respective parameter (see Overview of parameters for Switch QF axis enable (Page 4263)).

For additional information on **axis enables**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Switch QF axis enable

Remove QF axis enable

You use this command to remove the enables from an axis with a hydraulic drive (for axes with an electric drive, you use the Remove axis enable function).

The force/pressure control can also be enabled or disabled on axes with force/pressure control.

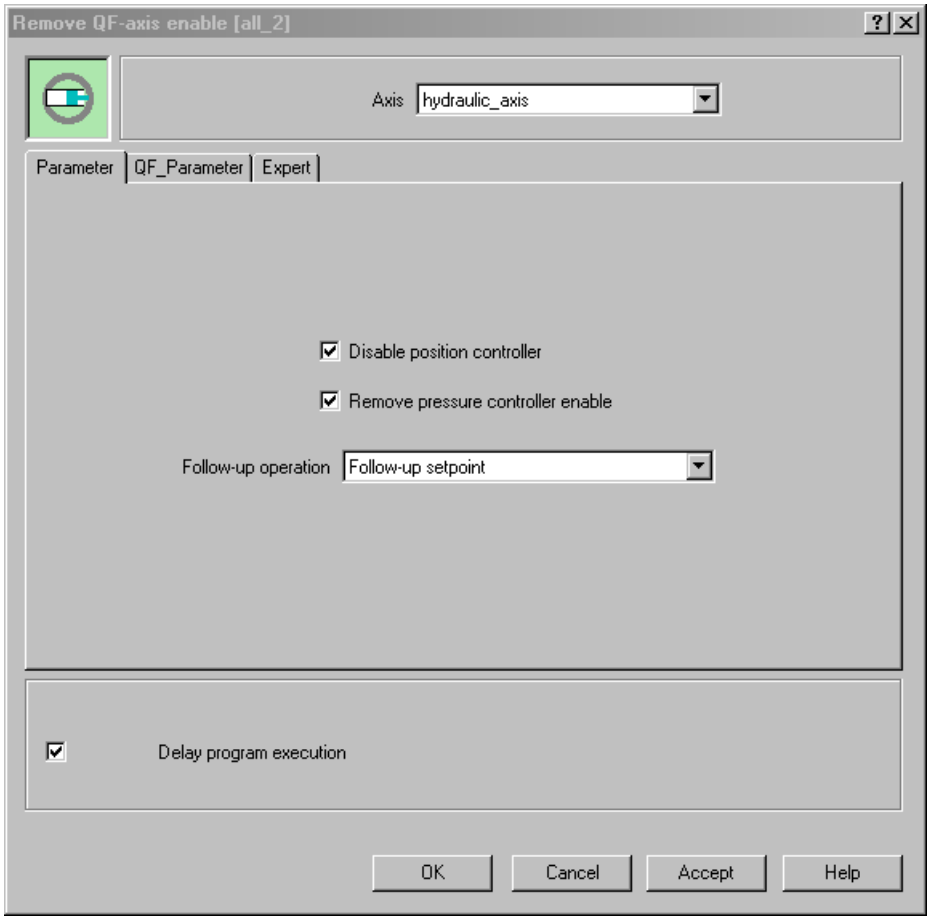

Figure 7-117 Parameter screen form: Remove QF axis enable

The following conditions must be fulfilled in order to execute motion commands on the axis:

1. If the Q-valve (actuator for volumetric flow) is assigned to multiple axes: Access to the Q-valve is ensured
2. Enable for the Q-valve is issued
3. Additional conditions for axes with force/pressure control by means of a pressure limitation valve (P-valve, actuator for force/pressure control):
   - If the pressure limitation valve is assigned to multiple axes: Access to the pressure limitation valve is ensured
   - Enable for the pressure limitation valve is issued
4. Additional conditions for position, synchronized and path axes: Position controller enable is issued
5. Follow-up mode canceled

Until all conditions are fulfilled, the axis remains in follow-up mode (see Follow-up mode for various axis technologies (Page 4253) table).

The current status of enables can be accessed via system variables, which are specified in the description of the respective parameter (see Overview of parameters for Remove QF axis enable (Page 4253)).

For additional information on **axis enables**, see the TO Axis Electric/Hydraulic Function Manual.

Speed preset

This command starts an axis in speed-controlled mode.

The axis is accelerated or decelerated to the programmed rotational speed (velocity). Once this speed is reached, it is held constant.

When the constant motion phase is limited (**Constant traversing time** parameter in the Dynamic response tab), the axis is decelerated to the set speed of 0 once the specified time has elapsed.

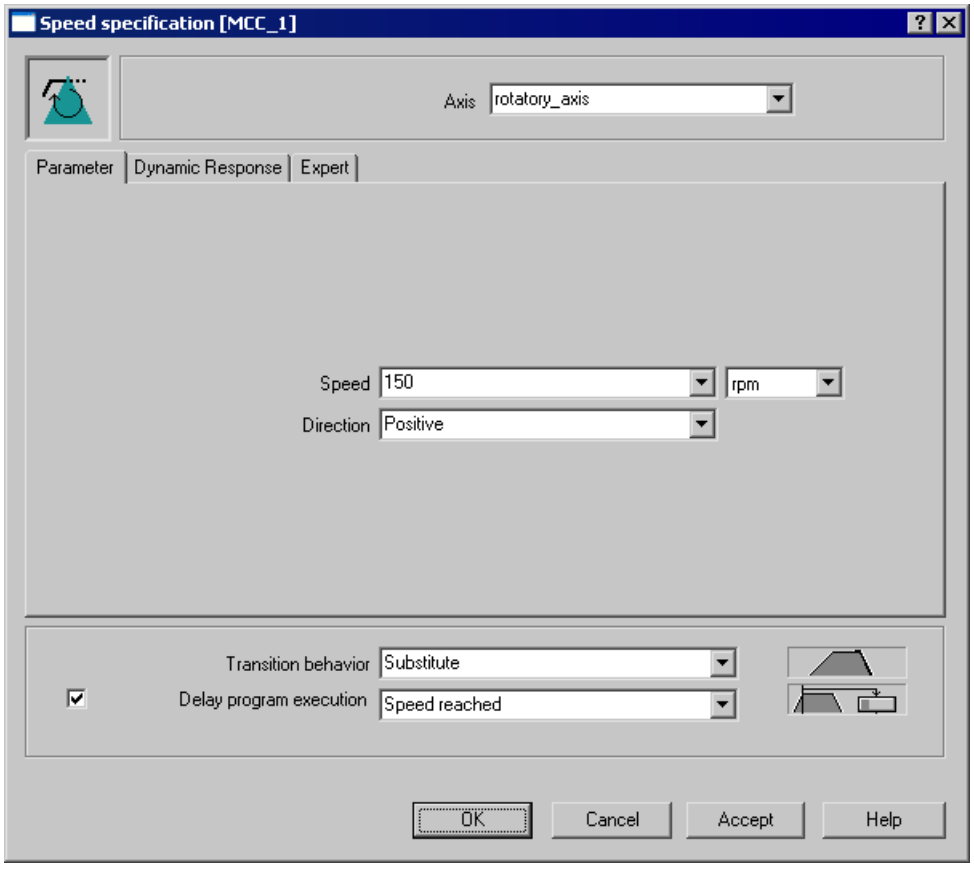

Figure 7-118 Parameter screen form: Speed specification

For additional information on **moving axes**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for speed specification

Table 7-135 Overview of parameters for speed specification

Field/button	Meaning/instruction
Axis	In Axis, select which axis the command is being programmed for. The list contains: • All axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.
Parameters tab	See Overview of parameters for Speed specification - Parameters tab (Page 4275)
Dynamic response tab	See Overview of parameters for Speed specification - Dynamic response tab (Page 4276)
Expert tab	See Overview of parameters for Speed specification - Expert tab (Page 4276)

Field/button	Meaning/instruction
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036)
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037)

Overview of parameters for Speed specification – Parameters tab

Table 7-136 Overview of parameters for Speed specification – Parameters tab

Field/Button	Explanation/Instructions
speed	Speed value during the constant speed phase. Enter the value in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Resulting velocity** An existing acceleration or deceleration motion of the axis is ended, taking into account the jerk parameters in the Dynamic response tab. The axis continues at the resulting velocity. The programmed transition behavior must be "Substitute". **Current** **last speed programmed** **Default** See also Selection list (combo box) (Page 4022) System variable for default: userDefaultDynamics.velocity See also the general description of the Dynamic response tab (Page 4031).
Direction	Select the direction of rotation. **From speed sign** Direction is obtained from speed sign. **Positive** Positive direction **Negative** Negative direction **last direction programmed** **Default** See also Selection list (combo box) (Page 4022) System variable for default: userDefaultDynamics.direction

Overview of parameters for Speed specification – Dynamic response tab

Table 7-137 Overview of parameters for Speed specification – Dynamic response tab

Field/Button	Explanation/Instructions
	The Dynamic response tab is described in detail in Overview of parameters - Dynamic response tab (Page 4031).
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefaultDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefaultDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefaultDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefaultDynamics.positiveAccelStartJerk userDefaultDynamics.positiveAccelEndJerk userDefaultDynamics.negativeAccelStartJerk userDefaultDynamics.negativeAccelEndJerk
Constant traversing time	A time limit can be programmed for the command. To do so, activate the check box and enter the time duration of the constant motion phase.

Start axis position-controlled

The command starts a position or synchronized axis in position-controlled mode.

The axis is accelerated or decelerated to the programmed velocity. Once this velocity is reached, it is held constant.

When the constant motion phase is limited (**Constant traversing time** parameter in the Dynamic response tab), the axis is decelerated to the set velocity of 0 once the specified time has elapsed.

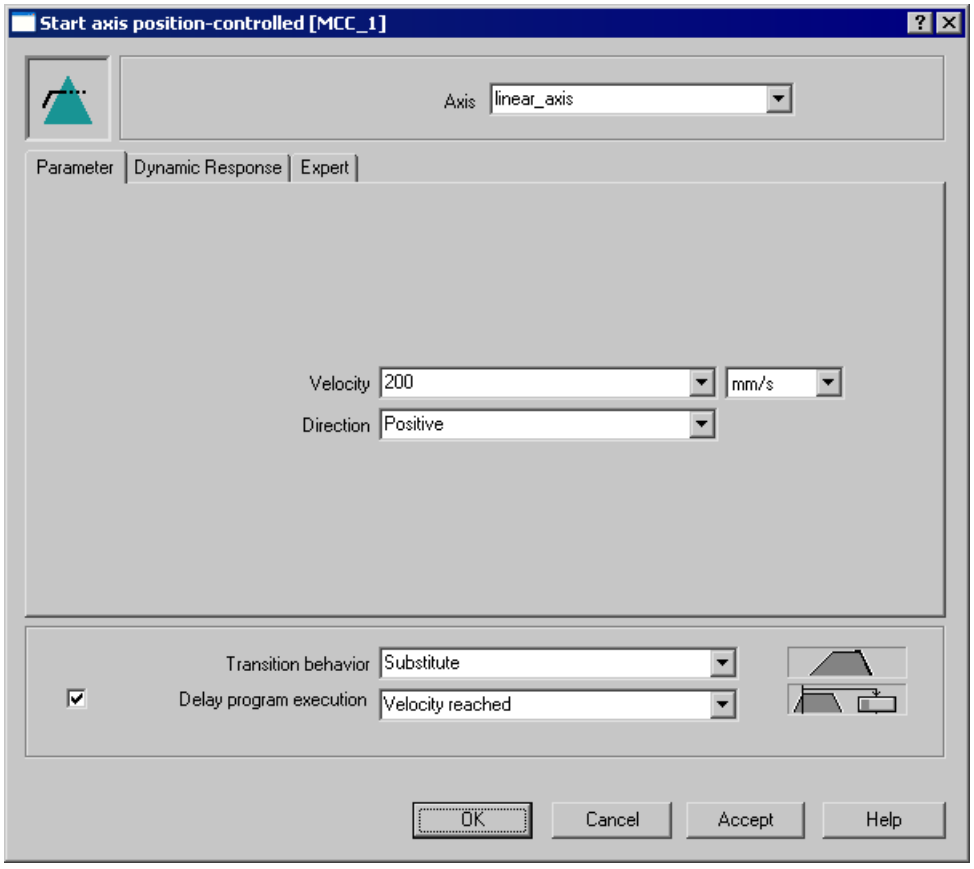

Figure 7-119 Parameter screen form: Start axis position-controlled

For additional information on **moving axes**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Start axis position-controlled

Table 7-140 Overview of parameters for Start axis position-controlled

Field/button	Meaning/instruction
Axis	In Axis, select the axis for which the command is to be programmed. The list contains: • All position, synchronized and path axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): PosAxis, FollowingAxis or _PathAxis.
Parameters tab	See Overview of parameters for Start axis position-controlled – Parameters tab (Page 4279)
Dynamic response tab	See Overview of parameters for Start axis position-controlled – Dynamic response tab (Page 4280)
Expert tab	See Overview of parameters for Start axis position-controlled – Expert tab (Page 4280)

Field/button	Meaning/instruction
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Stop axis

This command stops the motion of an axis and is effective for all single axis motions. The motion can be stopped with Normal stop or Quick stop.

- Normal stop: This command acts on all single axis motions (positioning and speed motions), but not on synchronous motions.
- Quick stop: This command also acts on synchronous motions. In addition, the axis is disabled with respect to further motion commands; this state can be canceled with the commands "Remove axis enable" (Page 4258)or "Reset object" (Page 4193).

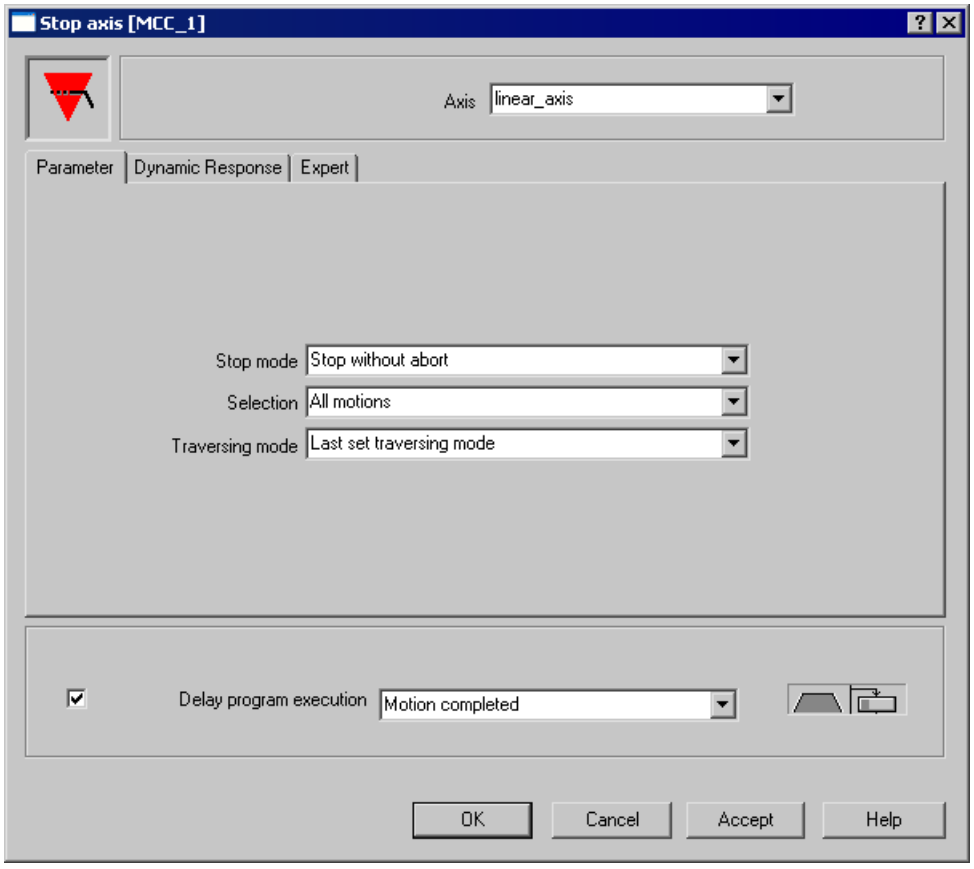

Figure 7-120 Parameter screen form: Stop axis

For additional information on the **quick stop** function, see the TO Axis Electric/Hydraulic Function Manual.

For additional information on the **normal stop** function, see the TO Axis Electric/Hydraulic Function Manual.

For additional information on the **traversing mode**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Stop axis

Table 7-145 Overview of parameters for Stop axis

Field/button	Meaning/instruction
Axis	In Axis, select which axis is to be stopped. The list contains: • All axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.
Parameters tab	See Overview of parameters for Stop axis – Parameters tab (Page 4284)

Field/button	Meaning/instruction
Expert tab	See Overview of parameters for Stop axis – Expert tab (Page 4286)
Delay program execution	• Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037)

Overview of parameters for Stop axis – Parameters tab

Table 7-146 Overview of parameters for Stop axis – Parameters tab

Field/button	Meaning/instruction
Stop mode	Select a stop mode here. Only those motions that have been stopped in "normal stop without abort" mode can be continued with the "Continue motion" (Page 4287) command. No other motions can be continued. In the case of a quick stop, the axis is disabled with respect to further motion commands; this state can be cancelled with the commands "Remove axis enable" (Page 4258) or "Reset object" (Page 4193). **Normal stop without abort** (default value) The motion specified in the **Selection** field is stopped with the programmed dynamic response parameters (**Dynamic response** tab – see Overview of parameters for Stop axis - Dynamic response tab (Page 4285)). It can be continued with the "Continue motion" (Page 4287) command. No other commands for the axis may be programmed between the stop command and the continue command. The command does not act on synchronous motions. **Normal stop with abort** The motion specified in the **Selection** field is stopped with the programmed dynamic response parameters (**Dynamic response** tab – see Overview of parameters for Stop axis - Dynamic response tab (Page 4285)). The motion cannot be continued. The command does not act on synchronous motions. **Quick stop at maximum deceleration** The motion is stopped according to interpolation using the maximum dynamic values on the axis. It cannot be continued. **Quick stop within defined period** The motion can be brought to a standstill in the programmed time. You program the time in the **Time for deceleration** parameter in the **Dynamic response** tab, see Overview of parameters for Stop axis - Dynamic response tab (Page 4285). The motion cannot be continued. **Stopping with preassigned braking ramp** The motion is stopped via the preconfigured braking ramp. This is set during configuration (configuration data emergencyRampGenerator.maxDeceleration). The motion cannot be continued. **Quick stop with dynamic response parameters** The motion is stopped with the programmed dynamic response parameters (**Dynamic response** tab – see Overview of parameters for Stop axis - Dynamic response tab (Page 4285)). The motion cannot be continued.
Selection	Select whether you want to stop the motion as a whole, only the basic motion, or only the superimposed motion. This parameter can only be selected for the following stop modes: • Normal stop without abort (default value) • Normal stop with abort **All motions** (default value) All motions of the programmed axis are stopped. **Basic motion** The basic motion is stopped. **Superimposed motion** The superimposed motion is stopped.

Field/button	Meaning/instruction
Traversing mode	**Position-controlled** For positioning and synchronous axes only: Axis is switched from the current traversing mode (for example, speed control, force control, or torque control) to position control, and stopped. **Speed controlled** Axis is switched from the current traversing mode (for example, position control, force control, or torque control) to speed control, and stopped. The speed ramp takes effect immediately; an existing following error does not have to be removed first. If position-controlled motions are stopped in speed-controlled mode, the axis is disabled with respect to further motion commands; this state can be cancelled with the commands **Remove axis enable** or **Reset object**. **Last set traversing mode** (default value) Axis is switched from the current traversing mode (for example, position control, speed control, force control, or torque control) to the last set traversing mode (position or speed control), and stopped.

Overview of parameters for Stop axis – Dynamic response tab

Table 7-147 Overview of parameters for Stop axis – Dynamic response tab

Field/button	Meaning/instruction
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031).
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefaultDynamics.profile
Acceleration	The meaning depends on the acceleration model used, which can be selected via the configuration data TypeOfAxis.DecodingConfig.directionDynamic: • **Non-direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = NO (default value) The value has no effect. • **Direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = YES The value causes deceleration when the direction of rotation is negative and has no effect when the direction of rotation is positive. The entered value acts during the constant deceleration phase. For additional information on specifying the acceleration and deceleration (acceleration model), see the TO Axis Electric/Hydraulic Function Manual. System variable for default: userDefaultDynamics.positiveAccel

Field/button	Meaning/instruction
Deceleration	The meaning depends on the acceleration model used, which can be selected via the configuration data TypeOfAxis.DecodingConfig.directionDynamic: • **Non-direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = NO (default) The value causes deceleration in the motion of the axis, independent of the direction of motion. • **Direction-based acceleration model** TypeOfAxis.DecodingConfig.directionDynamic = YES The value causes deceleration when the direction of rotation is positive and has no effect when the direction of rotation is negative. The entered value acts during the constant deceleration phase. For additional information on specifying the acceleration and deceleration (acceleration model), see the TO Axis Electric/Hydraulic Function Manual. System variable for default: userDefaultDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefaultDynamics.positiveAccelStartJerk userDefaultDynamics.positiveAccelEndJerk userDefaultDynamics.negativeAccelStartJerk userDefaultDynamics.negativeAccelEndJerk
Time for deceleration	The entered value determines the duration of the braking operation in the **Quick stop within defined period** stop mode. System variable for default: userDefaultDynamics.stopTime

Continue motion

This command continues a motion that has been stopped. The following motions can be continued:

- All speed-controlled motions that were brought to a standstill using the **Normal stop without abort** stop mode,
- all position-controlled motions that were brought to a standstill using the **Normal stop without abort** stop mode and not in speed-controlled mode.

The axis must not receive any new motion commands between interruption and continuation of the interrupted motion.

Home axis

With a position axis or synchronized axis, the position values that are displayed or entered refer to the coordinate system of the axis. The coordinate system of the axis must be aligned to the real physical position of the axis.

If you are using an absolute measuring system, the alignment need only be done once during commissioning. When commissioning is completed, the position value will be known when the machine is switched on.

With an incremental measuring system, the alignment must be repeated each time the machine is switched on. The alignment is achieved via homing.

Note

Traversing commands with relative position specification can always be executed.

The axis can be configured to indicate whether traversing commands with absolute position specification can also be executed on a non-homed axis. Configuration data: TypeOfAxis.homing.referencingNecessary.

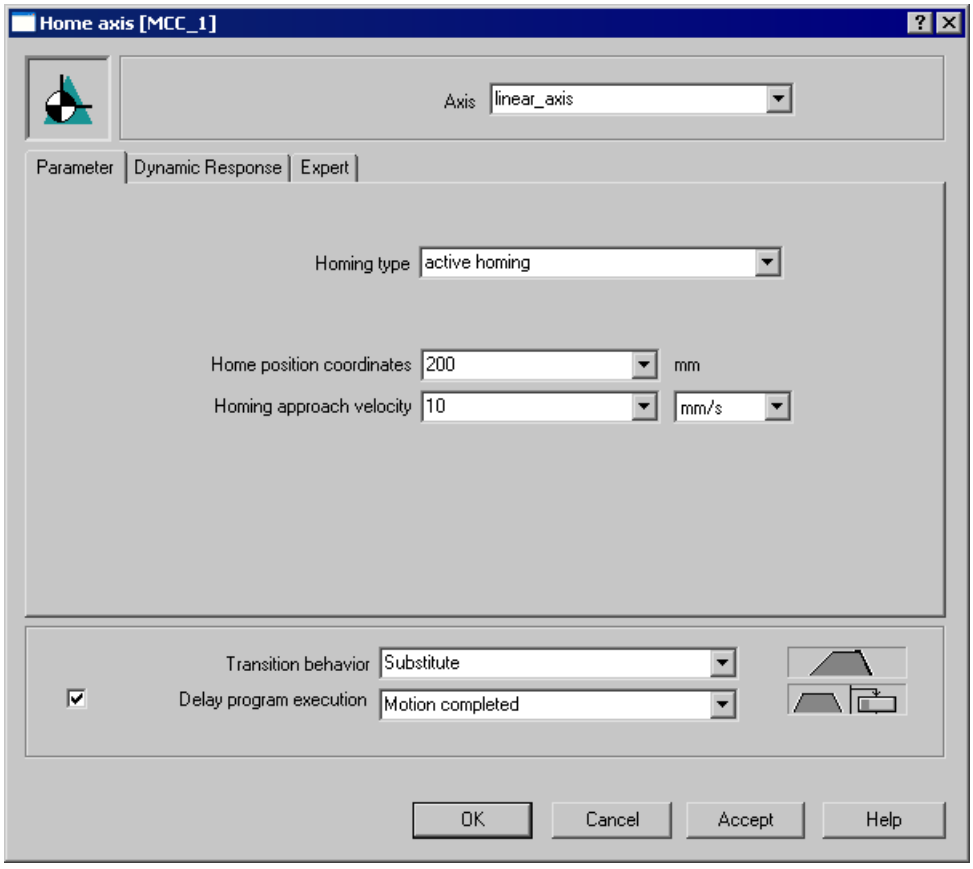

Figure 7-122 Parameter screen form: Home axis

For additional information on **homing**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Home axis

Table 7-154 Overview of parameters for Home axis

Field/button	Meaning/instruction
Axis	In Axis, select which axis is to be homed. The list contains: • All position, synchronized and path axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All variables with the following technology object data types declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): PosAxis, FollowingAxis or _PathAxis.
Parameters tab	See Overview of parameters for Home axis – Parameters tab (Page 4292)
Dynamic response tab	See Overview of parameters for Home axis – Dynamic response tab (Page 4294)
Expert tab	See Overview of parameters for Home axis – Expert tab (Page 4294)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036)
Delay program execution	• Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037)

Overview of parameters for Home axis – Parameters tab

Table 7-155 Overview of parameters for Home axis – Parameters tab

Field/button	Meaning/instruction
Homing type	Select among the permitted homing types: **Active homing** (default value) Homing occurs by means of a separate traversing motion of the axis. The homing mode is specified when you configure the axis during the commissioning phase. **Passive homing** The homing command itself does not trigger any active traversing motion of the axis. Rather, homing occurs during the next axis motion. The homing mode is specified when you configure the axis during the commissioning phase. Required settings: 1. For **Home axis** command: Deactivate the **Delay program execution** checkbox. 2. For the subsequent command: Select **Attach** as the **Transition behavior** from the active command. **Set home position** The value of the home position coordinate is assigned to the current position (actual value) of the axis. There is no active traversing motion. **Relative home position setting** The value of the home position coordinate is added to the current position (actual value) of the axis. There is no active traversing motion. **Absolute encoder adjustment** Absolute encoder adjustment is only possible if the axis was configured as an absolute encoder or a cyclic absolute encoder during commissioning. The offset between the axis zero point and the encoder zero point is determined by selecting a value for the absolute encoder offset. There is no active traversing motion. Generally speaking, the adjustment only needs to be repeated in exceptional circumstances (see Motion Control TO Axis Electric/Hydraulic, External Encoder Function Manual). **Absolute encoder adjustment with specification of the position value** Absolute encoder adjustment with specification of the position value is only possible if the axis was configured as an absolute encoder or a cyclic absolute encoder during commissioning. The value of the home position coordinate is assigned to the current position (actual value) of the axis, and the offset (absolute encoder offset) between the axis zero point and the encoder zero point is calculated from this. There is no active traversing motion. Generally speaking, the adjustment only needs to be repeated in exceptional circumstances (see Motion Control TO Axis Electric/Hydraulic, External Encoder Function Manual).
Home position coordinates	Not when homing type = absolute encoder adjustment. Coordinates of the home position in the reference system of the axis. Enter the value in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefaultHoming.homingPosition

Field/button	Meaning/instruction
Homing approach velocity	Only when homing type = Active homing. Velocity at which the axis approaches the homing output cam (only with homing mode **With homing output cam and encoder zero mark** or **Encoder zero mark only**) Enter the value in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Current** **last programmed** **default value** See Selection list (combo box) (Page 4022). System variable for default: userDefaultHoming.homingApproachVelocity

Note

Note that when the axis to be homed is defined on the device and configured with several axis data sets and different encoder types (e.g. absolute encoder or incremental encoder):

Only the homing types permitted for one encoder type are offered in the Parameters tab. This encoder type can be identified in the "Expert" (Page 4034) tab at **TO properties**. The configuration data or system variables that affect the parameter screen form are displayed there. These settings cannot be changed. See also Section "Using a technology object (Page 4024)".

Remedy (three options):

- Use the "System function call (Page 4161)" MCC command and configure the **_homing** system function.
  For the assignment of the parameters of the **_homing** system function to the parameters of the **Home axis** MCC command, see Section "Relevant system functions for Home axis (Page 4294)".
- Use the "ST zoom (Page 4188)" MCC command and program the **_homing** system function in the SIMOTION ST (Structured Text) programming language.
- Instead of using an axis defined on the device, use a variable of the appropriate data type, see Section "Data types of the technology objects (Page 4060)".
  In the "Expert (Page 4034)" tab, the configuration data or system variables that affect the parameter screen form are displayed at **TO properties**. Since the assignment of the variables to a technology object is not performed until the program runtime, the values of the configuration data or system variables can be freely selected and the parameter screen form adapted accordingly. See also Section "Using a variable of the technology object data type (Page 4024)".
  In this case, make sure the technology object is assigned correctly to the variables.

Overview of parameters for Home axis – Dynamic response tab

Table 7-156 Overview of parameters for Home axis – Dynamic response tab

Field/Button	Explanation/Instructions
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031). The parameters in the Dynamic response tab are evaluated only with homing type Active homing.
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefaultDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefaultDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefaultDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefaultDynamics.positiveAccelStartJerk userDefaultDynamics.positiveAccelEndJerk userDefaultDynamics.negativeAccelStartJerk userDefaultDynamics.negativeAccelEndJerk

Referencing mode

Various homing modes are possible for Active homing and Passive homing homing types. See table below.

You specify the homing modes separately for each encoder system when configuring the axis.

Table 7-159 Homing mode for active and passive homing

Referencing mode	Description	
	Active homing	**Passive homing**
	Homing occurs by means of a separate traversing motion of the axis. Configuration data for homing mode: TypeOfAxis.NumberOfEncoders. Encoder_x.IncHomingEncoder. homingMode.	The homing command itself does not trigger any active traversing motion of the axis. Rather, homing occurs during the next axis motion. Configuration data for homing mode: TypeOfAxis.NumberOfEncoders. Encoder_x.IncHomingEncoder. passiveHomingMode.
With homing output cam and encoder zero mark	The homing command initiates axis motion towards the homing output cam. After the homing output cam is crossed, the axis moves to the next zero mark of the measuring system. Once the first zero mark is detected, the measuring system is synchronized. The axis is then moved by the amount of the home position offset. The axis is then at the home position. The position value is set to the value indicated in the home position coordinates.	After the homing output cam is detected, the next zero mark of the measuring system is active for synchronization. Once the first zero mark is detected after the homing output cam, synchronization takes place. The position value of the axis is set to the value indicated in the home position coordinates.
External zero mark only	The homing command initiates axis motion towards the external zero mark (e.g., homing output cam). Once the external zero mark is crossed, the measuring system is synchronized to the edge of the external zero mark. The axis is then moved by the amount of the home position offset. The axis is then at the home position. The position value is set to the value indicated in the home position coordinates.	Once the external zero mark (e.g. homing output cam) has been detected, synchronization with the edge takes place. The position value of the axis is set to the value indicated in the home position coordinates.
Encoder zero mark only	The homing command initiates an axis motion towards the zero mark of the encoder. When the zero mark is crossed, the measuring system of the axis is synchronized to this zero mark. The axis is then moved by the amount of the home position offset. The axis is then at the home position. The position value is set to the value indicated in the home position coordinates.	Once the zero mark is detected, synchronization occurs. The position value of the axis is set to the value indicated in the home position coordinates.

Home position offset

If you do not wish the axis to be positioned on the synchronization point after homing, but traversed further by a defined distance, then you must enter a home position offset.

The home position is then calculated from the position of the zero mark and the amount of the home position offset.

Position axis

The command traverses the defined axis via a parameterizable velocity profile to the programmed target position. The position can be specified as an absolute or relative position.

The programmed position must lie within the software limit switches.

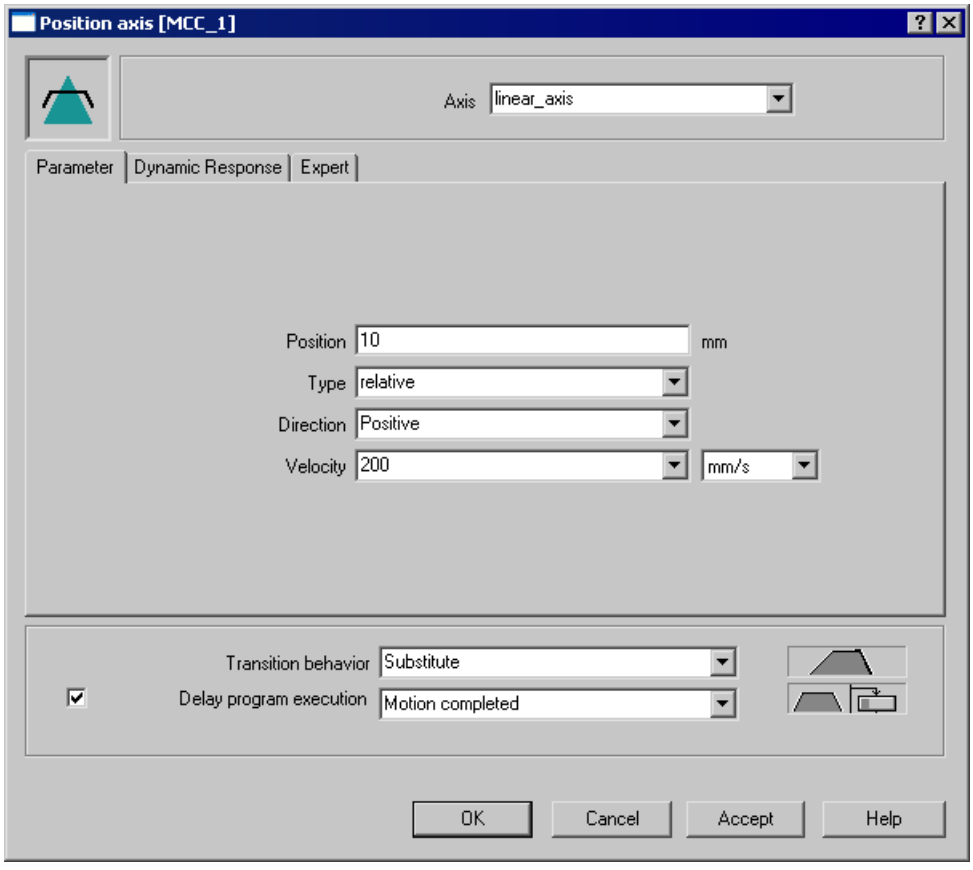

Figure 7-123 Parameter screen form: Position axis

For additional information on **position axes**, see the TO Axis Electric/Hydraulic Function Manual.

Parameter screen form: Position axis

Table 7-160 Parameter screen form: Position axis

Field/button	Meaning/instruction
Axis	In Axis, select which axis is to travel to a target position. The list contains: • All position, synchronized and path axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): PosAxis, FollowingAxis or _PathAxis.
Parameters tab	See Overview of parameters for Position axis – Parameters tab (Page 4298)
Dynamic response tab	See Overview of parameters for Position axis – Dynamic response tab (Page 4299)
Expert tab	See Overview of parameters for Position axis – Expert tab (Page 4300)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Position axis – Parameters tab

Table 7-161 Overview of parameters for Position axis – Parameters tab

Field/button	Meaning/instruction
Position	The meaning depends on the following **type** parameter: • "Absolute" type: End position of the motion • "Relative" type: Distance traversed during the motion, starting from the current axis position. Enter the value as a signed floating-point number.
Type	Here, you specify the meaning of the programmed position in more detail (see above). **Absolute** (default value) The programmed position value is the end position of the motion. **Relative** The value entered in Position generates the traversing distance of the motion, starting from the current axis position.

Field/button	Meaning/instruction
Direction	The direction of motion must be specified in the following cases: • Type of motion (see above) is relative. • Type of motion (see above) is absolute **and** the axis is a modulo axis. If a positive or negative direction is programmed, the direction has a higher priority than the position. The position is approached as an absolute value, a negative absolute value, or as a function of sign. The velocity sign is determined by the specified direction. Select the direction of motion. **From position** The direction of motion is determined by the position sign. **Positive** The direction of motion for the command is in the positive axis direction. With relative motion, the sign of the position is ignored. **Negative** The direction of motion for the command is in the negative axis direction. With relative motion, the sign of the position is ignored. **Shortest path** • For type absolute and modulo axis: The direction of motion for the current command is the direction in which the programmed target position can be reached via the shortest path. • For type relative: The direction of motion is determined by the position sign. **Last direction set in the program** See Selection list (combo box) (Page 4022)
Velocity	Velocity value during the constant velocity phase. Enter the value in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Current** **Last programmed velocity** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefaultDynamics.velocity See also Dynamic response tab (Page 4031).

Overview of parameters for Position axis – Dynamic response tab

Table 7-162 Overview of parameters for Position axis – Dynamic response tab

Field/Button	Explanation/Instructions
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031).
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefaultDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefaultDynamics.positiveAccel

Field/Button	Explanation/Instructions
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefaultDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefaultDynamics.positiveAccelStartJerk userDefaultDynamics.positiveAccelEndJerk userDefaultDynamics.negativeAccelStartJerk userDefaultDynamics.negativeAccelEndJerk

Overview of parameters for Position axis – Expert tab

Table 7-163 Overview of parameters for Position axis – Expert tab

Field/Button	Explanation/instructions
	The Expert tab is described in detail in Expert tab (Page 4034).
CommandID variable	If you enter the name of a CommandId-type variable, you can track the command status with this variable.
TO properties	Here, you can adapt the parameter dialog box as needed to reflect the effects of axis configuration data or system variables.
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Example of positioning

An axis must travel at a velocity of 100 mm/s to the position at 1,000 mm. The position controller enable must be set for the axis before it can be positioned. The pulse and drive enables must also be set.

Travel to fixed endstop

This command activates

- Monitoring of "Travel to fixed endstop" in parallel with an axis motion activated by a motion command
- Retention of a clamping torque after reaching the fixed end stop

This process is also referred to as "clamping". The method for detecting that the end stop has been reached (evaluation of the following error or axis torque) is specified during configuration.

This command can also be used to switch over the clamping torque during active clamping.

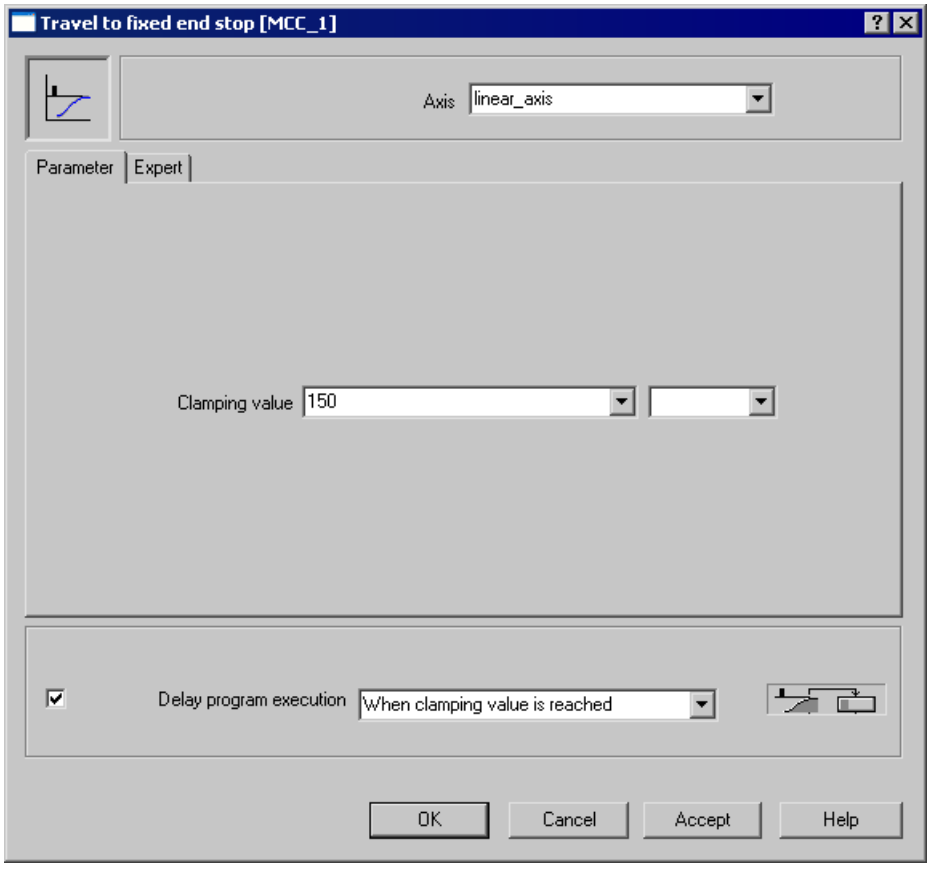

Figure 7-125 Parameter screen form: Travel to fixed end stop

For additional information on **traveling to fixed end stop**, see the TO Axis Electric/Hydraulic Function Manual.

Expert tab	See Overview of parameters for Switch on torque limiting – Expert tab (Page 4310)
Delay program execution	• Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. **If command has been completed or aborted** The next command is executed after the current command has been completed or aborted. **As soon as the torque is limited** The next command is executed as soon as limiting is initiated. **As soon as torque limiting is disabled** The next command is executed as soon as limiting is disabled. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Switch on torque limitation – Parameters tab

Table 7-172 Overview of parameters for Switch on torque limitation – Parameters tab

Field/button	Meaning/instruction
Limiting value	Value to which the torque or force is limited How this value is interpreted, is specified in the **Unit** field. Enter the value in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Last programmed** **Default value** See: Selection list (combo box) (Page 4022) System variable for default: userDefaultTorqueLimiting.torqueLimit. **Note:** In the **Unit** field, specify how this value will be interpreted: • As an absolute value on the motor side or load side in the unit selected on the axis. • As a percentage value of the default value on the motor side or load side.

Field/button	Meaning/instruction
Units	Definition of how the value in the **Limiting value** field will be interpreted. **Load side** The value in the **Limiting value** field will be interpreted as an absolute value for the load side: • For rotary axes: As torque in the unit selected on the axis, e.g. Nm • For linear axes: As force in the unit selected on the axis, e.g. N **Motor side** The value in the **Limiting value** field will be interpreted as an absolute value for the drive side: • For standard motors on rotary or linear axes: As torque in the unit selected on the axis, e.g. Nm • With linear motors: As force in the unit selected on the axis, e.g. N **Load side %** The interpretation of the value in the **Limiting value** field depends on whether a value has been entered directly or an option has been selected: • With direct value specification: The entered value is interpreted as a percentage of the default value (system variable userDefaultTorqueLimiting.torqueLimit). The absolute limiting value acts on the load side and is calculated as follows: Limiting value * userDefaultTorqueLimiting.torqueLimit / 100 – For rotary axes: As torque in the unit selected on the axis, e.g. Nm – For linear axes: As force in the unit selected on the axis, e.g. N • If you select the entry **Last programmed** or **Default value**: Same as the **Load side** selection. **Motor side %** The interpretation of the value in the **Limiting value** field depends on whether a value has been entered directly or an option has been selected: • With direct value specification: The entered value is interpreted as a percentage of the default value (system variable userDefaultTorqueLimiting.torqueLimit). The absolute limiting value acts on the drive side and is calculated as follows: Limiting value * userDefaultTorqueLimiting.torqueLimit / 100 – For standard motors on rotary or linear axes: As torque in the unit selected on the axis, e.g. Nm – With linear motors: As force in the unit selected on the axis, e.g. N • If you select the entry **Last programmed** or **Default value**: Same as the **Motor side** selection.

Time-dependent position profile

With this command, the axis moves along a position profile preset by a cam. The definition range (x-axis) of the cam is interpreted as time, the value range (y-axis) as the corresponding position.

The profile is traversed from a selectable starting time to the end of the cam.

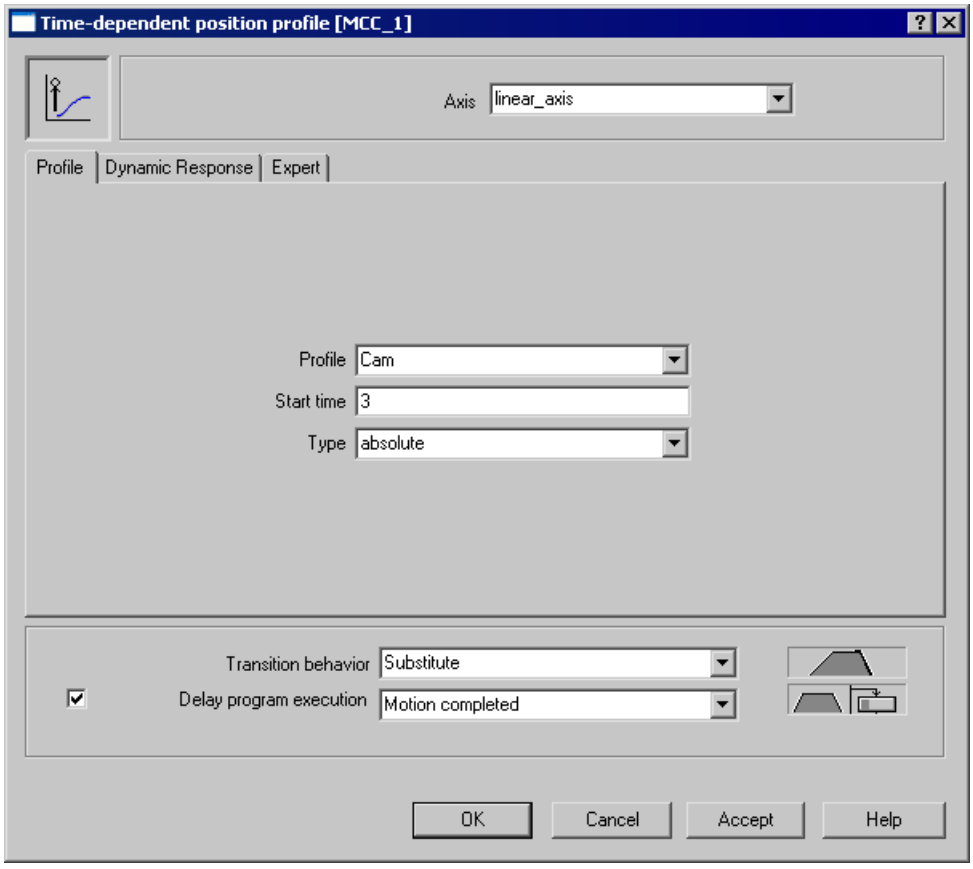

Figure 7-130 Parameter screen form: Time-dependent position profile

For additional information on the **time-dependent position profile**, see the TO Axis Electric/ Hydraulic Function Manual.

Overview of parameters for Time-dependent position profile

Table 7-182 Overview of parameters for Time-dependent position profile

Field/button	Meaning/instruction
Axis	In Axis, select the axis that is to move along the position profile. The list contains: • All position, synchronized and path axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart (see Description of the technology object data types (Page 4060)): PosAxis, FollowingAxis or _PathAxis.
Profile tab	See Overview of parameters for Time-dependent position profile – Profile tab (Page 4318)
Dynamic response tab	See Overview of parameters for Time-dependent position profile – Dynamic response tab (Page 4318)
Expert tab	See Overview of parameters for Time-dependent position profile – Expert tab (Page 4319)

Field/button	Meaning/instruction
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Time-dependent position profile – Profile tab

Table 7-183 Overview of parameters for Time-dependent position profile – Profile tab

Field/Button	Explanation/Instruction
Profile	Here, you select the cam that describes the time-dependent position profile. The following are available: • All cams that are defined on the relevant device. The cams are defined in the CAMS folder in the project navigator. • All technology object-type variables declared in the MCC source file or MCC chart (see Description of the technology object data types (Page 4060)): camType.
Start time	Here you define the start time within the cam for profile execution. If you enter 0.0, the profile is executed from the starting point of the cam. Enter the value as a floating-point number. See also input field (Page 4022).
Type	Here you can decide how the positions defined by the cam are approached: **Absolute**(default value) The y-values of the cam represent absolute position values. **Relative** The y-values of the cam represent relative references to the current axis position.

Overview of parameters for Time-dependent position profile – Dynamic response tab

Table 7-184 Overview of parameters for Time-dependent position profile – Dynamic response tab

Field/Button	Explanation/Instructions
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031). Just like all the parameters in the Dynamic response tab, this parameter is only evaluated while approaching and exiting the profile.
Velocity	The entered value acts during the constant velocity phase. System variable for default: userDefaultDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefaultDynamics.profile

Shift measuring system

This command redefines the actual position. It affects the programming, system variable, and display. You can choose whether to set either a new actual value or a new setpoint.

Note

The command is not associated with a motion.

Actual value and setpoint can also be altered by a defined amount while the axis is in motion (in the case of type relative).

Relative motions are not affected.

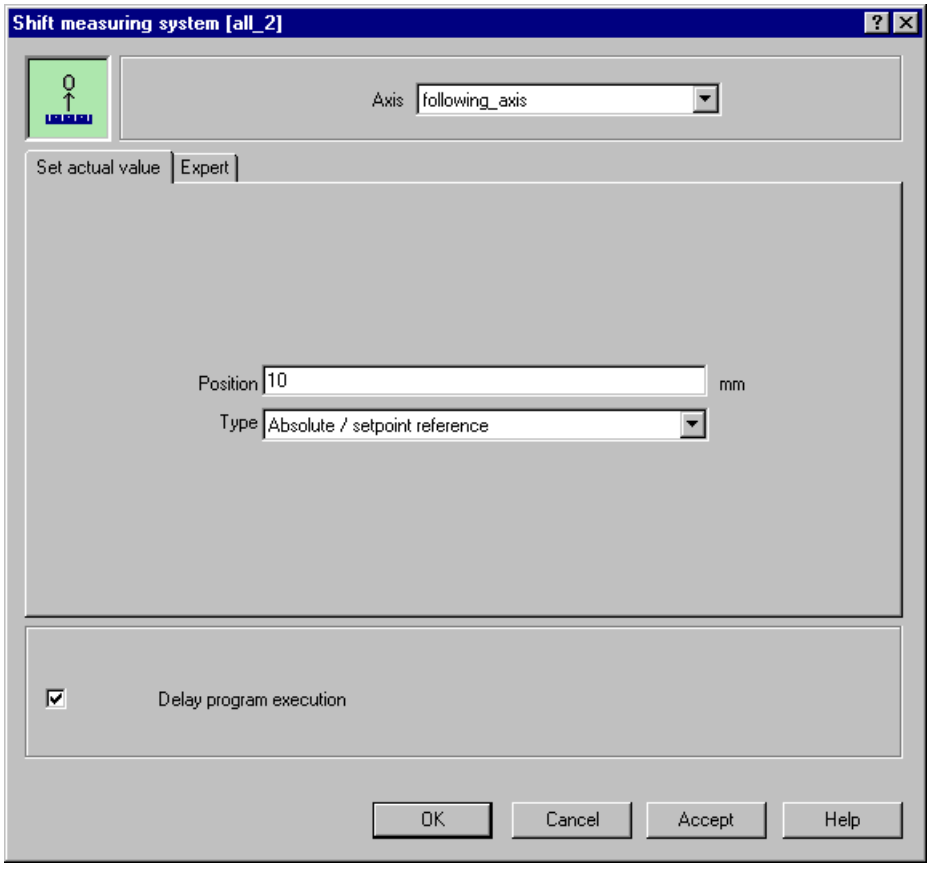

Figure 7-131 Parameter screen form: Shift measuring system

For additional information on **shifting the coordinate system**, see the TO Axis Electric/ Hydraulic Function Manual.

Overview of parameters for Shift measuring system

Table 7-187 Overview of parameters for Shift measuring system

Field/button	Meaning/instruction
Axis	Here, select the axis for which the position is to be reset. The list contains: • All position, synchronized and path axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object data type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): PosAxis, FollowingAxis or _PathAxis.
Set actual value tab	See Overview of parameters for Shift measuring system – Set actual value tab (Page 4322)
Expert tab	See Overview of parameters for Shift measuring system – Expert tab (Page 4322)
Delay program execution	Activate the checkbox if you wish to delay execution of the following command until the current command has been completed. If the checkbox is not activated, the next command is executed immediately.

Overview of parameters for Shift measuring system – Set actual value tab

Table 7-188 Overview of parameters for Shift measuring system – Set actual value tab

Field/Button	Explanation/Instruction
Position	Here, you enter the new position value. See also input field (Page 4022).
Type	Here, you select the position type. **Absolute / actual value reference** The programmed position is set as a new actual value, and the setpoint is corrected, taking into account the following error, and set. **Absolute/setpoint reference (default value)** The programmed position is set as a new setpoint, and the actual value is corrected, taking into account the following error, and set. **Absolute/setpoint reference of superimposed coordinate system** For superimposed motions: The programmed position is set as a new setpoint of the superimposed motion, and the actual value is corrected, taking into account the following error, and set. **Absolute/setpoint reference of basic coordinate system** For superimposed motions: The programmed position is set as the new setpoint of the main motion, and the actual value is corrected, taking into account the following error, and set. **Relative** The programmed position is added to the current setpoint, actual value.

Overview of parameters for Shift measuring system – Expert tab

Table 7-189 Overview of parameters for Shift measuring system – Expert tab

Field/Button	Explanation/instructions
	The Expert tab is described in detail in Expert tab (Page 4034).
CommandID variable	If you enter the name of a CommandId-type variable, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Online correction

The correction value you enter for overriding velocity and acceleration acts on currently active commands and all following commands.

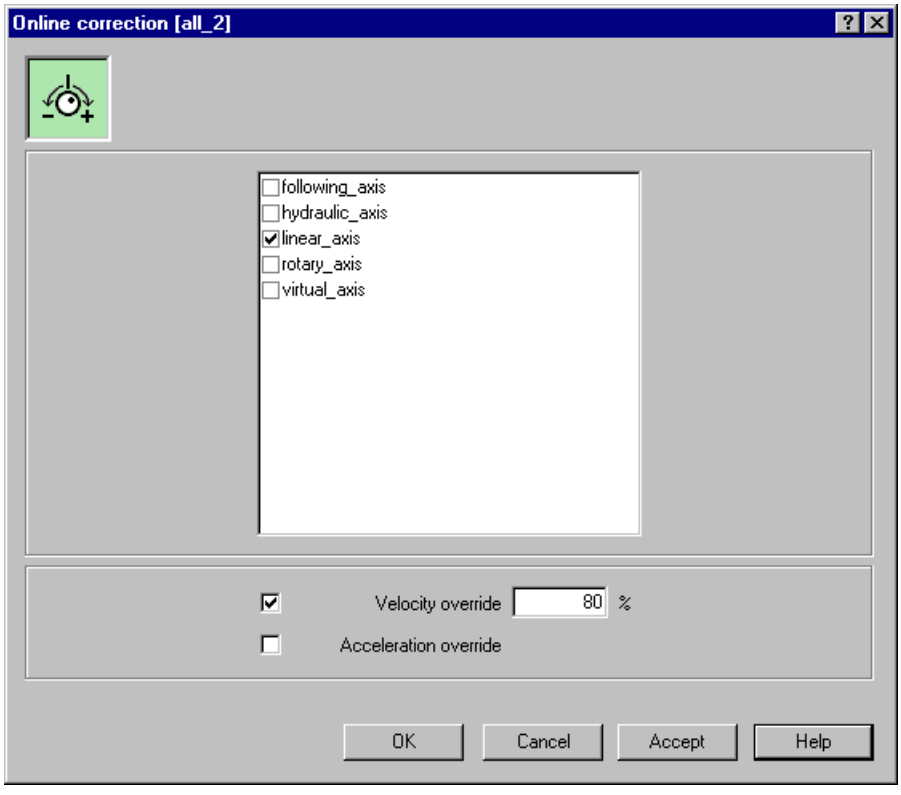

Figure 7-132 Parameter screen form: Online correction

For additional information on **online correction (override)**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Online correction

Table 7-191 Overview of parameters for Online correction

Field/button	Meaning/instruction
Axis	Select the axes for which you wish to program an override. The list contains: • All axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.
Velocity override	• Select this checkbox if you want to program a velocity override. • Enter the override factor here. The current velocity value is corrected by the specified percentage value. Units: Percentage Range of values: 0 - 200 The value acts on all presently active commands as well as on all of the subsequent commands. See also Input fields and selection lists (Page 4022).
Acceleration override	• Select this checkbox if you want to program an acceleration override. • Enter the override factor here. The current acceleration value is corrected by the specified percentage value. Units: Percentage Range of values: 1 - 1000 The value acts on all presently active commands as well as on all of the subsequent commands. See also Input fields and selection lists (Page 4022).

Relevant system variable for Online correction

System variable for drive axis, position axis and following axis technology objects:

- override

Table 7-192 Adjusts the velocity and acceleration override to correct the current velocity and acceleration by the specified percentage

Parameters of the MCC command Online correction	System variable of the technology object *axis*
Axis	
Velocity override	_to.*axis*.override.velocity
Acceleration override	_to.*axis*.override.acceleration

Set axis parameter

This command changes the default parameters (USERDEFAULT) for the specified axis.

The programmed axis parameters go into effect when the relevant parameter is set to the default in a subsequent motion command.

The USERDEFAULT value settings made during axis configuration take effect again after:

- Power On
- The **Reset object** command is made by activating the **Initialize system variables** checkbox.

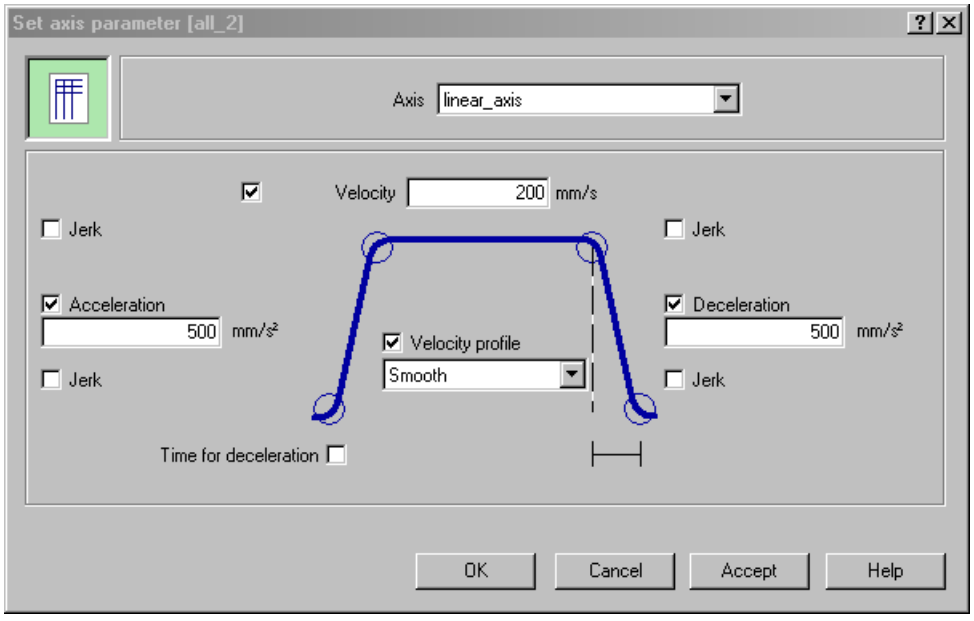

Figure 7-133 Parameter screen form: Set axis parameter

For additional information on **setting axis parameters**, see the TO Axis Electric/Hydraulic Function Manual.

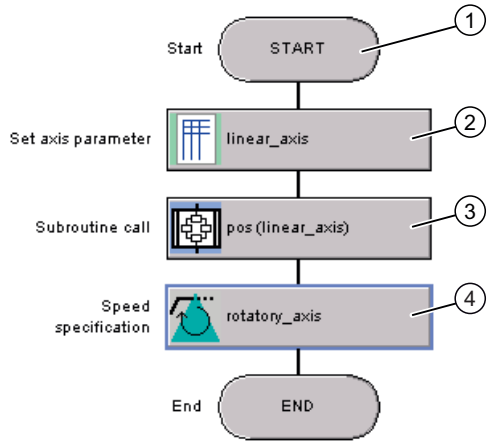
Overview of parameters for Set axis parameter

Table 7-193 Overview of parameters for Set axis parameter

Field/button	Meaning/instruction
Axis	In Axis, select the configured axis for which you wish to set one or more new preassigned values. The list contains: • All axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.
Speed	For speed-controlled axes only Default value for the speed during the constant speed phase. System variable: userDefaultDynamics.velocity • Select this checkbox if you want to alter the default value for the speed. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Velocity	Only for position, synchronized and path axes Preassigned value for velocity during the constant velocity phase. System variable: userDefaultDynamics.velocity • Select this checkbox if you want to alter the default value for velocity. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Velocity profile	Preassigned value for the velocity profile System variable: userDefaultDynamics.profile The velocity profile is used to specify the transitions between the individual motion phases. The velocity profile influences the motion transitions as follows: • At the start and end of the acceleration phase, the transition to the constant acceleration or constant velocity phase • At the start and end of the deceleration phase, the transition to the constant deceleration or constant velocity phase Proceed as follows to change the preassigned value for the velocity profile: • Activate the checkbox. • Select the preassigned value. **Smooth** A velocity profile with smooth acceleration characteristic takes effect for this command. Application: Velocity profile with controllable jerk characteristic **Trapezoidal** (default value) A trapezoidal velocity profile takes effect for this command. Acceleration and deceleration can be specified. See also Overview of parameters in the Dynamic response tab (Page 4031).

Field/button	Meaning/instruction
Acceleration	Preassigned value for the acceleration during the constant acceleration phase. System variable for default: userDefaultDynamics.positiveAccel • Select this checkbox if you want to alter the default value for acceleration. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Deceleration	Preassigned value for deceleration during the constant acceleration phase. System variable: userDefaultDynamics.negativeAccel • Select this checkbox if you want to alter the default value for deceleration. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Jerk at start of acceleration	Default value for the jerk (change in acceleration) at the start of the acceleration phase. System variable: userDefaultDynamics.positiveAccelStartJerk • Activate this checkbox if you want to alter the default value for the jerk at the start of the acceleration. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Jerk at end of acceleration	Default value for the jerk (change in acceleration) at the end of the acceleration phase. System variable: userDefaultDynamics.positiveAccelEndJerk • Activate this checkbox if you want to alter the default value for the jerk at the end of the acceleration. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Jerk at start of deceleration	Default value for the jerk (change in deceleration) at the start of the deceleration phase. System variable: userDefaultDynamics.negativeAccelStartJerk • Activate this checkbox if you want to alter the default value for the jerk at the start of the deceleration. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Jerk at end of deceleration	Default value for the jerk (change in deceleration) at the end of the deceleration phase. System variable: userDefaultDynamics.negativeAccelEndJerk • Activate this checkbox if you want to alter the default value for the jerk at the end of the deceleration. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).
Time for deceleration	Default value for the duration of the braking operation for a quick stop within a defined period, see "Stop axis" (Page 4281). System variable: userDefaultDynamics.stopTime • Activate the checkbox if you want to alter the default value for the duration of the braking operation. • Enter the default value, see input field (Page 4022). See also Overview of parameters in the Dynamic response tab (Page 4031).

Example of Set axis parameter



① Velocity set during configuration in USERDEFAULT = 300 m/s.
② A velocity of 500 m/s is programmed as the USERDEFAULT.
③ If all motion commands in the subroutine have been programmed with the default, the velocity is 500 m/s.
④ A speed of 200 rpm is programmed. The axis rotates at this speed.

Figure 7-134 Example of Set axis parameter

Relevant system variables for Set axis parameter

System variable for drive axis, position axis and following axis technology objects:

- userDefaultDynamics

Table 7-194 Adjusts the default parameters of the specified axis

Jerk at end of deceleration	_to.*axis*.userDefaultDynamics.negativeAccelEndJerk

Set virtual axis values

Use the Set virtual axis values command in order to transfer the position, velocity, and acceleration values for a real master axis or an encoder to a virtual axis. The axis can then, for example, be programmed using a positioning command.

The axis values of the virtual axis are set only when the master axis is moving. If the command is executed when the master axis is stationary, the axis values will not be set until the master axis is next started.

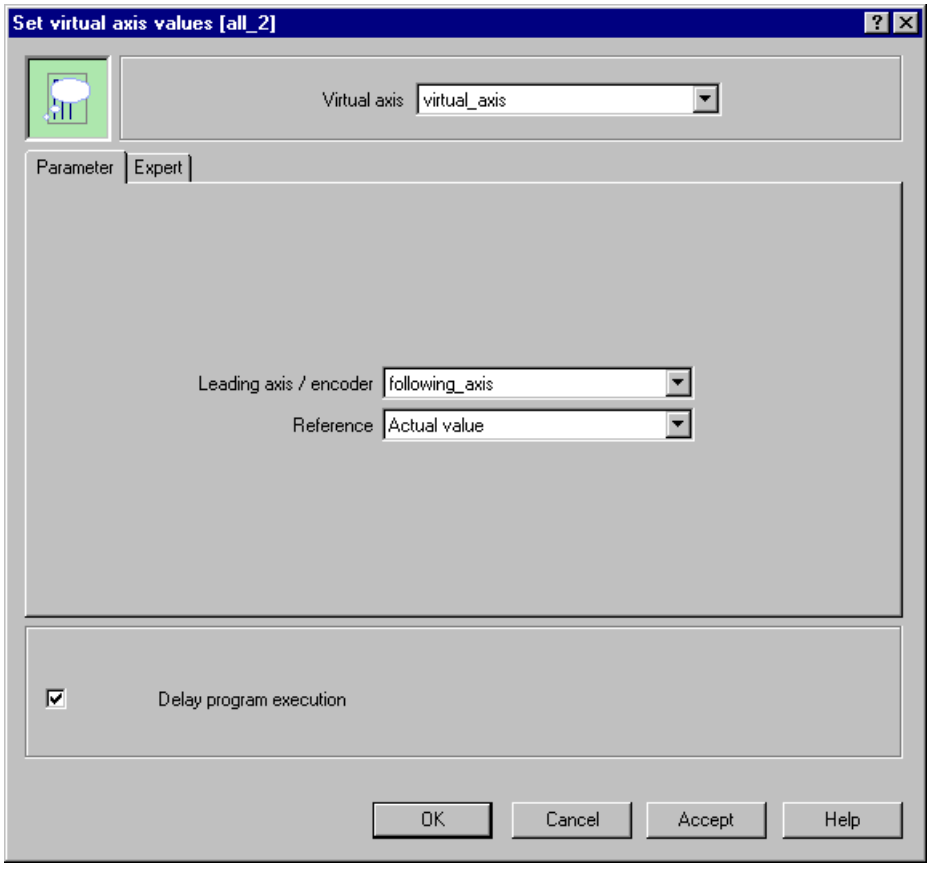

Figure 7-135 Parameter screen form: Set virtual axis values

For additional information on **shifting the coordinate system**, see the TO Axis Electric/ Hydraulic Function Manual.

Overview of parameters for Set virtual axis values

Table 7-195 Overview of parameters for Set virtual axis values

Field/button	Meaning/instruction
Virtual axis	Here, select the axis to be synchronized. All of the virtual axes of the device that have positioning or synchronous operation functionality are displayed.
Parameters tab	See Overview of parameters for Set virtual axis values – Parameters tab (Page 4330)
Expert tab	See Overview of parameters for Set virtual axis values – Expert tab (Page 4331)
Delay program execution	Activate the checkbox if you wish to delay execution of the following command until the current command has been completed. If the checkbox is not activated, the next command is executed immediately.

Overview of parameters for Set virtual axis values – Parameters tab

Table 7-196 Overview of parameters for Set virtual axis values – Parameters tab

Field/button	Meaning/instruction
Leading axis / encoder / external master value	Here, select the axis for which the position, velocity, or acceleration is to be transferred to the virtual axis. The list contains: • All position, following, and path axes and external encoders that are available on the device or a DP master. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types: PosAxis, FollowingAxis, _PathAxis and ExternalEncoderType
Reference	Here, decide whether the virtual axis is to be synchronized to the setpoints or actual values of the leading axis. **Setpoint** The setpoints of the leading axis are accepted for the virtual axis. **Actual value**(default value) The actual values of the leading axis are accepted for the virtual axis.

Delete command queue

The command queue is a memory for motion commands that have been issued by the program, but are not yet active. Commands that have not yet been executed can be deleted from the command queue.

This command allows commands for an axis to be selectively deleted after the axis has been stopped or the motion sequence has been modified.

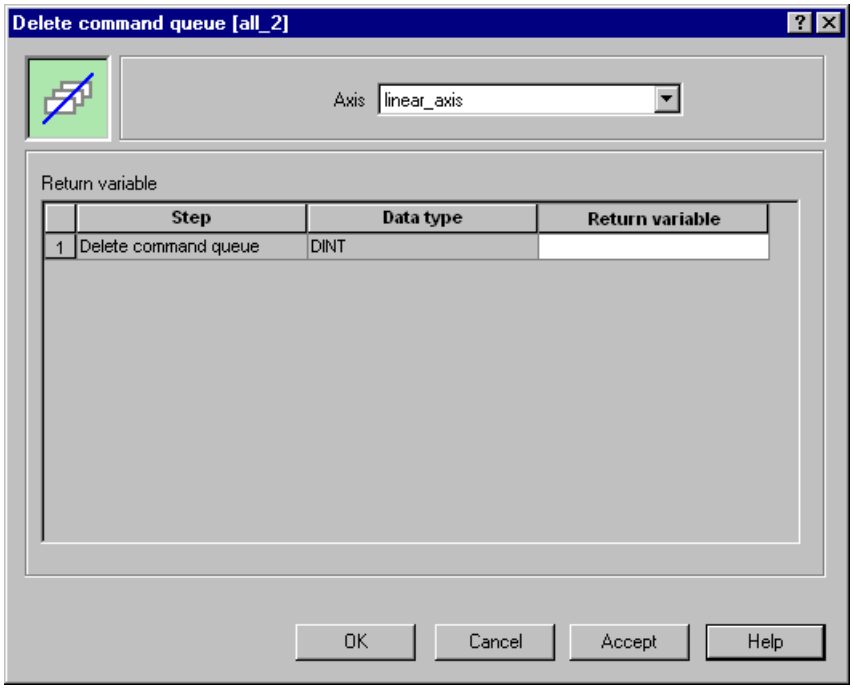

Figure 7-136 Parameter screen form: Delete command queue

For additional information on **deleting the command queue (motion buffer)**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Delete command queue

Table 7-199 Overview of parameters for Delete command queue

Field/button	Meaning/instruction
Axis	In Axis, select the axis for which the command is to be programmed. The list contains: • All axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.

Switch parameter set

Using this command, you can switch over the active controller data set.

Several data sets can be assigned to one Axis technology object, e.g. for multiple measuring systems/encoders. You can switch among multiple measuring systems/encoders, for example, by means of data set changeover. All configured measuring systems are internally active, and the measured values are updated cyclically.

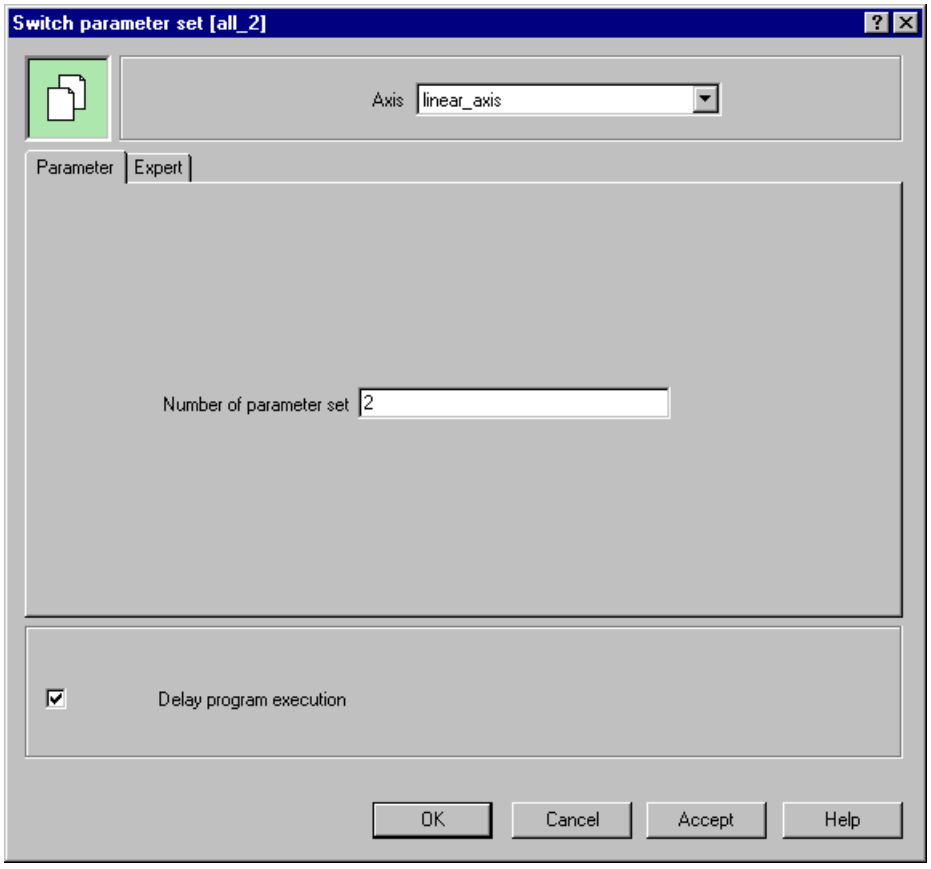

Figure 7-138 Parameter screen form: Switch parameter set

For additional information on **activating data sets**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for Switch parameter set

Table 7-201 Overview of parameters for Switch parameter set

Field/button	Meaning/instruction
Axis	Here, select the axis for which the controller data set is to be switched over. The list contains: • All axes that are defined on the relevant device. The axis is defined in the AXES folder in the project navigator. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): DriveAxis, PosAxis, FollowingAxis, or _PathAxis.

7.1.6.6 Commands for external encoders, measuring inputs and output cams

External encoder on

This command enables the external encoder for recording measured values.

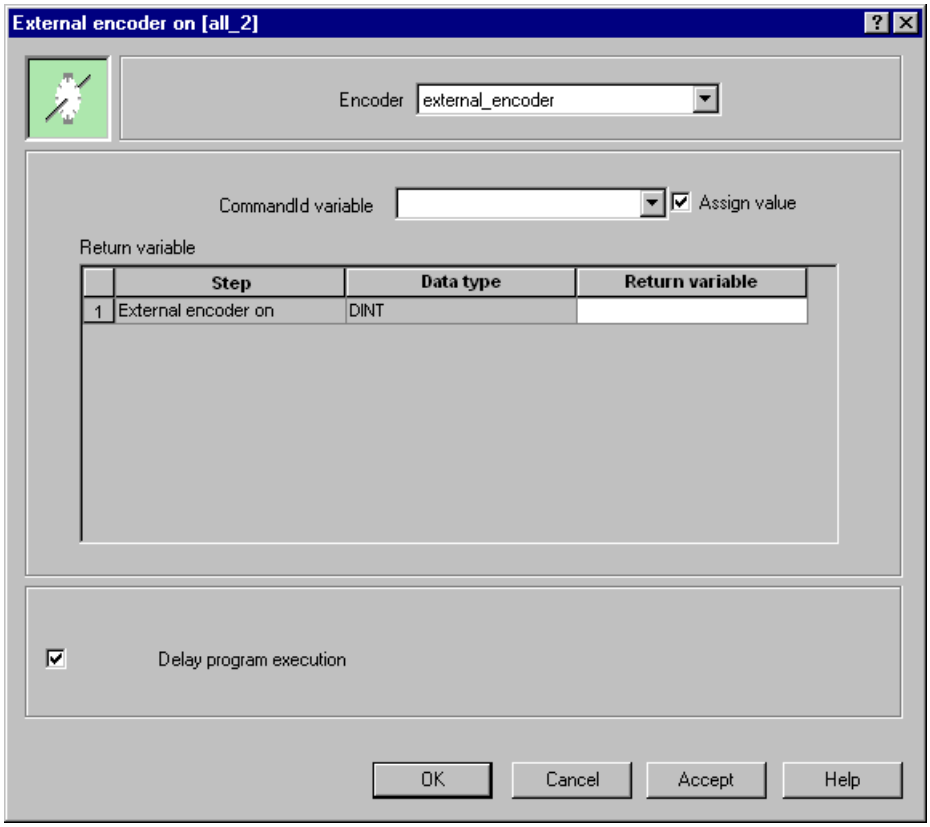

Figure 7-139 Parameter screen form: External encoder on

For additional information on the **external encoder**, see the TO Axis Electric/Hydraulic Function Manual.

Overview of parameters for External encoder on

Table 7-205 Overview of parameters for External encoder on

Field/Button	Explanation/Instructions
Encoder	Here, you select the external encoder. The list contains: • All encoders that are defined on the relevant device. An external encoder is defined in the EXTERNAL ENCODERS folder in the project navigator. • All technology object-type variables declared in the MCC source file or MCC chart (see Description of the technology object data types (Page 4060)): externalEncoderType.
CommandID variable	Enter the name of a variable of data type CommandIdType here. With the help of this variable, you can, for example, trace back the status of the command. Variables of data type CommandIdType declared in the MCC source file or MCC chart are provided for selection. If you leave the CommandID variable field empty, the CommandID is not assigned to any variables; this means that you cannot access the CommandID (standard). See also Overview of parameters for the Expert tab (Page 4034).
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).
Delay program execution	Activate the check box if you wish to delay execution of the following command until the current command has been completed. If the check box is not activated, the next command is executed immediately.

Delay program execution	Activate the check box if you wish to delay execution of the following command until the current command has been completed. If the check box is not activated, the next command is executed immediately.

Overview of parameters for Synchronize external encoder – Parameters tab

Table 7-210 Overview of parameters for Synchronize external encoder – Parameters tab

Field/Button	Explanation/Instructions
Homing type	Here, you select the homing type. **Set home position** (default value) The home position coordinates are directly set to the current axis coordinates. The current axis position is assigned to the value of the home coordinates. There is no active traversing motion. **Passive homing** The next time that the axis moves, the first available zero mark is searched for and the measuring system is synchronized to this zero mark. There is no active traversing motion as a result of the homing command. **Absolute encoder adjustment** This selection is only available for absolute encoders, i.e. encoders that have been configured as type "absolute encoder" or "absolute encoder, cyclic absolute".
Home position coordinate	Coordinates of the home position in the reference system of the axis. Enter the value in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Last programmed home position coordinate** **Default value** See Selection list (combo box) (Page 4022) System variables for default: userDefaultHoming.homePosition

Table 7-217 Overview of parameters for Encoder monitoring off

Field/Button	Explanation/instructions
Axis	Here, you select the axis for which encoder monitoring is to be disabled. At least two encoder systems must have been configured for the selected axis during commissioning (configuration data TypeOfAxis.NumberOfEncoders.numberOfEncoders > 1).
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Relevant system function for Encoder monitoring off

Cam technology package:

- _disableMonitoringOfEncoderDifference

Overview of parameters for Encoder monitoring off / _disableMonitoringOfEncoderDifference

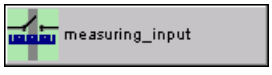
Parameters of the MCC Encoder monitoring off command	Parameters of the _disableMonitoringOfEncoderDifference system function
Axis	axis
Return variable	–

Activate measuring input



This command activates a measuring input for an axis or external encoder. A change in the signal (edge) at the configured measuring input (e.g. on the SIMOTION device or drive) causes the current act. position val. to be saved.

You can select how often the measurement is performed:

- One-time: The measuring process must be reactivated for each new measurement. Several IPO cycle clocks must be performed between the measurements.
- The measuring accuracy depends on the accuracy of the hardware used. It lies in the range of microseconds.
- Cyclic: The measurement is made cyclically in the configured processing cycle clock of the Measuring Input technology object.
  Cyclical measuring can only be performed with the following devices:
  - TM17 High Feature
  - C240 (inputs B1 to B4)
  - SIMOTION D (onboard measuring inputs)
  - SIMOTION CX32/CX32-2 Controller Extension
  - SINAMICS S120 Control Units

  When using global measuring inputs, you can detect and measure up to two edges in each processing cycle (a maximum of 2 edges every 3 servo cycles with D4xx, D4x5-2 X122/X132, and CX32/CX32-2 devices and SINAMICS S120 Control Units).
  The measured values must be read out by the user program before they are overwritten by a new measurement, i.e. if possible, in the SynchronousTask that corresponds to the processing cycle clock of the Measuring Input technology object.

For both types, you can also specify:

- The triggering edge of the input signal (e.g. rising, falling, both)
- A measuring range in which the measured value will be acquired

If the measurement is successful, the measurement result is available in the system variables below in the next cycle clock:

1. The measured values are stored in system variables measuredValue1 and measuredValue2 (for meaning, see the table below).
2. With one-time measuring, system variable state has the value TRIGGER_OCCURED.
3. With cyclic measuring, system variables counterMeasuredValue1 and counterMeasuredValue2 are incremented by 1 on each measurement result. New results can be traced immediately and can also be read from non-IPO-synchronous tasks.
   The only time these counters are set to 0 is in the event of a system ramp-up or technology object reset.

Table 7-219 Content of system variables measuredValue1 and measuredValue2 according to the measurement and the triggering edge.

Measurement	Trigger	measuredValue1	measuredValue2
once-only	One edge (rising or falling)	Measured value [1]	
	Two edges	1st measured value chronologically[1]	2nd measured value chronologically

Measurement	Trigger	measuredValue1	measuredValue2
Cyclic	One edge (rising or falling)	1st measured value chronologically[2]	2nd measured value chronologically[3][4]
	Two edges	Measured value at 1st rising edge[2]	Measured value at 1st falling edge[4]

1. In addition, system variable 'state' has the value TRIGGER_OCCURED.
2. In addition, system variable counterMeasuredValue1 is incremented by 1.
3. With 2 measured values in the same processing cycle clock.
4. In addition, system variable counterMeasuredValue2 is incremented by 1.

With one-time measuring, the command is active until the measurement result is received or the command is terminated by the "Deactivate measuring input" (Page 4353) command.

With cyclic measurements, the command is active until it is terminated by the "Deactivate measuring input" (Page 4353) command.

Various response times must be taken into account in the application for the measuring function, depending on the axis/external encoder connection (onboard C2xx, PROFIBUS axis), the drive used (611U, MASTERDRIVES MC, SINAMICS), and the processing cycle clock (IPO, IPO2 or position control cycle clock).

An Excel tool, which provides support when determining these times, is included in the SIMOTION Utilities & Applications. Depending on the type of measuring input used, you can determine the response times for the measuring input function and also the lead times for dynamic switching processes within the measuring range.

SIMOTION Utilities & Applications is provided as part of the SIMOTION SCOUT scope of delivery.

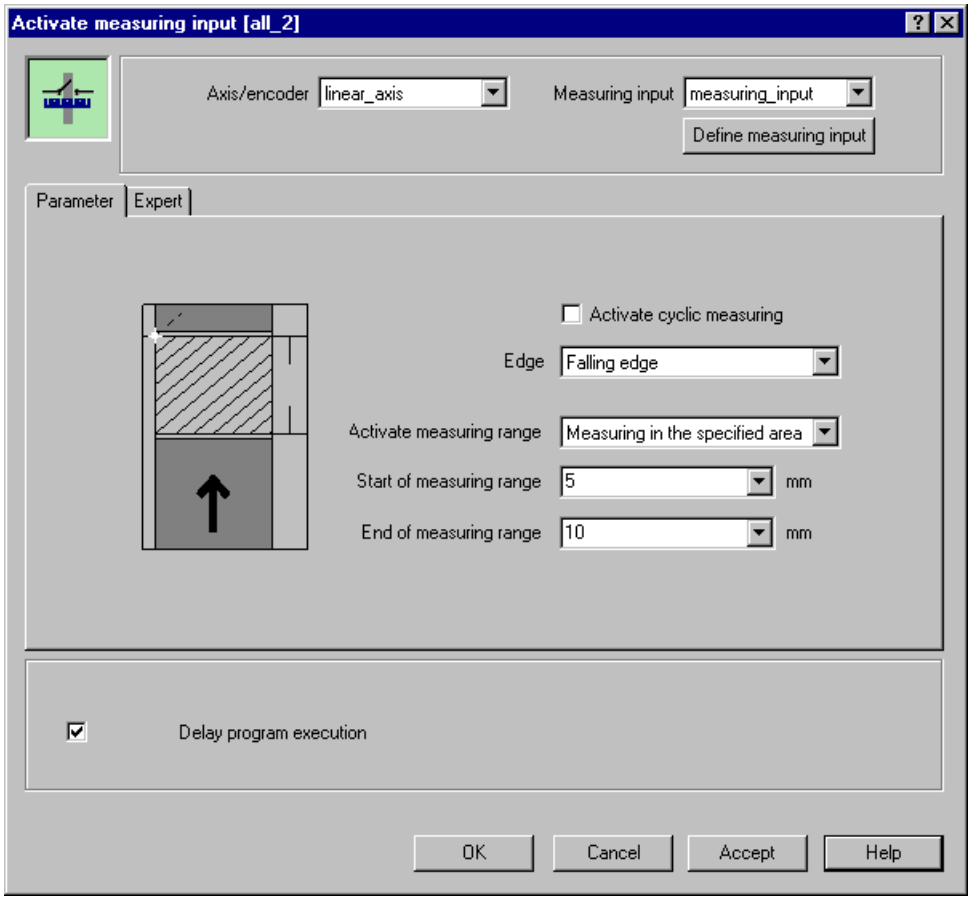


Figure 7-144 Parameter screen form: Activate measuring input

Further information:

- For information on the **Measuring Input technology object**, see the Output Cams and Measuring Inputs Function Manual

Overview of parameters for Activate measuring input

Table 7-220 Overview of parameters for Activate measuring input

Field/button	Meaning/instruction
Axis/encoder	Here, you select the axis or external encoder for which the actual value is to be measured using a measuring input. The list contains: • All position, synchronized, and path axes and external encoders that are defined on the relevant device. The measuring inputs associated with the selected axis or external encoder are automatically identified and displayed in the **Measuring input** field for selection, as appropriate. • **<Reference>** You select this entry if the measuring input is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type MeasuringInputType (references to measuring inputs) are available for selection in the **Measuring input** field, see also Technology object data types (Page 4060). **Note** You cannot select references to an axis or external encoder (variables of data type PosAxis, FollowingAxis, _PathAxis or ExternalEncoderType). There is no assignment for the reference to the associated measuring inputs. Instead, select the reference to the measuring input directly (variable of data type MeasuringInputType).
Measuring input	Here, the permissible measuring inputs are displayed according to the selected Axis/Encoder and are available for selection, as appropriate: • A position, following or path axis or external encoder defined on the device was selected as the axis/encoder: The measuring inputs associated with the selected axis/encoder are available for selection. If you wish to create a new measuring input, click the Create measuring input button and enter a new name. The measuring input is created for the technology object that has been selected in the Axis/Encoder field (not for variables). The configuration can be changed in the project navigator under the respective axis or external encoder in the MEASURING INPUTS folder. • **<Reference>** was selected as the axis/encoder: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: MeasuringInputType. These variables are references to measuring inputs.
Parameters tab	See Overview of parameters for Activate measuring input – Parameters tab (Page 4351)
Expert tab	See Overview of parameters for Activate measuring input – Expert tab (Page 4352)
Delay program execution	Only if the **Activate cyclic measuring** checkbox is not activated. • Activate the checkbox if you wish to delay execution of the following command until the current command has been completed. If the checkbox is not activated, the next command is executed immediately. If the **Activate cyclic measuring** checkbox is activated, the next command is always executed immediately.

Overview of parameters for Activate measuring input – Parameters tab

Table 7-221 Overview of parameters for Activate measuring input – Parameters tab

Field/button	Meaning/instruction
Activate cyclic measuring (SIMOTION Kernel V4.0 and higher)	Activate this checkbox if the actual values are to be acquired cyclically. If the checkbox is not activated, the actual value is acquired one time.
Edge for cyclic measuring (SIMOTION Kernel V4.0 and higher)	Only if the **Activate cyclic measuring** checkbox is activated. Here, you select whether the actual position is to be measured at a rising or falling edge of the measuring input. **All edges** The actual position is measured at both edges of the measuring input. **Rising edges only** The actual position is measured only at a rising edge of the measuring input. **Falling edges only** The actual position is measured only at a falling edge of the measuring input. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.measuredEdgeCyclicMode
Edge	Only if the **Activate cyclic measuring** checkbox is not activated. Here, you select whether the actual position is to be measured at a rising or falling edge of the measuring input. **Falling edge** The actual position is measured at the falling edge of the measuring input. **Both** The actual position is measured at both edges of the measuring input. **Both (starting at rising edge)** The actual position is measured at both edges of the measuring input; the first measurement takes place at a rising edge. **Both (starting at falling edge)** The actual position is measured at both edges of the measuring input; the first measurement takes place at a falling edge. **Rising edge** The actual position is measured at the rising edge of the measuring input. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.measuredEdge

Field/button	Meaning/instruction
Activate measuring range	Select whether the measuring input is only to be active within a certain measuring range. **Measurement in specified range** Measured value acquisition only takes place in the range specified by the Start of measuring range and End of measuring range fields. **Measurement without specified range** Measured value acquisition takes place without range limitation; the Start of measuring range and End of measuring range fields are not visible. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.measuringRangeMode
Start of measuring range	Enter the starting point of the measuring range in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** **Last programmed** See Selection list (combo box) (Page 4022) System variable for default: userDefault.measuringRangeStartPosition
End of measuring range	Enter the end point of the measuring range in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** **Last programmed** See Selection list (combo box) (Page 4022) System variable for default: userDefault.measuringRangeEndPosition

Switch output cam on

This command can be used to assign parameters for an output cam and then to switch it on.

An output cam generates position-dependent switching signals for position or synchronous axes or external encoders. The output cam types below are available. You specify the type during configuration of the output cam:

- Position-based cam
  The switching signal occurs between the starting position and end position of the output cam.
- Time-based cam
  The switching signal is supplied for a specified time period after the starting position is reached.
- Uni-directional output cam
  The switching signal occurs when the axis reaches the starting position; it can only be reset by switching off the output cam.

Position-based and time-based cams can also be assigned as counter cams.

The switching signal is available in system variable *state* and, if configured accordingly, also on a digital output.

The output cam can be switched off:

- With the commands
  - "Switch output cam off" (Page 4368) or
  - "Switch output cam signal" (Page 4371),
- By switching on the same output cam again with different parameters, if necessary

The parameter dialog box displays different parameters depending on the axis type and the configured output cam type.

Below are the parameter dialog boxes for a rotary axis and a linear axis showing the settings for different output cam types.

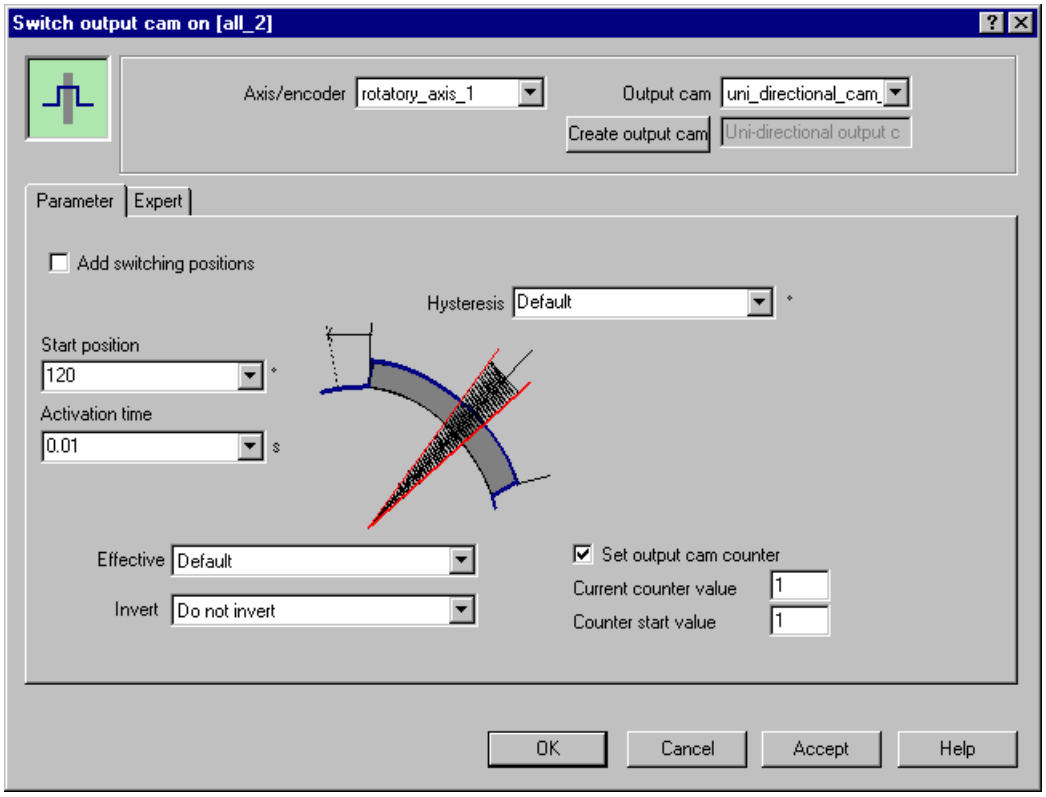

Figure 7-147 Parameter screen form: "Switch output cam on" for rotary axis with uni-directional output cam

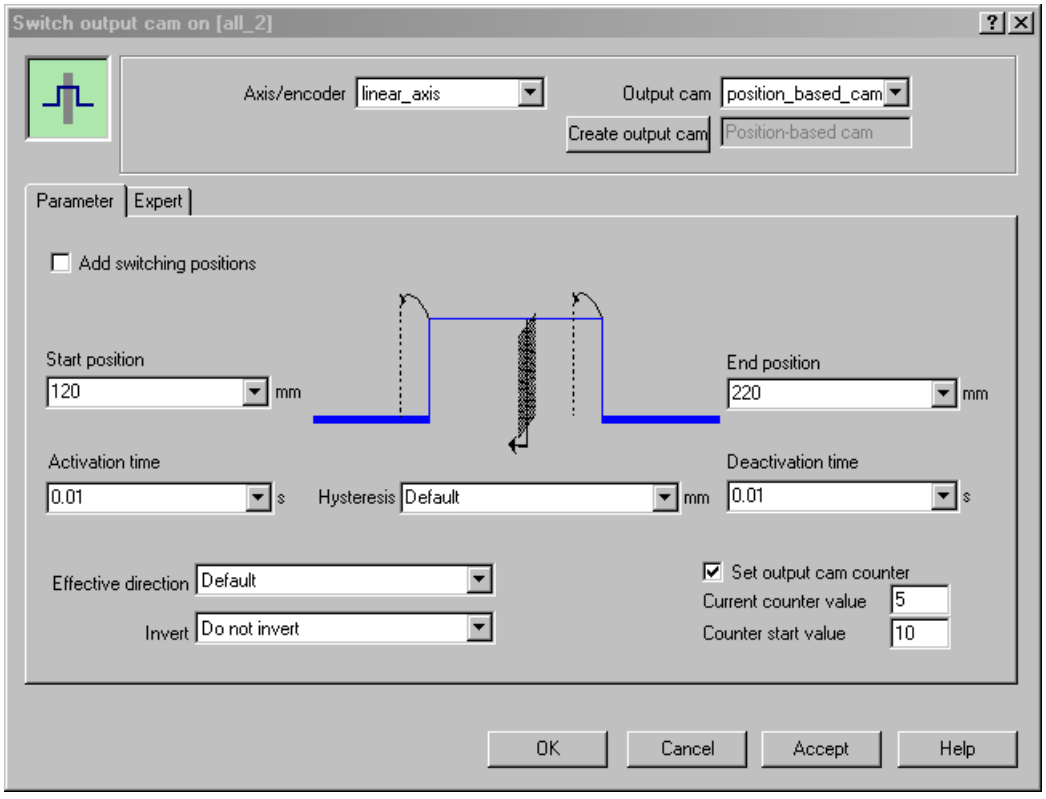

Figure 7-151 Parameter screen form: "Switch output cam on" for linear axis with position-based cam

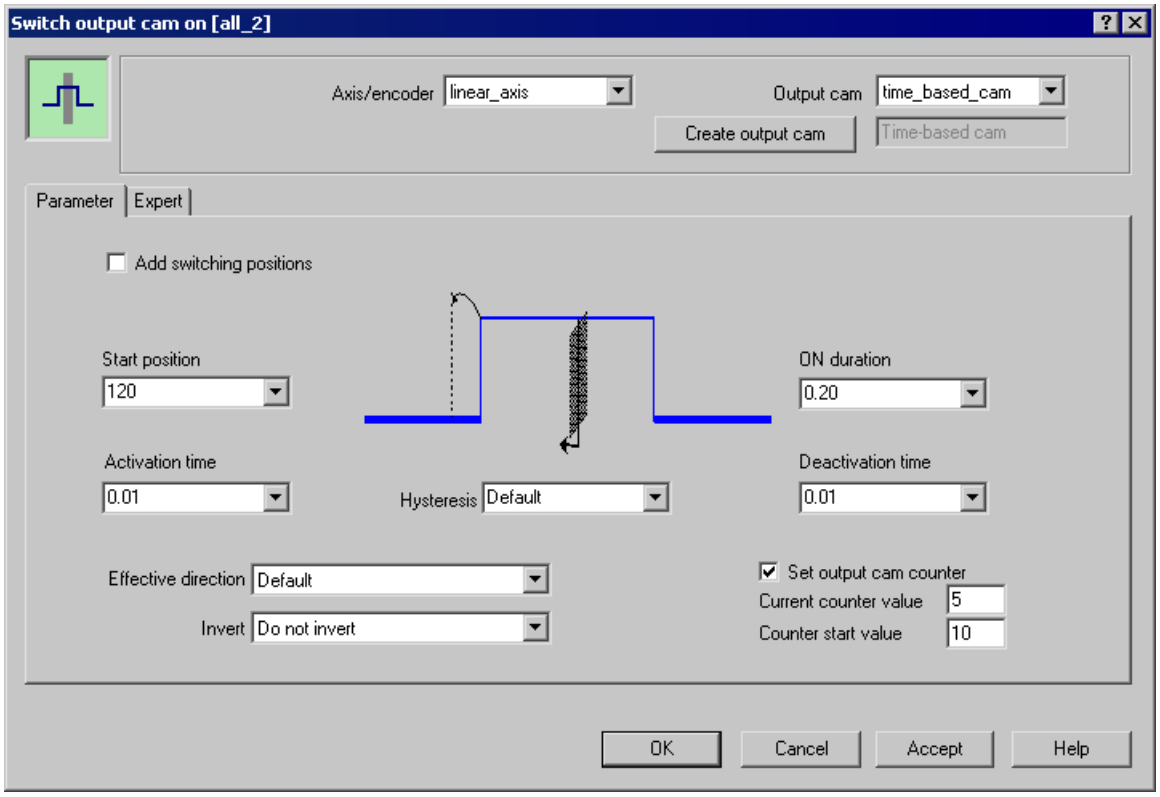

Figure 7-152 Parameter screen form: "Switch output cam on" for linear axis with time-based cam

For additional information on the **Output Cam technology object**, see the Output Cams and Measuring Inputs Function Manual.

For additional information on the **commands on the Output Cam technology object**, see the Output Cams and Measuring Inputs Function Manual.

Overview of parameters for Switch output cam on

Table 7-233 Overview of parameters for Switch output cam on

Field/button	Meaning/instruction
Axis/encoder	Here, you select the axis or external encoder with which the output cam to be switched on is associated. The list contains: • All position, synchronized, and path axes and external encoders that are defined on the relevant device. The output cams associated with the selected axis or external encoder are automatically identified and displayed in the Output cam field for selection, as appropriate. • **<Reference>** You select this entry if the output cam is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type OutputCamType (references to output cams) are available for selection in the Output cam field, see also Technology object data types (Page 4060). **Note** You cannot select references to an axis or external encoder (variables of data type PosAxis, FollowingAxis, _PathAxis or ExternalEncoderType). There is no assignment for the reference to the associated output cams. Instead, select the reference to the output cam directly (variable of data type OutputCamType).
Output cam	Here, the permissible output cams are displayed according to the selected Axis/Encoder and are available for selection, as appropriate: • A position, synchronized, or path axis or external encoder defined on the device was selected as the axis/encoder: The output cams associated with the selected axis/encoder are available for selection. If you wish to create a new output cam, click the Create output cam button and enter a new name. The output cam is created for the technology object that has been selected in the Axis/Encoder field (not for variables). The configuration can be changed in the project navigator under the respective axis or external encoder in the OUTPUT CAMS folder. • **<Reference>** was selected as the axis/encoder: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: OutputCamType. These variables are references to output cams.
Parameters tab	See Overview of parameters for Switch output cam on - Parameters tab (Page 4365)
Expert tab	See Overview of parameters for Switch output cam on - Expert tab (Page 4367)

Overview of parameters for Switch output cam on – Parameters tab

Table 7-234 Overview of parameters for Switch output cam on – Parameters tab

Field/button	Meaning/instruction
Starting position	With position-based cams: switching signal is activated between the starting position and end position. With time-based cams and unidirectional output cams: Position at which the switching signal is activated. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). The meaning is dependent on the **Add switching positions** checkbox. • Checkbox inactive: The entered value represents an absolute position. • Checkbox active: The entered value is relative and is added to the last programmed starting position. **Last programmed position** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.switchOnPosition
End position	For position-based cams only: switching signal is activated between the starting position and end position. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). The meaning is dependent on the **Add switching positions** checkbox. • Checkbox inactive: The entered value represents an absolute position. • Checkbox active: The entered value is relative and is added to the last programmed end position. **Last programmed position** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.switchOffPosition
Add switching positions	Activate the checkbox, if you want the entered values for the start position and the end position to be regarded as relative positions. The values are then added to the last programmed position each time. If this checkbox is deactivated, the entered values for the start position and the end position are regarded as absolute positions.
ON duration	ON duration for time-based cams. Once the axis has crossed the starting position, the switching signal of a time-based cam remains enabled for the programmed ON duration. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed ON duration** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.switchOnDuration

Field/button	Meaning/instruction
Activation time	The activation time shifts the switch-on instant of the output cam. Method of operation: • Negative value: Output cam activation is moved up. For example, this allows you to compensate for delay times of digital outputs and connected switching elements. • Positive value: Output cam activation is delayed. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.activationTime.
Deactivation time	The deactivation time shifts the switch-off instant of the output cam. Method of operation: • Negative value: Output cam deactivation is moved up. For example, this allows you to compensate for delay times of digital outputs and connected switching elements. • Positive value: Output cam deactivation is delayed. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.deactivationTime.
Hysteresis	The hysteresis defines a filter range around the switching position. The output signal is not switched if the axis moves in the hysteresis range around the switching position. This avoids flickering switching status changes. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed hysteresis** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.noSwitchingRange
Effective direction	Here, select the current effective direction. The output cam only switches when the direction of motion and effective direction are identical. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Both directions** The output cam switches in both axis directions. **Positive** The output cam switches when axis direction is positive. **Negative** The output cam switches when axis direction is negative. **Last programmed effective direction** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.forceDirection.

Field/button	Meaning/instruction
Invert	Here, you choose whether or not the switching state of the output of the output cam is to be inverted. **Do not invert** (default value) The output of the output cam is not inverted **Invert** The output of the output cam is inverted **Maintain current switching state** The current setting for inverting the output of the output cam is kept.
Set output cam counter	Activate this checkbox if the output cam is to be configured as a counter cam. If the checkbox is deactivated, the status of the counter cam remains unchanged. For a counter cam, it can be specified whether the output cam is to be output every time it switches or every nth time it switches. Every counter cam has a counter start value and a current counter value. The current count value for the output cam is reduced by 1 every time the output cam switches: • If the current count value reaches 0, the output cam is output (*state* system variable and output cam output). At the same time, the current counter value is reset to the counter start value. • If the current counter value does not reach 0, the output of the output cam is suppressed. The current counter value and the counter start value both have a preassigned value of 1; the current values can be queried with system variables counterCamData.actualValue and counterCamData.startValue. These values are not reset by the system, e.g. with the **Switch output cam off** command.
Current counter value	Only if the **Set output cam counter** checkbox is activated: Here, you enter the current counter value as an integer. See also input field (Page 4022).
Counter start value	Only if the **Set output cam counter** checkbox is activated: Here, you enter the counter start value as an integer. See also input field (Page 4022).

Switch output cam off

This command is used to switch off an output cam that was switched on with the "Switch output cam on" (Page 4359) command.

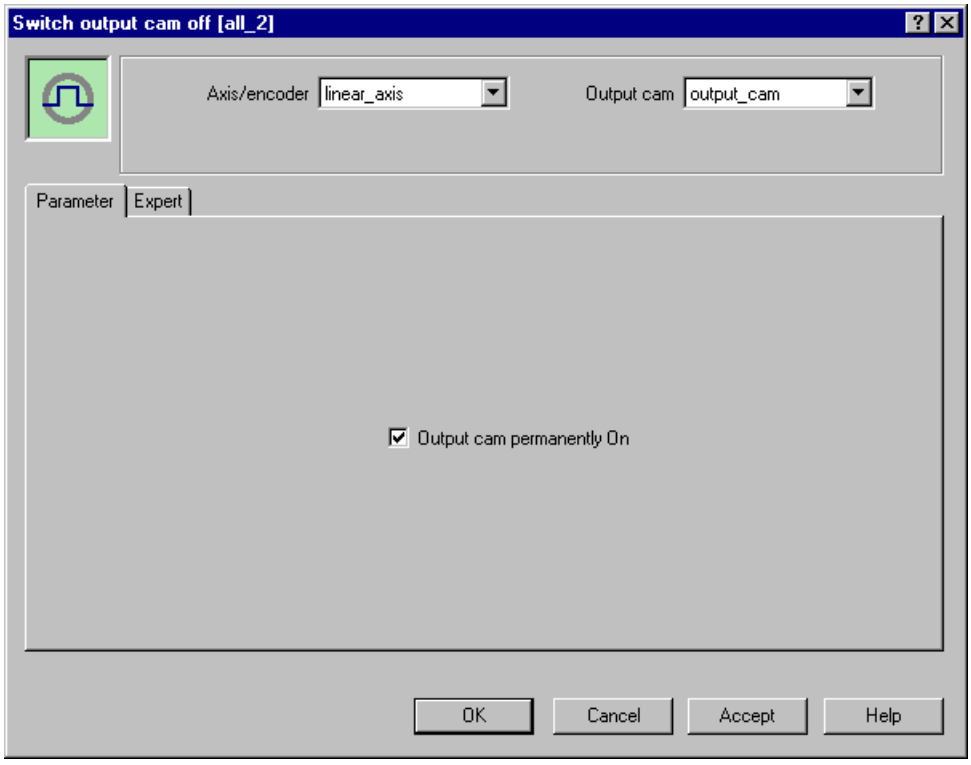

Figure 7-153 Parameter screen form: Switch output cam off

For additional information on the **Output Cam technology object**, see the Output Cams and Measuring Inputs Function Manual.

For additional information on the **commands on the Output Cam technology object**, see the Output Cams and Measuring Inputs Function Manual.

Overview of parameters for Switch output cam off

Table 7-237 Overview of parameters for Switch output cam off

Field/button	Meaning/instruction
Axis/encoder	Here, you select the axis or external encoder to which the output cam to be deactivated is associated. The list contains: • All position, synchronized, and path axes and external encoders that are defined on the relevant device. The output cams associated with the selected axis or external encoder are automatically identified and displayed in the Output cam field for selection, as appropriate. • **<Reference>** You select this entry if the output cam is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type OutputCamType (references to output cams) are available for selection in the Output cam field, see also Technology object data types (Page 4060). **Note** You cannot select references to an axis or external encoder (variables of data type PosAxis, FollowingAxis, _PathAxis or ExternalEncoderType). There is no assignment for the reference to the associated output cams. Instead, select the reference to the output cam directly (variable of data type OutputCamType).
Output cam	Here, the permissible output cams are displayed according to the selected Axis/Encoder and are available for selection, as appropriate: • A position, synchronized, or path axis or external encoder defined on the device was selected as the axis/encoder: The output cams associated with the selected axis/encoder are available for selection. • **<Reference>** was selected as the axis/encoder: All technology object-type variables declared in the MCC unit or MCC chart (see Description of the technology object data types (Page 4060)) are available for selection: OutputCamType. These variables are references to output cams.

Return variable	–

Switch output cam signal

This function is available in SIMOTION Kernel as of Version 4.1.

This command allows you to switch an output cam and set its switching signal to the specified value. This output cam signal is available in the *state* system variable and, if configured accordingly, is also available at a digital output. This terminates any current output cam processing that was started, for example, with the "Switch output cam on" (Page 4359) command.

If the output cam has been configured as a high-speed output cam on the relevant devices (e.g. SIMOTION D, C240, TM15, TM17 High Feature), the following also applies:

- You can switch the assigned digital output at specific times during the configured processing cycle clock of the output cam.
- The time offset specified in the command is added to the system-dependent output delay of the output cam signal (tOutput system variable). The resulting time offset (programmed time offset + value of tOutput system variable) must be smaller than the duration of the processing cycle clock.

Note

During a processing cycle clock, the output cam signal can only be switched on and switched off once. If an attempt is made to switch the output cam on or off more than once during a processing cycle clock, the values of the last effective command apply.

If the output cam is not configured as a high-speed output cam (output cam without time stamp, e.g. digital outputs on the SIMOTION C230-2 device), a programmed time offset is ignored. The tOutput system variable is assigned the value 0.0.

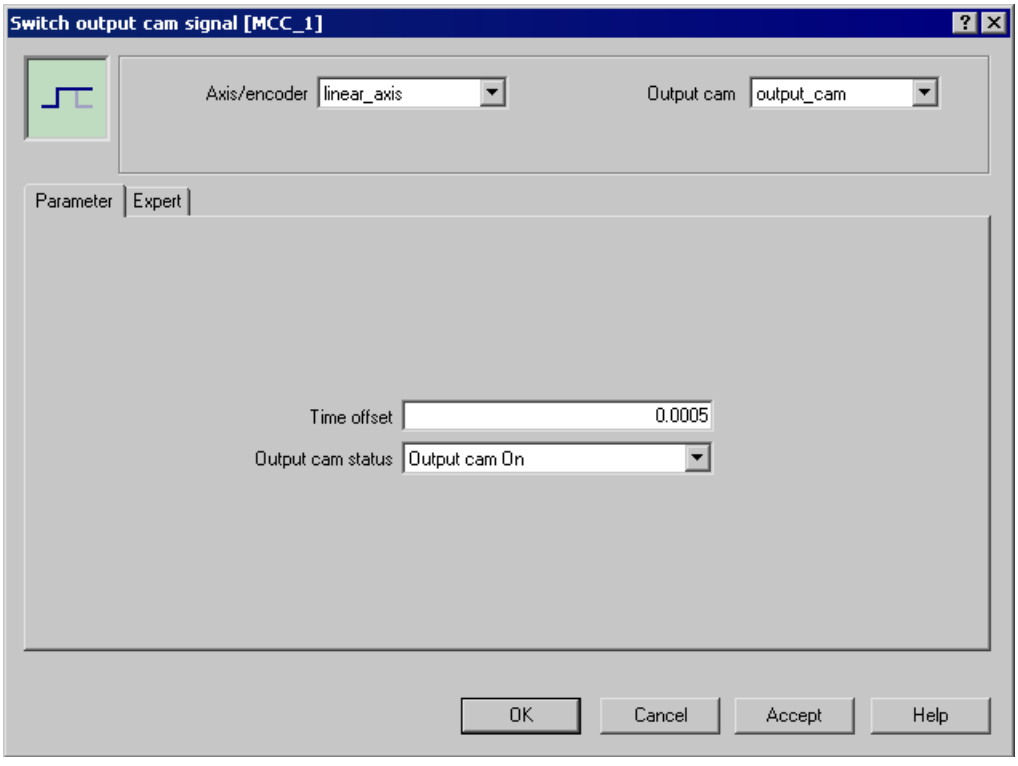

Figure 7-154 Parameter screen form: Switch output cam signal

For additional information on the **Output Cam technology object**, see the Output Cams and Measuring Inputs Function Manual.

For additional information about **exact time setting of an output and exact time output cams**, see the Output Cams and Measuring Inputs Function Manual.

Overview of parameters for Switch output cam signal

Table 7-241 Overview of parameters for Switch output cam signal

Field/button	Meaning/instruction
Axis/encoder	Here, you select the axis or external encoder to which the output cam to be switched on is associated. The list contains: • All position, synchronized, and path axes and external encoders that are defined on the relevant device. The output cams associated with the selected axis or external encoder are automatically identified and displayed in the Output cam field for selection, as appropriate. • **<Reference>** You select this entry if the output cam is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type OutputCamType (references to output cams) are available for selection in the Output cam field, see also Technology object data types (Page 4060). **Note** You cannot select references to an axis or external encoder (variables of data type PosAxis, FollowingAxis, _PathAxis or ExternalEncoderType). There is no assignment for the reference to the associated output cams. Instead, select the reference to the output cam directly (variable of data type OutputCamType).
Output cam	Here, the permissible output cams are displayed according to the selected Axis/Encoder and are available for selection, as appropriate: • A position, synchronized, or path axis or external encoder defined on the device was selected as the axis/encoder: The output cams associated with the selected axis/encoder are available for selection. • **<Reference>** was selected as the axis/encoder: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: OutputCamType. These variables are references to output cams.

Overview of parameters for Switch output cam signal – Parameters tab

Table 7-242 Overview of parameters for Switch output cam off – Parameters tab

Field/button	Meaning/instruction
Time offset	This parameter is only evaluated if the output cam was configured as a high-speed output cam on the corresponding hardware (e.g. SIMOTION D, C240, TM15, and TM17 High Feature SIMOTION devices). Here, you specify the time offset with which you can switch the assigned digital output at specific times during the configured processing cycle clock of the output cam. The specified time offset is added to the system-dependent output delay of the output cam signal (tOutput system variable). The resulting time offset (programmed time offset + value of tOutput system variable) must be smaller than the duration of the processing cycle clock. Enter the value as a signed floating-point number. See the input field (Page 4022). **Note** During a processing cycle clock, the output cam signal can only be switched on once and/or switched off once. If an attempt is made to switch the output cam on or off more than once during a processing cycle clock, the values of the last effective command apply.
Output cam status	You select the output cam signal (switching signal of the output cam) here. **Output cam on** The output cam signal is switched on. **Output cam off** The output cam signal is switched off.

Return variable	–

Output cam track On

This command is used to assign parameters for a cam track and then to switch it on.

A cam track provides the switching signal of multiple output cams of the same type (single output cams) in system variable *state*. If configured accordingly, the switching signal is also available on a digital output.

The output cam types below are available for single output cams. You specify the type during configuration of the cam track:

- Position-based cam
  The switching signal occurs between the starting position and end position of a single output cam.
- Time-based cam
  The switching signal is supplied for a specified time period after the starting position of a single cam is reached.
- Time-based cam with maximum ON length
  The switching signal is supplied for a specified time period after the starting position of a single cam is reached.
  A maximum ON length can also be defined. It limits the duration of the switching signal to the time it takes to cover this distance

The cam track can be switched off:

- With the "Cam track off" (Page 4381) command
- By switching on the same cam track again with different parameters, if necessary

Different screen forms are displayed depending on the axis type.

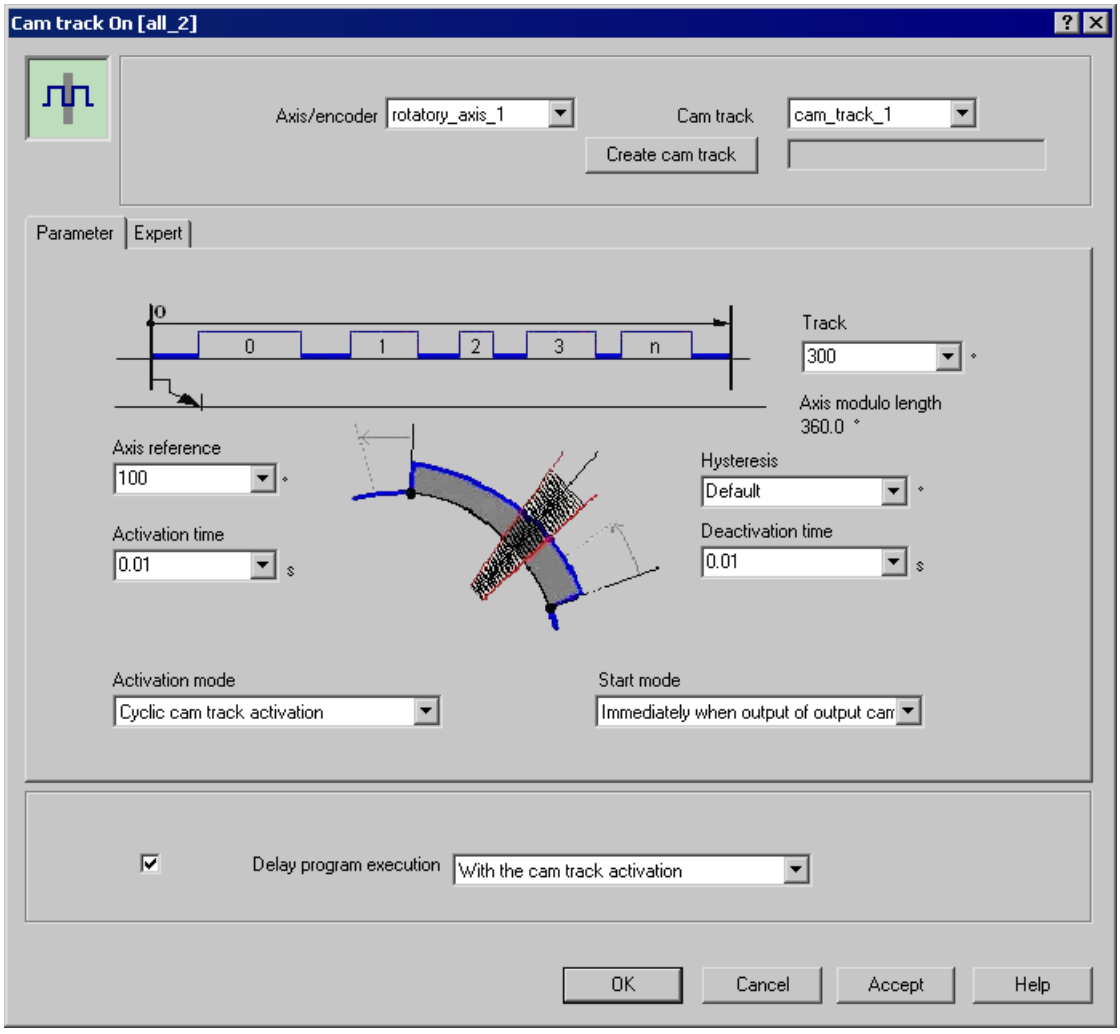

Figure 7-155 Parameter screen form: Cam track on for a rotary axis

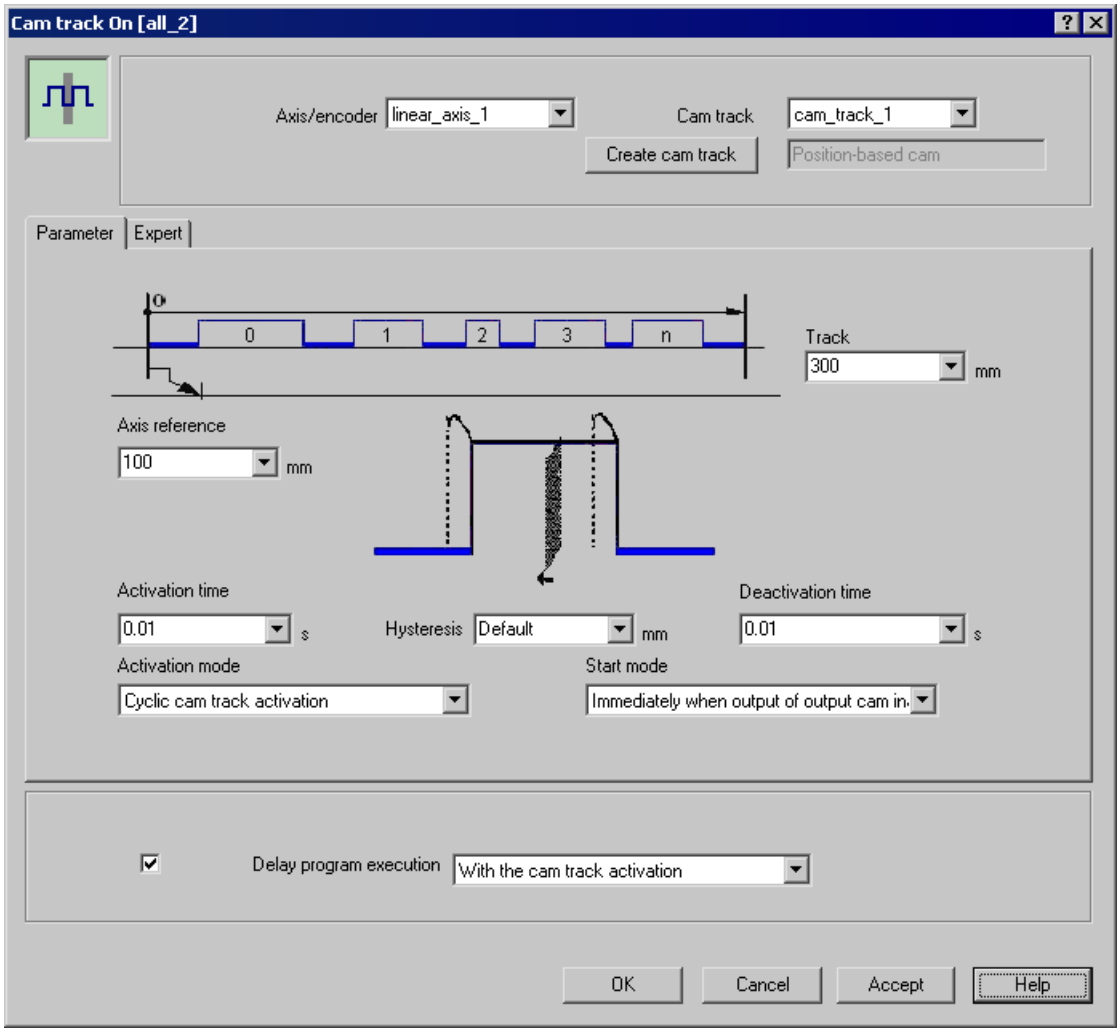

Figure 7-156 Parameter screen form: Cam track on for a linear axis

For additional information on the **Cam track technology object**, see the Output Cams and Measuring Inputs Function Manual.

For additional information on the **commands on the Cam Track technology object**, see the Output Cams and Measuring Inputs Function Manual.

Overview of parameters for Output cam track On

Table 7-245 Overview of parameters for Cam track on

Field/button	Meaning/instruction
Axis/encoder	Here, you select the axis or external encoder to which the cam track to be activated is associated. The list contains: • All position, synchronized, and path axes and external encoders that are defined on the relevant device. The cam tracks associated with the selected axis or external encoder are automatically identified and displayed in the Cam track field for selection as appropriate. • **<Reference>** You select this entry if the cam track is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type _CamTrackType (references to cam tracks) are available for selection in the Cam track field, see also Technology object data types (Page 4060). **Note** You cannot select references to an axis or external encoder (variables of data type PosAxis, FollowingAxis, _PathAxis or ExternalEncoderType). There is no assignment for the reference to the associated cam tracks. Instead, select the reference to the cam track directly (variable of data type _CamTrackType).
Cam track	Here, the permissible cam tracks are displayed according to the selected Axis/Encoder and are available for selection, as appropriate: • A position, following or path axis or external encoder defined on the device was selected as the axis/encoder: The cam tracks associated with the selected axis/encoder are available for selection. If you wish to create a new cam track, click the Create cam track button and enter a new name. The cam track is created for the technology object that has been selected in the Axis/Encoder field (not for variables). The configuration can be changed in the project navigator under the respective axis or external encoder in the OUTPUT CAMS folder. • **<Reference>** was selected as the axis/encoder: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: _CamTrackType. These variables are references to cam tracks.
Parameters tab	See Overview of parameters for Cam track on - Parameters tab (Page 4379)
Expert tab	See Overview of parameters for Cam track on - Expert tab (Page 4380)
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. **At cam track end** The next command is executed if the cam track processing is finished. **When cam track is activated** The next command is executed as soon as the cam track is activated. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Output cam track On – Parameters tab

Table 7-246 Overview of parameters for Cam track on – Parameters tab

Field/button	Meaning/instruction
Track length	Here, you define the length of the cam track. The individual output cams are mapped onto the cam track by converting their position values to modulo values with respect to the track length. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.camTrackLength.
Axis reference position	Here, you specify how the cam track is mapped onto the axis, i.e. the axis position starting from which the cam track is to be output. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.axisReferencePosition.
Activation time	The activation time shifts the switch-on instant of the single output cam. Method of operation: Negative value: Single output cam activation is moved up. For example, this allows you to compensate for delay times of digital outputs and connected switching elements. Positive value: Single output cam activation is delayed. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.activationTime
Deactivation time	The deactivation time shifts the switch-off instant of the single output cam. Method of operation: • Negative value: Single output cam deactivation is moved up. For example, this allows you to compensate for delay times of digital outputs and connected switching elements. • Positive value: Single output cam deactivation is delayed. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.deactivationTime.

Field/button	Meaning/instruction
Hysteresis	The hysteresis defines a filter range around the switching position. The output signal is not switched if the axis moves in the hysteresis range around the switching position. This avoids flickering switching status changes. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.hysteresisRange.
Activation mode	**Non-cyclical cam track activation** The cam track is mapped starting from the axis reference position, output once, and terminated automatically after it is exited. **Cyclical cam track activation** The track length of the cam track starting from the axis reference position is mapped and cyclically continued/repeated. **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.activationMode.
Start mode	The start mode is used to define when the cam track should become effective after activation or the process for switching between cam tracks. **With next track cycle** The cam track processing takes effect at the next cam cycle, i.e. as soon as the first single output cam switches the new track. Up to that point, a time-based cam of the previous cam track will be output. **Immediately** The cam track processing takes effect immediately. If an cam track is already active, it is aborted. **Immediately when output cam output is inactive** The cam track processing takes effect as soon as there are no more active single output cams of the previous cam track. An active single output cam of the previous cam track will be output completely. **Last programmed** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.startMode.

7.1.6.7 Commands for synchronous operation and camming

Gearing on

Gearing is characterized by a constant gear ratio between a master value (position value of a leading axis or external encoder) and a slave value (position value of a following axis). Gearing is thus in positional synchronism.

This transmission ratio (gear ratio) can be specified as the ratio of two integers (numerator/ denominator) or as a decimal number.

An offset in the zero point (a phase displacement) can also be specified.

When gearing is started, the slave value is synchronized to the master value with the programmed synchronization settings.

The master value can be defined in the command; the master value can be modified later with the "Switch master value" (Page 4458).

Other master value sources for SIMOTION devices as of Version V4.2 of SIMOTION Kernel only

As of Version V4.2 of SIMOTION Kernel, the instances of the following technology objects and the variables of the relevant technology object data type are available as master value sources:

- Drive axis
- Path object
- Addition object
- Controller object
- Fixed gear

- Formula object
- Sensor

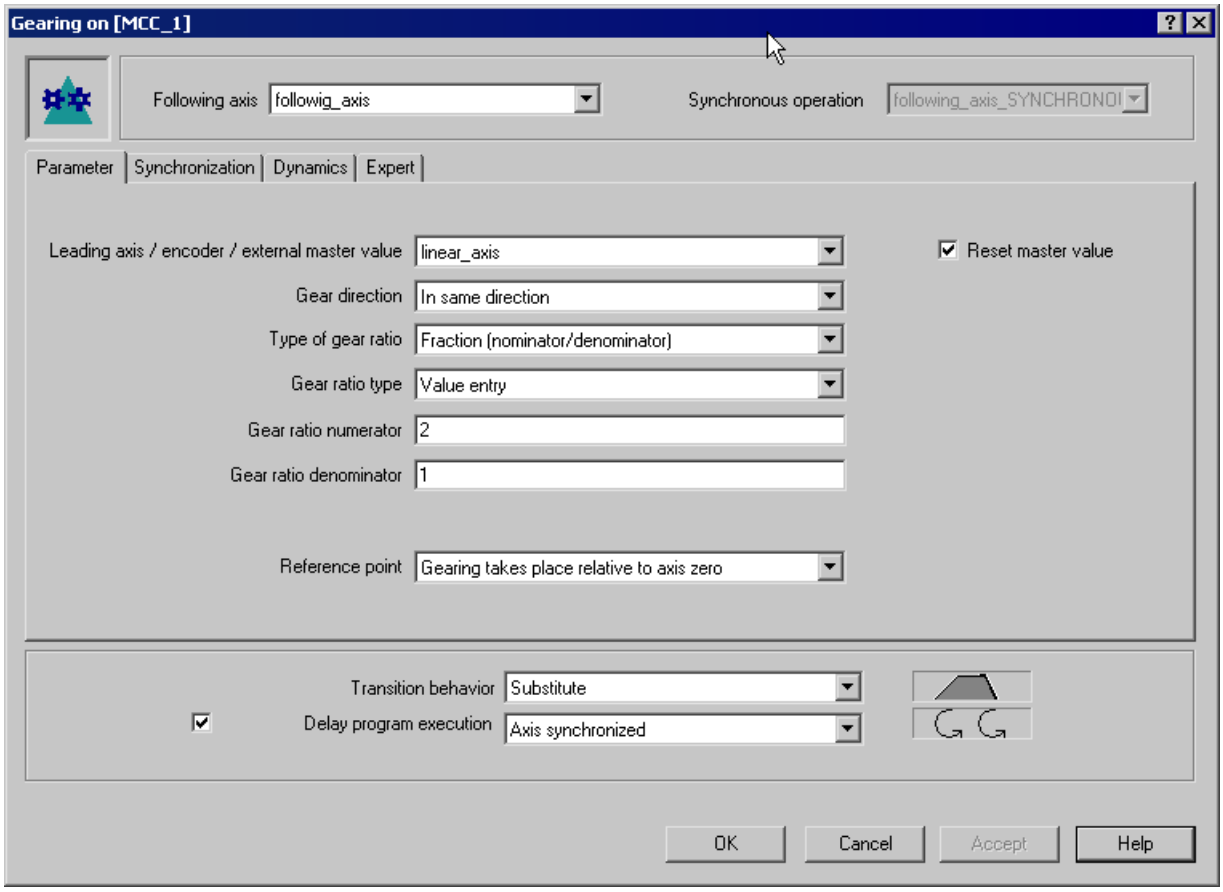

Figure 7-158 Parameter screen form: Gearing on

Active gearing can be offset both on the side of the master value and on the side of the slave value. The "Set offset on the gearing" (Page 4406) command is used for this purpose.

Gearing can be ended:

- With the "Gearing off" (Page 4399) command
- By starting another synchronous operation on the same synchronous object, e.g. with another "Gearing on" command
- By a canceling single axis command on the following axis

Note

The "Stop axis" (Page 4281) command will only terminate the synchronous operation if **Quick stop...** has been selected as the stop mode.

Further information:

- **General information on gearing**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on synchronization**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on switching over the master value source**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Gearing on

Table 7-253 Overview of parameters for Gearing on

Field/button	Meaning/instruction
Following axis	Here, you select the axis to be synchronized. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • **<Reference>** You select this entry if the axis to be synchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Following axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as a following axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as a following axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.
Parameters tab	See Overview of parameters for Gearing on - Parameters tab (Page 4388)
Synchronization tab	See Overview of parameters for Gearing on - Synchronization tab (Page 4391)
Dynamic response tab	See Overview of parameters for Gearing on - Dynamic response tab (Page 4397)
Expert tab	See Overview of parameters for Gearing on - Expert tab (Page 4397)

Field/button	Meaning/instruction
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Example:

See Example of Gearing on (Page 4398)

Overview of parameters for Gearing on – Parameters tab

Table 7-254 Overview of parameters for Gearing on – Parameters tab

Field/button	Meaning/instruction
Reset master value	Activate this checkbox if you want to set the master value of the synchronous relationship (default) If the checkbox is deactivated, a previous master value setting is retained. **Note** • As of Version V4.1 of the SIMOTION Kernel, the master value conversion takes place during the synchronization of the synchronous axis (in accordance with the transition behavior "with next synchronization" (Page 4461) with the command "Switch master value"). • From Version V4.0 of the SIMOTION Kernel, the master value conversion takes place immediately at the start of the command (in accordance with the transition behavior "direct" (Page 4461) with the command "Switch master value").
Leading axis / encoder / external master value	An entry can only be made in this field if the **Reset master value** checkbox is activated. Here, you select the axis or external encoder that generates the master value in the synchronous relationship. You can select from: • All position, following, and path axes and external encoders that are available on the device or a DP master. The following are also available as of Version V4.2 of SIMOTION Kernel: Drive axes, path objects, addition objects, controller objects, fixed gear, formula objects and sensors. • All technology object-type variables declared in the MCC unit or MCC chart, see Description of the technology object data types (Page 4060): PosAxis, FollowingAxis, _PathAxis and ExternalEncoderType The following are also available as of Version V4.2 of SIMOTION Kernel: DriveAxis, _PathObjectType, _AdditionObjectType, _ControllerObjectType, _FixedGearType, _FormulaObjectType, _SensorType. The master value remains assigned to the synchronous object until a change occurs.

Field/button	Meaning/instruction
Gear direction	Here, you select the effective direction of the gearing. **From sign of gear ratio** (default value) The effective direction of gearing is defined by the sign of the gear ratio. **Opposite direction** The following axis moves in the opposite direction from the leading axis. **Same direction** The following axis moves in the same direction as the leading axis. **Opposite current gearing direction** The gearing direction opposes the current gearing direction. **Current direction** **Last programmed direction** **Default** See Selection list (combo box) (Page 4022) System variable for default: userDefault.gearingSettings.direction
Gear ratio type	The gear ratio is the ratio between the distances covered by the following axis (= numerator) and the leading axis (= denominator), each expressed in the configured units. Here, you select whether the gear ratio is specified as a fraction (numerator/denominator) or as a floating-point number. **Fraction (numerator/denominator)** The ratio is specified as a fraction **Floating-point number** The ratio is specified as a floating-point number **Last programmed** **Default** See Selection list (combo box) (Page 4022) System variable for default: userDefault.gearingSettings.defineMode
Gear ratio type	Here you select which values are used for the gear ratio **Value entry** The values are entered directly in the parameter dialog box. • As fraction (numerator / denominator): In the Gear ratio numerator/denominator fields, or • As floating-point number: In the Gear ratio field **Last programmed value** **Default** See Selection list (combo box) (Page 4022) System variables for default: • userDefault.gearingSettings.numerator and userDefault.gearingSettings.denominator or • userDefault.gearingSettings.ratio
Gear ratio numerator	Here, you enter the numerator of the gear ratio as an integer. The unit configured for the following axis is displayed for your information. See also input field (Page 4022).

Field/button	Meaning/instruction
Gear ratio denominator	Here, you enter the denominator of the gear ratio as an integer. The unit configured for the leading axis is displayed for your information. See also input field (Page 4022).
Gear ratio	Enter the gear ratio as a floating-point number here. See also input field (Page 4022).
Reference point	Here, you select the reference point for gearing. **Gearing takes place relative to axis zero (default value)** Absolute gearing: In each case, the linear coupling of the slave value to the master value refers to the axis zero of the axes involved. Any offset between the master value and the slave value at the start of gearing is compensated for during synchronization. For some of the choices, an offset can be specified in the **Start of synchronization** field of the Synchronization tab (see Overview of parameters for Gearing on - Synchronization tab (Page 4391)). This value is retained as a constant phase shift between slave value and master value after conclusion of the synchronization operation. Otherwise, the phase shift is equal to 0. **Gearing relative to start position** Relative gearing: In each case, the linear coupling of the slave value to the master value refers to the position value of the axes involved at the start of gearing. Any offset between the master value and the slave value at the start of gearing is **not** compensated for during synchronization. This offset is retained as a constant phase shift between slave value and master value after conclusion of the synchronization operation. In addition, for some of the choices, an offset can be specified in the **Start of synchronization** field of the Synchronization tab (see Overview of parameters for Gearing on - Synchronization tab (Page 4391)). This value acts as a constant phase shift between slave value and master value after conclusion of the synchronization operation. **Last programmed reference point** **Default** See Selection list (combo box) (Page 4022) System variable for default: userDefault.syncProfile.syncProfileReference

Overview of parameters for Gearing on – Synchronization tab

Table 7-255 Overview of parameters for Gearing on – Synchronization

Field/button	Meaning/instruction
Synchronization reference	Here, you select the reference for the synchronization operation. **Leading axis** Length-related synchronization: Synchronization occurs (depending on the leading axis motion) within a defined range of the master value (**Synchronization length**). • Advantage: Synchronization occurs within a parameterizable range of the master value. • Disadvantage: The dynamic response of synchronization is dependent on the change in the master value (velocity). The dynamic response limit values of the following axis are not taken into account. **Time** Time-related synchronization: Synchronization occurs on the basis of specified dynamic values. Program the relevant values in the Dynamic response tab, see Overview of parameters for Gearing on - Dynamic response tab (Page 4397). • Advantage: The synchronization operation always takes place with the specified dynamic values. • Disadvantage: The master value range in which synchronization occurs cannot be predicted. **Last programmed setting** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncProfileReference

Field/button	Meaning/instruction
Start of synchronization	Here, you select when synchronization of gearing begins. Additional specifications are required for many of the choices; these are indicated in the description. **At leading axis position** The gear is enabled at a programmed leading axis position. Entries are required in the following fields: • Reference point of leading axis position • Leading axis position Synchronization occurs with respect to the following values: • Master value = programmed leading axis position • Slave value: Depending on the selection in **Reference point**, see Overview of parameters for Gearing on – Parameters tab (Page 4388): – For **gearing, relative to axis zero (default value)**: Slave value = gear ratio * position of leading axis – For **gearing, relative to start position**: Slave value = current slave value **At leading axis position with offset** The gear is enabled at a programmed leading axis position. An offset for the following axis is additionally programmed. Entries are required in the following fields: • Offset of the following axis • Reference point of leading axis position • Leading axis position Synchronization occurs with respect to the slave values: • Master value = programmed leading axis position • Slave value: See description in the field **Offset of the following axis** **Synchronize immediately** The gear is enabled immediately. Synchronization occurs with respect to the slave values: • Master value = current master value • Slave value: Depending on the selection in **Reference point**, see Overview of parameters for Gearing on – Parameters tab (Page 4388): – For **gearing, relative to axis zero (default value)**: Slave value = gear ratio * current master value – For **gearing, relative to start position**: Slave value = current slave value **...** (Continued in next row of table)

Field/button	Meaning/instruction
Start of synchronization (continued)	... **Synchronize immediately with offset** The gear is enabled immediately. An offset for the following axis is additionally programmed. An entry is required in the following field: • Offset of the following axis Synchronization occurs with respect to the slave values: • Master value = current master value • Slave value: See description in the field **Offset of the following axis** **At the following axis position** The gear is enabled at a programmed following axis position. Entries are required in the following fields: • Reference point of leading axis position • Following axis position Synchronization occurs with respect to the slave values: • Master value: Depending on the selection in **Reference point**, see Overview of parameters for Gearing on – Parameters tab (Page 4388): – For **gearing, relative to axis zero (default value)**: Master value = position of leading axis / gear ratio – For **gearing, relative to start position**: Master value = current master value • Slave value = last programmed following axis position **Last programmed setting** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.synchronizingMode
Offset of the following axis	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At leading axis position with offset • Synchronize immediately with offset Here, you enter a value that is used to calculate the offset of the following axis for linear coupling between the leading axis and following axis. Depending on the selection in **Reference point** (see Overview of parameters for Gearing on – Parameters tab (Page 4388)), the entered value has the following meaning: • For **gearing, relative to axis zero (default value)**: Slave value relative to which synchronization occurs • For **gearing, relative to start position:** Additional offset to any offset between the following axis and leading axis Depending on the selection in **Reference point**, see Overview of parameters for Gearing on – Parameters tab (Page 4388), the slave value relative to which synchronization occurs is thus: • For **gearing, relative to axis zero (default value)**: Slave value = programmed offset • For **gearing, relative to start position**: Slave value = current slave value + programmed offset See also input field (Page 4022).

Field/button	Meaning/instruction
Reference point of leading axis position	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At leading axis position • At leading axis position with offset • At the following axis position Here, you select how the programmed position (see the **Following axis position** or **Leading axis position** field) acts relative to the selected synchronization profile. **Synchronize before synchronization position** Synchronization is finished at the programmed position (preceding synchronization). **Symmetrical** This choice is available only for leading axis synchronization reference. Synchronization occurs in such a way that the programmed position is located symmetrically within the synchronization length. At the programmed position, the leading axis has covered half the distance that is required for synchronization. **Synchronize from synchronization position** Synchronization starts at the programmed position (succeeding synchronization). **Last programmed reference point of leading axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncPositionReference
Synchronization length	An entry is required in this field if you have selected the following in the **Synchronization reference** field: • Leading axis Enter the synchronization length in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed synchronization length** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncLength
Following axis position	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At the following axis position Enter the following axis position in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed following axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.syncPositionSlave

Field/button	Meaning/instruction
Leading axis position	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At leading axis position • At leading axis position with offset Enter the leading axis position in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed leading axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.syncPositionMaster

Field/button	Meaning/instruction
Synchronization with look-ahead	Per default, the position and the velocity of the master value are taken into account in the calculations for the synchronization. With succeeding synchronization (i.e. the synchronization starts at the programmed position), you can also select whether a constant acceleration or deceleration of the master value is to be taken into account (extended look-ahead). **Note** Extended look-ahead requires a lot of computing time. An entry in this field is possible in the following cases: • In the **Start of synchronization** field, you have selected**:** – Synchronize immediately – Synchronize immediately with offset • With a different selection in the **Start of synchronization** field, you ave also selected in the **Reference point of the leading axis position** field: – Synchronize from synchronization position – Default Select one of the following menu commands: **Standard** Position and velocity of the master value are taken into account in the synchronization calculations. **Expanded look ahead** In addition to the position and velocity of the master value, a constant acceleration or deceleration of the master value is also taken into account in the synchronization calculations. With preceding or symmetrical synchronization, this selection has no effect. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.synchronizingWithLookAhead
Synchronization direction	Here, you select the direction of motion in which the following axis is to be synchronized. **Retain system behavior** Synchronization occurs over the shortest path without direction specification. In the case of moving axes, a check is made to determine whether the current direction of motion can be maintained. **Maintain direction of the following axis** Synchronization takes place in the direction of motion of the following axis. **Positive** Synchronization occurs in the positive direction of motion. **Negative** Synchronization occurs in the negative direction of motion. **Shortest path** Synchronization occurs over the shortest path without direction specification. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.synchronizingDirection

Overview of parameters for Gearing on – Dynamic response tab

Table 7-256 Overview of parameters for Gearing on – Dynamic response tab

Field/button	Meaning/instruction
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031). The parameters on the Dynamic response tab are only evaluated for time synchronization reference.
Velocity	The entered value acts during the constant velocity phase. System variable for default: userDefault.syncDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefault.syncDynamics.profile **Note** A constant velocity profile only takes effect if configuration data syncingMotion.smoothAbsoluteSynchronization = YES is set. When syncingMotion.smoothAbsoluteSynchronization = NO (default), a trapezoidal velocity profile is always active.
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefault.syncDynamics.positiveAccelStartJerk, userDefault.syncDynamics.positiveAccelEndJerk, userDefault.syncDynamics.negativeAccelStartJerk, userDefault.syncDynamics.negativeAccelEndJerk

Overview of parameters for Gearing on – Expert tab

Table 7-257 Overview of parameters for Gearing on – Expert tab

Field/button	Meaning/instruction
	The Expert tab is described in detail in Expert tab (Page 4034).
CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Example of Gearing on

An axis (rotaryAxis_1) is to rotate at a velocity of 360 degrees/s. A second axis (synchronous axis) is to rotate in synchronism using a gear ratio.

The synchronous axis that is to be coupled with rotaryAxis_1 by means of a gear ratio must be assigned as a synchronous axis in SIMOTION SCOUT.

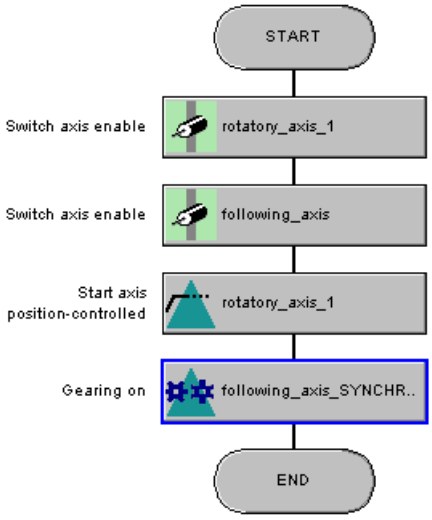

Figure 7-159 Example: MCC chart for gearing

Relevant system functions for Gearing on

Cam technology package:

- _enableGearing
- _setMaster

If the **Reset master value** checkbox is selected, the _setMaster system function is called first before _enableGearing.

Gearing off

This command enables you to terminate gearing that was started with the "Gearing on" (Page 4385) command. Desynchronization occurs with the programmed desynchronization settings.

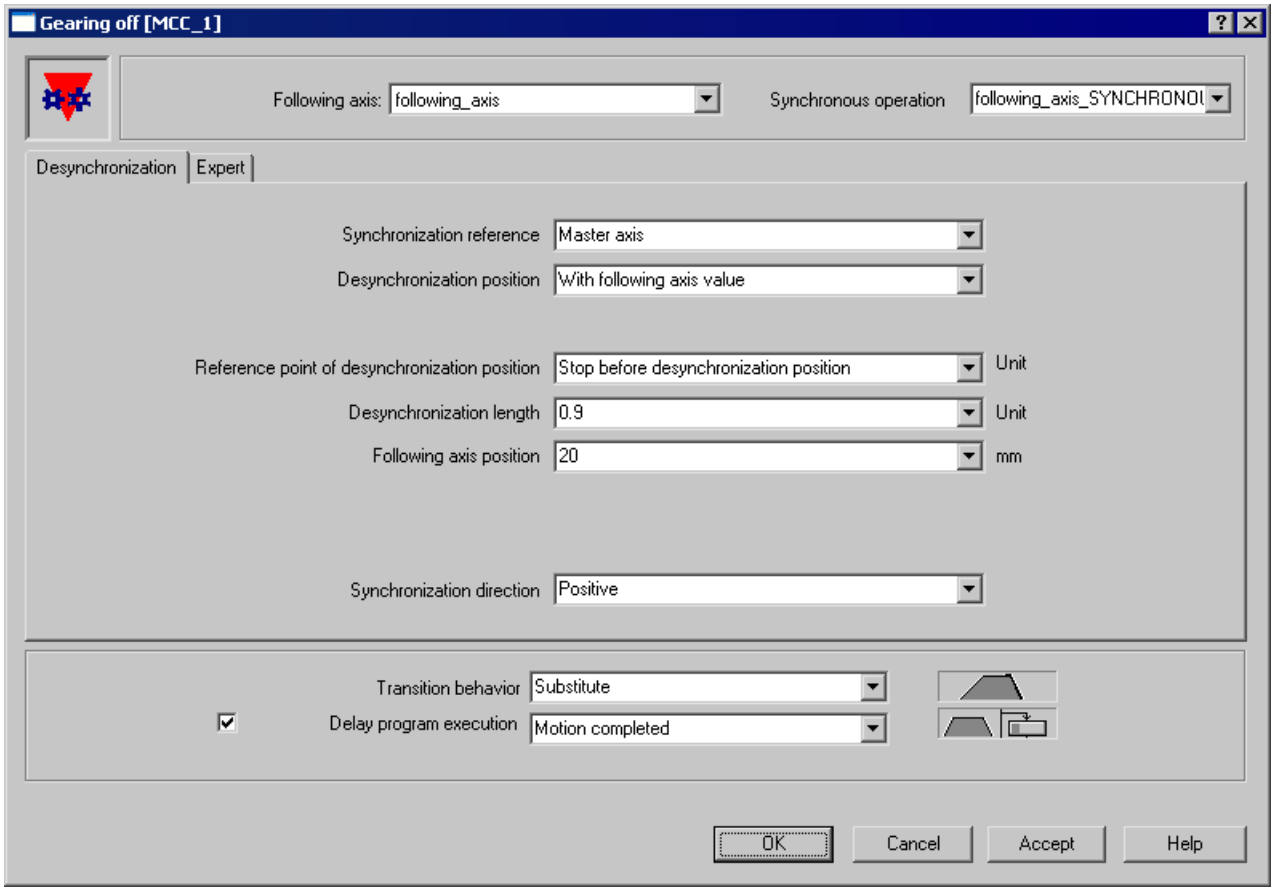

Figure 7-160 Parameter screen form: Gearing off

Further information:

- For **general information on gearing**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on synchronization**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on switching over the master value source**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Gearing off

Table 7-259 Overview of parameters for Gearing off

Field/button	Meaning/instruction
Following axis	Here, you select the axis to be desynchronized. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be desynchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Following axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as a following axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as a following axis: All technology object-type variables declared in the MCC unit or MCC chart (see Description of the technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.
Desynchronization tab	See Overview of parameters for Gearing off – Desynchronization tab (Page 4402)
Dynamic response tab	See Overview of parameters for Gearing off – Dynamic response tab (Page 4404)
Expert tab	See Overview of parameters for Gearing off – Expert tab (Page 4405)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036)
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037)

Overview of parameters for Gearing off – Desynchronization tab

Table 7-260 Overview of parameters for Gearing off – Desynchronization tab

Field/button	Meaning/instruction
Synchronization reference	Here you select the reference for the desynchronization operation. **Leading axis** Length-related synchronization: Synchronization occurs (depending on the leading axis motion) within a defined range of the master value (**Desynchronization length**). • Advantage: Synchronization occurs within a parameterizable range of the master value. • Disadvantage: The dynamic response of synchronization is dependent on the change in the master value (velocity). The dynamic response limit values of the following axis are not taken into account. **Time** Time-related synchronization: Synchronization occurs on the basis of specified dynamic values. Program the relevant values in the Dynamic response tab, see Overview of parameters for Gearing off - Dynamic response tab (Page 4404)). • Advantage: The synchronization operation always takes place with the specified dynamic values. • Disadvantage: The master value range in which synchronization occurs cannot be predicted. **Last programmed setting** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncProfileReference
Desynchronization position	Here, you select when desynchronization of gearing begins. Additional specifications are required for some of the choices; these are indicated in the description. **At leading axis value** Gearing is disabled at a programmed leading axis position. Entries are required in the following fields: • Reference point of desynchronization position • Leading axis position **Desynchronize immediately** Gearing is disabled immediately **At following axis value** Gearing is disabled at a programmed slave axis position. Entries are required in the following fields: • Reference point of desynchronization position • Following axis position **Last programmed start of desynchronization** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.syncOffMode

Field/button	Meaning/instruction
Reference point of desynchronization position	An entry is required in this field if you have selected the following in the **Desynchronization position** field: • At leading axis value • At following axis value Here, you select how the programmed position (see the **Following axis position** or **Leading axis position** field) acts relative to the selected desynchronization profile. **Stop before desynchronization position** Synchronization is finished at the programmed position. **Symmetrical** This choice is available only for leading axis synchronization reference. Desynchronization occurs in such a way that the programmed position is located symmetrically within the desynchronization length. At the programmed position, the leading axis has covered half the distance that is required for synchronization. **Stop from desynchronization position** Desynchronization starts at the programmed position. **Last programmed reference point of leading axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncOffPositionReference
Desynchronization length	An entry is required in this field if you have selected the following in the **Synchronization reference** field: • Leading axis Enter the synchronization length in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed desynchronization length** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncOffLength
Following axis position	An entry is required in this field if you have selected the following in the **Desynchronization position** field: • At following axis value Enter the following axis position in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncOffPositions.Slave

Field/button	Meaning/instruction
Leading axis position	An entry is required in this field if you have selected the following in the **Desynchronization position** field: • At leading axis value Enter the leading axis position in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncOffPositions.Master
Synchronization direction	Here, you select the direction of motion in which the following axis is to be desynchronized. **Retain system behavior** Synchronization occurs over the shortest path without direction specification. In the case of moving axes, a check is made to determine whether the current direction of motion can be maintained. **Maintain direction of the following axis** Synchronization takes place in the direction of motion of the following axis. **Positive** Synchronization occurs in the positive direction of motion. **Negative** Synchronization occurs in the negative direction of motion. **Shortest path** Synchronization occurs over the shortest path without direction specification. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.gearingSettings.synchronizingDirection

Set offset on the gearing

This command causes an offset in the leading axis or following axis range during the gearing operation. You can use a parameter to determine when the programmed offset is to take effect (as well as other properties).

- For the active gearing command
  and/or
- For subsequent gearing commands

Offsets that act on the active gearing command and offsets that are stored and applied to subsequent gearing commands can be read from the gearingAdjustment system variable.

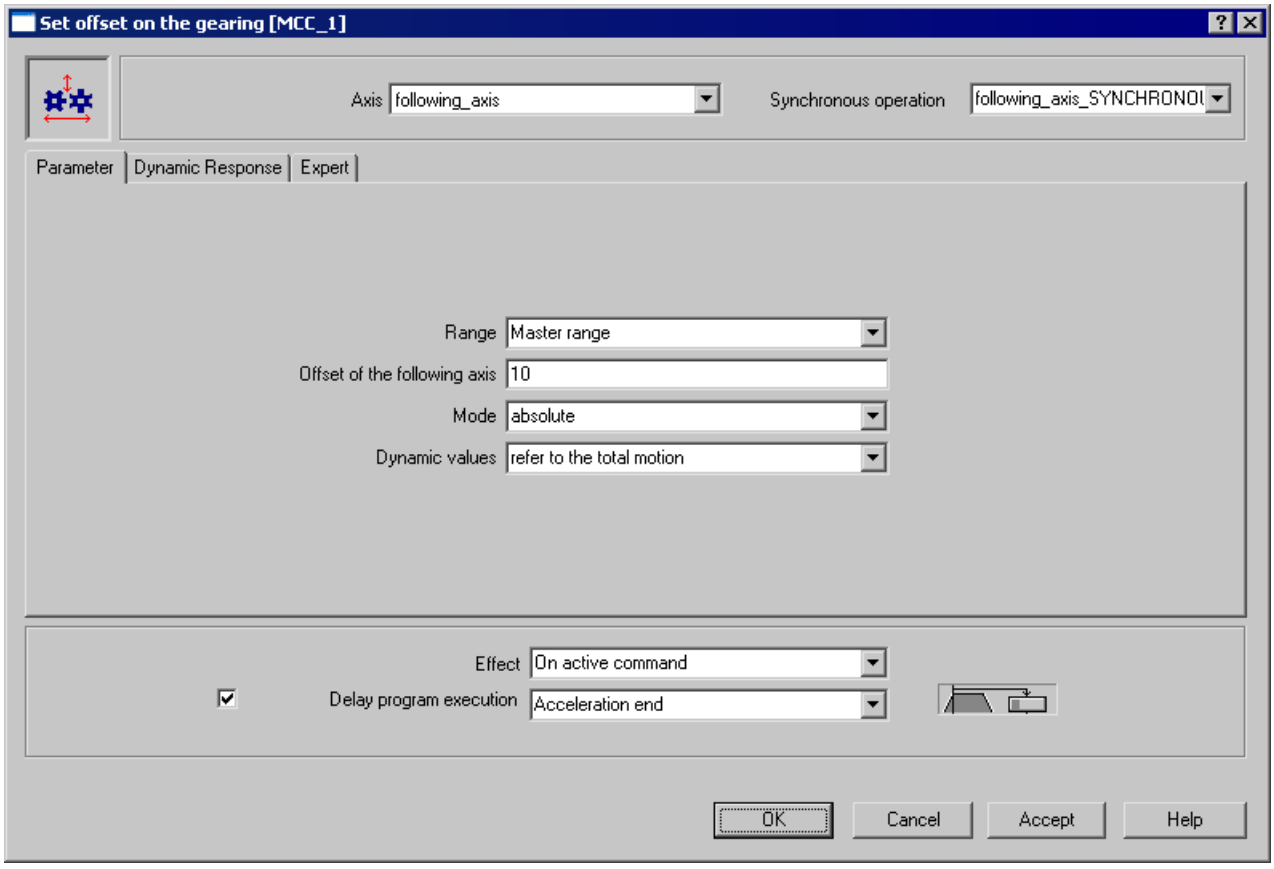

Figure 7-161 Parameter screen form: Set offset on the gearing

Further information:

- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For information on **scaling and offset**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Set offset on the gearing

Table 7-264 Overview of parameters for Set offset on the gearing

Field/button	Meaning/instruction
Axis	Here, you select the axis for which gearing is to be offset. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be synchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as an axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as the axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.
Parameters tab	See Overview of parameters for Set offset on the gearing – Parameters tab (Page 4409)
Dynamic response tab	See Overview of parameters for Set offset on the gearing – Dynamic response tab (Page 4410)
Expert tab	See Overview of parameters for Set offset on the gearing – Expert tab (Page 4410)

Field/button	Meaning/instruction
Effect	Here, you select which commands the offset will act on. **On active command** (default value) The offset acts on the active gearing command and remains active until this command is replaced or desynchronized using the "Gearing off" (Page 4399) command. The offset value is stored in system variables gearingAdjustment.master.offset or gearingAdjustment.slave.offset (depending on the range). **on following commands** The active gearing command is executed; the offset is stored and in effect for subsequent "Gearing on" (Page 4385) commands. The offset value is stored in system variables gearingAdjustment.defaultValueMaster.offset or gearingAdjustment.defaultValueSlave.offset (depending on the range). **On active command and following commands** The offset acts on the current gearing command and on all subsequent "Gearing on" (Page 4385) commands. The offset value is stored in system variables gearingAdjustment.master.offset and gearingAdjustment.defaultValueMaster.offset or gearingAdjustment.slave.offset and gearingAdjustment.defaultValueSlave.offset (depending on the range).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Synchronous velocity operation on

Velocity gearing is characterized by a constant gear ratio between a master value (velocity of a leading axis or external encoder) and a slave value (velocity of a following axis). Unlike gearing, velocity gearing is **not** in positional synchronism.

When velocity gearing is started, the slave value is synchronized to the master value with the programmed dynamic response settings.

The gear ratio is specified as a decimal number.

The master value can be defined in the command; the master value can be modified later with the "Switch master value" (Page 4458).

Other master value sources for SIMOTION devices as of Version V4.2 of SIMOTION Kernel only

As of Version V4.2 of SIMOTION Kernel, the instances of the following technology objects and the variables of the relevant technology object data type are available as master value sources:

- Drive axis
- Path object
- Addition object
- Controller object
- Fixed gear
- Formula object
- Sensor

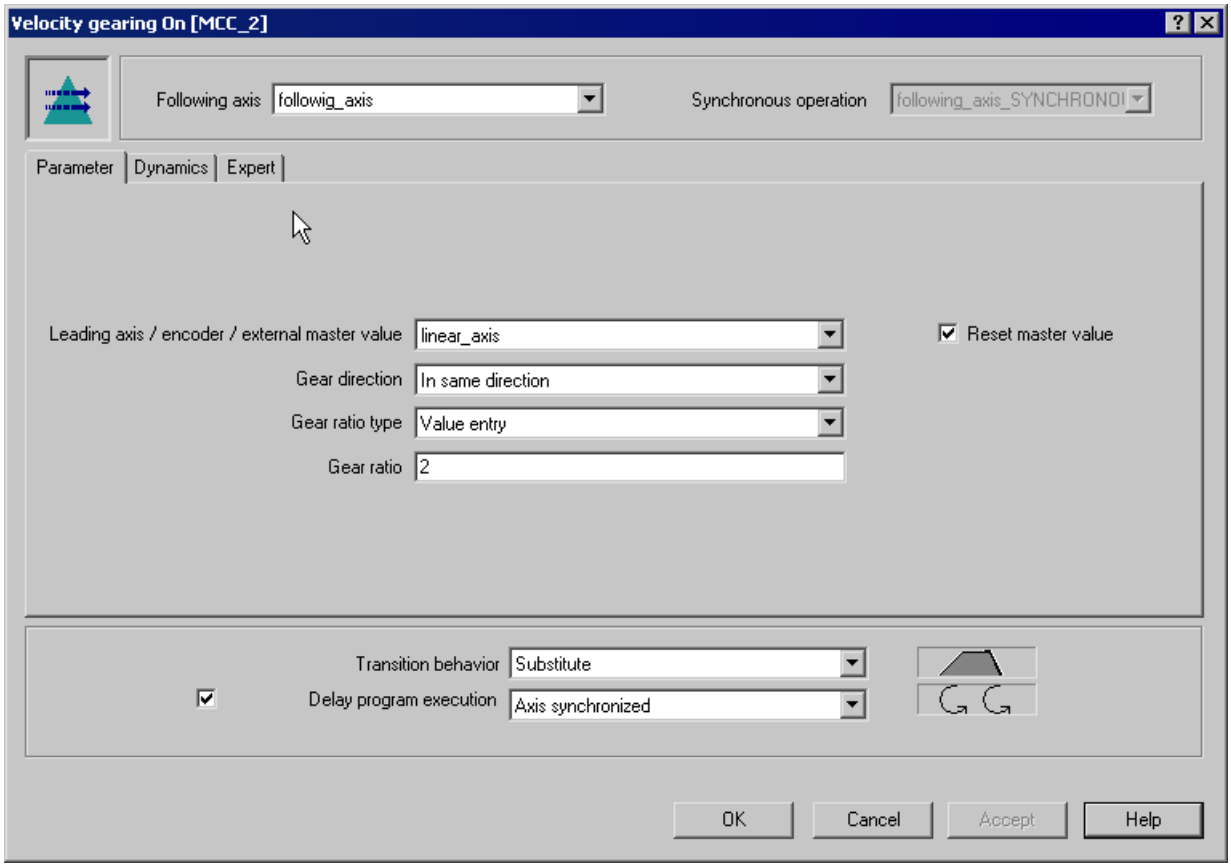

Figure 7-162 Parameter screen form: Velocity gearing on

Velocity gearing can be terminated:

- With the "Velocity gearing off" (Page 4417) command
- By starting another synchronous operation on the same synchronous object, e.g. with another "Velocity gearing on" command
- With a canceling single axis command on the following axis

Note

The "Stop axis" (Page 4281) command will only terminate the velocity gearing if **Quick stop...** has been selected as the stop mode.

Further information:

- For **general information on velocity gearing**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on switching over the master value source**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of Synchronous velocity operation on

Table 7-269 Overview of Velocity gearing on

Field/button	Meaning/instruction
Following axis	Here, you select the axis to be synchronized. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be synchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Following axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as a following axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as a following axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.
Parameters tab	See Overview of parameters for Velocity gearing on - Parameters tab (Page 4414)
Dynamic response tab	See Overview of parameters for Velocity gearing on - Dynamic response tab (Page 4415)

Field/button	Meaning/instruction
Expert tab	See Overview of parameters for Velocity gearing on - Expert tab (Page 4416)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Synchronous velocity operation on – Parameters tab

Table 7-270 Overview of parameters for Velocity gearing on – Parameters tab

Field/button	Meaning/instruction
Reset master value	Activate this checkbox if you want to set the master value of the velocity relationship (default). If the checkbox is deactivated, a previous master value setting is retained. **Note** • As of Version V4.1 of the SIMOTION Kernel, the master value conversion takes place during the synchronization of the synchronous axis (in accordance with the transition behavior "with next synchronization" (Page 4461) with the command "Switch master value"). • From Version V4.0 of the SIMOTION Kernel, the master value conversion takes place immediately at the start of the command (in accordance with the transition behavior "direct" (Page 4461) with the command "Switch master value").
Leading axis / encoder / external master value	An entry can only be made in this field if the **Reset master value** checkbox is activated. Here, you select the axis or external encoder that generates the master value in the velocity relationship. You can select from: • All position, following, and path axes and external encoders that are available on the device or a DP master. The following are also available as of Version V4.2 of SIMOTION Kernel: Drive axes, path objects, addition objects, controller objects, fixed gear, formula objects and sensors. • All variables with the following technology object data types declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)): PosAxis, FollowingAxis, _PathAxis and ExternalEncoderType. The following are also available as of Version V4.2 of SIMOTION Kernel: DriveAxis, _PathObjectType, _AdditionObjectType, _ControllerObjectType, _FixedGearType, _FormulaObjectType, _SensorType. The master value remains assigned to the velocity object until a change occurs.

Field/button	Meaning/instruction
Gear direction	Here, you select the effective direction of the gearing. **From sign of gear ratio** (default value) The effective direction of gearing is defined by the sign of the gear ratio. **Opposite direction** The following axis moves in the opposite direction from the leading axis. **Same direction** The following axis moves in the same direction as the leading axis. **Opposite current gearing direction** The gearing direction opposes the current gearing direction. **Current direction** **Last programmed direction** **Default** See Selection list (combo box) (Page 4022) System variable for default: userDefault.gearingSettings.direction
Gear ratio type	Here you select which values are used for the gear ratio **Value entry** The values are entered directly in the parameter dialog box (in the gear ratio field) **Last programmed value** **Default** See Selection list (combo box) (Page 4022) System variables for default: userDefault.gearingSettings.ratio
Gear ratio	Enter the gear ratio as a floating-point number here. See also input field (Page 4022).

Overview of parameters for Synchronous velocity operation on – Dynamic response tab

Table 7-271 Overview of parameters for Velocity gearing on – Dynamic response tab

Field/button	Meaning/instruction
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031).
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefault.syncDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefault.syncDynamics.positiveAccelStartJerk userDefault.syncDynamics.positiveAccelEndJerk userDefault.syncDynamics.negativeAccelStartJerk userDefault.syncDynamics.negativeAccelEndJerk

CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Example of Synchronous velocity operation on

An axis (rotaryAxis_1) is to rotate at a velocity of 360 degrees/s. A second axis (synchronous axis) is to rotate in synchronism using a gear ratio.

The synchronous axis that is to be coupled with rotaryAxis_1 by means of a gear ratio must be assigned as a synchronous axis in SIMOTION SCOUT.

Cam on

Camming is characterized by a variable gear ratio between a master value (position value of a leading axis or external encoder) and a slave value (position value of a following axis). Camming is thus in positional synchronism.

The variable gear ratio is described by a cam (transmission function).

You can adapt the camming functionality to your requirements using various programmable axis evaluations and cam execution modes.

When camming is started, the slave value is synchronized to the master value with the programmed synchronization settings. It is also possible to switch to another cam at the end of an active cam.

The master value can be defined in the command; the master value can be modified later with the "Switch master value" (Page 4458).

Other master value sources for SIMOTION devices as of Version V4.2 of SIMOTION Kernel only

As of Version V4.2 of SIMOTION Kernel, the instances of the following technology objects and the variables of the relevant technology object data type are available as master value sources:

- Drive axis
- Path object
- Addition object

- Controller object
- Fixed gear
- Formula object
- Sensor

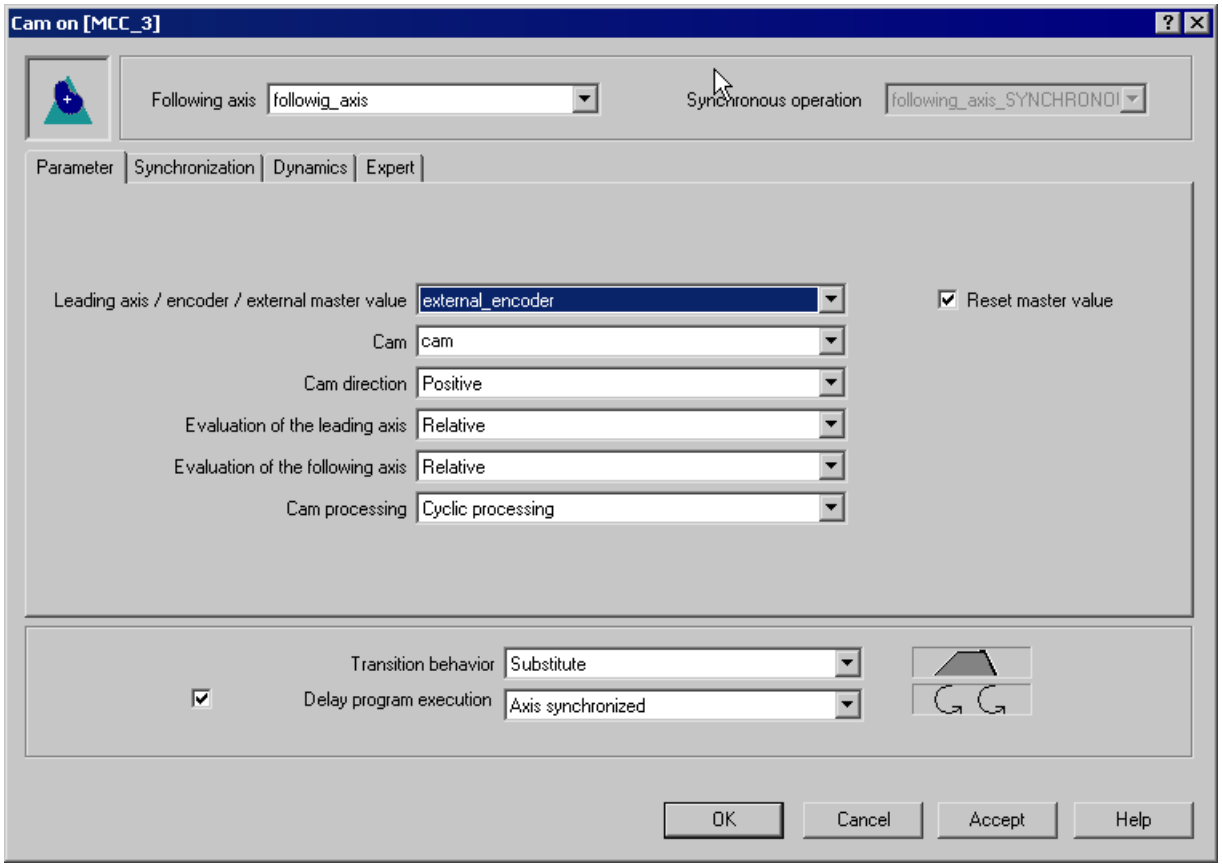

Figure 7-165 Parameter screen form: Cam on

Active camming can be scaled and offset both on the side of the master value and on the side of the slave value. This enables a cam to be adjusted individually in its definition and value range.

The following commands are used for this purpose.

- "Set scaling on camming" (Page 4442) and
- "Set offset on camming" (Page 4447)

In addition, the cam itself can be scaled and offset with the "Parameterize cam" (Page 4453) command.

Camming can be terminated:

- With the "Cam off" (Page 4435) command
- By starting another synchronous operation on the same synchronous object, e.g. with another "Cam on" command
- With a canceling single axis command on the following axis

Note

The "Stop axis" (Page 4281) command will only terminate the synchronous operation if **Quick stop...** has been selected as the stop mode.

Further information:

- For **general information on camming**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on switching over the master value source**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Cam on

Table 7-278 Overview of parameters for Cam on

Field/button	Meaning/instruction
Following axis	Here, you select the axis to be synchronized. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be synchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Following axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as a following axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as a following axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.

Field/button	Meaning/instruction
Dynamic response tab	See Overview of parameters for Cam on - Dynamic response tab (Page 4432)
Expert tab	See Overview of parameters for Cam on - Expert tab (Page 4433)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Cam on – Parameters tab

Table 7-279 Overview of parameters for Cam on – Parameters tab

Field/button	Meaning/instruction
Reset master value	Activate this checkbox if you want to set the master value of the synchronous relationship (default) If the checkbox is deactivated, a previous master value setting is retained. **Note** • As of Version V4.1 of the SIMOTION Kernel, the master value conversion takes place during the synchronization of the synchronous axis (in accordance with the transition behavior "with next synchronization" (Page 4461) with the command "Switch master value"). • From Version V4.0 of the SIMOTION Kernel, the master value conversion takes place immediately at the start of the command (in accordance with the transition behavior "direct" (Page 4461) with the command "Switch master value").
Leading axis / encoder / external master value	An entry can only be made in this field if the **Reset master value** checkbox is activated. Here, you select the axis or external encoder that generates the master value in the synchronous relationship. You can select from: • All position, following, and path axes and external encoders that are available on the device or a DP master. The following are also available as of Version V4.2 of SIMOTION Kernel: Drive axes, path objects, addition objects, controller objects, fixed gear, formula objects and sensors. • All variables with the following technology object data types declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): PosAxis, FollowingAxis, _PathAxis and ExternalEncoderType. The following are also available as of Version V4.2 of SIMOTION Kernel: DriveAxis, _PathObjectType, _AdditionObjectType, _ControllerObjectType, _FixedGearType, _FormulaObjectType, _SensorType. The master value remains assigned to the synchronous object until a change occurs.

Field/button	Meaning/instruction
Cam	Here, select the cam that describes the synchronous relationship. The following are available: • All cams that are defined on the relevant device. The cams are defined in the CAMS folder in the project navigator. • All variables with the following technology object data types declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): CamType. **Note** In the latter case, you must set up the relationships (links) between the cam and the synchronous object of the slave axis in the project navigator. The MCC Editor does this for standard cases.
Cam direction	Here, you select the direction in which the cam is moved when master values are increasing. **Positive** The cam is executed in the **same direction** as the change in the master value. • If the change in the master value is positive, the cam is executed in the direction of increasing definition range values (to the right). • If the change in the master value is negative, the cam is executed in the direction of decreasing definition range values (to the left). **Negative** The cam is executed in the **opposite direction** as the change in the master value. • If the change in the master value is positive, the cam is executed in the direction of decreasing definition range values (to the left). • If the change in the master value is negative, the cam is executed in the direction of increasing definition range values (to the right). **Last programmed direction** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.direction
Evaluation of the leading axis	Here, you select whether the master value behaves absolutely or relatively with respect to the cam. **Absolute** The master value is applied as an absolute value in the definition range of the cam. **Relative** The master value is applied as a relative value (relative to the starting point of camming) in the definition range of the cam. Please note that the value for the **Offset to cam starting point** field (see the parameter overview for Cam on – Synchronization tab (Page 4427)) must be within the cam's definition range. **Last programmed value** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.cammingSettings.masterMode

Field/button	Meaning/instruction
Evaluation of the following axis	Here, you select whether the slave value behaves absolutely or relatively with respect to the cam. **Absolute** The slave value can be calculated as an absolute value from the value range of the cam. If the cam is processed cyclically (see the **Cam processing** field), the slave value begins with the initial value at each new cam cycle. **Relative** The slave value can be calculated as a relative value (relative to the starting point of camming) from the value range of the cam. If the cam is processed cyclically (see the **Cam processing** field), the slave value continues with the end value of the previous cam cycle at each new cam cycle. **Last programmed value** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.cammingSettings.slaveMode
Processing the cam	Here, you select whether the cam is to be processed cyclically. **Cyclic processing** The master values are calculated modulo to the cam length. If the master value reaches the end point of the definition range of the cam, the cam continues to be processed with the start value. **Non-cyclic processing** The master values are limited to the definition range of the cam; the cam is executed once in the definition range. If the master value reaches the starting point or end point of the definition range of the cam, the cam is no longer processed. When the master values are passed through again in the same direction (modulo axis), the slave values do not change. **Last programmed cam mode** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.CammingSettings.cammingMode

Overview of parameters for Cam on – Synchronization tab

Table 7-280 Overview of parameters for Cam on – Synchronization tab

Field/button	Meaning/instruction
Synchronization reference	Here, you select the reference for the synchronization operation. **Leading axis** Length-related synchronization: Synchronization occurs (depending on the leading axis motion) within a defined range of the master value (**Synchronization length**). • Advantage: Synchronization occurs within a parameterizable range of the master value. • Disadvantage: The dynamic response of synchronization is dependent on the change in the master value (velocity). The dynamic response limit values of the following axis are not taken into account. **Time** Time-related synchronization: Synchronization occurs on the basis of specified dynamic values. Program the relevant values in the Dynamic response tab, see Overview of parameters for Cam on - Dynamic response tab (Page 4432). • Advantage: The synchronization operation always takes place with the specified dynamic values. • Disadvantage: The master value range in which synchronization occurs cannot be predicted. **Last programmed setting** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncProfileReference

Field/button	Meaning/instruction
Start of synchronization	Here, you select when synchronization of the cam begins. Additional specifications are required for many of the choices; these are indicated in the description. **At leading axis position** Camming is enabled at a programmed leading axis position. Entries are required in the following fields: • Reference point of leading axis position • Leading axis position Synchronization occurs with respect to the slave values: • Master value = last programmed leading axis position • Slave value: Depending on the selection in **Evaluation of the following axis**, see Overview of parameters for Cam on – Parameters tab (Page 4424): – For **Absolute**: Slave value is calculated with the cam from the programmed leading axis position, taking into account: Evaluation of the leading axis Processing the cam If applicable, offset to cam starting point – For **Relative**: Slave value = current slave value **At leading axis position with offset** Camming is enabled at a programmed leading axis position. An offset for the following axis is additionally programmed. Entries are required in the following fields: • Offset of the following axis • Reference point of leading axis position • Leading axis position Synchronization occurs with respect to the slave values: • Master value = programmed leading axis position • Slave value: Depending on the selection in **Evaluation of the following axis**, see Overview of parameters for Cam on – Parameters tab (Page 4424): – For **Absolute**: Slave value = calculated slave value + programmed offset The calculated slave value is determined the same way as for the **At leading axis position** selection. – For **Relative**: Slave value = current slave value + programmed offset ... (Continued in next row of table)

Field/button	Meaning/instruction
Start of synchronization (continued)	... **Synchronize immediately** Camming is enabled immediately. Synchronization occurs with respect to the slave values: • Master value = current master value • Slave value: Depending on the selection in **Evaluation of the following axis**, see Overview of parameters for Cam on – Parameters tab (Page 4424): – For **Absolute**: Slave value is calculated with the cam from the current master value, taking into account: Evaluation of the leading axis Processing the cam If applicable, offset to cam starting point – For **Relative**: Slave value = current slave value **Synchronize immediately with offset** Camming is enabled immediately. An offset for the following axis is additionally programmed. An entry is required in the following field: • Offset of the following axis Synchronization occurs with respect to the slave values: • Master value = current master value • Slave value: Depending on the selection in **Evaluation of the following axis**, see Overview of parameters for Cam on – Parameters tab (Page 4424): – For **Absolute**: Slave value = calculated slave value + programmed offset The calculated slave value is determined the same way as for the **Synchronize immediately** selection. – For **Relative**: Slave value = current slave value + programmed offset ... (Continued in next row of table)

Field/button	Meaning/instruction
Start of synchronization (continued)	... **At end of cam cycle** This choice is available only for Evaluation of the leading axis as Relative. Camming is enabled when both of the following occur: 1. A camming operation of this synchronous object is already active with another cam 2. The master value of the active camming operation reaches the end of the cam or the cam cycle This enables a switch from one cam to another at a defined point in time. An entry is required in the following field: • Reference point of leading axis position Synchronization occurs with respect to the slave values: • Master value = master value at the end of the cam cycle • Slave value: Depending on the selection in **Evaluation of the following axis**, see Overview of parameters for Cam on – Parameters tab (Page 4424): – For **Absolute**: Slave value is calculated with the cam from the master value at the end of the cam cycle, taking into account: Processing the cam Offset in relation to cam starting point – For **Relative**: Slave value = current slave value **Last programmed setting** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.synchronizingMode
Offset of the following axis	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At leading axis position with offset • Synchronize immediately with offset Here, you enter an offset that will be added to the calculated or current following axis position. See also input field (Page 4022).

Field/button	Meaning/instruction
Reference point of leading axis position	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At leading axis position • At leading axis position with offset • At end of cam cycle Here, you select how the programmed position (see the Leading axis position field) acts relative to the selected synchronization profile. **Synchronize before synchronization position** Synchronization is finished at the programmed position. **Symmetrical** This choice is available only for leading axis synchronization reference. Synchronization occurs in such a way that the programmed position is located symmetrically within the synchronization length. At the programmed position, the leading axis has covered half the distance that is required for synchronization. **Synchronize from synchronization position** Synchronization starts at the programmed position. **Last programmed reference point of leading axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncPositionReference
Synchronization length	An entry is required in this field if you have selected the following in the **Synchronization reference** field: • Leading axis The synchronization length is the master value range in which synchronization occurs. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed synchronization length** **Default** See Selection list (combo box) (Page 4022). System variable for default: userdefault.syncProfile.syncLength
Starting point in the cam for relative camming	An entry is required in this field if you have selected the following in the **Evaluation of the leading axis** field (see Overview of parameters for Cam on – Parameters tab (Page 4424)): • Relative The cam starting point for relative camming specifies the starting point of the cam within its definition range. Enter the value in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed starting point** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.camStartPosition
Following axis position	Enter the following axis position in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed following axis position** **Default** See Selection list (combo box) (Page 4022). System variable for default: userdefault.cammingSettings.syncPositionSlave

Field/button	Meaning/instruction
Leading axis position	An entry is required in this field if you have selected the following in the **Start of synchronization** field: • At leading axis position • At leading axis position with offset Enter the leading axis position in the editable selection list, see Editable selection list (editable combo box) (Page 4023). **Last programmed leading axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.syncPositionMaster
Synchronization direction	Here, you select the direction of motion in which the following axis is to be synchronized. **Retain system behavior** Synchronization occurs over the shortest path without direction specification. In the case of moving axes, a check is made to determine whether the current direction of motion can be maintained. **Maintain direction of the following axis** Synchronization takes place in the direction of motion of the following axis. **Positive** Synchronization occurs in the positive direction of motion. **Negative** Synchronization occurs in the negative direction of motion. **Shortest path** Synchronization occurs over the shortest path without direction specification. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.synchronizingDirection

Overview of parameters for Cam on – Dynamic response tab

Table 7-281 Overview of parameters for Cam on – Dynamic response tab

Field/button	Meaning/instruction
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031). The parameters on the Dynamic response tab are only evaluated for time synchronization reference.
Velocity	The entered value acts during the constant velocity phase. System variable for default: userDefault.syncDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefault.syncDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.positiveAccel

Field/button	Meaning/instruction
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefault.syncDynamics.positiveAccelStartJerk userDefault.syncDynamics.positiveAccelEndJerk userDefault.syncDynamics.negativeAccelStartJerk userDefault.syncDynamics.negativeAccelEndJerk

Overview of parameters for Cam on – Expert tab

Table 7-282 Overview of parameters for Cam on – Expert tab

Field/button	Meaning/instruction
	The Expert tab is described in detail in Expert tab (Page 4034).
CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type for each command step, you can use this variable to find out the result of the command step. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Example of Cam on

An axis (rotaryAxis_1) is to rotate at a velocity of 360 degrees/s. A second axis (synchronous axis) is to be coupled to rotary axis_1 by means of a cam.

The cam must be created and parameterized in SIMOTION SCOUT. The synchronous axis that is to be coupled with rotary axis_1 by means of a cam must be assigned as a synchronous axis in SIMOTION SCOUT.

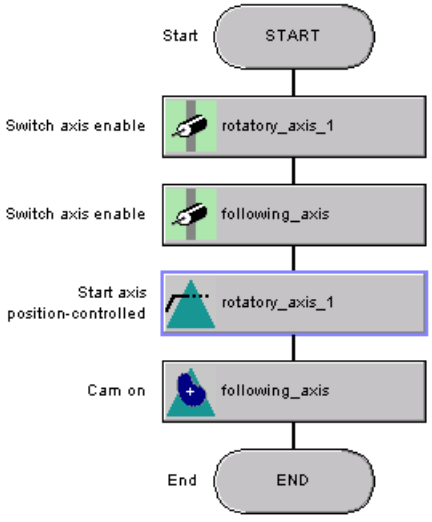

Figure 7-166 Example: MCC chart for a camming operation

Relevant system functions for Cam on

Cam technology package:

- _enableCamming
- _setMaster

If the **Reset master value** checkbox is activated, the _setMaster system function is called first before _enableCamming.

Overview of parameters for Cam on/_enableCamming, _setMaster

Cam off

This command enables you to terminate camming that was started with the "Cam on" (Page 4421) command. Desynchronization occurs with the programmed desynchronization settings.

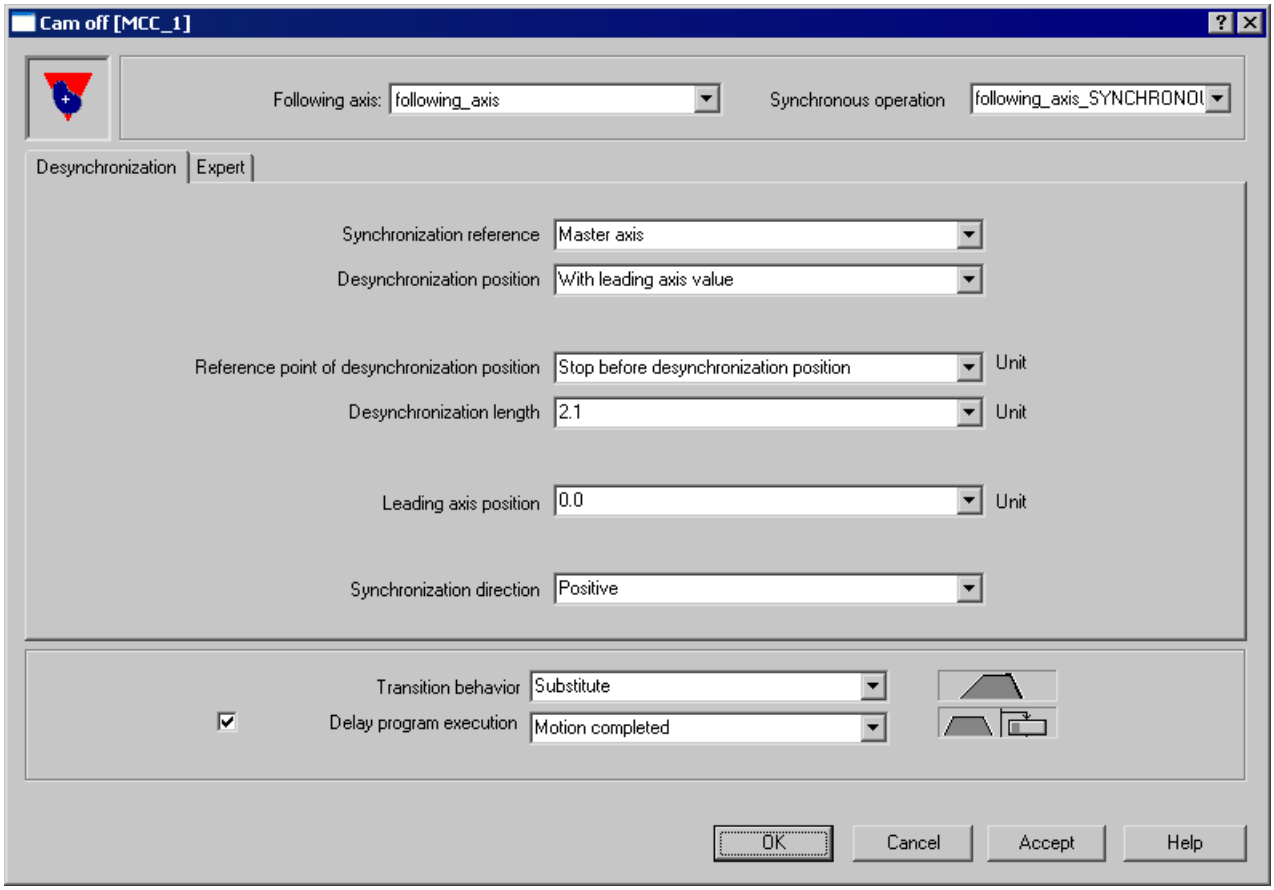

Figure 7-167 Parameter screen form: Cam off

Further information:

- For **general information on camming**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For **general information on switching over the master value source**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Cam off

Table 7-284 Overview of parameters for Cam off

Field/button	Meaning/instruction
Following axis	Here, you select the axis to be desynchronized. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be desynchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Following axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as a following axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as a following axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.
Desynchronization tab	See Overview of parameters for Cam off - Desynchronization tab (Page 4438)
Dynamic response tab	See Overview of parameters for Cam off - Dynamic response tab (Page 4440)
Expert tab	See Overview of parameters for Cam off - Expert tab (Page 4441)

Field/button	Meaning/instruction
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axis. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the command must be entered in the command buffer before the next command is executed. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Cam off – Desynchronization tab

Table 7-285 Overview of parameters for Cam off – Desynchronization tab

Field/button	Meaning/instruction
Synchronization reference	Here you select the reference for the desynchronization operation. **Leading axis** Length-related synchronization: Synchronization occurs (depending on the leading axis motion) within a defined range of the master value (**Desynchronization length**). • Advantage: Synchronization occurs within a parameterizable range of the master value. • Disadvantage: The dynamic response of synchronization is dependent on the change in the master value (velocity). The dynamic response limit values of the following axis are not taken into account. **Time** Time-related synchronization: Synchronization occurs on the basis of specified dynamic values. Program the relevant values in the Dynamic response tab, see Overview of parameters for Cam off - Dynamic response tab (Page 4440). • Advantage: The synchronization operation always takes place with the specified dynamic values. • Disadvantage: The master value range in which synchronization occurs cannot be predicted. **Last programmed setting** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncProfileReference
Desynchronization position	Here, you select when desynchronization of camming begins. Additional specifications are required for some of the choices; these are indicated in the description. **At leading axis value** Camming is disabled at a programmed leading axis position. Entries are required in the following fields: • Reference point of desynchronization position • Leading axis position **Desynchronize immediately** Camming is disabled immediately. **At following axis value** Camming is disabled at a programmed slave axis position. Entries are required in the following fields: • Reference point of desynchronization position • Following axis position **At end of cam cycle** Camming is disabled if the slave value reaches the end of the cam or the cam cycle. An entry is required in the following field: • Reference point of desynchronization position **Last programmed start of desynchronization** **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.syncOffMode

Field/button	Meaning/instruction
Reference point of desynchronization position	An entry is required in this field if you have selected the following in the **Desynchronization position** field: • At leading axis value • At following axis value • At end of cam cycle Here, you select how the programmed position (see the Following axis position or Leading axis position field) acts relative to the selected desynchronization profile. **Stop before desynchronization position** Synchronization is finished at the programmed position. **Symmetrical** This choice is available only for leading axis synchronization reference. Desynchronization occurs in such a way that the programmed position is located symmetrically within the desynchronization length. At the programmed position, the leading axis has covered half the distance that is required for synchronization. **Stop from desynchronization position** Desynchronization starts at the programmed position. **Last programmed reference point of leading axis position** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncOffPositionReference
Desynchronization length	An entry is required in this field if you have selected the following in the **Synchronization reference** field: • Leading axis Enter the synchronization length in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Last programmed desynchronization length** **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncProfile.syncOffLength
Following axis position	An entry is required in this field if you have selected the following in the **Desynchronization position** field: • At following axis value Enter the following axis position in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncOffPositions.Slave

Field/button	Meaning/instruction
Leading axis position	An entry is required in this field if you have selected the following in the **Desynchronization position** field: • At leading axis value Enter the leading axis position in the editable selection list (see Editable selection list (editable combo box) (Page 4023)). **Default** See Selection list (combo box) (Page 4022) System variable for default: userdefault.syncOffPositions.Master
Synchronization direction	Here, you select the direction of motion in which the following axis is to be desynchronized. **Retain system behavior** Synchronization occurs over the shortest path without direction specification. In the case of moving axes, a check is made to determine whether the current direction of motion can be maintained. **Maintain direction of the following axis** Synchronization takes place in the direction of motion of the following axis. **Positive** Synchronization occurs in the positive direction of motion. **Negative** Synchronization occurs in the negative direction of motion. **Shortest path** Synchronization occurs over the shortest path without direction specification. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userdefault.cammingSettings.synchronizingDirection

Set scaling on camming

This command causes scaling of the leading axis or following axis range of the associated cam during camming. You can use parameters to determine the following (among other things):

- Timing for when scaling becomes effective (immediately/next cam cycle)
- Effectiveness on the active camming command and/or subsequent camming commands

Scaling operations that act on the active camming command as well as scaling operations that are stored and act on subsequent commands can be read from the cammingAdjustment system variable.

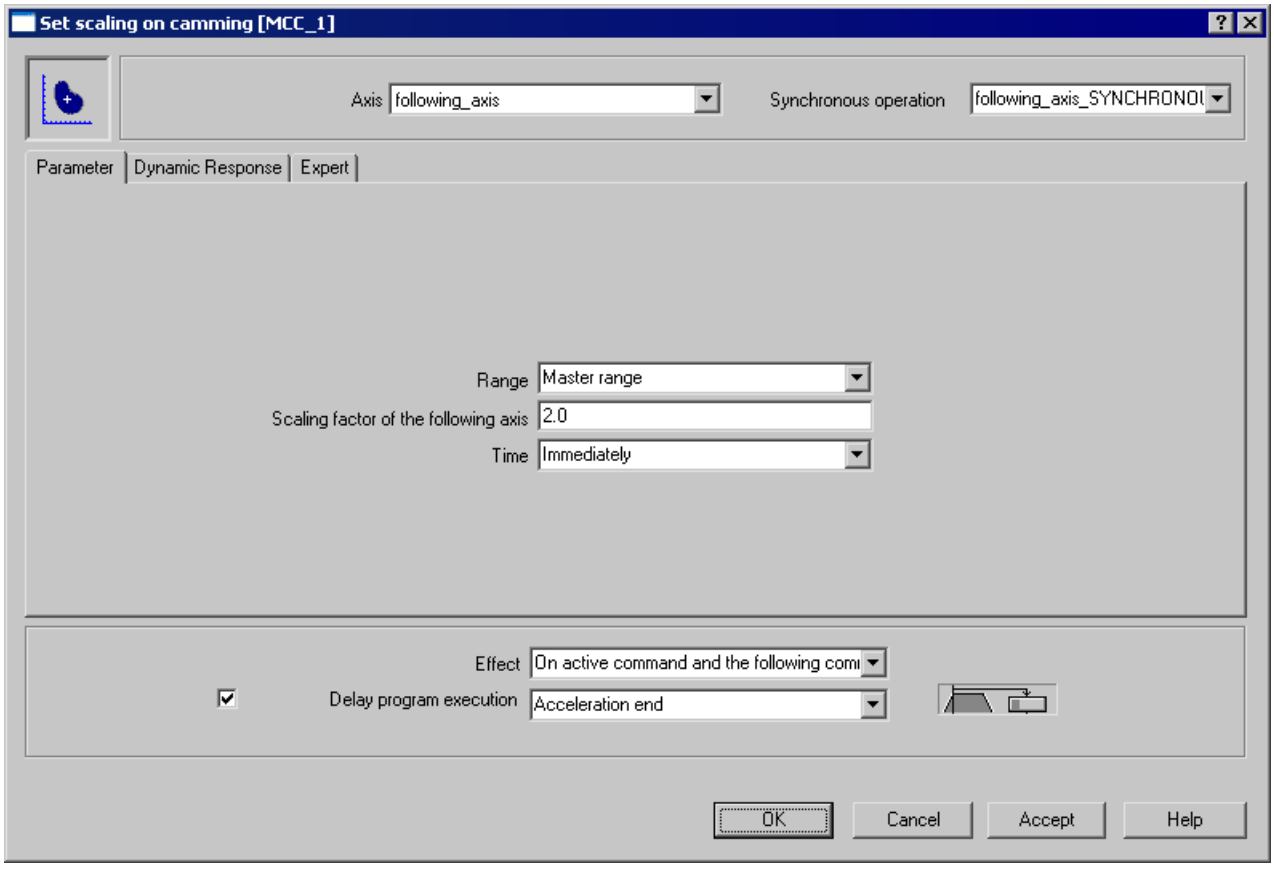

Figure 7-168 Parameter screen form: Set scaling on camming

Further information:

- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For information on **scaling and offset for a cam**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Set scaling on camming

Table 7-289 Overview of parameters for Set scaling on camming

Field/button	Meaning/instruction
Axis	Here, you select the axis for which the cam is to be scaled. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be synchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected **Axis** and are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as an axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <**Reference**> has been selected as the axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.

Dynamic response tab	See Overview of parameters for Set scaling on camming – Dynamic response tab (Page 4446)
Expert tab	See Overview of parameters for Set scaling on camming – Expert tab (Page 4446)

Field/button	Meaning/instruction
Effect	Here you select the commands on which scaling is active. **On active command** (default value) Scaling acts on the active camming command and remains active until this command is replaced or desynchronized using the "Cam off" (Page 4435) command. The scaling factor is stored (depending on the cam range) in system variable cammingAdjustment.master.scale or cammingAdjustment.slave.scale. **on following commands** The active camming command is executed; the scaling is stored and used for the following "Cam on" (Page 4421) commands. The scaling factor is stored (depending on the cam range) in system variable cammingAdjustment.defaultValueMaster.scale or cammingAdjustment.defaultValueSlave.scale. **On active command and following commands** The scaling acts on the current camming command and on all following "Cam on" (Page 4421) commands. The scaling factor is stored (depending on the cam range) in system variables cammingAdjustment.master.scale and cammingAdjustment.defaultValueMaster.scale, or cammingAdjustment.slave.scale and cammingAdjustment.defaultValueSlave.scale.
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Parameterize cam

This command enables a defined electronic cam to be scaled and/or offset.

The master and slave axes can be offset and scaled independently of one another.

Scaling takes place over the complete cam or within a range defined by the starting and end points. Scaling of the complete cam is referred to below as basic scaling; scaling of a range is referred to as range scaling. The definition range and value range each have one basic scaling and two range scalings.

For basic scaling, the zero point of the coordinate axis becomes the scaling point, while for range scaling the starting point of the specified scaling range is used.

This command enables simultaneous specification of one offset and/or basic scaling plus one range scaling each for the master and slave axes.

Expert tab	See Overview of parameters for Parameterize cam – Expert tab (Page 4457)

Overview of parameters for Parameterize cam – Offset tab

Table 7-300 Overview of parameters for Parameterize cam – Offset tab

Field/button	Meaning/instruction
Following axis offset	Select this checkbox if you want to program an offset for the following axis. Enter the offset for the following axis here. See also input field (Page 4022).
Leading axis offset	Select this checkbox if you want to program an offset for the leading axis. Enter the leading axis offset in this box. See also input field (Page 4022).
Calculation	Here, you select whether the newly programmed offset is applied absolutely or is added to the previously active offset. **Absolute**(default value) The programmed value is applied absolutely. **Relative** The programmed value is applied relatively.

Overview of parameters for Parameterize cam – Basic scaling tab

Table 7-301 Overview of parameters for Parameterize cam – Basic scaling tab

Field/button	Meaning/instruction
Following axis scaling factor	Select this checkbox if you wish to program a scaling factor for the complete following axis range. Here, you enter a scaling factor that is valid for the following axis, independent of the range. Using the range scaling (see Overview of parameters for Parameterize cam – Range scaling tab (Page 4456)), you can also activate scaling factors for individual ranges. These are superimposed over the complete scaling. See also input field (Page 4022).
Leading axis scaling factor	Select this checkbox if you want to program a scaling factor for the complete range of the leading axis. Here, you enter a scaling factor that is valid for the leading axis, independent of the range. Using the range scaling (see Overview of parameters for Parameterize cam – Range scaling tab (Page 4456)), you can also activate scaling factors for individual ranges. These are superimposed over the complete scaling. See also input field (Page 4022).

Table 7-302 Overview of parameters for Parameterize cam – Range scaling tab

Field/button	Meaning/instruction
Number of cam range	Here, you select the number of the scaling range (1 or 2). If you select the same number for a subsequent command, you can overwrite the previously programmed values.
Following axis	Activate this checkbox in order to program a scaling factor in a specific range of the following axis.
Start of range (following axis)	Here, you enter the following axis position at which scaling starts. See also input field (Page 4022).
End of range (following axis)	Here, you enter the following axis position at which scaling ends. See also input field (Page 4022).
Scaling factor (following axis)	Here, you enter the scaling factor for the following axis. This is effective within the specified range. See also input field (Page 4022).
Leading axis	Activate this checkbox to program a scaling factor in a specific range of the leading axis.
Start of range (leading axis)	Here, you enter the position of the leading axis at which scaling begins. See also input field (Page 4022).
End of range (leading axis)	Here, you enter the position of the leading axis at which scaling ends. See also input field (Page 4022).
Scaling factor (leading axis)	Here, you enter the scaling factor for the leading axis. This is effective within the specified range. See also input field (Page 4022).

Switch master setpoint

This command switches over the master value for an existing synchronous operation relationship. Switchover is possible when synchronous operation is active.

Other master value sources for SIMOTION devices as of Version V4.2 of SIMOTION Kernel only

As of Version V4.2 of SIMOTION Kernel, the instances of the following technology objects and the variables of the relevant technology object data type are available as master value sources:

- Drive axis
- Path object
- Addition object
- Controller object
- Fixed gear
- Formula object
- Sensor

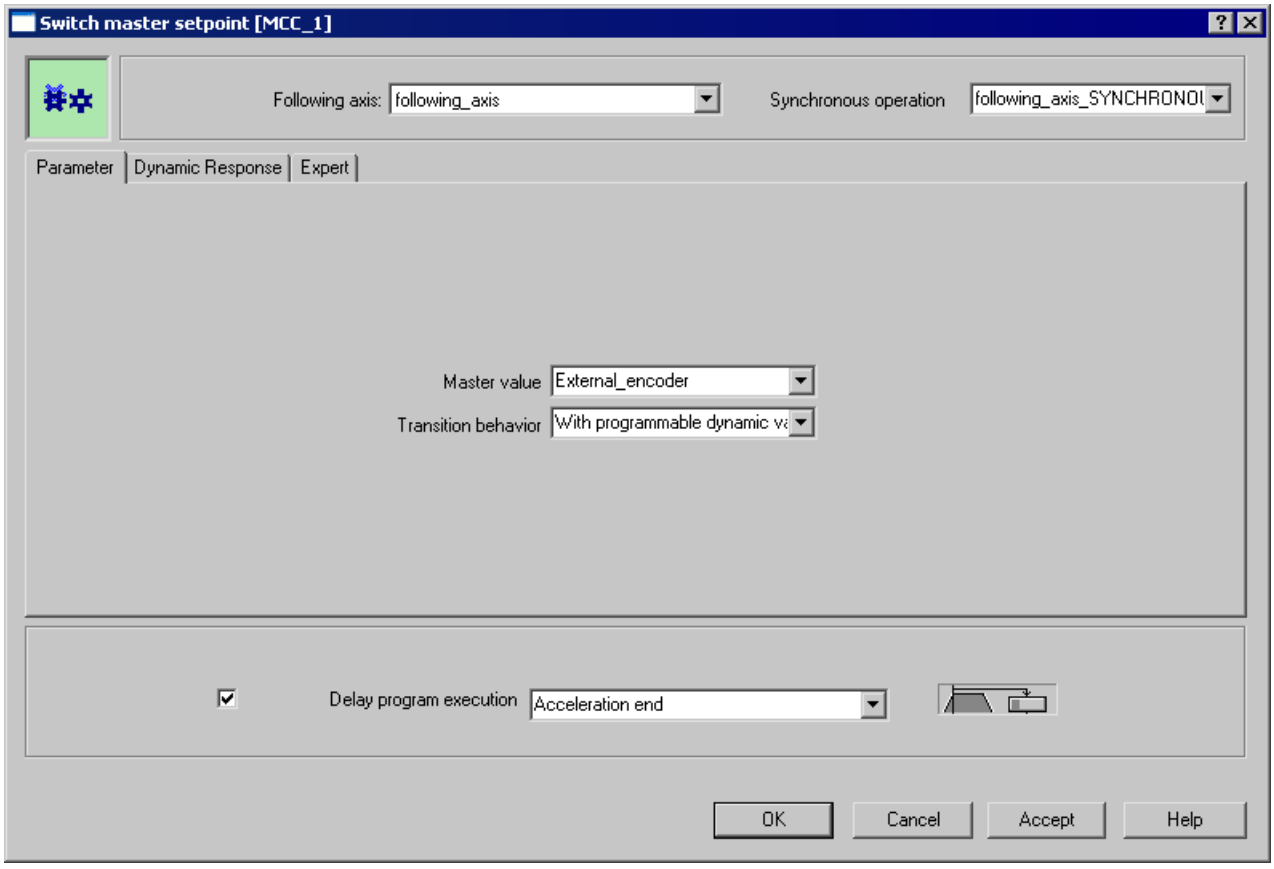

Figure 7-173 Parameter screen form: Switch master value

Further information:

- For **general information on switching over the master value source**, see the Technology Objects Synchronous Operation, Cam Function Manual
- For the **fundamentals of synchronous operation**, see the Technology Objects Synchronous Operation, Cam Function Manual

Overview of parameters for Switch master setpoint

Table 7-305 Overview of parameters for Switch master value

Field/button	Meaning/instruction
Following axis	Here, you select the axis for which the master value is to be switched. The following are available: • All synchronous axes that are defined on the relevant device. The axes are defined in the AXES folder in the project navigator. The synchronous objects associated with the selected synchronous axis are automatically identified and displayed in the **Synchronous operation** field for selection, as appropriate. • <**Reference**> You select this entry if the axis to be synchronized is not defined on the device but rather is specified as a reference (variable). All variables declared in the MCC unit or MCC chart with data type FollowingObjectType (references to synchronous objects) are available for selection in the **Synchronous operation** field, see also Technology object data types (Page 4060). **Note** You cannot select any references to a synchronous axis (variable of FollowingAxis data type). There is no assignment for the reference to the associated synchronous objects. Instead, select the reference to the synchronous object directly (variable of data type FollowingObjectType)
Synchronous operation	Here, the permissible synchronous objects are displayed according to the selected following axis, where they are available for selection, as appropriate: • A synchronous axis defined on the device has been selected as a following axis: The synchronous object associated with the selected following axis is displayed If more than one synchronous object is available (e.g. superimposed synchronous object), you can select the synchronous object. • <Reference> has been selected as a following axis: All technology object-type variables declared in the MCC unit or MCC chart (see Technology object data types (Page 4060)) are available for selection: FollowingObjectType. These variables are references to synchronous objects.
Parameters tab	See Overview of parameters for Switch master value – Parameters tab (Page 4461)
Dynamic response tab	See Overview of parameters for Switch master value – Dynamic response tab (Page 4461)
Expert tab	See Overview of parameters for Switch master value – Expert tab (Page 4462)
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Switch master setpoint – Parameters tab

Table 7-306 Overview of parameters for Switch master value – Parameters tab

Field/button	Meaning/instruction
Master value	Here, you select the axis or external encoder that generates the master value in the synchronous relationship. You can select from: • All position, following, and path axes and external encoders that are available on the device or a DP master. The following are also available as of Version V4.2 of SIMOTION Kernel: Drive axes, path objects, addition objects, controller objects, fixed gear, formula objects and sensors. • All variables with the following technology object data types declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): PosAxis, FollowingAxis, _PathAxis or ExternalEncoderType. The following are also available as of Version V4.2 of SIMOTION Kernel: DriveAxis, _PathObjectType, _AdditionObjectType, _ControllerObjectType, _FixedGearType, _FormulaObjectType, _SensorType. The master value remains assigned to the synchronous object until a change occurs.
Transition behavior	Here, you choose how the switchover to the selected master value is to occur. **direct** Selected master value is active immediately **With next synchronization** Selected master value is active the next time the following axis is synchronized. **With programmed dynamic values** The transition to the selected master value takes place with the values set in the Dynamic response tab (see Overview of parameters for Switch master value – Dynamic response tab (Page 4461)).

Overview of parameters for Switch master setpoint – Dynamic response tab

Table 7-307 Overview of parameters for Switch master value – Dynamic response tab

Field/button	Meaning/instruction
	The Dynamic response tab is described in detail in Dynamic response tab (Page 4031). The parameters on the Dynamic response tab are only evaluated with programmed dynamic values during transition behavior.
Velocity	The entered value acts during the constant velocity phase. System variables for default: userDefault.syncDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. System variables for default: userDefault.syncDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variable for default: userDefault.syncDynamics.positiveAccel

Field/button	Meaning/instruction
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used, see the general description of the Dynamic response tab (Page 4031). System variables for default: userDefault.syncDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefault.syncDynamics.positiveAccelStartJerk userDefault.syncDynamics.positiveAccelEndJerk userDefault.syncDynamics.negativeAccelStartJerk userDefault.syncDynamics.negativeAccelEndJerk

7.1.6.8 Commands for path interpolation

As of version V4.1 of the SIMOTION Kernel, SIMOTION provides path interpolation functions. This functionality enables up to 3 path axes to travel along specified paths. In addition, a position axis can be traversed synchronously with the path.

The **Path object** technology object (data type _PathObjectType) provides this functionality.

- With the Path object technology object, the following additional technology objects are interconnected during configuration:
  - At least 2 and up to 3 axes with the path interpolation technology (**path axes** - data type _PathAxis)
  - Optionally, 1 position axis (data type PosAxis, FollowingAxis or _PathAxis) that is traversed synchronously with the path motion. This facilitates, for example, the synchronous method of this axis to a preset endpoint (or by a predetermined travel) or the output of the actual length of the path motion on this axis.
  - Optionally, 1 cam (data type CamType) in order to specify a special velocity profile for the path motion
  - SIMOTION Kernel as of version V4.4:
    Optional 1 other position axis (data type PosAxis or FollowingAxis or _PathAxis) to output the current length of the path movement if the path-synchronous axis is moved to a preset endpoint (or by a predetermined travel).
- In addition, the motion inputs (MotionIn) of position axes can be interconnected with the 3 motion outputs (MotionOut) of the TO path object. This enables outputting of the 3 coordinates of the basic coordinate system on axes.

- The programming of the path motions is either:
  - In the basic coordinate system (BCS)
    The basic coordinate system is a static, right-handed, rectangular (Cartesian) coordinate system in accordance with DIN 66217
  - In an object coordinate system (OCS - as of version V4.3 of the SIMOTION Kernel)
    An object coordinate system is a coordinate system defined on the path object. It is defined with the system function _setPathObjectOcs. For this purpose, the translation (offset) along the 3 axes and the rotation around the 3 axes must be specified with regard to the basic coordinate system. In addition, it can also be coupled in the x direction synchronously to another motion (e.g. an axis).
    Up to 3 object coordinate systems can be defined on the path object.
- Adaptation of machine kinematics (i.e. axis coordinate system) to the basic coordinate system is done by means of kinematics transformations. You specify this when configuring the TO path object.

The following applies to the path motion:

- The paths can comprise individual path segments.
- These individual segments can be the following 2-dimensional or 3-dimensional motions (interpolations):
  - Linear motion: Traverse path linearly (Page 4464) command
  - Circular motion: Traverse path circularly (Page 4477) command
  - Polynomial motion: Traverse path using polynomials (Page 4491) command
- Blending is used to link individual segments in series to form one complete motion with no intermediary stop.
  As of version V4.3 of the SIMOTION Kernel, optionally a transition geometry (blending segment) can be inserted.
- The following applies for the dynamic response planning:
  - The following applies as of version V4.3 of the SIMOTION Kernel:
    The dynamic response planning is generally performed over 3 successive path segments. A transition geometry (blending segment) is also counted.
  - The following applies up to version V4.2 of the SIMOTION Kernel:
    The dynamic response planning is generally performed over 2 successive path segments.

Traverse path linearly

This function is available in SIMOTION Kernel as of Version 4.1.

This command moves the path axes interconnected with the specified path object on a straight line to an end point. The motion can be carried out in:

- Three dimensions
- Two dimensions in one of the main Cartesian planes

The end point entered can be absolute or relative.

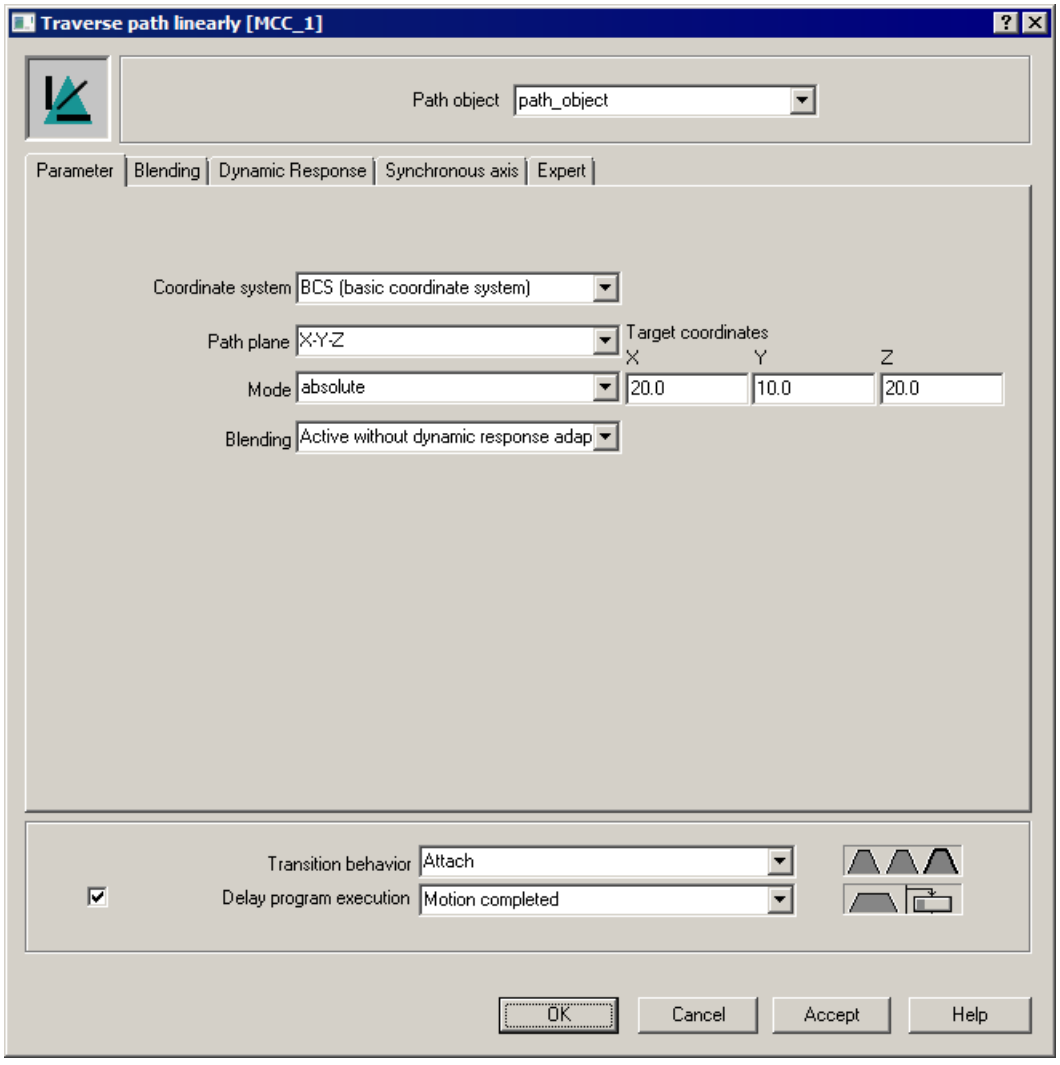

Figure 7-174 Parameter screen form: Traverse path linearly

For the **fundamentals of path interpolation**, see the TO Path Object Function Manual

For further information on **linear paths**, see the TO Path Object Function Manual.

Overview of parameters for Traverse path linearly

Table 7-310 Overview of parameters for Traverse path linearly

Field/button	Meaning/instruction
Path object	In Path object, select the path object whose assigned path axes are to be traversed to the end point. The list contains: • All path objects that are defined on the relevant device. The path objects are defined in the PATH OBJECTS folder in the project navigator. • All variables with the following data type of a technology object declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): _PathObjectType.
Parameters tab	See Overview of parameters for Traverse path linearly - Parameters tab (Page 4466)

Field/button	Meaning/instruction
Blending tab	See Overview of parameters for Traverse path linearly - Blending tab (Page 4469)
Dynamic response tab	See Overview of parameters for Traverse path linearly - Dynamic response tab (Page 4471)
Synchronous axis tab	See Overview of parameters for Traverse path linearly - Path-synchronous motion tab (Page 4474)
Expert tab	See Overview of parameters for Traverse path linearly - Expert tab (Page 4475)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the path object or on the axes involved. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Traverse path linearly – Parameters tab

Table 7-311 Overview of parameters for Traverse path linearly – Parameters tab

Field/button	Meaning/instruction
Coordinate system	This field is available as of SIMOTION Kernel version V4.3. Here you select the coordinate system to which the path motion to be programmed refers. **BCS (basic coordinate system)** (default value) Static, right-handed, rectangular (Cartesian) coordinate system in accordance with DIN 66217. **OCS (object coordinate system)** Coordinate system defined on the path object that is offset and rotated with regard to the basic coordinate system. It can also be coupled synchronously to another motion (e.g. an axis). Up to 3 object coordinate systems can be defined.
Number	This field is available as of SIMOTION Kernel version V4.3. An entry is required in this field if you have selected the following in the **Coordinate system** field: • OCS (object coordinate system) Select the number of the object coordinate system to be used. Possible values are 1 to 3. **1** (default value) Object coordinate system 1

Field/button	Meaning/instruction
Path plane	Here, you select whether the motion is to be carried out in 3 dimensions (3D) or 2 dimensions (2D). **X-Y-Z** Three-dimensional motion **X-Y main plane** **Y-Z main plane** **Z-X main plane** 2-dimensional motion in the selected main plane of the Cartesian basic coordinate system. The target coordinate located outside the selected plane is ignored. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.plane
Mode	The meaning of the subsequently programmed target coordinates is defined in more detail here. **Absolute** The programmed target coordinates refer to the zero point of the basic coordinate system. **Relative** The programmed target coordinates refer to the path position within the basic coordinate system when the path command is executed (point in time of change). **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.mode
Target coordinates X, Y, Z	The end point of the motion is specified here. The meaning depends on the **Mode** parameter (see above)**:** • Absolute mode: Absolute coordinates with respect to the zero point of the basic coordinate system. • Relative mode: Relative coordinates with respect to the path position within the basic coordinate system when the path command is executed (point in time of change). Enter the values as signed floating-point numbers. See the input field (Page 4022).

Field/button	Meaning/instruction
Blending	Using blending, the path segment programmed with this command can be linked to the previous path segment to form one complete path with no stop. At the transition, the system provides for a constant path velocity and a constant path acceleration. As of version V4.3 of the SIMOTION Kernel, a transition geometry (blending segment) can also be inserted. **Active with dynamic response adaptation** The dynamic response limit values of the individual path axes are also applied in the blending area or blending segment. • The following applies up to version V4.2 of the SIMOTION Kernel: This setting is evaluated only with the **Attach** or **Attach and discard the pending command** transition behavior. A blending segment is not inserted. The path velocity is nearly reduced to zero at transitions of path segments in which the gradients or curvatures are not smooth. For the **Substitute** transition behavior, see setting **Inactive**. • The following applies as of version V4.3 of the SIMOTION Kernel: The "Blending" tab (Page 4469) is displayed. There, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment. With the **Do not insert a segment** selection, the same behavior applies as up to version V4.2 of the SIMOTION Kernel. **Active without dynamic response adaptation** In the blending area or blending segment, path interpolation takes into account only the scalar dynamic response limit values of the path (path velocity, path acceleration and jerk). The dynamic response limit values specific to the axes are first taken into account during movement of the individual path axes. • The following applies up to version V4.2 of the SIMOTION Kernel: This setting is evaluated only with the **Attach** or **Attach and discard the pending command** transition behavior. Axis-specific deviations from the path can occur at transitions of path segments in which the gradients or curvatures are not smooth. For the **Substitute** transition behavior, see setting **Inactive**. • The following applies as of version V4.3 of the SIMOTION Kernel: The "Blending" tab (Page 4469) is displayed. There, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment. With the **Do not insert a segment** selection, the same behavior applies as up to version V4.2 of the SIMOTION Kernel.
Blending (continued)	**Inactive** The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: The motion programmed with this command does not begin until the setpoint interpolation of the previous command is complete and its motion has reached the target coordinates. The path velocity and path acceleration are therefore zero at the transition. • Transition behavior = **Substitute**: The motion with its dynamic response parameters programmed with this command immediately replaces the previous path motion. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.blending.mode

Overview of parameters for Traverse path linearly – Blending tab

Table 7-312 Overview of parameters for Traverse path linearly – Blending tab

Field/button	Meaning/instruction
	This tab is available as of SIMOTION Kernel version V4.3. It is only displayed when the value **Inactive** has **not** been selected in the Blending field of the Parameters tab. Here, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment.

Field/button	Meaning/instruction
Blending segment	Here, you specify whether a blending segment to the previous path segment will be inserted. **Do not insert a segment** (default value) A blending segment is not inserted. This corresponds to the behavior up to version V4.2 of the SIMOTION Kernel. See the description for the values **Active with dynamic response adaptation** and **Active without dynamic response adaptation** in the "Blending" field of the Parameters tab (Page 4466). **Insert circle segment** A circular blending segment is inserted. This is only possible between linear path segments (MCC command **Traverse path linearly**). The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: Starting from the end point or start point of the two path segments, the start point and end point of the blending segment is calculated with the blending distance. • Transition behavior = **Substitute**: The blending segment is inserted at the current path position. A fictitious end point or start point of the two path segments and the end point of the blending segment is calculated with the blending distance and the tangent at the path position. The blending segment is calculated so that at the transitions to the two path segments, the position and the velocity are smooth. **Insert polynomial segment** A blending segment described by a polynomial is inserted. This is always possible. The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: Starting from the end point or start point of the two path segments, the start point and end point of the blending segment is calculated with the blending distance. • Transition behavior = **Substitute**: The blending segment is inserted at the current path position. A fictitious end point or start point of the two path segments and the end point of the blending segment is calculated with the blending distance and the tangent at the path position. The blending segment is calculated so that at the transitions to the two path segments, the position, the velocity and the acceleration are smooth. **Stop** The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: The motion programmed with this command does not begin until the setpoint interpolation of the previous command is complete and its motion has reached the target coordinates. The path velocity and path acceleration are therefore zero at the transition. • Transition behavior = **Substitute**: The previous path motion is stopped immediately. The motion programmed with this command starts at the stop position. The dynamic response parameters of this command are also effective for the deceleration of the previous path motion. The path velocity and path acceleration are zero at the transition.

Field/button	Meaning/instruction
Blending distance	An entry is required in this field if you have selected the following in the **Blending segment** field: • Insert circle segment • Insert polynomial segment The blending distance is used to specify the distance from the end point or start point of the two path segments at which the transition geometry (blending segment) is inserted. The blending distance is measured as path length along the two path segments. Enter the value as a signed floating-point number. See also input field (Page 4022).
Velocity in the blending segment	An entry is required in this field if you have selected the following in the **Blending segment** field: • Insert circle segment • Insert polynomial segment Here you specify the velocity that is to be used in the blending segment. Acceleration and jerk are always taken from the current path command **High velocity** The higher velocity of the current and previous path command is used **Low velocity** The lower velocity of the current and previous path command is used

Overview of parameters for Traverse path linearly – Dynamic response tab

Table 7-313 Overview of parameters for Traverse path linearly – Dynamic response tab

Field/button	Meaning/instruction
	Here, you specify the dynamic response of the path motion. In standard cases, you define the dynamic response by means of a velocity profile with the associated values for the velocity, acceleration, deceleration and jerk. A detailed description of these parameters is provided in Overview of parameters – Dynamic response tab (Page 4031). Optionally, you can select a special velocity profile that is described by a cam.
Velocity	The entered value acts during the constant velocity phase. This parameter is evaluated only when **Special velocity profile** = **No**. System variable for default: userDefault.pathDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.profile

Field/button	Meaning/instruction
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. The parameters are evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variables for default: userDefault.pathDynamics.positiveAccelStartJerk userDefault.pathDynamics.positiveAccelEndJerk userDefault.pathDynamics.negativeAccelStartJerk userDefault.pathDynamics.negativeAccelEndJerk
Dynamic response adaptation	Here, you select whether the dynamic response limit values of the individual path axes are to be taken into account during path interpolation. **Inactive** The dynamic response limit values of the individual path axes are **not** taken into account during path interpolation. However, they remain active, and an error is triggered if they are exceeded. This setting should only be selected if it is ensured by other means (e.g. an appropriate specific velocity profile) that the limit values will not be exceeded. **Without segmentation across the path** The dynamic response limit values of the individual path axes for velocity and acceleration are taken into account during path interpolation. If a position axis is configured for the path-synchronous motion, its dynamic response limit values are also included. Path velocity and path acceleration are adapted for the entire path motion if necessary. **With segmentation across the path** The dynamic response limit values of the individual path axes for velocity and acceleration are taken into account during path interpolation. If a position axis is configured for the path-synchronous motion, its dynamic response limit values are also included. The path motion is divided up into individual segments, as determined by the system, if necessary. Within each segment, the path velocity and the path acceleration are adapted to the maximum axial dynamic response limit values. **Default** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.dynamicAdaption

Field/button	Meaning/instruction
Specific velocity profile	Here, you select whether the path dynamic response is specified with the velocity profile defined above or with a velocity profile that is defined by a cam. **No** (default value) The path dynamic response is specified with the velocity profile defined above with the parameters: **velocity profile**, **velocity**, **acceleration**, **deceleration**, and **jerk**. **Yes** The path dynamic response is specified with a velocity profile that is defined by a cam.
Cam	This field is only visible when **Specific velocity profile** = **Yes**. Here, you select the cam which defines the velocity profile. The following are available: • All cams that are defined on the relevant device. The cams are defined in the CAMS folder in the project navigator. • All variables with the following technology object data type declared in the MCC source file or MCC chart (see Technology object data types (Page 4060)): camType. The **Profile position at start of path** and **Profile position at end of path** parameters are used to select an area within the definition range of the cam (x axis) that is mapped by scaling to the length of the programmed path. The value range (y axis) is interpreted as the velocity in the unit configured on the path object.
Profile position at start of path Profile position at end of path	These two values determine the area within the definition range of the cam (x axis) that is mapped by scaling to the length of the programmed path. Enter the values as signed floating-point numbers. See the input field (Page 4022).

Overview of parameters for Traverse path linearly – Synchronous axis tab

Table 7-314 Overview of parameters for Traverse path linearly – Synchronous axis tab

Field/button	Meaning/instruction
	Here, you specify values for the motion of the additional position axis that is assigned to the path object and is traversed synchronously with the path motion.
Synchronous axis mode	Here, you specify how the synchronous axis (axis for path-synchronous motion) should be traversed with the path motion: **Absolute** The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. **Relative** The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. **Output path length** At the position axis for the path-synchronous motion w, the path length (i.e. the distance covered by the path motion) is outputted linearly, beginning from zero. **Output path length added** At the position axis for the path-synchronous motion w, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted at the beginning of the path motion. **w absolute and output of path length in w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) is outputted linearly beginning from zero. **w absolute and output of path length added to w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted linearly at the beginning of the path motion. **w absolute and output of path length in w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) is outputted linearly beginning from zero. **w relative and output of path length added to w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted linearly at the beginning of the path motion. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.w.mode

Field/button	Meaning/instruction
Synchronous axis direction	Select the direction of the path-synchronous motion. The direction must be specified in the following cases: • The **Synchronous axis mode** is relative • The axis for the path-synchronous motion is a modulo axis. **Positive** The direction of motion is the positive direction of the axis. With relative motion, the sign of the position is ignored. **Negative** The direction of motion is the negative direction of the axis. With relative motion, the sign of the position is ignored. **From position** The direction of motion is determined by the sign of the **Synchronous axis position**. **Shortest path** • With **Synchronous axis mode** relative: The direction of motion is determined by the sign of the **Synchronous axis position**. • With modulo axes: The direction of motion is the direction in which the programmed target position can be reached via the shortest path. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.w.direction
Synchronous axis position	This parameter is evaluated only for the following settings for **Synchronous axis mode** and has different meanings: • **Absolute** or **w absolute ...** : End point of the path-synchronous motion. • **Relative** or **w relative ...** : Traversing distance of the path-synchronous motion. Enter the values as signed floating-point numbers. See the input field (Page 4022).

Traverse path circularly

This function is available in SIMOTION Kernel as of Version 4.1.

This command moves the path axes interconnected with the specified path object on an arc to an end point. You can define the arc as follows:

- With the end point of the motion and the radius and orientation of the arc (enables only two-dimensional motion in one of the main Cartesian planes)
- With the center and angle of the arc (enables only two-dimensional motion in one of the main Cartesian planes)
- With the intermediate and endpoint of the motion (enables three-dimensional or two-dimensional motion in one of the main Cartesian planes)

The center, intermediate point, and end point can be specified as absolute or relative.

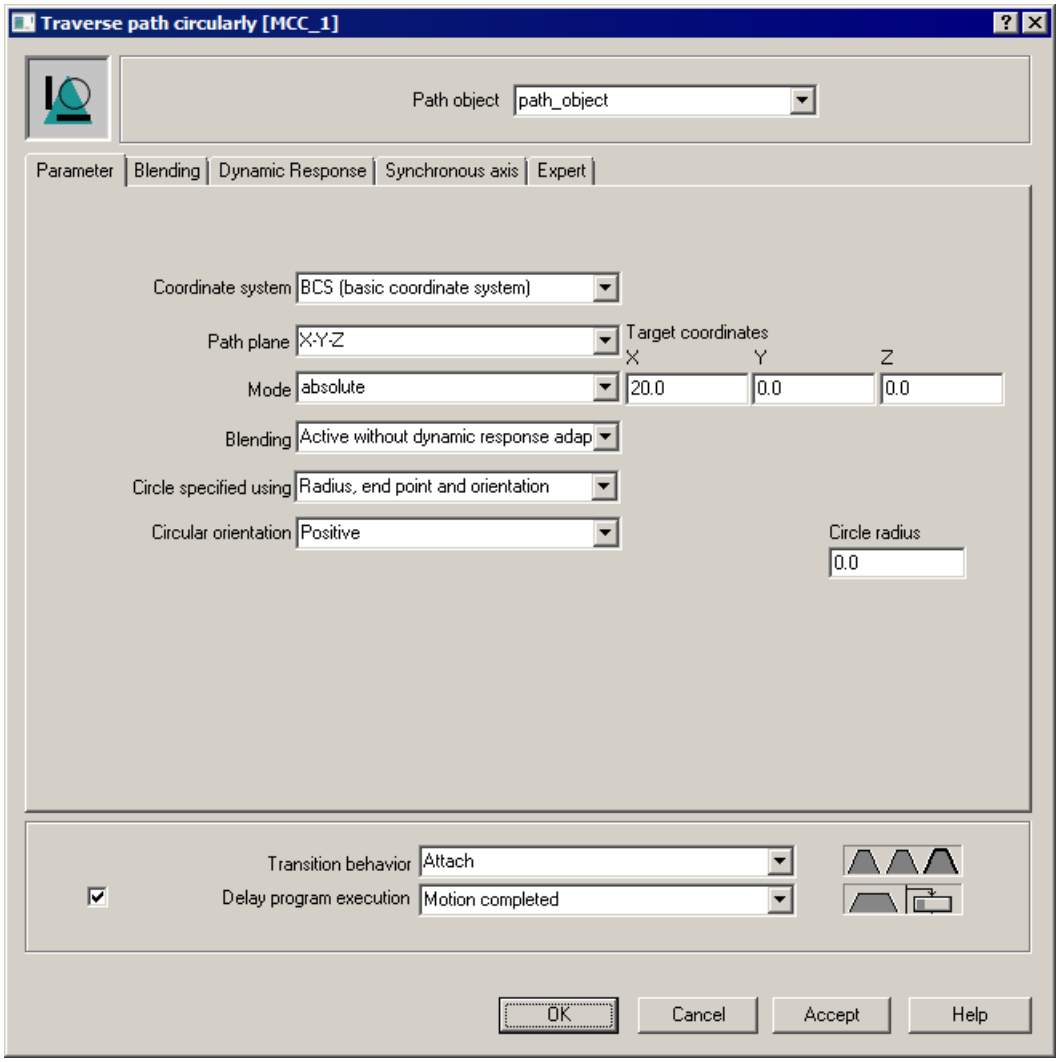

Figure 7-175 Parameter screen form: Traverse path circularly

For the **fundamentals of path interpolation**, see the TO Path Object Function Manual

For further information on **circular paths**, see the TO Path Object Function Manual.

Overview of parameters for Traverse path circularly

Table 7-317 Overview of parameters for Traverse path circularly

Field/button	Meaning/instruction
Path object	In Path object, select the path object whose assigned path axes are to be traversed to the end point. The list contains: • All path objects that are defined on the relevant device. The path objects are defined in the PATH OBJECTS folder in the project navigator. • All variables with the following data type of a technology object declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): _PathObjectType.
Parameters tab	See Overview of parameters for Traverse path circularly - Parameters tab (Page 4479)
Blending tab	See Overview of parameters for Traverse path circularly - Blending tab (Page 4484)
Dynamic response tab	See Overview of parameters for Traverse path circularly - Dynamic response tab (Page 4485)
Synchronous axis tab	See Overview of parameters for Traverse path circularly - Synchronous axis tab (Page 4488)
Expert tab	See Overview of parameters for Traverse path circularly - Expert tab (Page 4489)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the path object or on the axes involved. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Select the checkbox if you wish the system to delay execution of the following command in the MCC chart until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Traverse path circularly – Parameters tab

Table 7-318 Overview of parameters for Traverse path circularly – Parameters tab

Field/button	Meaning/instruction
Coordinate system	This field is available as of SIMOTION Kernel version V4.3. Here you select the coordinate system to which the path motion to be programmed refers. **BCS (basic coordinate system)** (default value) Static, right-handed, rectangular (Cartesian) coordinate system in accordance with DIN 66217. **OCS (object coordinate system)** Coordinate system defined on the path object that is offset and rotated with regard to the basic coordinate system. It can also be coupled synchronously to another motion (e.g. an axis). Up to 3 object coordinate systems can be defined.
Number	This field is available as of SIMOTION Kernel version V4.3. An entry is required in this field if you have selected the following in the **Coordinate system** field: • OCS (object coordinate system) Select the number of the object coordinate system to be used. Possible values are 1 to 3. **1** (default value) Object coordinate system 1
Path plane	Here, you select whether the motion is to be carried out in 3 dimensions (3D) or 2 dimensions (2D). **X-Y-Z** Three-dimensional motion **X-Y main plane** **Y-Z main plane** **Z-X main plane** 2-dimensional motion in the selected main plane of the Cartesian basic coordinate system. The target coordinate located outside the selected plane is ignored. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.plane
Mode	This parameter is evaluated only for: • Circle specified using radius, end point, and orientation • Circle specified using intermediate and end point The meaning of the subsequently programmed target coordinates is defined in more detail here. **Absolute** The programmed target coordinates refer to the zero point of the basic coordinate system. **Relative** The programmed target coordinates refer to the path position within the basic coordinate system when the path command is executed (point in time of change). **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.mode

Field/button	Meaning/instruction
Target coordinates X, Y, Z	These parameters are evaluated only for: • Circle specified using radius, end point, and orientation • Circle specified using intermediate and end point The end point of the motion is specified here. The meaning depends on the **Mode** parameter (see above)**:** • Absolute mode: Absolute coordinates with respect to the zero point of the basic coordinate system. • Relative mode: Relative coordinates with respect to the path position within the basic coordinate system when the path command is executed (point in time of change) Enter the values as signed floating-point numbers. See the input field (Page 4022).
Blending	Using blending, the path segment programmed with this command can be linked to the previous path segment to form one complete path with no stop. At the transition, the system provides for a constant path velocity and a constant path acceleration. As of version V4.3 of the SIMOTION Kernel, a transition geometry (blending segment) can also be inserted. **Active with dynamic response adaptation** The dynamic response limit values of the individual path axes are also applied in the blending area or blending segment. • The following applies up to version V4.2 of the SIMOTION Kernel: This setting is evaluated only with the **Attach** or **Attach and discard the pending command** transition behavior. A blending segment is not inserted. The path velocity is nearly reduced to zero at transitions of path segments in which the gradients or curvatures are not smooth. For the **Substitute** transition behavior, see setting **Inactive**. • The following applies as of version V4.3 of the SIMOTION Kernel: The "Blending" tab (Page 4484) is displayed. There, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment. With the **Do not insert a segment** selection, the same behavior applies as up to version V4.2 of the SIMOTION Kernel. **Active without dynamic response adaptation** In the blending area or blending segment, path interpolation takes into account only the scalar dynamic response limit values of the path (path velocity, path acceleration and jerk). The dynamic response limit values specific to the axes are first taken into account during movement of the individual path axes. • The following applies up to version V4.2 of the SIMOTION Kernel: This setting is evaluated only with the **Attach** or **Attach and discard the pending command** transition behavior. Axis-specific deviations from the path can occur at transitions of path segments in which the gradients or curvatures are not smooth. For the **Substitute** transition behavior, see setting **Inactive**. • The following applies as of version V4.3 of the SIMOTION Kernel: The "Blending" tab (Page 4484) is displayed. There, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment. With the **Do not insert a segment** selection, the same behavior applies as up to version V4.2 of the SIMOTION Kernel.

Field/button	Meaning/instruction
Blending (continued)	**Inactive** The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: The motion programmed with this command does not begin until the setpoint interpolation of the previous command is complete and its motion has reached the target coordinates. The path velocity and path acceleration are therefore zero at the transition. • Transition behavior = **Substitute**: The motion with its dynamic response parameters programmed with this command immediately replaces the previous path motion. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.blending.mode
Circle specified via	Here, you select the characteristic values specifying the arc to be traversed. **Radius, end point, and orientation** Only 2D interpolation is possible in the main plane of the coordinate system selected in the Path plane parameter. The end point specified with the target coordinates is approached on an arc starting from the current position. You define the arc with its radius and circular orientation. Note that for the circular orientation, in addition to the direction of rotation, you must specify whether traversing is to be performed along the large or small arc. **Center and angle** Only 2D interpolation is possible in the main plane of the coordinate system selected in the Path plane parameter. Starting from the current position, an arc is traversed. You define this arc by its center coordinates, the angle, and the circular orientation. **Intermediate and end point** 2D and 3D interpolation are possible. The end point specified with the target coordinates is approached on an arc starting from the current position. You define the arc using an intermediate point that you specify with its intermediate point coordinates. With 3D interpolation, you define the path plane through the current position at the beginning of the path, the intermediate point, and the end point. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.circularType

Field/button	Meaning/instruction
Circular orientation	This parameter is evaluated only for: • Circle specified using radius, end point, and orientation • Circle specified using center and angle Here, you enter the orientation of the arc. **Positive** (default value) Positive direction of rotation in the selected main plane. For a circle specified using radius, end point, and orientation, the angle traveled is less than or equal to 180 °. **Negative** Negative direction of rotation in the selected main plane. For a circle specified using radius, end point, and orientation, the angle traveled is less than or equal to 180 °. **Positive on large arc** Positive direction of rotation in the selected main plane. For a circle specified using radius, end point, and orientation, the angle traveled is greater than or equal to 180 °. **Negative on large arc** Negative direction of rotation in the selected main plane. For a circle specified using radius, end point, and orientation, the angle traveled is greater than or equal to 180 °.
Intermediate point mode	This parameter is evaluated only for: • Circle specified using center and angle • Circle specified using intermediate and end point The meaning of the subsequently programmed center and intermediate point coordinates is defined in more detail here. **Absolute** The programmed center and intermediate point coordinates refer to the zero point of the basic coordinate system. **Relative** The programmed center and intermediate coordinates refer to the path position within the basic coordinate system when the path command is executed (point in time of change). **As end point coordinate** The setting from the Mode parameter is taken for the programmed center and intermediate point coordinates. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.ijkMode
Center coordinates Center point coordinates I, J, K	These parameters are evaluated only for: • Circle specified using center and angle • Circle specified using intermediate and end point Here, you specify the center of the arc and the intermediate point of the circular motion. The meaning depends on the **Intermediate point mode** parameter (see above)**:** • Intermediate point absolute mode: Absolute coordinates with respect to the zero point of the basic coordinate system. • Intermediate point relative mode: Relative coordinates with respect to the path position within the basic coordinate system when the path command is executed (point in time of change). Enter the values as signed floating-point numbers. See Selection list (combo box) (Page 4022).

Field/button	Meaning/instruction
Angle	The parameter is evaluated only for circle specification with center point and angle: Here, you specify the angle of rotation of the arc. Enter the value as a signed floating-point number. See the input field (Page 4022).
Radius	The parameter is evaluated only for circle specification with radius, end point, and orientation: Here, you specify the radius of the arc. Enter the value as a signed floating-point number. See the input field (Page 4022).

Overview of parameters for Traverse path circularly – Blending tab

Table 7-319 Overview of parameters for Traverse path circularly – Blending tab

Field/button	Meaning/instruction
	This tab is available as of SIMOTION Kernel version V4.3. It is only displayed when the value **Inactive** has **not** been selected in the Blending field of the Parameters tab. Here, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment.
Blending segment	Here, you specify whether a blending segment to the previous path segment will be inserted. **Do not insert a segment** (default value) A blending segment is not inserted. This corresponds to the behavior up to version V4.2 of the SIMOTION Kernel. See the description for the values **Active with dynamic response adaptation** and **Active without dynamic response adaptation** in the "Blending" field of the Parameters tab (Page 4479). **Insert polynomial segment** A blending segment described by a polynomial is inserted. This is always possible. The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: Starting from the end point or start point of the two path segments, the start point and end point of the blending segment is calculated with the blending distance. • Transition behavior = **Substitute**: The blending segment is inserted at the current path position. A fictitious end point or start point of the two path segments and the end point of the blending segment is calculated with the blending distance and the tangent at the path position. The blending segment is calculated so that at the transitions to the two path segments, the position, the velocity and the acceleration are smooth. **Stop** The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: The motion programmed with this command does not begin until the setpoint interpolation of the previous command is complete and its motion has reached the target coordinates. The path velocity and path acceleration are therefore zero at the transition. • Transition behavior = **Substitute**: The previous path motion is stopped immediately. The motion programmed with this command starts at the stop position. The dynamic response parameters of this command are also effective for the deceleration of the previous path motion. The path velocity and path acceleration are zero at the transition.

Field/button	Meaning/instruction
Blending distance	An entry is required in this field if you have selected the following in the **Blending segment** field: • Insert circle segment • Insert polynomial segment The blending distance is used to specify the distance from the end point or start point of the two path segments at which the transition geometry (blending segment) is inserted. The blending distance is measured as path length along the two path segments. Enter the value as a signed floating-point number. See also input field (Page 4022).
Velocity in the blending segment	An entry is required in this field if you have selected the following in the **Blending segment** field: • Insert circle segment • Insert polynomial segment Here you specify the velocity that is to be used in the blending segment. Acceleration and jerk are always taken from the current path command **High velocity** The higher velocity of the current and previous path command is used **Low velocity** The lower velocity of the current and previous path command is used

Overview of parameters for Traverse path circularly – Dynamic response tab

Table 7-320 Overview of parameters for Traverse path circularly – Dynamic response tab

Field/button	Meaning/instruction
	Here, you specify the dynamic response of the path motion. In standard cases, you define the dynamic response by means of a velocity profile with the associated values for the velocity. Acceleration, deceleration, and jerk. A detailed description of these parameters is provided in Overview of parameters – Dynamic response tab (Page 4031). Optionally, you can select a special velocity profile that is described by a cam.
Velocity	The entered value acts during the constant velocity phase. This parameter is evaluated only when **Special velocity profile** = **No**. System variable for default: userDefault.pathDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.profile

Field/button	Meaning/instruction
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. The parameters are evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variables for default: userDefault.pathDynamics.positiveAccelStartJerk userDefault.pathDynamics.positiveAccelEndJerk userDefault.pathDynamics.negativeAccelStartJerk userDefault.pathDynamics.negativeAccelEndJerk
Dynamic response adaptation	Here, you select whether the dynamic response limit values of the individual path axes are to be taken into account during path interpolation. **Inactive** The dynamic response limit values of the individual path axes are **not** taken into account during path interpolation. However, they remain active, and an error is triggered if they are exceeded. This setting should only be selected if it is ensured by other means (e.g. an appropriate specific velocity profile) that the limit values will not be exceeded. **Without segmentation across the path** The dynamic response limit values of the individual path axes for velocity and acceleration are taken into account during path interpolation. If a position axis is configured for the path-synchronous motion, its dynamic response limit values are also included. Path velocity and path acceleration are adapted for the entire path motion if necessary. **With segmentation across the path** The dynamic response limit values of the individual path axes for velocity and acceleration are taken into account during path interpolation. If a position axis is configured for the path-synchronous motion, its dynamic response limit values are also included. The path motion is divided up into individual segments, as determined by the system, if necessary. Within each segment, the path velocity and the path acceleration are adapted to the maximum axial dynamic response limit values. **Default** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.dynamicAdaption

Field/button	Meaning/instruction
Specific velocity profile	Here, you select whether the path dynamic response is specified with the velocity profile defined above or with a velocity profile that is defined by a cam. **No** (default value) The path dynamic response is specified with the velocity profile defined above with the parameters: **velocity profile**, **velocity**, **acceleration**, **deceleration**, and **jerk**. **Yes** The path dynamic response is specified with a velocity profile that is defined by a cam.
Cam	This field is only visible when **Specific velocity profile** = **Yes**. Here, you select the cam which defines the velocity profile. The following are available: • All cams that are defined on the relevant device. The cams are defined in the CAMS folder in the project navigator. • All variables with the following technology object data type declared in the MCC unit or MCC chart (Description of technology object data types (Page 4060)): camType. The **Profile position at start of path** and **Profile position at end of path** parameters are used to select an area within the definition range of the cam (x axis) that is mapped by scaling to the length of the programmed path. The value range (y axis) is interpreted as the velocity in the unit configured on the path object.
Profile position at start of path Profile position at end of path	These two values determine the area within the definition range of the cam (x axis) that is mapped by scaling to the length of the programmed path. Enter the values as signed floating-point numbers. See the input field (Page 4022).

Overview of parameters for Traverse path circularly – Synchronous axis tab

Table 7-321 Overview of parameters for Traverse path circularly – Synchronous axis tab

Field/button	Meaning/instruction
	Here, you specify values for the motion of the additional position axis that is assigned to the path object and is traversed synchronously with the path motion.
Synchronous axis mode	Here, you specify how the synchronous axis (axis for path-synchronous motion) should be traversed with the path motion: **Absolute** The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. **Relative** The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. **Output path length** At the position axis for the path-synchronous motion w, the path length (i.e. the distance covered by the path motion) is outputted linearly, beginning from zero. **Output path length added** At the position axis for the path-synchronous motion w, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted at the beginning of the path motion. **w absolute and output of path length in w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) is outputted linearly beginning from zero. **w absolute and output of path length added to w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted linearly at the beginning of the path motion. **w absolute and output of path length in w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) is outputted linearly beginning from zero. **w relative and output of path length added to w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted linearly at the beginning of the path motion. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.w.mode

Field/button	Meaning/instruction
Synchronous axis direction	Select the direction of the path-synchronous motion. The direction must be specified in the following cases: • The **Synchronous axis mode** is relative • The axis for the path-synchronous motion is a modulo axis. **Positive** The direction of motion is the positive direction of the axis. With relative motion, the sign of the position is ignored. **Negative** The direction of motion is the negative direction of the axis. With relative motion, the sign of the position is ignored. **From position** The direction of motion is determined by the sign of the **Synchronous axis position**. **Shortest path** • With **Synchronous axis mode** relative: The direction of motion is determined by the sign of the **Synchronous axis position**. • With modulo axes: The direction of motion is the direction in which the programmed target position can be reached via the shortest path. **Default value** See Selection list (combo box) (Page 4022) System variable for default: userDefault.w.direction
Synchronous axis position	This parameter is evaluated only for the following settings for **Synchronous axis mode** and has different meanings: • **Absolute** or **w absolute ...** : End point of the path-synchronous motion. • **Relative** or **w relative ...** : Traversing distance of the path-synchronous motion. Enter the values as signed floating-point numbers. See the input field (Page 4022).

Traverse path using polynomials

This function is available in SIMOTION Kernel as of Version 4.1.

This command moves the path axes interconnected with the specified path object on a path described by a fifth order polynomial.

$\mathbf{P}(q) = \mathbf{a}_0 + \mathbf{a}_1 q + \mathbf{a}_2 q^2 + \mathbf{a}_3 q^3 + \mathbf{a}_4 q^4 + \mathbf{a}_5 q^5$, where $q \in [0, 1]$.

Here the polynomial coefficients $\mathbf{a}_0$ to $\mathbf{a}_5$ are three-dimensional vectors. You may specify these in the following ways:

- **By calculation from geometric data**
  In this case you specify the following values:
  - Start point (current position) and end point (target coordinates)
  - First geometric derivative (tangential vector) and second geometric derivative (curvature vector) at the start point
  - First geometric derivative (tangential vector) and second geometric derivative (curvature vector) at the end point.

  You can select how the first and second geometric derivatives are specified at the start point:
  - With explicit specification of values
  - By accepting the corresponding values at the end point of the previous path command

  The polynomial coefficients $\mathbf{a}_0$ to $\mathbf{a}_5$ are calculated from this geometric data.
  System functions are available for performing a geometric analysis of paths (e.g. determining the geometric derivatives at specified points).
- **By direct specification of the polynomial coefficients**
  In this case you specify the following values:
  - The start point (current position) corresponds to $\mathbf{P}(0)$.
  - The end point (target coordinates) corresponds to $\mathbf{P}(1)$.
  - The polynomial coefficients $\mathbf{a}_2$, $\mathbf{a}_3$, $\mathbf{a}_4$ and $\mathbf{a}_5$.

  The polynomial coefficients $\mathbf{a}_0$ and $\mathbf{a}_1$ are calculated from this data:
  - $\mathbf{a}_0 = \mathbf{P}(0)$
  - $\mathbf{a}1 = \mathbf{P}(1) - \mathbf{P}(0) - \mathbf{a}_2 - \mathbf{a}_3 - \mathbf{a}_4 - \mathbf{a}_5$.

The end point entered can be absolute or relative.

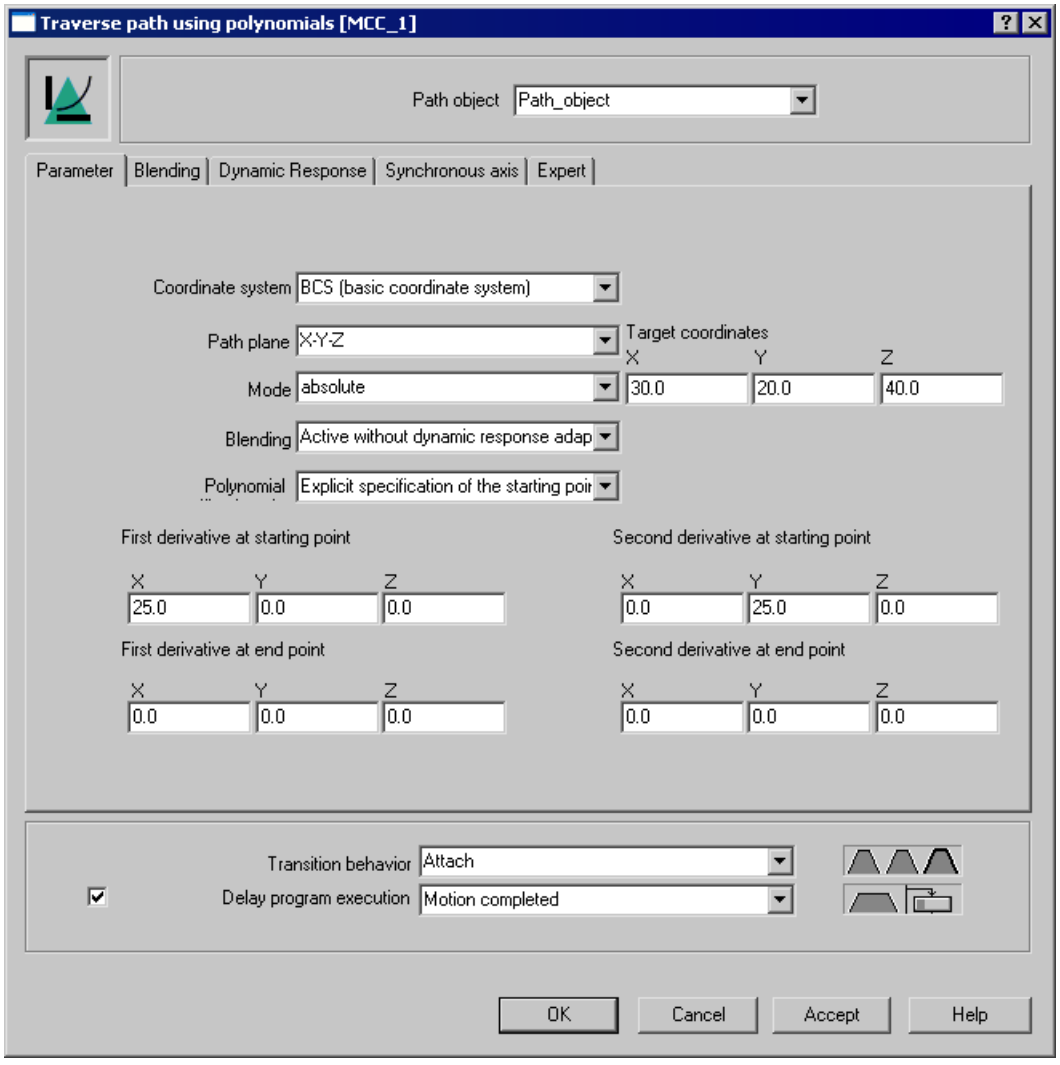

Figure 7-176 Parameter screen form: Traverse path using polynomials

For the **fundamentals of path interpolation**, see the TO Path Object Function Manual

For further information on **polynomial paths**, see the TO Path Object Function Manual.

Overview of parameters for Traverse path using polynomials

Table 7-324 Overview of parameters for Traverse path using polynomials

Field/button	Meaning/instruction
Path object	In Path object, select the path object whose assigned path axes are to be traversed to the end point. The list contains: • All path objects that are defined on the relevant device. The path objects are defined in the PATH OBJECTS folder in the project navigator. • All variables with the following data type of a technology object declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): _PathObjectType.
Parameters tab	See Overview of parameters for Traverse path using polynomials - Parameters tab (Page 4494)
Blending tab	See Overview of parameters for Traverse path using polynomials - Blending tab (Page 4499)
Dynamic response tab	See Overview of parameters for Traverse path using polynomials - Dynamic response tab (Page 4500)
Synchronous axis tab	See Overview of parameters for Traverse path using polynomials - Path-synchronous motion tab (Page 4503)
Expert tab	See Overview of parameters for Traverse path using polynomials - Expert tab (Page 4504)
Transition behavior	Here, you program the transition behavior between the programmed command and the command currently active on the axes involved. The selected behavior determines the position of the command in the command queue. See also Transition behavior from the currently active motion command (Page 4036).
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Traverse path using polynomials – Parameters tab

Table 7-325 Overview of parameters for Traverse path using polynomials – Parameters tab

Field/button	Meaning/instruction
Coordinate system	This field is available as of SIMOTION Kernel version V4.3. Here you select the coordinate system to which the path motion to be programmed refers. **BCS (basic coordinate system)** (default value) Static, right-handed, rectangular (Cartesian) coordinate system in accordance with DIN 66217. **OCS (object coordinate system)** Coordinate system defined on the path object that is offset and rotated with regard to the basic coordinate system. It can also be coupled synchronously to another motion (e.g. an axis). Up to 3 object coordinate systems can be defined.
Number	This field is available as of SIMOTION Kernel version V4.3. An entry is required in this field if you have selected the following in the **Coordinate system** field: • OCS (object coordinate system) Select the number of the object coordinate system to be used. Possible values are 1 to 3. **1** (default value) Object coordinate system 1
Path plane	Here, you select whether the motion is to be carried out in 3 dimensions (3D) or 2 dimensions (2D). **X-Y-Z** Three-dimensional motion **X-Y main plane** **Y-Z main plane** **Z-X main plane** 2-dimensional motion in the selected main plane of the Cartesian basic coordinate system. The target coordinate located outside the selected plane is ignored. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.plane
Mode	The meaning of the subsequently programmed target coordinates is defined in more detail here. **Absolute** The programmed target coordinates refer to the zero point of the basic coordinate system. **Relative** The programmed target coordinates refer to the path position within the basic coordinate system when the path command is executed (point in time of change). current axis position and specify the (straight) traversing path. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.mode

Field/button	Meaning/instruction
Target coordinates X, Y, Z	The end point of the motion is specified here. The meaning depends on the **Mode** parameter (see above)**:** • Absolute mode: Absolute coordinates with respect to the zero point of the basic coordinate system. • Relative mode: Relative coordinates with respect to the path position within the basic coordinate system when the path command is executed (point in time of change). Enter the values as signed floating-point numbers. See the input field (Page 4022).
Blending	Using blending, the path segment programmed with this command can be linked to the previous path segment to form one complete path with no stop. At the transition, the system provides for a constant path velocity and a constant path acceleration. As of version V4.3 of the SIMOTION Kernel, a transition geometry (blending segment) can also be inserted. **Active with dynamic response adaptation** The dynamic response limit values of the individual path axes are also applied in the blending area or blending segment. • The following applies up to version V4.2 of the SIMOTION Kernel: This setting is evaluated only with the **Attach** or **Attach and discard the pending command** transition behavior. A blending segment is not inserted. The path velocity is nearly reduced to zero at transitions of path segments in which the gradients or curvatures are not smooth. For the **Substitute** transition behavior, see setting **Inactive**. • The following applies as of version V4.3 of the SIMOTION Kernel: The "Blending" tab (Page 4499) is displayed. There, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment. With the **Do not insert a segment** selection, the same behavior applies as up to version V4.2 of the SIMOTION Kernel. **Active without dynamic response adaptation** In the blending area or blending segment, path interpolation takes into account only the scalar dynamic response limit values of the path (path velocity, path acceleration and jerk). The dynamic response limit values specific to the axes are first taken into account during movement of the individual path axes. • The following applies up to version V4.2 of the SIMOTION Kernel: This setting is evaluated only with the **Attach** or **Attach and discard the pending command** transition behavior. Axis-specific deviations from the path can occur at transitions of path segments in which the gradients or curvatures are not smooth. For the **Substitute** transition behavior, see setting **Inactive**. • The following applies as of version V4.3 of the SIMOTION Kernel: The "Blending" tab (Page 4499) is displayed. There, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment. With the **Do not insert a segment** selection, the same behavior applies as up to version V4.2 of the SIMOTION Kernel.

Field/button	Meaning/instruction
Blending (continued)	**Inactive** The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: The motion programmed with this command does not begin until the setpoint interpolation of the previous command is complete and its motion has reached the target coordinates. The path velocity and path acceleration are therefore zero at the transition. • Transition behavior = **Substitute**: The motion with its dynamic response parameters programmed with this command immediately replaces the previous path motion. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.blending.mode

Field/button	Meaning/instruction
Polynomial specified via	Here you select how the 5. order polynomial that describes the motion path is specified. **Explicit specification of start point data** The polynomial is calculated from geometric data. Specify explicitly: • Start point (current position) and end point (target coordinates) • First geometric derivative (tangential vector) and second geometric derivative (curvature vector) at the start point • First geometric derivative (tangential vector) and second geometric derivative (curvature vector) at the end point. System functions are available for performing a geometric analysis of paths (e.g. determining the geometric derivatives at specified points). **Attach continuously** The polynomial is calculated from geometric data. Specify explicitly: • Start point (current position) and end point (target coordinates) • First geometric derivative (tangential vector) and second geometric derivative (curvature vector) at the end point. The first geometric derivative (tangential vector) and the second geometric derivative (curvature vector) at the start point (current position) are set equal to the geometric derivatives at the end point of the previous path command. If the geometric derivatives cannot be determined in the start point (if no current motion is available), the command is not executed and error message 50002 "Calculation of the geometry element not possible, reason 3" is outputted. System functions are available for performing a geometric analysis of paths (e.g. determining the geometric derivatives at specified points). **Direct specification of the polynomial coefficients** Specify the polynomial coefficients explicitly through the following values: • Start point **P**(0) (current position). • End point **P**(1) (target coordinates). • Polynomial coefficients $\mathbf{a}_2$, $\mathbf{a}_3$, $\mathbf{a}_4$ and $\mathbf{a}_5$. The polynomial coefficients $\mathbf{a}_0$ and $\mathbf{a}_1$ are calculated from this data: • $\mathbf{a}_0 = \mathbf{P}(0)$ • $\mathbf{a}1 = \mathbf{P}(1) - \mathbf{P}(0) - \mathbf{a}_2 - \mathbf{a}_3 - \mathbf{a}_4 - \mathbf{a}_5$. **Default value** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.polynomialMode
First derivative at the start point X, Y, Z	This parameter is evaluated only with polynomial specification via **Explicit specification of the start point data**. Here, you specify the first geometric derivative (tangential vector) at the start point (current position). Enter the values as signed floating-point numbers. See the input field (Page 4022).
Second derivative at the start point X, Y, Z	This parameter is evaluated only with polynomial specification via **Explicit specification of the start point data**. Here, you specify the second geometric derivative (curvature vector) at the start point (current position). Enter the values as signed floating-point numbers. See the input field (Page 4022).

Field/button	Meaning/instruction
First derivative at the end point X, Y, Z	This parameter is evaluated only with polynomial specification via **Explicit specification of the start point data** and **Attach continuously**. Here, you specify the first geometric derivative (tangential vector) at the end point (target coordinates). Enter the values as signed floating-point numbers. See the input field (Page 4022).
Second derivative at the end point X, Y, Z	This parameter is evaluated only with polynomial specification via **Explicit specification of the start point data** and **Attach continuously**. Here, you specify the second geometric derivative (curvature vector) at the end point (target coordinates). Enter the values as signed floating-point numbers. See the input field (Page 4022).
Coefficient a2 X, Y, Z	These parameters are evaluated only with polynomial specification via **Direct specification of the polynomial coefficients**. Here you specify the coefficients $\mathbf{a}_2$, $\mathbf{a}_3$, $\mathbf{a}_4$ and $\mathbf{a}_5$ of the 5. order polynomial. Enter the values as signed floating-point numbers. See the input field (Page 4022).
Coefficient a3 X, Y, Z	
Coefficient a4 X, Y, Z	
Coefficient a5 X, Y, Z	

Overview of parameters for Traverse path using polynomials – Blending tab

Table 7-326 Overview of parameters for Traverse path using polynomials – Blending tab

Field/button	Meaning/instruction
	This tab is available as of SIMOTION Kernel version V4.3. It is only displayed when the value **Inactive** has **not** been selected in the Blending field of the Parameters tab. Here, for example, you can define whether a transition geometry (blending segment) will be inserted between the path segment programmed with this command and the previous path segment.
Blending segment	Here, you specify whether a blending segment to the previous path segment will be inserted. **Do not insert a segment** (default value) A blending segment is not inserted. This corresponds to the behavior up to version V4.2 of the SIMOTION Kernel. See the description for the values **Active with dynamic response adaptation** and **Active without dynamic response adaptation** in the "Blending" field of the Parameters tab (Page 4494). **Insert polynomial segment** A blending segment described by a polynomial is inserted. This is always possible. The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: Starting from the end point or start point of the two path segments, the start point and end point of the blending segment is calculated with the blending distance. • Transition behavior = **Substitute**: The blending segment is inserted at the current path position. A fictitious end point or start point of the two path segments and the end point of the blending segment is calculated with the blending distance and the tangent at the path position. The blending segment is calculated so that at the transitions to the two path segments, the position, the velocity and the acceleration are smooth. **Stop** The behavior depends on the selection at "Transition behavior": • Transition behavior = **Attach** or **Attach and discard existing command**: The motion programmed with this command does not begin until the setpoint interpolation of the previous command is complete and its motion has reached the target coordinates. The path velocity and path acceleration are therefore zero at the transition. • Transition behavior = **Substitute**: The previous path motion is stopped immediately. The motion programmed with this command starts at the stop position. The dynamic response parameters of this command are also effective for the deceleration of the previous path motion. The path velocity and path acceleration are zero at the transition.

Field/button	Meaning/instruction
Blending distance	An entry is required in this field if you have selected the following in the **Blending segment** field: • Insert circle segment • Insert polynomial segment The blending distance is used to specify the distance from the end point or start point of the two path segments at which the transition geometry (blending segment) is inserted. The blending distance is measured as path length along the two path segments. Enter the value as a signed floating-point number. See also input field (Page 4022).
Velocity in the blending segment	An entry is required in this field if you have selected the following in the **Blending segment** field: • Insert circle segment • Insert polynomial segment Here you specify the velocity that is to be used in the blending segment. Acceleration and jerk are always taken from the current path command **High velocity** The higher velocity of the current and previous path command is used **Low velocity** The lower velocity of the current and previous path command is used

Overview of parameters for Traverse path using polynomials – Dynamic response tab

Table 7-327 Overview of parameters for Traverse path using polynomials – Dynamic response tab

Field/Button	Meaning/instruction
	Here, you specify the dynamic response of the path motion. In standard cases, you define the dynamic response by means of a velocity profile with the associated values for the velocity. Acceleration, deceleration, and jerk. A detailed description of these parameters is provided in Overview of parameters – Dynamic response tab (Page 4031). Optionally, you can select a special velocity profile that is described by a cam.
Velocity	The entered value acts during the constant velocity phase. This parameter is evaluated only when **Special velocity profile** = **No**. System variable for default: userDefault.pathDynamics.velocity
Velocity profile	In this field, you define the transitions between the individual motion phases. The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.profile

Field/Button	Meaning/instruction
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.positiveAccel
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). The parameter is evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variable for default: userDefault.pathDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. The parameters are evaluated only in the following cases: • When **Special velocity profile** = **No** • When **Special velocity profile** = **Yes** and when accelerating to the velocity specified in the special velocity profile. System variables for default: userDefault.pathDynamics.positiveAccelStartJerk userDefault.pathDynamics.positiveAccelEndJerk userDefault.pathDynamics.negativeAccelStartJerk userDefault.pathDynamics.negativeAccelEndJerk
Dynamic response adaptation	Here, you select whether the dynamic response limit values of the individual path axes are to be taken into account during path interpolation. **Inactive** The dynamic response limit values of the individual path axes are **not** taken into account during path interpolation. However, they remain active, and an error is triggered if they are exceeded. This setting should only be selected if it is ensured by other means (e.g. an appropriate specific velocity profile) that the limit values will not be exceeded. **Without segmentation across the path** The dynamic response limit values of the individual path axes for velocity and acceleration are taken into account during path interpolation. If a position axis is configured for the path-synchronous motion, its dynamic response limit values are also included. Path velocity and path acceleration are adapted for the entire path motion if necessary. **With segmentation across the path** The dynamic response limit values of the individual path axes for velocity and acceleration are taken into account during path interpolation. If a position axis is configured for the path-synchronous motion, its dynamic response limit values are also included. The path motion is divided up into individual segments, as determined by the system, if necessary. Within each segment, the path velocity and the path acceleration are adapted to the maximum axial dynamic response limit values. **Default** See Selection list (combo box) (Page 4022). System variable for default: userDefault.path.dynamicAdaption

Field/Button	Meaning/instruction
Specific velocity profile	Here, you select whether the path dynamic response is specified with the velocity profile defined above or with a velocity profile that is defined by a cam. **No** (default value) The path dynamic response is specified with the velocity profile defined above with the parameters: **velocity profile**, **velocity**, **acceleration**, **deceleration**, and **jerk**. **Yes** The path dynamic response is specified with a velocity profile that is defined by a cam.
Cam	This field is only visible when **Specific velocity profile** = **Yes**. Here, you select the cam which defines the velocity profile. The following are available: • All cams that are defined on the relevant device. The cams are defined in the CAMS folder in the project navigator. • All variables with the following technology object data type declared in the MCC source file or MCC chart (see Technology object data types (Page 4060)): camType. The **Profile position at start of path** and **Profile position at end of path** parameters are used to select an area within the definition range of the cam (x axis) that is mapped by scaling to the length of the programmed path. The value range (y axis) is interpreted as the velocity in the unit configured on the path object.
Profile position at start of path Profile position at end of path	These two values determine the area within the definition range of the cam (x axis) that is mapped by scaling to the length of the programmed path. Enter the values as signed floating-point numbers. See the input field (Page 4022).

Overview of parameters for Traverse path using polynomials – Synchronous axis tab

Table 7-328 Overview of parameters for Traverse path using polynomials – Path-synchronous motion tab

Field/button	Meaning/instruction
	Here, you specify values for the motion of the additional position axis that is assigned to the path object and is traversed synchronously with the path motion.
Synchronous axis mode	Here, you specify how the synchronous axis (axis for path-synchronous motion) should be traversed with the path motion: **Absolute** The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. **Relative** The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. **Output path length** At the position axis for the path-synchronous motion w, the path length (i.e. the distance covered by the path motion) is outputted linearly, beginning from zero. **Output path length added** At the position axis for the path-synchronous motion w, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted at the beginning of the path motion. **w absolute and output of path length in w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) is outputted linearly beginning from zero. **w absolute and output of path length added to w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the end point of the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted linearly at the beginning of the path motion. **w absolute and output of path length in w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) is outputted linearly beginning from zero. **w relative and output of path length added to w2** (As of Kernel V4.4) The programmed **Synchronous axis position** is the path traversed by the path-synchronous motion w. At the position axis interconnected with w2, the path length (i.e. the distance covered by the path motion) added to the existing value is outputted linearly at the beginning of the path motion. **Default** See Selection list (combo box) (Page 4022) System variable for default: userDefault.w.mode

Field/button	Meaning/instruction
Synchronous axis direction	Select the direction of the path-synchronous motion. The direction must be specified in the following cases: • The **Synchronous axis mode** is relative • The axis for the path-synchronous motion is a modulo axis. **Positive** The direction of motion is the positive direction of the axis. With relative motion, the sign of the position is ignored. **Negative** The direction of motion is the negative direction of the axis. With relative motion, the sign of the position is ignored. **From position** The direction of motion is determined by the sign of the **Synchronous axis position**. **Shortest path** • With **Synchronous axis mode** relative: The direction of motion is determined by the sign of the **Synchronous axis position**. • With modulo axes: The direction of motion is the direction in which the programmed target position can be reached via the shortest path. **Default** See Selection list (combo box) (Page 4022) System variable for default: userDefault.w.direction
Synchronous axis position	This parameter is evaluated only for the following settings for **Synchronous axis mode** and has different meanings: • **Absolute** or **w absolute ...** : End point of the path-synchronous motion. • **Relative** or **w relative ...** : Traversing distance of the path-synchronous motion. Enter the values as signed floating-point numbers. See the input field (Page 4022).

Overview of parameters for Traverse path using polynomials – Expert tab

Table 7-329 Overview of parameters for Traverse path using polynomials – Expert tab

Field/Button	Explanation/Instructions
	The Expert tab is described in detail in Overview of parameters for Expert tab (Page 4034).
CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Stop path motion

This function is available in SIMOTION Kernel as of Version 4.1.

This command stops the current path motion (including the path-synchronous motion) with the programmed dynamic response parameters (deceleration ramp). You can choose whether the motion is aborted:

- Stop without abort: The motion can be continued with the Continue path motion (Page 4510) command.
- Stop with abort: The motion cannot be continued.

The last calculated positions of each path axis and the synchronous axis (setpoint values) are stored in the abortPosition system variable.

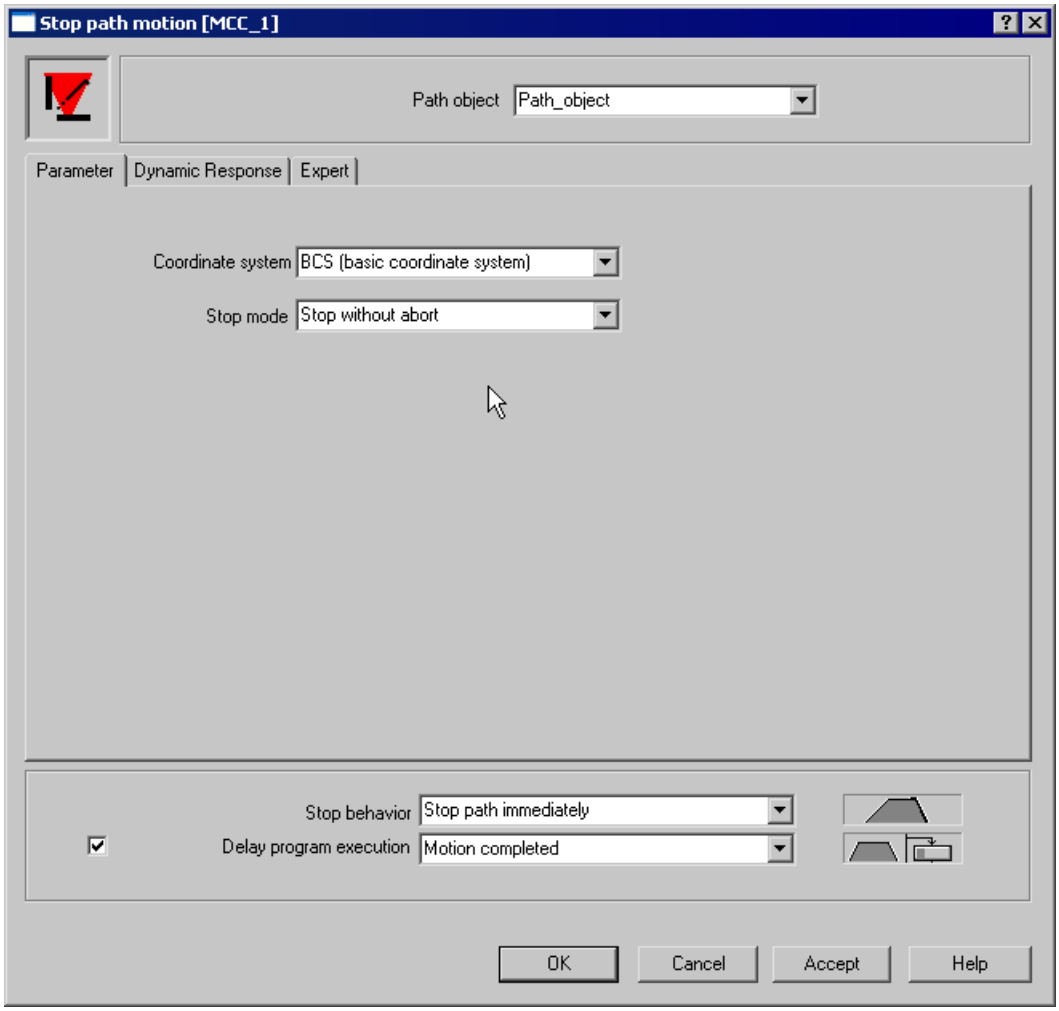

Figure 7-177 Parameter screen form: Stop path motion

For the **fundamentals of path interpolation**, see the TO Path Object Function Manual

For further information on **stopping and continuing path motion**, see the TO Path Object Function Manual.

Overview of parameters for Stop path motion

Table 7-331 Overview of parameters for Stop path motion

Field/button	Meaning/instruction
Path object	In Path object, select the path object whose assigned axes (path axes and synchronous axis) are to be stopped. The list contains: • All path objects that are defined on the relevant device. The path objects are defined in the PATH OBJECTS folder in the project navigator. • All variables with the following data type of a technology object declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): _PathObjectType.
Parameters tab	See Overview of parameters for Stop path motion - Parameters tab (Page 4508)
Dynamic response tab	See Overview of parameters for Stop path motion - Dynamic response tab (Page 4509)
Expert tab	See Overview of parameters for Stop path motion - Expert tab (Page 4509)
Stop behavior	Specifies when the command takes effect relative to the motion. **Stop path immediately** The active path motion is substituted immediately. All motion commands still pending in the command buffer are deleted. **Stop at the end of the path command.** Not relevant.
Delay program execution	• Activate the checkbox if execution of the following command in the MCC chart should be delayed until the selected condition has been satisfied. If the checkbox is not activated, the next command is executed immediately. • Select the condition that has to be satisfied before the system continues execution of the following command in the MCC chart. See also Delay program execution (step enabling condition) (Page 4037).

Overview of parameters for Stop path motion – Parameters tab

Table 7-332 Overview of parameters for Stop path motion – Parameters tab

Field/button	Meaning/instruction
Coordinate system	This field is available as of SIMOTION Kernel version V4.3. Here you select the coordinate system to which the path motion to be stopped refers. **BCS (basic coordinate system)** (default value) The motion is stopped in the basic coordinate system. **OCS (object coordinate system)** The motion is stopped in the currently effective object coordinate system.
Stop mode	Select a stop mode here. The path motion is stopped with the programmed dynamic response parameters (Dynamic response tab (Page 4509)). The last calculated positions (setpoint values) of the path axes and the synchronous axis assigned to the path object are stored in the abortPosition system variable. **Stop without abort** (default value) The motion can be continued with the **Continue path motion** command. **Stop with abort** The motion cannot be continued.

Overview of parameters for Stop path motion – Dynamic response tab

Table 7-333 Overview of parameters for Stop path motion – Dynamic response tab

Field/Button	Explanation/Instructions
	The Dynamic response tab is described in detail in Overview of parameters - Dynamic response tab (Page 4031).
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefault.pathDynamics.profile
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefault.pathDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefault.pathDynamics.positiveAccelEndJerk userDefault.pathDynamics.negativeAccelStartJerk userDefault.pathDynamics.negativeAccelEndJerk

Overview of parameters for Stop path motion – Expert tab

Table 7-334 Overview of parameters for Stop path motion – Expert tab

Field/Button	Explanation/Instruction
	The Expert tab is described in detail in Overview of parameters for Expert tab (Page 4034).
CommandID variable	If you enter the name of a variable of data type CommandIdType, you can track the command status with this variable.
Return variable	If you enter the name of a variable of the specified data type, you can use this variable to find out the result of the command call. Data type DINT; for a description, see Return value for system functions of the technology packages (Page 4040).

Continue path motion

This function is available in SIMOTION Kernel Version 4.1 and higher.

This command continues a path motion that has been stopped. It is only possible to continue path motions that were stopped with the **Stop without abort** stop mode.

During the time between the interruption and the continuation, the path object and all axes (path axes and axes for path-synchronous motion) assigned to it are not permitted to receive any new motion commands.

The following applies for the dynamic response parameters when continuing the path motion:

- The following applies up to version V4.2 of the SIMOTION Kernel:
  The dynamic response parameters of the stopped path motion are used.
- The following applies as of version V4.3 of the SIMOTION Kernel:
  Either the dynamic response parameters of the stopped path motion or specific dynamic response parameters (e.g. for velocity profile, acceleration, jerk) are used.

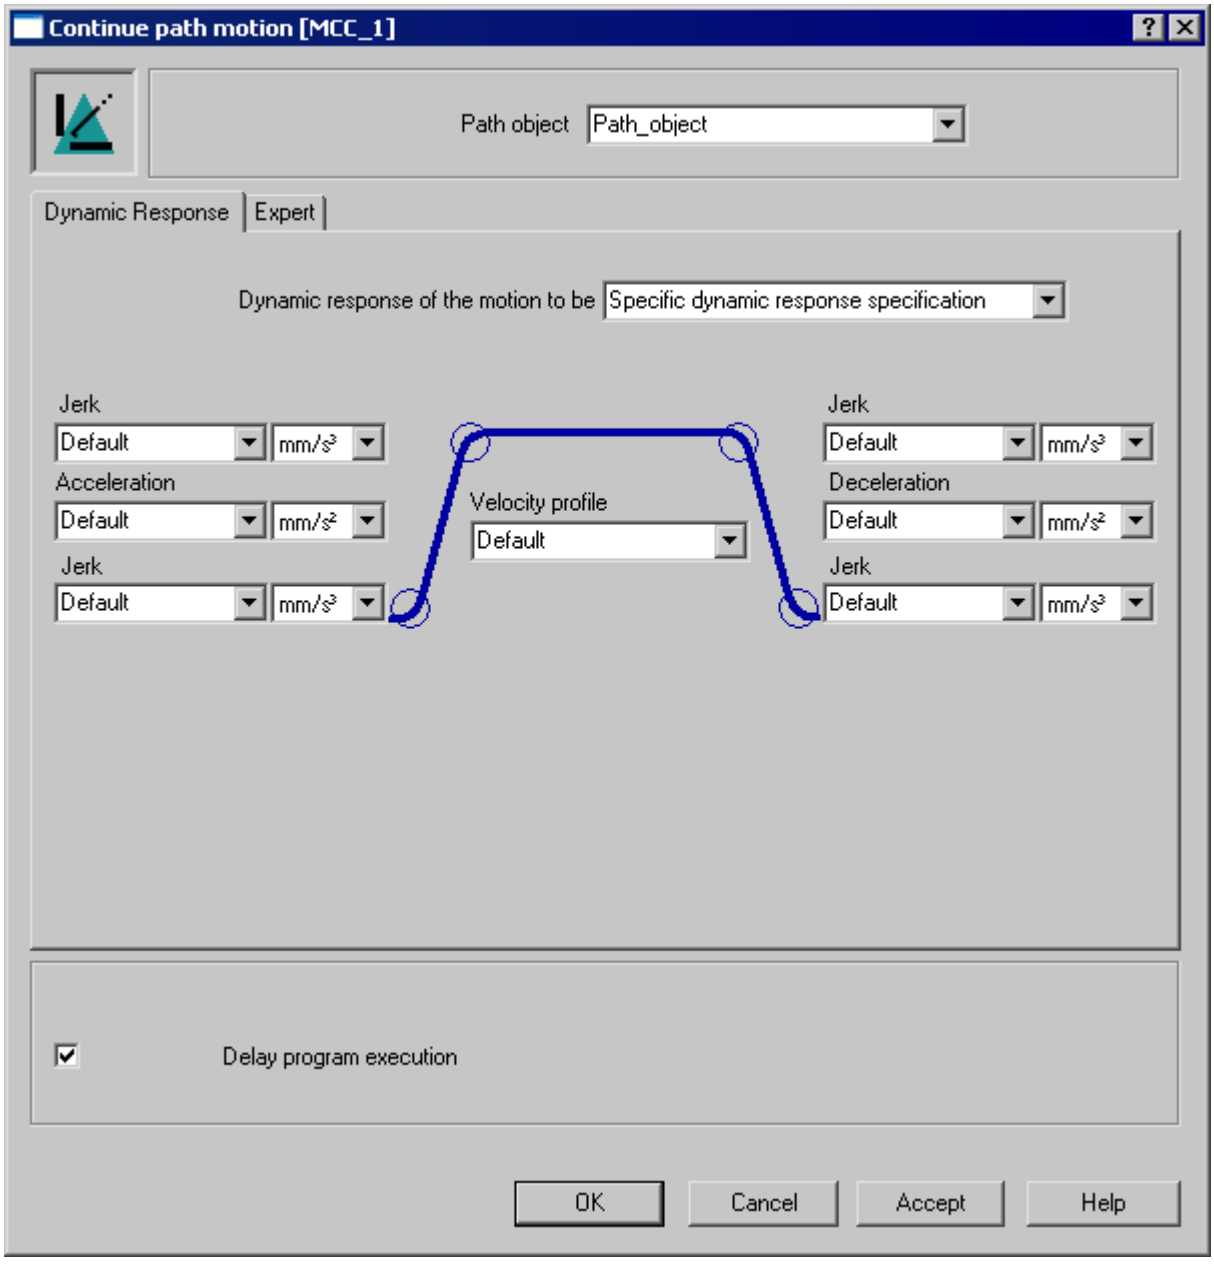

Figure 7-178 Parameter screen form: Continue path motion

For the **fundamentals of path interpolation**, see the TO Path Object Function Manual

For further information on **stopping and continuing path motion**, see the TO Path Object Function Manual.

Overview of parameters: Continue path motion

Table 7-336 Overview of parameters: Continue path motion

Field/button	Meaning/instruction
Path object	In Path object, select the path object for which the motion of the assigned axes (path axes and synchronous axis) is to be continued. The list contains: • All path objects that are defined on the relevant device. The path objects are defined in the PATH OBJECTS folder in the project navigator. • All variables with the following data type of a technology object declared in the MCC unit or MCC chart, see Technology object data types (Page 4060): _PathObjectType.
Dynamic response tab	See Overview of parameters for Continue path motion - Dynamic response tab (Page 4512)
Expert tab	See Overview of parameters for Continue path motion - Expert tab (Page 4513)
Delay program execution	Activate the checkbox if you wish to delay execution of the following command until the current command has been completed. If the checkbox is not activated, the next command is executed immediately.

Overview of parameters for Continue path motion - Dynamic response tab

Table 7-337 Overview of parameters for Continue path motion - Dynamic response tab

Field/button	Meaning/instruction
	This tab is available as of SIMOTION Kernel version V4.3.
Dynamic response of the motion to be continued	Here, you specify which dynamic response parameters are used to when continuing the stopped path motion. **Dynamic response of the interrupted motion** (default value) All dynamic response parameters the stopped path motion are used. This corresponds to the behavior up to version V4.2 of the SIMOTION Kernel. **Specific dynamic response specification** Velocity profile, acceleration, deceleration and jerk are specified for the motion to be continued. The corresponding input fields are displayed. The other dynamic response parameters are taken from the stopped path motion.
	The following fields are only displayed if you have selected the following in the **Dynamic response of the motion to be continued** field: • Specific dynamic response specification A detailed description of these parameters is provided in Overview of parameters – Dynamic response tab (Page 4031).
Velocity profile	In this field, you define the transitions between the individual motion phases. System variable for default: userDefault.pathDynamics.profile
Acceleration	The entered value acts during the constant acceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefault.pathDynamics.positiveAccel

Field/button	Meaning/instruction
Deceleration	The entered value acts during the constant deceleration phase. The meaning depends on the acceleration model used (see the general description of the Dynamic response tab (Page 4031)). System variable for default: userDefault.pathDynamics.negativeAccel
Jerk	The entered value limits the change in the acceleration or deceleration at the start and end of the respective phase. System variables for default: userDefault.pathDynamics.positiveAccelStartJerk userDefault.pathDynamics.positiveAccelEndJerk userDefault.pathDynamics.negativeAccelStartJerk userDefault.pathDynamics.negativeAccelEndJerk

7.1.7 Commissioning (software)

7.1.7.1 Assigning programs to a task and downloading them to the target system

assigning programs to a task

Programs must be assigned to a task before they can be downloaded to the target system (the SIMOTION device).

Various tasks are made available by SIMOTION, each with different priorities or system responses (e.g. during initialization). The Execution levels and tasks in SIMOTION table contains a brief description of the available tasks.

For further information, refer to the SIMOTION Basic Functions Function Manual.

Note

Programs need only be assigned to a task once; this assignment is retained if the program is recompiled.

Assigning programs to a task:

1. In the project navigator, double-click the EXECUTION SYSTEM element below the relevant SIMOTION device.
   The window for configuring the execution system is displayed. See figure below.
2. Select the required task (e.g. MotionTask_1) from the left pane.
3. Select the Program assignment tab.
4. Select the program to be assigned from the Programs list.
5. Click the >> button.
6. Select the Task Configuration tab, and specify any other required settings for the task there.

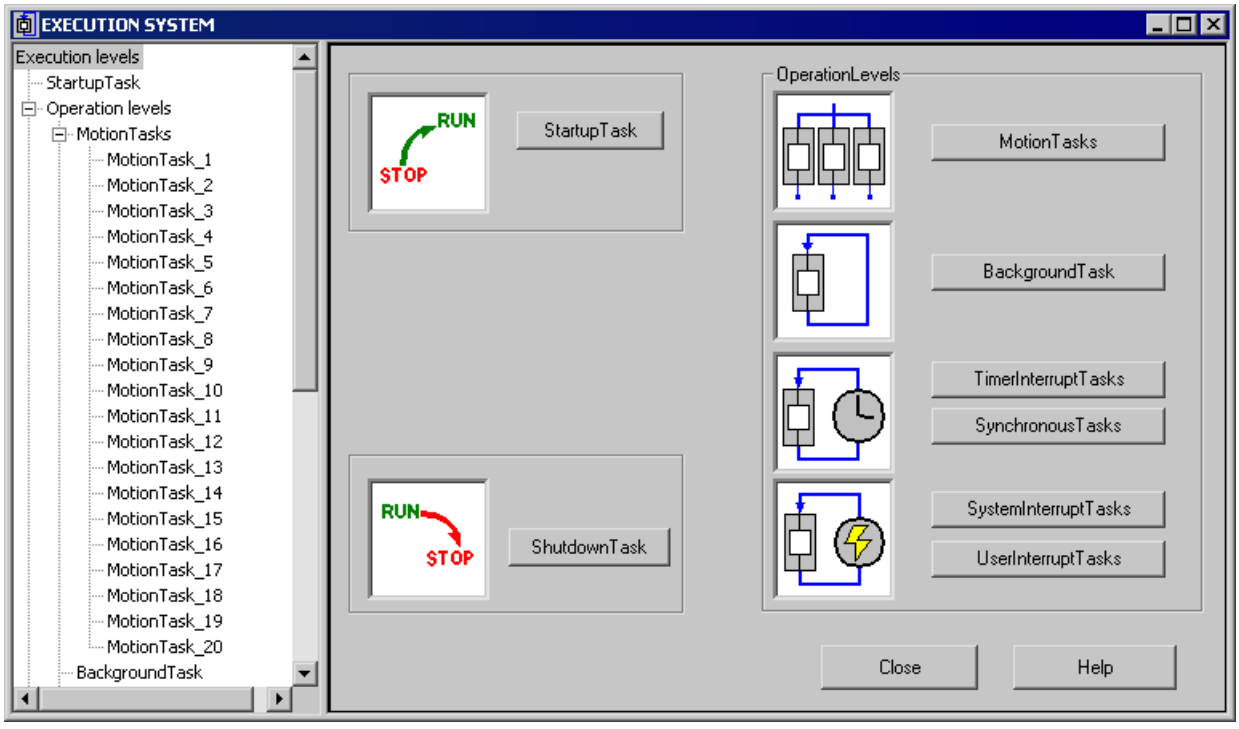

Figure 7-179 Configure execution system

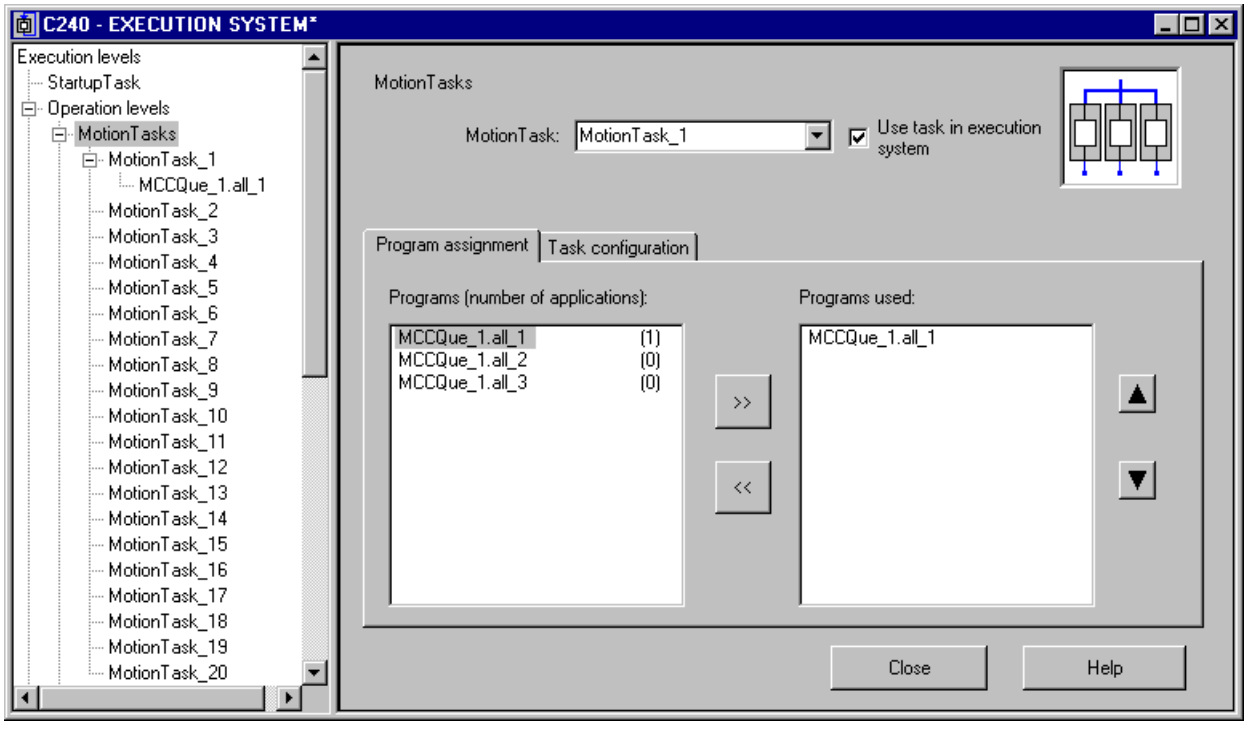

Figure 7-180 Assigning a program to a motion task

Execution levels and tasks in SIMOTION

Here the execution levels and the tasks assigned are shown in tabular format for an initial overview.

Further information on execution levels and tasks can be found in the SIMOTION Basic Functions Function Manual.

Table 7-340 Description of the execution levels and of the tasks

Execution level	Description
Time-controlled	Cyclic tasks: They are restarted automatically once the assigned programs have been executed.
• SynchronousTasks	Tasks are started periodically, synchronous with specified system cycle clock. • ServoTask_Fast: Synchronous with Servo_fast cycle clock. The Servo_fast cycle clock is a second servo cycle clock and only available: – For D445-2 DP/PN and D455-2 DP/PN as of version V4.2 – For D435-2 DP/PN as of version V4.3. • ServoSynchronousTask: Synchronous with the position control cycle clock • IpoTask_Fast: Synchronous with IPO_fast cycle clock. The IPO_fast cycle clock is the IPO cycle clock for the second servo cycle clock and only available: – For D445-2 DP/PN and D455-2 DP/PN as of version V4.2 – For D435-2 DP/PN as of version V4.3. • IPOsynchronousTask: Synchronous with interpolator cycle clock IPO • IPOsynchronousTask_2: Synchronous with interpolator cycle clock IPO_2 • PWMsynchronousTask: Synchronous with PWM cycle clock (for TControl technology package) • InputSynchronousTask_1: Synchronous with Input1 cycle clock (for TControl technology package) • InputSynchronousTask_2: Synchronous with Input2 cycle clock (for TControl technology package) • PostControlTask_1: Synchronous with Control1 cycle clock (for TControl technology package) • PostControlTask_2: Synchronous with Control2 cycle clock (for TControl technology package)
• TimerInterruptTasks	Tasks are started periodically in a fixed time frame. This time frame must be a multiple of interpolator cycle clock IPO.
Interrupts	Sequential tasks: They are executed once after the start and then terminated.
• SystemInterruptTasks	Started when a system event occurs: • ExecutionFaultTask: Error processing a program • PeripheralFaultTask: Error on I/O • TechnologicalFaultTask: Error on the technology object • TimeFaultBackgroundTask: BackgroundTask timeout • TimeFaultTask: TimerInterruptTask timeout
• UserInterruptTasks	They are started when a user-defined event occurs.

Execution level	Description
Round robin	MotionTasks and BackgroundTasks share the free time remaining after execution of the higher-priority system and user tasks. The proportion of the two levels can be assigned.
• MotionTasks	Sequential tasks: They are executed once after the start and then terminated. Start takes place: • Explicitly via a task control command in a program assigned to another task. • Automatically when RUN operating state is attained if the corresponding attribute was set during task configuration. The priority of a MotionTask can be increased temporarily: • In the MCC programming language with the "Wait for..." commands, see Wait for axis (Page 4175), Wait for signal (Page 4178), Wait for condition (Page 4180). • In the ST programming language with the WAITFORCONDITION statement.
• BackgroundTask	Cyclic task: It is restarted automatically once the assigned programs have been executed. The task cycle time depends on the runtime.
StartupTask	Task is executed once when there is a transition from STOP or STOP U operating state to RUN operating state. SystemInterruptTasks are started by their triggering system event.
ShutdownTask	Task is executed once when there is a transition from RUN operating state to STOP or STOP U operating state. STOP or STOP U operating state is reached by: • Activating the operating state switch • Calling the relevant system function, for example, MCC Change operating state command • Occurrence of a fault with the appropriate error response SystemInterruptTasks and PeripheralFaultTasks are started by their triggering system event.
For information on the behavior of sequential and cyclic tasks: • During initialization of local program variables: See Initialization of local variables (Page 4077). • In the event of execution errors in the program: See SIMOTION Basic Functions Function Manual. For information about options for accessing the process image and I/O variables: see Important properties for direct access and process image (Page 4091).	

Task start sequence

When the StartupTask is completed, RUN mode is reached.

The following tasks are then started:

- SynchronousTasks
- TimerInterruptTasks

- BackgroundTask
- MotionTasks with startup attribute.

Note

The sequence in which these tasks are first started after RUN mode has been reached does not conform to the task priorities.

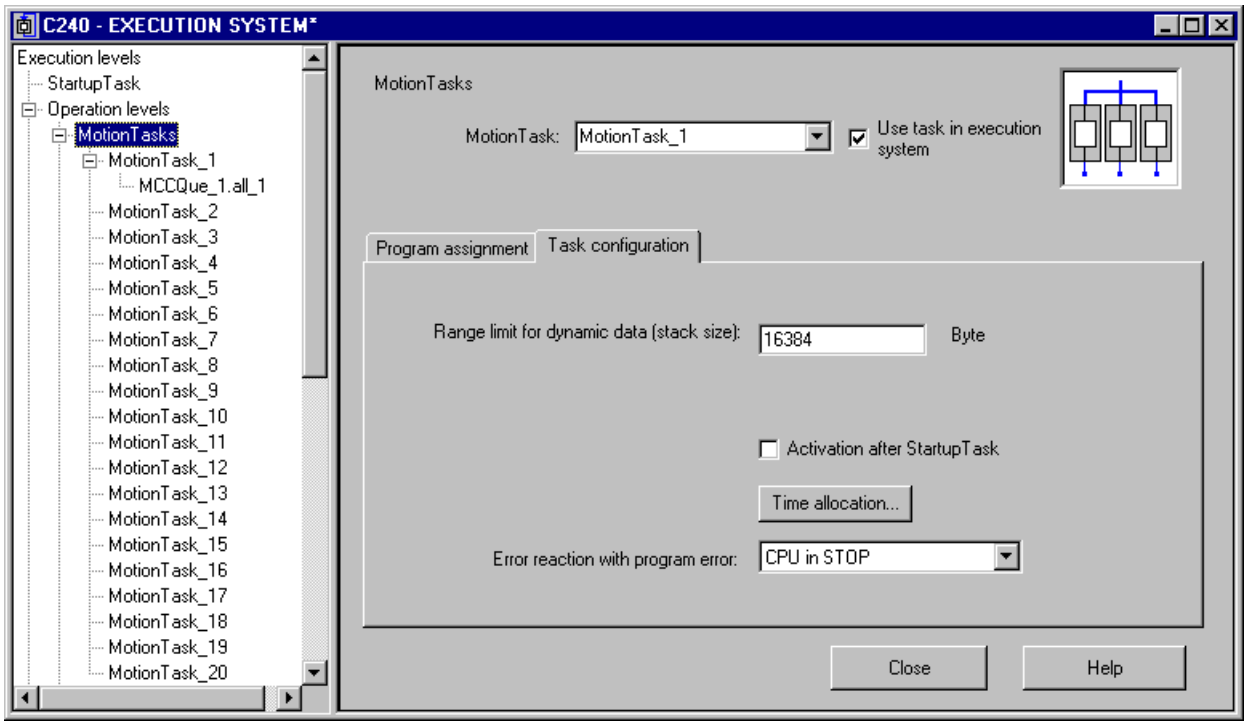

Figure 7-181 Task configuration for a MotionTask

downloading programs to the target system

The program has to be downloaded into the target system, together with the technology objects etc., before being executed.

To download the program to the target system, proceed as follows:

1. Select the **Project > Save and compile changes** menu command.
   The project is saved locally on the hard disk with due regard for all dependencies and only those changes made since the last compilation are compiled.
2. Select the **Project > Check consistency** menu command to check the project for consistency. This is not necessary if the option **Check consistency before loading** is activated in menu option **Options > Settings** in the **Download** tab (the default for this option is to be activated). This means the consistency check is performed automatically during the download to the target system.

3. Select the **Project > Connect to selected target devices** menu command or click the button.
   Online mode is activated.
4. Select the **Target system > Load > Project to target system** menu command or click the button.
   The project data (including the sample program) and the data of the hardware configuration are downloaded to the RAM of the target system.

For more information about downloading a program to the target system, see the SIMOTION Basic Functions Function Manual.

7.1.8 Error Handling and Program Test

7.1.8.1 Operating modes for program testing

Modes of the SIMOTION devices

Various SIMOTION device operating modes are available for program testing.

Table 7-341 Operating modes of a SIMOTION device

Operating mode	Meaning
Process mode	Program execution on the SIMOTION device is optimized for maximum system performance. The following diagnostic functions are available, although they may have only restricted functionality because of the optimization for maximum system performance: • Monitor variables in the symbol browser (Page 4525) or a watch table (Page 4529) • Program status (Page 4542) (only restricted): – Restricted monitoring of variables (e.g. variables in loops, return values for system functions). – Maximum of 1 program source (e.g. ST source file, MCC unit, LAD/FBD unit)[1] can be monitored. • Trace tool (only restricted) with measuring functions for drives and function generator, see online help: – Maximum of **1** trace on each SIMOTION device.
Test mode	The diagnostic functions of the process mode are available to the full extent: • Monitor variables in the symbol browser (Page 4525) or a watch table (Page 4529) • Program status (Page 4542): – Monitoring of all variables possible. – As of version V4.0 of the SIMOTION Kernel: Several program sources (e.g. ST source files, MCC units, LAD/FBD units)[1] can be monitored per task. – For version V3.2 of the SIMOTION Kernel: Maximum of 1 program source (e.g. ST source file, MCC unit, LAD/FBD unit)[1] can be monitored per task. • Trace tool with measuring functions for drives and function generator, see online help: – Maximum of **4** traces on each SIMOTION device. In addition, the following diagnostics function is available: • Trace (Page 4538) for monitoring the program execution in program branches which are executed cyclically (only for the MCC programming language and for SIMOTION Kernel V4.2 and higher). **Note** Runtime and memory utilization increase as the use of diagnostic functions increases.

Operating mode	Meaning
Debug mode	In addition to the diagnostic functions of the test mode, you can use the following functions: • Breakpoints Within a program source, you can set breakpoints (Page 4550). When an activated breakpoint is reached, selected tasks will be stopped. • Controlling MotionTasks On the "Task Manager" tab of the device diagnostics, you can use task control commands for MotionTasks; see the SIMOTION Basic Functions Function Manual. No more than 1 SIMOTION device of the project can be switched to debug mode. SIMOTION SCOUT is in online mode, i.e. connected to the target system. Observe the following section: Important information about the life-sign monitoring (Page 4522).

[1] Each with 1 MCC chart or 1 LAD/FBD program in a program source.

Selecting the operating mode

How to select the operating mode of a SIMOTION device:

1. Make sure a connection to the target system has been established (online mode).
2. Highlight the SIMOTION device in the project navigator.
3. Select the "Operating mode" context menu.
4. Select the required operating mode (see the table above).
   If you have selected "Debug mode":
   – Accept the safety information.
   – Parameterize the sign-of-life monitoring.

   Observe the following section: Important information about the life-sign monitoring (Page 4522).
5. Confirm with **OK**.
   The SIMOTION device switches to the selected operating mode (apart from with debug mode; see the explanation below).

Special features with debug mode

Debug mode can only be selected for one SIMOTION device.

If you have selected debug mode, only SIMOTION SCOUT switches to it; the SIMOTION device is in test mode.

- The project navigator indicates that debug mode is activated for SIMOTION SCOUT by means of a symbol next to the SIMOTION device.
- The breakpoints toolbar (Page 4555) is displayed.

Debug mode is not enabled for the SIMOTION device until at least one set breakpoint is activated. If all breakpoints are deactivated, debug mode is canceled for the SIMOTION device.

The status bar indicates that debug mode is activated for the SIMOTION device.

Important information about the life-sign monitoring.

⚠ WARNING

Dangerous plant states possible

If problems occur in the communication link between the PC and the SIMOTION device, this may result in dangerous plant states (e.g. the axis may start moving in an uncontrollable manner).

Therefore, use the debug mode or a control panel only with the life-sign monitoring function activated with a suitably short monitoring time!

You must observe the appropriate safety regulations.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

In the following cases, the SIMOTION device and SIMOTION SCOUT regularly exchange life-signs to ensure a correctly functioning connection:

- In debug mode with activated breakpoints.
- When controlling an axis or a drive via the control panel (control priority at the PC):

If the exchange of the life-signs is interrupted longer than the set monitoring time, the following reactions are triggered:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to the STOP operating state.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis is brought to a standstill.
  - The enables are reset.

Accept safety notes

After selecting the debug mode or a control panel, you must accept the safety notes. You can set the parameters for the life-sign monitoring.

Proceed as follows:

1. Click the **Settings** button.
   The "Debug Settings" window opens.
2. Read there, as described in the following section, the safety notes and parameterize the life-sign monitoring.

Parameterizing the life-sign monitoring

In the "Life-Sign Monitoring Parameters" window, proceed as described below:

1. Read the warning!
2. Click the **Safety notes** button to open the window with the detailed safety notes.
3. Do not make any changes to the defaults for life-sign monitoring.
   Changes should only be made in special circumstances and in observance of all danger warnings.
4. Click **Accept** to confirm you have read the safety notes and have correctly parameterized the life-sign monitoring.

Note

The life-sign monitoring also responds in the following cases:

- Pressing the spacebar.
- Switching to a different Windows application.
- Too high a communication load between the SIMOTION device and SIMOTION SCOUT (e.g. by uploading task trace data).

The following reactions are triggered:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to the STOP operating state.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis or the drive is brought to a standstill.
  - The enables are reset.

⚠ WARNING

Dangerous plant states possible

This function is not guaranteed in all operating states.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Life-sign monitoring parameters

Table 7-342 Life-sign monitoring parameter description

Field	Description
Life-sign monitoring	The SIMOTION device and SIMOTION SCOUT regularly exchange life-signs to ensure a correctly functioning connection. If the exchange of the life-signs is interrupted longer than the set monitoring time, the following reactions are triggered: • In debug mode for activated breakpoints: – The SIMOTION device switches to the STOP operating state. – The outputs are deactivated (ODIS). • For controlling an axis or a drive using the control panel (control priority for the PC): – The axis is brought to a standstill. – The enables are reset. The following parameterizations are possible: • Checkbox **active**: If the checkbox is activated, life-sign monitoring is active. The deactivation of the life-sign monitoring is not always possible. • Monitoring time: Enter the timeout. **Prudence** Do not make any changes to the defaults for life-sign monitoring, if possible. Changes should only be made in special circumstances and in observance of all danger warnings.
Safety information	**Please observe the warning!** Click the button to obtain further safety information. See: Important information about the life-sign monitoring (Page 4522)

7.1.8.2 Editing program sources in online mode

Online editing in process or test mode

If SIMOTION SCOUT is connected to a target system which is in the "process mode" or "test mode" operating mode, program sources (e.g. ST source files, MCC units with MCC charts) can generally be edited, compiled, and loaded to the target system in STOP operating mode. For information on downloading in RUN operating mode, see the corresponding section in the "SIMOTION Basic Functions" Function Manual.

However, you can only activate the "program status", "monitor program execution" (only for MCC), and trace (only for MCC) test functions for a program source or a program organization unit (POU) if the following conditions are met:

1. This program source or any POU of this source (e.g. MCC chart) does not contain any changes which have not been saved.
2. The program source (unit) in SCOUT is consistent with the target system.

Note

If the "program status" test function is activated, editing of the corresponding program source or one of its POUs is disabled.

If an MCC unit or MCC chart is changed and the "monitor program execution" or trace test functions are active for that unit or chart, the test functions are canceled.

Online editing in debug mode

If SIMOTION SCOUT is in debug mode, editing is possible as long as the SIMOTION device is not in debug mode, i.e. no breakpoints are activated.

You can only activate breakpoints and, as a result, switch the SIMOTION device to debug mode if the corresponding program source and all its POUs are saved, compiled so they are up to date, and consistent with the target system.

If you attempt to edit a program source or POU when the SIMOTION device is in debug mode, you are requested to deactivate all breakpoints and, as a result, to switch the SIMOTION device out of debug mode.

Note

If breakpoints have been activated and the SIMOTION device is in debug mode:

Entering a space switches the SIMOTION device to STOP operating mode and deactivates all outputs (ODIS).

7.1.8.3 Monitoring variables in the symbol browser and watch tables

Symbol browser

Characteristics

In the symbol browser, you can view and, if necessary, change the name, data type, and variable values. You can see the following variables in particular:

- Unit variables and static variables of a program or function block
- System variables of a SIMOTION device or a technology object
- I/O variables or global device variables.

For these variables, you can:

- View a snapshot of the variable values
- Monitor variable values as they change
- Change (modify) variable values

However, the symbol browser can only display/modify the variable values if the project has been loaded in the target system and a connection to the target system has been established.

Using the symbol browser

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system (see Download programs to the target system (Page 4518)).
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

The procedure depends on the memory area in which the variables to be monitored are stored.

Procedure

Proceed as follows:

1. Select the appropriate element in the project navigator in accordance with the following table.
2. In the detail view, click the **Symbol browser** tab.
   The corresponding variables are displayed in the symbol browser.
3. Select how each variable in the "Display format" column should be displayed.

Table 7-343 Elements in the project navigator and variables to be monitored in the symbol browser

Variables to be monitored in the symbol browser	Element to be selected in the project navigator
Variables in the unit's user memory or in the retentive memory, see SIMOTION ST Programming and Operating Manual: • Retentive and non-retentive unit variables of the interface section of a program source (unit) • Retentive and non-retentive unit variables of the implementation section of a program source (unit) • Static variables of the function blocks whose instances are declared as unit variables. • In addition, if the program source (unit) has been compiled with the "Only create program instance data once" compiler option (Page 3996): – Static variables of the programs. – Static variables of the function blocks whose instances are declared as static variables of programs.	Program source (unit)
Variables in the user memory of the task, see SIMOTION ST Programming and Operating Manual: If the program source (unit) was compiled without the "Only create program instance data once" (default) compiler option (Page 3996), the user memory of the task to which the program was assigned contains the following variables: • Static variables of the programs. • Static variables of the function blocks whose instances are declared as static variables of programs.	EXECUTION SYSTEM
System variables of a SIMOTION device	SIMOTION device
System variables of a technology object	Instance of the technology object
Global device variables	GLOBAL DEVICE VARIABLES
I/O variables (in the Address list tab of the detail view). The Address list tab of the detail view can be opened by double-clicking the ADDRESS LIST element in the project navigator.	ADDRESS LIST

Note

You can monitor temporary variables (together with unit variables and static variables) with **Program status** (see Properties of the program status (Page 4542)).

Note

Trace diagnostic function for MCC programming

Various internal variables, whose identifier begins with an underscore, are automatically created by the compiler for the trace diagnostic function. These variables are displayed in the symbol browser.

With activated diagnostic function, these variables are used for the control of the diagnostics function. These variables must not be used in the user program.

Status and controlling variables

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

⚠ WARNING

Dangerous plant states possible

You assign the entered values to the variables during control. This can result in dangerous plant states, e.g. unexpected axis motion.

Note

Note when you change the values of several variables:

The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the symbol browser. There is therefore no guarantee of consistency.

Working with the symbol browser

The functions of the symbol browser and how you work with them are described in detail in the online help.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the symbol browser (independently of the SIMOTION device):

Table 7-344 Display invalid floating-point numbers

Display	Meaning
1.#QNAN -1.#QNAN	Invalid bit pattern in accordance with IEEE 754 (NaN Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).
1.#INF -1.#INF	Bit pattern for + infinity in accordance with IEEE 754 Bit pattern for – infinity in accordance with IEEE 754
-1.#IND	Bit pattern for indeterminate

Watch table

Properties

With the symbol browser you see only the variables of an object within the project. With program status you see only the variables in certain MCC commands.

With watch tables, by contrast, you can monitor selected variables from different sources as a group (e.g. program sources, technology objects, SINAMICS drives - even on different devices).

You can see the data type of the variables in offline mode. You can view and also modify the value of the variables in online mode.

Creating a watch table

Procedure for creating a watch table and assigning variables:

1. In the project navigator, select the **Monitor** folder.
2. Select **Insert new object > Watch table** to create a watch table, and enter the name of the watch table. A watch table with this name appears in the **Monitor** folder.
3. In the project navigator, click the object from which you want to move variables to the watch table.
4. In the symbol browser, select the corresponding variable line by clicking its number in the left column.
5. From the context menu, select **Add to watch table** and the appropriate watch table, e.g. **Watch table_1**.
6. If you click the watch table, you will see in the detail view of the **Watch table** tab that the selected variable is now in the watch table.
7. Repeat steps 3 to 6 to monitor the variables of various objects.

If you are connected to the target system, you can monitor the variable contents.

Status and controlling variables

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

⚠ WARNING

Dangerous plant states possible

You assign the entered values to the variables during control. This can result in dangerous plant states, e.g. unexpected axis motion.

Note

Note when you change the values of several variables:

The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the watch table. There is therefore no guarantee of consistency.

Working with the watch table

The functions of the watch table and how you work with them are described in detail in the Online help.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the watch table (independently of the SIMOTION device):

Table 7-345 Display invalid floating-point numbers

Display	Meaning
1.#QNAN -1.#QNAN	Invalid bit pattern in accordance with IEEE 754 (NaN - Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).
1.#INF -1.#INF	Bit pattern for + infinity in accordance with IEEE 754 Bit pattern for – infinity in accordance with IEEE 754
-1.#IND	Bit pattern for indeterminate

7.1.8.4 Variable status

"Variable status" enables you to monitor the current value for an individual variable, selected using the cursor, in an open program source or program organization unit (e.g. ST source file, MCC chart, LAD program).

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system. For information on loading a project, see "downloading programs to the target system (Page 4518)".
- The program source containing the program organization unit (POE) whose variables you want to monitor must be consistent with the target system.

- The associated source (e.g. ST source file, MCC chart, LAD program) must be open.
- With the MCC programming language only: The parameter screen form for the command in which the variable you want to monitor is being used must be open.
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

Procedure

To monitor an individual variable using variable status:

1. Position the cursor above the identifier for a variable.
   - With the ST programming language: in the open ST source file
   - With the ST programming language: within an input field in the open parameter screen form
   - With the LAD/FBD programming language: within a network of the LAD/FBD program
2. Briefly position the cursor above the identifier.

The tool tip shows the current value of the variable. If you keep the cursor above the identifier for a longer period, the value is updated on an ongoing basis.

Note

With "variable status", the current value for the variable is displayed, wherever the selected variable is being used.

The "variable status" function enables you to monitor all those variables you are also able to monitor in the symbol browser (Page 4526) or the address list. These are:

- System variables of SIMOTION devices
- System variables of technology objects
- Global device variables
- Retentive and non-retentive unit variables of the interface section of a program source (unit)
- Retentive and non-retentive unit variables of the implementation section of a program source (unit)
- Static variables of the programs
- Static variables of the function blocks whose instances are declared as unit variables
- Static variables of the function blocks whose instances are declared as static variables of programs
- I/O variables

7.1.8.5 Monitoring the program execution

Tracking program execution via monitoring

Monitoring makes it possible to track program execution for sequential tasks, as these are low-priority tasks in the execution system, with predominantly "slow" commands being executed.

Tracking the execution of programs in sequential tasks does not affect the actual execution of the program, but does increase the communication load. This has an impact on the execution of MotionTasks and the BackgroundTask.

Program execution tracking can be switched on and off during program operation.

When program execution monitoring is enabled, the current active command is shown in yellow. The parameter screen forms of the active MCC chart can be opened and read, but no changes can be made.

Starting the program execution monitoring

Monitoring is started via an open MCC chart which is visible in the foreground and assigned to a task. The monitoring function, however, is not started at program level but at task level. This automatically starts the monitoring for all MCC charts assigned to this task.

If the MCC chart is assigned to multiple tasks, you can select whether the monitoring should be started for one, several or all of these tasks. This automatically starts the monitoring for all MCC charts assigned to the selected tasks.

Requirement

- The MCC chart is open and visible in the foreground.
- The MCC chart is assigned directly to one or more tasks as a program or indirectly to one or more tasks via the calling program as a subprogram. This indirect assignment can also be multistage if the subprogram is called in another subprogram, or up to the subprogram that is called in a program. The calling POUs can be created in the ST, MCC or LAD/FBD programming language.

Procedure

To start the monitoring function in the open MCC chart, proceed as follows:

- **The MCC chart is only assigned to one task**
  - Select the **MCC chart > Monitor** menu command or click the button.
    The monitoring of the program execution is started for this task and thereby for all MCC charts assigned to this task.
    The relevant task is highlighted in yellow ( ) in the "Task status" toolbar (Page 4564).
- **The MCC chart is assigned to more than one task**
  - Select the **MCC chart > Monitor** menu command or click the button.
    The "Selection of the Task To Be Monitored" dialog box opens.
  - By activating the relevant checkbox, select the tasks in which you want to monitor the program in this dialog box.
    The monitoring of the program execution is started for the selected tasks and thereby for all MCC charts assigned to these tasks.
    The relevant tasks concerned are highlighted in yellow ( ) in the "Task status" toolbar (Page 4564).
  - In the "Task status" function bar, select a task in which you want to monitor program execution.
    You can switch to another task at any time by selecting the required task in the "Task status" function bar.

The MCC_1 symbol on the tab for an open MCC chart indicates that monitoring has begun, as does the symbol for the combination of currently activated test functions (monitoring, single step, trace, program status, breakpoints).

MCC charts that are called as subprograms within the open MCC chart can also be monitored. To do so, open the relevant charts, as well.

Stopping the program execution monitoring

To stop the monitoring function in the open MCC chart, proceed as follows:

- **The MCC chart is only assigned to one task**
  - Select the **MCC chart > Monitor** menu command or click the button.
    The monitoring of the program execution is stopped for this task and thereby for all MCC charts assigned to this task.
- **The MCC chart is assigned to more than one task**
  - Select the **MCC chart > Monitor** menu command or click the button.
    The "Selection of the Task To Be Monitored" dialog box opens.
  - By deactivating the relevant checkbox, select the tasks in which you want to stop the monitoring of the program execution in this dialog box.
    The monitoring of the program execution is stopped for the selected tasks and thereby for all MCC charts assigned to these tasks.

The marking of the current command is deleted and the icon is removed from the tab.

Tracking program execution using single step

You can track the program execution of one or more MCC charts in single steps. This function is available in the **Process** and **Test** operating modes (Page 4520).

Note

Availability in the Debug mode

The availability in the **Debug** operating mode (Page 4520) depends on the SIMOTION Kernel version:

- SIMOTION Kernel up to version V4.3:
  This single-step monitoring is available. However, it cannot be used simultaneously with activated breakpoints (Page 4550).
- SIMOTION Kernel as of version V4.4:
  This form of single-step monitoring is not available. Instead, you can resume the program execution in single steps (Page 4563) from the activated breakpoints (Page 4550).

Single-step monitoring has no influence on the program execution itself, but it does extend the execution time of the program. This function can be switched on and off during program operation.

The program can be assigned to more than one task. Single-step monitoring can be started for none, one, several or all of these tasks. The program sequence is suspended in the tasks in which single-step monitoring has been started until the user initiates the next program step. The next command to be executed is highlighted in light blue. Once the next single step has been activated, this command is executed as an active command and remains highlighted in light blue until execution of the command has been completed. The next command to be executed then turns light blue and the task is suspended again.

In the tasks in which single-step monitoring has not been started, the program sequence is not suspended and therefore the program can run normally.

Note

Additional program code is generated when the compiler option **Permit single step** is activated. This results in a slightly modified runtime behavior and may lead to timeouts.

As the execution time of the program is extended, the time watchdog must be adapted accordingly for cyclical tasks (TimerInterruptTask, BackgroundTask) or, if necessary, disabled.

Jumps in functions and function blocks can also be monitored if single-step monitoring is enabled in their MCC charts. The relevant MCC chart is then opened when the function or function block is called.

Note

Single-step monitoring is not possible within the Synchronous start (Page 4219) command.

The parameter screen forms of the active MCC chart can be opened and read, but no changes can be made.

Note

When the compiler option **Permit single step** is activated, access to the TSI#dwuser_1 and TSI#dwuser_2 of the TaskStartInfo is created automatically by the compiler. These are displayed in the cross-reference list.

With activated single-step monitoring, these variables are used for the control of the single-step monitoring. These variables must not be used in the user program.

Activating single-step monitoring

Proceed as follows in order to enable single-step monitoring for an MCC unit:

1. Open the Properties window for the MCC unit, see Properties of an MCC unit (Page 3994).
2. Activate the **Permit single step** compiler option on the **Compiler** tab as the local compiler setting (Page 3997) for this MCC unit.

   Note

   Alternatively, select **Options > Settings > Compiler**, then activate the **Permit single step (MCC)** compiler option as the global compiler setting (Page 3996) for all MCC units.

3. Select the MCC unit in the project navigator, followed by **Accept and compile** in the context menu.

   Note

   If the **Permit single step (MCC)** global compiler option is changed, you need to select **Project > Save and compile changes** to compile all the MCC units affected by the change.

4. Download the programs to the target system.

Starting single-step monitoring

If the MCC chart is assigned to multiple tasks, you can select whether single-step monitoring should be started for one, several or all of these tasks. As a result, single-step monitoring is started automatically for all MCC charts assigned to the selected tasks and for whose MCC units single-step monitoring is switched on.

Single-step monitoring is started via an open MCC chart which is visible in the foreground and assigned to a task. The single-step monitoring function, however, is not started at program level but at task level. Here, single-step monitoring is started automatically for all MCC charts assigned to this task and for whose MCC units single-step monitoring is switched on.

- The MCC chart is open and visible in the foreground.
- Single-step monitoring is switched on for the MCC unit of the open MCC chart.

- The MCC chart is assigned directly to one or more tasks as a program or indirectly to one or more tasks via the calling program as a subprogram. This indirect assignment can also be multistage if the subprogram is called in another subprogram, or up to the subprogram that is called in a program. The calling POUs can be created in the ST, MCC or LAD/FBD programming language.
- No activated breakpoints in **Debug mode**.

Procedure

To start the single-step monitoring function in the open MCC chart, proceed as follows:

- **The MCC chart is only assigned to one task**
  - Select the **MCC chart > Single step** menu command or click the button.
    Single-step monitoring is started for this task and thereby for all MCC charts assigned to this task and for whose MCC units single-step monitoring is switched on.
    The relevant task is highlighted in blue ( ) in the "Task status" toolbar (Page 4564).
- **The MCC chart is assigned to more than one task**
  - Select the **MCC chart > Single step** menu command or click the button.
    The "Selection of the task to be monitored" dialog box opens.
  - By activating the relevant checkbox, select the tasks in which you want to monitor the program using single-step monitoring in this dialog box.
    Single-step monitoring is started for the selected tasks and thereby for all MCC charts assigned to these tasks and for whose MCC units single-step monitoring is switched on.
    The relevant tasks are highlighted in blue ( ) in the "Task status" toolbar (Page 4564).
  - In the "Task status" function bar, select a task in which you want to monitor program execution using single-step monitoring.
    You can switch to another task at any time by selecting the required task in the "Task status" function bar.

The MCC_1 symbol on the tab for an open MCC chart indicates that single-step monitoring has begun, as does the symbol for the combination of currently activated test functions (monitoring, single step, trace, program status, breakpoints).

Initiating the next single step

You can initiate the next single step in one of the following ways:

- By clicking the **Next step** button in the MCC editor function bar
- By selecting the **MCC chart > Next step** menu command, or
- By selecting the **Next step** command in the context menu in the project navigator.

If you jump to a subprogram whose MCC unit is also compiled with the "Permit single step" option, the following applies:

- The relevant MCC chart is opened and executed in single-step mode.
- The "Subprogram call" command in the calling MCC chart is marked with a cyan-colored triangle until the subprogram has been executed.

Note

Single-step monitoring in MCC charts with know-how protection

If during single-step monitoring, an MCC chart is called whose unit is know-how protected, the following applies:

- If the MCC unit (or a chart of this unit) is not already open and the login for the MCC unit has not been registered, then the MCC chart is not opened until the password for the displayed login has been entered.
- If the password cannot be entered (e.g. **Cancel** button), the MCC chart is not opened and executed time-controlled.
  Please note: The execution time of the program is significantly extended.

Note

Single-step monitoring for several MCC charts which are assigned to different tasks

If single-step monitoring is activated for several MCC charts which are assigned to different tasks, note the following:

If you change the active window (MCC charts), you may also have to select the relevant task in the "Task status" toolbar (Page 4564).

Note

The program stays in single-step mode if the SIMOTION device goes offline or the MCC chart is closed.

Note

Program status and single-step monitoring

If you have enabled program status (Page 4542) and single-step monitoring, the monitored variables for a command are only updated once the next single step has been triggered, i.e. not until you have changed from this command to the next command to be executed.

Stopping single-step monitoring

To stop single-step monitoring in the open MCC chart, proceed as follows:

- **The MCC chart is only assigned to one task**
  - Select the **MCC chart > Single step** menu command or click the  button.
    The single-step monitoring of the program execution is stopped for this task and thereby for all MCC charts assigned to this task.
- **The MCC chart is assigned to more than one task**
  - Select the **MCC chart > Single step** menu command or click the  button.
    The "Selection of the task to be monitored" dialog box opens.
  - By deactivating the relevant checkbox, select the tasks in which you want to stop the single-step monitoring of the program execution in this dialog box.
    The single-step monitoring of the program execution is stopped for the selected tasks and thereby for all MCC charts assigned to these tasks.

Deactivating single-step monitoring

1. First stop the "Single step" function (see Stopping single-step monitoring).
2. Open the Properties window for the MCC unit (see Properties of an MCC unit (Page 3994)).
3. Deactivate the **Permit single step** compiler option on the **Compiler** tab as the local compiler setting (Page 3997) for this MCC unit and click **OK** to confirm.

   Note

   If the **Permit single step (MCC)** compiler option is activated as the global compiler setting (Page 3996), you can deactivate this for either one MCC unit by deactivating the relevant **Use global settings** checkbox (see Local compiler settings (Page 3997)) or for all the MCC units by selecting **Options > Settings > Compiler**.

4. Recompile the program and download it to the target system.

   Note

   If the **Permit single step (MCC)** global compiler option is changed, you need to select **Project > Save and compile changes** to compile all the MCC units affected by the change.

Tracking program execution using the trace (as of Kernel V4.2)

This function is available as of SIMOTION Kernel version V4.2.

It supports program execution tracking for cyclic tasks and cyclic programs in MotionTasks.

Cyclic tasks are high-priority tasks in the execution system, with predominantly "fast" commands being executed. Cyclic programs in MotionTasks mainly contain commands capable of being executed "fast". Tracking program execution via monitoring (Page 4532) is too slow for "fast" commands and results in display errors.

Tracking the execution of programs using the trace does not affect the actual execution of the program, but does increase the communication load. This has an impact on the execution of MotionTasks and the BackgroundTask.

Program execution tracking can be switched on and off during program operation.

If program execution monitoring is enabled via the trace, the commands for program branches executed cyclically are displayed in yellow, which results in a trace. This provides a quick initial overview of the program branches being executed, making it possible, for example, to use program status (Page 4542) in a targeted manner within the executed program branches. The parameter screen forms of the active MCC chart can be opened and read, but no changes can be made.

Note

Additional program code is generated when the compiler option **Permit trace** is activated. This results in a slightly modified runtime behavior and may lead to timeouts.

If loops are programmed in the MCC chart that are run through quickly and frequently, all the executed commands may not be registered and displayed in yellow in SIMOTION SCOUT because of the limited buffer capacity.

Activating the trace function

You can only use the trace to monitor program execution if additional code has been created during compilation:

1. Select the **Project > Connect to selected target devices** menu command or click the button.
   Online mode is activated.
2. Select the SIMOTION device, followed by **Operating mode** in the context menu.
3. Select **Test mode** or **Debug mode**.
   The trace can only be activated for these two operating modes (see Operating modes for SIMOTION devices (Page 4520)).
4. Open the Properties window for the MCC unit (see Properties of an MCC unit (Page 3994)).
5. Activate the **Permit trace** compiler option on the **Compiler** tab as the local compiler setting (Page 3997) for this MCC unit.
   This compiler option can also be activated as the global compiler setting (Page 3996) (same as section "Enabling single-step monitoring" in Tracking program execution using single step (Page 4534)).
6. Select the **MCC unit > Accept and compile** menu command.
   The MCC unit is compiled.
7. Select the **Target system > Load > Project to target system** menu command or click the button.
   The programs are downloaded to the target system.

Note

Additional internal variables and functions, whose identifier begins with an underscore, are automatically created by the compiler when the **Permit trace** compiler option is activated. The TSI#currentTaskId variable of the TaskStartInfo is also used. These variables and functions are displayed in the cross-reference list and partly in the symbol browser.

With activated trace, these variables and functions are used for the control of the trace. These variables and functions must not be used in the user program.

Starting the trace

You can only start the trace for one MCC chart at a time.

Requirement

- **Test mode** or **Debug mode** is selected for the SIMOTION device.
- The relevant MCC chart is open and visible in the foreground.
- The trace function is switched on for the MCC unit of the open MCC chart.
- The MCC chart is assigned directly to one or more tasks as a program or indirectly to one or more tasks via the calling program as a subprogram. This indirect assignment can also be multistage if the subprogram is called in another subprogram, or up to the subprogram that is called in a program. The calling POUs can be created in the ST, MCC or LAD/FBD programming language.

- The MCC chart must not contain any changes that have not been saved.
- The MCC unit in SCOUT must be consistent with the target system.

Procedure

To start the trace:

1. Select the **MCC chart > Trace on/off** menu command or click the button.
   The **Trace Settings** dialog box opens.
2. Make the required settings in the dialog box (see the parameter description below) and click **OK** to confirm.
3. The trace function starts.
   The trace is visualized immediately or when the selected trigger condition is entered.
   The MCC_1 symbol on the tab for the open MCC chart indicates that the trace has started, as does the symbol for the combination of currently activated test functions (monitoring, single step, trace, program status, breakpoints).

The table below contains a description of the individual parameters.

Table 7-346 Parameters for trace settings

Parameter		Description
Call path		You can enter the call path here for the MCC chart for which the trace is to be activated.
	Calling task	This drop-down list box lists all the tasks whose open MCC chart has been directly/indirectly assigned in the execution system: • You have the option to select a single task here. The trace is only activated for the MCC chart in this task. • You have the option not to select any task. The trace is activated for the MCC chart in all tasks.
	Calling program	If the MCC chart is a subprogram, all call paths of the subprogram that are found within the task selected in the "Calling task" drop-down list box or in all tasks are listed in this drop-down list box: • Only when a single task is selected: You can select a single call path here (with the name of the program source, line number, name of POU). The trace will only be activated for this time call of the subprogram. • You cannot select a call path or "all call positions as of this call level". The trace will be activated every time the subprogram is called.
Trigger		You can select the required trigger condition here: • Endless recording (default setting) • Condition A trigger condition can be specified in the form of any kind of Boolean condition, e.g. myGlobalVar_1=MCC_1.myVar_2. Global device variables, I/O variables, and exported unit variables are permitted (see Overview of variable types (Page 4044)).

Parameter	Description
Display update	You can specify here when the trace display is to be updated: • Cyclic with manual new recording (default setting) [1)] • Cyclic with cycle-controlled new recording [2)] • Time-controlled with manual recording: You can select a value, based on 100 ms steps, within a range from 100 ms to 2 s.
Activate log	If this checkbox is activated, the MCC commands executed while the "trace" function is enabled are also logged. The log is output in the detail view when the trace has been stopped. You can enter the maximum possible number for the log entries here either directly as a value or select an increment of 100. The factory setting is 1000.

1) Manual new recording means that the trace displayed so far has to be reset manually, for example, via the menu **MCC chart > Rerecord trace**.
The log is not reset.

2) With cycle-controlled new recording, the trace is reset automatically before each cycle. This also applies to loop cycles.
The log is not reset.

Visualization of the trace

The trace is visualized in the MCC chart for the currently selected task.

Note

Make sure that the calling task is also selected in the "Task status" toolbar for the visualization of the trace. If required, select the **MCC chart > Trace on/off** menu command again or click the  button.

You can switch to another task at any time by selecting the required task in the "Task status" function bar. The trace for the previously selected task is deleted and the trace for the newly selected task is visualized immediately, provided that the trace function was also started for the MCC chart in the newly selected task.

This allows separate visualization of the MCC chart cycles in the various tasks. This has no impact on logging, however.

Stopping the trace

To stop the trace:

1. Select the **MCC chart > Trace on/off** menu command or click the  button.
   The trace function stops.

The visualized trace continues to be displayed and can be manually deleted by clicking the  button.

If the logging function is activated, the log is output in the detail view:

- A log entry containing the following information is created for each executed MCC command:
  - Time stamp of the SIMOTION device
  - Task name
  - Name of the MCC unit and the MCC chart
  - Command number
  - Command type
- By double-clicking on an entry, the corresponding MCC command is selected in the MCC chart.
- The log can be saved as a text file via the context menu of the detail view.
- The log is deleted when the trace is restarted or can be deleted manually via the context menu of the detail view.

Deactivating the trace function

When the trace is deactivated, the additional code is removed and CPU resources released.

To deactivate the trace, proceed as follows:

1. First stop the trace function (see Stopping the trace).
2. Open the Properties window for the MCC unit (see Properties of an MCC unit (Page 3994)).
3. Deactivate the **Permit trace** compiler option on the **Compiler** tab as the local compiler setting (Page 3997) for this MCC unit and click **OK** to confirm.
   If this compiler option is activated as the global compiler setting, the global compiler setting (Page 3996) must be deactivated accordingly (same as section "Disabling single-step monitoring" in Tracking program execution using single step (Page 4534)).
4. Select the SIMOTION device, followed by **Operating mode** in the context menu.
5. Select **Process mode**.
   Program execution is optimized for this operating mode to ensure maximum performance (see Operating modes for SIMOTION devices (Page 4520)).
6. Recompile the program and download it to the target system.

7.1.8.6 Program status

Program status can be used to monitor variables for the following commands.

- IF: Program branch (Page 4206)
- WHILE: Loop with condition at the start (Page 4208)
- UNTIL: Loop with condition at end (Page 4211)
- Variable assignment (Page 4187)
- ST zoom (Page 4188)
- Subprogram call (Page 4184)
- System function call (Page 4185)

The values of the following variables are displayed:

- Variables with elementary data type (INT, REAL, etc.)
- Individual elements of a structure, provided an assignment is given
- Individual elements of a field (array), provided an assignment is given
- Variables with enumeration data types

Note

The values of constants are not displayed.

In addition, the following values are not displayed for the IF (Page 4206), WHILE (Page 4208), UNTIL (Page 4211) or "Variable assignment" (Page 4187) commands that have been programmed in the LAD and FBD programming languages, see LAD/FBD/Formula (Page 4152):

- Variables of enumeration data types (Page 4059)
- Hexadecimal or binary values

Due to the restricted buffer capacity and the requirement for minimum runtime tampering, the following variables cannot be displayed:

- Complete arrays
- Complete structures

However, individual array elements or individual structure elements are displayed if an assignment is made in the MCC chart.

Program status requires additional CPU resources.

Activating program status

Before you can work with program status, additional code must be generated during compilation:

1. Select the **Project > Connect to selected target devices** menu command or click the button.
   Online mode is activated.
2. Select the SIMOTION device, followed by **Operating mode** in the context menu.
3. Select **Test mode**.
   Program status is available in this operating mode without restrictions, see Operating modes for SIMOTION devices (Page 4520).
4. Open the Properties window for the MCC unit, see Properties of an MCC source file (Page 3994).
5. Activate the **Permit program status** compiler option on the **Compiler** tab as the local compiler setting (Page 3997) for this MCC unit.
   This compiler option can also be activated as the global compiler setting (Page 3996) (same as section "Enabling single-step monitoring" in Tracking program execution using single step (Page 4534)).

6. Compile the MCC unit (**MCC unit > Accept and compile** menu command).
7. Select the **Target system > Load > Project to target system** menu command or click the button.
   The programs are downloaded to the target system.

Starting the Status program

Requirement

- The relevant MCC chart must be open.
- The MCC chart must not contain any changes that have not been saved.
- The MCC unit in SCOUT must be consistent with the target system.

Procedure

To start program status, proceed as follows:

1. Select the **MCC chart > Program status** menu command or click the button for **Program status** (keyboard shortcut Ctrl+F7).
   Program status is started.
2. If the MCC chart is assigned to more than one task, the **Call path/task selection Program status** dialog box opens:
   – In this dialog box, select the task in which you want to monitor the program.

   The MCC_1 symbol on the tab for the open MCC chart indicates that program status has begun, as does the symbol for the combination of currently activated test functions (monitoring, single step, trace, program status, breakpoints).
3. Open the commands for which you want to monitor the variables.
   You can open more than one command at a time, but you will only be able to monitor the variables in the active window (that is, the window in the foreground). You can size the window with the cursor so longer variable names can also be seen without any difficulty.

Note

Start program status for multiple windows for each SIMOTION device

A window can be an open ST source file, an open LAD/FBD program or an open MCC chart. An active window is located in the foreground and the current status values are displayed (MCC: open MCC command).

In **Process mode**, program status can only be started for one window.

In **Test mode**, program status can be started simultaneously for several windows per task. The maximum possible number depends on the utilization of the SIMOTION device.

If program status is started for an additional window (**Process mode**) or starting it causes the maximum possible number to be exceeded (**Test mode**), program status is automatically deactivated for the currently active window (**Process mode**) or the oldest active window (**Test mode**), i.e. momentarily paused, but not stopped. If a window with deactivated program status is brought to the foreground (MCC: open MCC command), program status is automatically reactivated and the current status values are displayed again.

Note

Program status and single-step monitoring

If you have activated program status and single-step monitoring, see Tracking single steps in the program (Page 4534), the monitored variables from a command are only updated once the next single step has been triggered, i.e. not until you have changed from this command to the next command to be processed.

Stopping program status

To stop program status, proceed as follows:

1. Select the **MCC chart > Program status** menu command or click the  button for **Program status** (keyboard shortcut Ctrl+F7).
   Program status is stopped.

Deactivating program status

Disabling program status frees up CPU resources.

To disable program status, proceed as follows:

1. First, stop the program status function, see Stopping program status.
2. Open the Properties window for the MCC unit, see Properties of an MCC source file (Page 3994).
3. Deactivate the **Permit program status** compiler option on the **Compiler** tab as the local compiler setting (Page 3997) for this MCC unit and click **OK** to confirm.
   If this compiler option is activated as the global compiler setting, the global compiler setting (Page 3996) must be deactivated accordingly (same as section "Disabling single-step monitoring" in Tracking program execution using single step (Page 4534)).
4. Select the SIMOTION device, followed by **Operating mode** in the context menu.
5. Select **Process mode**.
   Program execution is optimized for this operating mode to ensure maximum performance, see Operating modes for SIMOTION devices (Page 4520).
6. Recompile the program and download it to the target system.

7.1.8.7 Program run

Program run: Display code location and call path

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path.

Follow these steps:

1. Click the **Show program run** button on the Program run toolbar.
   The "Program run call stack (Page 4546)" window opens.
2. Select the desired MotionTask.
3. Click the **Update** button.

The window shows:

- The position in the code being executed (e.g. line of the ST source file) stating the program source and the POU.
- Recursively positions in the code of other POUs that call the code position being executed.

The following names are displayed for the SIMOTION RT program sources:

Table 7-347 SIMOTION RT program sources

Name	Meaning
taskbind.hid	Execution system
stdfunc.pck	IEC library
device.pck	Device-specific library
tp-name.pck	Library of the *tp-name* technology package, e.g. cam.pck for the library of the CAM technology package

Program run parameters

You can display the following for all configured tasks:

- the current code position in the program code (e.g. line of an ST source file)
- the call path of this code position

Table 7-348 Program run parameter description

Array	Description
Selected CPU	The selected SIMOTION device is displayed.
Refresh	Clicking the button reads the current code positions from the SIMOTION device and shows them in the open window.
Calling task	Select the task for which you want to determine the code position being executed. All configured tasks of the execution system.
Current code position	The position being executed in the program code (e.g. line of an ST source file) is displayed (with the name of the program source, line number, name of the POU).
is called by	The code positions that call the code position being executed within the selected task are shown recursively (with the name of the program source, line number, name of the POU, and name of the function block instance, if applicable).

For names of the SIMOTION RT program sources, refer to the table in Program run (Page 4545).

Program run toolbar

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path with this toolbar.

Table 7-349 Program run toolbar

Symbol	Meaning
	Display program run Click this symbol to open the Program run call stack window. In this window, you can display the currently active code position with its call path. See: Program run: Display code position and call path (Page 4545)

7.1.8.8 Trace

Trace allows you to log and graphically display the characteristics of signals and axis states.

You must configure the data that you wish to record in the SIMOTION trace tool (for description, see the online help).

Activate trace

Figure 7-182 Trace trigger

This command can be used to log the characteristics of signals and axis states at a defined position in the program.

In order for trace recording to start when the command is run, the trace must already have been started in the trace tool by clicking the ▶ button. Additional details about working with the trace tool can be found in the online help.

System variable traceState[n].tracestate on the SIMOTION device can be used to query whether the trace is still in progress or has already finished. You can monitor this variable in the symbol browser if you have selected the SIMOTION device in the project navigator.

If another trace recording is required after the current one has finished, the trace will need to be started again by clicking the ▶ button.

Overview of parameters

You can set the following parameters:

Field/Button	Explanation/Instructions
Trace Trigger 1	Trace is started when the following condition is fulfilled: "Trigger with TraceTrigger 1 program call".
Trace Trigger 2	Trace is started when the following condition is fulfilled: "Trigger with TraceTrigger 2 program call".

Example of Activate trace

The simultaneous starting of two axes (axis_1 and axis_2) will be recorded.

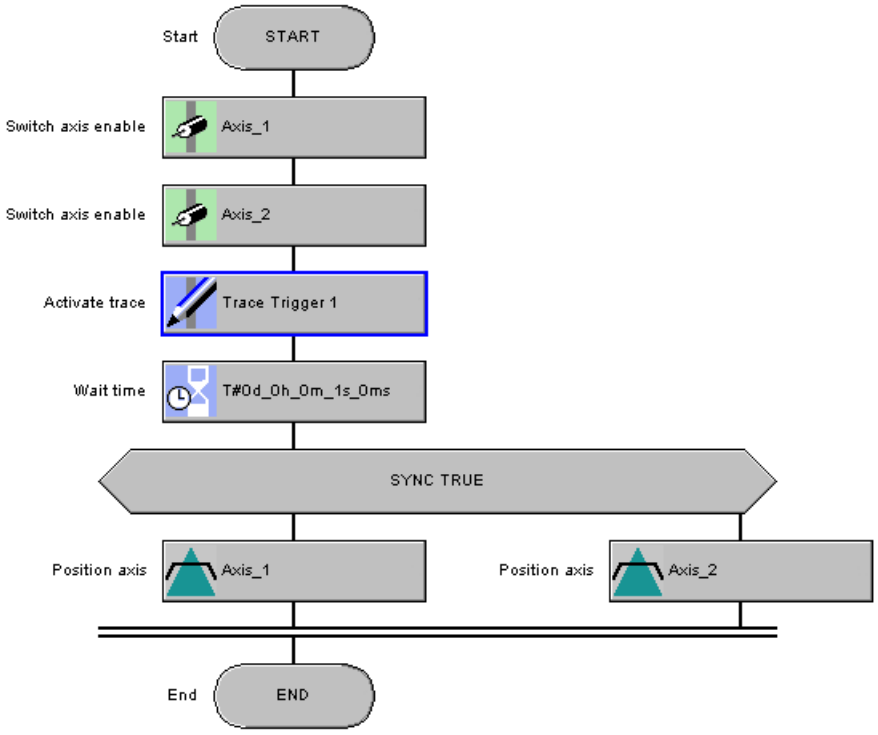

Figure 7-183 Trace recording of a synchronous start of two axes

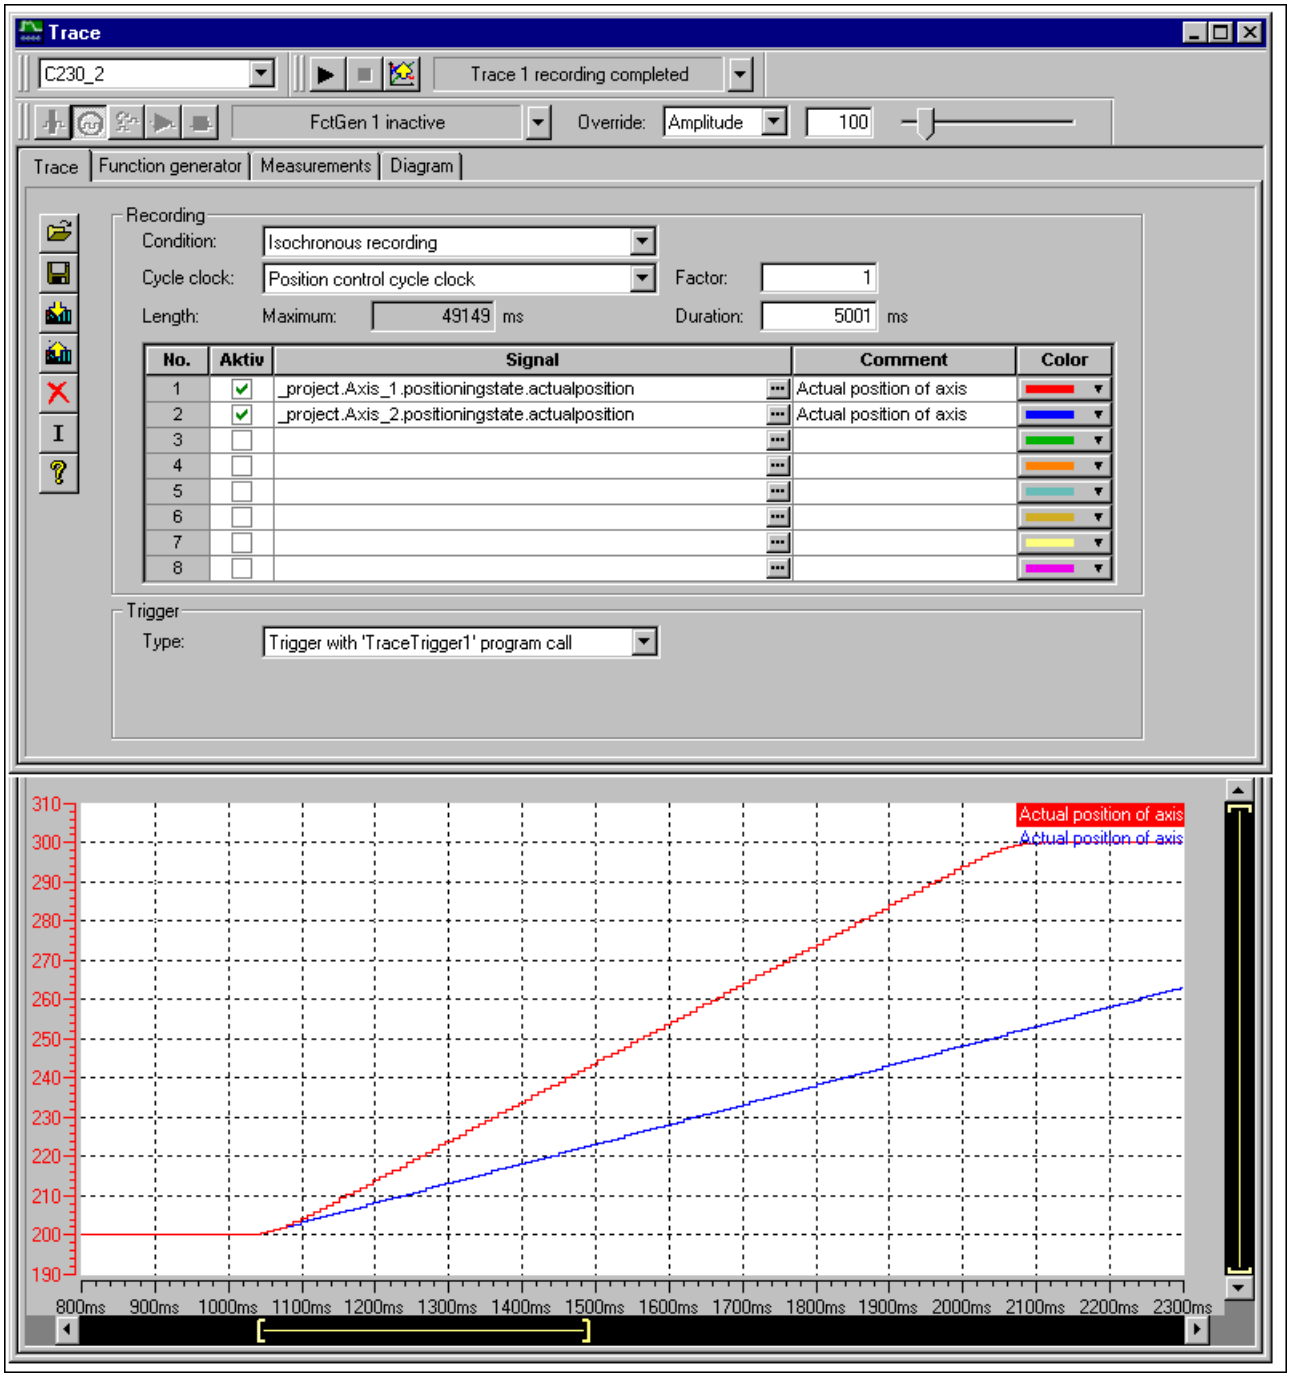

Figure 7-184 Trace recording of synchronous start

Relevant system variable for Activate trace

System variable of SIMOTION device: TraceControl

7.1.8.9 Breakpoints

General procedure for setting breakpoints

You can set breakpoints within a POU of a program source (e.g. ST source, MCC chart, LAD/FBD source). On reaching an activated breakpoint, the task in which the POU with the breakpoint is called is stopped. If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser.

Requirement:

- The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.

Procedure

Follow these steps:

1. Select "Debug mode" for the associated SIMOTION device; see Setting debug mode (Page 4550).
2. Specify the tasks to be stopped, see Specifying the debug task group (Page 4552).
3. Set breakpoints, see Setting breakpoints (Page 4553).
4. Define the call path, see Defining a call path for a single breakpoint (Page 4556).
5. Activate the breakpoints, see Activating breakpoints (Page 4560).

Setting the debug mode

⚠ WARNING

Dangerous plant states possible

If problems occur in the communication link between the PC and the SIMOTION device, this may result in dangerous plant states (e.g. the axis may start moving in an uncontrollable manner).

Therefore, use the debug mode only with activated life-sign monitoring (Page 4522) with a suitably short monitoring time!

You must observe the appropriate safety regulations.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect!

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Requirement

1. A connection to the target system must have been established (online mode)
2. Debug mode must not be selected for any SIMOTION device.

Procedure

To set the debug mode, proceed as follows:

1. Highlight the SIMOTION device in the project navigator.
2. Select **Operating mode** from the context menu.
3. Select **Debug** mode (Page 4520).
4. Accept the safety information
5. Parameterize the sign-of-life monitoring.
   See also section: Important information about the life-sign monitoring (Page 4522).
6. Confirm with **OK**.

SIMOTION SCOUT switches to debug mode for this device; the SIMOTION device itself remains in "test mode", as long as at least one breakpoint is activated:

The project navigator indicates that debug mode is activated for SIMOTION SCOUT by means of a symbol next to the SIMOTION device.

The breakpoints toolbar (Page 4555) is displayed.

As long as no breakpoints are activated, you can edit program sources in debug mode (Page 4524).

Debug mode is not enabled for the SIMOTION device until at least one set breakpoint is activated. If all breakpoints are deactivated, debug mode is canceled for the SIMOTION device. The status bar indicates that debug mode is activated for the SIMOTION device.

Note

Pressing the spacebar or switching to a different Windows application causes the following to happen if the SIMOTION device is in debug mode (breakpoints activated):

- The SIMOTION device switches to the STOP operating state.
- The outputs are deactivated (ODIS).

⚠ WARNING

Dangerous plant states possible

This function is not guaranteed in all operating states.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Define the debug task group

On reaching an activated breakpoint, all tasks that are assigned to the debug task group are stopped.

Requirement

1. A connection to the target system must have been established (online mode).
2. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4550).

Procedure

How to assign a task to the debug task group:

1. Highlight the relevant SIMOTION device in the project navigator.
2. Select **Debug task group** from the context menu.
   The Debug Task group window opens.
3. Select the tasks to be stopped on reaching the breakpoint:
   - If you only want to stop individual tasks (in RUN operating state): Activate the **Debug task group** selection option.
     Assign all tasks to be stopped on reaching a breakpoint to the **Tasks to be stopped** list.
   - If you only want to stop individual tasks (in HOLD operating state): Activate the **All tasks** selection option.
     In this case, also select whether the outputs and technology objects are to be released again after resumption of program execution.

Note

Note the different behavior when an activated breakpoint is reached, see the following table.

Table 7-350 Behavior at the breakpoint depending on the tasks to be stopped in the debug task group.

Property		Tasks to be stopped	
		Single selected tasks (debug task group)	All tasks
Behavior on reaching the breakpoint			
	Operating state	RUN	STOP
	Stopped tasks	Only tasks in the debug task group	All tasks
	Outputs	Active	Deactivated (ODIS activated)
	Technology	Closed-loop control active	No closed-loop control (ODIS activated)
	Runtime measurement of the tasks	Active for all tasks	Deactivated for all tasks
	Time monitoring of the tasks	Deactivated for tasks in the debug task group	Deactivated for all tasks
	Real-time clock	Continues to run	Continues to run

Property		Tasks to be stopped	
		Single selected tasks (debug task group)	All tasks
Behavior on resumption of program execution			
	Operating state	RUN	RUN
	Started tasks	All tasks in the debug task group	All tasks
	Outputs	Active	The behavior of the outputs and the technology objects depends on the **'Continue' activates the outputs (ODIS deactivated)** checkbox. • Active: ODIS will be deactivated. All outputs and technology objects are released. • Inactive: ODIS remains activated. All outputs and technology objects are only enabled for one STOP-RUN transition.
	Technology	Closed-loop control active	

Note

You can only make changes to the debug task group if no breakpoints are active.

The settings of the debug task group are retained after exiting "Debug mode".

Proceed as follows:

1. Set breakpoints (see Setting breakpoints (Page 4553)).
2. Define the call path (see Defining a call path for a single breakpoint (Page 4556)).
3. Activate the breakpoints (see Activating breakpoints (Page 4560)).

Setting breakpoints

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4550).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4552).

Procedure

How to set a breakpoint:

1. Select the code location where no breakpoint has been set:
   - SIMOTION ST: Place the cursor on a line in the ST source file that contains a statement.
   - SIMOTION MCC: Select an MCC command in the MCC chart (except module or comment block).
   - SIMOTION LAD/FBD: Set the cursor in a network of the LAD/FBD program.
2. Perform the following (alternatives):
   - Select the **Debug > Set/remove breakpoint** menu command (shortcut F9).
   - Click the  button in the Breakpoints toolbar.

To remove a breakpoint, proceed as follows:

1. Select the code position with the breakpoint.
2. Perform the following (alternatives):
   - Select the **Debug > Set/remove breakpoint** menu command (shortcut F9).
   - Click the  button in the Breakpoints toolbar.

To remove all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Remove all breakpoints** menu command (shortcut CTRL+F5).
  - Click the  button in the Breakpoints toolbar.

Note

You cannot set breakpoints:

- For SIMOTION ST: In lines that contain only comment.
- For SIMOTION MCC: On the module or comment block commands.
- For SIMOTION LAD/FBD: Within a network.
- At code locations in which other debug points (e.g. trigger points) have been set.

You can list the debug points in all program sources of the SIMOTION device in the debug table:

- Click the  button for "debug table" in the Breakpoints toolbar.

In the debug table, you can also remove all breakpoints (in all program sources) of the SIMOTION device:

- Click the button for "Clear all breakpoints".

The breakpoints set also remain saved after leaving debug mode; they are displayed in debug mode only.

You can use the program status (Page 4542) diagnosis functions and breakpoints together in a program source or POU. However, the following restrictions apply depending on the program languages:

- SIMOTION ST: For version V3.2 of the SIMOTION Kernel, the (marked) ST source file lines to be tested with program status must not contain a breakpoint.
- SIMOTION MCC and LAD/FBD: The commands of the MCC chart (or networks of the LAD/FBD program) to be tested with program status must not contain a breakpoint.

Proceed as follows

1. Define the call path, see Defining a call path for a single breakpoint (Page 4556).
2. Activate the breakpoints, see Activating breakpoints (Page 4560).

Breakpoints toolbar

This toolbar contains important operator actions for setting and activating breakpoints:

Table 7-351 Breakpoints toolbar

Symbol	Meaning
	Set/remove breakpoint Click this icon to set at breakpoint for the selected code position or to remove an existing breakpoint. See: Setting breakpoints (Page 4553).
	Activate/deactivate breakpoint Click this icon to activate or deactivate the breakpoint at the selected code position. See: Activating breakpoints (Page 4560).
	Edit the call path Click this icon to define the call path for the breakpoints: • If a code position **with** breakpoint is selected: The call path for this breakpoint. • If a code position **without** breakpoint is selected: The call path for all breakpoints of the POU. See: Defining the call path for a single breakpoint (Page 4556), Defining the call path for all breakpoints (Page 4558).
	Activate all breakpoints of the active POU Click this symbol to activate all breakpoints in the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Activating breakpoints (Page 4560).
	Deactivate all breakpoints of the active POU Click this symbol to deactivate all breakpoints in the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Activating breakpoints (Page 4560).
	Remove all breakpoints of the active POU Click this symbol to remove all breakpoints from the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Setting breakpoints (Page 4553).

Symbol	Meaning
	Debug table Click this icon to display the debug table. See: Debug table parameters.
	Display call stack Click this icon after reaching an activated breakpoint to: • View the call path at the current breakpoint. • View the code positions at which the other tasks of the debug task group have been stopped together with their call path. See: Displaying the call stack (Page 4562).
	Resume Click this icon to continue the program execution after reaching an activated breakpoint. See: Resuming program execution (Page 4563), Displaying the call stack (Page 4562).
	Next step (SIMOTION Kernel as of version V4.4) Only available for the MCC and LAD/FBD programming languages: Click this icon to resume the program execution until the next MCC command or LAD/FBD network is reached. See: Resume program execution in single steps (Page 4563).
	Step through the subprogram (SIMOTION Kernel as of version V4.4) Only available for the MCC programming language. Click this icon to jump to the called subprogram and stop at the first command. The subprogram must be created in the MCC or LAD/FBD programming language. See: Resume program execution in single steps (Page 4563).

Defining the call path for a single breakpoint

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4550).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4552).
5. Breakpoint is set, see Setting breakpoints (Page 4553).

Procedure

To define the call path for a single breakpoint, proceed as follows:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the  button for "edit call path" in the Breakpoints toolbar.
   In the Call path / task selection breakpoint window, the marked code position is displayed (with the name of the program source, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when the selected breakpoint is reached.
   The following are available:
   - **All calling locations starting at this call level**
     The user program will always be started when the activated breakpoint in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when the breakpoint in the selected task is reached. The task must be in the debug task group.
     The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).
   The following are available:
   - **All calling locations starting at this call level**
     No call path is specified. The user program is always stopped at the activated breakpoint if the POU in the selected tasks is called.
   - Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
     The call path is specified. The user program will be stopped at the activated breakpoint only when the POU is called from the selected code position.
     If the POU of the selected calling code position is also called from other code positions, further lines are displayed successively in which you proceed similarly.
5. If the breakpoint is only to be activated after the code position has been reached several times, select the number of times.

Note

You can also define the call path to the individual breakpoints in the debug table:

1. Click the button for "debug table" in the Breakpoints toolbar.
   The "Debug table" window opens.
2. Click the appropriate button in the "Call path" column.
3. Proceed in the same way as described above:
   – Specify the task.
   – Define the call path (only for functions and function blocks).
   – Specify the number of passes after which the breakpoint is to be activated.

Proceed as follows:

- Activate the breakpoints, see Activating breakpoints (Page 4560).

Note

You can use the "Display call stack (Page 4562)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

See also

Defining the call path for all breakpoints (Page 4558)

Defining the call path for all breakpoints

With this procedure, you can:

- Select a default setting for all future breakpoints in a POU (e.g. MCC chart, LAD/FBD program or POU in an ST source file).
- Accept and compare the call path for all previously set breakpoints in this POU.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4550).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4552).

Procedure

To define the call path for all future breakpoints of a POU, proceed as follows:

1. Select the code location where **no** breakpoint has been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the  button for "edit call path" in the Breakpoints toolbar.
   In the "Call path / task selection all breakpoints for each POU" window, the marked code position is displayed (with the name of the program source, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when a breakpoint in this POU is reached.
   The following are available:
   - **All calling locations starting at this call level**
     The user program will always be started when an activated breakpoint of the POU in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when a breakpoint in the selected task is reached.
     The task must be in the debug task group.
     The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).
   The following are available:
   - **All calling locations starting at this call level**
     No call path is specified. The user program is always stopped at an activated breakpoint when the POU in the selected tasks is called.
   - Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
     The call path is specified. The user program will be stopped at an activated breakpoint only when the POU is called from the selected code position.
     If the selected calling code position is in turn called by other code positions, further lines are displayed successively in which you proceed similarly.
5. If a breakpoint is only to be activated after the code position has been reached several times, select the number of times.
6. If you want to accept and compare this call path for all previously set breakpoints in this POU:
   - Click **Accept**.

Proceed as follows:

- Activate the breakpoints, see Activating breakpoints (Page 4560).

Note

You can use the "Display call stack (Page 4562)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

See also

Defining the call path for a single breakpoint (Page 4556)

Activating breakpoints

Breakpoints must be activated if they are to have an effect on program execution.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4550).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4552).
5. Breakpoints are set, see Setting breakpoints (Page 4553).
6. Call paths are defined, see Defining a call path for a single breakpoint (Page 4556).

Activating breakpoints

How to activate a single breakpoint:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source file.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Perform the following (alternatives):
   - Select the **Debug > Activate/deactivate breakpoint** menu command (shortcut F12).
   - Click the  button in the Breakpoints toolbar.

To activate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Activate all breakpoints** menu command.
  - Click the  button in the Breakpoints toolbar.

Once the first breakpoint has been activated, the SIMOTION device switches to debug mode. It remains in this mode until the last breakpoint is deactivated.

In the Task status function bar, (Page 4564) the tasks with activated breakpoints are highlighted in gray ( ).

Note

Breakpoints of all program sources of the SIMOTION device can also be activated and deactivated in the debug table:

1. Click the  button for "debug table" in the Breakpoints toolbar.
   The "Debug Table" window opens.
2. Perform the action below, depending on which breakpoints you want to activate or deactivate:
   - Single breakpoints: Check or clear the corresponding checkboxes.
   - All breakpoints (in all program sources): Click the corresponding button.

The following applies up to version V4.3 of the SIMOTION Kernel:

- In the case of activated breakpoints, the "Single step" (Page 4534) test function of the SIMOTION MCC programming language cannot be used.

The following applies as of version V4.4 of the SIMOTION Kernel:

- The "Single step" test function of the SIMOTION MCC programming language is not available in the Debug mode.

Breakpoints cannot be activate if the control priority is at the axis control panel. Conversely, you cannot fetch the control priority for the axis control panel when a breakpoint activated.

Behavior at the activated breakpoint

On reaching an activated breakpoint (possibly using the selected call path (Page 4556)), all tasks assigned to the debug task group will be stopped. The behavior depends on the tasks in the debug task group and is described in "Defining a debug task group (Page 4552)". The breakpoint is highlighted.

In the Task status function bar, (Page 4564) the task in which the breakpoint was reached is highlighted in red ( ).

The following applies to the programming languages MCC or LAD/FBD: If the debug task group is stopped by a breakpoint, then the user has the option to change to another task, belonging to the debug task group, in the combo box. Always the breakpoint of the currently selected task is visualized.

If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser (Page 4526).

You can use the "Display call stack (Page 4562)" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Resuming program execution

You can resume the execution of the stopped tasks, see "Resuming program execution" (Page 4563).

As of version V4.4 of the SIMOTION Kernel, you can resume the task in single steps that has been stopped at the activated breakpoint in the MCC and LAD/FBD programming languages, see Resuming program execution in single steps (Page 4563).

Deactivate breakpoints

To deactivate a single breakpoint, proceed as follows:

1. Select the code position with the activated breakpoint.
2. Perform the following (alternatives):
   - Select the **Debug > Activate/deactivate breakpoint** menu command (shortcut F12).
   - Click the  button in the Breakpoints toolbar.

To deactivate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Deactivate all breakpoints** menu command.
  - Click the  button in the Breakpoints toolbar.

Once the last breakpoint has been deactivated, the SIMOTION device switches to "test mode"; SIMOTION SCOUT continues to run in debug mode.

Display call stack

You can use the "Display call stack" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Requirement

The user program is stopped at an activated breakpoint, i.e. the tasks of the debug task group (Page 4552) have been stopped.

Procedure

To call the "Display call stack" function, proceed as follows:

- Click the  button for "display call stack" in the Breakpoints toolbar.
  The "Breakpoint call stack" dialog opens. The current call path (including the calling task and the number of the set passes) is displayed.
  The call path cannot be changed.

To use the "Display call stack" function, proceed as follows:

1. Keep the "Breakpoint call stack" dialog open.
2. To display the code position at which the other task was stopped, proceed as follows:
   – Select the appropriate task. All tasks of the debug task group can be selected.

   The code position, including the call path, is displayed. If the code position is contained in a user program, the program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) will be opened and the code position marked.
3. How to resume program execution:
   – Click the  button for "resume" (Ctrl+F8 shortcut) on the Breakpoint toolbar.

   When the next activated breakpoint is reached, the tasks of the debug task group will be stopped again. The current call path, including the calling task, is displayed.
4. Click **OK** to close the "Breakpoint call stack" dialog box.

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 4545)".

Resuming program execution

How to resume program execution:

- Perform the following (alternatives):
  – Select the **Debug > Continue** menu command (shortcut CTRL+F8).
  – Click the  button on the Breakpoint toolbar (Page 4555) to "Continue".

The stopped task is continued until the next active breakpoint is reached.

Resuming program execution in single steps (as of Kernel V4.4)

This function is available as of SIMOTION Kernel version V4.4.

In the MCC and LAD/FBD programming languages you can resume the task in single steps that was stopped at an activated breakpoint (Page 4550).

The current MCC command or the current LAD/FBD network and all stopped tasks of the debug task group are executed.

All tasks that are assigned to the debug task group are stopped at the following MCC command or LAD/FBD network or the next activated breakpoint within the debug task group.

Next step

To execute the current MCC command or the current LAD/FBD network at which the program has been stopped, proceed as follows:

- Perform the following (alternatives):
  – Select the **Debug > Next step** menu command (shortcut CTRL+F10).
  – Click the  button for "Next step" in the Breakpoints toolbar (Page 4555).

The current MCC command or the current LAD/FBD network is executed. The program is stopped at the following MCC command or the current LAD/FBD network.

A subprogram call is executed without interruption as long as no breakpoint is activated within the subprogram. If a

Stepping through the subprogram (MCC only)

If the program execution has been stopped at the "Subprogram call" (Page 4184) command in the MCC programming language, you can jump to the subprogram and run through it in single steps. The subprogram must have been created in the MCC or LAD/FBD programming language.

- Perform the following (alternatives):
  - Select the **Debug > Step through subprogram** menu command (shortcut CTRL+SHIFT +F10).
  - Click the  button on the Breakpoint toolbar (Page 4555) to "Step through subprogram".

The appropriate MCC chart or LAD/FBD program is opened and the program execution stopped at the first MCC command or LAD/FBD network.

Note

Stepping is not possible in MCC charts and LAD/FBD programs whose sources are in libraries.

Stepping is not possible in ST source files.

You can only open MCC charts and LAD/FBD programs with know-how protection if you have the required authorization (e.g. password).

7.1.8.10 Task status function bar

In a combo box, the Task status function bar displays all tasks of the active SIMOTION device, to which a program is assigned.

They are displayed under the following conditions:

1. SIMOTION SCOUT is in online mode.
2. The affected SIMOTION device is active, e.g.
   - In the project navigator, the SIMOTION device or an element in its subtree is selected (such as program source, technology object).
   - In the working area, an open window is active that belongs to an element in the subtree of the SIMOTION device.
3. The SIMOTION device is consistent.

A background color highlights the occurrence of specific events in the affected task, see the following table. The task in question is displayed in the combo box of the function bar according to the event priority.

Table 7-352 Meaning of background colors in the Task status function bar

Background color	Meaning	Priority
Cyan	The affected task waits for a command (Page 4534) at the "Single step" test function (only for SIMOTION MCC programming language).	Highest  Lowest
Red	The affected task is located at a breakpoint (Page 4560).	
Blue	In the affected task, the "Single step" test function (Page 4534) is activated (only for SIMOTION MCC programming language)	
Gray	In the affected task, at least 1 breakpoint (Page 4560) is activated.	
Yellow	In the affected task, the "Monitoring" test function (Page 4532) is activated (only for SIMOTION MCC programming language).	
White	In the affected task, none of the above-mentioned test functions are activated.	

Note

A selection of a task in the combo box is only possible:

- For the following test functions of the SIMOTION MCC programming language:
  - Monitoring (Page 4532)
  - Single step (Page 4534)
  - Trace (Page 4538)
- at activated breakpoints (Page 4560) in the MCC or LAD/FBD programming languages.

7.1.8.11 Project comparison

SIMOTION SCOUT has a **project comparison** function (start this via the **Start object comparison** button) for comparing objects within the same project and/or objects from different projects (online or offline).

Project comparison allows you to establish any differences and, if necessary, run a data transfer to rectify them.

Objects are devices and their sub-objects, programs, technology objects (TOs) or drive objects (DOs), and libraries. Comparing projects is useful if you need to carry out service work on the system.

Further information on project and detail comparisons can be found in the SIMOTION Project Comparison Function Manual.

7.1.9 Appendix

7.1.9.1 Basics of LAD/FBD/Formula for MCC

Ladder logic (LAD) for MCC

The LAD graphical programming language represents the program in the form of a circuit diagram. LAD enables you to track the flow of signals easily.

Note

You can switch between LAD and FBD provided that the programmed functions can be displayed in both languages.

The ladder diagram (LAD) for MCC has a limited set of operations.

The following operations are available in MCC:

- NO contact
- NC contact
- Comparator (CMP)
- Open/close branch

Every logic operation queries the signal status (0 or 1) of an electrical contact. The result is then stored or used to execute another operation.

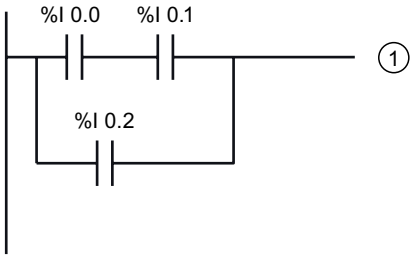
NO contact

This operation can be programmed to scan the signal status of a contact:

- Signal status=0: Contact is open.
- Signal status=1: Contact is closed.

The logic operation can be executed in a series connection or a parallel connection:

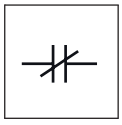
- In a **series connection**, the operation gates the result of its signal state scan according to the AND truth table.
- In a **parallel connection**, the operation gates the result of its signal state scan according to the OR truth table.



① The result of gating the three NO contacts is 1 if:
%I 0.0 is closed AND %I 0.1 is closed
OR
%I 0.2 is closed

Figure 7-185 Example of Normally open contact in a parallel circuit

NC contact

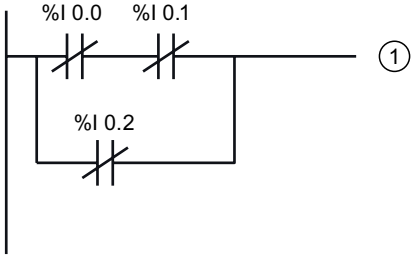


This operation can be programmed to scan the signal status of a contact:

- Signal status=0: Contact is closed.
- Signal status=1: Contact is open.

The logic operation can be executed in a series connection or a parallel connection:

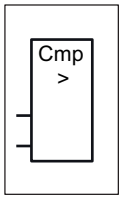
- In a **series connection**, the operation gates the result of its signal state scan according to the AND truth table.
- In a **parallel connection**, the operation gates the result of its signal state scan according to the OR truth table.



① The result of gating the three NC contacts is 1 if:
%I 0.0 is open AND %I 0.1 is open
OR
%I 0.2 is open

Figure 7-186 Example of Normally closed contact in a parallel circuit

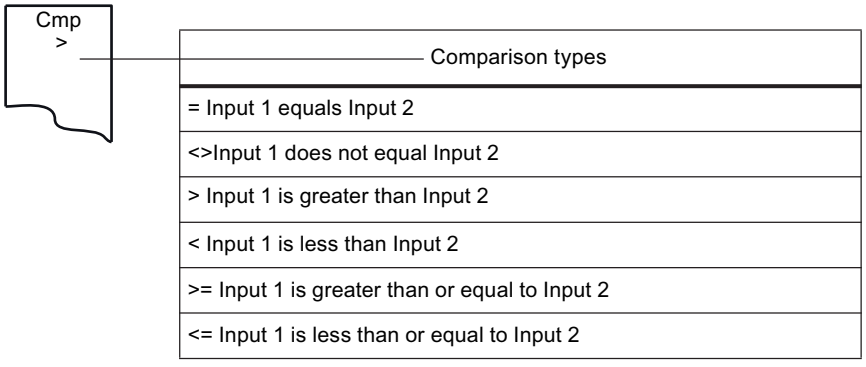
Comparator



This operation performs a comparison operation on integers or floating-point numbers.

Input 1 and Input 2 are compared according to the comparison type (see figure). If the result of the comparison is "true", then the result is "1" (otherwise "0").

There is no negation of the comparison result as this can be achieved by the opposite comparison operation in each case.

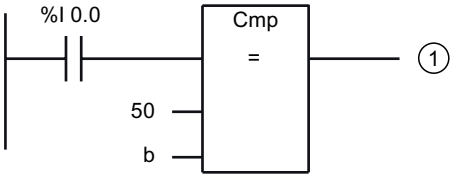


Comparison types
= Input 1 equals Input 2
<>Input 1 does not equal Input 2
> Input 1 is greater than Input 2
< Input 1 is less than Input 2
>= Input 1 is greater than or equal to Input 2
<= Input 1 is less than or equal to Input 2

Figure 7-187 Possible comparison types

You can use one of two different addressing methods:

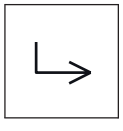
- Direct addressing with constant as operand
- Variable addressing with variable as operand



① The result is 1 if the following conditions are fulfilled:
%I 0.0 is closed AND the constant 50 is equal to variable b

Figure 7-188 Example of direct and variable addressing

Open/close branch



You can open and close parallel branches to fork the current flow. All operands and branches must be interlinked. Each branch must contain at least one operand.

Example of NO contact operations in a parallel circuit

The result is 0 or 1 depending on the position of the contacts (see figure).

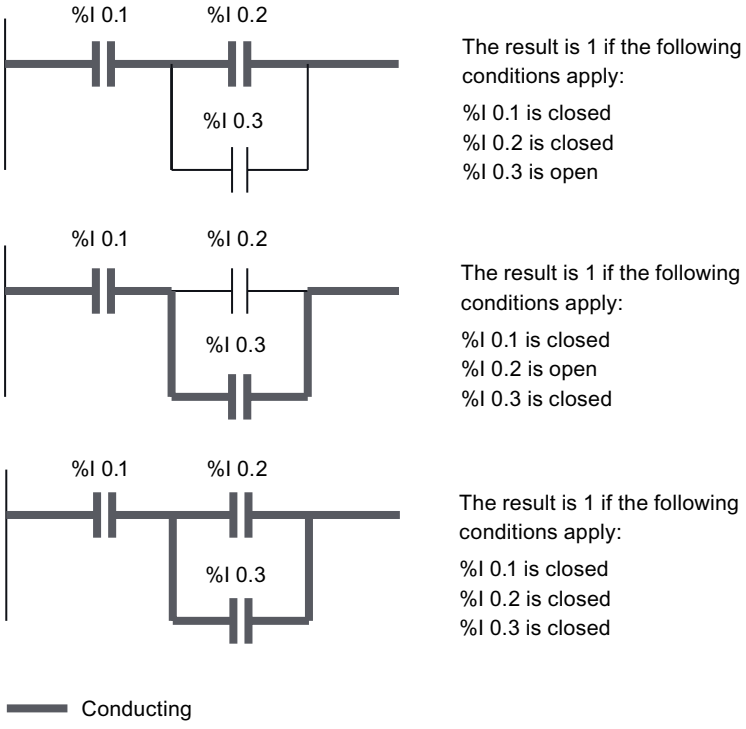


Figure 7-189 Example of NO contact operations in a parallel circuit

Function block diagram (FBD) for MCC

Function block diagram (FBD) is a graphical programming language that represents logic using the graphical logic symbols normally associated with Boolean algebra.

Note

You can switch between LAD and FBD provided that the programmed functions can be displayed in both languages.

The following operations are available in MCC:

- AND operation
- OR operation

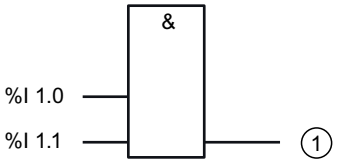
- Inverted input
- Comparator
- AND operation before OR operation
  OR operation before AND operation

Every logic operation queries the signal status (0 or 1) of an electrical contact. The result is then stored or used to execute another operation.

AND operation

The signal statuses of two or more operands are scanned:

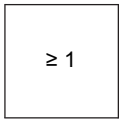
If the signal status of all operands is 1, the condition is fulfilled, otherwise the result of the operation is 0.



① The result is 1 if the following condition is fulfilled:
%I 1.0 = 1 AND %I 1.1 = 1

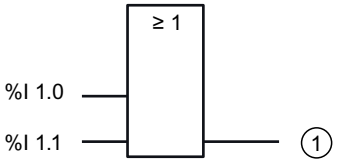
Figure 7-190 Example of an AND operation

OR operation



The signal statuses of two or more operands are scanned:

The condition is fulfilled if one operand has signal status "1", otherwise the result is "0".

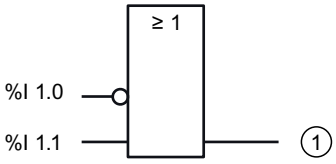


① The result is 1 if the following condition is fulfilled:
%I 1.0 = 1 OR %I 1.1 = 1

Figure 7-191 Example of an OR operation

Inverted input

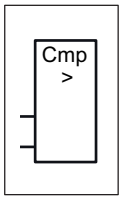
The signal status of the input is inverted by a dot at an operator input.



1 The result is 1 if the following condition is fulfilled:
%I 1.0 = 0 OR %I 1.1 = 1

Figure 7-192 Example of an OR operation with an inverted input

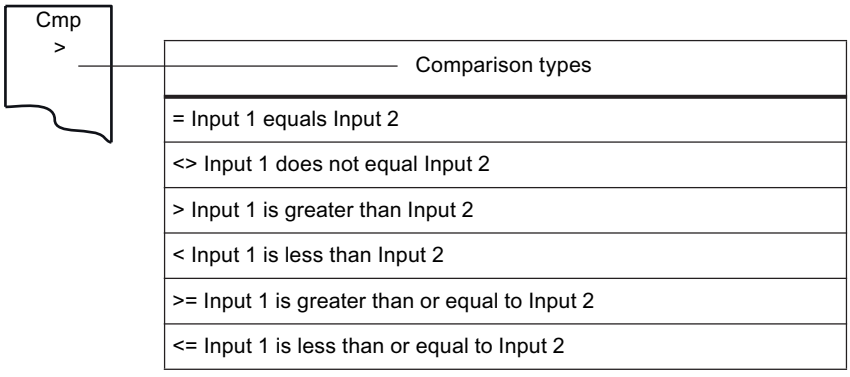
Comparator



This operation performs a comparison operation on integers or floating-point numbers.

Input 1 and Input 2 are compared according to the comparison type (see figure). If the result of the comparison is "true", then the result is "1" (otherwise "0").

There is no negation of the comparison result as this can be achieved by the opposite comparison operation in each case.

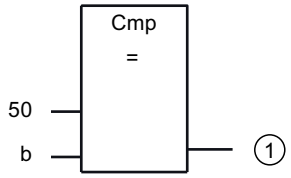


Comparison types
= Input 1 equals Input 2
<> Input 1 does not equal Input 2
> Input 1 is greater than Input 2
< Input 1 is less than Input 2
>= Input 1 is greater than or equal to Input 2
<= Input 1 is less than or equal to Input 2

Figure 7-193 Possible comparison types

You can use one of two different addressing methods:

- Direct addressing with constant as operand
- Variable addressing with variable as operand



① Constant 50 is the actual value at which Input 1 of the box should work. Constant 50 is the direct operand of the box.

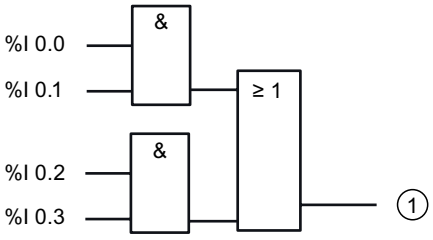
Input 2 is to work with the value of the variable b. Variable b is a direct operand.

Figure 7-194 Example of direct and variable addressing

AND operation before OR operationOR operation before AND operation

With the AND operation before OR operation, it is possible to scan the result of a signal status scan according to the OR truth table.

The result is "1" if at least one AND operation is fulfilled.

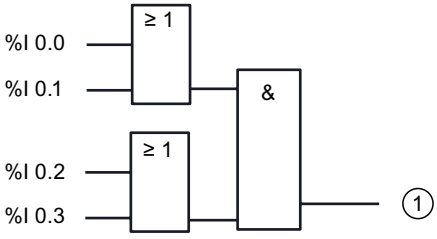


① The result of the operation is 1 if at least one AND operation is fulfilled.

Figure 7-195 Example of an AND operation before OR operation

With the OR before AND operation, it is possible to query the result of a signal state scan according to the AND truth table.

The result is "1" if all OR operations are fulfilled.



① The result of the operation is "1" if both OR operations are fulfilled.

Figure 7-196 Example of an OR operation before AND operation

Formula for MCC

Formula is a text-based, high-level language that essentially complies with IEC61131-3 in terms of language definition. It is suitable among other things for programming formula calculations and complex optimization algorithms.

System functions and operators can be moved from the command library to the programming window using a drag and drop operation.

Closed block comments (* ... *) are permitted, line comments (starting with //) not. Use the command comment on the MCC command (**Enter comment ...** context menu), see also "Display of commands in the MCC chart" (Page 4016).

Note

You can switch from Formula to LAD or FBD and vice versa provided that the programmed functions can be displayed in the other language.

Simple examples

The two examples illustrate an AND operation and an OR operation.

Table 7-353 Example of an AND operation (keyword AND)

Instruction	Description
%I0.0 AND a = 50	The result is 1 if input 0.0 is closed and variable a has a value of 50.

Table 7-354 Example of an AND operation (keyword AND)

Instruction	Description
%I0.0 OR %I0.1	The result is 1 if input 0.0 or input 0.1 is closed.

Querying a system variable

Formula is often used for scanning system variables; refer to the following example:

Table 7-355 Example of an AND operation (keyword AND)

Instruction	Description
Axis_1.positioningstate.homed = YES	The result = 1, if the axis has reached its homing position and is therefore homed.

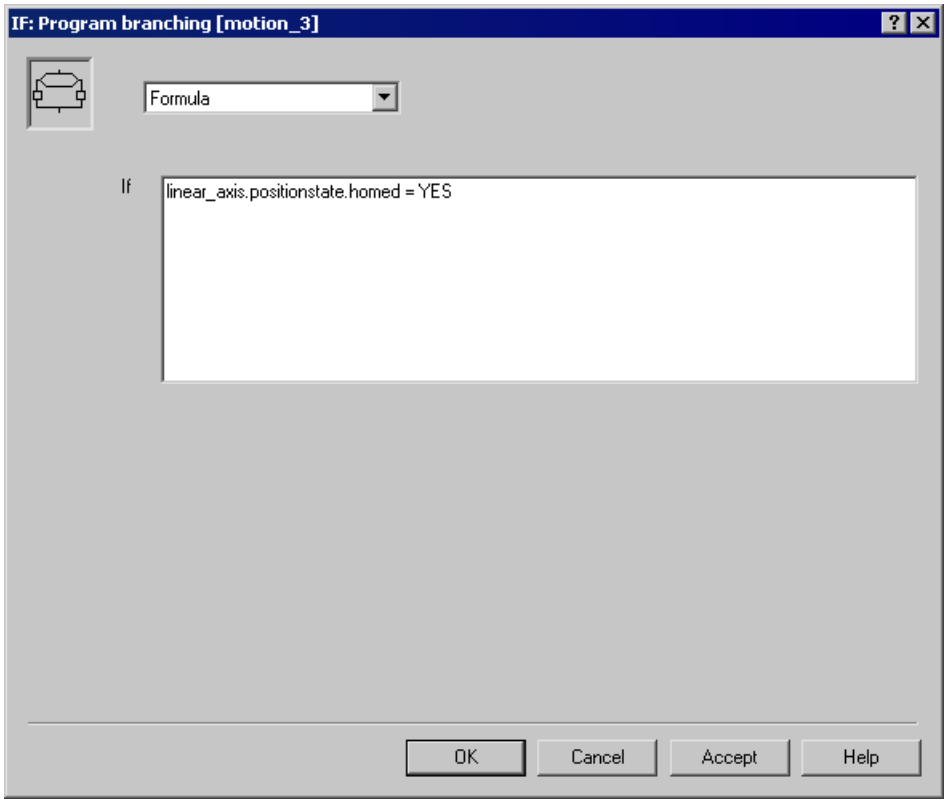


Figure 7-197 Scan whether an axis has been homed

7.1.9.2 Key combinations

The following key combinations are available:

Table 7-356 Shortcuts

Shortcut	Meaning
When MCC unit is open	
Ctrl+F4	Closes the active MCC unit.
Ctrl+B	Accepts and compiles the active MCC unit
Alt+Enter	Displays the properties of the active MCC unit for editing
Ctrl+R	Inserts an MCC chart in the MCC unit
Ctrl+P	Prints the MCC charts contained in the MCC unit
Ctrl+space	Automatic completion (Autocomplete) (Page 3979)
When an MCC chart is open	
Ctrl+F4	Closes the active MCC chart.
Ctrl+F7	Switches the program status (Page 4542) function on and off.
Shift+F7	Switches the observe (Page 4532) function on and off.
Ctrl+F9	Switches the single step (Page 4534) function on and off.
Alt+Enter	Displays the properties of the active MCC chart for editing

Shortcut		Meaning
	Ctrl+space	Automatic completion (Autocomplete) (Page 3979)
	Ctrl+Alt+O	Opens the user-defined FCs/FBs/programs ("program in program") and library FCs/FBs/programs ("program in program") directly following the subprogram call.
	Ctrl+Shift+O	Opens the overview window for the relevant MCC chart.
	↑	Selects the preceding command in the MCC chart
	↓	Selects the next command in the MCC chart.
	←	Selects the command to the left of the currently selected command (parallel branching).
	→	Selects the command to the right of the currently selected command (parallel branching).
	Ctrl+B	Accepts and compiles the MCC unit from the active MCC chart
	Ctrl+K	With a command selected, opens the brief comment box
	Ctrl+P	Prints the active MCC chart
	Ctrl+Z	Closes the brief comment box
	Pos1	Selects the left-hand branch (e.g. in a CASE statement)
	End	Selects the right-hand branch (e.g. in a CASE statement)
	Ctrl+Pos1	Selects the first command in the MCC chart
	Ctrl+End	Selects the last command in the MCC chart
	Pg Up	Moves the visible contents of the working area upwards by a distance of one window
	Pg Dn	Moves the visible contents of the working area downwards by a distance of one window
Edit menu		
	Ctrl+Z	Undoes the last action (except: Save).
	Ctrl+Y	Redoes the last action which was undone.
	Ctrl+X	Cuts a command
	Ctrl+C	Copies a command
	Ctrl+V	Inserts a command
	Del	Deletes selected commands in the MCC chart.
	Alt+Enter	Displays the properties of the active/selected object for editing.
	Enter	Opens the selected object.
	Ctrl+A	Highlights all the objects in the current window.
	Ctrl+B	Saves and compiles the active/selected object.
	Ctrl+F	Local search
	Ctrl+H	Local find and replace
	F3	Find next (for local search)
	Ctrl+Shift+F	Find in the project
	Ctrl+Shift+G	Find and replace in a project
	Ctrl+J	Next position (for search in the project)
Window menu		
	Ctrl+Shift+F5	Rearranges all windows opened in this application in horizontal tiled format.
	Ctrl+Shift+F3	Rearranges all windows opened in this application in vertical tiled format.
	Alt+F4	Closes all windows and ends the application.
View menu		

Shortcut	Meaning
Ctrl+F11	Maximizes the working area
Ctrl+F12	Maximizes the detail view
Ctrl+Num+	Enlarges the contents of the working area.
Ctrl+Num-	Reduces the contents of the working area.
Ctrl+Num /	Displays working area in its original size (100%).
F5	Updates the view.
Debug menu	
F12	Activate or deactivate a set breakpoint.
Ctrl+F8	Continue program execution at the activated breakpoint.
Ctrl+F10	Next step.
Ctrl+Shift+F10	Step through subprogram.
LAD and FBD: A number of MCC commands provide a limited command range for the LAD and FBD graphic programming languages (seeLAD/FBD/Formula (Page 4152)). The following shortcuts apply to both programming languages LAD and FBD.	
Cursor keys	With a selected operator: Navigation between the individual operators When an edit field is open: Navigates between individual operands
Del	Deletes an operator
Tab / Shift+Tab	Jumps forward to next button / input field / jumps back to previous button / input field
Pg Up	Reduces (zooms) display
Pg Dn	Enlarges (zooms) display
Pos1	Zooms to 100%
End	Zooms to total view
Return	Opens the edit field of the current operand or confirms the entry made in the edit field
Esc	Aborts the entry while edit field is open
Alt+I	Inserts a new variable (only active with variable assignment for the MCC command)
Alt+D	Deletes a variable (only active with variable assignment for the MCC command)
Within LAD The following shortcuts only apply to the LAD programming language.	
Alt+C	Inserts an NO contact
Alt+N	Inserts an NC contact
Alt+V	Inserts a comparator
Alt+P	Opens a branch
Alt+L	Closes a branch
Within FBD: The following shortcuts only apply to the FBD programming language.	
Alt+A	Inserts an AND
Alt+O	Inserts an OR
Alt+B	Adds an input

Shortcut		Meaning
	Alt+N	Negates an input
	Alt+V	Inserts a comparator

7.2 SIMOTION ST Structured Text

Preface

Scope

This document is part of the **SIMOTION Programming** documentation package.

This document applies to SIMOTION SCOUT, the engineering system of the SIMOTION product family in product version V5.4 in conjunction with:

- A SIMOTION device with the following versions of a SIMOTION Kernel:
  - V5.4
  - V5.3
  - V5.2
  - V5.1
  - V4.5
  - V4.4
  - V4.3
  - V4.2
  - V4.1 [1]
  - V4.0 [1]
  - V3.2 [1]

  [1] V4.5 is the last product version of SIMOTION SCOUT that will support these versions of the SIMOTION Kernel.
- The relevant version of the following SIMOTION Technology Packages, depending on the kernel:
  - Cam
  - Path (Kernel as of V4.1)
  - Cam_ext
  - TControl

This document describes the syntax and implementation of the SIMOTION ST Structured Text programming language for this version of SIMOTION SCOUT. It also includes information on the following topics:

- ST Editor and Compiler with program example
- Data storage and data management on SIMOTION devices
- Options for diagnosis and troubleshooting

The scope of the SIMOTION ST programming language may contain new syntax elements compared to earlier versions. These have only been tested using the current version of the SIMOTION kernel and are released only for this kernel version or higher versions.

Conversion of existing projects to the current SIMOTION SCOUT version

It is possible to upgrade existing projects to the current version of SIMOTION SCOUT and the SIMOTION ST programming language. In some cases, recompilation using the current version of the compiler can change the version identifiers in the data storage areas of the programs, thus resulting in deletion and initialization of all retentive and non-retentive data on the SIMOTION device. In exceptional cases, minor changes to the program source files may also be required.

If new syntax elements of the SIMOTION ST programming language are used on a SIMOTION device with an older version of the SIMOTION Kernel, the compiler outputs warning 16700. If these syntax elements are used anyway, the project can be stored in the old project format, but can no longer be converted using the compiler of an older version of SIMOTION SCOUT.

Information in this manual

The following is a list of chapters included in this manual along with a description of the information presented in each chapter.

- **Grouped safety messages** (Chapter 1)
- **Introduction** (Chapter 2)
- **Getting Started with ST** (Chapter 3)
  Requirements for creating programs and a sample program
- **ST Basics** (Chapter 4)
  Elements of the ST programming language, variable and data type declarations, statements
- **Functions, Function Blocks and Programs** (Chapter 5)
  Programming and call of the program organization units (POU)
- **Object-Oriented Programming - OOP (as of Kernel V4.5)** (Chapter 6)
  Programming and calling classes and methods
- **Integration of ST into SIMOTION** (Chapter 7)
  Behavior of variables, access to inputs and outputs, libraries, preprocessor
- **Error Sources and Program Test** (Chapter 8)
  Information on error sources, efficient programming, and program testing

- **Appendices**
  - **Formal Language Description** (Appendix A.1)
  - **Compiler Error Messages and Remedies** (Appendix A.2)
  - **Template for Example Unit** (Appendix A.3)
- **Index**

If you want to get started immediately, begin by working through Chapter 2.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

Click the following link to find information on the following topics:

- Documentation overview
- Additional links to download documents
- Using documentation online (find and search manuals/information)

https://support.industry.siemens.com/cs/ww/en/view/109479653

My Documentation Manager

Click the following link for information on how to compile documentation individually on the basis of Siemens content and how to adapt it for the purpose of your own machine documentation:

https://support.industry.siemens.com/My/ww/en/documentation

Training

Click the following link for information on SITRAIN - Siemens training courses for automation products, systems and solutions:

http://www.siemens.com/sitrain

FAQs

Frequently Asked Questions can be found in SIMOTION Utilities & Applications, which are included in the scope of delivery of SIMOTION SCOUT, and in the Service&Support pages in **Product Support**:

https://support.industry.siemens.com/cs/de/en/ps/14505/faq

Technical support

Country-specific telephone numbers for technical support are provided on the Internet under **Contact**:

https://support.industry.siemens.com/cs/ww/en/sc/2090

7.2.1 Fundamental safety instructions

7.2.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

7.2.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

7.2.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

7.2.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

7.2.2 Introduction

In addition to conventional open and closed-loop control tasks, today's automation systems are increasingly required to handle data management functions and complex mathematical calculations. ST (Structured Text) is specially designed for these tasks. Standardized to IEC 61131-3 (German standard DIN EN-61131-3), this programming language makes your job as a programmer easier.

7.2.2.1 High-level programming language

ST is a high-level, PASCAL-based programming language. This language is based on the IEC 61131-3 standard, which standardizes programming languages for programmable controllers (PLC). ST is based on the *Structured Text* part of this standard.

Using a high-level language like ST to program control systems offers the user a wide range of possibilities, for example:

- Data management
- Process optimization
- Mathematical/statistical calculations

7.2.2.2 Programming language with technology commands

In addition to IEC 61131-3 compliance, the SIMOTION ST programming language also contains commands for SIMOTION devices, motion control and technology.

Technology objects represent a technological functionality, e.g. positioning an axis or assigning parameters for an output cam. Technology commands are language commands provided by the technology objects. Such commands may be used, for example, to activate camming or to control motion sequences, for example, in order to position an axis.

7.2.2.3 Execution levels

The SIMOTION execution system provides different execution levels (cyclic, synchronous, time-controlled, alarm-controlled and sequential) for optimal support of the various tasks involved in creating user programs.

SIMOTION SCOUT is the engineering system of the SIMOTION product family. ST is the high-level language for creating user programs; in ST, you can develop user programs for the various execution levels.

The execution of user programs can be time-driven if you want them to run synchronously with the system clock or a defined time cycle. They can be interrupt-driven if they are to start and run once in response to a particular event. Alternatively, they can run sequentially or cyclically at the round robin execution level.

7.2.2.4 ST editor with tools for writing and testing programs

An easy-to-use text editor is provided for creating programs.

The ST compiler converts the edited program into executable code and indicates any syntax errors, specifying the program line and the cause of the error.

SIMOTION SCOUT provides test functions for testing ST programs. You can test and visualize your programs online.

7.2.3 Getting Started with ST

This chapter uses a simple example to describe how to write a program, compile it into executable code, run it, and test it.

7.2.3.1 Integration of ST in SCOUT

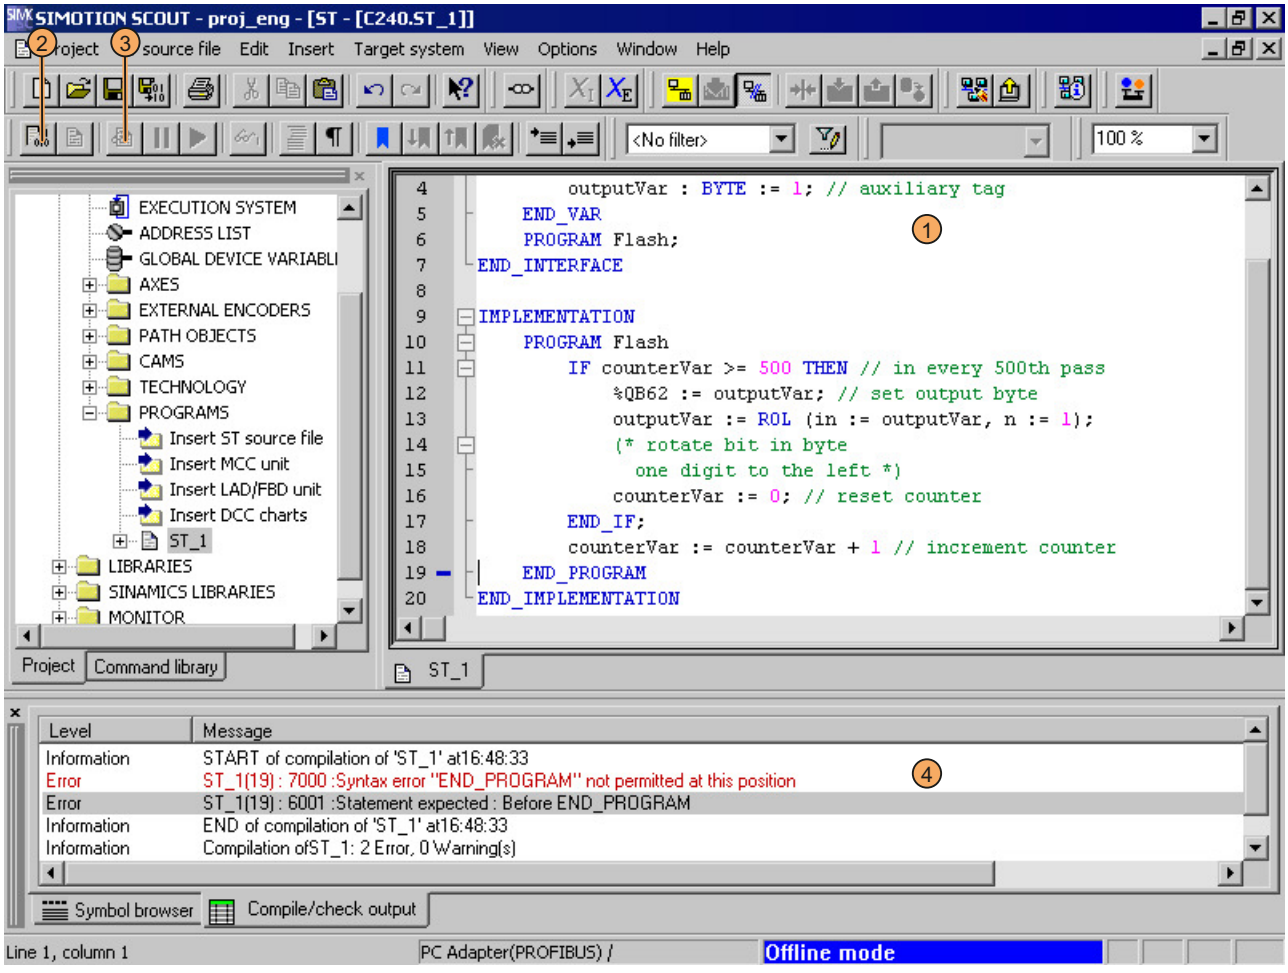
The program environment for ST comprises the following components:

- An **editor** for creating programs, consisting of functions (FC), function blocks (FB), and user-defined data types (UDT), etc.
- A **compiler** for compiling the previously edited ST program into executable machine code

- several diagnostics functions (e.g. **program status**) for assisting your search for logical program errors in the running program;
- a **detail view**, in which, for example, error messages of the compiler are displayed. An important tab of the detail view is the **Symbol browser**, where you can monitor and change variables.

The individual components are easy to use. They are integrated directly in the SIMOTION SCOUT workbench.

For more information about the operation of the workbench and its tools, refer to the SIMOTION SCOUT Configuration Manual.

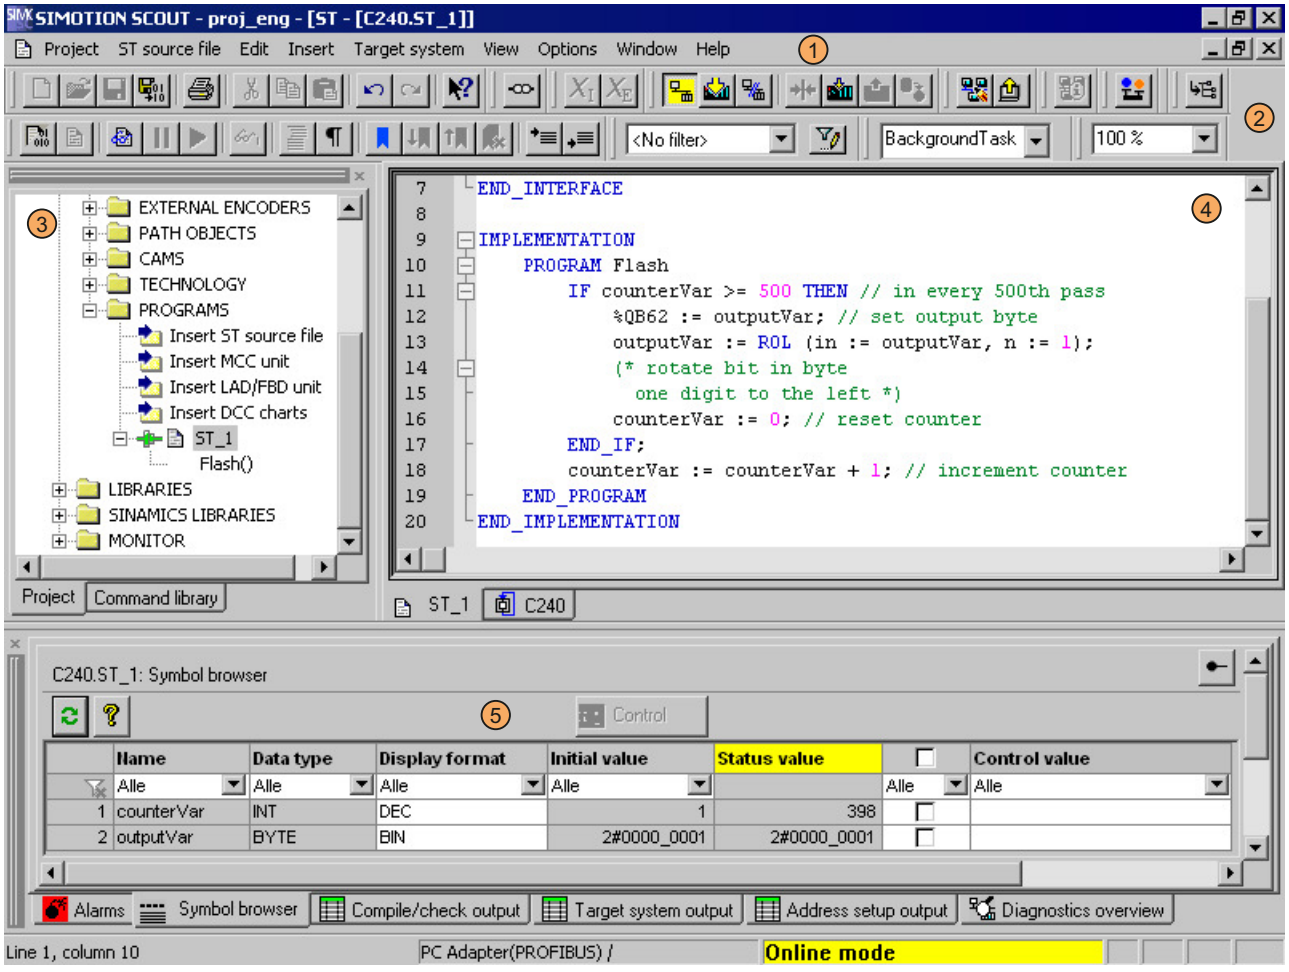


① Editor
② Compiler
③ Program status
④ Detail view (Compile/check output tab)

Figure 7-198 Development environment of ST

Getting to know the elements of the workbench

The workbench represents the framework for SIMOTION SCOUT. Its tools allow you to perform all the steps necessary to configure, optimize and program a machine for your application.



1) Menu bar
2) Toolbars
3) Project navigator
4) Working area
5) Detail view (Symbol browser tab)

Figure 7-199 Workbench elements

The workbench contains the following elements:

- Menus
  Menus contain menu commands with which you can control the workbench and call tools, etc.
- Toolbars
  You can execute many of the available menu commands by clicking the corresponding button in one of the toolbars.

- Project navigator
  The project navigator displays the entire project and its elements (e.g. CPU, axes, programs, cams) in a tree structure.
- Working area
  This window allows you to perform specific tasks either independently (by programming) or using wizards (by configuring).
- Detail view
  The detail view displays additional information about the elements selected in the project navigator, e.g. all global variables for a program or the **Compile/Test Output** window.

7.2.3.2 Requirements for program creation

This section describes the general conditions you will need to meet before writing a program. You will find detailed information in the SIMOTION SCOUT Configuring Manual and the SIMOTION Motion Control function descriptions.

Add or open a project

The project is the highest level in the data management hierarchy. SIMOTION SCOUT saves all data which belongs, for example, to a production machine, in the project directory.

This means that the project therefore brackets together all SIMOTION devices, drives, etc. belonging to one machine.

Once you have created a project, you can:

- Configure hardware
- Insert and configure technology objects

Configuring hardware

Within the project, the hardware used must be made known to the system, including:

- SIMOTION device
- Centralized I/O (with I/O addresses)
- Distributed I/O (with I/O addresses)

A SIMOTION device must be configured before you can insert and edit ST source files.

Insert and configure technology objects

The functionality of axes, output cams, etc. is represented in SIMOTION by technology objects (TOs).

You cannot program technology objects using system functions and access their system variables until you have inserted and configured them.

7.2.3.3 Working with the ST editor and the compiler

In this section, you will learn how to use the ST editor and the compiler.

Insert ST source file

ST source files are assigned to the SIMOTION device on which the programs contained in the source file will subsequently be run (e.g. SIMOTION C240).

They are stored in the project navigator under the SIMOTION device in the PROGRAMS folder.

Note

MCC units, LAD/FBD units and DCC charts are also stored in the **PROGRAMS** folder under the SIMOTION device.

For a description of the SIMOTION MCC (Motion Control Chart) programming language, refer to the SIMOTION MCC Programming and Operating Manual.

For a description of the SIMOTION LAD (Ladder Diagram) and SIMOTION FBD (Function Block Diagram) programming languages, refer to the SIMOTION LAD/FBD Programming and Operating Manual.

Procedure

1. Open the appropriate SIMOTION device in the project navigator.
2. Select the **PROGRAMS** folder.
3. Select the menu **Insert > Program > ST source file**.
4. Enter the name of the ST source file.
   The names of program sources must comply with the rules for identifiers (Page 4656): They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper- and lower-case letters.
   The permissible length of the name depends on the SIMOTION Kernel version:
   - As of version V4.1 of the SIMOTION Kernel: maximum 128 characters.
   - Up to version V4.0 of the SIMOTION Kernel: maximum 8 characters.

   Names must be unique within the SIMOTION device.
   Protected or reserved identifiers (Page 4657) are not permitted.
   Existing program sources (e.g. ST source files, MCC units) are displayed.
5. You can also enter an author, version, and a comment.
6. Activate the **Open editor automatically** checkbox.
7. If necessary, select further tabs to make local settings (only valid for this ST source file):
   - **Compiler** tab: Local settings of the compiler (Page 4626) for code generation and message display.
   - **Additional settings** tab: Definitions for preprocessor (Page 4635)
8. Confirm with **OK**.

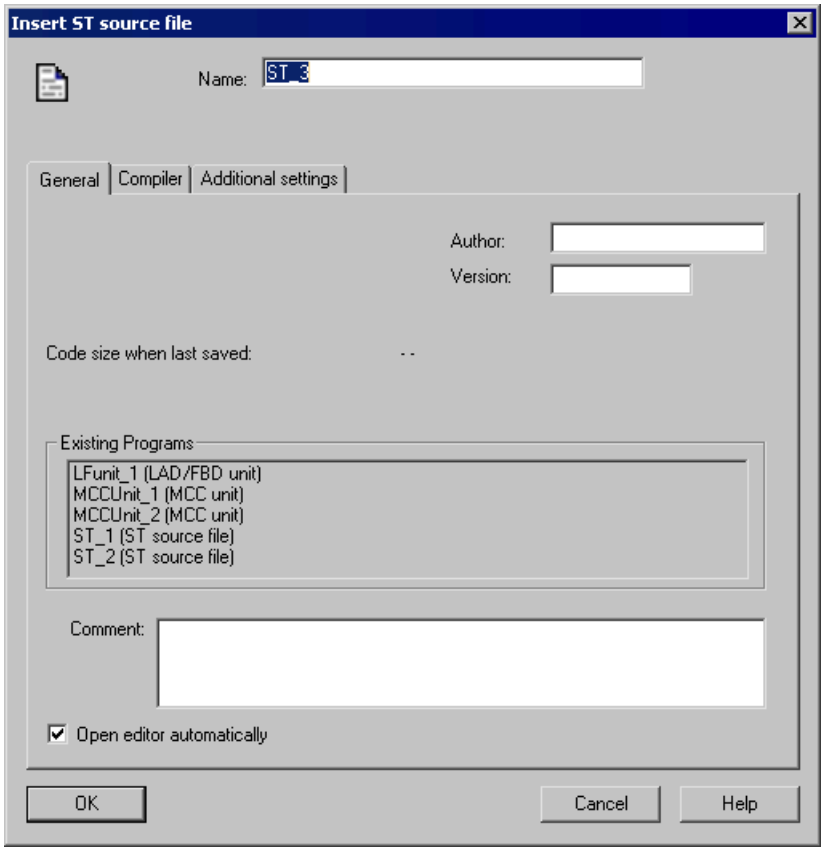


Figure 7-200 Insert ST source file

Note

When you click **OK**, the ST source file will only be transferred to the project. The data, together with the project, is only saved to the data carrier if you select, for example, **Project > Save**, **Project > Save and compile changes**, or **Project > Save and recompile all**.

Opening an existing ST source file

Procedure

How to open an ST source file:

1. Open the subtree of the appropriate SIMOTION device in the project navigator.
2. Open the **PROGRAMS** folder.
3. Select the desired ST source file.

4. Select the **Edit > Open object** menu command.
5. Only for ST source files with know-how protection:
   If the ST source file is not already open and the log-in details assigned to it have not yet been used to log in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this source file is canceled temporarily (until the file is closed).
   - If required, activate the "Use login as a standard login" checkbox.
     You will be logged in with this login and can now open additional units to which the same login is assigned without having to re-enter the password.

This ST source file is opened with the saved folding information (Page 4596) and bookmarks (Page 4607). Multiple units can be opened.

Note

You can also double-click the required ST source file to open it.

Changing the properties of an ST source file

Procedure

1. Under the SIMOTION device, open the **PROGRAMS** folder.
2. Select the desired ST source file.
3. Select the **Edit > Object Properties** menu command.
4. If necessary, select further tabs to make local settings (only valid for this ST source file):
   - **General** tab: General details for the ST source file, e.g. code size for the last compilation, time stamp of the last change, storage location of the project (see figure).
   - **Compiler** tab: Local settings of the compiler (Page 4626) for code generation and message display.
   - **Additional settings** tab: Definitions for the preprocessor (Page 4635) and display of compiler options (Page 4633) as specified in the current settings of the compiler. You also have the possibility of setting the ST source as read-only (Read-Only-mode).
   - **Compilation** tab: Display of the compiler options (Page 4633) for the last compilation of the ST source.
   - **Object address** tab: Set the internal object address of the ST source. The object addresses of the other program sources are displayed.

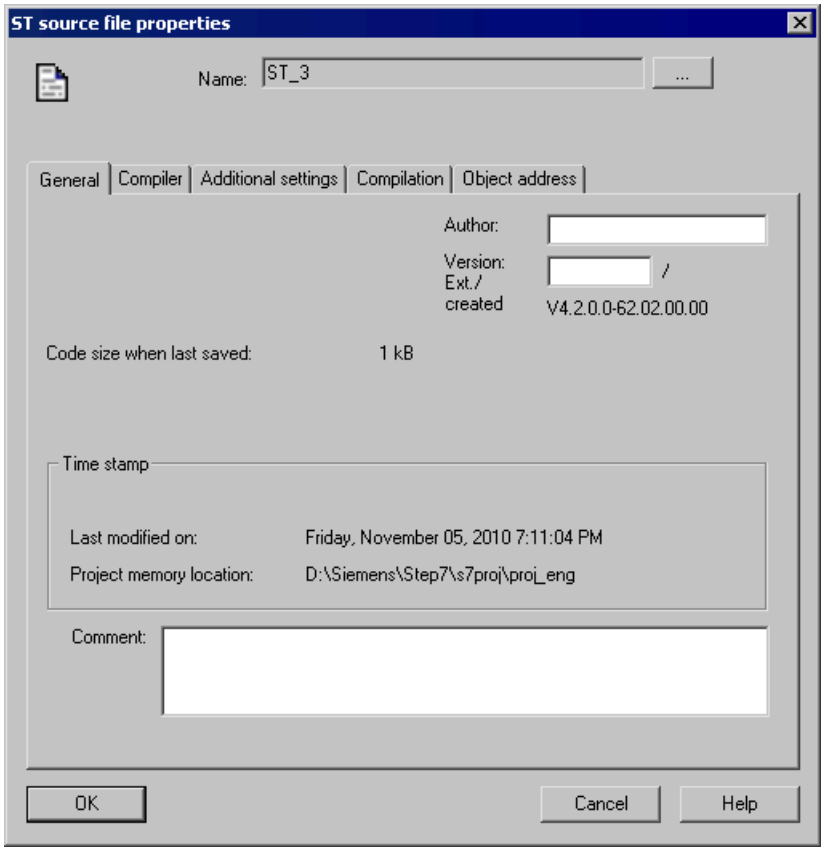

Figure 7-201 Properties of an ST source file

Changing the name of an ST source file

You can also change the names of the ST source file here. To do this, click the [...] button.

Names for program source files must satisfy the rules for identifiers: They are made up of letters (A ... Z, a ... z), numbers (0 ... 9), or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters.

The permissible length of the name depends on the SIMOTION Kernel version:

- As of Version V4.1 of the SIMOTION Kernel: maximum 128 characters.
- Up to Version V4.0 of the SIMOTION Kernel: maximum 8 characters.

Names must be unique within the SIMOTION device.

Protected or reserved identifiers (Page 4657) are not allowed.

Existing program sources (e.g. ST source files, MCC units) are displayed.

Note

With versions of the SIMOTION Kernel up to V4.0, a violation of the permissible length of the program source file name may not be detected until a consistency check or a download of the program source file is performed!

Read-only ST sources

You can set ST sources as read-only to prevent unintentional code changes during commissioning. To do this, navigate to "Additional settings" and set the option "Read-Only-Mode". Functions that would change the ST source are disabled in read-only mode. For this reason, the corresponding context menu entries and icons are inactive.

The following functions can still be used when an ST source is read-only:

- Status program
- Breakpoints
- Displaying the variable in the tooltip
- Pasting/removing bookmarks, jumping to bookmarks
- Selecting variables
- Searching (Ctrl +F)
- Compiling

Working with the ST editor

The ST editor makes it easier for you to work with the ST source file, variables and technology objects through the following operator controls:

- Syntax coloring
- Drag and drop
- Menu commands and shortcuts

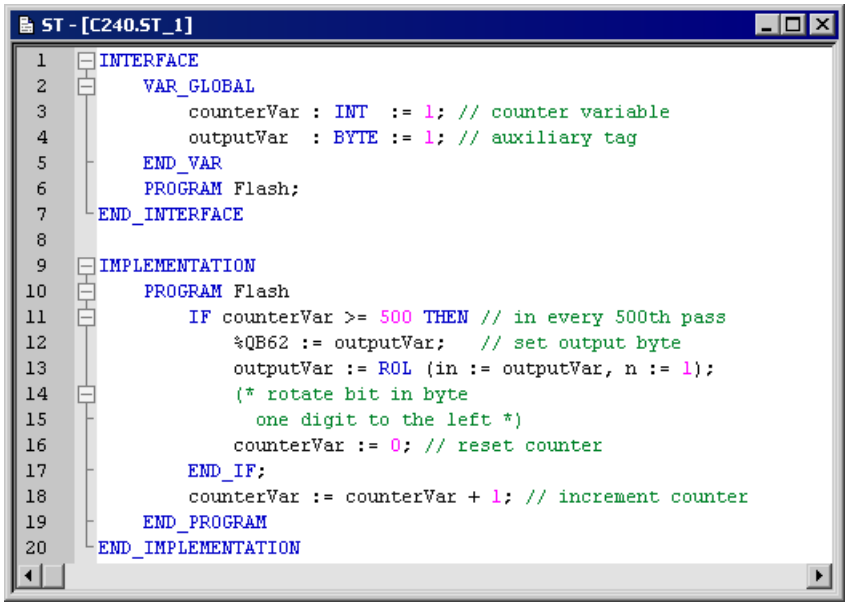

Figure 7-202 Opened ST source file in the ST editor

Syntax coloring

The ST editor represents language elements in different colors:

- Blue: Keywords and compiler built-in functions
- Magenta: Numbers, values
- Green: Comments
- Black: Technology objects, user code, variables

Drag&drop

Drag&drop

A drag-and-drop operation (dragging while keeping the left mouse button pressed) enables you to:

- Move selected text areas within an ST source file or to another opened ST source file.
- Copy names of variables from the symbol browser to the ST source file.
- Copy names (e.g. of technology objects, functions or function blocks) from the project navigator to the ST source file.
- Copy system functions from the command library to the ST source file.

To copy names of variables from the symbol browser to the ST source file:

1. Select the entire line of the desired variable in the symbol browser. To do this, click the line number at the start of the line.
2. Press the left mouse button and drag the line number to the desired position in the ST source file.
   The name of the selected variable is inserted in the ST source file.

To copy the name of an element (e.g. a technology object, a function or a function block) from the project navigator to the ST source file:

1. Select the **Project** tab in the project navigator.
2. Select the element in the project navigator.
3. Press the left mouse button and drag the element to the desired position in the ST source file.
   The name of the selected element is inserted in the ST source file.

To copy a system function from the command library to the ST source file:

1. Select the **Command Library** tab in the project navigator.
2. Select the system function in the command library.
3. Press the left mouse button and drag the system function to the desired position in the ST source file.
   The system function is inserted in the ST source file with its parameters.

Settings of the ST editor

Procedure:

1. Select the menu **Options > Settings**.
2. Select the **ST editor / scripting** tab.
3. Enter the settings.
4. Click **OK** or **Accept** to confirm.

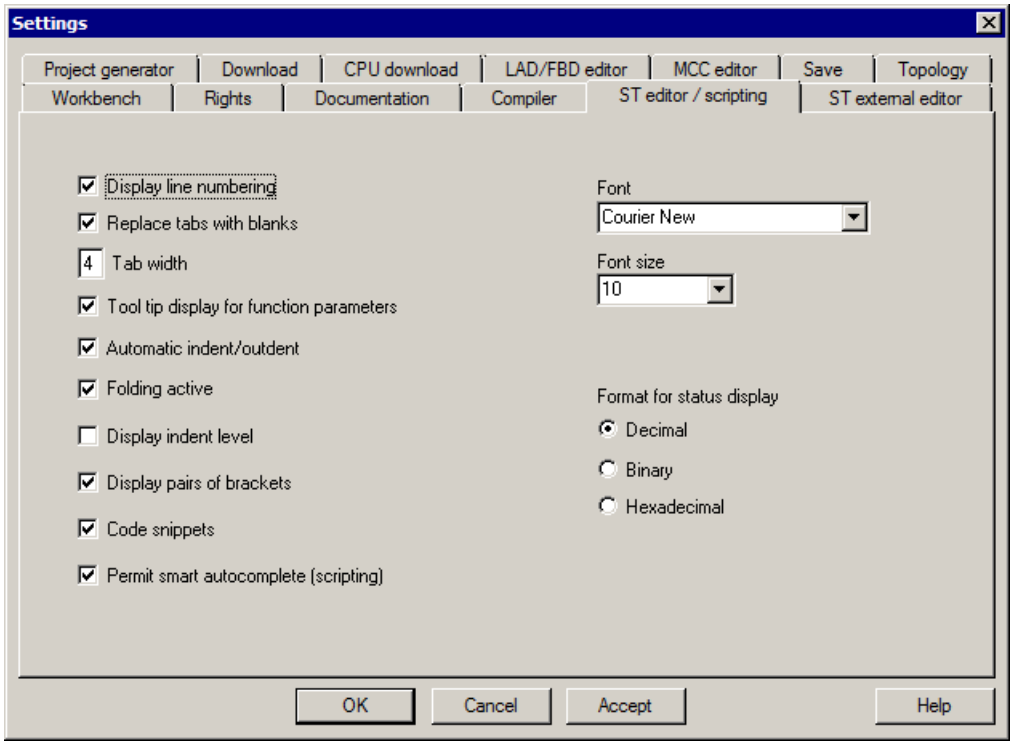

Figure 7-203 ST editor / scripting settings

The settings also apply to the script editor.

The table below contains a description of the individual parameters.

Table 7-357 ST editor / scripting parameter settings

Parameter	Description
Display line numbering	If active, the line numbers are displayed. See: Other ST editor tools (Page 4613).
Replace tabs with blanks	You select here how text indentation is performed (for the automatic indentation or by pressing the Tab key): • If active: By adding the appropriate number of space characters ($20). • If inactive: By adding the tab character ($09). See: Indentations and tabs (Page 4594).

Parameter	Description
Tab width	Number of characters skipped by a tab. See: Indentations and tabs (Page 4594).
Tooltip display for function parameters	When active, the parameters are displayed as tooltips for the functions.
Automatic indent/outdent	If active, for the text input, source file sections and blocks are indented automatically by the set tab width. See: Indentations and tabs (Page 4594).
Folding active	If active, the column with the folding information is displayed at the left-hand side next to the edit area. You can then hide blocks in an ST source file so that only the first line of the block remains visible. See: Folding (showing and hiding blocks) (Page 4596).
Display indentation level	If active, you can optically highlight the indent and outdent for blocks using vertical help lines (in accordance with the set tab size). See: Indentations and tabs (Page 4594).
Display bracket pairs	If active, the associated bracket of the pair that belongs to the bracket where the cursor is located will be found and optically highlighted. See: Other ST editor tools (Page 4613).
Code snippets	If active, after input of certain keywords (such as IF, WHILE, VAR), a window opens to display a code snippet for the associated keyword (e.g. IF (*condition*) ... END_IF). This code snippet can be transferred to the ST source file. See: Code snippets (Page 4611).
Permit Smart-autocomplete (scripting) [1]	If active, automatic completion of terms is permitted for the scripting editor.
Font	Font for the display of the text in the ST editor. All non-proportionally spaced fonts installed on the PC are available for selection.
Font size	Font size (in pt) for the display of the text in the ST editor. See: Change the font size in the ST editor (Page 4602).
Format for status display [2]	Format in which the variable values with bit data type are displayed for the program status or the variable status (for ST editor only). See: Properties of the program status (Page 4949), variable status (Page 4946)

1 Only for the scripting editor

2 Only for ST editor

Indentations and tabs

Specify tab width

The standard tab width for all ST sources is specified in the settings of the ST editor (Page 4593).

This setting is used for all ST source files opened subsequently.

Indent using tabs or spaces

You can select in the settings of the ST editor (Page 4593) how the text will be indented (e.g. with the automatic indent and outdent when the Tab key is pressed):

- By adding the appropriate number of space characters ($20).
- By adding the tab character ($09).

This setting is used for all ST source files opened subsequently.

Automatically indent and outdent blocks

The ST editor recognizes blocks introduced with a keyword and terminated with another keyword, e.g.:

- INTERFACE / END_INTERFACE
- IMPLEMENTATION / END_IMPLEMENTATION
- Declaration blocks (e.g. TYPE / END_TYPE, VAR / END_VAR)
- Program organization units (e.g. PROGRAM / END_PROGRAM)
- Control statements (e.g. IF / END_IF, FOR / END_FOR)

During the text input, the ST editor can automatically indent text within blocks by the tab size. The end line of the block will be outdented automatically.

This function is activated in the settings of the ST editor (Page 4593).

Note

This setting affects only the behavior during the text input. It does not have any effect on existing text in the ST sources.

Format current selection

You can use this function to force the blocks (see above) in an existing text to be indented by the tab size in accordance with their hierarchy. The number of the leading spaces or tabs will be changed:

- As specified by the current tab size of the ST source file.
- As specified by the current setting for the type of the indent (with tabs or spaces).

Follow these steps:

1. Select the text area in the ST editor that you want to format (see Select text (Page 4603)).
2. Select the **View > Format current selection** context menu.

Note

Leading tabs or spaces will be replaced in a line only when the formatting changes their number.

Indent or outdent selected area

You can use this function to indent or outdent selected sections of text by one tab width.

Follow these steps:

1. Select the text area that you want to indent or outdent in the ST editor (see Selecting text (Page 4603)).
   The selected text area must cover multiple lines.
2. Select the **Indent selected area** or **Undo selected area** context menu.

Indent help (Display indent level)

You can optically highlight the indent and outdent for blocks using vertical help lines (in accordance with the set tab size).

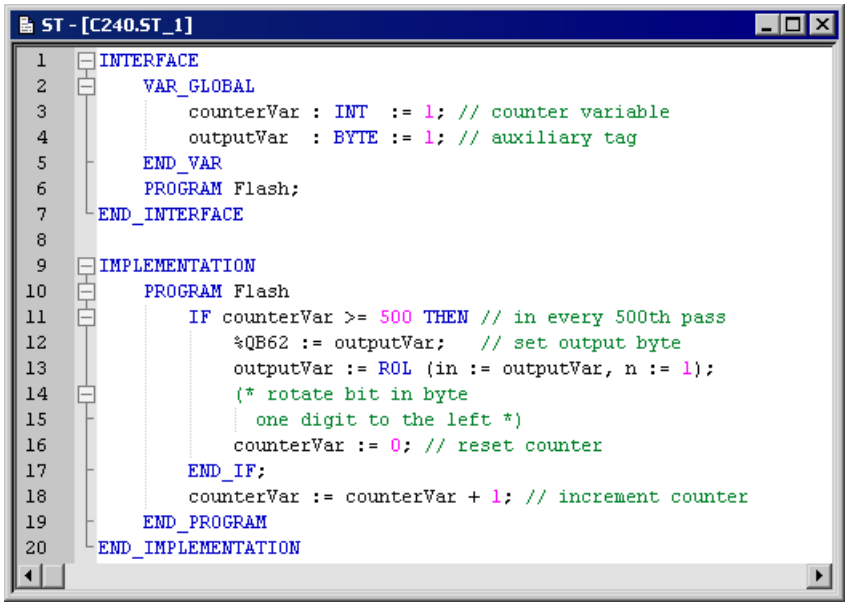

Figure 7-204 ST source with visible indent aid

You can activate or deactivate this function:

- For the active ST source
  - Select the **View > Indent help** context menu.

  This setting is not saved when the ST source file is closed.
- For all open ST sources:
  - Activate or deactivate the **Display indentation level** checkbox in the ST editor settings (Page 4593).

  This setting is also used for all ST source files opened subsequently.

Folds (show and hide blocks)

You can hide blocks in an ST source file so that only the first line of the block remains visible. This increases legibility when editing or reading a longer ST source file.

A block is introduced with a keyword and terminated with another keyword, e.g.:

- INTERFACE / END_INTERFACE
- IMPLEMENTATION / END_IMPLEMENTATION
- Declaration blocks (e.g. TYPE / END_TYPE, VAR / END_VAR)
- Program organization units (e.g. PROGRAM / END_PROGRAM)
- Control statements (e.g. IF / END_IF, FOR / END_FOR)
- Block comment (* / *)

Folding must be activated (see below) in order to show and hide blocks. Once this function has been activated, the column containing the folding information (to the left of the edit area) is displayed.

How to recognize that a block is displayed with folding activated:

- The ⊟ (minus) character appears next to the first line of the block.

How to recognize that a block is hidden:

- The ⊞ (plus) character appears next to the first visible line of the block.
- A hyphen is displayed below this line. This hyphen is visible even if the column containing the folding information is hidden.

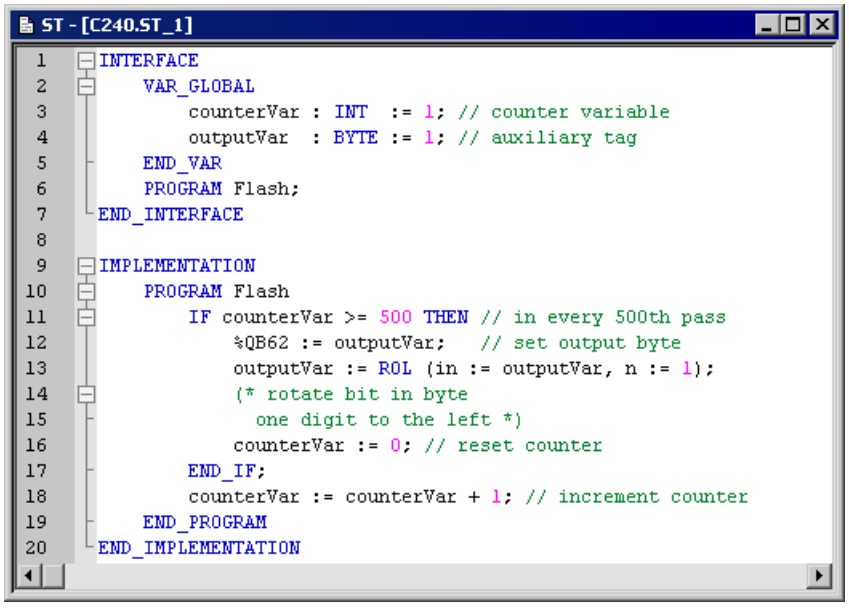

Figure 7-205 ST source file for which all blocks are shown

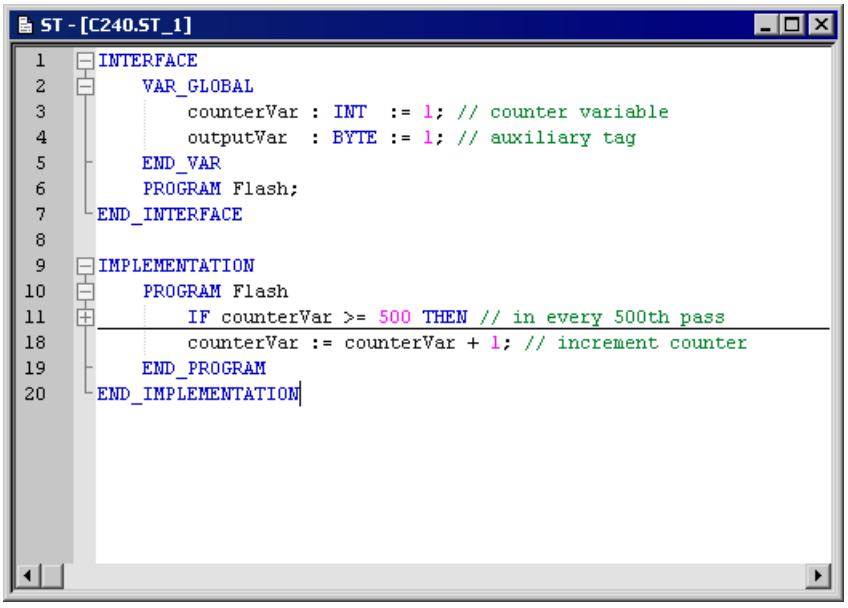

Figure 7-206 ST source file with hidden IF block (including block comment)

Activating or deactivating folding

Folding must be activated in order to be able to show and hide blocks. Once this function has been activated, the column containing the folding information (to the left of the edit area) is displayed.

How to activate or deactivate folding:

- For the active ST source file:
  - Select the **View > Folding** context menu.

  This setting is not saved when the ST source file is closed.
- For all open ST sources:
  - Activate or deactivate the **Folding active** checkbox in the settings of the ST editor (Page 4593).

  This setting is also used for all ST source files opened subsequently.

Showing and hiding blocks

You can only show or hide blocks if folding has been activated for the source file in question (see above). Once this function has been activated, the column containing the folding information is displayed.

How to show or hide blocks:

- Hide an individual block (options):
  - Click the ⊟ (minus) character in the column containing the folding information.
  - Position the cursor on the corresponding line of the block and press the **CTRL+ALT+T** shortcut.

  Only the first line of the block remains visible. All subsequent lines of the block (including lines of subordinate blocks) will be hidden.
  The show/hide status of the subordinate blocks is saved. This is reinstated when individual blocks are shown.
- Show an individual block (options):
  - Click the ⊞ (plus) character in the column containing the folding information.
  - Position the cursor on the visible line of the block and press the **CTRL+ALT+T** shortcut.

  All subsequent lines of the block will be shown. Subordinate blocks are shown as follows: If the show/hide status has been saved (when hiding individual blocks, for example), this will be reinstated.
- Hide all blocks:
  - Press the **CTRL+ALT+C** shortcut.

  All the blocks of the ST source file (including all the subordinate blocks) will be hidden. In each case, only the first line of the 1st-level blocks remain visible (usually INTERFACE and IMPLEMENTATION).
- Show all blocks:
  - Press the **CTRL+ALT+D** shortcut.

  All the blocks of the ST source file (including all the subordinate blocks) will be shown. All the lines of the ST source file will be visible.
- Hide subordinate blocks:
  - Position the cursor on the corresponding line of the block and press the **CTRL+ALT+V** shortcut.

  All the subordinate blocks for the current block will be hidden and the current block itself will be shown. Only the lines of the current block and the first lines of the blocks on the next level will be visible.
- Show subordinate blocks:
  - Position the cursor on the corresponding line of the block and press the **CTRL+ALT+R** shortcut.

  The current block and all subordinate blocks will be shown. All the lines of these blocks will be visible.

Note

The information relating to displayed and hidden blocks is saved in the project when the ST source file is closed.

This information is not transferred when the ST source file is exported (Page 4636).

Splitting the editor window

You can split the ST editor window into two segments, giving you two views of the same ST source file.

Splitting a window or canceling a split

How to split the current editor window into two segments or cancel such a split:

- Select the **ST source file > Split window** menu command.

Following the split, the cursor is located in the upper window segment.

The settings for splitting the editor window are not saved when the ST source file is closed. ST source files are always opened in an entire window (i.e. one that is not split).

Note

The editor window cannot be split if the program status (Page 4951) test function is being used.

The snippet editor is disabled when split window is used.

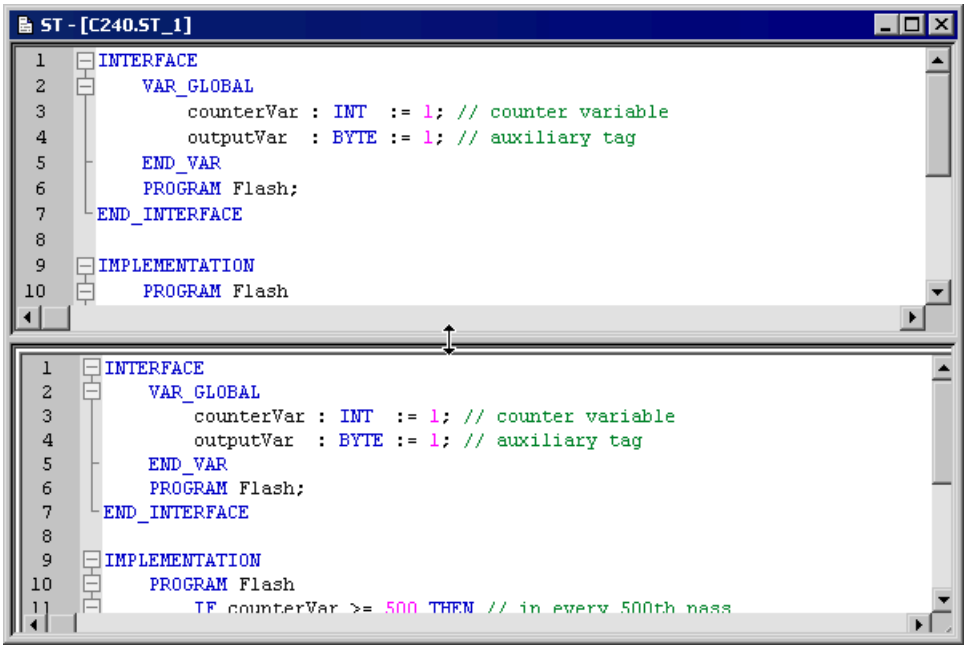

Figure 7-207 ST editor with split window

Adjusting the segment height

You can adjust the height of the two segments to your individual requirements:

1. Use the mouse to move the cursor to the dividing line between the two segments, until it turns into a double-headed arrow (see screenshot above).
2. Press and hold the left mouse button and drag the dividing line to the required position.

Displaying spaces, tabs and line ends

You can display spaces and tabs in the ST source files.

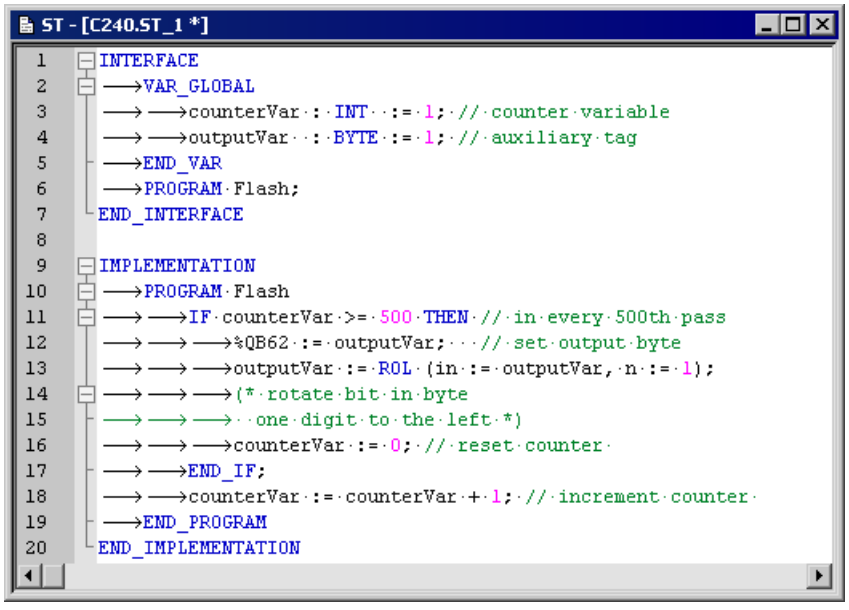

Figure 7-208 ST source file with visible spaces and tabs

In addition, you can display the line end (CR/LF).

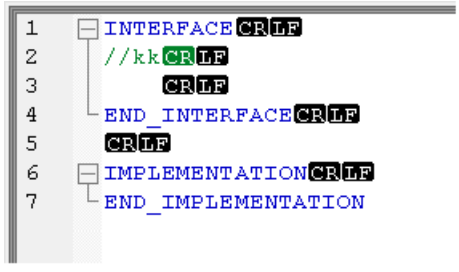

Figure 7-209 ST source with visible line end

Procedure

How to specify whether spaces and tabs are displayed in the active ST source file:

1. Set the cursor in the opened ST source.
2. Select the **View > Formatting symbols** context menu.

This setting is not saved when the ST source is closed.

Changing the font size in the ST editor

You can change the font size of the ST source in the editor. The font size of the line numbers and the size of other display elements (e.g. fold marks, bookmarks) will also be changed.

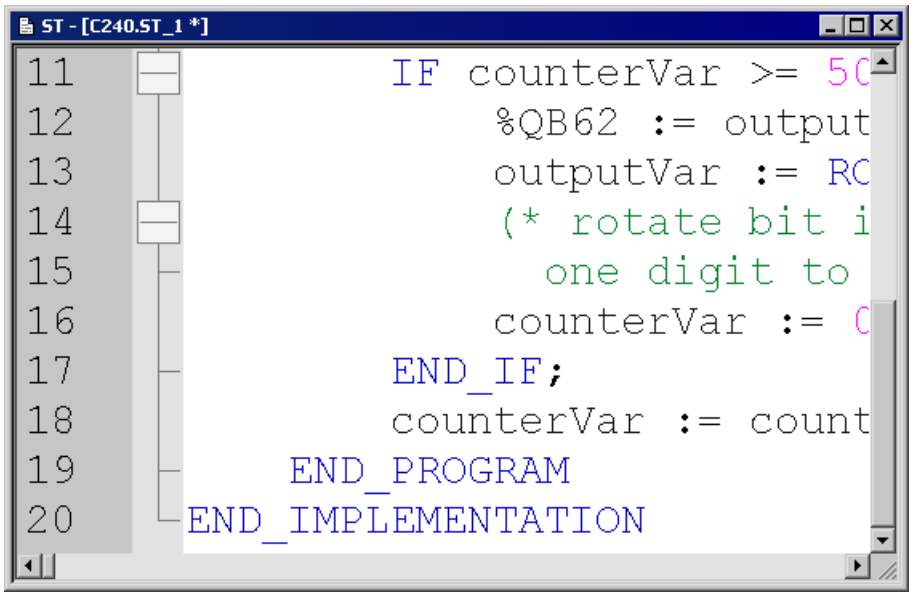

Figure 7-210 Increased size display of the ST source

Proceed as follows

You can change the font size:

- For the current ST source
- For ST source files to be opened subsequently

How to change the font size for the current ST source (alternative):

- Press the **CTRL** key while moving the mouse wheel
- Press concurrently the **CTRL** key and one of the following keys on the numeric block:
  - **ADD** (**+**) to increase,
  - **MINUS** (**-**) to reduce,
  - **DIV** for 100%.

How to change the font size for ST sources to be opened subsequently:

1. Open the settings for the ST editor (see Settings of the ST editor (Page 4593)).
2. Enter the required font size.

This setting will used for all ST sources that will be opened subsequently. It does not affect the currently opened ST sources.

Select text

Selecting lines of text

How to select lines of text:

- With the mouse:
  - With pressed left mouse button, scan the text to be selected.

  or

- With the keyboard or the mouse:
  - Place the cursor with the arrow keys of the keyboard or with the mouse at the start of the text to be selected.
  - Press the **Shift** key while placing the cursor at the end of the text to be selected. Please also refer to the keyboard shortcuts (Page 4619).

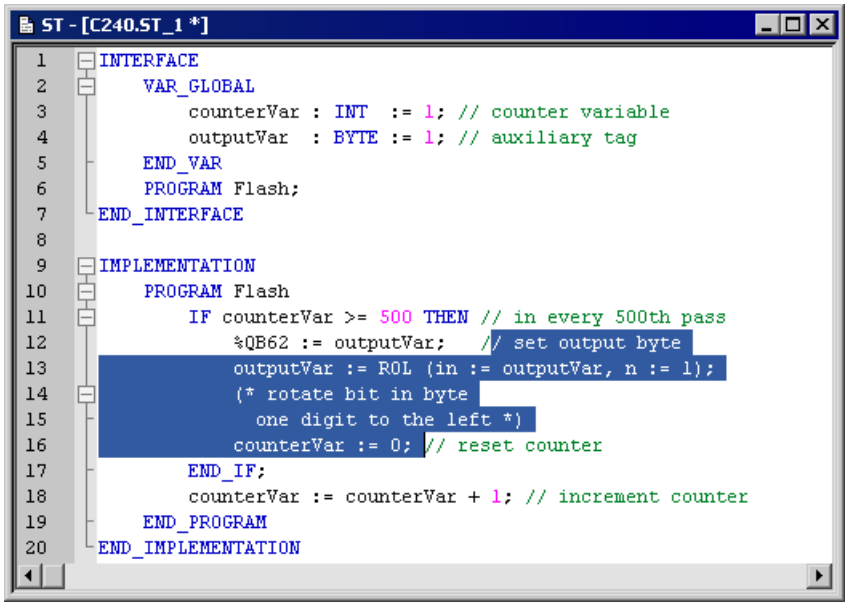

Figure 7-211 ST source with selected lines of text

Selecting columns of text

How to select columns of text:

- With the mouse:
  - Press the **Alt** key while keeping the left mouse button pressed, scan the text to be selected.

  or
- With the keyboard or the mouse:
  - Place the cursor with the arrow keys of the keyboard or with the mouse at the start of the text to be selected.
  - Press the **ALT+SHIFT** key combination while placing the cursor at the end of the text to be selected. Please also refer to the keyboard shortcuts (Page 4619).

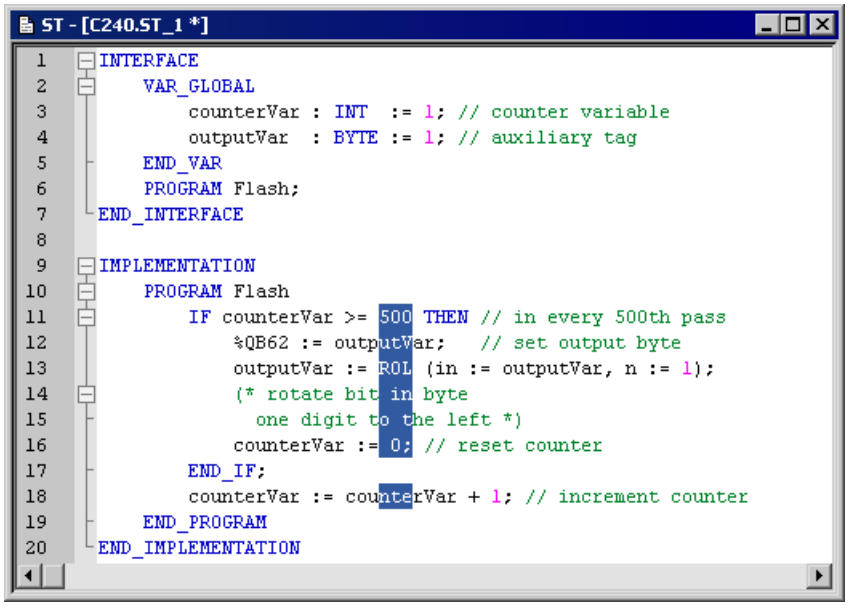

Figure 7-212 ST source with selected columns of text

Selecting a single line

How to select a single line:

- Left-click to the right of the line number of the appropriate line.

Selecting the complete text

How to select the complete text (alternatives):

- Press the **CTRL** key while clicking with the left mouse button in the column with the line numbers.
- Press the **CTRL+A** key combination.

Generating a simple series of numbers (generating a sequence)

You can generate simple series of integer numbers (sequences) that follow a specific pattern in the ST editor. This can be useful, for example, for the initialization of a field.

Procedure

1. In the ST editor, select all the numbers that you want to replace with a series of numbers (column-by-column, for example); see Selecting text (Page 4603).
2. Press the **CTRL+SHIFT+F7** shortcut.

The ST editor interprets all selected numbers as being possible elements and attempts to identify the pattern of the series from the initial elements and to calculate the subsequent elements (see below). The initial elements of the series must represent integer values. After the calculation has been performed, the ST editor replaces all the selected numbers which follow the initial elements with the calculated values.

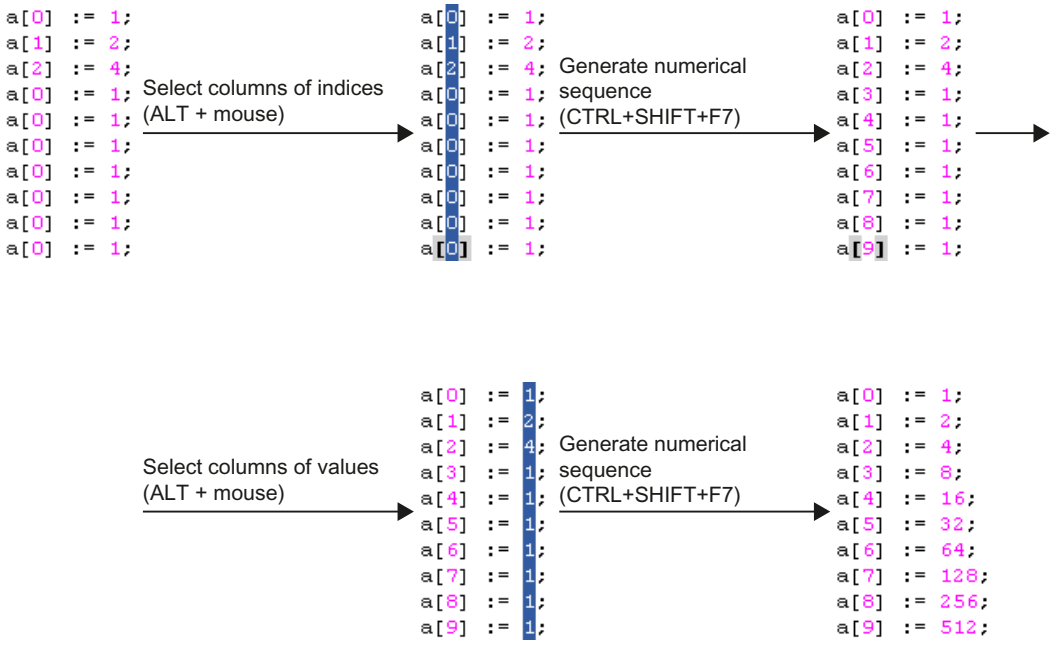

Figure 7-213 Example for generating series of numbers in the ST editor

Calculation of the elements

All the numbers selected in the ST editor are interpreted as being possible elements. The initial elements from which the series is calculated must represent integer values.

When determining the series of numbers, it is assumed that an element a_{n+1} can be determined from the previous element a_n using a linear function with the integer coefficients j and k. This means the following equation applies:

$$a_{n+1} = f(a_n) = j \cdot a_n + k$$

Coefficients j and k are calculated from the initial elements in the series:

1. First of all, an attempt is made to determine the integer coefficients j and k from the three initial elements of the series of numbers a_1, a_2 and a_3 ($j \geq 0$).
2. If this is not possible, only the first two elements a_1 and a_2 are used for the calculation:
   - Coefficient j will be set to 1.
   - Coefficient k will be determined from the resulting formula $a_2 = a_1 + k$.

These values are used to calculate the series of numbers. All selected numbers will be replaced by the calculated elements; the initial elements of the series which are used remain unchanged.

The following table shows some examples for series of numbers calculated in this manner.

Table 7-358 Examples for linear series of numbers with specified initial elements

Initial elements of the series			Calculated result			Resulting series of numbers
a_1	a_2	a_3	j	k	Equation	
0	1	2	1	1	$a_{n+1} = a_n + 1$	0, 1, 2, 3, 4, 5, 6, 7, 8, 9 ...
1	2	3	1	1	$a_{n+1} = a_n + 1$	1, 2, 3, 4, 5, 6, 7, 8, 9, 10 ...
0	2	4	1	2	$a_{n+1} = a_n + 2$	0, 2, 4, 6, 8, 10, 12, 14, 16, 18 ...
1	2	4	2	0	$a_{n+1} = 2a_n$	1, 2, 4, 8, 16, 32, 64, 128, 256, 512 ...
2	3	5	2	-1	$a_{n+1} = 2a_n - 1$	2, 3, 5, 9, 17, 33, 65, 129, 257, 513 ...
2	1	1	0	1	$a_{n+1} = 1$	2, 1, 1, 1, 1, 1, 1, 1, 1, 1 ...
3	2	1	1	-1	$a_{n+1} = a_n - 1$	3, 2, 1, 0, -1, -2, -3, -4, -5, -6 ...
0	1	0 [1]	1	1	$a_{n+1} = a_n + 1$	0, 1, 2, 3, 4, 5, 6, 7, 8, 9 ...
0	0	2 [1]	1	0	$a_{n+1} = a_n$	0, 0, 0, 0, 0, 0, 0, 0, 0, 0 ...

[1] Only the initial elements a_1 and a_2 of the series are used, a_3 is ignored and will be calculated.

Note

The initial elements of the series used for the calculation must represent integer values. However, they can also be entered as floating-point numbers.

When the series is calculated, the numbers to be taken into account must all be selected.

The selected area must only contain numbers and certain special characters (e.g. opening and closing brackets, commas).

The first time an impermissible character is encountered in the selected area, the calculation of the series will be aborted.

See the examples in the following figure.

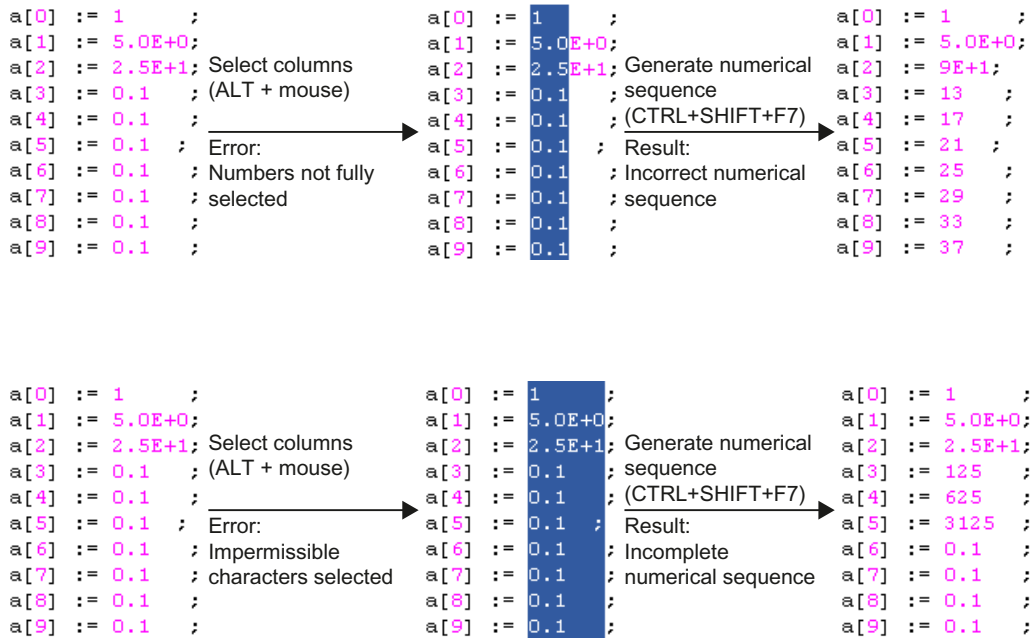

Figure 7-214 Examples of how incorrect selections cause unwanted results when generating a series of numbers in the ST editor

Use bookmarks

You can set bookmarks in the ST editor. This allows you to jump to specific selected lines within the ST source file.

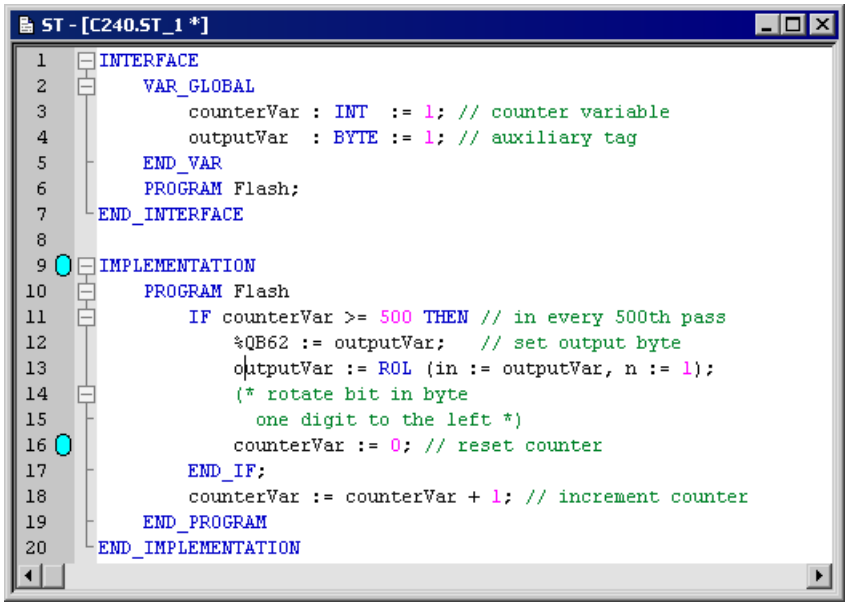

Figure 7-215 ST source with bookmarks

Setting and deleting bookmarks

How to set a bookmark for a line of the active ST source file or to delete an existing bookmark:

- With the keyboard and the mouse:
  - Press the **Ctrl** key.
  - Simultaneously, click with the left mouse button at the right-hand side next to the line number of the appropriate line.
- With the mouse:
  - Set the cursor in the appropriate line of the ST source.
  - Select the **Bookmarks > Insert/remove bookmark** context menu.

Note

Bookmarks are saved when the ST source file is closed.

Jump to bookmark

How to jump to the next bookmark within the ST source:

- Select the **Bookmarks > Next bookmark** context menu.

How to jump to the previous bookmark within the ST source:

- Select the **Bookmarks > Previous bookmark** context menu.

Delete all bookmarks

How to delete all bookmarks in an ST source:

- Select the **Bookmarks > Remove all bookmarks** context menu.

Automatic completion

In the ST editor, you can automatically complete identifiers. A selection list with identifiers that begin with the previously entered characters will be displayed.

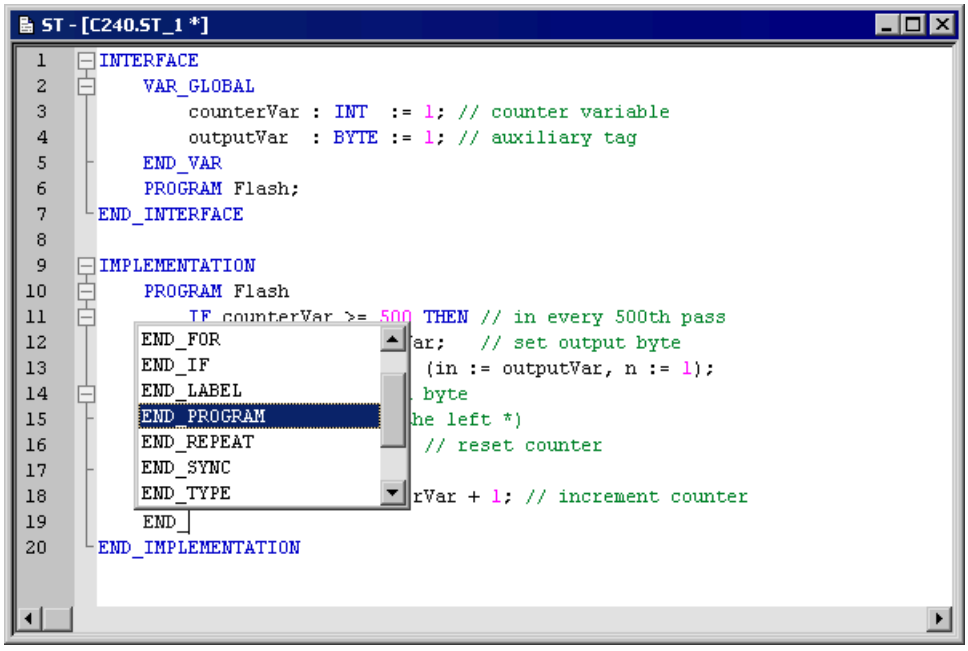

Figure 7-216 ST editor, automatic completion of an identifier (e.g. END_)

Procedure

How to automatically complete an identifier:

1. Write the first characters of the identifier (e.g. the letters of a word).
2. Press the **Ctrl+space** key combination.
   The selection possibilities are displayed in a window.
3. Expand or refine the selection options displayed:
   - Enter additional characters
   - Delete characters
   - Use the left/right arrow keys to move the cursor
4. Use the up/down arrow keys to select the required identifier.
5. Accept the identifier. The current word is overwritten.

Note

If only a single identifier is offered for selection, the selection window will not be opened and the identifier completed immediately.

Functional description

The following identifiers that begin with the specified character will be offered:

- Keywords of the Structured Text language
- Identifiers from the command library
- For technology objects including their system variables and configuration data
- Identifiers of the own ST source:
  - Program organization units (POU)
  - Data types
  - Variables and constants
  - Structure elements
- Identifiers from program sources used

Note

Identifiers from the own ST source or from program sources used will be displayed correctly only when the corresponding program source has been compiled.

The display is made context-sensitive, only those types of identifiers that are appropriate at the associated location of the ST source will be offered:

- Within a declaration block, only data types and keywords
- Within a program organization unit (POU), no data types
- For a structure (e.g. var_struct.xx), only structure components

Opening a called block

From the ST editor you can directly open and edit a user-defined program organization unit (POU), such as a function or a function block, which is called in the ST source file.

1. Position the cursor in the identifier of a program organization unit (POU), e.g. when calling a function or declaring an instance of a function block.
2. Select the **Open called block** context menu.

The subsequent response will depend on the programming language in which the source file of the called POU was written:

- SIMOTION ST programming language:
  The corresponding ST source file is opened, if necessary. The cursor is positioned at the start of the relevant POU in the implementation section.
  The cursor jumps to the start of the POU in the implementation section within the same ST source file.
  If a library is connected with an online CPU and is consistent online, the online functions are available under this library for all units.
- SIMOTION MCC or SIMOTION LAD/FBD programming languages:
  The corresponding POU (MCC chart, LAD/FBD program) is opened in the associated editor.

Code snippets

After the complete input of certain keywords (such as IF, WHILE, VAR), a window opens above the cursor to display a code snippet for the associated keyword (e.g. IF (*condition*) ... END_IF).

Further keywords with the same initial letter with available code snippets are displayed in the lower part of this window.

Pressing the **TAB** key transfers this code snippet to the ST source file. Pressing any other key closes this window.

Activating and deactivating code snippets

Code snippets must be activated before they can be used.

How to activate or deactivate code snippets:

- For the active ST source file:
  - Select the **View > Snippet Editor** context menu.

  This setting is not saved when the ST source file is closed.
- For all open ST source files:
  - Activate or deactivate the **Code snippets** checkbox in the ST editor settings.

  This setting is also used for all ST source files opened subsequently.

Creating user-defined snippets

You can create your own snippets for use in the ST editor. To do this, use the snippet editor, which you can display in the partitioned window at the same time as the ST editor. Observe the following rules for creation:

Rule	Description
Creating and naming snippets	You create new snippets with the snippet editor. Enter a unique name. Permissible characters are A-Z, a-z, 0-9 and _.
Renaming snippets	You can rename snippets that have already been created.
Deleting snippets	You can delete snippets that have already been created. Perform the Save function afterwards. Only then can the name of the deleted snippet be used again for new snippets.

Working with the snippet editor

Display the snippet editor via "ST source file > Snippet editor". Alternatively, you can reach the snippet editor via "ST editor > View > Snippet editor". The snippet editor shares the working area with the associated ST editor. In this way, the snippet editor is always tied to one, and only one, existing ST editor window. The snippet editor consists of three main sections:

- Snippet toolbar
- Snippet tree
- Snippet code editor

Snippet toolbar

The toolbar contains the following functionalities:

Function	Description
Load snippets into the editor – without saving	This function loads the changes that have been made in the snippet editor into the ST editor.
Save	This function saves the selected snippet or all of the snippets under the selected node in the tree.
Save all	This function saves all of the changes that have been made since the last save.
Reject	This function rejects the changes that have been made to the selected snippet or all of the changes in the selected node in the tree.
Reject all	This function rejects all of the changes that have been made since the last save.
Import	This function loads the user-defined snippets from the XML input file. The validity of the file is checked. If there is an error, a corresponding message is output. All existing user-defined snippers are deleted during the import.
Export	This function saves the user-defined snippets into an XML file. For this purpose, you create a new file or overwrite an existing one. The changes in the snippet are saved before the export.
Help	This function calls the context-sensitive online help.
Close	This function closes the snippet editor. Save your snippets before closing the editor.

Snippet tree

The snippet editor shows the hierarchy of all of the available snippets in a clear tree structure. The tree has a root node "Snippets" with two subordinate elements by the name of "STSnippets" for non_OOP- and "STSnippetsOOP for OOP-relevant snippets". Both contain pre-defined and user-defined snippets. The snippet IDs in the snippet tree are sorted alphabetically and all of the pre-defined snippets (recognizable by the lock icon) are listed first, in alphabetical order.

Only user-defined snippets can be created, changed, or deleted. Master elements, scope IDs or pre-defined snippets cannot be changed, deleted, or created. After you have created a new snippet, the new snippet key (name) will be alphabetically sorted into the user-defined snippets in the right position in the tree.

Snippet code editor

You insert the snippets in the snippet tree via the context menu. After inserting, assign the name and edit the snippet in the snippet code editor.

The snippet code editor is a simple text editor field in which you edit the associated part of the code (the currently selected element in the snippet tree). The text can be entered or inserted from the clipboard. Pre-defined snippets can be selected and copied, but are not edited.

Navigating between the identifiers

Snippets can have more identifiers marked with #identifier as placeholders to indicate that an identifier is missing. When a snippet is inserted into the ST source, the first #identifier that can be overwritten by the correct identifier is always marked. You then need to select all other identifiers. You jump to the next identifier with TAB. You jump to the previous identifier with Shift +TAB.

Other help for the ST editor

Display bracket pairs

The two brackets of a bracket-pair can be optically highlighted.

To do this, place the cursor next to a bracket. The editor attempts to find the associated brackets of the pair and highlights both brackets, where applicable. This simplifies the recognition of bracket pairs, in particular for nesting.

How to switch this function on or off:

- For the active ST source file:
  - Select the **View > Display bracket pairs** context menu.

  This setting is not saved when the ST source file is closed.
- For all open ST sources:
  - Activate or deactivate the **Display bracket pairs** checkbox in the ST editor settings (Page 4593).

  This setting is also used for all ST source files opened subsequently.

Showing and hiding line numbering

Line numbers can be displayed in the ST editor:

How to switch this function on or off:

- For the active ST source file:
  - Select the **View > Line numbering** context menu.

  This setting is not saved when the ST source file is closed.
- For all open ST sources:
  - Activate or deactivate the **Display line numbers** checkbox in the ST editor settings (Page 4593).

  This setting is also used for all ST source files opened subsequently.

Changing upper/lower case

You can change the case of selected text to upper case or lower case:

1. Select the text whose case you want to change; see Selecting text.
2. Select the **Selection in upper case** or **Selection in lower case** context menu.

Tool tip display

The ST editor provides support for some identifiers by displaying tool tips. These are shown if you briefly hover the cursor over the identifier.

For the identifiers of variables, for example, the associated data type is displayed in the tool tip. More tool tips will be available soon.

Using the command library

The command library is a tab in the project navigator. It contains the available system functions, system function blocks, and operators.

You can drag these elements from the command library to the ST editor window with drag&drop.

ST editor toolbar

This toolbar contains important operating actions for programming:

Table 7-359 ST editor toolbar

Symbol	Meaning
	Accept and compile Click this symbol to transfer the active ST source file to the project and compile it into executable code. See: Starting the compiler (Page 4622).
	Insert ST source file Click this icon to create a new ST source file. The icon is active only when the **PROGRAMS** folder where the ST source file is to be saved is selected in the project navigator. See: Insert ST source file (Page 4587).
	Program status Click this icon to start the **program status** test mode. During the program execution, you can monitor the values of the variables marked in the ST source. The following prerequisites are necessary: 1. The program must be compiled with the appropriate compiler option. 2. The project and the program must be loaded into the target system. 3. An online connection to the target system must have been established. Reclick this icon to end the **program status**. See: Using the program status (Page 4951). **Note:** Status program and the snippet editor cannot be active at the same time. • Close the snippet editor to open the status program.
	Stop monitoring of the program variables Click this icon in the **program status** test mode to stop the monitoring of the program variables. See Using the program status (Page 4951).
	Continue monitoring of the program variables Click this icon in the **program status** test mode to continue the monitoring of the program variables. See: Using the program status (Page 4951).
	Refresh Click this symbol in the **program status** test mode to force updating of the values displayed. The monitoring of the program variables must have been activated. See: Using the program status (Page 4951).

Symbol	Meaning
	Format current selection Click this symbol to indent the blocks in the selected text area by one tab width, in accordance with the block hierarchy. See Indentations and tabs (Page 4594).
	Formatting symbols on/off Click this symbol to show or hide blanks and tabs in the active ST source file. See Displaying blanks and tabs (Page 4601).
	Insert/remove bookmark Click this symbol to set a bookmark in the current line of the active ST source file or to delete an existing bookmark. See: Using bookmarks (Page 4607).
	Next bookmark Click this symbol to jump to the next bookmark in the active ST source file. See: Using bookmarks (Page 4607).
	Previous bookmark Click this symbol to jump to the previous bookmark in the active ST source file. See: Using bookmarks (Page 4607).
	Remove all bookmarks Click this symbol to remove all bookmarks from the active ST source file. See: Using bookmarks (Page 4607).
	Go to start of block Click this symbol to move the cursor to the start of the current or higher-level block.
	Go to end of block Click this symbol to move the cursor to the end of the current block.
	Insert comment character Click this icon to convert to comment on the selected lines or line fragments or to insert a comment character. See Comments (Page 4670).
	Remove comment character Click this icon to reactivate commented lines or line fragments. See Comments (Page 4670).

ST editor context menu

The ST editor context menu is shown if you right-click in an open ST source file.

Depending on the active application/editor or the mode (ONLINE/OFFLINE), certain commands are not displayed or cannot be selected.

As far as editor functions are concerned, this context menu also applies to the script editor.

You can select the following functions:

Table 7-360 ST editor and script editor context menu

Function	Meaning/information
Open called block [1]	If the cursor is positioned in the identifier of a user-defined program organization unit (POU), e.g. when calling a function or declaring an instance of a function block: Select this command to open and edit the source of this POU (ST source file, MCC chart, LAD/FBD program). See: Open called block (Page 4610).
Refactoring	You can change the case or rename. The function provides a list of suggested renames of the symbols used in the actual unit, which differ in terms of notation from the symbols declared in the cross-references. You can decide which changes need to be applied. To avoid inconsistencies, compile the project afterwards.
Surround with	Select this command to surround the selected text with pre-defined code snippets. E.g. surround the selected variable with an If instruction.
Cut	Select this command to cut the selected area from the ST source file and save it to the clipboard.
Copy	Select this command to copy the selected area to the clipboard.
Paste	Select this command to insert the contents of the clipboard into the ST source file at the current cursor position.
Copying text with syntax coloring	Select this command to copy the selected area in RTF format to the clipboard. This allows the insertion of text including syntax coloring into text processing programs. The copied text cannot be inserted into the ST editor.
Delete	Select this command to delete the selected area or the character to the right of the cursor.
Select all	Select this command to select all of the text in the ST source file. See: Select text (Page 4603).
View	

Function		Meaning/information
	Line numbering on/off	Select this command to show or hide the line numbers in the active ST source file. See: Other ST editor tools (Page 4613).
	Indent help	Select this command to highlight the indents and outdents for blocks in the active ST source file by means of vertical auxiliary lines (in accordance with the set tab width). See: Indentations and tabs (Page 4594).
	Display bracket pairs	Select this command to highlight both brackets of a pair in the active ST source file, if the cursor is positioned at one of the two brackets. See: Other ST editor tools (Page 4613).
	Formatting symbols	Select this command to show or hide blanks and tabs in the active ST source file. See: Displaying blanks and tabs (Page 4601).
	Folding	Select this command to activate or deactivate folding in the active ST source file. The folding information in the active ST source file is then displayed or hidden. See: Folding (showing and hiding blocks) (Page 4596).
	Format current selection	Select this command to indent the blocks in the selected text area by one tab width, in accordance with the block hierarchy. See: Indentations and tabs (Page 4594).
	Split window	Select this command to split the active window of the ST editor into two segments horizontally, giving you two views of the same ST source file. See: Splitting the editor window (Page 4600).
	Code snippets	Select this command to activate or deactivate code snippets in the activate ST source file. If active, after input of certain keywords (such as IF, WHILE, VAR), a window opens to display a code snippet for the associated keyword (e.g. IF (*condition*) ... END_IF). This code snippet can be transferred to the ST source file. See: Code snippets (Page 4611).
Bookmarks		
	Insert/remove bookmark	Select this command to set a bookmark in the current line of the active ST source file or to delete a bookmark which has been set there. See: Using bookmarks (Page 4607).
	Next bookmark	Select this command to jump to the next bookmark in the active ST source file. See: Using bookmarks (Page 4607).
	Previous bookmark	Select this command to jump to the previous bookmark in the active ST source file. See: Using bookmarks (Page 4607).
	Remove all bookmarks	Select this command to remove all bookmarks from the active ST source file. See: Using bookmarks (Page 4607).
Print		
	Complete source	Select this command to print the complete active ST source file.
	Selection	Select this command to print the selected lines of the active ST source file.
Variable declaration		Select this command to declare a variable "on-the-fly". See: Declaring variables in the Variable declaration dialog box ("on-the-fly" variable declaration) (Page 4860).
Selection in upper case		Select this command to change the selected text to upper case. See: Other ST editor tools (Page 4613).
Selection in lower case		Select this command to change the selected text to lower case. See: Other ST editor tools (Page 4613).

Function		Meaning/information
Code indentation		Select this command to format the text automatically.
Indent selected area		• If no text is selected: Select this command to move the text on the right of the cursor to the next tab position. • If text is selected in one single line: Select this command to delete the selected text and move the subsequent text to the next tab position. • If text is selected in multiple lines: Select this command to indent the selected area (Page 4594). A tab character ($09) or the equivalent number of spaces ($20) will be inserted, depending on the settings for the ST editor (Page 4593).
Undo selected area		• If no text is selected: Select this command to move the cursor to the previous tab position. • If text is selected in one single line: Select this command to cancel the selection and move the cursor to the previous tab position. • If text is selected in multiple lines: Select this command to outdent the selected area (Page 4594).
Go to start of block		Select this command to move the cursor to the start of the current or higher-level block.
Go to end of block		Select this command to move the cursor to the end of the current block.
Go to start of block, level 0		Select this command to move the cursor to the start of the higher-level block, 1st level.
Go to start of block, level 1		Select this command to move the cursor to the start of the higher-level block, 2nd level.
Go to line		Select this command to move the cursor to a specific line. A dialog box for specifying the line number is opened.
Set/remove breakpoint [1]		Select this command to set a breakpoint at the selected code position or to remove an existing breakpoint. See: Setting breakpoints (Page 4959).
Activate/deactivate breakpoint [1]		Select this command to activate or deactivate the breakpoint at the selected code position. See: Activating breakpoints (Page 4967).
Add to watch table [1]		
	New watch table	If the cursor is within a variable or if the variable is selected: Select this command to create a new watch table and to take it into this variable.
	(Name of a watch table)	If the cursor is within a variable or if the variable is selected: Select this command to take the variable into the selected watch table
Go to [1]		
	Local use >>	If the cursor is within a variable or if the variable is selected: Select this command to jump to the next use of the variable in the ST source file.
	Local use <<	If the cursor is within a variable or if the variable is selected: Select this command to jump back to the previous use of the variable in the ST source file.

Function		Meaning/information
	Declaration position	If the cursor is within a variable or if the variable is selected: Select this command to jump to the declaration position of the variable. If the variable is declared in a used source or library, the source or library is opened.
	Points of use	If the cursor is within a variable or if the variable is selected: Select this command to list all the points of use of the variable in the detail view.

[1] Not available in the script editor context menu.

Shortcuts

The ST editor also provides keyboard shortcuts. Some commands can also be called via the **Edit** or **ST editor** menus:

The keyboard shortcuts related to editor functions also apply to the script editor.

Table 7-361 Keyboard shortcuts for ST editor and script editor

Shortcuts	Description
F2	Jump to the next bookmark.
F3	Find next (menu **Edit > Find next**). A search is performed on the last text in the search field, even if it has been closed (see CTRL +F).
F9 [1]	Set or remove a breakpoint (menu **Debug > Set/remove breakpoint**).
F12 [1]	Activate or deactivate a set breakpoint (menu **Debug > Activate/deactivate breakpoint**).
BACK	Delete the character to the left of the cursor.
INS	Switch between insert mode and overwrite mode.
DEL	Delete the selected area or the character to the right of the cursor (menu **Edit > Delete**).
Arrow key	Move the cursor.
POS1	Move cursor to the beginning of the line.
END	Move cursor to the end of the line.
PG UP	Move up one page. The cursor follows.
PG DN	Move down one page. The cursor follows.
TAB	• If no text is selected: Move the text on the right of the cursor to the next tab position. • If text is selected in one single line: Delete the selected text and move the subsequent text to the next tab position. • If text is selected in multiple lines: Indent selected area. A tab character ($09) or the equivalent number of spaces ($20) will be inserted, depending on the settings for the ST editor.
SHIFT+F2	Jump to the previous bookmark.
SHIFT+BACK	Delete the character to the left of the cursor.
SHIFT+INS	Paste clipboard contents (menu **Edit > Paste**).
SHIFT+DEL	Cut the selected area (menu **Edit > Cut**).
SHIFT+Arrow key	Select line of text.
SHIFT+POS1	Select text back to the beginning of the line.

Shortcuts	Description
SHIFT+END	Select text to the end of the line.
SHIFT+PG UP	Move up one page. Select lines of text up to the new cursor position.
SHIFT+PG DN	Move down one page. Select lines of text up to the new cursor position.
SHIFT+TAB	• If no text is selected: Jump to the preceding tab position. • If text is selected in one single line: Jump to the preceding tab position. • If text is selected in multiple lines: Outdent selected area.
CTRL+A	Select all text (menu **Edit > Select All**).
CTRL+B [1]	Accept and compile ST source file (menu **ST source file > Accept and compile**).
CTRL+C	Copy the selected area to the clipboard (menu **Edit > Copy**).
CTRL+D	Duplicate the current line or the area selected.
CTRL+F	Find text in ST source file (menu **Edit > Find**) If text is selected in a single line, this is taken into the search screen form.
CTRL+H	Replace text in ST source file (menu **Edit > Replace**).
CTRL+J	Display the next search result in the project-wide search (menu **Edit > Display next position**).
CTRL+L	Copy the current line or the selected area to the clipboard.
CTRL+U	Change selected text to lower case.
CTRL+V	Paste clipboard contents (menu **Edit > Paste**).
CTRL+X	Cut the selected area (menu **Edit > Cut**).
CTRL+Y	Redo the last action (menu **Edit > Redo**).
CTRL+Z	Undo the last action (menu **Edit > Undo**).
CTRL+space	Automatic completion
CTRL+F2	Set or remove bookmarks.
CTRL+F4	Close the active window (e.g. menu **ST source file > Close**).
CTRL+F5 [1]	Remove all the breakpoints (in all the program source) in the SIMOTION device (menu **Debug > Remove all breakpoints**).
CTRL+F7 [1]	Activate or deactivate the program status function (menu **ST source file > Program status on/off**).
CTRL+F8 [1]	Continue to execute the program at the activated breakpoint (menu **Debug > Continue**).
CTRL+BACK	Delete the word to the left of the cursor.
CONTROL+INS	Copy the selected area to the clipboard (menu **Edit > Copy**).
CTRL+DEL	Delete the word to the right of the cursor.
CTRL+arrow key (left/right)	Move cursor left or right by one word.
CTRL+arrow key (up/down)	Scroll one row up or down. The cursor remains in the same position for as long as it is visible in the window.
CTRL+POS1	Move cursor to the beginning of the ST source file.
CTRL+END	Move cursor to the end of the ST source file.
CTRL+SHIFT+B	Highlight bracket pairs in the current ST source file.
CTRL+SHIFT+F	Search for texts within the project (menu **Edit > Search in the project**)
CTRL+SHIFT+G	Replace texts within the project (menu **Edit > Replace in the project**)
CTRL+SHIFT+H	Assign parameters to a call. Under development.
CTRL+SHIFT+L	Go to a line in the ST editor.

Shortcuts	Description
CTRL+SHIFT+S	Code indentation.
CTRL+SHIFT+U	Change selected text to upper case.
CTRL+SHIFT+F2	Remove all bookmarks from the ST source file.
CTRL+SHIFT+F3	Arrange windows, tile horizontally.
CTRL+SHIFT+F5	Arrange windows, tile vertically.
CTRL+SHIFT+F7	Generate a simple series of numbers (sequence) in the selected area.
CTRL+SHIFT+F8	Format selected area.
CTRL+SHIFT+F9	Move cursor to the start of the current or higher-level block.
CTRL+SHIFT+F10	Move cursor to the end of the current block.
CTRL+SHIFT+F11	Move cursor to the start of the higher-level block, 1st level.
CTRL+SHIFT+F12	Move cursor to the start of the higher-level block, 2nd level.
CTRL+SHIFT+BACK	Delete text to the left of the cursor up to the beginning of the line.
CTRL+SHIFT+DEL	Delete text to the right of the cursor up to the end of the line.
CTRL+SHIFT+arrow key (left/ right)	Select word to the left or right of the cursor.
CTRL+SHIFT+POS1	Select lines of text back to the beginning of the ST source file.
CTRL+SHIFT+END	Select lines of text up to the end of the ST source file.
CTRL+ALT+C	Folding: Hide all blocks of the current ST source file.
CTRL+ALT+D	Folding: Show all blocks of the current ST source file.
CTRL+ALT+F	Folding: Show or hide folding information in the current ST source file.
CTRL+ALT+I	Show indentation level in the current ST source file.
CTRL+ALT+L	Show or hide line numbers in the current ST source file.
CTRL+ALT+O [1]	If the cursor is in the identifier of a program organization unit (POU): Open called block, i.e. open program source of the POU and position the cursor.
CTRL+ALT+R	Folding: Show all subordinate blocks.
CTRL+ALT+S	Split window or cancel split (menu **ST source file > Split window**).
CTRL+ALT+T	Folding: Show/hide block.
CTRL+ALT+V	Folding: Hide all subordinate blocks.
CTRL+ALT+W	Show or hide blanks and tabs in the current ST source file.
CTRL+ADD (numeric keypad)	Increase font size in the current ST source file.
CTRL+MINUS (numeric keypad)	Decrease font size in the current ST source file.
CTRL+DIV (numeric keypad)	Change font size in the current ST source file to 100%.
ALT+N	Declare variable "on-the-fly" in the Variable declaration dialog box (Page 4860).
ALT+SHIFT+L	Change selected text to upper case.
ALT+SHIFT+S	Activate or deactivate code snippets (Page 4611).
ALT+SHIFT+U	Change selected text to lower case.
ALT+SHIFT+Arrow key	Select text by column.
ALT+SHIFT+POS1	Select columns of text back to the beginning of the line.
ALT+SHIFT+END	Select columns of text to the end of the line.
ALT+SHIFT+Pg Up	Move down one page. Select columns of text up to the new cursor position.
ALT+SHIFT+PG DN	Move down one page. Select columns of text up to the new cursor position.
ALT+Arrow key	Moves the selected code section up or down in the editor.

[1] Keyboard shortcut does not apply to the script editor.

Table 7-362 Combined keyboard and mouse actions for ST editor and script editor

Keyboard	Mouse	Description
	Single left-click in text	Set cursor.
	Double left-click in text	Select word.
	Press left button and drag mouse	Select line of text.
	Single left-click on line number	Select line.
	Turn mouse wheel	Scroll vertically. Cursor remains unchanged.
SHIFT	Single left-click in text	Select line of text.
SHIFT	Turn mouse wheel	Scroll horizontally.
CTRL	Single left-click on line number	Select all text (menu **Edit > Select All**).
CTRL	Single left-click in bookmark column	Set or delete bookmarks.
CTRL	Turn mouse wheel	Change font size.
ALT	Press left button and drag mouse	Select text by column.
ALT+SHIFT	Single left-click in text	Select text by column.

Starting the compiler

Requirement

The ST source file has been opened with the ST editor.

Proceed as follows

1. Click in the window with the ST editor. The dynamic ST source file menu appears.
2. Select the **ST source file** > **Accept and compile** menu command.

Note

The ST source file menu is dynamic. It only appears if the window of the ST editor is active.

The compiler checks the syntax of the ST source file. The "Compile/check output" tab of the detail view displays the successful compilation of the source text or compiler errors. The error details include: The name of the ST source file, the number of the line in which the error occurred, the error number and the error description.

Help for the error correction

To obtain help during error correction:

- Double-click the error message in the **Compile/check output** tab of the detail view.

The cursor is placed at the relevant line in the ST source file.

Making settings for the compiler

You can define the compiler settings (compiler options) as follows:

- Globally for the SIMOTION project, valid for all programming languages, see Global settings of the compiler (Page 4623)
- Locally for an individual ST source file within the SIMOTION project, see Local settings of the compiler (Page 4626)

Global compiler settings

The global settings are valid for all programming languages within the SIMOTION project.

Procedure

1. Select the menu **Options > Settings**.
2. Select the **Compiler** tab.
3. Define the settings according to the following table.
4. Confirm with **OK**.

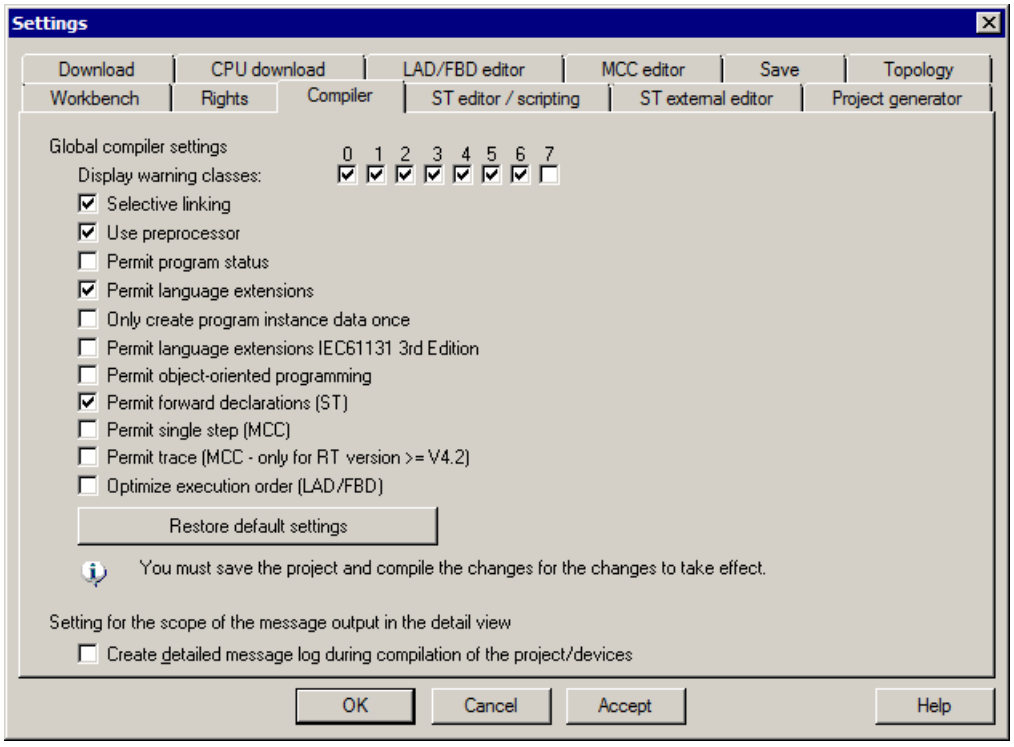

Figure 7-217 Global compiler settings

Parameter

Table 7-363 Parameters for global compiler settings

Parameter	Description
Display warning classes[1]	In addition to error messages, the compiler can issue warnings and information. You can set the scope of the warning messages to be output: **Active**: The compiler issues warnings and information for the selected class. **Inactive**: The compiler suppresses warnings and information for the respective class. See also Meanings of the warning classes (Page 4633).
Selective linking[1]	**Active** (standard): Unused code is removed from the executable program. **Inactive**: Unused code is retained in the executable program.
Use preprocessor[1]	**Active**: Preprocessor is used. **Inactive** (standard): Preprocessor is not used. See Controlling the preprocessor (Page 4918).
Enable program status[1]	**Active**: Additional program code is generated to enable monitoring of program variables (including local variables). **Inactive** (standard): Program status not possible. See Properties of the program status (Page 4949).
Permit language extensions[1]	**Active**: Language elements are permitted that do not comply with IEC 61131-3. • Direct bit access to variables of a bit data type (Page 4705) • Accessing the input parameter of a function block while outside the function block (Page 4756) • Calling a program while in a different program (Page 4762) **Inactive** (standard): Only language elements that comply with IEC 61131-3 are permitted.
Only create program instance data once[1]	**Active**: The local variables of a program are only stored once in the user memory of the unit. This setting is required for calling a program while inside a different program (Page 4762). This setting also improves the download in RUN mode, see corresponding section in the Basic Functions Function Manual. **Inactive** (standard): The local variables of a program are stored according to the task assignment in the user memory of the respective task. See Memory areas of the variable types (Page 4844).

Parameter	Description
Permit additional languages, IEC61131 3rd edition[1]	**Active**: Additional language elements can be used in accordance with IEC 61131-3 3rd edition. The corresponding keywords are locked as reserved or protected identifiers. • Nested block comments (Page 4670) • CONTINUE statement (Page 4727) • Standard-compliant system functions LOWER_BOUND and UPPER_BOUND (Page 4747) for determining the limits of a dynamic ARRAY • Additional system functions (see Basic Functions Function Manual): – FROM_BIG_ENDIAN – FROM_LITTLE_ENDIAN – IS_VALID – TO_BIG_ENDIAN – TO_LITTLE_ENDIAN **Inactive** (standard): The additional language elements cannot be used. The corresponding keywords are not locked. **Note** When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.
Permit object-oriented programming[1]	**Active**: With the ST programming language additional language elements for object-oriented programming can be used in accordance with IEC 61131-3 3rd edition. The corresponding key words are locked as reserved or protected identifiers in all programming languages. **Inactive** (standard): The keywords for object-oriented programming are not locked in all programming languages. The additional language elements cannot be used with the ST programming language. **Note** Independently of the setting the program organization units generated in ST sources using object-oriented programming (e.g. classes, methods) can be used in program sources for all programming languages. When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.
Permit forward declarations (ST)	Only for the ST programming language. Forward declarations enable you to use program organization units (POUs) before they are fully defined. Prototype declarations of program organization units are possible prior to their use, but are only required for an instance declaration of a function block or a class. **Active**: Forward declarations are permitted. **Inactive** (standard): Forward declarations are not permitted. See Forward declarations (Page 4929). Forward declarations are always permitted with the MCC and LAD/FBD programming languages. It is also possible to make a local setting on the ST source file (Page 4626). Please also refer to the description of the effectiveness of global or local compiler settings (Page 4630).

Parameter	Description
Permit single step (MCC)	Only for the MCC programming language. **Active**: An additional program code is created which enables individual program steps to be monitored. **Inactive**: Single step is not possible. This function facilitates debugging of your program. See "Tracking single steps in the program" in the MCC Programming Manual. It is also possible to make a local setting on the MCC unit. Please also refer to the description of the effectiveness of global or local compiler settings (Page 4630).
Permit trace (MCC - only for RT versions >= 4.2)	Only for the MCC programming language and for SIMOTION Kernel as of version V4.2. **Active**: An additional program code is created which enables monitoring of the program execution in program branches which are executed cyclically. **Inactive**: Trace is not possible. This function facilitates debugging of your program. See "Tracking program execution per trace" in the MCC Programming Manual. It is also possible to make a local setting on the MCC unit. Please also refer to the description of the effectiveness of global or local compiler settings (Page 4630).
Optimize execution order (LAD/FBD)	Only for LAD/FBD programming languages. **Active**: LAD/FBD networks are calculated in the optimized execution order. **Inactive**: LAD/FBD networks are calculated in the non-optimized execution order.
Default setting	Click the button to restore the default setting.
Create detailed message log during compilation of the project/devices[2]	Here, you can control the scope of the message log that will be displayed in the workbench's detail view when you call the **Save and compile changes** command in SIMOTION SCOUT. **Active**: A detailed message log is created that is similar to that for single compilation of an ST source file. **Inactive**: A compressed message log is created.
[1] Local settings also possible, see Local settings of the compiler (Page 4626). Please also refer to the description of the effectiveness of global or local compiler settings (Page 4630). [2] User-specific settings. Valid for all SIMOTION projects that the user processes.	

Note

You may have to save and compile the project for the settings to take effect.

Local compiler settings

Local settings are configured individually for each ST source file; local settings overwrite global settings.

Procedure

1. Open the Properties window for the ST source file, see Changing the properties of an ST source file (Page 4589):
   Select the ST source file in the project navigator and select the **Edit > Object properties** menu command.
2. Select the **Compiler** tab.

3. Define the settings according to the following table.
4. Confirm with **OK**.

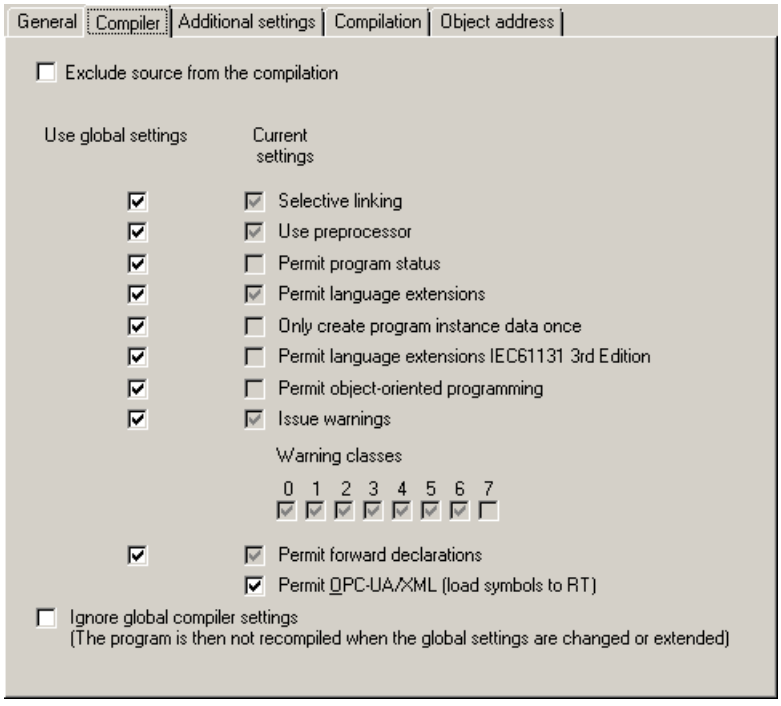

Figure 7-218 Local compiler settings for the ST source file

Parameter

Table 7-364 Parameters for the local compiler settings for the ST source file

Parameter	Description
Exclude source from the compilation	**Active**: This source is not compiled upon compilation of the project, the device or the library (e.g. Menu **Project > Save and recompile all**). The source is marked accordingly in the project navigator. Corresponding information is provided upon compilation. **Inactive** (standard): The source is compiled upon compilation of the project, the device or the library.
Use global settings	This checkbox is available for every parameter which also has a global setting. It can only be selected when the "Do not recompile the source if global compiler settings have been changed" checkbox is inactive. This is where you define whether the global settings are adopted or whether the local settings will apply. See the description under "Effectiveness of global or local compiler settings (Page 4630)". Use the second checkbox or the other checkboxes for the relevant parameters (described below) to define the local settings.
Selective linking[1]	**Active**: Unused code is removed from the executable program. **Inactive**: Unused code is retained in the executable program. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).

Parameter	Description
Use preprocessor[1]	**Active**: Preprocessor is used. **Inactive**: Preprocessor is not used. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Controlling the preprocessor (Page 4918).
Enable program status[1]	**Active**: Additional program code is generated to enable monitoring of program variables (including local variables). **Inactive**: Program status not possible. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Properties of the program status (Page 4949).
Permit language extensions[1]	**Active**: Language elements are permitted that do not comply with IEC 61131-3. • Direct bit access to variables of a bit data type (Page 4705) • Accessing the input parameter of a function block while outside the function block (Page 4756) • Calling a program while in a different program (Page 4762) **Inactive**: Only language elements that comply with IEC 61131-3 are permitted. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active).
Permit additional languages, IEC61131 3rd edition[1]	**Active**: Additional language elements can be used in accordance with IEC 61131-3 3rd edition. The corresponding keywords are locked as reserved or protected identifiers. • Nested block comments (Page 4670) • CONTINUE statement (Page 4727) • Standard-compliant system functions LOWER_BOUND and UPPER_BOUND (Page 4747) for determining the limits of a dynamic ARRAY • Additional system functions (see Basic Functions Function Manual): – FROM_BIG_ENDIAN – FROM_LITTLE_ENDIAN – IS_VALID – TO_BIG_ENDIAN – TO_LITTLE_ENDIAN **Inactive**: The additional language elements cannot be used. The corresponding keywords are not locked. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). **Note** When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

Parameter	Description
Permit object-oriented programming[1]	**Active**: Additional language elements for object-oriented programming can be used in accordance with IEC 61131-3 3rd edition. The corresponding keywords are locked as reserved or protected identifiers. **Inactive**: The additional language elements cannot be used. The corresponding keywords are not locked. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). **Note** Independently of the setting the program organization units created in other ST source files using object-oriented programming (e.g. classes, methods) can be used in this source. When saving the project in the old project format: Projects in which language elements that require this compiler option are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.
Only create program instance data once[1]	**Active**: The local variables of a program are only stored once in the user memory of the unit. This setting is required for calling a program while inside a different program (Page 4762). This setting also improves the download in RUN mode, see corresponding section in the Basic Functions Function Manual. **Inactive**: The local variables of a program are stored according to the task assignment in the user memory of the respective task. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Memory areas of the variable types (Page 4844). For further information, refer to the SIMOTION Basic Functions Function Manual.
Issue warnings Warning classes[1]	In addition to error messages, the compiler can issue warnings and information. You can set the scope of the warning messages to be issued. "Issue warnings" checkbox: **Active**: The compiler issues the warnings and information according to the warning class selection that follows. **Inactive**: The compiler suppresses all warnings and information concerning this unit. The checkboxes for the warning classes are hidden. **Gray background** (display only): Operating on a global setting basis, the compiler always issues warnings and information in accordance with the global warning class selection shown below (if "Use global settings" = active). "Warning classes" checkboxes (only if "Issue warnings" = active): **Active**: The compiler issues warnings and information for the selected class. **Inactive**: The compiler suppresses warnings and information for the respective class. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See also Meanings of the warning classes (Page 4633).
Permit forward declarations[1]	Forward declarations enable you to use program organization units (POUs) before they are fully defined. Prototype declarations of POUs are possible prior to their use, but only required for an instance declaration of a function block. **Active**: Forward declarations are permitted. **Inactive**: Forward declarations are not permitted. **Gray background** (display only): The global setting displayed is adopted (when "Use global settings" = active). See Forward declarations (Page 4929).

Parameter	Description
Permit OPC-UA / -XML (load symbols to RT)	**Active** (standard): Symbol information for the unit variables of the ST source file is available in the SIMOTION device. This is required for: • The *_exportUnitDataSet* and *_importUnitDataSet* functions; see the SIMOTION Basic Functions Function Manual • The watch function of IT DIAG. **Inactive:** Symbol information is not created.
Ignore global compiler settings (The program is not compiled again if the global settings are changed or extended.)	**Active:** The global settings of the compiler are ineffective for all parameters. The "Use global settings" checkboxes cannot be selected and are grayed out. When changing the global compiler settings, the ST source file is not recompiled. This setting is required for libraries that have a know-how protection program (Page 4635) with a "High" level: • For all program sources in this library. • For the library itself. **Inactive** (standard): The checkboxes "Use Global Settings" can be selected for all parameters and are presented against a white background. These checkboxes specify whether the global properties are taken over for the corresponding parameters. This setting means that in the following case the ST source file is compiled even though all "Accept global settings" checkboxes are inactive: • The global settings of the compiler have been changed and the menu **Project > Save and compile changes** is selected. See the description under "Effectiveness of global or local compiler settings (Page 4630)".
[1] Global setting also possible, see Global settings of the compiler (Page 4623). Please also refer to the description of the effectiveness of global or local compiler settings (Page 4630).	

Effectiveness of global or local compiler settings

You control the effectiveness of the global and local settings of a parameter using the local compiler settings (Page 4626).

"Ignore global compiler settings" checkbox

With the "Ignore global compiler settings" checkbox, you specify whether the global properties of the compiler influence the program source.

- **Active:** The global settings of the compiler are ineffective for all parameters. The "Use global settings" checkboxes cannot be selected and are grayed out. When changing the global compiler settings, the ST source file is not recompiled.
  This setting is required for libraries that have a know-how protection program (Page 4635) with a "High" level:
  - For all program sources in this library.
  - For the library itself.
- **Inactive:** The checkboxes "Use global settings" can be selected for all parameters and are presented against a white background. These checkboxes specify whether the global properties are applied to the corresponding parameter.
  This setting means that in the following case the program source is compiled even though all "Use global settings" checkboxes are inactive:
  - The global settings of the compiler have been changed and the menu **Project > Save and compile changes** is selected.

  This causes problems for libraries that have a know-how protection program (Page 4635) with a "High" level: Online inconsistencies can also occur for projects that have been converted from an earlier version of SIMOTION SCOUT.

Checkboxes for the other parameters

Every parameter that has a global setting also has at least two checkboxes:

- "Use global settings" checkbox:
  You use this checkbox to define whether global settings will be used. It can only be selected when the "Do not recompile the source if global compiler settings have been changed" checkbox is inactive.
  The following settings are possible:
  - **Active**:
    The global settings will be used for the corresponding parameter.
    No other checkboxes may be selected for this parameter; they are grayed out and show the global setting.
  - **Inactive**:
    The global settings are ignored for the corresponding parameter. Only the local settings, which you define with the other checkboxes, are effective.
- One or more checkboxes for current (local) settings:
  The function of these checkboxes depends on the "Use global settings" checkbox:
  - If the "Use global settings" checkbox is active:
    The global settings will be used for the corresponding parameter. The checkboxes for the current settings cannot be selected. They are grayed out and show the relevant global setting.
  - If the "Use global settings" checkbox is inactive:
    The checkboxes for the current settings can be selected and are displayed on a white background. You can use them to define the local settings for the corresponding parameter. The global settings are ignored.

This behavior applies to the following compiler settings:

- Selective linking
- Use preprocessor
- Enable program status
- Permit language extensions
- Only create program instance data once
- Permit additional languages, IEC61131 3rd edition
- Permit object-oriented programming
- Issue warnings with warning classes
- Permit forward declarations (only for the ST programming language)
- Permit single step (only in MCC programming language)
- Permit trace (only for the MCC programming language and for SIMOTION Kernel as of version V4.2)

Note

You can check the current compiler options which will be effective the next time the program source is compiled.

- To do this, select the "Additional settings" tab (Page 4633) in the Properties window of the program source.

Meanings of the warning classes

The table lists the warning classes and their meanings.

Table 7-365 Meanings of the warning classes

Warning class	Meaning
0	Warnings for unreferenced or unused code sections and data
1	Warnings for hidden identifiers
2	Warnings for data type conversion, e.g. for data change
3	Warnings about set compiler options
4	Warnings about semaphores (potentially faulty functions)
5	Warnings about alarm functions
6	Warnings about constructs in libraries (unit variables declared)
7	Messages of the preprocessor

For the detailed description of the compiler error messages, specify which warning classes are assigned to the individual warnings (Page 5058) and information (Page 5065).

Display of the compiler options

You can view for a program source the following:

- The current compiler options using the global or local settings of the compiler.
- The compiler options used for the last compilation of the program source.

Requirement

The Properties window of the program source (Page 4589) is open.

Procedure

To display the current compiler options using the global or local settings of the compiler (Page 4623):

- Select the **Additional settings** tab.
  The current compiler options for the program source are displayed. They are valid for a future compilation.

To display the compiler options used for the last compilation of the program source:

- Select the **Compiler** tab.
  The following are displayed for the last compilation of the program source:
  - The version of the used compiler.
  - The used compiler options.

Meaning of the compiler options

Compiler option	Meaning
-c[2]	Do not create debug and symbol information.
-C exclude	Exclude source from the compilation.
-C lang_enable_oop	"Permit object-oriented programming" active.
-C lang_disable_oop	"Permit object-oriented programming" inactive.
-C lang_enable_v3ext	"Permit language extensions IEC61131 3rd Edition" active.
-C lang_disable_V3ext	"Permit language extensions IEC61131 3rd Edition" inactive.
-C lang_ext	"Permit language extensions"[1] active.
-C lang_iec	"Permit language extensions" inactive.
-C opcsym	"Permit OPC-UA/-XML"[1] active.
-C no_opcsym	"Permit OPC-UA/-XML" inactive.
-C opcsym	"Use preprocessor"[1] active.
-C no_preproc	"Use preprocessor" inactive.
-C prog_once	"Only create program instance data once"[1] active.
-C prog_multi	"Only create program instance data once" inactive.
-C scan_twice	"Permit forward declarations"[1] active.
-C scan_once	"Permit forward declarations" inactive.
-D *text*	Preprocessor definition (Page 4635).
-e user[2]	Only global settings act.
-e local	"Do not recompile the source if global compiler settings have been changed"[1] active. Only local settings act. No details (default): "Do not recompile the source if global compiler settings have been changed" inactive. Global settings will be augmented with local settings.
-I[2]	Accept the package settings from device or library.
-l sel	"Selective linking"[1] active.
-l no_sel	"Selective linking" inactive.
-s	"Enable program status"[1] active.
-s_off	"Enable program status" inactive.
-w no_warn	"Suppress warnings"[1] active.
-w all_warn	Display all warnings.
-w *n*_off	Warning class *n* inactive[1].
-w *n*_on	Warning class *n* active[1].
Further options	Internal options of the SIMOTION compiler.

[1] Meaning of the compiler option: See "Local compiler settings" (Page 4626).
[2] Only when the compiler is called from the command line, e.g. using scripting.

Note

The compiler options can also be specified when the compiler is called from the command line, e.g. using scripting.

Know-how protection for ST source files

You can protect ST source files from access by unauthorized third parties. Protected ST source files can only be opened or exported as plain text files by entering a password.

The SIMOTION online help provides additional information on know-how protection.

Note

If you export in XML format, the ST source files are exported in an encrypted form. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

See also

Know-how protection for libraries (Page 4895)

Making preprocessor definitions

You can make definitions for the preprocessor (see Controlling the preprocessor (Page 4918)) in the Properties dialog box of the ST source file. This enables you to control the preprocessor for ST source files with know-how protection too (see Know-how protection for ST source files (Page 4635)).

Making preprocessor definitions in the Properties dialog box

1. Open the Properties window for the ST source file
   (see Changing the properties of an ST source file (Page 4589)):
   Select the ST source file in the project navigator, followed by the **Edit > Object properties** menu command.
2. Select the **Additional settings** tab.
3. Enter the preprocessor definitions (syntax as shown in the following table).
4. Confirm with **OK**.

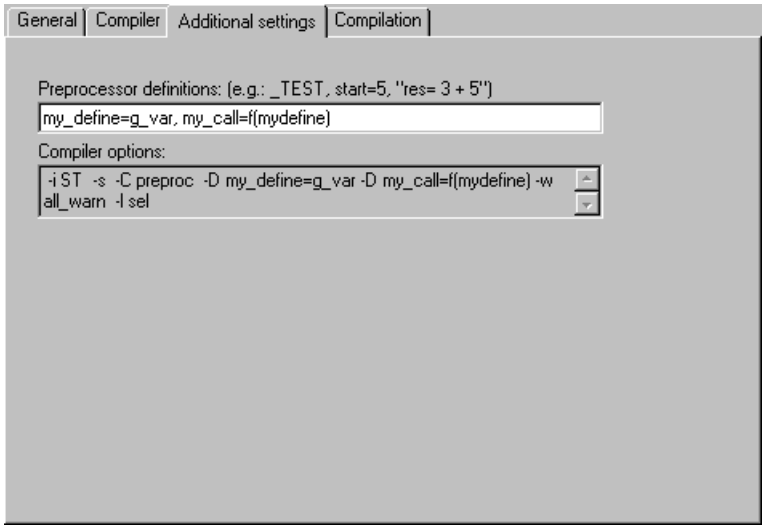

Figure 7-219 Preprocessor definitions

Table 7-366 Syntax of the preprocessor definitions

Syntax	Meaning
Identifier=text	The specified *identifier* is defined and replaced in the ST source file by the specified *text*. Permissible characters: See table footnote. If the expression contains blanks (e.g. in the text), the syntax *"Identifier=text"* must be used.
'Identifier=text'	
"Identifier=text"	
Identifier	The specified *identifier* is defined and replaced in the ST source file by blank text. Permissible characters: See table footnote.
Multiple preprocessor definitions are separated by commas: *Definition_1, Definition_2, ...* Permissible characters: • For *identifiers*: In accordance with the rules for identifiers: Series of letters (A ... Z, a ... z), digits (0 ... 9) or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters. • For *text*: Sequence of any characters other than \ (backslash), ' (single quote) and " (double quote). The keywords USES, USELIB and USEPACKAGE are not permitted.	

Note

Preprocessor definitions, which are made within an ST source file with pragmas, overwrite the definitions in the Properties dialog box.

Note the information relating to preprocessor statements (Page 4919).

Exporting, importing and printing an ST source file

An overview is provided here of the export, import and printing of an ST source file.

Exporting an ST source file as a text file (ASCII)

You can export an ST source file as a text file in ASCII format and then either reimport this file as an ST source file or edit it with any ASCII editor.

Procedure

To export an ST source file as an ASCII file:

1. Open the ST source file (Page 4588), entering the password if necessary (for ST source files with know-how protection (Page 4635)).
2. Make sure that the cursor is in the ST editor.
3. Select the **ST source file > Export** menu command.
4. Enter the path and file name for the ASCII file and click **Save** to confirm.

The ST source file is saved as an ASCII file; the file name is given the default extension *.st

Alternatively, you can also proceed as follows:

1. Select the ST source file in the project navigator.
2. Select **Export** from the context menu.
3. Only for ST source files with know-how protection (Page 4635) and which are not already open:
   If the user with the log-in details assigned to the ST source file has not yet logged in:
   - Enter the corresponding password for the displayed login.
     The know-how protection for this unit is temporarily canceled (for this export).
   - If required, activate the **Use login as a standard login** checkbox.
     You will be logged in with this login and can now export or open additional units to which the same login is assigned without having to re-enter the password.
4. Enter the path and file name for the ASCII file and click **Save** to confirm.

Note

Folding information (Page 4596) and bookmarks (Page 4607) are not exported.

An ST source file with know-how protection is exported without protection.

Exporting an ST source file in XML format

Follow these steps to export an ST source file in XML format:

1. Select the ST source file in the project navigator.
2. Select the context menu **Expert > Save project and export object**.
3. Specify the path for the XML export, and confirm with **OK**.

An XML file with the ST source file name and a folder with additional associated XML files are saved in the specified path.

Note

Know-how-protected ST source files can also be exported in XML format. The ST source files are exported encrypted. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

Folding information (Page 4596) and bookmarks (Page 4607) are not exported.

Importing a text file (ASCII) as an ST source file

To import an ASCII file as an ST source file:

1. Select the **PROGRAMS** folder under the appropriate SIMOTION device in the project navigator.
2. Select the menu **Insert > External source > ST source file**.
3. Select the ASCII file to be imported, and click **Open** to confirm.
   The dialog box for inserting an ST source file is displayed.
4. Enter the name of the ST source file and select the additional options (see Insert ST source file (Page 4587)).

The ASCII file is incorporated into the current project directory as an ST source file and can be opened.

Importing XML data into ST source files

Follow these steps to import XML data into an ST source file:

1. If applicable, insert a new ST source file (see Insert ST source file (Page 4587)).
2. Select the ST source file in the project navigator.
3. Select the context menu **Expert > Import object**.
4. Select the XML data to be imported.
   The imported XML data overwrites existing data in the selected ST source file. The entire project is saved and recompiled.

Alternative:

1. In the project navigator, select the **PROGRAMS** folder.
2. In the context menu, select **Import object**.
3. Select the XML data to be imported.
   A new ST source file is created, and the XML data is imported. This ST source file is assigned the name which is saved in the XML data; if a naming conflict occurs, it is automatically renamed. The entire project is saved and recompiled.

Note

Note that if the XML data to be imported was exported from an ST source file that was know-how protected: When importing the encrypted XML data, the know-how protection, including login and password, is retained.

Printing an ST source file

To print an ST source file:

1. Open the ST source file.
2. Make sure that the cursor is in the ST editor.
3. Select the menu **Project > Print**.

The program is printed with the name and date.

Using an external editor

What external editors can be used?

As an alternative to the default ST editor, you can use any other ASCII editor that supports the following function:

- External programs (for example, compiler) can be called and run on the active window.

In addition, the editor should be capable of highlighting certain text passages of the ST source file in color (syntax coloring).

Note

If you use an external editor, the dynamic ST source file menu and its entries are not available. The corresponding toolbar is also inactive.

It must be possible to start compilation of the ST source file from the external editor.

Program status (Page 4951) continues with the ST editor.

Settings for the use of an external editor

The settings are made in the SCOUT workbench:

1. Select the menu **Options > Settings**.
2. Select the **ST external editor** tab (see figure).
3. Activate the **Use external ST editor** checkbox.
4. Enter the path of the external editor:
   – Click **Browse...** and select the path and file name of the editor.

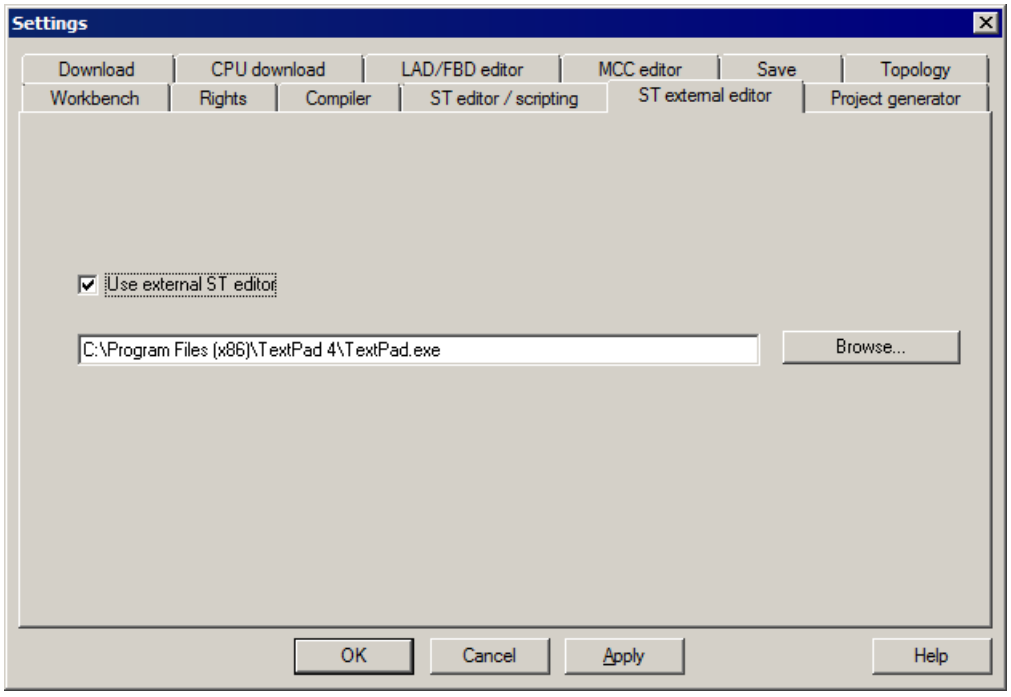

Figure 7-220 Settings for the use of an external editor

Making settings in the external editor

The following notes are of a general nature. Compare the operator instructions of the external editor.

1. Configure the path to the ST compiler in the external editor. The compiler is located in the STEP7 installation directory s7bin\u7wstcax.exe.
2. Syntax files are supplied for various editors. These enable the editor to highlight text passages in color (syntax coloring). Copy the syntax file to the relevant directory and configure the editor accordingly.

Note the following when using an external editor:

NOTICE
Data loss possible If you close a project or exit SIMOTION SCOUT before all windows of the external editor have been closed, data can be lost! Close all windows of the external editor before you close a project or exit SIMOTION SCOUT.

ST source file menus

ST source file menu

Depending on the active application/editor or the mode (ONLINE/OFFLINE), certain commands are not displayed or cannot be selected. The menu is only displayed if the ST editor is active in the working area.

You can select the following functions:

Table 7-367 ST Source File Menu

Function	Meaning/information
Close	Select this command to close the active ST source file. In the event of changes, you can decide whether you want to transfer the changed source file to the project and whether the changes should be saved in the snippet editor.
Properties	Select this command to display the properties of the active ST source file. Several tabs are provided to make local settings for this source. See: Changing the properties of an ST source file (Page 4589).
Accept and compile	Choose this command to transfer the current ST source file to the project and compile into executable code. See: Starting the compiler (Page 4622).
Execute preprocessor	As an option, the preprocessor scans an ST source file before compiling and can, for example, replace character strings in the file, which will then be taken into account during the compilation. You can specifically execute the preprocessor statements with this menu command.
Export	Select this command to export the active ST source file as text file (ASCII). See: Exporting an ST source file as a text file (ASCII) (Page 4637).
Split window	Select this command to split the active window of the ST editor into two segments horizontally, giving you two views of the same ST source file. See: Splitting the editor window (Page 4600).
Program status on/off	Select this command to start the **program status** test mode. During the program execution, you can monitor the values of the variables marked in the ST source. The following prerequisites are necessary: 1. The program must be compiled with the appropriate compiler option. 2. The project and the program must be loaded into the target system. 3. An online connection to the target system must have been established. Select the command again to close the **program status**. See: Using the program status (Page 4951).
Save variables	You can save retain, unit and global variables with this menu command. You can save these variables from the RAM/ROM memory of the target device and store them on a data medium as XML file. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device.
Restore variables	You can restore retain, unit and global variables from the previously exported variables with this menu command. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device.

ST source file context menu

The ST source file context menu is shown if you select an ST source file in the project navigator and then right-click it.

Depending on the active application/editor or the mode (ONLINE/OFFLINE), certain commands are not displayed or cannot be selected.

You can select the following functions:

Table 7-368 ST source file context menu

Function		Meaning/information
Open		Select this command to open the selected ST source file. See: Opening an existing ST source file (Page 4588).
Cut		The selected ST source files are deleted and saved on the clipboard.
Copy		The selected ST source files are copied to the clipboard.
Paste		The contents of the clipboard are inserted in the selected folder.
Delete		The selected ST source file is deleted, including all the data.
Rename		Select this command in order to change the name of the selected ST source file. Please note that with name changes, it is not possible to change the referencing to this name and that the new name must comply with the Rules for identifiers (Page 4656).
Save variables		You can save retain, unit and global variables with this menu command. You can save these variables from the RAM/ROM memory of the target device and store them on a data medium as XML file. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device.
Restore variables		You can restore retain, unit and global variables from the previously exported variables with this menu command. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device.
Expert		
	Import object	Select this command to import XML data to the selected ST source file from an ST source file which you have previously exported to another project. The existing data in the ST source file being imported is overwritten. See: Importing XML data into an ST source file (Page 4638).
	Save project and export object	Select this command to export the selected ST source file in XML format. You can import the exported data into other projects. See: Exporting an ST source file in XML format (Page 4637).
Accept and compile		Choose this command to transfer the current ST source file to the project and compile into executable code. See: Starting the compiler (Page 4622).
Execute preprocessor		As an option, the preprocessor scans an ST source file before compiling and can, for example, replace character strings in the file, which will then be taken into account during the compilation. You can specifically execute the preprocessor statements with this menu command.

Function	Meaning/information
Program status on/off	Select this command to start the **program status** test mode. During the program execution, you can monitor the values of the variables marked in the ST source file. The following requirements are necessary: 1. The program must be compiled with the appropriate compiler option. 2. The project and the program must be loaded into the target system. 3. An online connection to the target system must have been established. Select the command again to close the **program status**. See: Using the program status (Page 4951).
Export	Select this command to export the selected ST source file as a text file (ASCII). See: Exporting an ST source file as a text file (ASCII) (Page 4637).
Know-how protection	
Set	Select this command to protect the selected ST source file from unauthorized access by third parties. Protected ST source files can only be opened or exported as plain text files by entering a password. See: Know-how protection for ST source files (Page 4635).
Delete	Select this command to cancel the know-how protection for the selected source file permanently. The password needs to be entered in order to do this. See: Know-how protection for ST source files (Page 4635).
Display reference data	An error-free compilation is required for a correct, consistent display of the reference data. If required, compile the project, the CPU, the program or the library first. See: Reference data (Page 4910), creating a cross-reference list (Page 4910).
Cross references	The cross-reference list of the selected ST source file is generated and displayed. The cross-reference list contains the declaration and uses all the identifiers for the selected ST source file. See: Content of the cross-reference list (Page 4911).
Program structure	The program structure of the selected ST source file is generated and displayed. The program structure contains all the subprogram calls and their nesting within the selected ST source file. See: Content of the program structure (Page 4914).
Code attributes	The code attributes of the selected ST source file are generated and displayed. The code attributes contain information about the storage requirements of various data areas of the selected ST source file. See: Code attribute contents (Page 4916).
Print	Select this command to print the selected ST source file. You can choose whether you wish to print the text of the ST source file and/or their properties.
Print preview	Choose this command to generate a preview of the expected print output.
Properties	Select this command to display the properties of the selected ST source file. Several tabs are provided to make local settings for this source file. See: Changing the properties of an ST source file (Page 4589).

7.2.3.4 Creating a sample program

In this section, we create a short program to illustrate the steps involved, including starting and testing. Testing is described in Program test (Page 4934).

Function

The *Flash* program sets a bit in an output byte of your target system and rotates it within this byte. This causes each bit of the output byte to be set and reset in succession. After the last bit of the byte, the first bit is to be set again. You can observe the result of the program at the outputs of your target system.

Requirements

To create the sample program, you need

- A SIMOTION project and
- A SIMOTION device (e.g. SIMOTION C240) within the project whose output is configured at address 62.

Opening or creating a project

Projects contain all the information about the hardware and configuration. This includes the programs you use to control the hardware.

Proceed as follows

If a project does not yet exist, proceed as follows:

1. Select **Project** in the menu bar.
2. Select **New** or **Open**.
3. Specify a name for a new project, and click **OK** to confirm.

For details, see the online help.

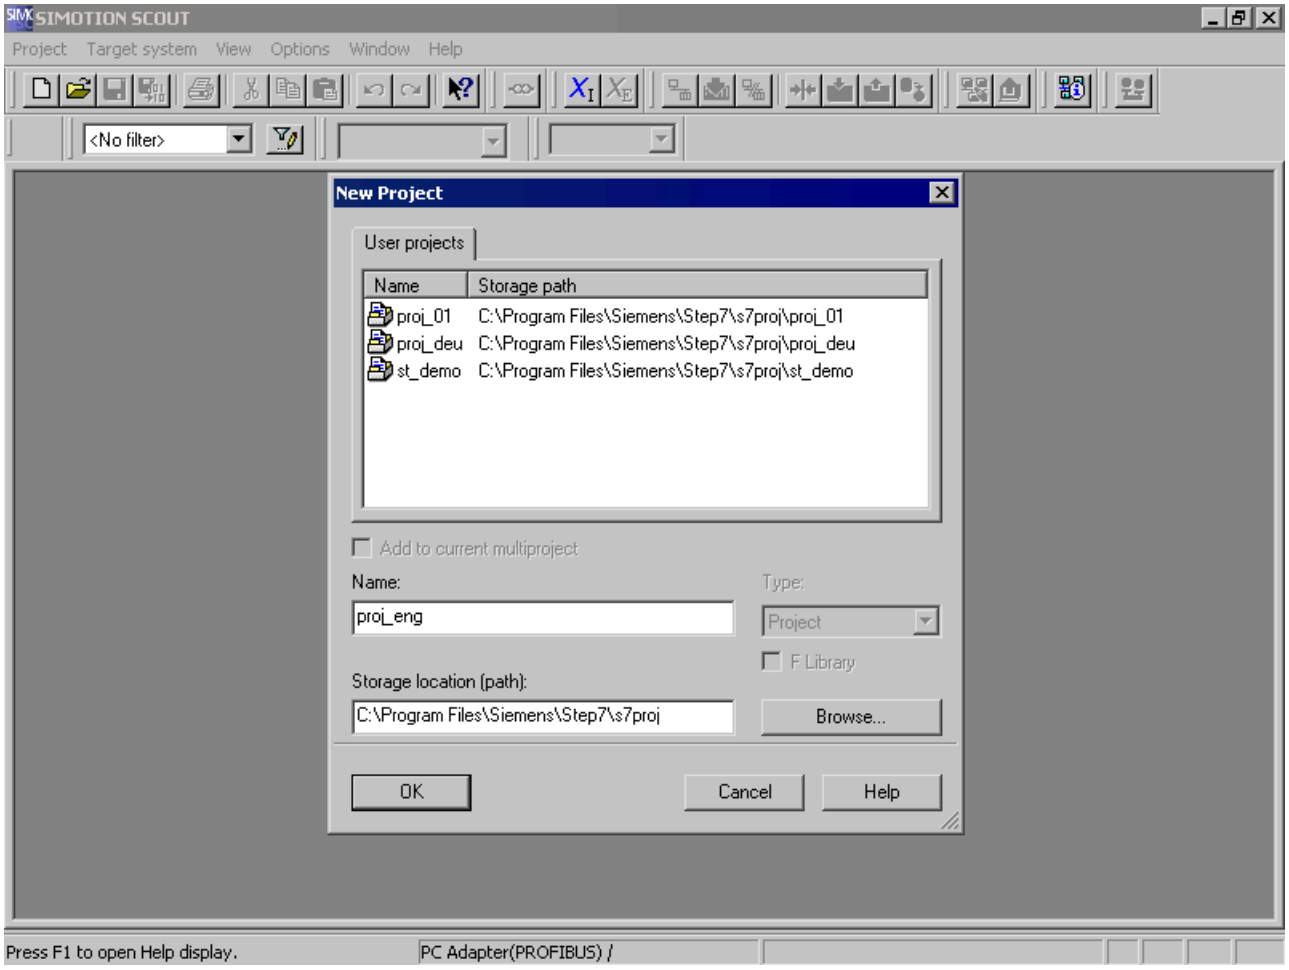

Figure 7-221 Creating a new project

Making the hardware known

The steps are as follows:

1. Create and configure a new SIMOTION device (e.g. C240 V4.2).
2. Configure an output in HW Config at Address 62.

For more details on steps 1 and 2, refer to the online help.

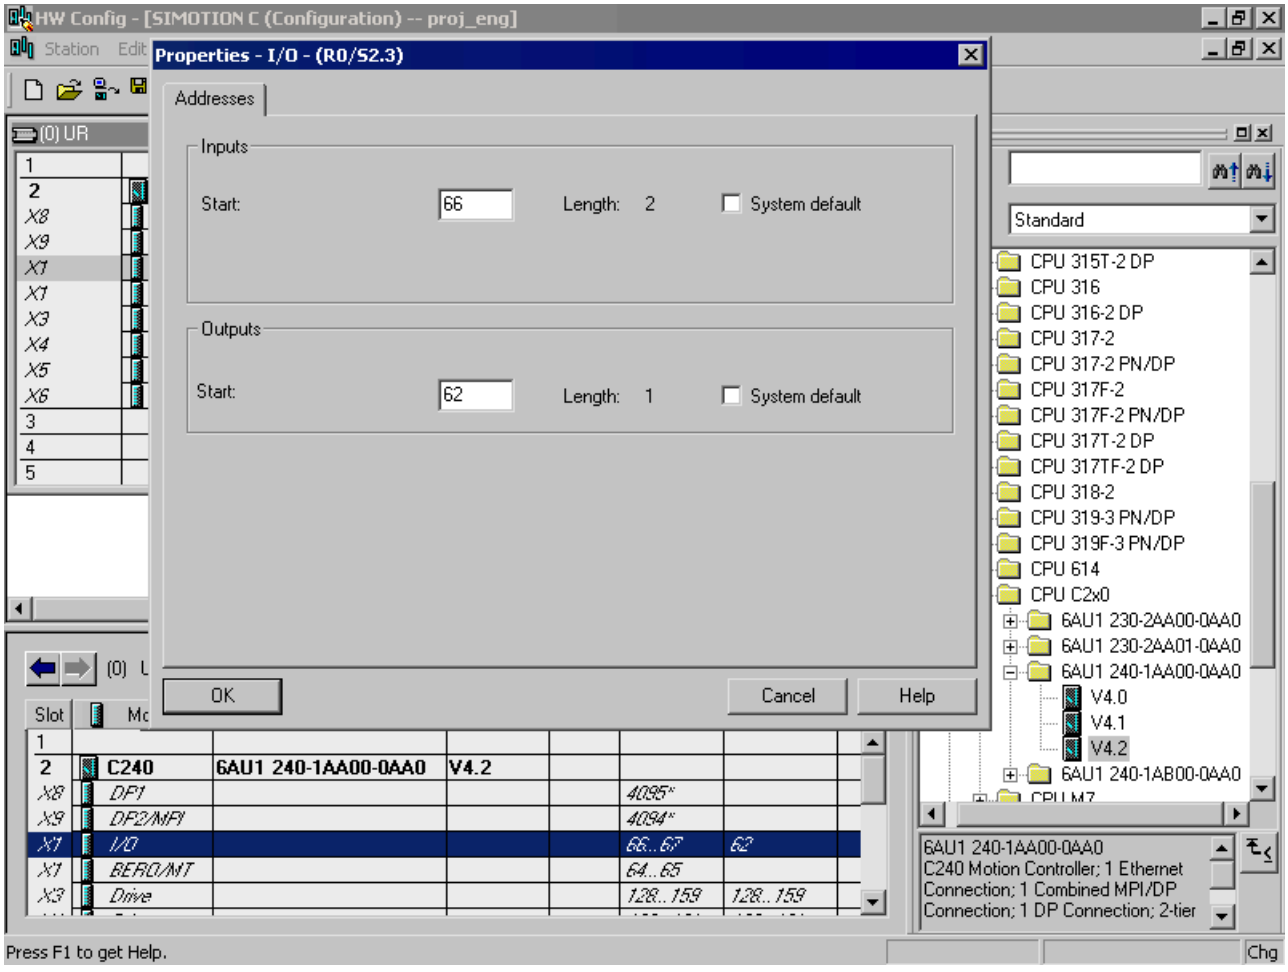

Figure 7-222 Change in HW Config

Entering source text with the ST editor

Proceed as follows

1. In the project navigator, open the tree for your SIMOTION device (programs are assigned to the SIMOTION device on which they are to run).
2. Select the **PROGRAMS** folder and choose **Insert > Program > ST source file**.
3. Enter a name for the ST source file consisting of up to 128 characters (see figure), e.g. **ST_1**, and click **OK** to confirm the entries.
   The ST editor appears in the working area. The ST source file **ST_1** is inserted in the navigator.
4. Enter the source text from Source text of the sample program (Page 4648), preferably with indented lines. To do this, press the TAB key.
   The features of the ST editor are described in Working with the ST editor (Page 4591); the structure of an ST source file is described in detail in Structure of the ST source file (Page 4668) and in Source file sections (Page 4806).

5. Use comments as often as possible. Enter your comment after the **//** characters if the comment fits on one line of text. If the comment extends across several lines, insert it between character pairs (* and *).
6. Save the complete project with **Project > Save**.

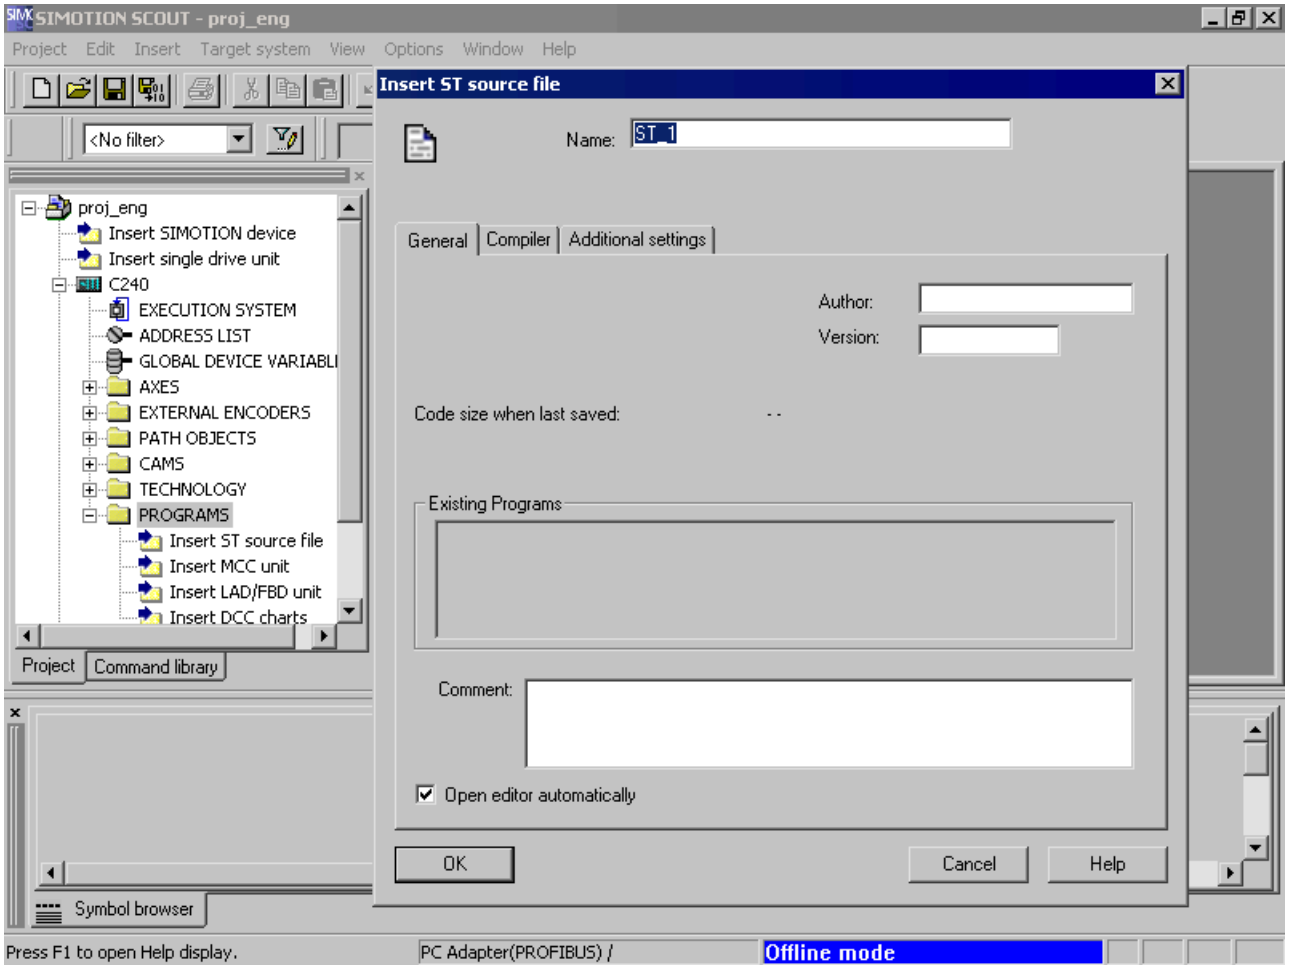

Figure 7-223 Naming the ST source file

Functions of the editor

In addition to simple text input, the ST editor provides the following advanced/convenience functions for documenting the functionality of your source text:

- Standard Windows user features (for example, Undo with Ctrl+Z or Redo with Ctrl+Y)
- Syntax coloring (different colors for different language elements)
- Source file printout in an appropriate layout with page number, source file name and printing date
- Export/import of the source file
- Source file archiving (via the project)

A detailed description of the functions is contained in Working with the ST editor (Page 4591) and in Making settings for the compiler (Page 4623).

Source text of the sample program

The table shows the source code of the sample program. You need to enter it in the same way to create executable code.

Table 7-369 Flash sample program

```
INTERFACE
    VAR_GLOBAL
        counterVar : INT  := 1; // counter variable
        outputVar  : BYTE := 1; // auxiliary tag
    END_VAR
    PROGRAM Flash;
END_INTERFACE

IMPLEMENTATION
    PROGRAM Flash
        IF counterVar >= 500 THEN // in every 500th pass
            %QB62 := outputVar;   // set output byte
            outputVar := ROL (in := outputVar, n := 1);
            (* // rotate bit in byte
              one digit to the left*)
            counterVar := 0; // reset counter
        END_IF;
        counterVar := counterVar + 1; // increment counter
    END_PROGRAM
END_IMPLEMENTATION
```

Compiling a sample program

Before you can run or test your program, you must compile it into executable machine code. The compiler performs this task.

Starting the compiler

Before you can run or test your program, you must compile it into executable machine code. The ST compiler performs this task.

Start the compiler as follows:

1. Click in the window with the ST editor to display the **ST source file** menu. This menu is a dynamic menu and is only displayed if the window of the ST editor is active.
2. Start the compiler by selecting the **ST source file > Accept and compile** menu command.

Correcting errors

The compiler checks the syntax of the ST source file. The **Compile/check output** tab of the detail view displays the successful compilation of the source text or compiler errors. The error details include: Name of the ST source file, the line number where the error occurred, the error number and an error description.

Proceed as follows to correct an error in the sample program:

1. Double-click the error message. The cursor is placed at the relevant line in the ST source file. See Example for error messages (Page 4649).
2. Start debugging the first error.
3. Start the compilation operation again.
4. Repeat the entire operation until no more errors are displayed (**0 errors**).

After a successful compilation, you will have created an application program with the name **flash**. This program is displayed in the project navigator below the **ST_1** program source file.

Example of error messages

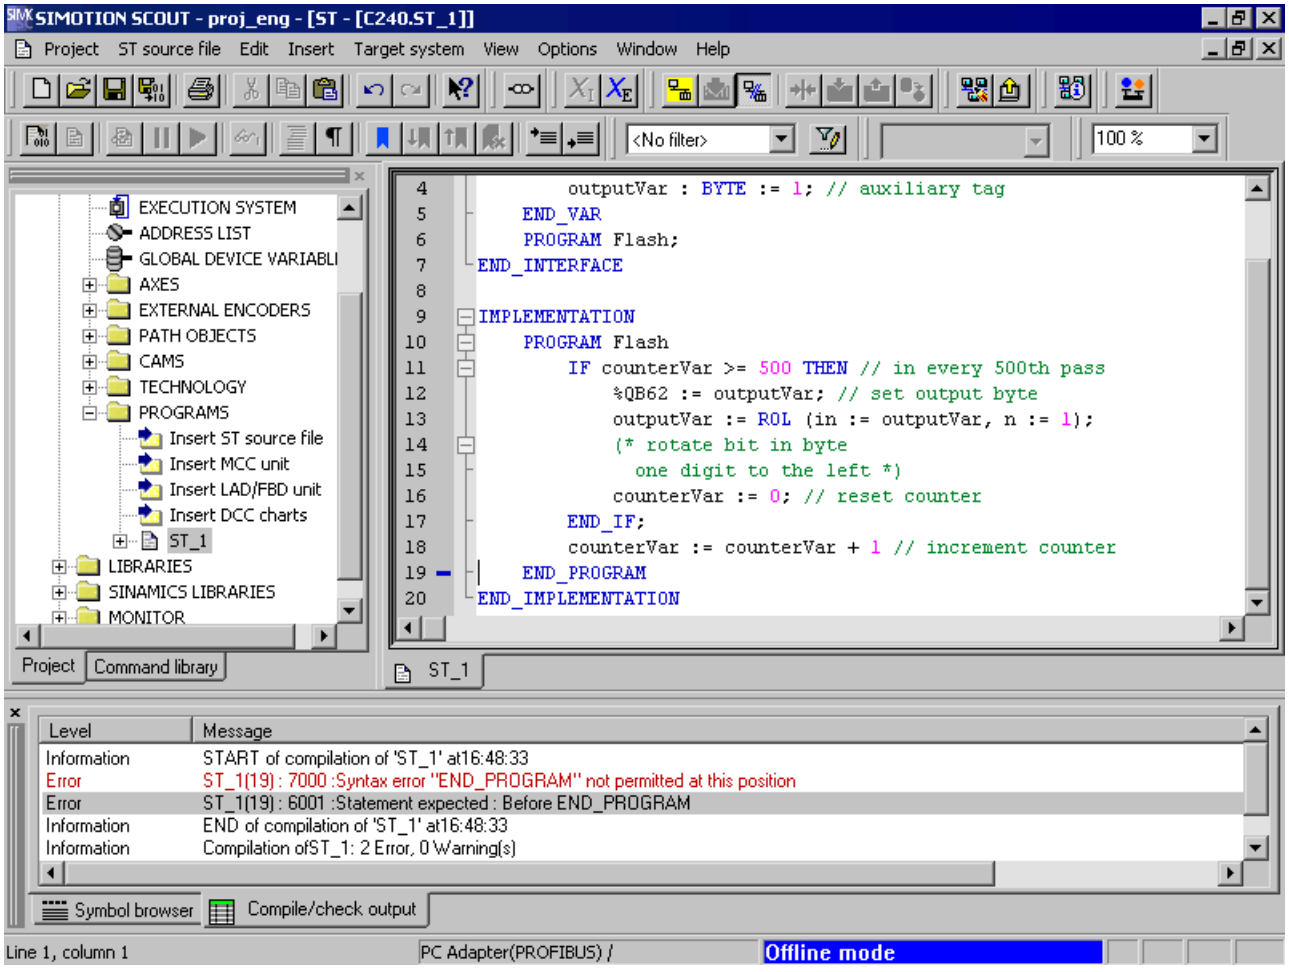

Figure 7-224 Error messages during ST source file compilation

The figure shows an example of compiling the ST source file ST_1 (see Source text of the sample program (Page 4648), in which the following change has been made: The semicolon is missing in the statement "counterVar := counterVar + 1" at the end of line 18.

The compiler does not detect the error until Line19, because it continues with the compilation after the missing semicolon.

Once the missing semicolon is added, the ST source file is compiled without errors.

A detailed list of all compiler error messages can be found in Compiler error messages and their correction (Page 5040).

Running the sample program

Before you can run the program, you must assign it to an execution level or task. When you have done this, you can establish the connection to the target system, download the program to the target system and then start it.

Assigning a sample program to an execution level

The execution levels specify the order in which the programs run. Each execution level contains one or more tasks to which you can assign programs.

The assignment of a program to a task can only be performed after compilation and before the program is loaded onto the target system.

Assign the sample program to the *BackgroundTask*. The *BackgroundTask* is provided for the programming of cyclic sequences without a fixed time frame. It is executed cyclically in the round robin execution level, which means it will be automatically restarted on completion.

How to assign the sample program to the *BackgroundTask*:

1. When you double-click the **Execution system** element in the project navigator, the window containing the execution system and the program assignment appears in the working area.
2. Click **BackgroundTask** to select it for the program assignment.
   The program assignment on the left side of the window shows you all the compiled programs that can be assigned to tasks.
3. In the **Programs** list, click sample program **ST_1.flash**. Then, click the **>>** button to assign the program to the BackgroundTask.
   The result is shown in the following figure. The program **ST_1.flash** is displayed in the **Programs used** list box.

For more information on the execution system and assignment of programs to tasks, see *SIMOTION Motion Control Basic Functions* Function Description.

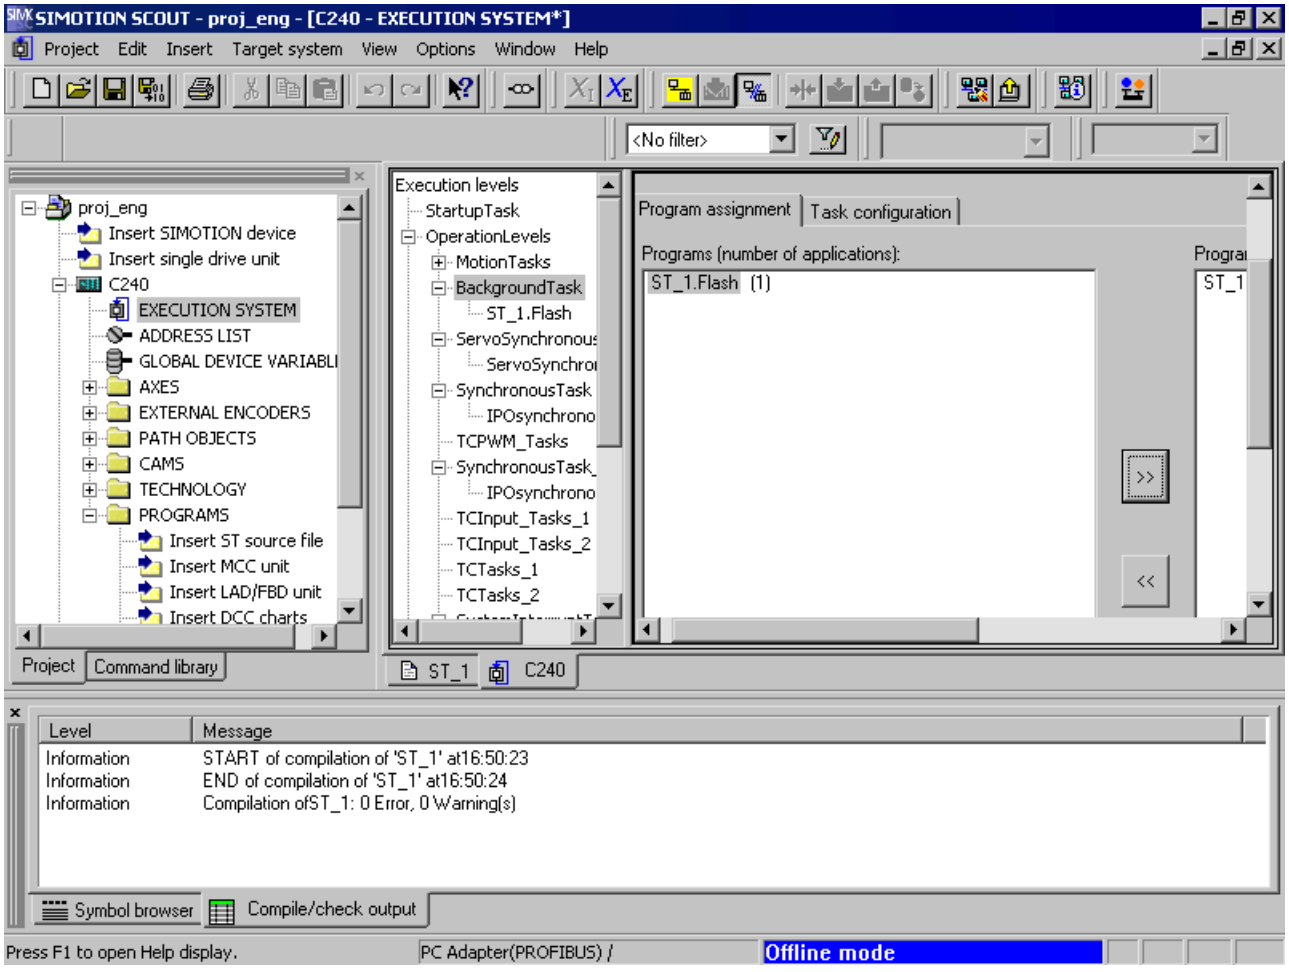

Figure 7-225 Assigning the sample program to the BackgroundTask

Establishing a connection to the target system

Before a connection to the target system can be set up, the PC interface card must be configured and connected to the target system.

Proceed as follows to connect to the target system:

1. Select the **Project > Connect to selected target devices** menu command.
   The **Diagnostics overview** tab is opened in the detail view. The diagnostics overview shows you the operating state, memory allocation and CPU utilization for the device you are connected to. You can see at the lower right edge of the screen that you are connected to the target system.

Note

For more detailed information, refer to the SIMOTION SCOUT Configuration Manual and SIMOTION SCOUT online help.

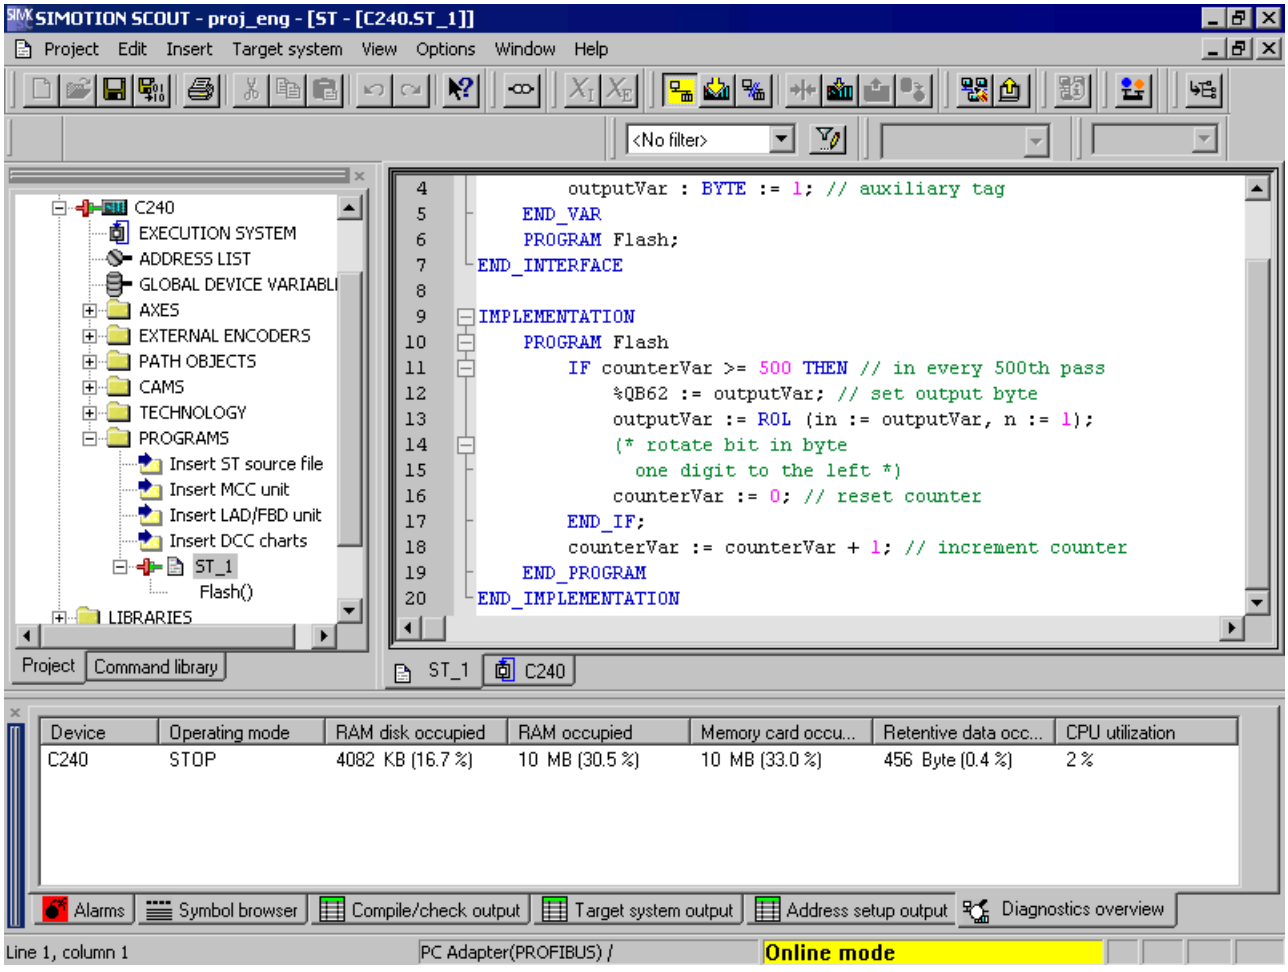

Figure 7-226 Establishing a connection to the target system

Downloading the sample program to the target system

Proceed as follows to download the sample program to the target system:

1. Switch the target system to **STOP**.
2. Select the **Target system > Download > Download project to target system** menu command.
3. Confirm all further queries.

The Target system output window in the detail view opens and displays the result of the download.

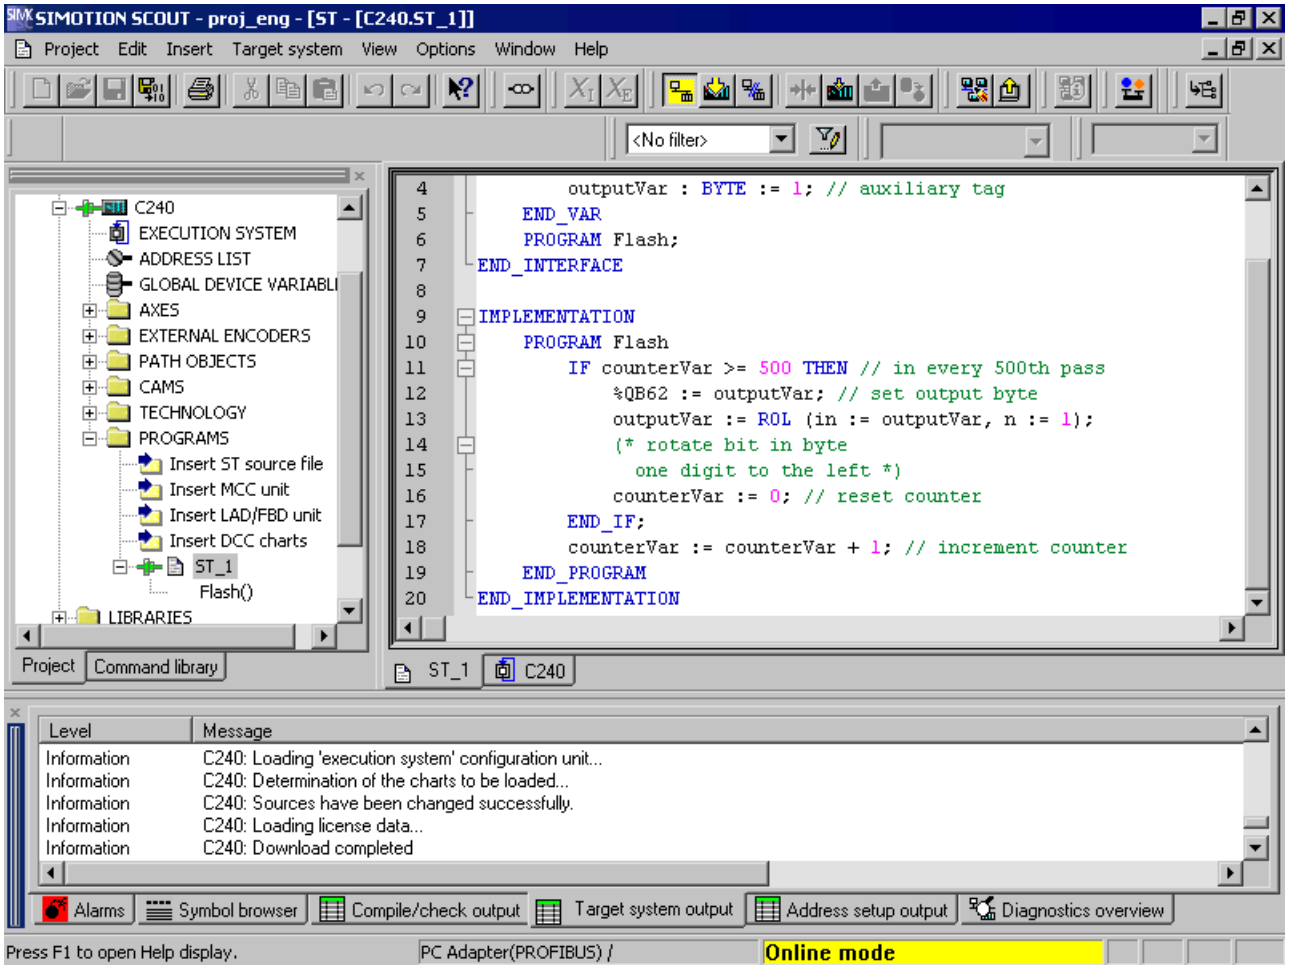

Figure 7-227 Downloading the sample program to the target system

Starting and testing the sample program

Starting sample program

Proceed as follows to start the sample program:

- Switch your target system to RUN (see hardware description).

The lamps flash in sequence at the outputs of your target system.

Testing a sample program

See Program test (Page 4934).

7.2.4 ST Fundamentals

This section describes the language resources available in ST and how to use them. Please note that functions, function blocks and the task control system are described in the following chapters. For a complete formal language description containing all the syntax diagrams, see Appendix Rules (Page 4988).

7.2.4.1 Language description resources

Syntax diagrams are used as a basis for the language description in the following sections of the manual. They provide you with an invaluable insight into the syntactic (i.e. grammatical) structure of ST.

Syntax diagram

The syntax diagram is a graphical representation of the language structure. The structure is described by a sequence of rules. A rule can build on existing rules.

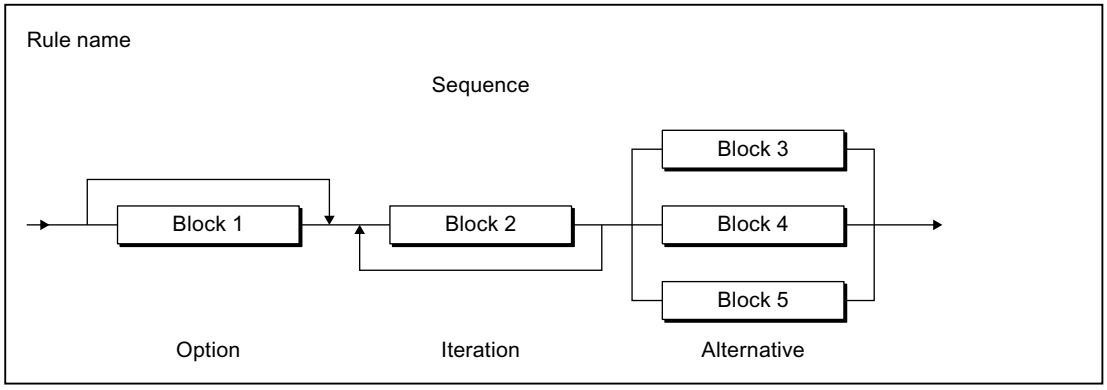

Figure 7-228 Syntax diagram

The syntax diagram in the previous figure is read from left to right. The following rule structures must be observed:

- Sequence: Sequence of blocks
- Option: Statement(s) that can be skipped
- Iteration: Repetition of one or more statements
- Alternative: Branch

Blocks in syntax diagrams

A block is a basic element or an element that is itself composed of blocks. The figure shows the symbol types used to represent the blocks:

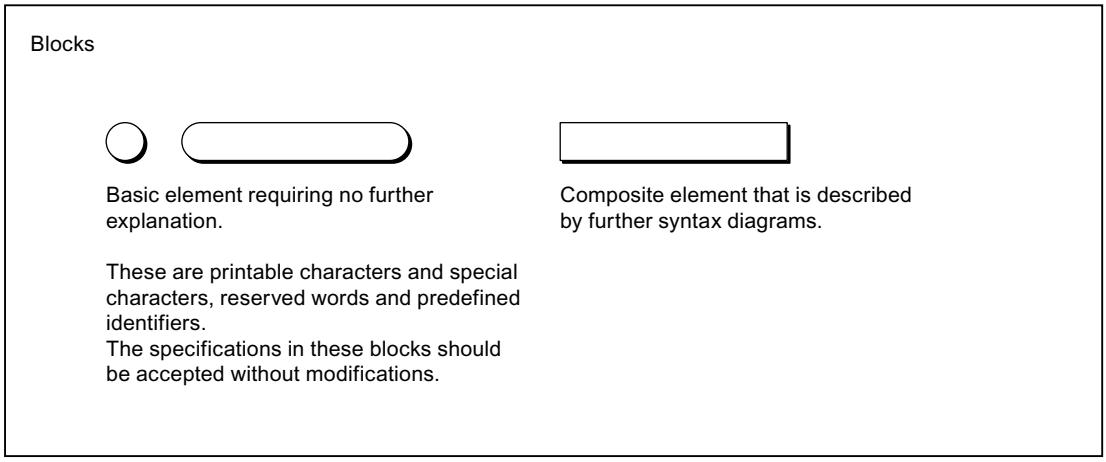

Figure 7-229 Blocks

Formatted and unformatted rules must be observed when entering source text, i.e. when converting the blocks or elements of a syntax diagram into source text, see Help for the language description (Page 4973).

Meaning of the rules (semantics)

Only the formal structure of the language can be represented in the rules. The meaning (i.e. semantics) is not always apparent. For this reason, additional information is written beside the rules if the meaning is critical. Examples include:

- Where elements of the same kind have a different meaning, an additional name is appended. For example, an addition is specified in the *date* rule for every *decimal digit string* element – either *year, month* or *day*, see Literals (Page 4989). The name indicates the usage.
- Important restrictions are noted next to the rules. For example, in the *integer* rule for - (minus), it is noted that the minus can appear only in front of decimal digit strings of data types SINT, INT, and DINT, see Literals (Page 4989).

7.2.4.2 Basic elements of the language

The basic elements of the ST language include the ST character set, reserved identifiers constructed from the ST character set (e.g. language commands), self-defined identifiers and numbers.

The ST character set and the reserved identifiers are basic elements (terminals) as they are described verbally and not by another rule. Self-defined identifiers and numbers are not terminals as they are described by other rules.

In the syntax diagrams, terminals are represented by circles or oval symbols, while composite elements are represented by rectangles, see Blocks in syntax diagrams (Page 4655). Below is a selection of the main terminals; for a complete overview, refer to Basic elements (terminals) (Page 4975).

ST character set

ST uses the following **letters and digits** from the ASCII character set:

- The lower and upper case letters from A to Z
- The Arabic digits from 0 to 9

Letters and digits are the most commonly used characters. For example, identifiers (see Identifiers in ST (Page 4656)) consist of a combination of letters, digits and the underscore. The underscore is one of the special characters.

Special characters have a fixed meaning in ST, see Basic elements (terminals) (Page 4975).

Identifiers in ST

Identifiers are names in ST. These names can be defined by the system, such as language commands. However, the names can also be user-defined, for example, for a constant, variable or function.

Rules for identifiers

Valid identifiers

Identifiers are made up of letters (A ... Z, a ... z), numbers (0 ... 9) or single underscores (_) in any order, whereby the first character must be a letter or underscore.

No distinction is made between upper and lower case letters (e.g. Anna and AnNa are considered to be identical by the compiler).

An identifier can by represented formally by the following syntax diagram:

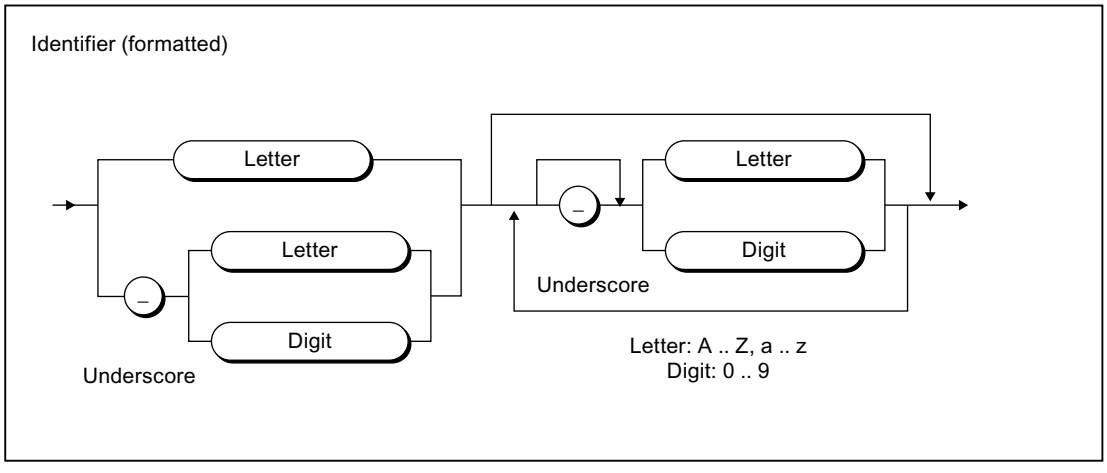

Figure 7-230 Syntax: Identifier

According to this syntax diagram, the first character of an identifier must be a letter or an underscore. An underscore must be followed by a letter or number, i.e. more than one underscore in succession is not allowed. This can be followed by any number or sequence of underscores, letters or numbers. The only exception here again is that two underscores may not appear together.

Permissible identifiers, which you can define (user-defined identifiers)

Identifiers which you define yourself, e.g. in variables declarations, data type declarations, and function names, must not be the same as reserved identifiers (Page 4657). When assigning a name, it is best to choose a unique, meaningful name that contributes to the clarity of the program.

Examples of identifiers

Examples of valid identifiers

The following names are valid identifiers:

```
x           y12         sum         temperature    P_CONTROLLER
name        area        myFB        table
```

Examples of invalid identifiers

The following names are **not** valid identifiers:

Invalid identifier	Reason
`4ter`	The first character must be a letter or underscore.
`*#AB`	Special characters (except underscores) are not permitted.
`RR__20`	Two underscores in succession are not permitted.
`S value`	Blank spaces are not permitted as they are special characters.
`Array`	ARRAY, REAL, and _sizeOf are valid identifiers from a technical point of view, but they are also reserved identifiers (Page 4657), i.e. they may only be used as predefined. This means you cannot use this name for your own purposes, for example, for a variable.
`REAL`	
`_sizeOf`	

Reserved identifiers

Reserved identifiers may only be used as predefined. You may not declare a variable or data type, for example, with the name of a reserved identifier.

There is no distinction between upper and lower case notation.

- Protected identifiers in the ST programming language (Page 4658)
- Reserved identifiers in the ST programming language (Page 4663)
- Other reserved identifiers (Page 4664), such as standard functions, system functions, system variables

A list of all identifiers with a predefined meaning can be found in the SIMOTION Basic Functions Function Manual.

Protected identifiers in the ST programming language

The protected identifiers of the ST language are listed in the table. They can only be used as predefined. A brief explanation can be found in the Appendix, under Reserved words (Page 4979). The associated syntax diagrams (Page 4654) can be found in the Appendix, under Rules (Page 4988).

Additional reserved identifiers

User definitions must avoid not only protected identifiers (Page 4658) and reserved identifiers (Page 4663) of the ST programming language, but also identifiers which have a defined meaning in SIMOTION or which are intended for future expansions.

Identifiers with a defined meaning in SIMOTION

Do not declare any identifiers (in variables declarations or data type declarations, for example) which are already defined in SIMOTION. If you do, your declarations can hide the identifiers defined in SIMOTION, which may make it impossible to access them. Under certain circumstances, the compiler may not be able to issue a corresponding warning if, for example, the associated technology package is not imported.

The following are defined as identifiers in SIMOTION:

- General standard functions including the associated data types
  (see also the SIMOTION Basic Functions Function Manual)
- General standard function blocks including the associated data types
  (see also the SIMOTION Basic Functions Function Manual)
- Functions for task control, runtime measurement, and message programming including the associated data types
  (see also the SIMOTION Basic Functions Function Manual)
- System functions and system variables of SIMOTION devices including the associated data types
  (see also the list manuals of the SIMOTION devices)
- System functions, system variables, and configuration data of technology objects including the associated data types
  (see also the list manuals of the technology packages)
- Protected and reserved identifiers of other programming languages

A list of all identifiers with a defined meaning can be found in the SIMOTION Basic Functions Function Manual.

Identifiers which are intended for future SIMOTION expansions

Avoid user-defined identifiers which are intended for future SIMOTION expansions. This is a precaution to ensure that your user-defined identifiers will not hide any identifiers defined in future versions of SIMOTION.

In particular, all identifiers starting with the following character strings are intended for future SIMOTION expansions:

- _ (underscore)
- **Command**
- **Enum**
- **Struct**

If you declare an identifier that starts with one of these character strings, a corresponding warning (e.g. warning number 16026) is issued.

Numbers and Boolean values

Numbers can be written in various ways in ST. A number can contain a sign, a decimal point or an exponent. The following rules apply to all numbers:

- Commas and blanks may not appear within a number.
- An underscore (_) is allowed as a visual separator.
- The number can be preceded by a plus (+) or minus (–). If no sign is used, it is assumed that the number is positive.
- Numbers may not violate certain maximum and minimum values.

Integers

An integer contains neither a decimal point nor an exponent. An integer is thus a sequence of numeric digits that can be preceded with a sign.

The following are valid integers:

```
0                1               +1              -1
743              -5280           60_000          -32_211_321
```

The following integers are **invalid** for the reasons indicated:

`123.456`	Commas are not permitted.
`36.`	An integer may not contain a decimal point.
`10 20 30`	Blanks are not permitted.

In ST, you can represent integers in different number systems. This is achieved by inserting a keyword prefix for the number system.

The following are used:

- 2# for the binary system
- 8# for the octal system
- 16# for the hexadecimal system.

Valid representations of the decimal number 15 are:

```
2#1111          8#17          16#F
```

Floating-point numbers

A floating-point number can contain a decimal point or an exponent (or both). A decimal point must appear between two digits. A floating-point number therefore cannot start or end with a decimal point.

The following are valid floating-point numbers:

```
0.0             1.3           -0.2          827,602
0000.0          +0.000743     60_000.15     -315.0066
```

The following floating-point numbers are **invalid**:

`1.`	A numeric digit must be present before the decimal point and after the decimal point.
`1,000.0`	Commas are not permitted.
`1,333,333`	Two points are not permitted.

Exponents

An exponent can be included to define the position of the decimal point. If no decimal point appears, it is assumed that it is on the right side of the digit. The exponent itself must be either a positive or negative integer. Base 10 is expressed by the letter E.

The magnitude 3×10^8 can be represented in ST by the following correct floating-point numbers:

```
3.0E+8          3.0E8          3e+8          3E8          0.3E+9
0.3e9           30.0E+7        30e7
```

The following floating-point numbers are **invalid**:

`3.E+8`	A numeric digit must be present before the decimal point and after the decimal point.
`8e2.3`	The exponent must be an integer.
`.333e-3`	A numeric digit must be present before the decimal point and after the decimal point.
`30 E8`	Blanks are not permitted.

Boolean values

Boolean values are bit constants. They must be represented by a value of zero (0) or one (1) or by the keywords FALSE or TRUE.

Example:

```
a := 1;         // corresponds to a := TRUE
b := FALSE;     // corresponds to b := 0
```

Data types of numbers

The compiler automatically selects the elementary data type that is suitable for the number depending on its value and use (in an expression or a value assignment).

You can also specify the data type directly: Place the data type (numeric data type or bit data type) and the character "#" in front of the number.

Examples:

```
INT#255                 INT#16#FF               INT#8#377
WORD#255                WORD#16#FF              WORD#8#377
REAL#255                REAL#16#FF              REAL#8#377
REAL#255.0              REAL#2.55E2             LREAL#255.0
```

Note

Floating-point numbers can only be assigned to data types REAL and LREAL.

Character strings

What is a character string?

A character string is a sequence of 0 or more characters with an apostrophe at the start and at the end. Each character is encoded with 1 byte (8 bits) in the string.

A character can be entered as follows:

- As printable characters (ASCII code $20 to $7E, $80 to $FF), except the dollar signs (ASCII code $24) and apostrophe (ASCII code $27), as these have a special function within the string
- As the two-digit hexadecimal ASCII code of the relevant character preceded by the dollar sign ($)
- As a combination of two characters according to the following table:

Table 7-372 Two-character combinations for special characters in strings

Character combination			Meaning
$$			Dollar sign $ ($24)
$'			Apostrophe ' ($27)
$L	or	$l	Line Feed LF ($0A)

Character combination			Meaning
$N	or	$n	Carriage Return + Line Feed CR + LF ($0D$0A)
$P	or	$p	Form Feed FF ($0C)
$R	or	$r	Carriage Return CR ($0D)
$T	or	$t	Horizontal tab (HT) ($09)

Examples:

''	Empty string (length 0).
'A'	String of length 1 containing the letter A.
' '	String of length 1 containing a blank.
'$''	String of length 1 containing an apostrophe.
'RL' '$0D$0A'	Two equivalent representations for a string of length 2 containing the characters CR and LF.
'$$1.00'	String of length 5 containing $1.00.
'Text$R$L'	String of length 6 containing the word Text followed by the characters CR and LF.
'ÄÖÜ' '$C4$D6$FC'	Two equivalent representations for a string of length 3 containing the German umlauts ÄÖü (A, O, u with diaresis).

7.2.4.3 Structure of an ST source file

An ST source basically consists of continuous text. This text can be structured by dividing it into logical sections. Detailed rules for this can be found in Source file modules (Page 4806).

A brief summary is given below:

- An **ST source file** is a logical unit that you create in your project and that can appear several times. It is often referred to as a unit.
- The logic sections of an ST source file are called **Sections** (see table).
- A **user program** is the sum of all program sources (e.g. ST source files, MCC units).

Each logical section of the ST source file has a beginning and end denoted by specific keywords:

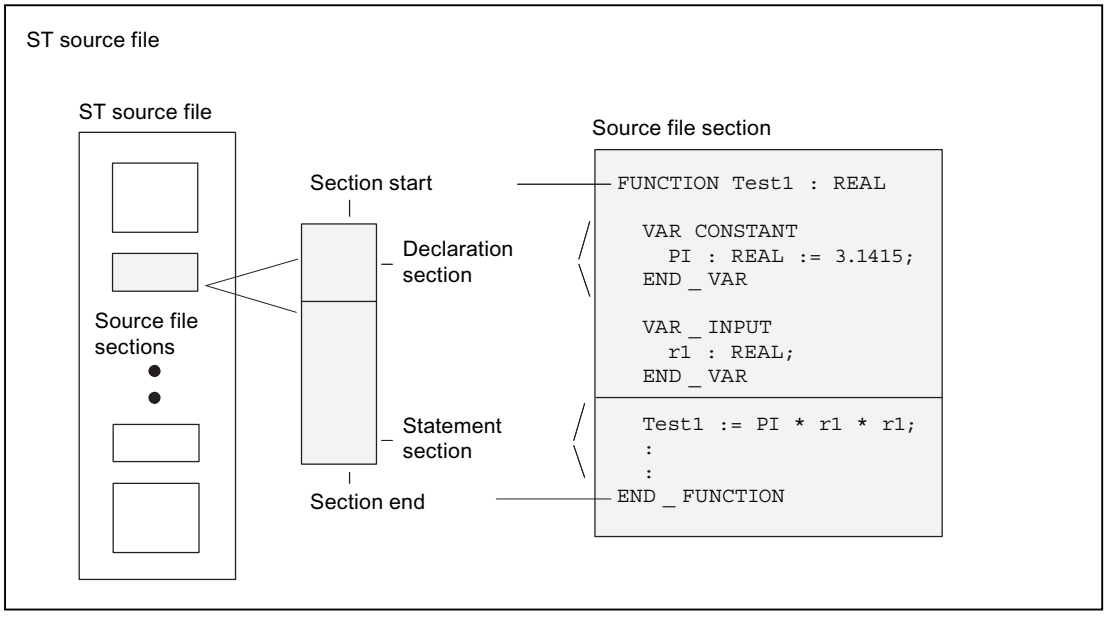

Figure 7-231 Structure of an ST source file

You do not have to program every function yourself. You can also make use of SIMOTION system components. These are preprogrammed sections such as system functions or the functions of the technology objects (TO functions).

Table 7-373 Major sections of an ST source file

Source file section	Description
Unit statement (optional)	Contains the name of the ST
Interface section	Contains instructions for making variables, data types and program organization units (POU) public, and for using other program sources.
Implementation section	Contains instructions for using other program sources and the executable sections of the ST source file.
POU (program organization unit)	Single executable section of the ST source file (program, function, function block)
Declaration section	Contains declarations (e.g. of variables and data types), can be included in the interface section and the implementation section as well as in a POU.
Statement section	Contains executable statements of a POU.

Note

An extensively annotated *template for example unit* is also available in the online help. You can use it as a template for a new ST source file.

Call the ST editor Help and click the relevant link. Copy the text to the open window of the ST editor and modify the template according to your requirements.

The section "Template for example unit" (Page 5068) contains a copy of this template.

Statements

The statement section of a program organization unit (POU – program, function, function block) consists of repeated single statements. It follows the declaration section of a POU and ends with the end of the POU. There are no explicit keywords for the start and end.

There are three basic types of statements in ST:

- Value assignments
  Assignment of an expression to a variable; see Variables declaration (Page 4694)
- Control statements
  Repetition or branching of statements; see Control statements (Page 4719)
- Subroutine execution
  Functions (FC) and function blocks (FB); see Functions, function blocks, programs (Page 4736)

Table 7-374 Examples of statements

```
...
// Value assignment
Status := 17;

// Control statement
IF a = b THEN
    FOR c := 1 TO 10 DO
        b := b + c;
    END_FOR;
END_IF;

// Function call
retVal := Test1(10.0);
...
```

Comments

Comments are used for documentation purposes and to help the user understand the source file section. After compilation, they have no meaning for the program execution.

There are two types of comments:

- Line comment
- Block comment

The line comment is preceded by **//**. The compiler will process the text which follows until the end of the line as a comment.

You can enter a block comment over several lines if it is preceded by (* and ends with *).

You can also use the corresponding buttons in the ST editor toolbar to show or hide comments. This is helpful for showing or hiding code positions.

Please note the following when inserting comments:

- The character pairs (* and *) are ignored within the line comment.
- Nesting of block comments is not allowed as standard. However, you can nest line comments in block comments.
  With activated compiler option “Permit language extensions IEC61131 3rd edition” only: block comments can be nested.
- You can use the complete extended ASCII character set in comments.
- Comments can be inserted at any position, but not in rules that have to be maintained, such as in names of identifiers. For more information about these rules, refer to Help for the language description (Page 4973).

Table 7-375 Examples of comments

```
// This is a one-line comment.
a := 5;

// This is an example of a single-line
// comment used several times in succession.
b := 23;

(* The example above is easier to maintain as a block comment.
*)
c := 87;

(* Block comments can only be nested with compiler option "Admit language
extensions IEC61131 3rd edition".
(* Nested block comment *)
*)
```

7.2.4.4 Data types

A data type is used to determine how the value of a variable or constant is to be used in a program source.

The following data types are available to the user:

- Elementary data types (Page 4672)
- User-defined data types (UDT) (Page 4675)
  - Simple derivatives
  - Arrays
  - Enumerators
  - Structures (Struct)
- Technology object data types (Page 4690)
- System data types (Page 4693)

Elementary data types

Elementary data types define the structure of data that cannot be broken down into smaller units. An elementary data type describes a memory area with a fixed length and stands for bit data, integers, floating-point numbers, duration, time, date and character strings.

All the elementary data types are listed in the table below:

Table 7-376 Bit widths and value ranges of the elementary data types

Type		Reserv. word	Bit width	Range of values
Bit data type Data of this type uses either 1 bit, 8 bits, 16 bits, or 32 bits. The initialization value of a variable of this data type is 0.				
	Bit	BOOL	1	0, 1 or FALSE, TRUE
	Byte	BYTE	8	16#0 to 16#FF
	Word	WORD	16	16#0 to 16#FFFF
	Double word	DWORD	32	16#0 to 16#FFFF_FFFF
Numeric types These data types are available for processing numeric values. The initialization value of a variable of this data type is 0 (all integers) or 0.0 (all floating-point numbers).				
	Short integer	SINT	8	-128 to 127 (-2**7 to 2**7-1)
	Unsigned short integer	USINT	8	0 to 255 (0 to 2**8-1)
	Integer	INT	16	-32_768 to 32_767 (-2**15 to 2**15-1)
	Unsigned integer	UINT	16	0 to 65_535 (0 to 2**16-1)
	Double integer	DINT	32	-2_147_483_648 to 2_147_483_647 (-2**31 to 2**31-1)
	Unsigned double integer	UDINT	32	0 to 4_294_967_295 (0 to 2**32-1)
	Floating-point number (per IEEE -754)	REAL	32	-3.402_823_466E+38 to -1.175_494_351E-38, 0.0, +1.175_494_351E-38 to +3.402_823_466E+38 Accuracy: 23-bit mantissa (corresponds to 6 decimal places), 8-bit exponent, 1-bit sign.
	Long floating-point number (in accordance with IEEE-754)	LREAL	64	-1.797_693_134_862_315_7E+308 to -2.225_073_858_507_201_4E-308, 0.0, +2.225_073_858_507_201_4E-308 to +1.797_693_134_862_315_7E+308 Accuracy: 52-bit mantissa (corresponds to 15 decimal places), 11-bit exponent, 1-bit sign.
Time types These data types are used to represent various date and time values.				

Type		Reserv. word	Bit width	Range of values
	Duration in increments of 1 ms	TIME	32	T#0d_0h_0m_0s_0ms to T#49d_17h_2m_47s_295ms Maximum of 2 digits for the values day, hour, minute, second and a maximum of 3 digits for milliseconds Initialization with T#0d_0h_0m_0s_0ms
	Date in increments of 1 day	DATE	32	D#1992-01-01 to D#2200-12-31 Leap years are taken into account, year has four digits, month and day are two digits each Initialization with D#0001-01-01
	Time of day in increments of 1 ms	TIME_OF_DAY (TOD)	32	TOD#0:0:0.0 to TOD#23:59:59.999 Maximum of two digits for the values hour, minute, second and maximum of three digits for milliseconds Initialization with TOD#0:0:0.0
	Date and time	DATE_AND_TIME (DT)	64	DT#1992-01-01-0:0:0.0 to DT#2200-12-31-23:59:59.999 DATE_AND_TIME consists of the data types DATE and TIME Initialization with DT#0001-01-01-0:0:0.0
String type Data of this type represents character strings, in which each character is encoded with the specified number of bytes. The length of the string can be defined at the declaration. Indicate the length in "[" and "]", e.g. STRING[100]. The default setting consists of 80 characters. The number of assigned (initialized) characters can be less than the declared length.				
	String with 1 byte/character	STRING	8	You may use all the characters in the extended ASCII character set (ASCII code $00 to $FF). Default ' ' (empty string)

Note

During variable export to other systems, the value ranges of the corresponding data types in the target system must be taken into account.

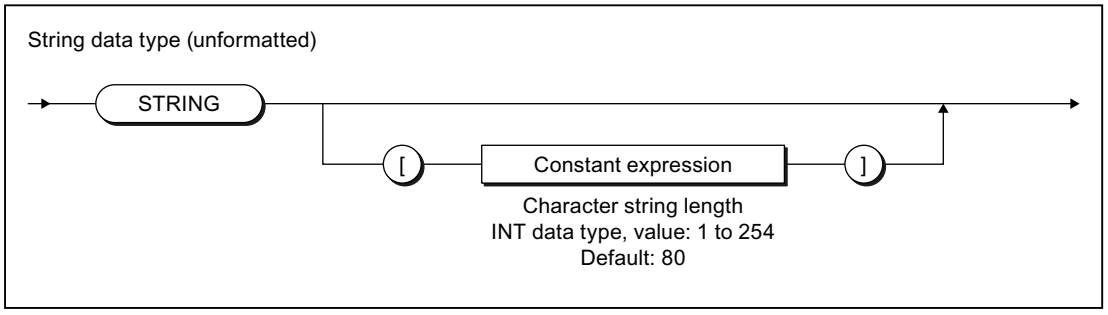

Figure 7-232 Syntax: STRING data type

Value range limits of elementary data types

The value range limits of certain elementary data types are available as constants.

Table 7-377 Symbolic constants for the value range limits of elementary data types

Symbolic constant	Data type	Value	Hex notation
SINT#MIN	SINT	-128	16#80
SINT#MAX	SINT	127	16#7F
INT#MIN	INT	-32768	16#8000
INT#MAX	INT	32767	16#7FFF
DINT#MIN	DINT	-2147483648	16#8000_0000
DINT#MAX	DINT	2147483647	16#7FFF_FFFF
USINT#MIN	USINT	0	16#00
USINT#MAX	USINT	255	16#FF
UINT#MIN	UINT	0	16#0000
UINT#MAX	UINT	65535	16#FFFF
UDINT#MIN	UDINT	0	16#0000_0000
UDINT#MAX	UDINT	4294967295	16#FFFF_FFFF
T#MIN TIME#MIN	TIME	T#0ms	16#0000_0000[1]
T#MAX TIME#MAX	TIME	T#49d_17h_2m_47s_295ms	16#FFFF_FFFF[1]
TOD#MIN TIME_OF_DAY#MIN	TOD	TOD#00:00:00.000	16#0000_0000[1]
TOD#MAX TIME_OF_DAY#MAX	TOD	TOD#23:59:59.999	16#0526_5BFF[1]
[1] Internal display only			

General data types

General data types are often used for the input and output parameters of system functions and system function blocks. The subroutine can be called with variables of each data type that is contained in the general data type.

The following table lists the available general data types:

Table 7-378 General data types

General data type	Data types contained
ANY_BIT	BOOL, BYTE, WORD, DWORD
ANY_INT	SINT, INT, DINT, USINT, UINT, UDINT
ANY_REAL	REAL, LREAL
ANY_NUM	ANY_INT, ANY_REAL
ANY_DATE	DATE, TIME_OF_DAY (TOD), DATE_AND_TIME (DT)
ANY_ELEMENTARY	ANY_BIT, ANY_NUM, ANY_DATE, TIME, STRING
ANY	ANY_ELEMENTARY, user-defined data types (UDT), system data types, data types of the technology objects

Note

You **cannot** use general data types as type identifiers in variable or type declarations.

The general data type is retained when a user-defined data type (UDT) is derived directly from an elementary data type (only possible with the SIMOTION ST programming language).

Elementary system data types

In the SIMOTION system, the data types specified in the table are treated in a similar way to the elementary data types. They are used with many system functions.

Table 7-379 Elementary system data types and their use

Identifier	Bit width	Use
StructAlarmId	32	Data type of the alarmId for the project-wide unique identification of the messages. The alarmId is used for the message generation. Please refer to the *SIMOTION Basic Functions* Function Manual. Initialization with STRUCTALARMID#NIL
StructTaskId	32	Data type of the taskId for the project-wide unique identification of the tasks in the execution system. Please refer to the *SIMOTION Basic Functions* Function Manual. Initialization with STRUCTTASKID#NIL

Table 7-380 Symbolic constants for invalid values of elementary system data types

Symbolic constant	Data type	Meaning
STRUCTALARMID#NIL	StructAlarmId	Invalid AlarmId
STRUCTTASKID#NIL	StructTaskId	Invalid TaskId

User-defined data types

User-defined data types (UDT) are created with the construct TYPE/END_TYPE in the declaration subsections of subsequent source file modules (see Breakdown of ST source file (Page 4668) and Source file modules (Page 4806)):

- Interface section
- Implementation section
- Program organization unit (POU)

You can continue to use the data types you created in the declaration section. The source file section determines the range of the type declaration.

Syntax of user-defined data types (type declaration) (Page 4676)
Derivation of elementary or derived data types (Page 4677)
Derived data type ARRAY (Page 4678)
Derived data type - Enumerator (Page 4681)
Derived data type STRUCT (structure) (Page 4682)

Syntax of user-defined data types (type declaration)

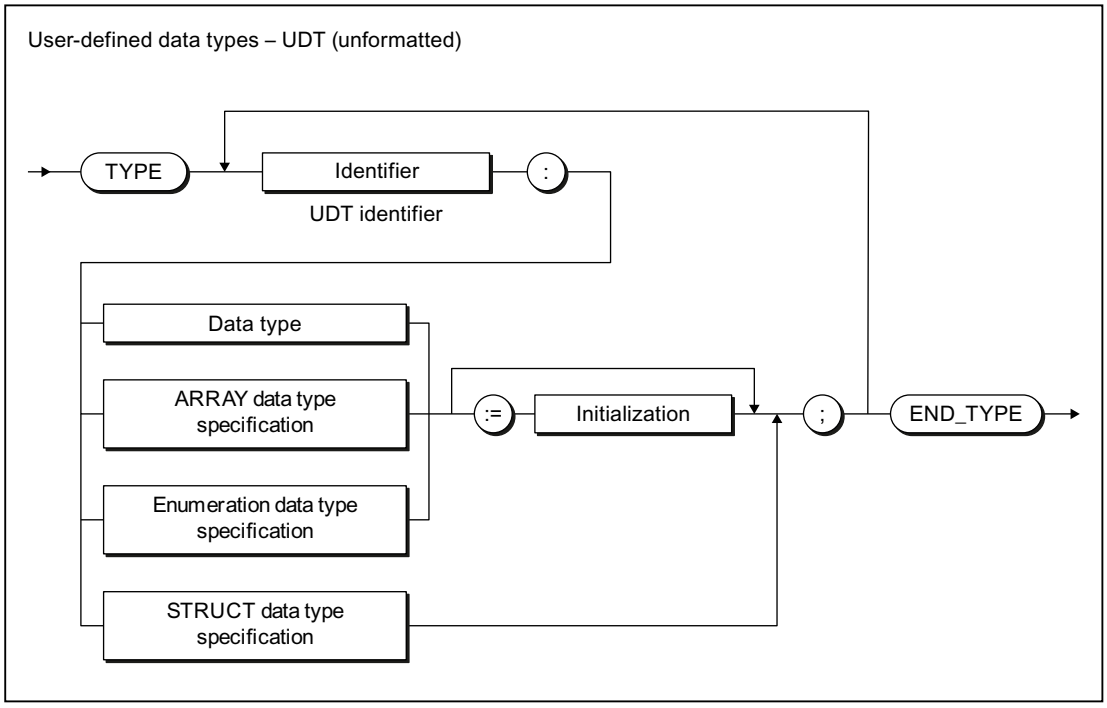

Figure 7-233 Syntax: User-defined data type

The declaration of the UDT is introduced with the keyword TYPE.

For each data type to be declared, this is followed by, see figure:

1. Name:
   The name of the data type must comply with the rules for identifiers.
2. Data type specification
   The term *data type* comprises, see Derivation of elementary or derived data types (Page 4677):
   - Elementary data types
   - Previously declared UDTs
   - TO data types
   - System data types

   The following data type specifications are also possible:
   - ARRAY data type specification, see Derived data type ARRAY - array (Page 4678)
   - Enumerator data type specification, see Derived data type enumeration – enumerator (Page 4681)
   - STRUCT data type specification, see Derived data type STRUCT – structure (Page 4682)

   The references in brackets refer to the following sections, in which the respective data type specification is described in detail.
3. Optional initialization:
   You can specify an initialization value for the data type. If you subsequently declare a variable of this data type, the initialization value is assigned to the variable.
   Exception: With the STRUCT data type specification, each individual component is initialized within the data type specification.
   See also Initialization of variables or data types (Page 4697).

The complete UDT declaration is terminated with the keyword END_TYPE. You can create any number of data types within the TYPE/END_TYPE construct. You can use the defined data types to declare variables or parameters.

UDTs can be nested in any way as long as the syntax in the figure is observed. For example, you can use previously defined UDTs or nested structures as a data type specification. Type declarations can only be used sequentially and not in nested structures.

Note

You can learn how to declare variables and parameters in Overview of all variable declarations (Page 4695), and how to assign values with UDT in Syntax for value assignment (Page 4703).

Below is a description of individual data type specifications for UDTs and examples demonstrating their use.

Derivation of elementary or derived data types

In the derivation of data types, an elementary or user-defined data type (UDT) is assigned to the data type to be defined in the TYPE/END_TYPE construct:

TYPE identifier: Elementary data type { := initialization } ; END_TYPE

TYPE identifier: User-defined data type { := initialization } ; END_TYPE

Once you have declared the data type, you can define variables of derived data type identifier. This is equivalent to declaring variables as data type *elementary data type*.

Table 7-381 Examples of derivation of elementary data types

```
TYPE
    I1: INT;      // Elementary data type
    R1: REAL;     // Elementary data type
    R2: R1;       //  Derived data type (UDT)
END_TYPE
VAR
    // These variables can be used wherever
    // variables of type INT can be used.
    myI1 : I1;
    myI2 : INT;   // No derived data type!

    // These variables can be used wherever
    // variables of type REAL can be used.
    myR1 : R1;
    myR2 : R2;
END_VAR
myI1 := 1;
myI2 := 2;
myR1 := 2.22;
myR2 := 3.33;
```

Derived data type ARRAY

The ARRAY derived data type combines a defined number of elements of the same data type in the TYPE/END_TYPE construct. The syntax diagram in the following figure shows this data type which is specified more precisely after the reserved identifier OF.

TYPE identifier: ARRAY data type specification { := initialization } ; END_TYPE

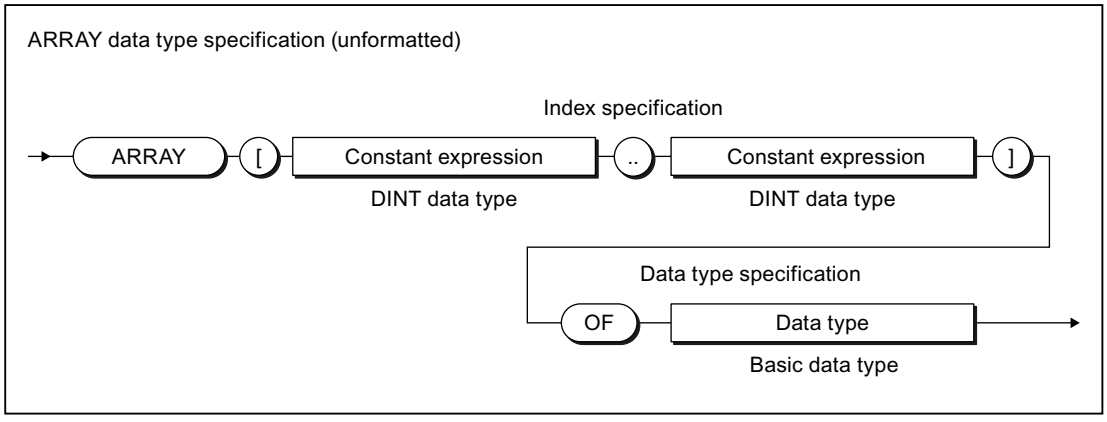

Figure 7-234 Syntax: ARRAY data type specification

The **index specification** describes the limits of the array:

- The array limits specify the minimum and maximum value for the index. They can be specified using constants or constant expressions; the data type is DINT (or can be implicitly converted to DINT – see Converting elementary data types (Page 4732)).
- The array limits must be separated by two periods.
- The entire index specification is enclosed in square brackets.
- The index itself can be an integer value of data type DINT (or it can be implicitly converted to DINT – see Converting elementary data types (Page 4732)).

Note

If array limits are violated during runtime, a processing error occurs in the program (see the "SIMOTION Basic Functions" Function Manual).

You specify the data type of the array elements with the **data type specification** (basic data type). All of the options described in this section can be used as data types, for example, even user-defined data types (UDT).

You can define the size of the memory space occupied by the ARRAY with _sizeOf (in := *array-name*). The following applies: _sizeOf (in := *array_of_type*) := _lengthIndexOf (in := *array_of_type*) * _sizeOf (in := *type*). The syntax of these functions is described in the "SIMOTION Basic Functions" Function Manual.

The _arrayCopy function can be used to copy an area of an array into another array with the same basic data type. The syntax of these functions is described in the "SIMOTION Basic Functions" Function Manual.

Note

As of SIMOTION Kernel version V4.2, you can declare arrays with a dynamic length as in-out parameters in functions and function blocks. For more information, refer to the corresponding section (Page 4747) for the FB and FC declaration subsection (Page 4741).

One- and multidimensional arrays

There are several different ARRAY types:

- The one-dimensional ARRAY type is a list of data elements arranged in ascending order.
- The two-dimensional ARRAY type is a table of data consisting of lines and columns. The first dimension refers to the line number, the second to the column number.
- The higher-dimensional ARRAY type is an expansion of the two-dimensional ARRAY type that includes additional dimensions.

Table 7-382 Examples of one-dimensional arrays

```
TYPE
    x : ARRAY[0..9] OF REAL;
    y : ARRAY[1..10] OF C1;
END_TYPE
```

Two-dimensional arrays are comparable to a table with lines and columns. You can create two- or multi-dimensional arrays by means of a multi-level type declaration, see example:

Table 7-383 Examples of multi-dimensional arrays

```
TYPE
    a       : ARRAY[1..3] OF INT;     // Single-dimensional array
                                      // (3 columns)
    matrix1: ARRAY[1..4] OF a;        // Two-dimensional array
                                      // (4 lines with 3 columns)
    b       : ARRAY[4..8] OF INT;     // single-dimensional field
                                      // (5 columns)
    matrix2: ARRAY[10..16] OF b;      // Two-dimensional array
                                      // (7 lines with 5 columns)
END_TYPE

VAR
    m : matrix1;     // Variable m of data type
                     // Two-dimensional array
    n : matrix2;     // Variable n of data type
                     // Two-dimensional array
END_VAR

m[4][3] := 9;       // Write in matrix1 in line 4, column 3
n[16][8] := 10;     // Write in matrix2 in line 7, column 5
```

In the example, you can define:

1. Table columns a[1] to a[3] as a one-dimensional array that will contain integers.
2. Table lines matrix1[1] to matrix1[4] also as an array, but take as the data type specification the array a you just created with the columns of the table.
   When you specify an array in the data type specification, you create a second dimension. You can create further dimensions in this way.

Now declare a variable using the data type created for the table. You address each dimension of the table using square brackets, in this case specifying the line and column.

Redeclaration

The data type definitions of arrays are recognized as identical (even in different sources) if the following conditions are met:

1. The identifier of the data type is identical.
2. Both array limits are identical.
3. The data type of the array elements is identical.
4. The optional array initialization list is identical (including repeat factors and constant expressions).

Initialization

Per default, the array elements are assigned the initialization value of the basic data type. Optionally the initialization value of the array element can be changed by assigning an array initialization list enclosed in square brackets [ ], see"Initialization of variables or data types" (Page 4697).

Derived data type - Enumerator

In the case of enumeration data types, a restricted set of identifiers or names is assigned to the data type to be defined in the TYPE/END_TYPE construct:

TYPE identifier: Enumeration data type specification { := initialization } ; END_TYPE

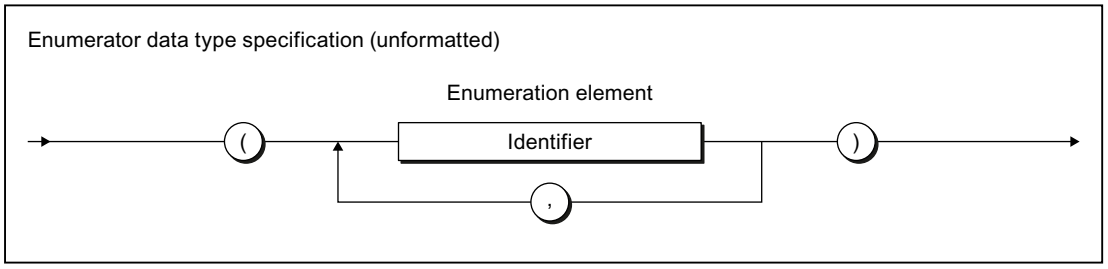

Figure 7-235 Syntax: Enumeration data type specification

Once you have declared the *identifier* data type, you can define variables in the enumeration data type. In the statement section, you can assign only elements from the list of defined identifiers (enumeration elements) to these variables.

You can also specify the data type directly: Place the enumeration data type identifier and the "#" sign in front of the enumeration element (see Table *Examples of enumeration data types*).

You can obtain the first and last value of an enumeration data type with *enum_type*#MIN and *enum_type*#MAX respectively, whereby *enum_type* is the enumeration data type identifier.

You can obtain the numeric value of an enumeration element with the ENUM_TO_DINT conversion function. The syntax of these functions is described in the "SIMOTION Basic Functions" Function Manual.

Example

Table 7-384 Examples of enumeration data types

```
TYPE
    C1 : (RED, GREEN, BLUE);
END_TYPE

VAR
    myC11, myC12, myC13 : C1;
END_VAR

myC11 := GREEN;
myC11 := C1#GREEN;
myC12 := C1#MIN;        // RED
myC13 := C1#MAX;        // BLUE
```

Note

You will also find enumeration data types as system data types.

Enumeration data types can be components of a structure, meaning that they can be found at any lower level in the user-defined data structure.

Redeclaration

The data type definitions of enumeration data types are recognized as identical (even in different sources) if the following conditions are met:

1. The identifier of the data type is identical.
2. All enumeration elements are identical.
3. The sequence of the enumeration elements is identical, so their numerical values are identical.
4. The optional initialization value is identical.

Initialization

Per default, an enumeration data type is assigned the 1st value of the enumeration as initialization value. Optionally the initialization value can be changed by assigning another enumeration element, see"Initialization of variables or data types" (Page 4697).

Derived data type STRUCT (structure)

The derived data type STRUCT, or structure, encompasses an area of a fixed number of components in the TYPE/END_TYPE construct; the data types of these components can vary:

TYPE identifier: STRUCT data type specification; END_TYPE

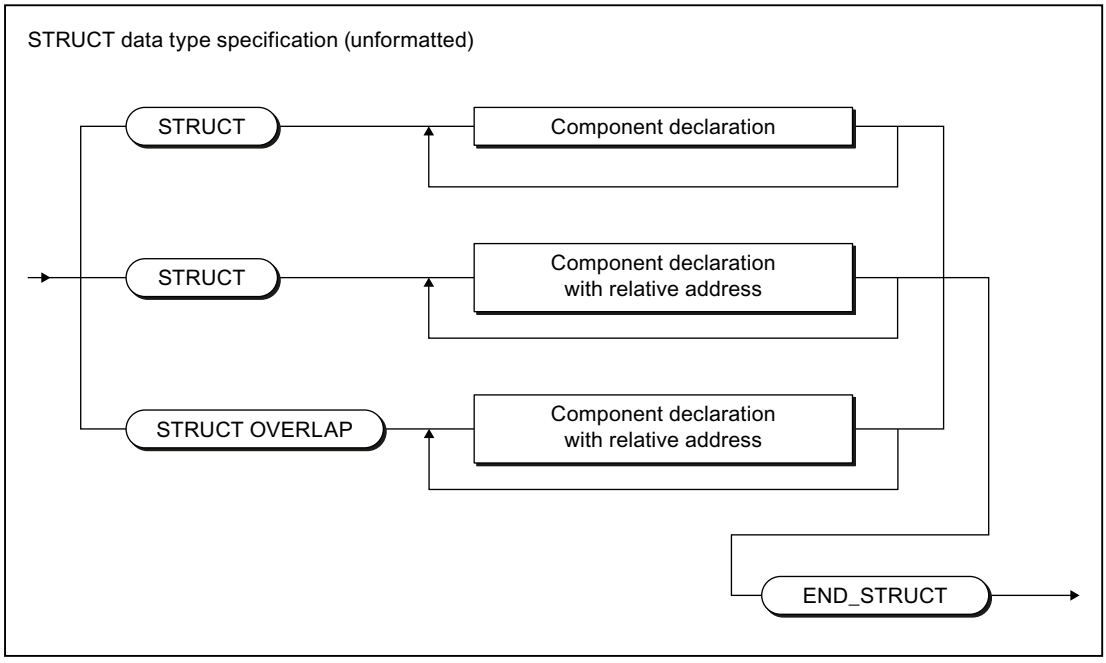

Figure 7-236 Syntax: STRUCT data type specification

Component declaration

Usually, a structure contains the definitions of the individual components between the keywords STRUCT and END_STRUCT.

The syntax of the component declaration is shown in the following figure. The components are arranged in the order of their declaration with this syntax. The relative addresses of the components within the structure are assigned automatically by the compiler.

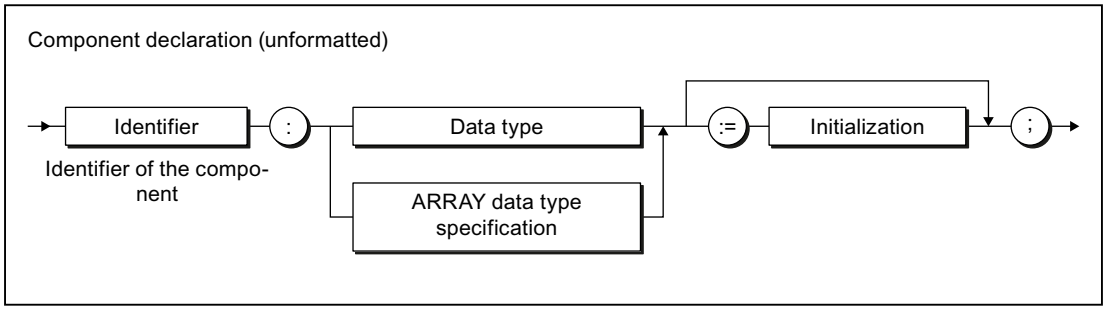

Figure 7-237 Syntax: Component declaration

The following are permitted as data types:

- Elementary data types
- Previously declared UDTs
- System data types
- TO data types
- ARRAY data type specification

You also have the option to assign initialization values to the components see "Initialization" in this section.

Note

The following data type specifications cannot be used directly within a component declaration:

- STRUCT data type specifications
- Enumeration data type specifications

Remedy:

Declare a UDT (user-defined data type) beforehand with the above-mentioned specifications and use this in the component declaration.

This allows you to nest STRUCT data types.

You will also find STRUCT data types as system data types.

Example

This example shows how a UDT is defined and how this data type is used within a variable declaration.

Table 7-385 Examples of derived data type STRUCT

```
TYPE    // UDT definition
    S1 : STRUCT
        var1 : INT;
        var2 : WORD := 16#AFA1;
        var3 : BYTE := 16#FF;
        var4 : TIME := T#1d_1h_10m_22s_2ms;
    END_STRUCT;
END_TYPE

VAR
    myS1 : S1;
END_VAR

myS1.var1 := -4;
myS1.var4 := T#2d_2h_20m_33s_2ms;
```

Redeclaration

The data type definitions of structures are recognized as identical (even in different sources) if the following conditions are met:

1. The identifier of the data type is identical.
2. All components of the structure are identical in terms of their:
   - Sequence
   - Identifier
   - Data types or ARRAY data type specifications
   - Initialization values (including any array or structure initialization lists)

Initialization

Per default, each component is assigned the initialization value of its data type. Optionally, the initialization value of the component can be changed by assigning an appropriate initialization.

When using the structure in another declaration (e.g. variable or data type declaration), the initialization values of individual components can be changed by assigning a structure initialization list, enclosed in round brackets ( ).

See "Initialization of variables or data types" (Page 4697).

Component declaration with specification of the relative addresses

You can assign the relative addresses of the components within the structure with the keyword AT in the component declarations, see following syntax diagram.

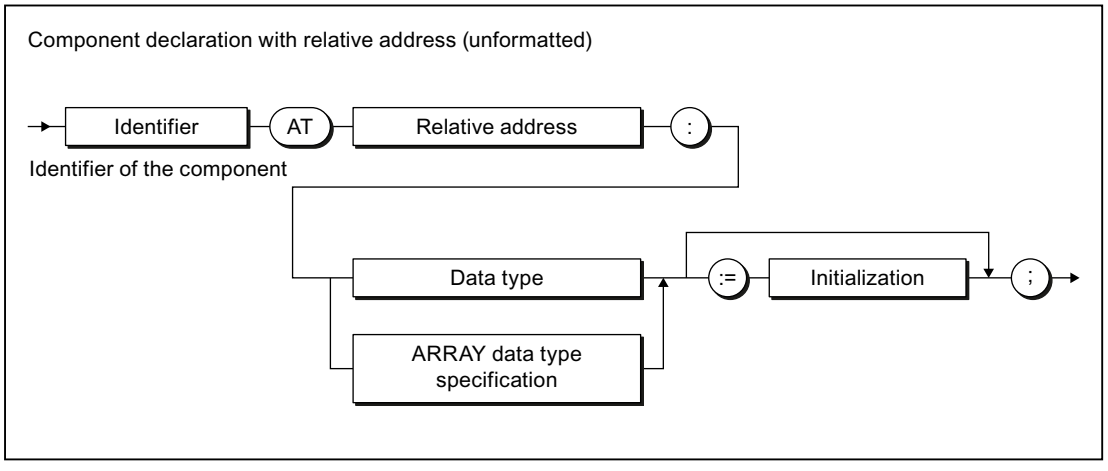

Figure 7-238 Syntax: Component declaration with relative address

Specify the relative address of the component (byte offset) as follows:

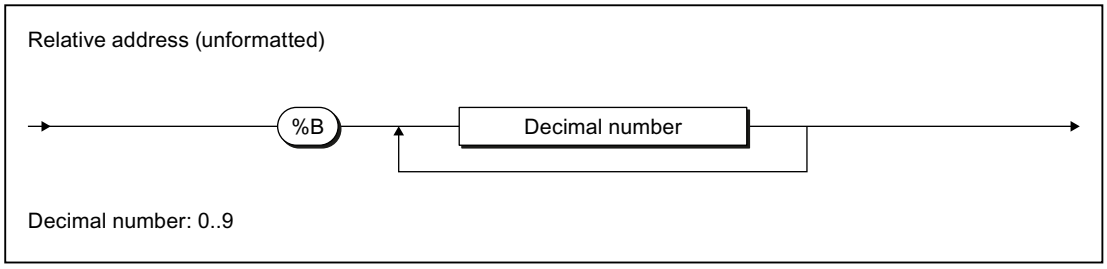

Figure 7-239 Syntax: Relative address

If you specify relative addresses of the structure components, you must do this for all components of this structure.

The permissible relative addresses of the components depends on their data type, see following table:

Table 7-386 Permissible addresses and length of various data types

Data type	Permissible address	Length
Elementary data types		
BOOL, BYTE, SINT, USINT	Any	1 byte
WORD, INT, UINT	Can be divided by 2	2 bytes
DWORD, DINT, UDINT, REAL TIME, DATE, TIME_OF_DAY (TOD)	Can be divided by 4	4 bytes
LREAL DATE_AND_TIME (DT)	Can be divided by 8	8 bytes
STRING	Any address	Declared length + 2 bytes (Default: 82 bytes)
User-defined data types (UDT)		
Derived data type	Corresponding to the basic data type	
ARRAY	Corresponding to the basic data type	Corresponding to the index specification and the basic data type
Enumerator	Can be divided by 4	4 bytes
STRUCT (structure)	Corresponding to the largest data type within the structure	Corresponding to the declaration of the structure
Further data types		
StructAlarmId, StructTaskId	Can be divided by 4	4 bytes
System data type	Corresponding to its declaration as STRUCT or enumerator	
TO data type, ANYOBJECT	Can be divided by 8	8 bytes

If the above addressing rules are violated, the compiler issues an error message which indicates the required divisor.

Table 7-387 Example of a structure with specification of the relative address

```
myLocatedStruct : STRUCT
    memb1 AT %B0 : INT;     // Relative address 0
                            // Bytes 0 and 1 assigned
    memb2 AT %B8 : REAL;    // Relative address 8
                            // Bytes 8 .. 11 assigned
                            // Bytes 2 .. 7 not assigned (gap)
END_STRUCT
```

The declaration order of the components is arbitrary when specifying the relative addresses. The structure in the following example is identical to that in the previous example.

Table 7-388 Identical structure to the previous example

```
myLocatedStruct : STRUCT
    memb2 AT %B8 : REAL;    // Relative address 8
                            // Bytes 8 .. 11 assigned
    memb1 AT %B0 : INT;     // Relative address 0
                            // Bytes 0 and 1 assigned
                            // Bytes 2 .. 7 not assigned (gap)
END_STRUCT
```

The address ranges of the components must not overlap except when the structure is declared with the keyword STRUCT OVERLAP, see following section.

Structure with overlapping address ranges (UNION)

If you make the component declarations with specification of the relative address (see above) between the keywords STRUCT OVERLAP and END_STRUCT, the address ranges can overlap.

The syntax diagram for the component declaration with relative address (see above) applies for the component declaration. See Table "Permissible addresses and length of various data types" for the permissible addresses.

Table 7-389 Example of a structure with overlapping address ranges

```
myOverLapStruct : STRUCT OVERLAP
    memb1 AT %B0 : REAL;    // Relative address 0
                            // Bytes 0 .. 3
    memb2 AT %B0 : INT;     // Also on relative address 0
                            // Bytes 0 and 1
    ar    AT %B0 : ARRAY [0..3] OF BYTE;
                            // Relative address 0 again
                            // Bytes 0 .. 3
END_STRUCT
```

If the address ranges of two components overlap, the following data types are **not** permitted in these components:

- STRING
- ANYOBJECT
- TO data type

They are permitted in components whose address ranges do not overlap. For example, the following declaration is permitted:

```
myOverLapStruct_2 : STRUCT OVERLAP
    dint_1  AT %B0 : DINT;
    udint_1 AT %B4 : UDINT;
    ar      AT %B0 : ARRAY [0..7] OF BYTE;
            //Bytes 0 .. 7 overlapping
    pos_1   AT %B8 : PosAxis;
            // Bytes 8 .. 15 not overlapping
END_STRUCT
```

Note

The declaration of a structure with overlapping ARRAY OF BYTE, as specified in the examples, does not replace the marshalling functions. The byte order (Little Endian or Big Endian) depends on the respective SIMOTION device. For information on the Little Endian and Big Endian byte order as well as the marshalling functions, see SIMOTION Basic Functions Function Manual.

Visibility of the components with overlapping address ranges

Symbol information (OPC-XML data) is only generated for the following components:

- Components without overlapping of address ranges
- For several components with overlapping address ranges:
  Only for the last declared component that uses the respective address range. The compiler issues a warning for the hidden components.

Only these components are visible:

- For the watch function of IT DIAG
- For the *_exportUnitDataSet* and *_importUnitDataSet* functions, see SIMOTION Basic Functions Function Manual
- For automatic displays in SIMOTION SCOUT (e.g. symbol browser (Page 4940), program status (Page 4949)).

Note

Hidden components can used in the programming. In the ST editor, they are shown in the "Automatic completion" (Page 4609) function.

You can monitor individual hidden components in a watch table (Page 4944), see the appropriate information in Section "Using a watch table" (Page 4944).

As an example, the visible components of the following structure declaration are explained in the table below.

The following examples of a structure declaration explain the behavior of the visible and hidden components. The visible components and the associated relative addresses are specified in the following table.

```
mystru : STRUCT OVERLAP
    a  AT %B0 : INT;    // Warning: Not visible for OPC-XML
    b  AT %B6 : INT;    // Warning: Not visible for OPC-XML
    c  AT %B8 : INT;    // Visible
    ar AT %B0 : ARRAY [0..6] OF BYTE; // Visible
END_STRUCT
```

	Relative address									
	0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
Declared components	a						b		c	
	ar[0]	ar[1]	ar[2]	ar[3]	ar[4]	ar[5]	ar[6]			
Visible components	ar[0]	ar[1]	ar[2]	ar[3]	ar[4]	ar[5]	ar[6]	-	c	

A change in the declaration order has an effect on the visible components:

```
mystru1 : STRUCT OVERLAP
    ar AT %B0 : ARRAY [0..6] OF BYTE; // Warning: For OPC-XML
                                      // Not visible
    a  AT %B0 : INT;    // Visible
    b  AT %B6 : INT;    // Visible
    c  AT %B8 : INT;    // Visible
END_STRUCT
```

	Relative address									
	0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
Declared components	ar[0]	ar[1]	ar[2]	ar[3]	ar[4]	ar[5]	ar[6]			
	a						b		c	
Visible components	a		-	-	-	-	b		c	

Initialization of the components with overlapping addresses

Initialization values are ignored for components that are not visible. The compiler issues an appropriate warning.

If initialization values are specified for the visible components, they are taken into account. These initialization values are also valid for the commonly used addresses of hidden components. The following applies to the addresses of hidden components that are not overlapped by the other components: They are assigned the default initialization value that was defined in the declaration of the appropriate data type, or zero.

The following examples of a structure declaration explain this initialization behavior. The initialization values of the respective relative addresses are specified in the following table.

```
mystru_init : STRUCT OVERLAP
    a  AT %B0 : INT := 16#AAAA;     // Initialization value warning
                                    // OPC-XML warning
    b  AT %B6 : INT := 16#BBBB;     // Initialization value warning
                                    // OPC-XML warning
    c  AT %B8 : INT := 16#CCCC;
    ar AT %B0 : ARRAY [0..6] OF BYTE := [7(1)];
END_STRUCT
```

	Relative address									
	0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
Declared components	a						b		c	
	ar[0]	ar[1]	ar[2]	ar[3]	ar[4]	ar[5]	ar[6]			
Initialization value	16#01	16#01	16#01	16#01	16#01	16#01	16#01	16#00	16#CCCC	

A change in the declaration order has an effect on the initialization values:

```
mystru_init1 : STRUCT OVERLAP
    ar AT %B0 : ARRAY [0..6] OF BYTE := [7(1)];
                                    // Initialization value warning
                                    // OPC-XML warning
    a  AT %B0 : INT := 16#AAAA;
    b  AT %B6 : INT := 16#BBBB;
    c  AT %B8 : INT := 16#CCCC;
END_STRUCT
```

	Relative address									
	0	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
Declared components	ar[0]	ar[1]	ar[2]	ar[3]	ar[4]	ar[5]	ar[6]			
	a						b		c	
Initialization value	16#AAAA		16#00	16#00	16#00	16#00	16#BBBB		16#CCCC	

Technology object data types

Description of the technology object data types

You can declare variables with the data type of a technology object (TO). The following table shows the data types for the available technology objects in the individual technology packages.

For example, you can declare a variable with the data type *posaxis* and assign it an appropriate instance of a position axis. Such a variable is often referred to as a reference.

Table 7-390 Data types of technology objects (TO data type)

Technology object	Data type	Contained in the technology package
Drive axis	DriveAxis	CAM, PATH[1], CAM_EXT
External encoder	ExternalEncoderType	CAM, PATH[1], CAM_EXT
Measuring input	MeasuringInputType	CAM, PATH[1], CAM_EXT
Output cam	OutputCamType	CAM, PATH[1], CAM_EXT
Cam track	_CamTrackType	CAM, PATH[1], CAM_EXT
Position axis	PosAxis	CAM, PATH[1], CAM_EXT
Following axis	FollowingAxis	CAM, PATH[1], CAM_EXT
Following object	FollowingObjectType	CAM, PATH[1], CAM_EXT
Cam	CamType	CAM, PATH[1], CAM_EXT
Path axis[1]	_PathAxis	PATH[1], CAM_EXT
Path object[1]	_PathObjectType	PATH[1], CAM_EXT
Fixed gear	_FixedGearType	CAM_EXT
Addition object	_AdditionObjectType	CAM_EXT
Formula object	_FormulaObjectType	CAM_EXT
Sensor	_SensorType	CAM_EXT
Controller object	_ControllerObjectType	CAM_EXT
Temperature channel	TemperatureControllerType	TControl
General data type, to which every TO can be assigned	ANYOBJECT	

[1] Available as of version V4.1.

You can access the elements of technology objects (configuration data and system variables) via structures (see SIMOTION Basic Functions Function Manual).

Table 7-391 Symbolic constants for invalid values of technology object data types

Symbolic constant	Data type	Meaning
TO#NIL	ANYOBJECT	Invalid technology object

See also

Inheritance of the properties for axes (Page 4692)

Examples of the use of technology object data types (Page 4692)

Inheritance of the properties for axes

Inheritance for axes means that all of the data types, system variables and functions of the TO driveAxis are fully included in the TO positionAxis. Similarly, the position axis is fully included in the TO synchronizedAxis, the following axis in the TO pathAxis. This has, for example, the following effects:

- If a function or a function block expects an input parameter of the driveAxis data type, you can also use a position axis or a synchronized axis or a path axis when calling.
- If a function or a function block expects an input parameter of the posAxis data type, you can also use a synchronized axis or a path axis when calling.

Examples of the use of technology object data types

Below, you will see an example of optional use of a variable with a technology object data type (you will find an example of mandatory use of a variable with a TO data type in the *SIMOTION Basic Functions* Function Manual). A second example shows the alternative without using a variable with TO data type.

A TO function will be used to enable an axis in the main part of a program so that the axis can be positioned. After the positioning operation, the current position of the axis will be recorded using a structure access.

The first example uses a variable with TO data type to demonstrate its use.

Table 7-392 Example of the use of a data type for technology objects

```
VAR
    myAxis : posAxis;   // Declaration variable for axis
    myPos : LREAL;      // Variable for position of axis
    retVal: DINT;      // Variable for return value of the
                // TO function
END_VAR
myAxis := Axis1;       // The name Axis1 was defined when the axis
                       // was configured in the project navigator.

// Call of function with variables of TO data type:
retVal := _enableAxis(axis := myAxis, commandId := _getCommandId());

// Axis is positioned.
retVal := _pos(axis := myAxis,
               position := 100,
               commandId:= _getCommandId() );

// Scan the position using structure access
myPos := myAxis.positioningState.actualPosition;
```

The second example does not use a variable with TO data type.

Table 7-393 Example of using a technology object

```
VAR
    myPos : LREAL;      // Variable for position of axis
    retVal: DINT;  // Variable for return value of TO function
END_VAR

// Call of function without variable of TO data type
// The name Axis1 was defined when the axis
// was configured in the project navigator.
retVal := _enableAxis(axis := Axis1,
                      commandId:= _getCommandId() );

// Axis is positioned.
retVal := _pos(axis := Axis1
               position := 100,
               commandId:= _getCommandId() );

// Scan the position using structure access
myPos := Axis1.positioningState.actualPosition;
```

You will find details for configuration of technology objects in the SIMOTION Motion Control function descriptions.

System data types

There are a number of system data types available that you can use without a previous declaration. And, each imported technology packages provides a library of system data types.

Additional system data types (primarily enumerator and STRUCT data types) can be found

- In parameters for the general standard functions (see *SIMOTION Basic Functions* Function Manual)
- In parameters for the general standard function modules (see *SIMOTION Basic Functions* Function Manual)
- In system variables of the SIMOTION devices (see relevant parameter manuals)
- In parameters for the system functions of the SIMOTION devices (see relevant parameter manuals)
- In system variables and configuration data of the technology objects (see relevant parameter manuals)
- In parameters for the system functions of the technology objects (see relevant parameter manuals)

7.2.4.5 Variable declaration

A variable defines a data item with variable contents that can be used in the ST source file. A variable consists of an identifier (e.g. *myVar1*) that can be freely selected and a data type (e.g. BOOL). Reserved identifiers (see Reserved identifiers (Page 4657)) must not be used as identifiers.

Syntax of variable declaration

Variables are always created according to the same pattern in the declaration section of a source file section:

1. Start a declaration block with an appropriate keyword (e.g. VAR, VAR_GLOBAL – see Overview of all variable declarations (Page 4695)).
2. This is followed by the actual variable declarations (see figure); you can create as many of these as you wish. The order is arbitrary.
3. End the declaration block with END_VAR.
4. You can create further declaration blocks (also with the same keyword).

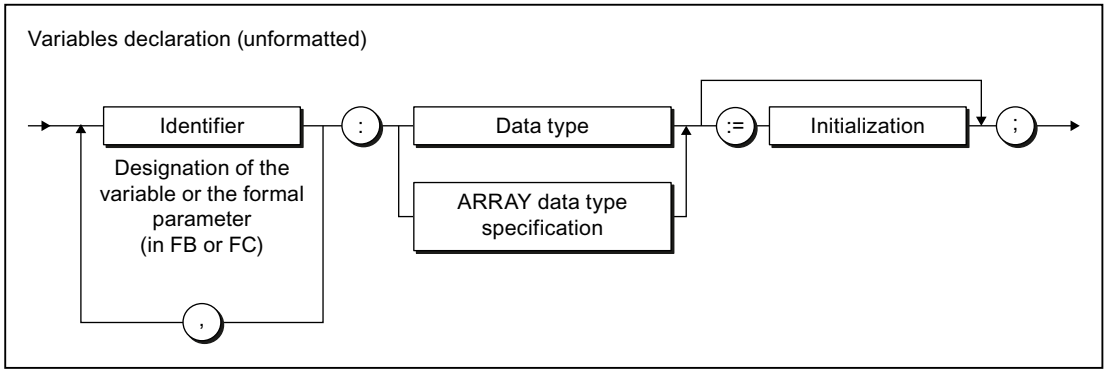

Figure 7-240 Syntax: Variable declaration

Note the following:

- The variable name must be an identifier, i.e. it can only contain letters, numbers or an underscore, but not special characters.
- The following are permissible as data types:
  - Elementary data types
  - UDT (user-defined data types)
  - System data types
  - TO data types
  - ARRAY data type specifications
  - Designation of a function block (instance declaration – see Calling functions and function modules (Page 4749)).
- You can assign initial values to the variables in the declaration statement. This is known as initialization (see Initialization of variables or data types (Page 4697)).

Deviations from the pattern presented are as follows:

- For constant declarations (a constant **must** be initialized with a value, see Constants (Page 4701)),
- For process image access (see Overview of all variable declarations (Page 4695)):
  - A variable declaration is not required for absolute process image access,
  - Initialization is not permitted for symbolic process image access.

Table 7-394 Examples of variable declarations

```
VAR CONSTANT
    PI : REAL := 3.1415;
END_VAR

VAR
    // Declaration of a variable ...
    var1 : REAL;
    // ... or if there are several variables of the same type:
    var2, var3, var4 : INT;
    // Declaration of a one-dimensional array:
    a1 : ARRAY[1..100] OF REAL;
    // Declaration of a character string:
    str1 : STRING[40];
END_VAR
```

Overview of all variable declarations

You declare the name, data type, and initial values of variables in the variable and parameter declarations. You always execute these declarations in the declaration sections of the following source file sections:

- Interface section
- Implementation section
- POU (program, function, function block, expression)

The source file section also determines which variables you can declare (see table), as well as their range.

For additional information about source file sections, refer to Breakdown of ST source file (Page 4668) and Source file sections (Page 4806).

Table 7-395 Keywords for declaration blocks

Keyword	Meaning	Declaration in the following declaration sections
VAR	Declaration of temporary or static variables See Variable model (Page 4831)	Any POU
VAR_GLOBAL	Declaration of unit variables See Variable model (Page 4831)	Interface section Implementation section

Keyword	Meaning	Declaration in the following declaration sections
VAR_IN_OUT	Variable declaration of in/out parameter; the POU accesses this variable directly (using a reference) and can change it immediately. See Defining functions (Page 4736), Defining function blocks (Page 4737), Defining methods (Page 4769)	Function Function block Expression Method [1]
VAR_INPUT	Variable declaration of input parameter, value is externally supplied and cannot be changed within the POU. See Defining functions (Page 4736), Defining function blocks (Page 4737), Defining methods (Page 4769)	Function Function block Expression Method [1]
VAR_OUTPUT	Variable declaration of output parameter; value is transmitted from the function block See Defining functions (Page 4736), Defining function blocks (Page 4737), Defining methods (Page 4769)	Function Function block Method [1]
VAR_TEMP	Declaration of temporary variables See Variable model (Page 4831)	Program Function Function block Method [1]
RETAIN	Declaration of retentive variables See Variable model (Page 4831)	Only as a supplement: • To VAR [2] in POU: – Program – Function block – Class [1] • To VAR_GLOBAL in the: – Interface section – Implementation section
CONSTANT	Declaration of constants See Constants (Page 4701)	Only as a supplement: • To VAR in POU: – Program – Function – Function block – Class [1 2] – Method [1] • To VAR_GLOBAL in the – Interface section – Implementation section
[1] Only with compiler option (Page 4623) "Permit object-oriented programming". [2] Only as of version V4.5 of the SIMOTION Kernel.		

Initialization of variables or data types

The assignment of initial values to the variables or data types within a declaration is optional; see Syntax of variables declaration (Page 4694) and Syntax of user-defined data types (Page 4676).

- If there is no initialization specified in the variable declaration, the compiler automatically assigns the initialization value specified in the data type declaration to the variables. The following applies for arrays (ARRAY): The array elements are assigned the initialization value of the basic data type.
- If there is no initialization specified in the data type declaration either, the compiler assigns the value of zero to the variables or data types.
  Exception:
  - For time data types: The initialization value for each data type.
  - For enumeration data types: 1st value of the enumeration.
  - For arrays (ARRAY): The array elements are assigned the initialization value of the basic data type.
  - For structures (STRUCT): The structure components are assigned the initialization value of the respective data type.

You preassign a variable or a user-defined data type with initial values by assigning a value (**:=**) after the data type specification.

- Assign the elementary data types (or data types derived from elementary data types) a constant expression in accordance with Figure *Syntax: constant expression*.
- Assign an array initialization list to an array (ARRAY) in accordance with the Figure *Syntax: Array initialization list*.
- Assign a structure initialization list to a structure (STRUCT) in accordance with Figure *Syntax: Structure initialization list* (even when the structure is used in other declarations).
  See also the explanation at the end of this section.
- Assign an enumeration element to an enumeration data type.

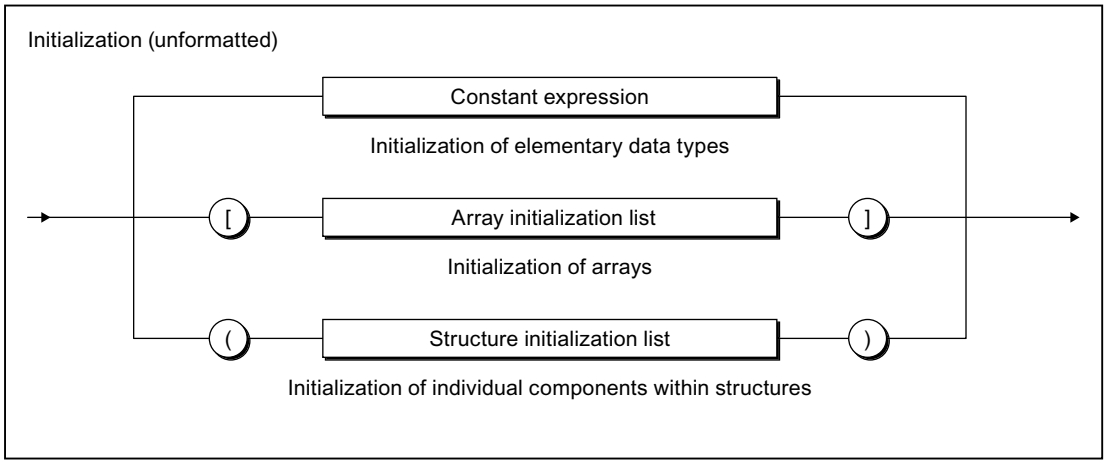

Figure 7-241 Syntax: Variable initialization

The initialization value assigned to a variable is calculated from the constant expression at the time of the compilation. For information about the syntax of the constant expression, see the figure titled *Syntax: Constant expression*.

Note that a variable list (a1, a2, a3, ... : INT := ...) can be initialized with a common value. In this case, you do not have to initialize the variables individually (a1 : INT := ... ; a2 : INT := ... ; etc.).

Note

The constant expressions used for initialization are calculated in the data type of the declared variables or in the declared data type.

Variables of a technology object data type cannot be assigned an initialization value. They are always initialized by the compiler with TO#NIL.

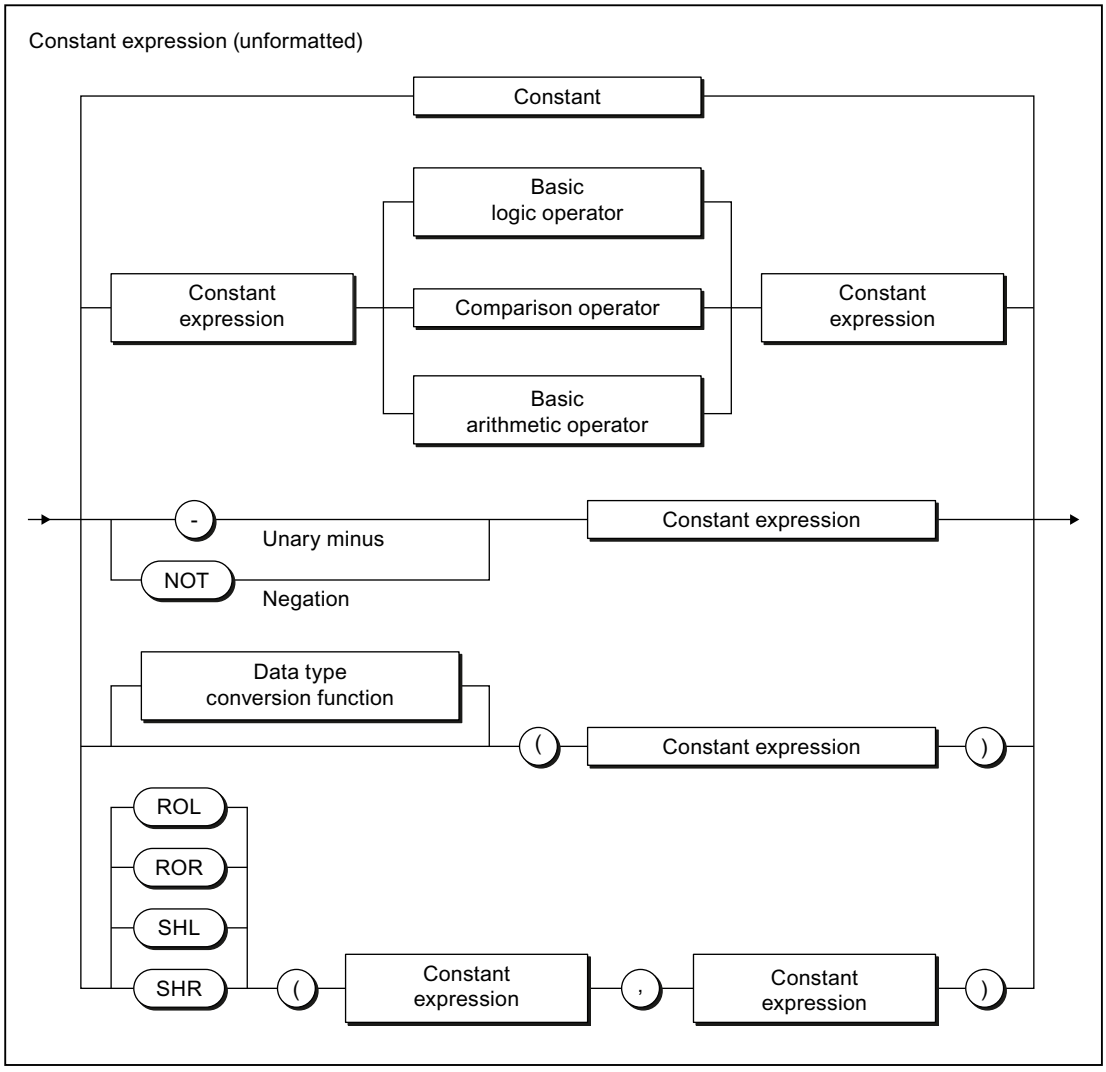

Figure 7-242 Syntax: Constant expression

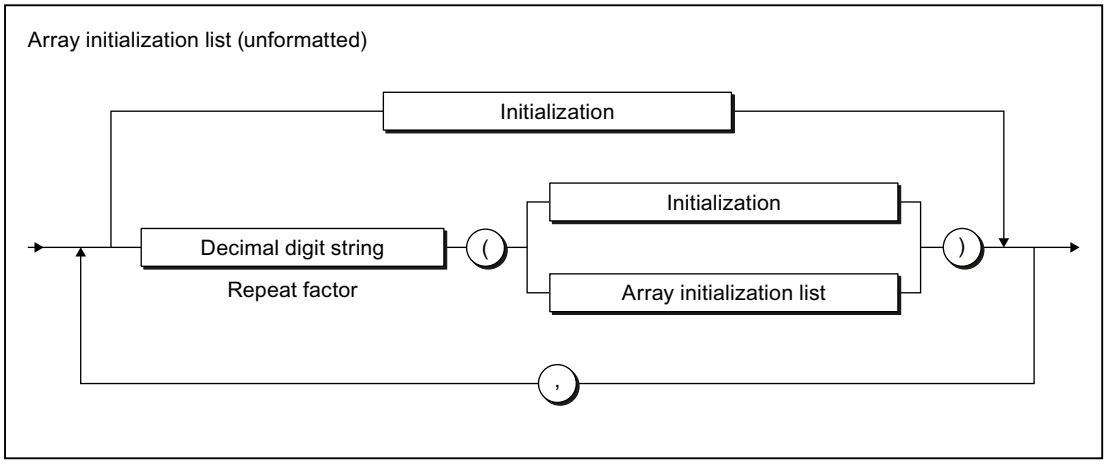

Figure 7-243 Syntax: Array initialization list

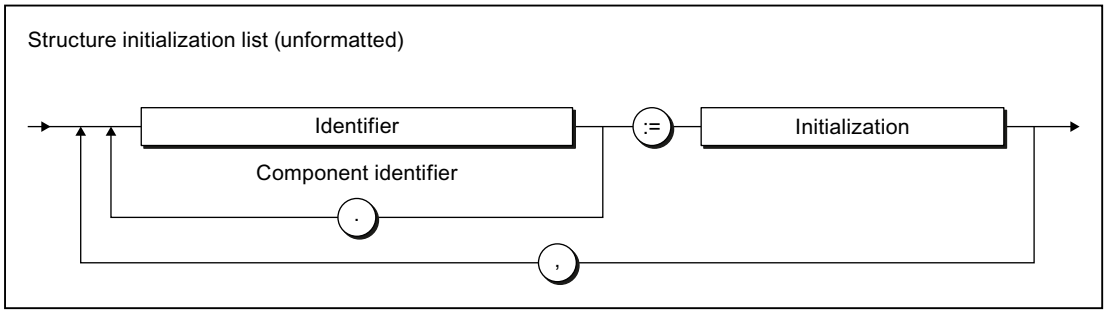

Figure 7-244 Syntax: Structure initialization list

Table 7-396 Examples of variable initialization

```
VAR
    // Declaration of a variable ...
    var1 : REAL := 100.0;
    // ... or if there are several variables of the same type:
    var2, var3, var4 : INT := 1;
    var5 : REAL := 3 / 2;
    var6 : INT := 5 * SHL(1, 4);
    myC1 : C1 := GREEN;
    array1 : ARRAY [0..4] OF INT := [1, 3, 8, 4, 0];
    array2 : ARRAY [0..5] OF DINT := [6 (7)];
    array3 : ARRAY [0..10] OF INT := [2 (2(3),3(1)),0];
                // is equivalent to [2(3),3(1),2(3),3(1)),0]
                // Initialization as follows:
                // Array elements 0, 1        with 3;
                // Array elements 2, 3, 4        with 1;
                // Array elements 5, 6        with 3;
                // Array elements 7, 8, 9        with 1;
                // Array element 10            with 0
    myAxis : PosAxis := TO#NIL;
END_VAR
```

Table 7-397 Examples of data type initialization

```
TYPE
    // Initialization of a derived data type
    type1 : REAL := 10.0;
    // Initialization of an enumeration data type
    cmyk_colour : (cyan, magenta, yellow, black) := yellow;
    // Initialization of structures
    var_rgb_colour : STRUCT
            red, green, blue : USINT := 255;// white
        END_STRUCT;
    new_colour : var_rgb_colour := (red := 0, blue := 0);// green
    myInt : INT := 9;
    myArray : ARRAY [0..5] OF myInt := [1, 2, 3];
                // Initialization as follows:
                // Array element 0            with 1;
                // Array element 1            with 2;
                // Array element 2            with 3;
                // Array elements 3, 4, 5     with 9
END_TYPE
```

Information about the circumstances when variables are initialized can be found in Section "Time of the variable initialization" (Page 4849).

Initialization of structures

To initialize a structure (data type STRUCT), assign to it a structure initialization list enclosed in brackets "(" ")". Assign the initialization value to the desired component in this initialization list, see the syntax diagram above.

The following methods can be used to initialize components of lower-level structures:

- You assign another structure initialization list enclosed in brackets to a component and then "nest" the lists inside one another.
- You aggregate the identifiers of the component, subcomponent, etc. as follows (use periods as separators): *comp_name.subcomp_name.subsubsomp_name* and assign the initialization value to this structure.

Note

Saving in an old project format:

Projects in which aggregated identifiers are used cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

You can use both notations within the same structure initialization list provided that you are initializing different components.

You can initialize arrays within structures by assigning an array initialization list enclosed in square brackets "[" "]" to the component. See example below:

Table 7-398 Examples of structure initialization

```
TYPE
    s_base : STRUCT
        i : INT;
        j : DINT;
    END_STRUCT
    s_deri : STRUCT
        x : INT;
        v_b : s_base := (i := 10);
        arr_b : ARRAY [0..2] OF s_base
           := [(i := 10, j := 15), (i := 12), (j := 13)];
    END_STRUCT
    s_up : STRUCT
        vup_d : s_deri := (x := 3);
        vup_a : ARRAY [0..1] OF s_deri;
    END_STRUCT
END_TYPE
VAR
    // Initialization with nested
    // structure initialization lists
    var_1 : s_up := (vup_d := (v_b := (i := 1) , x := 2));
    // Alternative with aggregated component identifiers
    var_2 : s_up := ( vup_d.v_b.i := 1, vup_d.x := 2);
    // Initialization of arrays of structures
    var3 : s_up := (vup_a := [ (v_b := (i := 5)), (v_b.i := 6) ] );
    var4 : ARRAY [0..7] OF s_up := [ 5((vup_d := (v_b := (i := 1)))),
                                     3((vup_d.v_b.i := 1)) ];
END_VAR
```

Constants

Constants are data with a fixed value that you cannot change during program runtime. Constants are declared in the same way as variables:

- In the declaration section of a POU for local constants (see Figure *Syntax: Constant block in a POU* and *syntax: Constant declaration*).
- In the interface or implementation section of the ST source file for unit constants (see Figure *Syntax: Unit constants in the interface or implementation section* and *syntax: Constant declaration*). You can import unit constants declared in the interface section into other ST source files (see Variable model (Page 4831)).

The source file section also determines the range of the constant declaration.

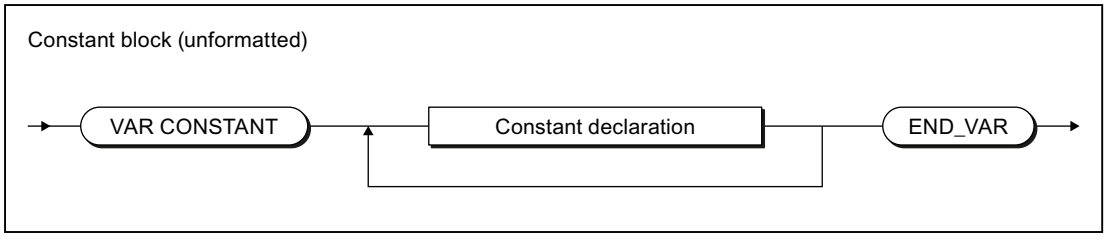

Figure 7-245 Syntax: Constant block in a POU

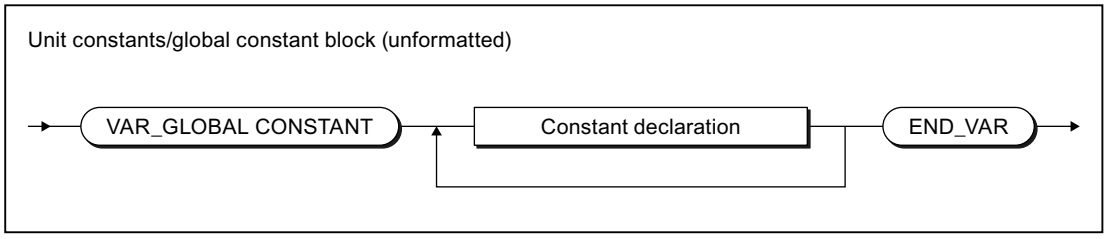

Figure 7-246 Syntax: Unit constants in interface or implementation section

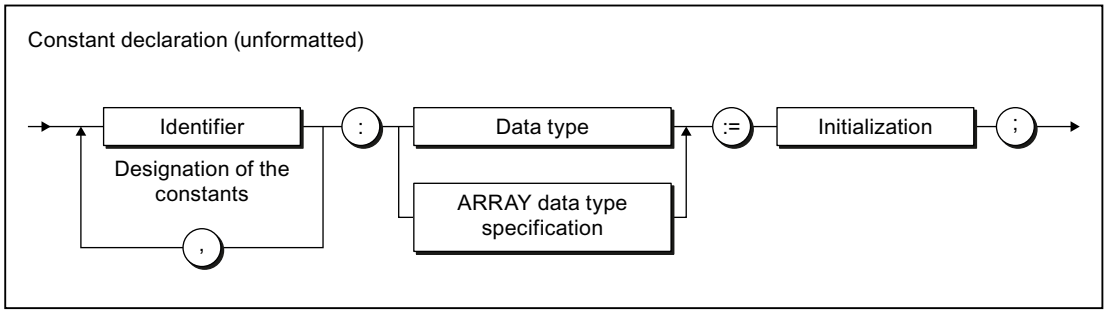

Figure 7-247 Syntax: Constant declaration

To initialize a constant, see "Initialization of variables or data types (Page 4697)". The value assigned to a constant is calculated from the constant expression at the time of compilation.

Table 7-399 Examples of constants

```
VAR CONSTANT
    PI            : REAL := 3.1415;
    intConst      : INT  := 10;
    sintConst     : SINT := 0;
    dintConst     : DINT := 10_000;
    timeConst     : TIME := TIME#1h;
    strConst      : STRING[40] := 'Example of a string';
    Two_PI        : REAL := 2 * PI;
END_VAR
```

7.2.4.6 Value assignments and expressions

You have no doubt already created value assignments with the character string :=. This may have been for a statement as part of an example (see table titled *Examples of statements* in Statements (Page 4670)) or when initializing variables in the declaration subsection of a source file module.

However, this is only a small range of the options available for formulating value assignments. This section of the manual now describes this important topic in detail using a large number of examples for illustration purposes.

See also

Notes on avoiding errors and on efficient programming (Page 4934)

Value assignments

Syntax of the value assignment

A value assignment is used to assign the value of an expression to a variable. The previous value is overwritten. Before a value can be correctly assigned, a variable must be declared in the declaration section (see Syntax of variable declaration (Page 4694)).

As shown in the following syntax diagram, the expression is evaluated on the right side of the assignment operator :=. The result is stored in the variable whose name is on the left side of the assignment operator (target variable). All target variables supported from a formal viewpoint are shown in the figure.

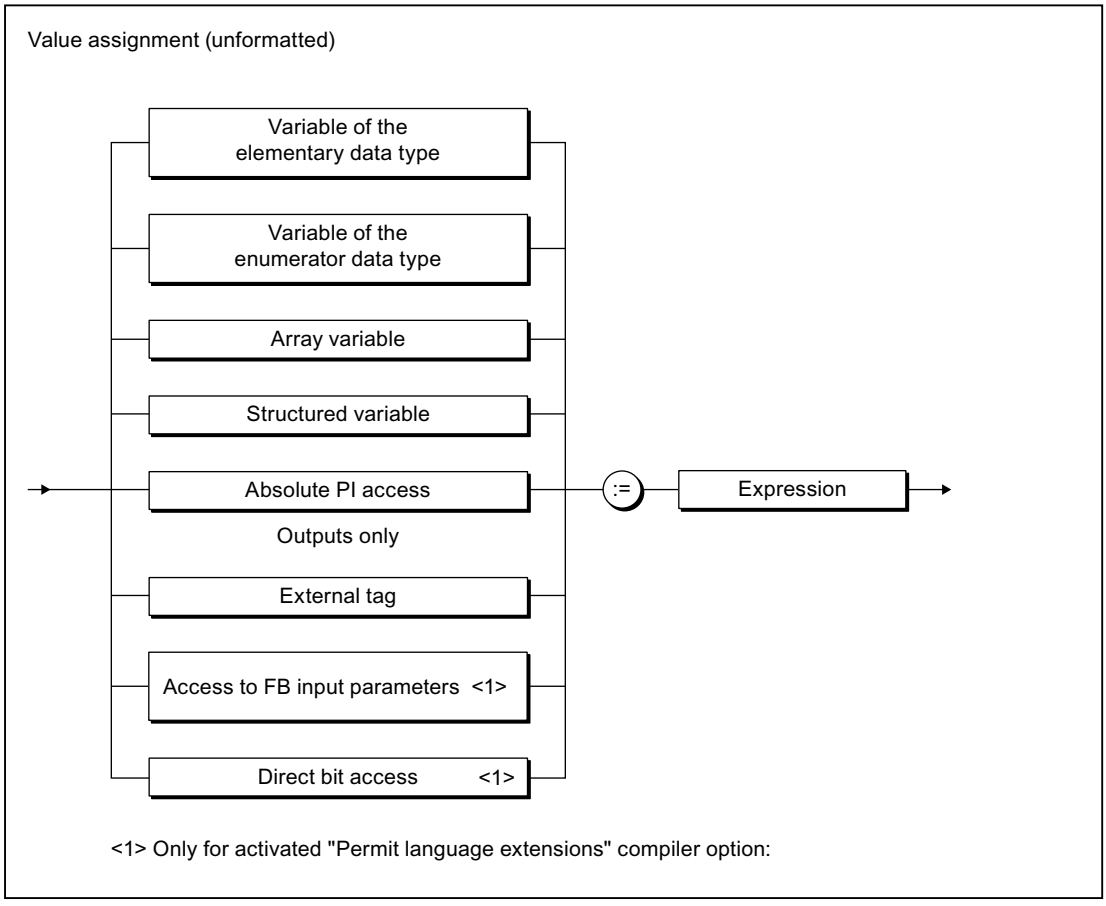

Figure 7-248 Syntax: Value assignment

The following contains explanations and examples for the left side of the value assignment:

- Value assignments with variables of an elementary data type (Page 4704) ,
- Value assignments with variables of the derived enumerator data type (Page 4707)
- Value assignments with variables of the derived ARRAY data type (Page 4707)
- Value assignments with variables of the derived STRUCT data type (Page 4708)
- Value assignments with absolute PI access (to addresses of the process image), see: Absolute access to the fixed process image of the BackgroundTask (absolute PI access) (Page 4887).

How the right side of a value assignment, i.e. an expression, is formed, is described in Expressions (Page 4709).

Value assignments with variables of an elementary data type

An expression with an elementary data type (Page 4672) can be assigned to a variable when one of the following conditions is fulfilled:

- Expression and target variable have the same data type.
  Note the following information on the STRING data type (Page 4704).
- The data type of the expression can be implicitly converted to the data type of the target variable (see Conversion of elementary data types (Page 4732) and *Functions for the conversion of numerical data types and bit data types* in the *SIMOTION Basic Functions* Function Manual).

Examples

```
elemVar         := 3*3;
elemVar         := elemVar1;
```

See also

Value assignments with variables of a bit data type (Page 4705)

Value assignments with variables of the STRING elementary data type

Assignments between variables of the STRING data type

There are no restrictions to assignments between variables of the STRING data type (character strings) that have been declared with different lengths. If the declared length of the target variable is shorter than the current length of the assigned character string, the character string is truncated to the length of the target variable.

Exception: The following applies for an in/out assignment (parameter transfer to an in/out parameter): The declared length of the assigned variable (actual parameter) must be greater than or equal to the declared length of the target variable (formal in/out parameter). See Parameter transfer to in/out parameters (Page 4751).

Please also refer to Syntax diagram of STRING data type (Page 4672):

Examples:

```
string20 := 'ABCDEFG';
string20 := string30;
```

Access to elements of a string

The individual elements of a string can be addressed in the same way as the elements of an array [1..n]. These elements are converted implicitly to the elementary data type BYTE. In this way assignments between string elements and variables of the BYTE data type are possible.

Examples:

```
byteVar := string20[5];
string20[10] := byteVar;
```

The following special cases have to be taken into account:

1. When assigning a variable of the BYTE data type to a string element (e.g. `stringVar[n] := byteVar`):
   - The string element to which the value is to be assigned lies outside of the declared length of the string:
     The string remains unchanged, TSI#ERRNO is set to 1.
   - The string element to which the value is to be assigned lies outside of the assigned length of the string (n > LEN(stringVar)), but within the declared length:
     The length of the string is adjusted, the string elements between LEN(stringvar) and n are set to $00.
2. When assigning a string element to a variable of the BYTE data type (`byteVar := stringVar[n]`):
   - The string element to which the variable is to be assigned lies outside of the assigned length of the string (n > LEN(stringVar)):
     The variable is set to 16#00, TSI#ERRNO to 2.

Editing strings

Various system functions are available for the editing of strings, such as the joining of strings, replacement and extraction of characters, see *SIMOTION Basic Functions* Function Manual.

Converting between numbers and strings

Various system functions are available for conversion between variables of numeric data types and strings; see Converting elementary data types (Page 4732) and the *SIMOTION Basic Functions* Function Manual.

Value assignments with variables of a bit data type

Access to individual bits of a bit data type variable

You can also access the individual bits of a variable of data type BYTE, WORD or DWORD:

- With standard functions, see SIMOTION Basic Functions Function Manual:
  You can read, write or invert any bit of a bit string with the functions _getBit, _setBit and _toggleBit.
  You can specify the number of the bit via a variable.
- With direct bit access:
  You can define the bit of the variable that you want to access as a constant, via a separate point behind the variable.
  You can only specify the number of the bit via a constant.
  To be able to use this option, you must activate the "Permit language extensions" compiler option, see Global compiler settings (Page 4623) and Local compiler settings (Page 4626).

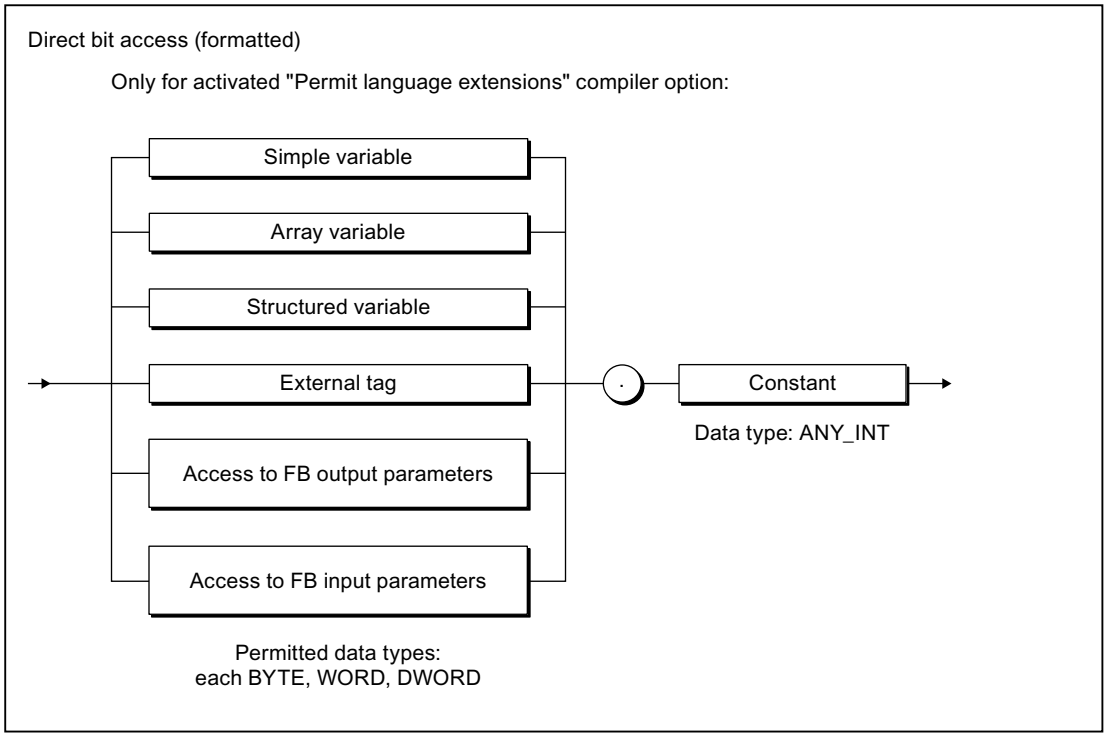

Figure 7-249 Syntax: Direct bit access

Table 7-400 Example of direct bit access

```
// Only with compiler option "Permit language extensions"
FUNCTION f : VOID
    VAR CONSTANT
        BIT_7 : INT := 7;
    END_VAR
    VAR
        dw : DWORD;
        b  : BOOL;
    END_VAR
    b := dw.BIT_7;  // Access to Bit 7
    b := dw.3;      // Access to Bit 3
//  b := dw.33;     // Compilation error:
                    // Bit 33 not permitted.
    dw.BIT_7 := b   // Access to Bit 7
    dw.3     := NOT dw.3  // Access to Bit 3
END_FUNCTION
```

Note

The access to bits of an I/O variable or system variable can be interrupted by other tasks. There is therefore no guarantee of consistency.

Editing variables of the bit data types

You can:

1. Combine several variables of the same data type into one variable of a higher-level data type (e.g. two variables of the BYTE data type into one of the WORD data type). Various system functions are available for this, e.g. WORD_FROM_2BYTE.
2. Split one variable into several variables of a lower-level data type (e.g. one variable of the DWORD data type into four of the BYTE data type). Various system functions are available for this, e.g. DWORD_TO_4BYTE.
3. Rotate or shift the bits within a variable. The bit string standard functions ROL, ROR, SHL and SHR are available for this.

These system functions and system function blocks are described in the *SIMOTION Basic Functions* Function Manual.

Logic operators

Variables of the bit data types can be combined with logic operators; see Logic expressions and bit-serial expressions (Page 4717).

Value assignments with variables of the derived enumerator data type

Each expression and each variable of the derived enumerator data type (see also: Derived enumerator data type (Page 4681)) can be assigned to another variable of the same type.

```
type1        := BLUE;
```

Value assignments with variables of the derived ARRAY data type

An array consists of several dimensions and array elements, all of the same type (see also: Derived ARRAY data type (Page 4678)).

There are various ways to assign arrays to variables. You can assign complete arrays, individual elements, or parts of arrays:

- A complete array can be assigned to another array if both the data types of the components and the array limits (the smallest and largest possible array indices) are the same. Valid assignments are:

```
array_1     := array_2;
```

- An individual array element is addressed by the array name followed by the index value in square brackets. An index must be an arithmetic expression of the data type SINT, USINT, INT, UINT or DINT.

```
elem1        := array [i];
array_1 [2]  := array_2 [5];
array [j]    := 14;
```

- A value assignment for a valid subarray can be obtained by omitting a pair of square brackets for each dimension of the array, starting at the right. This addresses a partial area of the array whose number of dimensions is equal to the number of remaining indices (see example below).
  Consequently, you can reference rows and individual components within a matrix but not closed columns (closed in the sense of from...to). Valid assignments are:

```
matrix1 [i]   := matrix2 [k];
array1        := matrix2 [k];
```

Value assignments with variables of the derived STRUCT data type

Variables of a user-defined data type that contain STRUCT data type specifications are called structured variables (see also Derived STRUCT data type (Page 4682)). They can either represent a complete structure or a component of this structure.

Valid parameters for a structure variable are:

```
struct1             // Identifier for a structure
struct1.elem1       // Identifier for a structure component
struct1.array1      // Identifier of a simple array
                    //within a structure
struct1.array1[5]   // Identifier of an array component
                    //within a structure
```

There are two ways to assign structures to variables. You can reference complete structures or structure components:

- A complete structure can only be assigned to another structure if the data type and the name of both structure components match.
  A valid assignment is:

```
struct1 := struct2;
```

- You can assign a type-compatible variable, a type-compatible expression or another structure component to each structure component.
  Valid assignments are:

```
struct1.elem1       := Var1;
struct1.elem1       := 20;
struct1.elem1       := struct2.elem1;
struct1.array1      := struct2.array1;
struct1.array1[10]  := 100;
```

Note

You also use structured variables in the *FBInstanceName.OutputParameter* format, e.g. *myCircle.circumference* to access the output variables of a function block, i.e. the result of the function block. For more detailed information about function blocks, refer to the explanations in Defining functions (Page 4736) and Defining function blocks (Page 4737).

A further application of structured variables is to access TO variables and the variables of the basic system.

Expressions

An expression represents a value that is calculated when the program is compiled or executed. It consists of operands (e.g. constants, variables or function values) and operators (e.g. *, /, +, -).

The data types of the operands and the operators involved determine the expression type.

ST uses the following types of expression:

- Arithmetic expressions (Page 4712)
- Relational expressions (Page 4715)
- Logic expressions and bit-serial expressions (Page 4717)

Result of an expression

The result of an expression can be:

- Assigned to a variable
- Used as a condition for a control statement
- Used as a parameter for a function or function block call.

The data type of the result of an arithmetical or bit-serial expression is determined by the data types of the operands. The data type used is the lowest common data type to which both operands can be implicitly converted.

An expression value can only be assigned to a variable (or a parameter of a function or function block) in the following cases:

- The expression calculated and the variable to be assigned are of the same data type.
- The data type of the calculated expression can be implicitly converted to the data type of the variable to be assigned.

For more information on this error source and its solution, see *SIMOTION Basic Functions* Function Manual.

Note

Expressions containing only the following elements can be used for variable initialization and index specification in ARRAY declarations (for initialization expressions – see Figure *Syntax: Constant expression* in Initialization of variables or data types (Page 4697)):

- Constants
- Basic arithmetic operations
- Logic and relational operations
- Bit string standard functions

The constant expressions used for initialization are calculated in the data type of the declared variables or in the declared data type.

Interpretation order of an expression

The interpretation order of an expression depends on the following:

- The priority of the operators used,
- The left-to-right rule,
- The use of parentheses (for operators of the same priority).

Expressions are processed according to specific **rules**:

- Operators are executed according to priority (see table in Operator priority (Page 4718)).
- Operators of the same priority are executed from left to right.
- A minus symbol in front of an identifier denotes multiplication by -1.
- An arithmetic operator cannot be followed immediately by another. The expression *a * -b* is therefore invalid, but *a * (-b)* is allowed.
- Parentheses override the operator priority order, i.e. parentheses have the highest priority.
- Expressions in parentheses are treated as individual operands and are always evaluated first.
- The number of opening parentheses must equal the number of closing parentheses.
- Arithmetic operations cannot be used on characters or logic data. For this reason, expressions such as *(n<=0) + (n<0)* are invalid.

Table 7-401 Examples of expressions

```
testVar          // Operand
A AND (B)        // Logical expression
A AND (NOT B)    // Logical expression with negation
(C) < (D)        // Comparison expression
3+3*4/2          // Arithmetic expression
```

Operands

Definition

Operands are objects which can be used to formulate expressions. Operands can be represented by the syntax diagram:

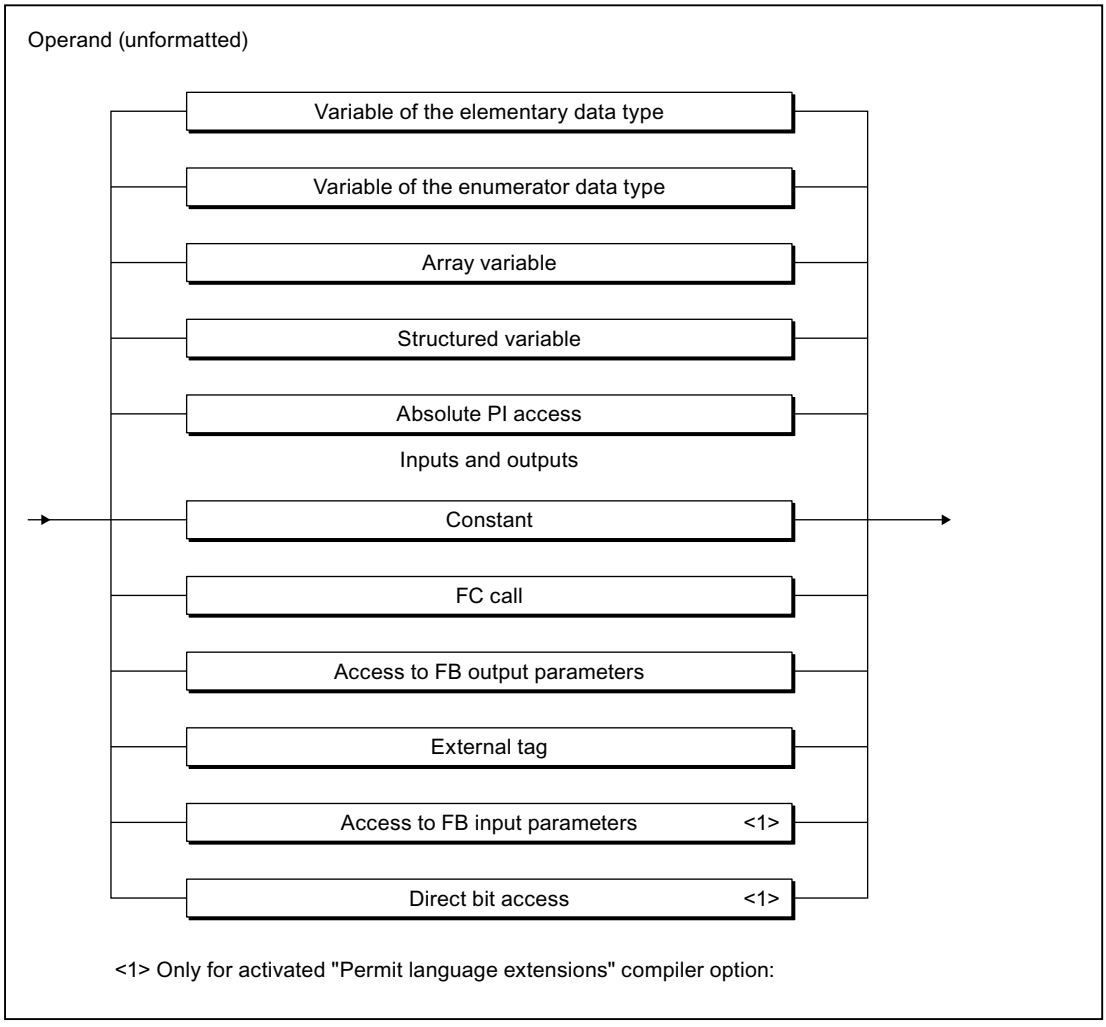

Figure 7-250 Syntax: Operand

Table 7-402 Examples of operands

```
intVar
5
%I4.0
PI
NOT TRUE
axis1.motionStateData.actualVelocity
```

Arithmetic expressions

An arithmetic expression is an expression formed with arithmetical operators. These expressions allow numerical data types to be processed.

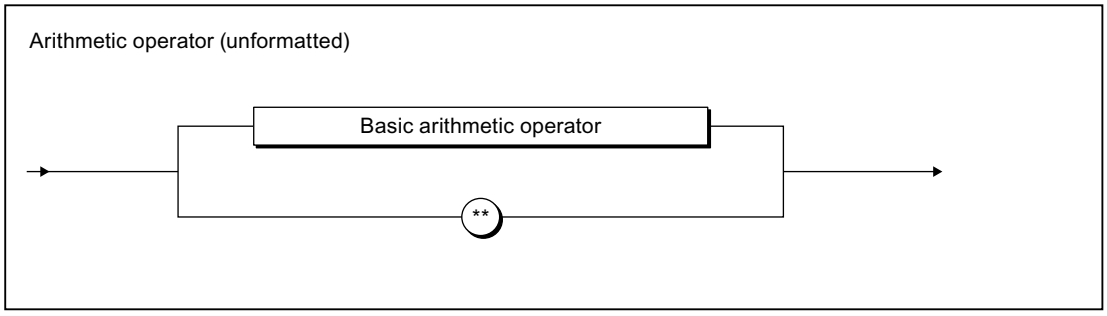

Figure 7-251 Syntax: Arithmetic operator

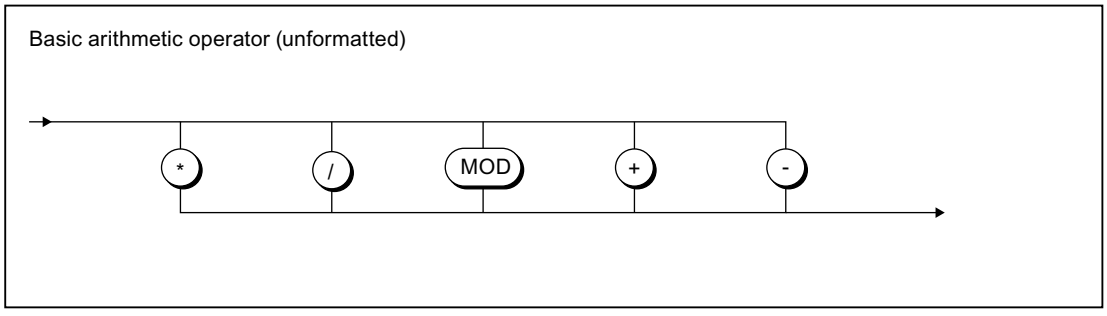

Figure 7-252 Syntax: Basic arithmetic operator

The following table shows for each arithmetic operation:

- The arithmetic operator
- The permitted data types of the operands
- The data type of the result.

Some of the General data types (Page 4674) are used here.

Note

Further operations are possible with standard numeric functions, see *Standard numeric functions* in the *SIMOTION Basic Functions* Function Manual.

It is recommended to enclose negative numbers in parentheses, even in cases where it is not absolutely necessary, in order to enhance legibility.

The arithmetic operators are processed in accordance with their rank (Page 4718).

Table 7-403 Arithmetic operators

Instruction	Operator	Data type		
		1st operand	2nd operand	Result[1]
Exponential (See also EXPT function)	**	ANY_REAL[2]	ANY_REAL	ANY_REAL[3]
Unary minus	–	ANY_NUM	(None)	ANY_NUM
Multiplication	*	ANY_NUM	ANY_NUM	ANY_NUM
		ANY_BIT[4]	ANY_BIT[4]	ANY_BIT
		TIME	ANY_NUM	TIME
Division	/	ANY_NUM	ANY_NUM[5]	ANY_NUM
		ANY_BIT[4]	ANY_BIT[4] [5]	ANY_BIT
		TIME	ANY_NUM[5]	TIME
		TIME	TIME[5]	UDINT
Modulo division	MOD	ANY_INT	ANY_INT[5]	ANY_INT
		ANY_BIT[4]	ANY_BIT[4] [5]	ANY_BIT
Addition	+	ANY_NUM	ANY_NUM	ANY_NUM
		ANY_BIT[4]	ANY_BIT[4]	ANY_BIT
		TIME	TIME	TIME[6]
		TOD	TIME	TOD[6]
		DT	TIME	DT[7]
Subtraction	–	ANY_NUM	ANY_NUM	ANY_NUM
		ANY_BIT[4]	ANY_BIT[4]	ANY_BIT
		TIME	TIME	TIME
		TOD	TIME[8]	TOD
		DATE	DATE	TIME[9]
		TOD	TOD	TIME[9]
		DT	TIME	DT
		DT	DT	TIME[9]

1) The data type of the result (unless explicitly stated) is the lowest common data type to which both operands can be implicitly converted.

2) The 1st operand must be greater than zero.
Exceptions as of version V4.1 of the SIMOTION Kernel:
– If the 2nd operand is an integer, the 1. operand can be less than zero.
– If the 2nd operand is positive, the 1st operand can be equal to zero.
The following applies up to version V4.0 of the SIMOTION Kernel: If the 1st operand is equal to zero, an error message can be caught with ExecutionFaultTask.

3) Data type of the 1st operand.

4) Other than BOOL data type. The calculation is made using the unsigned integer of the same bit width.

5) The 2nd operand must not be equal to zero.

6) Addition, possibly with overflow.

7) Addition with date correction.

8) Restriction of TIME to TOD before calculation.

9) These operations are based on the modulo of the maximum value of the TIME data type.

Note

If the limits of the value range are exceeded in operations with variables of the general ANY_REAL data type, the result contains the equivalent bit pattern according to IEEE 754.

In order to establish whether the value range was exceeded in the operation, you can verify the result using the function *_finite* (see *SIMOTION Basic Functions* Function Manual).

Examples of arithmetic expressions

Examples of arithmetic expressions with numbers

Assuming that *i* and *j* are integer variables (e.g. of data type INT) with the values of 11 and -3 respectively, some example integer expressions and their corresponding values are presented below:

Expression	Value
`i + j`	`8`
`i - j`	`14`
`i * j`	`-33`
`i MOD j`	`-2`
`i / j`	`-3`

Examples of valid arithmetic expressions with time specifications

Assume the following variables:

Variables	Content	Data type
`t1`	`T#1D_1H_1M_1S_1MS`	`TIME`
`t2`	`T#2D_2H_2M_2S_2MS`	`TIME`
`d1`	`D#2004-01-11`	`DATE`
`d2`	`D#2004-02-12`	`DATE`
`tod1`	`TOD#11:11:11.11`	`TIME_OF_DAY`
`tod2`	`TOD#12:12:12.12`	`TIME_OF_DAY`
`dt1`	`DT#2004-01-11-11:11:11.11`	`DATE_AND_TIME`
`dt2`	`DT#2004-02-12-12:12:12.12`	`DATE_AND_TIME`

Some expressions with these variables and their values are shown in the example.

Expression	Value
`t1 + t2`	`T#3D_3H_3M_3S_3MS`
`dt1 + t1`	`DT#2004-01-12-12:12:12.111`
`t1 - t2`	`T#48D_16H_1M_46S_295MS`
`t1 * 2`	`T#2D_2H_2M_2S_2MS`
`t1 / 2`	`T#12H_30M_30S_500MS`

```
DATE_AND_TIME_TO_TIME_OF_DAY(dt1)     TOD#11:11:11.110
DATE_AND_TIME_TO_DATE(dt1)            D#2004-01-11
```

Relational expressions

Definition

A relational expression is an expression of the BOOL data type formed with relational operators (see figure).

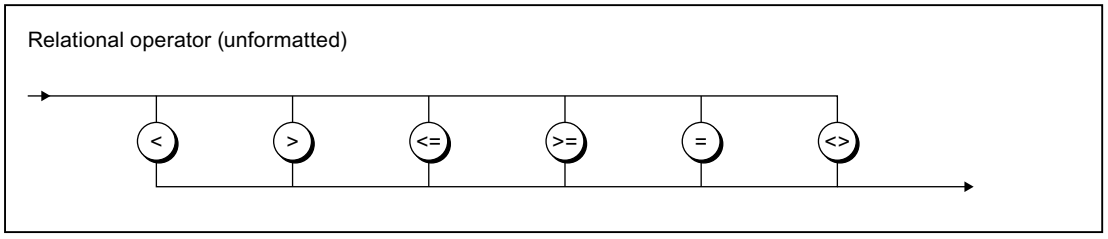

Figure 7-253 Syntax: Relational operators

Relational operators compare the values of 2 operands (see table) and return a Boolean value as result.

1st Operand Operator 2nd Operand -> Boolean value

Table 7-404 Meaning of relational operators

Operator	Meaning
>	1. operand is **greater than** the 2nd operand
<	1. operand is **less than** the 2nd operand
>=	1. operand is **greater than or equal to** the 2nd operand
<=	1. operand is **less than or equal to** the 2nd operand
=	1. operand is **equal to** the 2nd operand
<>	1. operand is **not equal to** the 2nd operand

The result of the relational expression is:

- 1 (TRUE), when the comparison is satisfied
- 0 (FALSE), when the comparison is not satisfied.

The following table shows permissible combinations of the data types for the two operands and relational operators.

Table 7-405 Relational expressions: Permissible combinations of the data types and relational operators

Data type		Permissible relational operators
1. Operand	2. Operand	
ANY_NUM	ANY_NUM[1)]	<, >, <=, >=, =, <>
ANY_BIT	ANY_BIT	<, >, <=, >=, =, <>
DATE	DATE	<, >, <=, >=, =, <>

Data type		Permissible relational operators
1. Operand	2. Operand	
TIME_OF_DAY (TOD)	TIME_OF_DAY (TOD)	<, >, <=, >=, =, <>
DATE_AND_TIME (DT)	DATE_AND_TIME (DT)	<, >, <=, >=, =, <>
TIME	TIME	<, >, <=, >=, =, <>
STRING	STRING[2)]	<, >, <=, >=, =, <>
Enumerator data type	Enumerator data type[3)]	=, <>
ARRAY	Field (ARRAY)[3)]	=, <>
Structure (STRUCT)	Structure (STRUCT)[3)]	=, <>

1) The comparison is made in the lowest common data type to which both operands can be implicitly converted.

2) Variables of the STRING data type can be compared irrespective of the declared length of the string. To compare two variables of the STRING data type with different lengths, the shorter character string is expanded to the length of the longer character string by inserting $00 on the right-hand side. The comparison starts from left to right and is based on the ASCII code of the respective characters. Example: 'ABC' < 'AZ' < 'Z' < 'abc' < 'az' < 'z'.

3) Data type of the 1. operand.

Relational expressions and variables or constants of the BOOL data type can be combined with logic operators to form logic expressions (see Logic expressions and bit-serial expressions (Page 4717)). This enables the implementation of queries such as *If a < b and b < c, then ...*.

Note

Relational operators have a higher priority than logic operators in an expression (see Operator priority (Page 4718)). Therefore the operands of a relational expression must be placed in brackets if they themselves are logic expressions or bit-serial expressions.

Note that errors can occur when comparing REAL or LREAL variables (also the corresponding system variables, e.g. axis position).

Table 7-406 Examples of relational expressions

```
IF A = 2 THEN
    ; //...
END_IF;

var_1 := B < C;          // var_1 of BOOL data type

IF D < E OR var_2 THEN  // var_2 of BOOL data type
    ; // ...
END_IF;

var_3 := 0 < F < 10      // var_3 of BOOL data type, TRUE value
    // The calculation is from left to right
    // in the following form: (0 < F) < 10
    // Initially 0 < F is calculated.
    // The result is from the BOOL data type (FALSE or TRUE)
    // and is compared with BYTE#10.
    // Equivalent expression:
var_3 : = BOOL_TO_BYTE (0 < F) < BYTE#10
```

Logic expressions and bit-serial expressions

Definition

With the logic operators AND, &, XOR, and OR, it is possible to combine operands and expressions of the general data type ANY_BIT (BOOL, BYTE, WORD, or DWORD).

With the logic operator NOT it is possible to negate operands and expressions of data type ANY_BIT.

The table provides information about the available operators:

Table 7-407 Logic operators

Instruction	Operator	1. Operand	2. Operand	Result[1]
Negation	NOT	ANY_BIT	-	ANY_BIT
Conjunction	AND or &	ANY_BIT	ANY_BIT	ANY_BIT
Exclusive disjunction	XOR	ANY_BIT	ANY_BIT	ANY_BIT
Disjunction	OR	ANY_BIT	ANY_BIT	ANY_BIT
[1] The data type of the result is determined by the most powerful data type of the operands.				

The expression is designated

- a **logic expression**, if only operands of data type BOOL are used.
  The operators have the effect on the operands stated in the following truth table.
  The result of a logic expression is 1 (TRUE) or 0 (FALSE).
- a **bit-serial expression**, if operands of data type BYTE, WORD, or DWORD are used.
  The operators have the effect on individual bits of the operands stated in the following truth table.

Table 7-408 Truth table of the logic operators

Operands (data type BOOL)		Result (data type BOOL)				
a	b	NOT a	NOT b	a AND b a & b	a XOR b	a OR b
0	0	1	1	0	0	0
0	1	1	0	0	1	1
1	0	0	1	0	1	1
1	1	0	0	1	0	1

Examples

Expression (let n = 10)	Value
`(n>0) AND (n<20)`	`TRUE`
`(n>0) AND (n<5)`	`FALSE`
`(n>0) OR (n<5)`	`TRUE`

```
(n>0) XOR (n<20)                          FALSE
NOT ((n>0) AND n<20))                     FALSE
```

Expression	Value
2#01010101 AND 2#11110000	2#01010000
2#01010101 OR 2#11110000	2#11110101
2#01010101 XOR 2#11110000	2#10100101
NOT 2#01010101	2#10101010

Expression in query (let value1 be 2#01, let value2 be 2#11)

```
IF (value1 AND value2) = 2#01 THEN...
```

Condition returns TRUE, because bit-serial expression returns 2#01.

Priority of operators

Some general rules for the formulation of expressions were described in Expressions (Page 4709). The table shows you the priority of the individual operators within an expression.

Instruction	Symbol	Priority
Parentheses	**(**Expression**)**	Highest
Function evaluation	**Identifier (**argument list**)** e.g. LN(a), EXPT (a,b), etc.	
Negation Complement	– **NOT**	
Exponentiation	**	
Multiplication Division Modulo	* / **MOD**	
Addition Subtraction	**+** **–**	
Comparison	**<, >, <=, >=**	
Equal Not equal	= <>	
Boolean AND	**&, AND**	
Boolean EXCLUSIVE OR	**XOR**	
Boolean OR	**OR**	Lowest

7.2.4.7 Control statements

Few source file sections can be programmed such that all statements are executed in sequence from start to end. Usually, some statements will be executed only if a condition is true (alternatives) and some will be executed repeatedly (loops). Program control statements within a source file section are the means for accomplishing this.

IF statement

Description

The IF statement is a conditional statement. It specifies one or more options and selects one (or none) of its statement sections for execution.

The specified logic expressions are evaluated when the conditional statement is executed. If the value of an expression is TRUE, the condition is fulfilled, if the value is FALSE, it is not fulfilled.

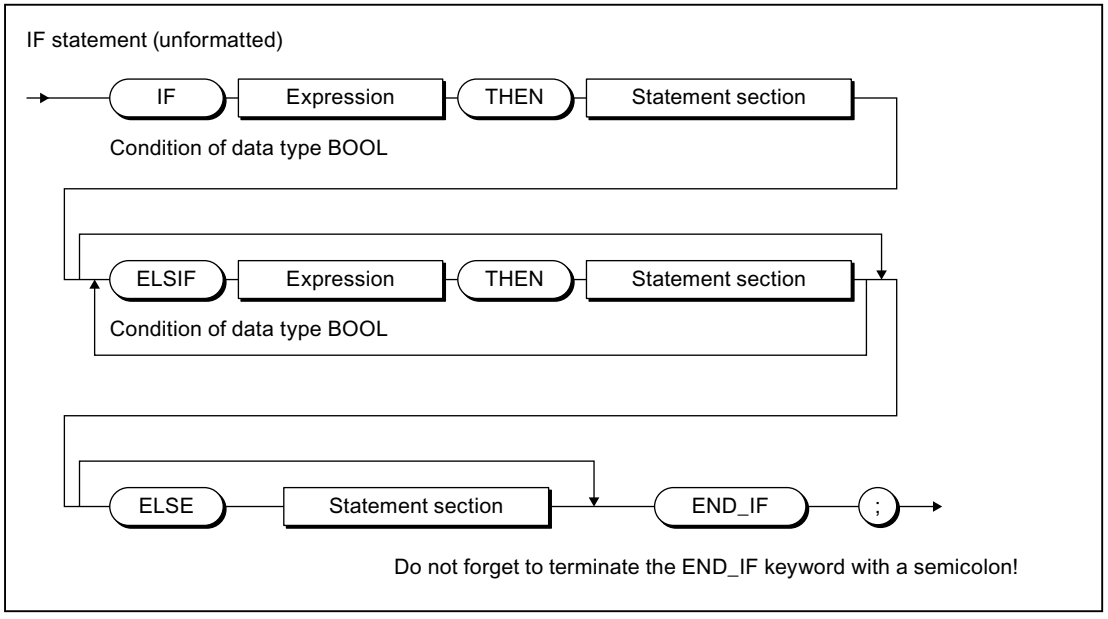

Figure 7-254 Syntax: IF statement

Sequence of execution

The IF statement is processed according to the following rules:

1. If the value of the first expression is TRUE, the statement section after the THEN is executed. The program is subsequently resumed after the END_IF.
2. If the value of the first expression is FALSE, the expressions in the ELSIF branches are evaluated. If a Boolean expression in one of the ELSIF branches is TRUE, the statement section following THEN is executed.
   The program is subsequently resumed after the END_IF.
3. If none of the Boolean expressions in the ELSIF branches is TRUE, the sequence of statements after the ELSE is executed (or, if there is no ELSE branch, no further statements are executed). The program is subsequently resumed after the END_IF.

Any number of ELSIF statements can be programmed.

Note that there may not be any ELSIF branches and/or ELSE branch. This is interpreted in the same way as if the branches existed with no statements.

Note

An advantage of using one or more ELSIF branches rather than a sequence of IF statements is that the logic expressions following a valid expression are no longer evaluated. This helps to reduce the processing time required for the program and to prevent execution of unwanted program routines.

Example

The following example illustrates the use of the IF statement:

Example of the IF statement

```
IF A = B THEN
    n:= 0;
END_IF;

IF temperature < 5.0 THEN
    %Q0.0 := TRUE;
ELSIF temperature > 10.0 THEN
    %Q0.2 := TRUE;
ELSE
    %Q0.1 := TRUE;
END_IF;
```

CASE statement

Description

The CASE statement is used to select 1 of n program sections.

This selection determines a selection expression (selector):

- Expression of general data type ANY_INT
- Variable of an enumeration data type (enumerator)

The selection is made from a list of values (value list), whereby a section of the program is assigned to each value or group of values.

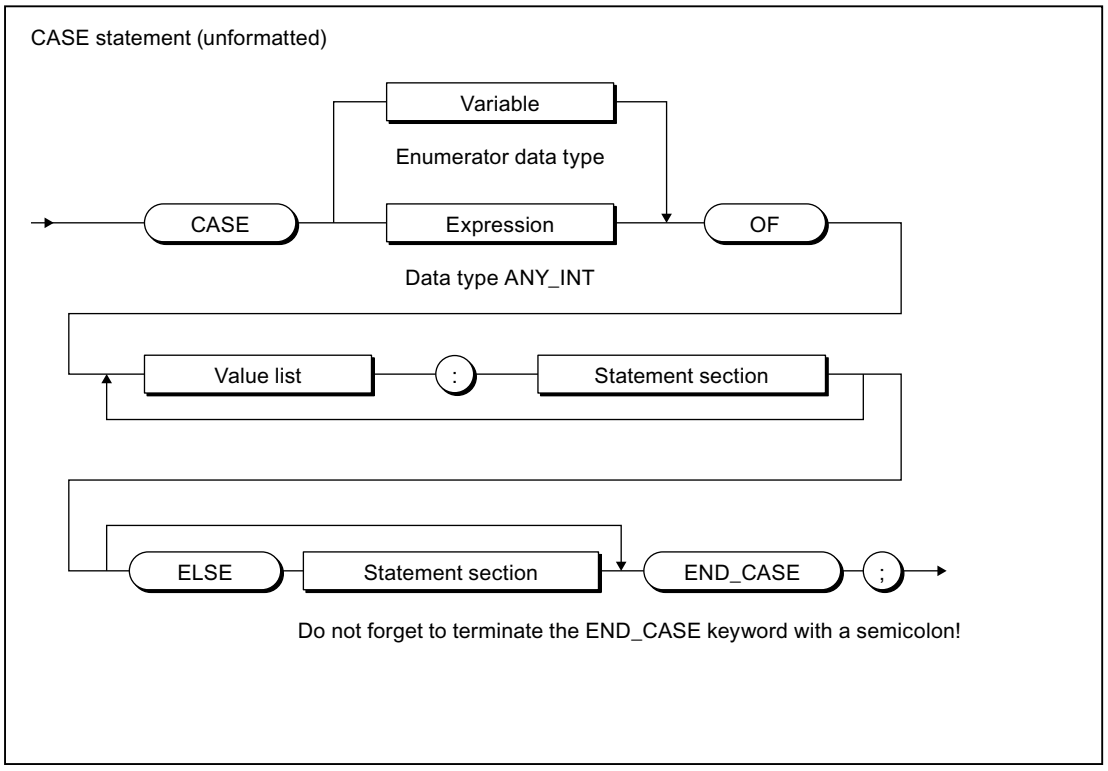

Figure 7-255 Syntax: CASE statement

Sequence of execution

The CASE statement is processed according to the following rules:

1. The selection expression (selector) is calculated. It must return a value of general data type ANY_INT (integer) or an enumeration data type.
2. Then a check is performed to determine whether the selector value is contained in the value list. Each value in the list represents one of the allowed values for the selection expression.
3. If a match is found, the program section assigned in the list is executed.
4. The ELSE branch is optional. It is executed if no match is found.
5. If the ELSE branch is missing and no match is found, the program is resumed after END_CASE.

Value list

The value list contains the allowed values for the selection expression.

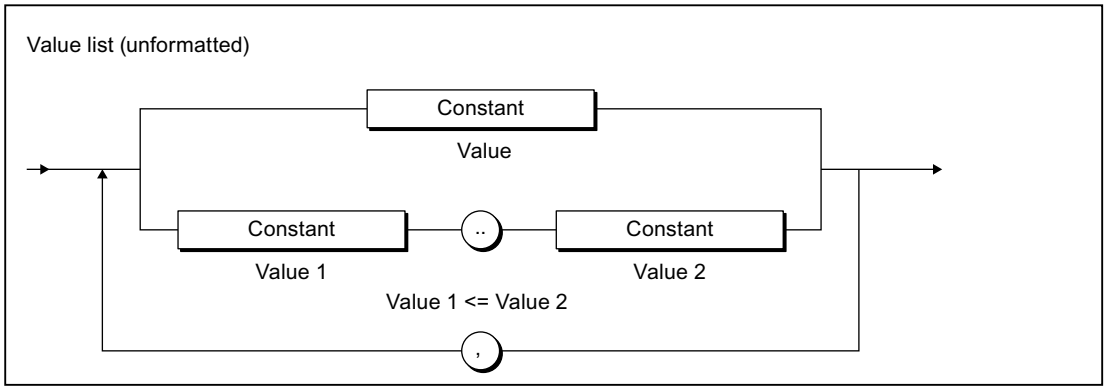

Figure 7-256 Syntax: Value list

Note the following when formulating the value list:

- Each value list can begin with a constant (*value*), a constant list (*value1, value2, value3, etc.*) or a constant range (*value1 to value2*).
- Values in the value list must be integer constants or elements of the enumeration data type of the selector.

Note

A value should only occur once in the value lists of a CASE statement.

In the event of multiple occurrence of a value, the compiler will issue an alarm, and only the section of the statement corresponding to the value list in which the value occurred first is executed.

Example

The following example illustrates the use of the CASE statement:

Example of the CASE statement

```
CASE intVar OF
    1    : a := 1;
    2,3  : b := 1;
    4..9 : c := 1; d := 2;
ELSE
    e := 5;
END_CASE;
```

FOR statement

Description

A FOR statement or a repeat statement executes a series of statements in a loop, whereby values are assigned to a variable (a count variable) on each pass. The count variable must be a local variable of type SINT, INT or DINT.

The definition of a loop with FOR includes the specification of a start and end value. Both variables must be the same data type as the count variable.

Note

You use the FOR statement when the number of loop passes is known at the programming stage.

If the number of cycles is not known, the WHILE or REPEAT statement is more suitable, see WHILE statement (Page 4725) and REPEAT statement (Page 4726).

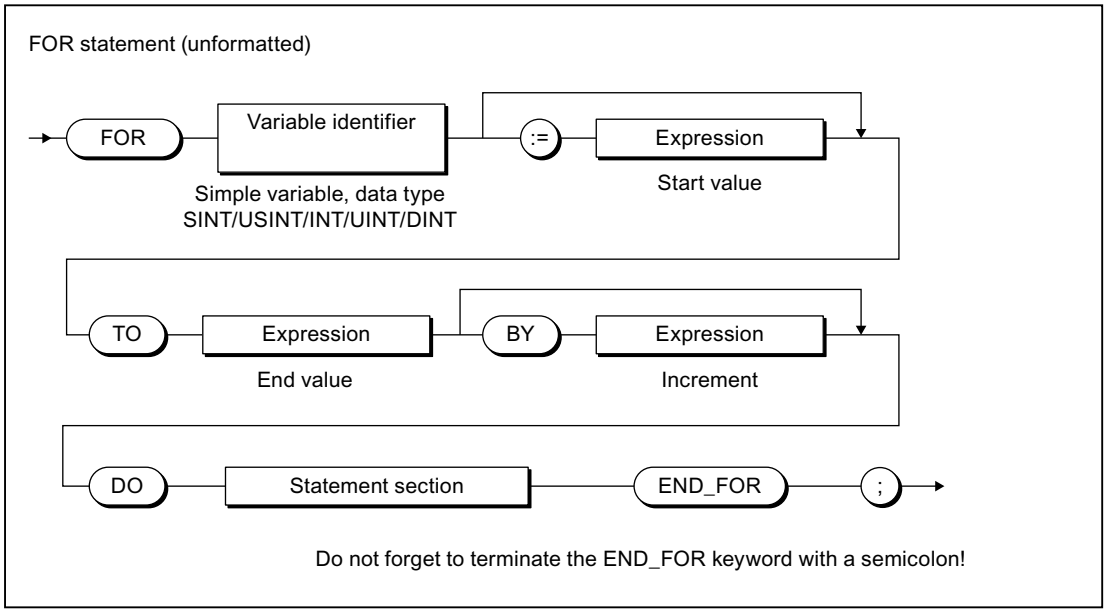

Figure 7-257 Syntax: FOR statement

Sequence of execution

The FOR statement is processed according to the following rules:

1. At the start of the loop, the count variable is set to the **start value** and is increased (positive increment) or decreased (negative increment) by the specified increment after each loop pass until the **end value** is reached. After the first loop pass, the content of the count variable is known as the **current value**.
2. On each pass, the system checks whether the following conditions are true:
   - **Start value or current value <= end value (**for **positive increment)** or
   - **Start value or current value >= end value (**for **negative increment)**

   If the condition is fulfilled, the sequence of statements is executed.
   If the condition is not fulfilled, the loop and, thus, the sequence of statements is skipped and the program is resumed after END_FOR.
3. If the FOR loop is not executed due to Step 2, the count variable retains the current value.

Rules

The following rules apply to the FOR statement:

- The *BY [increment]* specification can be omitted. If no increment is specified, the default is +1.
- The start value, end value and increment are expressions, see Expressions (Page 4709). The expression is evaluated once at the beginning of the FOR statement.
- If the start value and end value are of the data type DINT, the amount from (end value - start value) must be less than DINT#MAX (2**31 - 1), see also Value range limits of elementary data types (Page 4674).
- The count variable contains the value which triggers the loop exit, i.e. it is incremented before the loop is exited.
- During the loop execution, the count variable (current value) as well as the start value, the end value and the increment must not be changed.

Example

The following example illustrates the use of the FOR statement:

Example of the FOR statement

```
FOR k := 1 TO 10 BY 2 DO
    l := l + 1;
    // ...
END_FOR;
```

WHILE statement

Description

The WHILE statement allows a sequence of statements to be executed repeatedly under the control of an iteration condition. The iteration condition is formulated in accordance with the rules for a logic expression.

Note

You use the WHILE statement when the number of loop passes is not known at the programming stage.

If the number of passes is known, the FOR statement (Page 4723) is more suitable.

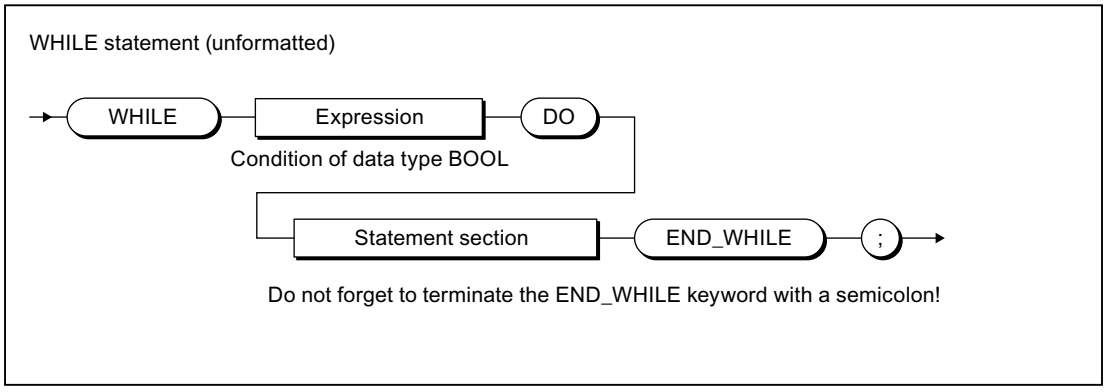

Figure 7-258 Syntax: WHILE statement

The statement section after DO is repeated until the iteration condition has the value TRUE.

Sequence of execution

The WHILE statement is processed according to the following rules:

1. The iteration condition is evaluated each time **before** the statement section is executed.
2. If the value is TRUE, the statement section is executed.
3. If the value is FALSE, the WHILE statement is terminated (this can occur the first time the condition is evaluated) and the program is resumed after END_WHILE.

Example

The following example illustrates the use of the WHILE statement:

Example of the WHILE statement

```
WHILE Index <= 50 DO
      Index:= Index + 2;
END_WHILE;
```

REPEAT statement

Description

A REPEAT statement causes a sequence of statements programmed between REPEAT and UNTIL to be executed repeatedly until a termination condition is true. The termination condition is formulated in accordance with the rules for a logic expression.

Note

You use the REPEAT statement when the number of loop passes is not known at the programming stage.

If the number of passes is known, the FOR statement (Page 4723) is more suitable.

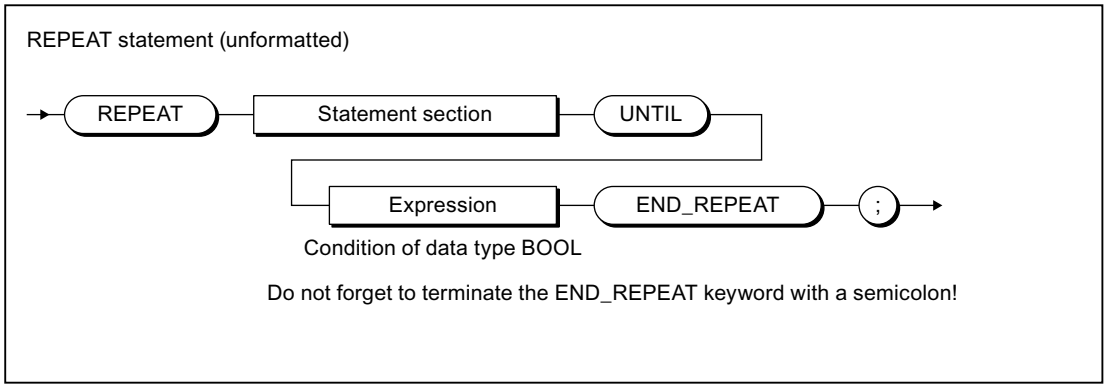

Figure 7-259 Syntax: REPEAT statement

The condition is checked **after** the statement section is executed. That means the statement section is executed at least once, even if the termination condition is true at the start.

Sequence of execution

The REPEAT statement is processed according to the following rules:

1. The iteration condition is evaluated each time **after** the statement section is executed.
2. If the value is FALSE, the statement section is executed again.
3. If the value is TRUE, execution of the REPEAT statement is terminated and program execution is resumed after END_REPEAT.

Example

The following example illustrates the use of the REPEAT statement:

Example of the REPEAT statement

```
Index := 1;
REPEAT
    Index := Index + 2;
UNTIL Index > 50
END_REPEAT;
```

EXIT statement

Description

An EXIT statement is used to exit a loop (FOR, WHILE or REPEAT loop) at any point, irrespective of whether the termination condition is true or false.

This statement has the effect of jumping directly out of the loop immediately surrounding the EXIT statement.

The program resumes after the end of the loop (e.g. after END_FOR).

Example

The following example illustrates the use of the EXIT statement:

Example of the EXIT statement

```
Index := 1;
FOR Index := 1 to 51 BY 2 DO
    IF %I0.0 THEN
        EXIT;
    END_IF;
END_FOR;
(*
The following value assignment is performed after the execution of EXIT or
after the regular end of the FOR loop.
*)
Index_find := Index_2;
```

CONTINUE statement

Description

The CONTINUE statement is only available if the compiler option **Language extensions IEC61131 3rd edition** is enabled, see Global settings of the compiler (Page 4623) and Local settings of the compiler (Page 4626).

It acts as a jump to the start of a loop (FOR, WHILE or REPEAT loop) from any point. Use this to jump to the start of the repeat statement which immediately surrounds the CONTINUE statement.

- With a FOR loop the run tag is increased by the programmed increment and compared with the full-scale value.
- With a WHILE loop the execution condition is reviewed.

Example

The following example illustrates the use of the CONTINUE statement:

Example of the CONTINUE statement:

```
sum := 0;
FOR i:= 1 TO 3 DO
    FOR j:= 1 TO 2 DO
        sum:= sum + 1;
        IF %I0.0 THEN
            CONTINUE;
        END_IF;
        sum:= sum + 1;
    END_FOR;
    sum:= sum + 1;
END_FOR;
(*
Once the loop has run the "sum" variable has the following value:
With %I0.0 = FALSE: sum = 15
With %I0.0 = TRUE:  sum =  9
*)
```

RETURN statement

Description

A RETURN statement causes termination of the POU currently being processed (program, function, function block).

When a function or a function block is terminated, program execution continues in the higher-level POU after the position where the function or function block was called.

Example

The following example illustrates the use of the RETURN statement:

Example of the RETURN statement

```
Index := 1;
FOR Index := 1 to 51 BY 2 DO
    IF %I0.0 THEN
        RETURN;
    END_IF;
END_FOR;
(*
The following value assignment is executed after the regular end of the FOR
loop, but not after the execution of RETURN.
*)
Index_find:= Index_2;
```

WAITFORCONDITION statement

Description

You can use the WAITFORCONDITION statement to wait for a programmable event or condition in a MotionTask. The statement suspends execution of the calling MotionTask until the condition is true. You program this condition in an Expression (Page 4763).

More information about the WAITFORCONDITION and expressions in this regard is contained in the *SIMOTION Basic Functions* Function Manual.

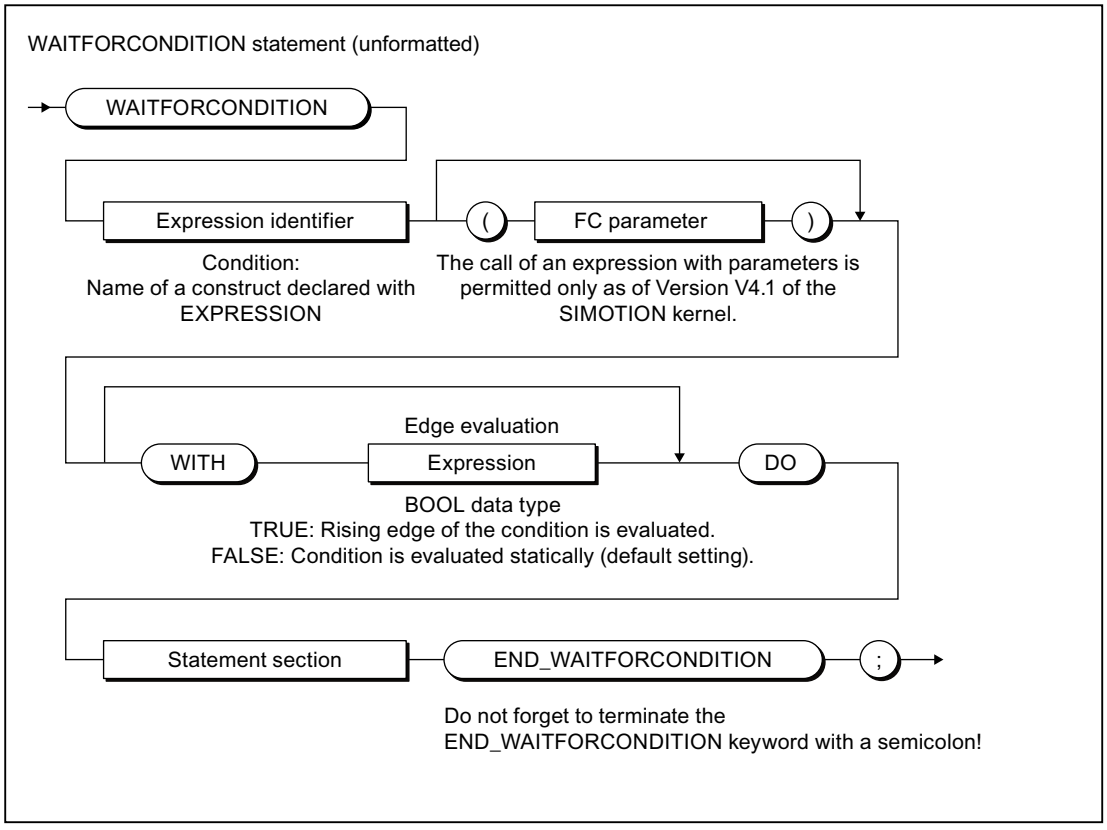

Figure 7-260 Syntax: WAITFORCONDITION statement

Expression identifier is a construct declared with EXPRESSION; its value defines (together with *WITH edge evaluation*, if necessary) whether the condition is considered as been satisfied.

The *WITH edge evaluation* sequence is optional. *Edge evaluation* is an expression of data type BOOL; it determines how the value of *expression identifier* is interpreted:

- *Edge evaluation* = TRUE:
  The rising edge of *expression identifier* is interpreted; i.e. the condition is satisfied when the value of *expression identifier* **changes** from FALSE to TRUE.
- *Edge evaluation* = FALSE:
  The static value of *expression identifier* is evaluated; i.e. the condition is satisfied when the value of *expression identifier* **is** TRUE.

If *WITH edge evaluation* is not specified, the default setting is FALSE, i.e. the static value of *expression identifier* is evaluated.

The statement section must contain at least one statement (empty statements also possible).

Example

The following example illustrates the use of the WAITFORCONDITION statement:

Example of the WAITFORCONDITION statement

```
// ...
// Call of the command with name of the expression
WAITFORCONDITION myExpression WITH TRUE DO
// At least one statement here, will be executed with higher priority, e.g.
    %Q0.0 := TRUE;
END_WAITFORCONDITION;
// ...
```

For a complete example, refer to the description for the Expression (Page 4763).

GOTO statement

The GOTO statement causes a jump to the jump label specified in the command (see Jump statement and labeling (Page 4933)).

You program jump statements with the GOTO statement and specify the jump label to which you want to jump. Jumps are only permitted within a POU.

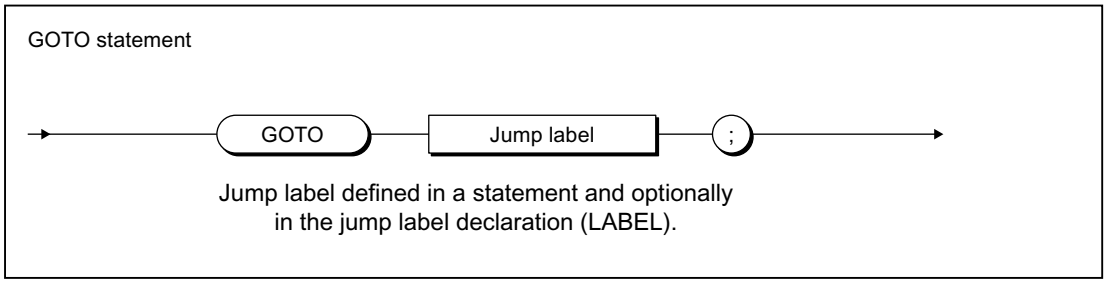

Figure 7-261 Syntax: GOTO statement

Note

You should only use the GOTO statement in special circumstances (for example, for troubleshooting). It should not be used at all according to the rules for structured programming.

Jumps are only permitted within a POU.

The following jumps are illegal:

- Jumps to subordinate control structures (WHILE, FOR, etc.)
- Jumps from a WAITFORCONDITION structure
- Jumps within CASE statements

Jump labels can only be declared in the POU in which they are used. If jump labels are declared, only the declared jump labels may be used.

7.2.4.8 Data type conversions

This section describes how you can implicitly and explicitly convert between elementary data types. It also contains an overview of the additional conversion possibilities.

Elementary data type conversion

The table presents an overview of the conversion options between numerical data types and bit data types. A distinction is made between:

- Implicit conversion (Page 4732): Conversion is automatic when different data types are used in an expression or when values are assigned by the compiler.
- Explicit conversion (Page 4734): Conversion is carried out when the user calls a conversion function (see *SIMOTION Basic Functions* Function Manual).

Table 7-409 Type conversion of numeric data types and bit data types

Source data type	Target data type												
	BOOL	**BYTE**	**WORD**	**DWORD**	**USINT**	**UINT**	**UDINT**	**SINT**	**INT**	**DINT**	**REAL**	**LREAL**	**STRING**
BOOL	–	Im/Ex	Im/Ex	Im/Ex	Val	Val	Val	Val	Val	Val	Val	Val	–
BYTE	Ex	–	Im/Ex	Im/Ex	Ex	Ex	Ex	Ex	Ex	Ex	Val	Val	Elem
WORD	Ex	Ex	–	Im/Ex	Ex	Ex	Ex	Ex	Ex	Ex	Val	Val	–
DWORD	Ex	Ex	Ex	–	Ex	Ex	Ex	Ex	Ex	Ex	Ex/Val	Val	–
USINT	Val	Ex	Ex	Ex	–	Im/Ex	Im/Ex	Ex	Im/Ex	Im/Ex	Im/Ex	Im/Ex	–
UINT	Val	Ex	Ex	Ex	Ex	–	Im/Ex	Ex	Ex	Im/Ex	Im/Ex	Im/Ex	–
UDINT	Val	Ex	Ex	Ex	Ex	Ex	–	Ex	Ex	Ex	Ex	Ex	Ex
SINT	Val	Ex	Ex	Ex	Ex	Ex	Ex	–	Im/Ex	Im/Ex	Im/Ex	Im/Ex	–
INT	Val	Ex	Ex	Ex	Ex	Ex	Ex	Ex	–	Im/Ex	Im/Ex	Im/Ex	–
DINT	Val	Ex	Ex	Ex	Ex	Ex	Ex	Ex	Ex	–	Ex	Im/Ex	Ex
REAL	Val	Val	Val	Ex/Val	Ex	Ex	Ex	Ex	Ex	Ex	–	Im/Ex	Ex
LREAL	Val	Val	Val	Val	Ex	Ex	Ex	Ex	Ex	Ex	Ex	–	Ex
STRING	–	Elem	–	–	–	–	Ex	–	–	Ex	Ex	Ex	–

Im: Implicit data type conversion possible

Ex: Explicit data type conversion possible by means of type conversion function *source data type*_TO_*target data type*

Val: Explicit data type conversion possible by means of type conversion function*source data type*_VALUE_TO_*target data type*

Elem: Implicit data type conversion with an element of the STRING data type

For information on conversion functions for date and time data types: Please refer to the *SIMOTION Basic Functions* Function Manual.

Implicit data type conversions

Implicit type conversion is always possible if an enlargement of the value range does not cause any value loss, e.g. from REAL to LREAL or from INT to REAL. The result is always defined.

The following figure provides a graphics-based view of all implicit type conversion chains. Each stage in the type conversion chain - reading from left to right or from top to bottom - always represents an enlargement of the value range.

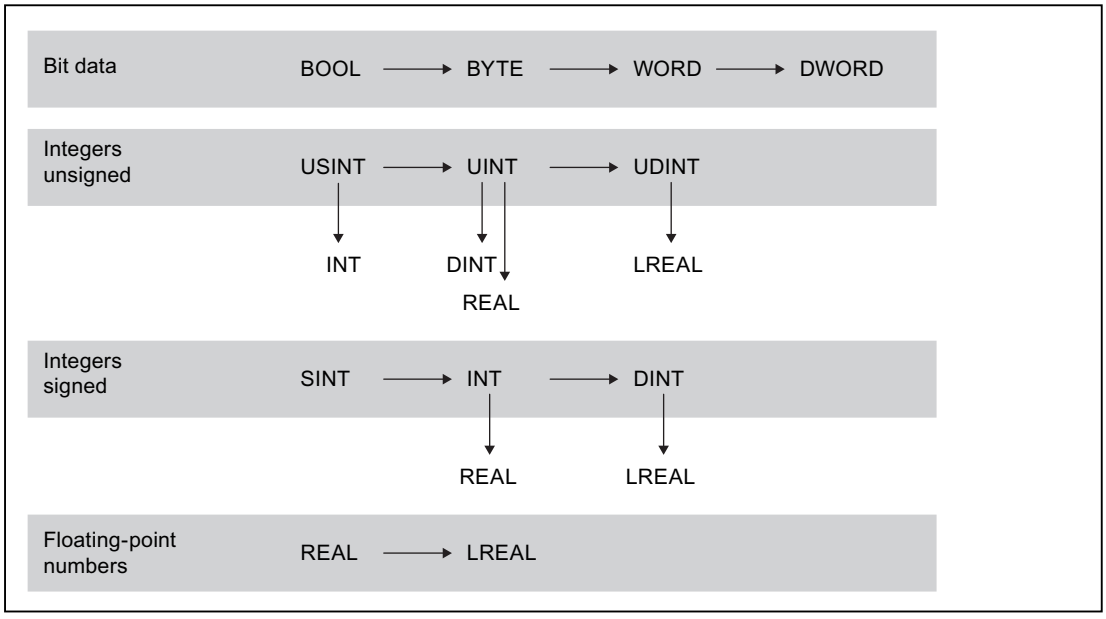

Figure 7-262 Implicit type conversion chains (one or more levels from left to right or one level from top to bottom)

The following implicit type conversions are supported:

1. Horizontally (from left to right) over one or more levels (e.g. USINT to UDINT)
2. Vertically (from top to bottom) over one level (e.g. UINT to REAL)

The implicit type conversions can be combined in the following order (e.g. INT to LREAL).

All other type conversions cannot be performed implicitly (e.g. UDINT to REAL), that is, you must use an explicit function (Page 4734) (see SIMOTION Basic Functions Function Manual).

Note

In arithmetic expressions, the result is always calculated in the largest number format contained in the expression.

A value can only be assigned to the expression if:

- The calculated expression and the variable to be assigned are of the same data type.
- The data type of the calculated expression can be implicitly converted to the data type of the variable to be assigned.

For more information on this error source and its solution: Please refer to the *SIMOTION Basic Functions* Function Manual.

Table 7-410 Example of data types in expressions and value assignments

```
VAR
    usint_var  : USINT;
    real_var   : REAL;
    byte_var   : BYTE;
    string_var : STRING[80] := 'example for string';
END_VAR

usint_var := 234 / 10;       // Expression data type: USINT
                             // Result = 23

real_var  := 234 / 10;       // Expression data type: USINT
                             // Implicit conversion possible
                             // Result = 23.0

usint_var := 234 / SINT#10;  // Expression data type: INT
                             // Implicit conversion and
                             // value assignment not possible

real_var  := 234 / 10.0;     // Expression data type: REAL
                             // Result = 23.4

usint_var := 234 / 10.0;     // Expression data type: REAL
                             // Implicit conversion and
                             // value assignment not possible

byte_var  := string_var[5];  // Implicit conversion possible
                             // Result = 16#70 ('p')

string_var[10] := byte_var;  // Implicit conversion possible
                             // Result = 'example fpr string'
```

Note

If applicable, specify the data type explicitly for numbers (e.g. UINT#127, if the number 127 is to be of data type UINT instead of USINT).

Explicit data type conversions

Explicit conversion is always required if information could be lost, for example, if the value range is decreased or the accuracy is reduced, as is the case for conversion from LREAL to REAL.

The conversion functions for numeric data types and bit data types are listed in the *SIMOTION Basic Functions* Function Manual.

The compiler outputs warnings when it detects conversions associated with loss of precision.

Note

The type conversion may cause errors when the program is running, which will trigger the error response set in the task configuration (see "Execution errors in programs" in the *SIMOTION Basic Functions* Function Manual).

Special attention is required when converting DWORD to REAL. The bit string from DWORD is taken unchecked as the REAL value. You must make sure that the bit string in DWORD corresponds to the bit pattern of a normalized floating-point number in accordance with IEEE. To do this, you can use the _finite and _isNaN functions.

Otherwise, an error can be triggered (FPU exception) as soon as the REAL value is first used for an arithmetic operation (for example, in the program or when monitoring in the symbol browser).

Note

The following applies if the value range limits are exceeded during conversion from LREAL to REAL:

- Underflow (absolute value of LREAL number is smaller than the smallest positive REAL number):
  Result is 0.0
- Overflow (absolute value of LREAL number is larger than the largest positive REAL number):
  The error response specified during task configuration is triggered.

Supplementary conversions

The ST system functions and ST system functions also permit the following conversions:

- **Combining bit-string data types**
  These functions combine multiple variables of a bit string data type into one variable of a higher-level data type.
- **Splitting bit-string data types**
  These function blocks split up a variable of a bit string data type into multiple variables of a higher-level data type.
- **Converting between any data types and byte arrays**
  They are commonly used to create defined transmission formats for data exchange between various devices.
  For further information (e.g. on the arrangement of the byte arrays, application example): Please refer to the *SIMOTION Basic Functions* Function Manual.
- **Conversion of technology object data types**
  It converts variables of a hierarchical TO data type (driveAxis, posAxis, or followingAxis) or of the general ANYOBJECT type to a compatible TO data type.

For Application Examples and further information: Please refer to the *SIMOTION Basic Functions* Function Manual.

7.2.5 Functions, Function Blocks, and Programs

This chapter describes how to create and call user-defined functions and function blocks. Standard functions are already available in the system for type conversion, trigonometry, and bit string manipulation. The *SIMOTION Basic Functions* Function Manual describes how to use system functions and functions of technology objects (TO functions).

A **function** (FC) is a logic block with no static data. All local variables lose their value when you exit the function and are reinitialized the next time you call the function.

A **function block** (FB) is a code block with static data. Since an FB has memory, its output parameters can be accessed at any time and from any point in the user program. Local variables retain their values between calls.

Programs are similar to FBs, but have no parameters. However, they can be assigned execution levels and tasks (see *SIMOTION Basic Functions* Function Manual).

FCs and FBs have the advantage that they can be reused, because they are encapsulated source file sections to which parameters can be assigned.

Functions, function blocks, and programs are program organization units (POUs), i.e. they are executable source file sections. You will find an overview of all source file sections in Use of the source file sections (Page 4807).

7.2.5.1 Creating and calling functions and function blocks

The following description explains how to create and call functions (FCs) and function blocks (FBs). For a complete example showing the differences between FCs and FBs see Comparison of functions and function blocks (Page 4758).

The order in which you must define and call the stipulated source file sections is given in Use of the source file sections (Page 4807).

For a description of how to make FCs and FBs public at other program sources or make them available for use by other program sources, see Declaring ST source files public and using them (Page 4827).

Defining functions

You can define a function (FC) within the implementation section of an ST source file in the section for program organization units (POE). If the compiler option (Page 4623) "Allow forward declaration" is not activated a FC must be defined before the POE (program, FB or FC) in which it is called.

Use the following syntax:

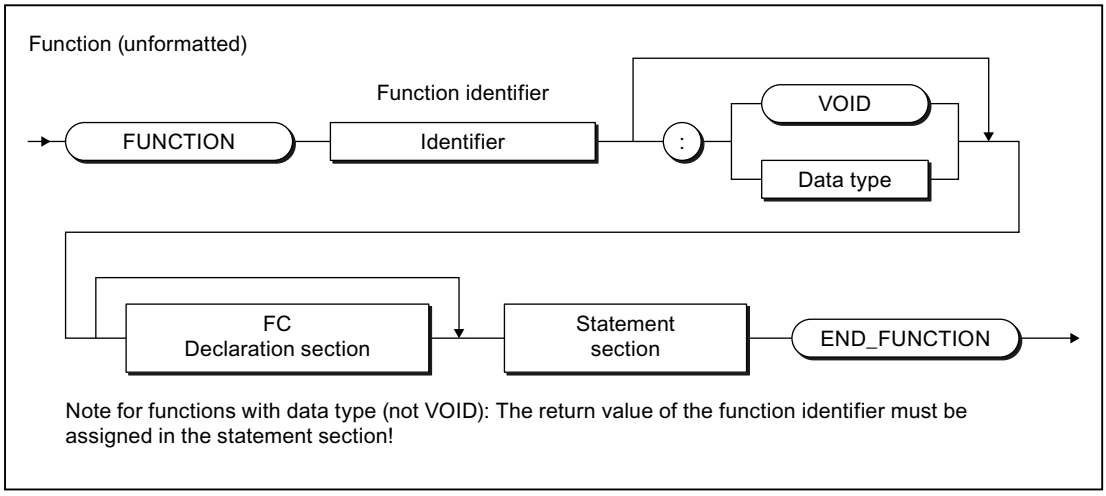

Figure 7-263 Syntax: Function (FC)

Enter in the following sequence, see example in Source file with comments (Page 4760)):

- The FUNCTION keyword
- An identifier as FC name
- If the function has a return value, the data type for the return value following a colon
  The symbolic data type VOID can also be entered for functions with no return value.

This is then followed by:

- The optional declaration section (Page 4741)
- The statement section (Page 4746)
- The END_FUNCTION keyword

Defining function blocks

Defining classic function blocks

You can define a function block (FB) within the implementation section of an ST source file in the section for program organization units (POE). If the compiler option (Page 4623) "Allow forward declaration" is not activated a FB must be defined before the POE (program, FB or FC) in which it is called.

Use the following syntax:

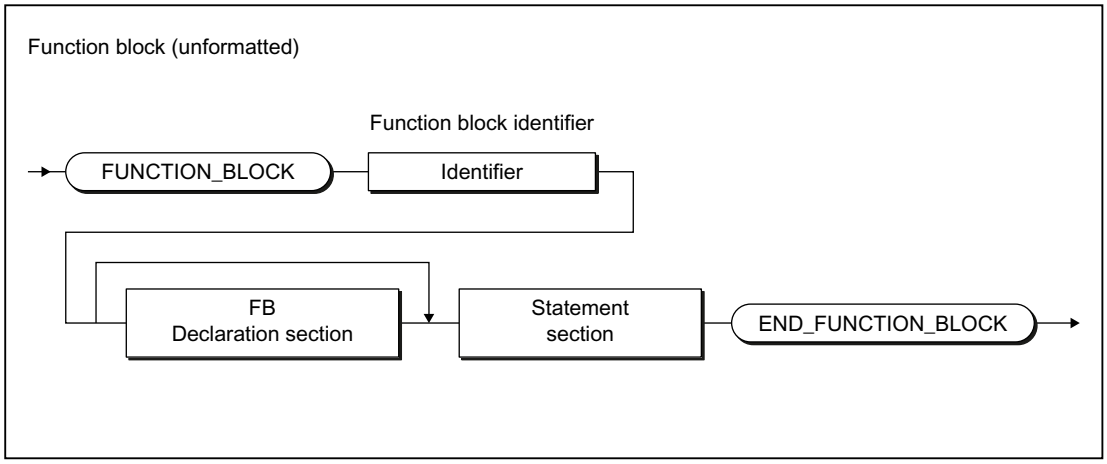

Figure 7-264 Syntax: Function block (FB)

Enter in the following sequence, see example in Source file with comments (Page 4760)):

- The FUNCTION_BLOCK keyword
- An identifier as FB name

This is then followed by:

- The optional declaration section (Page 4741)
- The statement section (Page 4746)
- The END_FUNCTION_BLOCK keyword

Defining object-oriented function blocks with methods

Function blocks can also be defined with methods. Reduced object-oriented programming is possible with this irrespective of the SIMOTON Kernel version. Only the compiler option (Page 4623) “Permit object-oriented programming" needs to be activated.

You can define object-oriented function blocks (FB) with methods and public variables within the implementation section of an ST source file in the section for program organization units (POE). If the compiler option (Page 4623) “Allow forward declaration" is not activated a FB must be defined before the POE (program, FB or FC) in which it is called.

Use the following syntax:

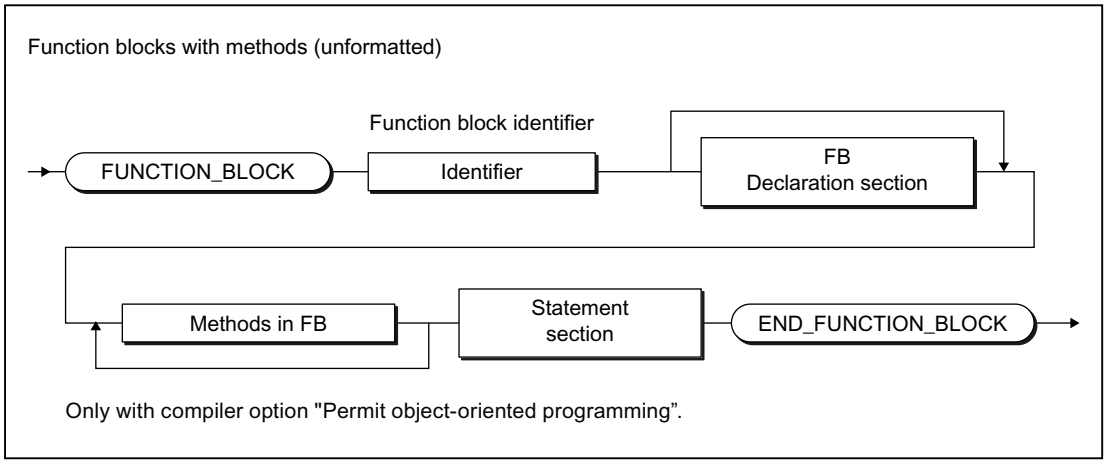

Figure 7-265 Syntax: Function block (FB) with methods

Enter in the following sequence:

- The FUNCTION_BLOCK keyword
- An identifier as FB name

This is then followed by:

- The optional declaration section (Page 4741)
- the methods in the function block
- The statement section (Page 4746)
- The END_FUNCTION_BLOCK keyword

Note

Object-oriented function blocks cannot be derived. Inheritance is therefore not possible for methods.

Defining methods in object-oriented FBs

Executable statements for an object-oriented function block can be summarized as methods. The methods are defined within a function block before the statement section for the FB.

A method roughly corresponds to a function (Page 4736). Specification of an access identifier determines the environment from which the method can be called.

If the compiler option (Page 4623) "Allow forward declaration" is not activated, a method must be defined before the program organization unit (program, FB, FC or class) or method in which it is called.

Use the following syntax:

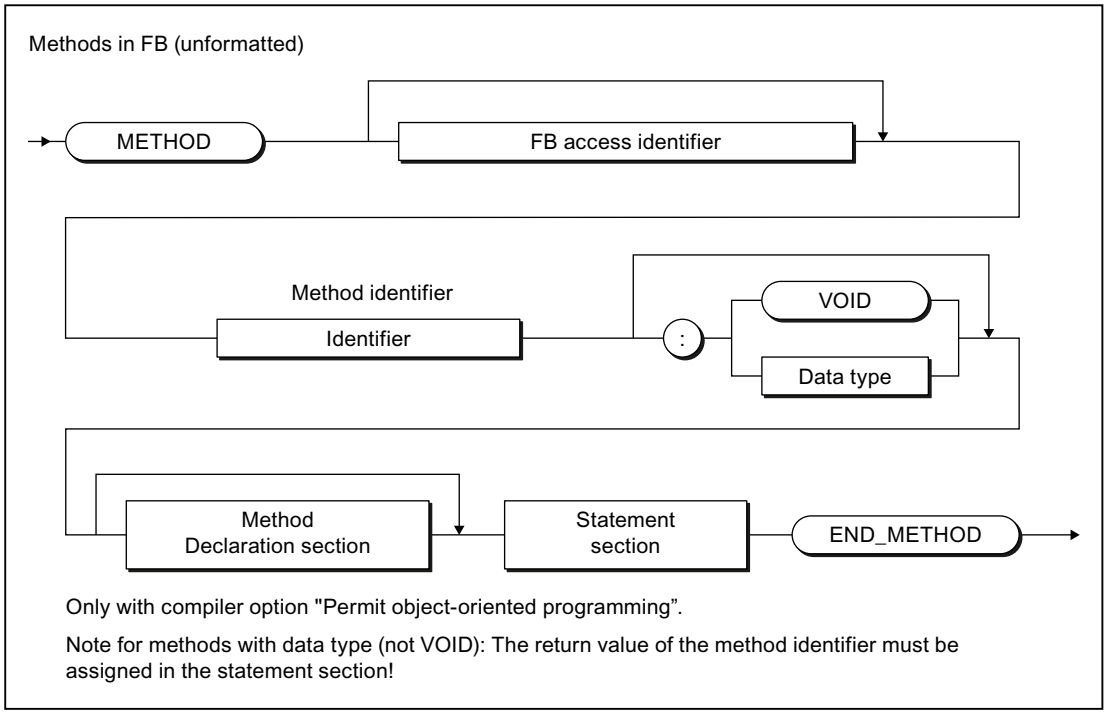

Figure 7-266 Syntax: Methods in the function block

Enter in the following sequence:

- The METHOD keyword.
- The optional FB access identifier (PUBLIC, PRIVATE or INTERNAL), default PRIVATE.
  For access identifier, see section "Access identifiers within object-oriented FBs" (Page 4740).
- An identifier as method name.
- if the method has a return value, the data type for the return value following a colon.
  The symbolic data type VOID can also be entered for a method with no return value.

This is then followed by:

- The optional declaration section (Page 4771)
- The statement section (Page 4773)
- The END_METHOD keyword

Access identifiers within object-oriented FBs

An access identifier may be specified within object-oriented function blocks for declaration blocks or methods:

- With declaration blocks:
  Directly after the keyword for the relevant block (e.g. TYPE, VAR).
  The access identifier is valid for all identifiers within this declaration block.
- With methods:
  Directly after the keyword METHOD.
  The access identifier is valid for the relevant method.

You use the access identifier to determine whether the identifiers or the method can be used only inside or outside of the function block, see the following table.

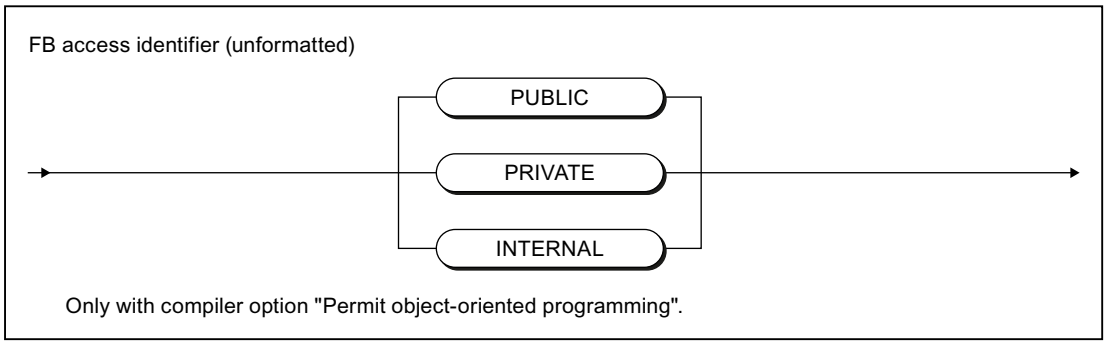

Figure 7-267 Syntax: FB access identifier

Table 7-411 Possible access identifiers within an object-oriented function block

Access identifier	Meaning
PRIVATE	The identifiers for the relevant declaration block (variables, data types, etc.) or the method can be used only within this function block. This is the default when no access identifier is specified.
INTERNAL	Only when the identifier is defined within an object-oriented namespace (Page 4904). The identifiers of the relevant declaration block (variables, data types, etc.) or the method can be used only within the higher-level namespace. Within the higher-level namespace, the following apply: • The declared identifiers can also be accessed outside the function block. This does not apply to retentive local variables (VAR RETAIN). • The method can also be called outside the function block.
PUBLIC	The identifiers for the relevant declaration block (variables, data types, etc.) or the method are public. • The declared identifiers can also be accessed outside the function block and outside the higher-level object-oriented namespace. • The method can also be called outside the function block and outside the higher-level object-oriented namespace. This access identifier is not permitted in declaration blocks for retentive local variables (VAR RETAIN / END_VAR).

Declaration section of FB and FC

A declaration section is subdivided into various declaration blocks that are each identified by a separate pair of keywords. Each block contains a declaration list for similar data, such as constants, local variables and parameters. Each type of block may only appear once; the blocks may appear in any order.

The following options are then available for the declaration section of an FC and an FB, see also the example in Source file with comments (Page 4760):

Permissible declaration blocks

Table 7-412 Declaration blocks for FC and FB: Options

Data	Syntax	FB	FC	Method in FB
Data type	**TYPE**[1] *Declaration list*[4] **END_TYPE**	X	X	–
Constant	**VAR CONSTANT**[1] *Declaration list*[4] **END_VAR**	X	X	X
Input parameter	**VAR_INPUT** *Declaration list*[4] **END_VAR**	X	X	X
In/out parameter	**VAR_IN_OUT** *Declaration list*[4] **END_VAR**	X	X	X
Output parameters	**VAR_OUTPUT** *Declaration list*[4] **END_VAR**	X	X	X
Local static variable	**VAR**[1 3] *Declaration list*[4] **END_VAR**	X	–	–
Local temporary variable	**VAR** *Declaration list*[4] **END_VAR**	–	X	X
	VAR_TEMP *Declaration list*[4] **END_VAR**	X	X	X
Retentive variable (as of version 4.5 of the SIMOTION Kernel)	**VAR RETAIN**[2 3] *Declaration list*[4] **END_VAR**	X	–	–

[1] Additional specification of the FB access identifier possible with FB and compiler option (Page 4623) "Permit object-oriented programming" activated: **PUBLIC**, **PRIVATE** or **INTERNAL**, default **PRIVATE**; see section "Access identifier within object-oriented FBs (Page 4740)". The relevant blocks may occur multiple times.

[2] Additional specification of the access identifier **PRIVATE** or **INTERNAL** possible with FB and activated compiler option (Page 4623) "Permit object-oriented programming". The relevant blocks may occur multiple times.

[3] Additional specification of the keyword **OVERRIDE** possible with FB and activated compiler option (Page 4623) "Permit object-oriented programming". This keyword enables the initialization values of variables to be overridden with the **PRIVATE** access identifier when the instance is declared.

[4] *Declaration list*: The list of identifiers of the type to be declared

Parameter blocks

Parameters are local data and are formal parameters of a function block, a function or a method in FB. When the FB or FC is called, the formal parameters are substituted by the actual parameters, thus providing a means of exchanging information between the called and calling source file sections.

- Formal input parameters receive the actual input values (data flow inwards).
- Formal output parameters are used to transfer output values (data flow outwards).
- Formal in/out parameters act as input and output parameters.

The following figures show the syntax for the parameter declaration of an FB, an FC or a method in the FB.

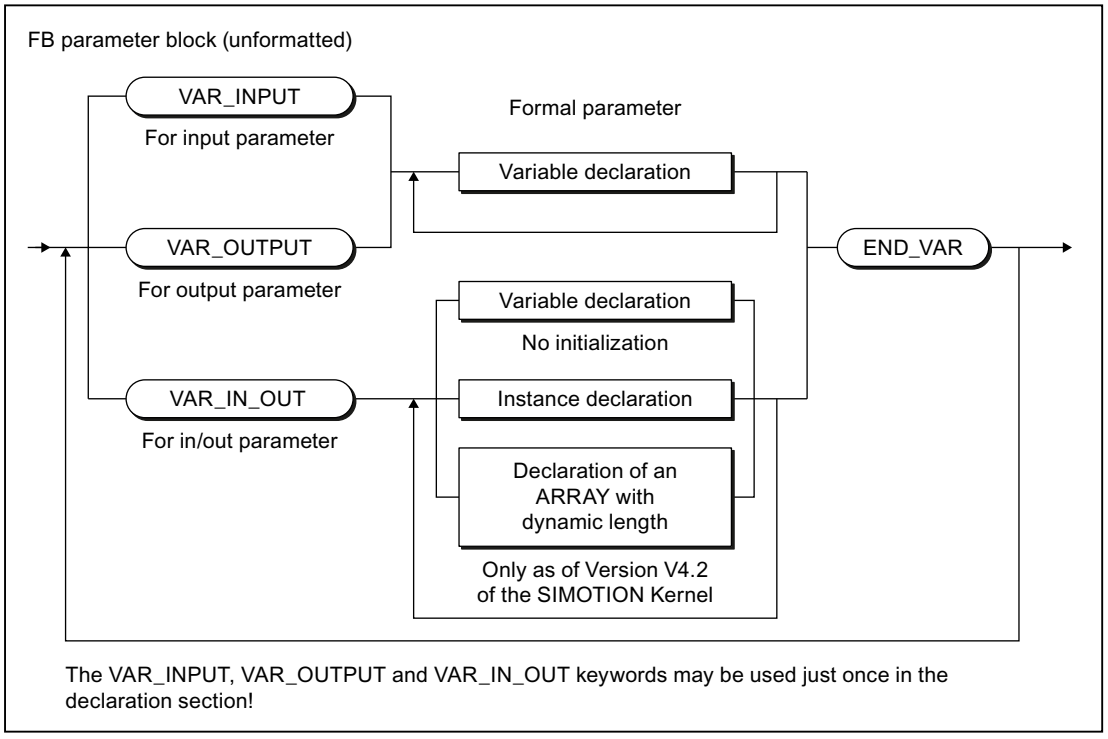

Figure 7-268 Syntax: FB parameter block

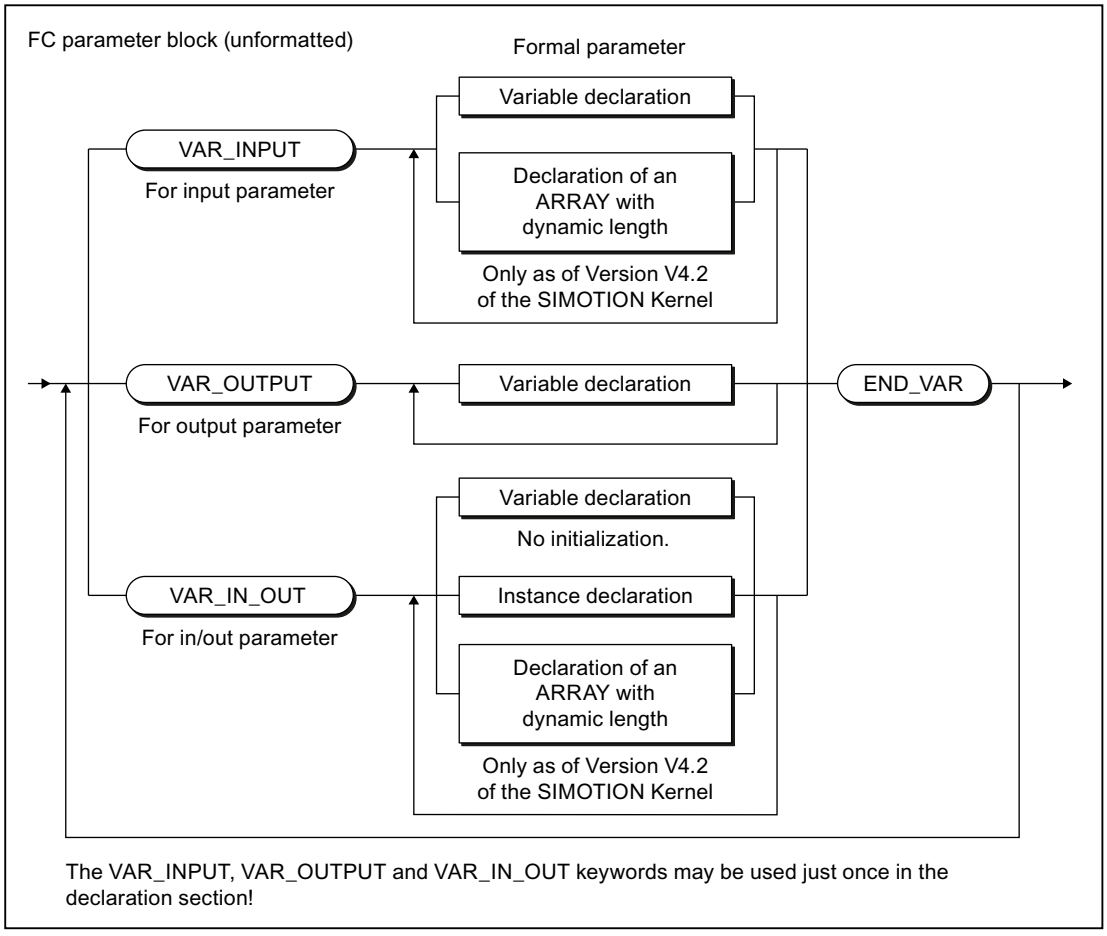

Figure 7-269 Syntax: FC parameter block

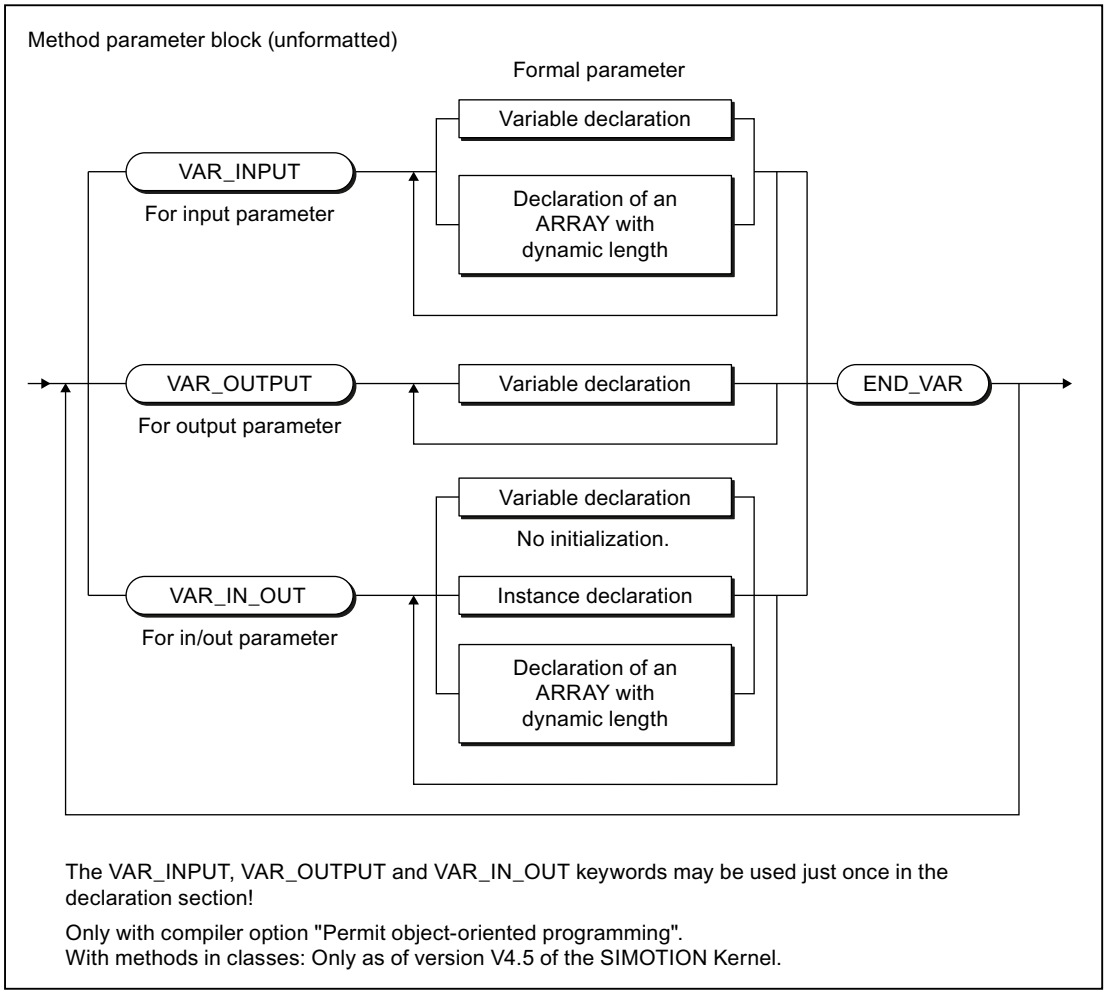

Figure 7-270 Syntax: Method parameter block

Apart from variables you can also declare the following in the parameter blocks:

- in the parameter block for in/out parameters:
  - Instances of function blocks (Page 4754)
  - Arrays with a dynamic length (Page 4747), as of version V4.2 of the SIMOTION Kernel.
- with functions in the parameter block for input parameters:
  - Arrays with a dynamic length (Page 4747), as of version V4.2 of the SIMOTION Kernel.

You can use the declared parameters the same as other variables within the FB or FC, with the following exception: You cannot assign values to input parameters.

From outside of an FB or an FC, you can access:

- The input and output parameters of an FB by means of structured variables (Page 4682). Input parameters can only be accessed when the compiler option (Page 4623) "Permit language extensions" has been activated.
  Data access to the output parameter is possible as standard.
- The return value of an FC by using the function in an expression and assigning this expression to a variable, for example. Specifying the function name calls the function and returns a result at the same time.

Note

When saving the project in the old project format:

Projects in which the output parameters for a function are declared cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

Statement section of FB and FC

The statement section of the FC or FB contains instructions that are executed when the FC or FB is called. There is no difference compared to the formal rules for creating a statement section; however, you should note the information in the following table.

Note

For tips on the efficient use of parameters, please refer to the Runtime-optimized Programming section in the SIMOTION Basic Functions Function Manual.

Table 7-413 Use of parameters and variables in FCs and FBs

Parameter/variable	Use
Input parameters	With the call of an FC or an FB, assign the current values to the input parameters. These values are used for data processing within the FC or the FB, for example, for calculations, but cannot be modified themselves. Only with "Permit language extensions" compiler option enabled (see Global compiler settings (Page 4623) or Local compiler settings (Page 4626)): The input parameters of an FB can be read and written using structured variables, including outside the FB (e.g. in the calling source file module).
In/out parameter	You assign a variable to an in/out parameter for the call of the FC or FB. The FC or the FB accesses this variable directly and can change this directly. Type conversions are not supported. The variable assigned to an in/out parameter must be able to be read and written directly. Therefore, system variables (of the SIMOTION device or a technology object), I/O variables or process image accesses cannot be assigned to an in/out parameter.

Parameter/variable	Use
Output parameters	You assign a variable to an output parameter for the call of an FC or FB using the **=>** operator. The value of the output parameter (result) is transferred to the variables when the FC or FB is closed. The following also applies to FBs: The output parameters of an FB can be read using structured variables, including outside the FB (e.g. in the calling source file section).
Local variables	Local variables are variables that are declared and used only within the block. All local variables (VAR ... END_VAR or VAR_TEMP ... END_VAR) are temporary in an FC, i.e. they lose their value when the FC is terminated. The next time the FC is called, they are reinitialized. A differentiation between static and temporary local variables is made in the FB: • Static variables (VAR ... END_VAR) retain their value when the FB is closed. • Temporary variables (VAR_TEMP ... END_VAR) lose their value when the FB is closed. The next time the FB is called, they are reinitialized. The value of a local variable cannot be queried directly by the calling block. This is only possible using an output parameter.

ARRAY with a dynamic length (as of Kernel V4.2)

Declaration as an in-out parameter

As of SIMOTION Kernel Version 4.2, you can declare arrays with a dynamic length in functions and function blocks. This is possible:

- With functions:
  - in the parameter block for in/out parameters (Page 4741) (VAR_IN_OUT / END_VAR).
  - in the parameter block for input parameters (Page 4741) (VAR_INPUT / END_VAR).
- With function blocks:
  in the parameter block for in/out parameters (Page 4741) (VAR_IN_OUT / END_VAR).

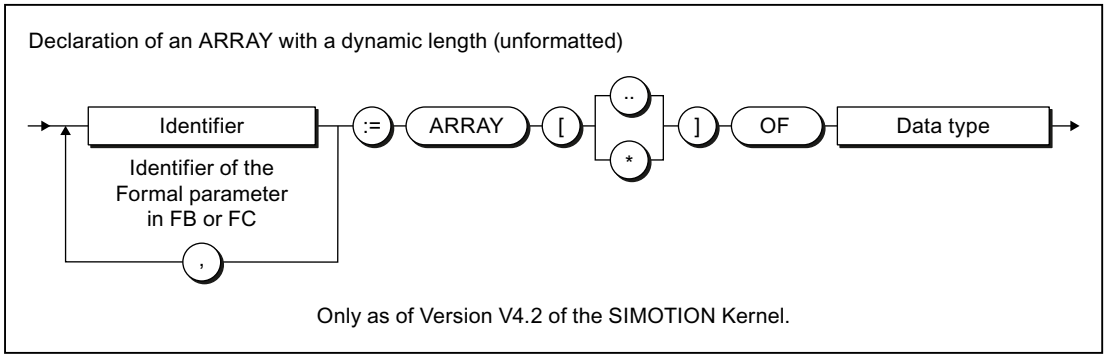

Figure 7-271 Syntax: Declaration of an ARRAY with a dynamic length

Note

When saving the project in the old project format:

Projects in which [*] is used to identify a dynamic array cannot be compiled correctly in SIMOTION SCOUT versions earlier than V4.5.

Using an ARRAY with a dynamic length

When the function or an instance of the function block is called, arrays of any length of the declared data type can be transferred. The reference to the transferred array and its index limits are saved on the local data stack (Page 4848).

You can use the _firstIndexOf (in := *array-name*) and _lastIndexOf (in := *array-name*) functions within the function or function block to define the lower and upper index limits. The _lengthIndexOf (in := *array-name*) function supplies the number of elements in the ARRAY. The following applies: _lengthIndexOf (x) := _lastIndexOf (x) - _firstIndexOf (x) + 1.

Note

With compiler option (Page 4623) "Permit language extensions IEC61131 3rd edition" enabled the standardized functions LOWER_BOUND (in := *array-name*) or UPPER_BOUND (in := *array-name*) can be used to determine the lower and upper index limits respectively.

You can define the size of the memory space occupied by the ARRAY with _sizeOf (in := *array-name*). The following applies: _sizeOf (in := *array_of_type*) := _lengthIndexOf (in := *array_of_type*) * _sizeOf (in := *type*).

The syntax of these functions is described in the "SIMOTION Basic Functions" Function Manual.

Note

The above functions are executed during runtime for an ARRAY with a dynamic length.

Example

Table 7-414 Example of using an ARRAY with a dynamic length

```
FUNCTION_BLOCK example_dyn_array
    VAR_IN_OUT
        flexarray : ARRAY [..] OF DINT;
    END_VAR

    VAR_TEMP
        i : DINT := 0;
    END_VAR

    i := _firstIndexOf (in := flexarray);

    WHILE i <= _lastIndexOf (in := flexArray) DO
        flexArray[i] := i;
        i := i + 1;
    END_WHILE;
END_FUNCTION_BLOCK

PROGRAM test_dyn_array
    VAR
        array_1 : ARRAY [0 .. 29] OF DINT;
        fb_example : example_dyn_array;
    END_VAR
    // ...
    fb_example (flexarray := array_1);
    // ...
END_PROGRAM
```

Call of functions and function block calls

This provides an overview of the call of the functions and function blocks.

Principle of parameter transfer

When you call an FC or FB, data exchange takes place between the calling and the called block. The parameters to be transferred must be specified as a parameter list in the call. The parameters are written in parentheses. Several parameters are separated by commas.

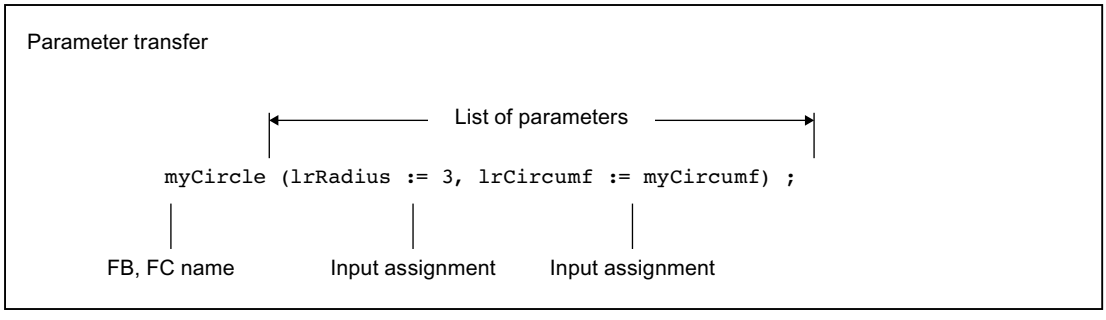

Figure 7-272 Principle of parameter transfer for the call

Input and in/out parameters are normally specified as a value assignment. In this way, you assign values (actual parameters) to the parameters you have defined in the declaration section of the called block (formal parameters).

The assignment of output parameters is made using the **=>** operator. In this way, you assign a variable (actual parameter) to the output parameters you have defined in the declaration section of the called block (formal parameters).

Parameter transfer to input parameters

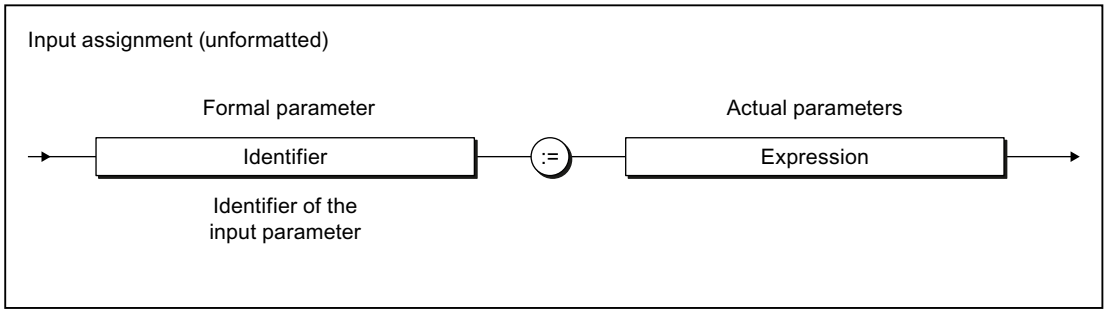

Figure 7-273 Syntax: Input assignment

You transfer the data (actual parameters) to the formal input parameters of an FB or FC by means of input assignments. You can specify the actual parameters in the form of expressions. You can use the formal input parameters in statements within the FB or FC, but you cannot modify their values.

A short form of parameter transfer is supported, but should not be applied in conjunction with user-defined FBs. This short form is required only for some FCs, see *SIMOTION Basic Functions* Function Manual.

The assignment of actual parameters is optional for an FB. If no input assignment is specified, the values of the last call are retained because an FB is a source file section with memory.

The assignment of an actual parameter is optional for an FC when an initialization expression was specified for the declaration of the formal parameter.

Also refer to the examples in Calling functions (Page 4753) and Calling function blocks (instance calls) (Page 4754).

You can also gain read and write access to an FB's input parameter at any time outside the FB. For further details, see: Accessing the FB's input parameter outside the FB (Page 4756).

Parameter transfer to in/out parameters

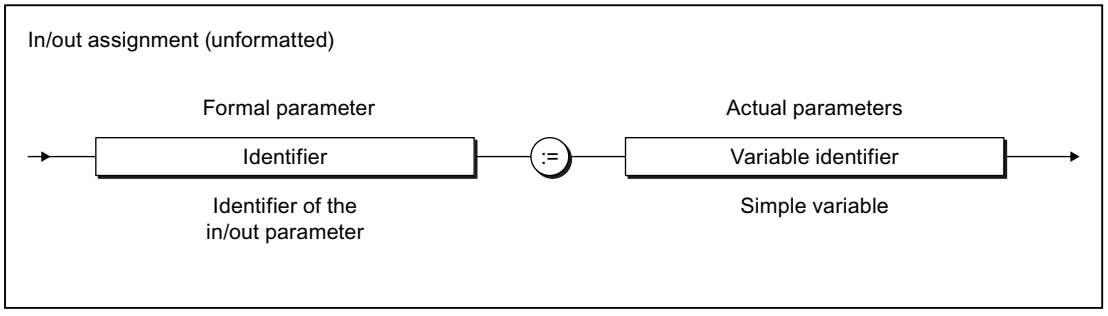

Figure 7-274 Syntax: In/out assignment

You transfer the data (actual parameters) to the formal in/out parameters of an FB or an FC using in/out assignments. You can only assign a variable of the same type to the formal in/out parameter, data type conversions are not possible.

You can use and change the formal in/out parameters in statements within the FC or the FB. The FC or the FB accesses the variable of the actual parameter directly and can change it directly.

See also the examples in Calling functions (Page 4753) and Calling function blocks (instance calls) (Page 4754).

When using the STRING data type in in/out assignments, the declared length of the actual parameter must be greater than or equal to the length of the formal in/out parameter (see following example).

Table 7-415 Example of the use of the STRING data type in in/out assignments

```
FUNCTION_BLOCK REF_STRING
    VAR_IN_OUT
        io : STRING[80];
    END_VAR
    ;    // Statements
END_FUNCTION_BLOCK

FUNCTION_BLOCK test
    VAR
        my_fb : REF_STRING;
        str1  : STRING [100];
        str2  : STRING [50] ;
    END_VAR
    my_fb (io := str1);    // Permissible call
    my_fb (io := str2);    // Illegal call,
                          // Compiler error message
END_FUNCTION_BLOCK
```

The variable assigned to an in/out parameter must be able to be read and written directly. Therefore, system variables (of the SIMOTION device or a technology object), I/O variables or process image accesses cannot be assigned to an in/out parameter.

Please note the different parameter access times!

Parameter transfer to output parameters

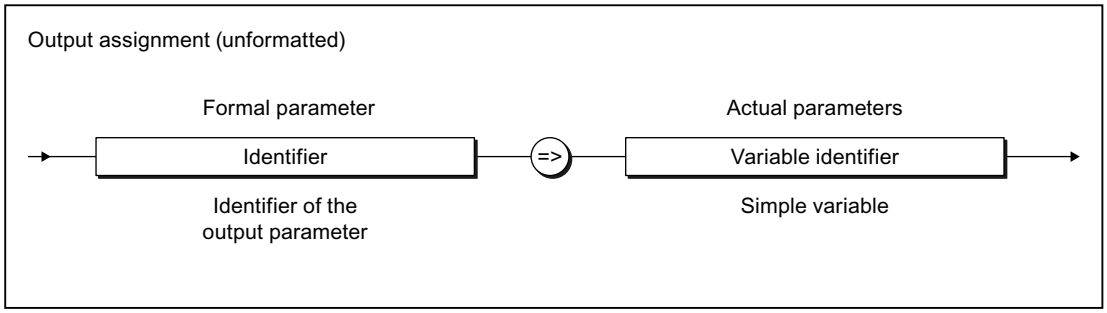

Figure 7-275 Syntax: Output assignment

You use an output assignment to assign the formal output parameters of an FC or FB to the variables (actual parameter) that accept the value of the formal output parameter when the FB is closed.

You can use and change the formal output parameters in statements within the FC or the FB.

See also the examples in Calling functions (Page 4753) and Calling function blocks (instance calls) (Page 4754).

Output assignments are optional for the parameter transfer. If there is no output assignment for an output parameter, the following applies:

- With functions (FC):
  The values for the output parameters are lost after the FC is terminated.
- With function blocks (FB):
  You can gain read and write access to an FB's output parameter at any time, including outside the FB. For further details, see: Accessing the FB's output parameter outside the FB (Page 4756).

Parameter access times

The types of access and thus the parameter access times are different:

- In the case of input assignments, the values of the actual parameters are copied into the formal parameters. If large structures, such as arrays, are copied and the FC or FB is called frequently, this can limit performance.
- Values are not copied in in/out assignments. Rather, in this case a link is established between the memory addresses of the formal parameters and those of the actual parameters. Transferring the variables is therefore faster than input assignments (especially where large volumes of data are involved). However, accessing variables from the FB can be slower.
- If you are using unit variables, nothing is copied to the function or function block because these variables are valid in the entire ST source file (see Variable model (Page 4831)).

Note

Using in/out parameters instead of input parameters is only faster if a large volume of data is to be passed to the function block.

If unit variables are used predominantly instead of parameters, the resulting program structure will be complex and confusing: object orientation, data encapsulation, multiple use of variable names (encapsulation of validity ranges), etc., are no longer possible.

Calling a function

A function is called as follows:

Function with return value (data type other than VOID)

The function is placed on the right-hand side of a value assignment. It can also appear as an operand within an expression. After calling the function, its return value is used at the appropriate point to calculate the expression.

Examples:

```
y := sin(x);
y := sin(in := x);
y := sqrt (1 - cos(x) * cos(x));
```

Note

In the function itself, the result (return value) is assigned to the function name.

Function without return value (no data type or VOID data type)

The assignment consists only of the function call.

The following example is valid provided a funct1 function has already been defined with the in1 and in2 input parameters along with the inout in/out parameter and the out1 and out2 output parameters.

Example:

```
funct1 (in1 := var11, in2 := var12, inout1 := var13, out1 => var14, out2 =>
var15);
```

Calling function blocks (declaring and calling instances)

Declaring an instance of a function block

Before you call a function block (FB), you must declare an instance. You declare a variable and enter the name of the function block as the data type. You declare this instance:

- Locally (within VAR/END_VAR in the declaration section of a program or function block)
- Globally (within VAR_GLOBAL/END_VAR in the interface of implementation section)
- As an in/out parameter (within VAR_IN_OUT / END_VAR in the declaration section of a function block or a function).

Instance-specific initialization of individual local variables of the function block is possible in the case of function blocks declared in ST source files by means of the compiler option (Page 4626) "Permit object-oriented programming". In this case, you override the initialization values that were stipulated in the function block declaration. Specification of the variables to be initialized is similar to the process for initializing a structure, and involves specifying a structure initialization list (Page 4699) that is enclosed in brackets.

You can in all cases initialize public variables of the function block (i.e. variables with the PUBLIC access identifier) specific to the instance. In order to be able to initialize private variables of the function block (i.e. variables with PRIVATE access identifier), the keyword OVERRIDE must be stated at their declaration block after the access identifier.

The following generally applies: The function block must be declared in the ST source file before an instance can be declared.

Exception: It is sufficient to define a POU prototype (Page 4929) beforehand if initialization is not specified and when compiler option (Page 4623) "Permit forward declarations" is activated.

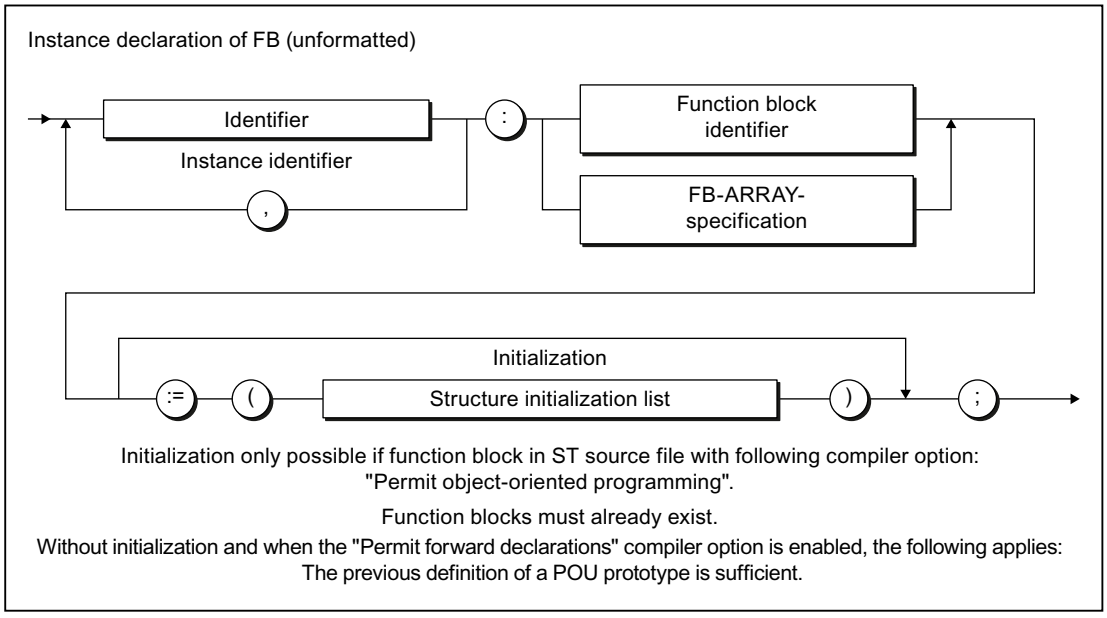

Figure 7-276 Syntax: Instance declaration of FB

Example of the instance declaration of an FB with initialization:

```
FB_inst : FB_name := (Var_publ1 := 12,
                      Var_publ2 := 123.456);
```

The instance declaration can also be an array, e.g.:

```
FB_inst : ARRAY [1..2] OF FB_name;
```

Note

Pay attention to the different initialization times for different variable types.

Calling an instance of a function block

You call a function block instance in the statement section of a POU (for information about syntax, see Figure). FB parameters are the input, in-out and output assignments separated by commas.

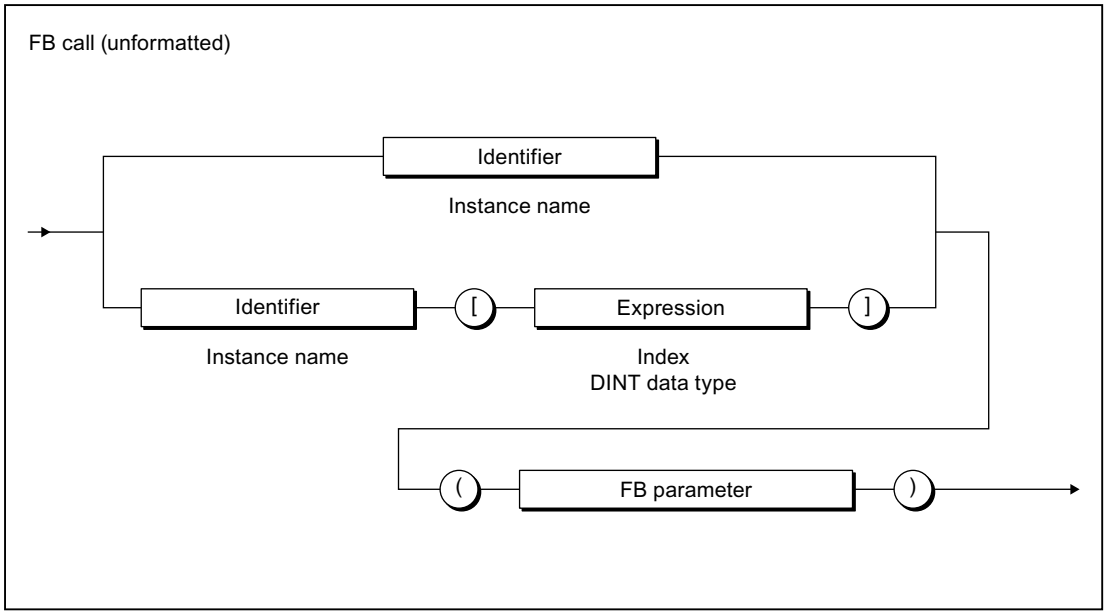

Figure 7-277 FB call syntax

The example in the following table is applicable, assuming that the *supply and motor* function blocks have already been defined:

- FB Supply:
  Input parameters in1, in2; in/out parameter inout; output parameter out
- FB motor:
  In/out parameters inout1, inout2; output parameters out1, out2

Table 7-416 Example of instance declaration, FB call, and access to output parameters

```
VAR
    Supply1, Supply2: Supply;
    Motor1 : Motor;
END_VAR

// Parameter transfer (output assignment) when calling the instance of an FB
Supply1 (in1 := var11, in2 := expr12, inout := var13, out => var14) ;
Supply2 (in1 := var21, in2 := expr22, inout := var23, out => var24) ;
Motor1 (inout1 := var31, inout2 := var32, out1 => var33, out2 => var34);
// ...

// Accessing the FB's output parameter outside the FB
var15 := Supply1.out;
var25 := Supply2.out;
var35 := Motor1.out1;
var36 := Motor1.out2;
var41 := Motor1.out1 * Motor1.out2 * (Supply1.out + Supply2.out);
```

Accessing the FB's output parameter outside the FB

In addition to the output assignment (Page 4752) for the call of an FB, it is always possible to access an FB's output parameter outside the FB.

To do so, use structured variables (Page 4682) in the *FB instance name.output parameter* format, e.g. *Supply1.out*.

Also refer to the examples in Calling function blocks (instance calls) (Page 4754).

The instance name of the FB itself must not be used in a value assignment!

Accessing the FB's input parameter outside the FB

In addition to the input assignment (Page 4750) for the call of an FB, it is always possible to read and write an FB's input parameter outside the FB.

To do so, use structured variables (Page 4682) in the *FB instance name.input parameter* format, e.g. *Supply1.in1*.

Note

To be able to use this option, the "Permit language extensions" compiler option must be activated, see Global compiler settings (Page 4623) and Local compiler settings (Page 4626).

The instance name of the FB itself must not be used in a value assignment!

Table 7-417 Example of assignment to input parameter

```
// Only with compiler option "Permit language extensions" activated
VAR
    var_fb   : _WORD_TO_2BYTE;
    var_word : WORD;
END_VAR
var_fb.wordin := var_word;
// ..
var_fb();
```

Access an FB's public variables outside of the FB

How to access a public local variable of a function block (i.e. variable with PUBLIC access identifier):

1. Declare an instance of the FB (unless this has already been done).
   See Calling function blocks (declaring and calling instances) (Page 4754).
2. For access purposes use a structured variable (Page 4708) in the format *FB-instancename.variablename*, e.g. *fb_inst.var_name*.

You can have read/write access to the public variable.

You access the public constants or data types of a function block in a similar manner.

Call methods within and outside of a FB

Inside a FB you can call all methods defined within this, irrespective of the access identifier (PUBLIC or PRIVATE). The call works in the same way as with a function, see Calling a function (Page 4753).

You can also call the public methods for a function block (i.e. methods with PUBLIC access identifier) outside of this FB, e.g. in programs, functions, function blocks or methods from other function blocks. Proceed as follows:

1. Declare an instance of the FB (unless this has already been done).
   See Calling function blocks (declaring and calling instances) (Page 4754).
2. To call the method, write the name of the FB instance and a period before the method name (similar to a structured variable (Page 4708)).
   The parameter transfer takes place as described in the Calling a function (Page 4753) section.

Error sources in FB calls

Note the following when calling a function block instance:

- **Only assign in/out parameters with variables that are stored directly in the memory.**
  Only the following variables are permissible actual parameters:
  - Global variables (unit variables and global device user variables)
  - Local variables
  - Variables of the data type of the TO (TO instances)

  The following are not possible, in particular:
  - System variables (TO variables)
  - Names of technological objects from the Engineering System
  - I/O variables
  - Absolute and symbolic process image access
- **Do not use functions (FCs) as in/out parameters.**
  The FC return value, i.e. the FC call, cannot be an actual parameter in an in/out assignment. You must first store the result of the FC in a local variable and then use this variable as an actual parameter in the in/out assignment.
- **Do not use constants as in/out parameters.**
  Only variables can be used as actual parameters of an in/out assignment because the value is written back.
- **In/out parameters cannot be initialized.**

7.2.5.2 Comparison of functions and function blocks

The differences between user-defined function blocks (FBs) and functions (FCs) are succinctly illustrated below using a complete example.

Description of example

The following example illustrates the differences between FBs and FCs. For simplicity, each type of parameter is used only once, although, in reality, you can define any number of parameters. The terms used are defined both in the detailed descriptions in Define functions (Page 4736) and Define function blocks (Page 4737).

A block will be created as an FB and an FC in the implementation section of an ST source file for use in calculating the circumference and the area of a circle for a radius input variable:

- An input parameter is defined for the radius.
- An in/out parameter is defined for the circumference of the circle, i.e. the value of the transferred variable is assigned directly during the call of the FB or the FC.
- There are several ways of defining the area of the circle for the FB and the FC:
  - For the FB, an output parameter is defined.
  - For the FC, its return value is used; the data type of the return value is defined appropriately.

- Each FB and FC call will be recorded in a counter (local variable). The explanations for the example state: We will see that this value will continue to be counted only in the FB.
- In the program section, the FB or the FC is called and the actual parameters assigned to the following formal parameters:
  - For the FB: Input, in/out and output parameters
  - For the FC: Input and in/out parameters.

  The values for the circumference and the area are available after calling the FB or the FC:
  - For the FB: in the actual parameters of the in/out and output parameter.
    The output parameter can be read even outside the FB.
  - For the FC: in the return value of the function and in the actual parameter of the in/out parameter.

    // myArea has the value 28,274

  END_PROGRAM
END_IMPLEMENTATION
```

Table 7-419 Example of the differences between FB and FC for the previous example

Function block (FB)	Function (FC)
Comments	
Reserved words for the definition: FUNCTION_BLOCK and END_FUNCTION_BLOCK	Reserved words for the definition: FUNCTION and END_FUNCTION
No return value permitted.	The data type of the return value must be specified after the name (VOID data type, if no return value).
Input parameters can be used to transfer values to the FB.	Input parameters can be used to transfer values to the FC.
In/out parameters can be used to read and write the transferred variables in the FB.	In/out parameters can be used to read and write the transferred variables in the FC.
Output parameters can be used to return values from an FB.	No output parameters permitted.
The local variables are static, i.e. they retain their value between FB calls. The *Counter* local variable is incremented; its value is retained when the FB is closed. The variable is, therefore, incremented each time the FB is called. To see this behavior: Assign the value of the local variables to a global variable in the FB. Monitor the value of the global variable after repeated FB calls.	The local variables are temporary, i.e. they lose their value when the function is terminated. Although the *Counter* local variable is incremented, its value is lost when the FC is exited. The variable is reinitialized (to 0 in the example) at the next FC call. To see this behavior: Assign the value of the local variables to a global variable in the FC. The value of the global variable remains unchanged after repeated FC calls.
In the statement section, the results (return values) are assigned to the output or in/out parameters.	In the statement section, the result (return value) is assigned to the function name (except when VOID data type is specified).
In the declaration section of the block that executes the call, an instance of the FB is declared: you declare a variable and specify the name of the FB as its data type. You use the declared instance name to call the FB and to access its output parameters. The name of the FB itself must not be used in the statement section.	
• You assign a variable to the in/out parameters when the FB instance is called. • With the call, you can assign the output parameters to a variable. • You can read an FB's output parameters, even outside the FB. For this purpose, use structured variables in the following format: *FB-instancename.outputparameter*.	• You assign a variable to the in/out parameters when the FB instance is called. • To obtain the return value of the FC: – Assign the function to a variable. – Use the function in an expression on the right side of a value assignment.
The program that executes the call cannot access variables other than the in/out variables and output parameters of the FB. Exception: If the "Permit language extensions" compiler option is activated (see Global compiler settings (Page 4623) or Local compiler settings (Page 4626)), the calling program can also access the input parameters of an FB. For this purpose, use structured variables in the following format: *FB-instancename.inputparameter*.	The program that executes the call cannot access any variables other than the return value.

7.2.5.3 Programs

Programs are a series of statements placed between the PROGRAM and END_PROGRAM keywords.

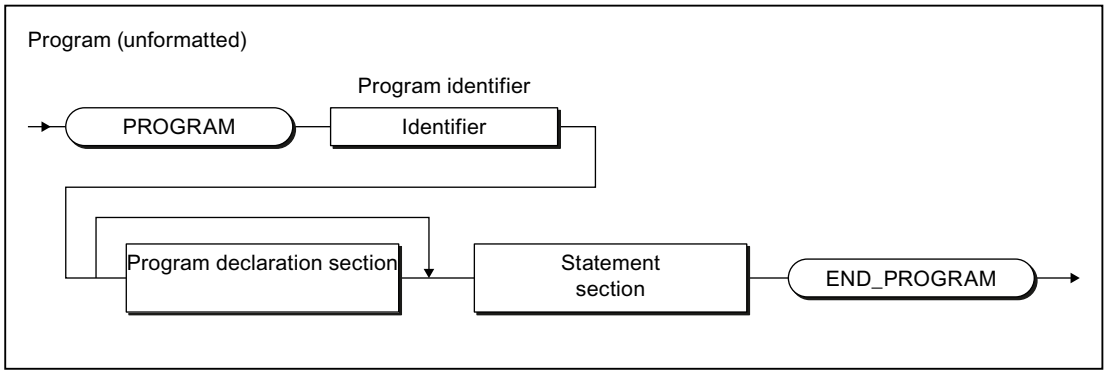

Figure 7-278 Syntax: Program

Programs are declared in the implementation section (Page 4809) of an ST source file and are comparable with the FB. Static local variables (VAR ... END_VAR), retentive local variables (VAR RETAIN ... END_VAR) or temporary local variables (VAR_TEMP ... END_VAR) can be created, for example. However, they do not have any formal parameters and so cannot be called with arguments. Examples of programs are contained in the Source file with comments (Page 4760) and Source text of the sample program (Page 4648) sections.

Assignment of a program in the execution system

By default, programs in the execution system are assigned to a task. The execution behavior of the programs, e.g. initialization of variables, is determined by the relevant task. For more information about the execution system and the tasks, refer to the *SIMOTION Basic Functions* Function Manual. This requires the program in the interface section (Page 4807) of the ST source file to be specified as a program organization unit to be declared public.

Calling a program in the program ("program in program")

Optionally, a program can also be called within a different program or a function block. This requires the following compiler options to be activated, see Global compiler settings (Page 4623) and Local compiler settings (Page 4626):

1. "Permit language extensions" for the program source of the calling program or function block and
2. "Create program instance data only once" for the program source of the calling program.

The call is performed as for a function with parameters and return value, see following example.

Note

The activated "Create program instance data only once" compiler option causes:

- The static variables of the programs (program instance data) to be stored in a different memory area (Page 4844). This also changes the initialization behavior (Page 4854).
- All called programs with the same name to use the same program instance data.

Table 7-420 Example for calling a program in a program

```
PROGRAM my_prog
    ; // ...
END_PROGRAM

PROGRAM main_prog
    ; // ...
    my_prog();
    ; // ...
END_PROGRAM
```

Note

Most of the programming work involved in assigning programs to tasks can be done if programs are called from within a program. In the execution system, only one calling program needs to be assigned to the associated tasks in each case.

7.2.5.4 Expressions

The expression is a special case of a function declaration:

- The data type of the return value is defined as BOOL and is not specified explicitly.

It is used in conjunction with the WAITFORCONDITION statement (Page 4729).

An expression can only be declared in the implementation section of the ST source file.

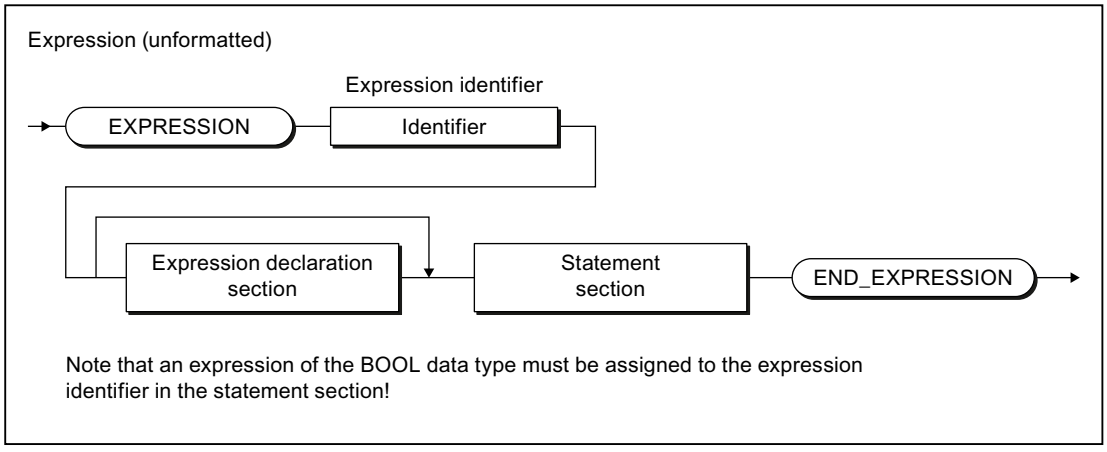

Figure 7-279 Syntax: Expression

Optionally, the following can be declared in the declaration section:

- Local (temporary) variables
- Local constants
- User-defined data types (UDT)
- Input and in/out parameters (as of version V4.1 of the SIMOTION Kernel)

The following can be accessed in the statement section:

- The local variables of the expression
- The input and in/out parameters (provided their declaration is permitted)
- Unit variables
- Global device variables, I/O variables, and the process image

An expression of data type BOOL must be assigned to the expression name in the statement section of the expression (see figure).

Note

The statement section of the expression cannot contain any function calls or loops.

Example

The following example assumes that the feeder program is running in a MotionTask. The option Activation after StartupTask is selected for this MotionTask. The assignment of programs to tasks is performed in SIMOTION SCOUT (see SIMOTION Motion Control Basic Functions Description of Functions).

Table 7-421 Example of an EXPRESSION and the WAITFORCONDITION statement

```
INTERFACE
    USEPACKAGE cam;
    PROGRAM feeder; // in MotionTask_1
END_INTERFACE

IMPLEMENTATION
    // Condition for WAITFORCONDITION statement
    EXPRESSION automaticExpr
        automaticExpr := IOfeedCam; // Digital input
    END_EXPRESSION

    PROGRAM feeder
        VAR
            retVal : DINT ;
        END_VAR ;
        retVal := _enableAxis (axis := realAxis,
            enableMode := ALL,
            servoCommandToActualMode := INACTIVE,
            nextCommand := WHEN_COMMAND_DONE,
            commandId := _getCommandId() );

        // Wait until the start condition is satisfied
        WAITFORCONDITION automaticExpr WITH TRUE DO
            // High-priority execution of all statements
            // to the END_WAITFORCONDITION command
            retVal := _pos (axis := realAxis,
                positioningMode := RELATIVE,
                position := 500,
                velocityType := DIRECT,
                velocity := 300,
                velocityProfile := TRAPEZOIDAL,
                mergeMode := IMMEDIATELY,
                nextCommand := WHEN_MOTION_DONE,
                commandId:= _getCommandId() );
        END_WAITFORCONDITION;

        retVal := _disableAxis (axis := realAxis,
            disableMode := ALL,
            servoCommandToActualMode := INACTIVE,
            nextCommand := WHEN_COMMAND_DONE,
            commandId := _getCommandId() );
    END_PROGRAM
END_IMPLEMENTATION
```

Further examples are contained in the SIMOTION Motion Control Basic Functions Function Manual. In particular, the manual describes how, as of version V4.1 of the SIMOTION Kernel, you

use an EXPRESSION with parameters and, for example, program a time monitoring in a WAITFORCONDITION statement.

7.2.6 Object-oriented programming - OOP (as of kernel V4.5)

7.2.6.1 Important note on object-oriented programming

As of version V4.5 the Structured Text programming language provides options for object-oriented programming.

You can use the object-oriented programming in individual or in all ST source files under the following conditions.

Conditions for object-oriented programming

The following conditions must be met in order to use the object-oriented programming in an ST source file:

- The higher-level SIMOTION device must be configured with a version of the SIMOTION Kernel as of V4.5.
- The corresponding version of the SIMOTION Kernel must be installed on the target device.
- The ST source file must be compiled with the compiler option **Permit object-oriented programming**, see Global compiler settings (Page 4623) and Local compiler settings (Page 4626).

Note

When using the compiler option **Permit object-oriented programming** there is an expanded list of protected identifiers (Page 4658) and of reserved identifiers (Page 4663)in the ST programming language.

The aforementioned conditions apply to the entire section **Object-Oriented Programming – OOP** in this Manual.

Further information and usage examples of object-oriented programming can be found in the following references:

Braun, Michael / Horn, Wolfgang: Objektorientiertes Programmieren mit SIMOTION (Object-Oriented Programming with SIMOTION) Grundlagen, Programmbeispiele und Softwarekonzepte nach IEC 61131-3 (Basic Principles, Example Programs and Software Concepts according to IEC61131-3) 1st edition, Erlangen: Publicis Publishing 2016. ISBN 978-3-89578-455-2.

7.2.6.2 Classes and methods

Creating classes (basic classes)

Defining classes (basic classes)

You define a class in the declaration part of the implementation section wherever possible before the section of the source file (program, FB, FC or class) in which it is called.

Use the following syntax:

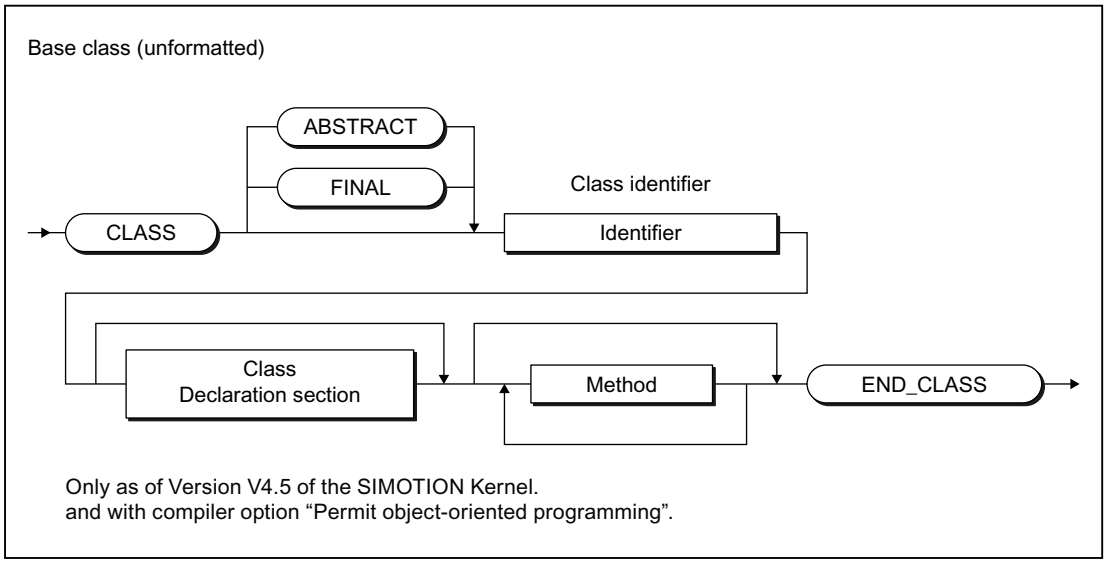

Figure 7-280 Syntax: Base class

Enter an identifier as the class name after the keyword CLASS and optionally FINAL or ABSTRACT.

Then enter, see example in Table 7-428 Example: Up and Down counter as a class (Page 4777):

- The optional declaration section (Page 4767)
- The methods
- Keyword END_CLASS

Declaration subsection of a class

A declaration section is subdivided into various declaration blocks that are each identified by a separate pair of keywords. Each block contains a declaration list for similar data, such as constants and local variables. Each block type may occur multiple times, any sequence is possible for the blocks.

Permissible declaration blocks

Table 7-422 Declaration blocks of a class: Options

Data	Syntax
Data type	**TYPE** *Accessidentifier_class* (optional) *Declaration list* **END_TYPE**
Constant	**VAR CONSTANT** *Accessidentifier_class* (optional) *Declaration list* **END_VAR**
Local variable (static)	**VAR** *Accessidentifier_class* (optional) **OVERRIDE** (optional) *Declaration list* **END_VAR**
Retentive variable	**VAR RETAIN** *access identifier* (optional) **OVERRIDE** (optional) *Declaration list* **END_VAR** (Only PROTECTED or PRIVATE access identifier permitted, default PROTECTED.)
Accessidentifier_class: **PUBLIC**, **PROTECTED**, **PRIVATE** or **INTERNAL**, default **PROTECTED**; see section "Access identifiers within classes" (Page 4768). **OVERRIDE**: Specifying this keyword enable an override of the initialization values for values with the access identifier PROTECTED or PRIVATE for the instance declaration (Page 4778). *Declaration list*: The list of identifiers of the type to be declared	

Access identifier within classes

An access identifier may be stated within classes with declaration blocks or methods:

- With declaration blocks:
  Directly after the keyword for the relevant block (e.g. TYPE, VAR).
  The access identifier is valid for all identifiers within this declaration block.
- With methods:
  Directly after the keyword METHOD.
  The access identifier is valid for the relevant method.

You use the access identifier to determine whether the identifier or the method can only be used within the class, in its derivations or outside of the class, see following table.

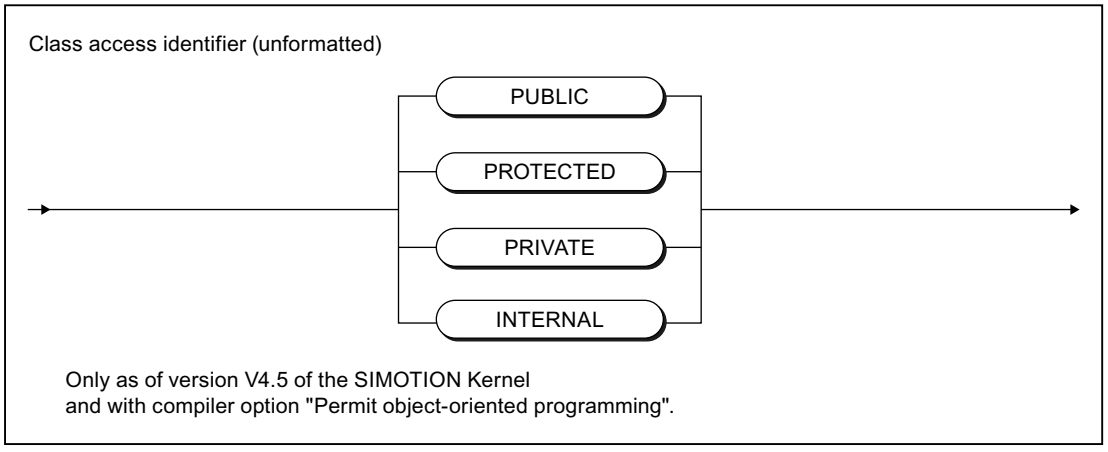

Figure 7-281 Syntax: Class access identifier

Table 7-423 Possible access identifiers within a class

Access identifier	Meaning
PRIVATE	The identifiers for the relevant declaration block (variables, data types, etc.) or the method can only be used within this class. These identifiers or the method cannot be used in derived classes.
PROTECTED	The identifier for the relevant declaration block (variables, data types, etc.) or the method can be used within this class and in classes derived from this. This is the default if there is no access identifier stated.
INTERNAL	Only when the identifier is defined within an object-oriented namespace (Page 4904). The identifiers of the relevant declaration block (variables, data types, etc.) or the method can be used only within the higher-level namespace. Within the higher-level namespace, the following apply: • The declared identifiers can also be accessed outside of the class. This does not apply to retentive local variables (VAR RETAIN). • The method can also be called outside of the class.
PUBLIC	The identifiers for the relevant declaration block (variables, data types, etc.) or the method are public. • The declared identifiers can also be accessed outside the class and outside the higher-level object-oriented namespace. • The method can also be called outside the class and outside the higher-level object-oriented namespace. This access identifier is not permitted in declaration blocks for retentive local variables (VAR RETAIN / END_VAR).

Creating methods

Defining methods

The executable instructions of a class are summarized in methods. Within a class the methods are defined after the declaration subsection for the class.

A method roughly corresponds to a function (Page 4736). Specification of an identifier determines the environment from which the method can be called.

If the compiler option (Page 4623) "Allow forward declaration" is not activated a method must be defined before the program organization unit (program, FB, FC or class) or method in which it is called.

Use the following syntax:

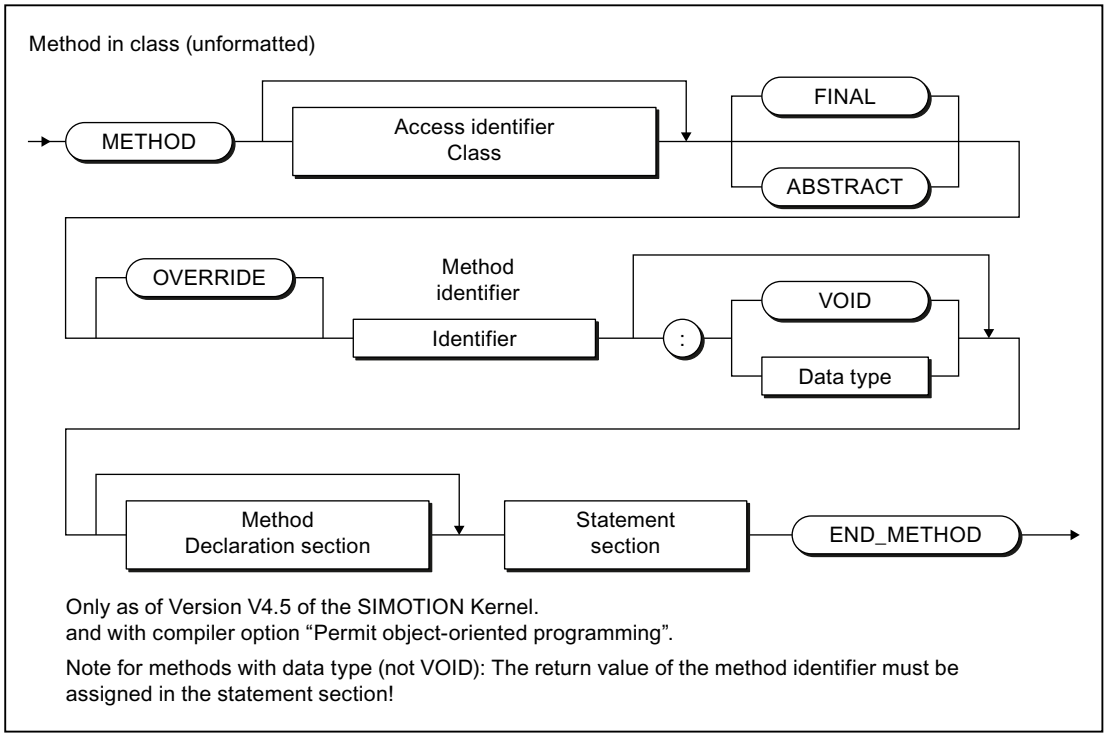

Figure 7-282 Syntax: Method

Enter in the following sequence, see Table 7-428 Example: Up and Down counter as a class (Page 4777):

- The METHOD keyword.
- the optional class access identifier (PUBLIC, PROTECTED or PRIVATE), default PROTECTED. See section "Access identifiers within Classes" (Page 4768) for access identifiers.
- The keywords FINAL, ABSTRACT and OVERRIDE are only relevant for methods in classes that are derived or are to be derived:
  - FINAL: Method cannot be overridden in a derived class.
  - ABSTRACT: Method cannot be called, it must be overridden in a class to be derived. Furthermore, this keyword renders the class in which the method is defined an abstract class. In this case, it is not possible to declare an instance of this class, see "Abstract classes" (Page 4790).
  - OVERRIDE: Method overrides the existing method with the same name in a derived class.
- An identifier as method name.
- if the method has a return value, the data type for the return value following a colon. The symbolic data type VOID can also be entered for a method with no return value.

This is then followed by:

- The optional declaration section (Page 4771)
- The statement section (Page 4773) (except in methods with keyword ABSTRACT)
- The END_METHOD keyword

Declaration subsection of methods

A declaration section is subdivided into various declaration blocks that are each identified by a separate pair of keywords. Each block contains a declaration list for similar data, such as constants, local variables and parameters. Each type of block may only appear once; the blocks may appear in any order.

The following options are then available for the declaration section of a method:

Permissible declaration blocks

Table 7-424 Declaration blocks for methods: Options

Data	Syntax
Constant	**VAR CONSTANT** *Declaration list* **END_VAR**
Input parameters	**VAR_INPUT** *Declaration list* **END_VAR**
In/out parameter	**VAR_IN_OUT** *Declaration list* **END_VAR**
Output parameters	**VAR_OUTPUT** *Declaration list* **END_VAR**
Local variable (temporary)	**VAR** or **VAR_TEMP** *Declaration list* **END_VAR**
Declaration list: The list of identifiers of the type to be declared	

Parameter blocks

Parameters are local data and are formal parameters of a method. When the method is called, the formal parameters are substituted by the actual parameters, thus providing a means of exchanging information between the called and calling source file sections.

- Formal input parameters receive the actual input values (data flow inwards).
- Formal output parameters are used to transfer output values (data flow outwards).
- Formal in/out parameters act as input and output parameters.

The following figures show the syntax for the parameter declaration of a method. This is identical to the syntax for the parameter declaration of a function (FC).

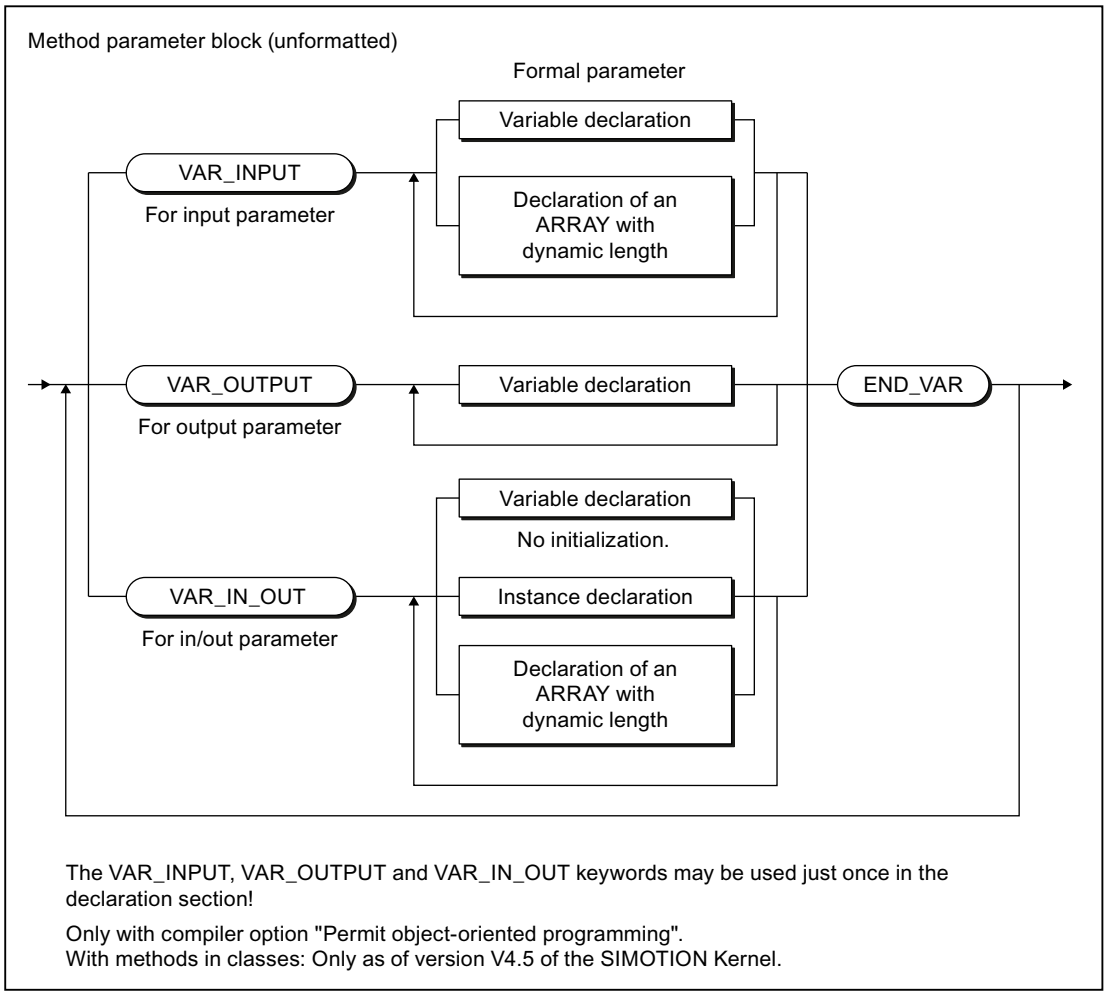

Figure 7-283 Syntax: Method parameter block

Apart from variables you can also declare the following in the parameter blocks:

- in the parameter block for in/out parameters:
  - Instances of function blocks (Page 4754)
  - Instances of classes (Page 4778)
  - Arrays with a dynamic length (Page 4747), as of version V4.2 of SIMOTION Kernel.
- in the parameter block for input parameters:
  - Arrays with a dynamic length (Page 4747), as of version V4.2 of SIMOTION Kernel.

You can use the declared parameters in the same way as other variables within a method, with the following exception: You cannot assign values to input parameters.

From outside the method you can only access the parameters by calling the method (including return value).

Statement section of methods

The statement section of a method contains statements that are executed when the method is called. There is no difference compared to the formal rules for creating a statement section; however, you should note the information in the following table.

Note

For tips on the efficient use of parameters, please refer to the Runtime-optimized Programming section in the SIMOTION Basic Functions Function Manual.

Table 7-425 Use of parameters and variables in methods

Parameter/variable	Use
Input parameters	With the call of a method, assign the current values to the input parameters. These values are used for data processing within the method, for example, for calculations, but cannot be modified themselves.
In/out parameter	You assign a variable to an in/out parameter for the call of the method. The method accesses this variable directly and can change it directly. Type conversions are not supported. The variable assigned to an in/out parameter must be able to be read and written directly. Therefore, system variables (of the SIMOTION device or a technology object), I/O variables or process image accesses cannot be assigned to an in/out parameter.
Output parameters	You assign a variable to an in/out parameter for the call of a method using the **=>** operator. The value of the output parameter (result) is transferred to the variables when the method is closed.
Local variables	Local variables are variables that are declared and used only within the block. All local variables (VAR ... END_VAR or VAR_TEMP ... END_VAR) are temporary in methods, i.e. they lose their value when the method is terminated. The next time the method is called, they are reinitialized.

Note

The statement section is omitted from methods that are declared with the keyword ABSTRACT.

Calling methods within the class

Calling methods

Methods can be called in other methods within a class. As with functions, the call is made by specifying the method identifier and the parameter list (FC parameters).

The method can also be specified more precisely by stating the keywords THIS or SUPER or by stating a class identifier, see syntax in the following figure as well as the following table.

- The following applies to methods with no return value or with data type VOID:
  The method call is an instruction within a different method.
- The following applies to methods with return values:
  The method call is part of an expression on the right side of a value assignment.

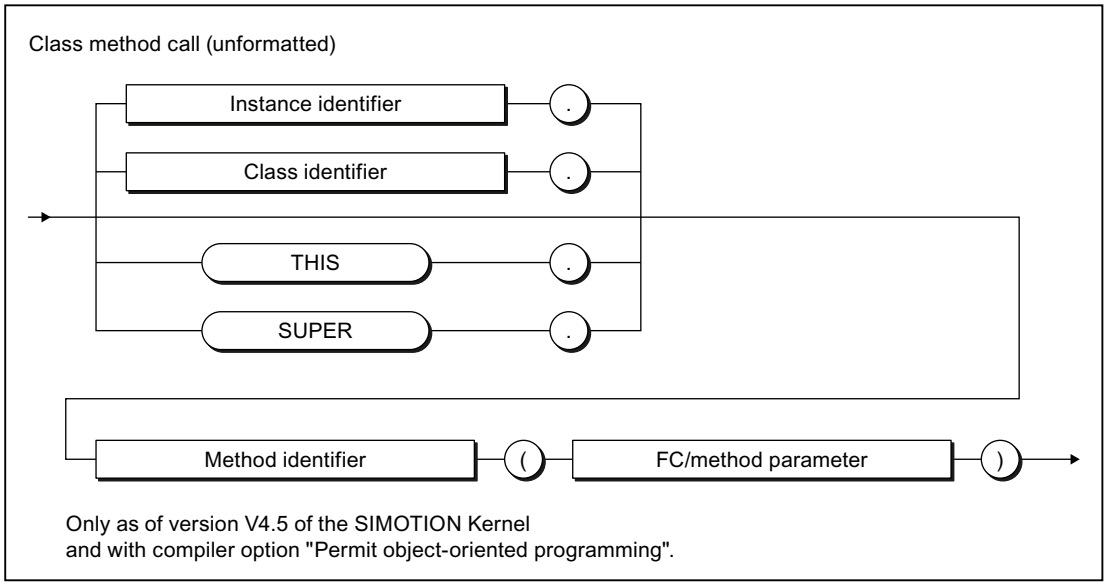

Figure 7-284 Syntax: Class method call

Table 7-426 Description of the method specification

Method specification	Description
(without)	Call of a method in a separate class with static binding. This means: If the stated method is overridden and called in a derived class, the original method is still called. Only methods that are defined in a separate class can be specified (i.e. not methods inherited from the base class).
THIS.	Call of a method in a separate class with dynamic binding. This means: If the stated method in a derived class is overridden and called, the current (overriding) method is called. All methods that are recognized in the class, including methods inherited from the base class, can be specified.
SUPER.	With derived classes: Explicit call of a method of the base class (static binding).
Class identifier.	Explicit call of a method of the stated class (static binding). Permitted class identifiers: Separate class and all base classes within a method implementation
Instance identifier.	Call of a method outside of the class, see Calling public methods of a class outside of this class (Page 4780).

Parameter transfer to input parameters

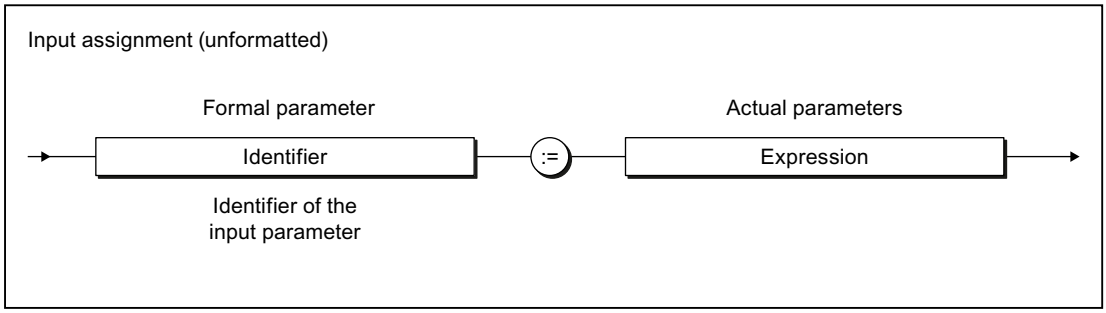

Figure 7-285 Syntax: Input assignment

You transfer the data (actual parameters) to the formal input parameters of a method by means of input assignments. You can specify the actual parameters in the form of expressions. You can use the formal input parameters in statements within the method, but you cannot modify their values.

The assignment of an actual parameter is optional when an initialization expression was specified for the declaration of the formal parameter.

See also Table 7-428 Example: Up and Down counter as a class (Page 4777).

Parameter transfer to in/out parameters

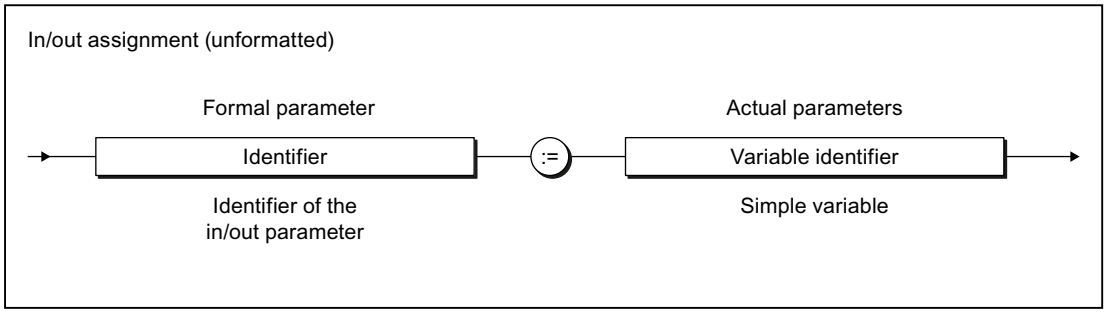

Figure 7-286 Syntax: In/out assignment

You transfer the data (actual parameters) to the formal in/out parameters of a method by means of in/out assignments. You can only assign a variable of the same type to the formal in/out parameter, data type conversions are not possible.

You can use and change the formal in/out parameters in statements within the method. The method accesses the variable of the actual parameter directly and can change it directly.

The variable assigned to an in/out parameter must be able to be directly read and written. Therefore, system variables (of the SIMOTION device or a technology object), I/O variables or process image accesses cannot be assigned to an in/out parameter.

When using the STRING data type in in/out assignments, the declared length of the actual parameter must be greater than or equal to the length of the formal in/out parameter (see following example).

Table 7-427 Example of the use of the STRING data type in in/out assignments

```
METHOD REF_STRING
    VAR_IN_OUT
        io : STRING[80];
    END_VAR
    ;    // Statements
END_METHOD

METHOD test
    VAR
        str1 : STRING [100];
        str2 : STRING [50] ;
    END_VAR
    REF_STRING (io := str1);    // Permissible call
    REF_STRING (io := str2);    // Illegal call,
                                // Compiler error message
END_METHOD
```

Please note the different parameter access times!

Parameter transfer to output parameters

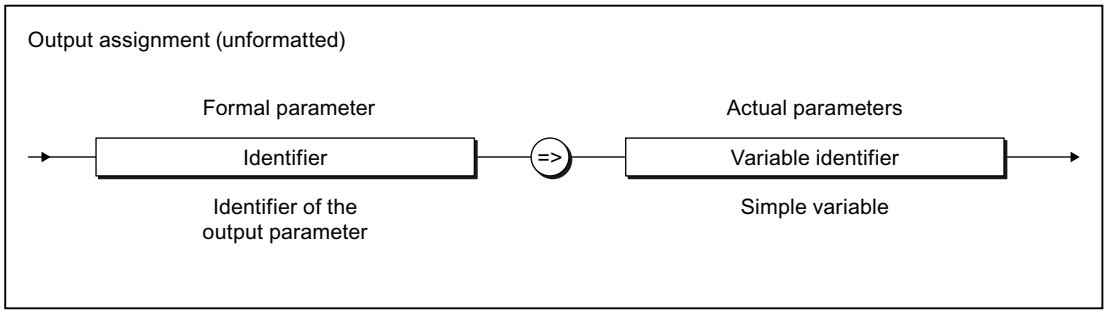

Figure 7-287 Syntax: Output assignment

You use an output assignment to assign the formal output parameters of a method to the variables (actual parameter) that adopt the value of the formal output parameter when the method is closed.

You can use and change the formal output parameters in statements within the method.

See also example: Table 7-429 Example: Call of the methods in the COUNTER class (Page 4781)

Output assignments are optional for the parameter transfer. If there is no output assignment for an output parameter, the values for the output parameters are lost once the method is terminated.

Example classes and methods

Example: Counter as a class

The classes and methods are explained in the following example using a counter.

In the COUNTER class the two methods UP and DOWN are defined for counting a variable CV up or down. They have the access identifier PUBLIC so that they can be called from outside, e.g. from a program.

The UP method increases the CV counter variable with every run-through by the input parameter INC (default = 1) until the upper limit value MAX_Val is reached.

The DOWN method decreases the CV counter variable with every run-through by the input parameter DEC (default = 1) until the lower limit value MIN_Val is reached. It calls the UP method internally and transfers the negative value of the input parameter DEC to it. Adding THIS. before the call for the UP method means that if the UP method is exceeded in a derived class the UP method effective there is called.

The declaration of the variables MAX_Val and MIN_Val with the keyword OVERRIDE allows the initialization values for the instance declaration of the class to be changed.

The return value for both methods contains the current value of the counter variables CV. The output parameter QU signals whether the upper limit value MAX_Val has been reached or the lower limit value MIN_Val has not been reached as relevant.

Table 7-428 Example: Up and Down counter as a class

```
CLASS COUNTER
    VAR
        CV : INT; // Current value of the counter
    END_VAR
    VAR OVERRIDE
        MAX_Val : INT := 100;
        MIN_Val : INT := 0;
    END_VAR

    // Method for incrementing by INC
    METHOD PUBLIC UP: INT
        VAR_INPUT
            INC : INT := 1;
        END_VAR
        VAR_OUTPUT
            QU : BOOL;
        END_VAR
        // Detection of upper limit
        IF CV <= MAX_Val - INC THEN
            CV := CV + INC; // Increment of the counter CV
            QU := FALSE;
        ELSE
            QU := TRUE; // Upper level limit reached
        END_IF;
        UP := CV; // Result of the method
    END_METHOD
```

```
    // Method for decrementing by DEC
    METHOD PUBLIC DOWN : INT
        VAR_INPUT
            DEC : INT := 1;
        END_VAR
        IF CV > MIN_Val THEN
            // Internal call for the UP method
            DOWN := THIS.UP (INC := - DEC);
        END_IF;
    END_METHOD
END_CLASS
```

Creating and using instances of classes

Declaring an instance of a class

Declaring an instance of a class

Before using methods or variables of a class you must declare an instance of the class. You declare a variable and enter the name of the class as the data type. You declare this instance:

- locally:
  within VAR / END_VAR in the declaration section of a program, a function block or a class
- globally:
  within VAR_GLOBAL / END_VAR in the interface section or implementation section of the ST source file
- as an in/out parameter:
  within VAR_IN_OUT / END_VAR in the declaration section of a function block, a function or a method

It is in all cases possible to declare the instance of a class in a program source at which the compiler option (Page 4623) "Permit object-oriented programming" is **not** active.

Exception: The compiler option (Page 4623) "Permit object-oriented programming" **must** be active at the ST source file in the following cases:

- With local declaration within classes.
  The access identifier class (Page 4768) (PUBLIC, PROTECTED or PRIVATE) can also be stated as an option after the keyword VAR.
- With local declaration within function blocks as long as the access identifier FB (PUBLIC or PRIVATE) is stated after the keyword VAR.
- With declaration as an in/out parameter in methods.

Instance-specific initialization of individual local variables of the class is possible. You thereby override the initialization values that were stipulated with the declaration of the class. Specification of the variables to be initialized is similar to the process for initializing a structure, and involves specifying a structure initialization list (Page 4699) in brackets.

You can in all cases initialize public variables of the class (i.e. variables with the PUBLIC access identifier) specific to the instance. In order to be able to initialize protected or private variables

of the class (i.e. variables with PROTECTED or PRIVATE access identifiers), the keyword OVERRIDE must be stated at their declaration block after the access identifier.

The following generally applies: The class must be declared in the ST source file before an instance can be declared.

Exception: It is sufficient to define a POU prototype (Page 4929) beforehand if initialization is not specified and when compiler option (Page 4623) "Permit forward declarations" is activated.

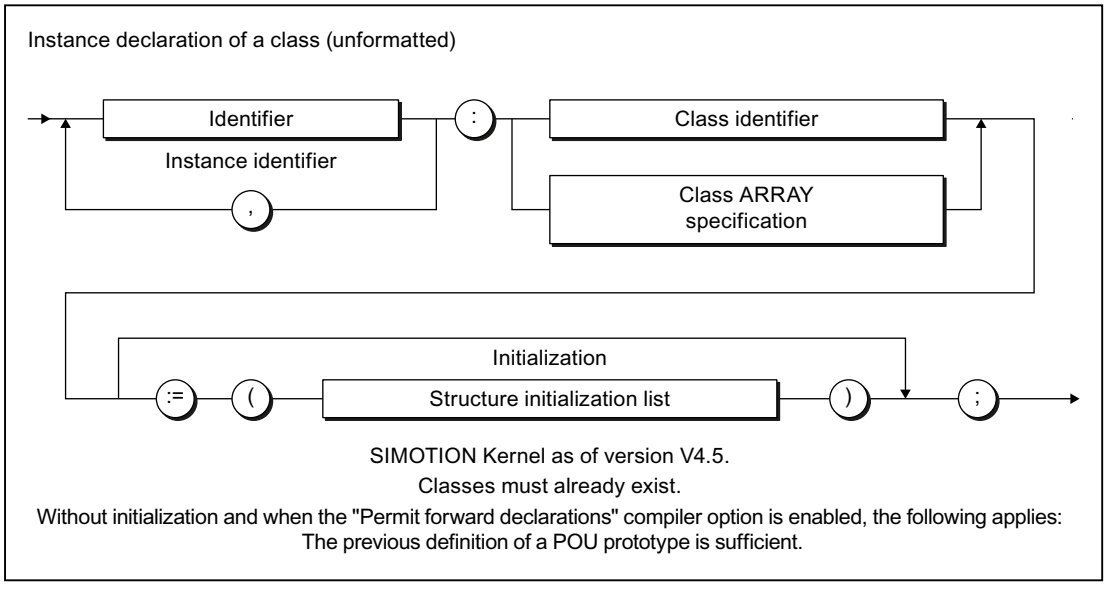

Figure 7-288 Syntax: Instance declaration of a class

Example of the instance declaration of a class:

```
Class_inst : Class_name := (Var_publ1 := 12,
                            Var_publ2 := 123.456);
```

The instance declaration can also be an array, e.g.:

```
Class_inst : ARRAY [1..2] OF Class_name;
```

Note

Pay attention to the different initialization times for different variable types.

Calling public methods of a class outside of this class

You can also call the public methods for a class (i.e. methods with PUBLIC access identifier) outside of this class, e.g. in programs, functions, function blocks or methods from other classes. Proceed as follows:

1. Declare an instance of the class (unless this has already been done).
   See Declaring an instance of a class (Page 4778).
2. To call the method, write the name of the method instance and a period before the method name (similar to a structured variable (Page 4708)).
   The parameter transfer takes place as described in the Calling methods within the class (Page 4773) section.

Accessing the public variables of a class outside of the class

How to access a public local variable of a class (i.e. variable with PUBLIC access identifier):

1. Declare an instance of the class (unless this has already been done).
   See Declaring an instance of a class (Page 4778).
2. For access purposes use a structured variable (Page 4708) in the format *class-instancename.variablenname*, e.g. *Class_inst.var_name*.

You can have read/write access to the public variable.

Access the public constants or data types of a class in a similar manner.

Example: Call of the counter method

The following program uses the COUNTER class declared in Table 7-428 Example: Up and Down counter as a class (Page 4777). It calls the methods UP and DOWN defined there. A C1 instance of the COUNTER class is declared for this, with the initialization values of the variables MAX-Val and MinVal modified in this process. Provided that Locking = FALSE, method C1.UP is called. Provided that the upper value is reached (UpValreached = TRUE), Locking becomes TRUE and the method C1.DOWN is called until the lower value is reached.

This program must be assigned to a cyclic task of the execution system (e.g. BackgroundTask).

The complete ST source file includes the class COUNTER from Table 7-428 Example: Up and Down counter as a class (Page 4777) in front of the program CallCounter.

Table 7-429 Example: Call of the methods in the COUNTER class

```
PROGRAM CallCounter_ST
    VAR
         C1 : COUNTER := (MAX_Val := 1000, MIN_Val := 0); // Instance
         CountOut     : INT;
         Locking      : BOOL;
         UpValreached : BOOL;
    END_VAR

    // Call of methods for incrementing and decrementing
    IF UpValreached = TRUE THEN
        Locking := TRUE;
    END_IF;
    IF Locking = FALSE THEN
        CountOut := C1.UP (QU => UpValreached); // Increment
    END_IF;
    IF Locking = TRUE THEN
        CountOut := C1.DOWN (); // Decrement
    END_IF;
    IF CountOut <= 0 THEN
        Locking      := FALSE;
        UpValreached := FALSE;
    END_IF;
END_PROGRAM
```

7.2.6.3 Inheritance of classes and methods

Inheritance of classes

In object-oriented programming, it is possible to derive subclasses from an existing class (base class). When a subclass is derived, it inherits all the properties of the base class, although the source code is not provided in the derived class:

- all data types that were declared in the base class,
- all variables and constants that were declared in the base class,
- all methods that were declared in the base class,
- all instance declarations of classes and function blocks within the base class.

The complete syntax diagram of a class definition is provided below.

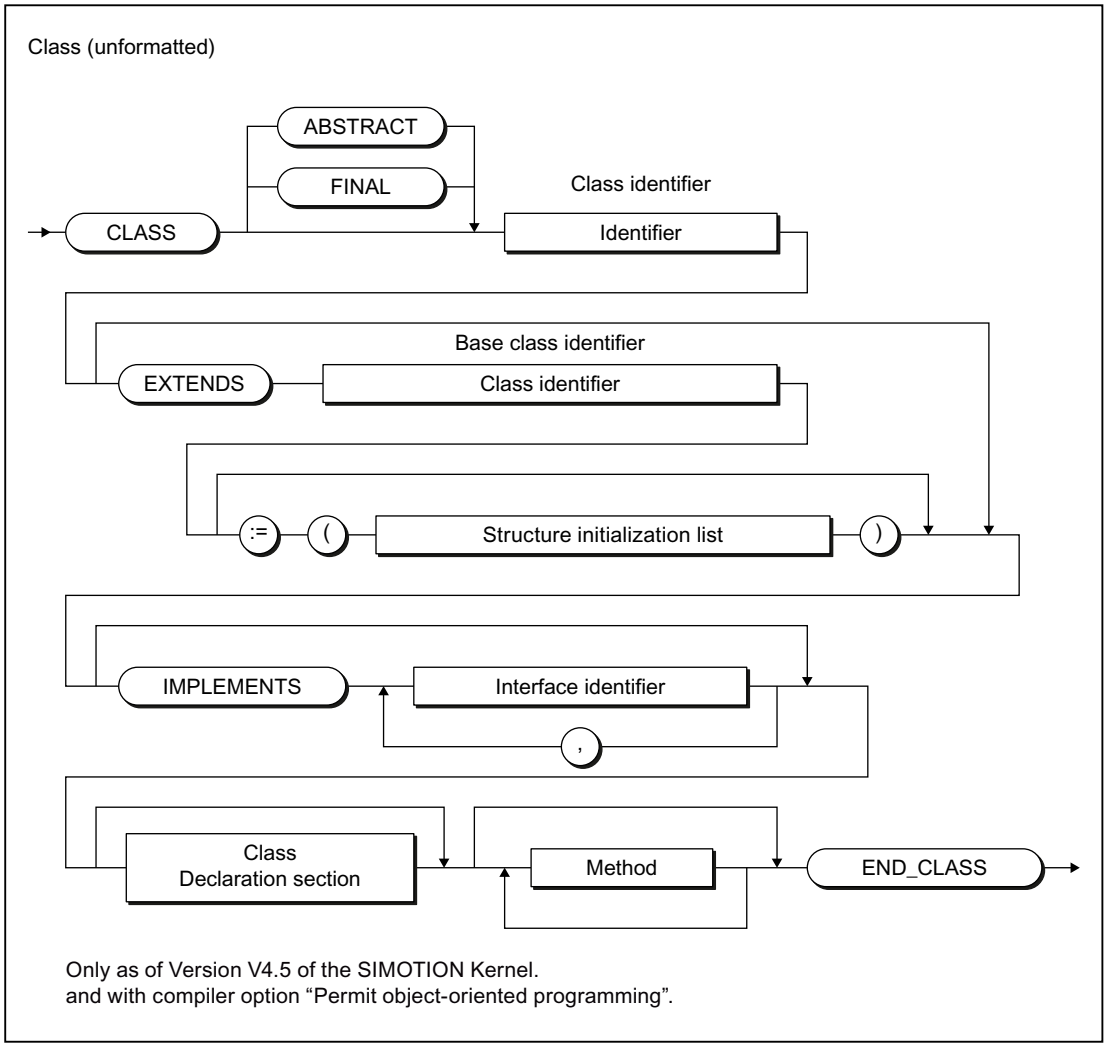

Figure 7-289 Syntax: Class

Use the keyword EXTENDS with the identifier for the base class in order to derive a class.

The properties for the derived class can now be adapted to the new circumstances:

- The initialization values for the variables from the base class can be modified:
  - public or protected variables (access identifiers PUBLIC or PROTECTED) without restrictions.
  - private variables (access identifier PRIVATE) only when the keyword OVERRIDE has been stated at their declaration block after the access identifier.
- Additional data types, variables and constants can be declared.
- Additional instances of classes and function blocks can be declared.
- Additional methods can be defined.
- Existing methods can be overridden.

Note

Data types, variables and constants that have been declared with the access identifier PRIVATE in the base class cannot be accessed in the derived class. Access is only possible via methods inherited from the base class.

Methods that have been defined with the access identifier PRIVATE in the base class cannot be called in the derived class. They can only be called from methods inherited from the base class.

Overriding methods

Public or protected methods of the base class (access identifiers PUBLIC or PROTECTED) can be overridden in a derived class.

For this proceed as described in the “Defining methods" (Page 4769) section and use the keyword OVERRIDE.

The following must be consistent in the overriding method and the methods from the base class:

- Access identifier
- Method name
- Data type of the return value
- Parameters in the declaration subsection of the method:
  - Type (input, in/out, output parameters)
  - Number and sequence
  - Identifier
  - Data type

The overriding method and the method from the base class may be different:

- with the temporary variables (VAR / END_VAR or VAR_TEMP / /END_VAR)
- In the statement section
  You can also call the same method from the base class in the statement section. Use the keyword SUPER or the identifier for the base class. See “Calling methods" (Page 4773).

The following methods from the base class cannot be overridden:

- Methods with the keyword FINAL.
- Methods with the access identifier PRIVATE.

The keyword ABSTRACT can only be used in the overriding method if it was also used in the method for the base class. Note that a class is abstract if it contains at least one abstract method. No instances can be declared from abstract classes.

Example: Counter in steps of 5 through inheritance

The following example is based on the COUNTER class from the Table 7-428 Example: Up and Down counter as a class (Page 4777) example. It shows how to obtain a COUNTER_5STEP class whose methods count up and down in steps of 5 by deriving from the COUNTER class and overriding its methods.

With the definition of the COUNTER_5STEP class the keyword EXTENDS signifies that this class is derived from the COUNTER class (= base class). The derived class inherits from the base class all variables, constants, instance declarations and methods that have been defined with the PUBLIC or PROTECTED access identifiers. In the example, these are:

- the variables CV, MAX_Val and MIN_Val,
- the methods UP and DOWN

The UP method is now overridden so that it counts up in steps of 5. With the method definition the keyword OVERRIDE signals that the method for the base class is overridden. The overriding method and the method from the base class must be consistent on the following points:

- Access identifier (PUBLIC in the example)
- Method identifier (UP in the example)
- Data type of the return value (INT in the example)
- Parameters in the declaration subsection of the method (input parameter INC and output parameter QU in the example)

The statement section for the overriding method UP is entirely new. The UP method is called from the base class with the keyword SUPER and 5x of the input parameter IC of the overriding class is transferred to it as the input parameter. Similarly the return value and the output parameter QU of the base function are transferred to the overriding method. It may be confusing to see the same parameter identifiers in the input and output assignments on both sides. However, these are functions independent of the parameters. The formal parameters of the method of the base class are on the left side of the assignments, the formal parameters of the overriding class are on the right side as actual parameter.

Table 7-430 Up and Down counter in steps of 5

```
CLASS COUNTER_5STEP EXTENDS COUNTER
    METHOD PUBLIC OVERRIDE UP: INT // Method override
        VAR_INPUT
            INC : INT := 1;
        END_VAR
        VAR_OUTPUT
            QU : BOOL;
        END_VAR

        UP := SUPER.UP (INC := 5 * INC, QU => QU);

    END_METHOD
END_CLASS
```

The DOWN method does not need to be overridden. Since the COUNTER_5STEP classes is derived from the COUNTER class then it also inherits the DOWN method. The DOWN method calls the UP method with the following statement: `DOWN := THIS.UP (INC := - DEC);`. The keyword

THIS means that the method applicable there is called in derived classes. Consequently the DOWN method calls the following methods:

- in the COUNTER class:
  the UP method for counting upwards in steps of 1
- in the COUNTER_5STEP class:
  the UP method for counting upwards in steps of 5

This means that the DOWN method

- in the COUNTER class counts downwards in steps of 1
- in the COUNTER_5STEP class counts downwards in steps of 5.

Example: Call of the methods for both counters

Call in a program

The following program extends the Table 7-429 Example: Call of the methods in the COUNTER class (Page 4781) program to include the call of the methods in the COUNTER_5STEP class. A C2 instance of the COUNTER_5STEP classes is declared for this: The statements for calling the UP and DOWN methods of the C1 instance of the COUNTER classes are duplicated and modified accordingly.

This program must be assigned to a cyclic task of the execution system (e.g. BackgroundTask).

The complete ST source file also includes the classes COUNTER and COUNTER_5_STEP from Table 7-430 Up and Down counter in steps of 5 (Page 4784) and Table 7-428 Example: Up and Down counter as a class (Page 4777) respectively in front of the program CallCounter_ST2.

Table 7-431 Call of the methods of the COUNTER and COUNTER_5STEP classes in stages

```
PROGRAM CallCounter_ST2
    VAR
        C1 : COUNTER;       // COUNTER instance
        C2 : COUNTER_5STEP; // COUNTER_5STEP instance
        CountOut      : INT;
        CountOut2     : INT;
        Locking       : BOOL;
        Locking2      : BOOL;
        UpValreached  : BOOL;
        UpValreached2 : BOOL;
    END_VAR
```

```
    // Call of methods from COUNTER (C1)
    IF UpValreached = TRUE THEN
        Locking := TRUE;
    END_IF;
    IF Locking = FALSE THEN
        CountOut := C1.UP (QU => UpValreached); // Increment
    END_IF;
    IF Locking = TRUE THEN
        CountOut := C1.DOWN (); // Decrement
    END_IF;
    IF CountOut <= 0 THEN
        Locking      := FALSE;
        UpValreached := FALSE;
    END_IF;
    // Call of methods from COUNTER_5STEP (C2)
    IF UpValreached2 = TRUE THEN
        Locking2 := TRUE;
    END_IF;
    IF Locking2 = FALSE THEN
        CountOut2 := C2.UP (QU => UpValreached2); // Increment
    END_IF;
    IF Locking2 = TRUE THEN
        CountOut2 := C2.DOWN (); // Decrement
    END_IF;
    IF CountOut2 <= 0 THEN
        Locking2      := FALSE;
        UpValreached2 := FALSE;
    END_IF;
END_PROGRAM
```

Call via function

The following example moves the same types of statements which call the methods of both classes in the above example to the CallSingleCounter function. The class and additional variables are transferred to the function via in/out parameters. Program maintenance is essentially simplified because the individual statements for calling the UP and DOWN methods do not need to be maintained twice.

The program CallCounter_ST3 must be assigned to a cyclic task of the execution system (e.g. BackgroundTask).

The complete ST source file also includes the classes COUNTER and COUNTER_5_STEP from Table 7-430 Up and Down counter in steps of 5 (Page 4784) and Table 7-428 Example: Up and Down counter as a class (Page 4777) respectively in front of the function CallSingleCounter.

Table 7-432 Call of the methods of the COUNTER and COUNTER_5STEP classes via a function

```
FUNCTION CallSingleCounter : VOID
    VAR_IN_OUT
        C : COUNTER;
        CountOut     : INT;
        Locking      : BOOL;
        UpValreached : BOOL;
    END_VAR
    // Call COUNTER ( C ) for increment/decrement
    IF UpValreached = TRUE THEN
        Locking := TRUE;
    END_IF;
    IF Locking = FALSE THEN
        CountOut := C.UP (QU => UpValreached); // increment
    END_IF;
    IF Locking = TRUE THEN
        CountOut := C.DOWN (); // decrement
    END_IF;
    IF CountOut <= 0 THEN
        Locking := FALSE;
    END_IF;
END_FUNCTION

PROGRAM CallCounter_ST3
    VAR
        C1 : COUNTER;
        C2 : COUNTER_5STEP;
        CountOut      : INT;
        CountOut2     : INT;
        Locking       : BOOL;
        Locking2      : BOOL;
        UpValreached  : BOOL;
        UpValreached2 : BOOL;
    END_VAR
    // Call COUNTER (C1) for increment/decrement
    CallSingleCounter (
        C := C1,
        CountOut     := CountOut,
        Locking      := Locking,
        UpValReached := UpValReached);
    // Call COUNTER_5STEP (C2) for increment/decrement
    CallSingleCounter (
        C := C2,
        CountOut     := CountOut2,
        Locking      := Locking2,
        UpValReached := UpValReached2);
END_PROGRAM
```

Initialization of derived classes and their instances

Initialization of derived classes

As stated in the syntax diagram Figure 7-289 Syntax: Class (Page 4782) the initialization values of the following variables of the base class can be modified when deriving from a class:

- Public and protected variables (access identifiers PUBLIC or PROTECTED) without restrictions.
- Private variables (access identifier PRIVATE) only when the keyword OVERRIDE has been stated at their declaration block after the access identifier.

How to change the initialization values of the variables of a derived class:

1. Enter the assignment operator := after the name of the base class.
2. Next state the variables to be amended in brackets and their initialization values in the form of a structure initialization list (Page 4699) (similar process as for the initialization with the user-defined data type structure).
   If the base class is itself a derived class, you can modify the initialization values of the variables inherited from its base class in the following way (as an alternative):
   - Enter the base class itself as an element of the structure initialization list or
   - Aggregate the identifiers of the base class and the variables in the form *class_name.var_name*.

   See also section "Initialization of structures" in chapter Initialization of variables or data types (Page 4697) and the example below.

Example

The example below supplements the example Table 7-430 Up and Down counter in steps of 5 (Page 4784).

Table 7-433 Derivation and initialization of the COUNTER class

```
CLASS COUNTER_5STEP EXTENDS COUNTER
                := (MAX_Val := 500)
    // MAX_Val = 500, MIN_Val = 0
    // ...
    // Override of method UP
END_CLASS

CLASS COUNTER_10STEP EXTENDS COUNTER_5STEP
                := (COUNTER := (MIN_Val := -500))
             // Alternative:
             // := (COUNTER.MIN_Val := -500)
    // MAX_Val = 500, MIN_Val = -500
    // ...
    // Override of method UP
END_CLASS
```

Initialization of instances of derived classes

As stated in the syntax diagram Figure 7-288 Syntax: Instance declaration of a class Instance declaration of a classSyntax (Page 4779) the initialization values of the following variables can be modified with the instance declaration of a class:

- Public variables (access identifier PUBLIC) without restrictions.
- Protected and private variables (access identifier PROTECTED or PRIVATE) only when the keyword OVERRIDE has been stated at their declaration block after the access identifier.

How to change the initialization values of the variables of an instance:

1. Enter the assignment operator := after the name of the class.
2. Next state the variables to be amended in brackets and their initialization values in the form of a structure initialization list (Page 4699) (similar process as for the initialization with the user-defined data type structure).
   If the class is itself a derived class, you can modify the initialization values of the variables inherited from its base class in the following way (as an alternative):
   - Enter the base class itself as an element of the structure initialization list.
   - Aggregate the identifiers of the base class and the variables in the form *class_name*.*var_name*.

   See also section "Initialization of structures" in chapter Initialization of variables or data types (Page 4697) and the example below.

Example

The following example supplements the examples Table 7-429 Example: Call of the methods in the COUNTER class (Page 4781) and Table 7-431 Call of the methods of the COUNTER and COUNTER_5STEP classes in stages (Page 4785).

Table 7-434 Initialization of instances of the COUNTER class and the derivations

```
VAR
    C1 : COUNTER := (MIN_Val := -100);
         // MAX_Val = 100, MIN_Val = -100

    C2 : COUNTER_5STEP
            := (COUNTER := (MIN_Val := -100));
         // Alternative:
         // := (COUNTER.MIN_Val := -100);
         // MAX_Val = 500, MIN_Val = -100

    C3 : COUNTER_10STEP
            := (COUNTER_5STEP := (COUNTER := (MAX_Val := 1000)));
         // Alternative:
         // := (COUNTER_5STEP.COUNTER.MAX_Val := 1000);
         // MAX_Val = 1000, MIN_Val = -500
END_VAR
```

7.2.6.4 Abstract classes

Definition

A class is described as abstract if one of the two following conditions is met:

- The class is marked with the keyword ABSTRACT, see Class syntax diagram (Page 4782).
- At least one method of the class is abstract, i.e. is marked with the keyword ABSTRACT, see Method syntax diagram (Page 4770).

No instances can be declared of an abstract class.

In order to be able to declare instances, derived classes must be declared from abstract classes with all abstract methods overridden and their statement sections formulated. Derived classes in which not all inherited methods are implemented remain abstract.

Use

Abstract classes are a means of structuring and abstraction often used in object-oriented programming. The common variables and common methods are defined with their interfaces (formal parameters) in an abstract class. The methods and specified in the derived classes and overridden and implemented in accordance with the relevant requirements.

There are different motor types in a machine, e.g. motors that can be switched on directly via a contactor or via a star-delta switch and speed-controlled drives. The concrete methods for switching the motors on and off differ. Nevertheless the methods for switching on and off in an abstract class can be stipulated with their signatures (identifier, access identifier, formal parameters) with variables also defined for the status of the motor (e.g. running, stationary, starting, stopping, actual speed, error). These methods and variables should be subject to uniform usage in all classes. In the derived classes the methods are specified in accordance with the motor type with the corresponding values assigned to the variables.

7.2.6.5 Object-oriented interface

Defining an object-oriented interface

Object-oriented interfaces define the call interface for public methods (access identifier PUBLIC). Method prototypes are defined for this purpose in the object-oriented interface. These methods with the definition "prototype" are formulated in classes which implement the object-oriented interfaces.

Object-oriented interfaces are defined in the interface section (Page 4807) or implementation section (Page 4809) of an ST source file. In most cases, they are declared in the interface section because they are generally declared PUBLIC.

They must always be declared in full before they are used in the declaration of an implementing class or an interface variable. This applies irrespective of the compiler option (Page 4623) "Permit forward declarations".

Note

While object-oriented interfaces start and end with the same keywords as the interface section (Page 4807) of a unit (INTERFACE / END_INTERFACE), they have different meanings and are used in different ways.

Syntax of the object-oriented interface

Use the following syntax:

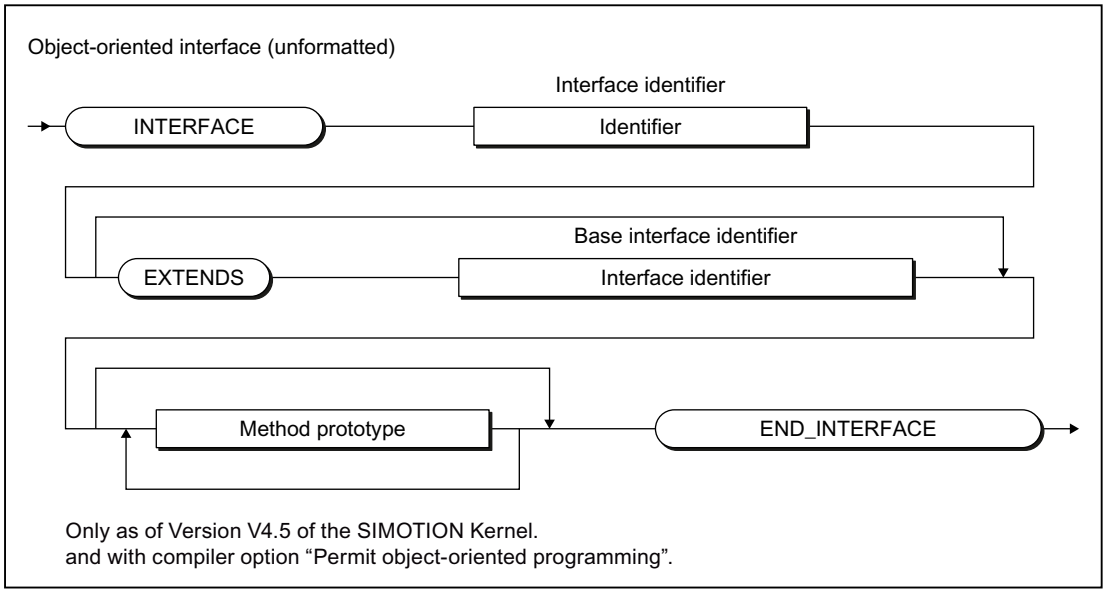

Figure 7-290 Syntax: Object-oriented interface

Enter an identifier as the interface name after the keyword INTERFACE.

This is then followed by:

- Optionally the keyword EXTENDS and the identifier of a different interface.
  This is how you derive an interface from an existing interface (base interface).
- The method prototypes in accordance with the following syntax
- The keyword END_INTERFACE

Method prototype

A method prototype determines the call interface for a method. This call interface includes:

- the method identifier (name),
- optionally the data type of the return value
- the input, in-out parameters and output parameters for the method

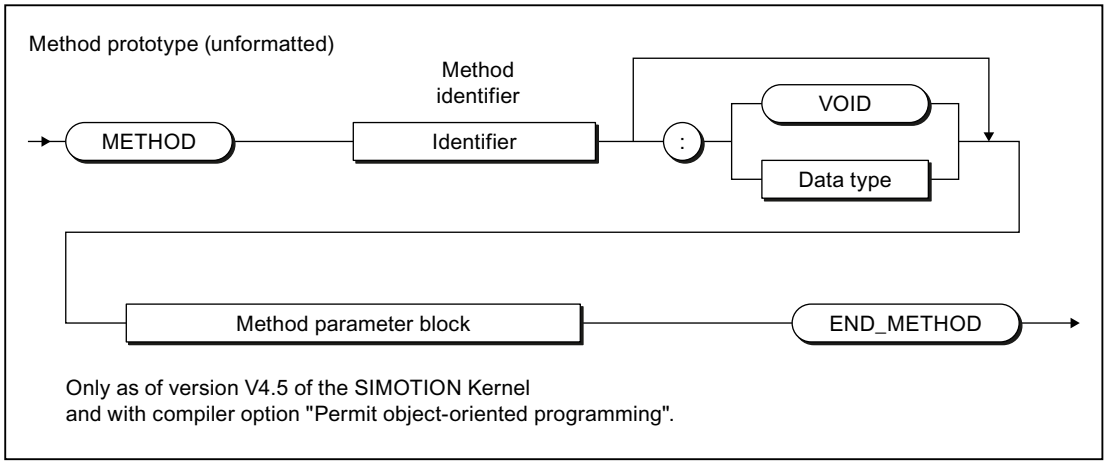

Figure 7-291 Syntax: Method prototype

These method prototypes must be formulated as public methods (access identifier PUBLIC) in the classes which implement the interface. Observe the following here:

- The following must still be adopted here:
  - the method identifier
  - the data type of the return value (if present)
  - the input, in/out and output parameters in the parameter block
- The following must or can be added:
  - Optional: Property of the method (FINAL, ABSTRACT)
  - Mandatory: Access identifier PUBLIC
  - Optional: Declaration of variables and data types
  - Mandatory: Statement section (except for methods with the property ABSTRACT: the statement section is omitted in this case).

Derivation of an object-oriented interface

With the keyword EXTENDS you can derive an object-oriented interface from an existing one. Only single derivations are possible, i.e. it is not possible to derive multiple interfaces.

Existing method prototypes cannot be changed or overridden in the derived object-oriented interface. Only method prototypes can be added.

Implementation of object-oriented interfaces in classes

Object-oriented interfaces are implemented in classes It is essential to declare the interfaces to be implemented before the implementing class in the ST source file.

The figure below repeats the syntax diagram for the class from the “Inheritance of classes" (Page 4781) section.

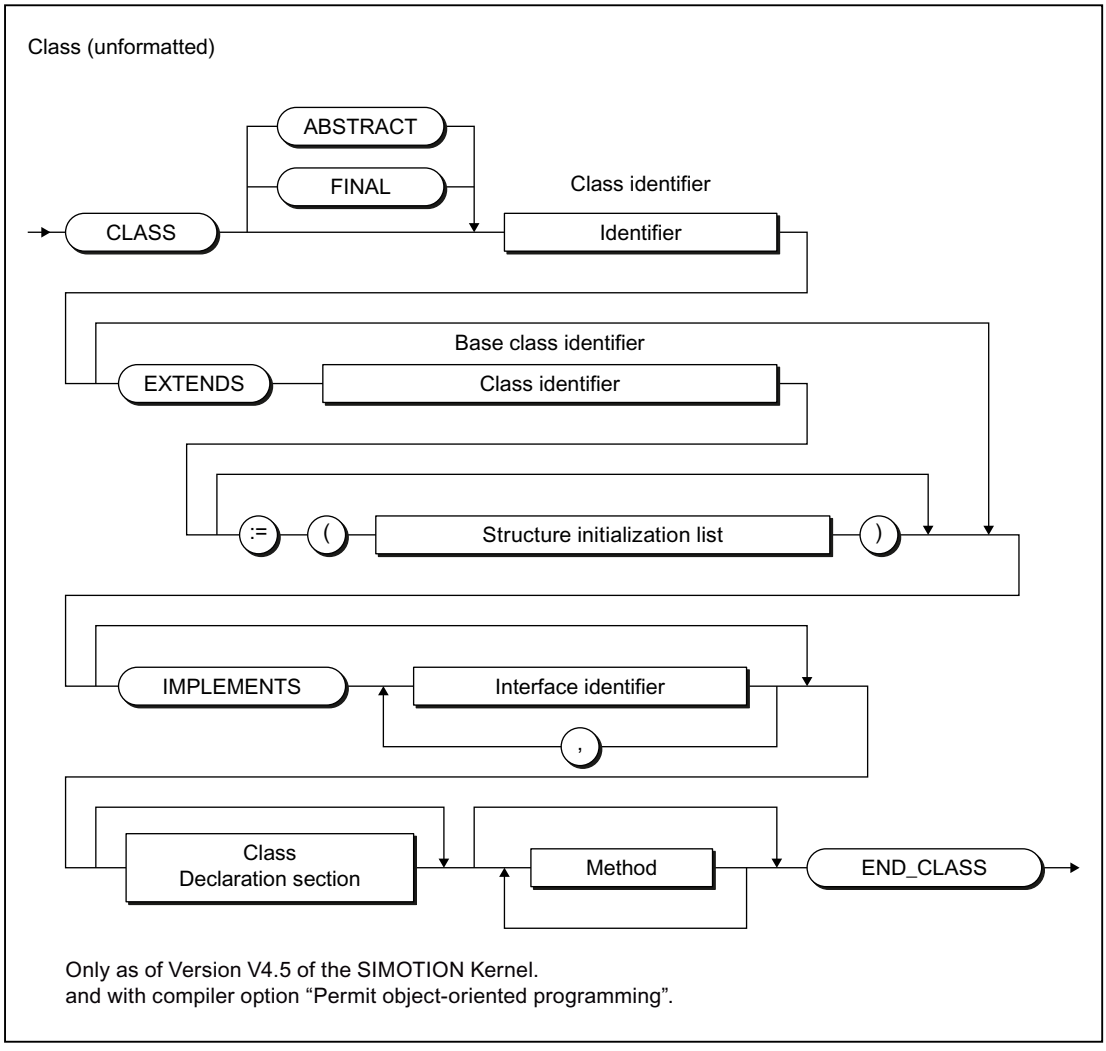

Figure 7-292 Syntax: Class

To implement one or more object-oriented interfaces use the keyword IMPLEMENTS, followed by the lists of the interfaces to be implemented separated by commas. A class can implement multiple interfaces.

The following must or can be supplemented for the definition of the implementing class:

- Optional: the class property (FINAL, ABSTRACT)
- Mandatory: the class identifier (name)
- Optional: the keyword EXTENDS with the identifier of a base class to be derived as well as the initialization (if applicable)
- Optional: the declaration subsection with the local variables and data type for the class

- Mandatory: all methods that have been defined as prototypes in the interfaces to be implemented.
  The following must still be adopted with this:
  - the method identifier
  - the data type of the return value (if present)
  - the input, in/out and output parameters in the parameter block

  The following must or can be added:
  - Optional: Property of the method (FINAL, ABSTRACT)
  - Mandatory: Access identifier PUBLIC
  - Optional: Declaration of local variables and data types
  - Mandatory: Statement section (except for methods with the property ABSTRACT: the statement section is omitted in this case).
- Optional: Additional methods (any access identifier possible).
  See: Creating methods (Page 4769).

All method identifiers must be unique within the class. This means that the object-oriented interface to be implemented

Derived classes and derived object-oriented interfaces

An object-oriented interface (base interface) is implemented in a class (base class). A further object-oriented interface containing additional method prototypes is derived from the base interface. This derived object-oriented interface is now implemented in another class that is also derived from the base class.

This derived class then inherits all the methods of the base class including those that have been defined as prototypes in the base interface. The additional method prototypes of the derived object-oriented interface are then the only elements still to be formulated in the derived class.

Variables of object-oriented interfaces

You can declare variables of object-oriented interfaces in program organization units and classes (e.g. in programs, function blocks, functions). Enter the name of the interface as its data type. Interface variables are initialized with "NULL". Only "NULL" is permissible for explicit specification of the initialization.

All variable types for the relevant program organization unit are permitted with the exception of:

- VAR_IN_OUT.
  Arrays, structures, function blocks or classes which contain interface variables may nonetheless be transferred as VAR_IN_OUT.
- VAR RETAIN or VAR_GLOBAL RETAIN is not meaningful.
  The interface variables are non-retentive when saved.
- VAR CONSTANT or VAR_GLOBAL CONSTANT is not meaningful.
  The interface variables must be initialized with "NULL".

Using the interface variables

Interface variables contain references to classes which implement the corresponding object-oriented interface. They permit access to the methods of the interface with the following syntax: *var_name.method-name*.

Once an instance of an implementing class has been assigned to the interface variable with the assignment operator :=, the method of the referencing class is called with the call in accordance with the syntax stated above.

An invalid reference is marked with the value "NULL" as the content of the variable. A check for a valid reference is easy therefore with the sequence `IF var_name <> NULL THEN (* … *) ; END_IF`, see example below.

Dynamic type conversion with the operator "?="

the operator ?= allows a dynamic type conversion for interface variables. It takes place during the program execution time.

A dynamic type conversion is performed if the following two conditions are satisfied:

1. The interface variable to the right of the operator contains the reference to the instance of a class.
2. This class implements the object-oriented interface that is the data type of the interface variable to the left of the operator.

In this case, the reference on the right-hand side is converted and transferred to the left-hand side.

If the type conversion fails, the variable on the left-hand side contains the "NULL" value.

This dynamic type conversion of references makes it easy to determine whether classes have implemented specific interfaces. The methods defined in the relevant interface can then be called. It is not necessary to know how the methods have actually been programmed.

Forcing instance-specific initialization in classes and function blocks

When instances of classes and function blocks are set up, their static variables can be initialized specific to the instance.

Instance-specific initialization can be forced for the variables of object-oriented interfaces. To do this, specify " `:= *` " after the identifier of the object-oriented interface when declaring these variables in classes or function blocks. The relevant static variable block must be assigned the OVERRIDE or PUBLIC identifier so that it can be initialized from an external source.

If a variable is declared in this way, the compiler checks whether all variables of this kind have been initialized at least with instances in VAR_GLOBAL or in the VAR declaration blocks of programs. In this case, initialization can take place even the instance was previously included in other classes or function blocks.

If a class or a function block possesses this kind of variable, the following needs to be noted when the instance is declared in the VAR blocks of other classes or function blocks:

- Either the instance itself is initialized,
- Or the variable block in which the instance is declared must be capable of initialization (OVERRIDE or PUBLIC identifier).

Initialization with NULL is permissible.

This feature can be used to define links between different instances via interfaces and to monitor by means of the compiler whether they have been meaningfully initialized.

Table 7-435 Example of forcing instance-specific initialization

```
INTERFACE IfTest
    // ...
END_INTERFACE
CLASS cl IMPLEMENTS IfTest
    // ...
END_CLASS
CLASS clTest
    VAR PROTECTED OVERRIDE
        myInterf : IfTest := *;
    END_VAR
END_CLASS
PROGRAM prog
    VAR
        clInst : cl;
        testInst : clTest := (myInterf := clInst);
    END_VAR
    ; // ...
END_PROGRAM
```

Example of interface variables

The example below illustrates the use of interface variables.

```
INTERFACE ITF1
    METHOD m1 END_METHOD
END_INTERFACE
INTERFACE ITF2
    METHOD m2 END_METHOD
END_INTERFACE
CLASS A IMPLEMENTS ITF1
    METHOD PUBLIC m1 (* ... *) ; END_METHOD
    // ...
END_CLASS
CLASS B IMPLEMENTS ITF2
    METHOD PUBLIC m2 (* ... *) ; END_METHOD
    // ...
END_CLASS
CLASS C IMPLEMENTS ITF1, ITF2
    METHOD PUBLIC m1 (* ... *) ; END_METHOD
    METHOD PUBLIC m2 (* ... *) ; END_METHOD
    // ...
END_CLASS
```

```
FUNCTION func_if1 : VOID
    VAR_INPUT i : ITF1; END_VAR
    IF i <> NULL THEN
        i.m1();
    END_IF;
END_FUNCTION
FUNCTION func_if2 : VOID
    VAR_INPUT i    : ITF2; END_VAR
    VAR       tmp  : ITF1; END_VAR
    IF i <> NULL THEN
        i.m2();
    END_IF;
    tmp ?= i;
    (* Dynamic type conversion to ITF1 *)
    IF tmp <> NULL THEN
        tmp.m1();
    END_IF;
END_FUNCTION
PROGRAM P
    VAR
        inst_a : A; // Instance of class A
        inst_b : B; // Instance of class B
        inst_c : C; // Instance of class C
        interf1: ITF1; // interf1 has value NULL
        interf2: ITF2; // interf2 has value NULL
    END_VAR

    interf1 := inst_a;
    (* interf1 contains a valid reference to inst_a. *)
    func_if1(interf1);
    (* The method inst_a.m1() is therefore called within the function. *)

    func_if1(inst_a);
   (* Equivalent call to the last two code lines *)

    interf2 := inst_b;
    (* interf2 contains a valid reference to inst_b. *)
    func_if2(interf2);
    (* The method inst_b.m2() is therefore called within the function.
       The method m1() is not called. The variable tmp contains the value NULL after
execution of the operator ?= because the class B does not implement the interface ITF1. *)

    interf2 := inst_c;
    (* interf2 contains a valid reference to inst_c. *)
    func_if2(interf2);
    (* The method inst_b.m2() is therefore called within the function.
      The method inst_c.m1() is also called. The variable tmp contains a valid reference to
inst_c after execution of the operator ?= because the class C also implements the interface
ITF1. *)
END_PROGRAM
```

Two object-oriented interfaces (ITF1 and ITF2) are defined in the example shown. Each interface contains one method as relevant: m1() in ITF1 and m2() in ITF2.

The following 3 classes implement both of these interfaces:

- Class A implements interface ITF1
- Class B implements interface ITF2
- Class C implements both interfaces ITF1 and ITF2.

For both functions func_if1 and func_if2:

- You have the option of adopting an interface variable via an input variable i with the relevant interface type.
- You can use the query " i<> NULL" to check whether i contains a valid reference.
  If the reference is valid, the functions call the methods of the relevant interfaces.
- Function func_if2 has the additional option of transferring (tmp ?= i) the reference of i to the tmp variable of type ITF1.
  - If i contains a reference that matches interface ITF1, the reference is transferred by the ?= operator.
  - If the reference does not match, a NULL is entered in tmp.

  If the reference in tmp is valid, method m1() is called.

The instances of classes A, B and C are generated and the interface variables interf1 and interf2 are declared in program P.

In the program statement section, the class instances are assigned to the relevant interface variables interf1 and interf2. Following each of these assignments one of the two functions is called with the corresponding interface variable also transferred. This results in different calls for the interface methods within the functions:

- First call of func_if1 (with transfer of the interface variables interf1):
  Since interf1 contains a valid reference to the instance of class A (inst_a); the function calls the method m1().
- Second call of func_if1 (with the transfer of instance inst_a):
  Since class A implements the interface ITF1, this call is functionally identical to the first call.
- First call of func_if2 (with transfer of the interface variables interf2):
  Since interf2 contains a valid reference to the instance of class B (inst_b); the function calls the method m2().
  The method m1() is not called, since the class B only implements the interface ITF2.
- Second call of func_if2 (with transfer of the interface variables interf2):
  Since interf2 contains a valid reference to the instance of class C (inst_c); the function calls both methods m1() and m2().
  Class C implements both interfaces (ITF1 and ITF2). The operator ?= therefore transfers the reference to inst_c successfully to the variable tmp of data type ITF1. The function therefore also calls the method m1().

This example demonstrates perfectly how interface variables with corresponding check functions can be handled and the degree of programming flexibility offered by this approach.

Note

This mechanism of course works in exactly the same way in methods, But we have used functions here instead of methods because the example was simpler.

This option of forming object references and interface variables makes it possible to independently develop and test program modules. Interfaces are a description of the interfaces shared by the program modules containing the program code of the methods to be implemented. This data description can then be used, for example, to perform a test in a program area with dummy methods and data supplied by reference transfer. When the formulated program sections are created later on, the tested sections will function automatically. Of course, this arrangement will work successfully only if the interfaces are not changed retrospectively. But the compiler monitors interfaces carefully for any changes.

7.2.6.6 Comparison between abstract class and object-oriented interface

If we compare the definition of an abstract class (Page 4790) and compare it to the definition of an object-oriented interface (Page 4790), we will find that both constructs are very similar. Both constructs contain prototype methods for which the appropriate functions must be programmed in a class.

The programmer must now decide which construct to use for the specific task in hand. The following information should provide a useful decision-making guide.

The table below compares the properties of the abstract class with the properties of the object-oriented interface.

Table 7-436 Comparison between abstract class and object-oriented interface

Abstract class	Object-oriented interface
Abstract classes can contain abstract methods as well as fully programmed methods, i.e. real methods.	An interface may contain only prototype methods (keyword ABSTRACT does not need to be specified).
Abstract classes can possess defined properties (attributes).	An interface cannot possess any properties (attributes).
The properties of methods can be selected (PUBLIC, PRIVATE, PROTECTED).	All methods in the interface are PUBLIC and cannot be changed retrospectively.
An abstract class cannot be instantiated.	Interface variables can be created.
The methods of an abstract class must be fully programmed when they are derived unless the derivation itself is also ABSTRACT.	All the methods of an interface must be programmed in the class in which the method is implemented, or identified as ABSTRACT
A class can be derived from an (abstract) class.	An interface can be derived from a base interface.
An (abstract) class can implement multiple interfaces.	-

Both constructs define methods as prototypes. This guarantees that the methods can be used according to their definition in the derived or implementing classes. A programmer can thus feel confident that the use (call) of methods defined as prototypes will function reliably when the entire program is finished and the individual program sections are joined together.

The basic difference between the two constructs can be summarized as follows:

- An abstract class constitutes a contract for use in the derivation chain, i.e. within the class hierarchy.
- Object-oriented interfaces constitute an external contract between different program sections.

The following decision-making guide can be derived from the above information:

- Object-oriented interfaces are used if the following two conditions are satisfied:
  - A more generalized definition between different programs is required.
  - The methods should or may be accessed by anyone.
- Abstract classes are used if one of the following conditions is satisfied:
  - A structure must be defined for a program area..
  - Methods must be concealed (i.e. must not be PUBLIC).

Abstract classes can be combined very effectively with object-oriented interfaces in object-oriented software and thus provide a wonderful tool for planning and designing the software structure.

The benefits of abstract classes are:

- Abstract classes allow full programming of methods. thereby reducing the time and effort involved in writing program sections that can be used by everyone in the same way. The methods are simply inherited when real classes are derived.
- The specification of access rights to methods enhances the security of programs.

The benefits of object-oriented interfaces are:

- Object-oriented interfaces allow different program sections to be connected in a highly flexible manner,
- so making it possible for software development teams to work more independently of one another.

7.2.6.7 General references

Defining general references

General references contain the address assignment to a variable or an instance of a function block or class. To do this, the REF_TO keyword creates a data type that can contain the address for an existing data type (reference data type).

- In a data type declaration:
```
TYPE
    ref_type : REF_TO data_type
END_TYPE
```
The declaration is also possible in an ARRAY or as element of a structure.
- In a variable declaration:
A reference already declared as data type or the REF_TO statement can be used directly.
```
VAR
    ref_var : ref_type // or
    ref_var := REF_TO data_type
END_VAR
```
The declaration is also possible in an ARRAY.

The associated declared data type is "Reference to the data type" (REF_TO *data_type*).

The following are permitted as data types to which references can be formed:

- Elementary data types (e.g. INT, DINT, REAL, WORD, TIME, STRING)
- User-defined data types (UDT)
- System data types
- Function blocks, provided they contain at least one static variable
- Classes

No references can be formed to the following data types because references exist already:

- Technology object data types
- Object-oriented interfaces
- General references
- I/O references

Variables of general references can be declared in the interface and implementation sections as well as in all program organization units and classes. The data type to be referenced must be declared beforehand and lie within the scope of the POU. The declaration as element of a structure or an ARRAY is also possible.

All variable types for the relevant program organization unit are permitted with the exception of:

- VAR_IN_OUT.
  Arrays, structures, function blocks or classes that contain general references may nonetheless be transferred as VAR_IN_OUT.
- VAR RETAIN or VAR_GLOBAL RETAIN is not permitted.
  However, structures that contain at least one element other than reference types (general references, data types of the technology objects, object-oriented interfaces), can be stored retentive.
- VAR CONSTANT or VAR_GLOBAL CONSTANT is not meaningful.
  General references must be initialized with "NULL".

Forming general references

A reference to a variable is formed with the REF standard function (in := *var_name*). This function is described in detail in the "SIMOTION Basic Functions" Function Manual.

The REF function can be used on the following variables:

- Retentive and non-retentive unit variables or instances of classes or function blocks or their elements declared as such.
- In methods within classes or function blocks:
  - Static variables (VAR) of the higher-level class or function block (including instance variables for classes or function blocks).
  - The THIS keyword. Enables access to the instance variable of the higher-level class or function block.
- In function blocks:
  - Static variables (VAR) of the function block (including instance variables of classes or function blocks).
  - The THIS keyword. Permits access to the instance variable of the function block.

The variable must be able to be read and written.

Not permitted are:

- Variables of technology object data types
- Variables of object-oriented interfaces
- Variables of general references
- Retentive local variables within classes or function blocks
- I/O variables
- Global device variables
- Constants

The return value has the data type "Reference to the data type of the input parameter *in*". The return value can be assigned with the assignment operator ":=" to a variable that has REF_TO *type* data type. A data type conversion is not possible.

Note

Note for instances of function blocks that are passed as in/out parameter (VAR_IN_OUT):

- The REF function cannot be used for static variables (VAR) of function blocks imported from technology packages or device-independent libraries.

The restriction does not apply to class instances.

Operations with general references

Assignment operator ":="

For the assignment of a reference variable, the address of the variable rather than the variable value is passed. Consequently, the reference data types must be identical on both sides of the operator. No implicit data type conversion is possible.

The only exception is for references to classes. A reference to a derived class of a reference to the base class can be assigned here.

For the assignment, no check is made for the validity of the reference; the assignment is always possible.

An explicit assignment with NULL is also possible.

The validity of references should be checked by comparing with NULL before use.

Dereferencing with operator "^"

The reference content can be accessed with the postfix operator "^", e.g. *ref_var*^.

If the reference does not contain a valid value at runtime, the processing task is aborted and the ExecutionFaultTask called.

Before access, a check for validity by comparison with NULL is recommended.

Multilevel dereferencing is possible, e.g. reference to a structure that contains further references. Dereferenced variables can be used anywhere in expressions.

If a method is called via a reference to a class or function block, the class or function block must be dereferenced.

Dereferenced values cannot be used as actual parameters for the _releaseSemaphore() and _testandSetSemaphore() system functions.

Dynamic type conversion with the operator "?="

The operator "?=" can be used for dynamic type conversion only with references to classes and with interface variables (variables for object-oriented interfaces). It supports the following variants:

- Assignment between references to classes.
- Assignment of a reference to a class for an interface variable.
  Whereby, the reference to a class must be specified with the dereferencing operator "^".
- Assignment of an interface variable for a reference to a class.
- Assignment between interface variables

A dynamic type conversion is performed if the following two conditions are satisfied:

1. The variable to the right of the operator contains the reference to the instance of a class.
2. For the variable to the left of the operator, the following applies:
   - The variable is an interface variable:
     The object-oriented interface that this variable has as data type must implement the class on the right-hand side.
   - The variable is a reference to a class:
     This class corresponds to the class on the right-hand side or is a base class for this class.

In this case, the reference on the right-hand side is converted and transferred to the left-hand side.

If the type conversion fails, the variable on the left-hand side contains the "NULL" value.

Comparison operators

Only the comparison operators "=" and "<>" can be used to check for equality or inequality.

The operators ">", "<", ">=", "<=" as well as the MIN and MAX standard functions are not permitted.

7.2.6.8 I/O references (as of kernel V5.1)

Forming I/O references

Declaration of I/O references

I/O references allow symbolic access to I/O variables within classes and function blocks. This allows the classes and function blocks also to be used in libraries.

The I/O references are declared exclusively in classes and function blocks in the declaration block for static variables (VAR). The declaration as retentive variable (VAR RETAIN) or constant VAR CONSTANT is not possible.

var_name AT %I : data_type* ; *ll* for inputs
var_name AT %Q* : *data_type ; ll* for outputs

The following are permissible as data types:

- Bit data types (e.g. BOOL, WORD)
- Integer data types (e.g. SINT, UINT)
- Arrays of these data types, other than arrays of the BOOL data type

Provided the variable block is not identified as PUBLIC, it must be identified with the OVERRIDE keyword so that the variables can be initialized instance-specific for the instance formation of the class or function block.

Example

```
FUNCTION_BLOCK myFB
  VAR OVERRIDE
    myInput AT %I*  : INT; // Declaration input
    myOutput AT %Q* : INT; // Declaration output
    myOutArr AT %Q* : ARRAY[0..3] OF BYTE;
                           // Array of outputs
  END_VAR
  ; // ...
END_FUNCTION_BLOCK
```

Initialization for the definition

I/O references are initialized with NULL. Only "NULL" is permissible for explicit specification of the initialization. With the specification of NULL as initialization value, for the instance declaration of the class or of the function block, the I/O reference must not necessarily be linked with an I/O variable from the address list. This allows the software to be structured so that, if necessary, it adapts itself to non-linked I/O references.

An I/O reference identified with NULL in the initialization must be checked for validity before use, as also usual for all other reference types. A comparison with NULL can be used for this purpose.

```
FUNCTION_BLOCK myFB
  VAR OVERRIDE
    myInput AT %I* : INT := NULL;
  END_VAR
  IF (myInput <> NULL) THEN
    // Validity check of the I/O reference
    Testvar := myInput;
    // Access to the value
  END_IF;
  // ...
END_FUNCTION_BLOCK
```

Principle

The following restrictions apply to I/O reference variables:

- I/O references cannot be forwarded as in/out parameters (VAR_INOUT) to other program organization units (POU).
- I/O references cannot be assigned general references and vice versa. In particular, the REF() standard function cannot be used on I/O variables to assign I/O references.
- I/O references cannot be passed to input parameters (VAR_INPUT) defined as variable-length ARRAY.
- I/O references are not displayed in the Symbol browser and in watch tables.
- I/O references cannot be read or written per HMI, Web access or OPC access.
- I/O references must not be declared in retentive variables (VAR RETAIN).
- Bit access is possible to I/O references of the BYTE, WORD or DWORD data type. This also applies to the associated standard functions (e.g. _setbit()).
- Use as argument for marshalling and endian functions is not possible.

Linking I/O references to I/O variables

For the instance declaration of the higher-level class or function block, I/O references are linked with an I/O variable. This is done with the instance-specific initialization of the class or function block. Whereby, the specified I/O reference is assigned an I/O variable from the address list rather than a constant.

The following apply:

- I/O references for inputs (%I*) can be linked with any I/O variable of an appropriate data type.
- I/O references for outputs (%Q*) can be linked only with an I/O variable for an output of an appropriate data type. This variable may not be identified with the attribute "read only".

For partial initialization, as usual for structures, the initialization value of the associated data type is used for non-explicitly specified components.

I/O references declared as ARRAY must be linked completely with an appropriate I/O ARRAY variable of the address list. Individual variables as I/O reference can also be linked with the individual elements of an I/O ARRAY variable by specifying a constant index value.

```
VAR_GLOBAL
  myFbInst1 : myFB := (myInput  := InputVarW3,
                       myOutput := OutputVarW10);
  myFbInst2 : myFB := (myInput  := InputVarW4,
                       myOutput := OutputVarW14);
END_VAR
```

The compiler checks whether all I/O references are linked with I/O variables at least with instances in VAR_GLOBAL or in the VAR declaration blocks of programs. Linking is also possible even such an instance was included previously in other classes or function blocks.

If a class or a function block possesses an I/O reference, the following must be observed when the instance is declared in the VAR blocks of other classes or function blocks:

- Either the instance itself is initialized,
- Or the variable block in which the instance is declared must be capable of initialization (OVERRIDE or PUBLIC identifier).

The above-mentioned checks are omitted when the I/O reference for the declaration was initialized with NULL.

7.2.7 Integration of ST in SIMOTION

This section describes the interoperability of ST programs and SIMOTION SCOUT.

7.2.7.1 Source file sections

An overview of the meaning of the source file sections has been provided in Structure of an ST source file (Page 4668). There you will find detailed information about, for example:

- the syntax of source file sections (Page 4807)
- how you can declare public and use (Page 4827) data between different ST source files.

Use of the source file sections

You must follow certain structure and syntax rules in your source file sections so that the ST source file can be compiled. A few general guidelines are presented here; details on source file sections are presented later in this section:

- When creating the source file, you should always pay attention to the order of the source file sections. A section that is to be called must always precede the calling section so that the former is recognized by the latter.
  For example, variables must always be declared before they are used and functions must be defined before they are called.
- The source text for the most common source file sections – program, function or function block – consists of the following:
  - Start of section with reserved word and identifier
  - Declaration section (optional)
  - Statement section
  - End of section with reserved word
- Identifiers for source file sections – hereinafter referred to as *name* or *name_list* - follow the general syntax rules for identifiers, see Identifiers in ST (Page 4656).

Note

A template with all possible source file sections (template for example unit) is available in the online help.

Interface section

The interface section contains statements for declaring data public and using data (data types, variables, function blocks, functions, programs). Technology packages and libraries can also be downloaded.

The interface section has the following syntax:

Syntax

```
INTERFACE
// Interface statements (optional)
END_INTERFACE
```

An individual identifier of the section cannot be specified.

Optionally, interface statements exist in the following order between reserved words INTERFACE and END_INTERFACE.

1. Specification of utilized technology package. Syntax:
   `USEPACKAGE tp-name [AS namespace];`
   For more details, refer to the *SIMOTION Basic Functions* Function Manual.
2. Specification of utilized libraries.
   Syntax:
   `USELIB library-name-list [AS namespace];`
   For more information, see "Using data types, functions and function blocks from libraries (Page 4896)".
3. Reference to other units in order to use their public components.
   The syntax is:
   `USES unit_name-list;`
   For more information, see "USES statement in a using unit (Page 4830)".
4. Declarations and information regarding declaration as public to other program sources:
   - Data type definitions (Page 4823):
     User-defined data types (UDT) that are public and valid within the entire ST source file
   - Variable declarations (Page 4824):
     Unit variables and unit constants that are public and valid within the entire ST source file.
     Permissible keywords: See Section "Variable declaration" (Page 4824).
   - Object-oriented interfaces (Page 4820):
     Object-oriented interfaces that are public and valid within the entire ST source file.
     As of version V4.5 of the SIMOTION Kernel and with compiler option (Page 4623) “Permit object-oriented programming” enabled.

     Note

     Object-oriented interfaces utilize the same keywords as the interface section (INTERFACE / END_INTERFACE).

   - Specification of the program organization units (POUs) to be declared public.
     Syntax:
     `FUNCTION fc_name;`
     `FUNCTION_BLOCK fb_name;`
     `PROGRAM program_name;`
     `CLASS class_name;` (as of version V4.5 of the SIMOTION Kernel and with compiler option (Page 4623) "Permit object-oriented programming” enabled)
     If the "Permit forward declarations" compiler option (Page 4623) is activated, they are also interpreted as POU prototypes for the forward declaration (Page 4929).
   - POU prototypes for the forward declaration (Page 4929).
     Specification of the prototypes for program organization units with forward declaration (only effective if the "Permit forward declarations" compiler option (Page 4623) is activated).
     They are also interpreted as POUs to be exported.

All technology packages, libraries, units used, data type declarations, variable declarations, object-oriented interfaces and program organization units listed in the interface section are declared public. For further information about declaring public, see "Interface section of a unit with Declare Public function (Page 4828)".

Sequence

The interface section is the first section of an ST source file.

Note

Optionally, the unit statement can precede the interface section, see "Identifier of the unit (Page 4827)".

The order of the interface statements 1 to 4 is fixed.

Within number 4, any order is permitted. The individual declaration blocks for data type definitions (including POU prototypes) and variables declarations can appear more than once.

Please note: Identifiers must be declared before they are used.

Only if the "Permit forward declarations" compiler option (Page 4623) is activated: When declaring an instance of a function block or a class, it is sufficient for the prototype of the function block to have been declared beforehand. It is not possible to initialize the function block or the class.

Frequency

Once per ST source file

Mandatory section

Yes

Implementation section

The implementation section contains the executable sections, comprising the main part of the ST source file.

The implementation section has the following syntax:

Syntax

```
IMPLEMENTATION
// Implementation statements (optional)
END_IMPLEMENTATION
```

An individual identifier of the section cannot be specified.

Optionally, implementation statements (main part of the ST source file) exist in the following order between the reserved words IMPLEMENTATION and END_IMPLEMENTATION:

1. Reference to other units in order to use their public components. Syntax:
   `USES unit_name-list;`
   For more information, see "USES statement in a using unit (Page 4830)".
2. Declarations
   - Data type definitions (Page 4823):
     User-defined data types (UDT) that are valid within the entire ST source file
   - Variable declarations (Page 4824):
     Unit variables and unit constants that are valid within the entire ST source file.
     Permissible keywords: See Section "Variable declaration" (Page 4824).
   - Object-oriented interfaces (Page 4820):
     Object-oriented interfaces that are valid within the entire ST source file
     As of version V4.5 of the SIMOTION Kernel and with compiler option (Page 4623) "Permit object-oriented programming" activated.
   - POU prototypes for the forward declaration (Page 4929).
     Specification of the prototypes for program organization units with forward declaration (only effective if the "Permit forward declarations" compiler option (Page 4623) is activated).

   Note

   Data types, variables or object-oriented interfaces that are to be declared public and used in other program sources must be fully declared in the interface section (Page 4807).
3. Program organization units (Page 4811).

Sequence

Always follows the interface section (Page 4807).

If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:

- The order of the implementation statements indicated above is mandatory; within numbers 2 and 3, any order is permitted.
- All identifiers must be declared before they are used.

If the "Permit forward declarations" compiler option (Page 4623) is activated, the following applies:

- As regards the order of the interface statements, the following applies:
  Numbers 2 and 3 need no longer be strictly separated. Declarations may be freely programmed between program organization units.
  Exception: POU prototypes must be declared before the relevant program organization unit is defined or used.
- As long as the following conditions are satisfied, the identifiers of program organization units (Page 4811) can be used before they are defined.
  - There are no restrictions with respect to functions (Page 4812), programs (Page 4815), expressions (Page 4816) or methods (Page 4819). Any order is permitted.
    A POU prototype may be optionally declared in advance for programs or functions.
  - This is possible for function blocks (Page 4813) or classes (Page 4817) subject to the following restrictions (e.g. when the instance is declared):
    Any order is permitted if initialization is not specified. In this case, however, it is absolutely essential that the prototype of the function block or class is declared beforehand.
    If initialization is specified, the function block or the class must be fully defined beforehand.
- All other identifiers (e.g. data types, variables) must be declared before they are used.

Frequency

Once per ST source file

Mandatory section

Yes

Program organization units (POUs)

Program organization units (POUs) are the executable source file sections:

- Functions (FC) (Page 4812)
- Function blocks (FB) (Page 4813)
- Programs (Page 4815)
- Expressions (Page 4816)
- Classes (Page 4817) (as of version V4.5 of the SIMOTION Kernel and with compiler option (Page 4623) "Permit object-oriented programming" activated)

The following applies for the sequence of the POUs in an ST source file:

- Usually, the called POUs must precede the calling POUs in the source file so that the former are recognized by the latter.
- **Exception**: Only if the "Permit forward declarations" compiler option (Page 4623) is activated.
  The sequence is arbitrary: The following applies to the specification of a prototype for forward declaration (Page 4929) in the interface section (Page 4807) or the implementation section (Page 4809):
  - Essential for declaring instances with function blocks and classes
  - Optional when calling functions and programs

Functions (FCs)

Functions (FC) are classified as program organization units (POUs). Functions are parameterized source file sections with temporary data that can be called from programs and function blocks. All internal variables lose their values when the function is exited and are reinitialized the next time the function is called.

FCs have the following syntax:

Syntax

```
FUNCTION name : function_data_type
// Declaration section
// Statement section
END_FUNCTION
```

name stands for the identifier of the function, while *function_data_type* stands for the data type of the return value.

Permissible keywords for the variable declaration in the declaration section (Page 4821): See Section "Variable declaration" (Page 4824).

Note the following for functions with *function_data_type* <> VOID: In the body (Page 4822), an expression of data type *function_data_type* must be assigned to the function identifier.

Sequence

FCs can only be defined in the implementation section (Page 4809).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  In the source file, functions must precede the POU from which they are called.
- If the "Permit forward declarations" compiler option (Page 4623) is activated, the following applies:
  The sequence is arbitrary: There is an option to specify a prototype for the forward declaration (Page 4929) in the interface section (Page 4807) or the implementation section (Page 4809).

The declaration section (Page 4821) must precede the statement section (Page 4822).

Frequency

Any number of times per ST source file

Mandatory section

No

Further information on functions (FC)

See Section "Creating and calling functions and function blocks" (Page 4736).

Function blocks (FBs)

Function blocks (FB) are classified as program organization units (POUs). They are source file sections with static data that can be called from programs and assigned parameters (internal variables retain their value between calls). Since an FB has memory, its output parameters can be accessed at any time and from any point in the user program.

FBs have the following syntax:

Syntax

```
FUNCTION_BLOCK name
// Declaration section
    // Methods (Only with compiler option (Page 4623) "Permit object-oriented programming")
// Statement section
END_FUNCTION_BLOCK
```

name stands for the identifier of the function block.

Permissible keywords for the declaration of variables in the declaration section: See Section "Variable declaration" (Page 4824).

Special features

Before you call a function block (FB), you must declare an instance: You declare a variable and enter the identifier of the function block as the data type. You can declare the instance locally (within VAR / END_VAR in the declaration sections of a program or a function block).

You can also declare the instance globally (within VAR_GLOBAL/END_VAR in the interface or implementation section).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  This is only possible with FBs which make used program sources and libraries available, but not with FBs which are defined in the same ST source file.
- If the "Permit forward declarations" compiler option (Page 4623) is activated, the following applies:
  You can declare global instances of FBs which are defined in the same ST source file.
  - For instance declaration without specification of initialization:
    The instance may be declared before the FB is fully defined. In this case, it is essential that a prototype for the forward declaration (Page 4929) is specified in the interface section (Page 4807) or the implementation section (Page 4809).
  - For instance declaration with specification of initialization:
    The instance must always be declared after the FB is fully defined.

You cannot declare an instance of an FB in functions or methods.

Sequence

FBs can only be defined in the implementation section (Page 4809).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  In the source file, an FB must precede the POU in which it is used, e.g. in which an instance of the FB is declared as local variable.
- If the "Permit forward declarations" compiler option (Page 4623) is enabled, the following applies:
  - Without specification of initialization:
    The POU which uses the FB may precede the definition of the FB. In this case, it is essential that a prototype for the forward declaration (Page 4929) is specified in the interface section (Page 4807) or the implementation section (Page 4809).
  - With specification of initialization (only with compiler option (Page 4623) "Permit object-oriented programming"):
    The FB must be fully defined before the POU in which it is used.

The declaration section (Page 4821) must precede the statement section (Page 4822).

Frequency

Any number of times per ST source file

Mandatory section

No

Further information about function blocks (FB)

See Section "Creating and calling functions and function blocks" (Page 4736).

Programs

Programs are classified as program organization units (POUs). They are called on the target system according to their task assignment (see *Configuring the execution system* in the *SIMOTION Basic Functions* Function Manual) and can call functions (FC) and function blocks (FB), as well as methods in classes and function blocks.

Programs have the following syntax:

Syntax

```
PROGRAM name
// Declaration section
// Statement section
END_PROGRAM
```

name stands for the name of the program.

Permissible keywords for the variable declaration in the declaration section: See Section "Variable declaration" (Page 4824).

Sequence

Programs can only be defined in the implementation section (Page 4809).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  Programs are expediently placed after FCs, FBs, expressions and classes. The program then recognizes these source file sections and can make use of them.
- If the "Permit forward declarations" compiler option (Page 4623) is enabled, the following applies:
  The sequence is arbitrary: When a program is called within a program, there is an option to specify a prototype for the forward declaration (Page 4929) in the interface section (Page 4807) or the implementation section (Page 4809).

The declaration section (Page 4821) must precede the statement section (Page 4822).

Frequency

Any number of times per ST source file

Mandatory section

No

Further information on programs

See Section "Programs" (Page 4762).

Expressions

Expressions are a special case of a function declaration with the specified data type BOOL of the return value. The expression within the EXPRESSION <expression identifier> ... END_EXPRESSION reserved words assigned to the function name is evaluated.

You can use the WAITFORCONDITION (Page 4729) construct to wait directly for a programmable event or condition in a MotionTask. The statement suspends the task that called it until the condition (expression) is true.

Expressions have the following syntax:

Syntax

```
EXPRESSION name
// Declaration section
// Statement section
END_EXPRESSION
```

name stands for the identifier of the expression.

Permissible keywords for the variable declaration in the declaration section: See Section "Variable declaration" (Page 4824).

Please note: In the body (Page 4822), an expression of data type BOOL must be assigned to the expression identifier.

Sequence

An expression can only be declared in the implementation section (Page 4809) of an ST source file.

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  Expressions must precede the program organization unit in which they are called from a WAITFORCONDITION control structure.
- If the "Permit forward declarations" compiler option (Page 4623) is activated, the following applies:
  The sequence is arbitrary: There is no option to specify a prototype for the forward declaration (Page 4929) in the interface section (Page 4807) or the implementation section (Page 4809).

The declaration section (Page 4821) must precede the statement section (Page 4822).

Frequency

Any number of times per ST source file

Mandatory section

No

Further information on expressions

See Section "Expressions" (Page 4763).

Examples in conjunction with the WAITFORCONDITION statement: See SIMOTION Basic Functions Function Manual

Classes (as of Kernel V4.5)

Classes belong to the program organization units (POE). They form a capsule for variables and methods (Page 4819). Only variables and methods that have the access identifier PUBLIC are visible outside of the class. Another class can be derived from a class (base class). This derived class inherits all the variables and methods from the base class.

A SIMOTION Kernel as of version V4.5 is mandatory for the purposes of defining and using classes. Classes can only be defined when compiler option (Page 4623) "Permit object-oriented programming" is enabled.

Classes have the following syntax:

Syntax (simplified)

```
CLASS name
// Declaration section
    // methods
END_CLASS
```

name stands for the identifier of the class.

Permissible keywords for the variable declaration in the declaration section: See Section "Variable declaration" (Page 4824).

For a complete syntax diagram see Figure 7-289 Syntax: Class (Page 4782).

Special features

Before using public methods or variables of a class you must declare an instance of the class: You declare a variable and enter the identifier of the class as the data type. You can declare the instance locally (within VAR / END_VAR in the declaration sections of a program, a function block or a class).

You can also declare the instance globally (within VAR_GLOBAL/END_VAR in the interface or implementation section).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  This is only possible with classes which make used program sources and libraries available, but not with classes which are defined in the same ST source file.
- If the "Permit forward declarations" compiler option (Page 4623) is activated, the following applies:
  You can declare global instances of classes which are defined in the same ST source file.
  - For instance declaration without specification of initialization:
    The instance may be declared before the class is fully defined. In this case, it is essential that a prototype for the forward declaration (Page 4929) is specified in the interface section (Page 4807) or the implementation section (Page 4809).
  - For instance declaration with specification of initialization:
    The instance must always be declared after the class is fully defined.

You cannot declare an instance of a class in functions or methods.

Sequence

Classes can only be defined in the implementation section (Page 4809).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  In the source file, a class must precede the POU in which it is used, e.g. in which an instance of the class is declared as a local variable.
- If the "Permit forward declarations" compiler option (Page 4623) is enabled, the following applies:
  - Without specification of initialization:
    The POU which uses the class may precede the definition of the class. In this case, it is essential that a prototype for the forward declaration (Page 4781) is specified in the interface section (Page 4807) or the implementation section (Page 4809).
  - With specification of initialization:
    The class must be fully defined before the POU in which it is used.

The declaration section (Page 4821) must precede the methods (Page 4819).

Frequency

Any number of times per ST source file

Mandatory section

No

Additional information on classes

See “Object-Oriented Programming - OOP (as of kernel V4.5)” (Page 4766) section

Methods

Methods belong to the program organization units (POE). They are callable and parameterizable source file sections with temporary data within classes (Page 4817) or function blocks (Page 4813). All internal variables lose their values when the method is exited and are reinitialized the next time the method is called.

Methods can only be defined when compiler option (Page 4623) “Permit object-oriented programming" is enabled.

Methods have the following syntax:

Syntax

```
METHOD access-spec name : method_data_type
    // Variable declaration
// Statement section
END_METHOD
```

access-spec stands for the optional access identifier (Page 4768):

- In classes: PUBLIC, PROTECTED, PRIVATE. Default setting: PROTECTED.
- In function blocks: PUBLIC, PRIVATE. PRIVATE is default setting.

name stands for the identifier of the method, while *method_data_type* stands for the data type of the return value.

Permissible keywords for the variable declaration in the declaration section (Page 4821): See Section "Variable declaration" (Page 4824).

Note the methods with *method_data_type* <> VOID: In the statement section (Page 4822), an expression of data type *method_data_type* must be assigned to the method identifier!

For a complete syntax diagram see Figure 7-282 Syntax: Method (Page 4770).

Special feature

The compiler option (Page 4623) “Permit object-oriented programming" needs to be enabled.

Sequence

Methods can only be defined within classes (Page 4817) and function blocks (Page 4813).

- If the "Permit forward declarations" compiler option (Page 4623) is **not** activated, the following applies:
  In the source file, methods must precede the POU from which they are called.
- If the "Permit forward declarations" compiler option (Page 4623) is activated.
  The sequence is arbitrary:

The declaration section (Page 4821) must precede the statement section (Page 4822).

Frequency

Any number of times per class or function block.

Mandatory section

No

Additional information on methods

See “Object-Oriented Programming - OOP (as of kernel V4.5)” (Page 4766) section

Object-oriented interface (as of Kernel V4.5)

Object-oriented interfaces define the call interface for public methods (Page 4819) (access identifier PUBLIC). Method prototypes are defined for this purpose in the object-oriented interface. These methods with the definition "prototype" are formulated in classes (Page 4817) which implement the object-oriented interfaces.

Another interface can be derived from an object-oriented interface (base interface). This derived interface inherits all of the method prototypes of the base interface.

Note

While object-oriented interfaces start and end with the same keywords as the interface section (Page 4807) of a unit (INTERFACE / END_INTERFACE), they have different meanings and are used in different ways.

Object-oriented interfaces can only be defined and used with a SIMOTION Kernel as of version V4.5. The compiler option (Page 4623) "Permit object-oriented programming" also needs to be activated.

Object-oriented interfaces have the following syntax:

Syntax (simplified)

```
INTERFACE name
    // Method prototype
    METHOD method_name : method_data_type
        // Variable declaration (parameters only)
    END_METHOD
    // Other method prototypes
END_INTERFACE
```

name stands for the identifier of the object-oriented interface.

For complete syntax diagrams see Figure 7-290 Syntax: Object-oriented interface (Page 4791) and Figure 7-291 Syntax: Method prototype (Page 4792).

Special features

In classes (Page 4817) that implement object-oriented interfaces, all methods (Page 4819)that are defined as prototypes in the interfaces must be formulated. These methods must always be declared public (access identifier PUBLIC). The call interface (input, output and in/out parameters) specified in the interface must be transferred unchanged.

Variables of object-oriented interfaces can also be declared. Instances of classes that implement the same object-oriented interface can be assigned to these variables.

Sequence

You can define object-oriented interfaces in the interface section (Page 4807) and the implementation section (Page 4809). In most cases, they are declared in the interface section because they are generally declared PUBLIC.

They must always be declared in full before they are used in the declaration of an interface variable or an implementing class. This applies irrespective of the compiler option (Page 4623) "Permit forward declarations".

Frequency

Any number of times per ST source file

Mandatory section

No

Further information about object-oriented interfaces

See section "Object-oriented interfaces" (Page 4790).

Declaration section

The declaration section of a program organization unit (POU) contains the data type definition and the variable declaration of the POU.

The declaration section has the following structure:

Structure

```
// Data type definition
// Variable declaration
```

Sequence

The declaration section has no explicit keywords at the start or end. It begins after the keyword of the respective program organization unit (POU) and ends with the first executable statement of the statement section.

It contains the following in any order:

- Data type definitions (Page 4823):
  User-defined data types (UDT) that are valid locally in the POU.
  Data types cannot be defined within methods.
- Variable declarations (Page 4824):
  Variables and constants that are valid locally in the POU
  Permissible keywords according to the respective POU: See Section "Variable declaration" (Page 4824).

Please note: Identifiers must be declared before they are used.

Frequency

Once per POU

Mandatory section

No

Statement section

The statement section of a POU consists of the individual (executable) statements.

The statement section has the following structure:

Configuration

```
// Statements
```

Sequence

The statement section has no explicit keywords at the start or end. It begins after the declaration section and ends with the keyword of the respective POU.

Frequency

Once per POU

Mandatory section

No

Further information on statements

See following sections:

- Value assignments and expressions (Page 4702)
- Control statements (Page 4719)

- Call of functions and function block calls (Page 4749)
- Calling methods (Page 4773)

Data type definition

For the data type definition, you specify user-defined data types (UDT). You can use them for variable declarations. UDTs can be defined in the interface section, the implementation section, and the declaration section of FCs, FBs, and programs.

The data type definition has the following syntax:

Syntax

```
TYPE
name : data_type_specification;
    // ...
END_TYPE
```

name represents the name of the individual data type that you use for the Variable declarations.

data_type_specification stands for any data type or a structure. Any number of individual data types can appear between TYPE and END_TYPE.

Sequence

You can define UDTs as follows:

- In the Interface section:
  The UDTs are recognized within the ST source file and will be exported
  They can be used in the interface and implementation section for declaration of unit variables and in all POUs for declaration of local variables.
  In addition, they can be used in all units which import this ST source file (in SIMOTION ST with the USES statement).
- In the Implementation section:
  The UDTs are recognized within the ST source file
  They can be used in the implementation section for declaration of unit variables and in all POUs for declaration of local variables.
- In the declaration section of a POU (FC, FB, program, expression, class):
  The UDTs are only recognized locally within the POU
  They can only be used within the POU for declaration of local variables.

UDTs must be defined before they are used in a variable declaration.

Frequency

The TYPE / END_TYPE declaration block may appear more than once in a source file section; any number of UDTs are possible within a declaration block.

Mandatory section

No

Further information on user-defined data types (UDT)

See Section "User-defined data types" (Page 4675).

Variable declaration

A declaration section contains variable declarations and can itself be contained in FCs, FBs, and programs (POUs) as well as in the interface section and the implementation section.

The variable declaration has the following syntax:

Syntax

```
variable_type
   name_list : data_type;
    // ...
END_VAR
```

variable_type represents the keyword of the variable type being declared. The permitted keywords depend on the source file section.

- In the Interface section or Implementation section of an ST source file:
  `VAR_GLOBAL`: Non-retentive unit variable
  `VAR_GLOBAL CONSTANT`: Unit constant
  `VAR_GLOBAL RETAIN`: Retentive unit variable
- In the Declaration section of a function:
  `VAR`: Local variable
  `VAR CONSTANT`: Local constant
  `VAR_INPUT`: Input parameter
  `VAR_OUTPUT`: Output parameters
  `VAR_IN_OUT`: In/out parameter

- In the Declaration section of a function block:
  VAR: Local variable
  - With activated compiler option (Page 4623) "Permit object-oriented programming", the following applies: An access identifier (Page 4740) (PUBLIC, PRIVATE, INTERNAL) can be optionally specified after the keyword. Default: PRIVATE.

  VAR CONSTANT: Local constant
  - With activated compiler option (Page 4623) "Permit object-oriented programming", the following applies: An access identifier (Page 4740) (PUBLIC, PRIVATE, INTERNAL) can be optionally specified after the keyword. Default: PRIVATE.

  VAR RETAIN: Retentive variable
  - With activated compiler option (Page 4623) "Permit object-oriented programming", the following applies: An access identifier (Page 4740) (PRIVATE, INTERNAL) can be optionally specified after the keyword. Default: PRIVATE.

  VAR_TEMP: Temporary variable
  VAR_INPUT: Input parameter
  VAR_OUTPUT: Output parameter
  VAR_IN_OUT: In/out parameter
- In the Declaration section of a program:
  VAR: Local variable
  VAR CONSTANT: Local constant
  VAR_TEMP: Temporary variable
- In the Declaration section of an expression:
  VAR: Local variable
  VAR CONSTANT: Local constant
  VAR_INPUT: Input parameter (as of Version 4.1 of the SIMOTION Kernel)
  VAR_IN_OUT: In/out parameter (as of Version 4.1 of the SIMOTION Kernel)
- In declaration section of a class (Page 4817) (as of version 4.5 of the SIMOTION Kernel):
  VAR: Local variable (static)
  - An access identifier (Page 4768) (PUBLIC, PROTECTED, PRIVATE, INTERNAL) can be optionally specified after the keyword. Default: PROTECTED.

  VAR CONSTANT: Local constant
  - An access identifier (Page 4768) (PUBLIC, PROTECTED, PRIVATE, INTERNAL) can be optionally specified after the keyword. Default: PROTECTED.

  VAR RETAIN: Retentive variable
  - An access identifier (Page 4768) (PROTECTED, PRIVATE, INTERNAL) can be optionally specified after the keyword. Default setting: PROTECTED.

- In the declaration section of a method (Page 4819):
  `VAR`: Local variable
  `VAR CONSTANT`: Local constant
  `VAR RETAIN`: Retentive variable
  `VAR_INPUT`: Input parameters
  `VAR_OUTPUT`: Output parameters
  `VAR_IN_OUT`: In/out parameter
- In the method prototypes within an object-oriented interface (Page 4820):
  `VAR_INPUT`: Input parameter
  `VAR_OUTPUT`: Output parameter
  `VAR_IN_OUT`: In-out parameter

name_list is the list of identifiers of the *data_type* data type to be declared.

Sequence

The variable is declared:

- In the Interface section of the ST source file:
  Permissible keywords: See above at *Syntax*.
  The unit variables are recognized within the ST source file and will be exported.
  They can be used in all POUs of the ST source file.
  In addition, they can be used in all units which import this ST source file (in SIMOTION ST with the USES statement).
- In the Implementation section of the ST source file:
  Permissible keywords: See above at *Syntax*.
  The unit variables are recognized within the ST source file.
  They can be used in all POUs of the ST source file.
- In the declaration section of a class:
  Permissible keywords: See above under *Syntax*.
  The variables are only recognized locally within the class.
- In the declaration section of a POU (FC, FB, program, expression):
  Permissible keywords according to the type of POU: See above at *Syntax*.
  The variables are only recognized locally within the POU.
  Exceptions:
  - You can also access the output parameters of a function block outside the FB.
  - You can access the input parameters of a function block from outside the FB when the compiler option (Page 4623) "Permit language extensions" has been activated.
- In the declaration section of a method:
  Permissible keywords: See above under *Syntax*.
  The variables are only recognized locally within the method.
- In the method prototypes within an object-oriented interface (Page 4820):
  Permissible keywords: See above under *Syntax*.
  The parameters define the call interface of the method.

Variables must be declared before they are used.

Frequency

The number of times the *variable_type* / END_VAR declaration block of a specific variable type can appear depends on the associated source file section:

- In the interface and implementation section of the ST source:
  The declaration blocks may appear more than once.
- In the declaration section of a POU (FC, FB, program, expression, class, method):
  Each declaration block (other than VAR CONSTANT / END_VAR) may appear just once in the declaration section.
- In the method prototypes within an object-oriented interface:
  Each declaration block may only occur once in each method prototype.

Permitted declaration blocks and keywords depending on the associated source file section: See above at *Syntax*.

Any number of variable declarations are possible within a declaration block.

Mandatory section

No

Further information about variable declaration

See Section "Variable declaration" (Page 4694).

Declaring ST source files public and using them

ST has a unit concept which can be used to access global variables, data types, functions (FC), function blocks (FB) and programs from other source files. Thus, for example, you can compile reusable subroutines and make them available.

Unit identifier

Below, unit refers to a program source file (e.g. ST source file, MCC source file). The name of the program source file defined in SIMOTION SCOUT is applied as the identifier.

Optionally, you can set the unit statement as first statement for an ST source file (preceding the interface section). Syntax:

```
UNIT name;
```

name corresponds to the name of the ST source file defined in SIMOTION SCOUT, see Add ST source (Page 4587) or Change the properties of an ST source file (Page 4589).

The unit statement is ignored if the name specified there differs from the name of the ST source file.

Interface section of a unit with Declare Public function

You can enter the following constructs in the interface section of a unit with Declare Public function. The syntax of the constructs is only implied here, for details, see "Interface section (Page 4807)".

- The data type declarations to be declared public
  TYPE
  User-defined data types with their complete declaration.
- The variable declarations to be declared public
  VAR_GLOBAL, VAR_GLOBAL RETAIN, or VAR_GLOBAL CONSTANT
  Non-retentive and retentive unit variables and unit constants with their complete declaration.
- The POU to be declared public (functions, function blocks, programs and classes)
  Specify each POU (function, function block, program or class) to be declared public with the relevant keyword (optional within the TYPE / END_TYPE construct). Close each entry with a semicolon.
  - FUNCTION_BLOCK *fb_name*;
  - FUNCTION *fc_name*;
  - PROGRAM *program_name*;
  - CLASS *class_name*; (as of version V4.5 of the SIMOTION Kernel and with compiler option (Page 4623) "Permit object-oriented programming" activated)

  If the "Permit forward declarations" compiler option (Page 4623) is activated, they are also interpreted as POU prototypes for the forward declaration (Page 4929).
  You program the POU itself in the implementation section (Page 4809) of the ST source file.
- The object-oriented interfaces to be declared public as of version V4.5 of the SIMOTION Kernel with compiler option (Page 4623) "Permit object-oriented programming" activated.
  INTERFACE *if_name* ... END_INTERFACE
  Object-oriented interfaces with their complete declaration.

The information can be specified in any sequence:

Note

The following further specifications are possible in the interface section, they are listed **before** the data types, variables and POUs to be declared public:

1. Specification of utilized technology packages (USEPACKAGE ...).
2. Specification of utilized libraries (USELIB ...).
3. Reference to other units in order to use their public components (USES ...).

These imported technology packages, libraries and units are also declared public. For inheritance, see "USES statement in a using unit (Page 4830)".

You must adhere to the order presented for the specifications in the interface section of a unit (ST source file), see "Interface section (Page 4807)". Otherwise, error-free compilation of the ST source file will not be possible.

Programs which are to be assigned to a task in the execution system must be listed in the interface section (see *Configuring the execution system* in the *SIMOTION Basic Functions*

Function Manual). The compiler outputs a warning message if programs are not declared public in the interface section of an ST source file.

Functions, function blocks, and programs that are only used in the ST source file should not be listed in the interface section.

Example of a unit with Declare Public function

Below is an example of a unit with Declare Public function (*myUnit_A*). It is imported by *myUnit_B* (see Example of a using unit (Page 4831)).

Table 7-437 Example of a unit with Declare Public function

```
UNIT myUnit_A;    // Optional, name of the ST source file

INTERFACE
    // ... USES statement also possible here
    TYPE        // Declaration of data types to be declared public
        color : (RED, GREEN, BLUE);
    END_TYPE
    VAR_GLOBAL
        cycle : INT := 1;  // Declaration of unit variables to be declared public
                           // unit variables to be exported
    END_VAR
    FUNCTION myFC;         // DECLARE PUBLIC statement of an FC
    FUNCTION_BLOCK myFB;   // DECLARE PUBLIC statement of an FB
    CLASS myClass;         // DECLARE PUBLIC statement of a class
                           // (as of version V4.5 of the SIMOTION Kernel)
                           // and activated compiler option
                           // "Permit object-oriented programming")
    PROGRAM myProgram_A;   // Export statement of a program
                           // (to interface with the execution system)
END_INTERFACE
IMPLEMENTATION
    Function myFC : LREAL   // Function written out
        ;     // ... (Statements)
    END_FUNCTION

    Function_BLOCK myFB     // Function block formulated
        ;     // ... (Statements)
    END_FUNCTION_BLOCK

    CLASS myClass          // Class formulated
                           // (as of version V4.5 of the SIMOTION Kernel)
                           // and activated compiler option
                           // "Permit object-oriented programming")
        ;     // ... (Statements)
    END_CLASS;

    PROGRAM myProgram_A    // Program formulated
        ;     // ... (Statements)
    END_PROGRAM
END_IMPLEMENTATION
```

USES statement in a using unit

Enter the following statement in the interface section or implementation section of a using unit:

```
USES unit_name-list
```

unit_name-list is a list of the units to be used separated by commas.

Example:

```
USES unit_1, unit_2, unit_3;
```

This enables you to access the following elements that are declared public in the interface section of the units used (e.g. ST source file, MCC unit):

- User-defined data types (UDT)
- Unit variables and unit constants
- Programs, functions, function blocks and classes
- Used technology packages, libraries and units

You can use the used elements as if they existed in the current unit.

Note

The keyword USES can only occur once in the interface section or in the implementation section of a unit. When multiple units are to be used, enter them as a list separated by commas after the keyword USES.

The USES statement can appear in either the interface section or the implementation section of a unit. This has far-reaching implications:

Table 7-438 Implications regarding placement of USES statement in interface section or in implementation section of the ST source file

Effect	USES statement in the interface section	USES statement in the implementation section
Inheritance	The current unit continues declaring the used unit public; the used unit is inherited by all other units that access the current unit. Example: 1. Unit B uses Unit A in the **interface** section. 2. Unit C in turn uses Unit B. 3. Then Unit C also uses Unit A automatically. A → B → C ⇒ A → C Because of inheritance, Unit A need not be used explicitly in Unit C.	Inheritance is interrupted. Example: 1. Unit B uses Unit A in the **implementation** section. 2. Unit C in turn uses Unit B. 3. Then Unit C has no automatic access to Unit A. Unit C must explicitly use Unit A if it wants to access Unit A.
Variable declaration	The declaration of a unit variable of a used data type is possible in: • Interface section • Implementation section	The declaration of a unit variable of a used data type is only possible in the implementation section.

Note

You will find tips for use of unit variables in the SIMOTION Basic Functions Function Manual.

Example of a using unit

Below is an example of a using unit (*myUnit_B*). This uses the *myUnit_A* unit from the Example of a unit with Declare Public function (Page 4829).

Table 7-439 Example of a using unit

```
UNIT myUnit_B;        // Optional, name of the ST source file
INTERFACE
    // ...  if applicable USES statement
    PROGRAM myProgram_B;
    // Specification of declared public programs, FBs, FCs, classes,
    // Data types and unit variables
END_INTERFACE

IMPLEMENTATION
    USES myUnit_A;              // Specification of used unit

    VAR_GLOBAL
        myInstance : myFB;      // Declaration of an instance
                                // of the public FB of the used unit
        mycolor : color;        // Declaration of a variable
                                // of the public data type of the used unit
    END_VAR

    PROGRAM myProgram_B
        mycolor := GREEN;       // Value assignment to variables
                                // of the public data type of the used unit
        cycle := cycle + 1;     // Value assignment to
                                // public variables of the used unit
    END_PROGRAM
END_IMPLEMENTATION
```

7.2.7.2 Variables in SIMOTION

This summarizes the variables available in ST.

Variable model

The following table shows all the variable types available for programming with ST.

- System variables of the SIMOTION device and the technology objects
- Global user variables (I/O variables, device-global variables, unit variables)
- Local user variables (variables within a program, a function, a method, a function block or a class)

System variables

Variable type	Meaning
System variables of the SIMOTION device	Each SIMOTION device and technology object has specific system variables. These can be accessed as follows: • Within the SIMOTION device from all programs • From HMI devices You can monitor system variables in the symbol browser.
System variables of technology objects	

Global user variables

Variable type	Meaning
I/O variables	You can assign symbolic names to the I/O addresses of the SIMOTION device or the peripherals. This allows you to have the following direct accesses and process image accesses to the I/O: • Within the SIMOTION device from all programs • From HMI devices You create these variables in the symbol browser after you have selected the I/O element in the project navigator. You can monitor I/O variables in the symbol browser.
Global device variables	User-defined variables which can be accessed by all SIMOTION device programs and HMI devices. You create these variables in the symbol browser after you have selected the GLOBAL DEVICE VARIABLES element in the project navigator. Global device variables can be defined as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor global device variables in the symbol browser.
Unit variables	User-defined variables that all programs, function blocks, and functions (e.g. ST source, MCC source, LAD/FBD source) can access within a unit. Declare these variables in the unit: • In the interface section: These variables are declared public and can be used in other units (e.g. ST source files, MCC units, LAD/FBD units). They are also available on HMI-device as standard. • In the implementation section: You can only access these variables within the associated unit. You can declare unit variables as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor unit variables in the symbol browser.

Local user variables

Variable type	Meaning
	User-defined variables which can be accessed from within the program (or function, function block) in which they were defined.
Variable of a program (program variable)	Variable is declared in a program. The variable can only be accessed within this program. A differentiation is made between static, temporary and retentive variables: • Static variables are initialized according to the memory area in which they are stored. Specify this memory area by means of a compiler option. By default, the static variables are initialized depending on the task to which the program is assigned (see *SIMOTION Basic Functions* Function Manual). You can monitor static variables in the symbol browser. • Temporary variables are initialized every time the program in a task is called. Temporary variables cannot be monitored in the symbol browser. • Retentive variables (as of version V4.5 of the SIMOTION Kernel) retain their value even when the SIMOTION device power supply is disconnected. You can monitor retentive variables in the symbol browser.
Variable of a function or method	Variable is declared in a function (FC) or method. The variable can only be accessed within this FC or method. Variables in functions or methods are temporary; they are initialized each time the FC or method is called. They cannot be monitored in the symbol browser.
Variable of a function block	Variable is declared in a function (FB). The variable can only be accessed within this function block. A differentiation is made between static, temporary and retentive variables: • Static variables retain their value when the FB terminates. They are initialized only when the instance of the FB is initialized; this depends on the variable type with which the instance of the FB was declared. You can monitor static variables in the symbol browser. Only when compiler option "Permit object-oriented programming" is activated: Static variables with the PUBLIC access identifier can be accessed externally. • Temporary variables lose their value when the FB terminates. The next time the FB is called, they are reinitialized. Temporary variables cannot be monitored in the symbol browser. • Retentive variables (as of version V4.5 of the SIMOTION Kernel) retain their value even when the SIMOTION device power supply is disconnected. You can monitor retentive variables in the symbol browser.
Variables of a class (as of version V4.5 of the SIMOTION Kernel)	Variable is declared in a class. A differentiation is made between static and retentive variables: • Static variables are initialized only when the instance of the class is initialized; this depends on the variable type with which the instance of the class has been declared. Static variables can only be accessed from within this class and derived classes. Only static variables with the PUBLIC access identifier can be accessed from outside the class. • Retentive variables retain their value even when the SIMOTION device power supply is disconnected. Retentive variables can only be accessed from within this class and derived classes. They cannot be accessed from outside the class. You can monitor the variables in the symbol browser.

Further information is available from the following sources:

- In the corresponding list manuals, you can find the compressed information on all system variables of the SIMOTION technology packages and SIMOTION devices.
- For more details on the use of system variables of technology objects, please refer to the *SIMOTION Motion Control Technology Objects* Function Manuals.
- In the *SIMOTION Basic Functions* Function Manual you can find information on how to access system variables and configuration data.
- This documentation contains information on:
  - Accessing I/O addresses with I/O variables (see Direct access and process image of the cyclic tasks (Page 4872))
  - Accessing the process image (see Access to the fixed process image of the BackgroundTask (Page 4881))
  - Creating and using global device variables (see Using global device variables (Page 4843))
  - Use of unit variables and local variables (static and temporary variables).

Note

Please note that downloading the ST source file to the target system and running tasks affect variable initialization and thus the contents of the variables, see Time of the variable initialization (Page 4849).

Unit variables

Unit variables are valid throughout the entire ST source file, i.e. they can be accessed in any source file section.

Unit variables are declared in the interface and/or implementation section of an ST source file; the location of the declaration determines the validity of the unit variable:

- If you declare the unit variables in the interface section, you create variables that can be used in other program sources (e.g. ST source files, MMC units). More information about declaring data public and using public data in other program sources can be found in Declaring ST source files public and using them (Page 4827).
  By default, these unit variables are also available on HMI devices. The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.
- If you declare the unit variables in the implementation section, you create variables that can be used by all program organization units (POUs) of the current source file.

You can change the default setting for the HMI export of the unit variables using a pragma within a declaration block, see Variables and HMI devices (Page 4864) and Controlling compiler with attributes (Page 4922).

You can define unit variables with different behavior, e.g. in case of power failure:

- Non-retentive unit variables (keyword VAR_GLOBAL): its value is lost in the event of a power failure.
- Retentive unit variables (keyword VAR_GLOBAL RETAIN): its value remains in the event of a power failure.
- Unit constants (keyword VAR_GLOBAL CONSTANT): its value is retained unchanged (see Constants (Page 4701)).

You will find tips for the efficient use of unit variables in the *SIMOTION Basic Functions* Function Manual.

Non-retentive unit variables

Non-retentive unit variables lose their value in the event of a power failure.

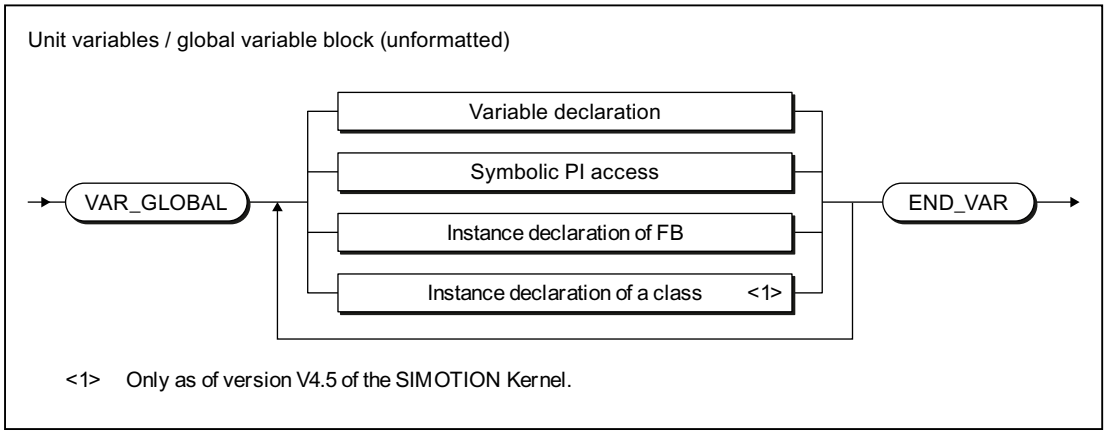

Figure 7-293 Syntax: Unit variables

This declaration block may appear more than once within an interface or implementation section. You specify the variable name and data type for the variable declaration (see Overview of all variable declarations (Page 4695) and Initialization of variables or data types (Page 4697)).

For the scope of the declaration and the HMI export, see Unit variables (Page 4834).

Note

For initialization of the non-retentive unit variables:

- See Initialization of non-retentive global variables (Page 4851).
- The behavior during downloading can be set (**Options > Settings** menu command, **Download** tab, **Initialize non-retentive program data and global device variables** checkbox)
- The type of version ID and therefore the initialization behavior on downloading depends on the SIMOTION Kernel version. For details, see Version ID of global variables and their initialization during download (Page 4858).

Table 7-440 Examples of non-retentive unit variables

```
INTERFACE
    VAR_GLOBAL    // These variables are declared public.
        rotation1        : INT;
        field1           : ARRAY [1..10] OF REAL;
        flag1            : BOOL;
        motor1           : motor;    // Instance declaration
    END_VAR
END_INTERFACE

IMPLEMENTATION
    VAR_GLOBAL    // These variables are not declared public.
        rotation2        : INT;
        field2           : ARRAY [1..10] OF REAL;
        flag2            : BOOL;
        motor2           : motor;    // Instance declaration
    END_VAR
END_IMPLEMENTATION
```

Retentive unit variables

Retentive unit variables permit permanent storage of variable values even throughout a power failure.

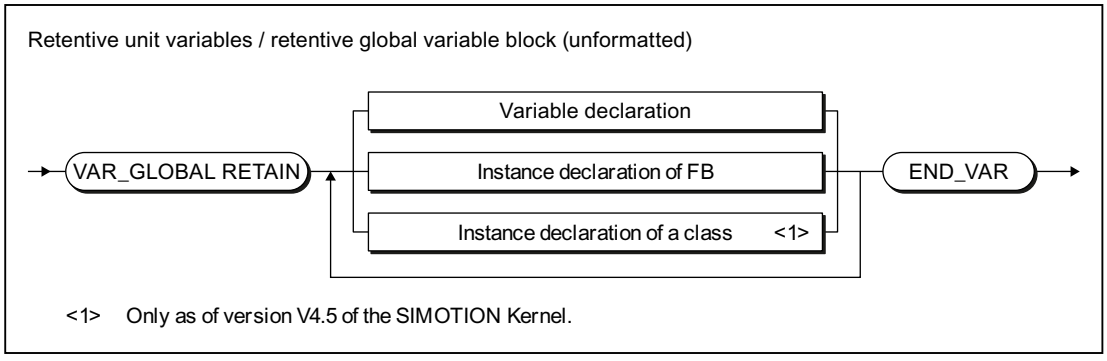

Figure 7-294 Syntax: Retentive global variable block

This declaration block may appear more than once within an interface or implementation section. You specify the variable name and data type for the variable declaration (see Overview of all variable declarations (Page 4695) and Initialization of variables or data types (Page 4697)).

For the scope of the declaration and the HMI export, see Unit variables (Page 4834).

Note

- For initialization of the retentive unit variables:
  - See Initialization of retentive global variables (Page 4849).
  - The behavior during downloading can be set (**Options > Settings** menu command, **Download** tab, **Initialize retentive program data and global device variables** checkbox)
  - The type of version ID and therefore the initialization behavior on downloading depends on the SIMOTION Kernel version. For details, see Version ID of global variables and their initialization during download (Page 4858).
- The amount of memory available for retentive variables depends on the device (see quantity framework in the SIMOTION SCOUT Configuration Manual).
  To make efficient use of limited memory space, use the memory in a single ST source file and sort the variables in descending order!
- Check the capacity utilization of the retentive memory in SIMOTION SCOUT.
  In online mode, call the **device diagnostics** of the SIMOTION device to be checked (see online help). In the **System utilization** tab under **Retentive data**, you can see how much memory is available.

Table 7-441 Examples of retentive unit variables

```
VAR_GLOBAL RETAIN
    Measuring field : ARRAY[1..10] OF REAL;
    Pass : INT;
    Switch : BOOL;
END_VAR
```

Local variables (static and temporary variables)

Local variables are valid only in the source file section (e.g. program, FC or FB) in which they were declared. We distinguish between the following:

- Static variables (Page 4840):
  Static variables retain their value over all passes of the source file section (block memory).
- Temporary variables (Page 4841):
  Temporary variables are initialized each time the unit section is called again.
- Retentive local variables (Page 4841)
  SIMOTION Kernel as of version V4.5.
  They retain their value:
  - in the event of a power failure
  - when the task is started
  - over all passes of the source file section

See also: Initialization of local variables (Page 4853).

Note

Local variables cannot be accessed outside the source file section in which they were declared.

The following table provides an overview of the declaration of retentive, static and temporary variables. It shows the source file sections in which these variables can be declared and the keywords that can be used to declare them.

Table 7-442 Keywords for declaring retentive, static and temporary variables depending on source file section

Source file section	Keywords for the declaration		
	Static variables	Temporary variables	Retentive local variables (as of kernel V4.5)
Function	–	VAR / END_VAR or VAR_TEMP / END_VAR or VAR_INPUT / END_VAR or VAR_IN_OUT / END_VAR[2] or VAR_OUTPUT / /END_VAR	–
Expression	–	VAR/ END_VAR or VAR_INPUT / END_VAR or VAR_IN_OUT / END_VAR[2]	–
Function block	VAR / END_VAR[1] or VAR_INPUT / END_VAR[1] or VAR_OUTPUT / END_VAR[1]	VAR_TEMP / END_VAR or VAR_IN_OUT / END_VAR[2]	VAR RETAIN / END_VAR
Program	VAR / END_VAR[3]	VAR_TEMP / END_VAR	VAR RETAIN / END_VAR
Methods (within a class or a function block)[4]	–	VAR / END_VAR or VAR_TEMP / END_VAR or VAR_INPUT / END_VAR or VAR_IN_OUT / END_VAR[2] or VAR_OUTPUT / /END_VAR	–
Class[4]	VAR / END_VAR[1]	–	VAR RETAIN / END_VAR

[1] The initialization of the variable depends on initialization of the declared instance. See Initialization of instances of function blocks (FBs) or classes (Page 4856).

[2] The reference (pointer) for the transferred variable is temporary.

[3] The initialization of the variables depends on the memory area in which they are stored. See Initialization of static program variables (Page 4854).

[4] Only with active compiler option “Permit object-oriented programming”.

Note

Please note that downloading the ST source file to the target system and running tasks affect variable initialization and thus the contents of the variables, see Time of the variable initialization (Page 4849).

Table 7-443 Examples of static and temporary variables

```
IMPLEMENTATION
    FUNCTION testFkt
        VAR            // Declaration of temporary variables
            flag : BOOL;
        END_VAR
    END_FUNCTION
    FUNCTION_BLOCK testFbst
        VAR RETAIN     // Declaration of retentive variables
            position1 : LREAL
        END_VAR

        VAR            // Declaration of static variables
            rotation1 : INT;
        END_VAR

        VAR_TEMP       // Declaration of temporary variables
            help1, help2 : REAL;
        END_VAR
    END_FUNCTION_BLOCK
    PROGRAM testPrg;
        VAR RETAIN     // Declaration of retentive variables
            position2 : LREAL
        END_VAR

        VAR           // Declaration of static variables
            rotation2 : INT;
        END_VAR

        VAR_TEMP      // Declaration of temporary variables
            help1, help2 : REAL;
        END_VAR
    END_PROGRAM
    CLASS testcls
        VAR RETAIN     // Declaration of retentive variables
            position3 : LREAL
        END_VAR

        VAR           // Declaration of static variables
            rotation3 : INT;
        END_VAR
    END_CLASS
END_IMPLEMENTATION
```

Static variables

Static variables retain their most recent value when the source file section is exited. This value is used again at the next call.

The following source file sections contain static variables:

- Programs
- Function blocks
- Classes (as of version V4.5 of the SIMOTION Kernel and with compiler option "Permit object-oriented programming" enabled)

Static variables are declared in a static variable block.

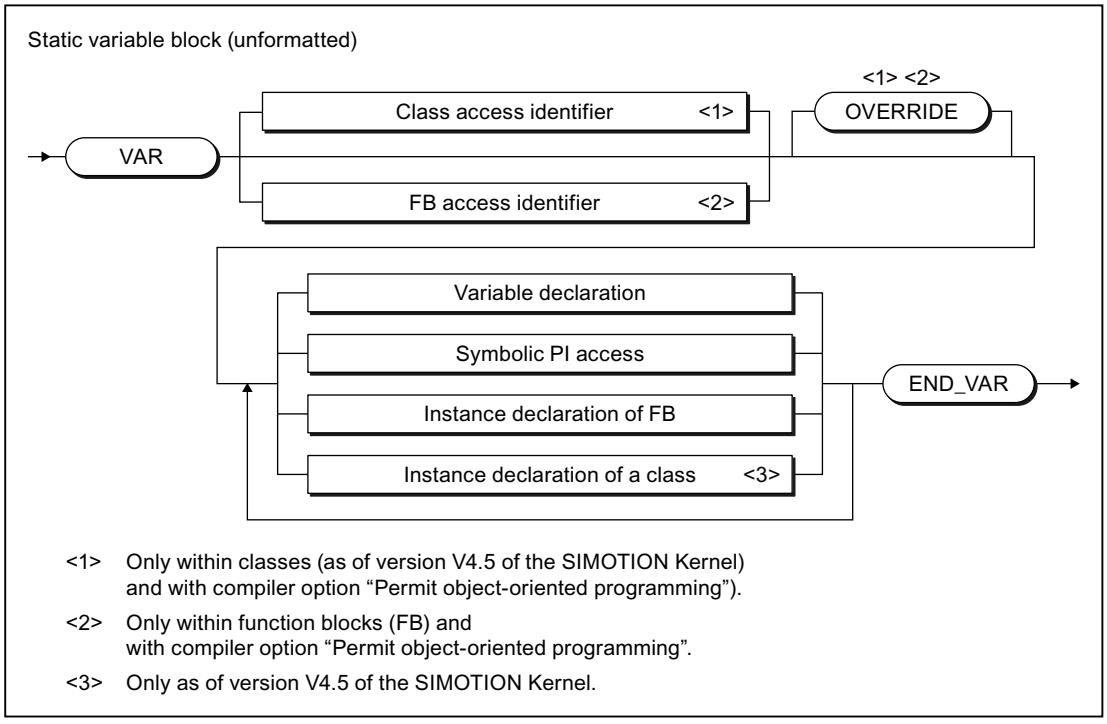

Figure 7-295 Syntax: Static variable block

You can do the following in the static variable block, according to the syntax in the figure:

- Declare variables (name and data type), optionally with initialization.
- Declare symbolic accesses to the process image of the BackgroundTask.
- Declare instances of the function blocks.
- Declaring instances of classes (SIMOTION Kernel as of version V4.5)

For initialization of the static variables:

- In programs: Depending on the execution behavior to which the program is assigned (see *SIMOTION Basic Functions* Function Manual).
  See also Initialization of static program variables (Page 4854).
- In function blocks: Depending on the initialization of the declared instance.
  See also Initialization of instances of function blocks (FBs) (Page 4856).

Temporary variables

Temporary variables are initialized each time the source file section is called. Their value is retained only during execution of the source file section.

The following source file sections contain temporary variables:

- Programs
- Function blocks
- Functions
- Methods (within classes or function blocks, with compiler option "Permit object-oriented programming")
- Expressions

In functions and expressions, you declare temporary variables in the FB temporary variable block (see following figure):

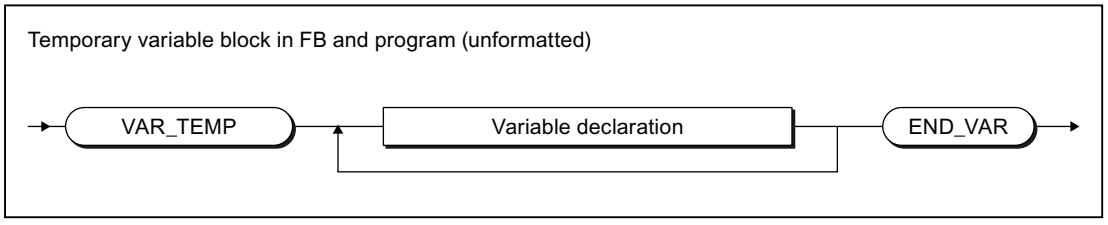

Figure 7-296 Syntax: Temporary variable block in the FB or program

In functions, methods and expressions, you declare temporary variables in the FC temporary variable block (see following figure):

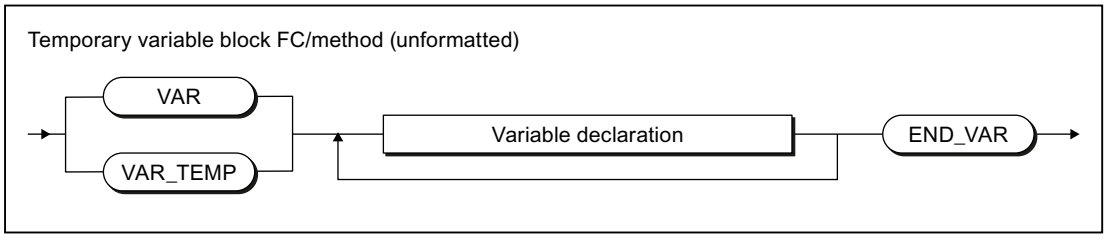

Figure 7-297 Syntax: Temporary variable block in an FC or a method

Retentive local variables (as of kernel V4.5)

You can declare retentive local variables in SIMOTION Kernel as of version V4.5.

They retain their value over all passes of the source file section in the event of a power failure or if the task is started.

The following source file sections contain retentive local variables:

- Programs
- Function blocks
- Classes (with compiler option "Permit object-oriented programming")

They are declared in the retentive local variable block.

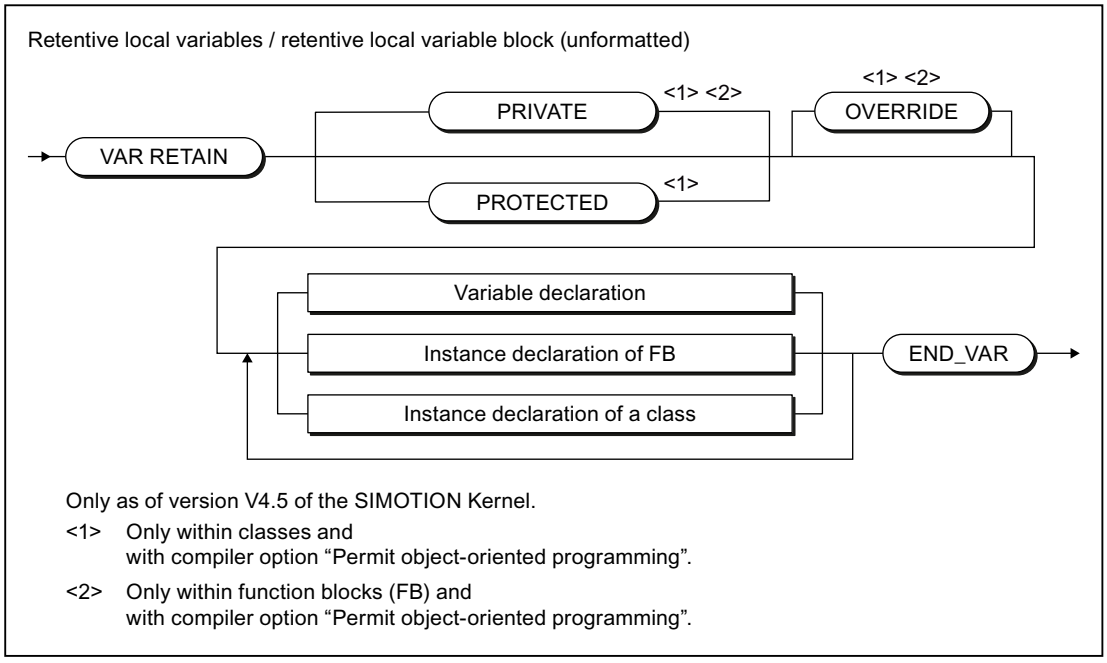

Figure 7-298 Syntax: Retentive local variable block

You can do the following in the retentive local variable block, according to the syntax in the figure:

- Declare variables (name and data type), optionally with initialization.
  Exception. No variables of data types can be declared in the retentive local variable block if they exclusively contain elements that cannot be saved (e.g. variables of data types of the technology objects).
- Declare instances of the function blocks.
  Exception: No instances of function blocks can be declared in the retentive local variable block if they contain the following:
  - Retentive local variables
  - Instances of system function blocks
- Declaring instances of classes (SIMOTION Kernel as of version V4.5)
  Exception: No instances of classes can be declared in the retentive local variable block if they contain the following:
  - Retentive local variables
  - Instances of system function blocks

For initialization of retentive local variables:

- In programs: dependent on the compiler option "Only create program instance data once”.
  See also Initialization of retentive local variables of programs (Page 4855).
- In function blocks or classes: dependent on the initialization of the retentive variables of the declared instance.
  See also Initialization of retentive local variables of function blocks and classes (Page 4857).

Use of global device variables

Global device variables are user-defined variables that you can access from all program sources (e.g. ST source files, MCC source files) of a SIMOTION device.

Global device variables are created in the symbol browser tab of the detail view; to do this, you must be working in offline mode.

Here is a brief overview of the procedure:

1. In the project navigator of SIMOTION SCOUT, select the **GLOBAL DEVICE VARIABLES** element in the SIMOTION device subtree.
2. In the detail view, select the **Symbol browser** tab and scroll down to the end of the variable table (empty row).
3. In the last (empty) row of the table, enter or select the following:
   - **Name** of variable
   - **Data type** of variable (only elementary data types are permitted)
4. Optionally, you can make the following entries:
   - Activation of **Retain** checkbox (This declares the variable as retentive, so that its value will be retained after a power failure.)
   - **Field length** (array size)
   - **Initial value** (if array, for each element)
   - **Display format** (if array, for each element)

You can now access this variable using the symbol browser or any program of the SIMOTION device.

In ST source files, you can use a global device variable, just like any other variable.

Note

If you have declared unit variables or local variables of the same name (e.g. *var-name*), specify the global device variable with *_device.var-name*.

An alternative to global device variables is the declaration of unit variables in a separate unit, which is imported into other units. This has the following advantages:

1. Variable structures can be used.
2. The initialization of the variables during the STOP-RUN transition is possible (via Program in StartupTask).
3. For newly created global unit variables, a download in RUN is also possible.

Please refer to the SIMOTION Basic Functions Function Manual.

Memory ranges of the variable types

The different variable types are stored in different memory areas, which are initialized at different times. The table shows:

- The available memory areas for variable types that are declared in ST source files (possibly dependent on the version of the SIMOTION Kernel).
- The initialization time for each memory area.

An explanation using an example is contained in the Example for memory areas (Page 4846) section.

Table 7-444 Memory areas assigned to different variable types and their initialization

Memory area	Assigned variable types	Initialization[3]
Retentive memory	• Retentive unit variables • As of version V4.5 of the SIMOTION Kernel: Retentive local variables of programs and function blocks	During download using the download settings
User memory of unit	• Non-retentive unit variables • Function block instances declared with VAR_GLOBAL, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT) • As of version V4.5 of the SIMOTION Kernel: Instances of classes declared with VAR_GLOBAL, including the associated variables (VAR) Also for the activated "Create program instance data only once" compiler option (Page 4623): • Local variables of the unit programs declared with VAR • Function block instances declared with VAR_GLOBAL, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT) • As of version V4.5 of the SIMOTION Kernel: Instances of classes declared with VAR within the programs of the unit, including the associated variables (VAR)	• When the device is switched on • During download using the download settings • For transition to the RUN mode: – Version V4.2 and higher of the SIMOTION Kernel: By activating the check box on the SIMOTION device, **Initialization of non-retentive global variables and program data during STOP-RUN transition**. – As of Version V4.1 of the SIMOTION Kernel: If the associated declaration block specifies the following pragma: { BlockInit_OnDeviceRun := ALWAYS; } See also Controlling compiler with attributes (Page 4922)
User memory of task	For the deactivated "Create program instance data only once" compiler option (Page 4623) (default): • Local variables declared with VAR of the assigned programs • Function block instances declared with VAR within the assigned programs, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT) • As of version V4.5 of the SIMOTION Kernel: Instances of classes declared with VAR within the programs of the unit, including the associated variables (VAR)	According to execution behavior of task: • Sequential tasks: Each time task is started • Cyclic tasks: For CPU transition to the RUN mode

Memory area	Assigned variable types	Initialization[3]
Local data stack of task[2]	• Reference (pointer) to the program called in the task • Local variables declared with VAR_TEMP of the program called in the task	On each call of the program in the task
	• Reference (pointer) to called function block instances • Local variables of function blocks declared with VAR_TEMP • In/out parameters of function blocks declared with VAR_IN_OUT[1]	Each time the function block instance is called
	• Variables of called functions or methods declared with VAR, VAR_INPUT, VAR_OUTPUT or VAR_IN_OUT[1] • Return value of called functions or methods	Each time the function or method is called

[1] References (pointers) to the transferred variables.

[2] See also Memory requirement of the variables on the local data stack (Page 4848).

[3] For a detailed description of the initialization behavior of the individual variable types, see Time of the variable initialization (Page 4849).

Example of memory areas

Table 7-445 Example of memory areas of the variable types - Part 1

```
INTERFACE
// The statements in the interface section specify,
// which source contents are declared public.
    FUNCTION FC1;
    FUNCTION_BLOCK FB1;
    PROGRAM p1;

    // Unit variables of the interface section are also visible
    // on HMI devices.
    VAR_GLOBAL               // Non-retentive unit variables
                             // are present in the UNIT user memory
        u1_if : INT;
    END_VAR
    VAR_GLOBAL CONSTANT      // Unit constants are located
                             // in the unit user memory
    END_VAR
    VAR_GLOBAL RETAIN        // Retentive unit variables are located
                             // in the retentive (power-fail-safe) memory
    END_VAR
END_INTERFACE

IMPLEMENTATION
// The implementation section contains the executable code sections
// in different program organization units (POU)
// A POU can be a program, FC, or FB.
    // Unit variables of the implementation section can only be used
    // within the source file.
    VAR_GLOBAL               // Non-retentive unit variables are located
                             // in the unit user memory
        u1_glob : INT;
    END_VAR
    VAR_GLOBAL CONSTANT      // Unit constants are located
                             // in the unit user memory
    END_VAR
    VAR_GLOBAL RETAIN        // Retentive unit variables are located
                             // in the retentive (power-fail-safe) memory
    END_VAR
//-----------------------------------------------------------------------
```

        u1_glob := 4711;
    END_PROGRAM
END_IMPLEMENTATION
```

Memory requirement of the variables on the local data stack

The variables stored on the local data stack of a task are listed in Memory ranges of the variable types (Page 4844). You set the stack size for each task in the **Task configuration** tab. For more information, see the Description for each user task in the Basic Functions Function Manual.

Note the following for memory requirements in the local stack:

- Temporary local variables require their own size on the stack.
- Global variables and static local variables do not require any resources on the stack.
  If you are using them as input parameters for a function, however, they require their own data size on the stack.

- Even if a function is called more than once in a task, it only uses the stack's resources once.
- Variables of type BOOL require 1 byte on the stack.

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 4914) function.

Time of the variable initialization

The timing of the variable initialization is determined by:

- Memory area to which the variable is assigned
- Operator actions (e.g. source file download to the target system)
- Execution behavior of the task (sequential, cyclic) to which the program was assigned.

All variable types and the timing of their variable initialization are shown in the following tables. You will find basic information about tasks in the *SIMOTION Basic Functions* Function Manual.

The behavior for variable initialization during download can be set: To do this, as a default setting select the **Options > Settings** menu and the **Download** tab or define the setting during the current download.

Note

You can upload values of unit variables or global device variables from the SIMOTION device into SIMOTION SCOUT and save them in XML format.

1. Save the required data segments of the unit variables or global device variables as a data set with the function *_saveUnitDataSet*.
2. Use the **Save variables** function in SIMOTION SCOUT.

You can use the **Restore variables** function to download these data sets and variables back to the SIMOTION device.

For more information, refer to the SIMOTION SCOUT Configuration Manual.

This makes it possible, for example, to obtain this data, even if it is initialized by a project download or if it becomes unusable (e.g. due to a version change of SIMOTION SCOUT).

Initialization of retentive global variables

Retentive variables retain their last value after a loss of power. All other data is reinitialized when the device is switched on again.

Retentive global variables are initialized:

- When the backup or buffer for retentive data fails.
- When a memory reset (MRES) is performed.
- With the restart function (Del. SRAM) in SIMOTION P320 or P350.
- By applying the *_resetUnitData* function, possible selectively for different data segments of the retentive data.

- When a download is performed according to the following description.
- With a firmware update (upgrade) or activation of a kernel in accordance with the following description.

Behavior during download

Table 7-448 Initializing retentive global variables during download

Variable type	Time of the variable initialization
Retentive global device variables	The behavior during the download depends on the *Initialization of retentive program data and retentive global device variables* setting[1]: • **Yes**[2]: All retentive global device variables are initialized. • **No**[3]: The retentive global device variables are only initialized if their version code is changed. See: Version code of global variables and their initialization during download (Page 4858).
Retentive unit variables	The behavior during the download depends on the *Initialization of retentive program data and retentive global device variables* setting[1]: • **Yes**[2]: All retentive unit variables (all units) are initialized. • **No**[3]: A data block (= declaration block)[4] of the retentive unit variables in the interface or implementation section is only initialized[5] if its version code is changed. See: Version code of global variables and their initialization during download (Page 4858).

[1] Default setting in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding check box is active.

[3] The corresponding check box is inactive.

[4] With the **SIMOTION ST** programming language:
A data block of the retentive unit variables corresponds to a VAR_GLOBAL RETAIN/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** and **SIMOTION LAD/FBD** programming languages:
A data block of the retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL RETAIN in the interface section or implementation section of the declaration table: Pragma lines within a section of the declaration table separate the variables into different data blocks.

[5] Initialization of a changed data block also occurs during a download in RUN mode, provided the following condition is fulfilled:
With the **SIMOTION ST** programming language
The following attribute has been specified within a pragma: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line is inserted in the declaration table with the following check box enabled in this line: *Initialization of VAR_GLOBAL RETAIN during a change*. All the variables declared with VAR_GLOBAL RETAIN up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see the SIMOTION Basic Functions Function Manual.

Behavior during upgrade or configuration change

When the SIMOTION device is upgraded to a new version of the SIMOTION Kernel or if the configuration is changed, the retentive variables are initialized as described below:

Table 7-449 Initialization of retentive global variables during upgrade or configuration change

Variable type	Time of the variable initialization
Retentive global device variables	This data is always initialized.
Retentive unit variables	This data can be retained. See section "Retaining retentive data" in the "Basic Functions for Modular Machines" Function Manual.

Initialization of non-retentive global variables

Non-retentive global variables lose their value during power outages. They are initialized:

- During the initialization of retentive global variables (Page 4849), e.g. during a firmware update or overall reset (MRES).
- During switch-on.
- By applying the *_resetUnitData* function, possible selectively for different data segments of the non-retentive data.
- During a download as described in the following table.
- During the transition from STOP to RUN mode as described at the end of the section.

Behavior during download

Table 7-450 Initializing non-retentive global variables during download

Variable type	Time of the variable initialization
Non-retentive global device variables	The behavior during the download depends on the *Initialization of non-retentive program data and non-retentive global device variables* setting[1]: • **Yes**[2]: All non-retentive global device variables are initialized. • **No**[3]: The non-retentive global device variables are only initialized if their version code is changed. See: Version code of global variables and their initialization during download (Page 4858).
Non-retentive unit variables	The behavior during the download depends on the *Initialization of non-retentive program data and non-retentive global device variables* setting[1]: • **Yes**[2]: All non-retentive unit variables (all units) are initialized. • **No**[3]: A data block (= declaration block)[4] of the non-retentive unit variables in the interface or implementation section is only initialized[5] if its version code is changed. See: Version code of global variables and their initialization during download (Page 4858).

[1] Default in the **Options > Settings** menu, **Download** tab, or the current setting for the download.

[2] The corresponding check box is active.

[3] The corresponding check box is inactive.

[4] With the **SIMOTION ST** programming language:
A data block of the non-retentive unit variables corresponds to a VAR_GLOBAL/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A data block of the non-retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL in the interface section or implementation section of the declaration table: Pragma lines within a section of the declaration table separate the variables into different data blocks.

[5] Initialization of a changed data block also occurs during a download in RUN, provided the following condition is fulfilled:
With the **SIMOTION ST**
programming language: The following attribute has been specified within a pragma in the relevant declaration block: { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line has been pasted into the declaration table and the following check box is activated: *Initialization of VAR_GLOBAL during a change*. All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see SIMOTION Basic Functions Function Manual.

Behavior during STOP-RUN transition

The values of non-retentive global variables are retained by default during the transition from STOP to RUN mode.

You can, however, make a setting whereby the non-retentive global variables are initialized during the STOP-RUN transition:

- **As of Version V4.2 of the SIMOTION Kernel**, by activating the (Page 4929) **Initialization of non-retentive global variables and program data during STOP-RUN transition** checkbox on the SIMOTION device.
  With non-retentive unit variables, this setting can be overwritten by a pragma or pragma line in the relevant data blocks of the program sources.
- **As of Version V4.1 of the SIMOTION Kernel**, by a pragma or pragma line in the relevant data blocks of the program sources (only with non-retentive unit variables):
  - With the **SIMOTION ST** programming language:
    Specify the following attribute within a pragma in the relevant VAR_GLOBAL/END_VAR declaration block: { BlockInit_OnDeviceRun := ALWAYS; }
  - With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
    Paste a pragma line with the following setting into the declaration table: "*Initialization during STOP-RUN transition* = **Always**". All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block which is initialized during the STOP-RUN transition.

Note

With SIMOTION devices up to SIMOTION Kernel Version V4.0, non-retentive global variables are never initialized during the STOP-RUN transition.

Initialization of local variables

Local variables are initialized:

- For the initialization of retentive unit variables (Page 4849).
- For the initialization of non-retentive unit variables (Page 4851).
- Also, according to the following description:

Table 7-451 Initialization of local variables

Variable type	Time of the variable initialization
Local program variables	Local variables of programs are initialized differently: • Static variables (VAR) are initialized according to the memory area in which they are stored. See: Initialization of static program variables (Page 4854). • Temporary variables (VAR_TEMP) are initialized every time the program of the task is called.
Local variables of function blocks (FB)	Local variables of function blocks are initialized differently: • Static variables (VAR, VAR_IN, VAR_OUT) are only initialized when the FB instance is initialized. See: Initialization of instances of function blocks (FBs) (Page 4856). • Temporary variables (VAR_TEMP) are initialized every time the FB instance is called.
Local variables of functions (FC)	Local variables of functions are temporary and are initialized every time the function is called.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 4914) function.

Initialization of static program variables

The following versions affect the following static variables:

- Local variables of a unit program declared with VAR
- Function block instances declared with VAR within a unit program, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT).

The initialization behavior is determined by the memory area in which the static variables are stored. This is determined by the "Only create program instance data once" (Page 4623) compiler option.

- For the deactivated "Only create program instance data once" compiler option (default):
  The static variables are stored in the user memory of each task which is assigned to the program.
  The initialization of the variables thus depends on the execution behavior of the task to which the program is assigned (see SIMOTION Basic Functions Function Manual):
  - Sequential tasks (MotionTasks, UserInterruptTasks, SystemInterruptTasks, StartupTask, ShutdownTask): The static variables are initialized every time the task is started.
  - Cyclic tasks (BackgroundTask, SynchronousTasks, TimerInterruptTasks): The static variables are only initialized only during the transition from STOP to RUN operating state.
- For the activated "Only create program instance data once" compiler option:
  This setting is necessary, for example, if a program is to be called within a program.
  The static variables of all programs from the program source (unit) involved are only stored once in the user memory of the unit.
  They are thus initialized together with the non-retentive unit variables, see Initialization of non-retentive global variables (Page 4851).
  They are not initialized by default during the transition from STOP to RUN operating state.
  You can, however, make a setting whereby they are initialized during the STOP-RUN transition:
  - **As of version V4.2 of the SIMOTION Kernel**, by activating the (Page 4929) **Initialization of non-retentive global variables and program data during STOP-RUN transition** checkbox on the SIMOTION device.
    This setting can be overwritten by a pragma or pragma line in the data block of the relevant program organization unit (POU).
  - **As of version V4.1 of the SIMOTION Kernel**, by a pragma or pragma line in the data block of the relevant program organization unit (POU):
    With the **SIMOTION ST** programming language:
    Specify the following attribute within a pragma in the VAR/END_VAR declaration block:
    { BlockInit_OnDeviceRun := ALWAYS; }
    With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
    The declaration table starts with a pragma line containing the following setting:
    "*Initialization during STOP-RUN transition* = **Always**". All the variables declared with VAR in the table are initialized during the STOP-RUN transition.

Initialization of retentive local variables of programs

The following versions relate to the following retentive variables:

- Local variables of a unit program declared with VAR RETAIN,
- Function block or class instances declared with VAR RETAIN within a unit program, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT).
- Function block instances declared with VAR within a unit program, or classes for their associated retentive variables (VAR RETAIN).

These retentive variables are initialized:

- When retentive unit variables are initialized (Page 4849).
- And also when a download is performed according to the following description.

The initialization behavior when downloading is determined by the compiler option (Page 4623) "Only create program instance data once".

- For the deactivated "Only create program instance data once" compiler option (default):
  The retentive variables are initialized in the following cases:
  - The data structure of the VAR RETAIN declaration blocks of the instances involved changes.
  - Additional tasks are activated in the execution system.
  - The assignment or sequence of the programs with retentive variables changes within a task.
- For the activated "Only create program instance data once" compiler option:
  The retentive variables are initialized in the following cases:
  - The data structure of the VAR RETAIN declaration blocks of the instances involved changes.
  - The sequence of the VAR_GLOBAL data blocks or of the programs (PROGRAM) changes in the implementation section of the source.

Initialization of instances of function blocks (FBs) or classes

The initialization of a function block instance (Page 4754) or a class instance (as of version V4.5 of the SIMOTION Kernel) (Page 4778) is determined by the location of its declaration:

- Global declaration (within VAR_GLOBAL/END_VAR in the interface of implementation section):
  Initialization as for a non-retentive unit variable, see Initialization of non-retentive global variables (Page 4851).
- Local declaration in a program (within VAR / END_VAR):
  Initialization as for static variables of programs, see Initialization of static variables of programs (Page 4854).
- Local declaration in a function block (within VAR / END_VAR):
  Initialization as for an instance of this function block.
- Declaration as in/out parameter in a function block or a function (within VAR_IN_OUT / END_VAR):
  For the initialization of the POU, only the reference (pointer) will be initialized with the instance of the function block remaining unchanged.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 4914) function.

Initialization of retentive local variables of function blocks (FBs) and classes

The initialization of retentive variables of a function block (FB) or a class (as of version V4.5 of the SIMOTION Kernel) is determined by the location at which the instance of a function block (Page 4754) or the instance of a class (Page 4778) is declared:

- Global declaration (within VAR_GLOBAL/END_VAR in the interface of implementation section):
  The retentive variables are initialized:
  - When retentive unit variables are initialized (Page 4849).
  - In addition to the download:
    The data structure of the VAR RETAIN declaration blocks of the instances involved changes.
    The sequence of the VAR_GLOBAL declaration blocks in the current source changes.
- Local declaration in a program (within VAR / END_VAR):
  Initialization as for retentive local variables of programs, see Initialization of retentive local variables of programs (Page 4855).
- Local declaration in a function block (within VAR / END_VAR):
  Initialization as with the retentive variables of an instance of this function block.
- Declaration as in/out parameter in a function block or a function (within VAR_IN_OUT / END_VAR):
  For the initialization of the POU, only the reference (pointer) will be initialized with the instance of the function block remaining unchanged.

Note

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 4914) function.

Initialization of system variables of technology objects

The system variables of a technology object are usually not retentive. Depending on the technology object, a few system variables are stored in the retentive memory area (e.g. absolute encoder calibration).

The initialization behavior (except in the case of download) is the same as for retentive and non-retentive global variables. See Initialization of retentive global variables (Page 4849) and Initialization of non-retentive global variables (Page 4851).

The behavior during the download is shown below for:

- Non-retentive system variables
- Retentive system variables

Table 7-452 Initializing technology object system variables during download

Variable type	Time of the variable initialization
Non-retentive system variables	Behavior during download, depending on the *Initialization of all non-retentive data for technology objects* setting[1]: • **Yes**[2]: All technology objects are initialized. – All technology objects are restructured and all non-retentive system variables are initialized. – All technological alarms are cleared. • **No**[3]: Only technology objects changed in SIMOTION SCOUT are initialized. – The technology objects in question are restructured and all non-retentive system variables are initialized. – All alarms that are pending on the relevant technology objects are cleared. – If an alarm that can only be acknowledged with *Power On* is pending on a technology object that will not be initialized, the download is aborted.
Retentive system variables	Only if a technology object was changed in SIMOTION SCOUT, will its retentive system variables be initialized. The retentive system variables of all other technology objects are retained (e.g. absolute encoder calibration).
[1] Default in the **Options > Settings** menu, **Download** tab, or the current setting for the download. [2] The corresponding checkbox is active. [3] The corresponding checkbox is inactive.	

Version ID of global variables and their initialization during download

Table 7-453 Version code of global variables and their initialization during download

Data segment		Description of version code
Global device variables		
	Retentive global device variables Non-retentive global device variables	• Separate version code for each data segment of the global device variables. • The version code of the data segment changes for: – Add or remove a variable within the data segment – Change of the identifier or the data type of a variable within the data segment • This version code does not change on: – Changes in the other data segment – Changes to initialization values[1] • During downloading[2], the rule is: This data segment is only initialized when the version code of a data segment is changed.
Unit variables of a unit		

Data segment		Description of version code
	Retentive unit variables in the interface section Retentive unit variables in the implementation section Non-retentive unit variables in the interface section Non-retentive unit variables in the implementation section	• Several data blocks (= declaration blocks)[3] are possible in each data segment. • **Separate version code** for each data block. • The version code of the data block changes for: – Add or remove a variable in the associated declaration block – Change of variable sequence in the relevant declaration block – Change of the identifier or the data type of a variable in the associated declaration block – Change of a data type definition (from a separate or imported[4] unit) used in the associated declaration block – Add or remove declaration blocks within the same data segment **before** the associated declaration block • This version code does not change on: – Add or remove declaration blocks in other data segments – Add or remove declaration blocks within the same data segment **after** the associated declaration block – Changes in other data blocks – Changes to initialization values[1] – Changes to data type definitions that are not used in the associated data block – Changes to functions • During downloading[2], the rule is: This data block is only initialized when the version code of a data block is changed[5]. • Functions for data backup and initialization take into account the version code of the data blocks.
Retentive variables of function blocks and classes (The instances are declared as non-retentive unit variables)		

Data segment		Description of version code
	Non-retentive unit variables in the interface section	Only as of version V4.5 of the SIMOTION Kernel. • The retentive variables of all instances within a declaration block (VAR_GLOBAL / END_VAR) are summarized as a separate retentive data block • to which a separate version code is assigned. • The version code of this retentive data block changes: – The data structure of the retentive local variables for the instances within the declaration block changes. – The sequence of the declaration blocks (VAR_GLOBAL / END_VAR) within the program source changes. • During downloading[2], the rule is: This data block is only initialized when the version code of a data block is changed[5]. • Functions for data backup and initialization take into account the version code of the data blocks.
	Non-retentive unit variables in the implementation section	

[1] Changed initialization values are not effective until the data block or data segment in question is initialized.

[2] If *Initialization of retentive program data and retentive global device variables* = No and *Initialization of non-retentive program data and non-retentive global device variables* = No.
In the case of other settings: See the sections "Initialization of retentive global variables (Page 4849)" and "Initialization of non-retentive global variables (Page 4851)".

[3] With the **SIMOTION ST** programming language:
A data block corresponds to a VAR_GLOBAL/END_VAR or VAR_GLOBAL RETAIN/END_VAR declaration block in the interface section or implementation section.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A data block of the non-retentive unit variables is formed as follows from the variables declared with VAR_GLOBAL or VAR_GLOBAL RETAIN in the interface section or implementation section of the declaration table: Pragma lines within a section of the declaration table separate the variables into different data blocks.

[4] The use of units depends on the programming language, refer to the relevant section (Page 4830).

[5] Initialization of a changed data block also occurs during a download in RUN mode, provided that the following condition is fulfilled:
With the **SIMOTION ST** programming language
The following attribute (Page 4917) has been specified within a pragma (Page 4922): { BlockInit_OnChange := TRUE; }.
With the **SIMOTION MCC** or **SIMOTION LAD/FBD** programming languages:
A pragma line is inserted in the declaration table with the following check box enabled in this line: *Initialization of VAR_GLOBAL during a change*. All the variables declared with VAR_GLOBAL up to the next pragma line or the end of the table form a data block accordingly.
For information on the general conditions for a download in RUN, see SIMOTION Basic Functions Function Manual.

Declaring variables in the Variable declaration dialog box ("on-the-fly" variable declaration)

You can declare a new variable in an ST source file without placing the cursor in the desired declaration block. For example, the cursor can remain at the code position in the body of a POU at which you want to use the new variable. You declare the variable "on-the fly" in the **Variable Declaration** dialog box.

Procedure

To define variables "on-the-fly" in the **Variable Declaration** dialog box, proceed as follows:

1. Place the cursor at the place of use of the new variable.
2. Optionally, enter the name of the new variable.

3. Select the **Variable declaration** context menu.
   The **Variable Declaration** dialog box appears.
   If necessary, the **Name** field is preassigned with the name of the new variable.

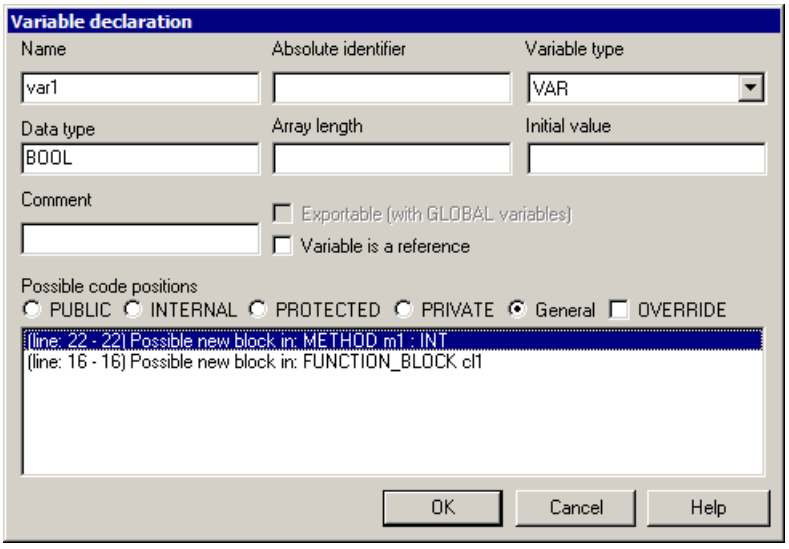

Figure 7-299 Variable Declaration dialog box

4. Make the other entries in the dialog box according to the following table.
5. Set the desired filter criteria according to the following table and select the desired code position.
6. Confirm with **OK**.

Principle

Table 7-454 Variable declaration parameter description

Field	Description
Name	Enter the name of the variable to be declared. The name must comply with the Rules for identifiers (Page 4656). The field is preassigned with the word in which the cursor is positioned when the window is called.
Absolute identifier	You define the variable as access to the fixed process image of the BackgroundTask (Page 4881) by entering an absolute identifier. The field is only active when a data type is selected that is contained in the general data types (Page 4674) ANY_BIT or ANY_INT. Enter the absolute identifier according to the syntax (Page 4888).
Variable type	Select the variable type. Available for selection are all permitted keywords for variable types (Page 4695). Default is VAR when the cursor is within a POU when the window is called, otherwise VAR_GLOBAL.
Data type	Enter the data type. You are supported by the "Automatic completion" (Page 4609) function (CTRL+space).

Field		Description
Array length		Not available when an absolute identifier is entered or the variable is a reference. You can define the variable as an array [0..N-1] by entering an array length N. You have the following options for entering the array length: • You can specify a constant positive integer value. • You can enter a value range with ".." separating the min. and max. values. • You can enter a constant expression of data type DINT (or of a data type which is implicitly convertible to DINT). If the array is empty, a single variable is created rather than an array.
Initial value		Not available when an absolute identifier is entered. You can specify this initialization value as a constant or as an expression. The following are permissible: • Constants • Arithmetic operations • Bit slice and data conversion functions
Comment		A comment can be entered in this column. All characters and special characters are permitted.
Exportable (for GLOBAL variables)		Only available when the keyword for a unit variable or unit constant has been selected as variable type (e.g. VAR_GLOBAL). If the checkbox is activated: • The variable declaration is inserted in the interface section of the ST source file. If the checkbox is deactivated: • The variable declaration is inserted in the implementation section of the ST source file.
Variable is a reference		Only available when a valid data type has been entered. With activated checkbox, a general reference (Page 4800) is created for the entered data type. The keyword REF_TO is set as prefix for the specified data type. The checkbox is activated automatically when the entered data type starts with the keyword REF_TO.
Possible code positions		
	Filter criteria	You can select the following as filter criteria: • An access identifier within classes, function blocks or namespaces – **PUBLIC** – **INTERNAL** – **PROTECTED** – **PRIVATE** – **General** (default, not an access identifier) • The keyword **OVERRIDE**.
	List of the code positions	A list of the possible code positions is displayed at which the variable can be declared. A distinction is made between: • Insertion in an existing variable block • Creation of a new variable block The first entry in the list is selected. In the editor window, the code position is displayed and selected at which the variable or the new variable block will be inserted. Select from the

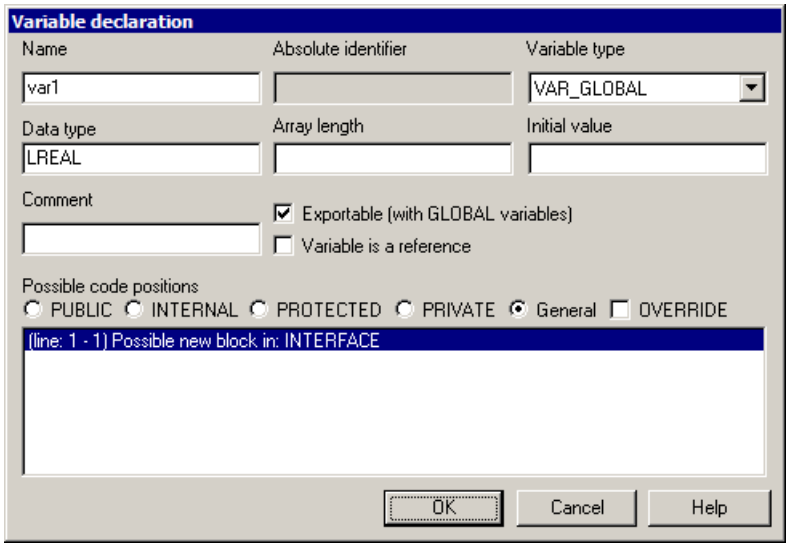

Figure 7-300 Example: Variable declaration

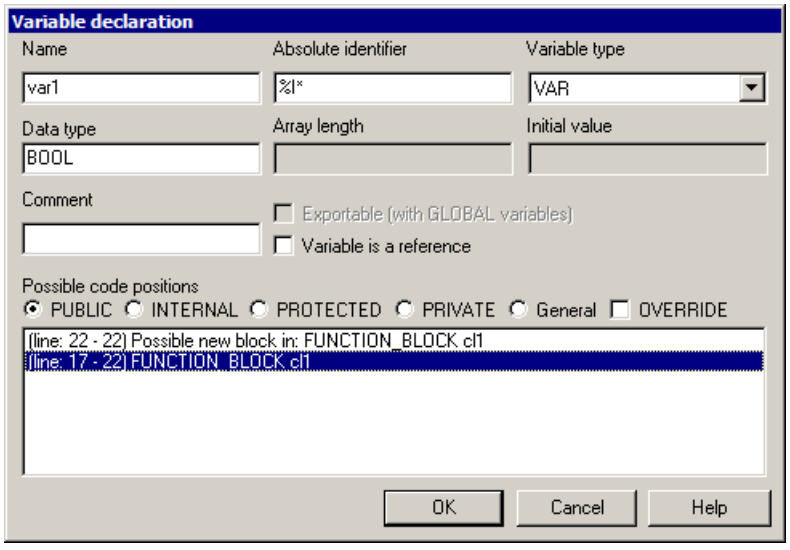

Figure 7-301 Example: Variable declaration (absolute name)

Result

The variable or the new variable block is inserted at the selected code position in the ST source file.

The cursor is at the same position before the dialog box was called.

Variables and HMI devices

Exported variables

The following variables are exported to HMI devices where they are available:

- System variables of the SIMOTION device
- System variables of technology objects
- I/O variables
- Global device variables
- Retentive and non-retentive unit variables of the interface section (default setting).
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes (Page 4922).
  - In the SIMOTION MCC and SIMOTION LAD/FBD programming languages:
    For the variable declarations following a pragma line, if you deactivate the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* parameters in this pragma line.

  The unit variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.
- Non-retentive static variables (VAR) of programs provided that the compiler option (Page 4623) "Only create program instance data once" is activated
- Non-retentive static variables (VAR) of function blocks
  This is the default setting when the compiler option (Page 4623) "Permit object-oriented programming" is enabled. Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes (Page 4922).

  The variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.
  The pragma is not evaluated if the compiler option "Permit object-oriented programming" is **not** activated. The export behavior cannot be changed.
- Non-retentive public variables (VAR PUBLIC) of classes (default setting, as of version V4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := FALSE; }`.
    See also Controlling compiler with attributes (Page 4922).

  The variables of a data block identified in this way are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.

Note

The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.

The effect of the `{ HMI_Export := FALSE; } / { HMI_Export := TRUE; }` pragma (or the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* settings in a pragma line) depends on the SIMOTION Kernel version:

- As of Version V4.1 of the SIMOTION Kernel:
  The pragma affects the export of the corresponding declaration block to HMI devices **and** the structure of the HMI address space:
  - Only those variables in declaration blocks exported to HMI devices occupy the HMI address space.
  - Within the HMI address space, the variables are arranged according to order of their declaration.
- Up to Version V4.0 of the SIMOTION Kernel:
  The pragma affects **only** the export of the corresponding declaration block to HMI devices. The HMI address space is also occupied by unit variables of the interface section whose declaration blocks are not assigned to HMI devices.
  Within the HMI address space, the variables are sorted in the following order:
  - Retentive unit variables of the interface section (exported and not exported).
  - Retentive unit variables of the implementation section (only exported).
  - Non-retentive unit variables of the interface section (exported and not exported).
  - Non-retentive unit variables of the implementation section (only exported).

  Within these segments, the variables are arranged according to order of their declaration.

Non-exported variables

The following variables are **not** exported to HMI devices and are **not** available there:

- Retentive and non-retentive unit variables of the implementation section (default setting)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`
    See also Controlling compiler with attributes (Page 4922).
  - In the SIMOTION MCC and SIMOTION LAD/FBD programming languages:
    For the variable declarations following a pragma line, if you activate the *VAR_GLOBAL for HMI devices* or *VAR_GLOBAL RETAIN for HMI devices* parameters in this pragma line.

  The unit variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
- Local variables (VAR, VAR_TEMP) of functions or methods
- Temporary variables (VAR_TEMP) of programs, function blocks or classes
- Retentive local variables (VAR RETAIN) of programs (as of version 4.5 of the SIMOTION Kernel)

- Retentive local variables (VAR RETAIN) of function blocks (as of version 4.5 of the SIMOTION Kernel)
  This is the default setting when the compiler option (Page 4623) "Permit object-oriented programming" is enabled. Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes (Page 4922).

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
  The pragma is not evaluated if the compiler option "Permit object-oriented programming" is **not** activated. The export behavior cannot be changed.
- Retentive local variables (VAR RETAIN) of classes (default setting, as of version 4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes (Page 4922).

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.
- Non-retentive static variables (VAR) of programs provided that the compiler option (Page 4623) "Only create program instance data once" is **not** activated
- Non-retentive protected or private variables (VAR, VAR PROTECTED, VAR PRIVATE) of classes (default setting, as of version V4.5 of the SIMOTION Kernel)
  Change this default as follows:
  - In the SIMOTION ST programming language:
    For each declaration block with the following pragma: `{ HMI_Export := TRUE; }`.
    See also Controlling compiler with attributes (Page 4922).

  The variables of a data block identified in this way are exported to HMI devices. Consequently, they undergo the HMI consistency check during downloading.

Example for the SIMOTION ST programming language

Table 7-455 Example for the control of the HMI export with the corresponding pragma

```
INTERFACE
    VAR_GLOBAL
        // HMI export
        x1 : DINT;
    END_VAR
    VAR_GLOBAL
        { HMI_Export := FALSE; }
        // No HMI export
        x2 : DINT;
    END_VAR
    // ...
END_INTERFACE

IMPLEMENTATION
    VAR_GLOBAL
        // No HMI export
        y1 : DINT;
    END_VAR
    VAR_GLOBAL
        { HMI_Export := TRUE; }
        // HMI export
        y2 : DINT;
    END_VAR
    // ...
END_IMPLEMENTATION
```

7.2.7.3 Access to inputs and outputs (process image, I/O variables)

Overview of access to inputs and outputs

SIMOTION provides several possibilities to access the device inputs and outputs of the SIMOTION device as well as the central and distributed I/O:

- Via direct access with I/O variables
  Direct access is used to access the corresponding I/O address directly.
  Define an I/O variable (name and I/O address) without assigning a task to it. The entire address space of the SIMOTION device can be used.
  It is preferable to use direct access with sequential programming (in MotionTasks); access to current input and output values at a particular point in time is especially important in this case.
  Further information: Direct access and process image of the cyclic tasks (Page 4872).
- Via the process image of cyclic tasks using I/O variables
  The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming).
  Define an I/O variable (name and I/O address) and assign a task to it. The entire address range of the SIMOTION device can be used.
  Direct access to this I/O variable is still possible: Specify direct access with *_direct.var-name*.
  Further information: Direct access and process image of the cyclic tasks (Page 4872).
- Using the fixed process image of the BackgroundTask
  The process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device, on which a subset of the I/O address space of the SIMOTION device is mirrored. The mirror image is refreshed with the BackgroundTask and is consistent throughout the entire cycle. This process image is used preferentially when programming the BackgroundTask (cyclic programming).
  The address range 0 .. 63 can be used. Exception: I/O addresses that are accessed using the process image of the cyclic task can only be used with the setting “Common process image” (Page 4883) (as of Kernel V4.2).
  Further information: Access to the fixed process image of the BackgroundTask (Page 4881).

A comparison of the most important properties is contained in "Important properties of direct access and process image" (Page 4869).

You can use I/O variables like any other variable, see "Access I/O variables" (Page 4892).

Note

An access via the process image is more efficient than direct access.

Important features of direct access and process image access

Table 7-456 Important properties of direct access and process image access

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
Permissible address range	Entire address range of the SIMOTION device **Exception**: I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously (example: PIW63 or PQD62 are not permitted).		Addresses 0 .. 63. **Exception**: Up to version V4.1 of the SIMOTION Kernel or the "Separate process image" setting, addresses used for the process image of the cyclic tasks are not permitted.
Address configuration	Necessary. The addresses used must be present in the I/O and appropriately configured. The "Rules for I/O addresses for direct access and the process image of the cyclic tasks" (Page 4875) must be observed.		Not necessary. Addresses that are not present in the I/O or have not been configured can also be used.
Assigned task	None.	Cyclic task for selection: • SynchronousTasks, • TimerInterruptTasks, • BackgroundTask.	BackgroundTask.
Memory area for process images	-	Depends on the SIMOTON Kernel version: • Up to version V4.1: Separate memory areas in all cases • As of version V4.2: Option to select a common memory area	

	Direct access	**Access to process image of cyclic tasks**	**Access to fixed process image of the BackgroundTask**
Update	• Onboard I/O of SIMOTION devices C230-2, C240, and C240 PN: Update occurs in a cycle clock of 125 µs. • With I/O devices – via PROFIBUS DP or PROFINET on an isochronous SIMOTION device[1] – via DRIVE-CLiQ – Onboard I/O of SIMOTION D devices: The update is performed in the position control cycle clock[2]. • With I/O devices – via PROFIBUS DP or PROFINET on a **non**-isochronous SIMOTION device[1] – via P-Bus: The update is performed in the interpolation cycle[2 3]. Inputs are read at the start of the cycle clock. Outputs are written at the end of the cycle clock.	Update occurs with the assigned task: • Inputs are read before the assigned task is started and transferred to the process input image. • Process output image is written to the outputs after the assigned task has been completed.	An update is made with the *BackgroundTask*: • Inputs are read before the *BackgroundTask* is started and is transferred to the process input image. • Process output image is written to the outputs when the *BackgroundTask* is complete.
Consistency	–	During the entire cycle of the assigned task. **Exception**: Direct access to output occurs.	During the entire cycle of the *BackgroundTask*. **Exception**: Direct access to output occurs.
	Consistency is only ensured for elementary data types. When using arrays, the user is responsible for ensuring data consistency.		
Use	Preferred in MotionTasks	Preferred in the assigned task	Preferred in the BackgroundTask
Declaration as variable	Necessary, for the entire device as an I/O variable in the symbol browser. Each byte of the address range may only be assigned to a single I/O variable. Syntax of I/O address: e.g. PIW1022, PQ63.3.		Possible, but not necessary: • For the entire device as I/O variable in the symbol browser • As unit variable • As local static variable in a program
Download of new or changed I/O variables	Only possible in STOP mode.		-
Use the absolute address	Not supported.		Possible, with the following syntax: E.g. %IW62, %Q63.3.

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
Byte order when forming the process image	-	As supplied by the I/O	Depends on the SIMOTION Kernel version and the memory area setting for the process images: • Up to version V4.1 or the "Separate process image" setting: Always Big Endian • As of version V4.2 and the "Common process image" setting: As supplied by the I/O
Byte order during access	Depends on I/O		Always Big Endian
Writeability of inputs	No	Depends on the SIMOTION Kernel version: • Up to version V4.1: No • As of version V4.2: Yes	Yes
Write protection for outputs	Possible; **Read only** status can be selected.	Not supported.	Not supported.
Declaration of arrays	Possible.		Not supported.
Further information	Direct access and process image of the cyclic tasks (Page 4872).		Access to the fixed process image of the BackgroundTask (Page 4881).
Responses in the event of an error	Error during access from user program, alternative reactions available: • CPU Stop[4] • Substitute value • Last value See SIMOTION Basic Functions Description of Functions.	Error during generation of process image, alternative reactions available: • CPU stop[5] • Substitute value • Last value See SIMOTION Basic Functions Description of Functions.	Error during generation of process image, reaction: CPU stop[5] **Exception**: If a direct access has been created at the same address, the behavior set there applies.
Access			
• In the RUN operating state	Without any restrictions.	Without any restrictions.	Without any restrictions.
• During the StartupTask	Possible with restrictions: • Inputs can be read. • Outputs are not written until StartupTask is complete.	Possible with restrictions: • Inputs are read at the start of the StartupTask. • Outputs are not written until StartupTask is complete.	Possible with restrictions: • Inputs are read at the start of the StartupTask. • Outputs are not written until StartupTask is complete.

	Direct access	Access to process image of cyclic tasks	Access to fixed process image of the BackgroundTask
• During the ShutdownTask	Without any restrictions.	Possible with restrictions: • Inputs retain status of last update • Outputs are no longer written.	Possible with restrictions: • Inputs retain status of last update • Outputs are no longer written.

[1] A SIMOTION device is considered isochronous if at least one PROFIBUS DP or PROFINET interface is operated isochronously (constant bus cycle time). For SIMOTION D there is an exception with the DP Integrated interface to which the SINAMICS Integrated is connected.

[2]The following SIMOTION devices are updated in the Servo_fast cycle or IPO_fast cycle, if the cycles are configured: D445-2 DP/PN, D455-2 DP/PN (as of version V4.2) and D435-2 DP/PN (as of version V4.3).

3 IPO or IPO_2 adjustable, see “Setting system cycle clocks" section in the Basic Functions Function Manual.

[4] Call the ExecutionFaultTask.

[5] Call the PeripheralFaultTask.

Direct access and process image of cyclic tasks

Property

Direct access to inputs and outputs and access to the process image of the cyclic task always take place via I/O variables. The entire address range of the SIMOTION device (Page 4874) can be used.

A comparison of the most important properties, including in comparison to the fixed process image of the BackgroundTask (Page 4881) is contained in "Important properties of direct access and process image" (Page 4869).

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4875).

It is particularly important that every address used in an I/O variable is available in the I/O and configured; each byte in the address range may be assigned to no more than one I/O variable (does not apply to access with data type BOOL).

A detailed status of I/O variables (Page 4879) can be read as of version V4.2 of the SIMOTION Kernel, for example, in order to check the availability of the I/O variables.

Direct access

Direct access is used to access the corresponding I/O address directly. Direct access is used primarily for sequential programming (in MotionTasks). The access to the current value of the inputs and outputs at a specific time is particularly important.

For direct access, you define an I/O variable (Page 4876) without assigning it a task.

Process image of the cyclic task

The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming). The consistency during the complete cycle of the task is particularly important.

For the process image of the cyclical task you define an I/O variable (Page 4876) and assign it a task.

Direct access to this I/O variable is still possible: Specify direct access with *_direct.var-name*.

Note

An access via the process image is more efficient than direct access.

Additional properties as of version V4.2 of the SIMOTION Kernel

As of version V4.2 of the SIMOTION Kernel, direct access to inputs/outputs and the process image of the cyclic tasks offers additional properties:

- As far as the process image of the cyclic tasks is concerned, a common memory area with the fixed process image of the BackgroundTask can be set (standard with newly created devices)
- As far as the process image of the cyclic tasks is concerned, I/O variables for inputs can be written to (i.e. they can be assigned values).
- A detailed status of I/O variables (Page 4879) can be read, for example, in order to check the availability of the I/O variables.

Memory area with the fixed process image of the BackgroundTask

- **As of version V4.2 of the SIMOTION Kernel**, selecting a "Common process image" setting on the device (Page 4929) ensures the memory area for the fixed process image of the BackgroundTask is a subset of the memory area for the process image of the cyclic tasks.
- **Up to version V4.1 of the SIMOTION Kernel** or the "Separate process image" setting on the device (as of version V4.2 of the SIMOTION Kernel), the fixed process image of the BackgroundTask and the process image of the cyclic tasks occupy different memory areas.

Note

If (and only if) you are also using the fixed process image of the BackgroundTask, it is important to consider the effects of the "Common process image" or "Separate process image" settings on the fixed process image of the BackgroundTask (Page 4881).

Table 7-457 Effect of "Common process image" or "Separate process image" settings on the process image of the cyclic tasks

	Common process image	Separate process image
Availability	Only available as of version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard for newly created devices	Up to version V4.1 of the SIMOTION Kernel applies: • System characteristic, not configurable. The following applies as of version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard with device upgrades
Download of new or changed I/O variables	Only possible in STOP mode.	Only possible in STOP mode.
Byte order when forming the process image and during access	Depends on connected I/O	
Effects on the fixed process image of the BackgroundTask	See the relevant table in "Access to the fixed process image of the BackgroundTask" (Page 4882).	
Further information	Common process image (Page 4883)	Separate process image (Page 4885)

Address range of the SIMOTION devices

The address range of the SIMOTION devices is specified in the following table according to the version of the SIMOTION Kernel concerned. The complete address range can be used for direct access and process image of the cyclical tasks.

Table 7-458 Address range of the SIMOTION devices according to the version of the SIMOTION Kernel

SIMOTION device	Address range for SIMOTION Kernel version					
	V3.2	V4.0	V4.1	4.2	V4.3	As of V4.4
C230-2	0 .. 2047 [3]	0 .. 2047 [3]	0 .. 2047 [3]	–	–	–
C240	–	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]
C240 PN [1]	–	–	0 .. 4095 [4]	0 .. 4095 [4]	0 .. 4095 [4]	0 .. 4095 [4]
D410 DP	–	–	0 .. 8191 [3]	0 .. 8191 [3]	0 .. 8191 [3]	–
D410 PN	–	–	0 .. 8191 [4]	0 .. 8191 [4]	0 .. 8191 [4]	–
D410-2	–	–	–	–	0 .. 8191 [3 4]	0 .. 8191 [3 4]
D425	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D425-2	–	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D435	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D435-2	–	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D445	0 .. 4095 [3]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–	–
D445-1 [1]	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]	–
D445-2	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]
D455-2	–	–	–	0 .. 16383 [3 4]	0 .. 16383 [3 4]	0 .. 16383 [3 4]
P320 [2]	–	–	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	–

SIMOTION device	Address range for SIMOTION Kernel version					
	V3.2	V4.0	V4.1	4.2	V4.3	As of V4.4
P320-4	–	–	–	–	–	0 .. 4095 [3]
P350	0 .. 2047 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	0 .. 4095 [3]	–

[1] Available as of V4.1 SP2 HF4

[2] Available as of V4.1 SP5

[3] For distributed I/O (over PROFIBUS DP), the transmission volume is restricted to 1024 bytes per PROFIBUS DP line.

[4] For distributed I/O (over PROFINET), the transmission volume is restricted to 4,096 bytes per PROFINET segment.

Rules for I/O addresses for direct access and the process image of the cyclical tasks

Note

You must observe the following rules for the I/O variable addresses for direct access and the process image of the cyclic task (Page 4872). Compliance with the rules is checked during the consistency check of the SIMOTION project (e.g. during the download).

1. Addresses used for I/O variables must be present in the I/O and configured appropriately in the HW Config.
2. I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously.
   The following I/O addresses are not permitted:
   - Inputs: PIW63, PID61, PID62, PID63
   - Outputs: PQW63, PQD61, PQD62, PQD63
3. All addresses of an I/O variable comprising more than one byte (e.g. WORD, ARRAY data type) must be within a continuous address range configured in HW Config, e.g. within the address range (slot or subslot) of *one* I/O module.
4. An I/O address (input or output) can only be used by a single I/O variable of data type BYTE, WORD or DWORD or an array of these data types. Access to individual bits with I/O variables of data type BOOL is possible.
5. If several processes (e.g. I/O variable, technology object, PROFIdrive telegram) access an I/O address, the following applies:
   - Only a single process can have write access to an I/O address of an output (BYTE, WORD or DWORD data type).
     Read access to an output with an I/O variable that is used by another process for write access, is possible.
   - All processes must use the same data type (BYTE, WORD, DWORD or ARRAY of these data types) to access this I/O address. Access to individual bits is possible irrespective of this. Please be aware of the following, for example, if you wish to use an I/O variable to read the PROFIdrive telegram transferred to or from the drive: The length of the I/O variable must match the length of the telegram.
   - Write access to different bits of an address is possible from several processes; however, write access with the data types BYTE, WORD or DWORD is then not possible.

Note

These rules do not apply to accesses to the fixed process image of the BackgroundTask (Page 4881). These accesses are not taken into account during the consistency check of the project (e.g. during download).

Creating I/O variables for direct access or process image of cyclic tasks

Create I/O variables for direct access or a process image of the cyclic tasks in the address list of the detail view.

This is only possible in offline mode.

Here is a brief overview of the procedure:

1. Select the "Address list" tab in the detail view and choose the SIMOTION device
   or
   In the project navigator of SIMOTION SCOUT, double-click the "ADDRESS LIST" element in the SIMOTION device subtree.
2. Select the line before which you want to insert the I/O variable and, from the context menu, select **Insert new line**
   or
   Scroll to the end of the table of variables (empty line).
3. In the empty row of the table, enter or select the following:
   - Names of the **I/O variables**
   - **I/O address**
     Select the "IN" or "OUT" entries if you wish to assign symbols to the I/O variable (input or output). As of Version V4.2 of the SIMOTION Kernel the symbolic assignment must be activated, menu **Project > Use symbolic assignment**.
     Or enter a fixed address according to "Syntax for entering I/O addresses" (Page 4878).
   - Optional for outputs:
     Activate the **Read only** checkbox if you only want to have read access to the output. You can then read an output that is already being written by another process (e.g. output of an output cam, PROFIdrive telegram).
     A read-only output variable cannot be assigned to the process image of a cyclic task.
   - **Data type** of the variables in accordance with "Possible data types of the I/O variables" (Page 4879).

4. Optionally, you can also enter or select the following (not for data type BOOL):
   - **Array length** (array size).
   - **Process image** or direct access:
     Can only be assigned if the **Read only** checkbox is deactivated.
     For process image, select the cyclic task to which you want to assign the I/O variable. To select a task, it must have been activated in the execution system.
     For direct access, select the blank entry.
   - **Strategy** for behavior in the event of an error, see SIMOTION Basic Functions Function Manual.
   - **Display format** (if array, for each element), when you monitor the variable in the address list
   - **Substitute value** (if array, for each element).
5. Only if you have selected "IN" or "OUT" as the I/O address (symbolic assignment).
   - In the **Assignment** column, click the **[...]** button.
     A window opens displaying the possible assignment targets of the SIMOTION device and, if necessary, of SINAMICS Integrated. Only those assignment targets are displayed that match the data direction (input/output) and data type.
   - Select the assignment target.
     The **Assignment status** column indicates whether the assignment was successful or not.

   For details regarding symbolic assignment, refer to the SIMOTION Basic Functions Function Manual.

You can now access this variable using the address list or any program of the SIMOTION device.

Details on how to manage the address list can be found in the online help.

Note

Note the following for the process image for cyclic tasks:

- A variable can only be assigned to one task.
- Each byte of an input or output can only be assigned to one I/O variable.

In the case of data type BOOL, please note:

- The process image for cyclic tasks and a strategy for errors cannot be defined. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access or CPU stop).
- The individual bits of an I/O variable can also be accessed using the bit access functions.

Take care when making changes within the I/O variables (e.g. inserting and deleting I/O variables, changing names and addresses):

- In some cases the internal addressing of other I/O variables may change, making all I/O variables inconsistent.
- If this happens, all program sources that contain accesses to I/O variables must be recompiled.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and then use them in your program sources (e.g. ST sources, MCC sources, LAD/FBD sources).

Outputs can be read and written to, but inputs can only be read.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables" (Page 4892).

Syntax for entering I/O addresses

Syntax

For the input of the I/O address for the definition of an I/O variable for direct access or process image of cyclical tasks (Page 4872), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

Table 7-459 Syntax for the input of the I/O addresses for direct access or process image of the cyclic tasks

Data type	Syntax for		Permissible address range					
	Input	Output	Direct access		Process image		e.g. direct access D435 V4.1	
BOOL	PIn.x	PQn.x	n: x:	0 .. *MaxAddr* 0 .. 7		-[1]	n: x:	0 .. 16383 0 .. 7
BYTE	PIBn	PQBn	n:	0 .. *MaxAddr*	n:	0 .. *MaxAddr*	n:	0 .. 16383
WORD	PIWn	PQWn	n:	0 .. 62 64 .. *MaxAddr* - 1	n:	0 .. 62 64 .. *MaxAddr* - 1	n:	0 .. 62 64 .. 16382
DWORD	PIDn	PQDn	n:	0 .. 60 64 .. *MaxAddr* - 3	n:	0 .. 60 64 .. *MaxAddr* - 3	n:	0 .. 60 64 .. 16380
n = logical address x = bit number								
MaxAddr =	Maximum I/O address of the SIMOTION device depending on the SIMOTION Kernel version, see Address range of the SIMOTION devices (Page 4874).							
[1] For data type BOOL, it is not possible to define the process image for cyclic tasks. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access).								

Examples

Input at logic address 1022, WORD data type: **PIW1022**.

Output at logical address 63, bit 3, BOOL data type: **PQ63.3**.

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4875).

Possible data types of I/O variables

The following data types can be assigned to the I/O variables for direct access and process image of the cyclical tasks (Page 4872). The width of the data type must correspond to the data type width of the I/O address.

If you assign a numeric data type to the I/O variables, you can access these variables as integer.

Table 7-460 Possible data types of the I/O variables for direct access and the process image of the cyclical tasks

Data type of I/O address	Possible data types for I/O variables
BOOL (PIn.x, PQn.x)	BOOL
BYTE (PIBn, PQBn)	BYTE, SINT, USINT
WORD (PIWn, PQWn)	WORD, INT, UINT
DWORD (PIDn, PQDn)	DWORD, DINT, UDINT

For details of the data type of the I/O address, see also "Syntax for entering I/O addresses" (Page 4878).

Detailed status of the I/O variables (as of Kernel V4.2)

As of version V4.2 of the SIMOTION Kernel, the status of an I/O variable can be queried using *_quality.var-name*, for example, in order to check the availability of the I/O variables. It is supplied as an OR logic operation of the following status values in the DWORD data type and can be assigned to an appropriate variable, for example. The value 16#0000_0000 indicates the connected I/O are operating without error.

The same value is supplied for every I/O variable within an address range (slot or subslot) configured in HW Config.

Table 7-461 Meanings of status values of I/O variables

Value (DWORD)	Bit x = 1	Meaning
16#0000_0000	-	No error occurred.
16#0000_0001	0	**Maintenance required** The connected module signals that it requires maintenance. The component needs to be checked within a foreseeable period (e.g. the printer cartridge must be changed within a period of several days).
16#0000_0002	1	**Maintenance demanded** The connected module demands maintenance. The component needs to be checked soon (e.g. the printer cartridge must be changed immediately).
16#0000_0004	2	**Warning pending** (drive warning, TM17 warning, etc.) The connected module has signaled a warning. This has been entered in the diagnostics buffer. The precise cause can be determined from the documentation for the relevant module.
16#0000_0008	3	**Fault pending** (diagnostic interrupt, drive fault, TM17 fault, etc.) The connected module has signaled an error. This has been entered in the diagnostics buffer. The precise cause can be determined from the documentation for the relevant module.

Value (DWORD)	Bit x = 1	Meaning
16#0000_0010	4	**This parameter assignment does not match the parameter assignment being compared.** A difference was detected when this parameter assignment was compared with the parameter assignment of the connected module. As such, the required functionality cannot be guaranteed. Remedy: Save the project and compile changes, reload both application and counterpart.
16#0000_0020	5	**Application and counterpart are not isochronous** (error involving the dynamic life-sign). Certain telegrams (axis, synchronous operation, output cam, measuring input telegrams) are synchronized by exchanging cyclic life-signs. Errors are detected when the cyclic life-sign is checked. This invalidates the data in the telegram. Remedy: Await synchronization, check the parameter assignment (e.g. does the master application cycle set on the device in HW Config match the position control cycle clock), save the project and compile changes, reload both application and counterpart.
16#0000_0040	6	**I/O cannot be used synchronously in all cycles.** A fast application cycle (Servo_fast) and a slow application cycle (Servo) are running asynchronously in relation to one another. The I/O can only be used synchronously in the cycles associated with the bus cycle. Access from other cycles is asynchronous and inconsistent. Remedy: Call the _synchronizeDpInterfaces() function.
16#0000_0080	7	**I/O cannot be used synchronously** The SIMOTION control is the sync slave on a bus. The bus connection is running synchronously in relation to the sync master, but is not yet running synchronously in relation to the application cycles of the SIMOTION control. Access to the I/O is asynchronous and inconsistent. Remedy: Call the _synchronizeDpInterfaces() function.
16#0000_0100	8	**Bus connection (sync slave) is not isochronous in relation to the sync master.** The SIMOTION control is the sync slave on a bus and has not yet synchronized its bus connection with the sync master. The isochronous I/O on this bus cannot be used yet. Remedy: Switch on/connect the sync master.
16#0000_0200	9	**DP station is deactivated.** The partner module has been deactivated. Remedy: Activate the partner module (_activateDpSlave() function).
16#0000_0400	10	**The partner of the inputs (e.g. I-device, I-slave) is in STOP.** The connected module is in STOP mode and not sending any new data as a result. Remedy: Switch the connected module to RUN.
16#0000_0800	11	**PROFINET: Failure detected by submodule** (e.g. channel error) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0000_1000	12	**PROFINET: Failure detected by module** (e.g. submodule failed, removed, etc.) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0000_2000	13	**PROFINET: Failure detected by device** (e.g. device in STOP, module removed, etc.) The connection to the connected device is OK. The error must be searched for in the connected device. Troubleshooting: Diagnostics buffer, device diagnostics with HW Config

Value (DWORD)	Bit x = 1	Meaning
16#0000_4000	14	**PROFINET: Failure detected by controller** (e.g. not connected, etc.) There is no connection to a partner on PROFINET. Possible cause: Partner is switched off, cable pulled out, incorrect parameter assignment for connection Troubleshooting: Best to use the PROFINET topology editor in HW Config.
16#0000_8000	15	**Slot/subslot is not connected** (disconnection alarm). The connection to the connected device is OK. The error must be searched for in the connected device (e.g. module/submodule removed). Troubleshooting: Diagnostics buffer, device diagnostics with HW Config
16#0001_0000	16	**Device is not connected** (station failure). There is no connection to a partner. Possible cause: Partner is switched off, cable pulled out.
16#0002_0000	17	**Substitute value behavior during access** There is no connection to the counterpart (sum signal from bits 9 to 16), i.e. there is no valid input data or the output data is not reaching the terminal. The substitute value behavior set (substitute value, last value) takes effect during direct access to this address or during process image updates.
16#4000_0000	30	**Diagnostics address only** No cyclic I/O data is configured for this address. It is possible, however, to query submodule diagnostic information.
16#8000_0000	31	**Address gap** There is no hardware configured for this logical address.

Access to fixed process image of the BackgroundTask

The fixed process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device on which a subset of the I/O address space of the SIMOTION device is mirrored. Preferably, it should be used for programming the BackgroundTask (cyclic programming) as it is consistent throughout the entire cycle.

The size of the fixed process image of the BackgroundTask for all SIMOTION devices is 64 bytes (address range 0 .. 63).

Note

The fixed process image of the BackgroundTask can be used to access addresses that are not available in the I/O or not configured in HW Config. These are treated like normal memory addresses.

Memory area

- **As of Version V4.2 of the SIMOTION Kernel**, selecting a "Common process image" setting on the device (Page 4929) ensures the memory area for the fixed process image of the BackgroundTask is a subset of the memory area for the process image of the cyclic tasks. I/O addresses can be read and written to using both the fixed process image of the BackgroundTask and the process image of the cyclic tasks.
- **With Version V4.1 and lower of the SIMOTION Kernel** or the "Separate process image" setting on the device (as of Version V4.2 of the SIMOTION Kernel), the fixed process image of the BackgroundTask and the process image of the cyclic tasks occupy different memory areas. I/O addresses accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask. They are treated like normal memory addresses.

Table 7-462 Effect of "Common process image" or "Separate process image" settings on the fixed process image of the BackgroundTask

	Common process image	Separate process image
Availability	Only available as of Version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard for newly created devices	Version V4.1 and lower of the SIMOTION Kernel applies: • System characteristic, not configurable The following applies as of Version V4.2 of the SIMOTION Kernel: • Setting available for selection • Standard with device upgrades
Memory area	Subset of the memory area for the process image of the cyclic tasks	Separate memory area for the process image of the cyclic tasks
Using I/O addresses accessed using the process image of the cyclic tasks	Possible. Updates use the configured cyclic tasks.	Not supported. The addresses are treated like normal memory addresses.
Byte order when forming the process image	As supplied by the I/O	Always Big Endian
Byte order when accessing the process image	Always Big Endian	Always Big Endian
Access to I/O operating in the Little Endian byte order	Same result as during direct access or for the process image of cyclic tasks (apart from WORD or DWORD data types).	Results differ depending on the I/O variables created for direct access.
Effects on the process image of the cyclic tasks	See the relevant table in "Direct access and process image of the cyclic tasks (Page 4874)".	
Further information	Common process image (Page 4883)	Separate process image (Page 4885)

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

A comparison of the most important properties in comparison to the direct access and process image of the cyclic tasks (Page 4872) is contained in "Important properties of direct access and process image" (Page 4869).

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4875) do **not** apply. Access to the fixed process image of the BackgroundTask is not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

You can access the fixed process image of the BackgroundTask by means of:

- Using an absolute PI access (Page 4887): The absolute PI access identifier contains the address of the input/output and the data type.
- Using a symbolic PI access (Page 4889): You declare a variable that references the relevant absolute PI access:
  - A unit variable
  - A static local variable in a program.
- Using an I/O variable (Page 4891): In the symbol browser, you define a valid I/O variable for the entire device that references the corresponding absolute PI access.

Common process image (as of Kernel V4.2)

As of Version V4.2 of the SIMOTION Kernel, the "Common process image" setting (Page 4929) can be selected on the SIMOTION device. This means addresses 0 .. 63 of the process image of the cyclic tasks and the fixed process image of the BackgroundTask occupy the same memory area.

This is the default for SIMOTION devices newly created in the project as of Version V4.2.

Property of the common process image

1. The memory area for the fixed process image of the BackgroundTask (Page 4881) is a subset of the memory area for the process image of the cyclic tasks (Page 4872).
2. This means I/O addresses already accessed using the process image of the cyclic tasks may also continue to be used for the fixed process image of the BackgroundTask. Updates, however, use the configured cyclic tasks.
3. The following applies when forming the fixed process image of the BackgroundTask: The byte order is the same as supplied by the I/O:
   - Big Endian, e.g. for I/O via PROFIBUS DP, PROFINET, P-Bus, DRIVE-CLiQ
   - Little Endian, e.g. for onboard I/O of C240, C240 PN SIMOTION devices

   Any I/O variable created for the relevant addresses for the purpose of direct access or the process image of the cyclic tasks has no effect on the byte order.

4. Access to the fixed process image of the BackgroundTask always takes place using the Big Endian byte order.
5. These last two properties (nos. 3 and 4) affect access to inputs and outputs operating with the Little Endian byte order (e.g. onboard I/O of C240, C240 PN SIMOTION devices).
   If the fixed process image of the BackgroundTask is used for access, this leads to the following behavior, regardless of whether I/O variables have been created for the relevant addresses for the purpose of direct access or the process image of the cyclic tasks:
   - Access to individual bytes always supplies the same result via an I/O variable or the fixed process image of the BackgroundTask.
   - With the fixed process image of the BackgroundTask, bytes only change places if data type WORD is used for access.

   Please also refer to the example below.

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

Example for common process image: Access to I/O operating with the Little Endian byte order

The digital inputs of the C240 SIMOTION device operate with the Little Endian byte order and occupy addresses 66 (bits 0 ..7) and 67 (bits 0.. 3) by default. The start address is changed to 60 in HW Config to ensure it is in the range occupied by the fixed process image of the BackgroundTask. Addresses 60 and 61 are now accessed using various I/O variables and the process image of the BackgroundTask.

The following three scenarios are considered, which differ in terms of whether and which I/O variables are created for direct access or the process image of the cyclic tasks:

1. Scenario A:
   No I/O variables are created for addresses 60 and 61.
2. Scenario B:
   Two I/O variables with data type BYTE are created for addresses 60 and 61: io_byte_60 (PIB60) and io_byte_61 (PIB61).
3. Scenario C:
   For adresss 60, **one I/O-Variable** with data type WORD is created; this also covers address 61: io_word_60 (PIW60).

Two additional I/O variables are also created in each of the three scenarios, making it possible to access bit 3: io_bit_60_3 (PI60.3) and io_bit_61_3 (PI61.3).

The table below lists which values are generated with the following access types:

- Direct access or access to the process image of the cyclic tasks:
  - Access to individual bytes or the word using the relevant I/O variables
  - Access to each individual byte using the _getInOutByte function (direct access only)
  - Access to the respective bit 3 using the relevant I/O variables
- Access to the fixed process image of the BackgroundTask:
  - Access to individual bytes using an absolute name
  - Access to the word using an absolute name
  - Access to the respective bit 3 using an absolute name

Table 7-463 "Common process image" setting (as of Kernel V4.2): Different types of access to the process images of an input operating with the Little Endian byte order

	Access using	**Scenario A** [1]	**Scenario B** [1]	**Scenario C** [1]
Direct access or access to the process image of the cyclic tasks	io_byte_60 (PIB60)	-	16#08	-
	io_byte_61 (PIB61)	-	16#00	-
	io_word_60 (PIW60)	-	-	16#0008
	_getInOutByte (IN, 60)	16#08	16#08	16#08
	_getInOutByte (IN, 61)	16#00	16#00	16#00
	io_bit_60_3 (PI60.3)	TRUE	TRUE	TRUE
	io_bit_61_3 (PI61.3)	FALSE	FALSE	FALSE
Access to the fixed process image of the BackgroundTask	%IB60	16#08	16#08	16#08
	%IB61	16#00	16#00	16#00
	%IW60	**16#0800** [2]	**16#0800** [2]	**16#0800** [2]
	%I60.3	TRUE	TRUE	TRUE
	%I61.3	FALSE	FALSE	FALSE

[1] Scenarios A, B, or C determine whether and which I/O variables are created for direct access or the process image of the cyclic tasks; see the explanation provided in the body of the document.

[2] The two bytes in the word change places, as a value saved in the Little Endian byte order is being read using Big Endian.

Separate process image (up to Kernel V4.1)

With Version V4.1 and below of the SIMOTION Kernel, the process image of the cyclic task and the fixed process image of the BackgroundTask are stored in different memory areas (separate process image).

As of Version V4.2 of the SIMOTION Kernel, the "Separate process image" setting (Page 4929) can be selected on the SIMOTION device. This setting ensures there is compatibility with earlier Kernel versions.

It is the default for SIMOTION devices upgraded to Version V4.2 or higher.

Property of the separate process image

1. The fixed process image of the BackgroundTask (Page 4881) and the process image of the cyclic tasks (Page 4872) are stored in different memory areas.
2. This means I/O addresses that are already accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask. They are treated like normal memory addresses.
3. I/O variables for direct access influence the fixed process image of the BackgroundTask:
   – The fixed process image of the BackgroundTask is always formed for the relevant addresses in the Big Endian byte order.
4. Access to the fixed process image of the BackgroundTask always takes place using the Big Endian byte order.
5. These last two properties (nos. 3 and 4) affect access to inputs and outputs operating with the Little Endian byte order (e.g. onboard I/O of C230-2, C240, C240 PN SIMOTION devices). If an I/O variable is created for the relevant addresses for the purpose of direct access using data type WORD and access takes place using the fixed process image of the BackgroundTask, this leads to the following behavior:
   – Access with the data type WORD supplies the same result via the I/O variable and the fixed process image of the BackgroundTask.
   – Access to individual bytes using the _getInOutByte function (see SIMOTION Basic Functions Function Manual) supplies these in the Little Endian order.
   – Access to the individual bytes or bits with the fixed process image of the BackgroundTask supplies these in the Big Endian order.

   Please also refer to the example below.

For information on the order of the Little Endian and Big Endian bytes, please refer to the SIMOTION Basic Functions Function Manual.

Example for separate process image: Access to I/O operating with the Little Endian byte order

The digital inputs of the C240 SIMOTION device operate with the Little Endian byte order and occupy addresses 66 (bits 0 ..7) and 67 (bits 0.. 3) by default. The start address is changed to 60 in HW Config to ensure it is in the range occupied by the fixed process image of the BackgroundTask. Addresses 60 and 61 are now accessed using various I/O variables and the process image of the BackgroundTask.

The following three scenarios are considered, which differ in terms of whether and which I/O variables are created for direct access:

1. Scenario A:
   No I/O variables are created for addresses 60 and 61.
2. Scenario B:
   Two I/O variables with data type BYTE are created for addresses 60 and 61: io_byte_60 (PIB60) and io_byte_61 (PIB61).
3. Scenario C:
   For adresss 60, **one I/O-Variable** with data type WORD is created; this also covers address 61: io_word_60 (PIW60).

Two additional I/O variables are also created in each of the three scenarios, making it possible to access bit 3: io_bit_60_3 (PI60.3) and io_bit_61_3 (PI61.3).

The table below lists which values are generated with the following access types:

- Direct access:
  - Access to individual bytes or the word using the relevant I/O variables
  - Access to each individual byte using the _getInOutByte (Page 4872) function
  - Access to the respective bit 3 using the relevant I/O variables
- Access to the fixed process image of the BackgroundTask:
  - Access to individual bytes using an absolute name
  - Access to the word using an absolute name
  - Access to the respective bit 3 using an absolute name

Table 7-464 "Separate process image" setting or Kernel up to Version V4.1: Different types of access to the process images of an input operating with the Little Endian byte order

	Access using	**Scenario A** [1]	**Scenario B** [1]	**Scenario C** [1]
Direct access	io_byte_60 (PIB60)	-	16#08	-
	io_byte_61 (PIB61)	-	16#00	-
	io_word_60 (PIW60)	-	-	16#0008
	_getInOutByte (IN, 60)	16#08	16#08	16#08
	_getInOutByte (IN, 61)	16#00	16#00	16#00
	io_bit_60_3 (PI60.3)	TRUE	TRUE	TRUE
	io_bit_61_3 (PI61.3)	FALSE	FALSE	FALSE
Access to the fixed process image of the BackgroundTask	%IB60	16#08	16#08	**16#00** [3]
	%IB61	16#00	16#00	**16#08** [3]
	%IW60	**16#0800** [2]	**16#0800** [2]	16#0008
	%I60.3	TRUE	TRUE	**FALSE** [3]
	%I61.3	FALSE	FALSE	**TRUE** [3]

[1] Scenarios A, B, or C determine whether and which I/O variables are created for direct access; see the explanation provided in the body of the document.

[2] The two bytes in the word change places, as a value saved in the Little Endian order is being read using Big Endian.

[3] The two adjacent bytes change places, as the relevant word is saved in the Big Endian order.

Absolute access to the fixed process image of the BackgroundTask (absolute PI access)

You make absolute access to the fixed process image of the BackgroundTask (Page 4881) by directly using the identifier for the address (with implicit data type). The syntax of the identifier (Page 4888) is described in the following section.

You can use the identifier for the absolute PI access in the same manner as a normal variable (Page 4888).

Note

Outputs can be read and written to, but inputs can only be read.

Syntax for the identifier for an absolute process image access

For the absolute access to the fixed process image of the BackgroundTask (Page 4887), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

You also use these identifiers:

- For the declaration of a symbolic access to the fixed process image of the BackgroundTask (Page 4889).
- For the creation of an I/O variables for accessing the fixed process image of the BackgroundTask (Page 4891).

Table 7-465 Syntax for the identifier for an absolute process image access

Data type	Syntax for		Permissible address range	
	Input	Output		
BOOL	%In.x or %IXn.x [1]	%Qn.x or %QXn.x[1]	n: x:	0 .. 63 [2] 0 .. 7
BYTE	%IBn	%QBn	n:	0 .. 63 [2]
WORD	%IWn	%QWn	n:	0 .. 63 [2]
DWORD	%IDn	%QDn	n:	0 .. 63 [2]
n = logical address x = bit number				
[1] The syntax %IXn.x or %QXn.x is not permitted when defining I/O variables. [2] For a separate process image (Page 4885), the following applies: No addresses that are used in the process image of the cyclic tasks. See note below.				

Examples

Input at logic address 62, WORD data type: **%IW62**.

Output at logical address 63, bit 3, BOOL data type: **%Q63.3**.

Note

Up to Version V4.1 of the SIMOTION Kernel or the "Separate process image" (Page 4885) setting on the device (as of Version V4.2 of the SIMOTION Kernel), the following applies:

- Addresses accessed using the process image of the cyclic tasks cannot be read or written to using the fixed process image of the BackgroundTask.

This restriction no longer applies as of Version V4.2 of the SIMOTION Kernel or with the "Common process image" (Page 4883) setting on the device.

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 4875) do **not** apply. Access to the fixed process image of the BackgroundTask is not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

Several examples for the assignment of variables of the same type follow:

Table 7-466 Examples of absolute CPU memory access

```
status1 := %I1.1; // BOOL data type
status2 := %IB10; // BYTE data type
status3 := %IW20; // WORD data type
status4 := %ID20; // DWORD data type

%Q1.1 := status1; // BOOL data type
%QB20 := status2; // BYTE data type
%QW20 := status3; // WORD data type
%QD20 := status4; // DWORD data type
```

Symbolic access to the fixed process image of the BackgroundTask (symbolic PI access)

You can access the fixed process image of the BackgroundTask (Page 4881) symbolically without needing to always specify the absolute process image access.

You can declare symbolic access:

- As a static variable of a program (within the VAR/END_VAR structure in the declaration section)
- As a unit variable (within the VAR_GLOBAL / END_VAR structure in the interface or implementation section of the ST source file)

The syntax for declaring a symbolic name for the PI access is shown in the figure:

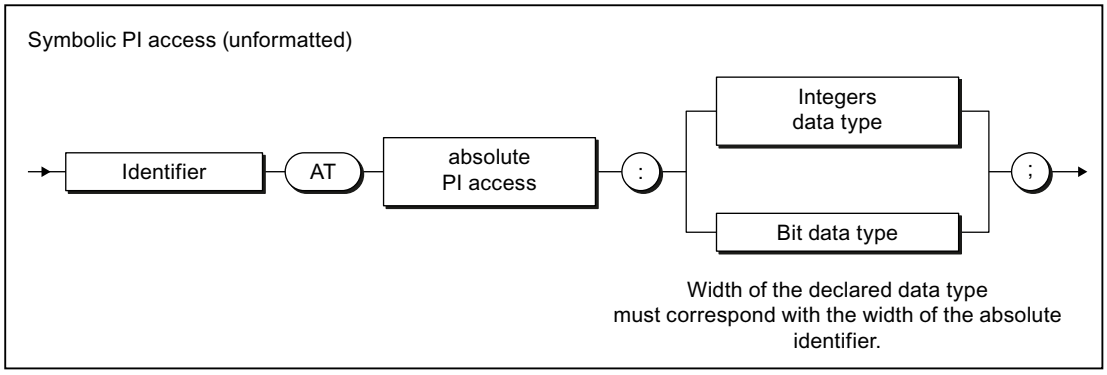

Figure 7-302 Declaration of a symbolic access to the process image

For the absolute PI access, see "Syntax for the identifier for an absolute PI access (Page 4888)".

The range of the declared integer or bit data type must correspond to the range of the absolute PI access, see "Possible data types of the symbolic PI access (Page 4890)". After declaring a numerical data type, you can address the contents of the process image as an integer.

See also Example for the declaration (Page 4891).

Possible data types for symbolic PI access

In the following cases, a data type that differs from that of the absolute PI access can be assigned to the fixed process image of the BackgroundTask (Page 4881). The data type width must correspond to the data type width of the absolute PI access.

- For the declaration of a symbolic PI access (Page 4889).
- For the creation of an I/O variable (Page 4891).

If you assign a numeric data type to the symbolic PI access or to the I/O variables, you can access these variables as integer.

Table 7-467 Possible data types for symbolic PI access

Data type of the absolute PI access	Possible data types of the symbolic PI access
BOOL (%In.x, %IXn.x, %Qn.x. %QXn.x)	BOOL
BYTE (%IBn, %QBn)	BYTE, SINT, USINT
WORD (%IWn, %QWn)	WORD, INT, UINT
DWORD (%IDn, %PQDn)	DWORD, DINT, UDINT

For the data type of the absolute PI access, see also "Syntax for the identifier for an absolute PI access (Page 4888)".

Example of symbolic PI access

If, for example, you want to access the CPU memory area (absolute PI access (Page 4888)) %IB10, but can respond flexibly to changes in your program, then declare a *myInput* variable with this CPU memory area as follows:

```
VAR
    myInput AT %IB10 : BYTE;
END_VAR
```

If you want to use the integer value of the memory area, declare the *myInput* variable as follows:

```
VAR
    myInput AT %IB10 : SINT;
END_VAR
```

If you want to use a CPU memory area other than %IB10 in your program at a later time, you only need to change the absolute PI access in the variable declaration.

Creating an I/O variable for access to the fixed process image of the BackgroundTask

You create I/O variables for access to the fixed process image for the background task in the symbol browser in the detail view; you must be in offline mode to do this.

Here is a brief overview of the procedure:

1. Select the "Address list" tab in the detail view and choose the SIMOTION device
   or
   In the project navigator of SIMOTION SCOUT, double-click the "ADDRESS LIST" element in the SIMOTION device subtree.
2. Select the line before which you want to insert the I/O variable and, from the context menu, select Insert new line
   or
   Scroll to the end of the table of variables (empty line).
3. In the detail view, select the Symbol browser tab and scroll down to the end of the variable table (empty row).
4. In the empty row of the table, enter or select the following:
   - **Name** of variable.
   - Under **I/O address**, the absolute PI access according to the "Syntax for the identifier for an absolute PI access" (Page 4888)
     (exception: The syntax %IXn.x or %QXn.x is not permitted for data type BOOL).
   - **Data type** of the I/O variables according to the "Possible data types of the symbolic PI access" (Page 4890).
5. Select optionally the display format used to monitor the variable in the symbol browser.

You can now access this variable using the address list or any program of the SIMOTION device.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and use them in your program sources.

Note that you can read and write outputs but you can only read inputs.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables" (Page 4892).

Accessing I/O variables

You have created an I/O variable for:

- Direct access or process image of the cyclic tasks (Page 4872).
- Access to the fixed process image of the BackgroundTask (Page 4881).

You can use this I/O variable just like any other variable.

Note

Consistency is only ensured for elementary data types.

When using arrays, the user is responsible for ensuring data consistency.

Note

If you have declared unit variables or local variables of the same name (e.g. *var-name*), specify the I/O variable using *_device.var-name* (predefined name space, see the "Predefined name spaces" table in "Name spaces").

It is possible to directly access an I/O variable that you created as a process image of a cyclic task. Specify direct access with *_direct.var-name* or *_device._direct.var-name*.

If you want to deviate from the default behavior when errors occur during variable access, you can use the _getSafeValue and _setSafeValue functions (see *SIMOTION Basic Functions* Function Manual).

For Errors associated with access to I/O variables, see *SIMOTION Basic Functions* Function Manual.

7.2.7.4 Using libraries

Libraries provide you with user-defined data types , functions and function blocks that can be used from all SIMOTION devices.

Libraries can be written in all programming languages; they can be used in all program sources (e.g. ST source files, MCC units).

You can obtain more details on inserting and managing libraries in the online help.

Note

The same rules as for the names of program source files apply to the library names, see Insert ST source file (Page 4587). In particular, the permissible length of the name depends on the SIMOTION Kernel version:

- As of Version V4.1 of the SIMOTION Kernel: maximum 128 characters.
- Up to Version V4.0 of the SIMOTION Kernel: maximum 8 characters.

With versions of the SIMOTION Kernel up to V4.0, a violation of the permissible length of the library name may not be detected until a consistency check or a download of the project is performed!

There is also the option of having a library make programs available, which can be called from other programs or function blocks. Please refer to the conditions which apply when calling a "program in a program" (Page 4762). In each case, the static data for the program called is stored once in the user memory of the device on which the library program is called. The same program instance data is used every time the program is called on the same device. A library program cannot be assigned to the execution system.

Compiling a library

In libraries, you can use all ST commands except for the ones listed in the table. In addition, you are not allowed to access some variables; these variables are also listed in this table .

Table 7-468 Illegal ST commands and variable access in libraries

Prohibited commands:

- *_getTaskId* function (see *SIMOTION Basic Functions* Function Manual).
- *_getAlarmId* function (see *SIMOTION Basic Functions* Function Manual).
- *_checkEqualTask* function (see *SIMOTION Basic Functions* Function Manual).
- If the library is not device-dependent (i.e. compiled without reference to a SIMOTION device or SIMOTION Kernel version):
  - System functions of SIMOTION devices (see the Parameter Manual for SIMOTION devices)
  - Version-dependent system functions

Prohibited variable accesses:

- Unit variables (retentive and non-retentive)
- Global device variables (retentive and non-retentive)
- I/O variables
- Instances of the technology objects and their system variables
- Variables of task names and configured messages (*_task* and *_alarm* namespaces, see Namespaces (Page 4902), *Predefined namespaces* table)
- If the library is not device-dependent (i.e. compiled without reference to a SIMOTION device or SIMOTION Kernel version):
  - System variables of SIMOTION devices (see the Parameter Manual for SIMOTION devices)
  - Configuration data of technology objects (see Parameter Manual of configuration data for the relevant SIMOTION technology package)

Note

The **Program status** debug function is not available in libraries.

Compiling an individual library

To compile an individual library, proceed as follows:

1. Select the library in the project navigator.
2. Select the **Edit > Object Properties** menu command.
3. Select the **Technology package** tab.
4. Select the SIMOTION devices (with SIMOTION kernel version) and the technology packet that you want to use as a basis for compiling the library; see the *SIMOTION Basic Functions* Function Manual.
5. Select **Accept and compile** from the context menu.

The library is compiled with reference to **all** selected SIMOTION devices, SIMOTION kernel versions and technology packages (and independently of devices).

Note

If the library to be compiled imports another library, note the following:

1. For the imported library, at least the same devices and SIMOTION kernel versions must be selected as for the importing library.
   Alternatively, the imported library can be compiled independently of devices if the prerequisites for this are fulfilled (refer to the *SIMOTION Basic Functions* Function Manual).
2. The imported library must already be compiled individually with reference to all configured devices, kernel versions and technology packages.
   Compilation of the library as part of a project-wide compilation is generally not sufficient.

Compiling a library as part of a project-wide compilation

When you compile the whole SIMOTION project (e.g. by choosing **Project > Save and recompile all** or by performing an XML import), the libraries used are also compiled.

Note

When performing project-wide compilation, note the following:

1. The system automatically identifies dependencies between libraries and selects the appropriate compilation sequence.
2. A library is **only** compiled with reference to the SIMOTION devices (including versions of the SIMOTION kernel) that are configured in the project and which use the library.
3. Other SIMOTION devices and kernel versions set for the library are ignored.

Know-how protection for libraries

You can protect libraries and their source files against unauthorized access by third parties. Protected libraries or sources can only be opened or exported as plain text files by entering a password.

You can:

- Provide individual sources of a library with know-how protection:
  Only the sources are protected against unauthorized access.
  The setting of the SIMOTION devices including the versions of the SIMOTION Kernel and the technology packages, for which the library is to be compiled, can still be changed and adapted by the user. Please refer to the *SIMOTION Basic Functions* Function Manual.
  The user can thus use the library for other SIMOTION devices and kernel versions.
- Provide the library with know-how protection:
  The following is then protected against unauthorized access:
  - All sources of the library
  - The setting of the SIMOTION device including the versions of the SIMOTION Kernel and the technology packages for which the library is to be compiled.

  You thus prevent that the user can use the library for other SIMOTION devices and kernel versions.
  Only use this setting if this is intended.

The SIMOTION online help provides additional information on know-how protection.

Note

If you export in XML format, the libraries or sources are exported in an encrypted form. When importing the encrypted XML files, the know-how protection, including login and password, is retained.

Using data types, functions and function blocks from libraries

Before using data types, functions or function blocks from libraries, you must make them known to the ST source file. To do so, use the following construct in the interface section of the ST source file:

```
USELIB library-name [AS namespace];
```

In this case, *library-name* is the name of the library as it appears in the project navigator.

When multiple libraries are to be specified, enter them as a list separated by commas, e.g.:

```
USELIB library-name_1 [AS namespace_1],
    library-name_2 [AS namespace_2],
    library-name_3 [AS namespace_1], ...
```

You can use the optional *AS namespace* add-on to define a namespace (Page 4902).

- You can then access data types, functions, and function blocks in the library that have the same name as such an ST source file of a SIMOTION device (in the PROGRAMS folder).
- You can also use namespaces to change the names of data types, functions and function blocks in the library so that they have different names.

You can also assign the same namespace to different libraries.

Table 7-469 Example of use of namespaces with libraries

```
INTERFACE
    USELIB Bib_1 AS NS_1, Bib_2 AS NS_2;
    PROGRAM Main_Program;
END_INTERFACE

IMPLEMENTATION
    FUNCTION Function1 : VOID
        VAR
            ComID : CommandIdType;
        END_VAR
        ComId := _getCommandId();
    END_FUNCTION

    PROGRAM Main_program
        function1();         // Function from this source
        NS_1.Var1:=1;
        NS_2.Var1:=2;
        NS_1.function1();    // Function from the Bib1 library
        NS_2.function1();    // Function from the Bib2 library
    END_PROGRAM
END_IMPLEMENTATION
```

7.2.7.5 Use of the same identifiers and namespaces

Use of the same identifiers

General Information

It is possible to use unit variables and local variables (program variables, FB variables, FC variables) with the same name. When compiling a program source, the compiler searches for identifiers beginning with the current POU. The smaller validity range always takes priority over the larger validity range.

You can therefore use the same identifiers in different source file sections, as long as the rules below are adhered to. If a higher-level identifier is hidden by an identifier in a unit or POU, the compiler issues a warning.

Note

Under certain circumstances, the compiler may not issue a warning if, for example, the associated technology package is not imported.

Identifier in a program organization unit (POU)

All following identifiers in a POU must be unique:

- Local variables of the POU.
- Local data types of the POU.

They must not be identical to the following identifiers either:

- Reserved identifiers.
- Identifiers of the POU itself.

The compiler issues a warning when the following identifiers are hidden:

- Unit variables, data types and POU or the same or imported units
- Standard system functions, standard system function blocks, and associated data types.
- System functions and system data types of the SIMOTION device.
- Program organization units (POUs) and data types from imported libraries
  - This can be resolved by entering a user-defined namespace.
- System functions and system data types from imported technology packages.
  - This can be resolved by entering a user-defined namespace.
- SIMOTION device variables (system variables, I/O variables, global device variables).
  - This can be resolved by entering the predefined namespace *_device*.
- Technology objects configured on the SIMOTION device
  - This can be resolved by entering the predefined namespace *_to*.

Identifiers in a unit

Public identifiers of all units (unit variables, data types, and POUs) must be unique throughout the device.

All the following identifiers must be unique within a unit:

- Unit variables (declared in the interface or implementation section)
- Data types (declared in the interface or implementation section)
- Program organization units (POUs)

They must not be identical to the following identifiers either:

- Reserved identifiers.
- Unit variables, data types and POU imported units.
- Standard system functions, standard system function blocks, and associated data types.
- System functions and system data types of the SIMOTION device.

- Program organization units (POUs) and data types from imported libraries
  - This can be resolved by entering a user-defined namespace.
- System functions and system data types from imported technology packages.
  - This can be resolved by entering a user-defined namespace.

The compiler issues a warning when the following identifiers are hidden:

- SIMOTION device variables (system variables, I/O variables, global device variables).
  - This can be resolved by entering the predefined namespace *_device*.
- Technology objects configured on the SIMOTION device.
  - This can be resolved by entering the predefined namespace *_to*.

Identifiers on the SIMOTION device (e.g. I/O variables, global device variables)

All the following identifiers on the SIMOTION device must be unique:

- I/O variables
- Global device variables
- System variables of the SIMOTION device
- System functions and system data types of the SIMOTION device.

They must not be identical to the following identifiers either:

- Reserved identifiers.
- Standard system functions, standard system function blocks, and associated data types.

Example

The following example illustrates this situation. It shows that for use of identical names for unit variables (large validity range) and FC variables (small variable scope), only the variables declared in the function are valid within this source file section. The unit variables are only valid in POUs in which no local variables of the same name were declared. See the example.

Example of identifier validity

```
TYPE
    type_a : (enum1, enum2, enum3);
END_TYPE

VAR_GLOBAL
    var_a, var_b : DINT; // Unit variables
END_VAR

FUNCTION fc_1 : VOID
    VAR
        var_a : type_a;  // Declaration hides UNIT variable
        var_c : DINT;    // Local variable
    END_VAR
    // Permitted statements
    var_a := enum2;      // Access to local variable
    var_b := 100;        // Access to unit variable
    var_c := -1;         // Access to local variable
    // Invalid statement
    // var_a := 200;
END_FUNCTION

FUNCTION fc_2 : VOID
    VAR
        var_b : type_a;  // Declaration hides UNIT variable
        var_c : type_a;  // Local variable
    END_VAR
    // Permitted statements
    var_a := -100;       // Access to unit variable
    var_b := enum3;      // Access to local variable
    var_c := enum1;      // Access to local variable
    // Invalid statement
    // var_b := 200;
END_FUNCTION
```

Namespaces

You can also access data types, unit variables, functions, and function blocks defined outside of a program source (e.g. in libraries, technology packages, and on the SIMOTION device) using their names.

When compiling a program source, the compiler searches for identifiers beginning with the current POU. The data types, variables, functions, or function blocks declared in a program source therefore hide identifiers with the same name which have been defined outside the source, see Use of the same identifiers (Page 4897). In order to still access these hidden identifiers, you can use namespaces in certain cases.

Namespaces for libraries and technology packages

In the import statement for libraries and technology packages, you can define namespaces in order to access the data types, functions, or function blocks of these libraries and technology packages.

```
USELIB library-name_1 [AS lib_namespace_1],
    library-name_2 [AS lib_namespace_2],
    library-name_3 [AS lib_namespace_1], ...

USEPACKAGE tp-name_1 [AS tp_namespace_1],
    tp-name_2 [AS tp_namespace_2],
    tp-name_3 [AS tp_namespace_1], ...
```

You can also use namespaces to make names consistent within different libraries.

If you wish to use a data type, a function or a function block from a library or a technology package, place the namespace identifier in front of the name, separated by a period, for example, *namespace.fc-name*, *namespace.fb-name*, *namespace.type-name*

Example

The following example shows how to select the Cam technology package, assign it the namespace Cam1 and use the namespace:

Example of selecting a technology package and using a namespace

```
INTERFACE
    USEPACKAGE Cam AS Cam1;
    USES ST_2;
    FUNCTION function1;
END_INTERFACE

IMPLEMENTATION
    FUNCTION function1 : VOID
    VAR_INPUT
        p_Axis : posAxis;
    END_VAR
    VAR
        retVal : DINT;
    END_VAR

    retVal:= Cam1._enableAxis (
            axis := p_Axis,
            nextCommand := Cam1.WHEN_COMMAND_DONE,
            commandId := _getCommandId() );
    END_FUNCTION
END_IMPLEMENTATION
```

Note

If a namespace is defined for an imported library or technology package, this must **always** be specified if a function, function block, or data type from this library or technology package is being used. See above example: Cam1._enableAxis, Cam1.WHEN_COMMAND_DONE.

Predefined namespaces

Namespaces are predefined for device- and project-specific variables as well as TaskID and AlarmID variables. If necessary, write their designation before the variable names, separated by a period, for example, *_device.var-name* or *_task.task-name*

Table 7-470 Predefined namespaces

Namespace	Description
_alarm	For AlarmId: The _alarm.*name* variable contains the AlarmId of the message with the *name* identifier (see SIMOTION Basic Functions Function Manual).
_device	For device-specific variables (global device variables, I/O variables, and system variables of the SIMOTION device).
_direct	For direct access to I/O variables – see Direct access and process image of the cyclic tasks (Page 4872). Local namespace for _device. Nesting as in _device._direct.*name* is permitted.
_project	For names of SIMOTION devices in the project; only used with technology objects on other devices. With unique project-wide names of technology objects, used also for these names and their system variables.
_task	For TaskID: The _task.*name* variable contains the TaskId of the task with the *name* identifier (see SIMOTION Basic Functions Function Manual).
_quality	As of version V4.2 of the SIMOTION Kernel: For the detailed status of I/O variables (Page 4879). A value with data type DWORD is supplied. Local namespace for _device. Nesting as in _device._quality.*name* is permitted.
_to	For technology objects configured on the SIMOTION device, and their system variables and configuration data. Not for system functions and data types of the technology objects. In this case, if necessary, use the user-defined namespace for the imported technology package

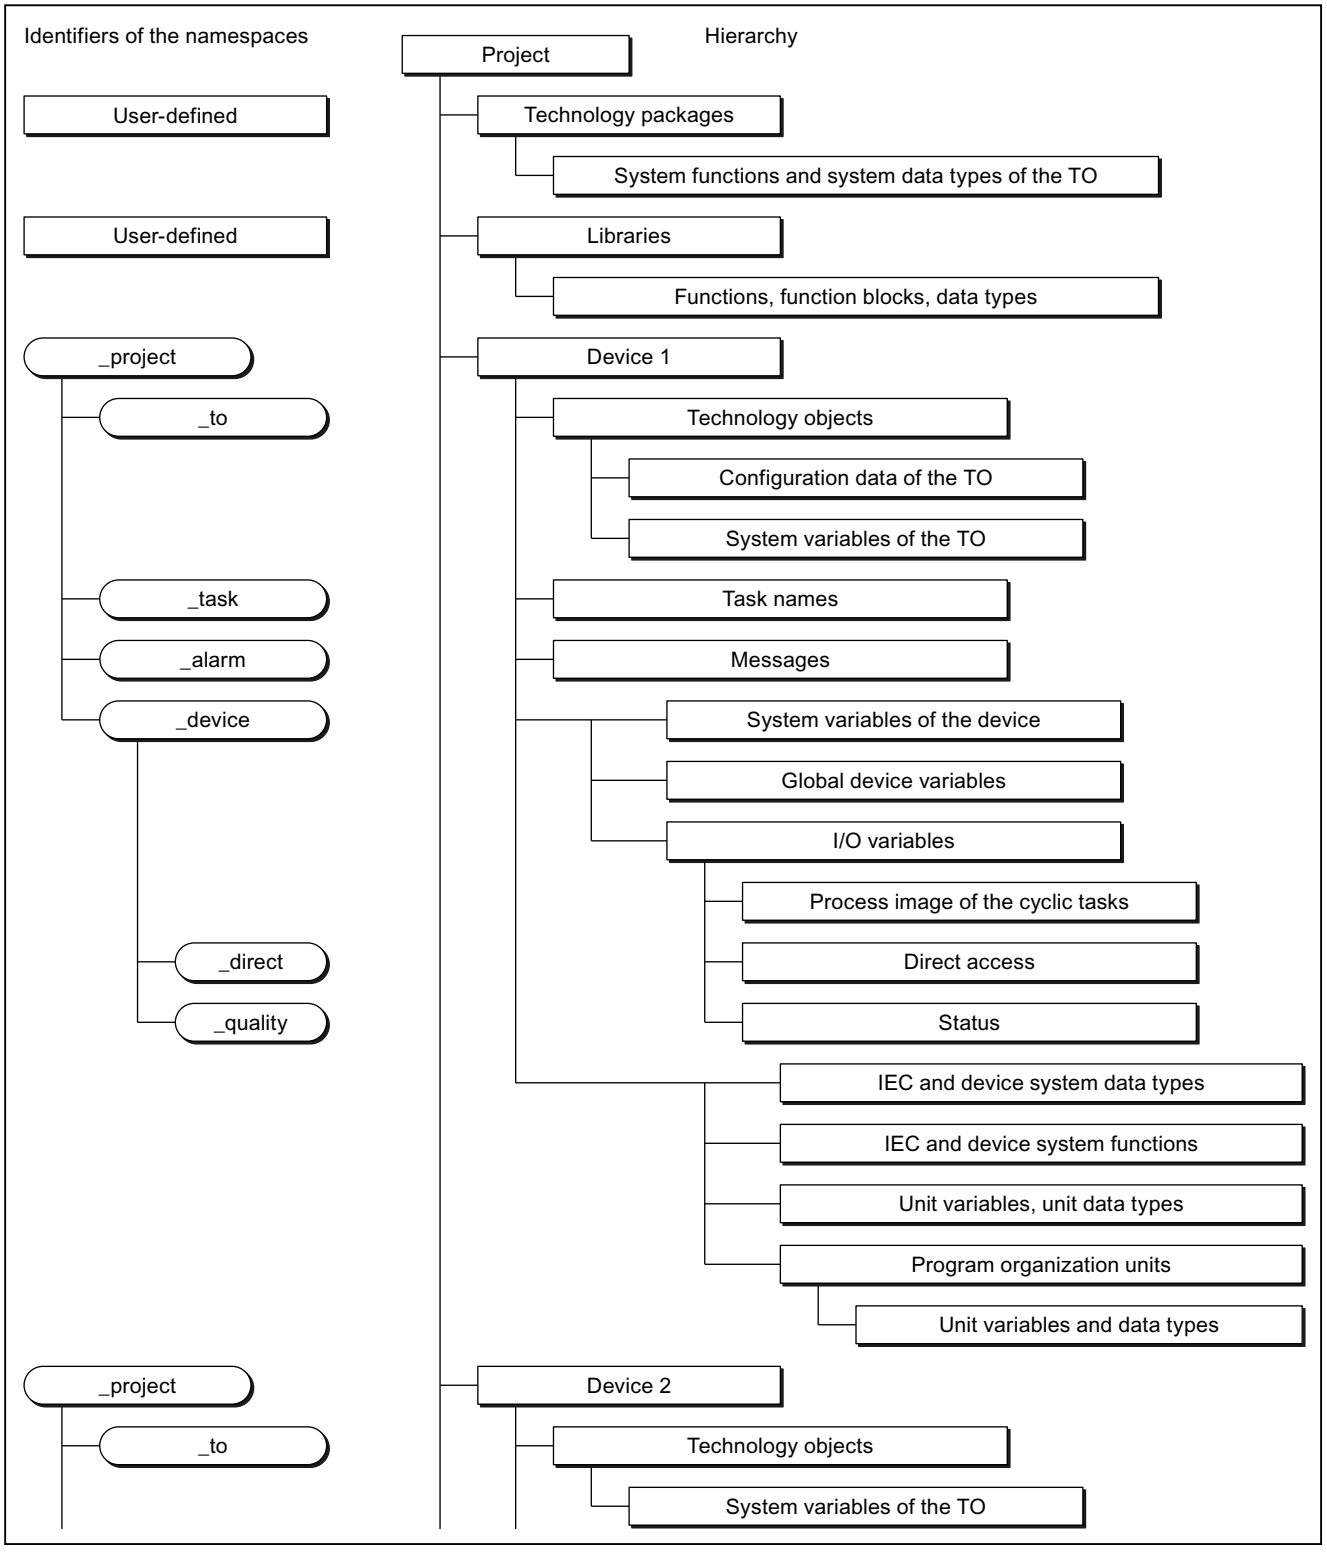

Figure 7-303 Namespaces and identifier hierarchy

Object-oriented namespace

Declaration of object-oriented namespaces

You declare object-oriented namespaces in the interface or implementation section of an ST source file or within another object-oriented namespace.

Use the following syntax:

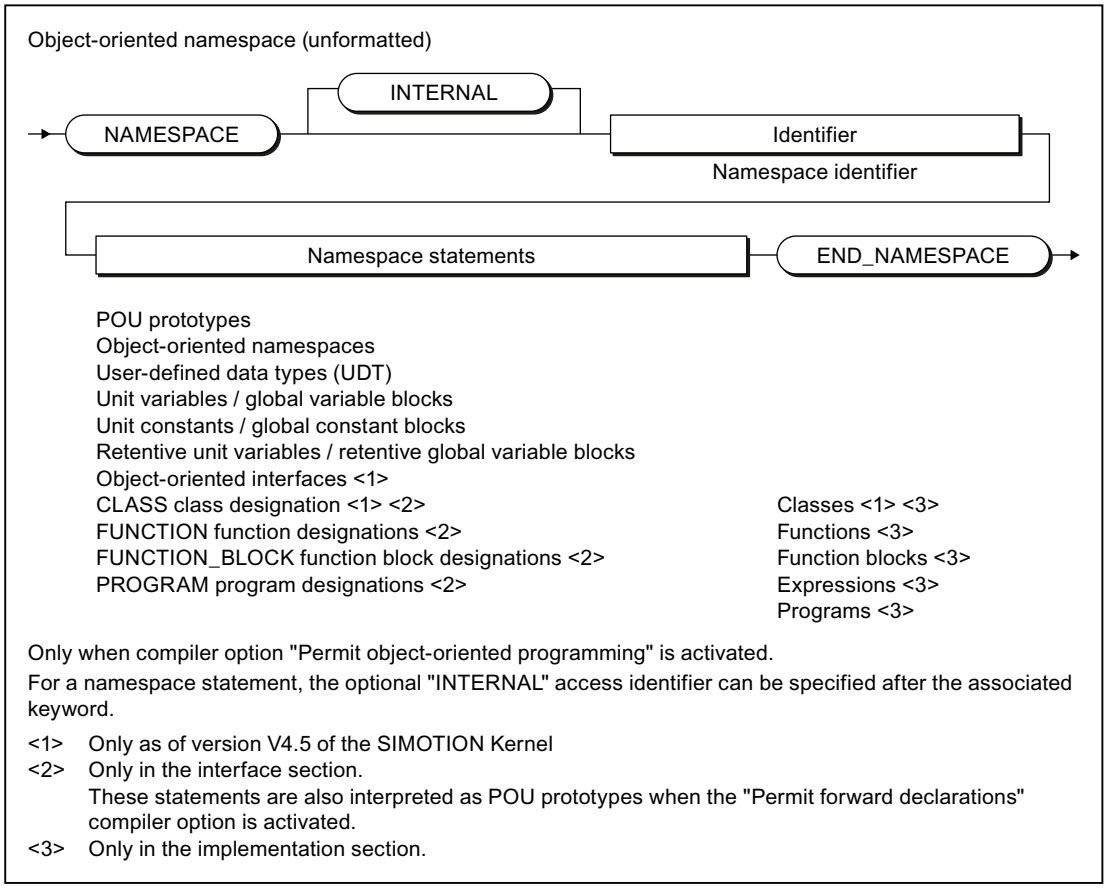

Figure 7-304 Syntax: Object-oriented namespace

Specify an identifier for the name of the namespace after the NAMESPACE and the optional INTERNAL keywords.

This is then followed by:

- The statements permitted in the namespace, e.g.:
  - Declarations of user-defined data types
  - Global variable declarations
  - Object-oriented interfaces
  - Program organization units, such as classes, functions, function blocks, programs and their prototypes
  - Other namespaces
- The END_NAMESPACE keyword

The INTERNAL keyword is possible only in namespace declarations within a namespace.

Object-oriented namespaces can be nested as required. Whereby, the nesting can be abbreviated by specifying a structured namespace path of the form *namespace_1.namespace_2*.

```
// Declaration of a nested namespace
NAMESPACE ns1
  NAMESPACE INTERNAL ns_int
    (* Elements of ns1.ns_int *)
  END_NAMESPACE
  (* Further elements of ns1 *)
END_NAMESPACE
// Declaration of a nested namespace
// by fully qualified name
// ns1 is public; INTERNAL acts only on the last name part
NAMESPACE INTERNAL ns1.ns_int
  (* Elements of ns1.ns_int *)
END_NAMESPACE
```

As for structured variables, access can be made from outside an object-oriented namespace to its elements by prefixing the namespace identifier separated with a period to the element identifier: *namespace.element*.

The INTERNAL access identifier can be specified for every element defined within a namespace (default is public). The INTERNAL access identifier immediately follows the associated keyword, e.g. VAR_GLOBAL, VAR_GLOBAL CONSTANT, TYPE, CLASS, INTERFACE, FUNCTION_BLOCK, FUNCTION, PROGRAM or NAMESPACE. Methods, type and variable declarations, as well as constants, can also be declared within INTERNAL classes and function blocks; see sections "Access identifier within classes (Page 4768)" and "Access identifiers within object-oriented FBs (Page 4740)". Access can be made to elements identified with INTERNAL only within the higher-level namespace.

Name conflicts for elements defined within a namespace are not permitted.

The definition of a namespace does not need to be closed. If a previously defined namespace with the same name is found, the content of the declaration is included there. This also applies when the namespace is specified with a USES statement.

Predefined namespaces (Page 4902) (e.g. _task, _alarm, _device, _project) cannot be extended. Consequently, it is not permitted to use these identifiers for a namespace definition. Access per USING with these namespaces is also not possible.

If a previously defined namespace (defined in a separate source or imported from a source or library with USES or USELIB) is redeclared, the previous access identifier must be retained.

- If no access identifier is specified with a new declaration of a previously declared INTERNAL namespace, a compiler warning is issued and the namespace remains INTERNAL.
- A compiler error message will be issued if an attempt is made to declare a previously published namespace as INTERNAL subsequently.
- If the same namespace is declared in two different sources or libraries as INTERNAL and public, and these sources/libraries are used together in another source, the namespace is indicated as INTERNAL there.

This ensures that the elements of a namespace declared as INTERNAL cannot be made public subsequently.

If public program organization units (POUs) are classified in namespaces, the namespace must be specified in the interface section and in the implementation section of the source.

Access to namespaces and their elements

Within a namespace, all included elements can be used without name prefix, even when they were declared as INTERNAL. If no element was found for an identifier within the namespace, a search is made for the identifier in the enclosing scope that can also be a namespace or the global scope of the source. Access without name prefix is also possible to such found elements. This also applies to elements declared as INTERNAL in the enclosing namespace, because the lower-level namespace in which the identifier search begins always belongs to the current namespace.

In addition to the above-mentioned search in the scope, it is also possible to access elements contained in the namespaces. This requires the complete designation of the namespace written separated with a period before the element identifier: *namespace_1.namespace_11.element*. Because an external access is typically involved, no access is possible to elements declared as INTERNAL.

Table 7-471 Example: Access to elements of a class declared as INTERNAL

```
NAMESPACE ns1
  CLASS INTERNAL cl_int
    METHOD PUBLIC m_public
      // Warning: Method is INTERNAL.
      // (The complete class is INTERNAL)
      ;
    END_METHOD
    METHOD INTERNAL m_internal
      ;
    END_METHOD
  END_CLASS
  VAR_GLOBAL
    vg_clint : cl_int;
    // Instance can be created, because within ns1.
  END_VAR
END_NAMESPACE
```

```
FUNCTION_BLOCK fb_test
  VAR
    v_clint : ns1.cl_int;
    // Instance cannot be created
    // cl_int is INTERNAL in ns1.
  END_VAR
  ns1.vg_clint.m_public();
  (* Access to method m_public not possible Although the instance vg_clint from ns1 is
visible, access is not possible to its elements *)
END_FUNCTION_BLOCK
```

Table 7-472 Example: Access to elements of a namespace declared as INTERNAL

```
NAMESPACE ns1
  NAMESPACE INTERNAL ns_int
    CLASS cl
      METHOD PUBLIC   m_public   ; END_METHOD
      METHOD INTERNAL m_internal ; END_METHOD
    END_CLASS
  END_NAMESPACE
  VAR_GLOBAL
    vg_cl : ns_int.cl;
    // Instance can be created, because within ns1.
  END_VAR
END_NAMESPACE
FUNCTION_BLOCK fb_test1
  VAR
    v_cl : ns1.ns_int.cl;
    // Instance cannot be created
    // ns_int is INTERNAL in ns1.
  END_VAR
  ns1.vg_cl.m_public();
  // Access possible to method m_public
  ns1.vg_cl.m_internal();
  // Access not possible to method m_internal
END_FUNCTION_BLOCK
```

USING directive

The USING directive has the following syntax:

```
USING namespace-list;
```

The namespace list is a list of namespace identifiers each separated by a comma.

Example:

```
USING namespace_1, namespace_2;
```

The USING directive affects the scope of the source file section in which it is specified. In this scope, the public elements of the namespaces specified in the USING directive can be used without details of the namespace identifier. These elements are considered as if they were declared themselves there.

This means name conflicts between the elements from different namespaces shown with USING, and elements of the current scope are not permitted. Compiler error messages are issued.

The USING directive always acts in the scope of the source file section in which it is specified. It does not apply to external accesses in this source file section. Consequently, the USING directive is always restricted to the current source. It has no effect in other sources that the current source uses.

The namespace identifier specified on the USING directive (possibly cascaded) must reference a namespace valid at this time. A USING directive does not implicitly declare namespaces.

USING directives can be specified at the following places, possibly several times successively:

- In the interface section of the source:
  Immediately after statements for importing technology packages, libraries and other sources (USEPACKAGE, USELIB, USES).
  This allows, for example, declared elements in namespaces for libraries to be shown in the global namespace.
- For the **first** declaration of a namespace within a source:
  Immediately on the following namespace identifier itself.
- Within a program organization unit (POU), e.g. class, function block, object-oriented interface, program, method:
  Immediately before the declaration section of the POU.

Examples

Table 7-473 Example: USING directive in the interface section of a source

```
INTERFACE
  USELIB mylib;   // Link with the mylib library
  USING ns_mylib; // Show the elements of the namespace
       // ns_mylib in the global namespace of the source
  // ...
END_INTERFACE
```

Table 7-474 Example: USING directive in a namespace

```
NAMESPACE ns2
  USING ns1;
  USING ns1.ns11;
  // ...
END_NAMESPACE
```

Table 7-475 Example: USING directive in the interface section of a program organization unit

```
CLASS cl
  USING ns1;
  USING ns1.ns11;
  // ...
  METHOD m : VOID
    USING ns1.ns11.ns111;
    ;
  END_METHOD
END_CLASS
```

Note

The USING directive cannot be used on namespaces included in the namespace path of the current source file section.

Table 7-476 Example: USING directive to a higher-level namespace not possible

```
NAMESPACE ns1.ns11.ns111
  CLASS cltest
    USING ns11; // Error: ns11 is part of its own declaration path
    // ...
  END_CLASS
END_NAMESPACE
```

Note

Namespace identifiers of other USING directives are not visible within a USING directive.

Table 7-477 Example: USING directive for nested namespaces

```
NAMESPACE ns1.ns11
// ...
END_NAMESPACE
NAMESPACE ns_test
  USING ns1;
  USING ns11;     // Error:
    // Namespace ns11 not visible for USING directive
  USING ns1.ns11; // Specification must be made as such
END_NAMESPACE
```

7.2.7.6 Reference data

The reference data provide you with an overview of:

- on utilized identifiers with information about their declaration and use (Cross-reference list (Page 4910)).
- on function calls and their nesting (Program structure (Page 4914))
- on the memory requirement for various data areas of the program sources (Code attributes (Page 4915))

Cross-reference list

The cross-reference list shows all identifiers in program sources (e.g. ST source files, MCC units):

- Declared as variables, data types, or program organization units (program, function, function block)
- Used as previously defined types in declarations
- Used as variables in the statement section of a program organization unit.

Generating and updating a cross-reference list

Initially, the cross-reference list is generated automatically when opening. Open a cross-reference list, e.g. after selecting an ST source file or library via the **Edit > Display reference data > Cross-references** menu. After changes, the update is partly performed automatically and can always be triggered manually in the detail view via the  button. When updating via the button, a check is performed as to whether a compilation is required. If a compilation is required, this is indicated by a yellow triangle next to the button.

Update of the cross-reference list when selecting a program

The list is updated automatically when opening the selected program. The local defined identifiers are therefore up-to-date.

External identifiers in the program are not updated when opening.

The opened cross-reference list is also updated automatically when compiling the program.

Update of the cross-reference list when selecting a tree (CPU, project, library, program folder)

The cross-reference list is generated automatically when opening the first time. There is no automatic update when opened again.

Note

An error-free compilation is required for a correct, consistent display of the reference data. If required, compile the project, the CPU, the program or the library first.

Content of the cross-reference list

The cross-reference list contains all the identifiers assigned to the element selected in the project navigator. The applications for the identifiers are also listed in a table:

Details of how to work with the cross-reference list are provided in the section titled "Working with the cross-reference list (Page 4913)".

Table 7-478 Meanings of columns and selected entries in the cross-reference list

Column	Entry in column	Meaning
Name		Identifier name
Type		Identifier type
	Name	• Data type of a variable (e.g. REAL, INT) • POU type (e.g. PROGRAM, FUNCTION)
	DERIVED	Derived data type
	DERIVED ANY_OBJECT	TO data type
	ARRAY ...	ARRAY data type
	ENUM ...	Enumerator data type
	STRUCT ...	STRUCT data type
Declaration		Location of declaration
	Name (UNIT)	Declaration in the program source *name*
	Name (LIB)	Declaration in the library *name*
	Name (TO)	System variable of the technology object *name*
	Name (TP)	Declaration in the default library specified: • Technology package *name* • std_fct = IEC library • device = device-specific library
	Name (DV)	Declaration on the SIMOTION device *name* (e.g. I/O variable or global device variable)
	_project	Declaration in the project (e.g. technology object)
	_device	Internal variable on the SIMOTION device (e.g. TaskStartInfo)
	_task	Task in the execution system
Use		Use of identifier
	CALL	Call as subprogram (static binding)
	CALL VTAB	Call of a method of the dynamic binding
	ENUM *name*	As element when declaring the enumerator data type *name*
	I/O	Declaration as I/O variable
	R	Read access
	R (TYPE)	As data type in a declaration
	R/W	Read and write access
	STRUCT *name*	As component when declaring the structure *name*
	TYPE	Declaration as data type or POU
	Variable type (e.g. VAR, VAR_GLOBAL)	Declaration as variable of the variable type specified
	W	Write access

Column	Entry in column	Meaning
Path specification		Path specification for the SIMOTION device or program source
	Name	SIMOTION device *name*
	Name1/*Name2*	• Program source *name2* on SIMOTION device *name1* • Program source *name2* in library *name1*
	Name/taskbind.hid	Execution system of the SIMOTION device *name*
Range		Range within the SIMOTION device or program source
	INTERFACE	Interface section of the program source
	POE type name (i.e. CLASS *name*, FUNCTION *name*, FUNCTION_BLOCK *name* INTERFACE *name* PROGRAM *name*)	Program Organization Unit (POU) *Name* within the program source. • In an MCC chart: Additional serial numbers for the command (block numbers) • In a LAD/FBD program: Additional serial numbers of the network
	I/O address	I/O variable
	METHOD *Name_1*::*Name_2*	Method *Name_2* within the class or the function block *Name_1*
	TASK *name*	Assignment for the task *name*
	UNIT	Implementation section of the program source, additional specification as POU to be made public in the interface section of the program source
	UNIT - IMPLEMENTATION	Implementation section of the program source
	_device	Global device variable
Language		Programming language of the program source
Line/Block		• In an ST source: Line number within the program source • In an MCC or LAD/FBD source: Relative line number within the command (block) or network. **Note** The absolute line number within the program source, which you need, for example, for the trace function "Trigger to code point", is obtained as follows: – Press the **Determine program line** button. – In the dialog box, press the button **Copy program line to the clipboard**.

Note

Single-step tracking and trace diagnostic functions in MCC programming

Additional variables and functions are created or used for these diagnostics functions:

- The variables TSI#dwuser_1 and TSI#dwuser_2 of the TaskStartInfo are used for the single-step tracking diagnostic function.
- Various internal functions and variables, whose identifier begins with an underscore, are automatically created by the compiler for the trace diagnostic function. The TSI#currentTaskId variable of the TaskStartInfo is also used.

With activated diagnostic function, these variables and functions are used for the control of the diagnostics function. These variables and functions must not be used in the user program.

Working with a cross-reference list

In the cross-reference list you are able to:

- Sort the column contents alphabetically:
  - To do this, click the header of the appropriate column.
- Search for an identifier or entry:
  - Click the "Search" button and enter the search term.
- Filter (Page 4913) the identifiers and entries displayed.
- Copy contents to the clipboard in order to paste them into a spreadsheet program, for example.
  - Select the appropriate lines and columns.
  - Press the CTRL+C shortcut.
- Print the content (**Project > Print**).
- Open the referenced program source and position the cursor on the relevant line of the ST source file (or MCC command or LAD/FBD element):
  - Double-click on the corresponding line in the cross-reference list.
    or
  - Place the cursor in the corresponding line of the cross-reference list and click the "Go to application" button.

Further details about working with cross-reference lists can be found in the online help.

Filtering the cross-reference list

You can filter the entries in the cross-reference list so that only relevant entries are displayed:

1. Click the "Filter settings" button.
   The "Filter Setting for Cross References" window will appear.
2. Activate the "Filter active" checkbox.
3. If you also want to display system variables and system functions:
   - Deactivate the "Display user-defined variables only" checkbox.
4. Set the desired filter criterion for the relevant columns:
   - Select the relevant entry from the drop-down list box or enter the criterion.
   - If you want to search for a character string within an entry: Deactivate the "Whole words only" checkbox.
5. Confirm with **OK**.

The contents of the cross-reference list will reflect the filter settings selected.

Note

A filter is automatically activated after the cross-reference list has been created.

Program structure

The program structure contains all the function calls and their nesting within a selected element.

You can display the program structure selectively for:

- An individual program source (e.g. ST source file, MCC unit, LAD/FBD source file)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Proceed as follows:

1. In the project navigator, select the element for which you want to display the program structure.
2. Select the **Edit > Display reference data > Program structure** menu command.
   The cross-reference tab is replaced by the program structure tab in the detail view.

Note

The display data is updated every time the program structure is opened.

You can update the detail view of an opened program structure with the F5 key.

Content of the program structure

A tree structure appears, showing:

- as base respectively
  - the program organization units (programs, functions, function blocks) declared in the program source, or
  - the execution system tasks used
- below these, the subroutines referenced in this program organization unit or task.

For structure of the entries, see table:

Table 7-479 Elements of the display for the program structure

Element	Description
Base (declared POU or task used))	List separated by a comma • Identifier of the program organization unit (POU) or task The specification *Name_1::Name_2* means: Method *Name_2* within the class or the function block *Name_1*. • Identifier of the program source in which the POU or task was declared, with add-on [UNIT] • Minimum and maximum stack requirement (memory requirement of the POU or task on the local data stack), in bytes [Min, Max] • Minimum and maximum overall stack requirement (memory requirement of the POU or task on the local data stack including all called POUs), in bytes [Min, Max]
Referenced POU	List separated by a comma: • Identifier of called POU The specification *Name_1::Name_2* means: Method *Name_2* within the class or the function block *Name_1*. • Optionally: Identifier of the program source / technology package in which the POU was declared: Add-on (UNIT): User-defined program source Add-on (LIB): Library Add-on (TP): System function from technology package • with function blocks or methods only: Identifier of the instance of the function block or the higher-level class • with function blocks or methods only: Identifier of program source in which the instance of the function block or of the higher-level class was declared: Add-on (UNIT): User-defined program source Add-on (LIB): Library • Number of the line in the (compiled) source in which the POE is called; several line numbers are separated by "/".

Code attributes

You can find information on or the memory requirement of various data areas of the program sources under code attribute.

You can display the code attributes selectively for:

- An individual program source (e.g. ST source file, MCC unit, LAD/FBD source file)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Proceed as follows:

1. In the project navigator, select the element for which you want to display the code attributes.
2. Select the **Edit > Display reference data > Code attributes** menu command.
   The **Cross-references** tab is now replaced by the **Code attributes** tab in the detail view.

Note

The display data is updated every time the code attributes are opened.

You can update the detail view of the opened code attributes with the F5 key.

Code attribute contents

The following are displayed in a table for all selected program sources:

- Identifier of program source,
- Memory requirement, in bytes, for the following data areas of the program source:
  - **Dynamic data**: All unit variables (retentive and non-retentive, in the interface and implementation sections),
  - **Retain data**: Retentive unit variables in the interface and implementation section,
  - **Interface data**: Unit variables (retentive and non-retentive) in the interface section,
- the **Code size** during the last compilation in bytes,
- the **Number of referenced sources**:
  The maximum number of connected sources is displayed (including system libraries), regardless of whether they are downloaded to the target system at a later date.

Reference to variables

If you have selected the identifier of a variable in the open Editor window for each programming language, you can use the other places of use over the context menu to list or to skip these variables.

You select the identifier of a variable:

- In SIMOTION ST: In the Editor window of an ST source.
- In SIMOTION MCC: In the input field on the parameter screen of an open MCC command within an MCC chart
- In SIMOTION LAD/FBD: In the Editor window of a LAD/FBD program

An identifier is recognized as a variable under the following conditions:

1. The identifier is declared as a variable. The scope of the variable includes the respective window (ST source, MCC chart, LAD/FBD program).
2. The program source is compiled.
3. The variable is selected as follows (in an open parameter screen within an MCC chart):
   - The identifier is fully marked
     or
   - The cursor is within the identifier.

Note

In arrays and structures, only the variable can be selected, not a single element.

Using the **Go to** context menu, you have the following options:

- To jump to the next local place of use:
  Select the context menu **Go to > Local use >>**.
  The next place of use of the variables within the same Editor window (ST source, MCC chart, LAD/FBD program) is selected. In an MCC chart, the corresponding MCC command opens.
- Jump to the previous local place of use:
  Select the context menu **Go to > Local use <<**.
  The previous place of use of the variables within the same Editor window (ST source, MCC chart, LAD/FBD program) is selected. In an MCC chart, the corresponding MCC command opens.
- Jump to the declaration position:
  Select the context menu **Go to > Declaration position**.
  The declaration position of the variables is selected. The corresponding program source is opened, if necessary.
- List all places of use
  Select the context menu **Go to > Places of use ...**.
  In the detailed view, all places of use of the variables within their scope (including the declaration position) are listed The structure of this list is similar to the List of cross references (Page 4911).
  This is how you jump to a preferred place of use:
  - Double-click on the corresponding line.
    or
  - Place the cursor in the corresponding line and click the "Go to application" button.

7.2.7.7 Controlling the preprocessor and compiler with pragmas

A pragma is used to insert an ST source file text (e.g. statements), which influences the compilation of the ST source file.

Pragmas are enclosed in { and } brackets and can contain (see figure):

- Preprocessor statements for controlling the preprocessor, see Controlling the preprocessor (Page 4918).
  The pragmas with preprocessor statements contained in an ST source file are evaluated by the preprocessor and interpreted as control statements.
- Attributes for compiler options to control the compiler, see Controlling compiler with attributes (Page 4922).
  The pragmas with attributes for compiler options contained in an ST source file are evaluated by the compiler and interpreted as control statements.
- Non-assigned compiler messages, see Issuing non-assigned compiler messages (Page 4926).
  Non-assigned compiler messages are issued in the "Compile/check output" tab in the detailed view.

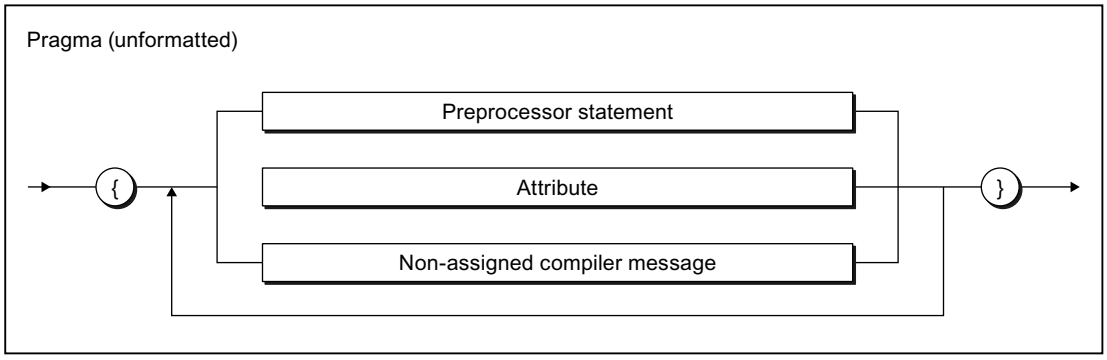

Figure 7-305 Syntax: Pragma

Note

Be sure to use the correct pragma syntax (e.g. upper- and lower-case notation of attributes).

Unrecognized pragmas are ignored with no warning message.

Controlling the preprocessor

The preprocessor prepares an ST source file for compilation. For example, character strings can be defined as replacement texts for identifiers, or sections of the source program can be hidden/ shown for compilation.

The preprocessor is disabled by default. You can activate it as follows:

- Globally for all program source files and programming languages within the project, see "Global settings of the compiler (Page 4623)".
- Local for a program source file, see "Local compiler settings (Page 4626)".

During the compilation of a program source file, you will be informed about the preprocessor actions. This requires, however, that the display of class 7 warnings is activated, see Meanings of the warning classes (Page 4633). You specify the details for issued warnings and information:

- In the global or local settings of the compiler.
- With the _U7_PoeBld_CompilerOption := warning:*n*:off or warning:*n*:on attribute within an ST source file, see "Controlling compiler with attributes (Page 4922)".

Like all compiler messages, information about the preprocessor actions is shown on the "Compile/check output" tab of the detail view.

Note

You can also view the text of the ST source file modified by the preprocessor:

1. Open the ST source file.
2. Select the **ST source file > Execute preprocessor** menu command.

The modified source text is shown in the "Compile/check output" tab of the detail view.

Preprocessor statement

You can control the preprocessor by means of statements in pragmas. The statements specified in the following syntax diagram can be used. These statements act on all subsequent lines of the ST source file.

They can be used in ST source files of a SIMOTION device or a library.

You can make definitions for the preprocessor (see Making preprocessor definitions (Page 4635)) in the property dialog box of the ST source file. This enables you also to control the preprocessor with ST source files with know-how protection (see Know-how protection for ST source files (Page 4635)).

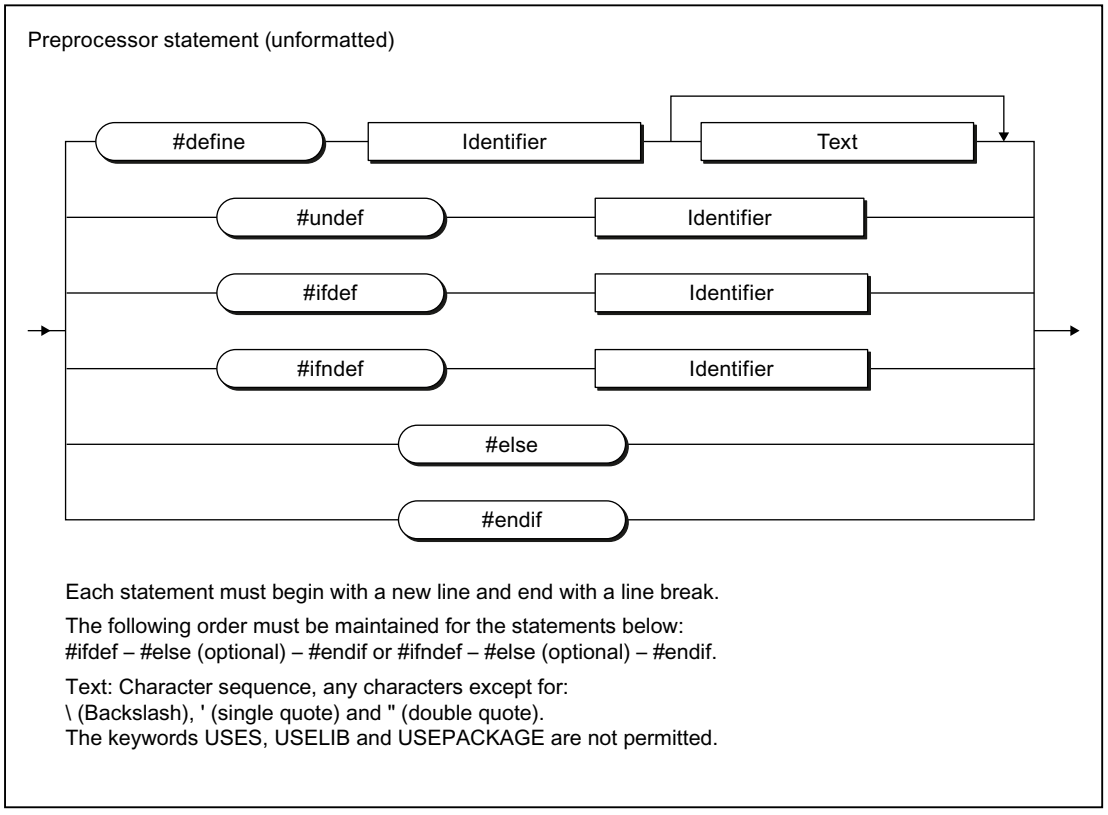

Figure 7-306 Syntax: Preprocessor statement

Table 7-480 Preprocessor statements

Statement	Meaning
#define	The specified identifier will be replaced below by the specified text. Permissible characters: See table footnote.
#undef	The replacement rule for the identifier is cancelled.
#ifdef	For variant formation (conditional compilation) If the specified identifier is defined, the following program lines (until the next pragma that contains #else or #endif) are compiled by the compiler.
#ifndef	For variant formation (conditional compilation) If the specified identifier is **not** defined, the following program lines (until the next pragma that contains #else or #endif) are compiled by the compiler.
#else	For variant formation (conditional compilation) Alternative branch to #ifdef or #ifndef. The following program lines (until the next pragma containing #endif) are compiled by the compiler, if the preceding query with #ifdef or #ifndef was not fulfilled.
#endif	Concludes variant formation with #ifdef or #ifndef.
Permissible characters: • For identifiers: In accordance with the rules for identifiers (Page 4656). • For text: Sequence of any characters other than \ (backslash), ' (single quote) and " (double quote). The keywords USES, USELIB and USEPACKAGE are not permitted.	

Note

Each preprocessor statement must begin with a new line and end with a line break. Consequently, the curly brackets ({ and }) enclosing the pragma must be placed in separate lines of the ST source file!

In the case of pragmas with #define statements, please note:

- Pragmas with #define statements in the interface section of an ST source file are declared public. The defined identifiers can be used with the USES statement into other ST source files of the same SIMOTION device or of the same library.
- Identifiers defined in pragmas of libraries cannot be imported into ST source files of a SIMOTION device.
- Redefinition of reserved identifiers is not possible.

You can also make preprocessor definitions in the Properties dialog box of the ST source file. In the case of different definitions of the same identifiers, #define statements within the ST source file have priority.

Example of preprocessor statements

Table 7-481 Example of preprocessor statements

ST source file With preprocessor statements

```
INTERFACE
    FUNCTION_BLOCK fb1;
    VAR_GLOBAL
        g_var     : INT;
    END_VAR
// Preprocessor definitions
{
#define my_define g_var
#define my_call f(my_define)
}
//     my_define -> g_var
//     my_call   -> f(g_var)
END_INTERFACE

IMPLEMENTATION
    FUNCTION f : INT
        VAR_INPUT
            i : INT;
        END_VAR
        f := i;
    END_FUNCTION

    FUNCTION_BLOCK fb1
        VAR_INPUT
            i_var : INT;
        END_VAR
        VAR_OUTPUT
            o_var : INT;
        END_VAR
        my_define := i_var;
// Delete the preprocessor definition
// For my_define
{
#undef my_define
}
        o_var := my_call + 1;
{
#ifdef my_define
}
        my_define := i_var;
{
#endif
}
    END_FUNCTION_BLOCK
END_IMPLEMENTATION
```

Preprocessor output

```
INTERFACE
    FUNCTION_BLOCK fb1;
    VAR_GLOBAL
        g_var     : INT;
    END_VAR

{

}

END_INTERFACE

IMPLEMENTATION
    FUNCTION f : INT
        VAR_INPUT
            i : INT;
        END_VAR
        f := i;
    END_FUNCTION

    FUNCTION_BLOCK fb1
        VAR_INPUT
            i_var : INT;
        END_VAR
        VAR_OUTPUT
            o_var : INT;
        END_VAR
        g_var := i_var;

{

}
        o_var := f(g_var) + 1;
{

}
    END_FUNCTION_BLOCK
END_IMPLEMENTATION
```

Controlling compiler with attributes

You can use attributes within a pragma to control the compiler.

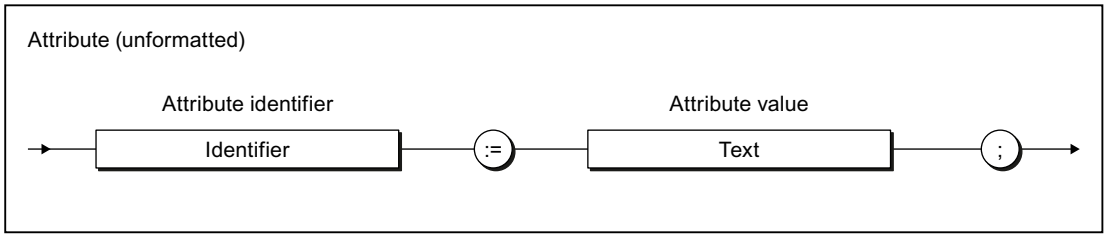

Figure 7-307 Syntax: Attributes for compiler options

Table 7-482 Permissible attributes for compiler options

Attribute identifier	Attribute value	Meaning
_U7_PoeBld_CompilerOption	The attribute affects the output of compiler warnings and information within an ST source file, as well as all subsequent lines of the ST source file.	
	warning:*n*:err	Outputs the warning or information specified by the number *n* as an error. Permissible values for *n*: *n* = 16000 and higher: Number for a warning or information:
	warning:*n*:off	Warnings or information specified by the number *n* are not displayed. Permissible values for *n*: *n* = 0 to 7: Warning class, see Meanings of the warning classes (Page 4633). *n* = 16000 and higher: Number for a warning or information:
	warning:*n*:on	Warnings specified by the number *n* are displayed Permissible values for *n*: *n* = 0 to 7: Warning class, see Meanings of the warning classes (Page 4633). *n* = 16000 and higher: Number for a warning or information:

Attribute identifier	Attribute value	Meaning
HMI_Export	The attribute changes the variables available on HMI devices by default. It must be placed directly after the associated keyword of the following declaration blocks: • In the interface or implementation section of an ST source file: – VAR_GLOBAL – VAR_GLOBAL RETAIN • In the declaration section of a function block provided that the compiler option (Page 4623) "Permit object-oriented programming" is activated: – VAR, VAR PUBLIC, VAR PRIVATE – VAR RETAIN, VAR PRIVATE RETAIN • In the declaration section of a class (as of version V4.5 of the SIMOTION Kernel): – VAR PUBLIC – VAR, VAR PROTECTED, VAR PRIVATE – VAR RETAIN, VAR PROTECTED RETAIN, VAR PRIVATE RETAIN It affects only the unit variables declared in the associated declaration block. Detailed description of the HMI export, in particular the effect of the attribute depending on the version of the SIMOTION kernel: see Variables and HMI devices (Page 4864).	
	FALSE	This attribute value is permissible: • In the interface section of an ST source file • In the following declaration blocks of a function block provided that the compiler option (Page 4623) “Permit object-oriented programming" is activated: – VAR, VAR PUBLIC, VAR PRIVATE • In the following declaration blocks of a class (as of version V4.5 of the SIMOTION Kernel): – VAR PUBLIC The variables declared in the associated declaration block are **not** available on HMI devices.
	TRUE	This attribute value is permissible: • In the implementation section of an ST source file. • In the following declaration blocks of a function block provided that the compiler option (Page 4623) "Permit object-oriented programming" is activated: – VAR RETAIN, VAR PRIVATE RETAIN • In the following declaration blocks of a class (as of version V4.5 of the SIMOTION Kernel): – VAR, VAR PROTECTED, VAR PRIVATE – VAR RETAIN, VAR PROTECTED RETAIN, VAR PRIVATE RETAIN The variables declared in the associated declaration block are available on HMI devices.

Attribute identifier	Attribute value	Meaning
BlockInit_OnChange	The attribute changes the standard definition whether a download in RUN mode is possible when a change is made to the version identification of the associated declaration block. It must be placed directly after the associated keyword of the following declaration blocks: • VAR_GLOBAL (in the interface and implementation section) • VAR_GLOBAL RETAIN (in the interface and implementation section) • VAR (only for programs in a unit if the "Create program instance data only once" compiler option is active). It affects only the variables declared in the associated declaration block. See also Version ID of global variables and their initialization during download (Page 4858).	
	FALSE	Download in RUN mode is **not** possible when the version identification of the declaration block is changed (default).
	TRUE	Download in RUN mode is possible despite the change to the version identification of the declaration block. The variables of the declaration block are initialized in the process.
BlockInit_OnDeviceRun	Only as of Version V4.1 of the SIMOTION kernel. The attribute changes the standard definition whether the variables of the associated declaration block will be initialized for the transition to the RUN mode. It must be placed directly after the associated keyword of the following declaration blocks: • VAR_GLOBAL (in the interface and implementation section) • VAR (only for programs in a unit if the "Create program instance data only once" compiler option is active). It affects only the variables declared in the associated declaration block. See also Memory ranges of the variable types (Page 4844).	
	DISABLE	The variables declared in the associated declaration block are **not** initialized during the transition of the operating mode from STOP to RUN.
	ALWAYS	The variables declared in the associated declaration block are initialized in the transition of the mode from STOP to RUN.
	Default: Up to version V4.1 of the SIMOTION Kernel: DISABLE Version V4.2 and higher of the SIMOTION Kernel: In accordance with the setting on the device	

Note

Be sure to use the correct upper- and lower-case notation for attributes!

Note

The insertion, deletion or changing of the HMI_Export, BlockInit_OnChange or BlockInit_OnDeviceRun attributes in a declaration block does not change its version identification!

Table 7-483 Example of attributes for compiler options

```
INTERFACE
    VAR_GLOBAL
        { HMI_Export := FALSE;
          BlockInit_OnChange := TRUE; }
        // No HMI export, download in RUN possible
        x : DINT;
    END_VAR
    FUNCTION_BLOCK fb1;
END_INTERFACE
IMPLEMENTATION
    VAR_GLOBAL
        { HMI_Export := TRUE;
          BlockInit_OnDeviceRun := ALWAYS; }
        // HMI export, initialization for the STOP -> RUN transition
        y : DINT;
    END_VAR
    FUNCTION_BLOCK fb1
        VAR_INPUT
            i_var    : INT;
        END_VAR
        VAR_OUTPUT
            o_var    : INT;
        END_VAR
        { _U7_PoeBld_CompilerOption := warning:2:on; }
        o_var := REAL_TO_INT(1.0);    // Warning 16004
        { _U7_PoeBld_CompilerOption := warning:2:off; }
        o_var := REAL_TO_INT(1.0);    // No warning 16004
        { _U7_PoeBld_CompilerOption := warning:16004:on; }
        o_var := REAL_TO_INT(1.0);    // Warning 16004
        { _U7_PoeBld_CompilerOption := warning:16004:off; }
        o_var := REAL_TO_INT(1.0);    // No warning 16004
        { _U7_PoeBld_CompilerOption := warning:2:off;
          _U7_PoeBld_CompilerOption := warning:16004:on; }
        o_var := REAL_TO_INT(1.0);    // Warning 16004
    END_FUNCTION_BLOCK
END_IMPLEMENTATION
```

Issue non-assigned compiler message

Within a Pragma (Page 4917) you are able to prompt the computer to write non-assigned compiler messages to the "Compile/check output" tab of the detailed view.

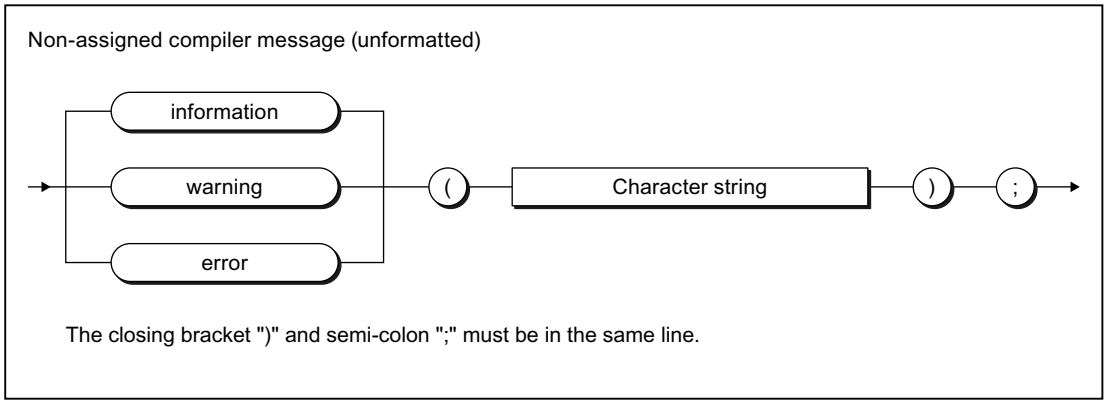

Figure 7-308 Syntax: Non-assigned compiler message

The keywords have the following meaning:

Keyword	Message number	Description
information	22002	Non-assigned information
warning	22001	Non-assigned warning
error	22000	Non-assigned error message

The text of the non-assigned message is stated after the keyword in brackets as a character string (Page 4667). A semi-colon completes the statement within the pragma.

Note

These pragma statements are not included when checking the backward compatibility of the project (Menu **Project > Old project format > Check the project for backward compatibility**).

The non-assigned compiler messages can e.g. be controlled with version formation by using preprocessor statements (Page 4919), see example below.

```
{ #ifdef test }
    ; // Statements
{ #else
    warning ('This message appears when "test" has not been defined');
#endif }
```

Pragmas for message output which are in hidden program sequences with the version formation are not taken into account.

7.2.7.8 SIMOTION devices

Rules for identifiers of the SIMOTION devices

General device identifiers

Identifiers for SIMOTION devices in the project navigator do not have to comply with the general Rules for identifiers (Page 4656).

All characters of the extended ASCII character set (ASCII code $20 to $7E, $80 to $FF) that can be displayed are permitted for the identifier of a SIMOTION device, except the following special characters:

- " (double inverted commas, ASCII code $22),
- & (Et character, ampersand, ASCII code $26),
- * (star, ASCII code $2A),
- : (colon, ASCII code $3A),
- < (less than character, ASCII code $3C),
- > (greater than character, ASCII code $3E),
- ? (question mark, ASCII code $3F),
- \ (backslash, ASCII code $5C),
- | (vertical line, ASCII code $7C).

Identifiers for the SIMOTION devices can only be specified in SIMOTION SCOUT or HW Config and only used in the programming languages.

Examples of valid device identifiers

- C240.2
- D455-2-DP (1)
- D445-2.PN-1

Device identifiers that do not comply with the general rules for identifiers can be used for SIMOTION devices of all versions (or all versions of the SIMOTION Kernel).

Note

Projects that contain device identifiers, which do not comply with the general Rules for identifiers (Page 4656), cannot be saved in the old project format (up to and including V4.2).

Device identifiers for PROFINET IO (name of station)

Device identifiers that are used as device names in PROFINET IO (name of station), must comply with the following- DNS conventions:

- Permissible lengths: 1 to 127 characters
- Organization using points "." is permissible in several labels; length of a single label: 1 to 63 characters
- Characters permitted within a label:
  - Letters "A" to "Z" and "a" to "z".
  - Numbers "0" to "9" (not at the beginning of the label)
  - Special character hyphen "-" (not at the beginning or end of a label)
  - Other special characters (such as accented characters, blank spaces, brackets, underscores) are not permitted.
- The following identifiers are not permitted for device names:
  - Identifiers that start with "port-xyz-" (x, y, z = 0 ... 9),
  - Identifiers of the form n.n.n.n (n = 0 ... 999).

Use of device identifiers in SIMOTION SCOUT

Identifiers for SIMOTION devices that do not comply with the general rules for identifiers **must** be enclosed in double inverted commas (", ASCII code $22) when used in SIMOTION SCOUT (e.g. in the programming languages).

Example:

- "D455-2 DP (1)".axis_1. motionStateData.actualVelocity
  Access to the system variable *motionStateData.actualVelocity* of the technology object *axis_1* on the device *D455-2 DP (1)*.

Note

Device identifiers that comply with the general Rules for identifiers (Page 4656) **can** also be enclosed in double inverted commas.

Example: The following notations are permitted for access to the system variable *motionStateData.motionState* of the technology object *axis_2* on the device *D435_2*:

- D435_2.axis_2.motionStateData.motionState
- "D435_2".axis_2.motionStateData.motionState

Making settings on the device (as of Kernel V4.2)

As of version V4.2 of the SIMOTION Kernel, you can make the following settings, among others, on the SIMOTION device:

- Memory area for the process image of the cyclic tasks and the fixed process image of the BackgroundTasks:
  - Separate memory areas for both process images - separate process image (Page 4885)
  - Common process image (Page 4883)
- Initialization of non-retentive global variables and program data during STOP-RUN transition
- Perform time synchronization with SINAMICS drive units
- Permit OPC-UA/XML for global device variables or I/O variables
  The symbol information of these variables is available in the SIMOTION device. This is necessary for the watch function of IT DIAG, for example.
- Restrict area for automatic address assignment during the message frame configuration (as of version V4.3 of the SIMOTION Kernel).
  When the checkbox is activated, the specified address area for the automatic message frame configuration is blocked. Specification of the blocked area has no effect when the message frames have already been configured.

You will find a detailed description in the online help.

Procedure

Settings on the device can be made as follows:

1. Select the SIMOTION device in the project navigator.
2. Select the **Edit > Object Properties** menu command.
3. Select the **Settings** tab.
4. Enter the settings.
5. Click **OK** to confirm.

7.2.7.9 Forward declarations

When creating the source file, you should always pay attention to the order of the source file modules. A module that is to be called must always precede the calling module so that the former is recognized by the latter.

For example, variables must be declared before they are used, functions must be defined before they are called, and function blocks must be defined prior to instance declaration.

Forward declaration for program organization units (POUs)

The compiler option (Page 4623) "Permit forward declarations" has the following effect:

- Declarations (e.g. global variable declarations) may be freely programmed between program organization units in the implementation section of an ST source file.
- The following statements within the TYPE / END_TYPE construct in the interface section (Page 4807) or the implementation section (Page 4809) of an ST source file are interpreted as prototypes of the relevant POU:
  - FUNCTION_BLOCK*fb-name*;
  - FUNCTION*fc-name*;
  - PROGRAM*prog-name*;
  - CLASS *class-name*; (as of version V4.5 of the SIMOTION Kernel and with compiler option (Page 4623) "Permit object-oriented programming" activated)

  See below for syntax diagram.
- After the corresponding POU prototype has been declared for a class or function block, the following declarations can be programmed before the relevant POU is defined:
  - Instance declaration of the function block (Page 4754) as a global variable or local variable in a program, in another function block or in a class
  - Instance declaration of the class (Page 4778) as a global variable or local variable in a program, in a function block or in another class
  - Use of the function block or class as a parameter in the definition of a function block, function or method

  Instance-specific initialization is not possible in this case.

  Note

  With instance-specific initialization (only when compiler option (Page 4623) "Permit object-oriented programming" is activated), the following applies:

  It is imperative that the function block or class is defined before the instance is declared or used. Declaration of the relevant POU prototype is not sufficient and therefore superfluous.

- All of the statement sections of program organization units are compiled in a second compiler run. For this reason, the following calls are possible regardless of the declaration position:
  - Call of a function block instance
  - Call of a function (Page 4753)
  - Call of a method
  - Call of a program within a program (Page 4762), provided that the other relevant requirements have been met.

  If a function or a program is called before it is implemented, the declaration of the prototype is optional; the call can still be carried out even if the prototype is not declared. Please note the additional relevant requirements when calling a program within a program.

POU prototypes

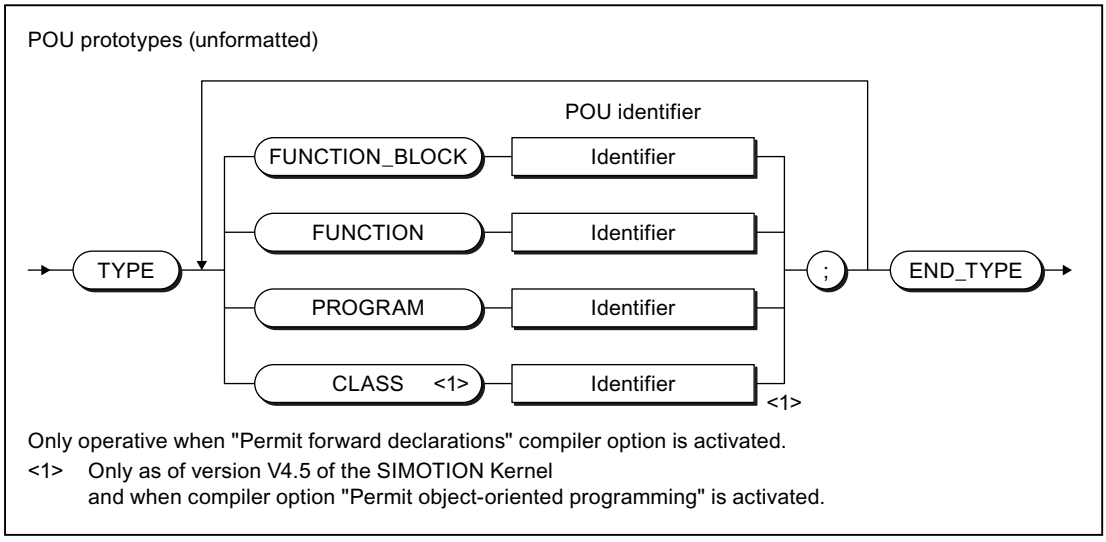

Figure 7-309 Syntax: POU prototypes

Note

If the POU prototypes are declared within the interface section, the corresponding POUs are declared public.

DECLARE PUBLIC statements for POUs within the interface section
(e.g. FUNCTION_BLOCK *fb-name;*) are also interpreted as prototypes.

If the "Permit forward declarations" compiler option (Page 4623) is not activated, the POU prototypes are ignored. Only the prototypes in the interface section are interpreted as DECLARE PUBLIC statements for the corresponding POU.

Example

Table 7-484 Sample program with forward declaration

```
(*
Only if the "Permit forward declarations" compiler option is activated.
*)

(*
The following compiler options also need to be activated due to a program
being called within the program:
"Permit language extensions" and "Only create program instance data once".
*)

INTERFACE
    PROGRAM prog_main;
END_INTERFACE
```

```
IMPLEMENTATION
    TYPE                        // POU prototypes
        FUNCTION_BLOCK fb_1; // Required for instance declaration
        FUNCTION fc_1;       // Optional
        PROGRAM prog_1;      // Optional
    END_TYPE
    // Instance declaration prior to implementation
    VAR_GLOBAL
        var_fb_1 : fb_1;
    END_VAR
    PROGRAM prog_main
        VAR
            var_1, var_2 : DINT;
            var_3, var_4 : INT;
        END_VAR

        var_fb_1 (x_in := var_3, x_out => var_4);

        // Call prior to implementation
        var_2 := fc_1 (var_1);
        prog_1();
    END_PROGRAM
    // Implementations

    FUNCTION_BLOCK fb_1
        VAR_INPUT
            x_in : INT;
        END_VAR

        VAR_OUTPUT
            x_out : INT;
        END_VAR

        x_out := x_in;
    END_FUNCTION_BLOCK
    FUNCTION fc_1: DINT
        VAR_INPUT
            x_in : DINT;
        END_VAR

        fc_1 := x_in;
    END_FUNCTION
    PROGRAM prog_1
        VAR
            var_int1, var_int2 : INT;
        END_VAR

        var_int1 := var_int2;
    END_PROGRAM
END_IMPLEMENTATION
```

7.2.7.10 Jump statement and label

As additional control statement (Page 4719), a jump statement is also available.

You program a jump statement (Page 4731) with the GOTO statement and specify the jump label to which you want to jump. Jumps are only permitted within a POU.

Enter the jump label (separated by a colon) in front of the statement at which you want the program to resume.

Alternatively, you can declare the jump labels in the POU (with the structure LABEL/END_LABEL in the POU). Only the declared jump labels can then be used in the statement section.

Syntax of jump statements and labels:

Example of syntax for jump statements

```
FUNCTION func : VOID
    VAR
        x, y, z : BOOL;
    END_VAR
    LABEL
        lab_1, lab_2;      // Declaration of the jump labels
    END_LABEL

    x := y;
  lab_1 : y := z;          // Jump label with statement
    IF x = y THEN
        GOTO lab_2;        // Jump statement
    END_IF;
    GOTO lab_1;            // Jump statement
  lab_2 : ;                // Jump label with blank statement
END_FUNCTION
```

Note

You should only use the GOTO statement in special circumstances (for example, for troubleshooting). It should not be used at all according to the rules for structured programming.

Jumps are only permitted within a POU.

The following jumps are illegal:

- Jumps to subordinate control structures (WHILE, FOR, etc.)
- Jumps from a WAITFORCONDITION structure
- Jumps within CASE statements

Jump labels can only be declared in the POU in which they are used. If jump labels are declared, only the declared jump labels may be used.

7.2.8 Error Sources and Program Debugging

This chapter describes various sources of programming errors and shows you how to program efficiently. You also learn what options are available for program testing. For all possible compilation error messages, i.e. compiler errors, see Compiler error messages and their remedies (Page 5040). Possible reactions and remedies are described for each error.

7.2.8.1 Notes on avoiding errors and on efficient programming

The SIMOTION *Basic Functions* Function Manual lists some common error sources, which hinder the compilers or prevent the proper execution of a program. There are notes on, e.g.:

- Data types for assigning arithmetic expressions
- Starting functions in cyclic tasks
- Wait times in cyclic tasks
- Errors on download
- CPU does not switch to RUN
- CPU goes to STOP
- Size of the local data stack
- etc.

In addition, you will also find notes on efficient programming there, particularly for

- runtime-oriented programming
- change-optimized programming

7.2.8.2 Program debugging

Syntax errors are detected and displayed by the ST compiler during the compilation procedure. Runtime errors in the execution of the program are displayed by system alarms or lead to the operating mode STOP. You can find logical programming errors with the test functions of ST, e.g. with the symbol browser, status program, trace.

To achieve the same results as shown below using the test functions, use of the sample program in Creating a sample program (Page 4643) is recommended.

Operating modes for program testing

Modes of the SIMOTION devices

Various SIMOTION device operating modes are available for program testing.

Table 7-485 Operating modes of a SIMOTION device

Operating mode	Meaning
Process mode	Program execution on the SIMOTION device is optimized for maximum system performance. The following diagnostic functions are available, although they may have only restricted functionality because of the optimization for maximum system performance: • Monitor variables in the symbol browser or a watch table • Program status (only restricted): – Restricted monitoring of variables (e.g. variables in loops, return values for system functions). – Maximum of 1 program source (e.g. ST source file, MCC unit, LAD/FBD unit)[1] can be monitored. • Trace tool (only restricted) with measuring functions for drives and function generator, see online help: – Maximum of **1** trace on each SIMOTION device.
Test mode	The diagnostic functions of the process mode are available to the full extent: • Monitor variables in the symbol browser or a watch table • Program status: – Monitoring of all variables possible. – As of version V4.0 of the SIMOTION Kernel: Several program sources (e.g. ST source files, MCC units, LAD/FBD units)[1] can be monitored per task. – For version V3.2 of the SIMOTION Kernel: Maximum of 1 program source (e.g. ST source file, MCC unit, LAD/FBD unit)[1] can be monitored per task. • Trace tool with measuring functions for drives and function generator, see online help: – Maximum of **4** traces on each SIMOTION device. In addition, the following diagnostics function is available: • Trace for monitoring the program execution in program branches which are executed cyclically (only for the MCC programming language and for SIMOTION Kernel V4.2 and higher). **Note** Runtime and memory utilization increase as the use of diagnostic functions increases.

Operating mode	Meaning
Debug mode	In addition to the diagnostic functions of the test mode, you can use the following functions: • Breakpoints Within a program source, you can set breakpoints (Page 4954). When an activated breakpoint is reached, selected tasks will be stopped. • Controlling MotionTasks On the "Task Manager" tab of the device diagnostics, you can use task control commands for MotionTasks; see the SIMOTION Basic Functions Function Manual. No more than 1 SIMOTION device of the project can be switched to debug mode. SIMOTION SCOUT is in online mode, i.e. connected to the target system. Observe the following section: Important information about the life-sign monitoring (Page 4937).

[1] Each with 1 MCC chart or 1 LAD/FBD program in a program source.

Selecting the operating mode

How to select the operating mode of a SIMOTION device:

1. Make sure a connection to the target system has been established (online mode).
2. Highlight the SIMOTION device in the project navigator.
3. Select the "Operating mode" context menu.
4. Select the required operating mode (see the table above).
   If you have selected "Debug mode":
   – Accept the safety information.
   – Parameterize the sign-of-life monitoring.

   Observe the following section: Important information about the life-sign monitoring (Page 4937).
5. Confirm with **OK**.
   The SIMOTION device switches to the selected operating mode (apart from with debug mode; see the explanation below).

Special features with debug mode

Debug mode can only be selected for one SIMOTION device.

If you have selected debug mode, only SIMOTION SCOUT switches to it; the SIMOTION device is in test mode.

- The project navigator indicates that debug mode is activated for SIMOTION SCOUT by means of a symbol next to the SIMOTION device.
- The breakpoints toolbar is displayed.

Debug mode is not enabled for the SIMOTION device until at least one set breakpoint is activated. If all breakpoints are deactivated, debug mode is canceled for the SIMOTION device.

The status bar indicates that debug mode is activated for the SIMOTION device.

Important information about the life-sign monitoring.

⚠ WARNING

Dangerous plant states possible

If problems occur in the communication link between the PC and the SIMOTION device, this may result in dangerous plant states (e.g. the axis may start moving in an uncontrollable manner).

Therefore, use the debug mode or a control panel only with the life-sign monitoring function activated with a suitably short monitoring time!

You must observe the appropriate safety regulations.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

In the following cases, the SIMOTION device and SIMOTION SCOUT regularly exchange life-signs to ensure a correctly functioning connection:

- In debug mode with activated breakpoints.
- When controlling an axis or a drive via the control panel (control priority at the PC):

If the exchange of the life-signs is interrupted longer than the set monitoring time, the following reactions are triggered:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to the STOP operating state.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis is brought to a standstill.
  - The enables are reset.

Accept safety notes

After selecting the debug mode or a control panel, you must accept the safety notes. You can set the parameters for the life-sign monitoring.

Proceed as follows:

1. Click the **Settings** button.
   The "Debug Settings" window opens.
2. Read there, as described in the following section, the safety notes and parameterize the life-sign monitoring.

Parameterizing the life-sign monitoring

In the "Life-Sign Monitoring Parameters" window, proceed as described below:

1. Read the warning!
2. Click the **Safety notes** button to open the window with the detailed safety notes.
3. Do not make any changes to the defaults for life-sign monitoring.
   Changes should only be made in special circumstances and in observance of all danger warnings.
4. Click **Accept** to confirm you have read the safety notes and have correctly parameterized the life-sign monitoring.

Note

The life-sign monitoring also responds in the following cases:

- Pressing the spacebar.
- Switching to a different Windows application.
- Too high a communication load between the SIMOTION device and SIMOTION SCOUT (e.g. by uploading task trace data).

The following reactions are triggered:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to the STOP operating state.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis or the drive is brought to a standstill.
  - The enables are reset.

⚠ WARNING

Dangerous plant states possible

This function is not guaranteed in all operating states.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Life-sign monitoring parameters

Table 7-486 Life-sign monitoring parameter description

Field	Description
Life-sign monitoring	The SIMOTION device and SIMOTION SCOUT regularly exchange life-signs to ensure a correctly functioning connection. If the exchange of the life-signs is interrupted longer than the set monitoring time, the following reactions are triggered: • In debug mode for activated breakpoints: – The SIMOTION device switches to the STOP operating state. – The outputs are deactivated (ODIS). • For controlling an axis or a drive using the control panel (control priority for the PC): – The axis is brought to a standstill. – The enables are reset. The following parameterizations are possible: • Checkbox **active**: If the checkbox is activated, life-sign monitoring is active. The deactivation of the life-sign monitoring is not always possible. • Monitoring time: Enter the timeout. **Prudence** Do not make any changes to the defaults for life-sign monitoring, if possible. Changes should only be made in special circumstances and in observance of all danger warnings.
Safety information	**Please observe the warning!** Click the button to obtain further safety information. See: Important information about the life-sign monitoring (Page 4937)

Editing program sources in online mode

Online editing in process or test mode

If SIMOTION SCOUT is connected to a target system which is in the "process mode" or "test mode" operating mode, program sources (e.g. ST source files, MCC units with MCC charts) can generally be edited, compiled, and loaded to the target system in STOP operating mode. For information on downloading in RUN operating mode, see the corresponding section in the "SIMOTION Basic Functions" Function Manual.

However, you can only activate the "program status", "monitor program execution" (only for MCC), and trace (only for MCC) test functions for a program source or a program organization unit (POU) if the following conditions are met:

1. This program source or any POU of this source (e.g. MCC chart) does not contain any changes which have not been saved.
2. The program source (unit) in SCOUT is consistent with the target system.

Note

If the "program status" test function is activated, editing of the corresponding program source or one of its POUs is disabled.

If an MCC unit or MCC chart is changed and the "monitor program execution" or trace test functions are active for that unit or chart, the test functions are canceled.

Online editing in debug mode

If SIMOTION SCOUT is in debug mode, editing is possible as long as the SIMOTION device is not in debug mode, i.e. no breakpoints are activated.

You can only activate breakpoints and, as a result, switch the SIMOTION device to debug mode if the corresponding program source and all its POUs are saved, compiled so they are up to date, and consistent with the target system.

If you attempt to edit a program source or POU when the SIMOTION device is in debug mode, you are requested to deactivate all breakpoints and, as a result, to switch the SIMOTION device out of debug mode.

Note

If breakpoints have been activated and the SIMOTION device is in debug mode:

Entering a space switches the SIMOTION device to STOP operating mode and deactivates all outputs (ODIS).

Symbol Browser

Properties of the symbol browser

In the symbol browser, you can view and, if necessary, change the name, data type, and variable values. In particular, you can: see the following variables:

- Unit variables and static variables of a program or function block
- System variables of a SIMOTION device or a technology object
- I/O variables or global device variables.

For these variables, you can:

- View a snapshot of the variable values
- Monitor variable values as they change
- Change (modify) variable values

However, the symbol browser can only display/modify the variable values if the project has been loaded in the target system and a connection to the target system has been established.

Using the symbol browser

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system. To load the project with the sample program, see "Executing the sample program (Page 4650)".
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

The procedure depends on the memory area in which the variables to be monitored are stored.

Procedure

Proceed as follows:

1. Select the appropriate element in the project navigator in accordance with the following table.
2. In the detail view, click the **Symbol browser** tab.
   The corresponding variables are displayed in the symbol browser.
3. Select how each variable in the "Display format" column should be displayed.

Table 7-487 Elements in the project navigator and variables to be monitored in the symbol browser

Variables to be monitored in the symbol browser	Element to be selected in the project navigator
For variables in the user memory of the unit or in the retentive memory, refer to Memory areas of the variable types (Page 4844): • Retentive and non-retentive unit variables of the interface section of a program source (unit) • Retentive and non-retentive unit variables of the implementation section of a program source (unit) • Static variables of the function blocks whose instances are declared as unit variables. • In addition, if the program source (unit) has been compiled with the "Only create program instance data once" compiler option (Page 4623): – Static variables of the programs. – Static variables of the function blocks whose instances are declared as static variables of programs.	Program source (unit)
Variables in the user memory of the task, refer to Memory areas of the variable types (Page 4844): If the program source (unit) was compiled without the "Only create program instance data once" (default) compiler option (Page 4623), the user memory of the task to which the program was assigned contains the following variables: • Static variables of the programs. • Static variables of the function blocks whose instances are declared as static variables of programs.	EXECUTION SYSTEM
System variables of a SIMOTION device	SIMOTION device
System variables of a technology object	Instance of the technology object
Global device variables	GLOBAL DEVICE VARIABLES
I/O variables (in the Address list tab of the detail view). The Address list tab of the detail view can be opened by double-clicking the ADDRESS LIST element in the project navigator.	ADDRESS LIST

Note

You can monitor temporary variables (together with unit variables and static variables) with **Program status** (see Properties of the program status (Page 4949)).

Note

Trace diagnostic function for MCC programming

Various internal variables, whose identifier begins with an underscore, are automatically created by the compiler for the trace diagnostic function. These variables are displayed in the symbol browser.

With activated diagnostic function, these variables are used for the control of the diagnostics function. These variables must not be used in the user program.

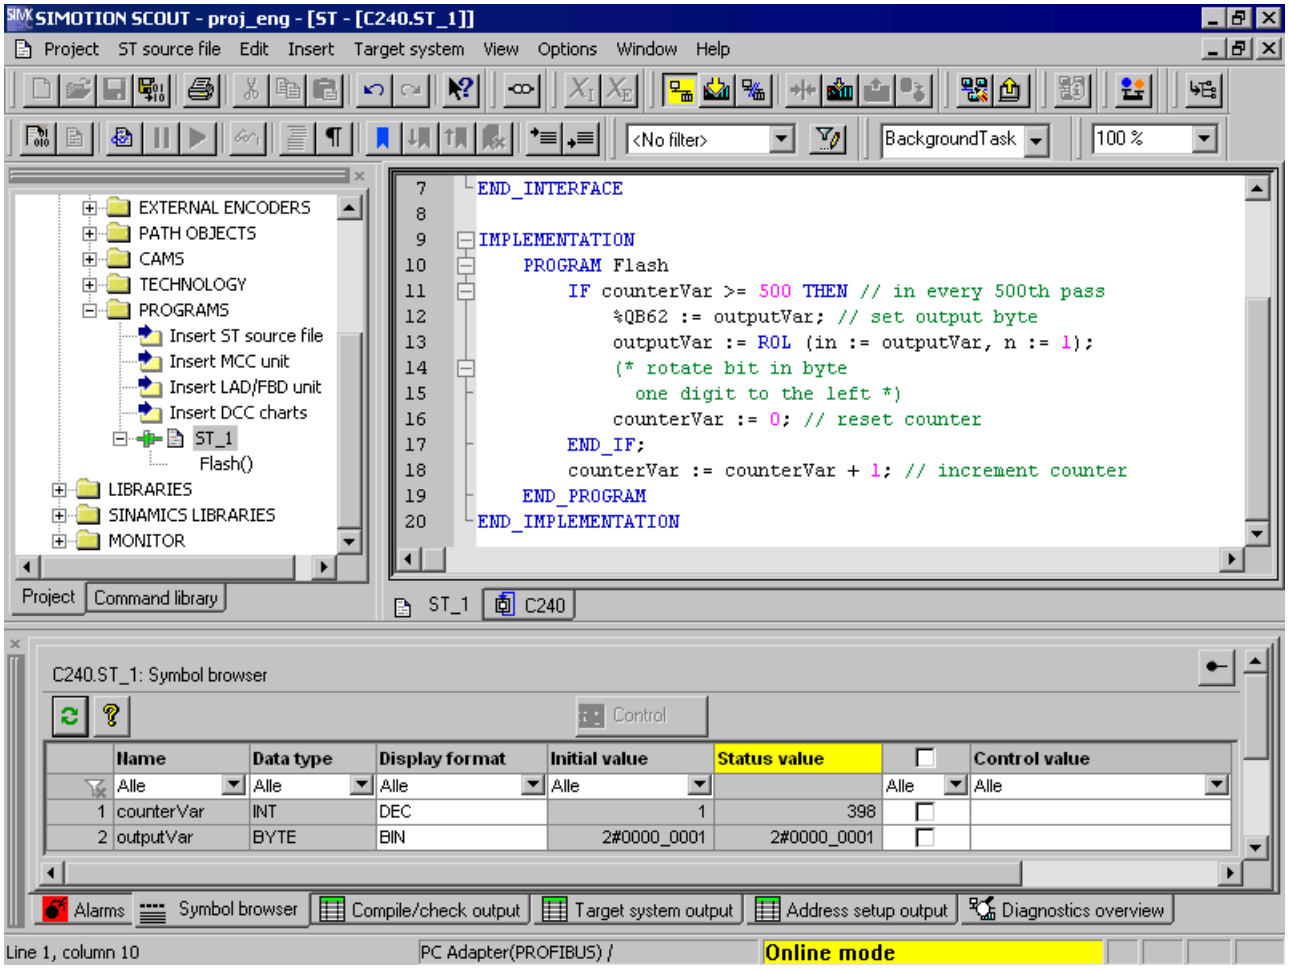

Figure 7-310 Viewing variables in the symbol browser

Status and controlling variables

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox adjacent to this column
3. Click the **Control** button.

The values you entered are written to the selected variables.

WARNING

Dangerous plant states possible

You assign the entered values to the variables during control. This can result in dangerous plant states, e.g. unexpected axis motion.

Note

Note when you change the values of several variables:

The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the symbol browser. There is therefore no guarantee of consistency.

Working with the symbol browser

The functions of the symbol browser and how you work with them are described in detail in the online help.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the symbol browser (independently of the SIMOTION device):

Table 7-488 Display invalid floating-point numbers

Display	Meaning
1.#QNAN -1.#QNAN	Invalid bit pattern in accordance with IEEE 754 (NaN Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).
1.#INF -1.#INF	Bit pattern for + infinity in accordance with IEEE 754 Bit pattern for – infinity in accordance with IEEE 754
-1.#IND	Bit pattern for indeterminate

Monitoring variables in watch table

Variables in the watch table

With the symbol browser you see only the variables of an object within the project. With program status you see only the variables of an ST source file within a freely selectable monitoring area.

With watch tables, in contrast, you can monitor selected variables from different sources as a group (e.g. program sources, technology objects, SINAMICS drives - even on different devices).

You can see the data type of the variables in offline mode. You can view and modify the value of the variables in online mode.

Using watch tables

You can group variables from various program sources, technology objects, SIMOTION devices, etc. (even on different devices), in a watch table where you can monitor them together and, if necessary, change them.

Creating a watch table

Procedure for creating a watch table and assigning variables:

1. In the Project navigator, select the **MONITOR** folder.
2. Select **Insert > Watch table** to create a watch table, and enter the name of the watch table. A watch table with this name appears in the **MONITOR** folder.
3. In the project navigator, click the object from which you want to move variables to the watch table.
4. In the symbol browser, select the corresponding variable line by clicking its number in the left column.
5. From the context menu, select **Add to watch table** and the appropriate watch table, e.g. **Watch table_1**.
6. If you click the watch table, you will see in the detail view of the **Watch table** tab that the selected variable is now in the watch table.
7. Repeat steps 3 to 6 to monitor the variables of various objects.

Status and controlling variables

If you are connected to the target system, you can monitor the variable contents.

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

⚠ WARNING

Dangerous plant states possible

You assign the entered values to the variables during control. This can result in dangerous plant states, e.g. unexpected axis motion.

Note

Note when you change the values of several variables:

The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the watch table. There is therefore no guarantee of consistency.

Working with the watch table

The functions of the symbol browser and how you work with them are described in detail in the online help.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the watch table (independently of the SIMOTION device):

Table 7-489 Display invalid floating-point numbers

Display	Meaning
1.#QNAN -1.#QNAN	Invalid bit pattern in accordance with IEEE 754 (NaN - Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).
1.#INF -1.#INF	Bit pattern for + infinity in accordance with IEEE 754 Bit pattern for – infinity in accordance with IEEE 754
-1.#IND	Bit pattern for indeterminate

Variable status

"Variable status" enables you to monitor the current value for an individual variable, selected using the cursor, in an open program source or program organization unit (e.g. ST source file, MCC chart, LAD program).

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system. For information on loading a project, see "Running the sample program (Page 4650)".
- The program source containing the program organization unit (POE) whose variables you want to monitor must be consistent with the target system.
- The associated source (e.g. ST source file, MCC chart, LAD program) must be open.
- With the MCC programming language only: The parameter screen form for the command in which the variable you want to monitor is being used must be open.
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

Procedure

To monitor an individual variable using variable status:

1. Position the cursor above the identifier for a variable.
   - With the ST programming language: in the open ST source file
   - With the ST programming language: within an input field in the open parameter screen form
   - With the LAD/FBD programming language: within a network of the LAD/FBD program
2. Briefly position the cursor above the identifier.

The tool tip shows the current value of the variable. If you keep the cursor above the identifier for a longer period, the value is updated on an ongoing basis.

Note

With "variable status", the current value for the variable is displayed, wherever the selected variable is being used.

The "variable status" function enables you to monitor all those variables you are also able to monitor in the symbol browser (Page 4941) or the address list. These are:

- System variables of SIMOTION devices
- System variables of technology objects
- Global device variables
- Retentive and non-retentive unit variables of the interface section of a program source (unit)
- Retentive and non-retentive unit variables of the implementation section of a program source (unit)
- Static variables of the programs
- Static variables of the function blocks whose instances are declared as unit variables
- Static variables of the function blocks whose instances are declared as static variables of programs
- I/O variables

Program run

Program run: Display code location and call path

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path.

Follow these steps:

1. Click the **Show program run** button on the Program run toolbar.
   The "Program run call stack (Page 4948)" window opens.
2. Select the desired MotionTask.
3. Click the **Update** button.

The window shows:

- The position in the code being executed (e.g. line of the ST source file) stating the program source and the POU.
- Recursively positions in the code of other POUs that call the code position being executed.

The following names are displayed for the SIMOTION RT program sources:

Table 7-490 SIMOTION RT program sources

Name	Meaning
taskbind.hid	Execution system
stdfunc.pck	IEC library
device.pck	Device-specific library
tp-name.pck	Library of the *tp-name* technology package, e.g. cam.pck for the library of the CAM technology package

Program run parameters

You can display the following for all configured tasks:

- the current code position in the program code (e.g. line of an ST source file)
- the call path of this code position

Table 7-491 Program run parameter description

Array	Description
Selected CPU	The selected SIMOTION device is displayed.
Refresh	Clicking the button reads the current code positions from the SIMOTION device and shows them in the open window.
Calling task	Select the task for which you want to determine the code position being executed. All configured tasks of the execution system.
Current code position	The position being executed in the program code (e.g. line of an ST source file) is displayed (with the name of the program source, line number, name of the POU).
is called by	The code positions that call the code position being executed within the selected task are shown recursively (with the name of the program source, line number, name of the POU, and name of the function block instance, if applicable).

For names of the SIMOTION RT program sources, refer to the table in Program run (Page 4947).

Program run toolbar

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path with this toolbar.

Table 7-492 Program run toolbar

Symbol	Meaning
	Display program run Click this symbol to open the Program run call stack window. In this window, you can display the currently active code position with its call path. See: Program run: Display code position and call path (Page 4947)

Program status

Properties of the program status

Status program enables monitoring the variable values accurately to the cycle during program execution.

You can select a monitoring area in the ST source file and monitor, in addition to global and static local variables, also temporary local variables (e.g. within a function) there.

The values of the following variables are displayed:

- Simple data type variables (INT, REAL, etc.)
- Individual elements of a structure, provided an assignment is made
- Individual elements of an array, provided an assignment is made
- Enumeration data type variables

Return values of the system function _trcVal are also displayed. This way interim results can be displayed in expressions. For the _trcVal function please refer to the "SIMOTION Basic Functions Function Manual (Page 1560)".

Note

The values of constants are not displayed.

Due to the restricted buffer capacity and the requirement for minimum runtime corruption, the following variables cannot be displayed:

- Complete arrays
- Complete structures

Individual array elements or individual structure elements are displayed, however, provided an assignment is made in the ST source file.

Method of operation of program status

On the SIMOTION device:

- While the selected monitoring range is running in the ST source file, the buffer for the variables to be monitored is filled with the corresponding values.
  The recording of the values depends on the operating mode (Page 4935) (process mode or test mode) of the SIMOTION device, see following table.
- Only after leaving the selected monitoring range or abort of the recording is the buffer displayed in SIMOTION SCOUT.

SIMOTION SCOUT calls the values which have been made available at regular intervals and displays them in the format you selected in the ST editor settings (Page 4593) under "Format for status display".

In the case of functions and function blocks, you can select a location in an ST source file where a function or instance of a function block is called (call path). This enables you to observe the variable values specifically for this call.

Table 7-493 Differences between process mode and test mode in Program Status

	Process mode	**Test mode**
Optimization of program execution	For maximum system performance, only restricted diagnostics are possible.	For full diagnosis options
Maximum number of monitored program sources (e.g. ST source files, MCC units, LAD/FBD units)	Maximum of 1 program source[1]	• As of version V4.0 of the SIMOTION Kernel: Multiple program sources[1] per task • For version V3.2 of the SIMOTION Kernel: Maximum of 1 program source[1] per task
Loops (e.g. WHILE, REPEAT, FOR)	The recording is interrupted on the first repeat loop. The values are provided. Therefore, the following applies for completely selected loops: • The appropriate values are displayed after the first run of the loop. • Changes or the values are not displayed during further runs.	If there are repeats, the recording continues correctly. Therefore, the following applies for completely selected loops: • As long as the loop is being run through, no values are displayed. • Only after leaving the monitoring range are the values displayed on the last run of the loop.
System functions that contain internal loops (e.g. functions for processing strings)	The recording is interrupted during the execution of the system function. Values are not correctly displayed in some cases.	The recording is performed correctly during the call of the system function. Values are displayed correctly.

[1] Each with 1 MCC chart or 1 LAD/FBD program in a program source

Note

Program status requires additional CPU resources.

Please note if you want to monitor several programs at the same time with the status program:

- Test mode must be activated (see Operating modes of the SIMOTION devices (Page 4935)).
- In version V3.2 of the SIMOTION Kernel, the programs must be assigned to various tasks.

Using the status program

Before you can work with the Status program, you must instruct the system to run in a special mode:

1. Make sure that the ST source file generates the additional debug code during compilation:
   - Select the ST source file in the project navigator and select the **Edit > Object properties** menu command.
   - Select the **Compiler** tab to change the local settings of the compiler (Page 4626).
   - Make sure that the **Enable Status program** checkbox is activated and confirm with **OK**. You can also change this compiler option at global settings of the compiler (Page 4623).
2. Open the ST source file and recompile it with **ST source file > Accept and compile**.
3. Download and start the program in the usual way.
4. Click the button for **program status** in the ST editor toolbar (Page 4614) to start this test mode.

The ST editor window is now divided vertically:

- In the left-hand pane of the window, you can see the ST source file. You can select an area here.
- The right-hand pane of the window displays the variables for the selected area and their values.

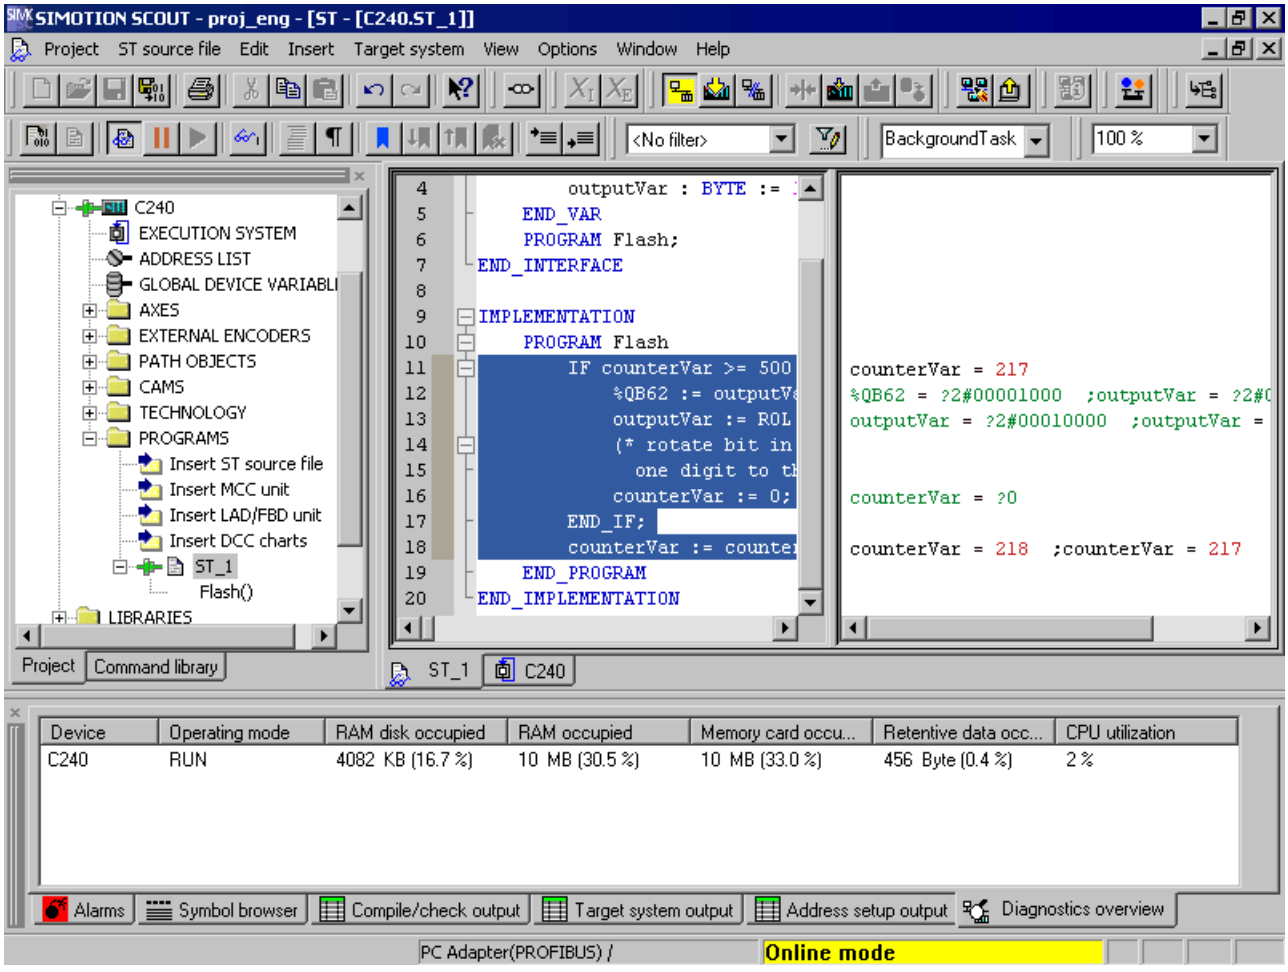

Figure 7-311 Part of an ST program in program status test mode

Follow the procedure below to test with program status:

1. In the left-hand pane, select the section of the ST source file you want to test.
2. If you have selected a section of a POU that is called by several positions in a program source file or several tasks:
   Enter the call path for program status (Page 4953).

The right-hand pane of the window displays the variables for the selected area and their values. The display of the variable values is updated cyclically. Variables with bit data type are updated cyclically and correspond to the format you selected in the ST editor settings (Page 4593) under "Format for status display":

- Values that have changed in the current pass are displayed in **red**.
- Values that have not changed are displayed in **black**.
- Variables without values, e.g. variables in an unused IF branch are shown in **green** and marked with a question mark.

If the display of the variable values changes too fast:

- Click the  button for **Stop monitoring of program variables** in the ST editor toolbar (Page 4614) to stop the display.
- Click the  button for **Continue monitoring of program variables** in the ST editor toolbar (Page 4614) to continue the display.

You can force the update of the displayed values:

- Click the  button for **Update** on the ST editor toolbar (Page 4614).
  The buffer of the SIMOTION device is read, even if the selected monitoring range has not yet been completely processed and the values are incomplete. This can be useful, for example, if the program is waiting for a WAITFORCONDITION statement.
  The monitoring of the program variables must have been activated.

Call path for program status

You can specify the call path when monitoring variable values of functions and function blocks. This enables you to observe the variable values specifically for this call.

For this purpose, the **Call path** window automatically opens in the following cases:

- You have selected a section of a function:
  The function is called at various points in the program source files (e.g. ST source files) of the SIMOTION device.
- You have selected a section of a function block:
  There are several instances of the function block or the instance is called at various points in the program source files (e.g. ST source files) of the SIMOTION device.
- You have selected a section of a program:
  The program is assigned to more than one task.

How to select the call path:

In the **Call path status program** window, the marked section of the POU (code position) is displayed (with the name of the ST source file, line number, name of the POU).

1. If the code position is called in several tasks:
   – Select the task.
2. Select the code position to be called (in the calling POU).
   You can select from the following:
   – The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
   If the selected calling code position is in turn called by several code positions, further lines are displayed in which you proceed similarly.
   – **All:**
   All displayed code positions are selected. Moreover, all code positions (up to the top level of the hierarchy) are selected from which the displayed code positions are called.

Parameter call path status program

Table 7-494 Program status call path parameter description

Field	Description
Calling task	Select the task. All tasks in which the selected code position is called are available for selection.
Current code position	The selected section of the POU (code position) is shown (with the name of the ST source file, line number, name of the POU)
is called by	Select the calling code position. The following are available: • The code positions to be called within the selected task (with the name of the program source, line number, name of the POU). If the selected calling code position is in turn called by several code positions, further lines are displayed in which you proceed similarly. • **All:** All displayed code positions are selected. Moreover, all code positions (up to the top level of the hierarchy) are selected from which the displayed code positions are called.

Breakpoints

General procedure for setting breakpoints

You can set breakpoints within a POU of a program source (e.g. ST source, MCC chart, LAD/FBD source). On reaching an activated breakpoint, the task in which the POU with the breakpoint is called is stopped. If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser.

Requirement:

- The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.

Procedure

Follow these steps:

1. Select "Debug mode" for the associated SIMOTION device; see Setting debug mode (Page 4955).
2. Specify the tasks to be stopped, see Specifying the debug task group (Page 4956).
3. Set breakpoints, see Setting breakpoints (Page 4959).
4. Define the call path, see Defining a call path for a single breakpoint (Page 4962).
5. Activate the breakpoints, see Activating breakpoints (Page 4967).

Setting the debug mode

⚠ WARNING

Dangerous plant states possible

If problems occur in the communication link between the PC and the SIMOTION device, this may result in dangerous plant states (e.g. the axis may start moving in an uncontrollable manner).

Therefore, use the debug mode only with activated life-sign monitoring (Page 4937) with a suitably short monitoring time!

You must observe the appropriate safety regulations.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect!

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Requirement

1. A connection to the target system must have been established (online mode)
2. Debug mode must not be selected for any SIMOTION device.

Procedure

To set the debug mode, proceed as follows:

1. Highlight the SIMOTION device in the project navigator.
2. Select **Operating mode** from the context menu.
3. Select **Debug** mode (Page 4935).
4. Accept the safety information
5. Parameterize the sign-of-life monitoring.
   See also section: Important information about the life-sign monitoring (Page 4937).
6. Confirm with **OK**.

SIMOTION SCOUT switches to debug mode for this device; the SIMOTION device itself remains in "test mode", as long as at least one breakpoint is activated:

The project navigator indicates that debug mode is activated for SIMOTION SCOUT by means of a symbol next to the SIMOTION device.

The breakpoints toolbar (Page 4961) is displayed.

As long as no breakpoints are activated, you can edit program sources in debug mode (Page 4939).

Debug mode is not enabled for the SIMOTION device until at least one set breakpoint is activated. If all breakpoints are deactivated, debug mode is canceled for the SIMOTION device. The status bar indicates that debug mode is activated for the SIMOTION device.

Note

Pressing the spacebar or switching to a different Windows application causes the following to happen if the SIMOTION device is in debug mode (breakpoints activated):

- The SIMOTION device switches to the STOP operating state.
- The outputs are deactivated (ODIS).

⚠ WARNING

Dangerous plant states possible

This function is not guaranteed in all operating states.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Define the debug task group

On reaching an activated breakpoint, all tasks that are assigned to the debug task group are stopped.

Requirement

1. A connection to the target system must have been established (online mode).
2. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4955).

Procedure

How to assign a task to the debug task group:

1. Highlight the relevant SIMOTION device in the project navigator.
2. Select **Debug task group** from the context menu.
   The Debug Task group window opens.
3. Select the tasks to be stopped on reaching the breakpoint:
   - If you only want to stop individual tasks (in RUN operating state): Activate the **Debug task group** selection option.
     Assign all tasks to be stopped on reaching a breakpoint to the **Tasks to be stopped** list.
   - If you only want to stop individual tasks (in HOLD operating state): Activate the **All tasks** selection option.
     In this case, also select whether the outputs and technology objects are to be released again after resumption of program execution.

Note

Note the different behavior when an activated breakpoint is reached, see the following table.

Table 7-495 Behavior at the breakpoint depending on the tasks to be stopped in the debug task group.

Property		Tasks to be stopped	
		Single selected tasks (debug task group)	**All tasks**
Behavior on reaching the breakpoint			
	Operating state	RUN	STOP
	Stopped tasks	Only tasks in the debug task group	All tasks
	Outputs	Active	Deactivated (ODIS activated)
	Technology	Closed-loop control active	No closed-loop control (ODIS activated)
	Runtime measurement of the tasks	Active for all tasks	Deactivated for all tasks
	Time monitoring of the tasks	Deactivated for tasks in the debug task group	Deactivated for all tasks
	Real-time clock	Continues to run	Continues to run
Behavior on resumption of program execution			
	Operating state	RUN	RUN
	Started tasks	All tasks in the debug task group	All tasks
	Outputs	Active	The behavior of the outputs and the technology objects depends on the **'Continue' activates the outputs (ODIS deactivated)** checkbox. • Active: ODIS will be deactivated. All outputs and technology objects are released. • Inactive: ODIS remains activated. All outputs and technology objects are only enabled for one STOP-RUN transition.
	Technology	Closed-loop control active	

Note

You can only make changes to the debug task group if no breakpoints are active.

The settings of the debug task group are retained after exiting "Debug mode".

Proceed as follows:

1. Set breakpoints (see Setting breakpoints (Page 4959)).
2. Define the call path (see Defining a call path for a single breakpoint (Page 4962)).
3. Activate the breakpoints (see Activating breakpoints (Page 4967)).

Debug task group parameters

Use this window to define the debug task group. On reaching an activated breakpoint, all tasks that are assigned to the debug task group are stopped.

This requires that the relevant SIMOTION device is in debug mode, see Modes of the SIMOTION devices (Page 4935).

Table 7-496 Debug settings parameter description

Field	Description
Debug task group	Select this selection option if you only want to stop individual tasks. The SIMOTION device remains in RUN mode after an activated breakpoint is reached. Outputs and technology objects remain activated. Assign all tasks to be stopped on reaching a breakpoint to the **Tasks to be stopped** list.
All tasks	Select this selection option if you only want to stop all user tasks. The SIMOTION device remains in STOP mode after an activated breakpoint is reached, all outputs and technology objects will be deactivated (ODIS activated). In this case, also select whether the outputs and technology objects are to be released again after resumption of program execution.
'Resume' activates the outputs (ODIS deactivated).	Only if **All tasks** is selected. Activate the checkbox, to release again the outputs and technology objects after program execution has been resumed. All outputs and technology objects can only be released after a download of the project with deactivated checkbox.

Note

Note the different behavior at the activated breakpoint depending on the tasks to be stopped, see table in Define the debug task group (Page 4956).

You can only make changes to the debug task group if no breakpoints are active.

Debug table parameter

The debug table shows all breakpoints in the program sources of a SIMOTION device.

Table 7-497 Debug table parameter description

Field		Description
Debug points (table)		
	Active	The activation state of the corresponding breakpoint is displayed and can be modified: **Active**: The breakpoint is activated. **Inactive**: The breakpoint is deactivated. See: Activating breakpoints (Page 4967).
	Source, line (POU)	The code position is shown with the set breakpoint (with the name of the program source file, line number, name of the POU).

Field		Description
	Call path	Click the button to define the call path for the breakpoint. See: Defining the call path for a single breakpoint (Page 4962).
All breakpoints ...		
	Activate	Click the button to activate all breakpoints (in all program sources) of the SIMOTION device. See: Activating breakpoints (Page 4967).
	Deactivate	Click the button to deactivate all breakpoints (in all program sources) of the SIMOTION device. See: Activating breakpoints (Page 4967).
	Delete	Click the button to clear all breakpoints (in all program sources) of the SIMOTION device. See: Setting breakpoints (Page 4959).

Setting breakpoints

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4955).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4956).

Procedure

How to set a breakpoint:

1. Select the code location where no breakpoint has been set:
   - SIMOTION ST: Place the cursor on a line in the ST source file that contains a statement.
   - SIMOTION MCC: Select an MCC command in the MCC chart (except module or comment block).
   - SIMOTION LAD/FBD: Set the cursor in a network of the LAD/FBD program.
2. Perform the following (alternatives):
   - Select the **Debug > Set/remove breakpoint** menu command (shortcut F9).
   - Click the  button in the Breakpoints toolbar.

To remove a breakpoint, proceed as follows:

1. Select the code position with the breakpoint.
2. Perform the following (alternatives):
   - Select the **Debug > Set/remove breakpoint** menu command (shortcut F9).
   - Click the  button in the Breakpoints toolbar.

To remove all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Remove all breakpoints** menu command (shortcut CTRL+F5).
  - Click the  button in the Breakpoints toolbar.

Note

You cannot set breakpoints:

- For SIMOTION ST: In lines that contain only comment.
- For SIMOTION MCC: On the module or comment block commands.
- For SIMOTION LAD/FBD: Within a network.
- At code locations in which other debug points (e.g. trigger points) have been set.

You can list the debug points in all program sources of the SIMOTION device in the debug table:

- Click the  button for "debug table" in the Breakpoints toolbar.

In the debug table, you can also remove all breakpoints (in all program sources) of the SIMOTION device:

- Click the button for "Clear all breakpoints".

The breakpoints set also remain saved after leaving debug mode; they are displayed in debug mode only.

You can use the program status (Page 4951) diagnosis functions and breakpoints together in a program source or POU. However, the following restrictions apply depending on the program languages:

- SIMOTION ST: For version V3.2 of the SIMOTION Kernel, the (marked) ST source file lines to be tested with program status must not contain a breakpoint.
- SIMOTION MCC and LAD/FBD: The commands of the MCC chart (or networks of the LAD/FBD program) to be tested with program status must not contain a breakpoint.

Proceed as follows

1. Define the call path, see Defining a call path for a single breakpoint (Page 4962).
2. Activate the breakpoints, see Activating breakpoints (Page 4967).

Breakpoints toolbar

This toolbar contains important operator actions for setting and activating breakpoints:

Table 7-498 Breakpoints toolbar

Symbol	Meaning
	Set/remove breakpoint Click this icon to set at breakpoint for the selected code position or to remove an existing breakpoint. See: Setting breakpoints (Page 4959).
	Activate/deactivate breakpoint Click this icon to activate or deactivate the breakpoint at the selected code position. See: Activating breakpoints (Page 4967).
	Edit the call path Click this icon to define the call path for the breakpoints: • If a code position **with** breakpoint is selected: The call path for this breakpoint. • If a code position **without** breakpoint is selected: The call path for all breakpoints of the POU. See: Defining the call path for a single breakpoint (Page 4962), Defining the call path for all breakpoints (Page 4964).
	Activate all breakpoints of the active POU Click this symbol to activate all breakpoints in the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Activating breakpoints (Page 4967).
	Deactivate all breakpoints of the active POU Click this symbol to deactivate all breakpoints in the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Activating breakpoints (Page 4967).
	Remove all breakpoints of the active POU Click this symbol to remove all breakpoints from the active program source or POU (e.g. ST source file, MCC chart, LAD/FBD program). See: Setting breakpoints (Page 4959).
	Debug table Click this icon to display the debug table. See: Debug table parameters (Page 4958).
	Display call stack Click this icon after reaching an activated breakpoint to: • View the call path at the current breakpoint. • View the code positions at which the other tasks of the debug task group have been stopped together with their call path. See: Displaying the call stack (Page 4970).
	Resume Click this icon to continue the program execution after reaching an activated breakpoint. See: Resuming program execution (Page 4971), Displaying the call stack (Page 4970).

Symbol	Meaning
	Next step (SIMOTION Kernel as of version V4.4) Only available for the MCC and LAD/FBD programming languages: Click this icon to resume the program execution until the next MCC command or LAD/FBD network is reached. See: Resume program execution in single steps.
	Step through the subprogram (SIMOTION Kernel as of version V4.4) Only available for the MCC programming language. Click this icon to jump to the called subprogram and stop at the first command. The subprogram must be created in the MCC or LAD/FBD programming language. See: Resume program execution in single steps.

Defining the call path for a single breakpoint

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4955).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4956).
5. Breakpoint is set, see Setting breakpoints (Page 4959).

Procedure

To define the call path for a single breakpoint, proceed as follows:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the  button for "edit call path" in the Breakpoints toolbar.
   In the Call path / task selection breakpoint window, the marked code position is displayed (with the name of the program source, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when the selected breakpoint is reached.
   The following are available:
   - **All calling locations starting at this call level**
     The user program will always be started when the activated breakpoint in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when the breakpoint in the selected task is reached. The task must be in the debug task group.
     The specification of a call path is possible.

4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).
   The following are available:
   - **All calling locations starting at this call level**
     No call path is specified. The user program is always stopped at the activated breakpoint if the POU in the selected tasks is called.
   - Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
     The call path is specified. The user program will be stopped at the activated breakpoint only when the POU is called from the selected code position.
     If the POU of the selected calling code position is also called from other code positions, further lines are displayed successively in which you proceed similarly.
5. If the breakpoint is only to be activated after the code position has been reached several times, select the number of times.

Note

You can also define the call path to the individual breakpoints in the debug table:

1. Click the  button for "debug table" in the Breakpoints toolbar.
   The "Debug table" window opens.
2. Click the appropriate button in the "Call path" column.
3. Proceed in the same way as described above:
   - Specify the task.
   - Define the call path (only for functions and function blocks).
   - Specify the number of passes after which the breakpoint is to be activated.

Proceed as follows:

- Activate the breakpoints, see Activating breakpoints (Page 4967).

Note

You can use the "Display call stack (Page 4970)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

See also

Defining the call path for all breakpoints (Page 4964)

Breakpoint call path / task selection parameters

Table 7-499 Breakpoint call path / task selection parameter description

Field	Description
Selected CPU	The selected SIMOTION device is displayed.
Calling task	Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when the selected breakpoint is reached. The following are available: • **All calling locations starting at this call level** The user program will always be started when the activated breakpoint in any task of the debug task group is reached. • The individual tasks from which the POU with the selected breakpoint can be reached. The user program will be stopped only when the breakpoint in the selected task is reached. The task must be in the debug task group. The specification of a call path is possible.
Current code position	The code position is shown with the set breakpoint (with the name of the program source file, line number, name of the POU).
Is called by	Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU). The following are available: • **All calling locations starting at this call level** **No** call path is specified. The user program will always be stopped at the activated breakpoint when the POU in the tasks is reached. • Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU). The call path is specified. The user program will be stopped at the activated breakpoint only when the POU is called from the selected code position. If the POU of the selected calling code position is also called from other code positions, further lines are displayed successively in which you proceed similarly.
The breakpoint will be activated at each nth pass.	If you do not want the breakpoint to be activated until the code position has been reached a certain number of times, set this number.

Note

You can only make changes to the debug task group if no breakpoints are active.

Defining the call path for all breakpoints

With this procedure, you can:

- Select a default setting for all future breakpoints in a POU (e.g. MCC chart, LAD/FBD program or POU in an ST source file).
- Accept and compare the call path for all previously set breakpoints in this POU.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4955).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4956).

Procedure

To define the call path for all future breakpoints of a POU, proceed as follows:

1. Select the code location where **no** breakpoint has been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the  button for "edit call path" in the Breakpoints toolbar.
   In the "Call path / task selection all breakpoints for each POU" window, the marked code position is displayed (with the name of the program source, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when a breakpoint in this POU is reached.
   The following are available:
   - **All calling locations starting at this call level**
     The user program will always be started when an activated breakpoint of the POU in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when a breakpoint in the selected task is reached.
     The task must be in the debug task group.
     The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).
   The following are available:
   - **All calling locations starting at this call level**
     No call path is specified. The user program is always stopped at an activated breakpoint when the POU in the selected tasks is called.
   - Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
     The call path is specified. The user program will be stopped at an activated breakpoint only when the POU is called from the selected code position.
     If the selected calling code position is in turn called by other code positions, further lines are displayed successively in which you proceed similarly.
5. If a breakpoint is only to be activated after the code position has been reached several times, select the number of times.
6. If you want to accept and compare this call path for all previously set breakpoints in this POU:
   - Click **Accept**.

Proceed as follows:

- Activate the breakpoints, see Activating breakpoints (Page 4967).

Note

You can use the "Display call stack (Page 4970)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

See also

Defining the call path for a single breakpoint (Page 4962)

Call path / task selection parameters of all breakpoints per POU

Here you can define a presetting for the call path of all future breakpoints to be set in a POU. Moreover, you can also accept this setting for all previously set breakpoints of this POU.

Table 7-500 Call path / task selection parameter description of all breakpoints per POU

Field	Description
Selected CPU	The selected SIMOTION device is displayed.
Calling task	Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when a breakpoint in this POU is reached. The following are available: • **All calling locations starting at this call level** The user program will always be started when an activated breakpoint of the POU in any task of the debug task group is reached. • The individual tasks from which the selected breakpoint can be reached. The user program will be stopped only when an activated breakpoint in the selected task is reached. The task must be in the debug task group. The specification of a call path is possible.
Current POU	The POU in which the cursor is located is displayed (with the name of the program source file, name of the POU).

Field	Description
Is called by	Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU). The following are available: • **All calling locations starting at this call level** **No** call path is specified. The user program will always be stopped at an activated breakpoint when the POU in the selected tasks is called. • Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU). The call path is specified. The user program will be stopped at an activated breakpoint only when the POU is called from the selected code position. If the POU of the selected calling code position is also called from other code positions, further lines are displayed successively in which you proceed similarly.
The breakpoint will be activated at each nth pass.	If you do not want the breakpoint to be activated until the code position has been reached a certain number of times, set this number.
Apply this call path to all previous breakpoints of this POU	Click the **Apply** button, if you want to apply the call path to all previously set breakpoints of the current POU. Any existing settings will be overwritten.

Activating breakpoints

Breakpoints must be activated if they are to have an effect on program execution.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. A connection to the target system must have been established (online mode).
3. SIMOTION SCOUT is in debug mode for the corresponding SIMOTION device; see Setting debug mode (Page 4955).
4. The tasks to be stopped are specified, see Specifying the debug task group (Page 4956).
5. Breakpoints are set, see Setting breakpoints (Page 4959).
6. Call paths are defined, see Defining a call path for a single breakpoint (Page 4962).

Activating breakpoints

How to activate a single breakpoint:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source file.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Perform the following (alternatives):
   - Select the **Debug > Activate/deactivate breakpoint** menu command (shortcut F12).
   - Click the  button in the Breakpoints toolbar.

To activate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Activate all breakpoints** menu command.
  - Click the  button in the Breakpoints toolbar.

Once the first breakpoint has been activated, the SIMOTION device switches to debug mode. It remains in this mode until the last breakpoint is deactivated.

In the Task status function bar, (Page 4971) the tasks with activated breakpoints are highlighted in gray ().

Note

Breakpoints of all program sources of the SIMOTION device can also be activated and deactivated in the debug table:

1. Click the  button for "debug table" in the Breakpoints toolbar.
   The "Debug Table" window opens.
2. Perform the action below, depending on which breakpoints you want to activate or deactivate:
   - Single breakpoints: Check or clear the corresponding checkboxes.
   - All breakpoints (in all program sources): Click the corresponding button.

The following applies up to version V4.3 of the SIMOTION Kernel:

- In the case of activated breakpoints, the "Single step" test function of the SIMOTION MCC programming language cannot be used.

The following applies as of version V4.4 of the SIMOTION Kernel:

- The "Single step" test function of the SIMOTION MCC programming language is not available in the Debug mode.

Breakpoints cannot be activate if the control priority is at the axis control panel. Conversely, you cannot fetch the control priority for the axis control panel when a breakpoint activated.

Behavior at the activated breakpoint

On reaching an activated breakpoint (possibly using the selected call path (Page 4962)), all tasks assigned to the debug task group will be stopped. The behavior depends on the tasks in the debug task group and is described in "Defining a debug task group (Page 4956)". The breakpoint is highlighted.

In the Task status function bar, (Page 4971) the task in which the breakpoint was reached is highlighted in red ( ).

The following applies to the programming languages MCC or LAD/FBD: If the debug task group is stopped by a breakpoint, then the user has the option to change to another task, belonging to the debug task group, in the combo box. Always the breakpoint of the currently selected task is visualized.

If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser (Page 4941).

You can use the "Display call stack (Page 4970)" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Resuming program execution

You can resume the execution of the stopped tasks, see "Resuming program execution" (Page 4971).

As of version V4.4 of the SIMOTION Kernel, you can resume the task in single steps that has been stopped at the activated breakpoint in the MCC and LAD/FBD programming languages, see Resuming program execution in single steps.

Deactivate breakpoints

To deactivate a single breakpoint, proceed as follows:

1. Select the code position with the activated breakpoint.
2. Perform the following (alternatives):
   - Select the **Debug > Activate/deactivate breakpoint** menu command (shortcut F12).
   - Click the button in the Breakpoints toolbar.

To deactivate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Perform the following (alternatives):
  - Select the **Debug > Deactivate all breakpoints** menu command.
  - Click the button in the Breakpoints toolbar.

Once the last breakpoint has been deactivated, the SIMOTION device switches to "test mode"; SIMOTION SCOUT continues to run in debug mode.

Display call stack

You can use the "Display call stack" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Requirement

The user program is stopped at an activated breakpoint, i.e. the tasks of the debug task group (Page 4956) have been stopped.

Procedure

To call the "Display call stack" function, proceed as follows:

- Click the  button for "display call stack" in the Breakpoints toolbar.
  The "Breakpoint call stack" dialog opens. The current call path (including the calling task and the number of the set passes) is displayed.
  The call path cannot be changed.

To use the "Display call stack" function, proceed as follows:

1. Keep the "Breakpoint call stack" dialog open.
2. To display the code position at which the other task was stopped, proceed as follows:
   – Select the appropriate task. All tasks of the debug task group can be selected.

   The code position, including the call path, is displayed. If the code position is contained in a user program, the program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) will be opened and the code position marked.
3. How to resume program execution:
   – Click the  button for "resume" (Ctrl+F8 shortcut) on the Breakpoint toolbar.

   When the next activated breakpoint is reached, the tasks of the debug task group will be stopped again. The current call path, including the calling task, is displayed.
4. Click **OK** to close the "Breakpoint call stack" dialog box.

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 4947)".

Breakpoints call stack parameter

When an activated breakpoint (Page 4967) is reached, you can display the following for each task in the debug task group (Page 4956):

- The position in the program code (e.g. line of an ST source file) at which the task stopped.
- The call path of this code position.

Table 7-501 Breakpoint call path parameter description

Field	Description
Selected CPU	The selected SIMOTION device is displayed.
Calling task	Select the task for which you want to display the code position at which the task was stopped. All tasks of the debug task group can be selected.
Current code position	The position in the program code (e.g. line of an ST source file) at which the selected task was stopped is displayed (with the name of the program source file, line number, name of the POU).
is called by	The code positions that call the current code position within the selected task are shown recursively (with the name of the program source file, line number, name of the POU, and name of the function block instance, if applicable).

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 4947)".

Resuming program execution

How to resume program execution:

- Perform the following (alternatives):
  - Select the **Debug > Continue** menu command (shortcut CTRL+F8).
  - Click the  button on the Breakpoint toolbar (Page 4961) to "Continue".

The stopped task is continued until the next active breakpoint is reached.

Task status function bar

In a combo box, the Task status function bar displays all tasks of the active SIMOTION device, to which a program is assigned.

They are displayed under the following conditions:

1. SIMOTION SCOUT is in online mode.
2. The affected SIMOTION device is active, e.g.
   - In the project navigator, the SIMOTION device or an element in its subtree is selected (such as program source, technology object).
   - In the working area, an open window is active that belongs to an element in the subtree of the SIMOTION device.
3. The SIMOTION device is consistent.

A background color highlights the occurrence of specific events in the affected task, see the following table. The task in question is displayed in the combo box of the function bar according to the event priority.

Table 7-502 Meaning of background colors in the Task status function bar

Background color	Meaning	Priority
Cyan	The affected task waits for a command at the "Single step" test function (only for SIMOTION MCC programming language).	Highest  Lowest
Red	The affected task is located at a breakpoint (Page 4967).	
Blue	In the affected task, the "Single step" test function is activated (only for SIMOTION MCC programming language)	
Gray	In the affected task, at least 1 breakpoint (Page 4967) is activated.	
Yellow	In the affected task, the "Monitoring" test function is activated (only for SIMOTION MCC programming language).	
White	In the affected task, none of the above-mentioned test functions are activated.	

Note

A selection of a task in the combo box is only possible:

- For the following test functions of the SIMOTION MCC programming language:
  - Monitoring
  - Single step
  - Trace
- at activated breakpoints (Page 4967) in the MCC or LAD/FBD programming languages.

Trace

Using the **trace tool**, you can record and store the course of variable values over time (z. B. unit variables, local variables, system variables, I/O variables). This allows you to document the optimization, for example, of axes.

You can set the recording time, display up to four channels, select trigger conditions, parameterize timing adjustments, select between different curve displays and scalings, etc.

Aside from isochronous recording, you can also select **Recording at code position**. This lets you record the values of variables whenever the program runs through a specific point in the ST source file.

The trace tool is described in detail in the online help.

Project comparison

SIMOTION SCOUT has a **project comparison** function (start this via the **Start object comparison** button) for comparing objects within the same project and/or objects from different projects (online or offline).

Project comparison allows you to establish any differences and, if necessary, run a data transfer to rectify them.

Objects are devices and their sub-objects, programs, technology objects (TOs) or drive objects (DOs), and libraries. Comparing projects is useful if you need to carry out service work on the system.

Further information on project and detail comparisons can be found in the SIMOTION Project Comparison Function Manual.

7.2.9 Appendix

7.2.9.1 Formal Language Description

In this chapter, you will find overviews of the basic elements of ST and a complete compilation of all syntax diagrams with the language elements. This appendix summarizes the basic features of the ST language.

Language description resources

Syntax diagrams are used as a basis for the language description in the individual sections. They provide you with an invaluable insight into the syntactic (i.e. grammatical) structure of ST.

Instructions for using syntax diagrams were presented in *Language description resources*. Information about the difference between formatted and unformatted rules, of interest to the advanced user, is presented below.

Formatted rules (lexical rules)

The lexical rules describe the structure of the elements processed by the compiler during lexical analysis. This means that the notation is formatted and the rules must be followed. In particular, that means:

- Insertion of formatting characters is not allowed.
- Block and line comments cannot be inserted.
- Attributes for identifiers cannot be inserted.

The following figure shows a lexical rule for legal identifiers.

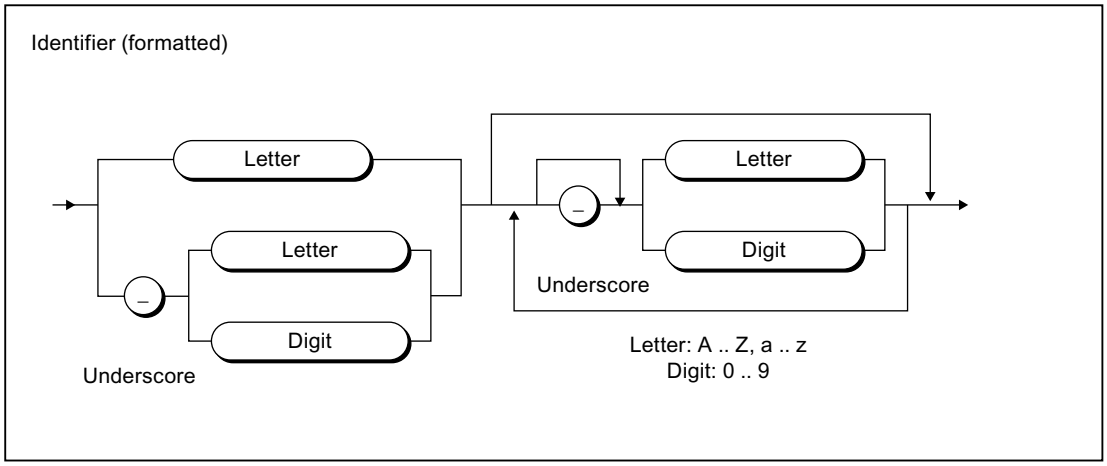

Figure 7-312 Example of a lexical rule

Valid examples according to this rule include:

```
R_CONTROLLER3
_A_ARRAY
_100_3_3_10
```

Unformatted rules (syntactic rules)

The syntactic rules build on the lexical rules and describe the structure of ST. You can write your ST program unformatted within the framework of these rules.

The unformatted property means:

- Formatting characters can be inserted anywhere.
- Block and line comments can be inserted.

The following example shows the syntactic rule for assigning a value in a statement.

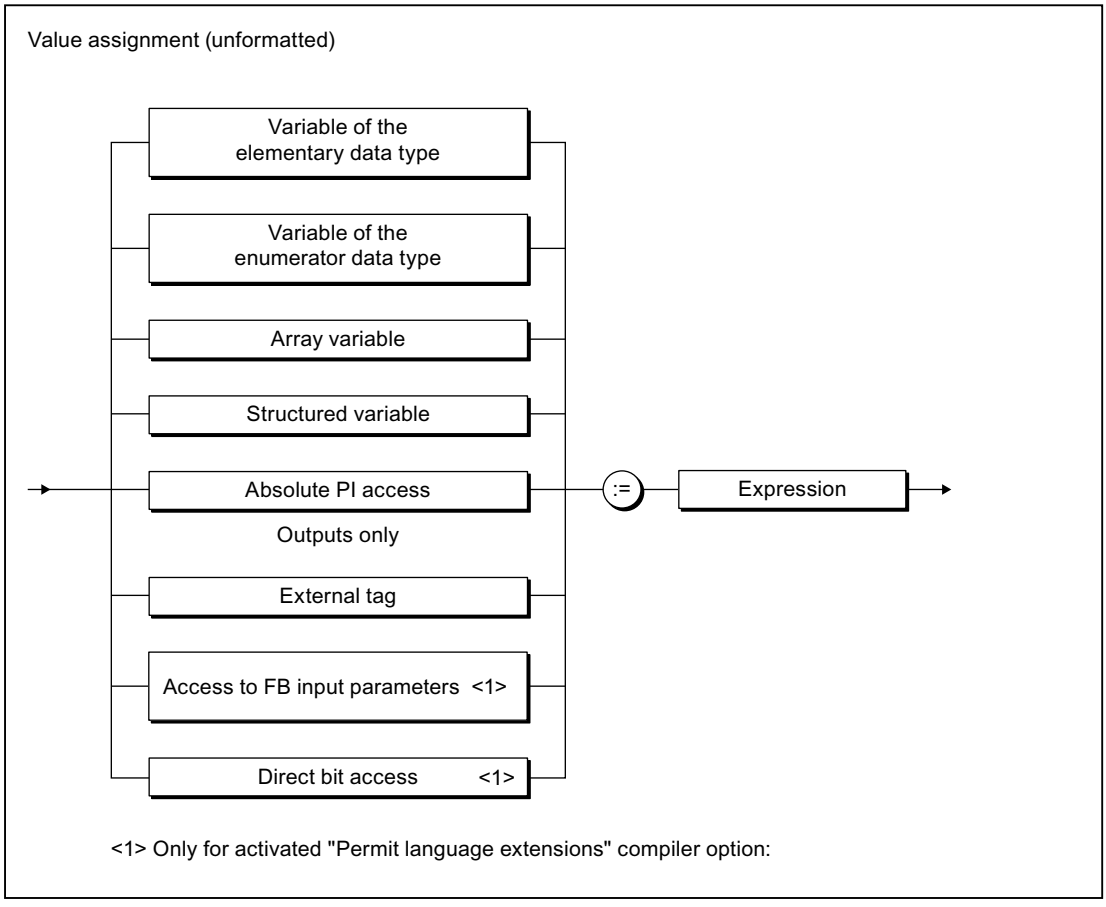

Figure 7-313 Example of a syntactic rule

Valid examples according to this rule include:

```
VARIABLE_1 := 100; SWITCH := FALSE;
//'This is a comment
VARIABLE_2:=3.2 +VARIABLE_1;
```

Basic elements (terminals)

A terminal is a basic element that is declared verbally and not by a further rule. It is represented in the syntax diagrams by an oval or circle.

Letters, digits and other characters

Letters and digits are the most commonly used characters. The *identifier*, for example, consists of a combination of letters, digits, and the underscore. The underscore is one of the special characters.

Table 7-503 Letters and digits

Characters	Subgroup	Character set elements
Letter	Upper case	A .. Z
	Lower case	a .. z
Digit	Decimal digit	0 .. 9
Octal digit	Octal digit	0 .. 7
Hexadecimal digit	Hexadecimal digit	0 .. 9, A .. F, a .. f
Bit	Binary digit	0, 1

You can use the complete extended ASCII character set in comments. You can use all printable ASCII code characters starting from decimal equivalent 32 (blank).

For language commands, identifiers, constants, expressions and operators, you can use special characters, i.e. characters other than letters and digits, only according to certain rules.

Formatting characters and separators in the rules

Formatting characters and separators are used differently in formatted (lexical) and unformatted (syntactic) rules. Language description resources (Page 4973) describes the differences between syntactic and lexical rules.

In the tables below, you will find the formatting characters and separators of the lexical and syntactic rules. You are also provided with a description and a list of all rules in which the formatting characters and separators are used as terminals (see Rules (Page 4988)).

Table 7-504 Formatting characters and separators in lexical rules

Characters	Description	Lexical rule
:	Separator between hours, minutes, and seconds	Time of day information
.	Separator for floating-point representation, time interval representation, absolute addressing	Floating-point representation, time-of-day information, decimal representation, access to local or global instance
_ Underscore	Separator for identifiers, separator for numerical values in constants	Identifiers, decimal digit string, binary digit string, octal digit string, hexadecimal digit string, sequence representation
%	Prefix for direct identifier on CPU memory access	Simple memory access
//	Comment	Line comment
(**)	Comment	Block comment

Table 7-505 Formatting characters and separators in syntactic rules

Characters	Description	Syntactic rule
:	Separator for type information	Function, variable declaration, component declaration, CASE statement, instance declaration
;	Ends a declaration or statement	Constant block, statement, variable declaration, instance declaration, component declaration, statement section
,	Separator for lists	Variable declaration, array initialization list, instance declaration, ARRAY data type specification, FB parameter, FC parameter, value list
..	Range information	Array data type specification, value list
.	Structure access	Structured variable
( )	Initialization list for arrays, parentheses in expressions, function and function block calls	Array initialization list, expression, simple multiplication, operand, exponent, FB call, function call
[ ]	Array declaration, structured variable section of array	Array data type specification

See also

Language description resources (Page 4654)

Formatting characters and separators for constants

Below, you will find all formatting characters and separators for constants with information on the lexical rule in which they are used.

Table 7-506 Formatting characters and separators for constants

Characters	Code for	Lexical rule
2#	Integer constant	Binary digit string
8#	Integer constant	Octal digit string
16#	Integer constant	Hexadecimal digit string
E	Separator for floating-point constants	Exponent
E	Separator for floating-point constants	Exponent
D#	Time information	Date
DATE#	Time information	Date
DATE_AND_TIME#	Time information	Date and time
DT#	Time information	Date and time
T#	Time information	Duration
TIME#	Time information	Duration
TIME_OF_DAY#	Time information	Time of day
TOD#	Time information	Time of day
d	Separator for time interval (day)	Days (rule: Sequence representation)

Characters	Code for	Lexical rule
h	Separator for time interval (hours)	Hours (rule: Sequence representation)
m	Separator for time interval (minutes)	Minutes (rule: Sequence representation)
ms	Separator for time interval (milliseconds)	Milliseconds (rule: Sequence representation)
s	Separator for time interval (seconds)	Seconds (rule: Sequence representation)

Predefined identifiers for process image access

Below is a list of all predefined variables in ST that you can use to access CPU memory areas (absolute identifiers). Note that you can read and write outputs but you can only read inputs.

Table 7-507 Absolute identifier

Identifier	Description	Lexical rule
%In.x or **%IXn.x**	CPU input range with byte and bit address	Absolute PI access
%IBn	CPU input range with byte address	Absolute PI access
%IWn	CPU input range with word address	Absolute PI access
%IDn	CPU input range with double word address	Absolute PI access
%Qn.x or **%QXn.x**	CPU output range with byte and bit address	Absolute PI access
%QBn	CPU output range with byte address	Absolute PI access
%QWn	CPU output range with word address	Absolute PI access
%QDn	CPU output range with double word address	Absolute PI access

Operators

Below is a list of all ST operators and the syntactic rules in which they are used.

Table 7-508 ST operators

Operator	Description	Rule
:=	Assignment operator (also for initialization values)	Value assignment, input assignment, in/out assignment, variable declaration, constant declaration, user-defined data types, component declaration, instance declaration
+, –	Arithmetic operators: Unary operators, sign	Expression, exponent
+, –, *, / **MOD**	Basic arithmetic operators	Expression, basic arithmetic operator
**	Arithmetic operators: Power operator	Expression
NOT	Logic operators: Negation	Expression, operand
AND, &, OR, XOR	Basic logic operators	Basic logic operator
<, >, <=, >=, =, <>	Relational operator	Relational operator
=>	Assignment operator	Output assignment
?= [1]	Dynamic type conversion	Dynamic type conversion
^	Dereferencing operator	Dereferencing of general references

[1] Only with compiler option "Permit object-oriented programming".

Reserved words

Below is an alphabetical list of keywords, predefined identifiers, and standard functions of the basic ST system. You are also provided with a description and the syntactic rule from *rules* in which they are used as terminals. An exception is standard functions, which are included only implicitly in the syntactic rule for *function calls* as the standard function name.

Note

Variables must not be assigned the names of keywords or predefined identifiers. For more information about identifiers, see *Identifiers in ST*. You will find an overview of the identifiers reserved for technology objects and other reserved identifiers in *Reserved identifiers*.

Table 7-509 ST keywords and predefined identifiers in the basic ST system

Keyword/identifier	Description	Rule
ABS	Standard numeric function	Function call
ABSTRACT [2]	Keyword	Class (Page 5002), Method in class (Page 5003)
ACOS	Standard numeric function	Function call
AND	Logic operator	Basic logic operator
ANYOBJECT	General data type for technology objects	TO data type

Keyword/identifier	Description	Rule
ANYOBJECT_TO_OBJECT	Standard function for type conversion (technology objects)	Function call
ANYTYPE_TO_BIGBYTEARRAY	Standard function (marshalling)	Function call
ANYTYPE_TO_LITTLEBYTEARRAY	Standard function (marshalling)	Function call
ARRAY	Introduces the specification of an array and is followed by the index list between **[** and **]**	ARRAY data type specification
AS	Introduces a namespace	–
ASIN	Standard numeric function	Function call
AT	Keyword for address specification	Component declaration with relative address, symbolic PI access
ATAN	Standard numeric function	Function call
BIGBYTEARRAY_TOANYTYPE	Standard function (marshalling)	Function call
BOOL	Elementary data type for binary data	Bit data type
BOOL_TO_BYTE	Standard function for type conversion	Function call
BOOL_TO_DWORD	Standard function for type conversion	Function call
BOOL_TO_WORD	Standard function for type conversion	Function call
BOOL_VALUE_TO_DINT	Standard function for type conversion	Function call
BOOL_VALUE_TO_INT	Standard function for type conversion	Function call
BOOL_VALUE_TO_LREAL	Standard function for type conversion	Function call
BOOL_VALUE_TO_REAL	Standard function for type conversion	Function call
BOOL_VALUE_TO_SINT	Standard function for type conversion	Function call
BOOL_VALUE_TO_UDINT	Standard function for type conversion	Function call
BOOL_VALUE_TO_UINT	Standard function for type conversion	Function call
BOOL_VALUE_TO_USINT	Standard function for type conversion	Function call
BY	Introduces the increment	FOR statement (Page 5036)
BYTE	Elementary data type	Bit data type
BYTE_TO_BOOL	Standard function for type conversion	Function call
BYTE_TO_DINT	Standard function for type conversion	Function call
BYTE_TO_DWORD	Standard function for type conversion	Function call
BYTE_TO_INT	Standard function for type conversion	Function call
BYTE_TO_SINT	Standard function for type conversion	Function call
BYTE_TO_UDINT	Standard function for type conversion	Function call
BYTE_TO_UINT	Standard function for type conversion	Function call
BYTE_TO_USINT	Standard function for type conversion	Function call
BYTE_TO_WORD	Standard function for type conversion	Function call
BYTE_VALUE_TO_LREAL	Standard function for type conversion	Function call
BYTE_VALUE_TO_REAL	Standard function for type conversion	Function call
CASE	Introduces a control statement for selection	CASE statement
CLASS [2]	Introduces the class	Class (Page 5002)
CONCAT	Standard function for string editing	Function call
CONCAT_DATE_TOD	Standard function for type conversion	Function call
CONSTANT	Introduces a constant definition	Constant block
CONTINUE [1]	Jump directly to the beginning of a loop	CONTINUE statement

Keyword/identifier	Description	Rule
COS	Standard numeric function	Function call
CTD	Down counter	Function block call
CTD_DINT	Down counter	Function block call
CTD_UDINT	Down counter	Function block call
CTU	Up counter	Function block call
CTU_DINT	Up counter	Function block call
CTU_UDINT	Up counter	Function block call
CTUD	Up/down counter	Function block call
CTUD_DINT	Up/down counter	Function block call
CTUD_UDINT	Up/down counter	Function block call
DATE	Elementary data type for date	Time data type
DATE_AND_TIME	Elementary data type for date and time	Time data type
DATE_AND_TIME_TO_DATE	Standard function for type conversion	Function call
DATE_AND_TIME_TO_TIME_OF_DAY	Standard function for type conversion	Function call
DELETE	Standard function for string editing	Function call
DINT	Elementary data type for double precision integer with value range -2**31 .. 2**31-1	Numeric data type
DINT_TO_BYTE	Standard function for type conversion	Function call
DINT_TO_DWORD	Standard function for type conversion	Function call
DINT_TO_INT	Standard function for type conversion	Function call
DINT_TO_LREAL	Standard function for type conversion	Function call
DINT_TO_REAL	Standard function for type conversion	Function call
DINT_TO_SINT	Standard function for type conversion	Function call
DINT_TO_STRING	Standard function for type conversion	Function call
DINT_TO_UDINT	Standard function for type conversion	Function call
DINT_TO_UINT	Standard function for type conversion	Function call
DINT_TO_USINT	Standard function for type conversion	Function call
DINT_TO_WORD	Standard function for type conversion	Function call
DINT_VALUE_TO_BOOL	Standard function for type conversion	Function call
DO	Introduces the body for a FOR statement, WHILE statement, or WAITFORCONDITION statement	FOR statement (Page 5036), WHILE statement (Page 5036), WAITFORCONDITION statement (Page 5038)
DT	Shorthand notation for DATE_AND_TIME	Time data type
DT_TO_DATE	Standard function for type conversion	Function call
DT_TO_TOD	Standard function for type conversion	Function call
DWORD	Elementary data type for double word	Bit data type
DWORD_TO_BOOL	Standard function for type conversion	Function call
DWORD_TO_BYTE	Standard function for type conversion	Function call
DWORD_TO_DINT	Standard function for type conversion	Function call
DWORD_TO_INT	Standard function for type conversion	Function call
DWORD_TO_REAL	Standard function for type conversion	Function call
DWORD_TO_SINT	Standard function for type conversion	Function call
DWORD_TO_UDINT	Standard function for type conversion	Function call

Keyword/identifier	Description	Rule
DWORD_TO_UINT	Standard function for type conversion	Function call
DWORD_TO_USINT	Standard function for type conversion	Function call
DWORD_TO_WORD	Standard function for type conversion	Function call
DWORD_VALUE_TO_LREAL	Standard function for type conversion	Function call
DWORD_VALUE_TO_REAL	Standard function for type conversion	Function call
ELSE	Introduces the clause to be executed if no condition true	IF statement, CASE statement
ELSIF	Introduces alternative condition	IF statement
END_CASE	Ends the CASE statement	CASE statement
END_CLASS [2]	Ends class	Class (Page 5002)
END_EXPRESSION	Ends the EXPRESSION statement	Expression (Page 5001)
END_FOR	Ends the FOR statement	FOR statement (Page 5036)
END_FUNCTION	Ends the function	Function (Page 5001)
END_FUNCTION_BLOCK	Ends the function block	Function block (Page 5001)
END_IF	Ends the IF statement	IF statement
END_IMPLEMENTATION	Ends implementation section	Implementation section
END_INTERFACE	Ends interface section, ends object-oriented interface [2]	Interface section, object-oriented interface (Page 5004)
END_LABEL	Ends the LABEL statement	Jump label declaration (Page 5015)
END_METHOD [2]	Ends method	Method in class (Page 5003), Method in FB (Page 5005), Method prototype (Page 5004)
END_NAMESPACE [2]	Ends the namespace	Namespace
END_PROGRAM	Ends the program	Program (Page 5002)
END_REPEAT	Ends the REPEAT statement	REPEAT statement (Page 5037)
END_STRUCT	Ends the specification of a structure	STRUCT data type specification
END_TYPE	Ends the UDT definition	User-defined data type
END_VAR	Ends a declaration block	Variable block, parameter block, constant block
END_WAITFORCONDITION	Ends the control statement for a task waiting for a programmable event	WAITFORCONDITION statement (Page 5038)
END_WHILE	Ends the WHILE statement	WHILE statement (Page 5037)
ENUM_TO_DINT	Standard function for type conversion	Function call
EXIT	Direct exit from loop execution	EXIT statement (Page 5037)
EXP	Standard numeric function	Function call
EXPD	Standard numeric function	Function call
EXPRESSION	Programmable event for waiting task	Expression (Page 5001)
EXPT	Standard numeric function	Function call
EXTENDS [2]	Derivation of a class	Class (Page 5002)
F_TRIG	Detects falling edge	Function block call

Keyword/identifier	Description	Rule
FALSE	Predefined Boolean constant: Logical condition false, value equal to 0	–
FINAL [2]	Keyword	Class (Page 5002), Method in class (Page 5003)
FIND	Standard function for string editing	Function call
FOR	Introduces the control statement for loop execution	FOR statement (Page 5036)
FROM_BIG_ENDIAN [1]	Standard function for endian conversion	Function call
FROM_LITTLE_ENDIAN [1]	Standard function for endian conversion	Function call
FUNCTION	Introduces the function	Function (Page 5001)
FUNCTION_BLOCK	Introduces the function block	Function block (Page 5001)
GOTO	Jump	GOTO statement (Page 5038)
IF	Introduces a control statement for selection	IF statement
IMPLEMENTATION	Introduces the implementation section	Implementation section
IMPLEMENTS [2]	Implements object-oriented interfaces	Class (Page 5002)
INSERT	Standard function for string editing	Function call
INT	Elementary data type for single precision integer with value range -2**15.. 2**15-1	Numeric data type
INT_TO_BYTE	Standard function for type conversion	Function call
INT_TO_DINT	Standard function for type conversion	Function call
INT_TO_DWORD	Standard function for type conversion	Function call
INT_TO_LREAL	Standard function for type conversion	Function call
INT_TO_REAL	Standard function for type conversion	Function call
INT_TO_SINT	Standard function for type conversion	Function call
INT_TO_TIME	Standard function for type conversion	Function call
INT_TO_UDINT	Standard function for type conversion	Function call
INT_TO_UINT	Standard function for type conversion	Function call
INT_TO_USINT	Standard function for type conversion	Function call
INT_TO_WORD	Standard function for type conversion	Function call
INT_VALUE_TO_BOOL	Standard function for type conversion	Function call
INTERFACE	Introduces interface section, introduces object-oriented interface [2]	Interface section, object-oriented interface (Page 5004)
IS_VALID [1]	Standard validity check function	Function call
LABEL	Definition of jump labels	Jump label declaration (Page 5015)
LEFT	Standard function for string editing	Function call
LEN	Standard function for string editing	Function call
LIMIT	Standard function for selection	Function call
LITTLEBYTEARRAY_TOANYTYPE	Standard function (marshalling)	Function call
LN	Standard numeric function	Function call
LOG	Standard numeric function	Function call
LOWER_BOUND [1]	Standard function for lower array boundary	Function call

Keyword/identifier	Description	Rule
LREAL	Elementary data type for 64-bit double-precision floating-point number (long real)	Numeric data type
LREAL_TO_DINT	Standard function for type conversion	Function call
LREAL_TO_INT	Standard function for type conversion	Function call
LREAL_TO_REAL	Standard function for type conversion	Function call
LREAL_TO_SINT	Standard function for type conversion	Function call
LREAL_TO_STRING	Standard function for type conversion	Function call
LREAL_TO_UDINT	Standard function for type conversion	Function call
LREAL_TO_UINT	Standard function for type conversion	Function call
LREAL_TO_USINT	Standard function for type conversion	Function call
LREAL_VALUE_TO_BOOL	Standard function for type conversion	Function call
LREAL_VALUE_TO_BYTE	Standard function for type conversion	Function call
LREAL_VALUE_TO_DWORD	Standard function for type conversion	Function call
LREAL_VALUE_TO_WORD	Standard function for type conversion	Function call
MAX	Standard function for selection	Function call
METHOD [2]	Introduces the method	Method in class (Page 5003), Method in FB (Page 5005), Method prototype (Page 5004)
MID	Standard function for string editing	Function call
MIN	Standard function for selection	Function call
MOD	Arithmetic operator for division remainder	Basic arithmetic operator
MUX	Standard function for selection	Function call
NOT	Logic operator, belongs to the unary operators	Expression, operand
NAMESPACE [2]	Introduces the namespace	Namespace
NULL	Invalid reference	-
OF	Keyword	ARRAY data type specification, CASE statement
OR	Logic operator	Basic logic operator
OVERLAP	Introduction for a structure with overlapping address ranges	STRUCT data type specification
OVERRIDE [2]	Keyword	Method in class (Page 5003), Static variable block, Retentive local variable block
PRIVATE [2]	Access identifier	Class access identifier (Page 5003), FB access identifier (Page 5005)
PROGRAM	Introduces the program	Program (Page 5002)
PROTECTED [2]	Access identifier	Class access identifier (Page 5003)
PUBLIC [2]	Access identifier	Class access identifier (Page 5003), FB access identifier (Page 5005)
R_TRIG	Detects rising edge	Function block call
REAL	Elementary data type for 32-bit single precision floating-point number (real)	Numeric data type

Keyword/identifier	Description	Rule
REAL_TO_DINT	Standard function for type conversion	Function call
REAL_TO_DWORD	Standard function for type conversion	Function call
REAL_TO_INT	Standard function for type conversion	Function call
REAL_TO_LREAL	Standard function for type conversion	Function call
REAL_TO_SINT	Standard function for type conversion	Function call
REAL_TO_STRING	Standard function for type conversion	Function call
REAL_TO_TIME	Standard function for type conversion	Function call
REAL_TO_UDINT	Standard function for type conversion	Function call
REAL_TO_UINT	Standard function for type conversion	Function call
REAL_TO_USINT	Standard function for type conversion	Function call
REAL_VALUE_TO_BOOL	Standard function for type conversion	Function call
REAL_VALUE_TO_BYTE	Standard function for type conversion	Function call
REAL_VALUE_TO_DWORD	Standard function for type conversion	Function call
REAL_VALUE_TO_WORD	Standard function for type conversion	Function call
REF [2]	Formation of general references	General reference
REF_TO [2]	Declaration of general references	General reference
REPEAT	Introduces the control statement for loop execution	REPEAT statement (Page 5037)
REPLACE	Standard function for string editing	Function call
RETAIN	Declaration of buffered variables	Retentive variable block
RETURN	Control statement for returning from subprogram	RETURN statement (Page 5037)
RIGHT	Standard function for string editing	Function call
ROL	Bit string standard functions	Function call
ROR	Bit string standard functions	Function call
RS	Bistable function block (priority reset)	Function block call
RTC	Real-time clock	Function block call
SEL	Standard function for selection	Function call
SHL	Bit string standard functions	Function call
SHR	Bit string standard functions	Function call
SIN	Standard numeric function	Function call
SINT	Elementary data type for short integer with value range -128 .. 127	Numeric data type
SINT_TO_BYTE	Standard function for type conversion	Function call
SINT_TO_DINT	Standard function for type conversion	Function call
SINT_TO_DWORD	Standard function for type conversion	Function call
SINT_TO_INT	Standard function for type conversion	Function call
SINT_TO_LREAL	Standard function for type conversion	Function call
SINT_TO_REAL	Standard function for type conversion	Function call
SINT_TO_UDINT	Standard function for type conversion	Function call
SINT_TO_UINT	Standard function for type conversion	Function call
SINT_TO_USINT	Standard function for type conversion	Function call
SINT_TO_WORD	Standard function for type conversion	Function call

Keyword/identifier	Description	Rule
SINT_VALUE_TO_BOOL	Standard function for type conversion	Function call
SQRT	Standard numeric function	Function call
SR	Bistable function block (set as priority)	Function block call
STRING	Elementary data type for character strings	String data type
STRING_TO_DINT	Standard function for type conversion	Function call
STRING_TO_LREAL	Standard function for type conversion	Function call
STRING_TO_REAL	Standard function for type conversion	Function call
STRING_TO_UDINT	Standard function for type conversion	Function call
STRUCT	Introduces the specification of a structure and is followed by a list of components	STRUCT data type specification
StructAlarmId	Data type for AlarmId	–
StructAlarmId_TO_DINT	Standard function for type conversion	Function call
StructTaskId	Data type for TaskId	–
SUPER [2]	Keyword for calling the method of the base class	Class method call
TAN	Standard numeric function	Function call
THEN	Introduces subsequent actions if condition true	IF statement
THIS [2]	Keyword for calling the currently valid method	Class method call, FB method call
TIME	Elementary data type for time information	Time data type
TIME_OF_DAY	Elementary data type for time of day	Time data type
TIME_TO_INT	Standard function for type conversion	Function call
TIME_TO_REAL	Standard function for type conversion	Function call
TO	Introduces end value	FOR statement (Page 5036)
TOD	Shorthand notation for TIME_OF_DAY	Time data type
TOF	OFF delay	Function block call
TON	ON delay	Function block call
TO_BIG_ENDIAN [1]	Standard function for endian conversion	Function call
TO_LITTLE_ENDIAN [1]	Standard function for endian conversion	Function call
TP	Pulse	Function block call
TRUE	Predefined Boolean constant: Logical condition true, value not equal to 0	–
TRUNC	Standard numeric function	Function call
TYPE	Introduces the UDT definition	User-defined data type
UDINT	Elementary data type for unsigned double precision integer with value range 0 .. 2**32-1	Numeric data type
UDINT_TO_BYTE	Standard function for type conversion	Function call
UDINT_TO_DINT	Standard function for type conversion	Function call
UDINT_TO_DWORD	Standard function for type conversion	Function call
UDINT_TO_INT	Standard function for type conversion	Function call
UDINT_TO_LREAL	Standard function for type conversion	Function call
UDINT_TO_REAL	Standard function for type conversion	Function call
UDINT_TO_SINT	Standard function for type conversion	Function call
UDINT_TO_STRING	Standard function for type conversion	Function call
UDINT_TO_UINT	Standard function for type conversion	Function call

Keyword/identifier	Description	Rule
UDINT_TO_USINT	Standard function for type conversion	Function call
UDINT_TO_WORD	Standard function for type conversion	Function call
UDINT_VALUE_TO_BOOL	Standard function for type conversion	Function call
UINT	Elementary data type for unsigned single precision integer with value range 0 .. 2**16-1	Numeric data type
UINT_TO_BYTE	Standard function for type conversion	Function call
UINT_TO_DINT	Standard function for type conversion	Function call
UINT_TO_DWORD	Standard function for type conversion	Function call
UINT_TO_INT	Standard function for type conversion	Function call
UINT_TO_LREAL	Standard function for type conversion	Function call
UINT_TO_REAL	Standard function for type conversion	Function call
UINT_TO_SINT	Standard function for type conversion	Function call
UINT_TO_UDINT	Standard function for type conversion	Function call
UINT_TO_USINT	Standard function for type conversion	Function call
UINT_TO_WORD	Standard function for type conversion	Function call
UINT_VALUE_TO_BOOL	Standard function for type conversion	Function call
UNIT	Introduces the UNIT section	Unit section
UNTIL	Introduces exit condition for REPEAT statement	REPEAT statement (Page 5037)
UPPER_BOUND [1]	Standard function for upper array boundary	Function call
USELIB	Introduces the library name	–
USEPACKAGE	Introduces the package name	–
USES	Introduces a reference to other units	–
USING [2]	Use of a namespace	Namespace
USINT	Elementary data type for unsigned short integer with value range 0 .. 255	Numeric data type
USINT_TO_BYTE	Standard function for type conversion	Function call
USINT_TO_DINT	Standard function for type conversion	Function call
USINT_TO_DWORD	Standard function for type conversion	Function call
USINT_TO_INT	Standard function for type conversion	Function call
USINT_TO_LREAL	Standard function for type conversion	Function call
USINT_TO_REAL	Standard function for type conversion	Function call
USINT_TO_SINT	Standard function for type conversion	Function call
USINT_TO_UDINT	Standard function for type conversion	Function call
USINT_TO_UINT	Standard function for type conversion	Function call
USINT_TO_WORD	Standard function for type conversion	Function call
USINT_VALUE_TO_BOOL	Standard function for type conversion	Function call
VAR	Introduces a declaration block for local variables or constants	Static variable block, temporary variable block in FC, constant block
VAR_GLOBAL	Introduces a declaration block for unit variables (global variables) or unit constants	Unit variables, unit constants
VAR_IN_OUT	Introduces a declaration block	Parameter block
VAR_INPUT	Introduces a declaration block	Parameter block

Keyword/identifier	Description	Rule
VAR_OUTPUT	Introduces a declaration block	Parameter block
VAR_TEMP	Introduces a declaration block	Temporary variable block in FB/program
VOID	No return value for function	Function (Page 5001)
WAITFORCONDITION	Introduces the control statement for a task waiting for a programmable event	WAITFORCONDITION statement (Page 5038)
WHILE	Introduces the control statement for loop execution	WHILE statement (Page 5037)
WITH	Use in conjunction with WAITFORCONDITION	WAITFORCONDITION statement (Page 5038)
WORD	Elementary data type for word	Bit data type
WORD_TO_BOOL	Standard function for type conversion	Function call
WORD_TO_BYTE	Standard function for type conversion	Function call
WORD_TO_DINT	Standard function for type conversion	Function call
WORD_TO_DWORD	Standard function for type conversion	Function call
WORD_TO_INT	Standard function for type conversion	Function call
WORD_TO_SINT	Standard function for type conversion	Function call
WORD_TO_UDINT	Standard function for type conversion	Function call
WORD_TO_UINT	Standard function for type conversion	Function call
WORD_TO_USINT	Standard function for type conversion	Function call
WORD_VALUE_TO_LREAL	Standard function for type conversion	Function call
WORD_VALUE_TO_REAL	Standard function for type conversion	Function call
XOR	Logic operator	Basic logic operator

1 Only with active compiler option "Permit language extensions, IEC61131 3rd edition".

2 Only with active compiler option "Permit object-oriented programming".

Rules

The following syntax rules of the ST language are subdivided into rules with formatted notation (lexical rules) and unformatted notation (syntactic rules). *Language description resources* describes the differences between syntactic and lexical rules.

Identifiers

Comments

Note the following when inserting comments:

- The character pairs (* and *) are ignored within the line comment.
- Nesting of block comments is not allowed as standard. However, you can nest line comments in block comments.
  With activated compiler option "Permit language extensions IEC61131 3rd edition" only: It is possible to nest block comments.
- You can use the complete extended ASCII character set in comments.
- Comments are not allowed in formatted (lexical) rules.

7.2.9.2 Compiler Error Messages and Remedies

This section provides an overview of the compiler error messages and their correction.

File access errors (1000 ... 1100)

Table 7-510 File access errors (1000 ... 1100)

Error	Description
1000	A read/write error has occurred on file access.
1001	Unable to load the file with the plain text error messages; cannot output error message texts. Please refer to the online help using the error number!
1002	The created code could not be stored. Please close some windows and recompile!
1003	A read/write error has occurred on opening the file. Please close the application and try again!
1100	The option for stating a preprocessor definition contains an invalid identifier as the defined token. The correct syntax of the call option is: -D identifier[=[text]] Examples: • -D myident // Definition of myident; this can be queried using #ifdef. • -D myident= // myident is defined as empty character string • -D "myident=This is a text" // myident is defined as character string 'This is a text'. The quotation marks only have to be used if the replacement text contains a blank.

Scanner errors (2001, 2002)

Table 7-511 Scanner errors (2001, 2002)

Error	Description
2001	The specified character is illegal.
2002	The specified identifier contains illegal characters or combinations of characters. According to IEC 61131, an identifier must start with a letter or an underscore. Any number of letters, digits, or underscores may follow, but no more than one underscore in a row.

Declaration errors in POU (3002 ... 3161)

Table 7-512 Declaration errors in POU (3002 ... 3100)

Error	Description
3002	Keyword "IMPLEMENTATION" to identify the code section of the load unit is expected.
3003	The specified declaration block is not permitted in this context.
3004	The VAR, VAR_INPUT, VAR_OUTPUT, VAR_IN_OUT, VAR CONSTANT, VAR RETAIN variable declaration blocks are permitted only once for each POU.
3005	TASK statement: The task link has already been made in the source file for the specified task. Further task linking not possible.
3006	Incorrect stack size for task specified. Only positive integers are permitted.
3007	The specified identifier must be a task identifier; see task configuration.
3008	The specified identifier must be a program identifier. The declaration is made in the statement PROGRAM xx ... END_PROGRAM.
3009	The EXPRESSION keyword must be followed by an identifier. The declaration is made in the statement EXPRESSION xx ... END_EXPRESSION.
3010	The specified identifier is not an EXPRESSION identifier. Check whether the declaration was made using the statement EXPRESSION xx ... END_EXPRESSION.
3011	The TASK statement is not permitted in the unit. Use the task configuration in the Workbench.
3012	The specified identifier has already been declared at another position. It cannot be used again as a function identifier.
3013	The specified identifier has already been declared at another position. It cannot be used again as a function block identifier.
3014	The UNIT statement is expected. The following forms are permissible: • UNIT myunit; • UNIT myunit : dvtype; The UNIT statement is only required when compiling at the ASCII file level. It is optional when the compiler is called from the Workbench.
3015	The source file is not ended with END_IMPLEMENTATION. Observe the structure for a source file!
3016	No further statements may be specified after keyword END_IMPLEMENTATION.
3017	The task declaration is not ended with END_TASK. Observe the structure for a source file!
3018	The POU declaration is not ended with END_FUNCTION, END_FUNCTION_BLOCK, or END_PROGRAM. Observe the structure for a source file!
3019	A POU starting with keywords FUNCTION, FUNCTION_BLOCK, or PROGRAM is expected.
3020	The task linking statement is expected. Structure: TASK tname ... END_TASK;
3021	Methods can only be declared within classes, function blocks or interfaces. In this case, no further statements may be inserted between the variable or data type declaration and the methods.
3022	The keyword INTERFACE is expected. See the structure for a source file.
3023	Keyword INTERFACE or IMPLEMENTATION is expected. See the structure for a source file.
3024	Syntax error in TASK statement. Correct structure: TASK tname ... END_TASK;
3025	The specified identifier has already been declared at another position. It cannot be used again as a program identifier.
3026	The WAITFORCONDITION statement cannot be used recursively. An attempt was made to use a WAITFORCONDITION statement a second time within a WAITFORCONDITION statement. This is not possible.

Error	Description
3027	An attempt was made to insert a WAITFORCONDITION statement within an EXPRESSION ... END_EXPRESSION block. This is not possible. The WAITFORCONDITION statement cannot be used within an expression.
3028	The specified identifier has already been declared at another position. It cannot be used again as a class identifier.
3029	The specified identifier has already been declared at another position. It cannot be used again as an interface identifier.
3040	The specified identifier does not reference a namespace. It cannot be used in the USING statement.
3041	The specified identifier references a namespace that cannot be accessed. The namespace is declared INTERNAL.
3042	The specified identifier references a namespace whose symbols could not be added to the current context.
3043	The specified identifier references a namespace used system-internal. The identifier cannot be used as user namespace.
3050	A class definition starting with the keyword CLASS is expected.
3051	The class definition does not end with END_CLASS. Observe the structure for a source file.
3052	A method definition starting with the keyword METHOD is expected.
3053	A method definition ends with END_METHOD. The method definition contains a syntax error. Observe the structure for a source file.
3060	It is not permissible to use the specified access identifier at this position. For example, the access identifier PROTECTED cannot be used within a FUNCTION_BLOCK.
3061	The specified method property cannot be accepted. For example, OVERRIDE, ABSTRACT or FINAL cannot be declared for a method within a FUNCTION_BLOCK. OVERRIDE can be used for methods in CLASS only if a base class exists in which the method has already been declared. In this case, OVERRIDE cannot be declared for PRIVATE methods.
3062	If a method is overridden in a derived class, the access identifiers must be identical. Accordingly, a PROTECTED method can only be overridden with PROTECTED and a PUBLIC method only with PUBLIC.
3063	If a method is to be overridden in a derived class, it is absolutely essential to specify the keyword OVERRIDE in the method declaration.
3064	A method that is already defined in the base class cannot be overridden with "ABSTRACT".
3065	The keyword "OVERRIDE" is used in the declaration of the specified method. Since the method is not defined in the base class, it is not permissible to specify this keyword.
3066	The method signatures are different in the specified classes. This is not compatible with override mechanisms. For example, not all the parameters have the same name or they are defined in a different sequence or they have different data types. Even the return value must have the same data type.
3067	If a method is declared with the PUBLIC identifier in a base class and a method of the same name is required by an object-oriented interface to be implemented, this method must already be declared PUBLIC in the base class. Methods in object-oriented interfaces are always PUBLIC. It is not possible to change the access level for derivations.
3068	A method that is already defined in the base class and identified as "FINAL" cannot be overridden.
3069	A method cannot be declared ABSTRACT if the class is identified as FINAL. This combination cannot be used because it is not possible to create any instances of this class.
3070	The specified data type cannot be used as a base class or a base interface. A CLASS can only ever be derived from another CLASS. An INTERFACE can only ever be derived from another INTERFACE. It is not possible to use mixtures of the two or to create derivations of other data types.
3071	The specified CLASS is identified with the keyword FINAL. A CLASS identified as FINAL cannot be used as a base class.

Error	Description
3072	The specified CLASS is not exported in the interface section of the unit or stems from a unit imported in the implementation section and cannot therefore be used as a base class of an exported CLASS. • If the CLASS mentioned in the error message is declared in the current unit, it must be exported in the interface section. CLASS <classname>; must be added there for this purpose. • If it is a CLASS from another unit, the USES statement for this unit must be moved from the implementation section to the interface section.
3073	The specified CLASS is identified with the keyword FINAL. However, the relevant class does not implement all of the methods (in base classes) identified as ABSTRACT and therefore cannot be instantiated. All ABSTRACT methods must either be implemented in the class, or the class cannot be identified as FINAL.
3075	The specified identifier does not refer to an INTERFACE. Only INTERFACE identifiers can be used for IMPLEMENTS.
3076	The specified INTERFACE is already implemented by the CLASS itself or by the base class(es). An INTERFACE can only ever be implemented once by a CLASS.
3077	The specified INTERFACE is not exported in the interface section of the unit or stems from a unit imported in the implementation section and cannot therefore be used at an exported CLASS (IMPLEMENTS). • If the INTERFACE mentioned in the error message is declared in the current unit, this declaration must be included in the interface section. For this purpose, the entire declaration must be moved to the interface section. • If it is an INTERFACE from another unit, the USES statement for this unit must be moved from the implementation section to the interface section.
3078	The specified INTERFACE is identified as a prototype. This is a programming error. Object-oriented interfaces must always be defined in full.
3080	A method that is identified as PRIVATE cannot be declared as either ABSTRACT or FINAL. It must always be implemented and no override mechanisms of any kind may be used.
3081	A method identifier is concealing a global identifier. This is only permissible if you activate the compiler option 'Permit forward declarations'. This ensures that calls of this method within the current CLASS or the current FUNCTION_BLOCK without a preceding name refer to this method in all other methods. The global identifier can no longer be accessed in the class because it is concealed by the method identifier.
3100	The specified identifier is already defined and identified as public in the base class. It cannot be declared again in the derived class.
3150	The specified identifier has already been identified as public without INTERNAL being specified. It is not possible to declare it INTERNAL again differently. • If this situation occurs for a POU, this POU has already been identified as public without INTERNAL in the INTERFACE section of the source. Add the INTERNAL identifier here to use the POU only within the namespace. • If this situation occurs for a namespace, an identically named namespace declaration from a source or library imported via USES/USELIB may also be present. In this case, all declarations must be either INTERNAL or not INTERNAL.
3151	The specified identifier has already been declared as INTERNAL in the current source or in an imported source or library. The current declaration location, however, does not contain the INTERNAL identifier. Add INTERNAL for the declaration of the affected element.

Error	Description
3160	The specification of USING within a namespace is possible only for the first declaration within the source and then applies to all blocks of the affected namespace. Move the USING statement to this position.
3161	The specification of USING within a namespace or a POU is permissible only for namespaces not contained in the declaration path. For example, a namespace NS1 or class, function, etc., declared in NS1, may not itself contain any USING statement for NS1.

Declaration errors in data type declarations (4001 ... 4105)

Table 7-513 Declaration errors in data type declarations (4001 ... 4105)

Error	Description
4001	The specified identifier is a standard function identifier that cannot be overwritten. Choose a different identifier.
4002	The specified identifier has already been used. Use as a type identifier is not possible. Choose a different identifier.
4003	The specified identifier has already been used. Use as a constant identifier is not possible. Choose a different identifier.
4004	The specified initialization value has an incorrect format. Choose the initialization value that corresponds to the data type declaration.
4005	Syntax error in type declaration.
4006	Syntax error in the structure element specification in the structure declaration.
4007	Syntax error in declaration of an ARRAY data type.
4008	Syntax error in the identifier list specification. The identifiers must be separated by commas.
4009	The specified constant identifier has been assigned different values. This occurs when enumeration data types are declared. Identical enumeration elements in different enumeration data types must be located in the same position in the type declaration.
4010	The specified type identifier is not exported from the source file, although the POU in which it is used, is exported. Use a different data type or declare the data type in the implementation section.
4011	A constant declaration requires the specification of an initialization value. Example: x : DINT := 5;
4012	The specified data type cannot be used at the current position. • When compiler option "Permit object-oriented programming" is not activated, type identifiers declared locally in the POU may not be used with VAR_INPUT, VAR_OUTPUT, and VAR_IN_OUT because they must also be known outside the POU for parameter transfer purposes. • When compiler option "Permit object-oriented programming" is activated, the local data types used for variables, parameters and other type declarations must have at least the same access definition as that applicable at the point of use. For example, a local data type used at the transfer parameters of a PROTECTED method must itself be declared as at least PROTECTED. PRIVATE data types may only be used at local variables.
4013	The specified value is used several times in the enumeration data type. The values in the enumeration data type must differ, however.
4020	The specified identifier has already been used as a data type identifier. However, the definition differs from the current definition. This is not permitted. Either choose a different identifier or adapt the type definitions. If this message appears on loading libraries or technology packages, you can use namespaces here too (e.g. USELIB mylib AS Namespace_1).

Error	Description
4050	The data type or variable declaration creates a data type that is larger than the specified maximum permissible data size.
4051	The variable declaration requires a memory area that is larger than the specified maximum permissible memory size.
4100	The definition of the structure component requires the specification of a user-defined offsets. If offsets are explicitly specified in a structure definition, the offset specification is necessary for all structure components. Furthermore, the keyword OVERLAP requires the explicit specification of the offsets.
4101	The offset specified in the definition of the structure component is not allowed because a component without an explicitly specified offset has already been defined. If offsets are explicitly specified in a structure definition, the offset specification is necessary for all structure components.
4102	The offset value specified in the definition of the structure component is not allowed. The value must be a multiple of the number specified in the error message so that the data elements are in the correct alignment.
4103	The offset values declared in the structure definition result in overlaps in the memory layout. This is only allowed for identification of the structure as OVERLAP.
4105	The overlaps in the memory space are not allowed for the following data types: STRING, ANYOBJECT and all TO-references derived thereof!

Declaration errors in variable declarations (5001 ... 5509)

Table 7-514 Declaration errors in variable declarations (5001 ... 5509)

Error	Description
5001	The specified constant value causes the value range to be exceeded and cannot be converted to the requested type.
5002	The specified identifier has already been used. Use as a variable identifier is not possible. Choose a different identifier.
5003	Syntax error in variable declaration.
5004	The specification of a data type is expected (simple or derived data type).
5005	The specified constant value has the wrong data type or causes the value range to be exceeded.
5006	Check the number of initialization values for array initialization.
5007	Syntax error in the specification of the time and date literals.
5008	An instance of a function block or a class cannot be created at the specified position. For example, instances of function blocks or classes cannot be created in functions or methods. The output parameters (VAR_OUTPUT) of function blocks cannot be FB instances. Furthermore, classes and function blocks that have been compiled under the compiler option "Permit object-oriented extensions" cannot be used as input parameters (VAR_INPUT). It is not possible to copy classes and function blocks of the kind that would be created if they were to be used in this way.
5009	The data type specified in the declaration cannot be applied to the variable with absolute address. An integer or bit data type with matching bit width must be used.
5010	An attempt was made to assign a memory address to a variable. This is not possible at the specified position. Use this assignment only within the VAR_GLOBAL declaration of a unit or within the VAR declaration of a PROGRAM.
5011	The data type stated in the declaration cannot be accessed. It is not identified as public. The data type must be declared as PUBLIC to allow external access and PROTECTED to allow access from a derived class.
5012	The specified variables cannot be preassigned an initialization value.

Error	Description
5014	Incorrect initialization of a data structure. The initialization value for a component was specified more than once.
5016	The initialization of variables and data types with technology objects defined in the project is not possible. Technology objects are themselves variables and so cannot be used for the initialization.
5030	If it is necessary for variable declarations and POU implementations to be compiled in an optional sequence in the implementation section of the source file, the compiler option "Permit forward declarations" must be activated.
5040	The specified data type cannot be used within a declaration of retentive variables (VAR RETAIN, VAR_GLOBAL RETAIN) because it already contains retentive elements (VAR RETAIN).
5041	The specified data type cannot be used within a declaration of retentive variables (VAR RETAIN, VAR_GLOBAL RETAIN). The data type does not contain any information that can be backed up or restored in the retentive memory. This message is issued, for example, if a class or a function block does not contain instance data of any kind. This message is also output for variables of type INTERFACE or with the data type of a technology object.
5042	The specified data type cannot be used within a declaration of retentive variables (VAR RETAIN, VAR_GLOBAL RETAIN). The data type contains at least one system function block in the instance data or is one itself. Since its information cannot be restored, this data type cannot be used in retentive variable declarations.
5050	The class definition is identified as ABSTRACT. As a result, it is not possible to create any instances of the relevant class.
5051	The specified method is identified as ABSTRACT and has not yet been implemented in a method override mechanism. As a result, it is not possible to create any instances of the relevant class.
5052	The class in which a method is defined cannot be used as a variable or parameter at methods within a class declaration. The same applies to function blocks and interfaces. In this case as well, the data type of the function block or interface cannot be used within the declaration section as a data type for variables or transfer parameters.
5053	A variable with the specified data type cannot be directly declared as an in/out parameter (VAR_IN_OUT). Since dynamic type conversion is not supported for in/out parameter calls, it is not possible, for example, to return an INTERFACE value or a reference to VAR_IN_OUT. Declare the variable as either VAR_INPUT or VAR_OUTPUT.
5054	The specified class does not possess any instance data. As a result, it is not possible to create any instances of the relevant class in the form of an ARRAY.
5055	Initialization is only possible with the stated value at the specified position. For example, INTERFACE variables that are defined within structures, methods or functions, or as VAR_TEMP or VAR_IN_OUT, cannot be initialized with class instances. In this case, only NULL can be specified as a value. References to technology objects that are defined within structures, methods or functions, or as VAR_TEMP or VAR_IN_OUT, may only be initialized with the value TO#NIL.
5056	An initialization value may not contain a variable ARRAY index. An initialization value is not a constant.
5057	The instance variables of classes or function blocks of type INTERFACE may only be initialized with exported global class instances. They can also be initialized with local class instances defined with the class or the base classes. They cannot be initialized with class instances from the IMPLEMENTATION area.
5058	Variables of type INTERFACE can only be initialized with the value NULL or with specified class instances. They cannot be initialized with the value of other variables of type INTERFACE.
5059	Method arguments of type INTERFACE cannot be initialized with class instances that are declared as retentive local variables (VAR RETAIN) within the CLASS or the FUNCTION_BLOCK.
5070	The specified variable must be initialized. Please enter a valid initialization value. To do this, use the valid syntax for instance initialization, i.e.: <var_name> : <var_type> := (<element_name1> := <value1>, <element_name2> := <value2>);

Error	Description
5071	The specified variable must be initialized. The variable must be declared before an initialization value can be specified: • either in a declaration section made accessible for initialization with OVERRIDE • or in a declaration section identified as PUBLIC.
5072	The specified data type has been declared by "forward declaration". It is not possible to specify instance-specific initialization values at the stated position. If it is a variable in the implementation section of the source file, check whether you can place it after the declaration of the relevant CLASS or FUNCTION_BLOCK. It is not generally possible to initialize variables created by "forward declaration" in the interface section of the source file.
5080	It is not permissible to specify the initialization value " * " for the specified data type. Instance-specific initialization can be forced using " * "' only for variables of data type INTERFACE or for the references of technology objects.
5081	The initialization value " * " may only be specified for static variables of the CLASS and FUNCTION_BLOCK. Furthermore, the declaration block that contains the variable(s) must permit initialization by OVERRIDE or PUBLIC.
5090	An I/O reference can be declared only within VAR declaration blocks for classes and function blocks. An attempt was made to declare such a variable in a different declaration section. This is not permitted.
5091	The specified data type is not permitted. Only the following data types can be used for I/O references: • Integer data types, e.g. SINT, UINT • Bit data types, e.g. BOOL, WORD • Arrays of these elementary data types, other than arrays of the BOOL data type Other data types cannot be used, because they cannot be specified in the address list.
5092	The I/O reference cannot be linked with the specified I/O variable. The I/O reference requires that the affected variable must be read/write. • I/O references declared with %I* can be linked with all variables of an appropriate data type from the address list. • I/O references declared with %Q* require a variable from the address list for an output. This variable may not be identified with the attribute "read only".
5100	The specified variables cannot be preassigned an initialization value.
5110	The following specifications containing the special character $... are permitted: $$, $', $L, $N, $P, $R, $T. Moreover, the numeric value of a character can be stated using $xx, where xx stands for the two-digit hexadecimal specification of the character code.
5111	The special character can only be specified via $... . This applies to: $L, $N, $P, $R, $T
5112	Multi-line character string constants are not permitted. To produce a new line in the output, use the appropriate special character in the character string, e.g. $N, RL.

Error	Description
5120	No general reference can be generated to the specified data type. General references can be generated for the following data types: • Elementary data types • User-defined data types • Classes • Function blocks with at least one static variable. References to the following data types are not permitted: • General references • Object-oriented interfaces • Technology object data types • Function blocks without static variables.
5200	The data type definition contains a recursion, either directly or indirectly. This is not permitted. Do not use this data type at the position concerned.
5201	The function call creates a recursion, either directly or indirectly. This is not permitted. Do not call the function at the position concerned.
5500	The specified jump label identifier was already defined. Choose a different name.
5501	The specified jump label identifier has not been defined. Include this identifier in the LABEL declaration.
5502	The jump label identifier has been assigned more than once. However, each jump label can only be used once as a label.
5503	The jump label is specified as a jump destination, but the associated label is missing.
5504	No jumps are possible in subordinate control structures (e.g. WHILE loops). The specified jump label cannot be used at this position.
5505	No jumps are possible in subordinate control structures (e.g. WHILE loops). The specified jump destination cannot be reached.
5506	No jumps are possible in WAITFORCONDITION blocks. The specified jump label cannot be used at this position.
5507	No jumps are possible in WAITFORCONDITION blocks. The specified jump destination cannot be reached.
5509	Jump labels cannot be used within a CASE statement. The syntax does not allow any differentiation between a jump label and the value list of the CASE statement.

Errors in the expression (6001 ... 6302)

Table 7-515 Errors in the expression (6001 ... 6302)

Error	Description
6001	Syntax error: A statement terminated with a semicolon is expected, e.g. a := b*c;
6002	Syntax error: An expression is expected, e.g. x < y .
6003	The specified identifier is no variable identifier. You must specify a variable identifier. Check whether the indicated identifier is covered. Up to and including V4.0, access to global device identifiers was possible within a program or function block of the same name despite warning 16021.
6004	The index for array access must be the DINT data type. Perform a suitable type conversion or use another expression.

Error	Description
6005	Type conflict in the expression. One of the operands cannot be converted to the data type of the calculation, or the result assignment produces a type conflict.
6006	The specified variable cannot be accessed. Therefore it cannot be used in the expression. Possible causes: • Variable cannot be read. • Attempt to access a local variable of a function or function block from outside.
6007	Cannot write specified variable. A value assignment is not possible.
6008	The specified function does not supply a return value. An application in the expression is therefore not possible (function declared with a return value of VOID).
6009	The specified identifier does not refer to a function or a function block instance. Therefore it cannot be used as function identifier. When calling a program, the compiler option "Allow language extensions" should have been set (-C lang_ext).
6010	The specified identifier is not included as an input parameter (VAR_INPUT) or in/out parameter (VAR_IN_OUT) in the declaration of the POU (function or function block). It cannot be used in the POU call.
6011	The number of function arguments in the call differs from the declaration, or the call parameters required are missing in the call.
6012	RETURN is not permitted syntactically at this position. RETURN may only be used in functions.
6013	EXIT is not permitted syntactically at this position. EXIT can only be used within FOR, WHILE, and REPEAT.
6014	The specified index value is outside the array limits. Only index values that match the array declaration are permissible.
6015	The specified task control command cannot be applied to the task. It is not permitted for this type of task.
6016	The specified task is deactivated in the execution system. It must be enabled before it can be used.
6017	Syntax error on specifying programs within a task. The programs must be listed by name and separated by commas.
6018	The specified identifier does not refer to a PROGRAM. Therefore it cannot be used as a program identifier.
6019	Multiple assignment of program to task. Only one assignment is possible.
6020	Syntax error on specifying directly displayed variables. Inputs must have the syntax %Ix.y and outputs the syntax %Qx.y. Further valid address declarations are %IBx or %QBx for byte access operations, %IWx or %QWx for word access operations and %IDx or %QDx for double word access operations.
6021	The specified byte offset of the directly displayed variables lies outside the permissible address space.
6022	The specified byte offset of the directly displayed variables lies outside the permissible address space. Values 0 to 7 are permissible.
6023	The return value of the function or method has not been assigned. An assignment is however imperative.
6024	A variable with the specified identifier is not included in the task start information.
6025	The condition variable and condition values of a CASE statement must be of the data type SINT, INT, DINT, USINT, UINT or UDINT. It must be possible to implicitly convert the condition values to the data type of the condition variables.
6026	The specified message identifier is not contained in the message configuration. Switch to the message configuration and add the identifier.

Error	Description
6027	System variable access is only possible directly by means of a technology object reference. Access by means of a structure or array is not possible. Create a local variable of type TO and assign the TO reference to this variable. You can then access the required system variable by means of this local TO variable.
6028	Type conflict in expression at specified operation. One of the operands cannot be converted to the data type of the calculation, or the result assignment produces a type conflict. The specified data type in the expression is expected.
6029	The specified function parameter does not have a default value, so it is imperative to specify a value when the function is called.
6030	An attempt was made to transfer an expression to an in/out parameter (VAR_IN_OUT). This is not possible. User variables must be specified as in/out parameters.
6031	An attempt was made to transfer a system variable (TO, I/O direct access) to an in/out parameter (VAR_IN_OUT). This is not possible. User variables must be specified as in/out parameters.
6032	An attempt was made to transfer a variable in the process image to an in/out parameter (VAR_IN_OUT). This is not possible. User variables must be specified as in/out parameters.
6033	An attempt was made to transfer a variable with a non-matching data type to an in/out parameter (VAR_IN_OUT). However, an Implicit type conversion is not possible. User variables with the correct data type must be specified as in/out parameters.
6034	An attempt was made to transfer a read only variable to an in/out parameter (VAR_IN_OUT). This is not possible. In/out parameters must be read/write.
6035	An attempt was made to transfer a constant to an in/out parameter (VAR_IN_OUT). This is not possible. In/out parameters must be user variables.
6036	An operation is applied to a constant. The value of the constant is outside the definition range for the function. Examples are: • Application of SQRT to a negative number. • Use of logarithmic functions on a number <= 0. • Use of ASIN or ACOS on a number outside the interval [0..1]
6037	An attempt was made to divide a constant by zero. This operation is not permitted.
6038	The specified function parameter occurs more than once in the argument list.
6039	The specified POU (function or function block) cannot be used. Possible causes: • The definition of the POU in the implementation section is missing. Only the prototype was specified in the interface section. • The POU is fully defined only after its use (e.g. call, instance declaration). If necessary, move this POU in the program source before the POU in which it is used. • An instance of the function block cannot be declared as unit variable in the same program source in which this function block is defined.
6040	Only simple variables may be used as semaphores; indexing is not possible.
6041	The message function requires an auxiliary value of the specified data type. Type conversion is not possible.
6042	The message function requires that you specify a message number. The specified message number is invalid.
6043	Only simple variables that belong to the static instance data of the class can be used as semaphores.
6050	There is a type conflict in the expression for the specified operation / variables. One of the operands cannot be converted to the type of the calculation, or the result assignment produces a type conflict. A conversion between source file type and target type is not possible.

Error	Description
6051	The expression contains a type conflict for the specified operation. One of the operands cannot be converted to the data type of the other operand to perform the calculation, or the operand data types are not permitted for this operation.
6052	Type conflict in the expression. The specified data type cannot be used for the operation (see marshalling functions).
6053	The expression contains a type conflict for the specified operation. This operation is not permissible on the specified data type.
6054	Type conflict in the expression. The specified variable cannot be used as indexed array variable.
6055	The expression contains a type conflict for the specified operation. Dynamic data type conversion is not permitted for the operand.
6060	At the function call, there is a mixture of assignments of function arguments and setting parameters. Use one form of the function call. Example: • f (x, y); or • f (in1 := x, in2 := y);
6061	The specified parameter of the function or the function block is an in/out parameter. Consequently, a variable must be assigned when the POU is called.
6062	The specified identifier cannot be used as a function argument. Only variables from the declaration blocks VAR_INPUT and VAR_IN_OUT are permitted.
6063	The specified identifier cannot be used as a function argument. Only variables from the declaration blocks VAR_INPUT and VAR_IN_OUT are permitted.
6064	The specified POU is a prototype, for which there is no implementation. Therefore, calling is not possible.
6070	Access to configuration data is only possible for variables that have been specified completely. Append the name according to the configuration data for the selected technology object.
6071	Access to configuration data is only possible for variables that have been specified completely. Therefore, array indices, which cannot be resolved until runtime, may not be used.
6080	The specified variable is no input or output variable that can be directly accessed. Such a variable must be declared in the I/O container of the associated device; it must have the syntax PI* or PQ*.
6085	The specified variable has been declared within the source file with a data type declared by forward declaration. It is not possible in this instance to use public subcomponents of this variable in other declaration sections as initialization values for other interface variables or references. The use of subcomponents by means of ARRAY access is also not possible.
6100	The specified construct can only be compiled if the device type to be used is stated. To do this, set the required device variants at the library. It is not possible to compile the construct as a device-neutral library.
6110	The specified construct cannot be used in libraries.
6111	The specified construct cannot be used in libraries.
6112	The specified construct cannot be used in libraries.
6113	Access to technology objects and devices is not permitted in libraries.
6114	A function block from a different source of the same library has been used. This is only possible within a library if the declaring source is compiled with the "Permit forward declarations" compiler setting activated.
6130	The specification of an interval is not permissible for the data type indicated in the CASE statement.
6140	The specification of a constant in ENUM_TO_DINT requires specifying the data type in the form of enum_type#value.

Error	Description
6141	An attempt has been made to access a value of an enumeration data type (ENUM) that cannot be assigned in the current scope. The specified value must be preceded by the declaration scope of the enumeration data type. This is the name of the CLASS, the FUNCTION_BLOCK or the NAMESPACE within which the relevant enumeration data type has been declared. Furthermore, you should enter the identifier of the enumeration data type before you specify the value. Use the following notation: <scope_name>.<enum_type_name>#<enum_value>.
6150	The specified bit offset lies outside the valid range for the specified data type.
6160	The stated array type without length specification is only permitted: • when VAR_IN_OUT parameters are declared in functions, function blocks or methods, • when VAR_INPUT parameters are declared in functions and methods. These kinds of variables cannot be declared in any other declaration sections.
6161	The direct assignment between arrays without length specification is not possible. You need to iterate over the elements for the assignment.
6170	The specified identifier is no variable identifier. You must specify a variable identifier. It should be noted that local variables of a POU are not usable in an independent EXPRESSION (condition).
6180	The specified function is not usable for variables that contain structures with overlapping memory spaces (OVERLAP).
6200	Only with compiler option "Permit language extensions" (-C lang_ext): The called PROGRAM contains instance data (VAR ... END_VAR declaration block) stored in the user memory of the assigned task. This means a call of the PROGRAM from another POU is not possible. Compile the source file with the "Create program instance data only once" compiler option (-C prog_once) or remove the instance data.
6201	Only with compiler option "Permit language extensions" (-C lang_ext): The call of a PROGRAM is not supported in functions. Such calls can be made only in function blocks or another PROGRAM.
6250	The specified method is not declared public. It has not been declared PUBLIC and cannot therefore be called.
6251	SUPER cannot be used in the current context. SUPER can be used in class methods only if the relevant class has a base class (EXTENDS required).
6252	The specified method is implemented in the base class. It cannot be called directly. To call the method, use either SUPER (call the method of the base class with static binding) or THIS (call with dynamic binding). A call that is not preceded by these names is supported only for methods implemented directly in the current class. The call syntax without a preceding name cannot be used for methods of the base class. An error message is also issued if a method without a preceding name is called that is programmed to be overridden after the current call point. In this case, the source file can be successfully compiled after the compiler option "Permit forward declarations" has been set.
6253	The specified method is not identified as public in the base class. It has not been declared as PUBLIC or PROTECTED and cannot therefore be called.
6254	The specified method is implemented in the base class. To be able to recognize any method override mechanism programmed in the current class, this method must either be specified before it is called for the first time or the compiler option "Permit forward declarations" must be activated. The method can be successfully compiled with this option even if the method is not to be overridden.

Error	Description
6260	A reference cannot be generated on the specified variable. References can only be generated on elements that are in the global memory of the controller (VAR_GLOBAL). It cannot be ensured that the specified variable is in the global memory of the controller. It is therefore not possible to generate references to the following variables: • Input parameters (VAR_INPUT) and output parameters (VAR_OUTPUT) for functions or methods • In/out parameters (VAR_IN_OUT) for functions, function blocks or methods • Temporary variables (VAR_TEMP as well as VAR in functions and methods) • Retentive local variables (VAR RETAIN) • Variables of technological objects • Variables of the address list
6261	A reference cannot be generated on the specified variable. Variables to which references are generated must be read/write. It is therefore not possible to generate references to constants.
6262	A reference cannot be generated on the specified variable. Type conversion and dereferencing is not possible within REF().
6300	Only when pragma "ToHookApplicable = YES" is specified: The call to the specified POU is not possible since this POU is not marked as ToHookApplicable. Only the other functions suitable for this can be used in hook functions.
6301	Only when pragma "ToHookApplicable = YES" is specified: The access to the specified variable is not possible while compiling for use in TO hooks. In TO hooks, the following variables cannot be accessed: • Variables of technology objects • I/O variables • Global device variables
6302	Only when pragma "ToHookApplicable = YES" is specified: It is not possible to call the specified method because this method requires a dynamic call (i.e. via the VTable). Only static method calls may be used in hook functions.

Syntax errors, errors in the expression (7000 ... 7014)

Table 7-516 Syntax errors, errors in the expression (7000 ... 7014)

Error	Description
7000	A syntax error has occurred. Possible causes: • Incorrectly ended control structures (e.g. END_IF missing) • Statements not terminated with ; • Missing brackets
7001	The specified identifier does not refer to a constant. Please enter one constant per value or identifier.
7002	A signed integer is expected. The integer can be of data type SINT, INT, or DINT.
7003	When specifying the interval, the initial value must be less than or equal to the end value. This applies to the declaration of arrays and the specification of the interval in CASE selection conditions.
7004	An initialization value is expected. The value must be a constant. Constants can be assigned as follows: • Directly per value • Symbolically via a preceding constant declaration • As an expression containing constants only

Error	Description
7005	If identical data types are to be initialized in different sources, this requires an identical initialization value too. Adapt the initialization values.
7009	An expression that supplies data type BOOL is expected as condition for WHILE, REPEAT, and IF. This can be specified as a variable of data type BOOL or via a comparison expression. You can also specify a function with a return value of data type BOOL.
7010	A syntax error has occurred. Possible causes: • Incorrectly terminated control structures (e.g. END_IF missing) • Statements not terminated with ; • Missing brackets
7011	A syntax error has occurred. Possible causes: • Incorrectly terminated control structures (e.g. END_IF missing) • Statements not terminated with ; • Missing brackets
7012	A syntax error in the statement, that starts at the specified line, has occurred. Possible causes: • Incorrectly terminated control structures (e.g. END_IF missing) • Statements not terminated with ; • Missing brackets
7013	A syntax error has occurred. An illegal construct is being used.
7014	A syntax error has occurred. Possible causes: • Incorrectly terminated control structures (e.g. END_IF missing) • Statements not terminated with ; • Missing brackets
7068	A source is being used by another source with incorrect RT interface stamp. Compile the used sources individually. In case of doubt, select "Project > Save and compile all".

Error when linking a source file (8001 ... 8010)

Table 7-517 Error when linking a source file (8001 ... 8010)

Error	Description
8001	The specified POU has been exported to the INTERFACE section, but an IMPLEMENTATION section is missing. Either delete the export statement or specify a valid implementation.
8002	The data structure of the specified POU cannot be determined. The cause of the problem is that the POU contains other POUs that are resulting in recursion in the data structure, or that POUs are used that have not been implemented. The message is issued in conjunction with the compiler option 'Permit forward declarations'. Note further error messages indicating the exact error location at which recursion or lack of implementation has been detected.
8010	The interface method is not implemented by the specified class. Since the interface is referenced at the class by IMPLEMENTS, it is absolutely essential that the method is implemented. This also applies if a base class already contains a method implementation of the same name. When an interface is linked, this implementation must be explicitly overridden in the class in which the interface link is programmed.

Errors while loading the interface of another UNIT or a technology package (10000 ... 10101)

Table 7-518 Errors while loading the interface of another UNIT or a technology package (10000 ... 10101)

Error	Description
10000	The specified unit has an invalid file format. Probably, the unit was created using an older version of the compiler or compiled using incompatible options. If a unit is involved, it should compiled first. Then repeat the current compilation. If a package is involved, a newer version should be installed.
10001	The unit name has an invalid format. The rules for identifiers in ST are also true for unit names; the following restrictions apply to their length: • Up to version V4.0 of the SIMOTION Kernel: 8 characters. • As of version V4.1 of the SIMOTION Kernel: 128 characters.
10002	Error while loading the interface of another UNIT, a library or technology package. The specified identifier is contained in two different imported units, libraries or technology packages. • Remove a unit, library or technology package from the import list or • Establish uniqueness between the identifiers in imported units, libraries or technology packages. Change the exporting units in the interface section or specify a namespace for a library or a technology package (USELIB ... AS namespace; USEPACKAGE ... AS namespace;).
10003	The specified data type has an invalid memory layout. Probably, the unit was created using an older version of the compiler or compiled using incompatible options. If a unit is involved, it should compiled first. Then repeat the current compilation. You can also perform "Save and recompile everything". If a package is involved, a newer version should be installed. If the error persists, inform the support department.
10004	The exported symbols of the stated unit could not be loaded. Compile the specified unit and try again. Alternatively, perform "Save and compile changes".
10005	A recursion was detected on loading packages. The specified package has already been loaded with USEPACKAGE and cannot be specified a second time.
10006	A recursion was detected on loading the unit. The specified unit has already been loaded with USES and cannot be specified a second time.
10007	The maximum number of imported units which can be referenced in a unit was exceeded. A maximum of 223 imported units per load unit are permissible. This number includes units that are imported directly with USES as well as units containing used variables or POUs that are indirectly imported by these units.
10008	The number of imported packages that can be referenced in a unit has been exceeded. A maximum of 127 imported packages per load unit are permissible.
10009	The specified package is used in the unit, but it is not available on the device. This error message occurs when you compile with the "implicit package utilization" option and have programmed a USEPACKAGE statement that has a different content than the packages specified on the device.
10010	The specified package is used in unit <a>, but not in unit <b>. This error message occurs when different packages have been specified with USEPACKAGE in units that reference each other with USES. Correct the USEPACKAGE statements.
10011	The specified unit is used directly or indirectly by itself via one or more units. Correct the USES statements.
10012	The specified unit is imported directly or indirectly into several units in different compilation versions. Recompile all units that reference the specified unit in the USES statement.
10013	The specified unit has not yet been compiled, or an error occurred during the last compilation. Compile this unit first to ensure successful compilation.

Error	Description
10014	The type of specified technology object (TO) is not supported by the package specified previously during compilation with USEPACKAGE. Use a package that contains the TO type.
10015	The maximum number of technology objects (TO) which can be referenced in a unit was exceeded. A maximum of 65535 TOs can be referenced.
10016	The device type parameter is not available. If the unit to be compiled is not allocated to a device, use the statement UNIT <unitname> : <typname>;
10017	The device type has not been specified uniquely. The statement UNIT <unitname> : <typname>; has been used to specify a device type in the unit that is different from the device type detected from the assignment of the unit to the device or library.
10018	The specified unit could not be found. Check whether the unit name is available in the PROGRAM container of Workbench or whether the specified file is contained in the current working directory (only u7bt00ax - command line).
10019	The specified technology package could not be found. Observe the preceding error outputs.
10020	Error occurred while loading the technology package. Observe further error outputs.
10021	The technology package is used in the specified source file, however, it is not selected on the device. Correct the USEPACKAGE statement, or select the technology package on the device.
10022	The specified technology package is being used with different versions. Correct the settings for the technology package selection on the device and, if required, in the library. Only one version of a technology package can be used on a device. If this message is issued after the CPU version has been upgraded, select "Save and recompile all".
10024	The specified technology package does not contain any components which can be used in the programming environment. Therefore, it cannot be used in the USEPACKAGE statement either.
10025	The specified identifier is not an identifier for a valid or an installed technology package. Therefore, it cannot be used in the USEPACKAGE statement either. If this technology package is an OEM package, the error message can be eliminated by installing this package. Otherwise remove the identifier from the statement.
10026	The technology package is used in the specified source file; however, it is not selected for the current device type on the library. Correct the USEPACKAGE statement in the source file or select the technology package for the device type.
10027	The specified source file is imported directly or indirectly into several units in different compilation versions. Recompile all units that use the specified unit. Do this using "Save and recompile all".
10030	The device type has not been specified uniquely. In the unit, the statement UNIT xx : dvtype; specifies a different device type than the one determined via the assignment of the unit to the library container.
10031	The specified library is used directly or indirectly by itself via one or more libraries. Correct the USELIB statements.
10032	The specified library could not be found. Check your project.
10033	A recursion was detected on loading the library. The specified library has already been loaded with USELIB and cannot be specified a second time.
10034	The specified library is not compiled for the required device type. Possible causes: • The device type is not selected at the library. • The specified library has not yet been compiled. The message might also be displayed if an error occurred in the last compilation. To remedy the situation, check the device settings at the library and compile the library.
10035	The specified library could not be found. Check whether the library name is available in the Workbench project or whether the specified file is contained in the current working directory (only u7bt00ax command line).

Error	Description
10036	The specified package is used in the source file, but it is not available in the library. Libraries are generally compiled against the package versions specified in the library container. You have programmed a USEPACKAGE statement that has a different content than the packages specified in the library. Either select the correct package version or remove the USEPACKAGE statement from the source file.
10037	The code variant for the current device type is not selected for the specified library. This means this library cannot be used. Activate the code variant for this library.
10038	A DCC library can only be used in the DCC. It is not permissible to integrate such a library into different programming languages.
10039	Compiling a library requires access to the sources. Access to the specified source is not possible due to the selected protection level of the know-how protection. You have to log in for compiling.
10050	All POUs exported by the specified libraries are identical. Simultaneous use of these libraries is not possible. Modify at least one exported element in one of the relevant libraries. Note: Typically, this error occurs in conjunction with know-how protected libraries when they are imported and used jointly in the project used to create the library.
10051	The specified POUs are identical. Simultaneous use of these classes and therefore these libraries is not possible. Note: Typically, this error occurs in conjunction with know-how protected libraries when they are imported and used jointly in the project used to create the library or when copies of such libraries are used jointly.
10100	The specified type of a technology object is contained in several packages that were referenced by the source file. Please choose the technology package that meets your requirements.
10101	The specified technology object is not compatible with the types of technology objects supported by the loaded packages Update the package or change the type of technology object.

Implementation restrictions (15001 ... 15700)

Table 7-519 Implementation restrictions (15001 ... 15700)

Error	Description
15001	The specified construct is not supported by the current version of the compiler.
15002	The currently selected device does not support the specified function. Select a different device version if you want to use this function. To do so, replace the CPU in the hardware catalog and, if necessary, update the firmware.
15003	The specified identifier is a keyword that is not supported and therefore cannot be used as user-specific in order to ensure compatibility with later compiler versions.
15004	The specified identifier denotes a standard function that is not supported and cannot be used as user-specific identifier in order to ensure compatibility with later compiler versions.
15005	The specified identifier denotes a non-supported standard function and cannot be used as user-specified identifier in order to ensure compatibility with later compiler versions.
15006	The specified construct can only be used in source files generated with MCC. Usage in ST is not possible.
15007	A source/library/package is used in the implementation section either directly or indirectly without specifying a namespace. In the interface section, it is used with a namespace. Solve this conflict by specifying a namespace in the interface section for the specified source/library/package.

Error	Description
15008	The specified source uses the library or the technology package with different namespace specification between the interface and implementation section. For successful compilation, the library or the technology package must have already been homed to the interface section with USELIB or USEPACKAGE.
15010	The current device setting does not support the specified function. Select a different device version if you want to use this function.
15060	The currently selected device does not support the specified function. Select a different device version if you want to use this function. To do this, exchange the CPU in the hardware catalog and, if necessary, update the firmware. For example, use of the keyword CLASS or INTERFACE requires a CPU version as of V4.5.
15061	The current device setting does not support the specified function. Select a different device version for the library if you want to use this functionality. For example, use of the keyword CLASS or INTERFACE requires a CPU version as of V4.5.
15070	The specified construct does not conform to the language standard; however, for compatibility reasons, it is supported for old platforms. Convert the usage to the specified alternative.
15152	A USES, USELIB, or USEPACKAGE statement was found in a source file section hidden by conditional compilation. This is not permitted. Source file sections that contain these statements cannot be complied conditionally.
15153	The specified definition is not considered during code generation. It is not possible to define keywords differently.
15154	It is not permitted to apply a line comment and to use multi-line comments in the definition section.
15200	The specification of a bit offset for a bitstring variable requires activation of the "Permit language extensions" compiler option (-C lang_ext).
15700	The specified construct is not supported by the version of SIMOTION SCOUT into which conversion is to be performed.

Warnings (16001 .. 16700)

You can control the output of warnings and information:

- In the global compiler settings
- In the local compiler settings
- In an ST source file by specifying the following attribute within a pragma:
  { _U7_PoeBld_CompilerOption := warning:*n*:on } or
  { _U7_PoeBld_CompilerOption := warning:*n*:off }, where *n* is the warning class or the number for the warning or information.

You can also redefine individual warnings and information as errors:

- In an ST source file by specifying the following attribute within a pragma:
  { _U7_PoeBld_CompilerOption := warning:*n*:err }, where *n* is the number of the warning or information.

Table 7-520 Warnings (16001 .. 16700)

Error	Description
16001	(Warning class: 0) Only in conjunction with the "Selective Linking" compiler option. The specified function, the function block, or the program are neither exported nor called in the current unit. No code is generated.
16002	(Warning class: 0) Only in conjunction with the "Selective Linking" compiler option. The specified unit does not contain any exported PROGRAM nor any task link. No code is generated for the unit.
16003	(Warning class: 2) The operands of the comparison operation do not contain any explicit type definition. The data type listed in the comparison can be seen in the warning message issued. Specify the data type of the used constants explicitly with <type>#<value>.
16004	(Warning class: 2) The specified type conversion may cause the variable value to change due to the reduced display width or inadequate accuracy of the target data type.
16005	(Warning class: 2) During type conversion, the dependency of the variable value can cause the sign to change.
16006	(Warning class: 2) The specified value will be rounded to the next displayable value due to insufficient display width. This is generally the value 0.0.
16007	(Warning class: 2) A loss of accuracy occurred during type conversion. Not all decimal places are considered.
16008	(Warning class: 2) A loss of accuracy occurred during initialization of the specified variables. The constant will be converted to the specified data type. Not all decimal places are considered.
16009	(Warning class: 0) Not in conjunction with compiler option "Selective linking". The specified unit does not contain any exported PROGRAMs nor a task link. Unable to access unit code. Unable to call relevant POU.
16010	(Warning class: 0) Specified program not exported to unit; therefore unable to use it in configuration of the execution level.
16011	(Warning class: 0) The source file does not contain any exported global variables. No data is loaded to the target system.
16012	(Warning class: 0) The specified source file name was taken over from the PROGRAMS container of the selected device. The designation of the source file in the UNIT statement was ignored.
16013	(Warning class: 2) Because of the marshalling function, the specified data type is not portably convertible. Only use SIMOTION devices in conjunction with this data type, or perform an explicit conversion of the data type.
16014	(Warning class: 2) With the specified operation, a data type conversion is performed between signed and unsigned. Because the bit string is adopted in this case, the resulting numerical value can differ from the specified value.
16015	(Warning class: 2) For the assignment of the character string constants to the variables, only part of the character string constants is transferred, because the length of the variable is insufficient to accept all characters.

Error	Description
16016	(Warning class: 2) The operands in the expression do not contain any explicit type definition. The data type of the operation is determined by specifying the values. The resulting data type in which the expression is calculated can be seen in the issued warning message. To define the data type: • Specify the data type of the used constants explicitly with <type>#<value> or • Use an explicit data type conversion.
16017	(Warning class: 2) The operands in the expression contain only constants. The data type of the operation can be determined by specifying the data type (in the form <type>#<value>) or explicit data type conversion. This output is used for troubleshooting, in particular, for the use of symbolic constants, because the data type of the operation cannot normally be determined easily.
16018	(Warning class: 2) The data type of the comparison operation is defined using the value of a constant that has a larger value range than the contained variable. The comparison is performed with the data type of the constant.
16019	(Warning class: 1) The declaration conceals the identifier declared in the scope of the class or the function block. This identifier can no longer be accessed from the POU in which the identifier is declared.
16020	(Warning class: 1) The declaration hides the specified identifier which has been globally defined in its own source file or an imported source file. Access to the global identifier is no longer possible from the POU where this identifier is declared locally.
16021	(Warning class: 1) The declaration hides the specified identifier which is defined on the device. You can access the global device identifier with _device.<name>.
16022	(Warning class: 1) The declaration conceals the specified identifier which is defined in the project (e.g. technology object or device). You can access the global project identifier with _project.<name>.
16023	(Warning class: 1) The declaration hides the specified identifier for the data type of a technology object. Access to the data type identifier is no longer possible.
16024	(Warning class: 1) The declaration hides the access to the technology object on the device. You can access this TO with _to.<name>.
16025	(Warning class: 1) The declaration hides the IEC standard function with the identical name. Access to this function is no longer possible in the current context.
16026	(Warning class: 1) The specified identifier is reserved by SIEMENS for potential extensions. The use of this identifier can cause compiler errors in later versions. If you want to avoid this, change this identifier.
16027	(Warning class: 1) The specified identifier which is reserved for access to I/O qualities, is already assigned on the device. This means that I/O qualities cannot be accessed.
16030	(Warning class: 1) A label has been specified several times in a CASE statement. Only the first label is ever evaluated. Other specifications have no effect.

Error	Description

16040	(Warning class: 1)
	Within a CASE statement, the stated identifier is interpreted as a jump label and not as a CASE selector. This may occur if a LABEL is defined in a control structure within a CASE statement:
	CASE sel OF
	first_val: IF TRUE THEN
	second_val: // -> warning 16040
	result := 2; END_IF;
	third_val: result := 3;
	END_CASE;
	This warning will not be issued if the jump label has been explicitly declared between LABEL and END_LABEL.

16102	(Warning class: 3) The option for output of code for the program status diagnosis function is ignored because no debug information was generated. Output of debug information was deactivated via compiler options.
16103	(Warning class: 3) The option for outputting code at the library for the program status diagnosis function is ignored. The code for program status is generated as defined in the option in the individual source files.
16110	(Warning class: 3) The specified pragma statement is not supported in the current version.
16111	(Warning class: 3) The specified pragma statement is not supported in the used context. The position of the pragma in the source text is not correct.
16112	(Warning class: 3) A valid pragma has been used. However, the value specified for the pragma is not valid. Use a valid value.
16113	(Warning class: 3) The pragma contains a syntax error in an attribute declaration. The valid syntax is as follows: <Attribute identifier> := <Attribute value>; .
16150	(Warning class: 7) A new definition has been made for the specified identifier. Consequently, the previous definition is invalid. This warning enables the work of the preprocessor to be tracked.
16151	(Warning class: 7) An attempt has been made to delete the definition of the specified identifier with #undef. However, the identifier is not defined or the definition is already deleted. This warning enables the work of the preprocessor to be tracked.
16152	(Warning class: 7) The specified definition is not considered during code generation. This may be caused by the preprocessor being deactivated for the compiled source.
16153	(Warning class: 7) The preprocessor is not active in the current source, even though preprocessor statements are used. Activate the preprocessor or remove the statements.
16154	(Warning class: 10) The preprocessor cannot be used to control the contents of USEPACKAGE, USELIB, and USES statements. It is no longer possible to automatically determine the dependencies between sources for the "Save project and compile changes" and "Save project and recompile all" functions.

Error	Description
16170	(Warning class: 10) The definitions from sources imported using USES are not considered during code generation.
16171	(Warning class: 10) The definition from the specified source imported using USES could not be loaded. Compile the specified source file beforehand.
16200	(Warning class: 4) The use of a semaphore requires a global variable to enable access to it from a different task. Local task operations do not have to be blocked via semaphores.
16210	(Warning class: 4) The basis of the exponential function (EXPT standard function or ** operator) is negative. The operation can be executed at run time only under the following conditions: 1. It can be used on a device with a version of the SIMOTION Kernel as of V4.1. 2. The exponent is an integer. The ExecutionFaultTask will be initiated for non-integer exponents or for use on a device with a version of the SIMOTION Kernel up to V4.0. The program will be aborted at this position.
16220	(Warning class: 4) The condition of an IF statement, WHILE statement or REPEAT statement is a constant expression.
16230	(Warning class: 4) The expression with the specified values does not cause any change to the result; optimized code will be created.
16240	(Warning class: 4) The expression with the specified values exceeds the definition range of the operation. The result may be incorrect.
16250	(Warning class: 4) A modification of the control variable of a FOR loop occurs inside this loop. This modification is either not effective or may cause an unexpected result when editing this loop. If the modification of the variables inside the loop is necessary, then use WHILE or REPEAT at this point instead of FOR.
16260	(Warning class: 4) With the values assigned to the specified function, it has no effect. Optimized code is generated.
16261	(Warning class: 4) The return value of the function or method has not been assigned. The result of the function is thus lost.
16270	(Warning class: 4) The operation for the dynamic type conversion is executed as assignment operation. The associated variables enable an evaluation at the time of the compilation. As a result of this message, it may be determined that a type conversion is not possible. An error message is output as for an assignment of the variables.
16280	(Warning class: 4) The INTERNAL access identifier was specified for an element not contained in any NAMESPACE. The identifier is ignored and the element is PUBLIC.
16281	(Warning class: 4) The specified identifier has already been declared as INTERNAL in the current source or in an imported source or library. The current declaration location, however, does not contain the INTERNAL identifier. Add INTERNAL for the declaration of the affected element.

Error	Description
16282	(Warning class: 4) The specified NAMESPACE was identified as public in one source and declared as INTERNAL in another source. This conflict is resolved by declaring the NAMESPACE as INTERNAL. Consequently, the contained elements can be accessed only in accordance with the rules that apply to INTERNAL.
16283	(Warning class: 4) Rather than the PUBLIC access identifier specified for the data type declaration, INTERNAL is used, because the complete POU was declared as INTERNAL. This identifies contained elements as INTERNAL, because they may not be accessed outside the NAMESPACE.
16300	(Warning class: 5) The auxiliary value has a data type that cannot be converted to the data type configured for the message.
16301	(Warning class: 5) The specified auxiliary value is not evaluated during output of the message.
16302	(Warning class: 5) The data type of the auxiliary value cannot be determined from the message configuration. The specified data type is used.
16303	(Warning class: 5) No auxiliary value has been specified for the function although the message configuration requires such a value. A default value of the corresponding data type was added.
16304	(Warning class: 5) An alarm accompanying value is specified using a constant or a constant expression. The resulting data type of the alarm accompanying value can be seen in the issued warning message. To define the data type: • Specify the data type of the used constants explicitly with <type>#<value> or • Use an explicit data type conversion.
16400	(Warning class: 6) A global variable has been declared in a library. This may mean that the library cannot be used more than once.
16401	(Warning class: 6) A PROGRAM has been declared in a library. This cannot be used in the process system. Set the compiler option "Only create program instance data once" (-C prog_once) or declare a FUNCTION_BLOCK.
16420	(Warning class: 6) The return value has not been assigned within the function or a method. If such a function or method is called, it returns a random value.
16421	(Warning class: 6) A variable that has neither been assigned nor read in the code has been declared. The output of this warning can only be suppressed for a POU by means of a pragma.
16430	(Warning class: 6) An attempt is being made to use a function block, which is either a system function block itself or includes one, as a temporary variable. This can result in runtime problems when using the block in a cyclic level.

Error	Description
16440	(Warning class: 10) A global variable that does not contain any user data that can be backed up has been created in the retentive memory area. These kinds of variables should not be declared in RETAIN areas. It is not meaningful to specify RETAIN in this case and this specification is supported only for compatibility reasons TO references are an example of a data type for which this message is output.
16441	(Warning class: 6) The specified data type contains some variables that cannot be restored in addition to those that can be backed up in RETAIN areas. Data types of this kind include, for example, TO references and INTERFACE variables.
16450	(Warning class: 10) A global variable has been created in the retentive memory range. This declaration is not permissible at the specified position.
16451	(Warning class: 10) The initialization of large arrays with values other than 0 causes a high data volume in the controller. This results in long load times as well as high memory utilization.
16452	(Warning class: 10) The specified program has a large quantity of instance data to be initialized. This can lead to a runtime violation when the task is started because both the initialization code and the user code are being executed. In particular, caution is advised in the case of SynchronousTasks.
16470	(Warning class: 10) The specified construct does not conform to the language standard; however, for compatibility reasons, it is supported for old platforms. Convert the usage to the specified alternative.
16600	(Warning class: 6) The specified variable is not contained in the initialization list. The default initialization value is used.
16601	(Warning class: 6) The specified variable is not contained in the initialization list. The default initialization value is used.
16602	(Warning class: 6) The specified variable is not contained in the initialization list. The default initialization value is used.
16603	(Warning class: 6) The specified function block does not contain any instance data and, as a result, has a size of 0 bytes. When transferred as a non-dimensional array for referencing purposes, the size of the element is defined as 1 element.
16604	(Warning class: 6) The data type used in the declaration has no unique initialization value. The initial value known last is used. In order to achieve a unique behavior at this point, the initial value for the variable or data type declaration must be specified explicitly.
16605	(Warning class: 6) The memory space of the specified variable overlaps with another variable. Thus, the initialization value cannot be included. The remaining memory space is assigned the default value 0.
16606	(Warning class: 6) The memory space of the specified variable overlaps with another variable. Thus, the data type cannot be transferred to the OPC XMP information. The component is symbolically unavailable and also not included in backups using _exportUnitDataSet.

Error	Description
16607	(Warning class: 6) The specified function block does not contain any instance data and, as a result, has a size of 0 bytes. The instance declaration in the form of an ARRAY is not appropriate.
16700	(Warning class: 3) The SIMOTION device can also be processed with previous versions of the SIMOTION SCOUT. The specified construct is not supported by all the earlier versions of the compiler.

Global compiler settings (Page 4623)

Local compiler settings (Page 4626)

Controlling the preprocessor and compiler with pragmas (Page 4917)

Controlling compiler with attributes (Page 4922)

Non-assigned compiler messages (22000 ... 22002)

You create non-assigned compiler messages within a pragma (Page 4917). Enter the desired message text as a character string (Page 4667) enclosed in brackets after the keyword "information", "warning" or "error". End the statement within the pragma with a semi-colon. See "Issuing non-assigned compiler message" (Page 4926).

Table 7-521 Non-assigned compiler messages (22000 ... 22002)

Error	*Description*
22000	This message is a user-defined error message. See error text.
22001	(Warning class: 0) This message is a user-defined warning. See warning text.
22002	(Warning class: 0) This message is a user-defined information message. See information text.

Information (32010 ... 32653)

You control this output of information together with the warnings (Page 5058):

Table 7-522 Information (32010 ... 32653)

Error	Description
32010	(Warning class: 6) The specified jump label identifier has been declared but not used.
32020	(Warning class: 10) The specified variable was declared globally in this source file or in another source file with the indicated data type. This may be a variable, a constant, or another identifier. This information helps when searching for the cause of compilation errors. It is issued together with error messages.

Error	Description
32021	(Warning class: 10) The specified variable was declared on the device as an I/O variable, a global device variable, or a system variable. This information helps when searching for the cause of compilation errors. It is issued together with error messages.
32022	(Warning class: 10) The specified variable was declared in the project as a global identifier. This may be a device identifier, a technology object or another identifier from the project. This information helps when searching for the cause of compilation errors. It is issued together with error messages.
32023	(Warning class: 10) Until now, no valid declaration has been found for the specified identifier. This information is issued together with error messages.
32024	(Warning class: 0) The specified variable has been declared as a global identifier in the current unit or in an importing unit. This information helps when searching for the cause of compilation errors. It is issued together with error messages.
32025	(Warning class: 10) The specified identifier was declared in this source or in another source in the specified namespace. In order to be able to use this identifier, it must be prefixed with the identifier of the namespace. This may be a variable, a constant or another identifier. This information is helpful when searching for the cause of compilation errors. It is issued together with error messages.
32026	(Warning class: 0) The specified identifier is a standard function that can be activated via a compiler option. In order to use the function, activate the required compiler options for language extensions.
32030	(Warning class: 0) The stated array initialization does not conform to IEC 61131-3. For portable programs, you should enclose the array initialization values in square brackets. Example of field initialization in compliance with the standard: x : ARRAY [0 to 1] OF INT := [1, 2];
32050	(Warning class: 0) The maximum size that can be reached via an HMI is 65536 bytes. This limit has been exceeded with the specified variable. All subsequent variables cannot be reached either.
32060	(Warning class: 0) The specified identifier is a keyword that can be activated via a compiler option. In order to use the keyword, activate the compiler option "Language extensions IEC61131-3rd Edition". This message is output as a guide for debugging syntax errors.
32061	(Warning class: 0) The specified identifier is a keyword that can be activated via a compiler option. In order to use the keyword, activate the compiler option "Permit object-oriented programming". This message is output as a guide for debugging syntax errors.
32300	(Warning class: 1) A label has been specified several times in a CASE statement. Only the first label is ever evaluated. Other specifications have no effect.

Error	Description
32650	(Warning class: 7) The specified identifier will be replaced thereafter by the output text. This information enables the work of the preprocessor to be tracked.
32651	(Warning class: 7) The definition of the specified identifier has been deleted with #undef. This information enables the work of the preprocessor to be tracked.
32652	(Warning class: 7) The identifier will be used with the specified replacement text in the source file. Compilation takes place with the replacement text. This information enables the work of the preprocessor to be tracked.
32653	(Warning class: 7) The specified identifier will be replaced thereafter by the output text. This information appears if additional replacements are loaded with a USES statement. This information enables the work of the preprocessor to be tracked.

7.2.9.3 Template for Example Unit

Preliminary information

This chapter presents a comprehensively annotated template that you can call in the online help. You can use it as a template for a new ST source file.

```
//============================================================================
//(organization)
//(division / place)
//(c)Copyright 2009  All Rights Reserved
//----------------------------------------------------------------------------
//  project name: (name)
//  file name: (name as soon as saved)
//  library: (that the source is dedicated to)
//  system: (target system)
//  version: (SIMOTION / SCOUT version)
//  application: (relation to project/ product/ usage)
//  restrictions:
//  requirements: (hardware, technological package, memory needed, etc.)
//  search items: (with the purpose of browser usage)
//  functionality: (that is implemented)
//----------------------------------------------------------------------------
//  change log table:
//  version    date      expert in charge     changes applied
//
//============================================================================

INTERFACE
    //  All statements added between INTERFACE and END_INTERFACE/
    //  Keywords are used to define which source contents
    //  (variables, functions, function blocks, etc.) also in other
    //  sources (units) are available or exported.

    USEPACKAGE cam;
    // The technology packages to be used are known here and thus
    // made usable in the source. Technology object (TO)-specific
    // Commands can be used in this UNIT only when the
    // appropriate package has been included.
    // If a source file that uses USEPACKAGE cam is integrated via USES,
    // it will be "inherited". USEPACKAGE can then be omitted.
    // The package used in this example is "cam". However, other
    // technology packages can also be used (see documentation).
    // USELIB testlib;

    // If library functions are to be used in the source file, they must be made
    // known in the source, too. If the library
    // with the name "testlib" does not exist in the project,
    // the error message
    // "Error 10035, "testlib.lib" library could not be loaded"
    // "Error 10032, "testlib" library could not be loaded"
    // will be output.
    // If libraries are not being used, this line can be
    // deleted..
```

```
// USES header;

// USES is used to import contents exported from a different source
// exported content imported and made usable in "sttemp_1_de".
// If the source with the name "header" does not exist in the project,
// the error message
// "Error 10018, "header" source could not be loaded"
// will be output.
```

Type definition in the interface

```
// ******************************************************
// * Type definition in the INTERFACE                   *
// ******************************************************

VAR_GLOBAL CONSTANT
       PI             : REAL := 3.1415;
       ARRAY_MAX1     : INT  := 4;
       ARRAY_MAX2     : INT  := 4;
       COLLECTION_MAX : INT  := 6;
       GLOBARRAY_MAX  : INT  := 12;
END_VAR
// Declaration of a global constant. In the source file
// no other value can be assigned to the identifier.
// User defined variable types (UDT) are
// defined between TYPE and END_TYPE.
TYPE
    ai16Dim1 : ARRAY [0..ARRAY_MAX1-1] OF INT;
    // Definition of a one-dimensional array with four array elements from
    // type INT under the name "ai16Dim1". With "ai16Dim1" as the data type
    // in all source file segments, one-dimensional arrays can now
    // be declared by type INT.
    aaDim2 : ARRAY [0..ARRAY_MAX2-1] OF ai16Dim1;
    // A two-dimensional array is an array of one-dimensional arrays.
    // Here a two-dimensional field with 16 elements occurs
    // of the type INT under the name "aaDim2"
    eTrafficLight : (RED, YELLOW, GREEN);
    // Definition of enumerator "eTrafficLight" as a
    // user-defined variable type. Variables of this type can
    // only accept the values "RED", "YELLOW" and "GREEN".
```

```
    sCollection : STRUCT
        toAxisX          : posaxis;
        aInStructDim1    : ai16Dim1;
        eTrafficInStruct : eTrafficLight;
        i16Counter       : INT;
        b16Status        : WORD;
    END_STRUCT;
    // A user-defined structure is created here. It is possible to
    // combine elementary data types (here INT and WORD) or already defined
    // user data types (here "array1dim" and "eTrafficLight") into
    // one structure. In addition, types
    // of technology objects can also be used.
    // In the example, the structure contains an element of
    type // a position axis (posaxis).
    // In the definition, make certain to sort the variables
    // by size in increasing sequence
    // (ARRAY, STRUCT, LREAL, DWORD, INT, BOOL ...)
    aCollection : ARRAY [0..5] OF sCollection;
    // Nesting is also possible. The type "aCollection"
    // contains a field comprising six elements of type "sCollection"
END_TYPE
```

Variable declaration in the interface

```
// ******************************************************
// * Variable declaration in the INTERFACE                *
// ******************************************************

VAR_GLOBAL  // In the user memory of the UNIT.
            // Also visible using HMI services.
    gaMyArray : ARRAY [0..GLOBARRAY_MAX-1] OF REAL := [3 (2(4), 2(18))];
    // Example of a declaration of a one-dimensional array without
    // previous type declaration. The initialization performed here is
    // read as follows:
    // Two elements each are initialized with the value 4,
    // two elements with the value 18. This pattern is used in the array
    // "gaMyArray" three times in succession.
    // The field elements are thus assigned as follows:
    // 4, 4, 18, 18, 4, 4, 18, 18, 4, 4, 18, 18.
    gaMy2dim : aaDim2;
    // Example of a declaration of a two-dimensional array
    gaMy1dim : ai16Dim1;
    // Example of a declaration of a one-dimensional array with
    // use of a type declaration.
    gsMyStruct : sCollection;
    // Variable of the type or with the structure of
    // user_struct.
    gaMyArrayOfStruct : aCollection;
    // The variable generated here contains a field from
    // structural elements as declared in section TYPE/END_TYPE
    //.
    gtMyTime : TIME := T#0d_1h_5m_17s_4ms;
    // ...as elementary time types and derived data types.
```

```
        geMyTraffic : eTrafficLight := RED;
        // An enumerator of type "eTrafficLight" is created here and
        // assigned the value "RED".
        gi16MyInt : INT := -17;
        // Variables of an elementary numerical data type can
        // also be declared in variable declarations...

    END_VAR
    VAR_GLOBAL RETAIN
    END_VAR
    // The variables declared with the add-on RETAIN are
    // RETAIN stored in the data area of the hardware platform used and
    // are therefore safe from network failure.

    // The declaration of VAR, VAR CONSTANT, VAR_TEMP, VAR_INPUT, VAR_OUTPUT
    // and VAR_IN_OUT is not permissible here.
    // Variables that are defined in this section and thus exported
    // can be reimported by means of the USES "sttemp_1_de" into another source file (UNIT)
    .
    FUNCTION FCmyFirst;
    FUNCTION_BLOCK FBmyFirst;
    PROGRAM myPRG;
    // The function blocks (FBs),
    // functions (FCs) and programs defined in the interface part are exported
    // so that they can be used in other units.
    // Non-exported FBs and FCs can only be used in this source file
    // ("information hiding", placing in the interface only
    // what other units absolutely need).
    // A program that has not been exported cannot be assigned to any TASK
    //.

END_INTERFACE
```

Implementation

```
// ****************************************************
// * IMPLEMENTATION section                           *
// ****************************************************

IMPLEMENTATION
    // In the IMPLEMENTATION section of a unit, the executable code sections
    // are stored in various program organization units (POUs).
    // A POU can be a program, FC, or FB.

    VAR_GLOBAL CONSTANT
    END_VAR
    TYPE
    END_TYPE
    // The type definition can also be made in the IMPLEMENTATION section.
    // However, this definition cannot be imported in another source file.
      The type definition can, however, be used for variables
    // in all POUs of the source file "sttemp_1_de". The definition of types must
    // be performed before the declaration of a variable.
```

```
VAR_GLOBAL  // In the user memory of the UNIT
    gboDigInput1 : BOOL;
    // Boolean variable for "EXPRESSION" example (see below).
END_VAR
VAR_GLOBAL RETAIN
END_VAR
// The variables declared with the add-on RETAIN are
// stored in the RETAIN data area of the hardware platform used and
// are therefore safe from network failure.
// Variable declaration in the IMPLEMENTATION section.
// The declaration of VAR, VAR CONSTANT, VAR_TEMP, VAR_INPUT, VAR_OUTPUT
// and VAR_IN_OUT is not permissible here.
EXPRESSION xCond
    xCond := gboDigInput1;
END_EXPRESSION
// Definition of an EXPRESSION.
// An EXPRESSION is a special function case, which recognizes only the
// return value TRUE and FALSE. It is used in conjunction with the
// statement WAITFORCONDITON (see myPRG) and should only be used
// if the program is executed as part of
// a MotionTask. If "gboDigInput1" (usual in a digital input or a
// condition in the program) takes on the value 1, the return value of the
// EXPRESSION TRUE.
```

Function

```
// ******************************************************
// * FUNCTION                                           *
// ******************************************************

// The declaration of an FB or FC must be placed in the source file
// before the actual use (the call), so that the code of the
// block is already known to the calling point.

FUNCTION FCmyFirst : INT
    // The statement section of the POU FUNCTION begins here. The return value
    // of the function has the type integer in this case.
    // The stack of the calling TASK is initialized on each call
    //.  The return value is located on the stack and is
    // written by the FUNCTION.
    VAR CONSTANT
    END_VAR
    TYPE
    END_TYPE
    // The type declaration can also be made in POUs. The
    // basic difference is the validity of the
    // type declaration. A type declared in a POU can only
    // be used for variables within associated POU.
    VAR_INPUT   // In the stack of the calling TASK, will be placed on
                // stack on call, assignment optional.
    END_VAR
```

```
    VAR         // In the stack of the calling TASK,
                // is used in FUNCTION.
    END_VAR
    // Variable declaration in an FC.
    // The declaration of VAR_GLOBAL, VAR_GLOBAL CONSTANT,
    // VAR_GLOBAL RETAIN and VAR_RETAIN is not permissible here.

    // The use of unit-global variables for data acceptance in FCs
    // and FBs is the fastest option for the runtime. The use
    // of the input parameters VAR_INPUT and the return via the
    // return value is slower, since the values are copied respectively.

    // Comment: Variables declared with VAR and VAR CONSTANT are
    // temporary. On the next call, the contents from the latest
    // call are no longer available, in contrast to the FB.
    // ****************************************
    // * Area for FC code or statements *
    // ****************************************)
    // Code is in the user memory.

    geMyTraffic := YELLOW; // e.g. change the traffic light.

    FCmyFirst := 17;
    // In this example, the function returns the value "17" to the
    // calling program.

END_FUNCTION
```

Function block

```
// ****************************************************
// * FUNCTION_BLOCK                                   *
// ****************************************************

// The declaration of an FB or FC must be placed in the source file
// before the actual use (the call), so that the code of the
// block is already known to the calling point.

FUNCTION_BLOCK FBmyFirst
    // The statement section of the POU FUNCTION_BLOCK begins here.
    // Instance data are dependent where the instance is formed
    // (see comments at the template end) in the user memory of UNIT
    // or TASK and are initialized with STOP->RUN or starting the TASK

    // The pointer to the instance data is transferred during the call.
    VAR CONSTANT
    END_VAR
    // Variables declared with VAR and VAR CONSTANT are
    // static, i.e., on the next block call, their contents remain
    // available and valid.
```

```
    TYPE
    END_TYPE
    // The type definition can also be made in POUs. The
    // basic difference is the validity of the
    // Type definition. A type defined in a POU can only
    // be used for variables within associated POU.
    VAR_INPUT   // In the user memory of the UNIT or TASK,
                // assignment optional on call.
    END_VAR
    VAR_IN_OUT  // In the user memory of the UNIT or TASK,
                // reference must be assigned on call.
    END_VAR
    VAR_OUTPUT  // In the user memory of the UNIT or TASK.
    END_VAR
    VAR         // In the user memory of the UNIT or TASK,
                // can be used in the FB.
    END_VAR
    VAR_TEMP    // In the stack of the calling TASK,
                // is initialized on each call.
    END_VAR
    // Variable declaration in an FB.
    // The declaration of VAR_GLOBAL, VAR_GLOBAL CONSTANT and
    // VAR_GLOBAL RETAIN is not permissible here.
    // ******************************************
    // * Area for FB code or statements *
    // ******************************************

    geMyTraffic := GREEN;  // e.g. change the traffic light.

END_FUNCTION_BLOCK
```

Program

```
// ******************************************************
// * PROGRAM                                            *
// ******************************************************

PROGRAM myPRG
    // The statement section of the POU PROGRAM begins here.
    VAR CONSTANT
    END_VAR
    TYPE
    END_TYPE
    // The type definition can also be made in POUs. The
    // basic difference is the validity of the
    // type definition. A type defined in a POU can only
    // be used for variables within associated POU.
```

```
        VAR  // In the user memory of the TASK.
            instFBMyFirst : FBmyFirst;
            // In order to be able to call an FB, an area for static
            // variables (forming an instance) must be generated. This has to do with
            // the "memory" of the FB.

            retFCMyFirst : INT;
            // Variable for the return value of the function.
        END_VAR
        VAR_TEMP    // In the stack of the TASK, initialized in each pass.
        END_VAR
        // Variable declaration in a PROGRAM.
        // The declaration of VAR_GLOBAL, VAR_GLOBAL CONSTANT,
        // VAR_GLOBAL RETAIN, VAR_INPUT, VAR_OUTPUT and VAR_IN_OUT
        // is not permissible here.
        // Comment: Whether the local variables declared via VAR
        // are temporary variables depends on the task context in which the
        // PROGRAM is used.
        //
        // In non-cyclic tasks (StartupTask, ShutdownTask, MotionTasks,
        // SystemInterruptTasks and UserInterruptTasks), the previous
        // contents of VAR and VAR_TEMP are no longer available.
        // The variables are thus temporary.
        //
        // In cyclic tasks (BackgroundTask, IPOsynchronousTask,
        // IPOsynchronousTask_2 and TimerInterruptTasks), the contents
        // of variables declared in the VAR section remain the same
        // for the following run. The variables are thus static.
        // Variables from VAR_TEMP are always temporary.
        instFBMyFirst ();
        // FB call with a valid instance.

        retFCMyFirst := FCmyFirst();
        // FC call and assignment of return value.

        WAITFORCONDITION xCond WITH TRUE DO
            // The statements programmed here come immediately for
            // execution if the condition EXPRESSION defined in the associated
            // "xcond" is logically true.
            ;
        END_WAITFORCONDITION;
        // WAITFORCONDITION is generally used only in MotionTasks.
          These remain in the location and the
        // condition defined in the EXPRESSION is checked with high priority.

    END_PROGRAM

END_IMPLEMENTATION
```

7.3 SIMOTION LAD/FBD

Preface

Scope

This document is part of the **SIMOTION Programming** documentation package.

This document applies to SIMOTION SCOUT, the engineering system of the SIMOTION product family in product version V5.4 in conjunction with:

- A SIMOTION device with the following versions of a SIMOTION Kernel:
  - V5.4
  - V5.3
  - V5.2
  - V5.1
  - V4.5
  - V4.4
  - V4.3
  - V4.2
  - V4.1 [1]
  - V4.0 [1]
  - V3.2 [1]

  [1] V4.5 is the last product version of SIMOTION SCOUT that will support these versions of the SIMOTION Kernel.
- The relevant version of the following SIMOTION Technology Packages, depending on the kernel:
  - Cam
  - Path (Kernel as of V4.1)
  - Cam_ext
  - TControl

Information in this manual

The following is a list of chapters included in this manual along with a description of the information presented in each chapter.

- **Description** (Chapter 1)
  This chapter shortly defines the LAD and FBD programming languages.
- **LAD/FBD Editor** (Chapter 2)
  In this chapter you can learn about the various operator control options in the LAD/FBD Editor.

- **Software Programming** (Chapter 3)
  This chapter shows how to proceed during programming.
- **Functions** (Chapter 4)
  This chapter describes how to apply individual LAD/FBD commands and gives an outline of their function.
- **Debugging Software / Error Handling** (Chapter 5)
  This chapter describes how to test a program and find errors in created programs.
- **Application Examples** (Chapter 6)
  You will be given an introduction to the LAD and FBD programming languages using some simple examples.
- **Appendix**
  - Key combinations
    This appendix contains the keystroke combinations for frequently used commands.
- **Index**
  Keyword index for locating information.

SIMOTION Documentation

An overview of the SIMOTION documentation can be found in the SIMOTION Documentation Overview document.

This documentation is included as electronic documentation in the scope of delivery of SIMOTION SCOUT. It comprises ten documentation packages.

The following documentation packages are available for SIMOTION product version V5.4:

- SIMOTION Engineering System Handling
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION IT
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P
- SIMOTION D
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

SIMOTION at a glance

We have compiled an overview page from our range of information about SIMOTION with the most important information on frequently asked topics - which can be opened with only one click.

Whether beginner or experienced SIMOTION user – the most important downloads, manuals, tutorials, FAQs, application examples, etc. can be found at

https://support.industry.siemens.com/cs/ww/en/view/109480700

Additional information

7.3.1 Fundamental safety instructions

7.3.1.1 General safety instructions

⚠ WARNING

Danger to life if the safety instructions and residual risks are not observed

The non-observance of the safety instructions and residual risks stated in the associated hardware documentation can result in accidents with severe injuries or death.

- Observe the safety instructions given in the hardware documentation.
- Consider the residual risks for the risk evaluation.

Malfunctions of the machine as a result of incorrect or changed parameter settings

⚠ WARNING

Malfunctions of the machine as a result of incorrect or changed parameter settings

As a result of incorrect or changed parameterization, machines can malfunction, which in turn can lead to injuries or death.

- Protect the parameterization against unauthorized access.
- Handle possible malfunctions by taking suitable measures, e.g. emergency stop or emergency off.

7.3.1.2 Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed visit (https://www.siemens.com/industrialsecurity).

7.3.1.3 Note regarding the general data protection regulation

Siemens observes the principles of data protection, in particular the principle of data minimization (privacy by design). For this product this means:

The product does not process / store any personal data, only technical functional data (e.g. time stamp). If the user links this data with other data (e.g. shift plans) or stores personal data on the same medium (e.g. hard disk) and thus establishes a personal reference, the user must ensure compliance with data protection regulations.

7.3.1.4 Danger to life due to software manipulation when using removable storage media

⚠ WARNING

Danger to life due to software manipulation when using removable storage media

The storage of files on removable storage media involves a high risk of infection, e.g. via viruses or malware. Incorrect parameter assignment can cause machines to malfunction, which can lead to injuries or death.

- Protect the files on removable storage media against harmful software through appropriate protective measures, e.g. virus scanners.

7.3.2 Description

7.3.2.1 Description

This chapter will give you a brief overview of ladder logic (LAD) and function block diagram (FBD).

7.3.2.2 What is LAD?
